Application overview

This application note describes how to control the STM8S-DISCOVERY from a terminal window running on a PC which is connected to the STM8S105C6T6 microcontroller UART through an RS232 cable.

After adding the required components to the board and downloading the application software, you will be able to use a terminal to manage STM8S GPIOs and TIM3 timer, and to configure the beeper output.

1 Prerequisites

The material required to run the STM8S-DISCOVERY terminal demonstration application is the following:

- A terminal window running on a PC: the terminal emulator software can be Windows Hyperterminal (see Appendix B), TeraTerm Pro, or any terminal software.
- An RS232 null-modem cable (transmit and receive line crosslinked).

2 Configuring the STM8S-DISCOVERY

Prior to running the application, the STM8S-DISCOVERY must be configured to enable the beeper output. The beeper output is an STM8S105C6T6 alternate function. It is enabled by setting the alternate function remap option bit AFR7 in OPT2 option byte to ‘1’.

For details on alternate function remapping and on option bytes, refer to user manual “Developing and debugging your STM8S-DISCOVERY application code” (UM0834), and to the STM8S105xx datasheet, respectively.

3 Application description

3.1 Hardware required

This application uses STM8S-DISCOVERY on-board LED (LD1) together with its associated resistor (R1).

The external passive components required by the application are listed in Table 1.

The application also makes use of a 5 V powered ST232B RS232 driver/receiver (see Table 2). This extra component is essential since the COM port of the PC operates from a nominal 12 V power supply. This is not compatible with the STM8S UART input/outputs operating at 5 V. This component is available in an SO16 package which fits the STM8S-DISCOVERY footprint. For more information on the ST232B refer to the ST232B datasheet.

3.2 Application schematics

Figure 1 shows the application electrical schematics.

If the RS232 cable is not a null-modem cable (transmit and receive lines not crosslinked), connect U1 pin14 to DB9 pin2 and U1 pin13 to DB9 pin3.

Figure 1. Application schematics
3.3 Application principle

This application sets up a standard communication interface between the STM8S105C6T6 microcontroller and a terminal window running on a PC. Communications are performed thanks to STM8S UART using the RS232 protocol. Both terminal window and UART must be configured in the same way (see Appendix B: Configuring your terminal window).

This document only describes the communications and data processing from the STM8S UART side. For more information about Windows HyperTerminal or similar software, refer to Microsoft® Help or suppliers web pages.

3.3.1 Running the application

To run the application, perform the following steps:

1. Launch and configure a terminal window on your PC (see Appendix B: Configuring your terminal window for an example regarding Windows HyperTerminal).
2. Compile and run the application firmware using the ST Visual Develop (STVD).
3. Connect your PC to the STM8S-DISCOVERY through an RS232 cable.
4. When the application has started, a menu is displayed on the Windows HyperTerminal (Figure 2.: Terminal window menu). It allows to:
   - Switch LD1 on or off.
   - Configure LD1 blinking speed.
   - Enable/disable the beeper and select the beep frequency.

   All the information displayed on this menu are sent by the STM8S microcontroller. When a key is struck on the HyperTerminal, the corresponding ASCII value is sent to the microcontroller and decoded.

Figure 2. Terminal window menu
3.3.2 Communication sequence between the STM8S-DISCOVERY and the terminal

1. The STM8S microcontroller sends the character string ‘Enter your choice’ to the PC terminal emulator software.
2. The terminal displays the string ‘Enter your choice’.
3. The user strikes key 2 on his keyboard.
4. The terminal emulator software sends back the corresponding ASCII code (0x52) to the microcontroller (see Appendix A: Standard ASCII character codes).
5. The microcontroller decodes the data received, sends back the code 0x52 for it to be displayed on the terminal, and stores the value ‘2’ in memory.
6. The terminal emulator software receives the code 0x52 and displays ‘2’.
7. The user strikes the Return key.
8. The terminal emulator software send back the code 0x0D corresponding to carriage return (see Appendix A: Standard ASCII character codes).
9. The STM8S105C6T6 microcontroller decode the data received, sends back the code 0x0D for it to be displayed it on the terminal, and performs the action associated to option 2.
4 Software description

4.1 STM8S peripherals used by the application

This application example uses the STM8S standard firmware library to control general purpose functions. It makes use of the following STM8S peripherals:

**UART2**

UART2 is used to communicate with the terminal window running on the PC. It must be configured as follows:

- Baud rate = 9600 baud
- Word length = 8 bits
- One stop bit
- No parity
- Receive and transmit enabled
- UART2 clock disabled

The communications are managed by polling each receive and transmit operation.

*Note:* The terminal window and the STM8S UART peripheral must be configured with the same baud rate, word length, number of stop bits, and parity.

**Timer 3 (TIM3)**

TIM3 timer is configured as a timebase with interrupt enabled to control LD1 blinking speed.

**GPIOs**

The GPIOs are used to interface the MCU with external hardware. Port PD0 is configured as output push-pull low to drive LD1.

**BEEPER**

To drive the buzzer, the BEEPER peripheral outputs a signal of 1, 2, or 4 KHz on the BEEP output pin.

4.2 Configuring STM8S standard firmware library

The `stm8s_conf.h` file of the STM8S standard firmware library allows to configure the library by enabling the peripheral functions used by the application.

The following define statements must be present:

- `#define _GPIO 1` enables the GPIOs
- `#define _TIM3 1` enables TIM3
- `#define _BEEPER 1` enables the BEEPER
- `#define _UART2 1` enables UART2
4.3 Application software flowcharts

This section describes the application software main loop and the function that controls data reception/transmission from/to the terminal window:

- **App_Menu**
  This function is used to display a menu on the terminal, and manage the information entered by the user.

- **SerialPutString**
  This function is used to transmit a string to the terminal.

- **SerialPutChar**
  This function is used to transmit a character to the terminal.

- **GetInputString**
  This function is used to receive a string from the terminal.

- **GetIntegerInput**
  This function is used to receive an integer from the terminal.

- **Get_Key**
  When a key is stroke, this function returns the corresponding hexadecimal code.
4.3.1 Application main routine

The application main routine configures the STM8S peripherals and enables all the standard interrupts used by the application. When the initialization is complete, the main routine displays the application menu on the terminal window (see Figure 3).

Figure 3. Main routine flowchart
4.3.2 **App_menu function**

The App_menu function is the main application routine. It displays a menu on the terminal through which the GPIOs, TIM2 and BEEPER can be configured. App_menu calls GetInputString, GetIntegerInput and SerialPutString to send and receive data through the RS232 interface.

**Figure 4. App_menu flowchart**

[Diagram of App_menu flowchart]
4.3.3 GetInputString function

The GetInputString function is used to receive and store the character strings sent through the terminal window. This function relies on the Get_key function to acquire and decode each character (see Section 4.3.4). Different actions can be performed according to the value of the character ASCII code:

- If ASCII code = ‘\b’
  
  A backspace has been sent by the terminal. The last character of the string is erased if the string is not empty.

- If ASCII code belongs to {0...1 or a...Z}
  
  The character is stored.

- If ASCII code = ‘\r’
  
  The GetInputString function stores the “end of string” value, ‘\0’, at the end of the string. The maximum number of ASCII codes stored in the buffP[bytes_read] buffer has been reached

  The software erases the recorded string and waits for another input from the terminal.

For more information on ASCII codes refer to Appendix A: Standard ASCII character codes.
Figure 5. GetInputString flowchart

START

bytes_read = 0

Get_Key()

Key = "b"?

Yes

No

bytes_read >= Max?

Yes

No

SerialPutString("Size overflow")

bytes_read = 0

key = 0..1 or a..Z?

Yes

No

Store ASCII code in buffP[bytes_read]

bytes_read ++

SerialPutChar(ASCII code)

key = 'r'

bytes_read = "0"

END
4.3.4 Get_key function

The Get_key function is used to detect a key stroke on the terminal by polling the UART RXNE flag. This function returns the received value.

Figure 6. Get_key function flowchart

```
START

Key = 0

UART2 RXNE flag set

No

Yes

Key = UART2 data register

Return Key
```
4.3.5 **SerialPutString and SerialPutChar functions**

The SerialPutString function is used to send a character string through the UART. The string characters are sent one by one by the SerialPutChar function as described in the flowcharts shown in *Figure 8* and *Figure 9*.

---

**Figure 7.** SerialPutChar flowchart

**Figure 8.** SerialPutString flowchart

- **START**
  - UART_sendData8(char)
  - char sent?
    - No
    - Yes
      - STOP

- **START**
  - i = 0
  - String[i] == '0'
    - Yes
      - STOP
    - No
      - SerialPutChar(String[i])
      - i++
4.3.6 GetIntegerInput function

The GetIntegerInput function is used to check that incoming data correspond to an integer. If so, the data are stored in the memory. Otherwise the user is prompted to enter new data.

Appendix B  Configuring your terminal window

The terminal window connected to the STM8S-DISCOVERY must be configured with the following settings valid for all terminal types:

- Communication port: COM1 or other available
- Bits per second: 9600
- Data bits: 8
- Parity: none
- Stop bits: 1
- Flow control: none

To provide a ready-to-use application example, a preconfigured terminal using Windows HyperTerminal and COM1 port is provided within the project folder. To launch it, simply execute the .ht file included in the project.

However, you can also set up a new connection with the STM8S-DISCOVERY based on Windows HyperTerminal and related to this example by following the steps below:

1. Open Windows HyperTerminal application and choose a connection name, such as “MyConnection” and validate it by clicking OK.

Figure 10. Launching Windows HyperTerminal

![Connection Description](image)
2. Select COM1 or any available port on your computer and validate your choice by clicking OK. Other fields can remain set to the default value.

Figure 11. Selecting communication port

![Selecting communication port](image1)

3. Configure the communication port properties as shown in Figure 12. Windows HyperTerminal is launched and communications can start.

Figure 12. Configuring connection properties

![Configuring connection properties](image2)
4. To check communication settings:
   a) Disconnect the HyperTerminal by choosing **Call > Disconnect** from the HyperTerminal main menu.
   b) Once communications are stopped, go to the **Settings** tab in **MyConnection Properties** menu. The parameters should be as shown below.

**Figure 13. Checking communication settings**

![MyConnection Properties window](image)
c) Finally, click **ASCII Setup** in **MyConnection properties** menu, check that the ASCII parameters match those shown in **Figure 14**, and modify them if needed.

**Figure 14. ASCII Setup parameters**

![ASCII Setup dialog box](image)

**ASCII Sending**
- Send line ends with line feeds
- Echo typed characters locally
- Line delay: 0 milliseconds.
- Character delay: 0 milliseconds.

**ASCII Receiving**
- Append line feeds to incoming line ends
- Force incoming data to 7-bit ASCII
- Wrap lines that exceed terminal width

---

d) Close **MyConnection Properties** menu, and restart communications by choosing **Call > Call** from the HyperTerminal main menu. Your STM8S-DISCOVERY application is now ready to start.
