Introduction

This application note is intended for system designers who require a hardware implementation overview of the development board features such as power supply, clock management, reset control, boot mode settings and debug management.

It shows how to use the STM32L4 Series and STM32L4+ Series MCUs and describes the minimum hardware resources required to develop an application using the STM32L4 Series and STM32L4+ Series devices.

Detailed reference design schematics are also contained in this document with descriptions of the main components, interfaces and modes.

1 Power supplies

1.1 Power supplies

The STM32L4 Series devices require a 1.71 V to 3.6 V $V_{DD}$ operating voltage supply. Several independent supplies ($V_{DDA}$, $V_{DDIO2}$, $V_{DDUSB}$, $V_{LCD}$, $V_{DDDSI}$), can be provided for specific peripherals:

- $V_{DD} = 1.71$ V to 3.6 V
  
  $V_{DD}$ is the external power supply for the I/Os, the internal regulator and the system analog such as reset, power management and internal clocks. It is provided externally through $V_{DD}$ pins.

- $V_{DD12} = 1.05$ V to 1.32 V
  
  $V_{DD12}$ is the external power supply bypassing the internal regulator when connected to an external SMPS. It is provided externally through $V_{DD12}$ pins and only available on packages with the external SMPS supply option. It does not need any external capacitance and cannot drive an external load.

- $V_{DDA} = 1.62$ V (ADCs/COMPs) / 1.8 V (DACs/OPAMPs) / 2.4 V ($V_{REFBUF}$) to 3.6 V
  
  $V_{DDA}$ is the external analog power supply for A/D converters, D/A converters, voltage reference buffer, operational amplifiers and comparators. The $V_{DDA}$ voltage level is independent from the $V_{DD}$ voltage.

- $V_{DDUSB} = 3.0$ V to 3.6 V (USB used)
  
  $V_{DDUSB}$ is the external independent power supply for USB transceivers. The $V_{DDUSB}$ voltage level is independent from the $V_{DD}$ voltage.

- $V_{DDIO2} = 1.08$ V to 3.6 V
  
  $V_{DDIO2}$ is the external power supply for 14 I/Os (Port G[15:2]). The $V_{DDIO2}$ voltage level is independent from the $V_{DD}$ voltage ($V_{DDIO2}$ is not available on STM32L45xxx/46xxx/43xxx/44xxx devices).

- $V_{LCD} = 2.5$ V to 3.6 V
  
  The LCD controller can be powered either externally through $V_{LCD}$ pin, or internally from an internal voltage generated by the embedded step-up converter. $V_{LCD}$ is multiplexed with PC3 which can be used as GPIO when the LCD is not used. $V_{LCD}$ is not available on STM32L4Rxxx/4Sxxx devices.

- $V_{BAT} = 1.55$ V to 3.6 V
  
  $V_{BAT}$ is the power supply for RTC, external clock 32 kHz oscillator and backup registers (through power switch) when $V_{DD}$ is not present.

- $V_{DDDSI}$ is an independent DSI power supply dedicated for the DSI regulator and the MIPI D-PHY. This supply must be connected to the global $V_{DD}$.

- $V_{CAPDSI}$ pin is the output of the DSI regulator (1.2 V) which must be connected externally to $V_{DD12DSI}$.

- $V_{DD12DSI}$ is used to supply the MIPI D-PHY, and to supply the clock and data lanes pins. An external capacitor of 2.2 µF must be connected on the $V_{DD12DSI}$ pin.

Note: When the functions supplied by $V_{DDA}$, $V_{DDIO2}$ or $V_{DDUSB}$ are not used, these supplies should preferably be shorted to $V_{DD}$.

- $V_{LCD}$
  
  The LCD controller can be powered either externally through $V_{LCD}$ pin, or internally from an internal voltage generated by the embedded step-up converter. $V_{LCD}$ is multiplexed with PC3 which can be used as GPIO when the LCD is not used. $V_{LCD}$ is not available on STM32L4Rxxx/4Sxxx devices.

Note: $V_{DDDSI}$, $V_{CAPDSI}$ and $V_{DD12DSI}$ are available only on STM32L4S9xxx/4R9xxx devices.
- **VREF−, VREF+**
  
  VREF+ is the input reference voltage for ADCs and DACs. It is also the output of the internal voltage reference buffer when enabled.
  
  When $V_{DDA} < 2$ V, $V_{REF+}$ must be equal to $V_{DDA}$.
  
  When $V_{DDA} \geq 2$ V, $V_{REF+}$ must be between 2 V and $V_{DDA}$.
  
  $V_{REF+}$ can be grounded when ADC and DAC are not active.
  
  The internal voltage reference buffer supports two output voltages, which are configured with VRS bit in the VREF_CSR register:
  
  - $V_{REF+}$ around 2.048 V. This requires $V_{DDA}$ equal to or higher than 2.4 V.
  - $V_{REF+}$ around 2.5 V. This requires $V_{DDA}$ equal to or higher than 2.8 V.
  
  $V_{REF−}$ and $V_{REF+}$ pins are not available on all packages. When not available, they are bonded to $V_{SSA}$ and $V_{DDA}$, respectively.
  
  When the $V_{REF+}$ is double-bonded with $V_{DDA}$ in a package, the internal voltage reference buffer is not available and must be kept disable (refer to datasheet for packages pinout description).
  
  $V_{REF−}$ must always be equal to $V_{SSA}$.

An embedded linear voltage regulator is used to supply the internal digital power $V_{CORE}$. $V_{CORE}$ is the power supply for digital peripherals and SRAMx. The Flash is supplied by $V_{CORE}$ and $V_{DD}$.

*Figure 1* presents the power supply overview of the STM32L4 Series and *Figure 2* the power supply overview of STM32L4+ Series.
On STM32L45xxx/46xxx/43xxx/44xxx devices there is no VDDIO2 power domain.
Figure 2. Power supply overview: STM32L4+ Series

1. \(V_{DDDSI}, V_{CAPDSI}\) and \(V_{DD12DSI}\) are only available on STM32L4R9xx/S9xx devices.
1.1.1 Independent analog peripherals supply

To improve ADC and DAC conversion accuracy and to extend the supply flexibility, the analog peripherals have an independent power supply which can be separately filtered and shielded from noise on the PCB.

- The analog peripherals voltage supply input is available on a separate VDDA pin.
- An isolated supply ground connection is provided on VSSA pin.

The VDDA supply voltage can be different from VDD. The presence of VDDA must be checked before enabling any of the analog peripherals supplied by VDDA (A/D converter, D/C converter, comparators, operational amplifiers, voltage reference buffer).

The VDDA supply can be monitored by the Peripheral Voltage Monitoring, and compared with two thresholds (1.65 V for PVM3 or 2.2 V for PVM4), refer to reference manual section: Peripheral Voltage Monitoring (PVM) for more details.

When a single supply is used, VDDA can be externally connected to VDD through the external filtering circuit in order to ensure a noise-free VDDA reference voltage.

ADC and DAC reference voltage

To ensure a better accuracy on low-voltage inputs and outputs, the user can connect to VREF+ a separate reference voltage lower than VDDA. VREF+ is the highest voltage, represented by the full scale value, for an analog input (ADC) or output (DAC) signal.

VREF+ can be provided either by an external reference or by an internal buffered voltage reference (VREF).

The internal voltage reference is enabled by setting the ENVR bit in the VREF control and status register (VREF_CSR). The voltage reference is set to 2.5 V when the VRS bit is set and to 2.048 V when the VRS bit is cleared. The internal voltage reference can also provide the voltage to external components through VREF+ pin. Refer to the device datasheet or reference manual for further information.

1.1.2 Independent I/O supply rail

Some I/Os from Port G (PG[15:2]) are supplied from a separate supply rail. The power supply for this rail can range from 1.08 V to 3.6 V and is provided externally through the VDDIO2 pin. The VDDIO2 voltage level is completely independent from VDD or VDDA. The VDDIO2 pin is available only for some packages. Refer to the pinout diagrams or tables in the related device datasheet(s) for I/O list(s).

After reset, the I/Os supplied by VDDIO2 are logically and electrically isolated and therefore are not available. The isolation must be removed before using any I/O from PG[15:2], by setting the IOSV bit in the PWR_CR2 register, once the VDDIO2 supply is present.

The VDDIO2 supply is monitored by the Peripheral Voltage Monitoring (PVM2) and compared with the internal reference voltage (3/4 VREFINT, around 0.9 V), refer to reference manual section: Peripheral Voltage Monitoring (PVM) for more details.

Note: This does not apply to STM32L45xxx/46xxx/43xxx/44xxx devices.
1.1.3 Independent USB transceivers supply

The USB transceivers are supplied from a separate V_{DDUSB} power supply pin. V_{DDUSB} range is from 3.0 V to 3.6 V and is completely independent from V_{DD} or V_{DDA}.

After reset, the USB features supplied by V_{DDUSB} are logically and electrically isolated and therefore are not available. The isolation must be removed before using the USB OTG peripheral, by setting the USV bit in the PWR_CR2 register, once the V_{DDUSB} supply is present.

The V_{DDUSB} supply is monitored by the Peripheral Voltage Monitoring (PVM1) and compared with the internal reference voltage (V_{REFINT}, around 1.2 V), refer to reference manual section: Peripheral Voltage Monitoring (PVM) for more details.

1.1.4 Independent LCD supply

The V_{LCD} pin is provided to control the contrast of the glass LCD. This pin can be used in two ways:

- It can receive from an external circuitry the desired maximum voltage that is provided on segment and common lines to the glass LCD by the microcontroller.
- It can also be used to connect an external capacitor that is used by the microcontroller for its voltage step-up converter. This step-up converter is controlled by software to provide the desired voltage to segment and common lines of the glass LCD.

The voltage provided to segment and common lines defines the contrast of the glass LCD pixels. This contrast can be reduced when the user configures the dead time between frames.

- When an external power supply is provided to the V_{LCD} pin, it should range from 2.5 V to 3.6 V. It does not depend on V_{DD}.
- When the LCD is based on the internal step-up converter, the V_{LCD} pin should be connected to a capacitor (see the product datasheet for further information).

*Note:* This does not apply to STM32L4+ Series nor STM32L45xxx/46xxx devices.

1.1.5 Independent DSI supply

The DSI (Display Serial Interface) sub-system uses several power supply pins which are independent from the other supply pins:

- V_{DDDSI} is an independent DSI power supply dedicated for the DSI Regulator and MIPI D-PHY. This supply must be connected to the global V_{DD}.
- V_{CAPDSI} is the output of DSI Regulator (1.2 V) which must be connected externally to V_{DD12DSI}.
- V_{DD12DSI} is used to supply the MIPI D-PHY, and to supply clock and data lanes pins. An external capacitor of 2.2 uF must be connected on V_{DD12DSI} pin.
- V_{SSDSI} pin is an isolated supply ground used for DSI sub-system.
If DSI functionality is not used at all, then:

- **V\textsubscript{DD\_DSI}** must be connected to global **V\textsubscript{DD}**.
- **V\textsubscript{CAP\_DSI}** can be left floating, otherwise connect it externally to **V\textsubscript{DD\_12\_DSI}** and the external capacitor is not needed.
- **V\textsubscript{SS\_DSI}** must be grounded.
- **V\textsubscript{DD\_DSI}** and **V\textsubscript{DD\_12\_DSI}** pins are not available on all packages. When not available, they are bonded to **V\textsubscript{DD}** and **V\textsubscript{CAP\_DSI}**, respectively.

**Note:** The DSI supply is available only on STM32L4R9xx/4S9xx.

### 1.1.6 Battery backup domain

To retain the content of the Backup registers and supply the RTC function when **V\textsubscript{DD}** is turned off, the **V\textsubscript{BAT}** pin can be connected to an optional backup voltage supplied by a battery or by another source.

The **V\textsubscript{BAT}** pin powers the RTC unit, the LSE oscillator and the PC13 to PC15 I/Os, allowing the RTC to operate even when the main power supply is turned off. The switch to the **V\textsubscript{BAT}** supply is controlled by the power-down reset embedded in the Reset block.

**Warning:** During t\textsubscript{RST\_TEMPO} (temporization at **V\textsubscript{DD}** startup) or after a PDR has been detected, the power switch between **V\textsubscript{BAT}** and **V\textsubscript{DD}** remains connected to **V\textsubscript{BAT}**.

During the startup phase, if **V\textsubscript{DD}** is established in less than t\textsubscript{RST\_TEMPO} (refer to the datasheet for the value of t\textsubscript{RST\_TEMPO}) and **V\textsubscript{DD}** > **V\textsubscript{BAT}** + 0.6 V, a current may be injected into **V\textsubscript{BAT}** through an internal diode connected between **V\textsubscript{DD}** and the power switch (**V\textsubscript{BAT}**).

If the power supply/battery connected to the **V\textsubscript{BAT}** pin cannot support this current injection, it is strongly recommended to connect an external low-drop diode between this power supply and the **V\textsubscript{BAT}** pin.

If no external battery is used in the application, it is recommended to connect **V\textsubscript{BAT}** externally to **V\textsubscript{DD}** with a 100 nF external ceramic decoupling capacitor.

When the backup domain is supplied by **V\textsubscript{DD}** (analog switch connected to **V\textsubscript{DD}**), the PC13, PC14 and PC15 pins, belonging to **V\textsubscript{BAT}** domain, can have these functions:

- GPIO pins
- RTC or LSE pins (refer to reference manual section: RTC functional description)

**Note:** Due to the fact that the analog switch can transfer only a limited amount of current (3 mA), the use of GPIO PC13 to PC15 in output mode is restricted: the frequency has to be limited to 2 MHz with a maximum load of 30 pF and these I/Os must not be used as a current source (e.g. to drive a LED).
When the backup domain is supplied by V_{BAT} (analog switch connected to V_{BAT} because V_{DD} is not present), the following functions are available:

- PC13, PC14 and PC15 can be controlled only by RTC or LSE refer to reference manual section: RTC functional description
- PA0 and PE6 can be used as tamper inputs by the RTC (RTC_TAMP2 and RTC_TAMP3 respectively).

### Backup domain access

After a system reset, the backup domain (RTC registers and backup registers) is protected against possible unwanted write accesses. To enable access to the backup domain, proceed as follows:

1. Enable the power interface clock by setting the PWREN bits in the APB1 peripheral clock enable register 1 (RCC_APB1ENR1).
2. Set the DBP bit in the Power control register 1 (PWR_CR1) to enable access to the backup domain.
3. Select the RTC clock source in the Backup domain control register (RCC_BDCR).

### V_{BAT} battery charging

When V_{DD} is present, it is possible to charge the external battery on V_{BAT} through an internal resistance.

The V_{BAT} charging is done either through a 5 kΩ resistor or through a 1.5 kΩ resistor depending on the V_{BRS} bit value in the PWR_CR4 register. The battery charging is enabled by setting V_{BE} bit in the PWR_CR4 register. It is automatically disabled in V_{BAT} mode.

### Voltage regulator

Two embedded linear voltage regulators supply all the digital circuitries, except for the Standby circuitry and the backup domain. The main regulator output voltage (V_{CORE}) can be programmed by software to two different power ranges (Range 1 and Range 2) in order to optimize the consumption depending on the system’s maximum operating frequency (refer to reference manual Section: Clock source frequency versus voltage scaling and to Section: Read access latency. For STM32L4+ Series, the Range 1 can be configured in normal mode or in boost mode.

The voltage regulators are always enabled after a reset. Depending on the application modes, the V_{CORE} supply is provided either by the main regulator (MR) or by the low-power regulator (LPR):

- In Run, Sleep and Stop 0 modes, both regulators are enabled and the main regulator (MR) supplies full power to the V_{CORE} domain (core, memories and digital peripherals).
- In low-power run and low-power sleep modes, the main regulator is off and the low-power regulator (LPR) supplies low power to the V_{CORE} domain, preserving the contents of the registers and of internal SRAM.
- In Stop 1 and Stop 2 modes, the main regulator is off and the low-power regulator (LPR) supplies low power to the V_{CORE} domain, preserving the contents of the registers and internal SRAMs.
In Standby mode with SRAM2 content preserved (RRS bit is set in the PWR_CR3 register), the main regulator (MR) is off and the low-power regulator (LPR) provides the supply to SRAM2 only. The core and digital peripherals (except Standby circuitry and backup domain) and SRAM1 are powered off.

In Standby mode, both regulators are powered off. The contents of the registers and SRAMs is lost except for the Standby circuitry and the backup domain.

In Shutdown mode, both regulators are powered off. When exiting from Shutdown mode, a power-on reset is generated. Consequently, the contents of the registers and of SRAMx is lost, except for the backup domain.

The STM32L4A6xG with external SMPS supply option allows to force an external \(V_{DD12}\) supply on the \(V_{CORE}\) power domain when the MR is in use.

When \(V_{DD12}\) is forced by an external source and is higher than the output of the internal LDO, the current is taken from this external supply and the overall power efficiency is significantly improved if using an external step down DC/DC converter.

### 1.1.8 Dynamic voltage scaling management

The dynamic voltage scaling is a power management technique which consists in increasing or decreasing the voltage used for the digital peripherals (\(V_{CORE}\)), according to the application performance and power consumption needs.

Dynamic voltage scaling to increase \(V_{CORE}\) is known as overvolting. It allows to improve the device performance.

Dynamic voltage scaling to decrease \(V_{CORE}\) is known as undervolting. It is performed to save power, particularly in laptop and other mobile devices where the energy comes from a battery and is thus limited.

- **Range 1:** High-performance range.

  For STM32L4+ Series the main regulator operates in two modes following the R1MODE bit in the PWR_CR5 register:
  - Main regulator Range 1 boost mode: the main regulator provides a typical output voltage at 1.28 V. It is used when the system clock frequency is greater than 80 MHz.
  - Main regulator Range 1 normal mode: the main regulator provides a typical output at 1.2 V. It is used when the system clock frequency is up to 80 MHz.

  For STM32L4 Series devices, the main regulator provides a typical output voltage at 1.2 V. The system clock frequency can be up to 80 MHz. The Flash access time for read access is minimum, the write and erase operations are possible.

- **Range 2:** Low-power range.

  The main regulator provides a typical output voltage at 1.0 V. The system clock frequency can be up to 26 MHz. The Flash access time for a read access is increased as compared to Range 1; write and erase operations are possible (except for STM32L4+ Series).

  Voltage scaling is selected through the \(V_{OS}\) bit in the PWR_CR1 register.

The sequence to go from Range 1 (Normal/Boost) to Range 2 is:
1. In case of switching from Range 1 boost mode to Range 2, the system clock must be divided by 2 using the AHB prescaler before switching to a lower system frequency for at least 1 us and then reconfigure the AHB prescaler.

2. Reduce the system frequency to a value lower than 26 MHz.

3. Adjust number of wait states according new frequency target in Range 2 (LATENCY bits in the FLASH_ACR).

4. Program the VOS bits to “10” in the PWR_CR1 register.

The sequence to go from Range 2 to Range 1 is:

1. Program the VOS bits to “01” in the PWR_CR1 register.

2. Wait until the VOSF flag is cleared in the PWR_SR2 register.

3. Adjust number of wait states according to the new frequency target in Range1 (LATENCY bits in the FLASH_ACR).

4. Increase the system frequency by following below procedure:

- If the system frequency is 26 MHz < SYSCLK <= 80 MHz, select the Range 1 mode and just configure and switch to PLL for a new system frequency. For STM32L4+ Series, the R1MODE bit must be set in the PWR_CR5 register for Range1 normal mode selection.

- If the system frequency is SYSCLK > 80 MHz, select the Range 1 boost mode (this is only available in STM32L4+ Series):
  - The system clock must be divided by 2 using the AHB prescaler before switching to a higher system frequency.
  - Clear the R1MODE bit in the PWR_CR5 register.
  - Configure and switch to PLL for a new system frequency.
  - Wait for at least 1 us and then reconfigure the AHB prescaler to get the needed HCLK clock frequency.

*Note: Range1 boost mode is available only in STM32L4+ Series.*
1.2 Power supply schemes

The circuit is powered by a stabilized power supply, $V_{\text{DD}}$.

- The $V_{\text{DD}}$ pins must be connected to $V_{\text{DD}}$ with external decoupling capacitors; one single Tantalum or ceramic capacitor (minimum 4.7 µF typical 10 µF) for the package + one 100 nF ceramic capacitor for each $V_{\text{DD}}$ pin).

- The $V_{\text{DD12}}$ pins, when available, can be connected to an external SMPS. As these $V_{\text{DD12}}$ pin are also connected to internal regulators, they cannot accommodate a decoupling capacitance, neither can they be shared with an external circuitry for other purposes.

- The $V_{\text{DDA}}$ pin must be connected to two external decoupling capacitors (10 nF ceramic capacitor + 1 µF Tantalum or ceramic capacitor). Additional precautions can be taken to filter digital noise: $V_{\text{DDA}}$ can be connected to $V_{\text{DD}}$ through a ferrite bead. In this case take care to keep a $(V_{\text{DDA}} - V_{\text{DD}})$ difference lower than 300 mV.

- The $V_{\text{REF+}}$ pin can be provided by an external voltage reference in which case an external capacitor of 100 and a 1 µF capacitor must be connected on this pin. It can also be provided internally by the Voltage Reference Buffer in which case an external capacitor of 1 µF (typical) must be connected on this pin.

- The $V_{\text{BAT}}$ pin can be connected to an external battery to preserve backup domain content.
  When $V_{\text{DD}}$ is present, it is possible to charge the external battery on $V_{\text{BAT}}$ through a 5 kΩ or 1.5 kΩ internal resistor.
  If no external battery is used in the application, it is recommended to connect $V_{\text{BAT}}$ externally to $V_{\text{DD}}$ with a 100 nF external ceramic decoupling capacitor.

- The $V_{\text{LCD}}$ pin can be provided by an external voltage reference in which case an external capacitor of 100 nF and a 1 µF capacitor must be connected on this pin.
  It can also be provided internally by the Step-up Converter in which case an external capacitor of 1 µF (typical) must be connected on this pin. (The $V_{\text{LCD}}$ pin is not available on STM32L4+ Series).

- $V_{\text{DD12DSI}}$ is used to supply the MIPI D-PHY, and to supply clock and data lanes pins. An external capacitor of 2.2 µF must be connected on the $V_{\text{DD12DSI}}$ pin.

- $V_{\text{DDDSI}}$ is an independent DSI power supply dedicated for the DSI regulator and the MIPI D-PHY. This supply must be connected to the global $V_{\text{DD}}$.

- $V_{\text{CAPDSI}}$ pin is the output of the DSI regulator (1.2 V) which must be connected externally to $V_{\text{DD12DSI}}$.

Note: $V_{\text{DDDSI}}, V_{\text{CAPDSI}}$ and $V_{\text{DD12DSI}}$ are available only on STM32L4S9xx/4R9xxx devices.
Figure 3. Power supply scheme

1. $V_{\text{REF}^+}$ is either connected to $V_{\text{DDA}}$ or to $V_{\text{REF}}$.
2. $n$ is the number of $V_{\text{DD}}$ inputs.
3. $m$ is the number of $V_{\text{DDIO2}}$ inputs.
4. There is no $V_{\text{DDIO2}}$ on STM32L45xxx/46xxx/43xxx/44xxx devices.
Figure 4. Optional LCD power supply scheme

- **Option 1**: LCD power supply is provided by a dedicated $V_{\text{LCD}}$ supply source, $V_{\text{SEL}}$ switch is open.
- **Option 2**: LCD power supply is provided by the internal step-up converter, $V_{\text{SEL}}$ switch is closed, an external capacitance is needed for correct behavior of this converter.

*Note:* $V_{\text{LCD}}$ is multiplexed on PC3 GPIO that needs to be configured as $V_{\text{LCD}}$ alternate function. This does not apply to STM32L4+ Series not STM32L45xxx/46xxx devices.

Figure 5. DSI power supply

*Note:* $V_{\text{DDDSI}}$, $V_{\text{CAPDSI}}$ and $V_{\text{DD12DSI}}$ are available only on STM32L4R9xx/4S9xx.
1.3 Reset and power supply supervisor

1.3.1 Power-on reset (POR) / power-down reset (PDR) / brown-out reset (BOR)

The device has an integrated power-on reset (POR) / power-down reset (PDR), coupled with a brown-out reset (BOR) circuitry. The BOR is active in all power modes except Shutdown mode, and cannot be disabled.

Five BOR thresholds can be selected through option bytes.

During power-on, the BOR keeps the device under reset until the supply voltage \( V_{DD} \) reaches the specified \( V_{BORx} \) threshold. When \( V_{DD} \) drops below the selected threshold, a device reset is generated. When \( V_{DD} \) is above the \( V_{BORx} \) upper limit, the device reset is released and the system can start.

For more details on the brown-out reset thresholds, refer to the electrical characteristics section in the datasheet.

![Figure 6. Brown-out reset waveform](image)

1.3.2 Power reset

A power reset is generated when one of the following events occurs:

1. a brown-out reset (BOR).
2. when exiting from Standby or Shutdown mode.

A brown-out reset, including power-on or power-down reset (POR/PDR), sets all registers to their reset values except the Backup domain.

When exiting Standby or Shutdown mode, all registers in the \( V_{CORE} \) domain are set to their reset value. Registers outside the \( V_{CORE} \) domain (RTC, WKUP, IWDG, and Standby/Shutdown modes control) are not impacted.
1.3.3 System reset

A system reset sets all registers to their reset values except the reset flags in the clock control/status register (RCC_CSR) and the registers in the Backup domain.

A system reset is generated when one of the following events occurs:
- A low level on the NRST pin (external reset)
- Window watchdog event (WWDG reset)
- Independent watchdog event (IWDG reset)
- A firewall event (FIREWALL reset)
- A software reset (SW reset)
- Low-power management reset
- Option byte loader reset
- A Brown-out reset

The reset source can be identified by checking the reset flags in the Control/Status register, RCC_CSR.

These sources act on the NRST pin and it is always kept low during the delay phase. The RESET service routine vector is fixed at address 0x0000_0004 in the memory map.

The system reset signal provided to the device is output on the NRST pin. The pulse generator guarantees a minimum reset pulse duration of 20 µs for each internal reset source. In case of an external reset, the reset pulse is generated while the NRST pin is asserted low.

In case on an internal reset, the internal pull-up R_{PU} is deactivated in order to save the power consumption through the pull-up resistor.

![Figure 7. Simplified diagram of the reset circuit](image)

Software reset

The SYSRESETREQ bit in Cortex®-M4 Application Interrupt and Reset Control Register must be set to force a software reset on the device (as described in STM32F3, STM32F4 and STM32L4 Series Cortex®-M4 programming manual (PM0214)).
Low-power mode security reset

To prevent that critical applications mistakenly enter a low-power mode, two low-power mode security resets are available. If enabled in option bytes, the resets are generated in the following conditions:

1. Entering Standby mode: this type of reset is enabled by resetting nRST_STDBY bit in User option Bytes. In this case, whenever a Standby mode entry sequence is successfully executed, the device is reset instead of entering Standby mode.

2. Entering Stop mode: this type of reset is enabled by resetting nRST_STOP bit in User option bytes. In this case, whenever a Stop mode entry sequence is successfully executed, the device is reset instead of entering Stop mode.

3. Entering Shutdown mode: this type of reset is enabled by resetting nRST_SHDW bit in User option bytes. In this case, whenever a Shutdown mode entry sequence is successfully executed, the device is reset instead of entering Shutdown mode.

For further information on the User Option Bytes, refer to reference manual section: Option bytes description.

Option byte loader reset

The option byte loader reset is generated when the OBL_LAUNCH bit (bit 27) is set in the FLASH_CR register. This bit is used to launch the option byte loading by software.

Charging/discharging the pull-down capacitor through the internal resistor adds to the device power consumption. The recommended value of 100 nF for the capacitor can be reduced to 10 nF to limit power consumption.

1.3.4 Backup domain reset

The backup domain has two specific resets.

A backup domain reset is generated when one of the following events occurs:

1. Software reset, triggered by setting the BDRST bit in the Backup domain control register (RCC_BDCR).

2. $V_{DD}$ or $V_{BAT}$ power on, if both supplies have previously been powered off.

A backup domain reset only affects the LSE oscillator, the RTC, the Backup registers and the RCC Backup domain control register.
2 Package

2.1 Package selection

Package should be selected by taking into account the constraints that are strongly dependent upon the application.

The list below summarizes the most frequent ones:

- Amount of interfaces required. Some interfaces might not be available on some packages. Some interfaces combinations might not be possible on some packages.
- PCB technology constrains. Small pitch and high ball density could require more PCB layers and higher class PCB.
- Package height.
- PCB available area.
- Noise emission or signal integrity of high speed interfaces. Smaller packages usually provide better signal integrity. This is further enhanced as Small pitch and high ball density requires multilayer PCBs which allow better supply/ground distribution.
- Compatibility with other devices.

2.2 SMPS packages

Some STM32L4 devices offer a package option allowing the connection of an external SMPS.

Such a connection is done through two $V_{DD12}$ pins that are replacing the two existing pins in the baseline package.

The compatibility is kept among the various STM32L4 derivatives regarding those two pins: The pins replaced are different across package types but are the same for all derivatives on similar packages.

Please refer to the product datasheet for details.
## 2.3 Pinout compatibility

---

1. PC3/VLCD is not available on the SM32L4Sxxx/4Rxxx/45xxx/46xxx devices.
2. Pin BOOT0 multiplexed with PH3 on STM32L4+ Series and STM32L49xxx/4Axxxx/43xxx/44xxx devices.
3. VDDD, VSSDSI, VDDA2DSI and VCAPDSI are available only on STM32L4S9xx/4R9xxx devices.
4. One single tantalum or ceramic capacitor (min. 4.7 uF, typ. 10 uF) for the package + one 100 nF ceramic capacitor for each VDD pin.
5. X/Y: X is for all STM32L4 Series and STM32L4+ Series devices and Y is only for STM32L4R9xx/4S9xx.
# Clocks

Four different clock sources can be used to drive the system clock (SYSCLK):

- **HSI16** (high speed internal) 16 MHz RC oscillator clock
- **MSI** (multispeed internal) RC oscillator clock
- **HSE** oscillator clock, from 4 to 48 MHz
- **PLL** clock

The **MSI** is used as system clock source after startup from Reset, configured at 4 MHz.

The devices have the following additional clock sources:

- **32 kHz low speed internal RC (LSI RC)** which drives the independent watchdog and optionally the RTC used for Auto-wakeup from Stop and Standby modes.
- **32.768 kHz low speed external crystal (LSE crystal)** which optionally drives the real-time clock (RTCCCLK).
- **RC 48 MHz internal clock sources (HSI48)** to potentially drive the USB full speed, the SDMMC and the RNG. (only on STM32L4+ Series and STM32L49xxx/4Axxx/45xxx/46xxx/43xxx/44xxx devices).

Each clock source can be switched on or off independently when it is not used, to optimize power consumption.

Several prescalers can be used to configure the AHB frequency, the high speed APB (APB2) and the low speed APB (APB1) domains. The maximum frequency of the AHB, the APB1 and the APB2 domains is 80 MHz and for STM32L4+ Series is 120 MHz.

## 3.1 HSE clock

The high speed external clock signal (HSE) can be generated from two possible clock sources:

- **HSE external crystal/ceramic resonator**
- **HSE user external clock**

The resonator and the load capacitors have to be placed as close as possible to the oscillator pins in order to minimize output distortion and startup stabilization time. The loading capacitance values must be adjusted according to the selected oscillator.
Table 7. HSE/ LSE clock sources

</tr>
<tr>
<td>Crystal/Ceramic resonators</td>
<td><img src="MSv46308V1" alt="Crystal/Ceramic resonators diagram" /></td>
</tr>
</tbody>
</table>

1. The value of \( R_{\text{EXT}} \) depends on the crystal characteristics. A typical value is in the range of 5 to 6 \( R_s \) (resonator series resistance). To fine tune the \( R_{\text{EXT}} \) value, refer to AN2867 (Oscillator design guide for ST microcontrollers).

2. Load capacitance, \( C_L \), has the following formula: \( C_L = C_{L1} \times C_{L2} / (C_{L1} + C_{L2}) + C_{\text{stray}} \) where \( C_{\text{stray}} \) is the pin capacitance and board or trace PCB-related capacitance. Typically, it is between 2 pF and 7 pF. Please refer to Section 6.4: Decoupling to minimize its value.
3.1.1 **External crystal/ceramic resonator (HSE crystal)**

The 4- to 48-MHz external oscillator has the advantage of producing a very accurate rate on the main clock.

The associated hardware configuration is shown in *Figure 7*. Refer to the electrical characteristics section of the *datasheet* for more details.

The HSERDY flag in the *Clock control register (RCC_CR)* indicates if the HSE oscillator is stable or not. At startup, the clock is not released until this bit is set by hardware. An interrupt can be generated if enabled in the *Clock interrupt enable register (RCC_CIER)*.

The HSE Crystal can be switched on and off using the HSEON bit in the *Clock control register (RCC_CR)*.

3.1.2 **External source (HSE bypass)**

In this mode, an external clock source must be provided. It can have a frequency of up to 48 MHz. The user selects this mode by setting the HSEBYP and HSEON bits in the Clock control register (RCC_CR). The external clock signal (square, sinus or triangle) with ~40-60 % duty cycle depending on the frequency (refer to the datasheet) has to drive the following pin (see *Figure 7*).

- On devices where OSC_IN and OSC_OUT pins are available: OSC_IN pin must be driven while the OSC_OUT pin can be used as a GPIO.
- Otherwise, the CK_IN pin must be driven.

*Note:* For details on pin availability, refers to the pinout section in the corresponding device *datasheet*.

To minimize the consumption, it is recommended to use the square signal.

3.2 **HSI16 clock**

The HSI16 clock signal is generated from an internal 16 MHz RC Oscillator.

The HSI16 RC oscillator has the advantage of providing a clock source at low cost (no external components). It also has a faster startup time than the HSE crystal oscillator however, even with calibration the frequency is less accurate than an external crystal oscillator or ceramic resonator.

The HSI16 signal can also be used as a backup source (Auxiliary clock) if the HSE crystal oscillator fails. Refer to reference manual *section: Clock security system (CSS)*.

3.3 **MSI clock**

The MSI clock signal is generated from an internal RC oscillator. Its frequency range can be adjusted by software by using the MSIRANGE[3:0] bits in the *Clock control register (RCC_CR)*. Twelve frequency ranges are available: 100 kHz, 200 kHz, 400 kHz, 800 kHz, 1 MHz, 2 MHz, 4 MHz (default value), 8 MHz, 16 MHz, 24 MHz, 32 MHz and 48 MHz.

The MSI RC oscillator has the advantage of providing a low-cost (no external components) low-power clock source. In addition, when trimmed by the 32.768 kHz external oscillator (LSE), the MSI can provide the USB device with very accurate clock removing the need for an external high speed crystal (HSE).
3.3.1 Hardware auto calibration with LSE (PLL-mode)

When a 32.768 kHz crystal is present in the application, it is possible to configure the MSI in a PLL-mode by setting the MSIPLLLEN bit in the Clock control register (RCC_CR). When configured in PLL-mode, the MSI automatically calibrates itself thanks to the LSE. This mode is available for all MSI frequency ranges. At 48 MHz, the MSI in PLL-mode can be used for the USB OTG FS device, saving the need of an external high-speed crystal.

For more details on how to calibrate the MSI frequency variation please refer to reference manual section: Internal/external clock measurement with TIM15/TIM16/TIM17.

3.4 LSE clock

The LSE crystal is a 32.768 kHz Low Speed External crystal or ceramic resonator. It has the advantage of providing a low-power but highly accurate clock source to the real-time clock peripheral (RTC) for clock/calendar or other timing functions.

The LSE crystal is switched on and off using the LSEON bit in Backup domain control register (RCC_BDCR). The crystal oscillator driving strength can be changed at runtime using the LSEDRV[1:0] bits in the Backup domain control register (RCC_BDCR) to obtain the best compromise between robustness and short start-up time on one side and low-power-consumption on the other side. The LSE drive can be decreased to the lower drive capability (LSEDRV=00) when the LSE is ON. However, once LSEDRV is selected, the drive capability can not be increased if LSEON=1.

The LSERDY flag in the AHB1 peripheral clocks enable in Sleep and Stop modes register (RCC_AHB1SMENR) indicates whether the LSE crystal is stable or not. At startup, the LSE crystal output clock signal is not released until this bit is set by hardware. An interrupt can be generated if enabled in the Clock interrupt enable register (RCC_CIER).

3.4.1 External source (LSE bypass)

In this mode, an external clock source must be provided. It can have a frequency of up to 1 MHz. The user selects this mode by setting the LSEBYP and LSEON bits in the AHB1 peripheral clocks enable in Sleep and Stop modes register (RCC_AHB1SMENR). The external clock signal (square, sinus or triangle) with ~50 % duty cycle has to drive the OSC32_IN pin while the OSC32_OUT pin can be used as GPIO. See Figure 7.
4 Boot configuration

4.1 Boot configuration for STM32L47xxx/48xxx devices

In STM32L47xxx/48xxx devices, three different boot modes can be selected through the BOOT0 pin and nBOOT1 bit in the User option byte, as shown in the following table.

<table>
<thead>
<tr>
<th>Boot mode selection</th>
<th>Boot mode</th>
<th>Aliasing</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOOT0(1)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>x</td>
<td>Main Flash memory</td>
<td>Main Flash memory is selected as boot space</td>
</tr>
<tr>
<td>0</td>
<td>System memory</td>
<td>System memory is selected as boot space</td>
</tr>
<tr>
<td>1</td>
<td>Embedded SRAM1</td>
<td>Embedded SRAM1 is selected as boot space</td>
</tr>
</tbody>
</table>

1. The BOOT1 value is the opposite of the nBOOT1 Option Bit.

The values on both BOOT0 pin and nBOOT1 bit are latched after a reset. It is up to the user to set nBOOT1 and BOOT0 to select the required boot mode.

The BOOT0 pin and nBOOT1 bit are also re-sampled when exiting from Standby mode. Consequently they must be kept in the required Boot mode configuration in Standby mode. After this startup delay has elapsed, the CPU fetches the top-of-stack value from address 0x0000 0000, then starts code execution from the boot memory at 0x0000 0004.

Depending on the selected boot mode, main Flash memory, system memory or SRAM1 is accessible as follows:

- **Boot from main Flash memory:** the main Flash memory is aliased in the boot memory space (0x0000 0000), but still accessible from its original memory space (0x0800 0000). In other words, the Flash memory contents can be accessed starting from address 0x0000 0000 or 0x0800 0000.

- **Boot from system memory:** the system memory is aliased in the boot memory space (0x0000 0000), but still accessible from its original memory space (0x1FFF 0000).

- **Boot from the embedded SRAM1:** the SRAM1 is aliased in the boot memory space (0x0000 0000), but it is still accessible from its original memory space (0x2000 0000).

**Note:** When the device boots from SRAM, in the application initialization code, the user has to relocate the vector table in SRAM using the NVIC exception table and the offset register. When booting from the main Flash memory, the application software can either boot from bank 1 or from bank 2. By default, boot from bank 1 is selected.

To select boot from Flash memory bank 2, set the BFB2 bit in the user option bytes. When this bit is set and the boot pins are in the boot from main Flash memory configuration, the device boots from system memory, and the boot loader jumps to execute the user application programmed in Flash memory bank 2. For further details, please refer to AN2606.

**Note:** When booting from bank 2, in the application initialization code, the user has to relocate the vector table to bank 2 base address, (0x0808 0000) using the NVIC exception table and offset register.
4.1.1 Physical remap

Once the boot pins are selected, the application software can modify the memory accessible in the code area (in this way the code can be executed through the ICode bus in place of the System bus). This modification is performed by programming the SYSCFG memory remap register (SYSCFG_MEMRMP) in the SYSCFG controller.

The following memories can thus be remapped:

- Main Flash memory
- System memory
- Embedded SRAM1 (96 Kbytes)
- FSMC bank 1 (NOR/PSRAM 1 and 2)
- Quad SPI memory

4.1.2 Embedded boot loader

The embedded boot loader is located in the System memory, programmed by ST during production. It is used to reprogram the Flash memory using one of the following serial interfaces:

- USART1 on pins PA9/PA10, USART2 on pins PA2/PA3, USART3 on pins PC10/PC11
- I2C1 on pins PB6/PB7, I2C2 on pins PB10/PB11, I2C3 on pins PC0/PC1
- SPI1 on pins PA4/PA5/PA6/PA7, SPI2 on pins PB12/PB13/PB14/PB15, SPI3 on pins PA15/PC10/PC11/PC12
- USB DFU interface on pins PA11/PA12
- CAN1 on pins PB8/PB9

For details concerning the boot loader serial interface corresponding I/O, refer to the device datasheet.

For further details on STM32 boot loader, please refer to AN2606.

4.1.3 BOOT0 pin connection

The BOOT0 pin of the STM32L4 Series has a lower VIL than the other GPIO, (for details see datasheet I/O static characteristics), thus as it does not fit CMOS requirement, when driven by another CMOS circuit the signal level must be verified.

4.2 Boot configuration for STM32L4+ Series and STM32L49xxx/4Axxx/45xxx/46xxx/43xxx/44xxx devices

In STM32L4+ Series and STM32L49xxx/4Axxx/45xxx/46xxx/43xxx/44xxx devices, three different boot modes can be selected through the BOOT0 pin or the nBOOT0 bit into the FLASH_OPTR register (if the nSWBOOT0 bit is cleared into the FLASH_OPTR register), and nBOOT1 bit in the FLASH_OPTR register, as shown in the following table:

<table>
<thead>
<tr>
<th>nBOOT1</th>
<th>nBOOT0</th>
<th>BOOT0 pin PH3</th>
<th>nSWBOOT0</th>
<th>Main Flash empty</th>
<th>Boot Memory Space Alias</th>
</tr>
</thead>
<tbody>
<tr>
<td>X</td>
<td>X</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>Main Flash memory is selected as boot area</td>
</tr>
<tr>
<td>X</td>
<td>X</td>
<td>0</td>

</tr>
<tr>
<td>0</td>
<td>X</td>
<td>1</td>
<td>1</td>
<td>X</td>
<td>Embedded SRAM1 is selected as boot area</td>
</tr>
</tbody>
</table>

1. When the FSMC is remapped at address 0x0000 0000, only the first two regions of bank 1 memory controller (bank 1 NOR/PSRAM 1 and NOR/PSRAM 2) can be remapped. When the QUADSPI is remapped at address 0x0000 0000, only 128 Mbytes are remapped. In remap mode, the CPU can access the external memory via ICode bus instead of system bus which boosts up the performance. Even when aliased in the boot memory space, the related memory is still accessible at its original memory space.
The values on both BOOT0 (coming from the pin or the option bit) and nBOOT1 bit are latched on the 4th edge of the internal startup clock source after reset release. It is up to the user to set nBOOT1 and BOOT0 to select the required boot mode.

The BOOT0 pin or user option bit (depending on the nSWBOOT0 bit value in the FLASH_OPTR register), and nBOOT1 bit are also re-sampled when exiting from Standby mode. Consequently they must be kept in the required Boot mode configuration in Standby mode. After this startup delay has elapsed, the CPU fetches the top-of-stack value from address 0x0000 0000, then starts code execution from the boot memory at 0x0000 0004.

Depending on the selected boot mode, main Flash memory, system memory or SRAM1 is accessible as follows:

- **Boot from main Flash memory:** the main Flash memory is aliased in the boot memory space (0x0000 0000), but still accessible from its original memory space (0x0800 0000). In other words, the Flash memory contents can be accessed starting from address 0x0000 0000 or 0x0800 0000.
- **Boot from system memory:** the system memory is aliased in the boot memory space (0x0000 0000), but still accessible from its original memory space (0x1FFF 0000).
- **Boot from the embedded SRAM1:** the SRAM1 is aliased in the boot memory space (0x0000 0000), but it is still accessible from its original memory space (0x2000 0000).

PH3/BOOT0 GPIO is configured in:

- Input mode during the complete reset phase if the option bit nSWBOOT0 is set into the FLASH_OPTR register and then switches automatically in analog mode after reset is released (BOOT0 pin).
- Input mode from the reset phase to the completion of the option byte loading if the bit nSWBOOT0 is cleared into the FLASH_OPTR register (BOOT0 value coming from the option bit). It switches then automatically to the analog mode even if the reset phase is not complete.

**Note:** When the device boots from SRAM, in the application initialization code, the user has to relocate the vector table in SRAM using the NVIC exception table and the offset register.
### Physical remap

Once the boot mode is selected, the application software can modify the memory accessible in the code area (in this way the code can be executed through the ICode bus in place of the System bus). This modification is performed by programming the SYSCFG memory remap register (SYSCFG_MEMRMP) in the SYSCFG controller.

The following memories can thus be remapped:
- Main Flash memory
- System memory
- Embedded SRAM1 (256 Kbytes for STM32L49xxx/4Axxx, 128 Kbytes for STM32L45xxx/46xxx, 48 Kbytes for STM32L43xxx/44xxx and 192 Kbytes for STM32L4+ Series)
- FSMC bank 1 (NOR/PSRAM 1 and 2) (for STM32L4+ Series and STM32L49xxx/4Axxx devices only)
- Quad-SPI memory (not available on STM32L4+ Series)
- Octo-SPI (OCTOSPI1 or OCTOSPI2) memory (available only on STM32L4+ Series).

#### Table 11. Memory mapping vs. Boot mode/Physical remap for STM32L4 Series

<td>System memory (28 Kbytes) Aliased</td>
<td>QUADSPI bank (128 Mbytes) Aliased</td>
</tr>
</tbody>
</table>

1. When the QUADSPI is remapped at address 0x0000 0000, only 128 Mbytes are remapped. In remap mode, the CPU can access the external memory via ICode bus instead of System bus which boosts up the performance.

Even when aliased in the boot memory space, the related memory is still accessible at its original memory space.
The embedded boot loader is located in the System memory, programmed by ST during production. It is used to reprogram the Flash memory using one of the following serial interfaces:

- **USART1** on pins PA9/PA10, **USART2** on pins PA2/PA3, **USART3** on pins PC10/PC11
- **I2C1** on pins PB6/PB7, **I2C2** on pins PB10/PB11, **I2C3** on pins PC0/PC1
- **I2C4** on pins PD12/PD13 (STM32L4+ Series and STM32L49xxx/4Axxx/45xxx/46xxx devices only)
- **SPI1** on pins PA4/PA5/PA6/PA7, **SPI2** on pins PB12/PB13/PB14/PB15, **SPI3** on pins PA15/PC10/PC11/PC12
- **USB DFU** interface on pins PA11/PA12
- **CAN1** on pins PB8/PB9
- **CAN2** on pins PB5/PB6 (STM32L49xxx/4Axxx devices only)

For details concerning the boot loader serial interface corresponding I/O, refer to the device’s datasheet.

For further details on STM32 boot loader, please refer to AN2606.
5 Debug management

5.1 Introduction

In the SWJ-DP, the two JTAG pins of the SW-DP are multiplexed with some of the five JTAG pins of the JTAG-DP.

The host/target interface is the hardware equipment that connects the host to the application board. This interface is made of three components: a hardware debug tool, a SW connector and a cable connecting the host to the debug tool.

*Figure 8* shows the connection of the host to a development board.

*Figure 8. Host-to-board connection*

![Host-to-board connection diagram]

The Nucleo demonstration board embeds the debug tools (ST-LINK) so it can be directly connected to the PC through an USB cable. The ST-LINK requires by default to have an enumeration with a host that is able to supply 100 mA to power the STM32L4 MCU, hence user shall use jumper JP1 on the Nucleo board which can be set in case maximum current consumption on U5V does not exceed 100 mA.

5.2 SWJ debug port (JTAG and serial wire)

The STM32L4 Series core integrates the serial wire / JTAG debug port (SWJ-DP). It is an ARM® standard CoreSight™ debug port that combines a JTAG-DP (5-pin) interface and a SW-DP (2-pin) interface.

- The JTAG debug port (JTAG-DP) provides a 5-pin standard JTAG interface to the AHP-AP port
- The serial wire debug port (SW-DP) provides a 2-pin (clock + data) interface to the AHP-AP port
5.3 Pinout and debug port pins

The STM32L4 MCU is offered in various packages with different numbers of available pins. As a result, some functionality related to the pin availability may differ from one package to another.

5.3.1 SWJ debug port pins

Five pins are used as outputs for the SWJ-DP as alternate functions of general-purpose I/Os (GPIOs). These pins, shown in Table 13, are available on all packages.

Table 13. Debug port pin assignment

<table>
<thead>
<tr>

</tr>
<tr>
<td>JNTRST</td>
<td>I</td>
<td>JTAG test nReset</td>
<td>-</td>
</tr>
</tbody>
</table>

5.3.2 Flexible SWJ-DP pin assignment

After reset (SYSRESETn or PORESETn), all five pins used for the SWJ-DP are assigned as dedicated pins which are immediately usable by the debugger host (note that the trace outputs are not assigned except if explicitly programmed by the debugger host).

However, the STM32L4 MCU implements a register to disable all or part of the SWJ-DP port, and so releases the associated pins for general-purpose I/O usage. This register is mapped on an APB bridge connected to the Cortex®-M4 system bus. It is programmed by the user software program and not by the debugger host.

Table 14 shows the different possibilities for releasing some pins. For more details, see the related STM32L4xxxx reference manual.

Table 14. SWJ I/O pin availability

<tr>
<td>JTAG-DP disabled and SW-DP enabled</td>
<td>X</td>
</tr>
<tr>
<td>JTAG-DP disabled and SW-DP disabled</td>
<td>Released</td>
</tr>
</tbody>
</table>
5.3.3 Internal pull-up and pull-down resistors on JTAG pins

The JTAG input pins must not be floating since they are directly connected to flip-flops which control the debug mode features. Special care must be taken with the SWCLK/TCK pin that is directly connected to the clock of some of these flip-flops.

To avoid any uncontrolled I/O levels, the STM32L4 Series embeds internal pull-up and pull-down resistors on the JTAG input pins:
- JNTRST: internal pull-up
- JTDI: internal pull-up
- JTMS/SWDIO: internal pull-up
- TCK/SWCLK: internal pull-down

Once a JTAG I/O is released by the user software, the GPIO controller takes control again. The reset states of the GPIO control registers put the I/Os in the following equivalent states:
- JNTRST: input pull-up
- JTDI: input pull-up
- JTMS/SWDIO: input pull-up
- JTCK/SWCLK: input pull-down
- JTDO: input floating

The software can then use these I/Os as standard GPIOs.

Note: The JTAG IEEE standard recommends to add pull-up resistors on TDI, TMS and nTRST but, there is no special recommendation for TCK. However, for the STM32L4 Series, an integrated pull-down resistor is used for JTCK. Having embedded pull-up and pull-down resistors removes the need to add external resistors.

5.3.4 SWJ debug port connection with standard JTAG connector

Figure 9 shows the connection between the STM32L4 MCU and a standard JTAG connector.

![Figure 9. JTAG connector implementation](image-url)
5.4 Serial wire debug (SWD) pin assignment

The same SWD pin assignment is available on all STM32L4 Series packages.

<table>
<thead>
<tr>
<th>SWD pin name</th>
<th>SWD port</th>
<th>Debug assignment</th>
<th>Pin assignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>SWDIO</td>
<td>I/O</td>
<td>Serial wire data input/output</td>
<td>PA13</td>
</tr>
<tr>
<td>SWCLK</td>
<td>I</td>
<td>Serial wire clock</td>
<td>PA14</td>
</tr>
</tbody>
</table>

5.4.1 SWD pin assignment

After reset (SYSRESETn or PORESETn), the pins used for the SWD are assigned as dedicated pins which are immediately usable by the debugger host.

However, the MCU offers the possibility to disable the SWD, therefore releasing the associated pins for general-purpose I/O (GPIO) usage. For more details on how to disable SWD port, refer to the I/O pin alternate function multiplexer and mapping section of the related STM32L4xx reference manual.
5.4.2 Internal pull-up and pull-down on SWD pins

Once the SWD I/O is released by the user software, the GPIO controller takes control of these pins. The reset states of the GPIO control registers put the I/Os in the equivalent states:

- SWDIO: alternate function pull-up
- SWCLK: alternate function pull-down

Having embedded pull-up and pull-down resistors removes the need to add external resistors.

5.4.3 SWD port connection with standard SWD connector

Figure 10 shows the connection between the STM32L4 MCU and a standard SWD connector.
6 Recommendations

6.1 Printed circuit board
For technical reasons, it is best to use a multilayer printed circuit board (PCB) with a separate layer dedicated to ground \((V_{SS})\) and another dedicated to the \(V_{DD}\) supply. This provides good decoupling and a good shielding effect. For many applications, economical reasons prohibit the use of this type of board. In this case, the major requirement is to ensure a good structure for ground and for the power supply.

6.2 Component position
A preliminary layout of the PCB must make separate circuits:
- High-current circuits
- Low-voltage circuits
- Digital component circuits
- Circuits separated according to their EMI contribution. This will reduce cross-coupling on the PCB that introduces noise.

6.3 Ground and power supply \((V_{SS}, V_{DD}, V_{SSA}, V_{DDA}, V_{DDUSB}, V_{DDIO2}, V_{DDDSI})\)
Every block (noisy, low-level sensitive, digital, etc.) should be grounded individually, and all ground returns should be to a single point. Loops must be avoided or have a minimum area. In order to improve analog performance, the user must use separate supply sources for \(V_{DD}\) and \(V_{DDA}\), and place the decoupling capacitors as close as possible to the device.

The power supplies should be implemented close to the ground line to minimize the area of the supplies loop. This is due to the fact that the supply loop acts as an antenna, and acts as the main transmitter and receiver of EMI. All component-free PCB areas must be filled with additional grounding to create a kind of shielding (especially when using single-layer PCBs).

6.4 Decoupling
All power supply and ground pins must be properly connected to the power supplies. These connections, including pads, tracks and vias should have as low an impedance as possible. This is typically achieved with thick track widths and, preferably, the use of dedicated power supply planes in multilayer PCBs.

In addition, each power supply pair should be decoupled with filtering ceramic capacitors \((100 \, \text{nF})\) and a Tantalum or ceramic capacitor of about \(10 \, \mu\text{F}\) connected in parallel on the STM32L4 Series device. Some package use a common \(V_{SS}\) for several \(V_{DD}\) instead of a pair of power supply (one \(V_{SS}\) for each \(V_{DD}\)), in that case the capacitors must be between each \(V_{DD}\) and the common \(V_{SS}\). These capacitors need to be placed as close as possible to, or below, the appropriate pins on the underside of the PCB. Typical values are \(10 \, \text{nF}\) to \(100 \, \text{nF}\), but exact values depend on the application needs. Figure 11 shows the typical layout of such a \(V_{DD}/V_{SS}\) pair.
6.5 Other signals

When designing an application, the EMC performance can be improved by closely studying the following:

- Signals for which a temporary disturbance affects the running process permanently (which is the case for interrupts and handshaking strobe signals but, not the case for LED commands).
  
  For these signals, a surrounding ground trace, shorter lengths, and the absence of noisy and sensitive traces nearby (crosstalk effect) improve EMC performance.
  
  For digital signals, the best possible electrical margin must be reached for the two logical states and slow Schmitt triggers are recommended to eliminate parasitic states.

- Noisy signals (example, clock)
- Sensitive signals (example, high impedance)

6.6 Unused I/Os and features

All microcontrollers are designed for a variety of applications and often a particular application does not use 100% of the MCU resources.

To increase EMC performance and avoid extra power consumption, the unused features of the device should be disabled and disconnected from the clock tree. The unused clock source should be disabled and the unused I/Os should not be left floating. The unused I/O pins should be configured as analog input by software; they should also be connected to a fixed logic level 0 or 1 by an external or internal pull-up or pull-down or configured as output mode using software.
7 Reference design

7.1 Description

The reference design shown in Figure 12 on page 45, is based on the STM32L4 Series LQFP144.

This reference design can be tailored to any STM32L4 Series device with a different package, using the pin correspondence given in Table 18: Reference connection for all packages on page 45.

7.1.1 Clock

Two clock sources are used for the microcontroller:
- LSE: X2 – 32.768 kHz crystal for the embedded RTC
- HSE: X1 – 8 MHz crystal for the STM32L4 Series microcontroller

Refer to Section 3: Clocks on page 26.

7.1.2 Reset

The reset signal in Figure 12 on page 45 is active low. The reset sources include:
- Reset button (B1)
- Debugging tools via the connector CN1

Refer to Section 1.3: Reset and power supply supervisor on page 20.

7.1.3 Boot mode

The boot option is configured by setting switches SW1 (Boot 0). Refer to Section 4: Boot configuration on page 30.

Note: When waking up from Standby mode, the Boot pin is sampled. In this situation, the user needs to pay attention to its value.

7.1.4 SWD interface

The reference design shows the connection between the STM32L4 MCU and a standard SWD connector. Refer to Section 5: Debug management on page 36.

Note: It is recommended to connect the reset pins so as to be able to reset the application from the tools.

7.1.5 Power supply

Refer to Section 1: Power supplies on page 7.

---

1. This table is not applicable for STM32L4R9xx/4S9xx as they are not compatible with STM32L4 Series.
2. PC3/VLCD not applicable on STM32L45xxx/46xxx devices.
3. Pin BOOT0 multiplexed with PH3 on STM32L49xx/4Axxx/45xxx/46xxx/43xxx/44xxx devices.
