GLOSSARY

Supply voltage (VCC) – Voltage difference between the two power pins where the op amp works correctly. In ST’s portfolio, one can find 5V, 16V and 36V products.

Quiescent current (Iq) – Supply current needed for each operational amplifier in the package for its operation.

Input offset voltage (VIO) – Differential input voltage of the + and - pins to get the output at the mid-range of the supply voltage. It originates from the matching of internal transistors.

Input bias current (IB) – Current flowing through an op amp’s inputs. Due to op amp biasing requirements and normal operation leakage, a very small amount of current (pA or nA range, depending on the technology) is flowing through the inputs. This may cause problems when large value resistors or sources with higher output impedances are connected at the op amp inputs. This causes relevant voltage drops at the op amp input and therefore errors.

Gain bandwidth product (GBP) – Product of an op amp’s gain and bandwidth. It is measured at 20 dB gain. Defined for small signals.

Slew rate (SR) – How fast an op amp can change its voltage on its output. An op amp’s output rate of change is limited to the slew rate value. It causes distortion if the signal to be amplified is too fast.

Rail-to-rail input – An op amp with single rail input is able to deal with input signals up to Vcc while a rail-to-rail input is able to deal with differential signals down to Voc. Rail-to-rail input op amps can handle input signals from Voc to Vcc.

Rail-to-rail output – Capability of an op amp to drive its output very close to the power supply rails.

Noise level – Op-amps generate random voltages at the output even when there is no signal applied on its input. Such noise comes from the thermal noise (white noise) or 1/f noise, also called flicker noise. For applications with high gain or bandwidth, a noise level may become considerable.

Capacitive load – Can cause an op amp to become an oscillator. The op amp output resistance in connection with a capacitive load results in an additional pole in the circuit transfer function. From the Bode, then it is clearly visible under which operating conditions the circuit can become unstable.

Zero drift – Chopper op amps designed to “self-correct” their VIO errors and also those happening over temperature and over the time. Thanks to their design, zero-drift op amps have their VIO in the range of microvolts and stabilize “nano-volt” per Celsius degree drift. Zero-drift op amps have virtually no 1/f noise and also their “aging” over the time is negligible.

Shut down – Op amp operation switch-off. Usually used to reduce the circuit standby current when an application does not run or amplification is not needed. Usually controlled by a dedicated op amp pin.

RTD: Resistance temperature detectors. Many RTD sensors are constructed from a fine metal wire which is wrapped around a ceramics/glass capillary.

Thermocouples – Every transition between different kinds of metals causes a tiny thermoelectrical voltage. This effect is used in some temperature sensors.

In today’s digital world, many signals start as an analog one. Most sensors already have their own analog signal conditioning circuit, but an operational amplifier is still a key device when you need more complex amplification and filtering, or just for interfacing analog signals with an ADC or a microcontroller. This reference guide provides you information about ST’s most recent operational amplifiers and their characteristics.

Amplification of low voltage signals
When amplifying low voltage signals, you definitely need high precision op amps since the input offset voltage directly affects your measurement. On the other hand, most low-voltage signals come from low impedance sources. Therefore, the input bias current is not critical. A differential amplifier or an instrumentation amplifier is a typical circuit. Current sensing is a typical application where you usually need low- or high-tot features and provides as an input to your ADC. Other applications include Wheatstone bridges circuits e.g. strain gauges, RTD sensors or resistive sensors. In such applications, rail-to-rail inputs are not needed in most cases, but you may require a low-noise device. The same can be applied for a current sensing application.

Small current amplification
Sensors providing a small current will require an op amp with a low input bias current. All of these applications use a transimpedance amplifier where the input offset voltage is not usually critical. A typical application is a photodiode current sensing circuit used in communications, light curtains, smoke detectors, and so on. Small current amplification is a typical circuit. Current sensing is a typical application where you usually need low- or high-tot features and provides as an input to your ADC. Other applications include Wheatstone bridges circuits e.g. strain gauges, RTD sensors or resistive sensors. In such applications, rail-to-rail inputs are not needed in most cases, but you may require a low-noise device. The same can be applied for a current sensing application.

TYPICAL OP AMP APPLICATIONS AND KEY PARAMETERS
Each application has different key requirements for operational amplifier performance. Generally, we can divide applications into several different categories.

T-Power Consumption
H-Speed
A-Precision
P-Input and Output Speed
S-Input Imbalance
M-Slew Rate
