

AN1040 APPLICATION NOTE

MONITORING THE V_{BUS} SIGNAL FOR USB SELF-POWERED DEVICES

by Microcontroller Division

INTRODUCTION

One of the [USB Compliance Checklist for Peripherals](#) items asks the following question: “Is the device’s pull-up active only when V_{BUS} is high?”.

This item refers to chapter 7.1.5 “Device Speed Identification” of the [USB Specification](#). It is mentioned that “the voltage source on the pull-up resistor must be derived from or controlled by the power supplied on the USB cable such that when V_{BUS} is removed, the pull-up resistor does not supply current on the data line to which it is attached”

This applies only to self-powered devices where power does not come from V_{BUS} .

1 V_{BUS} MONITORING

ST7 and ST9 microcontrollers with an embedded USB interface are equipped with an on-chip 3.3V voltage regulator that pulls up the appropriate data line with a 1.5 kΩ ±5% resistor.

This regulator can be switched on or off by software via the PDWN (*Power Down*) bit.

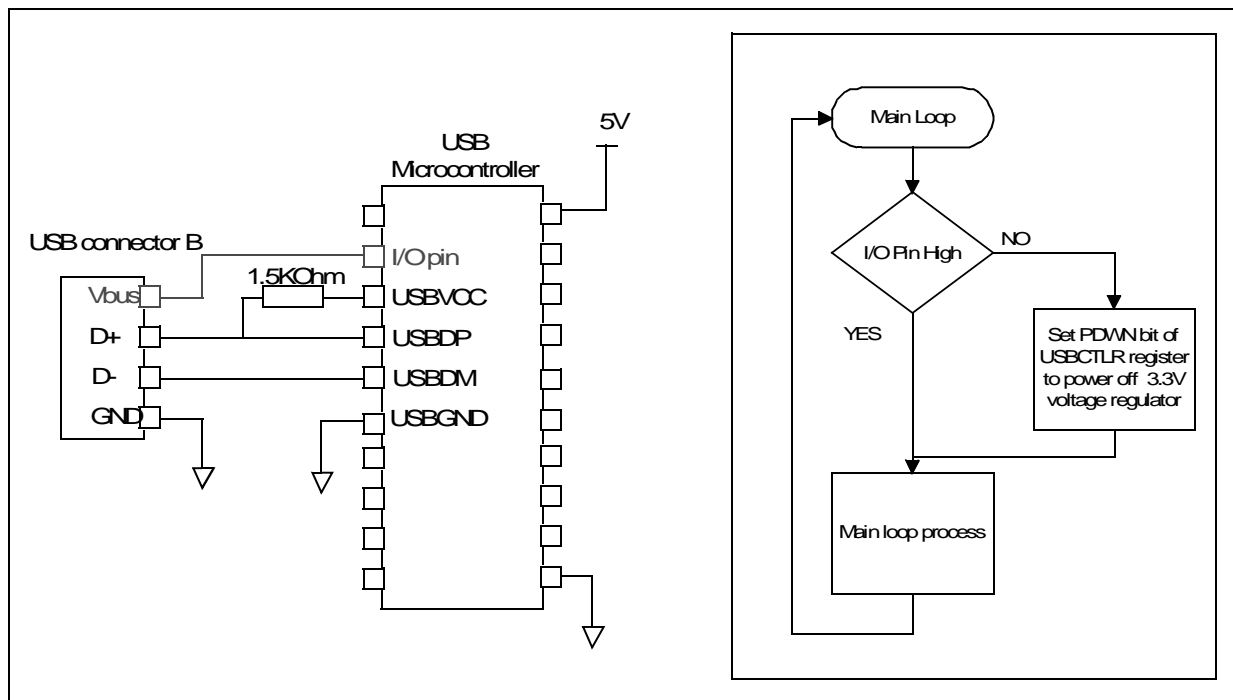

When the USB microcontroller is used in a self-powered application, it has to monitor the V_{BUS} signal to power off the 3.3 V voltage regulator if the USB cable is removed or if the V_{BUS} is switched off.

This can be implemented using an I/O pin configured as input CMOS.

Two monitoring schemes are possible:

1. Monitoring by polling the I/O pin in the main loop of the microcontroller program.
2. Monitoring by interrupt if the I/O pin connected to the V_{BUS} signal has interrupt capability. If V_{BUS} is removed, an interrupt will be generated on the falling edge.

Figure 1. V_{BUS} Configuration

When the V_{BUS} signal is removed, the program must set the PDWN bit. This will power off the 3.3V on-chip voltage regulator that supplies the external pull-up resistor and the transceiver and as a result, current will not be supplied on the data line attached to the V_{BUS} signal.
