Introduction

The SPC56xx and RPC56xx DSP function library 2 contains optimized functions for Root part number 1 family of processors with Signal Processing Engine (SPE APU).

1 Library functions

The library functions are presented in the following sections.

1.1 FFT

- bitrev_table_16bit - Bit Reversal Permutation for 16-bit data (frac16)
- bitrev_table_32bit - Bit Reversal Permutation for 32-bit data (frac32 and float)
- fft_radix4_float - N-point radix-4 complex to complex float in-place FFT, N is even power of two
- fft_radix4_frac32 - N-point radix-4 complex to complex frac16/frac32 in-place FFT, N is even power of two
- fft_quad_float - N-point quad radix-2 complex to complex float in-place FFT, N is even power of two
- fft_quad_frac32 - N-point quad radix-2 complex to complex frac16/frac32 in-place FFT, N is even power of two
- fft_radix2_last_stage_float - calculates the last stage of N-point radix-2 complex to complex float in-place FFT, together with fft_quad_float function is used to calculate N-point complex to complex float in-place FFT where N is odd power of two
- fft_radix2_last_stage_frac32 - calculates the last stage of N-point radix-2 complex to complex frac32 in-place radix-2 FFT, together with fft_quad_frac32 function is used to calculate N-point complex to complex in-place frac16/frac32 FFT where N is odd power of two
- fft_real_split_float - split function for N-point real to complex float FFT
- fft_real_split_frac32 - split function for N-point real to complex frac32 FFT
- window_apply_complex_float - complex float windowing function
- window_apply_complex_frac16 - complex frac16 windowing function
- window_apply_real_float - real float windowing function
- window_apply_real_frac16 - real frac16 windowing function

1.2 Pressure sensing

- mfb50_pmh - calculates mass fraction burned (MFB), MFB50 value and PMH index
- mfb50_index - calculates MFB50 position index

1.3 Image

- conv3x3 - 2-D convolution with 3x3 kernel
- sobel3x3 - sobel filter
- sobel3x3_horizontal - horizontal sobel filter
- sobel3x3_vertical - vertical sobel filter
1.4 Filter

- corr_frac16 - frac16 correlation function
- fir_float - float FIR filter
- fir_frac16 - frac16 FIR filter
- iir_float_1st - float first-order IIR filter
- iir_float_2nd - float second-order IIR filter
- iir_float_casc - cascade of float second-order IIR filters
- iir_frac16_1st - frac16 first-order IIR filter
- iir_frac16_2nd - frac16 second-order IIR filter
- iir_frac16_casc - cascade of frac16 second-order IIR filters
- iir_frac16_2nd_hc - frac16 second-order IIR filter with half coefficients

1.5 Macros

The library defines macros in libdsp2.h that encapsulate some of the previous functions to allow easy usage; see the libdsp2.h file and the examples in example directory.
2 Supported compilers

The library was built and tested using the following compilers:

- CodeWarrior for PowerPC V1.5 beta2
- Green Hills MULTI for PowerPC v4.2.1
- Wind River Compiler Version 5.2.1.0
3 Directory structure

- **doc** - contains library user's manual
- **example** - contains library example projects for Axiom-0321 MPC5554 development board, for each supported compiler
- **include** - contains library header file libdsp2.h
- **src** - contains library source files for CodeWarrior compiler and C source files
- **src\src_GHS** - contains library source files for Green Hills compiler
- **src\src_WR** - contains library source files for Wind River compiler
4 How to use the library in a project

- **CodeWarrior**
  - add library source files with required functions into your project window
  - add path to library include file libdsp2.h to "Target Settings (Alt-F7)->Access Paths->User Paths"
  - include file libdsp2.h into your source file

- **Green Hills**
  - add library source files with required functions into your project window
  - use -I compiler option -I{path to libdsp2.h},
  - include file libdsp2.h into your source file

- **Wind River**
  - add library source files with required functions into your project window
  - use -I compiler option -I{path to libdsp2.h}
  - include file libdsp2.h into your source file

**Code example:**

```c
#include "libdsp2.h"
#define N_MAX 512
float inout_buffer [2*N_MAX+8]; /* +8 to ensure there is 32 bytes of readable memory behind buffer, must be double-word aligned */
void main(void)
{
    /* compute complex to complex float in-place FFT */
    fft_quad_float_512(inout_buffer);
}
```
5 Example projects

The library contains ready to run example projects which are located in example directory. The projects are created for Axiom MPC5554 development board.

- **CodeWarrior**
  - CW_example.mcp - examples of float FFTs
  - CW_example1.mcp - examples of frac16/frac32 FFTs
  - CW_example2.mcp - examples of real to complex float FFTs
  - CW_example3.mcp - examples of real to complex frac16/frac32 FFTs
  - CW_example4.mcp - examples of real and complex float windowing functions
  - CW_example5.mcp - examples of real and complex frac16 windowing functions
  - CW_example6.mcp - examples of pressure sensing functions mfb50_pmh and mfb50_index
  - CW_example7.mcp - examples of 2D convolution with 3x3 kernel
  - CW_example8.mcp - examples of sobel filters
  - CW_example9.mcp - examples of frac16 data correlation and auto-correlation function
  - CW_example9a.mcp - examples of FIR filters
  - CW_example9b.mcp - examples of float data IIR filters
  - CW_example9c.mcp - examples of frac16 data IIR filters

- **Green Hills**
  - GHS_example.gpj - examples of float FFTs
  - GHS_example1.gpj - examples of frac16/frac32 FFTs
  - GHS_example2.gpj - examples of real to complex float FFTs
  - GHS_example3.gpj - examples of real to complex frac16/frac32 FFTs
  - GHS_example4.gpj - examples of real and complex float windowing functions
  - GHS_example5.gpj - examples of real and complex frac16 windowing functions
  - GHS_example6.gpj - examples of pressure sensing functions mfb50_pmh and mfb50_index
  - GHS_example7.gpj - examples of 2D convolution with 3x3 kernel
  - GHS_example8.gpj - examples of sobel filters
  - GHS_example9.gpj - examples of frac16 data correlation and auto-correlation function
  - GHS_example9a.gpj - examples of FIR filters
  - GHS_example9b.gpj - examples of float data IIR filters
  - GHS_example9c.gpj - examples of frac16 data IIR filters

- **Wind River**
  - makefile - examples of float FFTs
  - makefile1 - examples of frac16/frac32 FFTs
  - makefile2 - examples of real to complex float FFTs
  - makefile3 - examples of real to complex frac16/frac32 FFTs
  - makefile4 - examples of real and complex float windowing functions
– makefile5 - examples of real and complex frac16 windowing functions
– makefile6 - examples of pressure sensing functions mfb50_pmh and mfb50_index
– makefile7 - examples of 2D convolution with 3x3 kernel
– makefile8 - examples of sobel filters
– makefile9 - examples of frac16 data correlation and auto-correlation function
– makefile9a - examples of FIR filters
– makefile9b - examples of float data IIR filters
– makefile9c - examples of frac16 data IIR filters
6 Function API

6.1 Bit reversal permutation for 16-bit data

Function call:

```c
void bitrev_table_16bit(unsigned int n, short *inout_buffer,
                        unsigned short *seed_table);
```

Arguments:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>n</code></td>
<td>number of groups:</td>
</tr>
<tr>
<td></td>
<td>for radix-2 bit reverse permutation:</td>
</tr>
<tr>
<td></td>
<td>n = 8 for 64 and 128-point FFT</td>
</tr>
<tr>
<td></td>
<td>n = 16 for 256 and 512-point FFT</td>
</tr>
<tr>
<td></td>
<td>n = 32 for 1024 and 2048 point FFT</td>
</tr>
<tr>
<td></td>
<td>n = 64 for 4096 point FFT</td>
</tr>
<tr>
<td></td>
<td>for radix-4 2-bit reverse permutation:</td>
</tr>
<tr>
<td></td>
<td>n = 4 for 64-point FFT</td>
</tr>
<tr>
<td></td>
<td>n = 16 for 256 and 1024-point FFT</td>
</tr>
<tr>
<td></td>
<td>n = 64 for 4096 point FFT</td>
</tr>
<tr>
<td><code>inout_buffer</code></td>
<td>pointer to the input/output vector of length 2*N, vector must be word aligned</td>
</tr>
<tr>
<td></td>
<td>memory layout: x_Re(0) x_Im(0) x_Re(1) x_Im(1) ... x_Re(N-1) x_Im(N-1)</td>
</tr>
<tr>
<td></td>
<td>(Re - real part, Im - imaginary part)</td>
</tr>
<tr>
<td><code>seed_table</code></td>
<td>pointer to the seed table, use one of the predefined tables:</td>
</tr>
<tr>
<td></td>
<td>seed_radix2_16bit_64</td>
</tr>
<tr>
<td></td>
<td>seed_radix2_16bit_128</td>
</tr>
<tr>
<td></td>
<td>seed_radix2_16bit_256</td>
</tr>
<tr>
<td></td>
<td>seed_radix2_16bit_512</td>
</tr>
<tr>
<td></td>
<td>seed_radix2_16bit_1024</td>
</tr>
<tr>
<td></td>
<td>seed_radix2_16bit_2048</td>
</tr>
<tr>
<td></td>
<td>seed_radix2_16bit_4096</td>
</tr>
<tr>
<td></td>
<td>seed_radix4_16bit_64</td>
</tr>
<tr>
<td></td>
<td>seed_radix4_16bit_256</td>
</tr>
<tr>
<td></td>
<td>seed_radix4_16bit_1024</td>
</tr>
<tr>
<td></td>
<td>seed_radix4_16bit_4096</td>
</tr>
</tbody>
</table>

Performance: See Chapter 7: Performance.
Example 1. bitrev_table_16bit

```c
#include "libdsp2.h"
int inout_buffer[2*256];
void main() {
    /* bit reverse permutation and calculation of 256-point FFT */
    bitrev_table_16bit(16, (short *)(inout_buffer+256),
    seed_radix2_16bit_256);
    fft_quad_frac32(256, inout_buffer, w_table_radix2_frac32_256);
}
```

6.2 Bit reversal permutation for 32-bit data

**Function call:**

```c
void bitrev_table_32bit(unsigned int n, float *inout_buffer,
    unsigned short *seed_table);
```

**Arguments:**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td>number of groups: for radix-2 bit reverse permutation: n = 8 for 64 and 128-point FFT n = 16 for 256 and 512-point FFT n = 32 for 1024 and 2048 point FFT n = 64 for 4096 point FFT for radix-4 2-bit reverse permutation: n = 4 for 64-point FFT n = 16 for 256 and 1024-point FFT n = 64 for 4096 point FFT</td>
</tr>
<tr>
<td>inout_buffer</td>
<td>pointer to the input/output vector of length 2*N, vector must be double word aligned memory layout: x_Re(0) x_Im(0) x_Re(1) x_Im(1) ... x_Re(N-1) x_Im(N-1) (Re - real part, Im - imaginary part)</td>
</tr>
<tr>
<td>seed_table</td>
<td>pointer to the seed table, use one of the predefined tables: seed_radix2_32bit_64 seed_radix2_32bit_128 seed_radix2_32bit_256 seed_radix2_32bit_512 seed_radix2_32bit_1024 seed_radix2_32bit_2048 seed_radix2_32bit_4096 seed_radix4_32bit_64 seed_radix4_32bit_256 seed_radix4_32bit_1024 seed_radix4_32bit_4096</td>
</tr>
</tbody>
</table>
**RM0020 Function API**

**Performance:** See *Chapter 7: Performance*.

**Example 2. bitrev_table_32bit**

```c
#include "libdsp2.h"
float inout_buffer[2*256];
void main() {
    /* bit reverse permutation and calculation of 256-point FFT */
    bitrev_table_32bit(16, inout_buffer, seed_radix2_32bit_256);
    fft_quad_float(256, inout_buffer, w_table_radix2_float_256);
}
```

6.3 **N-point radix-4 complex to complex float in-place FFT**

**Function call:**

```c
void fft_radix4_float(unsigned int N, float *inout_buffer,
                      float *twiddle_factor_table);
```

**Arguments:**

<table>
<thead>
<tr>
<th>N</th>
<th>in/ out</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>inout_buffer</td>
<td>in/out</td>
<td>pointer to the input/output vector of length 2*N, vector must be double word aligned</td>
</tr>
<tr>
<td></td>
<td></td>
<td>memory layout: x_Re(0) x_Im(0) x_Re(1) x_Im(1) ... x_Re(N-1) x_Im(N-1) (Re - real part, Im - imaginary part)</td>
</tr>
<tr>
<td>twiddle_factor_table</td>
<td>in</td>
<td>pointer to the vector of twiddle factors of length 3*N/2-4, vector must be double word aligned</td>
</tr>
<tr>
<td></td>
<td></td>
<td>memory layout: w_Re(0) w_Im(0) w_Re(1) w_Im(1) ... w_Re(3<em>N/4-3) w_Im(3</em>N/4-3)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Use predefined w_table_radix4_float_N arrays. The w_table_radix4_float_N is computed according to this formula:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>[ w_{Re}(k) + i \cdot w_{Im}(k) = w_N^k ] for ( k = 0, 1, \ldots, 3\times N/4-3 )</td>
</tr>
</tbody>
</table>

**Description:** Computes the N-point radix-4 complex to complex float in-place fast Fourier transform (FFT). Input 2-bit reversed data are stored in inout_buffer, output data are written over the input data into inout_buffer. There is used radix-4 FFT algorithm.
Algorithm:

Equation 1
\[ X(n) = \sum_{k=0}^{N-1} x(k) \cdot w_n^k \] for each n from 0 to N-1

Equation 2
\[ w_n = e^{\frac{2\pi i}{N}} \]

where \( i \) is the imaginary unit with the property that: \( i^2 = -1 \).

Note: There must be at least 32 bytes of readable memory behind inout_buffer.

Performance: See Chapter 7: Performance and Table 32.

Example 3. fft_radix4_float

```c
#include "libdsp2.h"
float inout_buffer[2*256];
void main()
    /* bit reverse permutation and calculation of 256-point FFT */
    bitrev_table_32bit(16, inout_buffer, seed_radix4_32bit_256);
    fft_radix4_float (256, inout_buffer, w_table_radix4_float_256);
}
```

6.4 N-point radix-4 complex to complex frac16/frac32 in-place FFT

Function call:

```c
void fft_radix4_frac32(unsigned int N, int *inout_buffer,
    int *twiddle_factor_table);
```

Arguments:

<table>
<thead>
<tr>
<th>Table 4. fft_radix4_frac32 arguments</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
</tr>
<tr>
<td>inout_buffer</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>
Description: Computes the N-point radix-4 complex to complex frac16/frac32 in-place fast Fourier transform (FFT). Input 2-bit reversed 16-bit fractional data are stored in second half of inout_buffer, output 32-bit fractional data are written over the input data into inout_buffer. There is used radix-4 FFT algorithm.

The output scaling is configurable by constant definition in the function source file:

```c
.set SCALING 1 /* 0 - off, 1 - on */
```

By default it is turned on. The scaling is performed by dividing by 4 before each radix-4 stage.

Algorithm:

**Equation 3**

\[
X(n) = \sum_{k=0}^{N-1} x(k) \cdot w_N^k
\]

for each \( n \) from 0 to \( N-1 \), scaled down by \( N \) if scaling is turned on

**Equation 4**

\[
w_N = e^{\frac{2\pi i}{N}}
\]

where \( i \) is the imaginary unit with the property that: \( i^2 = -1 \).

*Note: There must be at least 32 bytes of readable memory behind inout_buffer.*

Performance: See *Chapter 7: Performance* and *Table 35*.

**Example 4. fft_radix4_frac32**

```c
#include "libdsp2.h"
int inout_buffer[2*256];
void main() {
    /* bit reverse permutation and calculation of 256-point FFT */
    bitrev_table_16bit(16, (short *)(inout_buffer+256),
                      seed_radix4_16bit_256);
```

---

### Table 4. fft_radix4_frac32 arguments (continued)

| twiddle_factor_table | in | pointer to the vector of twiddle factors of length 3*N/2-4, vector must be double word aligned memory layout: w_Re(0) w_Im(0) w_Re(1) w_Im(1) ... w_Re(3*N/4-3) w_Im(3*N/4-3) Use predefined w_table_radix4_frac32_N arrays. The w_table_radix4_frac32_N is computed according to this formula:

\[
w_Re(k) + i \cdot w_Im(k) = w_N^k \quad \text{for } k = 0, 1, ..., 3*N/4-3
\]
fft_radix4_frac32(256, inout_buffer, 
  w_table_radix4_frac32_256);
}

6.5 N-point quad radix-2 complex to complex float in-place FFT

Function call:

void fft_quad_float(unsigned int N, float *inout_buffer, float *twiddle_factor_table);

Arguments:

Table 5. fft_quad_float arguments

<table>
<thead>
<tr>
<th>N</th>
<th>in</th>
<th>FFT length, must be even power of two, tested for 64, 256, 1024, 4096</th>
</tr>
</thead>
<tbody>
<tr>
<td>inout_buffer</td>
<td>in/out</td>
<td>pointer to the input/output vector of length 2*N, vector must be double word aligned</td>
</tr>
<tr>
<td>twiddle_factor_table</td>
<td>in</td>
<td>pointer to the vector of twiddle factors of length N, vector must be double word aligned</td>
</tr>
</tbody>
</table>

memory layout:

- **x_Re(0) x_Im(0) x_Re(1) x_Im(1) ... x_Re(N-1) x_Im(N-1)**
- (Re - real part, Im - imaginary part)

- **w_Re(0) w_Im(0) w_Re(1) w_Im(1) ... w_Re(N/2-1) w_Im(N/2-1)**

Use predefined **w_table_radix2_float_N** arrays.

The **w_table_radix2_float_N** is computed according to this formula:

\[ w_{Re}(k) + i \cdot w_{Im}(k) = w_{N}^{k} \text{ for } k = 0, 1, ..., N/2-1 \]

Description: Computes the N-point quad radix-2 complex to complex float in-place fast Fourier transform (FFT). Input bit reversed data are stored in **inout_buffer**, output data are written over the input data into **inout_buffer**. There is used radix-2 algorithm in which two stages are calculated in one loop (quad butterfly).

Algorithm:

Equation 5

\[ X(n) = \sum_{k=0}^{N-1} x(k) \cdot w_{N}^{n \cdot k} \text{ for each } n \text{ from 0 to } N-1 \]

Equation 6

\[ w_{N} = e^{\frac{2\pi i}{N}} \]

where \( i \) is the imaginary unit with the property that: \( i^2 = -1 \).
Note: There must be at least 32 bytes of readable memory behind inout_buffer.

Performance: See Section 7 and Table 33.

Example 5. fft_quad_float

```c
#include "libdsp2.h"
float inout_buffer[2*256];
void main() {
    /* bit reverse permutation and calculation of 256-point FFT */
    bitrev_table_32bit(16, inout_buffer, seed_radix2_32bit_256);
    fft_quad_float(256, inout_buffer, w_table_radix2_float_256);
}
```

6.6 N-point quad radix-2 complex to complex frac16/frac32 in-place FFT

Function call:

```c
void fft_quad_frac32(unsigned int N, int *inout_buffer,
                     int *twiddle_factor_table);
```

Arguments:

</tr>
</tbody>
</table>
Description: Computes the N-point quad radix-2 complex to complex frac16/frac32 in-place fast Fourier transform (FFT). Input bit reversed 16-bit fractional data are stored in second half of inout_buffer, output 32-bit fractional data are written over the input data into inout_buffer. There is used radix-2 algorithm in which two stages are calculated in one loop (quad butterfly).

The output scaling is configurable by constant definition in the function source file:

```
.set SCALING 1    #/* 0 - off, 1 - on */
```

By default it is turned on. The scaling is performed by dividing by 4 before each pair of radix-2 stages.

Algorithm:

**Equation 7**

\[ X(n) = \sum_{k=0}^{N-1} x(k) \cdot w_N^n \cdot k \]

for each \( n \) from 0 to \( N-1 \), scaled down by \( N \) if scaling is turned on

**Equation 8**

\[ w_N = e^{2\pi i/N} \]

where \( i \) is the imaginary unit with the property that \( i^2 = -1 \).

Note: There must be at least 16 bytes of readable memory behind inout_buffer.

Performance: See Chapter 7: Performance and Table 36.

**Example 6. fft_quad_frac32**

```c
#include "libdsp2.h"
int inout_buffer[2*256];
void main() {
    /* bit reverse permutation and calculation of 256-point FFT */
    bitrev_table_16bit(16, (short *)(inout_buffer+256),
                      seed_radix2_16bit_256);
    fft_quad_frac32(256, inout_buffer, w_table_radix2_frac32_256);
}
```

**6.7 Last stage of N-point radix-2 complex to complex float in-place FFT**

**Function call:**

```c
void fft_radix2_last_stage_float(unsigned int N, float *inout_buffer,
                                  float *twiddle_factor_table);
```
Arguments:

**Table 7. fft_radix2_last_stage_float arguments**

<table>
<thead>

</tr>
</tbody>
</table>

**Description:** Computes the last stage of N-point radix-2 complex to complex float in-place fast Fourier transform (FFT). Input data are stored in inout_buffer, output data are written over the input data into inout_buffer. This function is used to calculate the FFT for lengths which are odd power of two (128, 512, 2048).

**Note:** There must be at least 16 bytes of readable memory behind inout_buffer.

**Performance:** See Chapter 7: Performance and Table 34.

**Example 7. fft_radix2_last_stage_float**

```c
#include "libdsp2.h"
float inout_buffer[2*512];
void main() {
    /* bit reverse permutation and calculation of 512-point FFT */
    bitrev_table_32bit(16, inout_buffer, seed_radix2_32bit_512);
    fft_quad_float(512, inout_buffer, w_table_radix2_float_512);
    fft_radix2_last_stage_float(512, inout_buffer, w_table_radix2_float_512);
}
```

6.8 Last stage of N-point radix-2 complex to complex frac32 in-place FFT

**Function call:**

```c
void fft_radix2_last_stage_frac32(unsigned int N, int *inout_buffer, int *twiddle_factor_table);
```
Arguments:

Description: Computes the last stage of N-point radix-2 complex to complex frac32 in-place fast Fourier transform (FFT). Input data are stored in inout_buffer, output data are written over the input data into inout_buffer. This function is used to calculate the FFT for lengths which are odd power of two (128, 512, 2048).

Note: There must be at least 16 bytes of readable memory behind inout_buffer.

Performance: See Chapter 7: Performance and Table 37.

Example 8. fft_radix2_last_stage_frac32

```c
#include "libdsp2.h"
int inout_buffer[2*512];
void main() {
    /* bit reverse permutation and calculation of 512-point FFT */
    bitrev_table_16bit(16, (short *)(inout_buffer+512),
    seed_radix2_16bit_512);
    fft_quad_frac32(512, inout_buffer, w_table_radix2_frac32_512);
    fft_radix2_last_stage_frac32(512, inout_buffer,
    w_table_radix2_frac32_512);
}
```

6.9 Split function of N-point real to complex float FFT

Function call:

```c
void fft_real_split_float(unsigned int N, float *y, float *wa,
    float *wb);
```
Arguments:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>in</td>
<td>FFT length, tested for 128, 256, 512, 1024, 2048, 4096</td>
</tr>
<tr>
<td>y</td>
<td>in/out</td>
<td>pointer to the input/output vector of length N, vector must be double word aligned</td>
</tr>
<tr>
<td>wa</td>
<td>in</td>
<td>pointer to the wa vector of twiddle factors of length N/4+1, vector must be double word aligned</td>
</tr>
<tr>
<td>wb</td>
<td>in</td>
<td>pointer to the wb vector of twiddle factors of length N/4+1, vector must be double word aligned</td>
</tr>
</tbody>
</table>

Description: Split function of N-point real to complex float in-place fast Fourier transform (FFT). Input data are stored in y, output data are written over the input data into y. The function gives the first half of the output spectrum.

The calculation of the N/2 item is configurable by constant definition in the function source file:

```
.set    N2_REALPART,          0    #/* 0/1 - real part of N/2 item
isn't/is inserted in imaginary part of 0th item, default value is 0 */
```

By default the N/2 output item is not calculated.
Here is the summary how the real to complex float in-place FFT can be calculated using the split function:

- on real input data in_Re(0) in_Re(1) ... in_Re(N-1), calculate complex to complex FFT of half the length
- call the split function which calculates the half of the spectrum X_Re(0) X_Im(0) X_Re(1) X_Im(1) ... X_Re(N/2-1) X_Im(N/2-1)
- if N2_REALPART is defined to 1, the split function saves the X_Re(N/2) into X_Im(0)

**Algorithm:**

Input data in memory:

\[
x_{\text{Re}}(0)x_{\text{Im}}(0)x_{\text{Re}}(1)x_{\text{Im}}(1)\ldots x_{\text{Re}}\left(\frac{N}{2} - 1\right)x_{\text{Im}}\left(\frac{N}{2} - 1\right)
\]

where

Re is the real part,
Im is the imaginary part

**Equation 9**

\[
x(k) = x_{\text{Re}}(k) + ix_{\text{Im}}(k)
\]

The split function performs calculation of the output sequence \(X(k)\) from the input sequence \(x(k)\) according to the following equations:

**Equation 10**

\[
X(0) = x_{\text{Re}}(0) + x_{\text{Im}}(0)
\]

**Equation 11**

\[
X(\frac{N}{2}) = x_{\text{Re}}(0) - x_{\text{Im}}(0)
\]

**Equation 12**

\[
X(k) = wa(k)x(k) + wb(k)x^\ast\left(\frac{N}{2} - k\right)
\]

for each \(k\) from 1 to \(N/2-1\)

where:
Equation 13
\[ w_a(k) = \frac{1}{2} (1 - iW_N^k) \]

Equation 14
\[ w_b(k) = \frac{1}{2} (1 + iW_N^k) \]

Equation 15
\[ W_N = e^{-\frac{2\pi}{N}} \]

* denotes complex conjugate operation
i is the imaginary unit

Equation 16
\[ X(k) = X_{\text{Re}}(k) + iX_{\text{Im}}(k) \]

output data in memory:

\[ X_{\text{Re}}(0)X_{\text{Im}}(0)X_{\text{Re}}(1)X_{\text{Im}}(1) \cdots X_{\text{Re}}\left(\frac{N}{2} - 1\right)X_{\text{Im}}\left(\frac{N}{2} - 1\right) \]

when
N2_REALPART is defined to 0

\[ X_{\text{Re}}(0)X_{\text{Re}}\left(\frac{N}{2}\right)X_{\text{Re}}(1)X_{\text{Im}}(1) \cdots X_{\text{Re}}\left(\frac{N}{2} - 1\right)X_{\text{Im}}\left(\frac{N}{2} - 1\right) \]

when
N2_REALPART is defined to 1

Performance: See Chapter 7: Performance and Table 38.

Example 9. fft_real_split_float

#include "libdsp2.h"
float inout_buffer [128+8]; /* +8 to ensure there is 32 bytes of readable memory behind buffer */

void main(void)
{

int i;

/* example real input data, sequence from 1 to 128 */
for (i = 0; i < 128; i++) inout_buffer[i] = i+1;
/* compute complex to complex FFT of half the length */
fft_radix4_float_64(inout_buffer);
/* call split function to get correct FFT result */
fft_real_split_float(128, inout_buffer, wa_table_float_128,
wb_table_float_128);

6.10 Split function of N-point real to complex frac32 FFT

Function call:

</tbody>
</table>
**RM0020 Function API**

**Description:**
Split function of N-point real to complex frac32 in-place fast Fourier transform (FFT). Input 32-bit fractional data are stored in y, output 32-bit fractional data are written over the input data into y. The function gives the first half of the output spectrum.

The calculation of the N/2 item is configurable by constant definition in the function source file:

```
.set    N2_REALPART, 0    #/* 0/1 - real part of N/2 item isn't/is inserted in imaginary part of 0th item, default value is 0 */
```

By default the N/2 output item is not calculated.

The output scaling is configurable by constant definition in the function source file:

```
.set    SCALING              1    #/* 0 - off, 1 - on */
```

By default it is turned on. The scaling is performed by dividing input data by 2 before calculation.

Here is the summary how the real to complex frac32 in-place FFT can be calculated using the split function:

1. on real input data in_Re(0) in_Re(1) ... in_Re(N-1), calculate complex to complex FFT of half the length
2. call the split function which calculates the half of the spectrum X_Re(0) X_Im(0) X_Re(1) X_Im(1) ... X_Re(N/2-1) X_Im(N/2-1)
3. if N2_REALPART is defined to 1, the split function saves the X_Re(N/2) into X_Im(0)
4. note that the FFT output is divided by N since scaling is by default turned on

**Algorithm:**

Input data in memory:

```
x_Re(0)x_Im(0)x_Re(1)x_Im(1) ... x_Re\left(\frac{N}{2} - 1\right)x_Im\left(\frac{N}{2} - 1\right)
```

**Table 10. fft_real_split_frac32 arguments (continued)**

<table>
<thead>
<tr>
<th>wb</th>
<th>in</th>
</tr>
</thead>
<tbody>
<tr>
<td>pointer to the wb vector of twiddle factors of length N/4+1, vector must be double word aligned</td>
<td></td>
</tr>
<tr>
<td>memory layout: wb_Re(0) wb_Im(0) wb_Re(1) wb_Im(1) ... wb_Re(N/4+1) wb_Im(N/4+1)</td>
<td></td>
</tr>
<tr>
<td>Use predefined wb_table_frac32_N arrays. The wb_table_frac32_N is computed according to this formula:</td>
<td></td>
</tr>
<tr>
<td>[ wb(k) = \frac{1}{2} \left(1 + i W_N^k \right) ] for k = 0, 1, ... N/4+1</td>
<td></td>
</tr>
<tr>
<td>[ W_N = e^{-\frac{2\pi i}{N}} ], where i is the imaginary unit</td>
<td></td>
</tr>
</tbody>
</table>

Alternate algorithm:

```
x_Re(0)x_Im(0)x_Re(1)x_Im(1) ... x_Re\left(\frac{N}{2} - 1\right)x_Im\left(\frac{N}{2} - 1\right)
```
where
Re is the real part,
Im is the imaginary part

Equation 17,

\[ x(k) = \frac{x_{Re}(k)}{2} + \frac{i x_{Im}(k)}{2} \]

divided by two only in the case when
SCALING is set to 1

The split function performs calculation of the output sequence \( X(k) \) from the input sequence \( x(k) \) according to the following equations:

Equation 18

\[ X(0) = x_{Re}(0) + x_{Im}(0) \]

Equation 19

\[ X\left(\frac{N}{2}\right) = x_{Re}(0) - x_{Im}(0) \]

Equation 20

\[ X(k) = w_a(k)x(k) + w_b(k)x^*\left(\frac{N}{2} - k\right) \]

for each \( k \) from 1 to \( N/2-1 \) where:

Equation 21

\[ w_a(k) = \frac{1}{2}\left(1 - iW_N^k\right) \]

Equation 22

\[ w_b(k) = \frac{1}{2}\left(1 + iW_N^k\right) \]
**Equation 23**

\[ W_N = e^{-\frac{2\pi}{N}i} \]

* denotes complex conjugate operation

\( i \) is the imaginary unit

**Equation 24**

\[ X(k) = X_{Re}(k) + iX_{Im}(k) \]

output data in memory:

\[ X_{Re}(0)X_{Im}(0)X_{Re}(1)X_{Im}(1)…X_{Re}\left(\frac{N}{2}-1\right)X_{Im}\left(\frac{N}{2}-1\right) \]

when

\( N2\_REALPART \) is defined to 0

\[ X_{Re}(0)X_{Re}\left(\frac{N}{2}\right)X_{Re}(1)X_{Im}(1)…X_{Re}\left(\frac{N}{2}-1\right)X_{Im}\left(\frac{N}{2}-1\right) \]

when

\( N2\_REALPART \) is defined to 1

Performance: See *Chapter 7: Performance* and *Table 40*.

**Example 10. fft_real_split_frac32**

```c
#include "libdsp2.h"
int inout_buffer[128+8]; /* +8 to ensure there is 32 bytes of readable memory behind buffer */

void main(void)
{
    int i;

    /* example real input data, sequence from 1/2^15 to 128/2^15 */
    for (i = 0; i < 128; i++) *(short *)(inout_buffer + 64) = (short) (i+1);
    /* compute complex to complex FFT of half the length */
    fft_radix4_frac32_64(inout_buffer);
    /* call split function to get correct FFT result divided by N */
    fft_real_split_frac32(128, inout_buffer, wa_table_frac32_128, wb_table_frac32_128);
}
```
6.11 Complex float windowing function

**Function call:**

```c
void window_apply_complex_float(unsigned int N, float *x, float *y, float *w);
```

**Arguments:**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>in</td>
</tr>
<tr>
<td>x</td>
<td>in</td>
</tr>
<tr>
<td>y</td>
<td>out</td>
</tr>
<tr>
<td>w</td>
<td>in</td>
</tr>
</tbody>
</table>

1. All vectors must be double word aligned. All vectors have the following memory layout: `re(0) im(0) re(1) im(1) ... re(N-1) im(N-1)`, where `re` is real part and `im` is imaginary part.

**Description:**

Windowing function for complex float data. Input data are stored in x vector, output data are written into y vector. The y vector can be the same as x vector (in-place windowing).

**Algorithm:**

**Equation 25**

\[ y(k) = x(k) \times w(k) \]

for each \( k = 0,1,...,N-1 \)

where \( x \) denotes complex multiplication.

**Note:** There must be 16 bytes of readable memory behind \( x \) and \( w \) buffers.

**Performance:** See Chapter 7: Performance and Table 42.

**Example 11. window_apply_complex_float**

```c
#include "libdsp2.h"
float x[2*64+4];    /* +4 to ensure there is 16 bytes of readable memory behind buffer, must be aligned to 8 bytes */
float w[2*64+4];    /* +4 to ensure there is 16 bytes of readable memory behind buffer, must be aligned to 8 bytes */

void main(void)
{
    unsigned int i, N;

    /* length of complex vectors is 64 */
    N = 64;
    /* prepare example input data */
    for (i = 0; i < 2*N; i++) x[i] = i+1;
```
for (i = 0; i < 2*N; i++) w[i] = i+2*N;  
/* windowing function on complex float data, x[i] = x[i]*w[i] */  
window_apply_complex_float(N, x, x, w);

6.12 Complex frac16 windowing function

Function call:

void window_apply_complex_frac16(unsigned int N, short *x, short *y,  
short *w);

Arguments:

| Table 12. window_apply_complex_frac16 arguments |
|-----------------|-----------------|-----------------|
| N   | in | length of complex vectors, must be multiple of 4 |
| x(1) | in | pointer to the input vector of length 2*N |
| y(1) | out | pointer to the output vector of length 2*N, y vector can be the same as x vector (in-place windowing). |
| w(1) | in | pointer to the window vector of length 2*N |

1. All vectors must be word aligned. All vectors have the following memory layout: re(0) im(0) re(1) im(1)... re(N-1) im(N-1), where re is real part and im is imaginary part.

Description: Windowing function for complex frac16 data. All the data are handled as signed fractional 16-bit (range -1 to 1-2^-15). Input data are stored in x vector, output data are written into y vector. The y vector can be the same as x vector (in-place windowing).

The output scaling is configurable by constant definition in the function source file:

```c
.set SCALING, 1    /* 0 - off, 1 - on (output divided by 2) */
```

By default it is turned on. The scaling is performed by dividing output data by 2.

Algorithm:

Equation 26

\[ y(k) = x(k) \times w(k) \]

for each k = 0,1,...N-1

where x denotes complex multiplication. The output value y(k) is divided by 2 when SCALING == 1.

Note: There must be 8 bytes of readable memory behind x and w buffers.

If SCALING == 1, then w array mustn't have any value equal to -1 (-32768) since there is used integer multiplication for fractional data.

Performance: See Chapter 7: Performance and Table 43.
Example 12. window_apply_complex_frac16

```c
#include "libdsp2.h"
short x[2*64+4]; /* +4 to ensure there is 8 bytes of readable memory behind buffer, must be aligned to 4 bytes */
short w[2*64+4]; /* +4 to ensure there is 8 bytes of readable memory behind buffer, must be aligned to 4 bytes */
void main(void)
{
    unsigned int i, N;
    /* length of complex vectors is 64 */
    N = 64;
    /* prepare example input data */
    for (i = 0; i < 2*N; i++) x[i] = (i+1)<<5;
    for (i = 0; i < 2*N; i++) w[i] = (i+2*N)<<5;
    /* windowing function on complex frac16 data, x[i] = x[i]*w[i] */
    window_apply_complex_frac16(N, x, x, w);
}
```

6.13 Real float windowing function

Function call:
```c
void window_apply_real_float(unsigned int N, float *x, float *y, float *w);
```

Arguments:

<table>
<thead>
<tr>
<th>Table 13. window_apply_real_float arguments</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
</tr>
<tr>
<td>x(1)</td>
</tr>
<tr>
<td>y(1)</td>
</tr>
<tr>
<td>w(1)</td>
</tr>
</tbody>
</table>

1. All vectors must be double word aligned. All vectors have the following memory layout: x(0) x(1) ... x(N-1).

Description: Windowing function for real float data. Input data are stored in x vector, output data are written into y vector. The y vector can be the same as x vector (in-place windowing).

Algorithm:

Equation 27

\[ y(k) = x(k)w(k) \]
for each $k = 0,1,...,N-1$

*Note:* There must be 16 bytes of readable memory behind input vector $x$ and 8 bytes of readable memory behind window vector $w$.

Performance: See Chapter 7: Performance and Table 44.

**Example 13. window_apply_real_float**

```c
#include "libdsp2.h"
float x[64+4];    /* +4 to ensure there is 16 bytes of readable memory behind buffer */
float w[64+2];    /* +2 to ensure there is 8 bytes of readable memory behind buffer */

void main(void)
{
    unsigned int i, N;

    /* length of vectors is 64 */
    N = 64;
    /* prepare example input data */
    for (i = 0; i < N; i++) x[i] = i+1;
    for (i = 0; i < N; i++) w[i] = i+N;
    /* windowing function on real float data, $x[i] = x[i] \times w[i]$ */
    window_apply_real_float(N, x, x, w);
}
```

### 6.14 Real frac16 windowing function

**Function call:**

```c
void window_apply_real_frac16(unsigned int N, short *x, short *y, short *w);
```

**Arguments:**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>length of complex vectors, must be multiple of 16</td>
</tr>
<tr>
<td>x</td>
<td>pointer to the input vector of length N</td>
</tr>
<tr>
<td>y</td>
<td>pointer to the output vector of length N, y vector can be the same as x vector (in-place windowing)</td>
</tr>
<tr>
<td>w</td>
<td>pointer to the window vector of length N</td>
</tr>
</tbody>
</table>

1. All vectors must be word aligned. All vectors have the following memory layout: $x[0], x[1], ..., x[N-1]$.

**Description:** Windowing function for real frac16 data. All the data are handled as signed fractional 16-bit (range -1 to 1-2^-15). Input data are stored in x vector, output data are written into y vector. The y vector can be the same as x vector (in-place windowing).
Algorithm:

Equation 28

\[ y(k) = x(k)w(k) \]

for each \( k = 0,1,...N-1 \)

*Note: There must be 16 bytes of readable memory behind input vector \( x \) and 8 bytes of readable memory behind window vector \( w \).*

Performance: See Chapter 7: Performance and Table 45.

Example 14. window_apply_real_frac16

```c
#include "libdsp2.h"
short x[64+4];    /* +4 to ensure there is 8 bytes of readable
memory behind buffer, must be aligned to 4 bytes */
short w[64+2];    /* +2 to ensure there is 4 bytes of readable
memory behind buffer, must be aligned to 4 bytes */

void main(void)
{
    unsigned int i, N;
    N = 64;
    /* prepare example input data */
    for (i = 0; i < N; i++) x[i] = (i+1)<<5;
    for (i = 0; i < N; i++) w[i] = (i+N)<<5;
    /* windowing function on real float data, \( x[i] = x[i] \times w[i] \) */
    window_apply_real_frac16(N, x, x, w);
}
```

6.15 mfb50_pmh - pressure sensing function 1

Function call:

```c
float mfb50_pmh(unsigned int N, float *P_MFB, float *V, float K,
float *PMH);
```

Arguments:

<table>
<thead>
<tr>
<th>Table 15. mfb50_pmh arguments</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>N</strong></td>
</tr>
<tr>
<td><strong>P_{MFB}</strong></td>
</tr>
<tr>
<td><strong>V</strong></td>
</tr>
</tbody>
</table>
Description: Pressure sensing function 1. The function is used for in-cylinder pressure sensor management. For each cylinder and every engine revolution, there is calculated the mass fraction burned function (MFB), MFB50 value and PMH torque index. As inputs there are used vector of in-cylinder pressure values $P_\text{MFB}$, vector of cylinder volume values $V$, and constant $K$. The function returns the MFB50 value, mass fraction burned function (MFB) is returned in $P_\text{MFB}$ vector and PMH index in a variable addresses by PMH pointer.

Algorithm:

Calculation of MFB and MFB50 value:

1. Acquisition of in-cylinder pressure at any sampling position $\theta[i]$ (acquisition window ranges from -180° before TDC to 180° after TDC): $P[0]$ $P[1]$ ... $P[N-1]$
2. Calculation of cylinder volume $V[i]$ at any sampling position $\theta[i]$, $V[i]$ can be precalculated and stored in a calibration vector: $V[0]$ $V[1]$ ... $V[N-1]$
3. Calculation of heat release rate (QIST), (supposed delta $\theta$ is constant e.g. 0.5°), for each $i = 1,2 ... N-2$:

   \[
   QV = K \cdot P[i] \cdot \frac{V[i + 1] - V[i - 1]}{(K - 1) \cdot 2 \cdot \Delta \theta} \\
   QP = V[i] \cdot \frac{P[i + 1] - P[i - 1]}{(K - 1) \cdot 2 \cdot \Delta \theta} \\
   QIST[i] = QV + QP
   \]

   Note: The function calculates the heat release rate without multiplication with constant $1 \over (K - 1) \cdot 2 \cdot \Delta \theta$ in both QV and QP equations.

4. Calculation of mass fraction burned MFB (integration of heat release rate), initial condition is $MFB[1] = 0$, then for each $i = 2,3...N-2$:

   \[
   MFB[i] = MFB[i - 1] + (QIST[i] + QIST[i - 1]) \cdot \frac{\Delta \theta}{2}
   \]

   Note: The function calculates the mass fraction burned without multiplication with constant $\Delta \theta \cdot \frac{\Delta \theta}{2}$.

| K | constant related to engine setup |
| PMH | pointer to variable where PMH index is returned |

1. Both pressure and volume vector must be double word aligned.

Table 15. mfb50_pmh arguments (continued)
Also note that the function writes calculated MFB[1] at the P_MFB array position 0.

5. Find maximum $MFB_{max}$ and minimum $MFB_{min}$ value from MFB[i], $i = 1, 2, \ldots N-2$

6. Calculate MFB50 value as:

Equation 31

$$MFB50 = \frac{MFB_{max} + MFB_{min}}{2}$$

Calculation of PMH index:

7. Starting with $PMH_{old} = 0$, calculate for each $i = 1, 2, \ldots N-1$:

Equation 32

$$DVA = V[i] - V[i - 1]$$

$$PMA = \frac{P[i] + P[i - 1]}{2}$$

$$PMH = PMH_{old} + PMA \cdot DVA$$

Note: There must be 8 bytes of readable memory behind input vector $P_{_MFB}$ and $V$.

Performance: See Chapter 7: Performance and Table 46.

Example 15. mfb50_pmh

```c
#include "libdsp2.h"
float P[740];
float V[740];
float K = 1.4F;
unsigned int N = 714;
float PMH;
unsigned int MFB50_index;
float MFB50;

void main(void)
{
    /* from pressure vector $P$ and volume vector $V$, calculate MFB50 value, PMH index and mass fraction burned (MFB), MFB returned back in P vector, MFB1 at P array position 0 */
    MFB50 = mfb50_pmh(N, P, V, K, &PMH);
    /* search for MFB50 value in mass fraction burned ($P$) vector and return index at which the MFB50 value was found */
    MFB50_index = mfb50_index(N, P, MFB50);
}
```

6.16 mfb50_index - pressure sensing function 2

Function call:

```c
unsigned int mfb50_index(unsigned int N, float *MFB, float MFB50);
```
Arguments:

<table>
<thead>
<tr>
<th>Table 16. mfb50_index arguments</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
</tr>
<tr>
<td>MFB(1)</td>
</tr>
<tr>
<td>MFB50</td>
</tr>
</tbody>
</table>

1. The MFB vector must be double word aligned.

Description: Pressure sensing function 2. The function is used for in-cylinder pressure sensor management. This function should follow the mfb50_pmh function call. The function searches the mass fraction burned (MFB) vector and returns index at which the MFB50 value was found. The returned index is called MFB50% position index.

Algorithm:

1. For each i = 2,3 ... N-2, calculate absolute value of difference MFB[i] and MFB50:

   Equation 33

   \[ \text{diff}[i] = |\text{MFB}[i] - \text{MFB50}| \]

2. Find index \( i \) at which the \( \text{diff}[i] \) has minimal value.

   Note: There must be 8 bytes of readable memory behind input vector MFB.

Performance: See Chapter 7: Performance and Table 47.

Example 16. mfb50_index

```c
#include "libdsp2.h"
float P[740];
float V[740];
float K = 1.4F;
unsigned int N = 714;
float PMH;
unsigned int MFB50_index;
float MFB50;

void main(void)
{
    /* from pressure vector P and volume vector V, calculate MFB50 value, PMH index and mass fraction burned (MFB), MFB returned back in P vector, MFB1 at P array position 0 */
    MFB50 = mfb50_pmh(N, P, V, K, &PMH);
    /* search for MFB50 value in mass fraction burned (P) vector and return index at which the MFB50 value was found */
    MFB50_index = mfb50_index(N, P, MFB50);
}
```
**6.17 conv3x3 - 2-D convolution with 3x3 kernel**

**Function call:**

```c
void conv3x3(unsigned char *a, unsigned char *b, signed char *c,
             unsigned short M, unsigned short N, unsigned short shift);
```

**Arguments:**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>a(1)</td>
<td>input image of size MxN</td>
</tr>
<tr>
<td>b(1)</td>
<td>output image of size MxN</td>
</tr>
<tr>
<td>c(2)</td>
<td>3x3 convolution kernel (mask)</td>
</tr>
<tr>
<td>M</td>
<td>number of rows of a and b, must be &gt;= 3</td>
</tr>
<tr>
<td>N</td>
<td>number of columns of a and b, must be multiple of 4, must be &gt;= 8</td>
</tr>
<tr>
<td>shift</td>
<td>number of bits result is shifted down</td>
</tr>
</tbody>
</table>

1. a and b must be word aligned.
2. c must be half word aligned and there must be 1 byte of readable memory behind c.

**Description:** Computes the 2-D convolution on MxN input image using a 3x3 convolution kernel. The computed convolution value is shifted by shift bits to the right and then range limited to 0..255. The output image is of the same size as input image and has one pixel border that is not computed. The first and the last row of output image is not changed, the first column is zeroed and the last column will contain not meaningful results. The last column can be zeroed when ZERO_LASTCOL is defined to 1 for the penalty of one more instruction inside the inner loop. The ZERO_LASTCOL is a symbol defined in function source file.

**Algorithm:**

a - input matrix, c - 3x3 convolution kernel, b - output matrix

\[
a = \begin{bmatrix}
a_{00} & a_{01} & a_{02} & \ldots & a_{0N-1} \\
a_{10} & a_{11} & a_{12} & \ldots & a_{1N-1} \\
a_{20} & a_{21} & a_{22} & \ldots & a_{2N-1} \\
\ldots & \ldots & \ldots & \ldots & \ldots \\
a_{(M-1)0} & a_{(M-1)1} & a_{(M-1)2} & \ldots & a_{M-1N-1}
\end{bmatrix}
\]

\[
c = \begin{bmatrix}
c_{00} & c_{01} & c_{02} \\
c_{10} & c_{11} & c_{12} \\
c_{20} & c_{21} & c_{22}
\end{bmatrix}
\]

\[
b = \begin{bmatrix}
b_{00} & b_{01} & b_{02} & \ldots & b_{0N-1} \\
b_{10} & b_{11} & b_{12} & \ldots & b_{1N-1} \\
b_{20} & b_{21} & b_{22} & \ldots & b_{2N-1} \\
\ldots & \ldots & \ldots & \ldots & \ldots \\
b_{(M-1)0} & b_{(M-1)1} & b_{(M-1)2} & \ldots & b_{M-1N-1}
\end{bmatrix}
\]

1. Compute 2-D convolution, i.e. for each \(i = 1,2 \ldots M-2, j = 1,2 \ldots N-2\) compute \(b_{ij}\):

**Equation 34**

\[b_{ij} = \sum_{k=0}^{2} \sum_{p=0}^{2} a_{(i+k-1)(j+p-1)} \cdot c_{(2-k)(2-p)}\]
2. Shift each computed bij by shift bits to the right: \( b_{ij} = b_{ij} / 2^{\text{shift}} \)

3. Range limit to 0..255:
   - if \( b_{ij} < 0 \) then \( b_{ij} = 0 \),
   - if \( b_{ij} > 255 \) then \( b_{ij} = 255 \)

**Note:** The input/output images and convolution kernel must be properly aligned in memory as described in Table 17. And there must be 1 byte of readable memory behind the convolution kernel \( c \).

Performance: See Chapter 7: Performance and Table 48.

**Example 17. conv3x3**

```c
#include "libdsp2.h"

/* #pragma and ALIGN macros used to align to 4 bytes */
#ifdef __ghs__
#pragma alignvar (4)
#endif
ALIGN_DCC(4)
unsigned char a[16*12];

/* #pragma and ALIGN macros used to align to 2 bytes */
#ifdef __ghs__
#pragma alignvar (2)
#endif
ALIGN_DCC(2)
signed char c[3*3] ALIGN_MWERKS(2) = {
    -1,   -2,   -1,
    0,    0,    0,
    1,    2,    1,
};

/* #pragma and ALIGN macros used to align to 4 bytes */
#ifdef __ghs__
#pragma alignvar (4)
#endif
ALIGN_DCC(4)
unsigned char b[16*12] ALIGN_MWERKS(4);

unsigned short M, N, shift;

void main(void)
{
    /******** 2-D convolution with 3x3 kernel **********/
    M = 16;
    N = 12;
    shift = 4;
    conv3x3(a, b, c, M, N, shift);
}
```
6.18 sobel3x3 - sobel filter

Function call:

void sobel3x3(unsigned char *a, unsigned char *b, unsigned short M, unsigned short N);

Arguments:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>a(1)</td>
<td>input image of size MxN</td>
</tr>
<tr>
<td>b(1)</td>
<td>output image of size MxN</td>
</tr>
<tr>
<td>M</td>
<td>number of rows of a and b, must be &gt;= 3</td>
</tr>
<tr>
<td>N</td>
<td>number of columns of a and b, must be multiple of 4, must be &gt;= 8</td>
</tr>
</tbody>
</table>

1. a and b must be word aligned.

Description: Computes the sobel filter on MxN input image. The function adds together absolute values of horizontal and vertical sobel filters and then limits output to 0..255. The output image is of the same size as input image and has one pixel border that is not computed. The first and the last row of output image is not changed, the first column is zeroed and the last column will contain not meaningful results. The last column can be zeroed when ZERO_LASTCOL is defined to 1 for the penalty of one more instruction inside the inner loop. The ZERO_LASTCOL is a symbol defined in function source file.

Algorithm:
1. Compute horizontal sobel filter, i.e. compute 2-D convolution with the following kernel:
   \[
   G_y = \begin{bmatrix}
   -1 & -2 & -1 \\
   0 & 0 & 0 \\
   1 & 2 & 0 
   \end{bmatrix}
   \]
2. Compute vertical sobel filter, i.e. compute 2-D convolution with the following kernel:
   \[
   G_x = \begin{bmatrix}
   -1 & 0 & 1 \\
   -2 & 0 & 2 \\
   -1 & 0 & 1 
   \end{bmatrix}
   \]
3. Add absolute values of horizontal and vertical sobel filters
4. Range limit to 0..255

Note: The input/output images must be properly aligned in memory as described in Table 18.

Performance: See Chapter 7: Performance and Table 49.

Example 18. sobel3x3

#include "libdsp2.h"

/* #pragma and ALIGN macros used to align to 4 bytes */
#ifdef __ghs__
#pragma alignvar (4)
#endif
ALIGN_DCC(4)
unsigned char a[16*12];

/* #pragma and ALIGN macros used to align to 4 bytes */
#ifndef __ghs__
#pragma alignvar (4)
#endif
ALIGN_DCC(4)
unsigned char b[16*12] ALIGN_MWERKS(4);

unsigned short M, N, shift;

void main(void)
{
  /******** Sobel filter ********/
  M = 16;
  N = 12;
  sobel3x3(a, b, M, N);
}

6.19 sobel3x3_horizontal - horizontal sobel filter

Function call:

void sobel3x3_horizontal(unsigned char *a, unsigned char *b,
                         unsigned short M, unsigned short N);

Arguments:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>input image of size MxN</td>
</tr>
<tr>
<td>b</td>
<td>output image of size MxN</td>
</tr>
<tr>
<td>M</td>
<td>number of rows of a and b, must be &gt;= 3</td>
</tr>
<tr>
<td>N</td>
<td>number of columns of a and b, must be multiple of 4, must be &gt;= 8</td>
</tr>
</tbody>
</table>

1. a and b must be word aligned.

Description: Computes the horizontal sobel filter on MxN input image. The absolute value of horizontal sobel filter result is range limited to 0..255. The output image is of the same size as input image and has one pixel border that is not computed. The first and the last row of output image is not changed, the first column is zeroed and the last column will contain not meaningful results. The last column can be zeroed when ZERO_LASTCOL is defined to 1 for the penalty of one more instruction inside the inner loop. The ZERO_LASTCOL is a symbol defined in function source file.
Algorithm:

1. Compute horizontal sobel filter, i.e. compute 2-D convolution with the following kernel:
   \[ G_y = \begin{bmatrix}
   -1 & -2 & -1 \\
   0 & 0 & 0 \\
   1 & 2 & 0 
   \end{bmatrix} \]

2. Get absolute value of result

3. Range limit to 0..255

Note: The input/output images must be properly aligned in memory as described in Table 19.

Performance: See Chapter 7: Performance and Table 50.

Example 19. sobel3x3_horizontal

```c
#include "libdsp2.h"

// #pragma and ALIGN macros used to align to 4 bytes */
#ifdef __ghs__
#pragma alignvar (4)
#endif
ALIGN_DCC(4)
unsigned char a[16*12];

// #pragma and ALIGN macros used to align to 4 bytes */
#ifdef __ghs__
#pragma alignvar (4)
#endif
ALIGN_DCC(4)
unsigned char b[16*12] ALIGN_MWERKS(4);

unsigned short M, N, shift;

void main(void)
{
    /******** Horizontal sobel filter **********/
    M = 16;
    N = 12;
    sobel3x3_horizontal(a, b, M, N);
}
```

6.20 sobel3x3_vertical - vertical sobel filter

Function call:

```c
void sobel3x3_vertical(unsigned char *a, unsigned char *b,  
unsigned short M, unsigned short N);
```
Arguments:

Table 20. sobel3x3_vertical arguments
<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>(1)</td>
<td>in</td>
</tr>
<tr>
<td>b</td>
<td>(1)</td>
<td>out</td>
</tr>
<tr>
<td>M</td>
<td>in</td>
<td>number of rows of a and b, must be &gt;= 3</td>
</tr>
<tr>
<td>N</td>
<td>in</td>
<td>number of columns of a and b, must be multiple of 4, must be &gt;= 8</td>
</tr>
</tbody>
</table>

1. a and b must be word aligned.

Description: Computes the vertical sobel filter on MxN input image. The absolute value of vertical sobel filter result is range limited to 0..255. The output image is of the same size as input image and has one pixel border that is not computed. The first and the last row of output image is not changed, the first column is zeroed and the last column will contain not meaningful results. The last column can be zeroed when ZERO_LASTCOL is defined to 1 for the penalty of one more instruction inside inner loop. The ZERO_LASTCOL is a symbol defined in function source file.

Algorithm:
1. Compute vertical sobel filter, i.e. compute 2-D convolution with the following kernel:

\[
G_x = \begin{bmatrix} -1 & 0 & 1 \\ -2 & 0 & 2 \\ -1 & 0 & 1 \end{bmatrix}
\]

2. Get absolute value of result
3. Range limit to 0..255

Note: The input/output images must be properly aligned in memory as described in Table 20.

Performance: See Chapter 7: Performance and Table 51.

Example 20. sobel3x3_vertical

```c
#include "libdsp2.h"

/* #pragma and ALIGN macros used to align to 4 bytes */
#ifdef __ghs__
#pragma alignvar (4)
#endif
ALIGN_DCC(4)
unsigned char a[16*12];

/* #pragma and ALIGN macros used to align to 4 bytes */
#ifdef __ghs__
#pragma alignvar (4)
#endif
ALIGN_DCC(4)
unsigned char b[16*12] ALIGN_MWERKS(4);
```
unsigned short M, N, shift;

void main(void)
{
    /******** Vertical sobel filter **********/
    M = 16;
    N = 12;
    sobel3x3_vertical(a, b, M, N);
}

6.21 corr_frac16 - frac16 correlation function

Function call:

void corr_frac16(unsigned short N, unsigned short M, short *x,
                 short *y, short *r);

Arguments:

<table>
<thead>
<tr>
<th>Table 21. corr_frac16 arguments(1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
</tr>
<tr>
<td>M</td>
</tr>
<tr>
<td>x</td>
</tr>
<tr>
<td>y</td>
</tr>
<tr>
<td>r</td>
</tr>
</tbody>
</table>

1. The x,y,r data are in fractional 16-bit format in range -1 to 1. The arrays x,r must be word aligned, the array y must be half-word aligned (implicit alignment of short data).

Description: Computes the correlation of the arrays x and y. The result is written to the array r. All data types are signed 16-bit fractional in range -1 to 1-2^{-15}. There is used the arithmetic with saturation so the output will never overflow.

Algorithm:

Correlation:

Equation 35

\[
\text{out}(j) = x(j)y(0) + x(j+1)y(1) + \ldots + x(N-1)y(N-j-1)
\]

for each j = 0, 1, ..., M-1

Note: The x and y can be the same array, in that case the auto-correlation is computed.

Performance: See Chapter 7: Performance and Table 52.
Example 21. corr_frac16

```c
#include "libdsp2.h"

/* #pragma and ALIGN macros used to align to 4 bytes */
#ifdef __ghs__
#pragma alignvar (4)
#endif
ALIGN_DCC(4)
short x[8] ALIGN_MWERKS(4) = {6554,10393,269,12670,2496,6233,9945,-303};
short y[8] = {8192,-6113,3558,4066,-4590,10723,-3612,6019};

/* #pragma and ALIGN macros used to align to 4 bytes */
#ifdef __ghs__
#pragma alignvar (4)
#endif
ALIGN_DCC(4)
short r[8] ALIGN_MWERKS(4);

unsigned short M, N;

void main(void)
{
    /* compute correlation of x and y */
    N = 16;
    M = 16;
    corr_frac16(N, M, x, y, r);
}
```

6.22 fir_float - float FIR filter

Function call:

```c
void fir_float (unsigned short N, unsigned short ntaps, float *x, float *y, float *h);
```

Arguments:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>length of output array y (must be multiple of 2)</td>
</tr>
<tr>
<td>ntaps</td>
<td>number of filter coefficients (must be &gt;= 4)</td>
</tr>
<tr>
<td>x</td>
<td>array of input samples of length N+ntaps-1, x(-ntaps+1) x(-ntaps+2) ... x(0) x(1) ... x(N-1)</td>
</tr>
<tr>
<td>y</td>
<td>array of output samples of length N, y(0) y(1) ... y(N-1)</td>
</tr>
<tr>
<td>h</td>
<td>array of filter coefficients stored in reversed order, h(ntaps-1) ... h(1) h(0)</td>
</tr>
</tbody>
</table>

1. The arrays x, y, h must be double-word aligned. There must be 8 bytes of readable memory behind the arrays h and x.
**Description:** Computes the real FIR filter on float data. The input samples are stored in the array \( x \), output samples are written to the array \( y \).

**Algorithm:**

\[
ntaps - 1
\]

\[
y(n) = \sum_{k = 0}^{\text{ntaps}} h(k) \cdot x(n-k) \quad \text{for each } n \text{ from 0 to } N-1
\]

Note: The filter coefficients must be stored in reversed order.

Performance: See Chapter 7: Performance and Table 53.

**Example 22. fir_float**

```c
#include "libdsp2.h"

/* #pragma and ALIGN macros used to align to 8 bytes */
#endif
#pragma alignvar (8)
#pragma alignvar (8)
ALIGN_DCC(8)
float x[288/*+2*/] ALIGN_MWERKS(8); /* +2 to ensure there are 8 bytes of readable memory behind x */

#include "libdsp2.h"

/* #pragma and ALIGN macros used to align to 8 bytes */
#endif
#pragma alignvar (8)
#pragma alignvar (8)
ALIGN_DCC(8)
float y [256] ALIGN_MWERKS(8);

#include "libdsp2.h"

/* #pragma and ALIGN macros used to align to 8 bytes */
#endif
#pragma alignvar (8)
#pragma alignvar (8)
ALIGN_DCC(8)
float hr[33/*+2*/] ALIGN_MWERKS(8) = { /* +2 to ensure there are 8 bytes of readable memory behind hr */

    -0.0025689987F, -0.0033815748F, -0.0031517229F, -0.0025120102F, -0.0031517229F, -0.0033815748F, -0.0025689987F, -0.0015288448F,
    -0.0019041377F, -0.0025120102F, -0.0031517229F, -0.0033815748F, -0.0025689987F, -0.0033815748F, -0.0031517229F, -0.0025120102F,
    -0.0031517229F, -0.0025689987F, -0.0033815748F, -0.0031517229F, -0.0025120102F, -0.0031517229F, -0.0033815748F, -0.0025689987F,
    -0.0031517229F, -0.0025689987F, -0.0033815748F, -0.0031517229F, -0.0025120102F, -0.0031517229F, -0.0033815748F, -0.0025689987F,
    -0.0031517229F, -0.0025689987F, -0.0033815748F, -0.0031517229F, -0.0025120102F, -0.0031517229F, -0.0033815748F, -0.0025689987F,
    0.0000000000F, 0.0049703708F, 0.0127558533F, 0.0233996311F, 0.0364901802F, 0.0511553726F, 0.0661431077F, 0.0799794722F, 0.0033815748F,
    -0.0025689987F, -0.0033815748F, -0.0031517229F, -0.0025120102F, -0.0019041377F,
};

unsigned short N, ntaps;

void main(void)
{
    /* filter the samples in x with FIR filter of 32nd order, */
/* write result into y, hr are filter coefficients stored */
/* in reversed order */
N = 256;
ntaps = 33;
fir_float(N, ntaps, x, y, hr);
}

6.23 fir_frac16 - frac16 FIR filter

Function call:

void fir_frac16(unsigned short N, unsigned short ntaps, short *x,
short *y, short *h);

Arguments:

<table>
<thead>
<tr>
<th>Table 23. fir_frac16 arguments(1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
</tr>
<tr>
<td>ntaps</td>
</tr>
<tr>
<td>x</td>
</tr>
<tr>
<td>y</td>
</tr>
<tr>
<td>h</td>
</tr>
</tbody>
</table>

1. The x,y,h data are in fractional 16-bit format in range -1 to 1. The arrays x, y must be word aligned, the array h must be half-word aligned (implicit alignment of short data). There must be 2 bytes of readable memory behind the array h and 4 bytes of readable memory behind the array x.

Description: Computes the real FIR filter on frac16 data. The input samples are stored in the array x, output samples are written to the array y. There is used arithmetic with saturation.

Algorithm:

\[
y(n) = \sum_{k=0}^{\text{ntaps} - 1} h(k) \cdot x(n - k) \quad \text{for each } n \text{ from 0 to } N-1
\]

Note: The coefficients stored in the array h must be scaled to prevent a saturation, i.e. the sum of the absolute values of all coefficients must be lower than \(2^{15}\):

\[
\sum_{k=0}^{\text{ntaps} - 1} |h(k)| < 2^{15}
\]

The filter coefficients must be stored in reversed order.

Performance: See Chapter 7: Performance and Table 54.
### Example 23. fir_frac16

```c
#include "libdsp2.h"

/* #pragma and ALIGN macros used to align to 4 bytes */
#elifdef __ghs__
#pragma alignvar (4)
#endif
ALIGN_DCC(4)
short x[288/*+2*/] ALIGN_MWERKS(4); /* +2 to ensure there are 4 bytes of readable memory behind x */
#elifdef __ghs__
#pragma alignvar (4)
#endif
ALIGN_DCC(4)
short y[256] ALIGN_MWERKS(4);
short hr[33/*+1*/] = { /* +1 to ensure there are 2 bytes of readable memory behind hr */
    -50,-62,-82,-103,-111,-84,0,163,418,767,1196,1676,2167,2621,2988,3227,3310,3227,2988,2621,2167,1676,1196,767,418,163,0,-84,-111,-103,-82,-62,-50,
};
unsigned short N, ntaps;

void main(void)
{
    /* filter the samples in x with FIR filter of 32nd order, */
    /* write result into y, hr are filter coefficients stored */
    /* in reversed order */
    N = 256;
    ntaps = 33;
    fir_frac16(N, ntaps, x, y, hr);
}
```

#### 6.24 iir_float_1st - float first-order IIR filter

**Function call:**

```c
void iir_float_1st (unsigned short N, float *x, float *y, float *c, float *s);
```

**Arguments:**

<table>
<thead>
<tr>
<th>Table 24. iir_float_1st arguments(1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
</tr>
<tr>
<td>x</td>
</tr>
<tr>
<td>y</td>
</tr>
</tbody>
</table>
Description: Computes the first-order IIR filter on float data. The input samples are stored in the array x, output samples are written to the array y.

Algorithm:

Equation 39

\[ y(n) = b(0)x(n) + b(1)x(n-1) - a(1)y(n-1) \]

for each \( n \) from 0 to \( N-1 \)

Performance: See Chapter 7: Performance and Table 55.

Example 24. iir_float_1st

```c
#include "libdsp2.h"

/* #pragma and ALIGN macros used to align to 8 bytes */
#endif __ghs__
#pragma alignvar (8)
#endif
ALIGN_DCC(8)
float x[256/*+4*/] ALIGN_MWERKS(8); /* +4 to ensure there are 16 bytes of readable memory behind x */

#endif __ghs__
#pragma alignvar (8)
#endif
ALIGN_DCC(8)
float y [256] ALIGN_MWERKS(8);

#endif __ghs__
#pragma alignvar (8)
#endif
ALIGN_DCC(8)
float s [2] ALIGN_MWERKS(8) = {0,0};
float c [3] = {0.5157131330F,0.5157131330F,0.0314262660F};

unsigned short N;
```
void main(void)
{
    /* filter the samples in x with first-order IIR filter, */
    /* write result into y */
    N = 256;
    iir_float_1st(N, x, y, c, s);
}

6.25  **iir_float_2nd - float second-order IIR filter**

**Function call:**

```c
void iir_float_2nd (unsigned short N, float *x, float *y, float *c,
    float *s);
```

**Arguments:**

<table>
<thead>
<tr>
<th>N</th>
<th>in/out</th>
<th>number of input and output samples (N must be multiple of 4, must be &gt;= 8)</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>in</td>
<td>array of input samples of length N, x(0) x(1) ... x(N-1)</td>
</tr>
<tr>
<td>y</td>
<td>out</td>
<td>array of output samples of length N, y(0) y(1) ... y(N-1)</td>
</tr>
<tr>
<td>c</td>
<td>in</td>
<td>array of filter coefficients, c[5] = {b0, b1, b2, a1, a2}</td>
</tr>
<tr>
<td>s</td>
<td>in/out</td>
<td>array of previous input and output values (state vector), s[4] = {x(-2), x(-1), y(-2), y(-1)}</td>
</tr>
</tbody>
</table>

1. The arrays x, y, s must be double-word aligned, the array c must be word aligned (implicit alignment of float data). There must be 16 bytes of readable memory behind the array x. There are returned new values of x(-2), x(-1), y(-2), y(-1) in the array s to be ready for next function call.

**Description:** Computes the second-order IIR filter on float data. The input samples are stored in the array x, output samples are written to the array y.

**Algorithm:**

**Equation 40**

\[ y(n) = b(0)x(n) + b(1)x(n-1) + b(2)x(n-2) - a(1)y(n-1) - a(2)y(n-2) \]

for each n from 0 to N-1

**Performance:** See [Chapter 7: Performance](#) and Table 56.

**Example 25. iir_float_2nd**

```c
#include "libdsp2.h"

/* #pragma and ALIGN macros used to align to 8 bytes */
#ifdef __ghs__
#pragma alignvar (8)
#endif
#pragma alignvar (8)
```
ALIGN_DCC(8)
float x[256/*+4*/] ALIGN_MWERKS(8); /* +4 to ensure there are 16 bytes of readable memory behind x */

#ifdef __ghs__
#pragma alignvar (8)
#endif
ALIGN_DCC(8)
float y[256] ALIGN_MWERKS(8);

#ifdef __ghs__
#pragma alignvar (8)
#endif
ALIGN_DCC(8)
float s[4] ALIGN_MWERKS(8) = {0,0,0,0};
float c[5] = {0.3115387742F,0.6230775485F,0.3115387742F,0.0736238464F,0.1725312505F};

unsigned short N;

void main(void)
{
    /* filter the samples in x with second-order IIR filter, */
    /* write result into y */
    N = 256;
    iir_float_2nd(N, x, y, c, s);
}

6.26 iir_float_casc - cascade of float second-order IIR filters

Function call:
#define iir_float_casc iir_float_casc_c
void iir_float_casc_c(unsigned short N, float *x, float *y, float *c,
                    float *s, unsigned short m);

Arguments:

<table>
<thead>
<tr>
<th>N</th>
<th>in</th>
<th>number of input and output samples (N must be multiple of 4, must be &gt;= 8)</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>in</td>
<td>array of input samples of length N, x(0) x(1) ... x(N-1)</td>
</tr>
<tr>
<td>y</td>
<td>out</td>
<td>array of output samples of length N, y(0) y(1) ... y(N-1)</td>
</tr>
<tr>
<td>c</td>
<td>in</td>
<td>array of filter coefficients for each second-order IIR filter, c[m*5] =</td>
</tr>
<tr>
<td></td>
<td></td>
<td>{b10, b11, b12, a11, a12, b20, b21, b22, a21, a22, ...}</td>
</tr>
<tr>
<td></td>
<td></td>
<td>bm0, bm1, bm2, am1, am2}</td>
</tr>
</tbody>
</table>
**Table 26. iir_float_casc arguments** (continued)

<table>
<thead>
<tr>
<th>s</th>
<th>in/out</th>
<th>m</th>
</tr>
</thead>
<tbody>
<tr>
<td>s[m*4] = {x1(-2), x1(-1), y1(-2), y1(-1), x2(-2), x2(-1), y2(-2), y2(-1), ..., xm(-2), xm(-1), ym(-2), ym(-1)}</td>
<td>array of previous input and output values (state vector)</td>
<td>number of second-order IIR filters in the cascade</td>
</tr>
</tbody>
</table>

1. The arrays x, y, s must be double-word aligned, the array c must be word aligned (implicit alignment of float data). There must be 16 bytes of readable memory behind the array x and y. There are returned new values of x(-2), x(-1), y(-2), y(-1) in the array s to be ready for next function call.

**Description:**

Computes the cascade of second-order IIR filters on float data. The input samples are stored in the array x, output samples are written to the array y. The function calls the iir_float_2nd function for each second-order IIR filter in the cascade.

**Algorithm:**

The filter equation for the i-order IIR filter (i = 2*m):

**Equation 41**

\[ y(n) = b(0)x(n) + b(1)x(n-1) + \ldots + b(i)x(n-i) - a(1)y(n-1) - \ldots - a(i)y(n-i) \]

for each \( n = 0,1,\ldots,N-1 \)

The i-order filter is implemented using the cascade of m IIR filters of second-order:

**Equation 42**

\[ y_1(n) = b(10)x(n) + b(11)x_1(n-1) + b(12)x_1(n-2) - a(11)y_1(n-1) - a(12)y_1(n-2) \]

**Equation 43**

\[ y_2(n) = b(20)y_1(n) + b(21)y_1(n-1) + b(22)y_1(n-2) - a(21)y_2(n-1) - a(22)y_2(n-2) \]

... 

**Equation 44**

\[ y_m(n) = b(m0)y_{m-1}(n) + b(m1)y_{m-1}(n-1) + b(m2)y_{m-1}(n-2) - a(m1)y_m(n-1) - a(m2)y_m(n-2) \]

for each \( n = 0,1,\ldots,N-1 \)

Performance: See Chapter 7: Performance and Table 57.
Example 26. iir_float_casc

```c
#include "libdsp2.h"

/* #pragma and ALIGN macros used to align to 8 bytes */
#elifdef __ghs__
#pragma alignvar (8)
#endif
ALIGN_DCC(8)
float x[256/*+4*/] ALIGN_MWERKS(8); /* +4 to ensure there are 16 bytes of readable memory behind x */

#elifdef __ghs__
#pragma alignvar (8)
#endif
ALIGN_DCC(8)
float y [256/*+4*/] ALIGN_MWERKS(8); /* +4 to ensure there are 16 bytes of readable memory behind y */

#elifdef __ghs__
#pragma alignvar (8)
#endif
ALIGN_DCC(8)
float s[3*4] ALIGN_MWERKS(8) = {0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0};
float c[3*5] = {0.3284466238F, 0.6596805377F, 0.3312418003F, 0.0639408215F, 0.0183196767F, 0.2531886900F, 0.5063763109F, 0.2531936959F, 0.0736238464F, 0.1725312505F, 0.4280607669F, 0.8524906977F, 0.4244401939F, 0.0998014847F, 0.5894355624F,};

unsigned short N;

void main(void)
{
    /* filter the samples in x with sixth-order IIR filter, */
    /* write result into y */
    N = 256;
    iir_float_casc(N, x, y, c, s, 3);
}
```

6.27 iir_frac16_1st - frac16 first-order IIR filter

Function call:

```c
void iir_frac16_1st(unsigned short N, short *x, short *y, short *c, short *s);
```
Arguments:

Table 27. iir_frac16_1st arguments\(^{(1)}\)

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>in</td>
<td>number of input and output samples (N must be multiple of 4)</td>
</tr>
<tr>
<td>x</td>
<td>in</td>
<td>array of input samples of length N, (x(0)) (x(1)) ... (x(N-1))</td>

</tr>
</tbody>
</table>

1. The \(x,y,c,s\) data are in fractional 16-bit format in range -1 to 1. The arrays \(x,y,s\) must be word aligned, the array \(c\) must be half-word aligned (implicit alignment of short data). There must be 4 bytes of readable memory behind the array \(x\). There are returned new values of \(x(-1), y(-1)\) in the array \(s\) to be ready for next function call.

Description: Computes the first-order IIR filter on frac16 data. The input samples are stored in the array \(x\), output samples are written to the array \(y\). There is used the arithmetic with saturation so the output will never overflow.

Algorithm:

Equation 45

\[
y(n) = b(0)x(n) + b(1)x(n - 1) - a(1)y(n - 1)
\]

for each \(n\) from 0 to \(N-1\)

Performance: See Chapter 7: Performance and Table 58.

Example 27. iir_frac16_1st

```c
#include "libdsp2.h"

/* #pragma and ALIGN macros used to align to 4 bytes */
#ifdef __ghs__
#pragma alignvar (4)
#endif
ALIGN_DCC(4)
short x[256/*+2*/] ALIGN_MWERKS(4); /* +2 to ensure there are 4 bytes of readable memory behind x */

#ifdef __ghs__
#pragma alignvar (4)
#endif
ALIGN_DCC(4)
short y[256] ALIGN_MWERKS(4);

#ifdef __ghs__
#pragma alignvar (4)
#endif
ALIGN_DCC(4)
short s[2] ALIGN_MWERKS(4) = \{0,0\};
```
short c[3] = {16899, 16899, 1030};

unsigned short N;

void main(void)
{
    /* filter the samples in x with first-order IIR filter, */
    /* write result into y */
    N = 256;
    iir_frac16_1st(N, x, y, c, s);
}

6.28 iir_frac16_2nd - frac16 second-order IIR filter

Function call:

    void iir_frac16_2nd(unsigned short N, short *x, short *y, short *c, short *s);

Arguments:

<table>
<thead>
<tr>
<th>N</th>
<th>in</th>
<th>number of input and output samples (N must be multiple of 4)</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>in</td>
<td>array of input samples of length N, x(0) x(1) ... x(N-1)</td>

<td>array of filter coefficients, c[5] = {b0, b1, b2, a1, a2}</td>
</tr>
<tr>
<td>s</td>
<td>in/out</td>
<td>array of previous input and output values (state vector), s[4] = {x(-2), x(-1), y(-2), y(-1)}</td>
</tr>
</tbody>
</table>

1. The x,y,c,s data are in fractional 16-bit format in range -1 to 1. The arrays x,y,s must be word aligned, the array c must be half-word aligned (implicit alignment of short data). There must be 4 bytes of readable memory behind the array x. There are returned new values of x(-2), x(-1), y(-2), y(-1) in the array s to be ready for next function call.

Description: Computes the second-order IIR filter on frac16 data. The input samples are stored in the array x, output samples are written to the array y. There is used the arithmetic with saturation so the output will never overflow.

Algorithm:

Equation 46

\[ y(n) = b(0)x(n) + b(1)x(n-1) + b(2)x(n-2) - a(1)y(n-1) - a(2)y(n-2) \]

for each n from 0 to N-1

Performance: See Chapter 7: Performance and Table 59.

Example 28. iir_frac16_2nd

#include "libdsp2.h"
/* #pragma and ALIGN macros used to align to 4 bytes */
#ifdef __ghs__
#pragma alignvar (4)
#endif
ALIGN_DCC(4)
short x[256/*+2*/] ALIGN_MWERKS(4); /* +2 to ensure there are 4 bytes of readable memory behind x */

#ifdef __ghs__
#pragma alignvar (4)
#endif
ALIGN_DCC(4)
short y[256] ALIGN_MWERKS(4);

#ifdef __ghs__
#pragma alignvar (4)
#endif
ALIGN_DCC(4)
short s[4] ALIGN_MWERKS(4) = {0,0,0,0};
short c[5] = {10209,20417,10209,2413,5654};

unsigned short N;
void main(void)
{
   /* filter the samples in x with second-order IIR filter, */
   /* write result into y */
   N = 256;
   iir_frac16_2nd(N, x, y, c, s);
}

6.29 iir_frac16_casc - cascade of frac16 second-order IIR filters

Function call:
#define iir_frac16_casc  iir_frac16_casc_c
void iir_frac16_casc_c(unsigned short N, short *x, short *y, short *c,
   short *s, unsigned short m);

Arguments:

<table>
<thead>
<tr>
<th>Table 29. iir_frac16_casc arguments</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
</tr>
<tr>
<td>x</td>
</tr>
<tr>
<td>y</td>
</tr>
</tbody>
</table>
Description: Computes the cascade of second-order IIR filters on frac16 data. The input samples are stored in the array \( x \), output samples are written to the array \( y \). The function calls the iir_float_2nd function for each second-order IIR filter in the cascade. There is used the arithmetic with saturation so the output will never overflow.

Algorithm:

The filter equation for the i-order IIR filter \( (i = 2^m) \):

Equation 47

\[
y(n) = b(0)x(n) + b(1)x(n-1) + ... + b(i)x(n-i) - a(1)y(n-1) - ... - a(i)y(n-i)
\]

for each \( n = 0,1,...N-1 \)

The i-order filter is implemented using the cascade of \( m \) IIR filters of second-order:

Equation 48

\[
y_1(n) = b(10)x_1(n) + b(11)x_1(n-1) + b(12)x_1(n-2) - a(11)y_1(n-1) - a(12)y_1(n-2)
\]

Equation 49

\[
y_2(n) = b(20)y_1(n) + b(21)y_1(n-1) + b(22)y_1(n-2) - a(21)y_2(n-1) - a(22)y_2(n-2)
\]

... 

Equation 50

\[
y_m(n) = b(m0)y_{m-1}(n) + b(m1)y_{m-1}(n-1) + b(m2)y_{m-1}(n-2) - a(m1)y_m(n-1) - a(m2)y_m(n-2)
\]

for each \( n = 0,1,...N-1 \)

Performance: See Chapter 7: Performance and Table 60.

    iir_frac16_casc(N, x, y, c, s, 3);
}

6.30 iir_frac16_2nd_hc - frac16 second-order IIR filter with half coefficients

Function call:

void iir_frac16_2nd_hc(unsigned short N, short *x, short *y, short *c, short *s);
Arguments: dkkdkdkkd
Returns: dkkdkdkkd
Table 30. iir_frac16_2nd_hc arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>number of input and output samples (N must be multiple of 4, N must be &gt;= 8)</td>
</tr>
<tr>
<td>x</td>
<td>array of input samples of length N, x(0) x(1) ... x(N-1)</td>
</tr>
<tr>
<td>y</td>
<td>array of output samples of length N, y(0) y(1) ... y(N-1)</td>
</tr>
<tr>
<td>c</td>
<td>array of filter coefficients divided by 2, c[5] = {b(0)/2, b(1)/2, b(2)/2, a(1)/2, a(2)/2}</td>
</tr>
<tr>
<td>s</td>
<td>array of previous input and output values (state vector), s[4] = {x(-2), x(-1), y(-2), y(-1)}</td>
</tr>
</tbody>
</table>

1. The x, y, c, s data are in fractional 16-bit format in range -1 to 1. The arrays x, y, s must be word aligned, the array c must be half-word aligned (implicit alignment of short data). There must be 4 bytes of readable memory behind the array x. There are returned new values of x(-2), x(-1), y(-2), y(-1) in the array s to be ready for next function call.

**Description:** Computes the second-order IIR filter on frac16 data. The input samples are stored in the array x, output samples are written to the array y. The filter coefficients are stored in the array c divided by 2. There is used the arithmetic with saturation so the output will never overflow.

**Algorithm:**

Equation 51

\[ y(n) = 2 \left( \frac{b(0)}{2} x(n) + \frac{b(1)}{2} x(n - 1) + \frac{b(2)}{2} x(n - 2) - \frac{a(1)}{2} y(n - 1) - \frac{a(2)}{2} y(n - 2) \right) \]

for each n from 0 to N-1

**Note:** The routine requires these conditions are met:
-1 <= b1/2-a1*b0/2 < 1
-1 <= b2/2-a1*b1/2 < 1
-1 <= -a1*b2/2 < 1
-1 <= a2/2-a1*a1/2 < 1
-1 <= -a1*a2/2 < 1

Performance: See Chapter 7: Performance and Table 61.

Example 30. iir_frac16_2nd_hc

#pragma alignvar (4)
```
#ifndef ALIGN_DCC(4)
short y[256] ALIGN_MWERKS(4);
#endif

#ifdef __ghs__
#pragma alignvar (4)
#endif
ALIGN_DCC(4)
short s[4] ALIGN_MWERKS(4) = {9830,13107,-3932,11665};
short c[5] = {10209,20417,10209,2413,5654};

unsigned short N;

void main(void)
{
  /* filter the samples in x with second-order IIR filter, */
  /* write result into y, coefficients in c are stored */
  /* divided by 2 */
  N = 256;
  iir_frac16_2nd_hc(N, x, y, c, s);
}
7 Performance

This section shows the code size and clock cycles for each function. The clock cycles were measured for the following conditions:

- Code Memory (Internal Flash) - cache on
- Data Memory (Internal RAM) - cache on
- Stack Memory - locked in cache
- Data acquired on the MPC5554 with SIU_MIDR = 0x55540011
- Branch Target Buffer (BTB) enabled
- BIUCR = 0x00094BFD

The “Improvement to C function” column shows performance increase comparing the assembly code to a respective C function, the value is calculated as a ratio of the number_of_clock_cycles_of_C_function/number_of_clock_cycles_of_optimized_library_function. The number of clock cycles are taken for the third function call. The C-code was compiled in CodeWarrior for PowerPC V1.5 beta2, Global Optimizations set to level 4, Optimize for Faster Execution Speed, Instruction Scheduling and Peephole Optimization turned on.

The IPC column shows instructions per cycle.

</table>

1. N2_REALPART configured to 0, for N2_REALPART configured to 1 code size is 460 bytes.
2. The code size is the same for N2_REALPART configured to 0 or 1.
3. Valid for both scaling on and off.
4. ZERO_LASTCOL configured to 0, if configured to 1 the size is 4 bytes greater for conv3x3 function and 8 bytes greater for the sobel functions.
5. The iir_float_casc (iir_frac16_casc) function calls function iir_float_2nd (iir_frac16_2nd). The code size in the table is valid for the CodeWarrior compiler with optimizations set to level 4, Instruction Scheduling and Peephole Optimization turned on.
