Introduction

The SPV1040 is a high efficiency, low power and low voltage DC-DC converter that provides a single output voltage up to 5.2 V. Startup is guaranteed at 0.3 V and the device operates down to 0.45 V when coming out from MPPT mode. It is a 100 kHz fixed frequency PWM step-up (or boost) converter able to maximize the energy generated by few solar cells (polycrystalline or amorphous). The duty cycle is controlled by an embedded unit running an MPPT algorithm with the goal of maximizing the power generated from the panel by continuously tracking its output voltage and current.

The SPV1040 guarantees the safety of overall application and of converter itself by stopping the PWM switching in the case of an overcurrent or overtemperature condition.

The IC integrates a 120 mΩ N-channel MOSFET power switch and a 140 mΩ P-channel MOSFET synchronous rectifier.

1 Application overview

Figure 1 shows the typical architecture of a boost converter based solar battery charger:

The SPV1040 adapts the characteristics of load to those of panel. In fact, a PV panel is made up of a series of PV cells. Each PV cell provides voltage and current which depend on the PV cell size, on its technology, and on the light irradiation power. The main electrical parameters of a PV panel (typically provided at light irradiation of 1000 W/m², $T_{amb}=25 \, ^{\circ}C$) are:

- $V_{OC}$ (open circuit voltage)
- $V_{MP}$ (voltage at maximum power point)
- $I_{SC}$ (short-circuit current)
- $I_{MP}$ (current at maximum power point)

Figure 2 shows the typical characteristics of a PV cell:

MPP (maximum power point) is the working point of the PV cell at which the product of the extracted voltage and current provides the maximum power.
2 Boost switching application

A step-up (or boost) converter is a switching DC-DC converter able to generate an output voltage higher than (or at least equal to) the input voltage.

Referring to Figure 1, the switching element (Sw) is typically driven by a fixed frequency square waveform generated by a PWM controller.

When Sw is closed (ton) the inductor stores energy and its current increases with a slope depending on the voltage across the inductor and its inductance value. During this time the output voltage is sustained by COUT and the diode does not allow any charge transfer from the output to input stage.

When Sw is open (toff), the current in the inductor is forced, flowing toward the output until voltage at the input is higher than the output voltage. During this phase the current in the inductor decreases while the output voltage increases.

Figure 3 shows the behavior of inductor current.

The energy stored in the inductor during ton is ideally equal to the energy released during toff, therefore the relation between ton and toff can be written as follows:

\[ D = \frac{ton}{(ton + toff)} \]

where “D” is the duty cycle of the square waveform driving the switching element.

Boost applications can work in two different modes depending on the minimum inductor current within the switching period, that is if it is not null or null respectively:

- Continuous mode (CM)
- Discontinuous mode (DCM)
Obviously the efficiency is normally higher in CM.

Inductance and switching frequency \((F_{sw})\) impact the working mode. In fact, in order to have the system working in CM, the rule below should be followed:

\[
L > \frac{V_{OUT}^2}{P_{IN}} \frac{(D \cdot (1 - D))^2}{2 \cdot F_{SW}}
\]

According to the above, \(L\) is minimum for \(D = 50\%\).
3 SPV1040 description

The following is a quick overview of SPV1040 functions, features, and operating modes.

Figure 5. Typical application schematic using the SPV1040

The SPV1040 acts as an impedance adapter between the input source and output load which is:

Figure 6. SPV1040 equivalent circuit

Through the MPPT algorithm, it sets up the DC working point properly by guaranteeing $Z_{IN} = Z_m$ (assuming $Z_m$ is the impedance of the supply source). In this way, the power extracted from the supply source ($P_{IN} = V_{IN} \times I_{IN}$) is maximum ($P_M = V_M \times I_M$).

The voltage-current curve shows all the available working points of the PV panel at a given solar irradiation. The voltage-power curve is derived from the voltage-current curve by plotting the product $V^*I$ for each voltage generated.
Figure 7. MPPT working principle

Figure 7 shows the logical sequence followed by the device which proceeds for successive approximations in the search for the MPP. This method is called “Perturb and Observe”. The diagram shows that a comparison is made between the digital value of the power \( P_n \) generated by the solar cells and sampled at instant \( n \), and the value acquired at the previous sampling period \( P_{n-1} \). This allows the MPPT algorithm to determine the sign of duty cycle and to increment or decrement it by a predefined amount. In particular, the direction of adjustment (increment or decrement of duty cycle) remains unchanged until condition \( P_n \geq P_{n-1} \) occurs, that is, for as long as it registers an increase of the instantaneous power extracted from the cells string. On the contrary, when it registers a decrease of the power \( P_n < P_{n-1} \), the sign of duty cycle adjustment is inverted.

In the meantime, SPV1040 sets its own duty cycle according to the MPPT algorithm, other controls are simultaneously executed in order to guarantee complete application safety. These controls are mainly implemented by integrated voltage comparators whose thresholds are properly set.

Figure 8. SPV1040 internal block diagram
The duty cycle set by the MPPT algorithm can be overwritten if one of the following is triggered:

- Overcurrent protection (OVC), peak current on low side switch \( \geq 1.8 \) A
- Overtemperature protection (OVT), internal temperature \( \geq 155 \) °C
- Output voltage regulation, \( V_{CTRL} \) pin triggers 1.25 V
- Output current regulation \( R_s \) * (\( I_{CTRL\_PLUS} - I_{CTRL\_MINUS} \)) \( \geq 50 \) mV
- MPP-SET voltage \( V_{MPP\_SET} \leq 300 \) mV at the start-up and \( V_{MPP\_SET} \leq 450 \) mV in working mode.

Application components must be carefully selected to avoid any undesired trigger of the above thresholds.

In order to improve the overall system efficiency, and to reduce the BOM, the SPV1040 also integrates a zero crossing block whose role is to turn-off the synchronous rectifier to prevent reverse current flowing from output to input.
4 Application example

Figure 9 and 10 show the demonstration board of a solar battery charger based on SPV1040 and on a status of charge indication circuit.

Figure 9. STEVAL-ISV006V2 top view

Figure 10. STEVAL-ISV006V2 bottom view

STEVAL-ISV006V2 has been designed to recharge any type of battery (except lithium compound) which maximum voltage \( V_{BATT_{max}} \leq 5.2 \) V and supplied by up to 5 W PV panels (constrained by \( V_{OC} < V_{BATT_{max}} \)).

By default STEVAL-ISV006V2 is set as follows:

- Loaded by a 220 mF super capacitor
- Supplied by a 200 mW PV panel \( (V_{OC} = 1.65 \) V, \( I_{SC} = 150 \) mA)
- Maximum output current 1 A

The output trimmer \( VR_2 \) allow regulating \( V_{CTRL} \) across battery.

Maximum output current can be regulated by replacing \( R_s \) current sensing resistor according to application requirements.

Please refer to Section 6: external component selection for details about the whole application set-up.
Further, STEVAL-ISV006V2 provides a simple charge status circuit with 2 LEDs:

- Red LED on and green LED off, if the battery voltage is lower than charge threshold
- Red LED off and green LED on, if the battery voltage is higher than charge threshold

Charge threshold can be regulated by trimmer VR10. Charge status circuit can be bypassed by opening jumper J1.

Table 1. BOM (continued)
6 External component selection

SPV1040 requires a set of external components and their proper selection guarantees both the best chip functionality and system efficiency.

Input voltage capacitor

$C_{IN}$ is the input capacitor connected to the input rail in order to reduce the voltage ripple.

According to the maximum current ($I_{SC}$) provided by the PV panel connected at the input, the following formula should be considered to select the proper capacitance value for a specified maximum input voltage ripple ($V_{IN_{rp\_max}}$):

$$C_{IN} \geq \frac{I_{SC}}{F_{SW} \cdot V_{IN_{rp\_max}}}$$

Maximum voltage of this capacitor is strictly dependent on the input source (typically between 1 V and 3 V).

Low-ESR capacitors are a good choice to increase the whole system efficiency. In order to reduce the ESR effect, it is suggested to split the input capacitance into two capacitors placed in parallel.

Input voltage partitioning

$V_{MPP\_SET}$ is the pin used to monitor the voltage generated by the solar cells.

The $V_{MPP\_SET}$ pin can be directly connected to PV+ rail through a 1 kΩ $R_3$ resistor.

With regard to the $V_{MPP\_SET}$ pin, two constraints must be taken into account:

- When SPV1040 is off, $V_{MPP\_SET}$ voltage must be $\geq 0.3$ to turn-on the device
- When SPV1040 is in operating mode, it enters BURST MODE if $V_{MPP\_SET}$ decreases triggering the 450 mV threshold.

Input voltage sensing capacitor

$C_4$ is placed as close as possible to the $V_{MPP\_SET}$ pin to reject noise on $V_{MPP\_SET}$ voltage.

However, $V_{MPP\_SET}$ must be able to follow the $V_{IN}$ waveform to allow SPV1040 to monitor input voltage variations.

It means that the time constant $R_3 \cdot C_4$ must be chosen according to system properties, which is the MPPT tracking time ($T_{MPP} \approx 1$ ms). The rule below must be followed in order to select $C_4$ capacitance:

$$C_4 \leq \frac{T_{MPP}}{R_3} = 10^{-3} \cdot \frac{1}{10^3}$$

Assuming $R_3 = 1$ kΩ then: $C_4 \leq 10 \mu F$
Inductor selection

Inductor selection is a crucial point for this application. The following application constraints must be taken into account:

- Maximum input current (i.e. $I_{MP}$ and $I_{SC}$ of PV panel)
- Maximum input voltage (i.e. $V_{MP}$ and $V_{oc}$ of PV panel)
- Overcurrent threshold of SPV1040 (1.8 A)
- Maximum duty cycle of SPV1040 (90 %).

The input current from the PV panel flows into the inductor, so:

$$I_{Lx_{rms}} \approx I_{MP} < I_{SC}$$

According to Figure 3, during the charge phase (switch on), peak current on the inductor depends on the applied voltage ($V_{IN}$) on the inductance ($L_x$), and on the duty cycle ($t_{on}$).

Considering the maximum duty cycle (90 %):

$$I_{Lx_{peak}} = I_{Lx_{rms}} + \frac{9 \cdot 10^{-6}V_{MP}}{2L_x}$$

Taking into account the overcurrent threshold:

$$I_{Lx_{peak}} < 1.8A$$

Finally, inductance should be chosen according to the following formula:

$$L_x > \frac{1}{2} \frac{9 \cdot 10^{-6}V_{MP}}{2 - I_{Lx_{rms}}} = \frac{1}{2} \frac{9 \cdot 10^{-6}V_{MP}}{2 - I_{MP}}$$

A safer choice is to replace $V_{MP}$ with $V_{OC}$.

Usually, inductances ranging between 10 $\mu$H to 100 $\mu$H satisfy most application requirements.

Other critical parameters for the inductor choice are $I_{rms}$, saturation current, and size. $I_{rms}$ is the self rising temperature of the inductor, affecting the nominal inductance value. In particular, the inductance decreases with $I_{rms}$ and the temperature increases. As a consequence the inductor current peak can reach or surpass 1.8 A.

Inductor size also affects the maximum current deliverable to the load. In any case, the saturation current of the choke should be higher than the peak current limit of the input source. Hence, the suggested saturation current must be > 1.8 A.

At the same size, small inductance values guarantee both faster response to load transients and higher efficiency.

Inductors with low series resistance are suggested in order to guarantee high efficiency.

Output voltage capacitor

A minimum output capacitance must be added at the output in order to reduce the voltage ripple.

Critical parameters for capacitors are: capacitance, maximum voltage, and ESR.
According to the maximum current ($I_{SC}$) provided by the PV panel connected at the input, the following formula can be used to select the proper capacitance value ($C_{OUT}$) for a specified maximum output voltage ripple ($V_{OUT\_rp\_max}$):

$$C_{OUT} \geq \frac{I_{SC}}{F_{SW} \cdot V_{OUT\_rp\_max}}$$

Maximum voltage of this capacitor is strictly dependent on the output voltage range. SPV1040 can support up to 5.2 V, so the suggested maximum voltage for these capacitors is 10 V.

Low-ESR capacitors are a good choice to increase the whole system efficiency.

**Output voltage partitioning**

$R_1$ and $R_2$ are the two resistors used for partitioning the output voltage.

The said $V_{OUT\_max}$, the maximum output voltage of the battery, $R_1$ and $R_2$ must be selected according to the following rule:

$$\frac{R_1}{R_2} = \frac{V_{OUT\_max}}{1.25} - 1$$

Also, in order to optimize the efficiency of the whole system, when selecting $R_1$ and $R_2$, their power dissipation must be taken into account.

Assuming a negligible current flowing into the $V_{CTRL}$ pin, maximum power dissipation on the series $R_1+R_2$ is:

$$P_{VCTRL\_sns} = \frac{(V_{OUT\_max})^2}{R_1 + R_2}$$

As an empirical rule, $R_1$ and $R_2$ should be selected to get:

$$P_{VCTRL\_sns} \approx 0.01 \cdot (V_{OUT\_max} \cdot I_{OUT\_max})$$

**Note:** In order to guarantee proper functionality of the $V_{CTRL}$ pin, the current flowing into the series $R_1+R_2$ should be in the range between 2 µA and 20 µA.

**Output voltage sensing capacitor**

$C_2$ is placed in parallel to $R_2$ and as close as possible to the $V_{CTRL}$ pin.

Its role is to reject the noise on the voltage sensed by the $V_{CTRL}$ pin.

Capacitance value depends on the time constant resulting from $R_2$ ($\tau_{OUT} = C_2 \cdot R_1/R_2$) and from the system switching frequency (100 kHz), as follows:

$$\tau_{OUT} \cong 10 \cdot \frac{1}{F_{SSW}}$$

$$C_2 \cong 10 \cdot \frac{1}{F_{SSW}} \cdot \left( \frac{1}{R_1/R_2} \right)$$
**Output current sensing filter**

Rs is placed in the output rail between the ICTRL_MINUS and ICTRL_PLUS pins. Its role is to sense the output current (IOUT) flowing toward the load. Voltage drop on Rs is sensed by the ICTRL_MINUS and ICTRL_PLUS pins and compared with the 50 mV internal threshold.

\[ R_s = \frac{50 \text{ mV}}{I_{OUMAX}} \]

The triangular waveform of the current and noise may cause unexpected triggering of the 50 mV threshold. This can be avoided with a filter such as the one shown below:

![Figure 12. STEVAL-ISV006V2 IOUT filter](AM06707v1.png)

Suggested values are:

- \( R_F1 = R_{F2} = 1 \, \text{k} \Omega \)
- \( C_F = 1 \, \mu \text{F} \)

**Output protection diode**

If the load is not a battery, DOUT is required and placed in parallel to the output load. Its role is to protect the devices in case a PV cell providing \( I_{MP} > 0.5 \, \text{A} \) is connected when very low load is connected.

In fact, SPV1040 is supplied by the VOUT pin, so in the above condition the device is still off when the PV cell is connected and a voltage spike can occur damaging the converter and the battery.

In order to guarantee the best system performance and reliability, DOUT should be selected as follows:

- \( V_{BR} > V_{OUT_{MAX}} \)
- \( V_{CL} \leq 5.5 \, \text{V} \)

DOUT must be able to dissipate the following maximum power:

\[ P_{\text{max}} = I_{SC} \times V_{CL} \]

**XSHUT resistor**

The XSHUT pin controls SPV1040 turn-on (0.3 V \( \leq XSHUT \leq 5.2 \, \text{V} \)) or turn-off (XSHUT < 0.3 V).
R₅ is a 0 Ω pull-up resistor shorting the XSHUT and MPP-SET pins.
Removing R₅ enables the external control of the XSHUT pin to turn the SPV1040 on/off.

6.1 Optional Schottky

An external Schottky diode between Lₓ and V_{OUT} pins is mandatory in all the applications with V_{BATT,max} > 4.8 V.

In fact, voltage on Lₓ pin can go above the maximum absolute voltage threshold (5.5 V) due to the voltage drop on the high side integrated switch when this is off (discontinuous mode) and current needs to flow from input to output.

This Schottky diode should be chosen according to the following criteria:

\[ V_F \leq 5.5 V - V_{BATT,max} \quad \text{and} \quad I_F \geq I_{L_{max}} \]

For setting up the application and simulating the related test results please go to www.st.com/edesignstudio.
7 Layout

Figure 13. STEVAL-ISV006V2 PCB top view

Figure 14. STEVAL-ISV006V2 PCB bottom view

Layout guidelines

PCB layout is very important in order to minimize voltage and current ripple, high frequency resonance problems, and electromagnetic interference. It is essential to keep the paths where the high switching current circulates as small as possible in order to reduce radiation and resonance problems.

Large traces for high current paths and an extended ground plane reduce noise and increase efficiency.

The output and input capacitors should be placed as close as possible to the device.

The external resistor dividers, if used, should be as close as possible to the \( V_{MPP\_SET} \) and \( V_{CTRL} \) pins of the device, and as far as possible from the high current circulating paths, in order to avoid picking up noise.
Appendix A  SPV1040 parallel and series connection

Output pins of many SPV1040s can be connected either in parallel or in series. In both cases the output power (Pout) depends on light irradiation of each panel, on application efficiency, and on the specific constraints of the selected topology.

The objective of this section is to explain how the output power is impacted by the selected topology.

An example with 3 PV panels (panel1, panel2, panel3) is presented, but the conclusion can be extended to a larger number of PV panels.

If the panel is lighted and the SPV1040 is on (it means that light irradiation intensity is such that \( V_{MPP,SET} \geq 0.3 \) V):

\[
P_{OUTx} = \eta P_{INx} \quad [x = 1..3]
\]

If the panel is completely shaded: \( P_{OUTx} = 0 \)

**SPV1040 parallel connection**

This topology guarantees the desired output voltage even when only one panel is irradiated. The obvious constraint of this topology is that \( V_{OUT} \) is limited to the SPV1040 maximum output voltage.

*Figure 15* shows the parallel connection topology:

*Figure 15. SPV1040 output parallel connection*

The output partitioning \( (R_1/R_2) \) of each SPV1040 must be coherent with the desired \( V_{OUTx} \).

According to the topology:

\[
V_{OUT} = V_{OUT1} = V_{OUT2} = V_{OUT3}
\]

\[
I_{OUT} = I_{OUT1} + I_{OUT2} + I_{OUT3}
\]
According to the light irradiation on each panel and to the system efficiency ($\eta$), the output power results:

\[ P_{\text{OUT}} = P_{\text{OUT}1} + P_{\text{OUT}2} + P_{\text{OUT}3} \]
\[ P_{\text{OUT}x} = V_{\text{OUT}x} \times I_{\text{OUT}x} \quad [x = 1..3] \]
\[ P_{\text{IN}x} = V_{\text{IN}x} \times I_{\text{IN}x} \quad [x = 1..3] \]

Therefore:

\[ P_{\text{OUT}} = V_{\text{OUT}} (I_{\text{OUT}1} + I_{\text{OUT}2} + I_{\text{OUT}3}) = \eta P_{\text{IN}1} + \eta P_{\text{IN}2} + \eta P_{\text{IN}3} \]

Each SPV1040 contributes to the output power providing $I_{\text{OUT}x}$.

Finally, the desired $V_{\text{OUT}}$ is guaranteed if at least one of the 3 PV panels provides enough power to turn-on the SPV1040 relating to it.

**SPV1040 series connection**

This topology provides an output voltage that is the sum of the output voltages of the SPV1040 connected in series. The objective of this section is to explain how the output power is impacted by the selected topology.

*Figure 16* shows the series connection topology:

*Figure 16. SPV1040 output series connection*

In this case, the topology imposes:

\[ I_{\text{OUT}} = I_{\text{OUT}1} = I_{\text{OUT}2} = I_{\text{OUT}3} \]
\[ V_{\text{OUT}} = V_{\text{OUT}1} + V_{\text{OUT}2} + V_{\text{OUT}3} \]

In case irradiation is the same for each panel:

\[ P_{\text{OUT}1} = P_{\text{OUT}2} = P_{\text{OUT}3} \]
\[ P_{\text{OUT}} = 3 \times P_{\text{OUT}x} \quad [x = 1..3] \]
\[ P_{\text{OUT}x} = \frac{1}{3} P_{\text{OUT}} \]
\[ P_{\text{OUT}x} = V_{\text{OUT}x} \times I_{\text{OUT}x} = V_{\text{OUT}1} \times I_{\text{OUT}} \]
Therefore:
\[ V_{OUTx} = \frac{1}{3} V_{OUT} \]

For example, assuming \( P_{OUT} = 3 \text{ W} \) and \( V_{OUT} = 12 \text{ V} \), then
\[ V_{OUTx} = 4 \text{ V} \]

Lower irradiation for one panel, for example on panel 2, causes lower output power, so lower \( V_{OUT2} \) due to the \( I_{OUT} \) imposed by the topology:
\[ V_{OUTx} = \frac{P_{OUTx}}{I_{OUT}} \]

The output voltage required by the load can be provided by the 1\text{st} and the 3\text{rd} SPV1040 but only up to the limit imposed by each of their \( R_1/R_2 \) partitionings.

Some examples can help in understanding the various scenarios assuming that each \( R_1/R_2 \) limits \( V_{OUTx} \) to 4.8 V.

Example 1:
Panel 2 has 75 \% irradiation of panels 1 and 3:

\[ V_{OUT2} = \frac{3}{4} \cdot V_{OUT1} = \frac{3}{4} \cdot V_{OUT3} \]
\[ P_{OUT1} = P_{OUT3} = 1 \text{ W} \]
\[ P_{OUT2} = \frac{3}{4} \cdot P_{OUT1} = 0.75 \text{ W} \]
\[ P_{OUT} = P_{OUT1} + P_{OUT2} + P_{OUT3} = 2.75 \text{ W} \]
\[ I_{OUT} = \frac{P_{OUT}}{V_{OUT}} = \frac{2.75}{12} = 0.23 \text{ A} \]
\[ V_{OUT1} = V_{OUT3} = \frac{1}{0.23} = 4.35 \text{ V} \]
\[ V_{OUT2} = \frac{0.75}{0.23} = 3.26 \text{ V} \]

Two SPV1040s (1\text{st} and 3\text{rd}) supply the voltage drop caused by the lower irradiation on panel 2.

---

**Warning:** SPV1040 is a boost controller, so \( V_{OUTx} \) must be higher than \( V_{INx} \), otherwise the SPV1040 turns off and the input power is transferred to the output stage through the integrated P-channel MOS without entering the switching mode.
Example 2:
Panel 2 has 50% irradiation of panels 1 and 3:

\[
P_{\text{OUT2}} = \frac{1}{2} P_{\text{OUT1}} = \frac{1}{2} P_{\text{OUT3}}
\]

\[
P_{\text{OUT1}} = P_{\text{OUT3}} = 1\text{W}
\]

\[
P_{\text{OUT2}} = \frac{1}{2} P_{\text{OUT1}} = 0.5\text{W}
\]

\[
P_{\text{OUT}} = P_{\text{OUT1}} + P_{\text{OUT2}} + P_{\text{OUT3}} = 2.5\text{W}
\]

\[
I_{\text{OUT}} = \frac{P_{\text{OUT}}}{V_{\text{OUT}}} = \frac{2.5}{12} = 0.21\text{A}
\]

\[
V_{\text{OUT1}} = V_{\text{OUT3}} = \frac{1}{0.21} = 4.76\text{V}
\]

\[
V_{\text{OUT2}} = \frac{0.5}{0.21} = 2.38\text{V}
\]

In this case the system is close to its maximum voltage limit, in fact, a lower irradiation on panel 2 impacts \(V_{\text{OUT1}}\) and/or \(V_{\text{OUT3}}\) which are very close to the maximum output voltage threshold (4.8 V) imposed by \(R_1/R_2\) partitioning.

Example 3:
Panel 2 completely shaded.

In this case the maximum \(V_{\text{OUT}}\) can be 9.6 V \((V_{\text{OUT1}} + V_{\text{OUT3}})\).

The current flow is guaranteed by the body diodes of the power MOSFETs integrated in the SPV1040 (or by the bypass diodes, if any, placed between \(V_{\text{OUT-}}\) and \(V_{\text{OUT+}}\)).
