Introduction

The primary objective of this manual is to help programmers provide software that is compatible across the family of processors that use the signal processing engine (SPE) auxiliary processing unit (APU).

Scope

The scope of this manual does not include a description of individual SPE implementations. Each PowerPC™ processor is unique in its implementation of the SPE.

Audience

This manual supports system software and application programmers who want to use the SPE APU to develop products. Users should understand the following concepts:

- Operating systems
- Microprocessor system design
- Basic principles of RISC processing
- SPE instruction set

The major sections of this manual provide a general understanding of what the programming model defines in the SPE APU.

It is useful for software engineers who need to understand how to access SPE functionality from high level languages such as C and C++.

It will describe all instructions in the e500 core complex as well as Book E instructions that are defined for 32-bit implementations, along with data manipulation, SPE floating-point status and control register (SPEFSCR) operations, ABI extensions (malloc(), realloc(), calloc(), and new), a printf example, and additional library routines.

Examples are given of valid and invalid initializations of the SPE data types.
Contents

1 Overview ................................................................. 14
  1.1 High-level language interface .................................. 14
  1.2 Application binary interface (ABI) .......................... 14

2 High-level language interface ........................................ 15
  2.1 Introduction ...................................................... 15
  2.2 High-level language interface .................................. 15

3 SPE operations ......................................................... 19
  3.1 Signal processing engine (SPE) APU registers .............. 19
  3.2 Notation .......................................................... 22
  3.3 Instruction fields ............................................... 22
  3.4 Description of instruction operation .......................... 25
  3.5 Intrinsics .......................................................... 28
  3.6 Basic instruction mapping ...................................... 285

4 Additional operations ................................................. 295
  4.1 Data manipulation ............................................... 295
  4.2 Signal processing engine (SPE) APU registers .............. 298
  4.3 Application binary interface (ABI) extensions .............. 303

5 Programming interface examples .................................... 306
  5.1 Data type initialization ......................................... 306
  5.2 Fixed-point accessors .......................................... 308
  5.3 Loads ............................................................. 309

6 Glossary of terms and abbreviations ............................... 311

7 Revision history ....................................................... 314

Figure 242. Signal processing and embedded floating-point status and control register (SPEFSCR) 299
1 Overview

This document defines a programming model to use with the signal processing engine (SPE) auxiliary processing unit (APU). This document describes three types of programming interfaces:

- A high-level language interface that is intended for use within programming languages, such as C or C++
- An application binary interface (ABI) that defines low-level coding conventions
- An assembly language interface

1.1 High-level language interface

The high-level language interface enables programmers to use the SPE APU from programming languages such as C and C++, and describes fundamental data types for the SPE programming model. See Chapter 2: High-level language interface on page 15, for details about this interface.

1.2 Application binary interface (ABI)

The SPE programming model extends the existing PowerPC ABIs. The extension is independent of the endian mode. The ABI reviews the data types and register usage conventions for vector register files and describes setup of the stack frame. Save and Restore functions for the vector register are included in the ABI section to advocate uniformity of method among compilers for saving and restoring vector registers.

The AltiVec™ Technology Programming Interface Manual, provides the valid set of argument types for specific AltiVec operations and predicates as well as specific AltiVec instructions that are generated for that set of arguments. The AltiVec operations and predicates are organized alphabetically in Chapter 4: Additional operations on page 295.
2 High-level language interface

2.1 Introduction

This document defines a programming model to use with the signal processing engine (SPE) auxiliary processing unit (APU) instruction set. The purpose of the programming model is to give users the ability to write code that utilizes the APU in a high-level language, such as C or C++.

Users should not be concerned with issues such as register allocation, scheduling, and conformity to the underlying ABI, which are all associated with writing code at the assembly level.

2.2 High-level language interface

The high-level language interface for SPE is intended to accomplish the following goals:

- Provide an efficient and expressive mechanism to access SPE functionality from programming languages such as C and C++
- Define a minimal set of language extensions that unambiguously describe the intent of the programmer while minimizing the impact on existing PowerPC compilers and development tools
- Define a minimal set of library extensions that are needed to support SPE

2.2.1 Data types

Table 1 describes a set of fundamental data types that the SPE programming model introduces.

Note: The type _ev64_ stands for embedded vector of data width 64 bits.

<table>
<thead>
<tr>
<th>New C/C++ type</th>
<th>Interpretation of contents</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ev64_u16</strong></td>
<td>4 unsigned 16-bit integers</td>
<td>0...65535</td>
</tr>
<tr>
<td><strong>ev64_s16</strong></td>
<td>4 signed 16-bit integers</td>
<td>-32768...32767</td>
</tr>
<tr>
<td><strong>ev64_u32</strong></td>
<td>2 unsigned 32-bit integers</td>
<td>0...2^{32} - 1</td>
</tr>
<tr>
<td><strong>ev64_s32</strong></td>
<td>2 signed 32-bit integers</td>
<td>-2^{31}...2^{31} - 1</td>
</tr>
<tr>
<td><strong>ev64_u64</strong></td>
<td>1 unsigned 64-bit integer</td>
<td>0...2^{64} - 1</td>
</tr>
<tr>
<td><strong>ev64_s64</strong></td>
<td>1 signed 64-bit integer</td>
<td>-2^{63}...2^{63} - 1</td>
</tr>
<tr>
<td><strong>ev64_fs</strong></td>
<td>2 floats</td>
<td>IEEE-754 single-precision values</td>
</tr>
<tr>
<td><strong>ev64_opaque</strong></td>
<td>any of the above</td>
<td>—</td>
</tr>
</tbody>
</table>

The __ev64_opaque__ data type is an opaque data type that can represent any of the specified __ev64_*__ data types. All of the __ev64_*__ data types are available to programmers.
2.2.2 Alignment

Refer to the e500 ABI for full alignment details.

Alignment of __ev64_*__ types

A defined data item of any __ev64_*__ data type in memory is always aligned on an 8-byte boundary. A pointer to any __ev64_*__ data type always points to an 8-byte boundary. The compiler is responsible for aligning any __ev64_*__ data types on an 8-byte boundary. When __ev64_*__ data is correctly aligned, a program is incorrect if it attempts to dereference a pointer to an __ev64_*__ type if the pointer does not contain an 8-byte aligned address.

In the SPE architecture, an unaligned load/store causes an alignment exception.

Alignment of aggregates and unions containing __ev64_*__ types

Aggregates (structures and arrays) and unions containing __ev64_*__ variables must be aligned on 8-byte boundaries and their internal organization must be padded, if necessary, so that each internal __ev64_*__ variable is aligned on an 8-byte boundary.

2.2.3 Extensions of C/C++ operators for the new types

Most C/C++ operators do not permit any of their arguments to be one of the __ev64_*__ types. Let 'a' and 'b' be variables of any __ev64_*__ type, and 'p' be a pointer to any __ev64_*__ type. The normal C/C++ operators are extended to include the operations in the following sections.

sizeof()

The functions sizeof(a) and sizeof(*p) return 8.

Assignment

Assignment is allowed only if both the left- and right-hand sides of an expression are the same __ev64_*__ type. For example, the expression a=b is valid and represents assignment of 'b' to 'a'. The one exception to the rule occurs when 'a' or 'b' is of type __ev64_opaque__. Let 'o' be of type __ev64_opaque__ and let 'a' be of any __ev64_*__ type.

The assignments a=o and o=a are allowed and have implicit casts. Otherwise, the expression is invalid, and the compiler must signal an error.

Address operator

The operation &a is valid if 'a' is an __ev64_*__ type. The result of the operation is a pointer to 'a'.

Pointer arithmetic

The usual pointer arithmetic can be performed on p. In particular, p+1 is a pointer to the next __ev64_*__ element after p.

Pointer dereferencing

If 'p' is a pointer to an __ev64_*__ type, *p implies either a 64-bit SPE load from the address, equivalent to the intrinsic __ev_ldd(p,0), or a 64-bit SPE store to that address,
equivalent to the intrinsic __ev_stdd(p,0). Dereferencing a pointer to a non-__ev64_* type produces the standard behavior of either a load or a copy of the corresponding type.

Alignment of __ev64_* types on page 16, describes unaligned accesses.

Type casting

Pointers to __ev64_* and existing types may be cast back and forth to each other. Casting a pointer to an __ev64_* type represents an (unchecked) assertion that the address is 8-byte aligned.

Casting from a integral type to a pointer to an __ev64_* type is allowed.

For example:

__ev64_u16__ *a = (__ev64_u16__ *) 0x48;

Casting between __ev64_* types and existing types is not allowed.

Casting between __ev64_* types and pointers to existing types is not allowed.

The behaviors expected from such casting are provided instead of using intrinsics.

The intrinsics provide the ability to extract existing data types out of __ev64_* variables as well as the ability to insert into and/or create __ev64_* variables from existing data types. Normal C casts provide casts from one __ev64_* type to another.

An implicit cast is performed when going to __ev64_opaque__ from any other __ev64_* type. An implicit cast occurs when going from __ev64_opaque__ to any other __ev64_* type. The implicit casts that occur when going between __ev64_opaque__ and any other __ev64_* type also apply to pointers of type __ev64_opaque__. When casting between any two __ev64_* types not including __ev64_opaque__, an explicit cast is required. When casting between pointers to any two __ev64_* types not including __ev64_opaque__, an explicit cast is required. No cast or promotion performs a conversion; the bit pattern of the result is the same as the bit pattern of the argument that is cast.

2.2.4 New operators

New operators are introduced to construct __ev64_* values and allow full access to the functionality that the SPE architecture provides.

**__ev64_* Initialization and literals**

The __ev64_opaque__ type is the only __ev64_* type that cannot be initialized. The remaining __ev64_* types can be initialized using the C99 array initialization syntax. Each type is treated as an array of the specified data contents of the appropriate size. The following code exemplifies the initialization of these types:

```c
__ev64_u16__ a = { 0, 1, 2, 3 };
__ev64_s16__ b = { -1, -2, -3, 4 };
__ev64_u32__ c = { 3, 4 };
__ev64_s32__ d = { -2, 4 };
__ev64_u64__ e = { 17 };
__ev64_s64__ f = { 23 };
__ev64_fs__ g = { 2.4, -3.2 };
```

```c
c = __ev_addw(a, (__ev64_s16__) [2,1,5,2]);
```
New operators representing SPE operations

New operators are introduced to allow full access to the functionality that the SPE architecture provides. Language structures that parse like function calls represent these operators in the programming language.

The names associated with these operations are all prefixed with "__ev__". The appearance of one of these forms can indicate one of the following:

- A specific SPE operation, like __ev_addw(__ev64_opaque__ a, __ev64_opaque__ b)
- A predicate computed from a SPE operation, like __ev_all_eq(__ev64_opaque__ a, __ev64_opaque__ b)
- Creation, insertion, extraction of __ev64_opaque__ values

Each operator representing an SPE operation takes a list of arguments representing the input operands (in the order in which they are shown in the architecture specification) and returns a result that could be void. The programming model restricts the operand types that are permitted for each SPE operation. Predicate intrinsics handle comparison operations in the SPE programming model.

Each compare operation has the following predicate intrinsics associated with it:

- _any_
- _all_
- _upper_
- _lower_
- _select_

Each predicate returns an integer (0/1) with the result of the compare. The compiler allocates a CR field for use in the comparison and to optimize conditional statements.

2.2.5 Programming interface

This document does not prohibit or require an implementation to provide any set of include files to provide access to the intrinsics. If an implementation requires that an include file be used before the use of the intrinsics described in this document, that file should be <spe.h>.

This document does require that prototypes for the additional library routines described are accessible by means of the include file <spe.h>. If an implementation should provide a __SPE__, define it with a nonzero value. That definition should not occur in the <spe.h> header file.
3 SPE operations

This chapter describes the following instructions:
- All instructions in the e500 core complex, including numerous instructions that Book E does not define.
- Book E instructions that are defined for 32-bit implementations, including many instructions that are not implemented on the e500 core complex.

3.1 Signal processing engine (SPE) APU registers

The SPE includes the following two registers:
- The signal processing and embedded floating-point status and control register (SPEFSCR), which is described in Chapter 3.1.1.
- A 64-bit accumulator, which is described in Chapter 3.1.2.

3.1.1 Signal processing and embedded floating-point status and control register (SPEFSCR)

The SPEFSCR, which is shown in Figure 1, is used for status and control of SPE instructions.

3.1.2 Accumulator (ACC)

The 64-bit architectural accumulator register shown in Figure 2 holds the results of multiply accumulate (MAC) forms of SPE integer instructions. The ACC allows back-to-back execution of dependent MAC instructions that are in inner loops of DSP code such as FIR filters. The ACC is partially visible to the programmer; its results need not be read explicitly to be used. Instead, the results are always copied into a 64-bit destination GPR specified by the instruction. The ACC, however, must be explicitly cleared when starting a new MAC loop. Depending on the instruction type, the ACC can hold either a 64-bit value or a vector of two 32-bit elements.

The Initialize Accumulator instruction (evmra), which is described in the Instruction Set chapter of Programmers reference manual for Book E processors, initializes the ACC.

3.4 Description of instruction operation

A series of statements that use a semi-formal language at the register transfer level (RTL) describes the operation of most instructions. RTL uses the general notation that is shown in Table 4 and Table 5 and conventions that are specific to RTL, shown in Table 6. Figure 3 on page 29 gives an example. Some of this notation is used in the formal descriptions of instructions.

The RTL descriptions cover the normal execution of the instruction, except that the standard settings of the condition register, integer exception register, floating-point status, and control register are not always shown. (Nonstandard setting of these registers, such as the setting of the condition register field 0 by the stwcx instruction, is shown.) The RTL descriptions do not cover all cases in which the interrupt may be invoked, or for which the results are boundedly undefined, and may not cover all invalid forms.

RTL descriptions specify the architectural transformation that the execution of an instruction performs. They do not imply any particular implementation.

Table 7 summarizes precedence rules for RTL operators. Operators that are higher in the table are applied before those that are lower in the table. Operators at the same level in the table associate from left to right, from right to left, or not at all, as shown. (For example, the – operator associates from left to right, so a–b–c = (a–b)–c.) Using parentheses can increase clarity or override the evaluation order that the table implies; parenthesized expressions are evaluated before serving as parameters.

3.5 Intrinsics

The rest of this chapter describes individual instructions, which are listed in alphabetical order by mnemonic. Figure 3 shows the format for instruction description pages.
### 3.5.1 Intrinsic definitions

For saturation, left shifts, and bit reversal, the pseudo RTL is provided here to more accurately describe those functions that are referenced in the instruction pseudo RTL.

#### Saturation

```plaintext
SATURATE(overflow, carry, saturated_underflow, saturated_overflow, value)
if overflow then
  if carry then
    return saturated_underflow
  else
    return saturated_overflow
else
  return value
```

---

**Figure 3. Instruction description**

- **Instruction mnemonic**: `__ev_addsmiaaw`
- **Instruction name**: Vector Add Signed, Modulo, Integer to Accumulator Word
- **Instruction syntax**: `d = __ev_addsmiaaw (a)`
  - `d0:31` `ACC0:31 + a0:31`
  - `d32:63` `ACC32:63 + a32:63`

  // update accumulator

  `ACC0:63` `d0:63`

  Each word element in A is added to the corresponding element in the accumulator. The sum is placed into the corresponding parameter d word and into the accumulator.

  Other registers altered: ACC

Maps to

- `__ev_addsmiaaw d, a`
Shift

\[ SL(value, \ cnt) \]
\[ if \ cnt > 31 \ then \]
\[ \quad return \ 0 \]
\[ else \]
\[ \quad return \ (value \ll cnt) \]

Bit reverse

\[ BITREVERSE(value) \]
\[ result \leftarrow 0 \]
\[ mask \leftarrow 1 \]
\[ shift \leftarrow 31 \]
\[ cnt \leftarrow 32 \]
\[ while \ cnt > 0 \ then \ do \]
\[ \quad t \leftarrow data \&\ mask \]
\[ \quad if \ shift \geq 0 \ then \]
\[ \quad \quad result \leftarrow (t \ll shift) \ | \ result \]
\[ \quad else \]
\[ \quad \quad result \leftarrow (t \gg -shift) \ | \ result \]
\[ \quad cnt \leftarrow cnt - 1 \]
\[ \quad shift \leftarrow shift - 2 \]
\[ \quad mask \leftarrow mask \ll 1 \]
\[ return \ result \]
**__brinc**

Bit reversed increment

\[
d = \text{__brinc}(a,b)
\]

\[
n \leftarrow \text{MASKBITS} \quad // \quad \text{Imp dependent # of mask bits}
\]

\[
\text{mask} \leftarrow \text{D}_{64-n:63} \quad // \quad \text{Least sig. n bits of register}
\]

\[
\text{temp0} \leftarrow \text{a}_{64-n:63}
\]

\[
\text{temp1} \leftarrow \text{bitreverse}(1 + \text{bitreverse}(a \mid \neg \text{mask}))
\]

\[
d \leftarrow \text{a}_{0:63-n} || (d \& \text{mask})
\]

**brinc** provides a way for software to access FFT data in a bit-reversed manner. Parameter \(a\) contains the index into a buffer that contains data on which FFT is to be performed. Parameter \(b\) contains a mask that allows the index to be updated with bit-reversed addressing. Typically this instruction precedes a load with index instruction; for example,

\[
\text{brinc } r2, r3, r4
\]

\[
\text{lhax } r8, r5, r2
\]

Parameter \(b\) contains a bit-mask that is based on the number of points in an FFT. To access a buffer containing \(n\) byte sized data that is to be accessed with bit-reversed addressing, the mask has \(\log_2 n\) 1s in the least significant bit positions and 0s in the remaining most significant bit positions. If, however, the data size is a multiple of a half word or a word, the mask is constructed so that the 1s are shifted left by \(\log_2 (\text{size of the data})\) and 0s are placed in the least significant bit positions. **Table 8** shows example values of masks for different data sizes and number of data.

</tr>
</tbody>
</table>

Architecture Note: An implementation can restrict the number of bits specified in a mask. The number of bits in a mask may not exceed 32.

Architecture Note: This instruction only modifies the lower 32 bits of the destination register in 32-bit implementations. For 64-bit implementations in 32-bit mode, the contents of the upper 32 bits of the destination register are undefined.

Architecture Note: Execution of brinc does not cause SPE Unavailable exceptions, regardless of the state of MSRSPE.
__ev_abs

Vector Absolute Value

\[ d = __ev\_abs(a) \]

\[ d_{0:31} \leftarrow \text{ABS}(a_{0:31}) \]

\[ d_{32:63} \leftarrow \text{ABS}(a_{32:63}) \]

The absolute value of each element of a parameter is placed in the corresponding elements of parameter d. An absolute value of 0x8000_0000 (most negative number) returns 0x8000_0000. No overflow is detected.

Figure 4. Vector absolute value (__ev_abs)

**__ev_addiw**

Vector Add Immediate Word

\[ d = __ev_addiw\ (a, b) \]

\[ d_{0:31} \leftarrow a_{0:31} + \text{EXTZ}(b) // \text{Modulo sum} \]

\[ d_{32:63} \leftarrow a_{32:63} + \text{EXTZ}(b) // \text{Modulo sum} \]

Parameter b is zero-extended and added to both the high and low elements of parameter a and the results are placed in the parameter d.

*Note:* The same value is added to both elements of the register.

**Figure 5.** Vector add immediate word (__ev_addiw)

<table>

Vector Floating-Point Divide

\[ d = \text{__ev_fsd}(a,b) \]

\[ d_{0:31} \leftarrow a_{0:31} \div b_{0:31} \]
\[ d_{32:63} \leftarrow a_{32:63} \div b_{32:63} \]

The single-precision floating-point value in each element of parameter \( a \) is divided by the corresponding elements in parameter \( b \), and the results are placed in parameter \( d \).

If an overflow is detected, parameter \( b \) is a Denorm (or 0 value), or parameter \( a \) is a NaN or Infinity and parameter \( b \) is a normalized number, the result is an appropriately signed maximum floating-point value.

If an underflow is detected or parameter \( b \) is a NaN or Infinity, the result is an appropriately signed floating-point 0.

The following status bits are set in the SPEFSCR:

- FINV, FINVH if the contents of parameter \( a \) or \( b \) are \(+\text{inf}, -\text{inf}, \text{Denorm}, \text{or NaN}\)
- FOVF, FOVFH if an overflow occurs
- FUNV, FUNVH if an underflow occurs
- FDBZS, FDBZ, FDBZH if a divide by zero occurs
- FINXS, FG, FGH, FX, FXH if the result is inexact or overflow occurred and overflow exceptions are disabled

</table>
__ev_fsmul

Vector Floating-Point Multiply

d = __ev_fsmul (a,b)
d_{0:31} ← a_{0:31} \times_{sp} b_{0:31}
d_{32:63} ← a_{32:63} \times_{sp} b_{32:63}

Each single-precision floating-point element of parameter a is multiplied with the corresponding element of parameter b, and the result is stored in parameter d. If an overflow is likely, pmax or nmax is stored in parameter d. If an underflow is likely, +0, or –0 is stored in parameter d. The following condition defines when an overflow is likely and the corresponding result for each element of the vector:

\[ ei = (ea - 127) + (eb - 127) + 127 \]

if (sa = sb) then
  if (ei ≥ 127) then r = pmax
  else if (ei < -126) then r = +0
else
  if (ei ≥ 127) then r = nmax
  else if (ei < -126) then r = -0

● If the contents of parameter a or b are +inf, –inf, Denorm, QNaN, or SNaN, at least one of the SPEFSCR[FINVH] or SPEFSCR[FINV] bits is set.
● If an overflow occurs or is likely, at least one of the SPEFSCR[FOVFH] or SPEFSCR[FOVF] bits is set.
● If an underflow occurs or is likely, at least one of the SPEFSCR[FUNFH] or SPEFSCR[FUNF] bits is set.
● If the exception is enabled for the high or low element in which the error occurs, the exception is taken.

</tbody>
</table>
Vector Floating-Point Subtract

\[
d = \_\text{ev\_fssub}\ (a, b)
\]

\[
d_{0:31} \leftarrow a_{0:31} - \text{sp} b_{0:31}
d_{32:63} \leftarrow a_{32:63} - \text{sp} b_{32:63}
\]

Each single-precision floating-point element of parameter \(b\) is subtracted from the corresponding element of parameter \(a\) and the result is stored in parameter \(d\). If an overflow is likely, \(\text{pmax}\) or \(\text{nmax}\) is stored in parameter \(d\). If an underflow is likely, \(+0\) or \(-0\) is stored in parameter \(d\). The following condition defines how boundary cases of inputs (+inf, -inf, Denorm, QNaN, SNaN) are treated, when an overflow is likely, and the corresponding result for each element of the vector:

\[
\begin{align*}
\text{if } ((s_a = 0) & \land (s_b = 1)) \text{ then} \\
& \text{if } (\max(e_a, e_b) \geq 127) \text{ then } r = \text{pmax} \\
\text{else if } ((s_a = 1) & (s_b = 0)) \text{ then} \\
& \text{if } (\max(e_a, e_b) \geq 127) \text{ then } r = \text{nmax} \\
\text{else if } (s_a = s_b) \text{ then} \\
& \text{// Boundary case to be defined later}
\end{align*}
\]

- If the contents of parameter \(a\) or \(b\) are +inf, -inf, Denorm, QNaN, or SNaN, at least one of the SPEFSCR[FINVH] or SPEFSCR[FINV] bits is set.
- If an overflow occurs or is likely, the SPEFSCR[FOVFH] or SPEFSCR[FOVF] bits is set.
- If an underflow occurs or is likely, at least one of the SPEFSCR[FUNFH] or SPEFSCR[FUNF] bits is set.
- If the exception is enabled for the high or low element in which the error occurs, the exception is taken.

\[ d = \text{\_ev\_mhegumfan}(a, b) \]

\[
\begin{align*}
\text{temp}_{0:31} & \leftarrow a_{32:47} \times_{\text{ui}} b_{32:47} \\
\text{temp}_{0:63} & \leftarrow \text{EXTZ}(\text{temp}_{0:31}) \\
d_{0:63} & \leftarrow \text{ACC}_{0:63} - \text{temp}_{0:63} \\
\end{align*}
\]

// update accumulator

\[ \text{ACC}_{0:63} \leftarrow d_{0:63} \]

The corresponding low even-numbered elements in parameters \( a \) and \( b \) are multiplied. The intermediate product is zero-extended and subtracted from the contents of the 64-bit accumulator. The result is placed into parameter \( d \) and into the accumulator.

**Note:** This difference is a modulo difference. Neither overflow check nor saturation is performed. Overflow of the 64-bit difference is not recorded into the SPEFSCR.

__ev_mhogumiaa

Vector Multiply Half Words, Odd, Guarded, Unsigned, Modulo, Integer and Accumulate

d = __ev_mhogumiaa (a,b)

temp0:31 ← a48:63 ×ui b48:63

temp0:63 ← EXTZ (temp0:31)

d0:63 ← ACC0:63 + temp0:63

// update accumulator

ACC0:63 ← d0:63

The corresponding low odd-numbered half-word unsigned integer elements in parameters a and b are multiplied. The intermediate product is zero-extended to 64 bits and added to the contents of the 64-bit accumulator. This sum is placed into parameter d and into the accumulator.

Note: This sum is a modulo sum. Neither overflow check nor saturation is performed. An overflow from the 64-bit sum, if one occurs, is not recorded into the SPEFSCR.

Figure 130. __ev_mhogumiaa (odd form)

\]

The corresponding odd-numbered half-word signed integer elements in parameters \( a \) and \( b \) are multiplied, producing a 32-bit product. Each 32-bit product is then added to the corresponding word in the accumulator, saturating if overflow occurs, and the result is placed in parameter \( d \) and the accumulator.

If there is an overflow or underflow from the addition, the overflow and summary overflow bits are recorded in the SPEFSCR.

__ev_mwsmi

Vector Multiply Word Signed, Modulo, Integer (to Accumulator)

\[
d = \text{__ev_mwsmi} (a,b) \quad (A = 0)
\]
\[
d = \text{__ev_mwsmia} (a,b) \quad (A = 1)
\]
\[
d_{0:63} \leftarrow a_{32:63} \times b_{32:63}
\]

// update accumulator
if \( A = 1 \) then \( \text{ACC}_{0:63} \leftarrow d_{0:63} \)

The low word signed integer elements in parameters \( a \) and \( b \) are multiplied. The product is placed into the parameter \( d \).

If \( A = 1 \), the result in parameter \( d \) is also placed into the accumulator.

Other registers altered: ACC (if \( A = 1 \))

\]

Both the high and low elements of parameter \(a\) are shifted right by an amount specified in parameter \(b\). The result is placed into parameter \(d\). The separate shift amounts for each element are specified by 6 bits in parameter \(b\) that lie in bit positions 26–31 and 58–63. Zero bits are shifted in to the most significant position.

Shift amounts from 32 to 63 give a zero result.

__ev_subfw

Vector Subtract from Word

\[
d = __ev_subfw(a, b)
\]

\[
d_{0:31} \leftarrow b_{0:31} - a_{0:31} // \text{Modulo difference}
\]

\[
d_{32:63} \leftarrow b_{32:63} - a_{32:63} // \text{Modulo difference}
\]

Each signed integer element of parameter \(a\) is subtracted from the corresponding element of parameter \(b\), and the results are placed into parameter \(d\).

**Figure 226. Vector subtract from word (__ev_subfw)**

| Table 233. __ev_subfw (registers altered by). |
|-------------------|-------------------|-------------------|-------------------|
|                  |                  |                  | Maps to           |
| d                | a                | b                | __evsubfw d,a,b   |
| __ev64_opaque    | __ev64_opaque    | __ev64_opaque    |                   |
**__ev_subifw**

Vector Subtract Immediate from Word

\[
d = __ev_subifw(a, b)
\]

\[
d_{0:31} \leftarrow b_{0:31} - \text{EXTZ(UIMM)} \quad \text{// Modulo difference}
\]

\[
d_{32:63} \leftarrow b_{32:63} - \text{EXTZ(UIMM)} \quad \text{// Modulo difference}
\]

UIMM is zero-extended and subtracted from both the high and low elements of parameter \(b\). Note that the same value is subtracted from both elements of the register. UIMM is 5 bits.

# LOAD/STORE

Note: The 5-bit unsigned literal in the immediate form is scaled by the size of the load or store to determine how many bytes the pointer 'p' is offset by. The size of the load is determined by the first letter after the 'l': 'd'—double-word (8 bytes), 'w'—word (4 bytes), 'h'—half word (2 bytes). For details, see Chapter 5".

```c

# creation/insertion/extraction
4 Additional operations

4.1 Data manipulation

The intrinsics in section one act like functions with parameters that are passed by value. Figure 240 and Figure 241 show the layout of a __ev64_opaque__ variable in the register with reference to creation, insertion, and extraction routines (regardless of endianess). Figure 241 shows byte, half-word, and word ordering.

4.1.1 Creation intrinsics

These intrinsics create new generic 64-bit opaque data types from the given inputs passed by value. More specifically, they are created from the following inputs: 1 signed or unsigned 64-bit integer, 2 single-precision floats, 2 signed or unsigned 32-bit integers, or 4 signed or unsigned 16-bit integers.

```c
__ev64_opaque__ __ev_create_u64( uint64_t a );
__ev64_opaque__ __ev_create_s64( int64_t a );
__ev64_opaque__ __ev_create_fs( float a, float b );
__ev64_opaque__ __ev_create_us32( uint32_t a, uint32_t b );
__ev64_opaque__ __ev_create_s32( int32_t a, int32_t b );
__ev64_opaque__ __ev_create_u16( uint16_t a, uint16_t b, uint16_t c, uint16_t d );
__ev64_opaque__ __ev_create_s16( int16_t a, int16_t b, int16_t c, int16_t d );
__ev64_opaque__ __ev_create_sfix32_fs( float a, float b );
__ev64_opaque__ __ev_create_ufix32_fs( float a, float b );
```
Additional operations

4.1.2 Convert intrinsics

These intrinsics convert a generic 64-bit opaque data type to a specific signed or unsigned integral form.

\[
\text{uint64}_t \text{ __ev_convert_u64}(\text{ __ev64_opaque__ a }) ;
\]
\[
\text{int64}_t \text{ __ev_convert_s64}(\text{ __ev64_opaque__ a }) ;
\]

4.1.3 Get intrinsics

These intrinsics allow the user to access data from within a specified location of the generic 64-bit opaque data type.

**Get_upper/lower**

These intrinsics specify whether the upper 32-bits or lower 32-bits of the 64-bit opaque data type are returned. Only signed/unsigned 32-bit integers or single-precision floats are returned.

\[
\text{uint32}_t \text{ __ev_get_upper_u32}(\text{ __ev64_opaque__ a }) ;
\]
\[
\text{uint32}_t \text{ __ev_get_lower_u32}(\text{ __ev64_opaque__ a }) ;
\]
\[
\text{int32}_t \text{ __ev_get_upper_s32}(\text{ __ev64_opaque__ a }) ;
\]
\[
\text{int32}_t \text{ __ev_get_lower_s32}(\text{ __ev64_opaque__ a }) ;
\]
\[
\text{float} \text{ __ev_get_upper_fs}(\text{ __ev64_opaque__ a }) ;
\]
\[
\text{float} \text{ __ev_get_lower_fs}(\text{ __ev64_opaque__ a }) ;
\]

// maps to __ev_get_upper_u32
\[
\text{uint32}_t \text{ __ev_get_upper_ufix32_u32}(\text{ __ev64_opaque__ a }) ;
\]

// maps to __ev_get_lower_u32
\[
\text{uint32}_t \text{ __ev_get_lower_ufix32_u32}(\text{ __ev64_opaque__ a }) ;
\]

// maps to __ev_get_upper_s32
\[
\text{int32}_t \text{ __ev_get_upper_sfix32_s32}(\text{ __ev64_opaque__ a }) ;
\]

// maps to __ev_get_lower_s32
\[
\text{int32}_t \text{ __ev_get_lower_sfix32_s32}(\text{ __ev64_opaque__ a }) ;
\]

// equivalent to __ev_get_sfix32_fs(a, 0);
\[
\text{float} \text{ __ev_get_upper_sfix32_fs}(\text{ __ev64_opaque__ a }) ;
\]

// equivalent to __ev_get_sfix32_fs(a, 1);
\[
\text{float} \text{ __ev_get_lower_sfix32_fs}(\text{ __ev64_opaque__ a }) ;
\]

// equivalent to __ev_get_ufix32_fs(a, 0);
\[
\text{float} \text{ __ev_get_upper_ufix32_fs}(\text{ __ev64_opaque__ a }) ;
\]
Get explicit position

These intrinsics allow the user to specify the position (pos) in the 64-bit opaque data type where the data is accessed and returned. The position is 0 or 1 for words and either 0, 1, 2, or 3 for half-words.

```c
uint32_t __ev_get_u32( __ev64_opaque__ a, uint32_t pos );
int32_t __ev_get_s32( __ev64_opaque__ a, uint32_t pos );
float __ev_get_fs( __ev64_opaque__ a, uint32_t pos );
uint16_t __ev_get_u16( __ev64_opaque__ a, uint32_t pos );
int16_t __ev_get_s16( __ev64_opaque__ a, uint32_t pos );
```

// maps to __ev_get_u32
```c
uint32_t __ev_get_ufix32_u32( __ev64_opaque__ a, uint32_t pos );
```

// maps to __ev_get_s32
```c
int32_t __ev_get_sfix32_s32( __ev64_opaque__ a, uint32_t pos );
float __ev_get_ufix32_fs( __ev64_opaque__ a, uint32_t pos );
float __ev_get_sfix32_fs( __ev64_opaque__ a, uint32_t pos );
```

4.1.4 Set intrinsics

These intrinsics provide the capability of setting values in a 64-bit opaque data type that the intrinsic or the user specifies.

**Set_upper/lower**

These intrinsics specify which word (either upper or lower 32-bits) of the 64-bit opaque data type is set to input value b.

```c
__ev64_opaque__ __ev_set_upper_u32( __ev64_opaque__ a, uint32_t b );
__ev64_opaque__ __ev_set_upper_u16( __ev64_opaque__ a, uint32_t b );
__ev64_opaque__ __ev_set_upper_u32( __ev64_opaque__ a, uint32_t b );
__ev64_opaque__ __ev_set_upper_s32( __ev64_opaque__ a, int32_t b );
__ev64_opaque__ __ev_set_upper_s32( __ev64_opaque__ a, int32_t b );
__ev64_opaque__ __ev_set_upper_s16( __ev64_opaque__ a, int32_t b );
__ev64_opaque__ __ev_set_upper_s16( __ev64_opaque__ a, int32_t b );
__ev64_opaque__ __ev_set_upper_fs( __ev64_opaque__ a, float b );
__ev64_opaque__ __ev_set_upper_fs( __ev64_opaque__ a, float b );
```

// maps to __ev_set_upper_u32
```c
__ev64_opaque__ __ev_set_upper_ufix32_u32( __ev64_opaque__ a, uint32_t b );
```

// maps to __ev_set_upper_s32
```c
__ev64_opaque__ __ev_set_upper_sfix32_s32( __ev64_opaque__ a, int32_t b );
```

// equivalent to __ev_set_sfix32_fs(a, b, 0);
```c
__ev64_opaque__ __ev_set_upper_sfix32_fs( __ev64_opaque__ a, float b );
```
// equivalent to __ev_set_sfix32_fs(a, b, 1);
__ev64_opaque__ __ev_set_lower_sfix32_fs( __ev64_opaque__ a, float b );

// equivalent to __ev_set_ufix32_fs(a, b, 0);
__ev64_opaque__ __ev_set_upper_ufix32_fs( __ev64_opaque__ a, float b );

// equivalent to __ev_set_ufix32_fs(a, b, 1);
__ev64_opaque__ __ev_set_lower_ufix32_fs( __ev64_opaque__ a, float b );

Set accumulator

These intrinsics initialize the accumulator to the input value a.

__ev64_opaque__ __ev_set_acc_u64( uint64_t a );
__ev64_opaque__ __ev_set_acc_s64( int64_t a );
__ev64_opaque__ __ev_set_acc_vec64( __ev64_opaque__ a );

Set explicit position

These intrinsics set the 64-bit opaque input value a to the value in b based on the position given in pos. Unlike the intrinsics in 4.1.4.1, the positional value is specified by the user to be either 0 or 1 for words or 0, 1, 2, or 3 for half-words.

__ev64_opaque__ __ev_set_u32( __ev64_opaque__ a, uint32_t b, uint32_t pos );
__ev64_opaque__ __ev_set_s32( __ev64_opaque__ a, int32_t b, uint32_t pos );
__ev64_opaque__ __ev_set_fs( __ev64_opaque__ a, float b, uint32_t pos );
__ev64_opaque__ __ev_set_u16( __ev64_opaque__ a, uint16_t b, uint32_t pos );
__ev64_opaque__ __ev_set_s16( __ev64_opaque__ a, int16_t b, uint32_t pos );

// maps to __ev_set_u32
__ev64_opaque__ __ev_set_ufix32_u32( __ev64_opaque__ a, uint32_t b, uint32_t pos );

// maps to __ev_set_s32
__ev64_opaque__ __ev_set_sfix32_s32( __ev64_opaque__ a, int32_t b, uint32_t pos );
__ev64_opaque__ __ev_set_ufix32_fs( __ev64_opaque__ a, float b, uint32_t pos );
__ev64_opaque__ __ev_set_sfix32_fs( __ev64_opaque__ a, float b, uint32_t pos );

4.2 Signal processing engine (SPE) APU registers

The SPE includes the following two registers:

● The signal processing and embedded floating-point status and control register (SPEFSCR), described in Chapter 4.2.1: Signal processing and embedded floating-point status and control register (SPEFSCR) on page 298.

● A 64-bit accumulator, described in Chapter 3.1.2: Accumulator (ACC) on page 21.

4.2.1 Signal processing and embedded floating-point status and control register (SPEFSCR)

The SPEFSCR, which is shown in Figure 242, is used for status and control of SPE instructions.

4.2.2 SPEFSCR intrinsics

The following sections discuss SPEFSCR low-level accessors and SPEFSCR clear and set functions.

**SPEFSCR low-level accessors**

These intrinsics allow the user to access specific bits in the status and control registers.

```c
uint32_t __ev_get_spefscr_sovh( );
uint32_t __ev_get_spefscr_ovh( );
uint32_t __ev_get_spefscr_fgh( );
uint32_t __ev_get_spefscr_fxh( );
uint32_t __ev_get_spefscr_finvh( );
uint32_t __ev_get_spefscr_fdbzh( );
uint32_t __ev_get_spefscr_funfh( );
uint32_t __ev_get_spefscr_fovfh( );
uint32_t __ev_get_spefscr_finxs( );
uint32_t __ev_get_spefscr_finvs( );
uint32_t __ev_get_spefscr_fdbzs( );
uint32_t __ev_get_spefscr_funfs( );
uint32_t __ev_get_spefscr_fovfs( );
uint32_t __ev_get_spefscr_mode( );
uint32_t __ev_get_spefscr_sov( );
uint32_t __ev_get_spefscr_ov( );
uint32_t __ev_get_spefscr_fg( );
uint32_t __ev_get_spefscr_fx( );
uint32_t __ev_get_spefscr_finv( );
uint32_t __ev_get_spefscr_fdbz( );
uint32_t __ev_get_spefscr_funf( );
uint32_t __ev_get_spefscr_fovf( );
uint32_t __ev_get_spefscr_finxe( );
uint32_t __ev_get_spefscr_finve( );
uint32_t __ev_get_spefscr_fdbze( );
uint32_t __ev_get_spefscr_funfe( );
uint32_t __ev_get_spefscr_fovfe( );
uint32_t __ev_get_spefscr_frmc( );
```

**SPEFSCR Clear and Set Functions**

Table 247. SPEFSCR field descriptions (continued)

<table>
<thead>
<tr>
<th>Bits</th>
<th>Name</th>
<th>Function</th>
</tr>
</thead>
</table>
| 61   | FOVFE| Embedded floating-point overflow exception enable  
|      |      | 0: Exception disabled  
|      |      | 1: Exception enabled  
|      |      | If the exception is enabled, a floating-point data exception is taken if FOVF or FOVFH is set by a floating-point instruction. |
| 62–63| FRMC | Embedded floating-point rounding mode control  
|      |      | 00: Round to nearest  
|      |      | 01: Round toward zero  
|      |      | 10: Round toward +infinity  
|      |      | 11: Round toward -infinity |
Note: These intrinsics allow the user to clear and set specific bits in the status and control register. The user can set only the rounding mode bits.

```c
void __ev_clr_spefscr_sovh( );
void __ev_clr_spefscr_sov( );

void __ev_clr_spefscr_finxs( );
void __ev_clr_spefscr_finvs( );
void __ev_clr_spefscr_fdbzs( );
void __ev CLR_spefscr_fovfs( );

void __ev_set_spefscr_frmc( uint32_t rnd );
    // rnd = 0 (nearest), rnd = 1 (zero),
    // rnd = 2 (+inf), rnd = 3 (-inf)
```
4.3 Application binary interface (ABI) extensions

The following sections discuss ABI extensions.

4.3.1 malloc(), realloc(), calloc(), and new

The malloc(), realloc(), and calloc() functions are required to return a pointer with the proper alignment for the object in question. Therefore, to conform to the ABI, these functions must return pointers to memory locations that are at least 8-byte aligned. In the case of the C++ operator new, the implementation of new is required to use the appropriate set of functions based on the alignment requirements of the type.

4.3.2 printf example

The programming model specifies several new conversion format tokens. The programming model expects a combination of existing format tokens, new format tokens, and __ev_get_* intrinsics. Table 248 lists new tokens specified to handle fixed-point data types.

Table 248. New tokens for fixed-point data types

<table>
<thead>
<tr>
<th>Token</th>
<th>Data representation</th>
</tr>
</thead>
<tbody>
<tr>
<td>%hr</td>
<td>Signed 16-bit fixed point</td>
</tr>
<tr>
<td>%r</td>
<td>Signed 32-bit fixed point</td>
</tr>
<tr>
<td>%lR</td>
<td>Signed 64-bit fixed point</td>
</tr>
<tr>
<td>%hR</td>
<td>Unsigned 16-bit fixed point</td>
</tr>
<tr>
<td>%R</td>
<td>Unsigned 32-bit fixed point</td>
</tr>
<tr>
<td>%lR</td>
<td>Unsigned 64-bit fixed point</td>
</tr>
</tbody>
</table>

Example:

```c
__ev64_opaque__ a;

a = __ev_create_s32(2, -3);

printf("%d %d \n", __ev_get_upper_s32(a), __ev_get_lower_s32(a));
```

// output:
// 2 -3

The default precision for the new tokens is 6 digits. The tokens should be treated like the %f token with respect to floating-point values. The same field width and precision options should be respected for the new tokens, as the following example shows:

```c
printf("%1r", 0x4000);==> "0.500000"
printf("%z", 0x400000000);==> "0.500000"
printf("%hr", 0x4000000000000000ull);=="0.500000"
printf("%09.5z", 0x400000000);=="000.50000"
printf("%09.5f",0.5);=="000.50000"
```

4.3.3 Additional library routines

The functions atosfix16, atosfix32, atosfix64, atoufix16, atoufix32, and atoufix64 need not affect the value of the integer expression errno on an error. If the value of the result cannot be represented, the behavior is undefined.
The `atosfix16`, `atosfix32`, `atosfix64`, `atoufix16`, `atoufix32`, `atoufix64` functions convert the initial portion of the string to which `str` points to the following numbers:

- 16-bit signed fixed-point number
- 32-bit signed fixed-point number
- 64-bit signed fixed-point number
- 16-bit unsigned fixed-point number
- 32-bit unsigned fixed-point number
- 64-bit unsigned fixed-point number

These numbers are represented as `int16_t`, `int32_t`, `int64_t`, `uint16_t`, `uint32_t`, and `uint64_t`, respectively.

Except for the behavior on error, they are equivalent to the following:

- `atosfix16`: `strtosfix16(str, (char **)NULL)`
- `atosfix32`: `strtosfix32(str, (char **)NULL)`
- `atosfix64`: `strtosfix64(str, (char **)NULL)`
- `atoufix16`: `strtoufix16(str, (char **)NULL)`
- `atoufix32`: `strtoufix32(str, (char **)NULL)`
- `atoufix64`: `strtoufix64(str, (char **)NULL)`

The `strtosfix16`, `strtosfix32`, `strtosfix64`, `strtoufix16`, `strtoufix32`, `strtoufix64` functions convert the initial portion of the string to which `str` points to the following numbers:

- 16-bit signed fixed-point number
- 32-bit signed fixed-point number
- 64-bit signed fixed-point number
- 16-bit unsigned fixed-point number
- 32-bit unsigned fixed-point number
- 64-bit unsigned fixed-point number

These numbers are represented as `int16_t`, `int32_t`, `int64_t`, `uint16_t`, `uint32_t`, and `uint64_t`, respectively.

The functions support the same string representations for fixed-point numbers that the `strtof`, `strtof`, `strtold` functions support, with the exclusion of `NAN` and `INFINITY` support.

For the signed functions, if the input value is greater than or equal to 1.0, positive saturation should occur and `errno` should be set to `ERANGE`. If the input value is less than -1.0, negative saturation should occur, and `errno` should be set to `ERANGE`.
For the unsigned functions, if the input value is greater than or equal to 1.0, saturation should occur to the upper bound, and errno should be set to ERANGE. If the input value is less than 0.0, saturation should occur to the lower bound and errno should be set to ERANGE.
5 Programming interface examples

5.1 Data type initialization

The following examples show valid and invalid initializations of the SPE data types.

5.1.1 __ev64_opaque__ initialization

The following examples show valid and invalid initializations of __ev64_opaque__:

- Example 1 (Invalid)
  ```
  __ev64_opaque__ x1 = { 0, 1 };
  ```
  This example is invalid because it lacks qualification for interpreting the array initialization. The compiler is unable to interpret whether the array consists of two unsigned integers, two signed integers, four unsigned integers, four signed integers, or two floats.

- Example 2 (Invalid)
  ```
  __ev64_opaque__ x2 = (__ev64_opaque__) { 0, 1 };
  ```
  This example is invalid because the qualification provides no additional information for interpreting the array initialization.

- Example 3 (Valid)
  ```
  __ev64_opaque__ x3 = (__ev64_u32__) { 0, 1 };
  ```
  This example is valid because the array initialization is qualified so that it provides the compiler with a unique interpretation. The array initialization is interpreted as an __ev64_u32__ with an implicit cast from the __ev64_u32__ to __ev64_opaque__.

- Example 4 (Valid)
  ```
  __ev64_opaque__ x4 = (__ev64_opaque__) (__ev64_u32__) { 0, 1 };
  ```
  Although this example is the same as Example 3, it includes an explicit cast, rather than depending on the implicit casting to __ev64_opaque__ on assignment.

- Example 5 (Valid)
  ```
  __ev64_opaque__ x5 = (__ev64_u16__) __ev64_opaque__
  (__ev64_u32__) { 0, 1 };
  ```
  This example shows a series of casts; at the end, the result in x5 is no different from what it would be in Example 3. The example depends on the implicit cast from __ev64_u16__ to __ev64_opaque__.

- Example 6 (Valid)
  ```
  __ev64_opaque__ x6 = __ev64_opaque__ (__ev64_u16__
  __ev64_u32__) { 0, 1 };
  ```
  This example shows a series of casts; at the end, the result in x6 is no different from what it would be in Example 3. The example explicitly casts to __ev64_opaque__ rather than depending on the implicit cast.

- Example 7 (Valid)
  ```
  __ev64_opaque__ x7 = (__ev64_u16__) __ev64_opaque__
  __ev64_u32__) { 0, 1 };
  ```
  This example shows a series of casts; at the end, the result in x6 is no different from what it would be in Example 3. The example depends on the implicit cast from __ev64_u16__ to __ev64_opaque__.

- Example 8 (Valid)
This example is similar to Example 3. It shows that any SPE data types except __ev64_opaque__ can be used to qualify the array initialization.

5.1.2 Array initialization of SPE data types

The following examples show array initialization of SPE data types:

- Example 1 shows how to initialize an array of four __ev64_u32__.
  ```
  __ev64_u32__ x1[4] = {
      { 0, 1 },
      { 2, 3 },
      { 4, 5 },
      { 6, 7 }
  };
  ```

- Example 2 shows how to initialize an array of four __ev64_u16__.
  ```
  __ev64_u16 x2[4] = {
      { 0, 1, 2, 3 },
      { 4, 5, 6, 7 },
      { 8, 9, 10, 11 },
      { 12, 13, 14, 15 }
  };
  ```

- Example 3 shows how to initialize an array of four __ev64_fs__.
  ```
  __ev64_fs__ x3[4] = {
      { 1.1f, 2.2f },
      { -3.3f, 4.4f },
      { 5.5f, 6.6f },
      { 7.7f, -8.8f }
  };
  ```

- Example 4 shows explicit casting, and is the same as Example 1:
  ```
  __ev64_u32__ x4[4] = {
      (__ev64_u32__) {0, 1},
      (__ev64_u32__) {2, 3},
      (__ev64_u32__) {4, 5},
      (__ev64_u32__) {6, 7}
  };
  ```

- Example 5 shows mixed explicit casting. x5[1] is equal to (__ev64_u32__) (131075, 262149).
  ```
  __ev64_u32__ x5[4] = {
      (__ev64_u32__) {0, 1},
      (__ev64_u16__) {2, 3, 4, 5},
      (__ev64_u32__) {6, 7},
      (__ev64_u32__) {8, 9}
  };
  ```
5.2 Fixed-point accessors

The following sections discuss fixed-point accessors.

5.2.1 __ev_create_sfix32_fs

The following examples show use of __ev_create_sfix32_fs:

- **Example 1**
  
  ```c
  __ev64_s32__ x1 = __ev_create_sfix32_fs (0.5, -0.125);
  // x1 = {0x40000000, 0xF0000000}
  
  The floating-point numbers 0.5 and -0.125 are converted to their fixed-point representations and stored in x1.
  ```

- **Example 2**
  
  ```c
  __ev64_s32__ x2 = __ev_create_sfix32_fs (-1.1, 1.0);
  // x2 = {0x80000000, 0x7fffffff}
  
  Both floating-point values, –1.1 and 1.0, are outside of the range that signed fixed-point [–1, 1) supports. Therefore, the results of the conversion are saturated to the most negative number, 0x80000000, and the most positive number, 0x7FFFFFFF.
  ```

5.2.2 __ev_create_ufix32_fs

The following examples show use of __ev_create_ufix32_fs:

- **Example 1**
  
  ```c
  __ev64_u32__ x1 = __ev_create_ufix32_fs(0.5, 0.125);
  // x1 = {0x80000000, 0x20000000}
  
  The floating-point numbers 0.5 and 0.125 are converted to their unsigned fixed-point representations and stored in x1.
  ```

- **Example 2**
  
  ```c
  __ev64_u32__ x2 = __ev_create_ufix32_fs(-1.1, 1.0);
  // x2 = {0x00000000, 0xFFFFFFFF}
  
  Both floating-point values, –1.1 and 1.0, are outside of the range that unsigned fixed-point [0, 1) supports. Therefore, the results of the conversion are saturated to the lower bound, 0x00000000, and the upper bound, 0xFFFFFFFF.
  ```

5.2.3 __ev_set_ufix32_fs

The following examples show use of __ev_set_ufix32_fs:

- **Example 1**
  
  ```c
  __ev64_u32__ x1a = { 0x00000000 0xffffffff };  
  __ev64_u32__ x1b = __ev_set_ufix32_fs (x1a, 0.5, 0);
  // x1b = {0x80000000, 0xffffffff}
  
  This example shows modification of an element in an SPE variable. The intrinsics work like the create routine in that the floating-point number 0.5 is converted to its unsigned fixed-point representation and placed into element 0.
  ```

- **Example 2**
  
  ```c
  __ev64_u32__ x2a = { 0x00000000 0xffffffff };  
  __ev64_u32__ x2b = __ev_set_ufix32_fs (x2a, 1.5, 0);
  ```
5.2.4 __ev_set_sfix32_fs

This example shows modification of an element in an SPE variable. The intrinsics work
like the create routine in that the floating-point number 1.5 is saturated to the upper
bound for unsigned fixed-point representation and placed into element 0.

Example 1
__ev64_u32__ x1a = { 0x00000000 0xffffffff };  
__ev64_u32__ x1b = __ev_set_sfix32_fs (x1a, 0.5, 0);  
// x1b = {0x40000000, 0xffffffff}

Example 2
__ev64_s32__ x2a = { 0x00000000 0xffffffff };  
__ev64_s32__ x2b = __ev_set_sfix32_fs (x2a, 1.5, 0);  
// x2b = {0x7fffffff, 0xffffffff}

5.2.5 __ev_get_ufix32_fs

This example shows extraction of a floating-point number from an SPE variable interpreted
as an unsigned fixed-point number. The intrinsic extracts element 1 of the variable and
converts it from an unsigned fixed-point number to the closest floating-point representation.

Example
__ev64_u32__ x1 = { 0x80000000, 0xffffffff };  
float f1 = __ev_get_ufix32_fs (x1, 1);  
// f1 = 1.0

5.2.6 __ev_get_sfix32_fs

This example shows extraction of a floating-point number from an SPE variable interpreted
as a signed fixed-point number. The intrinsic extracts element 0 of the variable and converts
it from a signed fixed-point number to the closest floating-point value.

Example
__ev64_s32__ x1 = { 0xf0000000, 0xffffffff };  
float f1 = __ev_get_sfix32_fs (x1, 0);  
// f1 = -0.125

5.3 Loads

These examples apply to load and store intrinsics. All of the examples reference the same
'ev_table':
__ev64_u32__ ev_table[] = {  
(__ev64_u32__) {0x01020304, 0x05060708},  
(__ev64_u32__) {0x090a0b0c, 0x0d0e0f10},  
(__ev64_u32__) {0x11121314, 0x15161718},  
(__ev64_u32__) {0x191a1b1c, 0x1d1e1f20},
5.3.1 __ev_lddx

This example shows indexing of double-word load. The base pointer is set to the address of ev_table. The intrinsic offsets the base pointer by 2 double-words (16 bytes). This load is equivalent to ev_table[2].

```c
__ev64_u32__ x1 = __ev_lddx((__ev64_opaque__ *)&ev_table[0], 16);
// x1 = {0x11121314, 0x15161718};
```

5.3.2 __ev_ldd

This example shows an immediate double-word load. The base pointer is set to the address of ev_table. The intrinsic offsets the base pointer by 2 double-words. This load is equivalent to ev_table[2]. The offset in the immediate pointer is scaled by the double-word load size.

```c
__ev64_u32__ x1 = __ev_ldd((__ev64_opaque__ *)&ev_table[0], 2);
// x1 = {0x11121314, 0x15161718};
```

5.3.3 __ev_lhhesplatx

This example shows an index half-word even splat load. The base pointer is set to the address of ev_table. The intrinsic offsets the base pointer by 4 bytes.

```c
__ev64_u32__ x1 = __ev_lhhesplatx((__ev64_opaque__ *)&ev_table[0], 4);
// x1 = {0x05060000, 0x05060000}
```

5.3.4 __ev_lhhesplat

This example shows an immediate half-word even splat load. The base pointer is set to the address of ev_table. The intrinsic offsets the base pointer by 4 half-words (8 bytes). Note that the load size, a half-word in this case, scales the offset in the immediate pointer.

```c
__ev64_u32__ x1 = __ev_lhhesplat((__ev64_opaque__ *)&ev_table[0], 4);
// x1 = {0x090a0000, 0x090a0000}
```
6 Glossary of terms and abbreviations

The glossary contains an alphabetical list of terms, phrases, and abbreviations used in this book. Some of the terms and definitions included in the glossary are reprinted from IEEE Std. 754-1985, IEEE Standard for binary floating-point arithmetic, copyright ©1985 by the Institute of Electrical and Electronics Engineers, Inc. with the permission of the IEEE.

Note that some terms are defined in the context of their usage in this manual.

A

Application binary interface (ABI). A standardized interface that defines calling conventions and stack usage between applications and the operating system.

Architecture. A detailed specification of requirements for a processor or computer system. It does not specify details for implementing the processor or computer system; instead it provides a template for a family of compatible implementations.

B

Biased exponent. An exponent whose range of values is shifted by a constant (bias). Typically a bias is provided to allow a range of positive values to express a range that includes both positive and negative values.

Big-endian. A byte-ordering method in memory where the address n of a word corresponds to the most-significant byte. In an addressed memory word, the bytes are ordered (left to right) 0, 1, 2, 3, with 0 as the most-significant byte. See Little-endian.

C

Cast. A cast expression consists of a left parenthesis, a type name, a right parenthesis, and an operand expression. The cast causes the operand value to be converted to the type name within the parentheses.

D

Denormalized number. A non zero floating-point number whose exponent has a reserved value, usually the format’s minimum, and whose explicit or implicit leading significand bit is zero.

E

Effective address (EA). The 32- or 64-bit address specified for a load, store, or an instruction fetch. This address is then submitted to the MMU for translation to either a physical memory address or an I/O address.

Exponent. In the binary representation of a floating-point number, the exponent is the component that normally signifies the integer power to which the value two is raised in determining the value of the represented number. See also Biased exponent.

F

Fixed-point. (see Fractional)
**Fractional.** SPE supports 16- and 32-bit signed fractional two's complement data formats. For these two N-bit fractional data types, data is represented using the 1. [N-1] bit format. The MSB is the sign bit (-2^0) and the remaining N-1 bits are fractional bits (2^-1 2^-2 ... 2^- (N-1)).

**G**

**General-purpose register** (GPR). Any of the 32 registers in the general-purpose register file. These registers provide the source operands and destination results for all integer data manipulation instructions. Integer load instructions move data from memory to GPRs and store instructions move data from GPRs to memory.

**I**

**IEEE 754.** A standard written by the Institute of Electrical and Electronics Engineers that defines operations and representations of binary floating-point arithmetic.

**Inexact.** Loss of accuracy in an arithmetic operation when the rounded result differs from the infinitely precise value with unbounded range.

**L**

**LSB** (Least-significant bit). The bit of least value in an address, register, data element, or instruction encoding.

**Little-endian.** A byte-ordering method in memory where the address n of a word corresponds to the least-significant byte. In an addressed memory word, the bytes are ordered (left to right) 3, 2, 1, 0, with 3 as the most-significant byte. See Big-endian.

**M**

**Mnemonic.** The abbreviated name of an instruction used for coding.

**Modulo.** A value v that lies outside the range of numbers that an n-bit wide destination type can represent is replaced by the low-order n bits of the two's complement representation of v.

**MSB** (Most-significant bit). The highest-order bit in an address, registers, data element, or instruction encoding.

**N**

**NaN.** An abbreviation for ‘Not a Number’; a symbolic entity encoded in floating-point format. The two types of NaNs are signaling NaNs (SNaNs) and quiet NaNs (QNaNs).

**Normalization.** A process by which a floating-point value is manipulated such that it can be represented in the format for the appropriate precision (single- or double-precision). For a floating-point value to be representable in the single- or double-precision format, the leading implied bit must be a 1.

**O**

**Overflow.** An error condition that occurs during arithmetic operations when the result cannot be stored accurately in the destination register(s). For example, if two 32-bit numbers are multiplied, the result may not be representable in 32 bits.
**R**

**Reserved field.** In a register, a reserved field is one that is not assigned a function. A reserved field may be a single bit. The handling of reserved bits is implementation-dependent. Software can write any value to such a bit. A subsequent reading of the bit returns 0 if the value last written to the bit was 0 and returns an undefined value (0 or 1) otherwise.

**S**

**Saturate.** A value \( v \) that lies outside the range of numbers representable by a destination type is replaced by the representable number closest to \( v \).

**Significand.** The component of a binary floating-point number that consists of an explicit or implicit leading bit to the left of its implied binary point and a fraction field to the right.

**SIMD** (Single-instruction, multiple-data). An instruction set architecture that performs operations on multiple, parallel values within a single operand.

**Splat.** To replicate a value in multiple elements of an SIMD target operand.

**Sticky bit.** A bit that when set must be cleared explicitly.

**Supervisor mode.** The privileged operation state of a processor. In supervisor mode, software, typically the operating system, can access all control registers and the supervisor memory space, among other privileged operations.

**U**

**Underflow.** An error condition that occurs during arithmetic operations when the result cannot be represented accurately in the destination register. For example, underflow can happen if two floating-point fractions are multiplied and the result requires a smaller exponent and/or mantissa than the single-precision format can provide. In other words, the result is too small for accurate representation.

**User mode.** The unprivileged operating state of a processor used typically by application software. In user mode, software can only access certain control registers and can access only user memory space. No privileged operations can be performed. Also known as problem state.

**V**

**Vector literal.** A constant expression with a value that is taken as a vector type.

**W**

**Word.** A 32-bit data element.
