Introduction

This reference manual targets application developers. It provides complete information on how to use the STM32H742xx, STM32H743/53xx and STM32H750xB microcontroller memory and peripherals.

The STM32H742, STM32H743/753 and STM32H750 are lines of microcontrollers with different memory sizes, packages and peripherals.

For ordering information, mechanical, and electrical device characteristics please refer to the corresponding datasheets.

For information on the Arm® Cortex®-M7 with FPU core, please refer to the corresponding Arm Technical Reference Manuals.

### 3 Embedded Flash memory (FLASH) ............................. 137
- 3.1 Introduction .............................................. 137
- 3.2 FLASH main features ....................................... 137
- 3.3 FLASH functional description ............................... 138
3.3.1 FLASH block diagram ........................................ 138
3.3.2 FLASH internal signals ........................................ 139
3.3.3 FLASH architecture and integration in the system .......... 139
3.3.4 Flash memory architecture and usage ...................... 141
3.3.5 FLASH system performance enhancements ............... 144
3.3.6 FLASH data protection schemes ......................... 144
3.3.7 Overview of FLASH operations .......................... 145
3.3.8 FLASH read operations ....................................... 146
3.3.9 FLASH program operations ................................... 149
3.3.10 FLASH erase operations ..................................... 153
3.3.11 FLASH parallel operations (STM32H743/753 devices only) .... 156
3.3.12 Flash memory error protections ......................... 156
3.3.13 Flash bank and register swapping (STM32H742/743/753 devices only) 158
3.3.14 FLASH reset and clocks ................................. 161

3.4 FLASH option bytes ...................................... 161
3.4.1 About option bytes .......................................... 161
3.4.2 Option byte loading ......................................... 162
3.4.3 Option byte modification ................................... 162
3.4.4 Option bytes overview ...................................... 165
3.4.5 Description of user and system option bytes ............ 167
3.4.6 Description of data protection option bytes ............. 168
3.4.7 Description of boot address option bytes ................ 169

3.5 FLASH protection mechanisms ............................... 170
3.5.1 FLASH configuration protection ......................... 170
3.5.2 Write protection ........................................... 171
3.5.3 Readout protection (RDP) ............................... 172
3.5.4 Proprietary code readout protection (PCROP) ............ 177
3.5.5 Secure access mode ....................................... 178

3.6 FLASH low-power modes .................................. 179

3.7 FLASH error management .................................. 181
3.7.1 Introduction .................................................. 181
3.7.2 Write protection error (WRPERR) ...................... 181
3.7.3 Programming sequence error (PGSERR) .................. 182
3.7.4 Strobe error (STRBERR) ................................. 183
3.7.5 Inconsistency error (INCERR) .......................... 183
3.7.6 Operation error (OPERR) ............................... 184
3.7.7 Error correction code error (SNECCERR/DBECCERR) .... 184
3.7.8 Read protection error (RDPERR) ........................................ 185
3.7.9 Read secure error (RDSERR) .......................................... 185
3.7.10 Option byte change error (OPTCHANGEERR) ...................... 185
3.7.11 Miscellaneous HardFault errors ...................................... 186

3.8 FLASH interrupts .............................................................. 186

3.9 FLASH registers ............................................................... 189
  3.9.1 FLASH access control register (FLASH_ACR) ....................... 189
  3.9.2 FLASH key register for bank 1 (FLASH_KEYR1) .................... 189
  3.9.3 FLASH option key register (FLASH_OPTKEYR) ..................... 190
  3.9.4 FLASH control register for bank 1 (FLASH_CR1) .................. 190
  3.9.5 FLASH status register for bank 1 (FLASH_SR1) .................... 195
  3.9.6 FLASH clear control register for bank 1 (FLASH_CCR1) ......... 198
  3.9.7 FLASH option control register (FLASH_OPTCR) ................... 199
  3.9.8 FLASH option status register (FLASH_OPTSR_CUR) ............... 200
  3.9.9 FLASH option status register (FLASH_OPTSR_PRG) ............... 203
  3.9.10 FLASH option clear control register (FLASH_OPTCCR) ......... 205
  3.9.11 FLASH protection address for bank 1 (FLASH_PRAR_CUR1) .... 205
  3.9.12 FLASH protection address for bank 1 (FLASH_PRAR_PRG1) .... 206
  3.9.13 FLASH secure address for bank 1 (FLASH_SCAR_CUR1) ......... 207
  3.9.14 FLASH secure address for bank 1 (FLASH_SCAR_PRG1) ......... 207
  3.9.15 FLASH write sector protection for bank 1 (FLASH_WPSN_CUR1R) .................................................. 208
  3.9.16 FLASH write sector protection for bank 1 (FLASH_WPSN_PRG1R) .................................................. 209
  3.9.17 FLASH register boot address FLASH_BOOT_CURR) ............... 209
  3.9.18 FLASH register boot address FLASH_BOOT_PRG) ............... 209
  3.9.19 FLASH CRC control register for bank 1 (FLASH_CRC_CR1) .... 210
  3.9.20 FLASH CRC start address register for bank 1 (FLASH_CRCADD1R) .................................................. 211
  3.9.21 FLASH CRC end address register for bank 1 (FLASH_CRCADD1R) .................................................. 212
  3.9.22 FLASH CRC data register (FLASH_CRC_DATAR) .................. 212
  3.9.23 FLASH ECC fail address for bank 1 (FLASH_ECC_FA1R) ....... 213
  3.9.24 FLASH key register for bank 2 (FLASH_KEYR2) .................. 213
  3.9.25 FLASH control register for bank 2 (FLASH_CR2) ................ 214
  3.9.26 FLASH status register for bank 2 (FLASH_SR2) ................. 218
  3.9.27 FLASH clear control register for bank 2 (FLASH_CCR2) ....... 221
  3.9.28 FLASH protection address for bank 2 (FLASH_PRAR_CUR2) .... 222
3.9.29 FLASH protection address for bank 2 (FLASH_PRAR_PRG2) .... 223
3.9.30 FLASH secure address for bank 2 (FLASH_SCAR_CUR2) .... 223
3.9.31 FLASH secure address for bank 2 (FLASH_SCAR_PRG2) ... 224
3.9.32 FLASH write sector protection for bank 2
   (FLASH_WPSN_CUR2R) ........................................ 225
3.9.33 FLASH write sector protection for bank 2
   (FLASH_WPSN_PRG2R) ........................................ 225
3.9.34 FLASH CRC control register for bank 2 (FLASH_CRCCR2) .... 226
3.9.35 FLASH CRC start address register for bank 2
   (FLASH_CRCSADD2R) ........................................ 227
3.9.36 FLASH CRC end address register for bank 2
   (FLASH_CRCEADD2R) ........................................ 228
3.9.37 FLASH ECC fail address for bank 2 (FLASH_ECC_FA2R) .... 228
3.10 FLASH register map and reset values .......................... 229

4 Secure internal Flash memory (SIFM) .............................. 234
4.1 Introduction .................................................... 234
4.2 Glossary ........................................................ 234
4.3 Secure access mode ............................................. 235
   4.3.1 Associated features ..................................... 236
   4.3.2 Boot state machine ..................................... 236
   4.3.3 Secure access mode configuration ..................... 237
4.4 Root secure services (RSS) .................................... 238

   4.4.2 Secure area exiting service ............................ 238
4.5 Secure user software .......................................... 239
   4.5.1 Access rules ............................................. 239
   4.5.2 Setting secure user memory areas ..................... 239
4.6 Summary of Flash protection mechanisms ..................... 240

5 Power control (PWR) ................................................ 241
5.1 Introduction .................................................... 241
5.2 PWR main features ............................................. 241
5.3 PWR block diagram ............................................. 242
   5.3.1 PWR pins and internal signals ......................... 243
5.4 Power supplies ............................................... 245
   5.4.1 System supply startup ................................ 248
5.4.2 Core domain ........................................... 250
5.4.3 PWR external supply .................................... 251
5.4.4 Backup domain .......................................... 252
5.4.5 VBAT battery charging .................................. 254
5.4.6 Analog supply ........................................... 254
5.4.7 USB regulator ........................................... 255

5.5 Power supply supervision .................................... 255
5.5.1 Power-on reset (POR)/power-down reset (PDR) ........ 256
5.5.2 Brownout reset (BOR) .................................... 256
5.5.3 Programmable voltage detector (PVD) .................. 257
5.5.4 Analog voltage detector (AVD) .......................... 259
5.5.5 Battery voltage thresholds .............................. 260
5.5.6 Temperature thresholds ................................. 261

5.6 Power management ........................................... 262
5.6.1 Operating modes ......................................... 263
5.6.2 Voltage scaling .......................................... 266
5.6.3 Power control modes ..................................... 267
5.6.4 Power management examples ............................ 271

5.7 Low-power modes ............................................ 277
5.7.1 Slowing down system clocks ............................ 277
5.7.2 Controlling peripheral clocks ......................... 277
5.7.3 Entering low-power modes .............................. 277
5.7.4 Exiting from low-power modes ......................... 278
5.7.5 CSleep mode .............................................. 279
5.7.6 CStop mode .............................................. 280
5.7.7 DStop mode .............................................. 281
5.7.8 Stop mode ................................................ 282
5.7.9 DStandby mode .......................................... 284
5.7.10 Standby mode .......................................... 286
5.7.11 Monitoring low-power modes .......................... 288

5.8 PWR register description .................................... 289
5.8.1 PWR control register 1 (PWR_CR1) ................. 289
5.8.2 PWR control status register 1 (PWR_CSR1) .......... 290
5.8.3 PWR control register 2 (PWR_CR2) ................ 291
5.8.4 PWR control register 3 (PWR_CR3) ................ 292
5.8.5 PWR CPU control register (PWR_CPUCR) ........... 294
5.8.6 PWR D3 domain control register (PWR_D3CR) .... 295
5.8.7 PWR wakeup clear register (PWR_WKUPCR) .................................. 296
5.8.8 PWR wakeup flag register (PWR_WKUPFR) .................................. 296
5.8.9 PWR wakeup enable and polarity register (PWR_WKUPEPR) .......... 297
5.8.10 PWR register map ................................................................. 298

6 Low-power D3 domain ............................................................... 299
6.1 Introduction ................................................................. 299
6.2 EXTI, RCC and PWR interconnections ................................. 299
   6.2.1 Interrupts and wakeup ...................................................... 301
   6.2.2 Block interactions .......................................................... 301
   6.2.3 Role of D3 domain DMAMUX2 ............................................ 302
6.3 Low-power application example based on LPUART1 transmission ........................................... 303
   6.3.1 Memory retention .......................................................... 303
   6.3.2 Memory-to-peripheral transfer using LPUART1 interface .......... 303
   6.3.3 Overall description of the low-power application example based on LPUART1 transmission .......... 308
   6.3.4 Alternate implementations .............................................. 309
6.4 Other low-power applications ............................................. 310

7 Reset and Clock Control (RCC) .................................................. 311
7.1 RCC main features .............................................................. 311
7.2 RCC block diagram ............................................................. 312
7.3 RCC pins and internal signals .............................................. 312
7.4 RCC reset block functional description .................................. 314
   7.4.1 Power-on/off reset .......................................................... 314
   7.4.2 System reset ................................................................. 315
   7.4.3 Local resets ................................................................. 316
   7.4.4 Reset source identification .............................................. 318
   7.4.5 Low-power mode security reset (lpwr_rst) ......................... 319
   7.4.6 Backup domain reset ....................................................... 319
   7.4.7 Power-on and wakeup sequences ....................................... 319
7.5 RCC clock block functional description .................................. 322
   7.5.1 Clock naming convention .................................................. 324
   7.5.2 Oscillators description .................................................... 324
   7.5.3 Clock Security System (CSS) ............................................. 329
   7.5.4 Clock output generation (MCO1/MCO2) ................................. 330

## 37.4.30 TIM1 timer input selection register (TIM1 TISEL) ........................................ 1628
37.4.31 TIM8 timer input selection register (TIM8 TISEL) ........................................ 1628
37.4.32 TIM1 register map ............................................................................................ 1630
37.4.33 TIM8 register map ............................................................................................ 1632

### 38 General-purpose timers (TIM2/TIM3/TIM4/TIM5) ............................................ 1635

#### 38.1 TIM2/TIM3/TIM4/TIM5 introduction ............................................................... 1635

#### 38.2 TIM2/TIM3/TIM4/TIM5 main features ............................................................. 1635

#### 38.3 TIM2/TIM3/TIM4/TIM5 functional description .............................................. 1637

- 38.3.1 Time-base unit .................................................................................................. 1637
- 38.3.2 Counter modes ............................................................................................... 1639
- 38.3.3 Clock selection ................................................................................................ 1649
- 38.3.4 Capture/Compare channels .......................................................................... 1653
- 38.3.5 Input capture mode ........................................................................................ 1655
- 38.3.6 PWM input mode .......................................................................................... 1656
- 38.3.7 Forced output mode ....................................................................................... 1657
- 38.3.8 Output compare mode .................................................................................... 1657
- 38.3.9 PWM mode .................................................................................................... 1658
- 38.3.10 Asymmetric PWM mode .............................................................................. 1662
- 38.3.11 Combined PWM mode ................................................................................ 1662
- 38.3.12 Clearing the OCxREF signal on an external event ...................................... 1663
- 38.3.13 One-pulse mode ........................................................................................... 1665
- 38.3.14 Retriggerable one pulse mode (OPM) .......................................................... 1666
- 38.3.15 Encoder interface mode ................................................................................ 1667
- 38.3.16 UIF bit remapping ......................................................................................... 1669
- 38.3.17 Timer input XOR function .......................................................................... 1669
- 38.3.18 Timers and external trigger synchronization .............................................. 1670
- 38.3.19 Timer synchronization ................................................................................ 1673
- 38.3.20 DMA burst mode ........................................................................................ 1677
- 38.3.21 Debug mode ................................................................................................ 1678

#### 38.4 TIM2/TIM3/TIM4/TIM5 registers ................................................................. 1679

- 38.4.1 TIMx control register 1 (TIMx CR1)(x = 2 to 5) ........................................... 1679
- 38.4.2 TIMx control register 2 (TIMx CR2)(x = 2 to 5) ........................................... 1680
- 38.4.3 TIMx slave mode control register (TIMx SMCR)(x = 2 to 5) ................... 1682
- 38.4.4 TIMx DMA/Interrupt enable register (TIMx DIER)(x = 2 to 5) .......... 1685
- 38.4.5 TIMx status register (TIMx SR)(x = 2 to 5) ................................................... 1686
38.4.6 TIMx event generation register (TIMx_EGR)(x = 2 to 5) .......................... 1687
38.4.7 TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1) 
(x = 2 to 5) ................................................................. 1689
38.4.8 TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1) 
(x = 2 to 5) ................................................................. 1691
38.4.9 TIMx capture/compare mode register 2 [alternate] (TIMx_CCMR2) 
(x = 2 to 5) ................................................................. 1693
38.4.10 TIMx capture/compare mode register 2 [alternate] (TIMx_CCMR2) 
(x = 2 to 5) ................................................................. 1694
38.4.11 TIMx capture/compare enable register (TIMx_CCR)(x = 2 to 5) ...... 1695
38.4.12 TIMx counter [alternate] (TIMx_CNT)(x = 2 to 5) ......................... 1696
38.4.13 TIMx counter [alternate] (TIMx_CNT)(x = 2 to 5) ......................... 1697
38.4.14 TIMx prescaler (TIMx_PSC)(x = 2 to 5) ....................................... 1697
38.4.15 TIMx auto-reload register (TIMx_ARR)(x = 2 to 5) ......................... 1698
38.4.16 TIMx capture/compare register 1 (TIMx_CCR1)(x = 2 to 5) .......... 1698
38.4.17 TIMx capture/compare register 2 (TIMx_CCR2)(x = 2 to 5) .......... 1699
38.4.18 TIMx capture/compare register 3 (TIMx_CCR3)(x = 2 to 5) .......... 1699
38.4.19 TIMx capture/compare register 4 (TIMx_CCR4)(x = 2 to 5) .......... 1700
38.4.20 TIMx DMA control register (TIMx_DCR)(x = 2 to 5) .................... 1701
38.4.21 TIMx DMA address for full transfer (TIMx_DMAR)(x = 2 to 5) ...... 1701
38.4.22 TIM2 alternate function option register 1 (TIM2_AF1) .................... 1702
38.4.23 TIM3 alternate function option register 1 (TIM3_AF1) .................... 1702
38.4.24 TIM4 alternate function option register 1 (TIM4_AF1) .................... 1703
38.4.25 TIM5 alternate function option register 1 (TIM5_AF1) .................... 1703
38.4.26 TIM2 timer input selection register (TIM2_TISEL) ......................... 1703
38.4.27 TIM3 timer input selection register (TIM3_TISEL) ......................... 1704
38.4.28 TIM4 timer input selection register (TIM4_TISEL) ......................... 1705
38.4.29 TIM5 timer input selection register (TIM5_TISEL) ......................... 1706
38.4.30 TIMx register map .................................................................. 1707

39 General-purpose timers (TIM12/TIM13/TIM14) .......................... 1710
39.1 TIM12/TIM13/TIM14 introduction ................................................... 1710
39.2 TIM12/TIM13/TIM14 main features ................................. 1710
39.2.1 TIM12 main features ......................................................... 1710

40.4.18 External trigger synchronization (TIM15 only) .............................. 1795
40.4.19 Slave mode – combined reset + trigger mode ............................... 1797
40.4.20 DMA burst mode ........................................................................ 1797
40.4.21 Timer synchronization (TIM15) .................................................... 1799
40.4.22 Debug mode .............................................................................. 1799

40.5 TIM15 registers .............................................................................. 1800
40.5.1 TIM15 control register 1 (TIM15_CR1) ......................................... 1800
40.5.2 TIM15 control register 2 (TIM15_CR2) ......................................... 1801
40.5.3 TIM15 slave mode control register (TIM15_SMCR) ...................... 1803
40.5.4 TIM15 DMA/interrupt enable register (TIM15_DIER) .................. 1804
40.5.5 TIM15 status register (TIM15_SR) ................................................. 1805
40.5.6 TIM15 event generation register (TIM15_EGR) ............................ 1807
40.5.7 TIM15 capture/compare mode register 1 [alternate] (TIM15_CCMR1) ................................................................................. 1808
40.5.8 TIM15 capture/compare mode register 1 [alternate] (TIM15_CCMR1) ................................................................................. 1809
40.5.9 TIM15 capture/compare enable register (TIM15_CCER) ............... 1812
40.5.10 TIM15 counter (TIM15_CNT) ....................................................... 1815
40.5.11 TIM15 prescaler (TIM15_PSC) ...................................................... 1815
40.5.12 TIM15 auto-reload register (TIM15_ARR) .................................... 1815
40.5.13 TIM15 repetition counter register (TIM15_RCR) ......................... 1816
40.5.14 TIM15 capture/compare register 1 (TIM15_CCR1) ..................... 1816
40.5.15 TIM15 capture/compare register 2 (TIM15_CCR2) ..................... 1817
40.5.16 TIM15 break and dead-time register (TIM15_BDTR) .................. 1817
40.5.17 TIM15 DMA control register (TIM15_DCR) ................................. 1820
40.5.18 TIM15 DMA address for full transfer (TIM15_DMAR) ............... 1820
40.5.19 TIM15 alternate register 1 (TIM15_AF1) ..................................... 1821
40.5.20 TIM15 input selection register (TIM15_TISEL) ......................... 1822
40.5.21 TIM15 register map .................................................................. 1823

40.6 TIM16/TIM17 registers ................................................................. 1825
40.6.1 TIMx control register 1 (TIMx_CR1)(x = 16 to 17) ....................... 1825
40.6.2 TIMx control register 2 (TIMx_CR2)(x = 16 to 17) ....................... 1826
40.6.3 TIMx DMA/interrupt enable register (TIMx_DIER)(x = 16 to 17) .... 1827
40.6.4 TIMx status register (TIMx_SR)(x = 16 to 17) .............................. 1828
40.6.5 TIMx event generation register (TIMx_EGR)(x = 16 to 17) .......... 1829
40.6.6 TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1) (x = 16 to 17) ................................................................. 1830
### 41 Basic timers (TIM6/TIM7) ................................................. 1848

#### 41.1 TIM6/TIM7 introduction ........................................... 1848

#### 41.2 TIM6/TIM7 main features ......................................... 1848

#### 41.3 TIM6/TIM7 functional description ............................... 1849

- 41.3.1 Time-base unit .................................................. 1849
- 41.3.2 Counting mode .................................................. 1851
- 41.3.3 UIF bit remapping ............................................... 1854
- 41.3.4 Clock source .................................................... 1854
- 41.3.5 Debug mode ..................................................... 1855

#### 41.4 TIM6/TIM7 registers ............................................... 1855

- 41.4.1 TIMx control register 1 (TIMx_CR1)(x = 6 to 7) ............ 1855
- 41.4.2 TIMx control register 2 (TIMx_CR2)(x = 6 to 7) .......... 1857
- 41.4.3 TIMx DMA/Interrupt enable register (TIMx_DIER)(x = 6 to 7)  1857
- 41.4.4 TIMx status register (TIMx_SR)(x = 6 to 7) .............. 1858
- 41.4.5 TIMx event generation register (TIMx_EGR)(x = 6 to 7) ... 1858
- 41.4.6 TIMx counter (TIMx_CNT)(x = 6 to 7) ....................... 1858
- 41.4.7 TIMx prescaler (TIMx_PSC)(x = 6 to 7) .................... 1859
- 41.4.8 TIMx auto-reload register (TIMx_ARR)(x = 6 to 7) ....... 1859
- 41.4.9 TIMx register map ............................................ 1860

## 43 System window watchdog (WWDG) .............................. 1890

43.1 Introduction ................................................. 1890
43.2 WWDG main features ......................................... 1890
43.3 WWDG functional description ................................. 1890
  43.3.1 WWDG block diagram ..................................... 1891
  43.3.2 WWDG internal signals .................................... 1891
  43.3.3 Enabling the watchdog .................................... 1891
  43.3.4 Controlling the downcounter .............................. 1891
  43.3.5 Advanced watchdog interrupt feature .................... 1892
  43.3.6 How to program the watchdog timeout ................... 1892
  43.3.7 Debug mode .............................................. 1893
43.4 WWDG registers ................................................ 1894
  43.4.1 Control register (WWDG_CR) .............................. 1894
  43.4.2 Configuration register (WWDG_CFR) ...................... 1894
  43.4.3 Status register (WWDG_SR) ............................... 1895
  43.4.4 WWDG register map ........................................ 1895

## 44 Independent watchdog (IWDG) ............................... 1897

44.1 Introduction .................................................. 1897
44.2 IWDG main features .......................................... 1897
44.3 IWDG functional description ................................. 1897
  44.3.1 IWDG block diagram ...................................... 1897
  44.3.2 IWDG internal signals .................................... 1898
  44.3.3 Window option ........................................... 1898
  44.3.4 Hardware watchdog ....................................... 1899
  44.3.5 Low-power freeze ........................................ 1899
  44.3.6 Register access protection .............................. 1899
  44.3.7 Debug mode .............................................. 1899
44.4 IWDG registers ................................................ 1900
  44.4.1 IWDG key register (IWDG_KR) ............................ 1900
  44.4.2 IWDG prescaler register (IWDG_PR) ...................... 1901
  44.4.3 IWDG reload register (IWDG_RLR) ....................... 1902
  44.4.4 IWDG status register (IWDG_SR) ......................... 1903
  44.4.5 IWDG window register (IWDG_WINR) ..................... 1904
  44.4.6 IWDG register map ....................................... 1905
## 45 Real-time clock (RTC)  ................................................................. 1906

45.1 Introduction ................................................................. 1906

45.2 RTC main features ......................................................... 1907

45.3 RTC functional description .............................................. 1907

45.3.1 RTC block diagram ..................................................... 1907

45.3.2 RTC pins and internal signals ....................................... 1909

45.3.3 GPIOs controlled by the RTC ........................................ 1910

45.3.4 Clock and prescalers .................................................. 1912

45.3.5 Real-time clock and calendar ...................................... 1913

45.3.6 Programmable alarms .................................................. 1913

45.3.7 Periodic auto-wake up ............................................... 1913

45.3.8 RTC initialization and configuration ............................. 1914

45.3.9 Reading the calendar ................................................. 1916

45.3.10 Resetting the RTC ..................................................... 1917

45.3.11 RTC synchronization .................................................. 1917

45.3.12 RTC reference clock detection .................................... 1918

45.3.13 RTC smooth digital calibration .................................... 1919

45.3.14 Time-stamp function ............................................... 1921

45.3.15 Tamper detection ..................................................... 1921

45.3.16 Calibration clock output .......................................... 1923

45.3.17 Alarm output .......................................................... 1924

45.4 RTC low-power modes ..................................................... 1924

45.5 RTC interrupts ............................................................. 1924

45.6 RTC registers ............................................................... 1925

45.6.1 RTC time register (RTC_TR) ........................................ 1925

45.6.2 RTC date register (RTC_DR) ........................................ 1926

45.6.3 RTC control register (RTC_CR) .................................... 1928

45.6.4 RTC initialization and status register (RTC_ISR) ............ 1931

45.6.5 RTC prescaler register (RTC_PRER) .............................. 1934

45.6.6 RTC wakeup timer register (RTC_WUTR) ......................... 1935

45.6.7 RTC alarm A register (RTC_ALMAR) .............................. 1936

45.6.8 RTC alarm B register (RTC_ALRMBR) ............................. 1937

45.6.9 RTC write protection register (RTC_WPR) ....................... 1938

45.6.10 RTC sub second register (RTC_SSR) ............................. 1938

45.6.11 RTC shift control register (RTC_SHIFTR) ....................... 1939

45.6.12 RTC timestamp time register (RTC_TSTR) ...................... 1940
Inter-integrated circuit (I2C) interface ............................................ 1952

46.1 Introduction ................................................................. 1952
46.2 I2C main features ......................................................... 1952
46.3 I2C implementation ...................................................... 1953
46.4 I2C functional description .............................................. 1953
  46.4.1 I2C block diagram .................................................. 1954
  46.4.2 I2C pins and internal signals ..................................... 1955
  46.4.3 I2C clock requirements ........................................... 1955
  46.4.4 Mode selection ....................................................... 1955
  46.4.5 I2C initialization .................................................. 1956
  46.4.6 Software reset ....................................................... 1961
  46.4.7 Data transfer ....................................................... 1962
  46.4.8 I2C slave mode ..................................................... 1964
  46.4.9 I2C master mode .................................................... 1973
  46.4.10 I2C_TIMINGR register configuration examples ................... 1985
  46.4.11 SMBus specific features ......................................... 1986
  46.4.12 SMBus initialization ............................................. 1990
  46.4.13 SMBus: I2C_TIMEOUTR register configuration examples ...... 1992
  46.4.14 SMBus slave mode ................................................. 1992
  46.4.15 Wakeup from Stop mode on address match ....................... 2000
  46.4.16 Error conditions .................................................. 2000
  46.4.17 DMA requests ...................................................... 2002
  46.4.18 Debug mode ....................................................... 2003

46.5 I2C low-power modes .................................................. 2003
46.6 I2C interrupts ........................................................... 2004
46.7 I2C registers ............................................................. 2005
46.7.1 I2C control register 1 (I2C_CR1) ........................................ 2005
46.7.2 I2C control register 2 (I2C_CR2) ........................................ 2008
46.7.3 I2C own address 1 register (I2C_OAR1) ............................ 2011
46.7.4 I2C own address 2 register (I2C_OAR2) ............................ 2012
46.7.5 I2C timing register (I2C_TIMINGR) ................................. 2013
46.7.6 I2C timeout register (I2C_TIMEOUTR) ............................. 2014
46.7.7 I2C interrupt and status register (I2C_ISR) ......................... 2015
46.7.8 I2C interrupt clear register (I2C_ICR) ................................. 2017
46.7.9 I2C PEC register (I2C_PECR) ........................................ 2018
46.7.10 I2C receive data register (I2C_RXDR) .............................. 2019
46.7.11 I2C transmit data register (I2C_TXDR) .............................. 2019
46.7.12 I2C register map ....................................................... 2020

47 Universal synchronous/asynchronous receiver transmitter (USART/UART) ........................................ 2022
47.1 USART introduction ....................................................... 2022
47.2 USART main features .................................................... 2023
47.3 USART extended features ............................................... 2024
47.4 USART implementation .................................................. 2024
47.5 USART functional description ......................................... 2025
  47.5.1 USART block diagram .............................................. 2025
  47.5.2 USART signals ....................................................... 2026
  47.5.3 USART character description ..................................... 2027
  47.5.4 USART FIFOs and thresholds ...................................... 2029
  47.5.5 USART transmitter .................................................. 2029
  47.5.6 USART receiver ..................................................... 2033
  47.5.7 USART baud rate generation ...................................... 2041
  47.5.8 Tolerance of the USART receiver to clock deviation .......... 2042
  47.5.9 USART Auto baud rate detection ................................. 2043
  47.5.10 USART multiprocessor communication ........................... 2045
  47.5.11 USART Modbus communication .................................... 2047
  47.5.12 USART parity control ............................................. 2047
  47.5.13 USART LIN (local interconnection network) mode .......... 2048
  47.5.14 USART synchronous mode ........................................ 2051
  47.5.15 USART single-wire Half-duplex communication .............. 2055
  47.5.16 USART receiver timeout ......................................... 2055
  47.5.17 USART Smartcard mode .......................................... 2056
47.18 USART IrDA SIR ENDEC block ........................................... 2060
47.19 Continuous communication using USART and DMA ............... 2063
47.20 RS232 Hardware flow control and RS485 Driver Enable ......... 2065
47.21 USART low-power management ...................................... 2068

47.6 USART interrupts ..................................................... 2071

47.7 USART registers ..................................................... 2074
  47.7.1 USART control register 1 [alternate] (USART_CR1) .......... 2074
  47.7.2 USART control register 1 [alternate] (USART_CR1) ........ 2078
  47.7.3 USART control register 2 (USART_CR2) ...................... 2081
  47.7.4 USART control register 3 (USART_CR3) ...................... 2085
  47.7.5 USART baud rate register (USART_BRR) ..................... 2090
  47.7.6 USART guard time and prescaler register (USART_GTPR) ... 2090
  47.7.7 USART receiver timeout register (USART_RTOR) .......... 2091
  47.7.8 USART request register (USART_RQR) ....................... 2092
  47.7.9 USART interrupt and status register [alternate] (USART_ISR) ... 2093
  47.7.10 USART interrupt and status register [alternate] (USART_ISR) ... 2099
  47.7.11 USART interrupt flag clear register (USART_ICR) ........ 2104
  47.7.12 USART receive data register (USART_RDR) ............... 2106
  47.7.13 USART transmit data register (USART_TDR) .............. 2106
  47.7.14 USART prescaler register (USART_PRES) ................. 2107
  47.7.15 USART register map ....................................... 2108

48 Low-power universal asynchronous receiver transmitter (LPUART) 2110
  48.1 LPUART introduction .............................................. 2110
  48.2 LPUART main features ........................................... 2111
  48.3 LPUART functional description .................................. 2112
    48.3.1 LPUART block diagram .................................... 2112
    48.3.2 LPUART signals ........................................... 2113
    48.3.3 LPUART character description ............................ 2113
    48.3.4 LPUART FIFOs and thresholds ............................ 2114
    48.3.5 LPUART transmitter ....................................... 2115
    48.3.6 LPUART receiver .......................................... 2118
    48.3.7 LPUART baud rate generation ............................. 2122
    48.3.8 Tolerance of the LPUART receiver to clock deviation ... 2124
    48.3.9 LPUART multiprocessor communication .................... 2124
    48.3.10 LPUART parity control .................................. 2126

1.1 General information

The STM32H742, STM32H743/753 and STM32H750 devices have an Arm® Cortex®-M7 with FPU core.

1.2 List of abbreviations for registers

The following abbreviations(b) are used in register descriptions:

read/write (rw) Software can read and write to this bit.
read-only (r) Software can only read this bit.
write-only (w) Software can only write to this bit. Reading this bit returns the reset value.
read/clear write0 (rc_w0) Software can read as well as clear this bit by writing 0. Writing 1 has no effect on the bit value.
read/clear write1 (rc_w1) Software can read as well as clear this bit by writing 1. Writing 0 has no effect on the bit value.
read/clear write (rc_w) Software can read as well as clear this bit by writing to the register. The value written to this bit is not important.
read/clear by read (rc_r) Software can read this bit. Reading this bit automatically clears it to 0. Writing this bit has no effect on the bit value.
read/set by read (rs_r) Software can read this bit. Reading this bit automatically sets it to 1. Writing this bit has no effect on the bit value.
read/set (rs) Software can read as well as set this bit. Writing 0 has no effect on the bit value.
read/write once (rwo) Software can only write once to this bit and can also read it at any time. Only a reset can return the bit to its reset value.
toggle (t) The software can toggle this bit by writing 1. Writing 0 has no effect.
read-only write trigger (rt_w1) Software can read this bit. Writing 1 triggers an event but has no effect on the bit value.
Reserved (Res.) Reserved bit, must be kept at reset value.

a. Arm is a registered trademark of Arm Limited (or its subsidiaries) in the US and/or elsewhere.
b. This is an exhaustive list of all abbreviations applicable to STM microcontrollers, some of them may not be used in the current document.
1.3 Glossary

This section gives a brief definition of acronyms and abbreviations used in this document:

- **Word**: data of 32-bit length.
- **Half-word**: data of 16-bit length.
- **Byte**: data of 8-bit length.
- **Double word**: data of 64-bit length.
- **Flash word**: data of 256-bit length
- **IAP (in-application programming)**: IAP is the ability to re-program the Flash memory of a microcontroller while the user program is running.
- **ICP (in-circuit programming)**: ICP is the ability to program the Flash memory of a microcontroller using the JTAG protocol, the SWD protocol or the bootloader while the device is mounted on the user application board.
- **Option bytes**: product configuration bits stored in the Flash memory.
- **AHB**: advanced high-performance bus.
- **APB**: advanced peripheral bus.
- **AXI**: Advanced extensible Interface protocol.
- **PCROP**: proprietary code readout protection.
- **RDP**: readout protection.

1.4 Availability of peripherals

For availability of peripherals and their number across all sales types, refer to the particular device datasheet.

The following table shows the availability of peripherals per product. The below legend is used:

1: STM32H742xI/G
2: STM32H743xI/G
3: STM32H750xB
4: STM32H753xI/G

2 Memory and bus architecture

2.1 System architecture

An AXI bus matrix, two AHB bus matrices and bus bridges allow interconnecting bus masters with bus slaves, as illustrated in Table 3 and Figure 1.

1. **Bold** font type denotes 64-bit bus, plain type denotes 32-bit bus.
2. "X" = access possible, "-" = access not possible, shading = access useful/usable.
3. Bank 2 is not available on STM32HF750xB devices.
Figure 1. System architecture for STM32H742/743/53xx and STM32H750xB devices

Flash memory bank 2 is not available on STM32H750xB devices.
2.1.1 Bus matrices

AXI bus matrix in D1 domain

The D1 domain multi AXI bus matrix ensures and arbitrates concurrent accesses from multiple masters to multiple slaves. This allows efficient simultaneous operation of high-speed peripherals.

The arbitration uses a round-robin algorithm with QoS capability.

Refer to Section 2.2: AXI interconnect matrix (AXIM) for more information on AXI interconnect.

AHB bus matrices in D2 and D3 domains

The AHB bus matrices in D2 and D3 domains ensure and arbitrate concurrent accesses from multiple masters to multiple slaves. This allows efficient simultaneous operation of high-speed peripherals.

The arbitration uses a round-robin algorithm.

2.1.2 TCM buses

The DTCM and ITCM (data and instruction tightly coupled RAMs) are connected through dedicated TCM buses directly to the Cortex-M7 core. The MDMA controller can access the DTCM and ITCM through AHBS, a specific CPU slave AHB. The ITCM is accessed by Cortex-M7 at CPU clock speed, with zero wait states.

2.1.3 Bus-to-bus bridges

To allow peripherals with different types of buses to communicate together, there is a number of bus-to-bus bridges in the system.

The AHB/APB bridges in D1 and D3 domains allow connecting peripherals on APB3 and APB4 to AHBS and AHB4, respectively. The AHB/APB bridges in D2 domain allow peripherals on APB1 and APB2 to connect to AHB1. These AHB/APB bridges provide full synchronous interfacing, which allows the AHB peripherals to operate with clocks independent of AHB that they connect to.

The AHB/APB bridges also allow APB1 and APB2 peripherals to connect to DMA1 and DMA2 peripheral buses, respectively, without transiting through AHB1.

The AHB/APB bridges convert 8-bit / 16-bit APB data to 32-bit AHB data, by replicating it to the three upper bytes / the upper half-word of the 32-bit word.

The AXI bus matrix incorporates AHB/AXI bus bridge functionality on its slave bus interfaces. The AXI/AHB bus bridges on its master interfaces marked as 32-bit in Figure 1 are outside the matrix.

The Cortex-M7 CPU provides AHB/TCM-bus (ITCM and DTCM buses) translation from its AHBS slave AHB, allowing the MDMA controller to access the ITCM and DTCM.
2.1.4 Inter-domain buses

**D2-to-D1 AHB**

This 32-bit bus connects the D2 domain to the AXI bus matrix in the D1 domain. It allows bus masters in the D2 domain to access resources (bus slaves) in the D1 domain and indirectly, via the D1-to-D3 AHB, in the D3 domain.

**D1-to-D2 AHB**

This 32-bit bus connects the D1 domain to the D2 domain AHB bus matrix. It allows bus masters in the D1 domain to access resources (bus slaves) in the D2 domain.

**D1-to-D3 AHB**

This 32-bit bus connects the D1 domain to the D3 domain AHB bus matrix. It allows bus masters in the D1 domain to access resources (bus slaves) in the D3 domain.

**D2-to-D3 AHB**

This 32-bit bus connects the D2 domain to the D3 domain AHB bus matrix. It allows bus masters in the D2 domain to access resources (bus slaves) in the D3 domain.

2.1.5 CPU buses

**Cortex®-M7 AXIM bus**

The Cortex®-M7 CPU uses the 64-bit AXIM bus to access all memories (excluding ITCM, and DTCM) and AHB3, AHB4, APB3 and APB4 peripherals (excluding AHB1, APB1 and APB2 peripherals).

The AXIM bus connects the CPU to the AXI bus matrix in the D1 domain.

**Cortex®-M7 ITCM bus**

The Cortex®-M7 CPU uses the 64-bit ITCM bus for fetching instructions from and accessing data in the ITCM.

**Cortex®-M7 DTCM bus**

The Cortex®-M7 CPU uses the 2x32-bit DTCM bus for accessing data in the DTCM. The 2x32-bit DTCM bus allows load/load and load/store instruction pairs to be dual-issued on the DTCM memory. It can also fetch instructions.

**Cortex®-M7 AHBS bus**

The Cortex®-M7 CPU uses the 32-bit AHBS slave bus to allow the MDMA controller to access the ITCM and the DTCM.

**Cortex®-M7 AHBP bus**

The Cortex®-M7 CPU uses the 32-bit AHBP bus for accessing AHB1, AHB2, APB1 and APB2 peripherals via the AHB bus matrix in the D2 domain.
2.1.6 Bus master peripherals

SDMMC1
The SDMMC1 uses a 32-bit bus, connected to the AXI bus matrix, through which it can access internal AXI SRAM and Flash memories, and external memories through the Quad-SPI controller and the FMC.

SDMMC2
The SDMMC2 uses a 32-bit bus, connected to the AHB bus matrix in D2 domain. Through the system bus matrices, it can access the internal AXI SRAM, SRAM1, SRAM2, SRAM3 and Flash memories, and external memories through the Quad-SPI controller and the FMC.

MDMA controller
The MDMA controller has two bus masters: an AXI 64-bit bus, connected to the AXI bus matrix and an AHB 32-bit bus connected to the Cortex-M7 AHBS slave bus.

The MDMA is optimized for DMA data transfers between memories since it supports linked list transfers that allow performing a chained list of transfers without the need for CPU intervention. Through the system bus matrices and the Cortex-M7 AHBS slave bus, the MDMA can access all internal and external memories through the Quad-SPI controller and the FMC.

DMA1 and DMA2 controllers
The DMA1 and DMA2 controllers have two 32-bit buses - memory bus and peripheral bus, connected to the AHB bus matrix in D2 domain.

The memory bus allows DMA data transfers between memories. Through the system bus matrices, the memory bus can access all internal memories except ITCM and DTCM, and external memories through the Quad-SPI controller and the FMC.

The peripheral bus allows DMA data transfers between two peripherals, between two memories or between a peripheral and a memory. Through the system bus matrices, the peripheral bus can access all internal memories except ITCM and DTCM, external memories through the Quad-SPI controller and the FMC, and all AHB and APB peripherals. A direct access to APB1 and APB2 is available, without passing through AHB1. Direct path to APB1 and APB2 bridges allows reducing the bandwidth usage on AHB1 bus by improving data treatment efficiency for APB and AHB peripherals.

BDMA controller
The BDMA controller uses a 32-bit bus, connected to the AHB bus matrix in D3 domain, for DMA data transfers between two peripherals, between two memories or between a peripheral and a memory. BDMA transfers are limited to the D3 domain resources. It can access the internal SRAM4, backup RAM, and AHB4 and APB4 peripherals through the AHB bus matrix in the D3 domain.

Chrom-Art Accelerator™ (DMA2D)
The DMA2D graphics accelerator uses a 64-bit bus, connected to the AXI bus matrix. Through the system bus matrices, internal AXI SRAM, SRAM1, SRAM2, SRAM3 and Flash memories, and external memories through the Quad-SPI controller and the FMC.
The LCD-TFT display controller, LTDC, uses a 64-bit bus, connected to the AXI bus matrix, through which it can access internal AXI SRAM and Flash memories, and external memories through the Quad-SPI controller and the FMC.

**Ethernet MAC**

The Ethernet MAC uses a 32-bit bus, connected to the AHB bus matrix in the D2 domain. Through the system bus matrices, it can access all internal memories except ITCM and DTCM, and external memories through the Quad-SPI controller and the FMC.

**USBHS1 and USBHS2 peripherals**

The USBHS1 and USBHS2 peripherals use 32-bit buses, connected to the AHB bus matrix in the D2 domain. Through the system bus matrices, they can access all internal memories except ITCM and DTCM, and external memories through the Quad-SPI controller and the FMC.

### 2.1.7 Clocks to functional blocks

Upon reset, clocks to blocks such as peripherals and some memories are disabled (except for the SRAM, DTCM, ITCM and Flash memory). To operate a block with no clock upon reset, the software must first enable its clock through RCC_AHBxENR or RCC_APBxENR register, respectively.

**2.2 AXI interconnect matrix (AXIM)**

#### 2.2.1 AXI introduction

The AXI (advanced extensible interface) interconnect is based on the Arm® CoreLink™ NIC-400 Network Interconnect. The interconnect has six initiator ports, or ASIBs (AMBA slave interface blocks), and seven target ports, or AMIBs (AMBA master interface blocks). The ASIBs are connected to the AMIBs via an AXI switch matrix.

Each ASIB is a slave on an AXI bus or AHB (advanced high-performance bus). Similarly, each AMIB is a master on an AXI or AHB bus. Where an ASIB or AMIB is connected to an AHB, it converts between the AHB and the AXI protocol.

The AXI interconnect includes a GPV (global programmer view) which contains registers for configuring certain parameters, such as the QoS (quality of service) level at each ASIB.

Any accesses to unallocated address space are handled by the default slave, which generates the return signals. This ensures that such transactions complete and do not block the issuing master and ASIB.

#### 2.2.2 AXI interconnect main features

- 64-bit AXI bus switch matrix with six ASIBs and seven AMIBs, in D1 domain
- AHB/AXI bridge function built into the ASIBs
- concurrent connectivity of multiple ASIBs to multiple AMIBs
- programmable traffic priority management (QoS - quality of service)
- software-configurable via GPV
2.2.3 AXI interconnect functional description

Block diagram

The AXI interconnect is shown in Figure 2.

1. Conversion to AHB protocol is done via an AXI/AHB bridge sitting between AXI interconnect and the connected slave.

Quality of service (QoS)

The AXI switch matrix uses a priority-based arbitration when two ASIB simultaneously attempt to access the same AMIB. Each ASIB has programmable read channel and write channel priorities, known as QoS, from 0 to 15, such that the higher the value, the higher the priority. The read channel QoS value is programmed in the AXI interconnect - INI x read QoS register (AXI_INIx_READ_QOS), and the write channel in the AXI interconnect - INI x write QoS register (AXI_INIx_WRITE_QOS). The default QoS value for all channels is 0 (lowest priority).

If two coincident transactions arrive at the same AMIB, the higher priority transaction passes before the lower priority. If the two transactions have the same QoS value, then a least-recently-used (LRU) priority scheme is adopted.

The QoS values should be programmed according to the latency requirements for the application. Setting a higher priority for an ASIB ensures a lower latency for transactions initiated by the associated bus master. This can be useful for real-time-constrained tasks, such as graphics processing (LTDC, DMA2D). Assigning a high priority to masters that can make many and frequent accesses to the same slave (such as the Cortex-M7 CPU) can block access to that slave by other lower-priority masters.

Global programmer view (GPV)

The GPV contains configuration registers for the AXI interconnect (see Section 2.2.4). These registers are only accessible by the Cortex-M7 CPU.
2.2.4 AXI interconnect registers

**AXI interconnect - peripheral ID4 register (AXI_PERIPH_ID_4)**

Address offset: 0x1FD0
Reset value: 0x0000 0004

Refer to *Section 2.3 on page 126* for the register boundary addresses.
2.3 Memory organization

2.3.1 Introduction

Program memory, data memory, registers and I/O ports are organized within the same linear 4-Gbyte address space.

The bytes are coded in memory in Little Endian format. The lowest numbered byte in a word is considered the word’s least significant byte and the highest numbered byte the most significant.

The addressable memory space is divided into eight main blocks, of 512 Mbytes each.
## 2.3.2 Memory map and register boundary addresses

All the memory map areas that are not allocated to on-chip memories and peripherals are considered "Reserved". For the detailed mapping of available memory and register areas, refer to the following table.
The following table gives the boundary addresses of the peripherals available in the devices.

1. Accessing a reserved area results in a bus error. Accessing undefined memory space in a peripheral returns zeros.
2.4 Embedded SRAM

The STM32H742/743/53xx and STM32H750xB devices feature:

- Up to 864 Kbytes of System SRAM
- 128 Kbytes of data TCM RAM
- 64 Kbytes of instruction TCM RAM
- 4 Kbytes of backup SRAM

The embedded system SRAM is divided into up to five blocks over the three power domains:

- **D1 domain, AXI SRAM:**
  - AXI SRAM is mapped at address 0x2400 0000 and accessible by all system masters except BDMA through D1 domain AXI bus matrix. AXI SRAM can be used for application data which are not allocated in DTCM RAM or reserved for graphic objects (such as frame buffers)

- **D2 domain, AHB SRAM:**
  - AHB SRAM1 is mapped at address 0x3000 0000 and accessible by all system masters except BDMA through D2 domain AHB matrix. AHB SRAM1 can be used as DMA buffers to store peripheral input/output data in D2 domain, or as code location for Cortex®-M4 CPU (application code available when D1 is powered off).
  - AHB SRAM2 is mapped at address 0x3002 0000 and accessible by all system masters except BDMA through D2 domain AHB matrix. AHB SRAM2 can be used as DMA buffers to store peripheral input/output data in D2 domain, or as read/write segment for application running on Cortex®-M4 CPU.
  - AHB SRAM3 is mapped at address 0x3004 0000 and accessible by all system masters except BDMA through D2 domain AHB matrix. AHB SRAM3 can be used as buffers to store peripheral input/output data for Ethernet and USB.

- **D3 domain, AHB SRAM:**
  - AHB SRAM4 is mapped at address 0x3800 0000 and accessible by most of system masters through D3 domain AHB matrix. AHB SRAM4 can be used as BDMA buffers to store peripheral input/output data in D3 domain. It can also be used to retain some application data when D1 and D2 domain enter DStandby mode.

The system AHB SRAM can be accessed as bytes, half-words (16-bit units) or words (32-bit units), while the system AXI SRAM can be accessed as bytes, half-words, words or double-words (64-bit units). These memories can be addressed at maximum system clock frequency without wait state.

The AHB masters can read/write-access an SRAM section concurrently with the Ethernet MAC or the USB OTG HS peripheral accessing another SRAM section. For example, the Ethernet MAC accesses the SRAM2 while the CPU accesses the SRAM1, concurrently.

The TCM SRAMs are dedicated to the Cortex®-M7:

- **DTCM-RAM on TCM interface** is mapped at the address 0x2000 0000 and accessible by Cortex®-M7, and by MDMA through AHBS slave bus of the Cortex®-M7 CPU. The DTCM-RAM can be used as read-write segment to host critical real-time data (such as stack and heap) for application running on Cortex®-M7 CPU.
- **ITCM-RAM on TCM interface** mapped at the address 0x0000 0000 and accessible by Cortex®-M7 and by MDMA through AHBS slave bus of the Cortex®-M7 CPU. The
ITCM-RAM can be used to host code for time-critical routines (such as interrupt handlers) that requires deterministic execution.

The backup RAM is mapped at the address 0x3880 0000 and is accessible by most of the system masters through D3 domain’s AHB matrix. With a battery connected to the V\textsubscript{BAT} pin, the backup SRAM can be used to retain data during low-power mode (Standby and V\textsubscript{BAT} mode).

**Error code correction (ECC)**

SRAM data are protected by ECC:

- 7 ECC bits are added per 32-bit word.
- 8 ECC bits are added per 64-bit word for AXI-SRAM and ITCM-RAM.

The ECC mechanism is based on the SECDED algorithm. It supports single-error correction and double-error detection.

When a half word is written to an internal SRAM and a reset occurs, this half word is not really written to the SRAM after reset. This due to the ECC behavior.

### 2.5 Flash memory overview

The Flash memory interface manages CPU AXI accesses to the Flash memory. It implements the erase and program Flash memory operations and the read and write protection mechanisms.

The Flash memory is organized as follows:

- Two main memory block divided into sectors.
- An information block:
  - System memory from which the device boots in System memory boot mode
  - Option bytes to configure read and write protection, BOR level, watchdog software/hardware and reset when the device is in Standby or Stop mode.

Refer to *Section 3: Embedded Flash memory (FLASH)* for more details.

### 2.6 Boot configuration

In the STM32H742, STM32H743/753 and STM32H750, two different boot areas can be selected through the BOOT pin and the boot base address programmed in the BOOT\_ADD0 and BOOT\_ADD1 option bytes as shown in the Table 9.
The values on the BOOT pin are latched on the 4th rising edge of SYSCLK after reset release. It is up to the user to set the BOOT pin after reset.

The BOOT pin is also re-sampled when the device exits the Standby mode. Consequently, they must be kept in the required Boot mode configuration when the device is in the Standby mode.

After startup delay, the selection of the boot area is done before releasing the processor reset.

The BOOT_ADD0 and BOOT_ADD1 address option bytes allows to program any boot memory address from 0x0000 0000 to 0x3FFF 0000 which includes:

- All Flash address space
- All RAM address space: ITCM, DTCM RAMs and SRAMs
- The TCM-RAM

The BOOT_ADD0 / BOOT_ADD1 option bytes can be modified after reset in order to boot from any other boot address after next reset.

If the programmed boot memory address is out of the memory mapped area or a reserved area, the default boot fetch address is programmed as follows:

- Boot address 0: FLASH at 0x0800 0000
- Boot address 1: ITCM-RAM at 0x0000 0000

When the Flash level 2 protection is enabled, only boot from Flash memory is available. If the boot address already programmed in the BOOT_ADD0 / BOOT_ADD1 option bytes is out of the memory range or belongs to the RAM address range, the default fetch will be forced from Flash memory at address 0x0800 0000.

**Embedded bootloader**

The embedded bootloader code is located in system memory. It is programmed by ST during production. It is used to reprogram the Flash memory using one of the following serial interfaces:

- USART1 on PA9/PA10 pins, USART2 on PA3/2pins, and USART3 on PB10/PB11 pins.
- I2C1 on PB6/9 pins, I2C2 on PF0/PF1 pins, I2C3 on PA8/PC9 pins, and I2C4 on PD12/13 pins
- USB OTG FS in Device mode (DFU) on PA11/PA12 pins
- SPI1 on PA7/6/5/4 pins, SPI2 on P13/2/1/0 pins, SPI3 on PC12/11/10/PA15pins, and SPI4 on PE14/13/12/11 pins.

3 Embedded Flash memory (FLASH)

3.1 Introduction

The embedded Flash memory (FLASH) manages the accesses of any master to the 2 Mbytes of embedded non-volatile memory. It implements the read, program and erase operations, error corrections as well as various integrity and confidentiality protection mechanisms.

The embedded Flash memory manages the automatic loading of non-volatile user option bytes at power-on reset, and implements the dynamic update of these options.

3.2 FLASH main features

- 2 Mbytes of non-volatile memory divided into two banks of 1 Mbyte each
- Flash memory read operations supporting multiple length (64 bits, 32 bits, 16 bits or one byte)
- Flash memory programming by 256 bits
- 128-Kbyte sector erase, bank erase and dual-bank mass erase
- Dual-bank organization supporting:
  - simultaneous operations: two read/program/erase operations executed in parallel on both banks (only available on STM32H742/743/753)
  - Bank swapping: the address mapping of the user Flash memory of each bank can be swapped, along with the corresponding registers.
- Error Code Correction (ECC): one error detection/correction or two error detections per 256-bit Flash word using 10 ECC bits
- Cyclic redundancy check (CRC) hardware module
- User configurable non-volatile option bytes
- Flash memory enhanced protections, activated by option bytes
  - Read protection (RDP), preventing unauthorized Flash memory dump to safeguard sensitive application code
  - Write-protection of sectors (WRPS), available per bank (128 Kbyte sectors)
  - Two proprietary code readout protection (PCROP) areas (one per user Flash bank). When enabled, this area is execute-only.
  - Two secure-only areas (one per user Flash bank). When enabled this area is accessible only if the STM32 microcontroller operates in Secure access mode.
- Read and write command queues to streamline Flash operations
3.3 FLASH functional description

3.3.1 FLASH block diagram

*Figure 3* shows the embedded Flash memory block diagram.

3.3.3 FLASH architecture and integration in the system

The embedded Flash memory is a central resource for the whole microcontroller. It serves as an interface to two non-volatile memory banks, and organizes the memory in a very specific way. The embedded Flash memory also proposes a set of security features to protect the assets stored in the non-volatile memory at boot time, at run-time and during firmware and configuration upgrades.

The embedded Flash memory offers two 64-bit AXI slave ports for code and data accesses, plus a 32-bit AHB configuration slave port used for register bank accesses.

*Note*: The application can simultaneously request a read and a write operation through each AXI interface.

The embedded Flash memory microarchitecture is shown in *Figure 4*. 
Behind the system interfaces, the embedded Flash memory implements various command queues and buffers to perform Flash read, write and erase operations with maximum efficiency.

Thanks to the addition of a read and write data buffer, the AXI slave port handles the following access types:

- Multiple length: 64 bits, 32 bits, 16 bits and 8 bits
- Single or burst accesses
- Write wrap burst must not cross 32-byte aligned address boundaries to target exactly one Flash word

The AHB configuration slave port supports 8-bit, 16-bit and 32-bit word accesses.

The embedded Flash memory is built in such a way that only one read or write operation can be executed at a time on a given bank.
### 3.3.4 Flash memory architecture and usage

#### Flash memory architecture

*Figure 5* shows the non-volatile memory organization supported by the embedded Flash memory.

*Figure 5. Embedded Flash memory organization*

---

1. On STM32H750xB, bank 2 is not available and bank 1 contains only one 128 Kbyte sector.

   The embedded Flash non-volatile memory is composed of:
   - For STM32H742/743/753 devices: a 2-Mbyte main memory block, organized as two banks of 1 Mbyte each. Each bank is in turn divided in eight 128-Kbyte sectors and features Flash-word rows of 256 bits + 10 bits of ECC per word.
   - For STM32H750xB devices: a 128-Kbyte user Flash memory block containing one user sector of 128 Kbytes (4 K Flash words).
   - A system memory block of 256 Kbytes, divided into two 128 Kbyte banks. The system memory is ECC protected.
   - A set of non-volatile option bytes loaded at reset by the embedded Flash memory and accessible by the application software only through the AHB configuration register interface.

The overall Flash memory architecture is summarized in *Table 11* and *Table 12*.

2. Cannot be erased by application software.
Partition usage

*Figure 6* shows how the embedded Flash memory is used both by STMicroelectronics and the application software.

**Figure 6. Embedded Flash memory usage**

User and system memories are used differently according to whether the microcontroller is configured by the application software in Standard mode or in Secure access mode. This selection is done through the SECURITY option bit (see Section 3.4.6):

- In Standard mode, the user memory contains the application code and data, while the system memory is loaded with the STM32 bootloader. When a reset occurs, the core jumps to the boot address configured through the BOOT pin and the BOOT_ADD0/1 option bytes.

- In Secure access mode, dedicated libraries can be used for secure boot. They are located in user Flash and system Flash memory:
  - ST libraries in system Flash memory assist the application software boot with special features such as secure boot and secure firmware install (SFI).
  - Application secure libraries in user Flash memory are used for secure firmware update (SFU).
In Secure access mode, the microcontroller always boots into the secure bootloader code (unique entry point). Then, if no secure services are required, this code securely jumps to the requested boot address configured through the BOOT pin and the option bytes, as shown in Figure 6 (see Section 4: Secure internal Flash memory (SIFM) for details).

**Note:** For more information on option byte setup for boot, refer to Section 3.4.7.

Additional partition usage is the following:
- The option bytes are used by STMicroelectronics and by the application software as non-volatile product options (e.g. boot address, protection configuration and reset behaviors).

**Note:** For further information on STM32 bootloader flashing by STMicroelectronics, refer to application note AN2606 “STM32 microcontroller system memory boot mode” available from www.st.com.

### Bank swapping

As shown in Figure 6, the embedded Flash memory offers a bank swapping feature that can be configured through the SWAP_BANK bit, always available for the application. For more information please refer to Section 3.3.13.

#### 3.3.5 FLASH system performance enhancements

The embedded Flash memory uses read and write command queues (one per bank) in order to enhance Flash operations.

#### 3.3.6 FLASH data protection schemes

*Figure 7* gives an overview of the protection mechanisms supported by the embedded Flash memory. A PCROP and a secure-only area can be defined for each bank. The properties of these protected areas are detailed in Section 3.5.

![FLASH protection mechanisms](Figure 7. FLASH protection mechanisms)
3.3.7 Overview of FLASH operations

Read operations

The embedded Flash memory can perform read operations on the whole non-volatile memory using various granularities: 64 bits, 32 bits, 16 bits or one byte. User and system Flash memories are read through the AXI interface, while the option bytes are read through the register interface.

The embedded Flash memory supports read-while-write operations provided the read and write operations target different banks. Similarly read-while-read operations are supported when two read operations target different banks.

To increase efficiency, the embedded Flash memory implements the buffering of consecutive read requests in the same bank.

For more details on read operations, refer to Section 3.3.8: FLASH read operations.

Program/erase operations

The embedded Flash memory supports the following program and erase operations:

- Single Flash word write (256-bit granularity), with the possibility for the application to force-write a user Flash word with less than 256 bits
- Single sector erase
- Bank erase (single or dual)
- Option byte update

Thanks to its dual bank architecture, the embedded Flash memory can perform any of the above write or erase operation on one bank while a read or another program/erase operation is executed on the other bank.

*Note:* Program and erase operations are subject to the various protection that could be set on the embedded Flash memory, such as write protection and global readout protection (see next sections for details).

To increase efficiency, the embedded Flash memory implements the buffering of consecutive write accesses in the same bank.

For more details refer to Section 3.3.9: FLASH program operations and Section 3.3.10: FLASH erase operations.

Protection mechanisms

The embedded Flash memory supports different protection mechanisms:

- Global readout protection (RDP)
- Proprietary code readout protection (PCROP)
- Write protection
- Secure access only protection

For more details refer to Section 3.5: FLASH protection mechanisms.
Option byte loading

Under specific conditions, the embedded Flash memory reliably loads the non-volatile option bytes stored in non-volatile memory, thus enforcing boot and security options to the whole system when the embedded Flash memory becomes functional again. For more details refer to Section 3.4: FLASH option bytes.

Bank/ register swapping

The embedded Flash memory allows swapping bank 1 and bank 2 memory mapping. This feature can be used after a firmware upgrade to restart the microcontroller on the new firmware after a system reset. For more details on the feature, refer to Section 3.3.13: Flash bank and register swapping (STM32H742/743/753 devices only).

3.3.8 FLASH read operations

Read operation overview

The embedded Flash memory supports, for each memory bank, the execution of one read command while two are waiting in the read command queue. Multiple read access types are also supported as defined in Section 3.3.3: FLASH architecture and integration in the system.

The read commands to each bank are associated with a 256-bit read data buffer.

*Note:* The embedded Flash memory can perform single error correction and double error detection while read operations are being executed (see Section 3.3.12: Flash memory error protections).

The AXI interface read channel operates as follows:

- When the read command queue is full, any new AXI read request stalls the bus read channel interface and consequently the master that issued that request.
- If several consecutive read accesses request data that belong to the same Flash data word (256 bits), the data are read directly from the current data read buffer, without triggering additional Flash read operations. This mechanism occurs each time a read access is granted. When a read access is rejected for security reasons (e.g. PCROP protected word), the corresponding read error response is issued by the embedded Flash memory and no read operation to Flash memory is triggered.

The Read pipeline architecture is summarized in Figure 8.

For more information on bus interfaces, refer to Section 3.3.3: FLASH architecture and integration in the system.
Figure 8. FLASH read pipeline architecture

**Single read sequence**

The recommended simple read sequence is the following:

1. Freely perform read accesses to any AXI-mapped area.
2. The embedded Flash memory effectively executes the read operation from the read command queue buffer as soon as the non-volatile memory is ready and the previously requested operations on this specific bank have been served.

**Adjusting read timing constraints**

The embedded Flash memory clock must be enabled and running before reading data from non-volatile memory.

To correctly read data from Flash memory, the number of wait states (LATENCY) must be correctly programmed in the Flash access control register (FLASH_ACR) according to the embedded Flash memory AXI interface clock frequency (sys_clk) and the internal voltage range of the device (V_{core}).

*Table 13* shows the correspondence between the number of wait states (LATENCY), the programming delay parameter (WRIHIGHFREQ), the embedded Flash memory clock frequency and its supply voltage ranges.
Adjusting system frequency

After power-on, a default 7 wait-state latency is specified in FLASH_ACR register, in order to accommodate AXI interface clock frequencies with a safety margin (see Table 13).

When changing the AXI bus frequency, the application software must follow the below sequence in order to tune the number of wait states required to access the non-volatile memory.

To increase the embedded Flash memory clock source frequency:
1. If necessary, program the LATENCY and WRHIGHFREQ bits to the right value in the FLASH_ACR register, as described in Table 13.
2. Check that the new number of wait states is taken into account by reading back the FLASH_ACR register.
3. Modify the embedded Flash memory clock source and/or the AXI bus clock prescaler in the RCC_CFGR register of the reset and clock controller (RCC).
4. Check that the new embedded Flash memory clock source and/or the new AXI bus clock prescaler value are taken in account by reading back the embedded Flash memory clock source status and/or the AXI interface prescaler value in the RCC_CFGR register of the reset and clock controller (RCC).

To decrease the embedded Flash memory clock source frequency:
1. Modify the embedded Flash memory clock source and/or the AXI bus clock prescaler in the RCC_CFGR register of reset and clock controller (RCC).
2. Check that the embedded Flash memory new clock source and/or the new AXI bus clock prescaler value are taken into account by reading back the embedded Flash memory clock source status and/or the AXI interface prescaler value in the RCC_CFGR register of reset and clock controller (RCC).
3. If necessary, program the LATENCY and WRHIGHFREQ bits to the right value in FLASH_ACR register, as described in Table 13.
4. Check that the new number of wait states has been taken into account by reading back the FLASH_ACR register.

1. Refer to the Reset and clock control section RCC section for the maximum product F<sub>ACLK</sub> frequency.
Error code correction (ECC)

The embedded Flash memory embeds an error correction mechanism. Single error correction and double error detection are performed for each read operation. For more details, refer to Section 3.3.12: Flash memory error protections.

Read errors

When the ECC mechanism is not able to correct the read operation, the embedded Flash memory reports read errors as described in Section 3.7.7: Error correction code error (SNECCERR/DBECCERR).

Read interrupts

See Section 3.8: FLASH interrupts for details.

3.3.9 FLASH program operations

Program operation overview

The virgin state of each non-volatile memory bitcell is 1. The embedded Flash memory supports programming operations that can change (reset) any memory bitcell to 0. However, these operations do not support the return of a bit to its virgin state. In this case, an erase operation of the entire sector is required.

A program operation consists in issuing write commands. The embedded Flash memory supports, for each memory bank, the execution of one write command while one command is waiting in the write command queue. Since a 10-bit ECC code is associated to each 256-bit data Flash word, only write operations by 256 bits are executed in the non-volatile memory.

Note: The application can decide to write as little as 8 bits to a 256 Flash word. In this case, a force-write mechanism to the 256 bits + ECC is used (see FW1/2 bit of FLASH_CR1/2 register).

System Flash memory bank 1 cannot be written by the application software. System Flash memory bank 2 can be written by STMicroelectronics secure firmware only.

It is not recommended to overwrite a Flash word that is not virgin. The result may lead to an inconsistent ECC code that will be systematically reported by the embedded Flash memory, as described in Section 3.7.7: Error correction code error (SNECCERR/DBECCERR).

The AXI interface write channel operates as follows:

- A 256-bit write data buffer is associated with each AXI interface. It supports multiple write access types (64 bits, 32 bits, 16 bits and 8 bits).
- When the write queue is full, any new AXI write request stalls the bus write channel interface and consequently the master that issued that request.

The write pipeline architecture is described in Figure 9.

For more information on bus interfaces, refer to Section 3.3.3: FLASH architecture and integration in the system.
Managing write protections

Before programming a user sector, the application software must check the protection of the targeted Flash memory area.

The embedded Flash memory checks the protection properties of the write transaction target at the output of the write queue buffer, just before the effective write operation to the non-volatile memory:

- If a write protection violation is detected, the write operation is canceled and write protection error (WRPERR1/2) is raised in FLASH_SRI/2 register.
- If the write operation is valid, the 10-bit ECC code is concatenated to the 256 bits of data and the write to non-volatile memory is effectively executed.

**Note:** *No write protection check is performed when the embedded Flash memory accepts AXI write requests.*

The write protection flag does not need to be cleared before performing a new programming operation.
Monitoring ongoing write operations

The application software can use three status flags located in FLASH_SR1/2 in order to monitor ongoing write operations. Those status are available for each bank.

- **BSY1/2**: this bit indicates that an effective write, erase or option byte change operation is ongoing to the non-volatile memory.
- **QW1/2**: this bit indicates that a write, erase or option byte change operation is pending in the write queue or command queue buffer. It remains high until the write operation is complete. It supersedes the BSY1/2 status bit.
- **WBNE1/2**: this bit indicates that the embedded Flash memory is waiting for new data to complete the 256-bit write buffer. In this state the write buffer is not empty. It is reset as soon as the application software fills the write buffer, force-writes the operation using FW1/2 bit in FLASH_CR1/2, or disables all write operations in the corresponding bank.

Enabling write operations

Before programming the user Flash memory in bank 1 (respectively bank 2), the application software must make sure that PG1 bit (respectively PG2) is set to 1 in FLASH_CR1 (respectively FLASH_CR2). If it is not the case, an unlock sequence must be used (see Section 3.5.1: FLASH configuration protection) and the PG1/2 bit must be set.

When the option bytes need to be modified or a mass erase needs to be started, the application software must make sure that FLASH_OPTCR is unlocked. If it is not the case, an unlock sequence must be used (see Section 3.5.1: FLASH configuration protection).

**Note:** The application software must not unlock a register that is already unlocked, otherwise this register will remain locked until next system reset.

If needed, the application software can update the programming delay and programming parallelism as described at the end of this section.

Single write sequence

The recommended single write sequence in bank 1/2 is the following:

1. Unlock the FLASH_CR1/2 register, as described in Section 3.5.1: FLASH configuration protection (only if register is not already unlocked).
2. Enable write operations by setting the PG1/2 bit in the FLASH_CR1/2 register.
3. Check the protection of the targeted memory area.
4. Write one Flash-word corresponding to 32-byte data starting at a 32-byte aligned address.
5. Check that QW1 (respectively QW2) has been raised and wait until it is reset to 0.

If step 4 is executed incrementally (e.g. byte per byte), the write buffer can become partially filled. In this case the application software can decide to force-write what is stored in the write buffer by using FW1/2 bit in FLASH_CR1/2 register. In this particular case, the unwritten bits are automatically set to 1. If no bit in the write buffer is cleared to 0, the FW1/2 bit has no effect.
Note: Using a force-write operation prevents the application from updating later the missing bits with a value different from 1, which is likely to lead to a permanent ECC error.

Any write access requested while the PG1/2 bit is cleared to 0 is rejected. In this case, no error is generated on the bus, but the PGSERR1/2 flag is raised.

Clearing the programming sequence error (PGSERR) and inconsistency error (INCERR) is mandatory before attempting a write operation (see Section 3.7: FLASH error management for details).

Adjusting programming timing constraints

Program operation timing constraints depend on the embedded Flash memory clock frequency, which directly impacts the performance. If timing constraints are too tight, the non-volatile memory will not operate correctly, if they are too lax, the programming speed will not be optimal.

The user must therefore trim the optimal programming delay through the WRHIGHFREQ parameter in the FLASH_ACR register. Refer to Table 13 in Section 3.3.8: FLASH read operations for the recommended programming delay depending on the embedded Flash memory clock frequency.

FLASH_ACR configuration register is common to both banks.

The application software must check that no program/erase operation is ongoing before modifying WRHIGHFREQ parameter.

Caution: Modifying WRHIGHFREQ while programming/erasing the Flash memory might corrupt the Flash memory content.

Adjusting programming parallelism

The parallelism is the maximum number of bits that can be written to 0 in one shot during a write operation. The programming parallelism is also used during sector and bank erase.

There is no hardware limitation on programming parallelism. The user can select different parallelisms depending on the application requirements: the lower the parallelism, the lower the peak consumption during a programming operation, but the longer the execution time.

The parallelism is configured through the PSIZE1/2 bits in FLASH_CR1/2 register. Two distinct values can be defined for bank 1 and 2 (refer to Table 14).

Table 14. FLASH parallelism parameter

<table>
<thead>
<tr>
<th>PSIZE1/2</th>
<th>Parallelism</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>8 bits (one byte)</td>
</tr>
<tr>
<td>01</td>
<td>16 bits</td>
</tr>
<tr>
<td>10</td>
<td>32 bits</td>
</tr>
<tr>
<td>11</td>
<td>64 bits</td>
</tr>
</tbody>
</table>

Caution: Modifying PSIZE1/2 while programming/erasing the Flash memory might corrupt the Flash memory content.

Programming errors

When a program operation fails, an error can be reported as described in Section 3.7: FLASH error management.
Programming interrupts

See Section 3.8: FLASH interrupts for details.

3.3.10 FLASH erase operations

Erase operation overview

The embedded Flash memory can perform erase operations on 128-Kbyte user sectors, on one user Flash memory bank or on two user Flash memory banks (i.e. mass erase). The system Flash memory (bank 2 only) can also be erased, but by STMicroelectronics secure firmware only.

*Note:* System Flash memory bank 1 cannot be erased by the application software.

The erase operation forces all non-volatile bit cells to high state, which corresponds to the virgin state. It clears existing data and corresponding ECC, allowing a new write operation to be performed. If the application software reads back a word that has been erased, all the bits will be read at 1, without ECC error.

Erase operations are similar to read or program operations except that the commands are queued in a special buffer (a two-command deep erase queue).

Erase commands are issued through the AHB configuration interface. If the embedded Flash memory receives simultaneously a write and an erase request for the same bank, both operations are accepted but the write operation is executed first.

Erase and security

A user sector can be erased only if it does not contain PCROP, secure-only or write-protected data (see Section 3.5: FLASH protection mechanisms for details). In other words, if the application software attempts to erase a user sector with at least one Flash word that is protected, the sector erase operation is aborted and the WRPERR1/2 flag is raised in the FLASH_SR1/2 register, as described in Section 3.7.2: Write protection error (WRPERR).

The embedded Flash memory allows the application software to perform an erase followed by an automatic protection removal (PCROP, secure-only area and write protection), as described hereafter.

Enabling erase operations

Before erasing a sector in bank 1 (respectively bank 2), the application software must make sure that FLASH_CR1 (respectively FLASH_CR2) is unlocked. If it is not the case, an unlock sequence must be used (see Section 3.5.1: FLASH configuration protection).

*Note:* The application software must not unlock a register that is already unlocked, otherwise this register will remain locked until next system reset.

Similar constraints apply to bank erase requests.
Flash sector erase sequence

To erase a 128-Kbyte user sector, proceed as follows:

1. Check and clear (optional) all the error flags due to previous programming/erase operation. Refer to Section 3.7: FLASH error management for details.
2. Unlock the FLASH_CR1/2 register, as described in Section 3.5.1: FLASH configuration protection (only if register is not already unlocked).
3. Set the SER1/2 bit and SNB1/2 bitfield in the corresponding FLASH_CR1/2 register. SER1/2 indicates a sector erase operation, while SNB1/2 contains the target sector number.
4. Set the START1/2 bit in the FLASH_CR1/2 register.
5. Wait for the QW1/2 bit to be cleared in the corresponding FLASH_SR1/2 register.

*Note:* If a bank erase is requested simultaneously to the sector erase (BER1/2 bit set), the bank erase operation supersedes the sector erase operation.

Standard Flash bank erase sequence

To erase all bank sectors except for those containing secure-only and protected data, proceed as follows:

1. Check and clear (optional) all the error flags due to previous programming/erase operation. Refer to Section 3.7: FLASH error management for details.
2. Unlock the FLASH_CR1/2 register, as described in Section 3.5.1: FLASH configuration protection (only if register is not already unlocked).
3. Set the BER1/2 bit in the FLASH_CR1/2 register corresponding to the targeted bank.
4. Set the START1/2 bit in the FLASH_CR1/2 register to start the bank erase operation. Then wait until the QW1/2 bit is cleared in the corresponding FLASH_SR1/2 register.

*Note:* BER1/2 and START1/2 bits can be set together, so above steps 3 and 4 can be merged.
If a sector erase is requested simultaneously to the bank erase (SER1/2 bit set), the bank erase operation supersedes the sector erase operation.
Flash bank erase with automatic protection-removal sequence

To erase all bank sectors including those containing secure-only and protected data without performing an RDP regression (see Section 3.5.3), proceed as follows:

1. Check and clear (optional) all the error flags due to previous programming/erase operation. Refer to Section 3.7: FLASH error management for details.
2. Unlock FLASH_OPTCR register, as described in Section 3.5.1: FLASH configuration protection (only if register is not already unlocked).
3. If a PCROP-protected area exists set DMEP1/2 bit in FLASH_PRAR_PRG1/2 register. In addition, program the PCROP area end and start addresses so that the difference is negative, i.e. PROT_AREA_END1/2 < PROT_AREA_START1/2.
4. If a secure-only area exists set DMES1/2 bit in FLASH_SCAR_PRG1/2 register. In addition, program the secure-only area end and start addresses so that the difference is negative, i.e. SEC_AREA_END1/2 < SEC_AREA_START1/2.
5. Set all WRPSn1/2 bits in FLASH_WPSN_PRG1/2R to 1 to disable all sector write protection.
6. Unlock FLASH_CR1/2 register, only if register is not already unlocked.
7. Set the BER1/2 bit in the FLASH_CR1/2 register corresponding to the target bank.
8. Set the START1/2 bit in the FLASH_CR1/2 register to start the bank erase with protection removal operation. Then wait until the QW1/2 bit is cleared in the corresponding FLASH_SR1/2 register. At that point a bank erase operation has erased the whole bank including the sectors containing PCROP-protected and/or secure-only data, and an option byte change has been automatically performed so that all the protections are disabled.

Note: BER1/2 and START1/2 bits can be set together, so above steps 8 and 9 can be merged.

Please note the following warnings regarding to above sequence:

- It is not possible to perform the above sequence on one bank while modifying the protection parameters of the other bank.
- No other option bytes than the one indicated above must be changed, and no protection change must be performed in the bank that is not targeted by the bank erase with protection removal request.
- When one or both of the events above occurs, a simple bank erase occurs, no option byte change is performed and no option change error is set.

Flash mass erase sequence

To erase all sectors of both banks simultaneously (STM32H742/743/753 only), excepted for those containing secure-only and protected data, the application software can set the MER bit to 1 in FLASH_OPTCR register, as described below:

1. Check and clear (optional) all the error flags due to previous programming/erase operation. Refer to Section 3.7: FLASH error management for details.
2. Unlock the two FLASH_CR1/2 registers and FLASH_OPTCR register, as described in Section 3.5.1: FLASH configuration protection (only if the registers are not already unlocked).
3. Set the MER bit to 1 in FLASH_OPTCR register. It automatically sets BER1, BER2, START1 and START2 to 1, thus launching a bank erase operation on both banks. Then wait until both QW1 and QW2 bits are cleared in the corresponding FLASH_SR1/2 register.
Flash mass erase with automatic protection-removal sequence

To erase all sectors of both banks simultaneously (STM32H742/743/753 only), including those containing secure-only and protected data, and without performing an RDP regression, proceed as follows:

1. Check and clear (optional) all the error flags due to previous programming/erase operation.
2. Unlock the twoFLASH_CR1/2 registers and FLASH_OPTCR register (only if the registers are not already unlocked).
3. If a PCROP-protected area exists, set DMEP1/2 bit in FLASH_PRAR_PRG1/2 register. In addition, program the PCROP area end and start addresses so that the difference is negative. This operation must be performed for both banks.
4. If a secure-only area exists, set DMES1/2 bit in FLASH_SCAR_PRG1/2 register. In addition, program the secure-only area end and start addresses so that the difference is negative. This operation must be performed for both banks.
5. Set all WRPSn1/2 bits in FLASH_WPSN_PRG1/2R to 1 to disable all sector write protections. This operation must be performed for both banks.
6. Set the MER bit to 1 in FLASH_OPTCR register, then wait until the QW1/2 bit is cleared in the corresponding FLASH_SR1/2 register. At that point, a Flash bank erase with automatic protection removal is executed on both banks. The sectors containing PCROP-protected and/or secure-only data become unprotected since an option byte change is automatically performed after the mass erase so that all the protections are disabled.

Caution: No other option bytes than the ones mentioned in the above sequence must be changed, otherwise a simple mass erase is executed, no option byte change is performed and no option change error is raised.

3.3.11 FLASH parallel operations (STM32H742/743/753 devices only)

As the non-volatile memory is divided into two independent banks, the embedded Flash memory interface can drive different operations at the same time on each bank. For example a read, write or erase operation can be executed on bank 1 while another read, write or erase operation is executed on bank 2.

In all cases, the sequences described in Section 3.3.8: FLASH read operations, Section 3.3.9: FLASH program operations and Section 3.3.10: FLASH erase operations apply.

3.3.12 Flash memory error protections

Error correction codes (ECC)

The embedded Flash memory supports an error correction code (ECC) mechanism. It is based on the SECDED algorithm in order to correct single errors and detects double errors.

This mechanism uses 10 ECC bits per 256-bit Flash word, and applies to user and system Flash memory.

More specifically, during each read operation from a 256-bit Flash word, the embedded Flash memory also retrieves the 10-bit ECC information, computes the ECC of the Flash word, and compares the result with the reference value. If they do not match, the
corresponding ECC error is raised as described in Section 3.7.7: Error correction code error (SNECCERR/DBECCERR).

During each program operation, a 10-bit ECC code is associated to each 256-bit data Flash word, and the resulting 266-bit Flash word information is written in non-volatile memory.

**Cyclic redundancy codes (CRC)**

The embedded Flash memory implements a cyclic redundancy check (CRC) hardware module. This module checks the integrity of a given user Flash memory area content (see Figure 4: Detailed FLASH architecture).

The area processed by the CRC module can be defined either by sectors or by start/end addresses. It can also be defined as the whole bank (user Flash memory area only).

*Note:* Only one CRC check operation on bank 1 or 2 can be launched at a time. To avoid corruption, do not configure the CRC calculation on the one bank, while calculating the CRC on the other bank.

When enabled, the CRC hardware module performs multiple reads by chunks of 4, 16, 64 or 256 consecutive Flash-word (i.e. chunks of 128, 512, 2048 or 8192 bytes). These consecutive read operations are pushed by the CRC module into the required read command queue together with other AXI read requests, thus avoiding to deny AXI read commands.

CRC computation uses CRC-32 (Ethernet) polynomial 0x4C11DB7:

\[ x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x + 1 \]

The CRC operation is concurrent with option byte change as the same hardware is used for both operations. To avoid the CRC computation from being corrupted, the application shall complete the option byte change (by reading the result of the change) before running a CRC operation, and vice-versa.

The sequence recommended to configure a CRC operation in the bank 1/2 is the following:

1. Unlock FLASH_CR1/2 register, if not already unlocked.
2. Enable the CRC feature by setting the CRC_EN bit in FLASH_CR1/2.
3. Program the desired data size in the CRC_BURST field of FLASH_CRCRR1/2.
4. Define the user Flash memory area on which the CRC has to be computed. Two solutions are possible:
   - Define the area start and end addresses by programming FLASH_CRCRRADD1/2R and FLASH_CRCRRCEED1/2R, respectively,
   - or select the targeted sectors by setting the CRC_BY_SECT bit in FLASH_CRCRR1/2 and by programming consecutively the target sector numbers in the CRC_SECT field of the FLASH_CRCRR1/2 register. Set ADD_SECT bit after each CRC_SECT programming.
5. Start the CRC operation by setting the START_CRC bit.
6. Wait until the CRC_BUSY1/2 flag is reset in FLASH_SR1/2 register.
7. Retrieve the CRC result in the FLASH_CRCRRDATAR register.

The CRC can be computed for a whole bank by setting the ALL_BANK bit in the FLASH_CRCRR1/2 register.
Note: The application should avoid running a CRC on PCROP- or secure-only user Flash memory area since it may alter the expected CRC value.

CRC computation does not raise standard read error flags such as RDSERR1/2, RDPERR1/2 and DBECCERR1/2.

3.3.13 Flash bank and register swapping (STM32H742/743/753 devices only)

Flash bank swapping

The embedded Flash memory bank 1 and bank 2 can be swapped in the memory map accessible through AXI interface. This feature can be used after a firmware upgrade to restart the device on the new firmware. Bank swapping is controlled by the SWAP_BANK bit of the FLASH_OPTCR register.

Note: The Flash bank swapping is not available on STM32H750xB devices. The SWAP_BANK option bit must be kept to '0'.

Table 15 shows the memory map that can be accessed from the embedded Flash memory AXI slave interface, depending on the SWAP_BANK bit configuration.

</tbody>
</table>

The SWAP_BANK bit in FLASH_OPTCR register is loaded from the SWAP_BANK_OPT option bit only after system reset or POR.

To change the SWAP_BANK bit (for example to apply a new firmware update), respect the sequence below:
1. Unlock OPTLOCK bit, if not already unlocked.
2. Set the new desired SWAP_BANK_OPT value in the FLASH_OPTSR_PRG register.
3. Start the option byte change sequence by setting the OPTSTART bit in the FLASH_OPTCR register.
4. Once the option byte change has completed, FLASH_OPTSR_CUR contains the expected SWAP_BANK_OPT value, but SWAP_BANK bit in FLASH_OPTCR has not yet been modified and the bank swapping is not yet effective.
5. Force a system reset or a POR. When the reset rises up, the bank swapping is effective (SWAP_BANK value updated in FLASH_OPTCR) and the new firmware shall be executed.

Note: The SWAP_BANK bit in FLASH_OPTCR is read-only and cannot be modified by the application software.

The SWAP_BANK_OPT option bit in FLASH_OPTSR_PRG can be modified whatever the RDP level (i.e. even in level 2), thus allowing advanced firmware upgrade in any level of readout protection.

Figure 10 gives an overview of the bank swapping sequence.
Configuration and option byte register swapping

The embedded Flash memory bank swapping option controlled by the SWAP_BANK bit also swaps the two sets of configuration and option byte registers, as shown in Table 16. One set of registers is related to bank 1 while the other is related to bank 2. Since some registers are not specific to any particular bank, they are mapped onto two different addresses so that the swapping does not affect the access to these registers.

1. As shown above, some registers are not dedicated to a specific bank and can be accessed at two different addresses.
3.3.14 **FLASH reset and clocks**

**Reset management**

The embedded Flash memory can be reset by a D1 domain reset (d1_rst), driven by the reset and clock control (RCC). The main effects of this reset are the following:

- All registers, except for option byte registers, are cleared, including read and write latencies. If the bank swapping option is changed, it will be applied.
- Most control registers are automatically protected against write operations. To unprotect them, new unlock sequences must be used as described in [Section 3.5.1: FLASH configuration protection](#).

The embedded Flash memory can be reset by a power-on reset (po_rst), driven by the reset and clock control (RCC). When the reset falls, all option byte registers are reset. When the reset rises up, the option bytes are loaded, potentially applying new features. During this loading sequence, the device remains under reset and the embedded Flash memory is not accessible.

The Reset signal can have a critical impact on the embedded Flash memory:

- The contents of the Flash memory are not guaranteed if a device reset occurs during a Flash memory write or erase operation.
- If a reset occurs while the option byte modification is ongoing, the old option byte values are kept. When it occurs, a new option byte modification sequence is required to program the new values.

**Clock management**

The embedded Flash memory uses the microcontroller system clock (sys_ck), here the AXI interface clock.

Depending on the device clock and internal supply voltage, specific read and write latency settings usually need to be set in the Flash access control register (FLASH_ACR), as explained in [Section 3.3.8: FLASH read operations](#) and [Section 3.3.9: FLASH program operations](#).

3.4 **FLASH option bytes**

3.4.1 **About option bytes**

The embedded Flash memory includes a set of non-volatile option bytes. They are loaded at power-on reset and can be read and modified only through configuration registers.

These option bytes are configured by the end-user depending on the application requirements. Some option bytes might have been initialized by STMicroelectronics during manufacturing stage.

This section documents:

- When option bytes are loaded
- How application software can modify them
- What is the detailed list of option bytes, together with their default factory values (i.e. before the first option byte change).
3.4.2 Option byte loading

There are multiple ways of loading the option bytes into embedded Flash memory:

1. Power-on wakeup

When the device is first powered, the embedded Flash memory automatically loads all the option bytes. During the option byte loading sequence, the device remains under reset and the embedded Flash memory cannot be accessed.

2. Wakeup from system Standby

When the D1 power domain, which contains the embedded Flash memory, is switched from DStandby mode to DRun mode, the embedded Flash memory behaves as during a power-on sequence.

3. Dedicated option byte reloading by the application

When the user application successfully modifies the option byte content through the embedded Flash memory registers, the non-volatile option bytes are programmed and the embedded Flash memory automatically reloads all option bytes to update the option registers.

Note: The option bytes read sequence is enhanced thanks to a specific error correction code.

In case of security issue, the option bytes may be loaded with default values (see Section 3.4.3: Option byte modification).

3.4.3 Option byte modification

Changing user option bytes

A user option byte change operation can be used to modify the configuration and the protection settings saved in the non-volatile option byte area of memory bank 1.

The embedded Flash memory features two sets of option byte registers:

- The first register set contains the current values of the option bytes. Their names have the _CUR extension. All “_CUR” registers are read-only. Their values are automatically loaded from the non-volatile memory after power-on reset, wakeup from system standby or after an option byte change operation.

- The second register set allows the modification of the option bytes. Their names contain the _PRG extension. All “_PRG” registers can be accessed in read/write mode.

When the OPTLOCK bit in FLASH_OPTCR register is set, modifying the _PRG registers is not possible.

When OPTSTART bit is set to 1, the embedded Flash memory checks if at least one option byte needs to be programmed by comparing the current values (_CUR) with the new ones (_PRG). If this is the case and all the other conditions are met (see Changing security option bytes), the embedded Flash memory launches the option byte modification in its non-volatile memory and updates the option byte registers with _CUR extension.

If one of the condition described in Changing security option bytes is not respected, the embedded Flash memory sets the OPTCHANGEERR flag to 1 in the FLASH_OPTSR_CUR register and aborts the option byte change operation. In this case, the _PRG registers are not overwritten by current option value. The user application can check what was wrong in their configuration.
Unlocking the option byte modification

After reset, the OPTLOCK bit is set to 1 and the FLASH_OPTCR is locked. As a result, the application software must unlock the option configuration register before attempting to change the option bytes. The FLASH_OPTCR unlock sequence is described in Section 3.5.1: FLASH configuration protection.

Option byte modification sequence

To modify user option bytes, follow the sequence below:

1. Unlock FLASH_OPTCR register as described in Section 3.5.1: FLASH configuration protection, unless the register is already unlocked.
2. Write the desired new option byte values in the corresponding option registers (FLASH_XXX_PRG1/2).
3. Set the option byte start change OPTSTART bit to 1 in the FLASH_OPTCR register.
4. Wait until OPT_BUSY bit is cleared.

Note: If a reset or a power-down occurs while the option byte modification is ongoing, the original option byte value is kept. A new option byte modification sequence is required to program the new value.

Changing security option bytes

On top of OPTLOCK bit, there is a second level of protection for security-sensitive option byte fields. Specific rules must be followed to update them:

- **Readout protection (RDP)**
  A detailed description of RDP option bits is given in Section 3.5.3. The following rules must be respected to modify these option bits:
  - When RDP is set to level 2, no changes are allowed (except for the SWAP bit). As a result, if the user application attempts to reduce the RDP level, an option byte change error is raised (OPTCHANGEERR bit in FLASH_OPSR_CUR register), and all the programmed changes are ignored.
  - When the RDP is set to level 1, requiring a change to level 2 is always allowed. When requiring a regression to level 0, an option byte change error can occur if some of the recommendations provided in this chapter have not been followed.
  - When the RDP is set to level 0, switching to level 1 or level 2 is possible without any restriction.

- **Sector write protection (WRPSn1/2)**
  These option bytes manage sector write protection in FLASH_WPSN_CUR1/2R registers. They can be changed without any restriction when the RDP protection level is different from level 2.

- **PCROP area size (PROT_AREA_START1/2 and PROT_AREA_END1/2)**
  These option bytes configure the size of the PCROP areas in FLASH_PRAR_CUR1/2 registers. They can be increased without any restriction by the Arm® Cortex®-M7 core. To remove or reduce a PCROP area, an RDP level 1 to 0 regression (see Section 3.5.3) or a bank erase with protection removal (see Section 3.3.10) must be
requested at the same time. DMEP must be set to 1 in either FLASH_PRAR_CUR1/2 or FLASH_PRAR_PRG1/2, otherwise an option byte change error is raised.

- **DMEP1/2**
  
  When this option bit is set, the content of the corresponding PCROP area is erased during a RDP level 1 to 0 regression (see Section 3.5.3) or a bank erase with protection removal (see Section 3.3.10). It is preserved otherwise.

  There are no restrictions in setting DMEP1/2 bit. Resetting DMEP1/2 bit from 1 to 0 can only be done when an RDP level 1 to 0 regression or a bank erase with protection removal is requested at the same time.

- **Secure access mode (SECURITY)**
  
  The SECURITY option bit activates the secure access mode described in Section 3.5.5. This option bit can be freely set by the application software if such mode is activated on the device. If at least one PCROP or secure-only area is defined as not null, the only way to deactivate the security option bit (from 1 to 0) is to perform an RDP level 1 to 0 regression, when DMEP1/2 is set to 1 in either FLASH_PRAR_CUR1/2 or FLASH_PRAR_PRG1/2 registers, and DMES1/2 is set to 1 in either FLASH_SCAR_CUR1/2 or FLASH_SCAR_PRG1/2.

  If no valid secure-only area and no valid PCROP area are currently defined, the SECURITY option bit can be freely reset.

  **Note:** It is recommended to have both SEC_AREA_START> SEC_AREA_END and PROT_AREA_START> PROT_AREA_END programmed when deactivating the SECURITY option bit during an RDP level 1 to 0 regression.

- **Secure-only area size (SEC_AREA_START1/2 and SEC_AREA_END1/2)**
  
  These option bytes configure the size of the secure-only areas in FLASH_SCAR_CUR1/2 registers. They can be changed without any restriction by the user secure application or by the ST secure library running on the device. For user non-secure application, the secure-only area size can be removed by performing a bank erase with protection removal (see Section 3.3.10), or an RDP level 1 to 0 regression when DMES1/2 set to 1 in either FLASH_SCAR_CUR1/2 or FLASH_SCAR_PRG1/2 (otherwise an option byte change error is raised).

- **DMES1/2**
  
  When this option bit is set, the content of the corresponding secure-only area is erased during an RDP level 1 to 0 regression or a bank erase with protection removal, it is preserved otherwise.

  DMES1/2 bits can be set without any restriction. Resetting DMES1/2 bit from 1 to 0 can only be performed when an RDP level 1 to 0 regression or a bank erase with protection removal is requested at the same time.
### 3.4.4 Option bytes overview

*Table 17* lists all the user option bytes managed through the embedded Flash memory registers, as well as their default values before the first option byte change (default factory value).

3.4.5 Description of user and system option bytes

Below the list of the general-purpose option bytes that can be used by the application:

- **Watchdog management**
  - IWDG_FZ_STOP: independent watchdog (IWDG1) counter active in Stop mode if 1 (stop counting or freeze if 0)
  - IWDG_FZ_SDBY: independent watchdog (IWDG1) counter active in Standby mode if 1 (stop counting or freeze if 0)
  - IWDG1_SW: hardware (0) or software (1) IWDG1 watchdog control selection

Note: If the hardware watchdog "control selection" feature is enabled (set to 0), the watchdog is automatically enabled at power-on, thus generating a reset unless the watchdog key register is written to or the down-counter is reloaded before the end-of-count is reached.

Depending on the configuration of IWDG_STOP and IWDG_STBY options, the IWDG can continue counting (1) or not (0) when the device is in Stop or Standby mode, respectively. When the IWDG is kept running during Stop or Standby mode, it can wake up the device from these modes.

- **Reset management**
  - BOR: Brownout level option, indicating the supply level threshold that activates/releases the reset
  - NRST_STDBY_D1/2: generates a reset when D1 (respectively D2) domain enters DStandby mode. It is active low.
  - NRST_STOP_D1/2: generates a reset when D1 (respectively D2) domain enters DStop mode. It is active low.

Note: Whenever a Standby (respectively Stop) mode entry sequence is successfully executed, the device is reset instead of entering Standby (respectively Stop) mode if NRST_STDBY (respectively NRST_STOP) is cleared to 0.

- **Bank swapping** (see Section 3.3.13 on page 158)
  - SWAP_BANK_OPT: bank swapping option, set to 1 to swap user sectors and registers after boot.

- **Device options**
  - IO_HSLV: I/O speed optimization at low-voltage if set to 1.
When STMicroelectronics delivers the device, the values programmed in the general-purpose option bytes are the following:

- **Watchdog management**
  - IWDG1 active in Standby and Stop modes (option byte value = 0x1)
  - IWDG1 not automatically enabled at power-on (option byte value = 0x1)

- **Reset management:**
  - BOR: brownout level option (reset level) equals brownout reset threshold 0 (option byte value = 0x0)
  - A reset is not generated when D1 or D2 domain enters DStandby or DStop low-power mode (option byte value = 0x1)

- **No bank swapping** (option byte value = 0x0)

- **Device working in the full voltage range with I/O speed optimization at low-voltage disabled** (IO_HSLV=0)

Refer to **Section 3.9: FLASH registers** for details.

### 3.4.6 Description of data protection option bytes

Below the list of the option bytes that can be used to enhance data protection:

- **RDP[7:0]**: Readout protection level (see **Section 3.5.3 on page 172** for details).

- **WRPSn1/2**: write protection option of the corresponding Bank 1 (respectively Bank 2) sector. It is active low. Refer to **Section 3.5.4 on page 177** for details.

  - **PROT_AREAx**: Proprietary code readout protection (refer to **Section 3.5.4 on page 177** for details)
    - PROT_AREA_START1 (respectively PROT_AREA_END1) contains the first (respectively last) 256-byte block of the PCROP zone in Bank 1
    - PROT_AREA_START2 (respectively PROT_AREA_END2) contains the first (respectively last) 256-byte block of the PCROP zone in Bank 2
    - DMEP1/2: when set to 1, the PCROP area in Bank 1 (respectively Bank 2) is erased during a RDP protection level regression (change from level 1 to 0) or a bank erase with protection removal.

- **SEC_AREAx**: secure access only zones definition (refer to **Section 3.5.5 on page 178** for details).
  - SEC_AREA_START1 (respectively SEC_AREA_END1) contains the first (respectively last) 256-byte block of the secure access only zone in Bank 1
  - SEC_AREA_START2 (respectively SEC_AREA_END2) contains the first (respectively last) 256-byte block of the secure access only zone in Bank 2
  - DMES1/2: when set to 1 the secure access only zone in Bank 1 (respectively Bank 2) is erased during a RDP protection level regression (change from level 1 to 0), or a bank erase with protection removal.

- **SECURITY**: this non-volatile option can be used by the application to manage secure access mode, as described in **Section 3.5.5**.

- **ST_RAM_SIZE**: this non-volatile option defines the amount of DTCM RAM root secure services (RSS) can use during execution. The DTCM RAM is always fully available for the application whatever the option byte configuration.
When STMicroelectronics delivers the device, the values programmed in the data protection option bytes are the following:

- RDP level 0 (option byte value = 0xAA)
- Flash bank erase operations impact secure-only data areas when enabled by the application (DMES1/2=1). They do not impact PCROP data areas (DMEP1/2=0).
- PCROP and secure-only zone protections disabled (start addresses higher than end addresses)
- Write protection enabled (all option byte bits set to 1)
- Secure access mode disabled (SECURITY option byte value= 0)
- RSS can use the DTCM RAM for executing its services (ST_RAM_SIZE = 00)

Refer to Section 3.9: FLASH registers for details.

3.4.7 Description of boot address option bytes

Below the list of option bytes that can be used to configure the appropriate boot address for your application:

- BOOT_ADD0/1: MSB of the Arm® Cortex®-M7 boot address when BOOT pin is low (respectively high)

When STMicroelectronics delivers the device, the values programmed in the data protection option bytes are the following:

- Arm® Cortex®-M7 boot address (MSB): 0x0800 (BOOT pin low for user Flash memory) and 0x1FF0 (BOOT pin high for System Flash memory)

Refer to Section 3.9: FLASH registers for details.
3.5 FLASH protection mechanisms

Since sensitive information can be stored in the Flash memory, it is important to protect it against unwanted operations such as reading confidential areas, illegal programming of protected area, or illegal Flash memory erasing.

The embedded Flash memory implements the following protection mechanisms that can be used by end-user applications to manage the security of embedded non-volatile storage:

- Configuration protection
- Global device Readout protection (RDP)
- Write protection
- Proprietary code readout protection (PCROP)
- Secure access mode areas

This section provides a detailed description of all these security mechanisms.

3.5.1 FLASH configuration protection

The embedded Flash memory uses hardware mechanisms to protect the following assets against unwanted or spurious modifications (e.g. software bugs):

- Option bytes change
- Write operations
- Erase commands
- Interrupt masking

More specifically, write operations to embedded Flash memory control registers (FLASH_CR1/2 and FLASH_OPTCR) are not allowed after reset.

The following sequence must be used to unlock FLASH_CR1/2 register:
1. Program KEY1 to 0x45670123 in FLASH_KEYR1/2 key register.
2. Program KEY2 to 0xCDEF89AB in FLASH_KEYR1/2 key register.
3. LOCK1/2 bit is now cleared and FLASH_CR1/2 is unlocked.

The following sequence must be used to unlock FLASH_OPTCR register:
1. Program OPTKEY1 to 0x08192A3B in FLASH_OPTKEYR option key register.
2. Program OPTKEY2 to 0x4C5D6E7F in FLASH_OPTKEYR option key register.
3. OPTLOCK bit is now cleared and FLASH_OPTCR register is unlocked.

Any wrong sequence locks up the corresponding register/bit until the next system reset, and generates a bus error.

The FLASH_CR1/2 (respectively FLASH_OPTCR) register can be locked again by software by setting the LOCK1/2 bit in FLASH_CR1/2 register (respectively OPTLOCK bit in FLASH_OPTCR register).

In addition the FLASH_CR1/2 register remains locked and a bus error is generated when the following operations are executed:

- programming a third key value
- writing to a different register belonging to the same bank than FLASH_KEYR1/2 before FLASH_CR1/2 has been completely unlocked (KEY1 programmed but KEY2 not yet programmed)
- writing less than 32 bits to KEY1 or KEY2.
Similarly the FLASH_OPTCR register remains locked and a bus error is generated when the following operations are executed:

- programming a third key value
- writing to a different register before FLASH_OPTCR has been completely unlocked (OPTKEY1 programmed but OPTKEY2 not yet programmed)
- writing less than 32 bits to OPTKEY1 or OPTKEY2.

The embedded Flash memory configuration registers protection is summarized in Table 18.

### 3.5.2 Write protection

The purpose of embedded Flash memory write protection is to protect the embedded Flash memory against unwanted modifications of the non-volatile code and/or data.

<table>
<thead>

</tr>
</tbody>
</table>
Any 128-Kbyte Flash sector can be independently write-protected or unprotected by clearing/setting the corresponding WRPSn1/2 bit in the FLASH_WPSN_PRG1/2R register. A write-protected sector can neither be erased nor programmed. As a result, a bank erase cannot be performed if one sector is write-protected, unless a bank erase is executed during an RDP level 1 to 0 regression (see Section: Flash bank erase with automatic protection-removal sequence for details).

The embedded Flash memory write-protection user option bits can be modified without any restriction when the RDP level is set to level 0 or level 1. When it is set to level 2, the write protection bitfield can no more be changed in the option bytes.

Note: PCROP or secure-only areas are write and erase protected.

Write protection errors are documented in Section 3.7: FLASH error management.

### 3.5.3 Readout protection (RDP)

The embedded Flash memory readout protection is global as it does not apply only to the embedded Flash memory, but also to the other secured regions. This is done by using dedicated security signals.

In this section other secured regions are defined as:
- Backup SRAM
- RTC backup registers

The global readout protection level is set by writing the values given in Table 19 into the readout protection (RDP) option byte (see Section 3.4.3: Option byte modification).

<table>
<thead>
<tr>
<th>RDP option byte value</th>
<th>Global readout protection level</th>
</tr>
</thead>
<tbody>
<tr>

<td>Level 0</td>
</tr>
<tr>
<td>0xCC</td>
<td>Level 2</td>
</tr>
<tr>
<td>Any other value</td>
<td>Level 1(1)</td>
</tr>
</tbody>
</table>

1. Default protection level when RDP option byte is erased.

**Definitions of RDP global protection level**

**RDP Level 0 (no protection)**

When the global read protection level 0 is set, all read/program/erase operations from/to the user Flash memory are allowed (if no others protections are set). This is true whatever the boot configuration (boot from user or system Flash memory, boot from RAM), and whether the debugger is connected to the device or not. Accesses to the other secured regions are also allowed.

**RDP Level 1 (Flash memory content protection)**

When the global read protection level 1 is set, the below properties apply:
- The Flash memory content is protected against debugger and potential malicious code stored in RAM. Hence as soon as any debugger is connected or has been connected,
or a boot is configured in embedded RAM (intrusion), the embedded Flash memory prevents any accesses to Flash memory.

- When no intrusion is detected (no boot in RAM, no boot in System Flash memory and no debugger connected), all read/program/erase operations from/to the user Flash memory are allowed (if no others protections are set). Accesses to the other secured regions are also allowed.

- When an intrusion is detected, no accesses to the user Flash memory can be performed. A bus error is generated when a read access is requested to the Flash memory. In addition, no accesses to other secured regions (read or write) can be performed.

- When performing an RDP level regression, i.e. programming the RDP protection to level 0, the user Flash memory and the other secured regions are erased, as described in RDP protection transitions.

- When booting on STM32 bootloader in standard system memory, only the identification services are available (GET_ID_COMMAND, GET_VER_COMMAND and GET_CMD_COMMAND).

- When booting from STMicroelectronics non-secure bootloader, only the identification services are available (GET_ID_COMMAND, GET_VER_COMMAND and GET_CMD_COMMAND).

RDP Level 2 (device protection and intrusion prevention)

When the global read protection level 2 is set, the below rules apply:

- All debugging features are disabled.

- Like level 0, all read/write/erase operations from/to the user Flash memory are allowed since the debugger and the boot from RAM and System Flash memory are disabled. Accesses to the other secured regions are also allowed.

- Booting from RAM is no more allowed.

- The user option bits described in Section 3.4 can no longer be changed except for the SWAP bit.

Caution: Memory read protection level 2 is an irreversible operation. When level 2 is activated, the level of protection cannot be changed back to level 0 or level 1.

Note: The JTAG port is permanently disabled when level 2 is active (acting as a JTAG fuse). As a consequence, STMicroelectronics is not able to perform analysis on defective parts on which the level 2 protection has been set.

Apply a power-on reset if the global read protection level 2 is set while the debugger is still connected.

The above RDP global protection is summarized in Table 20.
Table 20. Protection vs RDP Level\(^{(1)}\)

</tbody>
</table>

1. R = read, W = write, E = erase.
2. PCROP (see Section 3.5.4) and secure-only access control (see Section 3.5.5) applies.
3. Read accesses to secure boot and secure libraries stored in system Flash bank 1 possible only from STMicroelectronics code.
4. The "other secured regions" are defined at the beginning of this section.
5. JTAG interface disabled while secure libraries are executed.
6. Read protection error (RDPERR) with bus error on read operations, Write protection error (WRPERR) on write/erase operations.
RDP protection transitions

*Figure 11* shows how to switch from one RDP level to another. The transition is effective after successfully writing the option bytes including RDP (refer to *Section 3.4.3* for details on how to change the option bytes).

*Figure 11. RDP protection transition scheme*

![Diagram showing RDP protection transitions]

*Table 21* details the RDP transitions and their effects on the product.

1. Except for bank swapping option bit.
When the current RDP level is RDP level 1, requesting a new RDP level 0 can cause a full or partial erase:

- The user Flash memory area of the embedded Flash memory is fully or partially erased:
  - A partial sector erase occurs if PCROP (respectively secure-only) areas are preserved by the application. It happens when both DMEP1/2 bits (respectively DMES1/2 bits) are cleared to 0 in FLASH_PRAR_CUR1/2 and FLASH_PRAR_PRG1/2 (respectively FLASH_SCAR_CUR1/2 and FLASH_SCAR_PRG1/2). The sectors belonging to the preserved area(s) are not erased.
  - A full bank erase occurs when at least one DMEP1/2 bit is set to 1 in FLASH_PRAR_CUR1/2 or FLASH_PRAR_PRG1/2, and at least one DMES1/2 bit is set to 1 in FLASH_SCAR_CUR1/2 or FLASH_SCAR_PRG1/2.

**Note:** Data in write protection area are not preserved during RDP regression.

- The other secured regions are also erased (Backup SRAM and RTC backup registers)

During a level regression, if a PCROP area overlaps with a secure-only area, the embedded Flash memory performs the erase operation depending on the DMES/DMEP options bits (see strike-through areas in red in Figure 12). More specifically:

- When DMEP is set in FLASH_PRAR_CUR1/2 or FLASH_PRAR_PRG1/2, the PCROP area is erased (overlapped or not with secure-only area).
- When DMES is set in FLASH_SCAR_CUR1/2 or FLASH_SCAR_PRG1/2, the secure-only area is erased (overlapped or not with PCROP area).

**Note:** The sector protections (PCROP, secure-only) are removed only if the protected sector boundaries are modified by the user application.

**Legend:**
- secure access only
- execute only, no data access (PCROP)

### About RDP protection errors

Whatever the RDP level, the corresponding error flag is raised when an illegal read or write access is detected (see Section 3.7: FLASH error management).
3.5.4 Proprietary code readout protection (PCROP)

The embedded Flash memory allows the definition of an “executable-only” area in the user area of each Flash memory bank. In this area, only instruction fetch transactions from the system, i.e. no data access (data or literal pool) are allowed. This protection is particularly efficient to protect third party software intellectual property.

Note: Executable-only area usage requires the native code to be compiled accordingly using “execute-only” option.

PCROP area programming

One PCROP area can be defined in bank 1 (respectively bank 2) by setting the PROT_AREA_END1 and PROT_AREA_START1 (respectively PROT_AREA_END2 and PROT_AREA_START2) option bytes so that the END address is strictly higher than the START address. PROT_AREA_START and PROT_AREA_END are defined with a granularity of 256 bytes. This means that the actual PCROP area size (in bytes) is defined by:

\[
[(\text{PROT\_AREA\_END} - \text{PROT\_AREA\_START}) + 1] \times 256
\]

As an example, to set a PCROP area on the first 4 Kbytes of user bank 1 (i.e. from address 0x0800 0000 to address 0x0800 0FFF, both included), the embedded Flash memory must be configured as follows:

- PROT\_AREA\_START1\[11:0\] = 0x000
- PROT\_AREA\_END1\[11:0\] = 0x00F

The protected area size defined above is equal to:

\[
[(\text{PROT\_AREA\_END} - \text{PROT\_AREA\_START}) + 1] \times 256 = 16 \times 256 \text{ bytes} = 4 \text{ Kbytes.}
\]

The minimum execute-only PCROP area that can be set is 16 Flash words (or 512 bytes). The maximum area is the whole user Flash memory, configured by setting to the same value the PCROP area START and END addresses.

Note: It is recommended to align the PCROP area size with the Flash sector granularity in order to avoid access right issues.

PCROP area properties

Each valid PCROP area has the following properties:

- Arm® Cortex®-M7 debug events are ignored while executing code in this area.
- Only the CPU can access it (Master ID filtering), using only instruction fetch transactions. In all other cases, accessing the PCROP area is illegal (see below).
- Illegal transactions to a PCROP area (i.e. data read or write, not fetch) are managed as below:
  - Read operations return a zero, write operations are ignored.
  - No bus error is generated but an error flag is raised (RDPERR for read, WRPERR for write).
- A valid PCROP area is erase-protected. As a result:
  - No erase operations to a sector located in this area is possible (including the sector containing the area start address and the end address)
No mass erase can be performed if a single valid PCROP area is defined, except during level regression or erase with protection removal.

- Only the CPU can modify the PCROP area definition and DMEP1/2 bits, as explained in Changing user option bytes in Section 3.4.3.
- During an RDP level 1 to 0 regression where the PCROP area is not null
  - The PCROP area content is not erased if the corresponding DMEP1/2 bit are both cleared to 0 in FLASH_PRAR_CUR1/2 and FLASH_PRAR_PRG1/2 registers.
  - The PCROP area content is erased if either of the corresponding DMEP1/2 bit is set to 1 in FLASH_PRAR_CUR1/2 or FLASH_PRAR_PRG1/2 register.

For more information on PCROP protection errors, refer to Section 3.7: FLASH error management.

### 3.5.5 Secure access mode

The embedded Flash memory allows the definition of a secure-only area in the user area of each Flash memory bank. This area can be accessed only while the CPU executes secure application code. This feature is available only if the SECURITY option bit is set to 1.

Secure-only areas help isolating secure user code from application non-secure code. As an example, they can be used to protect a customer secure firmware upgrade code, a custom secure boot library or a third party secure library.

#### Secure-only area programming

One secure-only area can be defined in bank 1 (respectively bank 2) by setting the SEC_AREA_END1 and SEC_AREA_START1 (respectively SEC_AREA_END2 and SEC_AREA_START2) option bytes so that the END address is strictly higher than the START address. SEC_AREA_START and SEC_AREA_END are defined with a granularity of 256 bytes. This means that the actual secure-only area size (in bytes) is defined by:

\[
[(SEC\_AREA\_END - SEC\_AREA\_START) + 1] \times 256
\]

As an example, to set a secure-only area on the first 8 Kbytes of user bank 2 (i.e. from address 0x0810 0000 to address 0x0810 1FFF, both included), the embedded Flash memory must be configured as follows:

- SEC_AREA_START2[11:0] = 0x000
- SEC_AREA_END2[11:0] = 0x01F

The secure-only area size defined above is equal to:

\[
[(SEC\_AREA\_END - SEC\_AREA\_START) + 1] \times 256 = 32 \times 256 \text{ bytes} = 8 \text{ Kbytes.}
\]

**Note:** These option bytes can be modified only by the CPU running ST security library or application secure code, except during RDP level regression or erase with protection removal.

The minimum secure-only area that can be set is 16 Flash words (or 512 bytes). The maximum area is the whole user Flash memory bank, configured by setting to the same value the secure-only area START and END addresses.

**Note:** It is recommended to align the secure-only area size with Flash sector granularity in order to avoid access right issues.
Secure access-only area properties

- Arm® Cortex®-M7 debug events are ignored while executing code in this area.
- Only the CPU executing ST secure library or user secure application can access it (Master ID filtering). In all other cases, accessing the secure-only area is illegal (see below).
- Illegal transactions to a secure-only area are managed as follows:
  - Data read transactions return zero. Data write transactions are ignored. No bus error is generated but an error flag is raised (RDSERR for read, WRPERR for write).
  - Read instruction transactions generate a bus error and the RDSERR error flag is raised.
- A valid secure-only area is erase-protected. As a result:
  - No erase operations to a sector located in this area are possible (including the sector containing the area start address and the end address), unless the application software is executed from a valid secure-only area.
  - No mass erase can be performed if a single valid secure-only area is defined, except during level regression, erase with protection removal or when the application software is executed from a valid secure-only area.
- Only the CPU can modify the secure-only area definition and DMES1/2 bits, as explained in Changing user option bytes in Section 3.4.3.
- During an RDP level 1 to 0 regression where the secure-only area is not null:
  - the secure-only area content is not erased if the corresponding DMES1/2 bit are both cleared to 0 in FLASH_SCAR_CUR1/2 and FLASH_SCAR_PRG1/2 registers.
  - the secure-only area content is erased if either of the corresponding DMES1/2 bit is set to 1 in FLASH_SCAR_CUR1/2 or FLASH_SCAR_PRG1/2 register.

For more information on secure-only protection errors, refer to Section 3.7: FLASH error management.

3.6 FLASH low-power modes

Introduction

The table below summarizes the behavior of the embedded Flash memory in the microcontroller low-power modes. The embedded Flash memory belongs to the D1 domain.

<table>
<thead>
<tr>
<th>System state</th>
<th>Power mode</th>
<th>D1 domain voltage range</th>
<th>Allowed if FLASH busy</th>
<th>FLASH power mode (in D1 domain)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Run</td>
<td>DRun</td>
<td>DRun, DStop or DStandby</td>
<td>VOS1/2/3</td>
<td>Yes</td>
</tr>
<tr>
<td></td>
<td>DStop, DStandby</td>
<td>DStop or DStandby</td>
<td>Off</td>
<td>No</td>
</tr>
</tbody>
</table>
When the system state changes or within a given system state, the embedded Flash memory might get a different voltage supply range (VOS) according to the application. The procedure to switch the embedded Flash memory into various power mode (run, clock gated, stopped, off) is described hereafter.

Note: For more information in the microcontroller power states, refer to the Power control section (PWR).

Managing the FLASH domain switching to DStop or DStandby

As explain in Table 22, if the embedded Flash memory informs the reset and clock controller (RCC) that it is busy (i.e. BSY1/2, QW1/2, WBNE1/2 is set), the microcontroller cannot switch the D1 domain to DStop or DStandby mode.

Note: CRC_BUSY1/2 is not taken into account.

There are two ways to release the embedded Flash memory:

- Reset the WBNE1/2 busy flag in FLASH_SR1/2 register by any of the following actions:
  a) Complete the write buffer with missing data.
  b) Force the write operation without filling the missing data by activating the FW1/2 bit in FLASH_CR1/2 register. This forces all missing data “high”.
  c) Reset the PG1/2 bit in FLASH_CR1/2 register. This disables the write buffer and consequently lead to the loss of its content.
- Poll QW1/2 busy bits in FLASH_SR1/2 register until they are cleared. This will indicate that all recorded write, erase and option change operations are complete.

The microcontroller can then switch the domain to DStop or DStandby mode.
3.7 FLASH error management

3.7.1 Introduction

The embedded Flash memory automatically reports when an error occurs during a read, program or erase operation. A wide range of errors are reported:

- Write protection error (WRPERR)
- Programming sequence error (PGSERR)
- Strobe error (STRBERR)
- Inconsistency error (INCERR)
- Operation error (OPERR)
- Error correction code error (SNECCERR/DBECCERR)
- Read protection error (RDPERR)
- Read secure error (RDSERR)
- Option byte change error (OPTCHANGEERR)

The application software can individually enable the interrupt for each error, as detailed in Section 3.8: FLASH interrupts.

Note: For some errors, the application software must clear the error flag before attempting a new operation.

Each bank has a dedicated set of error flags in order to identify which bank generated the error. They are available in Flash Status register 1 or 2 (FLASH_SR1/2).

3.7.2 Write protection error (WRPERR)

When an illegal erase/program operation is attempted to the non-volatile memory bank 1 (respectively bank 2), the embedded Flash memory sets the write protection error flag WRPERR1 (respectively WRPERR2) in FLASH_SR1 register (respectively FLASH_SR2).

An erase operation is rejected and flagged as illegal if it targets one of the following memory areas:

- A sector belonging to a valid PCROP area (even partially)
- A sector belonging to a valid secure-only area (even partially) except if the application software is executed from a valid secure-only area
- A sector write-locked with WRPSn
An program operation is ignored and flagged as illegal if it targets one of the following memory areas:

- The system Flash memory (bank 2 only) while the device is not executing ST bootloader code
- A user Flash sector belonging to a valid PCROP area while the device is not executing an ST secure library
- A user Flash sector belonging to a valid secure-only area while the device is not executing user secure code or ST secure library
- A user sector write-locked with WRPSn
- The bank 1 system Flash memory
- The user main Flash memory when RDP level is 1 and a debugger has been detected on the device, or the CPU has not booted from user Flash memory.
- A reserved area

When WRPERR1/2 flag is raised, the operation is rejected and nothing is changed in the corresponding bank. If a write burst operation was ongoing, WRPERR1/2 is raised each time a Flash word write operation is processed by the embedded Flash memory.

Note: **WRPERR1/2 flag does not block any new erase/program operation.**

Not resetting the write protection error flag (WRPERR1/2) does not generate a PGSERR error.

WRPERR1/2 flag is cleared by setting CLR_WRPERR1/2 bit to 1 in FLASH_CCR1/2 register.

If WRPERRIE1/2 bit in FLASH_CR1/2 register is set to 1, an interrupt is generated when WRPERR1/2 flag is raised (see **Section 3.8: FLASH interrupts** for details).

### 3.7.3 Programming sequence error (PGSERR)

When the programming sequence to the bank 1 (respectively bank 2) is incorrect, the embedded Flash memory sets the programming sequence error flag PGSERR1 (respectively PGSERR2) in FLASH_SR1 register (respectively FLASH_SR2).

More specifically, PGSERR1/2 flag is set if one of below conditions is met:

- A write operation is requested but the program enable bit (PG1/2) has not been set in FLASH_CR1/2 register prior to the request.
- The inconsistency error (INCERR1/2) has not been cleared to 0 before requesting a new write operation.

When PGSERR1/2 flag is raised, the current program operation is aborted and nothing is changed in the corresponding bank. The corresponding write data buffer is also flushed. If a write burst operation was ongoing, PGSERR1/2 is raised at the end of the burst.

Note: **When PGSERR1/2 flag is raised, there is a risk that the last write operation performed by the application has been lost because of the above protection mechanism. Hence it is recommended to generate interrupts on PGSERR and verify in the interrupt handler if the last write operation has been successful by reading back the value in the Flash memory.**

The PGSERR1/2 flag also blocks any new program operation. This means that PGSERR1 (respectively 2) must be cleared before starting a new program operation on bank 1 (respectively bank 2).
PGSERR1/2 flag is cleared by setting CLR_PGSERR1/2 bit to 1 in FLASH_CCR1/2 register.

If PGSERRIE1/2 bit in FLASH_CR1/2 register is set to 1, an interrupt is generated when PGSERR1/2 flag is raised. See Section 3.8: FLASH interrupts for details.

### 3.7.4 Strobe error (STRBERR)

When the application software writes several times to the same byte in bank 1 (respectively bank 2) write buffer, the embedded Flash memory sets the strobe error flag STRBERR1 (respectively STRBERR2) in FLASH_SR1 register (respectively FLASH_SR2).

When STRBERR1/2 flag is raised, the current program operation is not aborted and new byte data replace the old ones. The application can ignore the error, proceed with the current write operation and request new write operations. If a write burst was ongoing, STRBERR1/2 is raised at the end of the burst.

STRBERR1/2 flag is cleared by setting CLR_STRBERR1/2 bit to 1 in FLASH_CCR1/2 register.

If STRBERRIE1/2 bit in FLASH_CR1/2 register is set to 1, an interrupt is generated when STRBERR1/2 flag is raised. See Section 3.8: FLASH interrupts for details.

### 3.7.5 Inconsistency error (INCERR)

When a programming inconsistency to bank 1 (respectively bank 2) is detected, the embedded Flash memory sets the inconsistency error flag INCERR1 (respectively INCERR2) in register FLASH_SR1 (respectively FLASH_SR2).

More specifically, INCERR flag is set when one of the following conditions is met:

- A write operation is attempted before completion of the previous write operation, e.g.
  - The application software starts a write operation to fill the 256-bit write buffer, but sends a new write burst request to a different Flash memory address before the buffer is full.
  - One master starts a write operation, but before the buffer is full, another master starts a new write operation to the same address or to a different address.
- A wrap burst request issued by a master overlaps two or more 256-bit Flash-word addresses, i.e. wrap bursts must be done within 256-bit Flash-word address boundaries.

**Note:** INCERR flag must be cleared before starting a new write operation, otherwise a sequence error (PGSERR) is raised.

It is recommended to follow the sequence below to avoid losing data when an inconsistency error occurs:

1. Execute a handler routine when INCERR1 or INCERR2 flag is raised.
2. Stop all write requests to embedded Flash memory.
3. Verify that the write operations that have been requested just before the INCERR event have been successful by reading back the programmed values from the memory.
4. Clear the corresponding INCERR1/2 bit.
5. Restart the write operations where they have been interrupted.

INCERR1/2 flag is cleared by setting CLR_INCERR1/2 bit to 1 in FLASH_CCR1/2 register.
If INCERRIE1/2 bit in FLASH_CR1/2 register is set to 1, an interrupt is generated when INCERR1/2 flag is raised (see Section 3.8: FLASH interrupts for details).

### 3.7.6 Operation error (OPERR)

When an error occurred during a write or an erase operation to bank 1 (respectively bank 2), the embedded Flash memory sets the operation error flag OPERR1 (respectively OPERR2) in FLASH_SR1 register (respectively FLASH_SR2). This error may be caused by an incorrect non-volatile memory behavior due to cycling issues or to a previous modify operation stopped by a system reset.

When OPERR1/2 flag is raised, the current program/erase operation is aborted.

OPERR1/2 flag is cleared by setting CLR_OPERR1/2 bit to 1 in FLASH_CCR1/2 register.

If OPERRIE1/2 bit in FLASH_CR1/2 register is set to 1, an interrupt is generated when OPERR1/2 flag is raised (see Section 3.8: FLASH interrupts for details).

### 3.7.7 Error correction code error (SNECCERR/DBECCERR)

When a single error correction is detected during a read from bank 1 (respectively bank 2) the embedded Flash memory sets the single error correction flag SNECCERR1 (respectively SNECCERR2) in FLASH_SR1 register (respectively FLASH_SR2).

When two ECC errors are detected during a read to bank 1 (respectively bank 2), the embedded Flash memory sets the double error detection flag DBECCERR1 (respectively DBECCERR2) in FLASH_SR1 register (respectively FLASH_SR2). When SNECCERR1/2 flag is raised, the corrected read data are returned. Hence the application can ignore the error and request new read operations.

If a read burst operation was ongoing, SNECCERR1/2 or DBECCERR1/2 flag is raised each time a new data is sent back to the requester through the AXI interface.

When SNECCERR1/2 or DBECCERR1/2 flag is raised, the address of the Flash word that generated the error is saved in the FLASH_ECC_FA1/2R register. This register is automatically cleared when the associated flag that generated the error is reset.

Note: In case of successive single correction or double detection errors, only the address corresponding to the first error is stored in FLASH_ECC_FA1/2R register.

When DBECCERR1/2 flag is raised, a bus error is generated. In case of successive double error detections, a bus error is generated each time a new data is sent back to the requester through the AXI interface.

Note: It is not mandatory to clear SNECCERR1/2 or DBECCERR1/2 flags before starting a new read operation.

SNECCERR1/2 (respectively DBECCERR1/2) flag is cleared by setting to 1 CLR_SNECCERR1/2 bit (respectively CLR_DBECCERR1/2 bit) in FLASH_CCR1/2 register.

If SNECCERR1/2 (respectively DBECCERR1/2) bit in FLASH_CR1/2 register is set to 1, an interrupt is generated when SNECCERR1/2 (respectively DBECCERR1/2) flag is raised. See Section 3.8: FLASH interrupts for details.
3.7.8 Read protection error (RDPERR)

When a read operation to a PCROP, a secure-only or a RDP protected area is attempted in non-volatile memory bank 1 (respectively bank 2), the embedded Flash memory sets the read protection error flag RDPERR1 (respectively RDPERR2) in FLASH_SR1 register (respectively FLASH_SR2).

When RDPERR1/2 flag is raised, the current read operation is aborted but the application can request new read operations. If a read burst was ongoing, RDPERR1/2 is raised each time a data is sent back to the requester through the AXI interface.

Note: A bus error is raised if a standard application attempts to execute on a secure-only or a RDP protected area.

RDPERR1/2 flag is cleared by setting CLR_RDPERR1/2 bit to 1 in FLASH_CCR1/2 register.

If RDPERRIE1/2 bit in FLASH_CR1/2 register is set to 1, an interrupt is generated when RDPERR1/2 flag is raised (see Section 3.8: FLASH interrupts for details).

3.7.9 Read secure error (RDSERR)

When a read operation is attempted to a secure address in bank 1 (respectively bank 2), the embedded Flash memory sets the read secure error flag RDSERR1 (respectively RDSERR2) in FLASH_SR1 register (respectively FLASH_SR2). For more information, refer to Section 3.5.5: Secure access mode.

When RDSERR1/2 flag is raised, the current read operation is aborted and the application can request new read operations. If a read burst was ongoing, RDSERR1/2 is raised each time a data is sent back to the requester through the AXI interface.

Note: The bus error is raised only if the illegal access is due to an instruction fetch.

RDSERR1/2 flag is cleared by setting CLR_RDSERR1/2 bit to 1 in FLASH_CCR1/2 register.

If RDSERRIE1/2 bit in FLASH_CR1/2 register is set to 1, an interrupt is generated when RDSERR1/2 flag is raised (see Section 3.8: FLASH interrupts for details).

3.7.10 Option byte change error (OPTCHANGEERR)

When the embedded Flash memory finds an error during an option change operation, it aborts the operation and sets the option byte change error flag OPTCHANGEERR in FLASH_OPSR_CUR register.

OPTCHANGEERR flag is cleared by setting CLR_OPTCHANGEERR bit to 1 in FLASH_OPTCCR register.

If OPTCHANGEERRIE bit in FLASH_OPTCR register is set to 1, an interrupt is generated when OPTCHANGEERR flag is raised (see Section 3.8: FLASH interrupts for details).
3.7.11 Miscellaneous HardFault errors

The following events generate a bus error on the corresponding bus interface:

- On AXI system bus:
  - accesses to user Flash memory while RDP is set to 1 and an illegal condition is detected (boot from system Flash memory, boot from RAM, or debugger connected)
  - fetching to secure-only user Flash memory without the correct access rights
- On AHB configuration bus:
  - wrong key input to FLASH_KEYR1/2 or FLASH_OPTKEYR

3.8 FLASH interrupts

The embedded Flash memory can generate a maskable interrupt to signal the following events on a given bank:

- Read and write errors (see Section 3.7: FLASH error management)
  - Single ECC error correction during read operation
  - Double ECC error detection during read operation
  - Write inconsistency error
  - Bad programming sequence
  - Strobe error during write operations
  - Non-volatile memory write/erase error (due to cycling issues)
  - option change operation error
- Security errors (see Section 3.7: FLASH error management)
  - Write protection error
  - Read protection error
  - Read secure error
  - CRC computation on PCROP or secure-only area error
- Miscellaneous events (described below)
  - End of programming
  - CRC computation complete

These multiple sources are combined into a single interrupt signal, flash_it, which is the only interrupt signal from the embedded Flash memory that drives the NVIC (nested vectored interrupt controller).

You can individually enable or disable embedded Flash memory interrupt sources by changing the mask bits in the FLASH_CR1/2 register. Setting the appropriate mask bit to 1 enables the interrupt.

Note: Prior to writing, FLASH_CR1/2 register must be unlocked as explained in Section 3.5.1: FLASH configuration protection

Table 23 gives a summary of the available embedded Flash memory interrupt features. As mentioned in the table below, some flags need to be cleared before a new operation is triggered.
The status of the individual maskable interrupt sources described in Table 23 (except for option byte error) can be read from the FLASH_SR1/2 register. They can be cleared by setting to 1 the adequate bit in FLASH_CCR1/2 register.

**Note:** No unlocking mechanism is required to clear an interrupt.
End-of-program event

Setting the end-of-operation interrupt enable bit (EOPIE1/2) in the FLASH_CR1/2 register enables the generation of an interrupt at the end of an erase operation, a program operation or an option byte change on bank 1/2. The EOP1/2 bit in the FLASH_SR1/2 register is also set when one of these events occurs.

Setting CLR_EOP1/2 bit to 1 in FLASH_CCR1/2 register clears EOP1/2 flag.

CRC end of calculation event

Setting the CRC end-of-calculation interrupt enable bit (CRCENDIE1/2) in the FLASH_CR1/2 register enables the generation of an interrupt at the end of a CRC operation on bank 1/2. The CRCEND1/2 bit in the FLASH_SR1/2 register is also set when this event occurs.

Setting CLR_CRCEND1/2 bit to 1 in FLASH_CCR1/2 register clears CRCEND1/2 flag.
3.9 FLASH registers

3.9.1 FLASH access control register (FLASH_ACR)

Address offset: 0x000 or 0x100
Reset value: 0x0000 0037

For more details, refer to Section 3.3.8: FLASH read operations and Section 3.3.9: FLASH program operations.

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:4 WRHIGHFREQ: Flash signal delay
These bits are used to control the delay between non-volatile memory signals during programming operations. The application software has to program them to the correct value depending on the embedded Flash memory interface frequency. Please refer to Table 13 for details.

Note: No check is performed by hardware to verify that the configuration is correct.

Bits 3:0 LATENCY: Read latency
These bits are used to control the number of wait states used during read operations on both non-volatile memory banks. The application software has to program them to the correct value depending on the embedded Flash memory interface frequency and voltage conditions.

0000: zero wait state used to read a word from non-volatile memory
0001: one wait state used to read a word from non-volatile memory
0010: two wait states used to read a word from non-volatile memory
... 0100: four wait states used to read a word from non-volatile memory

Note: No check is performed by hardware to verify that the configuration is correct.

3.9.2 FLASH key register for bank 1 (FLASH_KEYR1)

Address offset: 0x004
Reset value: 0x0000 0000

FLASH_KEYR1 is a write-only register. The following values must be programmed consecutively to unlock FLASH_CR1 register:

1. 1st key = 0x4567 0123
2. 2nd key = 0xCDEF 89AB
3.9.3 **FLASH option key register (FLASH_OPTKEYR)**

Address offset: 0x008 or 0x108

Reset value: 0x0000 0000

FLASH_OPTKEYR is a write-only register. The following values must be programmed consecutively to unlock FLASH_OPTCR register:

1. 1st key = 0x0819 2A3B
2. 2nd key = 0x4C5D 6E7F

Bits 31:0 **KEY1R**: Non-volatile memory bank 1 configuration access unlock key

3.9.4 **FLASH control register for bank 1 (FLASH_CR1)**

Address offset: 0x00C

Reset value: 0x0000 0031
Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **CRCENDIE1**: Bank 1 CRC end of calculation interrupt enable bit

When CRCENDIE1 bit is set to 1, an interrupt is generated when the CRC computation has completed on bank 1. CRCENDIE1 can be programmed only when LOCK1 is cleared to 0.

- 0: no interrupt generated when CRC computation complete on bank 1
- 1: interrupt generated when CRC computation complete on bank 1

Bit 26 **DBECCERRIE1**: Bank 1 ECC double detection error interrupt enable bit

When DBECCERRIE1 bit is set to 1, an interrupt is generated when an ECC double detection error occurs during a read operation from bank 1. DBECCERRIE1 can be programmed only when LOCK1 is cleared to 0.

- 0: no interrupt generated when an ECC double detection error occurs on bank 1
- 1: interrupt generated if an ECC double detection error occurs on bank 1

Bit 25 **SNECCERRIE1**: Bank 1 ECC single correction error interrupt enable bit

When SNECCERRIE1 bit is set to 1, an interrupt is generated when an ECC single correction error occurs during a read operation from bank 1. SNECCERRIE1 can be programmed only when LOCK1 is cleared to 0.

- 0: no interrupt generated when an ECC single correction error occurs on bank 1
- 1: interrupt generated when an ECC single correction error occurs on bank 1

Bit 24 **RDSERRIE1**: Bank 1 secure error interrupt enable bit

When RDSERRIE1 bit is set to 1, an interrupt is generated when a secure error (access to a secure-only protected address) occurs during a read operation from bank 1. RDSERRIE1 can be programmed only when LOCK1 is cleared to 0.

- 0: no interrupt generated when a secure error occurs on bank 1
- 1: an interrupt is generated when a secure error occurs on bank 1

Bit 23 **RDPERRIE1**: Bank 1 read protection error interrupt enable bit

When RDPERRIE1 bit is set to 1, an interrupt is generated when a read protection error occurs (access to an address protected by PCROP or by RDP level 1) during a read operation from bank 1. RDPERRIE1 can be programmed only when LOCK1 is cleared to 0.

- 0: no interrupt generated when a read protection error occurs on bank 1
- 1: an interrupt is generated when a read protection error occurs on bank 1

Bit 22 **OPERRIE1**: Bank 1 write/erase error interrupt enable bit

When OPERRIE1 bit is set to 1, an interrupt is generated when an error is detected during a write/erase operation to bank 1. OPERRIE1 can be programmed only when LOCK1 is cleared to 0.

- 0: no interrupt generated when a write/erase error occurs on bank 1
- 1: interrupt generated when a write/erase error occurs on bank 1

Bit 21 **INCERRIE1**: Bank 1 inconsistency error interrupt enable bit

When INCERRIE1 bit is set to 1, an interrupt is generated when an inconsistency error occurs during a write operation to bank 1. INCERRIE1 can be programmed only when LOCK1 is cleared to 0.

- 0: no interrupt generated when a inconsistency error occurs on bank 1
- 1: interrupt generated when a inconsistency error occurs on bank 1

Bit 20 Reserved, must be kept at reset value.
Bit 19 **STRBERRIE1**: Bank 1 strobe error interrupt enable bit
When STRBERRIE1 bit is set to 1, an interrupt is generated when a strobe error occurs (the master programs several times the same byte in the write buffer) during a write operation to bank 1. STRBERRIE1 can be programmed only when LOCK1 is cleared to 0.
0: no interrupt generated when a strobe error occurs on bank 1
1: interrupt generated when strobe error occurs on bank 1.

Bit 18 **PGSERRIE1**: Bank 1 programming sequence error interrupt enable bit
When PGSERRIE1 bit is set to 1, an interrupt is generated when a sequence error occurs during a program operation to bank 1. PGSERRIE1 can be programmed only when LOCK1 is cleared to 0.
0: no interrupt generated when a sequence error occurs on bank 1
1: interrupt generated when sequence error occurs on bank 1.

Bit 17 **WRPERRIE1**: Bank 1 write protection error interrupt enable bit
When WRPERRIE1 bit is set to 1, an interrupt is generated when a protection error occurs during a program operation to bank 1. WRPERRIE1 can be programmed only when LOCK1 is cleared to 0.
0: no interrupt generated when a protection error occurs on bank 1
1: interrupt generated when a protection error occurs on bank 1.

Bit 16 **EOPIE1**: Bank 1 end-of-program interrupt control bit
Setting EOPIE1 bit to 1 enables the generation of an interrupt at the end of a program operation to bank 1. EOPIE1 can be programmed only when LOCK1 is cleared to 0.
0: no interrupt generated at the end of a program operation to bank 1.
1: interrupt enabled when at the end of a program operation to bank 1.

Bit 15 **CRC_EN**: Bank 1 CRC control bit
Setting CRC_EN bit to 1 enables the CRC calculation on bank 1. CRC_EN does not start CRC calculation but enables CRC configuration through FLASH_CRCCR1 register.
When CRC calculation is performed on bank 1, it can only be disabled by setting CRC_EN bit to 0. Resetting CRC_EN clears CRC configuration and resets the content of FLASH_CRCDATAR register.
Clearing CRC_EN to 0 sets CRCDATA to 0x0.
CRC_EN can be programmed only when LOCK1 is cleared to 0.

Bit 14 Reserved, must be kept at reset value.

Bits 13:11 Reserved, must be kept at reset value.

Bits 10:8 **SNB1**: Bank 1 sector erase selection number
These bits are used to select the target sector for a sector erase operation (they are unused otherwise). SNB1 can be programmed only when LOCK1 is cleared to 0.
000: sector 0 of bank 1
001: sector 1 of bank 1
...
111: sector 7 of bank 1

Bit 7 **START1**: Bank 1 erase start control bit
START1 bit is used to start a sector erase or a bank erase operation. START1 can be programmed only when LOCK1 is cleared to 0.
The embedded Flash memory resets START1 when the corresponding operation has been acknowledged. The user application cannot access any embedded Flash memory register until the operation is acknowledged.
Bit 6  **FW1**: Bank 1 write forcing control bit

FW1 forces a write operation even if the write buffer is not full. In this case all bits not written are set to 1 by hardware. FW1 can be programmed only when LOCK1 is cleared to 0. The embedded Flash memory resets FW1 when the corresponding operation has been acknowledged. The user application cannot access any embedded Flash memory register until the operation is acknowledged.

*Note*: Using a force-write operation prevents the application from updating later the missing bits with something else than 1, because it is likely that it will lead to permanent ECC error.

Write forcing is effective only if the write buffer is not empty (in particular, FW1 does not start several write operations when the force-write operations are performed consecutively).

Bits 5:4  **PSIZE1**: Bank 1 program size

PSIZE1 selects the parallelism used by the non-volatile memory during write and erase operations to bank 1. PSIZE1 can be programmed only when LOCK1 is cleared to 0.

00: programming executed with byte parallelism
01: programming executed with half-word parallelism
10: programming executed with word parallelism
11: programming executed with double word parallelism

Bit 3  **BER1**: Bank 1 erase request

Setting BER1 bit to 1 requests a bank erase operation on bank 1 (user Flash memory only). BER1 can be programmed only when LOCK1 is cleared to 0.

BER1 has a higher priority than SER1: if both are set, the embedded Flash memory executes a bank erase.

0: bank erase not requested on bank 1
1: bank erase requested on bank 1

*Note*: Write protection error is triggered when a bank erase is required and some sectors are protected.
Bit 2  **SER1**: Bank 1 sector erase request  
Setting SER1 bit to 1 requests a sector erase on bank 1. SER1 can be programmed only when LOCK1 is cleared to 0.  
BER1 has a higher priority than SER1: if both bits are set, the embedded Flash memory executes a bank erase.  
0: sector erase not requested on bank 1  
1: sector erase requested on bank 1  
*Note*: **Write protection error is triggered when a sector erase is required on a protected sector.**

Bit 1  **PG1**: Bank 1 internal buffer control bit  
Setting PG1 bit to 1 enables internal buffer for write operations to bank 1. This allows preparing program operations even if a sector or bank erase is ongoing.  
PG1 can be programmed only when LOCK1 is cleared to 0. When PG1 is reset, the internal buffer is disabled for write operations to bank 1, and all the data stored in the buffer but not sent to the operation queue are lost.  
0: Internal buffer disabled for write operations to bank 1  
1: Internal buffer enabled for write operations to bank 1

Bit 0  **LOCK1**: Bank 1 configuration lock bit  
This bit locks the FLASH_CR1 register. The correct write sequence to FLASH_KEYR1 register unlocks this bit. If a wrong sequence is executed, or if the unlock sequence to FLASH_KEYR1 is performed twice, this bit remains locked until the next system reset.  
LOCK1 can be set by programming it to 1. When set to 1, a new unlock sequence is mandatory to unlock it. When LOCK1 changes from 0 to 1, the other bits of FLASH_CR1 register do not change.  
0: FLASH_CR1 register unlocked  
1: FLASH_CR1 register locked
3.9.5 **FLASH status register for bank 1 (FLASH_SR1)**

Address offset: 0x010
Reset value: 0x0000 0000

Bits 31:28 Reserved, must be kept at reset value.

**Bit 27 CRCEND1**: Bank 1 CRC end of calculation flag
CRCEND1 bit is raised when the CRC computation has completed on bank 1. An interrupt is generated if CRCENDIE1 is set to 1. It is not necessary to reset CRCEND1 before restarting CRC computation. Writing 1 to CLR_CRCEND1 bit in FLASH_CCR1 register clears CRCEND1.
0: CRC computation not complete on bank 1
1: CRC computation complete on bank 1

**Bit 26 DBECCERR1**: Bank 1 ECC double detection error flag
DBECCERR1 flag is raised when an ECC double detection error occurs during a read operation from bank 1. An interrupt is generated if DBECCERRIE1 is set to 1. Writing 1 to CLR_DBECCERR1 bit in FLASH_CCR1 register clears DBECCERR1.
0: no ECC double detection error occurred on bank 1
1: ECC double detection error occurred on bank 1

**Bit 25 SNECCERR1**: Bank 1 single correction error flag
SNECCERR1 flag is raised when an ECC single correction error occurs during a read operation from bank 1. An interrupt is generated if SNECCERRIE1 is set to 1. Writing 1 to CLR_SNECCERR1 bit in FLASH_CCR1 register clears SNECCERR1.
0: no ECC single correction error occurs on bank 1
1: ECC single correction error occurs on bank 1

**Bit 24 RDSERR1**: Bank 1 secure error flag
RDSERR1 flag is raised when a read secure error (read access to a secure-only protected word) occurs on bank 1. An interrupt is generated if RDSERRIE1 is set to 1. Writing 1 to CLR_RDSERR1 bit in FLASH_CCR1 register clears RDSERR1.
0: no secure error occurs on bank 1
1: a secure error occurs on bank 1

**Bit 23 RDPERR1**: Bank 1 read protection error flag
RDPERR1 flag is raised when an read protection error (read access to a PCROP-protected or a RDP-protected area) occurs on bank 1. An interrupt is generated if RDPERRIE1 is set to 1. Writing 1 to CLR_RDPERR1 bit in FLASH_CCR1 register clears RDPERR1.
0: no read protection error occurs on bank 1
1: a read protection error occurs on bank 1
Bit 22  **OPERR1**: Bank 1 write/erase error flag

OPERR1 flag is raised when an error occurs during a write/erase to bank 1. An interrupt is generated if OPERRIE1 is set to 1. Writing 1 to CLR_OPERR1 bit in FLASH_CCR1 register clears OPERR1.

0: no write/erase error occurs on bank 1
1: a write/erase error occurs on bank 1

Bit 21  **INCERR1**: Bank 1 inconsistency error flag

INCERR1 flag is raised when an inconsistency error occurs on bank 1. An interrupt is generated if INCERRIE1 is set to 1. Writing 1 to CLR_INCERR1 bit in the FLASH_CCR1 register clears INCERR1.

0: no inconsistency error occurs on bank 1
1: a inconsistency error occurs on bank 1

Bit 20  Reserved, must be kept at reset value.

Bit 19  **STRBERR1**: Bank 1 strobe error flag

STRBERR1 flag is raised when a strobe error occurs on bank 1 (when the master attempts to write several times the same byte in the write buffer). An interrupt is generated if the STRBERRIE1 bit is set to 1. Writing 1 to CLR_STRBERR1 bit in FLASH_CCR1 register clears STRBERR1.

0: no strobe error occurs on bank 1
1: a strobe error occurs on bank 1

Bit 18  **PGSERR1**: Bank 1 programming sequence error flag

PGSERR1 flag is raised when a sequence error occurs on bank 1. An interrupt is generated if the PGSERRIE1 bit is set to 1. Writing 1 to CLR_PGSERR1 bit in FLASH_CCR1 register clears PGSERR1.

0: no sequence error occurs on bank 1
1: a sequence error occurs on bank 1

Bit 17  **WRPERR1**: Bank 1 write protection error flag

WRPERR1 flag is raised when a protection error occurs during a program operation to bank 1. An interrupt is also generated if the WRPERRIE1 is set to 1. Writing 1 to CLR_WRPERR1 bit in FLASH_CCR1 register clears WRPERR1.

0: no write protection error occurs on bank 1
1: a write protection error occurs on bank 1

Bit 16  **EOP1**: Bank 1 end-of-program flag

EOP1 flag is set when a programming operation to bank 1 completes. An interrupt is generated if the EOPIE1 is set to 1. It is not necessary to reset EOP1 before starting a new operation. EOP1 bit is cleared by writing 1 to CLR_EOP1 bit in FLASH_CCR1 register.

0: no programming operation completed on bank 1
1: a programming operation completed on bank 1

Bits 15:4  Reserved, must be kept at reset value.

Bit 3  **CRC_BUSY1**: Bank 1 CRC busy flag

CRC_BUSY1 flag is set when a CRC calculation is ongoing on bank 1. This bit cannot be forced to 0. The user must wait until the CRC calculation has completed or disable CRC computation on bank 1.

0: no CRC calculation ongoing on bank 1
1: CRC calculation ongoing on bank 1
Bit 2  **QW1**: Bank 1 wait queue flag

QW1 flag is set when a write, erase or option byte change operation is pending in the command queue buffer of bank 1. It is not possible to know what type of programming operation is present in the queue.

This flag is reset by hardware when all write, erase or option byte change operations have been executed and thus removed from the waiting queue(s). This bit cannot be forced to 0. It is reset after a deterministic time if no other operations are requested.

0: no write, erase or option byte change operations waiting in the operation queues of bank 1
1: at least one write, erase or option byte change operation is waiting in the operation queue of bank 1

Bit 1  **WBNE1**: Bank 1 write buffer not empty flag

WBNE1 flag is set when the embedded Flash memory is waiting for new data to complete the write buffer. In this state, the write buffer is not empty. WBNE1 is reset by hardware each time the write buffer is complete or the write buffer is emptied following one of the event below:

- the application software forces the write operation using FW1 bit in FLASH_CR1
- the embedded Flash memory detects an error that involves data loss
- the application software has disabled write operations in this bank

This bit cannot be forced to 0. To reset it, clear the write buffer by performing any of the above listed actions, or send the missing data.

0: write buffer of bank 1 empty or full
1: write buffer of bank 1 waiting data to complete

Bit 0  **BSY1**: Bank 1 busy flag

BSY1 flag is set when an effective write, erase or option byte change operation is ongoing on bank 1. It is not possible to know what type of operation is being executed.

BSY1 cannot be forced to 0. It is automatically reset by hardware every time a step in a write, erase or option byte change operation completes.

0: no programming, erase or option byte change operation being executed on bank 1
1: programming, erase or option byte change operation being executed on bank 1
3.9.6 FLASH clear control register for bank 1 (FLASH_CCR1)

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **CLR_CRCEND1**: Bank 1 CRCEND1 flag clear bit
Setting this bit to 1 resets to 0 CRCEND1 flag in FLASH_SR1 register.

Bit 26 **CLR_DBECCERR1**: Bank 1 DBECCERR1 flag clear bit
Setting this bit to 1 resets to 0 DBECCERR1 flag in FLASH_SR1 register. If the SNECCERR1 flag of FLASH_SR1 register is cleared to 0, FLASH_ECC_FA1R register is reset to 0 as well.

Bit 25 **CLR_SNECCERR1**: Bank 1 SNECCERR1 flag clear bit
Setting this bit to 1 resets to 0 SNECCERR1 flag in FLASH_SR1 register. If the DBECCERR1 flag of FLASH_SR1 register is cleared to 0, FLASH_ECC_FA1R register is reset to 0 as well.

Bit 24 **CLR_RDSERR1**: Bank 1 RDSERR1 flag clear bit
Setting this bit to 1 resets to 0 RDSERR1 flag in FLASH_SR1 register.

Bit 23 **CLR_RDPERR1**: Bank 1 RDPERR1 flag clear bit
Setting this bit to 1 resets to 0 RDPERR1 flag in FLASH_SR1 register.

Bit 22 **CLR_OPERR1**: Bank 1 OPERR1 flag clear bit
Setting this bit to 1 resets to 0 OPERR1 flag in FLASH_SR1 register.

Bit 21 **CLR_INCERR1**: Bank 1 INCERR1 flag clear bit
Setting this bit to 1 resets to 0 INCERR1 flag in FLASH_SR1 register.

Bit 20 Reserved, must be kept at reset value.

Bit 19 **CLR_STRBERR1**: Bank 1 STRBERR1 flag clear bit
Setting this bit to 1 resets to 0 STRBERR1 flag in FLASH_SR1 register.

Bit 18 **CLR_PGSERR1**: Bank 1 PGSERR1 flag clear bit
Setting this bit to 1 resets to 0 PGSERR1 flag in FLASH_SR1 register.
Bit 17 CLR_WRPERR1: Bank 1 WRPERR1 flag clear bit
   Setting this bit to 1 resets to 0 WRPERR1 flag in FLASH_SR1 register.

Bit 16 CLR_EOP1: Bank 1 EOP1 flag clear bit
   Setting this bit to 1 resets to 0 EOP1 flag in FLASH_SR1 register.

Bits 15:0 Reserved, must be kept at reset value.

Bit 31 **SWAP_BANK**: Bank swapping option configuration bit
   SWAP_BANK controls whether bank 1 and bank 2 are swapped or not. This bit is loaded with
   the SWAP_BANK_OPT bit of FLASH_OPTSR_CUR register only after reset or POR.
   0: bank 1 and bank 2 not swapped
   1: bank 1 and bank 2 swapped
   **Note**: The Flash bank swapping is not available on STM32H750xB devices. The
   SWAP_BANK option bit must be kept to '0'.

Bit 30 **OPTCHANGEERRIE**: Option byte change error interrupt enable bit
   OPTCHANGEERRIE bit controls if an interrupt has to be generated when an error occurs
   during an option byte change.
   0: no interrupt is generated when an error occurs during an option byte change
   1: an interrupt is generated when and error occurs during an option byte change.

Bits 29:5 Reserved, must be kept at reset value.

Bit 4 **MER**: mass erase request
   Setting this bit launches a non-volatile memory bank erase on both banks (i.e. mass erase).
   Programming MER bit to 1 automatically sets BER1, BER2, START1 and START2 to 1.
   FLASH_OPTCR, FLASH_CR1 and FLASH_CR2 must be unlocked prior to setting MER
   high.
Bits 3:2  Reserved, must be kept at reset value.

Bit 1  **OPTSTART**: Option byte start change option configuration bit

OPTSTART triggers an option byte change operation. The user can set OPTSTART only when the OPTLOCK bit is cleared to 0. The embedded Flash memory resets OPTSTART when the option byte change operation has been acknowledged.

The user application cannot modify any embedded Flash memory register until the option change operation has been completed.

Before setting this bit, the user has to write the required values in the FLASH Xxx PRG registers. The FLASH Xxx PRG registers will be locked until the option byte change operation has been executed in non-volatile memory.

It is not possible to start an option byte change operation if a CRC calculation is ongoing on bank 1 or bank 2. Trying to set OPTSTART when CRC_BUSY1/2 of FLASH SR1/2 register is set has no effect; the option byte change does not start and no error is generated.

Bit 0  **OPTLOCK**: FLASH_OPTCR lock option configuration bit

The OPTLOCK bit locks the FLASH_OPTCR register as well as all _PRG registers. The correct write sequence to FLASH_OPTKEYR register unlocks this bit. If a wrong sequence is executed, or the unlock sequence to FLASH_OPTKEYR is performed twice, this bit remains locked until next system reset.

It is possible to set OPTLOCK by programming it to 1. When set to 1, a new unlock sequence is mandatory to unlock it. When OPTLOCK changes from 0 to 1, the others bits of FLASH_OPTCR register do not change.

0: FLASH_OPTCR register unlocked
1: FLASH_OPTCR register locked.

### 3.9.8 FLASH option status register (FLASH_OPTSR_CUR)

Address offset: 0x01C or 0x11C

Reset value: 0xXXXX XXXX (see *Table 17: Option byte organization*).

This read-only register reflects the current values of corresponding option bits.
Bit 31 **SWAP_BANK_OPT**: Bank swapping option status bit

SWAP_BANK_OPT reflects whether bank 1 and bank 2 are swapped or not.

SWAP_BANK_OPT is loaded to SWAP_BANK of FLASH_OPTCR after a reset.

0: bank 1 and bank 2 not swapped
1: bank 1 and bank 2 swapped

*Note:* The Flash bank swapping is not available on STM32H750xB devices. The SWAP_BANK option bit must be kept to '0'.

Bit 30 **OPTCHANGEERR**: Option byte change error flag

OPTCHANGEERR flag indicates that an error occurred during an option byte change operation. When OPTCHANGEERR is set to 1, the option byte change operation did not successfully complete. An interrupt is generated when this flag is raised if the OPTCHANGEERRIE bit of FLASH_OPTCR register is set to 1.

Writing 1 to CLR_OPTCHANGEERR of register FLASH_OPTCCR clears OPTCHANGEERR.

0: no option byte change errors occurred
1: one or more errors occurred during an option byte change operation.

Bit 29 **IO_HSLV**: I/O high-speed at low-voltage status bit

This bit indicates that the product operates below 2.5 V.

0: Product working in the full voltage range, I/O speed optimization at low-voltage disabled
1: Product operating below 2.5 V, I/O speed optimization at low-voltage feature allowed

Bits 28:26 Reserved, must be kept at reset value.

Bits 25:24 Reserved, must be kept at reset value.

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **SECURITY**: Security enable option status bit

0: Security feature disabled
1: Security feature enabled.

Bits 20:19 **ST_RAM_SIZE[1:0]**: ST RAM size option status

00: 2 Kbytes reserved to ST code
01: 4 Kbytes reserved to ST code
10: 8 Kbytes reserved to ST code
11: 16 Kbytes reserved to ST code

*Note:* This bitfield is effective only when the security is enabled (**SECURITY = 1**).

Bit 18 **IWDG_FZ_SDBY**: IWDG Standby mode freeze option status bit

When set the independent watchdog IWDG1 is frozen in system Standby mode.

0: Independent watchdog frozen in Standby mode
1: Independent watchdog keep running in Standby mode.

Bit 17 **IWDG_FZ_STOP**: IWDG Stop mode freeze option status bit

When set the independent watchdog IWDG1 is in system Stop mode.

0: Independent watchdog frozen in system Stop mode
1: Independent watchdog keep running in system Stop mode.

Bit 16 Reserved, must be kept at reset value.
Bits 15:8 **RDP**: Readout protection level option status byte  
0xAA: global readout protection level 0  
0xCC: global readout protection level 2  
others values: global readout protection level 1.

Bit 7 **NRST_STDY_D1**: D1 domain DStandby entry reset option status bit  
0: a reset is generated when entering DStandby mode on D1 domain  
1: no reset generated when entering DStandby mode on D1 domain.

Bit 6 **NRST_STOP_D1**: D1 domain DStop entry reset option status bit  
0: a reset is generated when entering DStop mode on D1 domain  
1: no reset generated when entering DStop mode on D1 domain.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **IWDG1_SW**: IWDG1 control mode option status bit  
0: IWDG1 watchdog is controlled by hardware  
1: IWDG1 watchdog is controlled by software

Bits 3:2 **BOR_LEV**: Brownout level option status bit  
These bits reflects the power level that generates a system reset.  
00: $V_{\text{BOR}_0}$, brownout reset threshold 0  
01: $V_{\text{BOR}_1}$, brownout reset threshold 1  
02: $V_{\text{BOR}_2}$, brownout reset threshold 2  
03: $V_{\text{BOR}_3}$, brownout reset threshold 3  
*Note: Refer to device datasheet for the values of $V_{\text{BOR}_x}$, $V_{\text{DD}}$ reset thresholds.*

Bit 1 Reserved, must be kept at reset value.

Bit 0 **OPT_BUSY**: Option byte change ongoing flag  
OPT_BUSY indicates if an option byte change is ongoing. When this bit is set to 1, the embedded Flash memory is performing an option change and it is not possible to modify any embedded Flash memory register.  
0: no option byte change ongoing  
1: an option byte change ongoing and all write accesses to Flash registers are blocked until the option byte change completes.
3.9.9 FLASH option status register (FLASH_OPTSR_PRG)

Address offset: 0x020 or 0x120

Reset value: 0xXXXX XXXX (see Table 17: Option byte organization)

This register is used to program values in corresponding option bits. Values after reset reflects the current values of the corresponding option bits.

Bit 31 SWAP_BANK_OPT: Bank swapping option configuration bit

SWAP_BANK_OPT option bit is used to configure whether the bank 1 and bank 2 are swapped or not. This bit is loaded with the SWAP_BANK_OPT bit of FLASH_OPTSR_CUR register after a reset.

0: bank 1 and bank 2 not swapped
1: bank 1 and bank 2 swapped

Bit 30 Reserved, must be kept at reset value.

Bit 29 IO_HSLV: I/O high-speed at low-voltage configuration bit

This bit indicates that the product operates below 2.5 V.

0: Product working in the full voltage range, I/O speed optimization at low-voltage disabled
1: Product operating below 2.5 V, I/O speed optimization at low-voltage feature allowed

Bits 28:26 Reserved, must be kept at reset value.

Bits 25:24 Reserved, must be kept at reset value.

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 SECURITY: Security enable option configuration bit

The SECURITY option bit enables the secure access mode of the device during an option byte change. The change will be taken into account at next reset (next boot sequence). Once it is enabled, the security feature can be disabled if no areas are protected by PCROP or Secure access mode. If there are secure-only or PCROP protected areas, perform a level regression (from level 1 to 0) and set all the bits to unprotect secure-only areas and PCROP areas.

0: Security feature disabled
1: Security feature enabled.
Bits 20:19 \textbf{ST_RAM_SIZE[1:0]}: ST RAM size option configuration bits

- 00: 2 Kbytes reserved to ST code
- 01: 4 Kbytes reserved to ST code
- 10: 8 Kbytes reserved to ST code
- 11: 16 Kbytes reserved to ST code

\textit{Note: This bitfield is effective only when the security is enabled (SECURITY \text{= 1}).}

Bit 18 \textbf{IWDG_FZ_SDBY}: IWDG Standby mode freeze option configuration bit

This option bit is used to freeze or not the independent watchdog IWDG1 in system Standby mode.

- 0: Independent watchdog frozen in Standby mode
- 1: Independent watchdog keep running in Standby mode

Bit 17 \textbf{IWDG_FZ_STOP}: IWDG Stop mode freeze option configuration bit

This option bit is used to freeze or not the independent watchdog IWDG1 in system Stop mode.

- 0: Independent watchdog frozen in system Stop mode
- 1: Independent watchdog keep running in system Stop mode

Bit 16 Reserved, must be kept at reset value.

Bits 15:8 \textbf{RDP}: Readout protection level option configuration bits

RDP bits are used to change the readout protection level. This change is possible only when the current protection level is different from level 2. The possible configurations are:

- 0xAA: global readout protection level 0
- 0xCC: global readout protection level 2
- others values: global readout protection level 1

Bit 7 \textbf{NRST_STDY_D1}: D1 domain DStandby entry reset option configuration bit

- 0: a reset is generated when entering DStandby mode on D1 domain.
- 1: no reset generated when entering DStandby mode on D1 domain

Bit 6 \textbf{NRST_STOP_D1}: D1 domain DStop entry reset option configuration bit

- 0: a reset is generated when entering DStop mode on D1 domain.
- 1: no reset generated when entering DStop mode on D1 domain

Bit 5 Reserved, must be kept at reset value.

Bit 4 \textbf{IWDG1_SW}: IWDG1 control mode option configuration bit

IWDG1_SW option bit is used to select if IWDG1 independent watchdog is controlled by hardware or by software.

- 0: IWDG1 watchdog is controlled by hardware
- 1: IWDG1 watchdog is controlled by software

Bits 3:2 \textbf{BOR_LEV}: Brownout level option configuration bit

These option bits are used to define the power level that generates a system reset.

- 00: \(V_{\text{BOR0}}\): brownout reset threshold 0
- 01: \(V_{\text{BOR1}}\): brownout reset threshold 1
- 02: \(V_{\text{BOR2}}\): brownout reset threshold 2
- 03: \(V_{\text{BOR3}}\): brownout reset threshold 3

\textit{Note: Refer to device datasheet for the values of \(V_{\text{BORx}}\) \(V_{\text{DD}}\) reset thresholds.}

Bits 1:0 Reserved, must be kept at reset value.
3.9.10  FLASH option clear control register (FLASH_OPTCCR)

Address offset: 0x024 or 0x124
Reset value: 0x0000 0000

<table>

</tr>
</thead>
</table>

Bit 31  Reserved, must be kept at reset value.

Bit 30  CLR_OPTCHANGEERR: OPTCHANGEERR reset bit
This bit is used to reset the OPTCHANGEERR flag in FLASH_OPTSR_CUR register.
FLASH_OPTCCR is write-only.
It is reset by programming it to 1.

Bits 29:0  Reserved, must be kept at reset value.

3.9.11  FLASH protection address for bank 1 (FLASH_PRAR_CUR1)

Address offset: 0x028
Reset value: 0xXXXX 0XXX (see Table 17: Option byte organization)

This read-only register reflects the current values of corresponding option bits.

Bit 31 DMEP1: Bank 1 PCROP protected erase enable option status bit
If DMEP1 is set to 1, the PCROP protected area in bank 1 is erased when a protection level regression (change from level 1 to 0) or a bank erase with protection removal occurs.

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:16 PROT_AREA_END1: Bank 1 PCROP area end status bits
These bits contain the last 256-byte block of the PCROP area in bank 1.
If this address is equal to PROT_AREA_START1, the whole bank 1 is PCROP protected.
If this address is lower than PROT_AREA_START1, no protection is set on bank 1.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 PROT_AREA_START1: Bank 1 PCROP area start status bits
These bits contain the first 256-byte block of the PCROP area in bank 1.
If this address is equal to PROT_AREA_END1, the whole bank 1 is PCROP protected.
If this address is higher than PROT_AREA_END1, no protection is set on bank 1.
3.9.13  FLASH secure address for bank 1 (FLASH_SCAR_CUR1)

Address offset: 0x030
Reset value: 0xXXXX 0XXX (see Table 17: Option byte organization)
This read-only register reflects the current values of corresponding option bits.

<table>
<thead>

Bit 31  DMES1: Bank 1 secure access protected erase enable option status bit
If DMES1 is set to 1, the secure access only area in bank 1 is erased when a protection level regression (change from level 1 to 0) or a bank erase with protection removal occurs.

Bits 30:28  Reserved, must be kept at reset value.

Bits 27:16  SEC_AREA_END1: Bank 1 secure-only area end status bits
These bits contain the last 256-byte block of the secure-only area in bank 1.
If this address is equal to SEC_AREA_START1, the whole bank 1 is secure access only.
If this address is lower than SEC_AREA_START1, no protection is set on bank 1.

Bits 15:12  Reserved, must be kept at reset value.

Bits 11:0  SEC_AREA_START1: Bank 1 secure-only area start status bits
These bits contain the first 256 bytes of block of the secure-only area in bank 1.
If this address is equal to SEC_AREA_END1, the whole bank 1 is secure access only.
If this address is higher than SEC_AREA_END1, no protection is set on bank 1.

3.9.14  FLASH secure address for bank 1 (FLASH_SCAR_PRG1)

Address offset: 0x034
Reset value: 0xXXXX 0XXX (see Table 17: Option byte organization)
This register is used to program values in corresponding option bits.

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Settable</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>

</tbody>
</table>

Bit 31  DMES1: Bank 1 secure access protected erase enable option status bit
If DMES1 is set to 1, the secure access only area in bank 1 is erased when a protection level regression (change from level 1 to 0) or a bank erase with protection removal occurs.

Bits 30:28  Reserved, must be kept at reset value.

Bits 27:16  SEC_AREA_END1: Bank 1 secure-only area end status bits
These bits contain the last 256-byte block of the secure-only area in bank 1.
If this address is equal to SEC_AREA_START1, the whole bank 1 is secure access only.
If this address is lower than SEC_AREA_START1, no protection is set on bank 1.

Bits 15:12  Reserved, must be kept at reset value.

Bits 11:0  SEC_AREA_START1: Bank 1 secure-only area start status bits
These bits contain the first 256 bytes of block of the secure-only area in bank 1.
If this address is equal to SEC_AREA_END1, the whole bank 1 is secure access only.
If this address is higher than SEC_AREA_END1, no protection is set on bank 1.
Bit 31  **DMES1**: Bank 1 secure access protected erase enable option configuration bit
   If DMES1 is set to 1, the secure access only area in bank 1 is erased when a protection level regression (change from level 1 to 0) or a bank erase with protection removal occurs.

Bits 30:28  Reserved, must be kept at reset value.

Bits 27:16  **SEC_AREA_END1**: Bank 1 secure-only area end configuration bits
   These bits contain the last block of 256 bytes of the secure-only area in bank 1.
   If this address is equal to SEC_AREA_START1, the whole bank 1 is secure access only.
   If this address is lower than SEC_AREA_START1, no protection is set on bank 1.

Bits 15:12  Reserved, must be kept at reset value.

Bits 11:0  **SEC_AREA_START1**: Bank 1 secure-only area start configuration bits
   These bits contain the first block of 256 bytes of the secure-only area in bank 1.
   If this address is equal to SEC_AREA_END1, the whole bank 1 is secure access only.
   If this address is higher than SEC_AREA_END1, no protection is set on bank 1.

### 3.9.15  **FLASH write sector protection for bank 1**

**FLASH_WPSN_CUR1R**

Address offset: 0x038  
Reset value: 0x0000 00XX  
This read-only register reflects the current values of corresponding option bits.

Bits 31:16  BOOT_ADD1: Arm® Cortex®-M7 boot address 1
These bits reflect the MSB of the Arm® Cortex®-M7 boot address when the BOOT pin is high.

Bits 15:0  BOOT_ADD0: Arm® Cortex®-M7 boot address 0
These bits reflect the MSB of the Arm® Cortex®-M7 boot address when the BOOT pin is low.

3.9.18  FLASH register boot address FLASH_BOOT_PRGR)

Address offset: 0x044 or 0x144
Reset value: 0xXXXX XXXX (see Table 17: Option byte organization)

This register is used to program values in corresponding option bits.
### 3.9.19 FLASH CRC control register for bank 1 (FLASH_CRCCR1)

Address offset: 0x050

Reset value: 0x001C 0000

This register can be modified only if CRC_EN bit is set to 1 in FLASH_CR1 register.

<table>
<thead>
<tr>
<th>Bit 31:22</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit 21:20</td>
<td><strong>CRC_BURST</strong>: Bank 1 CRC burst size</td>
</tr>
<tr>
<td>CRC_BURST</td>

<td></td>
</tr>
<tr>
<td>10:   every burst has a size of 64 Flash words (256-bit)</td>
<td></td>
</tr>
<tr>
<td>11:   every burst has a size of 256 Flash words (256-bit)</td>
<td></td>
</tr>
<tr>
<td>Bit 19:18</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
<tr>
<td>Bit 17</td>
<td><strong>CLEAN_CRC</strong>: Bank 1 CRC clear bit</td>
</tr>
<tr>
<td>CLEAN_CRC</td>
<td>Setting CLEAN_CRC to 1 clears the current CRC result stored in the FLASH_CRCDDR register.</td>
</tr>
</tbody>
</table>
Bit 16  **START_CRC**: Bank 1 CRC start bit  
START_CRC bit triggers a CRC calculation on bank 1 using the current configuration. No CRC calculation can launched when an option byte change operation is ongoing because all write accesses to embedded Flash memory registers are put on hold until the option byte change operation has completed.

Bits 15:11  Reserved, must be kept at reset value.

Bit 10  **CLEAN_SECT**: Bank 1 CRC sector list clear bit  
Setting CLEAN_SECT to 1 clears the list of sectors on which the CRC is calculated.

Bit 9  **ADD_SECT**: Bank 1 CRC sector select bit  
Setting ADD_SECT to 1 adds the sector whose number is CRC_SECT to the list of sectors on which the CRC is calculated.

Bit 8  **CRC_BY_SECT**: Bank 1 CRC sector mode select bit  
When CRC_BY_SECT is set to 1, the CRC calculation is performed at sector level, on the sectors present in the list of sectors. To add a sector to this list, use ADD_SECT and CRC_SECT bits. To clean the list, use CLEAN_SECT bit.

When CRC_BY_SECT is reset to 0, the CRC calculation is performed on all addresses between CRC_START_ADDR and CRC_END_ADDR.

Bit 7  **ALL_BANK**: Bank 1 CRC select bit  
When ALL_BANK is set to 1, all bank 1 user sectors are added to list of sectors on which the CRC is calculated.

Bits 6:3  Reserved, must be kept at reset value.

Bits 2:0  **CRC_SECT**: Bank 1 CRC sector number  
CRC_SECT is used to select one or more user Flash sectors to be added to the list of sectors on which the CRC is calculated. The CRC can be computed either between two addresses (using registers FLASH_CRSADD1R and FLASH_CREADD1R) or on a list of sectors. If this latter option is selected, it is possible to add a sector to the list of sectors by programming the sector number in CRC_SECT and then setting ADD_SECT to 1.

The list of sectors can be erased either by setting CLEAN_SECT bit or by disabling the CRC computation. CRC_SECT can be set only when CRC_EN of FLASH_CR register is set to 1.

000: sector 0 of bank 1  
001: sector 1 of bank 1  
...  
111: sector 7 of bank 1

FAIL_ECC_ADDR1

Bits 31:15  Reserved, must be kept at reset value.

Bits 14:0  FAIL_ECC_ADDR1: Bank 1 ECC error address

When an ECC error occurs (both for single correction or double detection) during a read operation from bank 1, the FAIL_ECC_ADDR1 bitfield contains the address that generated the error.

FAIL_ECC_ADDR1 is reset when the flag error in the FLASH_SR1 register (CLR_SNECCERR1 or CLR_DBECCERR1) is reset.

The embedded Flash memory programs the address in this register only when no ECC error flags are set. This means that only the first address that generated an ECC error is saved.

The address in FAIL_ECC_ADDR1 is relative to the Flash memory area where the error occurred (user Flash memory, system Flash memory).

3.9.24  FLASH key register for bank 2 (FLASH_KEYR2)

Address offset: 0x104
Reset value: 0x0000 0000

FLASH_KEYR2 is a write-only register. The following values must be programmed consecutively to unlock FLASH_CR2 register and allow programming/erasing it:

1.  1st key = 0x4567 0123
2.  2nd key = 0xCDEF 89AB

Bits 31:28 Reserved, must be kept at reset value.

**Bit 27 CRCENDIE2:** Bank 2 CRC end of calculation interrupt enable bit  
When CRCENDIE2 bit is set to 1, an interrupt is generated when the CRC computation has completed on bank 2. CRCENDIE2 can be programmed only when LOCK2 is cleared to 0.  
0: no interrupt generated when CRC computation complete on bank 2  
1: interrupt generated when CRC computation complete on bank 2

**Bit 26 DBECCERRIE2:** Bank 2 ECC double detection error interrupt enable bit  
When DBECCERRIE2 bit is set to 1, an interrupt is generated when an ECC double detection error occurs during a read operation from bank 2. DBECCERRIE2 can be programmed only when LOCK2 is cleared to 0.  
0: no interrupt generated when an ECC double detection error occurs on bank 2  
1: interrupt generated if an ECC double detection error occurs on bank 2

**Bit 25 SNECCERRIE2:** Bank 2 ECC single correction error interrupt enable bit  
When SNECCERRIE2 bit is set to 1, an interrupt is generated when an ECC single correction error occurs during a read operation from bank 2. SNECCERRIE2 can be programmed only when LOCK2 is cleared to 0.  
0: no interrupt generated when an ECC single correction error occurs on bank 2  
1: interrupt generated when an ECC single correction error occurs on bank 2

**Bit 24 RDSEERRIE2:** Bank 2 secure error interrupt enable bit  
When RDSEERRIE2 bit is set to 1, an interrupt is generated when a secure error (access to a secure-only protected address) occurs during a read operation from bank 2. RDSEERRIE2 can be programmed only when LOCK2 is cleared to 0.  
0: no interrupt generated when a secure error occurs on bank 2  
1: an interrupt is generated when a secure error occurs on bank 2

**Bit 23 RDPERRIE2:** Bank 2 read protection error interrupt enable bit  
When RDPERRIE2 bit is set to 1, an interrupt is generated when a read protection error occurs (access to an address protected by PCROP or by RDP level 1) during a read operation from bank 2. RDPERRIE2 can be programmed only when LOCK2 is cleared to 0.  
0: no interrupt generated when a read protection error occurs on bank 2  
1: an interrupt is generated when a read protection error occurs on bank 2
Bit 22 **OPERRIE2**: Bank 2 write/erase error interrupt enable bit
When OPERRIE2 bit is set to 1, an interrupt is generated when an error is detected during a write/erase operation to bank 2. OPERRIE2 can be programmed only when LOCK2 is cleared to 0.
0: no interrupt generated when a write/erase error occurs on bank 2
1: interrupt generated when a write/erase error occurs on bank 2

Bit 21 **INCERRIE2**: Bank 2 inconsistency error interrupt enable bit
When INCERRIE2 bit is set to 1, an interrupt is generated when an inconsistency error occurs during a write operation to bank 2. INCERRIE2 can be programmed only when LOCK2 is cleared to 0.
0: no interrupt generated when a inconsistency error occurs on bank 2
1: interrupt generated when a inconsistency error occurs on bank 2.

Bit 20 Reserved, must be kept at reset value.

Bit 19 **STRBERRIE2**: Bank 2 strobe error interrupt enable bit
When STRBERRIE2 bit is set to 1, an interrupt is generated when a strobe error occurs (the master programs several times the same byte in the write buffer) during a write operation to bank 2. STRBERRIE2 can be programmed only when LOCK2 is cleared to 0.
0: no interrupt generated when a strobe error occurs on bank 2
1: interrupt generated when a strobe error occurs on bank 2.

Bit 18 **PGSERRIE2**: Bank 2 programming sequence error interrupt enable bit
When PGSERRIE2 bit is set to 1, an interrupt is generated when a sequence error occurs during a program operation to bank 2. PGSERRIE2 can be programmed only when LOCK2 is cleared to 0.
0: no interrupt generated when a sequence error occurs on bank 2
1: interrupt generated when a sequence error occurs on bank 2.

Bit 17 **WRPERRIE2**: Bank 2 write protection error interrupt enable bit
When WRPERRIE2 bit is set to 1, an interrupt is generated when a protection error occurs during a program operation to bank 2. WRPERRIE2 can be programmed only when LOCK2 is cleared to 0.
0: no interrupt generated when a protection error occurs on bank 2
1: interrupt generated when a protection error occurs on bank 2.

Bit 16 **EOPIE2**: Bank 2 end-of-program interrupt control bit
Setting EOPIE2 bit to 1 enables the generation of an interrupt at the end of a program operation to bank 2. EOPIE2 can be programmed only when LOCK2 is cleared to 0.
0: no interrupt generated at the end of a program operation to bank 2
1: interrupt enabled when at the end of a program operation to bank 2.

Bit 15 **CRC_EN**: Bank 2 CRC control bit
Setting CRC_EN bit to 1 enables the CRC calculation on bank 2. CRC_EN does not start CRC calculation but enables CRC configuration through FLASH_CRCCR2 register. When CRC calculation is performed on bank 2, it can only be disabled by setting CRC_EN bit to 0. Resetting CRC_EN clears CRC configuration and resets the content of FLASH_CRCDATAR register. CRC_EN can be programmed only when LOCK2 is cleared to 0.

Bit 14 **SPSS2**: Bank 2 special sector selection bit
Set this bit when accessing non-user sectors of the Flash memory. This bit can be programmed only when LOCK2 is cleared to 0.
0: User sectors selection in bank 2
1: Non-user, special sectors selection in bank 2
Bits 13:11  Reserved, must be kept at reset value.

Bits 10:8  **SNB2**: Bank 2 sector erase selection number

These bits are used to select the target sector for a sector erase operation (they are unused otherwise). SNB2 can be programmed only when LOCK2 is cleared to 0.

- 000: sector 0 of bank 2
- 001: sector 1 of bank 2
- ...
- 111: sector 7 of bank 2

Bit 7  **START2**: Bank 2 erase start control bit

START2 bit is used to start a sector erase or a bank erase operation. START2 can be programmed only when LOCK2 is cleared to 0.

The embedded Flash memory resets START2 when the corresponding operation has been acknowledged. The user application cannot access any embedded Flash memory register until the operation is acknowledged.

Bit 6  **FW2**: Bank 2 write forcing control bit

FW2 forces a write operation even if the write buffer is not full. FW2 can be programmed only when LOCK2 is cleared to 0.

The embedded Flash memory resets FW2 when the corresponding operation has been acknowledged. The user application cannot access any Flash register until the operation is acknowledged.

Write forcing is effective only if the write buffer is not empty. In particular, FW2 does not start several write operations when the write operations are performed consecutively.

Bits 5:4  **PSIZE2**: Bank 2 program size

PSIZE2 selects the maximum number of bits that can be written to 0 in one shot during a write operation (programming parallelism). PSIZE2 can be programmed only when LOCK2 is cleared to 0.

- 00: programming parallelism is byte (8 bits)
- 01: programming parallelism is half-word (16 bits)
- 10: programming parallelism is word (32 bits)
- 11: programming parallelism is double-word (64 bits)

Bit 3  **BER2**: Bank 2 erase request

Setting BER2 bit to 1 requests a bank erase operation on bank 2 (user Flash memory only). BER2 can be programmed only when LOCK2 is cleared to 0.

BER2 has a higher priority than SER2: if both are set, the embedded Flash memory executes a bank erase.

- 0: bank erase not requested on bank 2
- 1: bank erase requested on bank 2

*Note:* Write protection error is triggered when a bank erase is required and some sectors are protected.
Bit 2  **SER2**: Bank 2 sector erase request  
Setting SER2 bit to 1 requests a sector erase on bank 2. SER2 can be programmed only when LOCK2 is cleared to 0.  
BER2 has a higher priority than SER2: if both are set, the embedded Flash memory executes a bank erase.  
0: sector erase not requested on bank 2  
1: sector erase requested on bank 2  
*Note*: Write protection error is triggered when a sector erase is required on protected sector(s).

Bit 1  **PG2**: Bank 2 internal buffer control bit  
Setting PG2 bit to 1 enables internal buffer for write operations to bank 2. This allows the preparation of program operations even if a sector or bank erase is ongoing.  
PG2 can be programmed only when LOCK2 is cleared to 0. When PG2 is reset, the internal buffer is disabled for write operations to bank 2 and all the data stored in the buffer but not sent to the operation queue are lost.

Bit 0  **LOCK2**: Bank 2 configuration lock bit  
This bit locks the FLASH_CR2 register. The correct write sequence to FLASH_KEYR2 register unlocks this bit. If a wrong sequence is executed, or the unlock sequence to FLASH_KEYR2 is performed twice, this bit remains locked until next system reset.  
LOCK2 can be set by programming it to 1. When set to 1, a new unlock sequence is mandatory to unlock it. When LOCK2 changes from 0 to 1, the other bits of FLASH_CR2 register do not change.  
0: FLASH_CR2 register unlocked  
1: FLASH_CR2 register locked
### 3.9.26 FLASH status register for bank 2 (FLASH_SR2)

Address offset: 0x110  
Reset value: 0x0000 0000

</tbody>
</table>

Bits 31:28 Reserved, must be kept at reset value.

- **Bit 27 CRCEND2**: Bank 2 CRC end of calculation flag  
  CRCEND2 bit is raised when the CRC computation has completed on bank 2. An interrupt is generated if CRCENDIE2 is set to 1. It is not necessary to reset CRCEND2 before restarting CRC computation. Writing 1 to CLR_CRCEND2 bit in FLASH_CCR2 register clears CRCEND2.  
  - 0: CRC computation not complete on bank 2  
  - 1: CRC computation complete on bank 2

- **Bit 26 DBECCERR2**: Bank 2 ECC double detection error flag  
  DBECCERR2 flag is raised when an ECC double detection error occurs during a read operation from bank 2. An interrupt is generated if DBECCERRIE2 is set to 1. Writing 1 to CLR_DBECCERR2 bit in FLASH_CCR2 register clears DBECCERR2.  
  - 0: no ECC double detection error occurs on bank 2  
  - 1: ECC double detection error occurs on bank 2

- **Bit 25 SNECCERR2**: Bank 2 single correction error flag  
  SNECCERR2 flag is raised when an ECC single correction error occurs during a read operation from bank 2. An interrupt is generated if SNECCERRIE2 is set to 1. Writing 1 to CLR_SNECCERR2 bit in FLASH_CCR2 register clears SNECCERR2.  
  - 0: no ECC single correction error occurs on bank 2  
  - 1: ECC single correction error occurs on bank 2

- **Bit 24 RDSERR2**: Bank 2 secure error flag  
  RDSERR2 flag is raised when a read secure error (read access to a secure-only protected word) occurs on bank 2. An interrupt is generated if RDSERRIE2 is set to 1. Writing 1 to CLR_RDSERR2 bit in FLASH_CCR2 register clears RDSERR2.  
  - 0: no secure error occurs on bank 2  
  - 1: a secure error occurs on bank 2

- **Bit 23 RDPERR2**: Bank 2 read protection error flag  
  RDPERR2 flag is raised when a read protection error (read access to a PCROP-protected word or a RDP-protected area) occurs on bank 2. An interrupt is generated if RDPERRIE2 is set to 1. Writing 1 to CLR_RDPERR2 bit in FLASH_CCR2 register clears RDPERR2.  
  - 0: no read protection error occurs on bank 2  
  - 1: a read protection error occurs on bank 2
Bit 22  **OPERR2**: Bank 2 write/erase error flag
OPERR2 flag is raised when an error occurs during a write/erase to bank 2. An interrupt is generated if OPERRIE2 is set to 1. Writing 1 to CLR_OPERR2 bit in FLASH_CCR2 register clears OPERR2.
0: no write/erase error occurred on bank 2
1: a write/erase error occurred on bank 2

Bit 21  **INCERR2**: Bank 2 inconsistency error flag
INCERR2 flag is raised when an inconsistency error occurs on bank 2. An interrupt is generated if INCERRIE2 is set to 1. Writing 1 to CLR_INCERR2 bit in the FLASH_CCR2 register clears INCERR2.
0: no inconsistency error occurred on bank 2
1: an inconsistency error occurred on bank 2.

Bit 20  Reserved, must be kept at reset value.

Bit 19  **STRBERR2**: Bank 2 strobe error flag
STRBERR2 flag is raised when a strobe error occurs on bank 2 (when the master attempts to write several times the same byte in the write buffer). An interrupt is generated if the STRBERRIE2 bit is set to 1. Writing 1 to CLR_STRBERR2 bit in FLASH_CCR2 register clears STRBERR2.
0: no strobe error occurred on bank 2
1: a strobe error occurred on bank 2.

Bit 18  **PGSERR2**: Bank 2 programming sequence error flag
PGSERR2 flag is raised when a sequence error occurs on bank 2. An interrupt is generated if the PGSERRIE2 bit is set to 1. Writing 1 to CLR_PGSERR2 bit in FLASH_CCR2 register clears PGSERR2.
0: no sequence error occurred on bank 2
1: a sequence error occurred on bank 2.

Bit 17  **WRPERR2**: Bank 2 write protection error flag
WRPERR2 flag is raised when a protection error occurs during a program operation to bank 2. An interrupt is also generated if the WRPERRIE2 is set to 1. Writing 1 to CLR_WRPERR2 bit in FLASH_CCR2 register clears WRPERR2.
0: no write protection error occurred on bank 2
1: a write protection error occurred on bank 2

Bit 16  **EOP2**: Bank 2 end-of-program flag
EOP2 flag is set when a programming operation to bank 2 completes. An interrupt is generated if the EOPIE2 is set to 1. It is not necessary to reset EOP2 before starting a new operation. EOP2 bit is cleared by writing 1 to CLR_EOP2 bit in FLASH_CCR2 register.
0: no programming operation completed on bank 2
1: a programming operation completed on bank 2

Bits 15:4  Reserved, must be kept at reset value.

Bit 3  **CRC_BUSY2**: Bank 2 CRC busy flag
CRC_BUSY2 flag is set when a CRC calculation is ongoing on bank 2. This bit cannot be forced to 0. The user must wait until the CRC calculation has completed or disable CRC computation on bank 2.
0: no CRC calculation ongoing on bank 2
1: CRC calculation ongoing on bank 2.
Bit 2  **QW2**: Bank 2 wait queue flag

QW2 flag is set when a write or erase operation is pending in the command queue buffer of bank 2. It is not possible to know what type of operation is present in the queue. This flag is reset by hardware when all write/erase operations have been executed and thus removed from the waiting queue(s). This bit cannot be forced to 0. It is reset after a deterministic time if no other operations are requested.

- 0: no write or erase operation is waiting in the operation queues of bank 2
- 1: at least one write or erase operation is pending in the operation queues of bank 2

Bit 1  **WBNE2**: Bank 2 write buffer not empty flag

WBNE2 flag is set when embedded Flash memory is waiting for new data to complete the write buffer. In this state the write buffer is not empty. WBNE2 is reset by hardware each time the write buffer is complete or the write buffer is emptied following one of the event below:

- the application software forces the write operation using FW2 bit in FLASH_CR2
- the embedded Flash memory detects an error that involves data loss
- the application software has disabled write operations in this bank

This bit cannot be forced to 0. To reset it, clear the write buffer by performing any of the above listed actions or send the missing data.

- 0: write buffer of bank 2 empty or full
- 1: write buffer of bank 2 waiting data to complete

Bit 0  **BSY2**: Bank 2 busy flag

BSY2 flag is set when an effective write or erase operation is ongoing to bank 2. It is not possible to know what type of operation is being executed.

BSY2 cannot be forced to 0. It is automatically reset by hardware every time a step in a write, or erase operation completes.

- 0: no write or erase operation is executed on bank 2
- 1: a write or an erase operation is being executed on bank 2
### 3.9.27 FLASH clear control register for bank 2 (FLASH_CCR2)

**Address offset:** 0x114  
**Reset value:** 0x0000 0000

Bits 31:28 Reserved, must be kept at reset value.

- **Bit 27 CLR_CRCEND2:** Bank 2 CRCEND2 flag clear bit  
  Setting this bit to 1 resets to 0 CRCEND2 flag in FLASH_SR2 register.

- **Bit 26 CLR_DBECCERR2:** Bank 2 DBECCERR2 flag clear bit  
  Setting this bit to 1 resets to 0 DBECCERR2 flag in FLASH_SR2 register. If the SNECCERR2 flag of FLASH_SR2 register is cleared to 0, FLASH_ECC_FA2R register is reset to 0 as well.

- **Bit 25 CLR_SNECCERR2:** Bank 2 SNECCERR2 flag clear bit  
  Setting this bit to 1 resets to 0 SNECCERR2 flag in FLASH_SR2 register. If the DBECCERR2 flag of FLASH_SR2 register is cleared to 0, FLASH_ECC_FA2R register is reset to 0 as well.

- **Bit 24 CLR_RDSERR2:** Bank 2 RDSERR2 flag clear bit  
  Setting this bit to 1 resets to 0 RDSERR2 flag in FLASH_SR2 register.

- **Bit 23 CLR_RDPERR2:** Bank 2 RDPERR2 flag clear bit  
  Setting this bit to 1 resets to 0 RDPERR2 flag in FLASH_SR2 register.

- **Bit 22 CLR_OPERR2:** Bank 2 OPERR2 flag clear bit  
  Setting this bit to 1 resets to 0 OPERR2 flag in FLASH_SR2 register.

- **Bit 21 CLR_INCERR2:** Bank 2 INCERR2 flag clear bit  
  Setting this bit to 1 resets to 0 INCERR2 flag in FLASH_SR2 register.

- **Bit 20 Reserved, must be kept at reset value.

- **Bit 19 CLR_STRBERR2:** Bank 2 STRBERR2 flag clear bit  
  Setting this bit to 1 resets to 0 STRBERR2 flag in FLASH_SR2 register.

- **Bit 18 CLR_PGSERR2:** Bank 2 PGSERR2 flag clear bit  
  Setting this bit to 1 resets to 0 PGSERR2 flag in FLASH_SR2 register.
3.9.28  **FLASH protection address for bank 2 (FLASH_PRAR_CUR2)**

Address offset: 0x128

Reset value: 0xXXXX 0XXX (see *Table 17: Option byte organization*)

This read-only register reflects the current values of corresponding option bits.

<table>
<thead>

</tr>
</tbody>
</table>

Bit 31 **DMEP2**: Bank 2 PCROP protected erase enable option status bit

If DMEP2 is set to 1, the PCROP protected area in bank 2 is erased when a protection level regression (change from level 1 to 0) or a bank erase with protection removal occurs.

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:16 **PROT_AREA_END2**: Bank 2 PCROP area end status bits

These bits contain the last 256-byte block of the PCROP area in bank 2.

If this address is equal to PROT_AREA_START2, the whole bank 2 is PCROP protected.

If this address is lower than PROT_AREA_START2, no protection is set on bank 2.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **PROT_AREA_START2**: Bank 2 PCROP area start status bits

These bits contain the first 256-byte block of the PCROP area in bank 2.

If this address is equal to PROT_AREA_END2, the whole bank 2 is PCROP protected.

If this address is higher than PROT_AREA_END2, no protection is set on bank 2.
3.9.29  **FLASH protection address for bank 2 (FLASH_PRAR_PRG2)**

Address offset: 0x12C

Reset value: 0xXXXX 0XXX (see *Table 17: Option byte organization*)

This register is used to program values in corresponding option bits.

Bit 31  **DMEP2**: Bank 2 PCROP protected erase enable option configuration bit

If DMEP2 is set to 1, the PCROP protected area in bank 2 is erased when a protection level regression (change from level 1 to 0) or a bank erase with protection removal occurs.

Bits 30:28  Reserved, must be kept at reset value.

Bits 27:16  **PROT_AREA_END2**: Bank 2 PCROP area end configuration bits

These bits contain the last 256-byte block of the PCROP area in bank 2.

If this address is equal to PROT_AREA_START2, the whole bank 2 is PCROP protected.

If this address is lower than PROT_AREA_START2, no protection is set on bank 2.

Bits 15:12  Reserved, must be kept at reset value.

Bits 11:0  **PROT_AREA_START2**: Bank 2 PCROP area start configuration bits

These bits contain the first 256-byte block of the PCROP area in bank 2.

If this address is equal to PROT_AREA_END2, the whole bank 2 is PCROP protected.

If this address is higher than PROT_AREA_END2, no protection is set on bank 2.

3.9.30  **FLASH secure address for bank 2 (FLASH_SCAR_CUR2)**

Address offset: 0x130

Reset value: 0xXXXX 0XXX (see *Table 17: Option byte organization*)

This read-only register reflects the current values of corresponding option bits.

Bit 31 **DMES2**: Bank 2 secure access protected erase enable option configuration bit

If DMES2 is set to 1, the secure access only area in bank 2 is erased when a protection level regression (change from level 1 to 0) or a bank erase with protection removal occurs.

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:16 **SEC_AREA_END2**: Bank 2 secure-only area end configuration bits

These bits contain the last 256 bytes block of the secure-only area in bank 2.

If this address is equal to SEC_AREA_START2, the whole bank 2 is secure access only.

If this address is lower than SEC_AREA_START2, no protection is set on bank 2.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **SEC_AREA_START2**: Bank 2 secure-only area start configuration bits

These bits contain the first of 256 bytes block of the secure-only area in bank 2.

If this address is equal to SEC_AREA_END2, the whole bank 2 is secure access only.

If this address is higher than SEC_AREA_END2, no protection is set on bank 2.
### 3.9.32 FLASH write sector protection for bank 2
*(FLASH_WPSN_CUR2R)*

Address offset: 0x138

Reset value: 0x0000 00XX

This read-only register reflects the current values of corresponding option bits.

<table>

</tr>
</thead>
</table>

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **WRPSn2**: Bank 2 sector write protection option status byte

Each FLASH_WPSGN_CUR2R bit reflects the write protection status of the corresponding bank 2 sector (0: sector is write protected; 1: sector is not write protected)

### 3.9.33 FLASH write sector protection for bank 2
*(FLASH_WPSN_PRG2R)*

Address offset: 0x13C

Reset value: 0x0000 00XX

This register is used to program values in corresponding option bits.

<table>

<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **WRPSn2**: Bank 2 sector write protection option status byte

Setting WRPSn2 bits to 0 write protects the corresponding bank 2 sector (0: sector is write protected; 1: sector is not write protected)
3.9.34 FLASH CRC control register for bank 2 (FLASH_CRCCR2)

Address offset: 0x150
Reset value: 0x001C 0000

The values in this register can be changed only if CRC_EN bit is set to 1 in FLASH_CR2 register.

<table>
<thead>
<tr>
<th>Address offset: 0x150</th>
<th>Reset value: 0x001C 0000</th>
</tr>
</thead>
</table>

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16

15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0
CLEAN_SECT ADD_SECT CRC_BY_SECT ALL_BANK CRC_SECT

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:20 CRC_BURST: Bank 2 CRC burst size
CRC_BURST bits set the size of the bursts that are generated by the CRC calculation unit.
00: every burst has a size of 4 Flash words (256-bit)
01: every burst has a size of 16 Flash words (256-bit)
10: every burst has a size of 64 Flash words (256-bit)
11: every burst has a size of 256 Flash words (256-bit)

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 CLEAN_CRC: Bank 2 CRC clear bit
Setting CLEAN_CRC to 1 clears the current CRC result stored in the FLASH_CRCDATAR register.

Bit 16 START_CRC: Bank 2 CRC start bit
START_CRC bit triggers a CRC calculation on bank 2 using the current configuration. It is not possible to start a CRC calculation when an option byte change operation is ongoing because all write accesses to embedded Flash memory registers are put on hold until the option byte change operation has completed.

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 CLEAN_SECT: Bank 2 CRC sector list clear bit
Setting CLEAN_SECT to 1 clears the list of sectors on which the CRC is calculated.

Bit 9 ADD_SECT: Bank 2 CRC sector select bit
Setting ADD_SECT to 1 adds the sector whose number is CRC_SECT to the list of sectors on which the CRC is calculated.
3.9.35FLASH_CRC start address register for bank 2 (FLASH_CRCSADD2R)

Address offset: 0x154

</table>

**CRC_END_ADDR[19:16]**

Bits 31:20  Reserved, must be kept at reset value.

Bits 19:2  **CRC_END_ADDR[19:2]:**  CRC end address on bank 2  
CRC_END_ADDR is used when CRC_BY_SECT is cleared to 0. It must be programmed to the end address of the bank 2 memory area on which the CRC calculation is performed.

Bits 1:0  Reserved, must be kept at reset value.

3.9.37  **FLASH ECC fail address for bank 2**  
*(FLASH_ECC_FA2R)*

Address offset: 0x160  
Reset value: 0x0000 0000

<table>
<thead>
<tr>

<td>0</td>
</tr>
</tbody>
</table>

**FAIL_ECC_ADDR2**

Bits 31:15  Reserved, must be kept at reset value.

Bits 14:0  **FAIL_ECC_ADDR2: Bank 2 ECC error address**

When an ECC error occurs (both for single error correction or double detection) during a read operation from bank 2, the FAIL_ECC_ADDR2 bitfield contains the address that generated the error.

FAIL_ECC_ADDR2 is reset when the flag error in the FLASH_SR2 register (CLR_SNECCERR2 or CLR_DBECCERR2) is reset.

The embedded Flash memory programs the address in this register only when no ECC error flags are set. This means that only the first address that generated an ECC error is saved.
### 3.10 FLASH register map and reset values

#### Table 24. Register map and reset value table

| Offset | Register name reset | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

Refer to Section 2.3 on page 126 for the register boundary addresses.
4 Secure internal Flash memory (SIFM)

4.1 Introduction

STM32H750xB and STM32H753xI microcontrollers offer a first set of protection mechanisms, which are similar to other STM32 Series:

- Global readout device protection (RDP)
- Write protection (WRP)
- Proprietary code readout protection (PCROP)

A detailed description of these protection mechanisms is given in Section 3: Embedded Flash memory (FLASH).

STM32H750xB and STM32H753xI also offer an additional enhanced protection mode, the Secure access mode, that makes possible the development of user-defined secure services (e.g., secure firmware update or secure boot) and guarantees of a safe execution and protection of both code and data. This mechanism is described in details in Section 4.3: Secure access mode, Section 4.4: Root secure services (RSS) and Section 4.5: Secure user software.

The secure internal Flash memory unit is contained inside the D1 domain.

4.2 Glossary

The following terms will be used in herein:

<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Device Security Level</strong></td>
<td></td>
</tr>
<tr>
<td>Standard mode</td>
<td>Device state which allows the access to the user Flash memory, the option bytes and the bootloader area.</td>
</tr>
<tr>
<td>Secure access mode</td>
<td>Device state which allows the access to all the memory areas of the device.</td>
</tr>
<tr>
<td><strong>Memory areas</strong></td>
<td></td>
</tr>
<tr>
<td>System memory</td>
<td>ST reserved memory area used to store ST ROM code.</td>
</tr>
<tr>
<td>User Flash memory</td>
<td>Flash memory area used to store user code and data.</td>
</tr>
<tr>
<td>Secure user memory/area</td>
<td>This area can be configured to be accessed once after reset and be hidden for the firmware stored in the user Flash memory after the code stored in this area is executed.</td>
</tr>
</tbody>
</table>
4.3 Secure access mode

Some sensitive functions require safe execution from potential malicious software attacks. Secure firmware update (SFU) software is a good example of code that requires a high level of protection since it handles secret data (such as cryptographic keys) that shall not be retrieved by other processes.

STM32H750xB and STM32H753xI microcontrollers feature secure memory areas with restricted access. They allow building secure services that will be executed prior to any user application. These secure areas, together with the software they contain, are only accessible when configuring the device in Secure access mode.

*Figure 13* gives an overview of Flash memory areas and services in Standard and Secure access modes.

<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootloader</td>
<td>STMicroelectronics software executed at reset which allows the download of firmware from regular communication ports.</td>
</tr>
<tr>
<td>Root secure services (RSS)</td>
<td>STMicroelectronics software which allows the access to secure services.</td>
</tr>
<tr>
<td>Secure user software</td>
<td>User software executed once after reset, which can be used to implement secure boot and secure firmware update (SFU). Secure user software is located in secure user memory.</td>
</tr>
</tbody>
</table>
4.3.1 Associated features

The Secure access mode can be configured through option bytes. When it is set, it enables access to:

- STMicroelectronics root secure services to set secure user areas (see Section 4.4: Root secure services (RSS))
- Secure user memory which embeds secure user code and data.

For a summary of access rights for each core, refer to Section 4.6: Summary of Flash protection mechanisms.

4.3.2 Boot state machine

In Secure access mode, booting is forced in the RSS whatever the boot configuration (boot pins and boot addresses). The RSS can either set a secure user memory area if one has been requested (see Section 4.5.2: Setting secure user memory areas) or jump directly to the existing secure user memory. The code located in secure user memory is executed before the main user application and the bootloader. If no service is required and no secure area is defined, the RSS jumps to the boot address selected by BOOT0 pin value.

Figure 14 shows STM32H750xB and STM32H753xl boot state machine.
4.3.3 Secure access mode configuration

Enabling Secure access mode

There is no restriction on how to activate Secure access mode on the device. It is configured through the SECURITY option bit in FLASH_OPTSR_CUR register (see Section 3.9.8: FLASH option status register (FLASH_OPTSR_CUR)).

The Secure access mode becomes active after a system reset.

Disabling Secure access mode

Disabling Secure access mode is a more sensitive task as it can only be done if no more protected code exists on the device. As a result, to come back to Standard mode, secure user memories and PCROP/execute-only areas shall be removed before clearing the SECURITY option bit in the FLASH_OPTSR_CUR register.

Protected areas can be removed by performing a Flash mass erase (refer to Section 3.3.10: FLASH erase operations for more details on mass erase sequence).
4.4 Root secure services (RSS)

4.4.1 Secure area setting service

STMicroelectronics provides a service to perform the initialization of secure areas. This service can be called only once. It is executed after a system reset in Secure access mode prior to any other software stored in the device.

RSS software cannot be accessed (read, write, execute and debug) when the STM32H750xB and STM32H753xI operates in Standard mode. The service can be automatically accessed with ST programming tool, STM32CubeProgrammer, or called through a direct call to the `resetAndInitializeSecureAreas` function defined below.

```
resetAndInitializeSecureAreas

Prototype void resetAndInitializeSecureAreas(RSS_SecureArea_t area)

Arguments Secure user areas start and end addresses. One or two secure user areas can be set.

Description This service sets secure user area boundaries, following the values stored in the option byte registers:
- SEC_AREA_START1 and SEC_AREA_END1 for bank 1
- SEC_AREA_START2 and SEC_AREA_END2 for bank 2
This service can be used only when a secure area is set for the first time.
A system reset is triggered after service completion.
```

4.4.2 Secure area exiting service

The RSS also provides the `exitSecureArea` service. This service must be called to jump to user application. It allows closing safely the secure user area to guarantee that its content can no more be accessed. On the other hand, the content will still be accessible in Secure access mode.

Contrary to the `resetAndInitializeSecureAreas` service, it does not trigger any system reset. The `exitSecureArea` function is defined below:

```
exitSecureArea

Prototype void exitSecureArea(unsigned int vectors)

Arguments Address of application vectors where to jump after exit

Description This service is used to exit from secure user software and jump to user main application.
There is no system reset triggered by this service
```
4.5 Secure user software

A secure user software is a trusted piece of code that is executed after device power-on or after a system reset. It allows building secure applications such as:

- code signature or integrity checking (user secure boot).
- software license checking
- secure firmware update
- secure initialization

4.5.1 Access rules

Only accessible in Secure access mode, the secure user software is stored in the secure memory areas.

Only one user secure area can be configured per bank. If two secure areas are defined, the secure software that is executed is the one closer to current boot address.

After secure user software execution, the code shall jump to the main user application and prevent access to the secure user area. This is done by calling `exitSecureAreas` secure service with the application code address given as parameter.

Once in the application code, any access to the secure user area triggers a Flash error.

4.5.2 Setting secure user memory areas

One secure area of configurable size can be set in each bank. The size of each area can be set from 512 bytes to full bank with a granularity of 256 bytes:

- Secure area in bank 1
  - Boundaries are configured through SEC_AREA_START1 and SEC_AREA_END1 option bits in FLASH_SCAR_CUR1 (see Section 3.9.13: FLASH secure address for bank 1 (FLASH_SCAR_CUR1)).

- Secure area in bank 2
  - Boundaries are configured through SEC_AREA_START2 and SEC_AREA_END2 option bits in FLASH_SCAR_CUR2 (see Section 3.9.30: FLASH secure address for bank 2 (FLASH_SCAR_CUR2)).

Note: If the secure area start address is equal to the secure area end address, the full bank is considered as secure protected.

The above option bits can only be initialized through `exitandinitializeSecureAreas` service.

If a secure area already exists, the secure user area code can update its own secure user area size or create a new one in the other bank.
4.6 Summary of Flash protection mechanisms

*Figure 15* and *Table 26* summarize the access rights of the different Flash memory areas, both in Secure access and Standard modes.

5 Power control (PWR)

5.1 Introduction

The Power control section (PWR) provides an overview of the supply architecture for the different power domains and of the supply configuration controller.

It also describes the features of the power supply supervisors and explains how the $V_{\text{CORE}}$ supply domain is configured depending on the operating modes, the selected performance (clock frequency) and the voltage scaling.

5.2 PWR main features

- Power supplies and supply domains
  - Core domains ($V_{\text{CORE}}$)
  - $V_{\text{DD}}$ domain
  - Backup domain ($V_{\text{SW}}, V_{\text{BKP}}$)
  - Analog domain ($V_{\text{DDA}}$)
- System supply voltage regulation
  - Voltage regulator (LDO)
- Peripheral supply regulation
  - USB regulator
- Power supply supervision
  - POR/PDR monitor
  - BOR monitor
  - PVD monitor
  - AVD monitor
  - $V_{\text{BAT}}$ thresholds
  - Temperature thresholds
- Power management
  - $V_{\text{BAT}}$ battery charging
  - Operating modes
  - Voltage scaling control
  - Low-power modes

5.4 Power supplies

The device requires \( V_{DD} \) power supply as well as independent supplies for \( V_{DDLDO} \), \( V_{DDA} \), \( V_{DDUSB} \), and \( V_{CAP} \). It also provides regulated supplies for specific functions (voltage regulator, USB regulator).

- \( V_{DD} \) external power supply for I/Os and system analog blocks such as reset, power management and oscillators
- \( V_{BAT} \) optional external power supply for backup domain when \( V_{DD} \) is not present (\( V_{BAT} \) mode)
  This power supply shall be connected to \( V_{DD} \) when no battery is used.
- \( V_{DDLDO} \) external power supply for voltage regulator
- \( V_{CAP} \) digital core domain supply
  This power supply is independent from all the other power supplies:
  - When the voltage regulator is enabled, \( V_{CORE} \) is delivered by the internal voltage regulator.
  - When the voltage regulator is disabled, \( V_{CORE} \) is delivered by an external power supply through \( V_{CAP} \) pin.
- \( V_{DDA} \) external analog power supply for ADCs, DACs, OPAMPs, comparators and voltage reference buffers
  This power supply is independent from all the other power supplies.
- \( V_{REF}^+ \) external reference voltage for ADC and DAC.
  - When the voltage reference buffer is enabled, \( V_{REF}^+ \) and \( V_{REF}^- \) are delivered by the internal voltage reference buffer.
  - When the voltage reference buffer is disabled, \( V_{REF}^+ \) is delivered by an independent external reference supply.
- \( V_{SSA} \) separate analog and reference voltage ground.
- \( V_{DD50USB} \) external power supply for USB regulator.
- \( V_{DD3USB} \) USB regulator supply output for USB interface.
  - When the USB regulator is enabled, \( V_{DD3USB} \) is delivered by the internal USB regulator.
  - When the USB regulator is disabled, \( V_{DD3USB} \) is delivered by an independent external supply input.
- \( V_{SS} \) common ground for all supplies and analog regulator.

Note: Depending on the operating power supply range, some peripherals might be used with limited features and performance. For more details, refer to section “General operating conditions” of the device datasheets.

5.4.1 System supply startup

The system startup sequence from power-on in different supply configurations is the following (see Figure 19 for LDO supply):

1. When the system is powered on, the POR monitors V_{DD} supply. Once V_{DD} is above the POR threshold level, the voltage regulator is enabled in the default supply configuration:
   - The Voltage converter output level is set at 1.0 V in accordance with the VOS3 level configured in PWR_D3 domain control register (PWR_D3CR).
2. The system is kept in reset mode as long as V_{CORE} is not correct.
3. Once V_{CORE} is correct, the system is taken out of reset and the HSI oscillator is enabled.
4. Once the oscillator is stable, the system is initialized: Flash memory and option bytes are loaded and the CPU starts in limited run mode (Run*).
5. The software shall then initialize the system including supply configuration programming in PWR control register 3 (PWR_CR3). Once the supply configuration has been configured, the ACTVOSRDY bit in PWR control status register 1 (PWR_CSR1) shall be checked to guarantee valid voltage levels:
   a) As long as ACTVOSRDY indicates that voltage levels are invalid, the system is in Run* mode, write accesses to the RAMs are not permitted and VOS shall not be changed.
   b) Once ACTVOSRDY indicates that voltage levels are valid, the system is in normal Run mode, write accesses to RAMs are allowed and VOS can be changed.

The software has to program the supply configuration in PWR control register 3 (PWR_CR3).
1. In Run* mode, write operations to RAM are not allowed.
2. Write operations to RAM are allowed and VOS can be changed only when ACTVOSRDY is valid.

When exiting from Standby mode, the supply configuration is known by the system since the PWR control register 3 (PWR_CR3) register content is retained. However the software shall still wait for the ACTVOSRDY bit to be set in PWR control status register 1 (PWR_CSR1) to indicate V CORE voltage levels are valid, before performing write accesses to RAM or changing VOS.

When V CORE is supplied in Bypass mode (LDO and SMPS OFF), the V CORE voltage must first settles at a default level higher than 1.1 V. Due to the LDO default state after power-up (enabled by default), the external V CORE voltage must remain higher than 1.1 V until the LDO is disabled by software.

When the LDO is disabled, the external V CORE voltage can be adjusted according to the user application needs (refer to section General operating conditions of the datasheet for details on V CORE level versus the maximum operating frequency).
5.4.2 Core domain

The $V_{\text{CORE}}$ core domain supply can be provided by the voltage regulator or by an external supply ($V_{\text{CAP}}$). $V_{\text{CORE}}$ supplies all the digital circuitries except for the backup domain and the Standby circuitry. The $V_{\text{CORE}}$ domain is split into 3 sections:

- D1 domain containing the CPU (Cortex®-M7), Flash memory and peripherals.
- D2 domain containing peripherals.
- D3 domain containing the system control, I/O logic and low-power peripherals.

When a system reset occurs, the voltage regulator is enabled and supplies $V_{\text{CORE}}$. This allows the system to start up in any supply configurations (see Figure 18).

After a system reset, the software shall configure the used supply configuration in $PWR$ control register 3 ($PWR\_CR3$) register before changing VOS in $PWR$ D3 domain control register ($PWR\_D3CR$) or the RCC $ck\_sys$ frequency. The different system supply configurations are controlled as shown in Table 29.
Voltage regulator

The embedded voltage regulator (LDO) requires external capacitors to be connected to V_CAP pins.

The voltage regulator provides three different operating modes: Main (MR), Low-power (LP) or Off. These modes will be used depending on the system operating modes (Run, Stop and Standby).

- **Run mode**
  The LDO regulator is in Main mode and provides full power to the V_CORE domain (core, memories and digital peripherals). The regulator output voltage can be scaled by software to different voltage levels (VOS0\(^{(a)}\), VOS1, VOS2, and VOS3) that are configured through VOS bits in PWR D3 domain control register (PWR_D3CR). The VOS voltage scaling allows optimizing the power consumption when the system is clocked below the maximum frequency. By default VOS3 is selected after system reset. VOS can be changed on-the-fly to adapt to the required system performance.

- **Stop mode**
  The voltage regulator supplies the V_CORE domain to retain the content of registers and internal memories.
  The regulator can be kept in Main mode to allow fast exit from Stop mode, or can be set in LP mode to obtain a lower V_CORE supply level and extend the exit-from-Stop latency. The regulator mode is selected through the SVOS and LPDS bits in PWR control register 1 (PWR_CR1). Main mode and LP mode are allowed if SVOS3 voltage scaling is selected, while only LP mode is possible for SVOS4 and SVOS5 scaling. Due to a lower voltage level for SVOS4 and SVOS5 scaling, the Stop mode consumption can be further reduced.

- **Standby mode**
  The voltage regulator is OFF and the V_CORE domains are powered down. The content of the registers and memories is lost except for the Standby circuitry and the backup domain.

**Note:** For more details, refer to the voltage regulator section in the datasheets.

5.4.3 PWR external supply

When V_CORE is supplied from an external source, different operating modes can be used depending on the system operating modes (Run, Stop or Standby):

- **In Run mode**
  The external source supplies full power to the V_CORE domain (core, memories and digital peripherals). The external source output voltage is scalable through different voltage levels (VOS0, VOS1, VOS2 and VOS3). The externally applied voltage level shall be reflected in the VOS bits of PWR_D3CR register. The RAMs shall only be

---

\(a\). VOS0 corresponds to V_CORE boost allowing to reach the system maximum frequency (refer to Section : VOS0 activation/desactivation sequence)
accessed for write operations when the external applied voltage level matches VOS settings.

- **In Stop mode**
  The external source supplies $V_{\text{CORE}}$ domain to retain the content of registers and internal memories. The regulator can select a lower $V_{\text{CORE}}$ supply level to reduce the consumption in Stop mode.

- **In Standby mode**
  The external source shall be switched OFF and the $V_{\text{CORE}}$ domains powered down. The content of registers and memories is lost except for the Standby circuitry and the backup domain. The external source shall be switched ON when exiting Standby mode.

### 5.4.4 Backup domain

To retain the content of the backup domain (RTC, backup registers and backup RAM) when $V_{\text{DD}}$ is turned off, $V_{\text{BAT}}$ pin can be connected to an optional standby voltage which is supplied from a battery or from another source.

The switching to $V_{\text{BAT}}$ is controlled by the power-down reset embedded in the Reset block that monitors the $V_{\text{DD}}$ supply.

---

**Warning:**

During $t_{\text{RSTTEMPO}}$ (temporization at $V_{\text{DD}}$ startup) or after a PDR is detected, the power switch between $V_{\text{BAT}}$ and $V_{\text{DD}}$ remains connected to $V_{\text{BAT}}$.

During the a startup phase, if $V_{\text{DD}}$ is established in less than $t_{\text{RSTTEMPO}}$ (see the datasheet for the value of $t_{\text{RSTTEMPO}}$) and $V_{\text{DD}} > V_{\text{BAT}} + 0.6 \text{ V}$, a current may be injected into $V_{\text{BAT}}$ through an internal diode connected between $V_{\text{DD}}$ and the power switch ($V_{\text{BAT}}$).

If the power supply/battery connected to the $V_{\text{BAT}}$ pin cannot support this current injection, it is strongly recommended to connect an external low-drop diode between this power supply and the $V_{\text{BAT}}$ pin.

---

When the $V_{\text{DD}}$ supply is present, the backup domain is supplied from $V_{\text{DD}}$. This allows saving $V_{\text{BAT}}$ power supply battery life time.

If no external battery is used in the application, it is recommended to connect $V_{\text{BAT}}$ externally to $V_{\text{DD}}$ through a 100 nF external ceramic capacitor.

When the $V_{\text{DD}}$ supply is present and higher than the PDR threshold, the backup domain is supplied by $V_{\text{DD}}$ and the following functions are available:

- PC14 and PC15 can be used either as GPIO or as LSE pins.
- PC13 can be used either as GPIO or as RTC_AF1 or RTC_TAMP1 pin assuming they have been configured by the RTC.
- PI8/RTC_TAMP2 and PC1/RTC_TAMP3 when they are configured by the RTC as tamper pins.
Since the switch only sinks a limited amount of current, the use of PC1, PC13 to PC15 and PI8 GPIOs is restricted: only one I/O can be used as an output at a time, at a speed limited to 2 MHz with a maximum load of 30 pF. These I/Os must not be used as current sources (e.g. to drive an LED).

In \(V_{\text{BAT}}\) mode, when the \(V_{\text{DD}}\) supply is absent and a supply is present on \(V_{\text{BAT}}\), the backup domain is supplied by \(V_{\text{BAT}}\) and the following functions are available:

- PC14 and PC15 can be used as LSE pins only.
- PC13 can be used as RTC\_AF1 or RTC\_TAMP1 pin assuming they have been configured by the RTC.
- PI8/RTC\_TAMP2 and PC1/RTC\_TAMP3 when they are configured by the RTC as tamper pins.

### Accessing the backup domain

After reset, the backup domain (RTC registers and RTC backup registers) is protected against possible unwanted write accesses. To enable access to the backup domain, set the DBP bit in the **PWR control register 1 (PWR\_CR1)**.

For more detail on RTC and backup RAM access, refer to Section 7: Reset and Clock Control (RCC).

### Backup RAM

The backup domain includes 4 Kbytes of backup RAM accessible in 32-bit, 16-bit or 8-bit data mode. The backup RAM is supplied from the Backup regulator in the backup domain. When the Backup regulator is enabled through BREN bit in **PWR control register 2 (PWR\_CR2)**, the backup RAM content is retained even in Standby and/or \(V_{\text{BAT}}\) mode (it can be considered as an internal EEPROM if \(V_{\text{BAT}}\) is always present.)

The Backup regulator can be ON or OFF depending whether the application needs the backup RAM function in Standby or \(V_{\text{BAT}}\) modes.

The backup RAM is not mass erased by a tamper event, instead it is read protected to prevent confidential data, such as cryptographic private key, from being accessed. To regain access to the backup RAM after a tamper event, the memory area needs to be first erased. The backup RAM can be erased:

- through the Flash interface when a protection level change from level 1 to level 0 is requested (refer to the description of Read protection (RDP) in the Flash programming manual).
- After a tamper event, by performing a dummy write with zero as data to the backup RAM.
5.4.5 **V\textsubscript{BAT} battery charging**

When V\textsubscript{DD} is present, the external battery connected to V\textsubscript{BAT} can be charged through an internal resistance.

V\textsubscript{BAT} charging can be performed either through a 5 k\,\Omega resistor or through a 1.5 k\,\Omega resistor, depending on the VBRS bit value in \textit{PWR control register 3 (PWR\_CR3)}.

The battery charging is enabled by setting the VBE bit in \textit{PWR control register 3 (PWR\_CR3)}. It is automatically disabled in V\textsubscript{BAT} mode.

5.4.6 **Analog supply**

**Separate V\textsubscript{DDA} analog supply**

The analog supply domain is powered by dedicated V\textsubscript{DDA} and V\textsubscript{SSA} pads that allow the supply to be filtered and shielded from noise on the PCB, thus improving ADC and DAC conversion accuracy:

- The analog supply voltage input is available on a separate V\textsubscript{DDA} pin.
- An isolated supply ground connection is provided on V\textsubscript{SSA} pin.

**Analog reference voltage V\textsubscript{REF+}/V\textsubscript{REF-}**

To achieve better accuracy low-voltage signals, the ADC and DAC also have a separate reference voltage, available on V\textsubscript{REF+} pin. The user can connect a separate external reference voltage on V\textsubscript{REF+}.

The V\textsubscript{REF+} controls the highest voltage, represented by the full scale value, the lower voltage reference (V\textsubscript{REF-}) being connected to V\textsubscript{SSA}.
When enabled by ENVR bit in the VREFBUF control and status register (see Section 26: Voltage reference buffer (VREFBUF)), VREF+ is provided from the internal voltage reference buffer. The internal voltage reference buffer can also deliver a reference voltage to external components through VREF+/VREF- pins.

When the internal voltage reference buffer is disabled by ENVR, VREF+ is delivered by an independent external reference supply voltage.

5.4.7 USB regulator

The USB transceivers are supplied from a dedicated VDD33USB supply that can be provided either by the integrated USB regulator, or by an external USB supply.

When enabled by USBREGEN bit in PWR control register 3 (PWR_CR3), the VDD33USB is provided from the USB regulator. Before using VDD33USB, check that it is available by monitoring USB33RDY bit in PWR control register 3 (PWR_CR3). The VDD33USB supply level detector shall be enabled through USB33DEN bit in PWR_CR3 register.

When the USB regulator is disabled through USBREGEN bit, VDD33USB can be provided from an external supply. In this case VDD33USB and VDD50USB shall be connected together. The VDD33USB supply level detector must be enabled through USB33DEN bit in PWR_CR3 register before using the USB transceivers.

For more information on the USB regulator (see Section 56: USB on-the-go high-speed (OTG_HS)).

Figure 22. USB supply configurations

5.5 Power supply supervision

Power supply level monitoring is available on the following supplies:

- V_DD via POR/PDR (see Section 5.5.1), BOR (see Section 5.5.2) and PVD monitor (see Section 5.5.3)
- V_DDA via AVD monitor (see Section 5.5.4)
- V_BAT via VBAT threshold (see Section 5.5.5)
- V_SW via rst_vsw, which keeps V_SW domain in Reset mode as long as the level is not OK.
- V_BKP via a BRRDY bit in PWR control register 2 (PWR_CR2).
- V_DD33USB via USBRDY bit in PWR control register 3 (PWR_CR3).
5.5.1 Power-on reset (POR)/power-down reset (PDR)

The system has an integrated POR/PDR circuitry that ensures proper startup operation. The system remains in Reset mode when V\text{DD} is below a specified V\text{POR} threshold, without the need for an external reset circuit. Once the V\text{DD} supply level is above the V\text{POR} threshold, the system is taken out of reset (see Figure 23). For more details concerning the power-on/power-down reset threshold, refer to the electrical characteristics section of the datasheets.

The PDR can be enabled/disabled by the device PDR\_ON input pin.

![Figure 23. Power-on reset/power-down reset waveform](image)

1. For thresholds and hysteresis values, please refer to the datasheets.

5.5.2 Brownout reset (BOR)

During power-on, the Brownout reset (BOR) keeps the system under reset until the V\text{DD} supply voltage reaches the specified V\text{BOR} threshold.

The V\text{BOR} threshold is configured through system option bytes. By default, BOR is OFF. The following programmable V\text{BOR} thresholds can be selected:

- BOR OFF (V\text{BOR}_0)
- BOR Level 1 (V\text{BOR}_1)
- BOR Level 2 (V\text{BOR}_2)
- BOR Level 3 (V\text{BOR}_3)

For more details on the brown-out reset thresholds, refer to the section “Electrical characteristics” of the product datasheets.

A system reset is generated when the BOR is enabled and V\text{DD} supply voltage drops below the selected V\text{BOR} threshold.
BOR can be disabled by programming the system option bytes. To disable the BOR function, \( V_{DD} \) must have been higher than \( V_{BOR0} \) to start the system option byte programming sequence. The power-down is then monitored by the PDR (see Section 5.5.1).

Figure 24. BOR thresholds

1. For thresholds and hysteresis values, please refer to the datasheets.

5.5.3 Programmable voltage detector (PVD)

The PVD can be used to monitor the \( V_{DD} \) power supply by comparing it to a threshold selected by the PLS[2:0] bits in the PWR control register 1 (PWR_CR1). The PVD can also be used to monitor a voltage level on the PVD_IN pin. In this case PVD_IN voltage is compared to the internal \( \text{VREFINT} \) level.

The PVD is enabled by setting the PVDE bit in PWR control register 1 (PWR_CR1).

A PVDO flag is available in the PWR control status register 1 (PWR_CSR1) to indicate if \( V_{DD} \) or PVD_IN voltage is higher or lower than the PVD threshold. This event is internally connected to the EXTI and can generate an interrupt, assuming it has been enabled through the EXTI registers. The pwr_pvd_wkup output interrupt can be generated when \( V_{DD} \) or PVD_IN voltage drops below the PVD threshold and/or when \( V_{DD} \) or PVD_IN voltage rises above the PVD threshold depending on EXTI rising/falling edge configuration. As an example the service routine could perform emergency shutdown tasks.
1. For thresholds and hysteresis values, please refer to the datasheets.
5.5.4 Analog voltage detector (AVD)

The AVD can be used to monitor the $V_{DDA}$ supply by comparing it to a threshold selected by the ALS[1:0] bits in the *PWR control register 1 (PWR_CR1)*.

The AVD is enabled by setting the AVDEN bit in *PWR control register 1 (PWR_CR1)*.

An AVDO flag is available in the *PWR control status register 1 (PWR_CSR1)* to indicate whether $V_{DDA}$ is higher or lower than the AVD threshold. This event is internally connected to the EXTI and can generate an interrupt if enabled through the EXTI registers. The pwr_avd_wkup interrupt can be generated when $V_{DDA}$ drops below the AVD threshold and/or when $V_{DDA}$ rises above the AVD threshold depending on EXTI rising/falling edge configuration. As an example the service routine could indicate when the $V_{DDA}$ supply drops below a minimum level.

![Figure 26. AVD thresholds](msv40343v1.png)

1. For thresholds and hysteresis values, please refer to the datasheets.
5.5.5 Battery voltage thresholds

The battery voltage supply monitors the backup domain $V_{SW}$ level. $V_{SW}$ is monitored by comparing it with two threshold levels: $V_{BAT_{high}}$ and $V_{BAT_{low}}$. VBATH and VBATL flags in the PWR control register 2 (PWR_CR2), indicate if $V_{SW}$ is higher or lower than the threshold.

The $V_{BAT}$ supply monitoring can be enabled/disabled via MONEN bit in PWR control register 2 (PWR_CR2). When it is enabled, the battery voltage thresholds increase power consumption. As an example the $V_{SW}$ levels monitoring could be used to trigger a tamper event for an over or under voltage of the RTC power supply domain (available in VBAT mode).

VBATH and VBATL are connected to RTC tamper signals (see Section 45: Real-time clock (RTC)).

Note: Battery voltage monitoring is only available when the backup regulator is enabled (BREN bit set in PWR control register 2 (PWR_CR2)).

When the device does not operate in VBAT mode, the battery voltage monitoring checks $V_{DD}$ level. When $V_{DD}$ is available, $V_{SW}$ is connected to $V_{DD}$ through the internal power switch (see Section 5.4.4: Backup domain).

Figure 27. VBAT thresholds

1. For thresholds and hysteresis values, please refer to the datasheets.
### 5.5.6 Temperature thresholds

The junction temperature can be monitored by comparing it with two threshold levels, $\text{TEMP}_{\text{high}}$ and $\text{TEMP}_{\text{low}}$. $\text{TEMPH}$ and $\text{TEMPL}$ flags, in the PWR control register 2 ($\text{PWR\_CR2}$), indicate whether the device temperature is higher or lower than the threshold. The temperature monitoring can be enabled/disabled via MONEN bit in PWR control register 2 ($\text{PWR\_CR2}$). When enabled, the temperature thresholds increase power consumption.

The temperature thresholds are available only when the backup regulator is enabled (BREN bit set in the PWR CR2 register).

$\text{TEMPH}$ and $\text{TEMPL}$ wakeup interrupts are available on the RTC tamper signals (see Section 45: Real-time clock (RTC)).

---

1. For thresholds and hysteresis values, please refer to the datasheets.

---

**Figure 28. Temperature thresholds**
5.6 Power management

The power management block controls the $V_{\text{CORE}}$ supply in accordance with the system operation modes (see Section 5.6.1).

The $V_{\text{CORE}}$ domain is split into the following power domains.

- D1 domain containing some peripherals and the Cortex®-M7 Core (CPU).
- D2 domain containing a large part of the peripherals.
- D3 domain containing some peripherals and the system control.

The D1, D2 and system D3 power domains can operate in one of the following operating modes:

- DRun/Run/Run* (power ON, clock ON)
- DStop/Stop (power ON, clock OFF)
- DStandby/Standby (Power OFF, clock OFF).

The operating modes for D1 domain and D2 domain are independent. However system D3 domain power modes depend on D1 and D2 domain modes:

- For system D3 domain to operate in Stop mode, both D1 and D2 domains must be in DStop or DStandby mode.
- For system D3 domain to operate in Standby mode, both D1 and D2 domains must be in DStandby too.

D1, D2 and system D3 domains are supplied from a single regulator at a common $V_{\text{CORE}}$ level. The $V_{\text{CORE}}$ supply level follows the system operating mode (Run, Stop, Standby). The D1 domain and/or D2 domain supply can be powered down individually when the domains are in DStandby mode.

The following voltage scaling features allow controlling the power with respect to the required system performance (see Section 5.6.2: Voltage scaling):

- To obtain a given system performance, the corresponding voltage scaling shall be set in accordance with the system clock frequency. To do this, configure the VOS bits to the Run mode voltage scaling.
- To obtain the best trade-off between power consumption and exit-from-Stop mode latency, configure the SVOS bits to Stop mode voltage scaling.
5.6.1 Operating modes

Several system operating modes are available to tune the system according to the performance required, i.e. when the CPU does not need to execute code and is waiting for an external event. It is up to the user to select the operating mode that gives the best compromise between low power consumption, short startup time and available wakeup sources.

The operating modes allow controlling the clock distribution to the different system blocks and powering them. The system operating mode is driven by the CPU subsystem, D2 domain and system D3 autonomous wakeup. The CPU subsystem can include multiple domains depending on its peripheral allocation (see Section 7.5.11: Peripheral clock gating control).

The following operating modes are available for the different system blocks (see Table 30):

- **CPU subsystem modes:**
  - **CRun**
    CPU and CPU subsystem peripheral(s) allocated via RCC PERxEN bits are clocked.
  - **CSleep**:
    The CPU clocks is stalled and the CPU subsystem allocated peripheral(s) clock operate according to RCC PERxLPEN.
  - **CStop**:
    CPU and CPU subsystem peripheral(s) clocks are stalled.

- **D1 domain mode:**
  - **DRun**
    The domain bus matrix is clocked. The CPU subsystem operates in CRun or CSleep mode.
  - **DStop**
    The domain bus matrix clock is stalled.
    The CPU subsystem operates in CStop mode and the PDDS_D1(a) bit selects DStop mode.
  - **DStandby**
    The domain is powered down.
    The CPU subsystem operates in CStop mode and the PDDS_D1 bit selects DStandby mode.

- **D2 domain mode:**
  - **DRun**
    The domain bus matrix is clocked.
    The CPU subsystem has an allocated peripheral in the D2 domain and the CPU subsystem operates in CRun or CSleep mode.

---

a. The PDDS_Dn bits belong to PWR CPU control register (PWR CPUCR).
The domain bus matrix clock is stalled.
The CPU subsystem has no peripherals allocated in the D2 domain and
PDDS_D2\(^a\) bit selects DStop mode,

or

the CPU subsystem has an allocated peripheral in D2 domain, the CPU
subsystem operates in CStop mode and PDDS_D2 bit selects DStop mode.

DStandby
The domain is powered down.
The CPU subsystem has no peripherals allocated in the D2 domain and
PDDS_D2 bit selects DStandby mode,

or

the CPU subsystem has an allocated peripheral in the D2 domain, the CPU
subsystem operates in CStop mode and PDDS_D2 bit selects DStandby mode.

System \(D^3\) domain modes

– Run/Run*
The system clock and D3 domain bus matrix clock are running:
- The CPU subsystem is in CRun or CSleep mode
or
- A wakeup signal is active. (i.e. System D3 autonomous mode)
The Run* mode is entered after a POR reset and a wakeup from Standby. In Run* mode, the performance is limited and the system supply configuration shall be programmed in *PWR control register 3 (PWR_CR3)*. The system enters Run mode only when the ACTVOSRDY bit in *PWR control status register 1 (PWR_CSR1)* is set to 1.

– Stop
The system clock and D3 domain bus matrix clock is stalled:
- The CPU subsystem is in CStop mode.
and
- all wakeup signals are inactive.
and
- At least one PDDS_Dn\(^a\) bit for any domain select Stop mode.

– Standby
The system is powered down:
- The CPU subsystem is in CStop mode
and
- all wakeup signals are inactive.
and
- All PDDS_Dn\(^a\) bits for all domains select Standby mode.

In Run mode, power consumption can be reduced by one of the following means:

- Lowering the system performance by slowing down the system clocks and reducing the \(V_{\text{CORE}}\) supply level through VOS voltage scaling bits.
- Gating the clocks to the APBx and AHBx peripherals when they are not used, through PERxEN bits.

1. The CPU subsystem has an allocated peripheral in the D2 domain and operates in CRun or CSleep mode.
2. The CPU subsystem peripherals that have a PERxLPEN bit will operate accordingly.
3. If the CPU subsystem has an allocated peripheral in the D2 domain, it must operate in CStop mode.
4. The CPU subsystem peripherals that have a PERxAMEN bit will operate accordingly.
5. All domains need to be in DStop or DStandby.
6. When the CPU is in CStop and D3 domain in autonomous mode, the last EXTI Wakeup source is cleared.
7. When the system oscillator HSI or CSI is used, the state is controlled by HSIKERON and CSIKERON, otherwise the system oscillator is OFF.
8. All domains are in DStandby mode.
5.6.2 Voltage scaling

The D1, D2, and D3 domains are supplied from a single voltage regulator supporting voltage scaling with the following features:

- Run mode voltage scaling
  - VOS0: Scale 0 (V\textsubscript{CORE} boost)
  - VOS1: Scale 1
  - VOS2: Scale 2
  - VOS3: Scale 3

- Stop mode voltage scaling
  - SVOS3: Scale 3
  - LP-SVOS4: Scale 4
  - LP-SVOS5: Scale 5

For more details on voltage scaling values, refer to the product datasheets.

After reset, the system starts on the lowest Run mode voltage scaling (VOS3). The voltage scaling can then be changed on-the-fly by software by programming VOS bits in PWR D3 domain control register (PWR_D3CR) according to the required system performance. When exiting from Stop mode or Standby mode, the Run mode voltage scaling is reset to the default VOS3 value.

Before entering Stop mode, the software can preselect the SVOS level in PWR control register 1 (PWR_CR1). The Stop mode voltage scaling for SVOS4 and SVOS5 also sets the voltage regulator in Low-power (LP) mode to further reduce power consumption. When preselecting SVOS3, the use of the voltage regulator low-power mode (LP) can be selected by LPDS register bit.

VOS0 activation/desactivation sequence

The system maximum frequency can be reached by boosting the voltage scaling level to VOS0. This is done through the ODEN bit in the SYSCFG_PWRCR register.

The sequence to activate the VOS0 is the following:

1. Ensure that the system voltage scaling is set to VOS1 by checking the VOS bits in PWR D3 domain control register (PWR_D3 domain control register (PWR_D3CR))
2. Enable the SYSCFG clock in the RCC by setting the SYSCFGEN bit in the RCC_APB4ENR register.
3. Enable the ODEN bit in the SYSCFG_PWRCR register.
4. Wait for VOSRDY to be set.

Once the V\textsubscript{CORE} supply has reached the required level, the system frequency can be increased.

The sequence to deactivate the VOS0 is the following:

1. Ensure that the system frequency was decreased.
2. Ensure that the SYSCFG clock is enabled in the RCC by setting the SYSCFGEN bit set in the RCC_APB4ENR register.
3. Reset the ODEN bit in the SYSCFG_PWRCR register to disable VOS0.
Once VOS0 is disabled, the voltage scaling can be reduced further by configuring VOS bits in PWR D3 domain control register (PWR_D3CR) according to the required system performance.

**Note:** VOS0 can be enabled only when VOS1 is programmed in PWR D3 domain control register (PWR_D3CR) VOS bits. VOS0 deactivation must be managed by software before the system enters low-power mode.

**Figure 29.** $V_{\text{CORE}}$ voltage scaling versus system power modes

### 5.6.3 Power control modes

The power control block handles the $V_{\text{CORE}}$ supply for system Run, Stop and Standby modes.

The system operating mode depends on the CPU subsystem modes (CRun, CSleep, CStop), on the domain modes (DRun, DStop, DStandby), and on the system D3 autonomous wakeup:

- In Run mode, $V_{\text{CORE}}$ is defined by the VOS voltage scaling.
  The CPU subsystem is in CRun or CSleep or an EXTI wakeup is active.
- In Stop mode, $V_{\text{CORE}}$ is defined by the SVOS voltage scaling.
  The CPU subsystem is in CStop mode and all EXTI wakeups are inactive. The D1 domain and D2 domain are either in DStop or DStandby mode.
- In Standby mode, $V_{\text{CORE}}$ supply is switched off.
  The CPU subsystem is in CStop mode and all EXTI wakeups are inactive. The D1 domain and D2 domain are both in DStandby mode.
The domain operating mode can depend on the CPU subsystem when peripherals are allocated in the corresponding domain. The domain mode selection between DStop and DStandby is configured via domain dedicated PDDS_Dn bits in *PWR CPU control register (PWR_CPUCR)*. The CPU can choose to keep a domain in DStop, or allow a domain to enter DStandby mode.

If a domain is in DStandby mode, the corresponding power is switched off.

All the domains can be configured for the system mode (Stop or Standby) through PDDS_Dn bits in *PWR CPU control register (PWR_CPUCR)*. The system enters Standby only when all PDDS_Dn bits for all domains have allowed it.

CPU sub-system having an allocated peripheral in D2 domain

CPU sub-system having an allocated peripheral in D2 domain

CPU sub-system having an allocated peripheral in D2 domain
After a system reset, the CPU is in CRun mode.

Power control state transitions are initiated by the following events:

- CPU going to CStop mode (state transitions in Run mode are marked in green and red)
  - Green transitions: CPU wakes up as from CSleep.
  - Red transitions: CPU wakes up with domain reset. The SBF_Dn is set.
- Allocating or de-locating a peripheral in a domain (state transitions in Run mode are marked in orange and red)
  - Orange transitions: the domain wakes up from DStop
  - Red transitions: the domain wakes up from DStandby. The SBF_Dn is set.
- The system enters or exits from Stop mode (state transitions marked in blue)
  - Blue transitions the system wakes up from Stop mode. The STOPF is set.
- The system enters or exits from Standby mode (state transitions in Stop and Standby mode are marked in red).
  - When exiting from Standby mode, the SBF is set.

When a domain exits from DStandby, the domain peripherals are reset, while the domain SBF_Dn bit is set (state transitions causing a domain reset are marked in red).

*Table 32* shows the flags that indicate from which mode the domain/system exits. The CPU features a set of flags which can be read from *PWR CPU control register (PWR_CPUCR)*.

5.6.4 Power management examples

- Figure 31 shows \( V_{\text{CORE}} \) voltage scaling behavior in Run mode.
- Figure 32 shows \( V_{\text{CORE}} \) voltage scaling behavior in Stop mode.
- Figure 33 shows \( V_{\text{CORE}} \) voltage regulator and voltage scaling behavior in Standby mode.
- Figure 34 shows \( V_{\text{CORE}} \) voltage scaling behavior in Run mode with D1 and D2 domains are in DStandby mode

Example of \( V_{\text{CORE}} \) voltage scaling behavior in Run mode

Figure 31 illustrates the following system operation sequence example:

1. After reset, the system starts from HSI with VOS3.
2. The system performance is first increased to a medium-speed clock from the PLL with voltage scaling VOS2. To do this:
   a) Program the voltage scaling to VOS2.
   b) Once the \( V_{\text{CORE}} \) supply has reached the required level indicated by VOSRDY, increase the clock frequency by enabling the PLL.
   c) Once the PLL is locked, switch the system clock.
3. The system performance is then increased to high-speed clock from the PLL with voltage scaling VOS1. To do this:
   a) Program the voltage scaling to VOS1.
   b) Once the \( V_{\text{CORE}} \) supply has reached the required level indicated by VOSRDY, increase the clock frequency.
4. The system performance is then reduced to a medium-speed clock with voltage scaling VOS2. To do this:
   a) First decrease the system frequency.
   b) Then decrease the voltage scaling to VOS2.
5. The next step is to reduce the system performance to HSI clock with voltage scaling VOS3. To do this:
   a) Switch the clock to HSI.
   b) Disable the PLL.
   c) Decrease the voltage scaling to VOS3.
6. The system performance can then be increased to high-speed clock from the PLL. To do this:
   a) Program the voltage scaling to VOS1.
   b) Once the \( V_{\text{CORE}} \) supply has reached the required level indicated by VOSRDY, increase the clock frequency by enabling the PLL.
   c) Once the PLL is locked, switch the system clock.

When the system performance (clock frequency) is changed, VOS shall be set accordingly, otherwise the system might be unreliable.
Example of $V_{\text{CORE}}$ voltage scaling behavior in Stop mode

1. The system is running from the PLL in high-performance mode (VOS1 voltage scaling).
2. The CPU subsystem deallocates all the peripheral in the D2 domain that will first enter DStop mode. D2 system clock is stopped. The system still provides the high-performance system clock, hence the voltage scaling shall stay at VOS1 level.
3. In a second step, the CPU subsystem enters CStop mode, D1 domain enters DStop mode and the system enters Stop mode. The system clock is stopped and the hardware lowers the voltage scaling to the software preselected SVOS4 level.
4. The CPU subsystem is then woken up. The system exits from Stop mode, the D1 domain exits from DStop mode and the CPU subsystem exits from CStop mode. The hardware then sets the voltage scaling to VOS3 level and waits for the requested supply level to be reached before enabling the HSI clock. Once the HSI clock is stable, the system clock and the D1 system clock are enabled.
5. The CPU subsystem allocates a peripheral in the D2 domain. The D2 system clock is enabled.
6. The system performance is then increased. To do this:
   a) The software first sets the voltage scaling to VOS1.
   b) Once the $V_{\text{CORE}}$ supply has reached the required level indicated by VOSRDY, the clock frequency can be increased by enabling the PLL.
   c) Once the PLL is locked, the system clock can be switched.
Figure 32. Dynamic voltage scaling behavior with D1, D2 and system in Stop mode

Example of $V_{\text{CORE}}$ voltage regulator and voltage scaling behavior in Standby mode

*Figure 33* illustrates the following system operation sequence example:

1. The system is running from the PLL in high-performance mode (VOS1 voltage scaling).
2. The CPU subsystem deallocates all the peripherals in the D2 domain that will first enter DStandby mode. The D2 domain bus matrix clock is stopped and the power is switched off. The system performance is unchanged hence the voltage scaling does not change.
3. The CPU subsystem then enters to CStop mode, D1 domain enters DStandby mode and the system enters Standby mode. The system clock is stopped and the voltage regulator switched off.
4. The system is then woken up by a wakeup source. The system exits from Standby mode. The hardware sets the voltage scaling to the default VOS3 level and waits for the requested supply level to be reached before enabling the default HSI oscillator. Once the HSI clock is stable, the system clock and D1 subsystem clock are enabled.
Since there are no allocated peripherals in the D2 domain, this domain remains in DStop mode. The software shall then check the ACTVOSRDY is valid before changing the system performance.

5. In a next step, increase the system performance. To do this:
   a) The software first increases the voltage scaling to VOS1 level
   b) Before enabling the PLL, it waits for the requested supply level to be reached by monitoring VOSRDY bit.
   c) Once the PLL is locked, the system clock can be switched.

6. The CPU subsystem puts the D2 domain in DStandby mode.

Figure 33. Dynamic Voltage Scaling D1, D2, system Standby mode

1. The status of the register bits at each step is shown in blue.
Example of $V_{\text{CORE}}$ voltage scaling behavior in Run mode with D1 and D2 domains in DStandby mode

*Figure 34* illustrates the following system operation sequence example:

1. The system is running from the PLL with system in high performance mode (VOS1 voltage scaling).

2. The CPU subsystem deallocates all the peripherals in the D2 domain that will first enter DStandby mode. The D2 domain bus matrix clock is stopped and its power switched off. The system performance is unchanged hence the voltage scaling does not change.

3. The CPU subsystem then enters CStop mode and the D1 domain enters DStandby mode. The D1 domain bus matrix clock is stopped and its power switched off. At the same time the system enters Stop mode. The system clock is stopped and the hardware lowers the voltage scaling to the software preselected SVOS4 level.

4. The system is then woken up by a D3 autonomous mode wakeup event. The system exits from Stop mode. The hardware sets the voltage scaling to the default VOS3 level and waits for the requested supply level to be reached before enabling the HSI clock. Once the HSI clock is stable, the system clock is enabled. The system is running in D3 autonomous mode.

5. The D3 autonomous mode wakeup source is then cleared, causing the system to enter Stop mode. The system clock is stopped and the voltage scaling is lowered to the software preselected SVOS4 level.

6. The CPU subsystem is then woken up. The system exits from Stop mode, the D1 domain exits from DStandby mode and the CPU subsystem exits from CStop mode. The hardware sets the voltage scaling to the default VOS3 level and waits for the requested supply level to be reached before enabling the default HSI oscillator. Once the HSI clock is stable, the system clock and the D1 subsystem clock are enabled. The D2 domain remains in DStandby mode.
Figure 34. Dynamic voltage scaling behavior with D1 and D2 in DStandby mode and D3 in autonomous mode

1. The status of the register bits at each step is shown in blue.
5.7 **Low-power modes**

Several low-power modes are available to save power when the CPU does not need to execute code (i.e. when waiting for an external event). It is up to the user application to select the mode that gives the best compromise between low power consumption, short startup time and available wakeup sources:

- Slowing down system clocks (see *Section 7.5.6: System clock (sys_ck)*)
- Controlling individual peripheral clocks (see *Section 7.5.11: Peripheral clock gating control*)
- Low-power modes
  - CSleep (CPU clock stopped)
  - CStop (CPU subsystem clock stopped)
  - DStop (Domain bus matrix clock stopped)
  - Stop (System clock stopped)
  - DStandby (Domain powered down)
  - Standby (System powered down)

5.7.1 **Slowing down system clocks**

In Run mode, the speed of the system clock ck_sys can be reduced. For more details refer to *Section 7.5.6: System clock (sys_ck)*.

5.7.2 **Controlling peripheral clocks**

In Run mode, the HCLKx and PCLKx for individual peripherals can be stopped by configuring at any time PERxEN bit in RCC_C1_xxxxENR or RCC_DnxxxxENR to reduce power consumption.

To reduce power consumption in CSleep mode, the individual peripheral clocks can be disabled by configuring PERxLPEN bit in RCC_C1_xxxxLPENR or RCC_DnxxxxLPENR. For the peripherals still receiving a clock in CSleep mode, their clock can be slowed down before entering CSleep mode.

5.7.3 **Entering low-power modes**

CPU subsystem CSleep and CStop low-power modes are entered by the MCU when executing the WFI (Wait For Interrupt) or WFE (Wait for Event) instructions, or when the SLEEPONEXIT bit in the Cortex® -M System Control register is set on Return from ISR.

A domain can enter DStop or DStandby low-power mode when the CPU subsystem has an allocated peripheral in the domain and enters CStop mode, or when all D2 domain peripherals are deallocated.

The system can enter Stop or Standby low-power mode when all EXTI wakeup sources are cleared and the other domains are in DStop or DStandby mode.
5.7.4 Exiting from low-power modes

The CPU subsystem exits from CSleep mode through any interrupt or event depending on how the low-power mode was entered:

- If the WFI instruction or Return from ISR was used to enter to low-power mode, any peripheral interrupt acknowledged by the NVIC can wake up the system.
- If the WFE instruction is used to enter to low-power mode, the CPU exits from low-power mode as soon as an event occurs. The wakeup event can be generated either by:
  - An NVIC IRQ interrupt.

  When SEVONPEND = 0 in the Cortex®-M7 System Control register, the interrupt must be enabled in the peripheral control register and in the NVIC.

  When the MCU resumes from WFE, the peripheral interrupt pending bit and the NVIC peripheral IRQ channel pending bit in the NVIC interrupt clear pending register have to be cleared. Only NVIC interrupts with sufficient priority will wakeup and interrupt the MCU.

  When SEVONPEND = 1 in the Cortex®-M7 System Control register, the interrupt must be enabled in the peripheral control register and optionally in the NVIC.

  When the MCU resumes from WFE, the peripheral interrupt pending bit and, when enabled, the NVIC peripheral IRQ channel pending bit (in the NVIC interrupt clear pending register) have to be cleared.

  All NVIC interrupts will wakeup the MCU, even the disabled ones.

  Only enabled NVIC interrupts with sufficient priority will wakeup and interrupt the MCU.

  - An event

  An EXTI line must be configured in event mode. When the CPU resumes from WFE, it is not necessary to clear the EXTI peripheral interrupt pending bit or the NVIC IRQ channel pending bit as the pending bits corresponding to the event line is not set. It might be necessary to clear the interrupt flag in the peripheral.

The CPU subsystem exits from CStop, DStop and Stop modes by enabling an EXTI interrupt or event depending on how the low-power mode was entered (see above).

The system can wakeup from Stop mode by enabling an EXTI wakeup, without waking up a CPU subsystem. In this case the system will operate in D3 autonomous mode.

The CPU subsystem exits from DStandby mode by enabling an EXTI interrupt or event, regardless on how DStandby mode was entered. Program execution restarts from CPU local reset (such as a reset vector fetched from System configuration block (SYSCFG)).

The D2 domain can exit from DStop or DStandby mode when the CPU allocates a first peripheral in the domain.

The CPU subsystem exits from Standby mode by enabling an external reset (NRST pin), an IWDG reset, a rising edge on one of the enabled WKUPx pins or a RTC event. Program execution restarts in the same way as after a system reset (such as boot pin sampling, option bytes loading or reset vector fetched).
5.7.5 CSleep mode

The CSleep mode applies only to the CPU subsystem. In CSleep mode, the CPU clock is stopped. The CPU subsystem peripheral clocks operate according to the values of PERxLPEN bits in RCC_C1_xxxxENR or RCC_DnxxxxENR.

Entering CSleep mode

The CSleep mode is entered according to Section 5.7.3: Entering low-power modes, when the SLEEPDEEP bit in the Cortex®-M System Control register is cleared.

Refer to Table 33 for details on how to enter to CSleep mode.

Exiting from CSleep mode

The CSleep mode is exited according to Section 5.7.4: Exiting from low-power modes.

Refer to Table 33 for more details on how to exit from CSleep mode.

Table 33. CSleep mode

5.7.6 CStop mode

The CStop mode applies only to the CPU subsystem. In CStop mode, the CPU clock is stopped. Most CPU subsystem peripheral clocks are stopped too and only the CPU subsystem peripherals having a PERxAMEN bit operate accordingly.

In CStop mode, the CPU subsystem peripherals that have a kernel clock request can still request their kernel clock. For the peripheral that have a PERxAMEN bit, this bit shall be set to be able to request the kernel clock.

Entering CStop mode

The CStop mode is entered according to Section 5.7.3: Entering low-power modes, when the SLEEPDEEP bit in the Cortex®-M System Control register is set.

Refer to Table 34 for details on how to enter to CStop mode.

Exiting from CStop mode

The CStop mode is exited according to Section 5.7.4: Exiting from low-power modes.

Refer to Table 34 for more details on how to exit from CStop mode.

Table 34. CStop mode

<table>
<thead>

</tbody>
</table>
5.7.7 DStop mode

D1 domain and/or D2 domain enters DStop mode only when the CPU subsystem is in CStop mode and has allocated peripheral in the domain (see Table 35). In DStop mode the domain bus matrix clock is stopped.

The Flash memory can enter low-power Stop mode when it is enabled through FLPS in PWR_CR1 register. This allows a trade-off between domain DStop restart time and low power consumption.

### Table 35. DStop mode overview

<td>CStop</td>
<td>DStop</td>
<td>DStop</td>
<td></td>
</tr>
</tbody>
</table>

In DStop mode domain peripherals using the LSI or LSE clock and peripherals having a kernel clock request are still able to operate.

**Entering DStop mode**

The DStop mode is entered according to Section 5.7.3: Entering low-power modes, when at least one PDDS_Dn bit in PWR CPU control register (PWR_CPUCR) for the domain select Stop.

Refer to Table 36 for details on how to enter DStop mode.

If Flash memory programming is ongoing, the DStop mode entry is delayed until the memory access is finished.

If an access to the domain bus matrix is ongoing, the DStop mode entry is delayed until the domain bus matrix access is complete.

**Exiting from DStop mode**

The DStop mode is exited according to Section 5.7.4: Exiting from low-power modes.

Refer to Table 36 for more details on how to exit from DStop mode.

When exiting from DStop mode, the CPU subsystem clocks, domain(s) bus matrix clocks and voltage scaling depend on the system mode.

- When the system did not enter Stop mode, the CPU subsystem clocks, domain(s) bus matrix clocks and voltage scaling values are the same as when entering DStop mode.
- When the system has entered Stop mode, the CPU subsystem clocks, domain(s) bus matrix clocks and voltage scaling are reset.
5.7.8 Stop mode

The system D3 domain enters Stop mode only when the CPU subsystem is in CStop mode, the EXTI wake-up sources are inactive and at least one PDDS_Dn bit in PWR CPU control register (PWR_CPUCR) for any domain request Stop. In Stop mode, the system clock including a PLL and the D3 domain bus matrix clocks are stopped. When HSI or CSI is selected, the system oscillator operates according to the HSIKERON and CSIKERON bits in RCC_CR register. Other system oscillator sources are stopped.

In system D3 domain Stop mode, D1 domain and D2 domain are either in DStop and/or DStandby mode.

In Stop mode, the domain peripherals that use the LSI or LSE clock, and the peripherals that have a kernel clock request to select HSI or CSI as source, are still able to operate.

In system Stop mode, the following features can be selected to remain active by programming individual control bits:

- **Independent watchdog (IWDG)**
  The IWDG is started by writing to its Key register or by hardware option. Once started it cannot be stopped except by a Reset (see Section 44.3 in Section 44: Independent watchdog (IWDG)).

- **Real-time clock (RTC)**
  This is configured via the RTCEN bit in the RCC Backup Domain Control Register (RCC_BDCR).

- **Internal RC oscillator (LSI RC)**
  This is configured via the LSION bit in the RCC Clock Control and Status Register (RCC_CSR).

- **External 32.768 kHz oscillator (LSE OSC)**
  This is configured via the LSEON bit in the RCC Backup Domain Control Register (RCC_BDCR).

### Table 36. DStop mode

<table>
<thead>
<tr>
<th>DStop mode</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Mode entry** | - The domain CPU subsystem enters CStop.  
- The CPU subsystem has an allocated peripheral in the D2 domain and enters CStop.  
- The CPU subsystem deallocated its last peripheral in the D2 domain.  
- The PDDS_Dn bit for the domain selects Stop mode. |
| **Mode exit** | - The domain CPU subsystem exits from CStop mode (see Table 34)  
- The CPU subsystem has an allocated peripheral in the D2 domain and exits from CStop mode (see Table 34)  
- The CPU subsystem allocates a first peripheral in the D2 domain. |
| **Wakeup latency** | EXTI and RCC wakeup synchronization (see Section 7.4.7: Power-on and wakeup sequences). |
Peripherals capable of running on the LSI or LSE clock.
- Peripherals having a kernel clock request.
- Internal RC oscillators (HSI and CSI)
- This is configured via the HSIKERON and CSIKERON bits in the RCC Clock Control and Status Register (RCC_CSR).
- The ADC or DAC can also consume power during Stop mode, unless they are disabled before entering this mode. To disable them, the ADON bit in the ADC_CR2 register and the ENx bit in the DAC_CR register must both be written to 0.

The selected SVOS4 and SVOS5 levels add an additional startup delay when exiting from system Stop mode (see Table 37).

### Table 37. Stop mode operation

<table>
<thead>
<tr>
<th>SVOS</th>
<th>LPDS</th>
<th>Stop mode Voltage regulator operation</th>
<th>Wake-up Latency</th>
</tr>
</thead>
<tbody>
<tr>
<td>SVOS3</td>
<td>0</td>

<tr>
<td>SVOS4 or SVOS5</td>
<td>x</td>
<td>LP</td>
<td>Voltage Regulator wakeup time from LP mode + voltage level wakeup time for SVOS4 or SVOS5 level to VOS3 level</td>
</tr>
</tbody>
</table>

### Entering Stop mode

The Stop mode is entered according to Section 5.7.3: Entering low-power modes, when at least one PDDS_Dn bit in PWR CPU control register (PWR_CPUCR) for any domain request Stop.

Refer to Table 38 for details on how to enter Stop mode.

If Flash memory programming is ongoing, the Stop mode entry is delayed until the memory access is finished.

If an access to a bus matrix (AXI, AHB or APB) is ongoing, the Stop mode entry is delayed until the bus matrix access is finished.

To allow peripherals having a kernel clock request to operate in Stop mode, the system must use SVOS3 level.

**Note:** Use a DSB instruction to ensure that outstanding memory transactions complete before entering stop mode.

Before entering Stop mode, the software must ensure that VOS0 is not active.

### Exiting from Stop mode

The Stop mode is exited according to Section 5.7.4: Exiting from low-power modes.

Refer to Table 38 for more details on how to exit from Stop mode.

When exiting from Stop mode, the system clock, D3 domain bus matrix clocks and voltage scaling are reset.

STOPF status flag in PWR CPU control register (PWR_CPUCR) indicates that the system has exited from Stop mode (see Table 32).
I/O states in Stop mode
I/O pin configuration remain unchanged in Stop mode.

5.7.9 DStandby mode

Like DStop mode, DStandby mode is based on the CPU subsystem CStop mode. However the domain \( V_{\text{CORE}} \) supply is powered off. A domain enters DStandby mode only when the CPU subsystem is in CStop mode if peripherals are allocated in the domain.

A domain enters DStandby mode only when the CPU subsystem is in CStop mode if peripherals are allocated in the domain and the PDDS_Dn bit in \( \text{PWR CPU control register (PWR_CPUCR)} \) for the domain is configured accordingly. In DStandby mode, the domain is powered down and the domain RAM and register contents are lost.

Entering DStandby mode

The DStandby mode is entered according to Section 5.7.3: Entering low-power modes, when the PDDS_Dn bit in \( \text{PWR CPU control register (PWR_CPUCR)} \) for the Dn domain selects Standby mode.

Refer to Table 39 for details on how to enter DStandby mode.

If Flash memory programming is ongoing, the DStandby mode entry is delayed until the memory access is finished.

If an access to the domain bus matrix is ongoing, the DStandby mode entry is delayed until the domain bus matrix access is finished.

**Note:** When the CPU sets the PDDS_D2 bit to select Standby mode, the D2 domain enters DStandby mode (the CPU has no allocated peripherals in the D2 domain).

Exiting from DStandby mode

The DStandby mode is exited according to Section 5.7.4: Exiting from low-power modes.

Refer to Table 39 for more details on how to exit from DStandby mode.

**Note:** When the D2 domain is in DStandby mode and the CPU sets the domain PDDS_D2 bit to select Stop mode, the D2 domain remains in DStandby mode. The D2 domain will only exit DStandby when the CPU allocates a peripheral in the D2 domain.

---

Table 38. Stop mode

<table>
<thead>
<tr>
<th>Stop mode</th>
<th>Description</th>
</tr>
</thead>
</table>
| Mode entry | – When the CPU is in CStop mode and there is no active EXTI Wakeup source and Run_D3 = 0.  
– At least one PDDS_Dn bit for any domain select Stop. |
| Mode exit | – On a EXTI Wakeup. |
| Wakeup latency | System oscillator startup (when disabled).  
+ EXTI and RCC wakeup synchronization.  
+ Voltage Scaling refer to Table 37 (see Section 5.6.2: Voltage scaling) |
When exiting from DStandby mode, the domain CPU and peripherals are reset. However the state of the CPU subsystem clocks, domain(s) bus matrix clocks and voltage scaling depends on the system mode:

- When the system did not enter Stop mode, the CPU subsystem clocks, domain(s) bus matrix clocks and voltage scaling are the same as when entering DStandby mode.
- When the system has entered Stop or Standby mode, the CPU subsystem clocks, domain(s) bus matrix clocks and voltage scaling are reset.

When the D2 domain exits from DStandby mode due to the CPU subsystem (i.e. when allocating a first peripheral or when peripherals are allocated in the D2 domain and the CPU subsystem exits from CStop mode), the CPU shall verify that the domain has exited from DStandby mode. To ensure correct operation, it is recommended to follow the sequence below:

1. First check that the domain bus matrix clock is available. The domain bus matrix clock state can be checked in RCC_CR register:
   - When RCC DnCKRDY = 0, the domain bus matrix clock is stalled.
   - If RCC DnCKRDY = 1, the domain bus matrix clock is enabled.
2. Then wait for the domain has exited from DStandby mode. To do this, check the SBF_Dn flag in PWR CPU control register (PWR_CPUCR). The domain is powered and can be accessed only when SBF_Dn is cleared. Below an example of code:

   ```
   Loop
   write PWR SBF_Dn = 0 ; try to clear bit.
   read PWR SBF_Dn
   While 1 ==> loop
   ```

<table>
<thead>
<tr>
<th>DStandby mode</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Mode entry** | – The domain CPU subsystem enters CStop.  
– The CPU subsystem has an allocated peripheral in D2 domain and enters CStop.  
– The CPU subsystem deallocated its last peripheral in the D2 domain.  
– The PDDS_Dn bits for the domain select Standby mode.  
– All WKUPF bits in Power Control/Status register (PWR_WKUPFR) are cleared. |
| **Mode exit**  | – The CPU subsystem exits from CStop mode (see Table 34)  
– The CPU subsystem has an allocated peripheral in the D2 domain and exits from CStop mode (see Table 34)  
– The CPU subsystem allocates a first peripheral in the D2 domain. |
| **Wakeup latency** | EXTI and RCC wakeup synchronization.  
+ Domain power up and reset. (see Section 7.4.7: Power-on and wakeup sequences) |
5.7.10 Standby mode

The Standby mode allows achieving the lowest power consumption. Like Stop mode, it is based on CPU subsystem C
Stop mode. However the VCore supply regulator is powered off.

The system D3 domain enters Standby mode only when the D1 and D2 domain are in D
Standby. When the system D3 domain enters Standby mode, the voltage regulator is disabled. The complete VCore domain is consequently powered off. The PLLs, HSI oscillator, CSI oscillator, HSI48 and the HSE oscillator are also switched off. SRAM and register contents are lost except for backup domain registers (RTC registers, RTC backup register and backup RAM), and Standby circuitry (see Section 5.4.4: Backup domain).

In system Standby mode, the following features can be selected by programming individual control bits:

• Independent watchdog (IWDG)
  The IWDG is started by programming its Key register or by hardware option. Once started, it cannot be stopped except by a reset (see Section 44.3 in Section 44: Independent watchdog (IWDG)).

• Real-time clock (RTC)
  This is configured via the RTCE
N bit in the backup domain control register (RCC_BDCR).

• Internal RC oscillator (LSI RC)
  This is configured by the LSION bit in the Control/status register (RCC_CSR).

• External 32.768 kHz oscillator (LSE OSC)
  This is configured by the LSEON bit in the backup domain control register (RCC_BDCR).

Entering Standby mode

The Standby mode is entered according to Section 5.7.3: Entering low-power modes, when all PDDS_Dn bits in PWR CPU control register (PWR_CPUCR) for all domains request Standby.

Refer to Table 41 for more details on how to enter to Standby mode.

Note: Before entering Standby mode, the software must ensure that VOS0 is not active.

Exiting from Standby mode

The Standby mode is exited according to Section 5.7.4: Exiting from low-power modes.

Refer to Table 41 for more details on how to exit from Standby mode.

The system exits from Standby mode when an external Reset (NRST pin), an IWDG Reset, a WKUP pin event, a RTC alarm, a tamper event, or a time stamp event is detected. All registers are reset after waking up from Standby except for power control and status registers (PWR control register 2 (PWR_CR2), PWR control register 3 (PWR_CR3)), SBF bit in PWR CPU control register (PWR_CPUCR), PWR wakeup flag register (PWR_WKUPFR), and PWR wakeup enable and polarity register (PWR_WKUPEPR).

After waking up from Standby mode, the program execution restarts in the same way as after a system reset (boot option sampling, boot vector reset fetched, etc.). The SBF status flags in PWR CPU control register (PWR_CPUCR) registers indicate from which mode the system has exited (see Table 40).
In Standby mode, all I/O pins are high impedance without pull, except for:

- Reset pad (still available)
- RTC_AF1 pin if configured for tamper, time stamp, RTC Alarm out, or RTC clock calibration out
- WKUP pins (if enabled). The WKUP pin pull configuration can be defined through WKUPPUPD register bits in PWR wakeup enable and polarity register (PWR_WKUPEPR).
5.7.11 Monitoring low-power modes

The devices feature state monitoring pins to monitor the CPU and Domain state transition to low-power mode (refer to Table 42 for the list of pins and their description). The GPIO pin corresponding to each monitoring signal has to be programmed in alternate function mode.

This feature is not available in Standby mode since these I/O pins are switched to high impedance. It is available only on devices revision V.

<table>
<thead>
<tr>

1. The full domain is in power off state and the CPU is powered off.
5.8 PWR register description

The PWR registers can be accessed in word, half-word and byte format, unless otherwise specified.

5.8.1 PWR control register 1 (PWR_CR1)

Address offset: 0x000

Reset value: 0xF000 C000

| Bits 31:19 | Reserved, must be kept at reset value. |
| Bits 18:17 | ALS: Analog voltage detector level selection |
|           | These bits select the voltage threshold detected by the AVD. |
|           | 00: 1.7 V |
|           | 01: 2.1 V |
|           | 10: 2.5 V |
|           | 11: 2.8 V |
| Bit 16    | AVDEN: Peripheral voltage monitor on VDDA enable |
|           | 0: Peripheral voltage monitor on VDDA disabled. |
|           | 1: Peripheral voltage monitor on VDDA enabled |
| Bits 15:14 | SVOS: System Stop mode voltage scaling selection |
|           | These bits control the VCORE voltage level in system Stop mode, to obtain the best trade-off between power consumption and performance. |
|           | 00: Reserved |
|           | 01: SVOS5 Scale 5 |
|           | 10: SVOS4 Scale 4 |
|           | 11: SVOS3 Scale 3 (default) |
| Bits 13:10 | Reserved, must be kept at reset value. |
| Bit 9     | FLPS: Flash low-power mode in DStop mode |
|           | This bit allows to obtain the best trade-off between low-power consumption and restart time when exiting from DStop mode. |
|           | When it is set, the Flash memory enters low-power mode when D1 domain is in DStop mode. |
|           | 0: Flash memory remains in normal mode when D1 domain enters DStop (quick restart time). |
|           | 1: Flash memory enters low-power mode when D1 domain enters DStop mode (low-power consumption). |
Bit 8 **DBP**: Disable backup domain write protection
In reset state, the RCC_BDCR register, the RTC registers (including the backup registers),
BREN and MOEN bits in PWR_CR2 register, are protected against parasitic write access.
This bit must be set to enable write access to these registers.
0: Access to RTC, RTC Backup registers and backup SRAM disabled
1: Access to RTC, RTC Backup registers and backup SRAM enabled

Bits 7:5 **PLS**: Programmable voltage detector level selection
These bits select the voltage threshold detected by the PVD.
000: 1.95 V
001: 2.1 V
010: 2.25 V
011: 2.4 V
100: 2.55 V
101: 2.7 V
110: 2.85 V
111: External voltage level on PVD_IN pin, compared to internal $V_{REFINT}$ level.
Note: Refer to Section “Electrical characteristics” of the product datasheet for more details.

Bit 4 **PVDE**: Programmable voltage detector enable
0: Programmable voltage detector disabled.
1: Programmable voltage detector enabled

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **LPDS**: Low-power Deepsleep with SVOS3 (SVOS4 and SVOS5 always use low-power,
regardless of the setting of this bit)
0: Voltage regulator in Main mode (MR) when SVOS3 is selected for Stop mode
1: Voltage regulator in Low-power mode (LPR) when SVOS3 is selected for Stop mode

### 5.8.2 PWR control status register 1 (PWR_CSR1)

Address offset: 0x004
Reset value: 0x0000 4000.
5.8.3 PWR control register 2 (PWR_CR2)

Address offset: 0x008

Reset value: 0x0000 0000

This register is not reset by wakeup from Standby mode, RESET signal and V_DD POR. It is only reset by V_SW POR and VSWRST reset.

This register shall not be accessed when VSWRST bit in RCC_BDCR register resets the V_SW domain.

After reset, PWR_CR2 register is write-protected. Prior to modifying its content, the DBP bit in PWR_CR1 register must be set to disable the write protection.
Bits 31:24  Reserved, must be kept at reset value.

Bit 23 **TEMPH**: Temperature level monitoring versus high threshold
0: Temperature below high threshold level.
1: Temperature equal or above high threshold level.

Bit 22 **TEMPL**: Temperature level monitoring versus low threshold
0: Temperature above low threshold level.
1: Temperature equal or below low threshold level.

Bit 21 **VBATH**: \( V_{BAT} \) level monitoring versus high threshold
0: \( V_{BAT} \) level below high threshold level.
1: \( V_{BAT} \) level equal or above high threshold level.

Bit 20 **VBATL**: \( V_{BAT} \) level monitoring versus low threshold
0: \( V_{BAT} \) level above low threshold level.
1: \( V_{BAT} \) level equal or below low threshold level.

Bits 19:17 Reserved, must be kept at reset value.

Bit 16 **BRRDY**: Backup regulator ready
This bit is set by hardware to indicate that the Backup regulator is ready.
0: Backup regulator not ready.
1: Backup regulator ready.

Bits 15:5 Reserved, must be kept at reset value.

Bit 4 **MONEN**: \( V_{BAT} \) and temperature monitoring enable
When set, the \( V_{BAT} \) supply and temperature monitoring is enabled.
0: \( V_{BAT} \) and temperature monitoring disabled.
1: \( V_{BAT} \) and temperature monitoring enabled.

*Note:* \( V_{BAT} \) and temperature monitoring are only available when the backup regulator is enabled (BREN bit set to 1).

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **BREN**: Backup regulator enable
When set, the Backup regulator (used to maintain the backup RAM content in Standby and \( V_{BAT} \) modes) is enabled.
If BREN is reset, the backup regulator is switched off. The backup RAM can still be used in Run and Stop modes. However, its content will be lost in Standby and \( V_{BAT} \) modes.
If BREN is set, the application must wait till the Backup Regulator Ready flag (BRRDY) is set to indicate that the data written into the SRAM will be maintained in Standby and \( V_{BAT} \) modes.
0: Backup regulator disabled.
1: Backup regulator enabled.

### 5.8.4 PWR control register 3 (PWR_CR3)

Address offset: 0x00C
Reset value: 0x0000 0006 (reset only by POR only, not reset by wakeup from Standby mode and RESET pad).

The lower byte of this register is written once after POR and shall be written before changing VOS level or \( ck\_sys \) clock frequency. No limitation applies to the upper bytes.
Programming data corresponding to an invalid combination of LDOEN and BYPASS bits (see Table 29) will be ignored: data will not be written, the written-once mechanism will lock the register and any further write access will be ignored. The default supply configuration will be kept and the ACTVOSRDY bit in PWR control status register 1 (PWR_CSR1) will go on indicating invalid voltage levels. The system shall be power cycled before writing a new value.

**Bits 31:12** Reserved, must be kept at reset value.

**Bit 11** **RUN_D3**: Keep system D3 domain in Run mode regardless of the CPU subsystem modes
- 0: D3 domain follows CPU subsystem modes.
- 1: D3 domain remains in Run mode regardless of CPU subsystem modes.

**Bit 10** Reserved, must be kept at reset value.

**Bit 9** **CSSF**: Clear Standby and Stop flags (always read as 0)
- This bit is cleared to 0 by hardware.
  - 0: No effect.
  - 1: STOPF, SBF, SBF_D1, and SBF_D2 flags are cleared.

**Bit 8** **SBF_D2**: D2 domain DStandby flag
- This bit is set by hardware and cleared by any system reset or by setting the CSSF bit. Once set, this bit can be cleared only when the D2 domain is no longer in DStandby mode.
  - 0: D2 domain has not been in DStandby mode
  - 1: D2 domain has been in DStandby mode.

**Bit 7** **SBF_D1**: D1 domain DStandby flag
- This bit is set by hardware and cleared by any system reset or by setting the CSSF bit. Once set, this bit can be cleared only when the D1 domain is no longer in DStandby mode.
  - 0: D1 domain has not been in DStandby mode
  - 1: D1 domain has been in DStandby mode.

**Bit 6** **SBF**: System Standby flag
- This bit is set by hardware and cleared only by a POR (Power-on Reset) or by setting the CSSF bit
  - 0: System has not been in Standby mode
  - 1: System has been in Standby mode

**Bit 5** **STOPF**: STOP flag
- This bit is set by hardware and cleared only by any reset or by setting the CSSF bit.
  - 0: System has not been in Stop mode
  - 1: System has been in Stop mode

**Bits 4:3** Reserved, must be kept at reset value.
Bit 2 **PDDS_D3**: System D3 domain Power Down Deepsleep.  
This bit allows defining the Deepsleep mode for System D3 domain.  
0: Keep Stop mode when D3 domain enters Deepsleep.  
1: Allow Standby mode when D3 domain enters Deepsleep.

Bit 1 **PDDS_D2**: D2 domain Power Down Deepsleep.  
This bit allows defining the Deepsleep mode for D2 domain.  
0: Keep DStop mode when D2 domain enters Deepsleep.  
1: Allow DStandby mode when D2 domain enters Deepsleep.

Bit 0 **PDDS_D1**: D1 domain Power Down Deepsleep selection.  
This bit allows defining the Deepsleep mode for D1 domain.  
0: Keep DStop mode when D1 domain enters Deepsleep.  
1: Allow DStandby mode when D1 domain enters Deepsleep.

### 5.8.6 PWR D3 domain control register (PWR_D3CR)

This register allows controlling D3 domain power.

**Address offset**: 0x018  
**Reset value**: 0x0000 4000 (Following reset VOSRDY will be read 1 by software).

Bits 31:16  **Reserved, must be kept at reset value.**

Bits 15:14  **VOS**: Voltage scaling selection according to performance  
These bits control the $V_{\text{CORE}}$ voltage level and allow to obtain the best trade-off between power consumption and performance:  
– When increasing the performance, the voltage scaling shall be changed before increasing the system frequency.  
– When decreasing performance, the system frequency shall first be decreased before changing the voltage scaling.  
00: Reserved (Scale 3 selected).  
01: Scale 3 (default)  
10: Scale 2  
11: Scale 1

Bit 13  **VOSRDY**: VOS Ready bit for $V_{\text{CORE}}$ voltage scaling output selection.  
This bit is set to 1 by hardware when Bypass mode is selected in PWR control register 3 (PWR_CR3).  
0: Not ready, voltage level below VOS selected level.  
1: Ready, voltage level at or above VOS selected level.

Bits 12:0  **Reserved, must be kept at reset value.**
5.8.7 **PWR wakeup clear register (PWR_WKUPCR)**

Address offset: 0x020

Reset value: 0x0000 0000 (reset only by system reset, not reset by wakeup from Standby mode)

5 wait states are required when writing this register (when clearing a WKUPF bit in PWR_WKUPFR, the AHB write access will complete after the WKUPF has been cleared).

Bits 31:6 Reserved, always read as 0.

Bits 5:0 **WKUPCn+1**: Clear Wakeup pin flag for WKUPn+1.

These bits are always read as 0.

0: No effect
1: Writing 1 clears the WKUPFn+1 Wakeup pin flag (bit is cleared to 0 by hardware)

5.8.8 **PWR wakeup flag register (PWR_WKUPFR)**

Address offset: 0x024

Reset value: 0x0000 0000 (reset only by system reset, not reset by wakeup from Standby mode)

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **WKUPn+1**: Wakeup pin WKUPn+1 flag.

This bit is set by hardware and cleared only by a Reset pin or by setting the WKUPCn+1 bit in the PWR wakeup clear register (PWR_WKUPCR).

0: No wakeup event occurred
1: A wakeup event was received from WKUPn+1 pin
5.8.9 **PWR wakeup enable and polarity register (PWR_WKUPEPR)**

Address offset: 0x028

Reset value: 0x0000 0000 (reset only by system reset, not reset by wakeup from Standby mode)

Bits 31:28  Reserved, must be kept at reset value.

Bits 27:16 **WKUPPUPD[truncate(n/2)-7]**: Wakeup pin pull configuration for WKUP[truncate(n/2)-7]

These bits define the I/O pad pull configuration used when WKUP[truncate(n/2)-7] = 1. The associated GPIO port pull configuration shall be set to the same value or to ‘00’.

The Wakeup pin pull configuration is kept in Standby mode.

00: No pull-up
01: Pull-up
10: Pull-down
11: Reserved

Bits 15:14  Reserved, must be kept at reset value.

Bits 13:8 **WKUPPn-7**: Wakeup pin polarity bit for WKUPn-7

These bits define the polarity used for event detection on WKUPn-7 external wakeup pin.

0: Detection on high level (rising edge)
1: Detection on low level (falling edge)

Bits 7:6  Reserved, must be kept at reset value.

Bits 5:0 **WKUPENn+1**: Enable Wakeup Pin WKUPn+1

Each bit is set and cleared by software.

0: An event on WKUPn+1 pin does not wakeup the system from Standby mode.
1: A rising or falling edge on WKUPn+1 pin wakes-up the system from Standby mode.

*Note:* An additional wakeup event is detected if WKUPn+1 pin is enabled (by setting the WKUPENn+1 bit) when WKUPn+1 pin level is already high when WKUPPn+1 selects rising edge, or low when WKUPPn+1 selects falling edge.
### 5.8.10 PWR register map

Table 44. Power control register map and reset values

| Offset | Register name | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

Refer to Section 2.3 on page 126 for the register boundary addresses.
6 Low-power D3 domain

This section describes, through an example, how to use the D3 domain to implement low-power applications.

6.1 Introduction

The first part of the description explains how the EXTI, RCC and PWR blocks interact with each other and with the other system blocks. A detailed explanation on how the DMAMUX2 can be used to free the CPU is also provided.

The second part explains how to use the Autonomous mode to perform simple data transfers through an example of LINUART1 transmission.

Register programming is detailed only for the blocks related to the Autonomous mode.

6.2 EXTI, RCC and PWR interconnections

*Figure 35* shows the main EXTI, RCC and PWR interconnections.
Figure 35. EXTI, RCC and PWR interconnections
6.2.1 Interrupts and wakeup

Three kinds of signals are exchanged between the peripherals. They can be used to wake up the system from Stop mode:

- **Wakeup events** (or asynchronous interrupts)
  
  Some peripherals can generate interrupt events, even if their bus interface clock is not present. These interrupt events are called wakeup events (or asynchronous interrupts).
  
  Example: i2c1_wkup, usart1_wkup and lptim1_wkup.

- **Signals**
  
  Some peripherals generate a pulse instead of an interrupt signal. These pulses are called signals.
  
  Examples: lptim2_out and lptim3_out.

- **Interrupts**
  
  Contrary to signals, the interrupts should be cleared by a CPU or any other bus master, either by clearing the corresponding event bit in the peripheral register or by updating the FIFO interrupt level.

  All the interrupts associated to system peripherals are directly connected to the NVIC, except for the peripherals which are able to wake up the system from Stop mode or the CPU from CStop. In this latter case, the interrupts, signals or wakeup events are connected to the NVIC via the EXTI.

  Example: spi1_it, tim1_brk_it and tim1_upd_it.

The interrupt and wakeup sources that require to be cleared in the peripheral itself are connected to EXTI Direct Event inputs. The EXTI does not manage any CPU status pending bit.

The peripherals signals are connected to EXTI Configurable Event inputs. These EXTI inputs provide a CPU status pending bit which needs to be cleared by the application.

6.2.2 Block interactions

**Interaction between EXTI and PWR blocks**

The EXTI delivers wakeup requests signals (**exti_c_wkup, exti_d3_wkup**) to the PWR controller. These signals are activated according to the state of the interrupts, signals or wakeup events connected to the EXTI. These wakeup requests are used by the PWR controller to supply the domain who needs to handle the activated wakeup event generated by the peripherals.

**Interaction between PWR and RCC blocks**

The PWR block controls the $V_{CORE}$ supply according to the system operating mode (CRun, CSleep or CStop). The PWR block also controls the power switches (ePODs) that delivers $V_{CORE}$ supply to D1 and D2 domains.

The RCC block controls the clock generation in accordance with the system operating mode. It is also responsible for reset generation.
To synchronize the system mode transitions, the RCC block is tightly coupled with the PWR controller:

- The RCC informs the PWR controller when peripherals located in Dx domain are allocated by the CPU (c_per_alloc_d2, c_per_alloc_d1).
- The RCC also warns the PWR block when a domain clock is activated/deactivated. These signals are used in case of domain transition from DRun to DStop or DStandby. In this case, the PWR controller waits until the domain clock has been gated, before switching down this domain.
- Similarly, the PWR controller informs the RCC about the V\text{CORE} supply status of each domain (pwr_d[1:3]_wkup). This information is used by the RCC when a domain transition from DStop or DStandby to DRun occurs.

**Interaction between EXTI and D3 domain**

All the wakeup event inputs received by the EXTI from the peripherals located in D3 domain are forwarded back to the D3 domain after system clock re-synchronization. These events are used by the D3 domain to perform autonomous operations without activating the CPU.

The EXTI D3\_PenClear[3:0] inputs received from the D3 domain are used to acknowledge the ongoing wakeup requests generated by peripherals located in the D3 domain. The D3\_PenClear[3:0] inputs allow switching the system D3 domain from Run to Stop mode.

### 6.2.3 Role of D3 domain DMAMUX2

The DMAMUX2 implemented in the D3 domain allows chaining BDMA transfers. BDMA requests are synchronized thanks to trigger events (dmamux2\_evtx) which can be generated when the expected amount of data has been transferred.

These events can also trigger DMAMUX2 request generators (REQ\_GEN[3:0]), and thus chain several BDMA transfers. In fact REQ\_GEN[3:0] can be triggered indirectly by all the wakeup events generated by all D3 domain peripherals.

Like LPTIM5 and LPTIM4 outputs, dmamux2\_evt7 and dmamux2\_evt6 events are connected to the EXTI. They can be used to switch the D3 domain from DRun to DStop mode when the task requested by the wakeup event is complete.
6.3 Low-power application example based on LPUART1 transmission

This section illustrates, through an example, the benefit of the D3 domain usage on power consumption. To help the user program the device, only the key register settings are given herein.

Refer to Section 7: Reset and Clock Control (RCC) and Section 5: Power control (PWR) for additional details.

6.3.1 Memory retention

The D3 domain features 64 Kbytes of SRAM (SRAM4), which can be used to retain data while the D1 and D2 domains enter DStandby mode.

This feature can be used in several use-cases:
- to retain the application code in order to recover properly from DStandby
- to retain the data from/to a sensor when the CPU enters CStop with D1 or D2 domain in DStandby) between two consecutive operations.

Note: SRAM4 remains available as long as the system is not in Standby mode. If the system is in Standby mode, it is still possible to use the BKUP_SRAM. However, its size is limited to 4 Kbytes.

6.3.2 Memory-to-peripheral transfer using LPUART1 interface

Example description

Figure 36 shows the proposed implementation. At a regular time interval given by LPTIM4, the CPU wakes up from CStop mode (which domain is in DStandby). When the CPU is in Run mode, it prepares the data to be transmitted via LPUART1, transfers them to SRAM4, and goes back to CStop. The D3 domain is configured to perform data transfers via LPUART1 and go back to Stop mode when the transfer is complete.

The LPTIM4 interface is used to wake up the system from Standby at regular time intervals. The CPU must then perform the following operations:
1. Recover the application from the system Standby mode (RECO).
2. Process the new data to be sent via LPUART1 (PROC).
3. Transfer the data into SRAM4 (XFER).
4. Configure the DMAMUX2, the BDMA, the LPUART1, and the RCC (CFG).
5. Configure the EXTI (CFG).
6.Configure the PWR block to allow the D1 domain to go to DStandby mode (STP).
7. Set the CPU to Stop mode.

The D3 domain executes the following tasks in Autonomous mode:
1. Transfer the data from SRAM4 to LPUART1, using BDMA.
2. When the LPUART1 interface indicates that the last byte has been transferred, the D3 domain is switched to Stop mode.
Note: In the above example described in this section, the D3 domain cannot be kept in Run mode when D1 and D2 domains are in DStop/DStandby by using the RUN_D3 bit of PWR_CPUCR register. RUN_D3 will force the D3 domain to Run mode, but it will not be able to go back to Stop on its own.

If the application needs to toggle the D3 domain between Stop and Run modes, then the Run mode must be triggered by a wakeup event so that the D3 domain can clear this event is needed.

**RCC programming**

In this example, the CPU sub-system also includes the peripherals of D3 domain that are used for the data transfer, that is BDMA, DMAMUX2, LPUART1 and LPTIM4. These peripherals must be programmed in Autonomous mode, in order to operate even when the CPU is in CSTOP mode.

LPUART1 can use its own APB clock as kernel clock. Since the system will not enter Stop mode before LPUART1 has completed data transfer, PLLx can be used to provide clocks to the peripherals.

**PWR programming**

In this example, the PWR block must be programmed in order to:
- Prevent system D3 domain to enter Standby mode when the data transfer is complete.
- Allow the D1 domain to enter DStandby.
- Define the working voltage according to system modes.

Note: D3 domain could enter Standby as well, but in this case the LPTIM4 could not be used to wake up the system and the AWU should be used instead. In addition, everything must be reprogrammed when the system wakes up.
**EXTI programming**

The EXTI block must be configured to provide the following services:

- Keep D3 domain running when D1 domain is in DStandby. This will be done by a software event.
- Set the device to Stop mode when the data transfer via LPUART1 is complete.
- Wake up the product from Stop when LPTIM4 time interval has elapsed.

The EXTI block is configured once before performing the first data transfer. For incoming data transfers, the programmed configuration remains unchanged; only some events need to be triggered or acknowledged.

*Note:* The CPU uses the event input number 0 to generate a software event. LPTIM4 wakeup signal is connected to event input number 52 (direct event input).

All other event inputs must be disabled: EXTI_RTSRx_TRy = ‘0’ and EXTI_FTSRx_TRy = ‘0’.

To generate a wakeup event for D3 domain, the CPU must write SWIER0 bit of EXTI_SWIER1 to ‘1’. The GPIO connected to this event input must not toggle in order to avoid spurious wakeup. To prevent the GPIO to disturb, the following sequence can be done:

**BDMA and DMAMUX2 programming**

Two BDMA channels are required to execute data transfers via LPUART1.

- A BDMA channel, such as channel 0, is used to transfer data from SRAM4 to LPUART1, using the TXE flag.
- The second BDMA channel role is to switch the D3 domain to Stop mode. For that purpose, DMAMUX2 request generator channel 0 (REQ_GEN0) and DMAMUX2 channel 7 synchronization block (SYNC7) are used in conjunction with BDMA channel 7.

BDMA channel 0 does not use DMAMUX2 trigger capabilities. Refer to *Table 45* for initialization details.

BDMA channel 7 uses REQ_GEN0 to generate BDMA requests. The generation of BDMA requests is triggered by the LPUART1 transmit interrupt (*luart1_tx_it*). The LPUART1 interface generates *luart1_tx_it* interrupt when the transmit complete event is detected. The BDMA then clears the pending interrupt by performing a write operation to the LPUART1.

The SYNC7 block is programmed in Free-running mode. It generates a pulse on its *dmamux2Evt7* output when the BDMA request generated by the REQ_GEN0 is complete. *dmamux2Evt7* signal is used by the EXTI to switch back the D3 domain to Stop mode.

*Figure 37* shows the active signal paths via DMAMUX2. The grayed blocks represent the unused paths.
Table 45 explain how to program BDMA and DMAMUX2 key functions. The way errors are handled is not described.

**LPTIM4 programming**

When LPTIM4 wakeup event occurs, the CPU reboots and D3 domain mode is also set to Run mode.

An interrupt issued by LPTIM4 is pending on the CPU NVIC. LPTIM4 interrupt handler must acknowledge this LPTIM4 interrupt by writing ARRMCF bit in LPTIM4_ICR register to ‘1’ (LPTIM4_Ack).

**LPUART programming**

In the use-case described herein, the capability of the LPUART1 to request the kernel clock according to some events is not used.

LPUART1 is programmed so that is generates a BDMA request when its TX-FIFO is not full.

LPUART1 also generates an interrupt when the TX-FIFO and its transmit shift register are empty. This interrupt is used to switch the D3 domain to Stop mode.

*Table 46* gives the key settings concerning the handling of Stop mode for LPUART1.
Respect the sequence described in Table 47 to enable LPUART1.

#### 6.3.3 Overall description of the low-power application example based on LPUART1 transmission

After a Power-on reset, the CPU perform the following operations:

1. Boot sequence (not described here).
2. Full initialization of RCC, PWR, EXTI, LPUART1, GPIOs, LPTIM4, DMAMUX2, BDMA and NVIC.
   - Only the relevant steps of RCC, EXTI, LPUART1, BDMA and DMAMUX2 initialization related to the Autonomous mode are described herein. Refer to the previous sections for additional details.
3. The CPU processes the data to be transferred and copies them to SRAM4.
4. The CPU generates a wakeup event (EXTI_Event) to maintain D3 in Run mode when D1 enters DStandby.
5. The CPU enables the BDMA to start LPUART transmission and goes to Stop mode. As it is allowed to do so, D1 domain enters DStandby while D3 remains in Run mode. The data stored in SRAM4 are retained while the D1 domain is in DStandby mode.
6. As soon as the BDMA is enabled, it serves the request from LPUART1 in order to fill its TX-FIFO. In parallel, serial data transmission can start.
7. When the expected amount of data has been transmitted (NDT bits of BDMA_CNDTR0 set to 0), the BDMA no longer provides data to the LPUART1. The LPUART1 generates an interrupt when the TX-FIFO and the transmit buffer are empty.
8. This interrupt triggers DMAMUX2 REQ_GEN0, thus activating a data transfer via BDMA channel 7 (BDMA_Ch7). This transfer clears LPUART1 TC flag, and the lpuart1_tx_it is reset to ‘0’.
9. The end of this transfer triggers a dmamux2_evt7 signal which is used to clear the wakeup request generated by the CPU.
10. As a consequence, the D3 domain (i.e. the system) enters Stop mode and the system clock is gated. LPTIM4 still operates since it uses cklsi clock.
11. LPTIM4 lptim4_wkup interrupt wakes up the system. The device exits from Stop mode with the HSI clock. The CPU must restore the proper clock configuration during the warm re-boot sequence and perform the following tasks:
   a) Acknowledge LPTIM4 wakeup interrupt,
   b) Process the next data block and transfers them to SRAM4,
   c) Generate again a wakeup event for D3 domain,
   d) Start the BDMA,
   e) Go back to CStop mode.

Note: The CPU does not need to initialize BDMA, DMAMUX2 and LPUART1 again.

Figure 38. Timing diagram of LPUART1 transmission with D3 domain in Autonomous mode

6.3.4 Alternate implementations

More power efficient implementations are also possible. As an example the system clock can be stopped once the data have been transferred to LPUART1 TX-FIFO, instead of remaining activated during the whole transmission as in the example presented above. In this case, the LPUART1 must use ck_hsi or ck_csi as kernel clock when the system switches from Run to Stop mode. LPUART1 must be programmed to wake up D3 domain when its TX-FIFO is almost empty. This asynchronous interrupt can be used as trigger by the REQ_GENx of the DMAMUX2, which will perform a given number (e.g. 14) of data transfers to LPUART1_TDR and then switch back the D3 domain to Stop mode. This implementation is possible because the LPUART1 can request the kernel clock as long as the TX-FIFO and transmit buffer are not empty.
6.4 Other low-power applications

Other peripherals located in D3 domain, such as I2C4, SPI6, SAI4 or ADC3, can be used to implement low-power applications.
7 Reset and Clock Control (RCC)

The RCC block manages the clock and reset generation for the whole microcontroller. The RCC block is located in the D3 domain (refer to Section 5: Power control (PWR) for a detailed description).

The operating modes this section refers to are defined in Section 5.6.1: Operating modes of the PWR block.

7.1 RCC main features

Reset block
  • Generation of local and system reset
  • Bidirectional pin reset allowing to reset the microcontroller or external devices
  • WWDG reset supported

Clock generation block
  • Generation and dispatching of clocks for the complete device
  • 3 separate PLLs using integer or fractional ratios
  • Possibility to change the PLL fractional ratios on-the-fly
  • Smart clock gating to reduce power dissipation
  • 2 external oscillators:
    – High-speed external oscillator (HSE) supporting a wide range of crystals from 4 to 48 MHz frequency
    – Low-speed external oscillator (LSE) for the 32 kHz crystals
  • 4 internal oscillators
    – High-speed internal oscillator (HSI)
    – 48 MHz RC oscillator (HSI48)
    – Low-power Internal oscillator (CSI)
    – Low-speed internal oscillator (LSI)
  • Buffered clock outputs for external devices
  • Generation of two types of interrupts lines:
    – Dedicated interrupt lines for clock security management
    – One general interrupt line for other events
  • Clock generation handling in Stop and Standby mode
  • D3 domain Autonomous mode
7.2 RCC block diagram

Figure 39 shows the RCC block diagram.

Figure 39. RCC Block diagram

7.3 RCC pins and internal signals

Table 48 lists the RCC inputs and output signals connected to package pins or balls.

<table>

### 7.4 RCC reset block functional description

Several sources can generate a reset:
- An external device via NRST pin
- A failure on the supply voltage applied to V_DD
- A watchdog timeout
- A software command

The reset scope depends on the source that generates the reset. Three reset categories exist:
- Power-on/off reset
- System reset
- Local resets

#### 7.4.1 Power-on/off reset

The power-on/off reset (pwr_por_rst) is generated by the power controller block (PWR). It is activated when the input voltage (V_DD) is below a threshold level. This is the most complete reset since it resets the whole circuit, except the backup domain. The power-on/off reset function can be disabled through PDR_ON pin (see Section 5.5: Power supply supervision).

Refer to Table 50: Reset distribution summary for details.

7.4.2 System reset

A system reset (nreset) resets all registers to their default values except for the reset status flags in the RCC_RSR (or RCC_C1_RSR) register, the debug features, the Flash memory and the Backup domain registers.

A system reset can be generated from one of the following sources:

- A reset from NRST pin (external reset)
- A reset from the power-on/off reset block (pwr_por_rst)
- A reset from the brownout reset block (pwr_bor_rst)

Refer to Section 5.5.2: Brownout reset (BOR) for a detailed description of the BOR function.

- A reset from the independent watchdogs (iwdg1_out_rst)
- A software reset from the Cortex®-M7 core
  It is generated via the SYSRESETREQ signal issued by the Cortex®-M7 core. This signal is also named SFTRESET in this document.
- A reset from the window watchdogs depending on WWDG configuration (wwdg1_out_rst)
- A reset from the low-power mode security reset, depending on option byte configuration (lpwr[2:1]_rst)

Note: The SYSRESETREQ bit in Cortex®-M7 Application Interrupt and Reset Control Register must be set to force a software reset on the device. Refer to the Cortex®-M7 with FPU technical reference manual for more details (see http://infocenter.arm.com).

As shown in Figure 40, some internal sources (such as pwr_por_rst, pwr_bor_rst, iwdg1_out_rst) perform a system reset of the circuit, which is also propagated to the NRST pin to reset the connected external devices. The pulse generator guarantees a minimum reset pulse duration of 20 μs for each internal reset source. In case of an external reset, the reset pulse is generated while the NRST pin is asserted Low.

Note: It is not recommended to let the NRST pin unconnected. When it is not used, connect this pin to ground via a 10 to 100 nF capacitor (C_R in Figure 40).

Figure 40. System reset circuit
7.4.3 Local resets

CPU reset

The CPU can reset itself by means of the CPURST bit in RCC AHB3 Reset Register (RCC_AHB3RSTR).

Domain reset

Some resets also dependent on the domain status. For example, when D1 domain exits from DStandby, it is reset (d1_rst). The same mechanism applies to D2.

When the system exits from Standby mode, a stby_rst reset is applied. The stby_rst signal generates a reset of the complete V CORE domain as long the V CORE voltage provided by the internal regulator is not valid.

*Table 50* gives a detailed overview of reset sources and scopes.

7.4.4 Reset source identification

The CPU can identify the reset source by checking the reset flags in the RCC_RSR (or RCC_C1_RSR) register.

The CPU can reset the flags by setting RMVF bit.

Table 51 shows how the status bits of RCC_RSR (or RCC_C1_RSR) register behaves, according to the situation that generated the reset. For example when an IWDG1 timeout occurs (line #10), if the CPU is reading the RCC_RSR (or RCC_C1_RSR) register during the boot phase, both PINRSTF and IWDG1RSTF bits are set, indicating that the IWDG1 also generated a pin reset.

7.4.5 Low-power mode security reset (lpwr_rst)

To prevent critical applications from mistakenly enter a low-power mode, two low-power mode security resets are available. When enabled through nRST_STOP_D1 option bytes, a system reset is generated if the following conditions are met:

- CPU accidentally enters CStop mode
  This type of reset is enabled by resetting nRST_STOP_D1 user option byte. In this case, whenever the CPU CStop mode entry sequence is successfully executed, a system reset is generated.

- D1 domain accidentally enters DStandby mode
  This type of reset is enabled by resetting nRST_STDBY_D1 user option byte. In this case, whenever a D1 domain DStandby mode entry sequence is successfully executed, a system reset is generated.

LPWRRSTF bits in RCC Reset Status Register (RCC_RSR) indicates that a low-power mode security reset occurred (see line #12 in Table 51).

lpwr_rst is activated when a low-power mode security reset due to D1 or CPU occurred.
Refer to Section 3.4: FLASH option bytes for additional information.

7.4.6 Backup domain reset

A backup domain reset is generated when one of the following events occurs:

- A software reset, triggered by setting BDRST bit in the RCC Backup Domain Control Register (RCC_BDCR). All RTC registers and the RCC_BDCR register are reset to their default values. The backup RAM is not affected.

- \( V_{SV} \) voltage is outside the operating range. All RTC registers and the RCC_BDCR register are reset to their default values. In this case the content of the backup RAM is no longer valid.

There are two ways to reset the backup RAM:

- through the Flash memory interface by requesting a protection level change from 1 to 0
- when a tamper event occurs.

Refer to Section 5.4.4: Backup domain section of PWR block for additional information.

7.4.7 Power-on and wakeup sequences

For detailed diagrams refer to Section 5.4.1: System supply startup in the PWR section.

The time interval between the event which exits the product from a low-power and the moment where the CPU is able to execute code, depends on the system state and on its configuration. Figure 41 shows the most usual examples.

Power-on wakeup sequence

The power-on wakeup sequence shown in Figure 41 gives the most significant phases of the power-on sequence. It is the longest sequence since the circuit was not powered. Note that this sequence remains unchanged, whatever \( V_{BAT} \) was present or not.
Boot from pin reset

When a pin reset occurs, $V_{DD}$ is still present. As a results:

- The regulator settling time is faster since the reference voltage is already stable.
- The HSI restart delay may be needed if the HSI was not enabled when the NRST occurred, otherwise this restart delay phase is skipped.
- The Flash memory power recovery delay can also be skipped if the Flash memory was enabled when the NRST occurred.

Note: The boot sequence is similar for pwr_bo_rst, lpwr_rst, STFxRESET, iwdg1_out_rst and wwdg1_out_rst (if WW1RSC = '1').

Boot from system Standby

When waking up from system Standby, the reference voltage is stable since $V_{DD}$ has not been removed. As a result, the regulator settling time is fast. Since $V_{CORE}$ was not present, the restart delay for the HSI, the Flash memory power recovery and the option byte reloading cannot be skipped.

Restart from system Stop

When restarting from system Stop, $V_{DD}$ is still present. As a result, the sequence is mainly composed of two steps:

1. Regulator settling time to reach VOS3 (default voltage)
2. HSI/CSI restart delay. This step can be skipped if HSIKERON or CSIKERON bit, in RCC Source Control Register (RCC_CR) is set to '1'.

Boot from domain DStandby

The boot sequence of a domain from domain DStandby is mainly composed of two steps:

1. The power switch settling time (the regulator is already activated).
2. The Flash memory power recovery.

Restart from domain DStop

The restart sequence of a domain from domain DStop is mainly composed of the handshake between the RCC, EXTI and PWR blocks.
Figure 41. Boot sequences versus system states

- VDD > POR: Power-on wake-up (with or without VBAT)
- NRST goes HIGH: PAD Reset (or pwr_bor_rst, SFTRESET, iwdg1_out_rst…)
- Wakeup event: Wake-up from system Standby
- Wakeup event: Re-start from system Stop
- Wakeup event: Wake-up from Domain DStandby
- Wakeup event: Re-start from Domain DStop
7.5 RCC clock block functional description

The RCC provides a wide choice of clock generators:

- HSI (High-speed internal oscillator) clock: ~ 8, 16, 32 or 64 MHz
- HSE (High-speed external oscillator) clock: 4 to 48 MHz
- LSE (Low-speed external oscillator) clock: 32 kHz
- LSI (Low-speed internal oscillator) clock: ~ 32 kHz
- CSI (Low-power internal oscillator) clock: ~4 MHz
- HSI48 (High-speed 48 MHz internal oscillator) clock: ~48 MHz

It offers a high flexibility for the application to select the appropriate clock for CPU and peripherals, in particular for peripherals that require a specific clock such as Ethernet, USB OTG-FS and HS, SPI/I2S, SAI and SDMMC.

To optimize the power consumption, each clock source can be switched ON or OFF independently.

The RCC provides up to 3 PLLs; each of them can be configured with integer or fractional ratios.

As shown in the Figure 42, the RCC offers 2 clock outputs (MCO1 and MCO2), with a great flexibility on the clock selection and frequency adjustment.

The SCGU block (System Clock Generation Unit) contains several prescalers used to configure the CPU and bus matrix clock frequencies.

The PKSU block (Peripheral Kernel clock Selection Unit) provides several dynamic switches allowing a large choice of kernel clock distribution to peripherals.

The PKEU (Peripheral Kernel clock Enable Unit) and SCEU (System Clock Enable Unit) blocks perform the peripheral kernel clock gating, and the bus interface/cores/bus matrix clock gating, respectively.
Figure 42. Top-level clock tree

The selected input can be changed on-the-fly without spurs on the output signal

$\square$ Represents the selected mux input after a system reset
7.5.1 Clock naming convention

The RCC provides clocks to the complete circuit. To avoid misunderstanding, the following terms are used in this document:

- **Peripheral clocks**
  The peripheral clocks are the clocks provided by the RCC to the peripherals. Two kinds of clock are available:
  - The bus interface clocks
  - The kernel clocks

A peripheral receives from the RCC a bus interface clock in order to access its registers, and thus control the peripheral operation. This clock is generally the AHB, APB or AXI clock depending on which bus the peripheral is connected to. Some peripherals only need a bus interface clock (e.g. RNG, TIMx).

Some peripherals also require a dedicated clock to handle the interface function. This clock is named "kernel clock". As an example, peripherals such as SAI have to generate specific and accurate master clock frequencies, which require dedicated kernel clock frequencies. Another advantage of decoupling the bus interface clock from the specific interface needs, is that the bus clock can be changed without reprogramming the peripheral.

- **CPU clocks**
  The CPU clock is the clock provided to the CPU. It is derived from the system clock (sys_ck).

- **Bus matrix clocks**
  The bus matrix clocks are the clocks provided to the different bridges (APB, AHB or AXI). These clocks are derived from the system clock (sys_ck).

7.5.2 Oscillators description

**HSE oscillator**

The HSE block can generate a clock from two possible sources:

- External crystal/ceramic resonator
- External clock source

![Figure 43. HSE/LSE clock source](image-url)
External clock source (HSE bypass)

In this mode, an external clock source must be provided to OSC_IN pin. This mode is selected by setting the HSEBYP and HSEON bits of the RCC Source Control Register (RCC_CR) to ‘1’. The external clock source (square, sinus or triangle) with ~50% duty cycle has to drive the OSC_IN pin.

External crystal/ceramic resonator

The oscillator is enabled by setting the HSEBYP bit to ‘0’ and HSEON bit to ‘1’.

The HSE can be used when the product requires a very accurate high-speed clock.

The associated hardware configuration is shown in Figure 43: the resonator and the load capacitors have to be placed as close as possible to the oscillator pins in order to minimize output distortion and startup stabilization time. The loading capacitance values must be adjusted according to the selected crystal or ceramic resonator. Refer to the electrical characteristics section of the datasheet for more details.

The HSERDY flag of the RCC Source Control Register (RCC_CR), indicates whether the HSE oscillator is stable or not. At startup, the hse_ck clock is not released until this bit is set by hardware. An interrupt can be generated if enabled in the RCC Clock Source Interrupt Enable Register (RCC_CIER).

The HSE can be switched ON and OFF through the HSEON bit. Note that the HSE cannot be switched OFF if one of the two conditions is met:
- The HSE is used directly (via software mux) as system clock
- The HSE is selected as reference clock for PLL1, with PLL1 enabled and selected to provide the system clock (via software mux).

In that case the hardware does not allow programming the HSEON bit to ‘0’.

The HSE is automatically disabled by hardware, when the system enters Stop or Standby mode (refer to Section 7.5.7: Handling clock generators in Stop and Standby mode for additional information).

In addition, the HSE clock can be driven to the MCO1 and MCO2 outputs and used as clock source for other application components.

LSE oscillator

The LSE block can generate a clock from two possible sources:
- External crystal/ceramic resonator
- External user clock

External clock source (LSE bypass)

In this mode, an external clock source must be provided to OSC32_IN pin. The input clock can have a frequency up to 1 MHz. This mode is selected by setting the LSEBYP and LSEON bits of RCC Backup Domain Control Register (RCC_BDCR) to ‘1’. The external clock signal (square, sinus or triangle) with ~50% duty cycle has to drive the OSC32_IN pin.
External crystal/ceramic resonator (LSE crystal)

The LSE clock is generated from a 32.768 kHz crystal or ceramic resonator. It has the advantage to provide a low-power highly accurate clock source to the real-time clock (RTC) for clock/calendar or other timing functions.

The LSERDY flag of the RCC Backup Domain Control Register (RCC_BDCR) indicates whether the LSE crystal is stable or not. At startup, the LSE crystal output clock signal is not released until this bit is set by hardware. An interrupt can be generated if enabled in the RCC Clock Source Interrupt Enable Register (RCC_CIER).

The LSE oscillator is switched ON and OFF using the LSEON bit. The LSE remains enabled when the system enters Stop or Standby mode.

In addition, the LSE clock can be driven to the MCO1 output and used as clock source for other application components.

The LSE also offers a programmable driving capability (LSEDRV[1:0]) that can be used to modulate the amplifier driving capability. The driving capability can be changed dynamically from high drive to medium high drive, and then to medium low drive.

HSI oscillator

The HSI block provides the default clock to the product.

The HSI is a high-speed internal RC oscillator which can be used directly as system clock, peripheral clock, or as PLL input. A predivider allows the application to select an HSI output frequency of 8, 16, 32 or 64 MHz. This predivider is controlled by the HSIDIV.

The HSI advantages are the following:
- Low-cost clock source since no external crystal is required
- Faster startup time than HSE (a few microseconds)

The HSI frequency, even with frequency calibration, is less accurate than an external crystal oscillator or ceramic resonator.

The HSI can be switched ON and OFF using the HSION bit. Note that the HSI cannot be switched OFF if one of the two conditions is met:
- The HSI is used directly (via software mux) as system clock
- The HSI is selected as reference clock for PLL1, with PLL1 enabled and selected to provide the system clock (via software mux).

In that case the hardware does not allow programming the HSION bit to ‘0’.

Note that the HSIDIV cannot be changed if the HSI is selected as reference clock for at least one enabled PLL (PLlxON bit set to ‘1’). In that case the hardware does not update the HSIDIV with the new value. However it is possible to change the HSIDIV if the HSI is used directly as system clock.

The HSIRDY flag indicates if the HSI is stable or not. At startup, the HSI output clock is not released until this bit is set by hardware.

The HSI clock can also be used as a backup source (auxiliary clock) if the HSE fails (refer to Section : CSS on HSE). The HSI can be disabled or not when the system enters Stop mode, please refer to Section 7.5.7: Handling clock generators in Stop and Standby mode for additional information.

In addition, the HSI clock can be driven to the MCO1 output and used as clock source for other application components.
Care must be taken when the HSI is used as kernel clock for communication peripherals, the application must take into account the following parameters:

- the time interval between the moment where the peripheral generates a kernel clock request and the moment where the clock is really available,
- the frequency accuracy.

**Note:** The HSI can remain enabled when the system is in Stop mode (see Section 7.5.7 for additional information).

HSION, HSIRDY and HSIDIV bits are located in the RCC Source Control Register (RCC_CR).

**HSI calibration**

RC oscillator frequencies can vary from one chip to another due to manufacturing process variations. That is why each device is factory calibrated by STMicroelectronics to improve accuracy (refer to the product datasheet for more information).

After a power-on reset, the factory calibration value is loaded in the HSICAL[11:0] bits.

If the application is subject to voltage or temperature variations, this may affect the RC oscillator frequency. The user application can trim the HSI frequency using the HSITRIM bits.

**Note:** HSICAL and HSITRIM bits are located in RCC Internal Clock Source Calibration Register (RCC_ICSCR). for revision Y devices and in RCC HSI configuration register (RCC_HSICFGR) for revision V devices.

**CSI oscillator**

The CSI is a low-power RC oscillator which can be used directly as system clock, peripheral clock, or PLL input.

The CSI advantages are the following:

- Low-cost clock source since no external crystal is required
- Faster startup time than HSE (a few microseconds)
- Very low-power consumption,

The CSI provides a clock frequency of about 4 MHz, while the HSI is able to provide a clock up to 64 MHz.

CSI frequency, even with frequency calibration, is less accurate than an external crystal oscillator or ceramic resonator.

The CSI can be switched ON and OFF through the CSION bit. The CSIRDY flag indicates whether the CSI is stable or not. At startup, the CSI output clock is not released until this bit is set by hardware.

The CSI cannot be switched OFF if one of the two conditions is met:

- The CSI is used directly (via software mux) as system clock
- The CSI is selected as reference clock for PLL1, with PLL1 enabled and selected to provide the system clock (via software mux).

In that case the hardware does not allow programming the CSION bit to ‘0’.

The CSI can be disabled or not when the system enters Stop mode (refer to Section 7.5.7: Handling clock generators in Stop and Standby mode for additional information).
In addition, the CSI clock can be driven to the MCO2 output and used as clock source for other application components.

Even if the CSI settling time is faster than the HSI, care must be taken when the CSI is used as kernel clock for communication peripherals: the application has to take into account the following parameters:

- the time interval between the moment where the peripheral generates a kernel clock request and the moment where the clock is really available,
- the frequency precision.

**Note:** CSICAL and CSITRIM bits are located into the RCC Source Control Register (RCC_CR) or revision Y devices and RCC CSI configuration register (RCC_CSICFGR) for revision V devices.

**CSI calibration**

RC oscillator frequencies can vary from one chip to another due to manufacturing process variations, this is why each device is factory calibrated by STMicroelectronics to achieve improve (refer to the product datasheet for more information).

After reset, the factory calibration value is loaded in the CSICAL[7:0] bits.

If the application is subject to voltage or temperature variations, this may affect the RC oscillator frequency. The user application can trim the CSI frequency using the CSITRIM bits.

**Note:** CSICAL and CSITRIM bits are located in RCC Internal Clock Source Calibration Register (RCC_ICSCR) for revision Y devices and in RCC CSI configuration register (RCC_CSICFGR) for revision V devices.

**HSI48 oscillator**

The HSI48 is an RC oscillator that delivers a 48 MHz clock that can be used directly as kernel clock for some peripherals.

The HSI48 oscillator mainly aims at providing a high precision clock to the USB peripheral by means of a special Clock Recovery System (CRS) circuitry, which could use the USB SOF signal, the LSE, or an external signal, to automatically adjust the oscillator frequency on-the-fly, in very small granularity.

The HSI48 oscillator is disabled as soon as the system enters Stop or Standby mode. When the CRS is not used, this oscillator is free running and thus subject to manufacturing process variations. That is why each device is factory calibrated by STMicroelectronics to achieve an accuracy of ACC_{HSI48} (refer to the product datasheet of the for more information).

For more details on how to configure and use the CRS, please refer to Section 8: Clock recovery system (CRS).

The HSI48RDY flag indicates whether the HSI48 oscillator is stable or not. At startup, the HSI48 output clock is not released until this bit is set by hardware.

The HSI48 can be switched ON and OFF using the HSI48ON bit.

The HSI48 clock can also be driven to the MCO1 multiplexer and used as clock source for other application components.

**Note:** HSI48ON and HSI48RDY bits are located in the RCC Source Control Register (RCC_CR).
LSI oscillator

The LSI acts as a low-power clock source that can be kept running when the system is in Stop or Standby mode for the independent watchdog (IWDG) and Auto-Wakeup Unit (AWU). The clock frequency is around 32 kHz. For more details, refer to the electrical characteristics section of the datasheet.

The LSI can be switched ON and OFF using the LSION bit. The LSIRDY flag indicates whether the LSI oscillator is stable or not. If an independent watchdog is started either by hardware or software, the LSI is forced ON and cannot be disabled.

The LSI remains enabled when the system enters Stop or Standby mode (refer to Section 7.5.7: Handling clock generators in Stop and Standby mode for additional information).

At LSI startup, the clock is not provided until the hardware sets the LSIRDY bit. An interrupt can be generated if enabled in the RCC Clock Source Interrupt Enable Register (RCC_CIER).

In addition, the LSI clock can be driven to the MCO2 output and used as a clock source for other application components.

Note: Bits LSION and LSIRDY are located into the RCC Clock Control and Status Register (RCC_CSR).

7.5.3 Clock Security System (CSS)

CSS on HSE

The clock security system can be enabled by software via the HSECSSON bit. The HSECSSON bit can be enabled even when the HSEON is set to '0'.

The CSS on HSE is enabled by the hardware when the HSE is enabled and ready, and HSECSSON set to ‘1’.

The CSS on HSE is disabled when the HSE is disabled. As a result, this function does not work when the system is in Stop mode.

It is not possible to clear directly the HSECSSON bit by software.

The HSECSSON bit is cleared by hardware when a system reset occurs or when the system enters Standby mode (see Section 7.4.2: System reset).

If a failure is detected on the HSE clock, the system automatically switches to the HSI in order to provide a safe clock. The HSE is then automatically disabled, a clock failure event is sent to the break inputs of advanced-control timers (TIM1, TIM8, TIM15, TIM16, and TIM17), and an interrupt is generated to inform the software about the failure (CSS interrupt: rcc_hsecss_it), thus allowing the MCU to perform rescue operations. If the HSE output was used as clock source for PLLs when the failure occurred, the PLLs are also disabled.

If an HSE clock failure occurs when the CSS is enabled, the CSS generates an interrupt which causes the automatic generation of an NMI. The HSECSSF flag in RCC Clock Source Interrupt Flag Register (RCC_CIFR) is set to ‘1’ to allow the application to identify the failure source. The NMI routine is executed indefinitely until the HSECSSF bit is cleared. As a consequence, the application has to clear the HSECSSF flag in the NMI ISR by setting the HSECSSC bit in the RCC Clock Source Interrupt Clear Register (RCC_CICR).
**CSS on LSE**

A clock security system on the LSE oscillator can be enabled by software by programming the LSECSSON bit in the *RCC Backup Domain Control Register (RCC_BDCR)*. This bit can be disabled only by hardware when the following conditions are met:

- after a pwr_vsw_rst (VSW software reset)
- or after a failure detection on LSE.

LSECSSON bit must be written after the LSE is enabled (LSEON bit set by software) and ready (LSERDY set by hardware), and after the RTC clock has been selected through the RTCSEL bit.

The CSS on LSE works in all modes (Run, Stop and Standby) except VBAT.

If an LSE failure is detected, the LSE clock is no more delivered to the RTC but the value of RTCSEL, LSECSSON and LSEON bits are not changed by the hardware.

A wakeup is generated in Standby mode. In other modes an interrupt (*rcc_lsecss_it*) can be sent to wake up the software. The software must then disable the LSECSSON bit, stop the defective LSE (clear LSEON bit), and can change the RTC clock source (no clock or LSI or HSE) through RTCSEL bits, or take any required action to secure the application.

### 7.5.4 Clock output generation (MCO1/MCO2)

Two micro-controller clock output (MCO) pins, MCO1 and MCO2, are available. A clock source can be selected for each output. The selected clock can be divided thanks to configurable prescaler (refer to *Figure 42* for additional information on signal selection).

MCO1 and MCO2 outputs are controlled via MCO1PRE[3:0], MCO1[2:0], MCO2PRE[3:0] and MCO2[2:0] located in the *RCC Clock Configuration Register (RCC_CFRG)*.

The GPIO port corresponding to each MCO pin, has to be programmed in alternate function mode.

The clock provided to the MCOs outputs must not exceed the maximum pin speed (refer to the product datasheet for information on the supported pin speed).
### 7.5.5 PLL description

The RCC features three PLLs:
- A main PLL, PLL1, which is generally used to provide clocks to the CPU and to some peripherals.
- Two dedicated PLLs, PLL2 and PLL3, which are used to generate the kernel clock for peripherals.

The PLLs integrated into the RCC are completely independent. They offer the following features:
- Two embedded VCOs:
  - A wide-range VCO (VCOH)
  - A low-frequency VCO (VCOL)
- Input frequency range:
  - 1 to 2 MHz when VCOL is used
  - 2 to 16 MHz when VCOH is used
- Capability to work either in integer or Fractional mode
- 13-bit Sigma-Delta modulator, allowing to fine-tune the VCO frequency by steps of 11 to 0.3 ppm.
- The Sigma-Delta modulator can be updated on-the-fly, without generating frequency overshoots on PLLs outputs.
- Each PLL offer 3 outputs with post-dividers

![Figure 44. PLL block diagram](image-url)
The PLLs are controlled via RCC_PLLxDIVR, RCC_PLLxFRACR, RCC_PLLCFGR and RCC_CR registers.

The frequency of the reference clock provided to the PLLs (refx_ck) must range from 1 to 16 MHz. The user application has to program properly the DIVMx dividers of the RCC PLLs Clock Source Selection Register (RCC_PLLCKSELR) in order to match this condition. In addition, the PLLxRGE of the RCC PLLs Configuration Register (RCC_PLLCFGR) field must be set according to the reference input frequency to guarantee an optimal performance of the PLL.

The user application can then configure the proper VCO: if the frequency of the reference clock is lower or equal to 2 MHz, then VCOL must be selected, otherwise VCOH must be chosen. To reduce the power consumption, it is recommended to configure the VCO output to the lowest frequency.

DIVNx loop divider has to be programmed to achieve the expected frequency at VCO output. In addition, the VCO output range must be respected.

The PLLs operate in integer mode when the value of SH_REG (FRACNx shadow register) is set to ‘0’. The SH_REG is updated with the FRACNx value when PLLxFRACEN bit goes from ‘0’ to ‘1’. The Sigma-Delta modulator is designed in order to minimize the jitter impact while allowing very small frequency steps.

The PLLs can be enabled by setting PLLxON to ‘1’. The bits PLLxRDY indicate that the PLL is ready (i.e. locked).

Note: Before enabling the PLLs, make sure that the reference frequency (refx_ck) provided to the PLL is stable, so the hardware does not allow changing DIVMx when the PLLx is ON and it is also not possible to change PLLSRC when one of the PLL is ON.

The hardware prevents writing PLL1ON to ‘0’ if the PLL1 is currently used to deliver the system clock. There are other hardware protections on the clock generators (refer to sections HSE oscillator, HSI oscillator and CSI oscillator).

The following PLL parameters cannot be changed once the PLL is enabled: DIVNx, PLLxRGE, PLLxVCOSEL, DIVPx, DIVQx, DIVRx, DIVPxEN, DIVQxEN and DIVRxEN.

To insure an optimal behavior of the PLL when one of the post-divider (DIVP, DIVQ or DIVR) is not used, the application shall set the enable bit (DIVyEN) as well as the corresponding post-divider bits (DIVP, DIVQ or DIVR) to ‘0’.

If the above rules are not respected, the PLL output frequency is not guaranteed.

Output frequency computation

When the PLL is configured in integer mode (SH_REG = ‘0’), the VCO frequency (FVCO) is given by the following expression:

$$ F_{VCO} = F_{REF\_CK} \times DIVM $$

$$ F_{PLL\_x\_CK} = \left( F_{VCO} / (DIVy + 1) \right) \text{ with } y = P, Q \text{ or } R $$

When the PLL is configured in fractional mode (SH_REG different from ‘0’), the DIVN divider must be initialized before enabling the PLLs. However, it is possible to change the value of FRACNx on-the-fly without disturbing the PLL output.
This feature can be used either to generate a specific frequency from any crystal value with a good accuracy, or to fine-tune the frequency on-the-fly.

For each PLL, the VCO frequency is given by the following formula:

\[ F_{VCO} = F_{\text{ref,ck}} \times \left( \text{DIVN} \times \frac{\text{FRACN}}{2^{13}} \right) \]

**Note:** For PLL1, DIVP bitfield can only take odd values.

The PLLs are disabled by hardware when:
- The system enters Stop or Standby mode.
- An HSE failure occurs when HSE or PLL (clocked by HSE) are used as system clock.

**PLL initialization phase**

*Figure 45* shows the recommended PLL initialization sequence in integer and fractional mode. The PLLx are supposed to be disabled at the start of the initialization sequence:

1. Initialize the PLLs registers according to the required frequency.
   - Set PLLxFRACEN of *RCC PLLs Configuration Register (RCC_PLLCFGR)* to ‘0’ for integer mode.
   - For fractional mode, set FRACN to the required initial value (FracInitValue) and then set PLLxFRACEN to ‘1’.

2. Once the PLLxON bit is set to ‘1’, the user application has to wait until PLLxRDY bit is set to ‘1’. If the PLLx is in fractional mode, the PLLxFRACEN bit must not be set back to ‘0’ as long as PLLxRDY = ‘0’.

3. Once the PLLxRDY bit is set to ‘1’, the PLLx is ready to be used.

4. If the application intends to tune the PLLx frequency on-the-fly (possible only in fractional mode), then:
   a) PLLxFRACEN must be set to ‘0’.
      When PLLxFRACEN = ‘0’, the Sigma-Delta modulator is still operating with the value latched into SH_REG.
   b) A new value must be uploaded into PLLxFRACR (FracValue(n)).
   c) PLLxFRACEN must be set to ‘1’, in order to latch the content of PLLxFRACR into its shadow register.

**Note:** When the PLLxRDY goes to ‘1’, it means that the difference between the PLLx output frequency and the target value is lower than ±2%.

7.5.6 System clock (sys_ck)

System clock selection

After a system reset, the HSI is selected as system clock and all PLLs are switched OFF. When a clock source is used for the system clock, it is not possible for the software to disable the selected source via the xxxON bits.

Of course, the system clock can be stopped by the hardware when the System enters Stop or Standby mode.

When the system is running, the user application can select the system clock (sys_ck) among the 4 following sources:

- HSE
- HSI
- CSI
- or pll1_p_ck

This function is controlled by programming the RCC Clock Configuration Register (RCC_CFGR). A switch from one clock source to another occurs only if the target clock source is ready (clock stable after startup delay or PLL locked). If a clock source that is not yet ready is selected, the switch occurs when the clock source is ready.

The SWS status bits in the RCC Clock Configuration Register (RCC_CFGR) indicate which clock is currently used as system clock. The other status bits in the RCC_CR register indicate which clock(s) is (are) ready.

System clock generation

Figure 46 shows a simplified view of the clock distribution for the CPU and busses. All the dividers shown in the block diagram can be changed on-the-fly without generating timing violations. This feature is a very simply solution to adapt the busses frequencies to the application needs, thus optimizing the power consumption.

The D1CPRE divider can be used to adjust the CPU clock. However this also impacts the clock frequency of all bus matrix and HRTIM.

In the same way, HPRE divider can be used to adjust the clock for D1 domain bus matrix, but this also impacts the clock frequency of bus matrix of D2 and D3 domains.

Most of the prescalers are controlled via RCC_D1CFGR, RCC_D2CFGR and RCC_D3CFGR registers.
This block also provides the clock for the timers (rcc_timx_ker_ck and rcc_timy_ker_ck). The frequency of the timers clock depends on the APB prescaler corresponding to the bus to which the timer is connected, and on TIMPRE bit. Table 52 shows how to select the timer clock frequency.

SYSv41929V3
7.5.7 Handling clock generators in Stop and Standby mode

When the whole system enters Stop mode, all the clocks (system and kernel clocks) are stopped as well as the following clock sources:

- CSI, HSI (depending on HSIKERON, and CSIKERON bits)
- HSE
- PLL1, PLL2 and PLL3
- HSI48

The content of the RCC registers is not altered except for PLL1ON, PLL2ON, PLL3ON HSEON and HSI48ON which are set to '0'.

Exiting Stop mode

When the microcontroller exits system Stop mode via a wake-up event, the application can select which oscillator (HSI and/or CSI) will be used to restart. The STOPWUCK bit selects the oscillator used as system clock. The STOPKERWUCK bit selects the oscillator used as kernel clock for peripherals. The STOPKERWUCK bit is useful if after a system Stop a peripheral needs a kernel clock generated by an oscillator different from the one used for the system clock.

All these bits belong to the **RCC Clock Configuration Register (RCC_CFGR)**. Table 53 gives a detailed description of their behavior.

### Table 53. STOPWUCK and STOPKERWUCK description

1. D2PPRE1 and D2PPRE2 belong to **RCC Domain 2 Clock Configuration Register (RCC_D2CFGR)**.
2. TIMPRE belongs to **RCC Clock Configuration Register (RCC_CFGR)**.
During Stop mode

There are two specific cases where the HSI or CSI can be enabled during system Stop mode:

- When a dedicated peripheral requests the kernel clock:
  In this case the peripheral will receive the HSI or CSI according to the kernel clock source selected for this peripheral (via PERxSRC).
- When the bits HSIKERON or CSIKERON are set:
  In this case the HSI and CSI are kept running during Stop mode but the outputs are gated. In that way, the clock will be available immediately when the system exits Stop mode or when a peripheral requests the kernel clock (see Table 54 for details).

HSIKERON and CSIKERON bits belong to RCC Source Control Register (RCC_CR). Table 54 gives a detailed description of their behavior.

<table>
<thead>
<tr>
<th>HSIKERON (CSIKERON)</th>
<th>HSI (CSI) state during Stop mode</th>
<th>HSI (CSI) Setting time</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>1</td>
<td>Running and Gated</td>
<td>Immediate</td>
</tr>
</tbody>
</table>

1. \( t_\text{su}(\text{HSI}) \) and \( t_\text{su}(\text{CSI}) \) are the startup times of the HSI and CSI oscillators (see refer to the product datasheet for the values of these parameters).

Table 54. HSIKERON and CSIKERON behavior

When the microcontroller exists system Standby mode, the HSI is selected as system and kernel clock, the RCC registers are reset to their initial values except for the RCC_RSR (or RCC_C1_RSR) and RCC_BDCR registers.

Note as well that the HSI and CSI outputs provide two clock paths (see Figure 42):

- one path for the system clock (hsi_ck or csi_ck)
- one path for the peripheral kernel clock (hsi_ker_ck or csi_ker_ck).

When a peripheral requests the kernel clock in system Stop mode, only the path providing the hsi_ker_ck or csi_ker_ck is activated.

**Caution:** It is not guaranteed that the CPU will get automatically the same clock frequencies when leaving CStop mode: this mainly depends on the System state. For example If the CPU goes to CStop, while the D3 domain is kept in CRun, when the CPU exits from CStop, the clock settings remain unchanged. If the D3 domain goes to CStop while the CPU is also in CStop, then when the CPU exits from CStop, the CPU will operate with HSI or CSI when it left the CStop mode.
7.5.8 Kernel clock selection

Some peripherals are designed to work with two different clock domains that operate asynchronously:

- a clock domain synchronous with the register and bus interface (\texttt{ckg\_bus\_perx} clock)
- and a clock domain generally synchronous with the peripheral (kernel clock).

The benefit of having peripherals supporting these two clock domains is that the user application has more freedom to choose optimized clock frequency for the CPU, bus matrix and for the kernel part of the peripheral.

As a consequence, the user application can change the bus frequency without reprogramming the peripherals. As an example an on-going transfer with UART will not be disturbed if its APB clock is changed on-the-fly.

\textit{Table 55} shows the kernel clock that the RCC can deliver to the peripherals. Each row of \textit{Table 55} represents a MUX and the peripherals connected to its output. The columns starting from number 5 represents the clock sources. Column 3 gives the maximum allowed frequency at each MUX output. It is up to the user to respect these requirements.

### Notes:

1. The bus clocks are the bus interface clocks to which the peripherals are connected, it can be APB, AHB or AXI clocks.
2. The per_ck clock could be hse_ck, hsi_ker_ck or csi_ker_ck according to CKPERSEL selection.
3. Clock CSI divided by 122.
4. With a duty cycle close to 50%, meaning that DIV[P/Q/R]x values shall be even. For SDMMCx, the duty cycle shall be 50% when supporting DDR.
5. Clock HSE divided by RTCPRE.
Figure 47 to Figure 56 provide a more detailed description of kernel clock distribution. To simplify the drawings, the bus interface clocks (pclk, hclk) are not represented, even if they are gated with enable signals. Refer to Section 7.5.11: Peripheral clock gating control for more details.

To reduce the amount of switches, some peripherals share the same kernel clock source. Nevertheless, all peripherals have their dedicated enable signal.

Peripheral dedicated to audio applications

The audio peripherals generally need specific accurate frequencies, except for SPDIFRX. As shown in Figure 47, the kernel clock of the SAIs or SPI(I2S)s can be generated by:

- The PLL1 when the amount of active PLLs has to be reduced
- The PLL2 or 3 for optimal flexibility in frequency generation
- HSE, HSI or CSI for use-cases where the current consumption is critical
- I2S_CKIN when an external clock reference need to be used.

Note: The SPDIFRX does not require a specific frequency, but only a kernel clock frequency high enough to make the peripheral work properly. Refer to the SPDIFRX description for more details.

DFSDM1 can use the same clock as SAI1A. This is useful when DFSDM1 is used for audio applications.

To improve the flexibility, SAI4 can use different clock for each sub-block.

The SPI/I2S1, 2, and 3 share the same kernel clock source (see Figure 48).
Peripherals dedicated to control and data transfer

Peripherals such as SPIs, I2Cs, UARTs do not need a specific kernel clock frequency but a clock fast enough to generate the correct baud rate, or the required bit clock on the serial interface. For that purpose the source can be selected among:

- PLL1 when the amount of active PLLs has to be reduced
- PLL2 or PLL3 if better flexibility is required. As an example, this solution allows changing the frequency bus via PLL1 without affecting the speed of some serial interfaces.
- HSI or CSI for low-power use-cases or when the peripheral has to quickly wake up from Stop mode (i.e. UART, I2C...).
**Note:** UARTs also need the LSE clock when high baud rates are not required.

**RTC/AWU clock**

The \( \text{rtc}_\text{ck} \) clock source can be:
- the \( \text{hse}_\text{1M}_\text{ck} \) (\( \text{hse}_\text{ck} \) divided by a programmable prescaler)
- the \( \text{lse}_\text{ck} \)
- or the \( \text{lsi}_\text{ck} \) clock

The source clock is selected by programming the RTCSEL[1:0] bits in the **RCC Backup Domain Control Register (RCC_BDCR)** and the RTCPRE[5:0] bits in the **RCC Clock Configuration Register (RCC_CFGCR)**.

This selection cannot be modified without resetting the Backup domain.

If the LSE is selected as RTC clock, the RTC will work normally even if the backup or the \( V_{\text{DD}} \) supply disappears.
The LSE clock is in the Backup domain, whereas the other oscillators are not. As a consequence:

- If LSE is selected as RTC clock, the RTC continues working even if the VDD supply is switched OFF, provided the VBAT supply is maintained.
- If LSI is selected as the RTC clock, the AWU state is not guaranteed if the VDD supply is powered off.
- If the HSE clock is used as RTC clock, the RTC state is not guaranteed if the VDD supply is powered off or if the VCORE supply is powered off.

The rtc_ck clock is enabled through RTCEN bit located in the RCC Backup Domain Control Register (RCC_BDCR).

The RTC bus interface clock (APB clock) is enabled through RTCAPBEN and RTCAPBLPEN bits located in RCC_APB4ENR/LPENR registers.

**Note:** To read the RTC calendar register when the APB clock frequency is less than seven times the RTC clock frequency \( F_{APB} < 7 \times F_{RTCCLK} \), the software must read the calendar time and date registers twice. The data are correct if the second read access to RTC_TR gives the same result than the first one. Otherwise a third read access must be performed.

### Watchdog clocks

The RCC provides the clock for the four watchdog blocks available on the circuit. The independent watchdog (IWDG1) is connected to the LSI. The window watchdog (WWDG1) are connected to the APB clock.

If an independent watchdog is started by either hardware option or software access, the LSI is forced ON and cannot be disabled. After the LSI oscillator setup delay, the clock is provided to the IWDGs.

**Caution:** Before enabling the WWDG1, the application must set the WW1RSC bit to ‘1’. If the WW1RSC remains to ‘0’, when the WWDG1 is enabled, its the behavior is not guaranteed. The WW1RSC bit is located in RCC Global Control Register (RCC_GCR).

### Clock frequency measurement using TIMx

Most of the clock source generator frequencies can be measured by means of the input capture of TIMx.

- **Calibrating the HSI or CSI with the LSE**

  The primary purpose of having the LSE connected to a TIMx input capture is to be able to accurately measure the HSI or CSI. This requires to use the HSI or CSI as system clock source either directly or via PLL1. The number of system clock counts between consecutive edges of the LSE signal gives a measurement of the internal clock period. Taking advantage of the high precision of LSE crystals (typically a few tens of ppm) we can determine the internal clock frequency with the same resolution, and trim the source to compensate for manufacturing-process and/or temperature- and voltage-related frequency deviations.

  The basic concept consists in providing a relative measurement (e.g. HSI/LSE ratio); the precision is therefore tightly linked to the ratio between the two clock sources. The greater the ratio is, the more accurate the measurement is.

  The HSI and CSI oscillators have dedicated user-accessible calibration bits for this purpose (see RCC Internal Clock Source Calibration Register (RCC_ICSCR) for revision Y devices and RCC HSI configuration register (RCC_HSICFR)/RCC CSI configuration register (RCC_CSICFR) for revision V devices). When the HSI or CSI
are used via the PLLx, the system clock can also be fine-tuned by using the fractional divider of the PLLs.

- Calibrating the LSI with the HSI
  The LSI frequency can also be measured: this is useful for applications that do not have a crystal. The ultralow power LSI oscillator has a large manufacturing process deviation. By measuring it versus the HSI clock source, it is possible to determine its frequency with the precision of the HSI. The measured value can be used to have more accurate RTC time base timeouts (when LSI is used as the RTC clock source) and/or an IWDG timeout with an acceptable accuracy.

7.5.9 General clock concept overview

The RCC handles the distribution of the CPU, bus interface and peripheral clocks for the system (D1, D2 and D3 domains), according to the operating mode of each function (refer to Section 7.5.1: Clock naming convention for details on clock definitions).

For each peripheral, the application can control the activation/deactivation of its kernel and bus interface clock. Prior to use a peripheral, the CPU has to enable it (by setting PERxEN to ‘1’), and define if this peripheral remains active in CSleep mode (by setting PERxLPEN to ‘1’). This is called ‘allocation’ of a peripheral to the CPU (refer to Section 7.5.10: Peripheral allocation for more details).

The peripheral allocation is used by the RCC to automatically control the clock gating according to the CPU and domain modes, and by the PWR to control the supply voltages of D1, D2 and D3 domains.

Figure 57 gives an example of peripheral allocation:

- The CPU enabled SDMMC1, SPI5 and SRAM1, AXISRAM, ITCM, DTCM1, DTCM2 and SRAM4 are implicitly allocated to the CPU. The group composed of the CPU, bus matrix 1/2/3 and allocated peripherals makes up a sub-system (CPU_SS).

Note: The FLASH, AXISRAM, ITCM, DTCM1, DTCM2, SRAM4, IWGD1, IWGD2, PWR, EXTI and RCC are common resources and are implicitly allocated to the CPU.
When the CPU enters CStop mode, the RCC automatically disables the bus interface and kernel clocks of all the peripherals of the CPU_SS as well as the CPU clock. The PLLs, if enabled, are not disabled by the RCC since D3 is still running.

The D3 domain can be kept in DRun mode while the CPU is in CStop mode and D1 and D2 domains are in DStop or DStandby mode. This is done by setting RUN_D3 bit in PWR_CPUCR registers.

- If RUN_D3 is set to ‘1’, then D3 is maintained in DRun mode, independently from the CPU modes (see PWR CPU control register (PWR_CPUCR)).
- If RUN_D3 is set to ‘0’, then D3 domain enters DStop or DStandby mode when the CPU enters CStop mode (see Table 56).

Note that the CPU can control if D1, D2 or D3 domains are allowed to enter in DStandby when conditions are met, via bits PDDS_D1, PDDS_D2 and PDDS_D3 of PWR CPU control register (PWR_CPUCR).

A wakeup event will be able to exit D1, D2 and D3 domains from DStandby or DStop mode.

In addition, more autonomy can be given to some peripherals located into D3 domain (refer to Section : D3 domain Autonomous mode for details).
D3 domain Autonomous mode

The Autonomous mode allows to deliver the peripheral clocks to peripherals located in D3, even if the CPU is in CStop mode. When a peripheral has its autonomous bit enabled, it receives its peripheral clocks according to D3 domain state, if the CPU is in CStop mode:

- If the D3 domain is in DRun mode, peripherals with Autonomous mode activated receive their peripheral clocks,
- If the D3 domain is in DStop mode, no peripheral clock is provided.

The Autonomous mode does not prevent the D3 domain to enter DStop or DStandby mode. The autonomous bits are located in **RCC D3 Autonomous mode Register (RCC_D3AMR)**.

For example, the CPU can enter CStop mode, while the SAI4 is filling the SRAM4 with data received from an external device via BDMA. When the amount of received data is reached, the CPU can be activated by a wakeup event. This can be done by setting the SAI4, the BDMA, and SRAM4 in Autonomous mode, while keeping D3 in DRun mode (RUN_D3 set to ‘1’). In this example, the RCC does not switch off the PLLs as the D3 domain is always in DRun mode.

It is possible to go a step further with power consumption reduction by combining the Autonomous mode with the capability of some peripherals (UARTs, I2Cs) to request the kernel clock on their own, without waking-up the CPU. For example, if the system is expecting messages via I2C4, the whole system can be put in Stop mode. When the I2C4 peripheral detects a START bit, it will generate a “kernel clock request”. This request enables the HSI or CSI, and a kernel clock is provided only to the requester (in our example the I2C4). The I2C4 then decodes the incoming message. Several cases are then possible:

- If the device address of the message does not match, then I2C4 releases its “kernel clock request” until a new START condition is detected.
- If the device address of the incoming message matches, it has to be stored into D3 local memory. I2C4 is able to generate a wakeup event on address match to switch the D3 domain to DRun mode. The message is then transferred into memory via BDMA, and the D3 domain go back to DStop mode without any CPU activation. Note that if the amount of data transferred into memory reached the transfer count, the BDMA can also generate an interrupt to wake-up the CPU.
- If the device address of the incoming message matches and the peripheral is setup to wake up the CPU, then I2C4 generates a wakeup event to activate the CPU.

Please refer to the description of EXTI block in order see which peripheral is able to perform a wake-up event to which domain.

Memory handling

The CPU can access all the memory areas available in the product:

- AXISRAM, ITCM, DTCM1, DTCM2 and FLASH,
- SRAM1, SRAM2 and SRAM3,
- SRAM4 and BKPRAM.

As shown in Figure 57, FLASH, AXISRAM, SRAM4, ITCM, DTCM1 and DTCM2 are implicitly allocated to the CPU. As a result, there is no enable bit allowing the CPU to allocate these memories.

If the CPU wants to use memories located into D2 domain (SRAM1, SRAM2 and SRAM3), it has to enable them.
The BKPRAM has a dedicated enable in order to gate the bus interface clock. The CPU needs to enable the BKPRAM prior to use it.

Note: The memory interface clocks (Flash and RAM interfaces) can be stopped by software during CSleep mode (via DxSRAMyLPEN bits).

Refer to Peripheral clock gating control and CPU and bus matrix clock gating control sections for details on clock enabling.

System states overview

Table 56 gives an overview of the system states with respect to the D1, D2 and D3 domain modes.

- The system remains in Run mode as long as D3 is in DRun mode. Several sub-states of system Run exist that are not detailed here (refer Power control (PWR) for more information).
- When the D1 domain is in DRun, the D2 domain can be in DRun, DStop or DStandby. When the D1 domain is in DStop or DStandby, the D2 domain can no longer remain in DRun it will switch to DStop or DStandby according to PDDS_D2 bit.
- D3 can run while D1 and D2 are in DStop/DStandby mode thanks to RUN_D3 bits of PWR_CPUCR registers or when D3 is in Autonomous mode.
- The system remains in Stop mode as long as D3 is in DStop mode. This means implicitly that D1 and D2 are in DStop or DStandby. As soon as D1 or D2 exits DStop or DStandby, D3 switches to DRun mode.
- The system remains in Standby mode as long as D1, D2 and D3 are in DStandby.

Domain states versus CPU states:
- When the D1 domain is in DRun mode, it means that its bus matrix is clocked, and the CPU is in CRun mode.
- When the D2 domain is in DRun mode, it means that its bus matrix is clocked, and the CPU is in CRun mode with at least a peripheral of D2 domain allocated.
- When the D1 domain is in DStop mode it means that its bus matrix is no longer clocked, and the CPU is in CStop mode.
- When the D2 domain is in DStop mode it means that its bus matrix is no longer clocked. This situation happens when:
  - the CPU did not allocate peripherals of D2 domain,
  - the CPU allocated peripherals of D2 domain, but the CPU is in CStop or CStandby,
- When a domain is in DStandby mode, it means that the domain including its CPU are powered down.

7.5.10 Peripheral allocation

The CPU can allocate a peripheral and hence control its kernel and bus interface clock. The CPU can allocate a peripheral by setting the dedicated PERxEN bit located into:
- RCC_xxxxENR registers or
- RCC_C1_xxxxENR registers.

The CPU can control the peripheral clocks gating when it is in CSleep mode via the PERxLPEN bits located into:
- RCC_xxxxLPENR registers or
- RCC_C1_xxxxLPENR registers.

Refer to Section 7.7.1: Register mapping overview for additional information.

The peripheral allocation bits (PERxEN bits) are used by the hardware to provide the kernel and bus interface clocks to the peripherals. However they are also used to link peripherals to the CPU (CPU sub-system). In this way, the hardware is able to safely gate the peripheral clocks and bus matrix clocks according to CPU states. The PWR block also uses this information to control properly the domain states.

Clock switches and gating

- Clock switching delays

The input selected by the kernel clock switches can be changed dynamically without generating spurs or timing violation. As a consequence, switching from the original to the new input can only be performed if a clock is present on both inputs. If it not the case, no clock will be provided to the peripheral. To recover from this situation, the user has to provide a valid clock to both inputs.

During the transition from one input to another, the kernel clock provided to the peripheral will be gated, in the worst case, during 2 clock cycles of the previously selected clock and 2 clock cycles of the new selected clock. As shown in Figure 58, both input clocks shall be present during transition time.

Figure 58. Kernel Clock switching
Clock enabling delays

In the same way, the clock gating logic synchronizes the enable command (coming generally from a kernel clock request or PERxEN bits) with the selected clock, in order to avoid generation of spurs.

- A maximum delay of two periods of the enabled clock may occur between the enable command and the first rising edge of the clock. The enable command can be the rising edge of the PERxEN bits of RCC_xxxxENR registers, or a kernel clock request asserted by a peripheral.
- A maximum delay of 1.5 periods of the disabled clock may occur between the disable command and the last falling edge of the clock. The disable command can be the falling edge of the PERxEN bits of RCC_xxxxENR registers, or a kernel clock request released by a peripheral.

**Note:** Both the kernel clock and the bus interface clock are affected by this re-synchronization delay.

In addition, the clock enabling delay may strongly increase if the application is enabling for the first time a peripheral which is not located into the same domain. This is due to the fact that the domain where the peripheral is located could be in DStop or DStandby mode. The domain must be switched to DRun mode before the application can use this peripheral.

As an example, if the CPU enables a peripheral located in the D2 domain while the D2 domain is in DStop/DStandby mode, then the power controller (PWR) has first to provide a supply voltage to D2, then the RCC has to wait for an acknowledge from the PWR before enabling the clocks of the D2 domain. To handle properly this situation the RCC and the PWR blocks feature four flags:

- D1CKRDY/D2CKRDY located in **RCC Source Control Register (RCC_CR)**
- SBF_D1 and SBF_D2 located in **PWR CPU control register (PWR_CPUCR)**.

The following sequence can be followed to avoid this issue:

a) Enable the peripheral clocks (i.e. allocate the peripheral) by writing the corresponding PERxEN bit to ‘1’ in the RCC_xxxxENR register,

b) Read back the RCC_xxxxENR register to make sure that the previous write operation is not pending into a write buffer.

c) If the peripheral is located in a different domain, perform the two next steps:
   - Read DxCKRDY until it is set to ‘1’.
   - Write SBF_Dx to zero and read-back the value, in order to check if the domain where the peripheral is located is still in DStandby. If the corresponding bit is read at ‘1’, it means that the domain is still in DStandby. Repeat this operation until SBF_Dx is equal to ‘0’, then continue the other steps.

   d) Perform a dummy read operation into a register of the enabled peripheral. This operation will take at least 2 clock cycles, which is equal to the max delay of the enable command.

   e) The peripheral can then be used.

**Note:** When the bus interface clock is not active, read or write accesses to the peripheral registers are not supported. A read access will return invalid data. A write access will be ignored and will not create any bus errors.
7.5.11 Peripheral clock gating control

As mentioned previously, each peripheral requires a bus interface clock, named `rcc_perx_bus_ck` (for peripheral ‘x’). This clock can be an APB, AHB or AXI clock, according to which bus the peripheral is connected.

The clocks used as bus interface for peripherals located in D1 domain, could be `rcc_aclk`, `rcc_hclk3` or `rcc_pclk3`, depending on the bus connected to each peripheral. For simplicity sake, these clocks are named `rcc_bus_d1_ck`.

In the same way, the signal named `rcc_bus_d2_ck` represents `rcc_hclk1`, `rcc_hclk2`, `rcc_pclk1` or `rcc_pclk2`, depending on the bus connected to each peripheral of D2 domain.

Similarly, the signal `rcc_bus_d3_ck` represents `rcc_hclk4` or `rcc_pclk4` for peripherals located in D3.

Some peripherals (SAI, UART...) also require a dedicated clock for their communication interface. This clock is generally asynchronous with respect to the bus interface clock. It is named kernel clock (`perx_ker_ckreq`). Both clocks can be gated according to several conditions detailed hereafter.

As shown in Figure 59, enabling the kernel and bus interface clocks of each peripheral depends on several input signals:

- PERxEN and PERxLPEN bits
  PERxEN represents the peripheral enable (allocation) bit for the CPU. The CPU can write these bits to ‘1’ via RCC_C1_xxxxENR or RCC_xxxxENR registers.

- PERxAMEN bits
  The PERxAMEN bits are belong to `RCC D3 Autonomous mode Register (RCC_D3AMR)`.

- CPU state (`c_sleep` and `c_deepsleep` signals)

- D3 domain state (`d3_deepsleep` signal)

- The kernel clock request (`perx_ker_ckreq`) of the peripheral itself, when the feature is available.

Refer to Section 7.5.10: Peripheral allocation for more details.
Figure 59. Peripheral kernel clock enable logic details

When the peripheral offers the feature...
Table 57 gives a detailed description of the enabling logic of the peripheral clocks for peripherals located in D1 or D2 domain and allocated by the CPU.

The bus interface clock is no provided as the CPU is in CStop |
| 1      | 1        | hsi_ker_ck or csi_ker_ck | 0         | CStop     | 0        | 0        | No clock provided to the peripheral because CPU is in CStop, and no kernel clock request pending |

1. For RNG block, the kernel clock is not delivered if the CPU to which it is allocated is in CStop mode, even if the clock selected is lsi_ck or lse_ck.
As a summary, we can state that the kernel clock is provided to the peripherals located on domains D1 and D2 when the following conditions are met:

1. The CPU is in CRun mode, and the peripheral is allocated.
2. The CPU is in CSleep mode, and the peripheral is allocated with PERxLPEN = ‘1’.
3. The CPU is in CStop mode, and the peripheral is allocated with PERxLPEN = ‘1’, and the peripheral generates a kernel clock request, and the selected clock is $hsi_{\_}ker_{\_}ck$ or $csi_{\_}ker_{\_}ck$.
4. The CPU is in CStop mode, and the peripheral is allocated with PERxLPEN = ‘1’, and the kernel source clock of the peripheral is $lse_{\_}ck$ or $lsi_{\_}ck$.

The bus interface clock will be provided to the peripherals only when conditions 1 or 2 are met.

Table 58 gives a detailed description of the enabling logic of the kernel clock for all peripherals located in D3.

Table 58. Peripheral clock enabling for D3 peripherals
As a summary, we can state that the kernel clock is provided to the peripherals of D3 if the following conditions are met:

1. The CPU is in CRun mode, and the peripheral is allocated.
2. The CPU is in CSleep mode, and the peripheral is allocated with PERxLPEN = ‘1’.
3. The CPU is in CStop mode, and the peripheral is allocated and D3 domain is in DRun mode with PERxAMEN = ‘1’.
4. The CPU is in CStop mode, and the peripheral is allocated, and D3 domain is in DStop mode with PERxAMEN = ‘1’, and the peripheral is generating a kernel clock request and the kernel clock source is hsi_ker_ck or csi_ker_ck.
5. The CPU is in CStop mode, and the peripheral is allocated, and D3 domain is in DStop mode with PERxAMEN = ‘1’, and the kernel clock source of the peripheral is lse_ck or lsi_ck.

The bus interface clock will be provided to the peripherals only when condition 1, 2 or 3 is met.
Note: When they are set to ‘1’, the autonomous bits indicate that the associated peripheral will receive a kernel clock according to D3 state, and not according to the mode of the CPU. Only I2C, U(S)ART and LPUART peripherals are able to request the kernel clock. This feature gives to the peripheral the capability to transfer data with an optimal power consumption.

The autonomous bits dedicated to some peripherals located in D3 domain allow the data transfer with external devices without activating the CPU.

In order for the LPTIMER to operate with lse_ck or lsi_ck when the circuit is in Stop mode, the user application has to select the lsi_ck or lse_ck input via LPTIMxSEL fields, and set bit LPTIMxAMEN and LPTIMxLPEN to ‘1’.

7.5.12 CPU and bus matrix clock gating control

For each domain it is possible to control the activation/deactivation of the CPU clock and bus matrix clock.

For information about convention naming, refer to Section 7.5.11: Peripheral clock gating control.

The clocks of the CPU, AHB and AXI bridges and APB busses are enabled according to the rules hereafter:

- The CPU clock rcc_c_ck is enabled when the CPU is in CRun mode.
- The AXI bridge clock is enabled when the CPU is in CRun mode.
- The D2 domain AHB bridges clocks are enabled when:
  - The CPU is in CRun or,
  - If the CPU is in CSleep with at least a peripheral (master) connected to this bus having both its PERxEN and PERxLPEN set to ‘1’ or,
  - If the CPU is in CSleep with at least an APB bus having its clock enabled.
- The D3 domain AHB bridge clock is enabled when:
  - The CPU is in CRun or CSleep mode or,
  - When the RUN_D3 bit is set to ‘1’, independently of CPU modes or,
  - When the d3_deepsleep signal is inactive (‘0’), independently of CPU modes.
- The APB1,2,3 busses are enabled when:
  - The CPU is in CRun or,
  - If the CPU is in CSleep with at least a peripheral connected to this bus having both its PERxEN and PERxLPEN set to ‘1’.
- The APB4 bus is enabled when: the D3 domain is in DRun.

As shown in the Figure 60, the enabling of the core and bus clock of each domain depends on several input signals:

- c_sleep and c_deepsleep signals from the CPU,
- d3_sleepdeep signal,
- RCC_xxxENR.PERxEN bits of peripherals located on D2 domain
Figure 60. Bus clock enable logic

run_c is a combination of NOT c_deepsleep and NOT c_sleep
rcc_bus_dx represents the clocks for the bus matrix and the peripheral bus interface for domain x
7.6 RCC Interrupts

The RCC provides 3 interrupt lines:

- **rcc_it**: a general interrupt line, providing events when the PLLs are ready, or when the oscillators are ready.
- **rcc_hsecss_it**: an interrupt line dedicated to the failure detection of the HSE Clock Security System.
- **rcc_lsecss_it**: an interrupt line dedicated to the failure detection of the LSE Clock Security System.

The interrupt enable is controlled via **RCC Clock Source Interrupt Enable Register (RCC_CIER)**, except for the HSE CSS failure. When the HSE CSS feature is enabled, it not possible to mask the interrupt generation.

The interrupt flags can be checked via **RCC Clock Source Interrupt Flag Register (RCC_CIFR)**, and those flags can be cleared via **RCC Clock Source Interrupt Clear Register (RCC_CICR)**.

**Note:** The interrupt flags are not relevant if the corresponding interrupt enable bit is not set. **Table 59** gives a summary of the interrupt sources, and the way to control them.

**Table 59. Interrupt sources and control**

1. The security system feature must also be enabled (LSECSSON = ‘1’), in order to generate interrupts.
2. It is not possible to mask this interrupt when the security system feature is enabled (HSECSSON = ‘1’).
7.7 RCC register description

7.7.1 Register mapping overview

Note that the control of PERxEN and PERxLPEN bits can be performed at two different address offset: 0x0D0 and 0x130. So the application can use the registers named:

- RCC_xxxxENR or RCC_C1_xxxxENR to control the PERxEN bits
- RCC_xxxxLPENR or RCC_C1_xxxxLPENR to control the PERxLPEN bits
- RCC_RSR or RCC_C1_RSR to control the reset flag status bits.

This feature is provided to insure the compatibility with other products of this family.

*Figure 61* shows the RCC mapping overview.

</tbody>
</table>

Bits 31:30  Reserved, must be kept at reset value.

Bit 29 **PLL3RDY**: PLL3 clock ready flag  
Set by hardware to indicate that the PLL3 is locked.  
0: PLL3 unlocked (default after reset)  
1: PLL3 locked

Bit 28 **PLL3ON**: PLL3 enable  
Set and cleared by software to enable PLL3.  
Cleared by hardware when entering Stop or Standby mode.  
0: PLL3 OFF (default after reset)  
1: PLL3 ON

Bit 27 **PLL2RDY**: PLL2 clock ready flag  
Set by hardware to indicate that the PLL2 is locked.  
0: PLL2 unlocked (default after reset)  
1: PLL2 locked

Bit 26 **PLL2ON**: PLL2 enable  
Set and cleared by software to enable PLL2.  
Cleared by hardware when entering Stop or Standby mode.  
0: PLL2 OFF (default after reset)  
1: PLL2 ON

Bit 25 **PLL1RDY**: PLL1 clock ready flag  
Set by hardware to indicate that the PLL1 is locked.  
0: PLL1 unlocked (default after reset)  
1: PLL1 locked

Bit 24 **PLL1ON**: PLL1 enable  
Set and cleared by software to enable PLL1.  
Cleared by hardware when entering Stop or Standby mode. Note that the hardware prevents writing this bit to ‘0’, if the PLL1 output is used as the system clock.  
0: PLL1 OFF (default after reset)  
1: PLL1 ON

Bits 23:20  Reserved, must be kept at reset value.
Bit 19 **HSECSSON**: HSE Clock Security System enable
Set by software to enable Clock Security System on HSE.
This bit is "set only" (disabled by a system reset or when the system enters in Standby mode).
When HSECSSON is set, the clock detector is enabled by hardware when the HSE is ready and
disabled by hardware if an oscillator failure is detected.
0: Clock Security System on HSE OFF (Clock detector OFF) (default after reset)
1: Clock Security System on HSE ON (Clock detector ON if the HSE oscillator is
stable, OFF if not).

Bit 18 **HSEBYP**: HSE clock bypass
Set and cleared by software to bypass the oscillator with an external clock. The external
clock must be enabled with the HSEON bit, to be used by the device.
The HSEBYP bit can be written only if the HSE oscillator is disabled.
0: HSE oscillator not bypassed (default after reset)
1: HSE oscillator bypassed with an external clock

Bit 17 **HSERDY**: HSE clock ready flag
Set by hardware to indicate that the HSE oscillator is stable.
0: HSE clock is not ready (default after reset)
1: HSE clock is ready

Bit 16 **HSEON**: HSE clock enable
Set and cleared by software.
Cleared by hardware to stop the HSE when entering Stop or Standby mode.
This bit cannot be cleared if the HSE is used directly (via SW mux) as system clock or if the HSE is
selected as reference clock for PLL1 with PLL1 enabled (PLL1ON bit set to ‘1’).
0: HSE is OFF (default after reset)
1: HSE is ON

Bit 15 **D2CKRDY**: D2 domain clocks ready flag
Set by hardware to indicate that the D2 domain clocks are available.
0: D2 domain clocks are not available (default after reset)
1: D2 domain clocks are available

Bit 14 **D1CKRDY**: D1 domain clocks ready flag
Set by hardware to indicate that the D1 domain clocks (CPU, bus and peripheral) are available.
0: D1 domain clocks are not available (default after reset)
1: D1 domain clocks are available

Bit 13 **HSI48RDY**: HSI48 clock ready flag
Set by hardware to indicate that the HSI48 oscillator is stable.
0: HSI48 clock is not ready (default after reset)
1: HSI48 clock is ready

Bit 12 **HSI48ON**: HSI48 clock enable
Set by software and cleared by software or by the hardware when the system enters to Stop or
Standby mode.
0: HSI48 is OFF (default after reset)
1: HSI48 is ON

Bits 11:10 Reserved, must be kept at reset value.
Bit 9 **CSIKERON**: CSI clock enable in Stop mode
Set and reset by software to force the CSI to ON, even in Stop mode, in order to be quickly available as kernel clock for some peripherals. This bit has no effect on the value of CSION.
- 0: no effect on CSI (default after reset)
- 1: CSI is forced to ON even in Stop mode

Bit 8 **CSIRDY**: CSI clock ready flag
Set by hardware to indicate that the CSI oscillator is stable. This bit is activated only if the RC is enabled by CSION (it is not activated if the CSI is enabled by CSIKERON or by a peripheral request).
- 0: CSI clock is not ready (default after reset)
- 1: CSI clock is ready

Bit 7 **CSION**: CSI clock enable
Set and reset by software to enable/disable CSI clock for system and/or peripheral.
Set by hardware to force the CSI to ON when the system leaves Stop mode, if STOPWUCK = ‘1’ or STOPKERWUCK = ‘1’.
- This bit cannot be cleared if the CSI is used directly (via SW mux) as system clock or if the CSI is selected as reference clock for PLL1 with PLL1 enabled (PLL1ON bit set to ‘1’).
- 0: CSI is OFF (default after reset)
- 1: CSI is ON

Bit 6 Reserved, must be kept at reset value.

Bit 5 **HSIDIVF**: HSI divider flag
Set and reset by hardware.
As a write operation to HSIDIV has not an immediate effect on the frequency, this flag indicates the current status of the HSI divider. HSIDIVF will go immediately to ‘0’ when HSIDIV value is changed, and will be set back to ‘1’ when the output frequency matches the value programmed into HSIDIV.
- 0: new division ratio not yet propagated to $\text{hsi(\_ker)}\_\text{ck}$ (default after reset)
- 1: $\text{hsi(\_ker)}\_\text{ck}$ clock frequency reflects the new HSIDIV value

Bits 4:3 **HSIDIV[1:0]**: HSI clock divider
Set and reset by software.
These bits allow selecting a division ratio in order to configure the wanted HSI clock frequency. The HSIDIV cannot be changed if the HSI is selected as reference clock for at least one enabled PLL (PLLxON bit set to ‘1’). In that case, the new HSIDIV value is ignored.
- 00: Division by 1, $\text{hsi(\_ker)}\_\text{ck} = 64 \text{ MHz}$ (default after reset)
- 01: Division by 2, $\text{hsi(\_ker)}\_\text{ck} = 32 \text{ MHz}$
- 10: Division by 4, $\text{hsi(\_ker)}\_\text{ck} = 16 \text{ MHz}$
- 11: Division by 8, $\text{hsi(\_ker)}\_\text{ck} = 8 \text{ MHz}$
Bit 2  **HSIRDY**: HSI clock ready flag
   Set by hardware to indicate that the HSI oscillator is stable.
   0: HSI clock is not ready (default after reset)
   1: HSI clock is ready

Bit 1  **HSIKERON**: High Speed Internal clock enable in Stop mode
   Set and reset by software to force the HSI to ON, even in Stop mode, in order to be quickly available as kernel clock for peripherals. This bit has no effect on the value of HSION.
   0: no effect on HSI (default after reset)
   1: HSI is forced to ON even in Stop mode

Bit 0  **HSION**: High Speed Internal clock enable
   Set and cleared by software.
   Set by hardware to force the HSI to ON when the product leaves Stop mode, if STOPWUCK = ‘0’ or STOPKERWUCK = ‘0’.
   Set by hardware to force the HSI to ON when the product leaves Standby mode or in case of a failure of the HSE which is used as the system clock source.
   This bit cannot be cleared if the HSI is used directly (via SW mux) as system clock or if the HSI is selected as reference clock for PLL1 with PLL1 enabled (PLL1ON bit set to ‘1’).
   0: HSI is OFF
   1: HSI is ON (default after reset)
7.7.3 RCC Internal Clock Source Calibration Register (RCC_ICSCR)

Bit 31 Reserved, must be kept at reset value.

Bits 30:26 **CSITRIM[4:0]**: CSI clock trimming
Set by software to adjust calibration.
CSITRIM field is added to the engineering option bytes loaded during reset phase (flash_csi_opt) in order to form the calibration trimming value.
CSICAL = CSITRIM + flash_csi_opt.

*Note: The reset value of the field is 0x10.*

Bits 25:18 **CSICAL[7:0]**: CSI clock calibration
Set by hardware by option byte loading during system reset nreset.
Adjusted by software through trimming bits CSITRIM.
This field represents the sum of engineering option byte calibration value and CSITRIM bits value.

Bits 17:12 **HSITRIM[5:0]**: HSI clock trimming
Set by software to adjust calibration.
HSITRIM field is added to the engineering option bytes loaded during reset phase (flash_hsi_opt) in order to form the calibration trimming value.
HSICAL = HSITRIM + flash_hsi_opt.

*Note: The reset value of the field is 0x20.*

Bits 11:0 **HSICAL[11:0]**: HSI clock calibration
Set by hardware by option byte loading during system reset nreset.
Adjusted by software through trimming bits HSITRIM.
This field represents the sum of engineering option byte calibration value and HSITRIM bits value.
7.7.4 RCC HSI configuration register (RCC_HSICFGR)

Address offset: 0x004
Reset value: 0x4000 0xxx
This register is available only on revision V devices.

</table>

Bits 31:29 MCO2[2:0]: Micro-controller clock output 2
Set and cleared by software. Clock source selection may generate glitches on MCO2.
It is highly recommended to configure these bits only after reset, before enabling the external oscillators and the PLLs.
000: System clock selected (sys_ck) (default after reset)
001: PLL2 oscillator clock selected (pll2_p_ck)
010: HSE clock selected (hse_ck)
011: PLL1 clock selected (pll1_q_ck)
100: HSI clock selected (hsi_ck)
101: LSI clock selected (lsi_ck)
others: reserved

Bits 28:25 MCO2PRE[3:0]: MCO2 prescaler
Set and cleared by software to configure the prescaler of the MCO2. Modification of this prescaler may generate glitches on MCO2. It is highly recommended to change this prescaler only after reset, before enabling the external oscillators and the PLLs.
0000: prescaler disabled (default after reset)
0001: division by 1 (bypass)
0010: division by 2
0011: division by 3
0100: division by 4
... 1111: division by 15

Bits 24:22 MCO1[2:0]: Micro-controller clock output 1
Set and cleared by software. Clock source selection may generate glitches on MCO1.
It is highly recommended to configure these bits only after reset, before enabling the external oscillators and the PLLs.
000: HSI clock selected (hsi_ck) (default after reset)
001: LSE oscillator clock selected (lse_ck)
010: HSE clock selected (hse_ck)
011: PLL1 clock selected (pll1_q_ck)
100: HSI48 clock selected (hsi48_ck)
others: reserved
Bits 21:18 **MCO1PRE[3:0]**: MCO1 prescaler
Set and cleared by software to configure the prescaler of the MCO1. Modification of this prescaler may generate glitches on MCO1. It is highly recommended to change this prescaler only after reset, before enabling the external oscillators and the PLLs.
0000: prescaler disabled (default after reset)
0001: division by 1 (bypass)
0010: division by 2
0011: division by 3
0100: division by 4
... 1111: division by 15

Bits 17:16 Reserved, must be kept at reset value.

Bit 15 **TIMPRE**: Timers clocks prescaler selection
This bit is set and reset by software to control the clock frequency of all the timers connected to APB1 and APB2 domains.
0: The Timers kernel clock is equal to \( rcc\_hclk1 \) if \( D2PPREx \) is corresponding to division by 1 or 2, else it is equal to \( 2 \times F_{rcc\_pclkx\_d2} \) (default after reset)
1: The Timers kernel clock is equal to \( rcc\_hclk1 \) if \( D2PPREx \) is corresponding to division by 1, 2 or 4, else it is equal to \( 4 \times F_{rcc\_pclkx\_d2} \)
Please refer to Table 52: Ratio between clock timer and pclk

Bit 14 **HRTIMSEL**: High Resolution Timer clock prescaler selection
This bit is set and reset by software to control the clock frequency of high resolution the timer (HRTIM).
0: The HRTIM prescaler clock source is the same as other timers. (default after reset)
1: The HRTIM prescaler clock source is the CPU clock (\( rcc\_c\_ck \)).

Bits 13:8 **RTCPRE[5:0]**: HSE division factor for RTC clock
Set and cleared by software to divide the HSE to generate a clock for RTC.
Caution: The software has to set these bits correctly to ensure that the clock supplied to the RTC is lower than 1 MHz. These bits must be configured if needed before selecting the RTC clock source.
000000: no clock (default after reset)
000001: no clock
000010: HSE/2
000011: HSE/3
000100: HSE/4
... 111110: HSE/62
111111: HSE/63

Bit 7 **STOPKERWUCK**: Kernel clock selection after a wake up from system Stop
Set and reset by software to select the Kernel wakeup clock from system Stop.
0: The HSI is selected as wake up clock from system Stop (default after reset)
1: The CSI is selected as wake up clock from system Stop
See Section 7.5.7: Handling clock generators in Stop and Standby mode for details.
Bit 6  **STOPWUCK**: System clock selection after a wake up from system Stop
   Set and reset by software to select the system wakeup clock from system Stop.
   The selected clock is also used as emergency clock for the Clock Security System on HSE.
   0: The HSI is selected as wake up clock from system Stop (default after reset)
   1: The CSI is selected as wake up clock from system Stop
   See *Section 7.5.7: Handling clock generators in Stop and Standby mode* for details.
   **Caution:** STOPWUCK must not be modified when the Clock Security System is enabled (by HSECSSON bit) and the system clock is HSE (SWS="10") or a switch on HSE is requested (SW="10").

Bits 5:3  **SWS[2:0]**: System clock switch status
   Set and reset by hardware to indicate which clock source is used as system clock.
   000: HSI used as system clock (*hsi_ck*) (default after reset)
   001: CSI used as system clock (*csi_ck*)
   010: HSE used as system clock (*hse_ck*)
   011: PLL1 used as system clock (*pll1_p_ck*)
   others: Reserved

Bits 2:0  **SW[2:0]**: System clock switch
   Set and reset by software to select system clock source (*sys_ck*).
   Set by hardware in order to:
   – force the selection of the HSI or CSI (depending on STOPWUCK selection) when leaving a system Stop mode
   – force the selection of the HSI in case of failure of the HSE when used directly or indirectly as system clock.
   000: HSI selected as system clock (*hsi_ck*) (default after reset)
   001: CSI selected as system clock (*csi_ck*)
   010: HSE selected as system clock (*hse_ck*)
   011: PLL1 selected as system clock (*pll1_p_ck*)
   others: Reserved
7.7.8 RCC Domain 1 Clock Configuration Register (RCC_D1CFGR)

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:8 D1CPRE[3:0]: D1 domain Core prescaler
Set and reset by software to control D1 domain CPU clock division factor.
Changing this division ratio has an impact on the frequency of the CPU clock, and all bus matrix clocks.
The clocks are divided by the new prescaler factor. This factor ranges from 1 to 16 periods of the slowest APB clock among rcc_pclk[4:1] after D1CPRE update. The application can check if the new division factor is taken into account by reading back this register.
0xxx: sys_ck not divided (default after reset)
1000: sys_ck divided by 2
1001: sys_ck divided by 4
1010: sys_ck divided by 8
1011: sys_ck divided by 16
1100: sys_ck divided by 64
1101: sys_ck divided by 128
1110: sys_ck divided by 256
1111: sys_ck divided by 512
Bit 7  Reserved, must be kept at reset value.

Bits 6:4  D1PPRE[2:0]: D1 domain APB3 prescaler
Set and reset by software to control the division factor of rcc_pclk3.
The clock is divided by the new prescaler factor from 1 to 16 cycles of rcc_hclk3 after D1PPRE write.
0xx: rcc_pclk3 = rcc_hclk3 (default after reset)
100: rcc_pclk3 = rcc_hclk3 / 2
101: rcc_pclk3 = rcc_hclk3 / 4
110: rcc_pclk3 = rcc_hclk3 / 8
111: rcc_pclk3 = rcc_hclk3 / 16

Bits 3:0  HPRE[3:0]: D1 domain AHB prescaler
Set and reset by software to control the division factor of rcc_hclk3 and rcc_aclk. Changing this division ratio has an impact on the frequency of all bus matrix clocks.
0xxx: rcc_hclk3 = sys_d1cpre_ck (default after reset)
1000: rcc_hclk3 = sys_d1cpre_ck / 2
1001: rcc_hclk3 = sys_d1cpre_ck / 4
1010: rcc_hclk3 = sys_d1cpre_ck / 8
1011: rcc_hclk3 = sys_d1cpre_ck / 16
1100: rcc_hclk3 = sys_d1cpre_ck / 64
1101: rcc_hclk3 = sys_d1cpre_ck / 128
1110: rcc_hclk3 = sys_d1cpre_ck / 256
1111: rcc_hclk3 = sys_d1cpre_ck / 512

Note: The clocks are divided by the new prescaler factor from 1 to 16 periods of the slowest APB clock among rcc_pclk[4:1] after HPRE update.

Caution: Care must be taken when using the voltage scaling. Due to the propagation delay of the new division factor, after a prescaler factor change and before lowering the VCORE voltage, this register must be read in order to check that the new prescaler value has been taken into account.

Depending on the clock source frequency and the voltage range, the software application has to program a correct value in HPRE to make sure that the system frequency does not exceed the maximum frequency.
### RCC Domain 2 Clock Configuration Register (RCC_D2CFGR)

Address offset: 0x01C

</table>
Bit 19 DIVP2EN: PLL2 DIVP divider output enable
Set and reset by software to enable the pll2_p_ck output of the PLL2.
This bit can be written only when the PLL2 is disabled (PLL2ON = '0' and PLL2RDY = '0').
To save power, DIVR3EN and DIVR3 bits must be set to '0' when the pll3_r_ck is not used.
0: pll2_p_ck output is disabled
1: pll2_p_ck output is enabled (default after reset)

Bit 18 DIVR1EN: PLL1 DIVR divider output enable
Set and reset by software to enable the pll1_r_ck output of the PLL1.
This bit can be written only when the PLL1 is disabled (PLL1ON = '0' and PLL1RDY = '0').
To save power, DIVR3EN and DIVR3 bits must be set to '0' when the pll3_r_ck is not used.
0: pll1_r_ck output is disabled
1: pll1_r_ck output is enabled (default after reset)

Bit 17 DIVQ1EN: PLL1 DIVQ divider output enable
Set and reset by software to enable the pll1_q_ck output of the PLL1.
In order to save power, when the pll1_q_ck output of the PLL1 is not used, the pll1_q_ck must be disabled.
This bit can be written only when the PLL1 is disabled (PLL1ON = '0' and PLL1RDY = '0').
0: pll1_q_ck output is disabled
1: pll1_q_ck output is enabled (default after reset)

Bit 16 DIVP1EN: PLL1 DIVP divider output enable
Set and reset by software to enable the pll1_p_ck output of the PLL1.
This bit can be written only when the PLL1 is disabled (PLL1ON = '0' and PLL1RDY = '0').
In order to save power, when the pll1_p_ck output of the PLL1 is not used, the pll1_p_ck must be disabled.
0: pll1_p_ck output is disabled
1: pll1_p_ck output is enabled (default after reset)

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:10 PLL3RGE[1:0]: PLL3 input frequency range
Set and reset by software to select the proper reference frequency range used for PLL3.
These bits must be written before enabling the PLL3.
00: The PLL3 input (ref3_ck) clock range frequency is between 1 and 2 MHz (default after reset)
01: The PLL3 input (ref3_ck) clock range frequency is between 2 and 4 MHz
10: The PLL3 input (ref3_ck) clock range frequency is between 4 and 8 MHz
11: The PLL3 input (ref3_ck) clock range frequency is between 8 and 16 MHz

Bit 9 PLL3VCOSEL: PLL3 VCO selection
Set and reset by software to select the proper VCO frequency range used for PLL3.
This bit must be written before enabling the PLL3.
0: Wide VCO range:192 to 836 MHz (default after reset)
1: Medium VCO range:150 to 420 MHz

Bit 8 PLL3FRACEN: PLL3 fractional latch enable
Set and reset by software to latch the content of FRACN3 into the Sigma-Delta modulator.
In order to latch the FRACN3 value into the Sigma-Delta modulator, PLL3FRACEN must be set to '0', then set to '1': the transition 0 to 1 transfers the content of FRACN3 into the modulator. Please refer to Section: PLL initialization phase for additional information.
Reset and Clock Control (RCC)

Bits 7:6  **PLL2RGE[1:0]**: PLL2 input frequency range
- Set and reset by software to select the proper reference frequency range used for PLL2.
- These bits must be written before enabling the PLL2.
- 00: The PLL2 input (ref2_ck) clock range frequency is between 1 and 2 MHz (default after reset)
- 01: The PLL2 input (ref2_ck) clock range frequency is between 2 and 4 MHz
- 10: The PLL2 input (ref2_ck) clock range frequency is between 4 and 8 MHz
- 11: The PLL2 input (ref2_ck) clock range frequency is between 8 and 16 MHz

Bit 5  **PLL2VCOSEL**: PLL2 VCO selection
- Set and reset by software to select the proper VCO frequency range used for PLL2.
- This bit must be written before enabling the PLL2.
- 0: Wide VCO range: 192 to 836 MHz (default after reset)
- 1: Medium VCO range: 150 to 420 MHz

Bit 4  **PLL2FRACEN**: PLL2 fractional latch enable
- Set and reset by software to latch the content of FRACN2 into the Sigma-Delta modulator.
- In order to latch the FRACN2 value into the Sigma-Delta modulator, PLL2FRACEN must be set to ‘0’, then set to ‘1’: the transition 0 to 1 transfers the content of FRACN2 into the modulator. Please refer to Section : PLL initialization phase for additional information.

Bits 3:2  **PLL1RGE[1:0]**: PLL1 input frequency range
- Set and reset by software to select the proper reference frequency range used for PLL1.
- This bit must be written before enabling the PLL1.
- 00: The PLL1 input (ref1_ck) clock range frequency is between 1 and 2 MHz (default after reset)
- 01: The PLL1 input (ref1_ck) clock range frequency is between 2 and 4 MHz
- 10: The PLL1 input (ref1_ck) clock range frequency is between 4 and 8 MHz
- 11: The PLL1 input (ref1_ck) clock range frequency is between 8 and 16 MHz

Bit 1  **PLL1VCOSEL**: PLL1 VCO selection
- Set and reset by software to select the proper VCO frequency range used for PLL1.
- These bits must be written before enabling the PLL1.
- 0: Wide VCO range: 192 to 836 MHz (default after reset)
- 1: Medium VCO range: 150 to 420 MHz

Bit 0  **PLL1FRACEN**: PLL1 fractional latch enable
- Set and reset by software to latch the content of FRACN1 into the Sigma-Delta modulator.
- In order to latch the FRACN1 value into the Sigma-Delta modulator, PLL1FRACEN must be set to ‘0’, then set to ‘1’: the transition 0 to 1 transfers the content of FRACN1 into the modulator. Please refer to Section : PLL initialization phase for additional information.

Bit 31  Reserved, must be kept at reset value.

Bits 30:24   DIVR[6:0]: PLL1 DIVR division factor
Set and reset by software to control the frequency of the pll1_r_ck clock.
These bits can be written only when the PLL1 is disabled (PLL1ON = ‘0’ and PLL1RDY = ‘0’).
0000000: pll1_r_ck = vco1_ck
0000001: pll1_r_ck = vco1_ck / 2 (default after reset)
0000010: pll1_r_ck = vco1_ck / 3
0000011: pll1_r_ck = vco1_ck / 4
...
1111111: pll1_r_ck = vco1_ck / 128

Bit 23  Reserved, must be kept at reset value.
Bits 22:16  **DIVQ1[6:0]**: PLL1 DIVQ division factor
Set and reset by software to control the frequency of the **pll1_q_ck** clock.
These bits can be written only when the PLL1 is disabled (PLL1ON = ‘0’ and PLL1RDY = ‘0’).

- 0000000: \( \text{pll1}_q\_\text{ck} = \text{vco1}_\text{ck} \)
- 0000001: \( \text{pll1}_q\_\text{ck} = \text{vco1}_\text{ck} / 2 \) (default after reset)
- 0000010: \( \text{pll1}_q\_\text{ck} = \text{vco1}_\text{ck} / 3 \)
- 0000011: \( \text{pll1}_q\_\text{ck} = \text{vco1}_\text{ck} / 4 \)
...
- 1111111: \( \text{pll1}_q\_\text{ck} = \text{vco1}_\text{ck} / 128 \)

Bits 15:9  **DIVP1[6:0]**: PLL1 DIVP division factor
Set and reset by software to control the frequency of the **pll1_p_ck** clock.
These bits can be written only when the PLL1 is disabled (PLL1ON = ‘0’ and PLL1RDY = ‘0’).

Note that odd division factors are not allowed.

- 0000000: \( \text{pll1}_p\_\text{ck} = \text{vco1}_\text{ck} \)
- 0000001: \( \text{pll1}_p\_\text{ck} = \text{vco1}_\text{ck} / 2 \) (default after reset)
- 0000010: Not allowed
- 0000011: \( \text{pll1}_p\_\text{ck} = \text{vco1}_\text{ck} / 4 \)
...
- 1111111: \( \text{pll1}_p\_\text{ck} = \text{vco1}_\text{ck} / 128 \)

Bits 8:0  **DIVN1[8:0]**: Multiplication factor for PLL1 VCO
Set and reset by software to control the multiplication factor of the VCO.
These bits can be written only when the PLL is disabled (PLL1ON = ‘0’ and PLL1RDY = ‘0’).

- 0x003: \( \text{DIVN1} = 4 \)
- 0x004: \( \text{DIVN1} = 5 \)
- 0x005: \( \text{DIVN1} = 6 \)
...
- 0x080: \( \text{DIVN1} = 129 \) (default after reset)
...
- 0x1FF: \( \text{DIVN1} = 512 \)
Others: wrong configurations

**Caution:** The software has to set correctly these bits to insure that the VCO output frequency is between its valid frequency range, which is:
- 192 to 836 MHz if PLL1VCOSEL = ‘0’
- 150 to 420 MHz if PLL1VCOSEL = ‘1’

VCO output frequency = \( F_{\text{ref1}_\text{ck}} \times \text{DIVN1} \), when fractional value 0 has been loaded into FRACN1, with:
- DIVN1 between 4 and 512
- The input frequency \( F_{\text{ref1}_\text{ck}} \) between 1MHz and 16 MHz
7.7.14 RCC PLL1 Fractional Divider Register (RCC_PLL1FRACR)

<td>0</td>
</tr>
</tbody>
</table>

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:3 **FRACN1[12:0]**: Fractional part of the multiplication factor for PLL1 VCO

Set and reset by software to control the fractional part of the multiplication factor of the VCO. These bits can be written at any time, allowing dynamic fine-tuning of the PLL1 VCO.

**Caution:** The software has to set correctly these bits to insure that the VCO output frequency is between its valid frequency range, which is:

- 192 to 836 MHz if PLL1VCOSEL = ‘0’
- 150 to 420 MHz if PLL1VCOSEL = ‘1’

VCO output frequency = \( F_{\text{ref1\_ck}} \times \left( \text{DIVN1} + \left( \frac{\text{FRACN1}}{2^{13}} \right) \right) \), with

- DIVN1 shall be between 4 and 512
- FRACN1 can be between 0 and \( 2^{13} - 1 \)
- The input frequency \( F_{\text{ref1\_ck}} \) shall be between 1 and 16 MHz.

To change the FRACN value on-the-fly even if the PLL is enabled, the application has to proceed as follow:

- set the bit PLL1FRACEN to ‘0’,
- write the new fractional value into FRACN1,
- set the bit PLL1FRACEN to ‘1’.

Bits 2:0 Reserved, must be kept at reset value.

- **Bit 31**  Reserved, must be kept at reset value.
- **Bits 30:24**  **DIVR2[6:0]:** PLL2 DIVR division factor  
  - Set and reset by software to control the frequency of the `pll2_r_ck` clock.  
  - These bits can be written only when the PLL2 is disabled (PLL2ON = ‘0’ and PLL2RDY = ‘0’).
  - 0000000:  `pll2_r_ck = vco2_ck`
  - 0000001:  `pll2_r_ck = vco2_ck / 2` (default after reset)
  - 0000010:  `pll2_r_ck = vco2_ck / 3`
  - 0000011:  `pll2_r_ck = vco2_ck / 4`
  - ...  
  - 1111111:  `pll2_r_ck = vco2_ck / 128`

- **Bit 23**  Reserved, must be kept at reset value.
Bits 22:16 **DIVQ2[6:0]**: PLL2 DIVQ division factor
Set and reset by software to control the frequency of the **pll2_q_ck** clock.
These bits can be written only when the PLL2 is disabled (PLL2ON = '0' and PLL2RDY = '0').

0000000: **pll2_q_ck** = **vco2_ck**
0000001: **pll2_q_ck** = **vco2_ck** / 2 (default after reset)
0000010: **pll2_q_ck** = **vco2_ck** / 3
0000011: **pll2_q_ck** = **vco2_ck** / 4
... 1111111: **pll2_q_ck** = **vco2_ck** / 128

Bits 15:9 **DIVP2[6:0]**: PLL2 DIVP division factor
Set and reset by software to control the frequency of the **pll2_p_ck** clock.
These bits can be written only when the PLL2 is disabled (PLL2ON = '0' and PLL2RDY = '0').

0000000: **pll2_p_ck** = **vco2_ck**
0000001: **pll2_p_ck** = **vco2_ck** / 2 (default after reset)
0000010: **pll2_p_ck** = **vco2_ck** / 3
0000011: **pll2_p_ck** = **vco2_ck** / 4
... 1111111: **pll2_p_ck** = **vco2_ck** / 128

Bits 8:0 **DIVN2[8:0]**: Multiplication factor for PLL2 VCO
Set and reset by software to control the multiplication factor of the VCO.
These bits can be written only when the PLL is disabled (PLL2ON = '0' and PLL2RDY = '0').

**Caution:** The software has to set correctly these bits to insure that the VCO output frequency is
between its valid frequency range, which is:
- 192 to 836 MHz if PLL2VCOSEL = '0'
- 150 to 420 MHz if PLL2VCOSEL = '1'

VCO output frequency = \( F_{ref2_{ck}} \times DIVN2 \), when fractional value 0 has been loaded into FRACN2, with
- DIVN2 between 4 and 512
- The input frequency \( F_{ref2_{ck}} \) between 1MHz and 16MHz

0x003: DIVN2 = 4
0x004: DIVN2 = 5
0x005: DIVN2 = 6
... 0x080: DIVN2 = 129 (default after reset)
... 0x1FF: DIVN2 = 512
Others: wrong configurations
7.7.16 RCC PLL2 Fractional Divider Register (RCC_PLL2FRACR)

Address offset: 0x03C
Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:3 FRACN2[12:0]: Fractional part of the multiplication factor for PLL2 VCO

Set and reset by software to control the fractional part of the multiplication factor of the VCO. These bits can be written at any time, allowing dynamic fine-tuning of the PLL2 VCO.

Caution: The software has to set correctly these bits to insure that the VCO output frequency is between its valid frequency range, which is:

- 192 to 836 MHz if PLL2VCOSEL = ‘0’
- 150 to 420 MHz if PLL2VCOSEL = ‘1’

VCO output frequency = F_{ref2\_ck} \times \left( \text{DIVN2} + \frac{\text{FRACN2}}{2^{13}} \right)

- DIVN2 shall be between 4 and 512
- FRACN2 can be between 0 and 2^{13} - 1
- The input frequency F_{ref2\_ck} shall be between 1 and 16 MHz

In order to change the FRACN value on-the-fly even if the PLL is enabled, the application has to proceed as follow:

- set the bit PLL2FRACEN to ‘0’,
- write the new fractional value into FRACN2,
- set the bit PLL2FRACEN to ‘1’.

Bits 2:0 Reserved, must be kept at reset value.

- 11: csi_ker_ck clock is selected as kernel clock
Bits 11:10  Reserved, must be kept at reset value.

Bits 9:8  **RNGSEL[1:0]**: RNG kernel clock source selection
Set and reset by software.
- 00: **hsi8_ck** clock is selected as kernel clock (default after reset)
- 01: **pll1_q_ck** clock is selected as kernel clock
- 10: **lse_ck** clock is selected as kernel clock
- 11: **lsi_ck** clock is selected as kernel clock

Bits 7:6  Reserved, must be kept at reset value.

Bits 5:3  **USART16SEL[2:0]**: USART1 and 6 kernel clock source selection
Set and reset by software.
- 00: **rcc_pclk2** clock is selected as kernel clock (default after reset)
- 01: **pll2_q_ck** clock is selected as kernel clock
- 10: **pll3_q_ck** clock is selected as kernel clock
- 11: **hsi_ker_ck** clock is selected as kernel clock
- 100: **csi_ker_ck** clock is selected as kernel clock
- 101: **lse_ck** clock is selected as kernel clock
- others: reserved, the kernel clock is disabled

Bits 2:0  **USART234578SEL[2:0]**: USART2/3, UART4,5, 7/8 (APB1) kernel clock source selection
Set and reset by software.
- 00: **rcc_pclk1** clock is selected as kernel clock (default after reset)
- 01: **pll2_q_ck** clock is selected as kernel clock
- 010: **pll3_q_ck** clock is selected as kernel clock
- 011: **hsi_ker_ck** clock is selected as kernel clock
- 100: **csi_ker_ck** clock is selected as kernel clock
- 101: **lse_ck** clock is selected as kernel clock
- others: reserved, the kernel clock is disabled

1. Changing the clock source on-the-fly is allowed, and will not generate any timing violation. However the user has to make sure that both the previous and the new clock sources are present during the switching, and for the whole transition time. Please refer to Section : Clock switches and gating.

Bit 31 Reserved, must be kept at reset value.

Bits 30:28 **SPI6SEL[2:0]**: SPI6 kernel clock source selection  
Set and reset by software.
- 000: *rcc_pclk4* clock selected as kernel peripheral clock (default after reset)
- 001: *pll2_q_ck* clock selected as kernel peripheral clock
- 010: *pll3_q_ck* clock selected as kernel peripheral clock
- 011: *hsi_ker_ck* clock selected as kernel peripheral clock
- 100: *csi_ker_ck* clock selected as kernel peripheral clock
- 101: *hse_ck* clock selected as kernel peripheral clock
- others: reserved, the kernel clock is disabled

Bit 27 Reserved, must be kept at reset value.

Bits 26:24 **SAI4BSEL[2:0]**: Sub-Block B of SAI4 kernel clock source selection  
Set and reset by software.

**Caution:** If the selected clock is the external clock and this clock is stopped, it will not be possible to switch to another clock. Refer to Section : Clock switches and gating for additional information.
- 000: *pll1_q_ck* clock selected as kernel peripheral clock (default after reset)
- 001: *pll2_p_ck* clock selected as kernel peripheral clock
- 010: *pll3_p_ck* clock selected as kernel peripheral clock
- 011: *i2s_ck* clock selected as kernel peripheral clock
- 100: *per_ck* clock selected as kernel peripheral clock
- others: reserved, the kernel clock is disabled

**Note:** *i2s_ck* is an external clock taken from a pin.
Bits 23:21  **SAI4ASEL[2:0]**: Sub-Block A of SAI4 kernel clock source selection
Set and reset by software.

**Caution:** If the selected clock is the external clock and this clock is stopped, it will not be possible to switch to another clock. Refer to *Section: Clock switches and gating* for additional information.

- 000: **pll1_q_ck** clock selected as kernel peripheral clock (default after reset)
- 001: **pll2_p_ck** clock selected as kernel peripheral clock
- 010: **pll3_p_ck** clock selected as kernel peripheral clock
- 011: **I2S_CKIN** clock selected as kernel peripheral clock
- 100: **per_ck** clock selected as kernel peripheral clock
- others: reserved, the kernel clock is disabled

**Note:** *I2S_CKIN* is an external clock taken from a pin.

Bits 20:18  Reserved, must be kept at reset value.

Bits 17:16  **ADCSEL[1:0]**: SAR ADC kernel clock source selection
Set and reset by software.
- 00: **pll2_p_ck** clock selected as kernel peripheral clock (default after reset)
- 01: **pll3_r_ck** clock selected as kernel peripheral clock
- 10: **per_ck** clock selected as kernel peripheral clock
- others: reserved, the kernel clock is disabled

Bits 15:13  **LPTIM345SEL[2:0]**: LPTIM3,4,5 kernel clock source selection
Set and reset by software.
- 000: **rcc_pclk4** clock selected as kernel peripheral clock (default after reset)
- 001: **pll2_p_ck** clock selected as kernel peripheral clock
- 010: **pll3_r_ck** clock selected as kernel peripheral clock
- 011: **lse_ck** clock selected as kernel peripheral clock
- 100: **lsi_ck** clock selected as kernel peripheral clock
- 101: **per_ck** clock selected as kernel peripheral clock
- others: reserved, the kernel clock is disabled

Bits 12:10  **LPTIM2SEL[2:0]**: LPTIM2 kernel clock source selection
Set and reset by software.
- 000: **rcc_pclk4** clock selected as kernel peripheral clock (default after reset)
- 001: **pll2_p_ck** clock selected as kernel peripheral clock
- 010: **pll3_r_ck** clock selected as kernel peripheral clock
- 011: **lse_ck** clock selected as kernel peripheral clock
- 100: **lsi_ck** clock selected as kernel peripheral clock
- 101: **per_ck** clock selected as kernel peripheral clock
- others: reserved, the kernel clock is disabled
Bits 9:8  **I2C4SEL[1:0]**: I2C4 kernel clock source selection

Set and reset by software.
- 00: **rcc_pclk4** clock selected as kernel peripheral clock (default after reset)
- 01: **pll3_r_ck** clock selected as kernel peripheral clock
- 10: **hsi_ker_ck** clock selected as kernel peripheral clock
- 11: **csi_ker_ck** clock selected as kernel peripheral clock

Bits 7:3  Reserved, must be kept at reset value.

Bits 2:0  **LPUART1SEL[2:0]**: LPUART1 kernel clock source selection

Set and reset by software.
- 000: **rcc_pclk_d3** clock is selected as kernel peripheral clock (default after reset)
- 001: **pll2_q_ck** clock is selected as kernel peripheral clock
- 010: **pll3_q_ck** clock is selected as kernel peripheral clock
- 011: **hsi_ker_ck** clock is selected as kernel peripheral clock
- 100: **csi_ker_ck** clock is selected as kernel peripheral clock
- 101: **lse_ck** clock is selected as kernel peripheral clock
- others: reserved, the kernel clock is disabled

Bits 31:10  Reserved, must be kept at reset value.

- **Bit 9 LSECSSIE**: LSE clock security system Interrupt Enable  
  Set and reset by software to enable/disable interrupt caused by the Clock Security System on external 32 kHz oscillator.  
  - 0: LSE CSS interrupt disabled (default after reset)  
  - 1: LSE CSS interrupt enabled

- **Bit 8 PLL3RDYIE**: PLL3 ready Interrupt Enable  
  Set and reset by software to enable/disable interrupt caused by PLL3 lock.  
  - 0: PLL3 lock interrupt disabled (default after reset)  
  - 1: PLL3 lock interrupt enabled

- **Bit 7 PLL2RDYIE**: PLL2 ready Interrupt Enable  
  Set and reset by software to enable/disable interrupt caused by PLL2 lock.  
  - 0: PLL2 lock interrupt disabled (default after reset)  
  - 1: PLL2 lock interrupt enabled

- **Bit 6 PLL1RDYIE**: PLL1 ready Interrupt Enable  
  Set and reset by software to enable/disable interrupt caused by PLL1 lock.  
  - 0: PLL1 lock interrupt disabled (default after reset)  
  - 1: PLL1 lock interrupt enabled

- **Bit 5 HSI48RDYIE**: HSI48 ready Interrupt Enable  
  Set and reset by software to enable/disable interrupt caused by the HSI48 oscillator stabilization.  
  - 0: HSI48 ready interrupt disabled (default after reset)  
  - 1: HSI48 ready interrupt enabled

- **Bit 4 CSIRDYIE**: CSI ready Interrupt Enable  
  Set and reset by software to enable/disable interrupt caused by the CSI oscillator stabilization.  
  - 0: CSI ready interrupt disabled (default after reset)  
  - 1: CSI ready interrupt enabled

- **Bit 3 HSERDYIE**: HSE ready Interrupt Enable  
  Set and reset by software to enable/disable interrupt caused by the HSE oscillator stabilization.  
  - 0: HSE ready interrupt disabled (default after reset)  
  - 1: HSE ready interrupt enabled
Bit 2  **HSIRDYIE**: HSI ready Interrupt Enable
Set and reset by software to enable/disable interrupt caused by the HSI oscillator stabilization.
0: HSI ready interrupt disabled (default after reset)
1: HSI ready interrupt enabled

Bit 1  **LSERDYIE**: LSE ready Interrupt Enable
Set and reset by software to enable/disable interrupt caused by the LSE oscillator stabilization.
0: LSE ready interrupt disabled (default after reset)
1: LSE ready interrupt enabled

Bit 0  **LSIRDYIE**: LSI ready Interrupt Enable
Set and reset by software to enable/disable interrupt caused by the LSI oscillator stabilization.
0: LSI ready interrupt disabled (default after reset)
1: LSI ready interrupt enabled
### 7.7.24 RCC Clock Source Interrupt Flag Register (RCC_CIFR)

</tbody>
</table>

Bits 31:11 Reserved, must be kept at reset value.

**Bit 10 HSECSSF:** HSE clock security system Interrupt Flag  
Reset by software by writing HSECSSC bit.  
Set by hardware in case of HSE clock failure.  
0: No clock security interrupt caused by HSE clock failure (default after reset)  
1: Clock security interrupt caused by HSE clock failure

**Bit 9 LSECSSF:** LSE clock security system Interrupt Flag  
Reset by software by writing LSECSSC bit.  
Set by hardware when a failure is detected on the external 32 kHz oscillator and LSECSSIE is set.  
0: No failure detected on the external 32 kHz oscillator (default after reset)  
1: A failure is detected on the external 32 kHz oscillator

**Bit 8 PLL3RDYF:** PLL3 ready Interrupt Flag  
Reset by software by writing PLL3RDYC bit.  
Set by hardware when the PLL3 locks and PLL3RDYIE is set.  
0: No clock ready interrupt caused by PLL3 lock (default after reset)  
1: Clock ready interrupt caused by PLL3 lock

**Bit 7 PLL2RDYF:** PLL2 ready Interrupt Flag  
Reset by software by writing PLL2RDYC bit.  
Set by hardware when the PLL2 locks and PLL2RDYIE is set.  
0: No clock ready interrupt caused by PLL2 lock (default after reset)  
1: Clock ready interrupt caused by PLL2 lock

**Bit 6 PLL1RDYF:** PLL1 ready Interrupt Flag  
Reset by software by writing PLL1RDYC bit.  
Set by hardware when the PLL1 locks and PLL1RDYIE is set.  
0: No clock ready interrupt caused by PLL1 lock (default after reset)  
1: Clock ready interrupt caused by PLL1 lock

**Bit 5 HSI48RDYF:** HSI48 ready Interrupt Flag  
Reset by software by writing HSI48RDYC bit.  
Set by hardware when the HSI48 clock becomes stable and HSI48RDYIE is set.  
0: No clock ready interrupt caused by the HSI48 oscillator (default after reset)  
1: Clock ready interrupt caused by the HSI48 oscillator
Bit 4  **CSIRDYF**: CSI ready Interrupt Flag
    Reset by software by writing CSIRDYC bit.
    Set by hardware when the CSI clock becomes stable and CSIRDYIE is set.
    0: No clock ready interrupt caused by the CSI (default after reset)
    1: Clock ready interrupt caused by the CSI

Bit 3  **HSERDYF**: HSE ready Interrupt Flag
    Reset by software by writing HSERDYC bit.
    Set by hardware when the HSE clock becomes stable and HSERDYIE is set.
    0: No clock ready interrupt caused by the HSE (default after reset)
    1: Clock ready interrupt caused by the HSE

Bit 2  **HSIRDYF**: HSI ready Interrupt Flag
    Reset by software by writing HSIRDYC bit.
    Set by hardware when the HSI clock becomes stable and HSIRDYIE is set.
    0: No clock ready interrupt caused by the HSI (default after reset)
    1: Clock ready interrupt caused by the HSI

Bit 1  **LSERDYF**: LSE ready Interrupt Flag
    Reset by software by writing LSERDYC bit.
    Set by hardware when the LSE clock becomes stable and LSERDYIE is set.
    0: No clock ready interrupt caused by the LSE (default after reset)
    1: Clock ready interrupt caused by the LSE

Bit 0  **LSIRDYF**: LSI ready Interrupt Flag
    Reset by software by writing LSIRDYC bit.
    Set by hardware when the LSI clock becomes stable and LSIRDYIE is set.
    0: No clock ready interrupt caused by the LSI (default after reset)
    1: Clock ready interrupt caused by the LSI

Bits 31:11 Reserved, must be kept at reset value.

- **Bit 10 HSECSSC**: HSE clock security system Interrupt Clear  
  Set by software to clear HSECSSF.  
  Reset by hardware when clear done.  
  0: HSECSSF no effect (default after reset)  
  1: HSECSSF cleared

- **Bit 9 LSECSSC**: LSE clock security system Interrupt Clear  
  Set by software to clear LSECSSF.  
  Reset by hardware when clear done.  
  0: LSECSSF no effect (default after reset)  
  1: LSECSSF cleared

- **Bit 8 PLL3RDYC**: PLL3 ready Interrupt Clear  
  Set by software to clear PLL3RDYF.  
  Reset by hardware when clear done.  
  0: PLL3RDYF no effect (default after reset)  
  1: PLL3RDYF cleared

- **Bit 7 PLL2RDYC**: PLL2 ready Interrupt Clear  
  Set by software to clear PLL2RDYF.  
  Reset by hardware when clear done.  
  0: PLL2RDYF no effect (default after reset)  
  1: PLL2RDYF cleared

- **Bit 6 PLL1RDYC**: PLL1 ready Interrupt Clear  
  Set by software to clear PLL1RDYF.  
  Reset by hardware when clear done.  
  0: PLL1RDYF no effect (default after reset)  
  1: PLL1RDYF cleared

- **Bit 5 HSI48RDYC**: HSI48 ready Interrupt Clear  
  Set by software to clear HSI48RDYF.  
  Reset by hardware when clear done.  
  0: HSI48RDYF no effect (default after reset)  
  1: HSI48RDYF cleared
Bit 4  **CSIRDYC**: CSI ready Interrupt Clear
Set by software to clear CSIRDYF.
Reset by hardware when clear done.
0: CSIRDYF no effect (default after reset)
1: CSIRDYF cleared

Bit 3  **HSERDYC**: HSE ready Interrupt Clear
Set by software to clear HSERDYF.
Reset by hardware when clear done.
0: HSERDYF no effect (default after reset)
1: HSERDYF cleared

Bit 2  **HSIRDYC**: HSI ready Interrupt Clear
Set by software to clear HSIRDYF.
Reset by hardware when clear done.
0: HSIRDYF no effect (default after reset)
1: HSIRDYF cleared

Bit 1  **LSERDYC**: LSE ready Interrupt Clear
Set by software to clear LSERDYF.
Reset by hardware when clear done.
0: LSERDYF no effect (default after reset)
1: LSERDYF cleared

Bit 0  **LSIRDYC**: LSI ready Interrupt Clear
Set by software to clear LSIRDYF.
Reset by hardware when clear done.
0: LSIRDYF no effect (default after reset)
1: LSIRDYF cleared
7.7.26 RCC Backup Domain Control Register (RCC_BDCR)

Address offset: 0x070

Reset value: 0x0000 0000, reset by Backup domain reset.

Access: 0 ≤ wait state ≤ 7, word, half-word and byte access. Wait states are inserted in case of successive accesses to this register.

After a system reset, the RCC_BDCR register is write-protected. To modify this register, the DBP bit in the PWR control register 1 (PWR_CR1) has to be set to ‘1’. RCC_BDCR bits are only reset after a backup domain reset (see Section 7.4.6: Backup domain reset). Any other internal or external reset will not have any effect on these bits.

<table>

</tr>
<tr>
<td>Bit 7</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
</tbody>
</table>
Bit 6 **LSECSSD**: LSE clock security system failure detection
Set by hardware to indicate when a failure has been detected by the Clock Security System on the external 32 kHz oscillator.
0: No failure detected on 32 kHz oscillator (default after backup domain reset)
1: Failure detected on 32 kHz oscillator

Bit 5 **LSECSSON**: LSE clock security system enable
Set by software to enable the Clock Security System on 32 kHz oscillator.
LSECSSON must be enabled after LSE is enabled (LSEON enabled) and ready (LSERDY set by hardware), and after RTCSEL is selected.
Once enabled this bit cannot be disabled, except after a LSE failure detection (LSECSSD = ‘1’). In that case the software must disable LSECSSON.
0: Clock Security System on 32 kHz oscillator OFF (default after backup domain reset)
1: Clock Security System on 32 kHz oscillator ON

Bits 4:3 **LSEDRV[1:0]**: LSE oscillator driving capability
Set by software to select the driving capability of the LSE oscillator.
00: Lowest drive (default after backup domain reset)
01: Medium low drive
10: Medium high drive
11: Highest drive

Bit 2 **LSEBYP**: LSE oscillator bypass
Set and reset by software to bypass oscillator in debug mode. This bit must not be written when the LSE is enabled (by LSEON) or ready (LSERDY = ‘1’)
0: LSE oscillator not bypassed (default after backup domain reset)
1: LSE oscillator bypassed

Bit 1 **LSERDY**: LSE oscillator ready
Set and reset by hardware to indicate when the LSE is stable. This bit needs 6 cycles of lse_ck clock to fall down after LSEON has been set to ‘0’.
0: LSE oscillator not ready (default after backup domain reset)
1: LSE oscillator ready

Bit 0 **LSEON**: LSE oscillator enabled
Set and reset by software.
0: LSE oscillator OFF (default after backup domain reset)
1: LSE oscillator ON
7.7.27 RCC Clock Control and Status Register (RCC_CSR)

Address offset: 0x074
Reset value: 0x0000 0000
Access: 0 ≤ wait state ≤ 7, word, half-word and byte access

Wait states are inserted in case of successive accesses to this register.

</tbody>
</table>

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **LSIRDY**: LSI oscillator ready
- Set and reset by hardware to indicate when the Low Speed Internal RC oscillator is stable.
- This bit needs 3 cycles of lsi_ck clock to fall down after LSION has been set to ‘0’.
- This bit can be set even when LSION is not enabled if there is a request for LSI clock by the Clock Security System on LSE or by the Low Speed Watchdog or by the RTC.
- 0: LSI clock is not ready (default after reset)
- 1: LSI clock is ready

Bit 0 **LSION**: LSI oscillator enable
- Set and reset by software.
- 0: LSI is OFF (default after reset)
- 1: LSI is ON

Bits 31:17 Reserved, must be kept at reset value.

**Bit 16 SDMMC1RST**: SDMMC1 and SDMMC1 delay block reset
- Set and reset by software.
- 0: does not reset SDMMC1 and SDMMC1 Delay block (default after reset)
- 1: resets SDMMC1 and SDMMC1 Delay block

**Bit 15** Reserved, must be kept at reset value.

**Bit 14 QSPIRST**: QUADSPI and QUADSPI delay block reset
- Set and reset by software.
- 0: does not reset QUADSPI and QUADSPI Delay block (default after reset)
- 1: resets QUADSPI and QUADSPI Delay block

**Bit 13** Reserved, must be kept at reset value.

**Bit 12 FMCRST**: FMC block reset
- Set and reset by software.
- 0: does not reset FMC block (default after reset)
- 1: resets FMC block

Bits 11:6 Reserved, must be kept at reset value.

**Bit 5 JPGDECRST**: JPGDEC block reset
- Set and reset by software.
- 0: does not reset JPGDEC block (default after reset)
- 1: resets JPGDEC block
Bit 4  **DMA2DRST**: DMA2D block reset  
   Set and reset by software.  
   0: does not reset DMA2D block (default after reset)  
   1: resets DMA2D block

Bits 3:1 Reserved, must be kept at reset value.

Bit 0  **MDMARST**: MDMA block reset  
   Set and reset by software.  
   0: does not reset MDMA block (default after reset)  
   1: resets MDMA block

Bits 31:28 Reserved, must be kept at reset value.

- **Bit 27 USB2OTGRST**: USB2OTG (OTG_HS2) block reset  
  Set and reset by software.  
  0: does not reset USB2OTG block (default after reset)  
  1: resets USB2OTG block

- **Bit 26** Reserved, must be kept at reset value.

- **Bit 25 USB1OTGRST**: USB1OTG (OTG_HS1) block reset  
  Set and reset by software.  
  0: does not reset USB1OTG block (default after reset)  
  1: resets USB1OTG block

Bits 24:16 Reserved, must be kept at reset value.

- **Bit 15 ETH1MACRST**: ETH1MAC block reset  
  Set and reset by software.  
  0: does not reset ETH1MAC block (default after reset)  
  1: resets ETH1MAC block

Bits 14:6 Reserved, must be kept at reset value.

- **Bit 5 ADC12RST**: ADC1 and 2 block reset  
  Set and reset by software.  
  0: does not reset ADC1 and 2 block (default after reset)  
  1: resets ADC1 and 2 block
Bits 4:2  Reserved, must be kept at reset value.

Bit 1  **DMA2RST**: DMA2 block reset
       Set and reset by software.
       0: does not reset DMA2 block (default after reset)
       1: resets DMA2 block

Bit 0  **DMA1RST**: DMA1 block reset
       Set and reset by software.
       0: does not reset DMA1 block (default after reset)
       1: resets DMA1 block
### 7.7.30 RCC AHB2 Peripheral Reset Register (RCC_AHB2RSTR)

Bits 31:10  Reserved, must be kept at reset value.

- **Bit 9**  SDMMC2RST: SDMMC2 and SDMMC2 Delay block reset  
  Set and reset by software.  
  0: does not reset SDMMC2 and SDMMC2 Delay block (default after reset)  
  1: resets SDMMC2 and SDMMC2 Delay block

Bits 8:7  Reserved, must be kept at reset value.

- **Bit 6**  RNGRST: Random Number Generator block reset  
  Set and reset by software.  
  0: does not reset RNG block (default after reset)  
  1: resets RNG block

- **Bit 5**  HASHRST: Hash block reset  
  Set and reset by software.  
  0: does not reset hash block (default after reset)  
  1: resets hash block

- **Bit 4**  CRYPTRST: Cryptography block reset  
  Set and reset by software.  
  0: does not reset cryptography block (default after reset)  
  1: resets cryptography block

Bits 3:1  Reserved, must be kept at reset value.

- **Bit 0**  CAMITFRST: CAMITF block reset  
  Set and reset by software.  
  0: does not reset the CAMITF block (default after reset)  
  1: resets the CAMITF block

Bits 31:30  Reserved, must be kept at reset value.

- **Bit 29**  HRTIMRST: HRTIM block reset  
  Set and reset by software.  
  0: does not reset the HRTIM block (default after reset)  
  1: resets the HRTIM block

- **Bit 28**  DFSDM1RST: DFSDM1 block reset  
  Set and reset by software.  
  0: does not reset DFSDM1 block (default after reset)  
  1: resets DFSDM1 block

Bits 27:25  Reserved, must be kept at reset value.

- **Bit 24**  SAI3RST: SAI3 block reset  
  Set and reset by software.  
  0: does not reset the SAI3 block (default after reset)  
  1: resets the SAI3 block

- **Bit 23**  SAI2RST: SAI2 block reset  
  Set and reset by software.  
  0: does not reset the SAI2 block (default after reset)  
  1: resets the SAI2 block

- **Bit 22**  SAI1RST: SAI1 block reset  
  Set and reset by software.  
  0: does not reset the SAI1 (default after reset)  
  1: resets the SAI1

- **Bit 21**  Reserved, must be kept at reset value.

- **Bit 20**  SPI5RST: SPI5 block reset  
  Set and reset by software.  
  0: does not reset the SPI5 block (default after reset)  
  1: resets the SPI5 block

- **Bit 19**  Reserved, must be kept at reset value.
Bit 18 **TIM17RST**: TIM17 block reset
   Set and reset by software.
   0: does not reset the TIM17 block (default after reset)
   1: resets the TIM17 block

Bit 17 **TIM16RST**: TIM16 block reset
   Set and reset by software.
   0: does not reset the TIM16 block (default after reset)
   1: resets the TIM16 block

Bit 16 **TIM15RST**: TIM15 block reset
   Set and reset by software.
   0: does not reset the TIM15 block (default after reset)
   1: resets the TIM15 block

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **SPI4RST**: SPI4 block reset
   Set and reset by software.
   0: does not reset the SPI4 block (default after reset)
   1: resets the SPI4 block

Bit 12 **SPI1RST**: SPI1 block reset
   Set and reset by software.
   0: does not reset the SPI1 block (default after reset)
   1: resets the SPI1 block

Bits 11:6 Reserved, must be kept at reset value.

Bit 5 **USART6RST**: USART6 block reset
   Set and reset by software.
   0: does not reset the USART6 block (default after reset)
   1: resets the USART6 block

Bit 4 **USART1RST**: USART1 block reset
   Set and reset by software.
   0: does not reset the USART1 block (default after reset)
   1: resets the USART1 block

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **TIM8RST**: TIM8 block reset
   Set and reset by software.
   0: does not reset the TIM8 block (default after reset)
   1: resets the TIM8 block

Bit 0 **TIM1RST**: TIM1 block reset
   Set and reset by software.
   0: does not reset the TIM1 block (default after reset)
   1: resets the TIM1 block

Bit 9  **LPTIM2RST**: LPTIM2 block reset  
Set and reset by software.  
0: does not reset the LPTIM2 block (default after reset)  
1: resets the LPTIM2 block

Bit 8  Reserved, must be kept at reset value.

Bit 7  **I2C4RST**: I2C4 block reset  
Set and reset by software.  
0: does not reset the I2C4 block (default after reset)  
1: resets the I2C4 block

Bit 6  Reserved, must be kept at reset value.

Bit 5  **SPI6RST**: SPI6 block reset  
Set and reset by software.  
0: does not reset the SPI6 block (default after reset)  
1: resets the SPI6 block

Bit 4  Reserved, must be kept at reset value.

Bit 3  **LPUART1RST**: LPUART1 block reset  
Set and reset by software.  
0: does not reset the LPUART1 block (default after reset)  
1: resets the LPUART1 block

Bit 2  Reserved, must be kept at reset value.

Bit 1  **SYSCFGRST**: SYSCFG block reset  
Set and reset by software.  
0: does not reset the SYSCFG block (default after reset)  
1: resets the SYSCFG block

Bit 0  Reserved, must be kept at reset value.

7.7.38 RCC D3 Autonomous mode Register (RCC_D3AMR)

The Autonomous mode allows providing the peripheral clocks to peripherals located in D3, even if the CPU is in CStop mode. When a peripheral is enabled, and has its autonomous bit enabled, it receives its peripheral clocks according to D3 domain state, if the CPU is in CStop mode.

Address offset: 0x0A8

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **SRAM4AMEN**: SRAM4 Autonomous mode enable
- Set and reset by software.
- 0: SRAM4 clock is disabled when the CPU is in CStop (default after reset)
- 1: SRAM4 peripheral bus clock enabled when D3 domain is in DRun.
- Refer to Section 7.5.11: Peripheral clock gating control for additional information

Bit 28 **BKPRAMAMEN**: Backup RAM Autonomous mode enable
- Set and reset by software.
- 0: Backup RAM clock is disabled when the CPU is in CStop (default after reset)
- 1: Backup RAM clock enabling is controlled by D3 domain state.
- Refer to Section 7.5.11: Peripheral clock gating control for additional information

Bit 27 Reserved, must be kept at reset value.

Bits 26:25 Reserved, must be kept at reset value.

Bit 24 **ADC3AMEN**: ADC3 Autonomous mode enable
- Set and reset by software.
- 0: ADC3 peripheral clocks are disabled when the CPU is in CStop (default after reset)
- 1: ADC3 peripheral clocks enabled when D3 domain is in DRun.
- Refer to Section 7.5.11: Peripheral clock gating control for additional information

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **SAI4AMEN**: SAI4 Autonomous mode enable
- Set and reset by software.
- 0: SAI4 peripheral clocks are disabled when the CPU is in CStop (default after reset)
- 1: SAI4 peripheral clocks enabled when D3 domain is in DRun.
- Refer to Section 7.5.11: Peripheral clock gating control for additional information

Bit 20 Reserved, must be kept at reset value.
Bit 19  **CRCAMEN**: CRC Autonomous mode enable  
Set and reset by software.  
0: CRC peripheral clocks are disabled when the CPU is in CStop (default after reset)  
1: CRC peripheral clocks enabled when D3 domain is in DRun.  
Refer to Section 7.5.11: Peripheral clock gating control for additional information

Bits 18:17  Reserved, must be kept at reset value.

Bit 16  **RTCAMEN**: RTC Autonomous mode enable  
Set and reset by software.  
0: RTC peripheral clocks are disabled when the CPU is in CStop (default after reset)  
1: RTC peripheral clocks enabled when D3 domain is in DRun.  
Refer to Section 7.5.11: Peripheral clock gating control for additional information

Bit 15  **VREFAMEN**: VREF Autonomous mode enable  
Set and reset by software.  
0: VREF peripheral clocks are disabled when the CPU is in CStop (default after reset)  
1: VREF peripheral clocks enabled when D3 domain is in DRun.  
Refer to Section 7.5.11: Peripheral clock gating control for additional information

Bit 14  **COMP12AMEN**: COMP12 Autonomous mode enable  
Set and reset by software.  
0: COMP12 peripheral clocks are disabled when the CPU is in CStop (default after reset)  
1: COMP12 peripheral clocks enabled when D3 domain is in DRun.  
Refer to Section 7.5.11: Peripheral clock gating control for additional information

Bit 13  Reserved, must be kept at reset value.

Bit 12  **LPTIM5AMEN**: LPTIM5 Autonomous mode enable  
Set and reset by software.  
0: LPTIM5 peripheral clocks are disabled when the CPU is in CStop (default after reset)  
1: LPTIM5 peripheral clocks enabled when D3 domain is in DRun.  
Refer to Section 7.5.11: Peripheral clock gating control for additional information

Bit 11  **LPTIM4AMEN**: LPTIM4 Autonomous mode enable  
Set and reset by software.  
0: LPTIM4 peripheral clocks are disabled when the CPU is in CStop (default after reset)  
1: LPTIM4 peripheral clocks enabled when D3 domain is in DRun.  
Refer to Section 7.5.11: Peripheral clock gating control for additional information

Bit 10  **LPTIM3AMEN**: LPTIM3 Autonomous mode enable  
Set and reset by software.  
0: LPTIM3 peripheral clocks are disabled when the CPU is in CStop (default after reset)  
1: LPTIM3 peripheral clocks enabled when D3 domain is in DRun.  
Refer to Section 7.5.11: Peripheral clock gating control for additional information

Bit 9  **LPTIM2AMEN**: LPTIM2 Autonomous mode enable  
Set and reset by software.  
0: LPTIM2 peripheral clocks are disabled when the CPU is in CStop (default after reset)  
1: LPTIM2 peripheral clocks enabled when D3 domain is in DRun.  
Refer to Section 7.5.11: Peripheral clock gating control for additional information

Bit 8  Reserved, must be kept at reset value.

Bit 7  **I2C4AMEN**: I2C4 Autonomous mode enable  
Set and reset by software.  
0: I2C4 peripheral clocks are disabled when the CPU is in CStop (default after reset)  
1: I2C4 peripheral clocks enabled when D3 domain is in DRun.  
Refer to Section 7.5.11: Peripheral clock gating control for additional information
Bit 6  Reserved, must be kept at reset value.
Bit 5  **SPI6AMEN**: SPI6 Autonomous mode enable
  Set and reset by software.
  0: SPI6 peripheral clocks are disabled when the CPU is in CStop (default after reset)
  1: SPI6 peripheral clocks enabled when D3 domain is in DRun.
  Refer to *Section 7.5.11: Peripheral clock gating control* for additional information
Bit 4  Reserved, must be kept at reset value.
Bit 3  **LPUART1AMEN**: LPUART1 Autonomous mode enable
  Set and reset by software.
  0: LPUART1 peripheral clocks are disabled when the CPU is in CStop (default after reset)
  1: LPUART1 peripheral clocks enabled when D3 domain is in DRun.
  Refer to *Section 7.5.11: Peripheral clock gating control* for additional information
Bits 2:1  Reserved, must be kept at reset value.
Bit 0  **BDMAAMEN**: BDMA and DMAMUX Autonomous mode enable
  Set and reset by software.
  0: BDMA and DMAMUX peripheral clocks are disabled when the CPU is in CStop (default after reset)
  1: BDMA and DMAMUX peripheral clocks enabled when D3 domain is in DRun.
  Refer to *Section 7.5.11: Peripheral clock gating control* for additional information
7.7.39  **RCC Reset Status Register (RCC_RSR)**

This register can be accessed via two different offset address.

<table>
<thead>
<tr>
<th>Register Name</th>
<th>Address Offset</th>
<th>Reset Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>RCC_RSR</td>
<td>0x0D0</td>
<td>0x00FE 0000 (1)</td>

<tr>
<td>RCC_C1_RSR</td>
<td>0x130</td>
<td></td>
</tr>
</tbody>
</table>

1. Reset by power-on reset only

Access: 0 ≤ wait state ≤ 7, word, half-word and byte access. Wait states are inserted in case of successive accesses to this register.

### Bit 31
Reserved, must be kept at reset value.

### Bit 30  **LPWRRSTF**
Reset due to illegal D1 DStandby or CPU CStop flag (1)

- Reset by software by writing the RMVF bit.
- Set by hardware when D1 domain goes erroneously in DStandby or when CPU goes erroneously in CStop.
- 0: No illegal reset occurred (default after power-on reset)
- 1: Illegal D1 DStandby or CPU CStop reset occurred

### Bit 29
Reserved, must be kept at reset value.

### Bit 28  **WWDG1RSTF**
Window Watchdog reset flag (1)

- Reset by software by writing the RMVF bit.
- Set by hardware when a window watchdog reset occurs.
- 0: No window watchdog reset occurred from WWDG1 (default after power-on reset)
- 1: Window watchdog reset occurred from WWDG1

### Bit 27
Reserved, must be kept at reset value.

### Bit 26  **IWGD1RSTF**
Independent Watchdog reset flag (1)

- Reset by software by writing the RMVF bit.
- Set by hardware when an independent watchdog reset occurs.
- 0: No independent watchdog reset occurred (default after power-on reset)
- 1: Independent watchdog reset occurred

### Bit 25
Reserved, must be kept at reset value.
Bit 24 **SFTRSTF**: System reset from CPU reset flag \(^{(1)}\)
   - Reset by software by writing the RMVF bit.
   - Set by hardware when the system reset is due to CPU. The CPU can generate a system reset by writing SYSRESETREQ bit of AIRCR register of the CM7.
   - 0: No CPU software reset occurred (default after power-on reset)
   - 1: A system reset has been generated by the CPU

Bit 23 **PORRSTF**: POR/PDR reset flag \(^{(1)}\)
   - Reset by software by writing the RMVF bit.
   - Set by hardware when a POR/PDR reset occurs.
   - 0: No POR/PDR reset occurred
   - 1: POR/PDR reset occurred (default after power-on reset)

Bit 22 **PINRSTF**: Pin reset flag (NRST) \(^{(1)}\)
   - Reset by software by writing the RMVF bit.
   - Set by hardware when a reset from pin occurs.
   - 0: No reset from pin occurred
   - 1: Reset from pin occurred (default after power-on reset)

Bit 21 **BORRSTF**: BOR reset flag \(^{(1)}\)
   - Reset by software by writing the RMVF bit.
   - Set by hardware when a BOR reset occurs (pwr_bor_rst).
   - 0: No BOR reset occurred
   - 1: BOR reset occurred (default after power-on reset)

Bit 20 **D2RSTF**: D2 domain power switch reset flag \(^{(1)}\)
   - Reset by software by writing the RMVF bit.
   - Set by hardware when a D2 domain exits from DStandby or after of power-on reset. Refer to Table 51 for details.
   - 0: No D2 domain power switch reset occurred
   - 1: A D2 domain power switch (ePOD2) reset occurred (default after power-on reset)

Bit 19 **D1RSTF**: D1 domain power switch reset flag \(^{(1)}\)
   - Reset by software by writing the RMVF bit.
   - Set by hardware when a D1 domain exits from DStandby or after of power-on reset. Refer to Table 51 for details.
   - 0: No D1 domain power switch reset occurred
   - 1: A D1 domain power switch (ePOD1) reset occurred (default after power-on reset)

Bit 18 Reserved, must be kept at reset value.

Bit 17 **CPURSTF**: CPU reset flag \(^{(1)}\)
   - Reset by software by writing the RMVF bit.
   - Set by hardware every time a CPU reset occurs.
   - 0: No CPU reset occurred
   - 1: A CPU reset occurred (default after power-on reset)

Bit 16 **RMVF**: Remove reset flag
   - Set and reset by software to reset the value of the reset flags.
   - 0: Reset of the reset flags not activated (default after power-on reset)
   - 1: Reset the value of the reset flags

Bits 15:0 Reserved, must be kept at reset value.

1. Refer to Table 51: Reset source identification (RCC_RSR) for details on flag behavior.
7.7.40 RCC AHB3 Clock Register (RCC_AHB3ENR)

This register can be accessed via two different offset address.

Table 61. RCC_AHB3ENR address offset and reset value

<table>
<thead>
<tr>
<th>Register Name</th>

</tbody>
</table>

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 SDMMC1EN: SDMMC1 and SDMMC1 Delay Clock Enable
Set and reset by software.
0: SDMMC1 and SDMMC1 Delay clock disabled (default after reset)
1: SDMMC1 and SDMMC1 Delay clock enabled

Bit 15 Reserved, must be kept at reset value.

Bit 14 QSPIEN: QUADSPI and QUADSPI Delay Clock Enable
Set and reset by software.
0: QUADSPI and QUADSPI Delay clock disabled (default after reset)
1: QUADSPI and QUADSPI Delay clock enabled

Bit 13 Reserved, must be kept at reset value.

Bit 12 FMCEN: FMC Peripheral Clocks Enable
Set and reset by software.
0: FMC peripheral clocks disabled (default after reset)
1: FMC peripheral clocks enabled
The peripheral clocks of the FMC are: the kernel clock selected by FMCSEL and provided to fmc_ker_ck input, and the rcc_hclk3 bus interface clock.

Bits 11:6 Reserved, must be kept at reset value.

Bit 5 JPGDECEN: JPGDEC Peripheral Clock Enable
Set and reset by software.
0: JPGDEC peripheral clock disabled (default after reset)
1: JPGDEC peripheral clock enabled
Bit 4  **DMA2DEN**: DMA2D Peripheral Clock Enable  
Set and reset by software.  
0: DMA2D peripheral clock disabled (default after reset)  
1: DMA2D peripheral clock enabled  

Bits 3:1  Reserved, must be kept at reset value.  

Bit 0  **MDMAEN**: MDMA Peripheral Clock Enable  
Set and reset by software.  
0: MDMA peripheral clock disabled (default after reset)  
1: MDMA peripheral clock enabled
7.7.41 RCC AHB1 Clock Register (RCC_AHB1ENR)

This register can be accessed via two different offset address.

**Table 62. RCC_AHB1ENR address offset and reset value**

Bits 31:28 Reserved, must be kept at reset value.

**Bit 27 USB2OTGHSEN**: USB2OTG (OTG_HS2) Peripheral Clocks Enable
Set and reset by software.
0: USB2OTG peripheral clocks disabled (default after reset)
1: USB2OTG peripheral clocks enabled
The peripheral clocks of the USB2OTG are: the kernel clock selected by USBSEL and the rcc_hclk1 bus interface clock.

**Bit 26 USB1OTGHSULPIEN**: USB_PHY1 Clocks Enable
Set and reset by software.
0: USB1ULPI PHY clocks disabled (default after reset)
1: USB1ULPI PHY clocks enabled

**Bit 25 USB1OTGHSLEN**: USB1OTG (OTG_HS1) Peripheral Clocks Enable
Set and reset by software.
0: USB1OTG peripheral clocks disabled (default after reset)
1: USB1OTG peripheral clocks enabled
The peripheral clocks of the USB1OTG are: the kernel clock selected by USBSEL and the rcc_hclk1 bus interface clock.

Bits 24:19 Reserved, must be kept at reset value.

**Bit 18 USB2OTGHSULPIEN**: Enable USB_PHY2 clocks
Set and reset by software.
0: USB2ULPI PHY clocks disabled (default after reset)
1: USB2ULPI PHY clocks enabled
Bit 17 **ETH1RXEN**: Ethernet Reception Clock Enable
   Set and reset by software.
   0: Ethernet Reception clock disabled (default after reset)
   1: Ethernet Reception clock enabled

Bit 16 **ETH1TXEN**: Ethernet Transmission Clock Enable
   Set and reset by software.
   0: Ethernet Transmission clock disabled (default after reset)
   1: Ethernet Transmission clock enabled

Bit 15 **ETH1MACEN**: Ethernet MAC bus interface Clock Enable
   Set and reset by software.
   0: Ethernet MAC bus interface clock disabled (default after reset)
   1: Ethernet MAC bus interface clock enabled

Bits 14:6 Reserved, must be kept at reset value.

Bit 5 **ADC12EN**: ADC1/2 Peripheral Clocks Enable
   Set and reset by software.
   0: ADC1 and 2 peripheral clocks disabled (default after reset)
   1: ADC1 and 2 peripheral clocks enabled
   The peripheral clocks of the ADC1 and 2 are: the kernel clock selected by ADCSEL and provided to adc_ker_ck_input, and the **rcc_hclk1** bus interface clock.

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **DMA2EN**: DMA2 Clock Enable
   Set and reset by software.
   0: DMA2 clock disabled (default after reset)
   1: DMA2 clock enabled

Bit 0 **DMA1EN**: DMA1 Clock Enable
   Set and reset by software.
   0: DMA1 clock disabled (default after reset)
   1: DMA1 clock enabled
7.7.42 RCC AHB2 Clock Register (RCC_AHB2ENR)

This register can be accessed via two different offset address.

Bit 31 **SRAM3EN**: SRAM3 block enable

Set and reset by software.

When set, this bit indicates that the SRAM3 is allocated by the CPU. It causes the D2 domain to take into account also the CPU operation modes, i.e. keeping D2 domain in DRun when the CPU is in CRun.

0: SRAM3 interface clock is disabled. (default after reset)
1: SRAM3 interface clock is enabled.

Bit 30 **SRAM2EN**: SRAM2 block enable

Set and reset by software.

When set, this bit indicates that the SRAM2 is allocated by the CPU. It causes the D2 domain to take into account also the CPU operation modes, i.e. keeping D2 domain in DRun when the CPU is in CRun.

0: SRAM2 interface clock is disabled. (default after reset)
1: SRAM2 interface clock is enabled.

Bit 29 **SRAM1EN**: SRAM1 block enable

Set and reset by software.

When set, this bit indicates that the SRAM1 is allocated by the CPU. It causes the D2 domain to take into account also the CPU operation modes, i.e. keeping D2 domain in DRun when the CPU is in CRun.

0: SRAM1 interface clock is disabled. (default after reset)
1: SRAM1 interface clock is enabled.

Bits 28:10 Reserved, must be kept at reset value.

Bit 9 **SDMMC2EN**: SDMMC2 and SDMMC2 delay clock enable

Set and reset by software.

0: SDMMC2 and SDMMC2 Delay clock disabled (default after reset)
1: SDMMC2 and SDMMC2 Delay clock enabled

Bits 8:7 Reserved, must be kept at reset value.
Bit 6  **RNGEN**: RNG peripheral clocks enable
Set and reset by software.
0: RNG peripheral clocks disabled (default after reset)
1: RNG peripheral clocks enabled:
The peripheral clocks of the RNG are: the kernel clock selected by RNGSEL and provided to *rng_ker_ck* input, and the *rcc_hclk2* bus interface clock.

Bit 5  **HASHEN**: HASH peripheral clock enable
Set and reset by software.
0: HASH peripheral clock disabled (default after reset)
1: HASH peripheral clock enabled

Bit 4  **CRYPTEN**: CRYPT peripheral clock enable
Set and reset by software.
0: CRYPT peripheral clock disabled (default after reset)
1: CRYPT peripheral clock enabled

Bits 3:1 Reserved, must be kept at reset value.

Bit 0  **DCMIEN**: DCMI peripheral clock enable
Set and reset by software.
0: DCMI peripheral clock disabled (default after reset)
1: DCMI peripheral clock enabled
7.7.43 RCC AHB4 Clock Register (RCC_AHB4ENR)

This register can be accessed via two different offset address.

Table 64. RCC_AHB4ENR address offset and reset value

<table>

</tbody>
</table>

| Bits 31:29    | Reserved, must be kept at reset value. |
| Bit 28       | **BKPRAMEN**: Backup RAM Clock Enable |
|              | Set and reset by software.             |
|              | 0: Backup RAM clock disabled (default after reset) |
|              | 1: Backup RAM clock enabled            |
| Bits 27:26   | Reserved, must be kept at reset value. |
| Bit 25       | **HSEmen**: HSEM peripheral clock enable |
|              | Set and reset by software.             |
|              | 0: HSEM peripheral clock disabled (default after reset) |
|              | 1: HSEM peripheral clock enabled       |
| Bit 24       | **ADC3EN**: ADC3 Peripheral Clocks Enable |
|              | Set and reset by software.             |
|              | 0: ADC3 peripheral clocks disabled (default after reset) |
|              | 1: ADC3 peripheral clocks enabled      |
|              | The peripheral clocks of the ADC3 are: the kernel clock selected by ADCSEL and provided to adc_ker_ck_input, and the rcc_hclk4 bus interface clock. |
| Bits 23:22   | Reserved, must be kept at reset value. |
| Bit 21       | **BDMAEN**: BDMA and DMAMUX2 Clock Enable |
|              | Set and reset by software.             |
|              | 0: BDMA and DMAMUX2 clock disabled (default after reset) |
|              | 1: BDMA and DMAMUX2 clock enabled      |
| Bit 20       | Reserved, must be kept at reset value. |

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **BKPRAMEN**: Backup RAM Clock Enable
Set and reset by software.
0: Backup RAM clock disabled (default after reset)
1: Backup RAM clock enabled

Bits 27:26 Reserved, must be kept at reset value.

Bit 25 **HSEmen**: HSEM peripheral clock enable
Set and reset by software.
0: HSEM peripheral clock disabled (default after reset)
1: HSEM peripheral clock enabled

Bit 24 **ADC3EN**: ADC3 Peripheral Clocks Enable
Set and reset by software.
0: ADC3 peripheral clocks disabled (default after reset)
1: ADC3 peripheral clocks enabled
The peripheral clocks of the ADC3 are: the kernel clock selected by ADCSEL and provided to adc_ker_ck_input, and the rcc_hclk4 bus interface clock.

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **BDMAEN**: BDMA and DMAMUX2 Clock Enable
Set and reset by software.
0: BDMA and DMAMUX2 clock disabled (default after reset)
1: BDMA and DMAMUX2 clock enabled

Bit 20 Reserved, must be kept at reset value.
Bit 19 **CRCEN**: CRC peripheral clock enable
Set and reset by software.
0: CRC peripheral clock disabled (default after reset)
1: CRC peripheral clock enabled

Bits 18:11 Reserved, must be kept at reset value.

Bit 10 **GPIOKEN**: GPIOK peripheral clock enable
Set and reset by software.
0: GPIOK peripheral clock disabled (default after reset)
1: GPIOK peripheral clock enabled

Bit 9 **GPIOJEN**: GPIOJ peripheral clock enable
Set and reset by software.
0: GPIOJ peripheral clock disabled (default after reset)
1: GPIOJ peripheral clock enabled

Bit 8 **GPIOIEN**: GPIOI peripheral clock enable
Set and reset by software.
0: GPIOI peripheral clock disabled (default after reset)
1: GPIOI peripheral clock enabled

Bit 7 **GPIOHEN**: GPIOH peripheral clock enable
Set and reset by software.
0: GPIOH peripheral clock disabled (default after reset)
1: GPIOH peripheral clock enabled

Bit 6 **GPIOGEN**: GPIOG peripheral clock enable
Set and reset by software.
0: GPIOG peripheral clock disabled (default after reset)
1: GPIOG peripheral clock enabled

Bit 5 **GPIOFEN**: GPIOF peripheral clock enable
Set and reset by software.
0: GPIOF peripheral clock disabled (default after reset)
1: GPIOF peripheral clock enabled

Bit 4 **GPIOEEN**: GPIOE peripheral clock enable
Set and reset by software.
0: GPIOE peripheral clock disabled (default after reset)
1: GPIOE peripheral clock enabled

Bit 3 **GPIODEN**: GPIOD peripheral clock enable
Set and reset by software.
0: GPIOD peripheral clock disabled (default after reset)
1: GPIOD peripheral clock enabled
Bit 2  **GPIOCEN**: GPIOC peripheral clock enable
   Set and reset by software.
   0: GPIOC peripheral clock disabled (default after reset)
   1: GPIOC peripheral clock enabled

Bit 1  **GPIOBEN**: GPIOB peripheral clock enable
   Set and reset by software.
   0: GPIOB peripheral clock disabled (default after reset)
   1: GPIOB peripheral clock enabled

Bit 0  **GPIOAEN**: GPIOA peripheral clock enable
   Set and reset by software.
   0: GPIOA peripheral clock disabled (default after reset)
   1: GPIOA peripheral clock enabled
### 7.7.44 RCC APB3 Clock Register (RCC_APB3ENR)

This register can be accessed via two different offset address.

<table>
<thead>
<tr>
<th>Register Name</th>
<th>Address Offset</th>
<th>Reset Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>RCC_APB3ENR</td>
<td>0x0E4</td>
<td>0x0000 0000</td>
</tr>
<tr>

<td></td>
</tr>
</tbody>
</table>

Table 65. RCC_APB3ENR address offset and reset value

<table>
<thead>
<tr>
<th>Address Offset</th>
<th>Reset Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x0E4</td>
<td>0x0000 0000</td>
</tr>
<tr>
<td>0x144</td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:7 Reserved, must be kept at reset value.

**Bit 6 WWGD1EN: WWGD1 Clock Enable**
- Set by software, and reset by hardware when a system reset occurs.
- Note that in order to work properly, before enabling the WWGD1, the bit WW1RSC must be set to ‘1’.
  - 0: WWGD1 peripheral clock disable (default after reset)
  - 1: WWGD1 peripheral clock enabled

**Bits 5:4 Reserved, must be kept at reset value.**

**Bit 3 LTDCEN: LTDC peripheral clock enable**
- Provides the pixel clock (`ltdc_ker_ck`) to the LTDC block.
- Set and reset by software.
  - 0: LTDC peripheral clock disabled (default after reset)
  - 1: LTDC peripheral clock provided to the LTDC block

**Bits 2:0 Reserved, must be kept at reset value.**
7.7.45 RCC APB1 Clock Register (RCC_APB1LENR)

This register can be accessed via two different offset address.

Table 66. RCC_APB1ENR address offset and reset value

<table>
<thead>
<tr>
<th>Register Name</th>
<th>Address Offset</th>
<th>Reset Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>RCC_APB1LENR</td>
<td>0x0E8</td>
<td>0x0000 0000</td>

<tr>
<td>RCC_C1_APB1LENR</td>
<td>0x148</td>
<td></td>
</tr>
</tbody>
</table>

Bit 31 **UART8EN**: UART8 Peripheral Clocks Enable
Set and reset by software.
0: UART8 peripheral clocks disable (default after reset)
1: UART8 peripheral clocks enabled
The peripheral clocks of the UART8 are: the kernel clock selected by USART234578SEL and provided to usart_ker_ck input, and the rcc_pclk1 bus interface clock.

Bit 30 **UART7EN**: UART7 Peripheral Clocks Enable
Set and reset by software.
0: UART7 peripheral clocks disable (default after reset)
1: UART7 peripheral clocks enabled
The peripheral clocks of the UART7 are: the kernel clock selected by USART234578SEL and provided to usart_ker_ck input, and the rcc_pclk1 bus interface clock.

Bit 29 **DAC12EN**: DAC1 and 2 peripheral clock enable
Set and reset by software.
0: DAC1 and 2 peripheral clock disable (default after reset)
1: DAC1 and 2 peripheral clock enabled

Bit 28 **Reserved, must be kept at reset value.**

Bit 27 **CECEN**: HDMI-CEC peripheral clock enable
Set and reset by software.
0: HDMI-CEC peripheral clock disable (default after reset)
1: HDMI-CEC peripheral clock enabled
The peripheral clocks of the HDMI-CEC are: the kernel clock selected by CECSEL and provided to cec_ker_ck input, and the rcc_pclk1 bus interface clock.

Bits 26:24 **Reserved, must be kept at reset value.**
Bit 23  **I2C3EN**: I2C3 Peripheral Clocks Enable  
Set and reset by software.  
0: I2C3 peripheral clocks disable (default after reset)  
1: I2C3 peripheral clocks enabled  
The peripheral clocks of the I2C3 are: the kernel clock selected by I2C123SEL and provided to i2c_ker_ck input, and the rcc_pclk1 bus interface clock.

Bit 22  **I2C2EN**: I2C2 Peripheral Clocks Enable  
Set and reset by software.  
0: I2C2 peripheral clocks disable (default after reset)  
1: I2C2 peripheral clocks enabled  
The peripheral clocks of the I2C2 are: the kernel clock selected by I2C123SEL and provided to i2c_ker_ck input, and the rcc_pclk1 bus interface clock.

Bit 21  **I2C1EN**: I2C1 Peripheral Clocks Enable  
Set and reset by software.  
0: I2C1 peripheral clocks disable (default after reset)  
1: I2C1 peripheral clocks enabled  
The peripheral clocks of the I2C1 are: the kernel clock selected by I2C123SEL and provided to i2c_ker_ck input, and the rcc_pclk1 bus interface clock.

Bit 20  **UART5EN**: UART5 Peripheral Clocks Enable  
Set and reset by software.  
0: UART5 peripheral clocks disable (default after reset)  
1: UART5 peripheral clocks enabled  
The peripheral clocks of the UART5 are: the kernel clock selected by USART234578SEL and provided to uart_ker_ck input, and the rcc_pclk1 bus interface clock.

Bit 19  **UART4EN**: UART4 Peripheral Clocks Enable  
Set and reset by software.  
0: UART4 peripheral clocks disable (default after reset)  
1: UART4 peripheral clocks enabled  
The peripheral clocks of the UART4 are: the kernel clock selected by USART234578SEL and provided to uart_ker_ck input, and the rcc_pclk1 bus interface clock.

Bit 18  **USART3EN**: USART3 Peripheral Clocks Enable  
Set and reset by software.  
0: USART3 peripheral clocks disable (default after reset)  
1: USART3 peripheral clocks enabled  
The peripheral clocks of the USART3 are: the kernel clock selected by USART234578SEL and provided to usart_ker_ck input, and the rcc_pclk1 bus interface clock.

Bit 17  **USART2EN**: USART2 Peripheral Clocks Enable  
Set and reset by software.  
0: USART2 peripheral clocks disable (default after reset)  
1: USART2 peripheral clocks enabled  
The peripheral clocks of the USART2 are: the kernel clock selected by USART234578SEL and provided to usart_ker_ck input, and the rcc_pclk1 bus interface clock.

Bit 16  **SPDIFRXEN**: SPDIFRX Peripheral Clocks Enable  
Set and reset by software.  
0: SPDIFRX peripheral clocks disable (default after reset)  
1: SPDIFRX peripheral clocks enabled  
The peripheral clocks of the SPDIFRX are: the kernel clock selected by SPDIFSEL and provided to spdifrx_ker_ck input, and the rcc_pclk1 bus interface clock.
Bit 15  **SPI3EN**: SPI3 Peripheral Clocks Enable
Set and reset by software.
0: SPI3 peripheral clocks disable (default after reset)
1: SPI3 peripheral clocks enabled
The peripheral clocks of the SPI3 are: the kernel clock selected by I2S123SRC and provided to `spi_ker_ck` input, and the `rcc_pclk1` bus interface clock.

Bit 14  **SPI2EN**: SPI2 Peripheral Clocks Enable
Set and reset by software.
0: SPI2 peripheral clocks disable (default after reset)
1: SPI2 peripheral clocks enabled
The peripheral clocks of the SPI2 are: the kernel clock selected by I2S123SRC and provided to `spi_ker_ck` input, and the `rcc_pclk1` bus interface clock.

Bits 13:10  Reserved, must be kept at reset value.

Bit 9  **LPTIM1EN**: LPTIM1 Peripheral Clocks Enable
Set and reset by software.
0: LPTIM1 peripheral clocks disable (default after reset)
1: LPTIM1 peripheral clocks enabled
The peripheral clocks of the LPTIM1 are: the kernel clock selected by LPTIM1SEL and provided to `lptim_ker_ck` input, and the `rcc_pclk1` bus interface clock.

Bit 8  **TIM14EN**: TIM14 peripheral clock enable
Set and reset by software.
0: TIM14 peripheral clock disable (default after reset)
1: TIM14 peripheral clock enabled

Bit 7  **TIM13EN**: TIM13 peripheral clock enable
Set and reset by software.
0: TIM13 peripheral clock disable (default after reset)
1: TIM13 peripheral clock enabled

Bit 6  **TIM12EN**: TIM12 peripheral clock enable
Set and reset by software.
0: TIM12 peripheral clock disable (default after reset)
1: TIM12 peripheral clock enabled

Bit 5  **TIM7EN**: TIM7 peripheral clock enable
Set and reset by software.
0: TIM7 peripheral clock disable (default after reset)
1: TIM7 peripheral clock enabled

Bit 4  **TIM6EN**: TIM6 peripheral clock enable
Set and reset by software.
0: TIM6 peripheral clock disable (default after reset)
1: TIM6 peripheral clock enabled

Bit 3  **TIM5EN**: TIM5 peripheral clock enable
Set and reset by software.
0: TIM5 peripheral clock disable (default after reset)
1: TIM5 peripheral clock enabled
Bit 2  **TIM4EN**: TIM4 peripheral clock enable  
Set and reset by software.  
0: TIM4 peripheral clock disable (default after reset)  
1: TIM4 peripheral clock enabled  

Bit 1  **TIM3EN**: TIM3 peripheral clock enable  
Set and reset by software.  
0: TIM3 peripheral clock disable (default after reset)  
1: TIM3 peripheral clock enabled  

Bit 0  **TIM2EN**: TIM2 peripheral clock enable  
Set and reset by software.  
0: TIM2 peripheral clock disable (default after reset)  
1: TIM2 peripheral clock enabled
### 7.7.46 RCC APB1 Clock Register (RCC_APB1HENR)

This register can be accessed via two different offset address.

**Bits 31:9** Reserved, must be kept at reset value.

- **Bit 8** **FDCANEN**: FDCAN Peripheral Clocks Enable
  
  Set and reset by software.
  
  0: FDCAN peripheral clocks disable (default after reset)
  
  1: FDCAN peripheral clocks enabled:
  
  The peripheral clocks of the FDCAN are: the kernel clock selected by FDCANSEL and provided to `fdcan_ker_ck` input, and the `rcc_pclk1` bus interface clock.

- **Bits 7:6** Reserved, must be kept at reset value.

- **Bit 5** **MDIOSEN**: MDIOS peripheral clock enable
  
  Set and reset by software.
  
  0: MDIOS peripheral clock disable (default after reset)
  
  1: MDIOS peripheral clock enabled

- **Bit 4** **OPAMPEN**: OPAMP peripheral clock enable
  
  Set and reset by software.
  
  0: OPAMP peripheral clock disable (default after reset)
  
  1: OPAMP peripheral clock enabled

- **Bit 3** Reserved, must be kept at reset value.
Bit 2  **SWPEN**: SWPMI Peripheral Clocks Enable
   Set and reset by software.
   0: SWPMI peripheral clocks disable (default after reset)
   1: SWPMI peripheral clocks enabled:
      The peripheral clocks of the SWPMI are: the kernel clock selected by SWPSEL and provided to
      `swpmi_ker_ck` input, and the `rcc_pclk1` bus interface clock.

Bit 1  **CRSEN**: Clock Recovery System peripheral clock enable
   Set and reset by software.
   0: CRS peripheral clock disable (default after reset)
   1: CRS peripheral clock enabled

Bit 0  Reserved, must be kept at reset value.
7.7.47 **RCC APB2 Clock Register (RCC_APB2ENR)**

This register can be accessed via two different offset address.

Table 68. RCC_APB2ENR address offset and reset value

<table>
<thead>
<tr>
<th>Register Name</th>
<th>Address Offset</th>
<th>Reset Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>RCC_APB2ENR</td>

</tbody>
</table>

| Bits 31:30 Reserved, must be kept at reset value. |
| Bit 29 **HRTIMEN**: HRTIM peripheral clock enable  |
| Set and reset by software.                        |
| 0: HRTIM peripheral clock disabled (default after reset) |
| 1: HRTIM peripheral clock enabled                 |

| Bit 28 **DFSDM1EN**: DFSDM1 Peripheral Clocks Enable |
| Set and reset by software.                           |
| 0: DFSDM1 peripheral clocks disabled (default after reset) |
| 1: DFSDM1 peripheral clocks enabled                  |

DFSDM1 peripheral clocks are: the kernel clocks selected by SAI1SEL and DFSDM1SEL and provided to \( A_{ck} \) and \( cl_{k} \) inputs respectively, and the \( rcc_{pclk2} \) bus interface clock.

| Bits 27:25 Reserved, must be kept at reset value. |
| Bit 24 **SAI3EN**: SAI3 Peripheral Clocks Enable |
| Set and reset by software.                        |
| 0: SAI3 peripheral clocks disabled (default after reset) |
| 1: SAI3 peripheral clocks enabled                 |

The peripheral clocks of the SAI3 are: the kernel clock selected by SAI23SEL and provided to \( sai_{a}_{ker}_{ck} \) and \( sai_{b}_{ker}_{ck} \) inputs, and the \( rcc_{pclk2} \) bus interface clock.

| Bit 23 **SAI2EN**: SAI2 Peripheral Clocks Enable |
| Set and reset by software.                        |
| 0: SAI2 peripheral clocks disabled (default after reset) |
| 1: SAI2 peripheral clocks enabled                 |

The peripheral clocks of the SAI2 are: the kernel clock selected by SAI23SEL and provided to \( sai_{a}_{ker}_{ck} \) and \( sai_{b}_{ker}_{ck} \) inputs, and the \( rcc_{pclk2} \) bus interface clock.
Bit 22 **SAI1EN**: SAI1 Peripheral Clocks Enable
Set and reset by software.
0: SAI1 peripheral clocks disabled (default after reset)
1: SAI1 peripheral clocks enabled:
The peripheral clocks of the SAI1 are: the kernel clock selected by SAI1SEL and provided to
\texttt{sai\_a\_ker\_ck} and \texttt{sai\_b\_ker\_ck} inputs, and the \texttt{rcc\_pclk2} bus interface clock.

Bit 21 Reserved, must be kept at reset value.

Bit 20 **SPI5EN**: SPI5 Peripheral Clocks Enable
Set and reset by software.
0: SPI5 peripheral clocks disabled (default after reset)
1: SPI5 peripheral clocks enabled:
The peripheral clocks of the SPI5 are: the kernel clock selected by SPI45SEL and provided to
\texttt{spi\_ker\_ck} input, and the \texttt{rcc\_pclk2} bus interface clock.

Bit 19 Reserved, must be kept at reset value.

Bit 18 **TIM17EN**: TIM17 peripheral clock enable
Set and reset by software.
0: TIM17 peripheral clock disabled (default after reset)
1: TIM17 peripheral clock enabled

Bit 17 **TIM16EN**: TIM16 peripheral clock enable
Set and reset by software.
0: TIM16 peripheral clock disabled (default after reset)
1: TIM16 peripheral clock enabled

Bit 16 **TIM15EN**: TIM15 peripheral clock enable
Set and reset by software.
0: TIM15 peripheral clock disabled (default after reset)
1: TIM15 peripheral clock enabled

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **SPI4EN**: SPI4 Peripheral Clocks Enable
Set and reset by software.
0: SPI4 peripheral clocks disabled (default after reset)
1: SPI4 peripheral clocks enabled:
The peripheral clocks of the SPI4 are: the kernel clock selected by SPI45SEL and provided to
\texttt{spi\_ker\_ck} input, and the \texttt{rcc\_pclk2} bus interface clock.

Bit 12 **SPI1EN**: SPI1 Peripheral Clocks Enable
Set and reset by software.
0: SPI1 peripheral clocks disabled (default after reset)
1: SPI1 peripheral clocks enabled:
The peripheral clocks of the SPI1 are: the kernel clock selected by I2S123SRC and provided to
\texttt{spi\_ker\_ck} input, and the \texttt{rcc\_pclk2} bus interface clock.

Bits 11:6 Reserved, must be kept at reset value.

Bit 5 **USART6EN**: USART6 Peripheral Clocks Enable
Set and reset by software.
0: USART6 peripheral clocks disabled (default after reset)
1: USART6 peripheral clocks enabled:
The peripheral clocks of the USART6 are: the kernel clock selected by USART16SEL and provided to
\texttt{usart\_ker\_ck} input, and the \texttt{rcc\_pclk2} bus interface clock.
Bit 4 **USART1EN**: USART1 Peripheral Clocks Enable
   Set and reset by software.
   0: USART1 peripheral clocks disabled (default after reset)
   1: USART1 peripheral clocks enabled:
   The peripheral clocks of the USART1 are: the kernel clock selected by USART16SEL and provided to `usart_ker_ck` input, and the `rcc_pclk2` bus interface clock.

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **TIM8EN**: TIM8 peripheral clock enable
   Set and reset by software.
   0: TIM8 peripheral clock disabled (default after reset)
   1: TIM8 peripheral clock enabled

Bit 0 **TIM1EN**: TIM1 peripheral clock enable
   Set and reset by software.
   0: TIM1 peripheral clock disabled (default after reset)
   1: TIM1 peripheral clock enabled
7.7.48 RCC APB4 Clock Register (RCC_APB4ENR)

This register can be accessed via two different offset address.

Table 69. RCC_APB4ENR address offset and reset value

<table>
<thead>
<tr>
<th>Register Name</th>
<th>Address Offset</th>
<th>Reset Value</th>

<td></td>
</tr>
</tbody>
</table>

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:22 Reserved, must be kept at reset value.

Bit 21 SAI4EN: SAI4 Peripheral Clocks Enable
Set and reset by software.
0: SAI4 peripheral clocks disabled (default after reset)
1: SAI4 peripheral clocks enabled
The peripheral clocks of the SAI4 are: the kernel clocks selected by SAI4ASEL and SAI4BSEL, and provided to sai_a_ker_ck and sai_b_ker_ck inputs respectively, and the rcc_pclk4 bus interface clock.

Bits 20:17 Reserved, must be kept at reset value.

Bit 16 RTCAPBEN: RTC APB Clock Enable
Set and reset by software.
0: The register clock interface of the RTC (APB) is disabled
1: The register clock interface of the RTC (APB) is enabled (default after reset)

Bit 15 VREFEN: VREF peripheral clock enable
Set and reset by software.
0: VREF peripheral clock disabled (default after reset)
1: VREF peripheral clock enabled

Bit 14 COMP12EN: COMP1/2 peripheral clock enable
Set and reset by software.
0: COMP1/2 peripheral clock disabled (default after reset)
1: COMP1/2 peripheral clock enabled

Bit 13 Reserved, must be kept at reset value.
Bit 12 **LPTIM5EN**: LPTIM5 Peripheral Clocks Enable  
Set and reset by software.  
0: LPTIM5 peripheral clocks disabled (default after reset)  
1: LPTIM5 peripheral clocks enabled  
The peripheral clocks of the LPTIM5 are: the kernel clock selected by LPTIM345SEL and provided to `lptim_ker_ck` input, and the `rcc_pclk4` bus interface clock.

Bit 11 **LPTIM4EN**: LPTIM4 Peripheral Clocks Enable  
Set and reset by software.  
0: LPTIM4 peripheral clocks disabled (default after reset)  
1: LPTIM4 peripheral clocks enabled  
The peripheral clocks of the LPTIM4 are: the kernel clock selected by LPTIM345SEL and provided to `lptim_ker_ck` input, and the `rcc_pclk4` bus interface clock.

Bit 10 **LPTIM3EN**: LPTIM3 Peripheral Clocks Enable  
Set and reset by software.  
0: LPTIM3 peripheral clocks disabled (default after reset)  
1: LPTIM3 peripheral clocks enabled  
The peripheral clocks of the LPTIM3 are: the kernel clock selected by LPTIM345SEL and provided to `lptim_ker_ck` input, and the `rcc_pclk4` bus interface clock.

Bit 9 **LPTIM2EN**: LPTIM2 Peripheral Clocks Enable  
Set and reset by software.  
0: LPTIM2 peripheral clocks disabled (default after reset)  
1: LPTIM2 peripheral clocks enabled  
The peripheral clocks of the LPTIM2 are: the kernel clock selected by LPTIM2SEL and provided to `lptim_ker_ck` input, and the `rcc_pclk4` bus interface clock.

Bit 8 Reserved, must be kept at reset value.

Bit 7 **I2C4EN**: I2C4 Peripheral Clocks Enable  
Set and reset by software.  
0: I2C4 peripheral clocks disabled (default after reset)  
1: I2C4 peripheral clocks enabled  
The peripheral clocks of the I2C4 are: the kernel clock selected by I2C4SEL and provided to `i2c_ker_ck` input, and the `rcc_pclk4` bus interface clock.

Bit 6 Reserved, must be kept at reset value.

Bit 5 **SPI6EN**: SPI6 Peripheral Clocks Enable  
Set and reset by software.  
0: SPI6 peripheral clocks disabled (default after reset)  
1: SPI6 peripheral clocks enabled  
The peripheral clocks of the SPI6 are: the kernel clock selected by SPI6SEL and provided to `spi_ker_ck` input, and the `rcc_pclk4` bus interface clock.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **LPUART1EN**: LPUART1 Peripheral Clocks Enable  
Set and reset by software.  
0: LPUART1 peripheral clocks disabled (default after reset)  
1: LPUART1 peripheral clocks enabled  
The peripheral clocks of the LPUART1 are: the kernel clock selected by LPUART1SEL and provided to `lpuart_ker_ck` input, and the `rcc_pclk4` bus interface clock.
Bit 2  Reserved, must be kept at reset value.

Bit 1  SYSCFGEN: SYSCFG peripheral clock enable
       Set and reset by software.
       0: SYSCFG peripheral clock disabled (default after reset)
       1: SYSCFG peripheral clock enabled

Bit 0  Reserved, must be kept at reset value.
7.7.49 RCC AHB3 Sleep Clock Register (RCC_AHB3LPENR)

This register can be accessed via two different offset address.

Bit 14 **QSPI\_LPEN**: QUADSPI and QUADSPI Delay Clock Enable During CSleep Mode
Set and reset by software.
0: QUADSPI and QUADSPI Delay clock disabled during CSleep mode
1: QUADSPI and QUADSPI Delay clock enabled during CSleep mode (default after reset)

Bit 13 Reserved, must be kept at reset value.

Bit 12 **FMCL\_LPEN**: FMC Peripheral Clocks Enable During CSleep Mode
Set and reset by software.
0: FMC peripheral clocks disabled during CSleep mode
1: FMC peripheral clocks enabled during CSleep mode (default after reset):
The peripheral clocks of the FMC are: the kernel clock selected by FMCSEL and provided to `fmc\_ker\_ck` input, and the `rcc\_hclk3` bus interface clock.

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **FLASH\_LPEN**: Flash interface Clock Enable During CSleep Mode
Set and reset by software.
0: Flash interface clock disabled during CSleep mode
1: Flash interface clock enabled during CSleep mode (default after reset)

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **JPG\_DECL\_LPEN**: JPGDEC Clock Enable During CSleep Mode
Set and reset by software.
0: JPGDEC peripheral clock disabled during CSleep mode
1: JPGDEC peripheral clock enabled during CSleep mode (default after reset)

Bit 4 **DMA2D\_LPEN**: DMA2D Clock Enable During CSleep Mode
Set and reset by software.
0: DMA2D peripheral clock disabled during CSleep mode
1: DMA2D peripheral clock enabled during CSleep mode (default after reset)

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **MDMA\_LPEN**: MDMA Clock Enable During CSleep Mode
Set and reset by software.
0: MDMA peripheral clock disabled during CSleep mode
1: MDMA peripheral clock enabled during CSleep mode (default after reset)
7.7.50 RCC AHB1 Sleep Clock Register (RCC_AHB1LPENR)

This register can be accessed via two different offset address.

Table 71. RCC_AHB1LPENR address offset and reset value

Bits 31:29 Reserved, must be kept at reset value.

- **Bit 28** USB2OTGHSULPEN: USB_PHY1 clock enable during CSleep mode
  - Set and reset by software.
  - 0: USB_PHY1 peripheral clock disabled during CSleep mode
  - 1: USB_PHY1 peripheral clock enabled during CSleep mode (default after reset)

- **Bit 27** USB2OTGHSLPEN: USB2OTG (OTG_US2) peripheral clock enable during CSleep mode
  - Set and reset by software.
  - 0: USB2OTG peripheral clocks disabled during CSleep mode
  - 1: USB2OTG peripheral clocks enabled during CSleep mode (default after reset)
  - The peripheral clocks of the USB2OTG are: the kernel clock selected by USBSEL and the rcc_hclk1 bus interface clock.

- **Bit 26** USB1OTGHSULPEN: USB_PHY1 clock enable during CSleep mode
  - Set and reset by software.
  - 0: USB_PHY1 peripheral clock disabled during CSleep mode
  - 1: USB_PHY1 peripheral clock enabled during CSleep mode (default after reset)

- **Bit 25** USB1OTGHSLPEN: USB1OTG (OTG_HS1) peripheral clock enable during CSleep mode
  - Set and reset by software.
  - 0: USB1OTG peripheral clock disabled during CSleep mode
  - 1: USB1OTG peripheral clock enabled during CSleep mode (default after reset)
  - The peripheral clocks of the USB1OTG are: the kernel clock selected by USBSEL and the rcc_hclk1 bus interface clock.

Bits 24:18 Reserved, must be kept at reset value.
Bit 17 **ETH1RXLPEN**: Ethernet Reception Clock Enable During CSleep Mode  
Set and reset by software.  
0: Ethernet Reception clock disabled during CSleep mode  
1: Ethernet Reception clock enabled during CSleep mode (default after reset)

Bit 16 **ETH1TXLPEN**: Ethernet Transmission Clock Enable During CSleep Mode  
Set and reset by software.  
0: Ethernet Transmission clock disabled during CSleep mode  
1: Ethernet Transmission clock enabled during CSleep mode (default after reset)

Bit 15 **ETH1MACLPEN**: Ethernet MAC bus interface Clock Enable During CSleep Mode  
Set and reset by software.  
0: Ethernet MAC bus interface clock disabled during CSleep mode  
1: Ethernet MAC bus interface clock enabled during CSleep mode (default after reset)

Bits 14:6 Reserved, must be kept at reset value.

Bit 5 **ADC12LPEN**: ADC1/2 Peripheral Clocks Enable During CSleep Mode  
Set and reset by software.  
0: ADC1/2 peripheral clocks disabled during CSleep mode  
1: ADC1/2 peripheral clocks enabled during CSleep mode (default after reset)  
The peripheral clocks of the ADC1 and 2 are: the kernel clock selected by ADCSEL and provided to adc_ker_ck_input, and the rcc_hclk1 bus interface clock.

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **DMA2LPEN**: DMA2 Clock Enable During CSleep Mode  
Set and reset by software.  
0: DMA2 clock disabled during CSleep mode  
1: DMA2 clock enabled during CSleep mode (default after reset)

Bit 0 **DMA1LPEN**: DMA1 Clock Enable During CSleep Mode  
Set and reset by software.  
0: DMA1 clock disabled during CSleep mode  
1: DMA1 clock enabled during CSleep mode (default after reset)
7.7.51  RCC AHB2 Sleep Clock Register (RCC_AHB2LPENR)

This register can be accessed via two different offset address.

#### Bit 31  SRAM3LPEN: SRAM3 Clock Enable During CSleep Mode
- Set and reset by software.
- 0: SRAM3 clock disabled during CSleep mode
- 1: SRAM3 clock enabled during CSleep mode (default after reset)

#### Bit 30  SRAM2LPEN: SRAM2 Clock Enable During CSleep Mode
- Set and reset by software.
- 0: SRAM2 clock disabled during CSleep mode
- 1: SRAM2 clock enabled during CSleep mode (default after reset)

#### Bit 29  SRAM1LPEN: SRAM1 Clock Enable During CSleep Mode
- Set and reset by software.
- 0: SRAM1 clock disabled during CSleep mode
- 1: SRAM1 clock enabled during CSleep mode (default after reset)

#### Bits 28:10  Reserved, must be kept at reset value.

#### Bit 9  SDMMC2LPEN: SDMMC2 and SDMMC2 Delay Clock Enable During CSleep Mode
- Set and reset by software.
- 0: SDMMC2 and SDMMC2 Delay clock disabled during CSleep mode
- 1: SDMMC2 and SDMMC2 Delay clock enabled during CSleep mode (default after reset)

#### Bits 8:7  Reserved, must be kept at reset value.

#### Bit 6  RNGLPEN: RNG peripheral clock enable during CSleep mode
- Set and reset by software.
- 0: RNG peripheral clocks disabled during CSleep mode
- 1: RNG peripheral clock enabled during CSleep mode (default after reset)

The peripheral clocks of the RNG are: the kernel clock selected by RNGSEL and provided to `rng_ker_ck` input, and the `rcc_hclk2` bus interface clock.
Bit 5 **HASHLPEN**: HASH peripheral clock enable during CSleep mode
   Set and reset by software.
   0: HASH peripheral clock disabled during CSleep mode
   1: HASH peripheral clock enabled during CSleep mode (default after reset)

Bit 4 **CRYPTLPEN**: CRYPT peripheral clock enable during CSleep mode
   Set and reset by software.
   0: CRYPT peripheral clock disabled during CSleep mode
   1: CRYPT peripheral clock enabled during CSleep mode (default after reset)

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **DCMILPEN**: DCMI peripheral clock enable during CSleep mode
   Set and reset by software.
   0: DCMI peripheral clock disabled during CSleep mode
   1: DCMI peripheral clock enabled during CSleep mode (default after reset)
7.7.52 RCC AHB4 Sleep Clock Register (RCC_AHB4LPENR)

This register can be accessed via two different offset address.

Bit 31 **UART8LPEN**: UART8 Peripheral Clocks Enable During CSleep Mode
- Set and reset by software.
- 0: UART8 peripheral clocks disabled during CSleep mode
- 1: UART8 peripheral clocks enabled during CSleep mode (default after reset):
  The peripheral clocks of the UART8 are: the kernel clock selected by USART234578SEL and provided to `usart_ker_ck` input, and the `rcc_pclk1` bus interface clock.

Bit 30 **UART7LPEN**: UART7 Peripheral Clocks Enable During CSleep Mode
- Set and reset by software.
- 0: UART7 peripheral clocks disabled during CSleep mode
- 1: UART7 peripheral clocks enabled during CSleep mode (default after reset):
  The peripheral clocks of the UART7 are: the kernel clock selected by USART234578SEL and provided to `usart_ker_ck` input, and the `rcc_pclk1` bus interface clock.

Bit 29 **DAC12LPEN**: DAC1/2 peripheral clock enable during CSleep mode
- Set and reset by software.
- 0: DAC1/2 peripheral clock disabled during CSleep mode
- 1: DAC1/2 peripheral clock enabled during CSleep mode (default after reset)

Bit 28 **Reserved, must be kept at reset value.**

Bit 27 **CECLPEN**: HDMI-CEC Peripheral Clocks Enable During CSleep Mode
- Set and reset by software.
- 0: HDMI-CEC peripheral clocks disabled during CSleep mode
- 1: HDMI-CEC peripheral clocks enabled during CSleep mode (default after reset)
  The peripheral clocks of the HDMI-CEC are: the kernel clock selected by CECSEL and provided to `cec_ker_ck` input, and the `rcc_pclk1` bus interface clock.

Bits 26:24 **Reserved, must be kept at reset value.**
Bit 23  **I2C3LPEN**: I2C3 Peripheral Clocks Enable During CSleep Mode  
Set and reset by software.  
0: I2C3 peripheral clocks disabled during CSleep mode  
1: I2C3 peripheral clocks enabled during CSleep mode (default after reset):  
The peripheral clocks of the I2C3 are: the kernel clock selected by I2C123SEL and provided to  
\textit{i2c\_ker\_ck} input, and the \textit{rcc\_pclk1} bus interface clock.  

Bit 22  **I2C2LPEN**: I2C2 Peripheral Clocks Enable During CSleep Mode  
Set and reset by software.  
0: I2C2 peripheral clocks disabled during CSleep mode  
1: I2C2 peripheral clocks enabled during CSleep mode (default after reset):  
The peripheral clocks of the I2C2 are: the kernel clock selected by I2C123SEL and provided to  
\textit{i2c\_ker\_ck} input, and the \textit{rcc\_pclk1} bus interface clock.  

Bit 21  **I2C1LPEN**: I2C1 Peripheral Clocks Enable During CSleep Mode  
Set and reset by software.  
0: I2C1 peripheral clocks disabled during CSleep mode  
1: I2C1 peripheral clocks enabled during CSleep mode (default after reset):  
The peripheral clocks of the I2C1 are: the kernel clock selected by I2C123SEL and provided to  
\textit{i2c\_ker\_ck} input, and the \textit{rcc\_pclk1} bus interface clock.  

Bit 20  **UART5LPEN**: UART5 Peripheral Clocks Enable During CSleep Mode  
Set and reset by software.  
0: UART5 peripheral clocks disabled during CSleep mode  
1: UART5 peripheral clocks enabled during CSleep mode (default after reset)  
The peripheral clocks of the UART5 are: the kernel clock selected by USART234578SEL and  
provided to \textit{uart\_ker\_ck} input, and the \textit{rcc\_pclk1} bus interface clock.  

Bit 19  **UART4LPEN**: UART4 Peripheral Clocks Enable During CSleep Mode  
Set and reset by software.  
0: UART4 peripheral clocks disabled during CSleep mode  
1: UART4 peripheral clocks enabled during CSleep mode (default after reset)  
The peripheral clocks of the UART4 are: the kernel clock selected by USART234578SEL and  
provided to \textit{uart\_ker\_ck} input, and the \textit{rcc\_pclk1} bus interface clock.  

Bit 18  **USART3LPEN**: USART3 Peripheral Clocks Enable During CSleep Mode  
Set and reset by software.  
0: USART3 peripheral clocks disabled during CSleep mode  
1: USART3 peripheral clocks enabled during CSleep mode (default after reset):  
The peripheral clocks of the USART3 are: the kernel clock selected by USART234578SEL and  
provided to \textit{usart\_ker\_ck} input, and the \textit{rcc\_pclk1} bus interface clock.  

Bit 17  **USART2LPEN**: USART2 Peripheral Clocks Enable During CSleep Mode  
Set and reset by software.  
0: USART2 peripheral clocks disabled during CSleep mode  
1: USART2 peripheral clocks enabled during CSleep mode (default after reset):  
The peripheral clocks of the USART2 are: the kernel clock selected by USART234578SEL and  
provided to \textit{usart\_ker\_ck} input, and the \textit{rcc\_pclk1} bus interface clock.  

Bit 16  **SPDIFRXLPEN**: SPDIFRX Peripheral Clocks Enable During CSleep Mode  
Set and reset by software.  
0: SPDIFRX peripheral clocks disabled during CSleep mode  
1: SPDIFRX peripheral clocks enabled during CSleep mode (default after reset)  
The peripheral clocks of the SPDIFRX are: the kernel clock selected by SPDIFSEL and provided to  
\textit{spdifrx\_ker\_ck} input, and the \textit{rcc\_pclk1} bus interface clock.
Bit 15  **SPI3LPEN**: SPI3 Peripheral Clocks Enable During CSleep Mode
       Set and reset by software.
       0: SPI3 peripheral clocks disabled during CSleep mode
       1: SPI3 peripheral clocks enabled during CSleep mode (default after reset)
       The peripheral clocks of the SPI3 are: the kernel clock selected by I2S123SRC and provided to
       `spi_ker_ck` input, and the `rcc_pclk1` bus interface clock.

Bit 14  **SPI2LPEN**: SPI2 Peripheral Clocks Enable During CSleep Mode
       Set and reset by software.
       0: SPI2 peripheral clocks disabled during CSleep mode
       1: SPI2 peripheral clocks enabled during CSleep mode (default after reset)
       The peripheral clocks of the SPI2 are: the kernel clock selected by I2S123SRC and provided to
       `spi_ker_ck` input, and the `rcc_pclk1` bus interface clock.

Bits 13:10  Reserved, must be kept at reset value.

Bit 9  **LPTIM1LPEN**: LPTIM1 Peripheral Clocks Enable During CSleep Mode
       Set and reset by software.
       0: LPTIM1 peripheral clocks disabled during CSleep mode
       1: LPTIM1 peripheral clocks enabled during CSleep mode (default after reset)
       The peripheral clocks of the LPTIM1 are: the kernel clock selected by LPTIM1SEL and provided to
       `lptim_ker_ck` input, and the `rcc_pclk1` bus interface clock.

Bit 8  **TIM14LPEN**: TIM14 peripheral clock enable during CSleep mode
       Set and reset by software.
       0: TIM14 peripheral clock disabled during CSleep mode
       1: TIM14 peripheral clock enabled during CSleep mode (default after reset)

Bit 7  **TIM13LPEN**: TIM13 peripheral clock enable during CSleep mode
       Set and reset by software.
       0: TIM13 peripheral clock disabled during CSleep mode
       1: TIM13 peripheral clock enabled during CSleep mode (default after reset)

Bit 6  **TIM12LPEN**: TIM12 peripheral clock enable during CSleep mode
       Set and reset by software.
       0: TIM12 peripheral clock disabled during CSleep mode
       1: TIM12 peripheral clock enabled during CSleep mode (default after reset)

Bit 5  **TIM7LPEN**: TIM7 peripheral clock enable during CSleep mode
       Set and reset by software.
       0: TIM7 peripheral clock disabled during CSleep mode
       1: TIM7 peripheral clock enabled during CSleep mode (default after reset)

Bit 4  **TIM6LPEN**: TIM6 peripheral clock enable during CSleep mode
       Set and reset by software.
       0: TIM6 peripheral clock disabled during CSleep mode
       1: TIM6 peripheral clock enabled during CSleep mode (default after reset)

Bit 3  **TIM5LPEN**: TIM5 peripheral clock enable during CSleep mode
       Set and reset by software.
       0: TIM5 peripheral clock disabled during CSleep mode
       1: TIM5 peripheral clock enabled during CSleep mode (default after reset)
Bit 2  **TIM4LPEN**: TIM4 peripheral clock enable during CSleep mode
   Set and reset by software.
   0: TIM4 peripheral clock disabled during CSleep mode
   1: TIM4 peripheral clock enabled during CSleep mode (default after reset)

Bit 1  **TIM3LPEN**: TIM3 peripheral clock enable during CSleep mode
   Set and reset by software.
   0: TIM3 peripheral clock disabled during CSleep mode
   1: TIM3 peripheral clock enabled during CSleep mode (default after reset)

Bit 0  **TIM2LPEN**: TIM2 peripheral clock enable during CSleep mode
   Set and reset by software.
   0: TIM2 peripheral clock disabled during CSleep mode
   1: TIM2 peripheral clock enabled during CSleep mode (default after reset)
### 7.7.55 RCC APB1 High Sleep Clock Register (RCC_APB1HLPENR)

This register can be accessed via two different offset address.

Bit 2 **SWPLPEN**: SWPMI Peripheral Clocks Enable During CSleep Mode
Set and reset by software.
0: SWPMI peripheral clocks disabled during CSleep mode
1: SWPMI peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the SWPMI are: the kernel clock selected by SWPSEL and provided to
swpmi_ker_ck input, and the rcc_pclk1 bus interface clock.

Bit 1 **CRSLPEN**: Clock Recovery System peripheral clock enable during CSleep mode
Set and reset by software.
0: CRS peripheral clock disabled during CSleep mode
1: CRS peripheral clock enabled during CSleep mode (default after reset)

Bit 0 Reserved, must be kept at reset value.
7.7.56 RCC APB2 Sleep Clock Register (RCC_APB2LPENR)

This register can be accessed via two different offset address.

Table 77. RCC_APB2LPENR address offset and reset value

</table>

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **HRTIMLPEN**: HRTIM peripheral clock enable during CSleep mode

Set and reset by software.

0: HRTIM peripheral clock disabled during CSleep mode
1: HRTIM peripheral clock enabled during CSleep mode (default after reset)

Bit 28 **DFSDM1LPEN**: DFSDM1 Peripheral Clocks Enable During CSleep Mode

Set and reset by software.

0: DFSDM1 peripheral clocks disabled during CSleep mode
1: DFSDM1 peripheral clocks enabled during CSleep mode (default after reset)

DFSDM1 peripheral clocks are: the kernel clocks selected by SAI1SEL and DFSDM1SEL and provided to Aclk and clk inputs respectively, and the rcc_pclk2 bus interface clock.

Bits 27:25 Reserved, must be kept at reset value.

Bit 24 **SAI3LPEN**: SAI3 Peripheral Clocks Enable During CSleep Mode

Set and reset by software.

0: SAI3 peripheral clocks disabled during CSleep mode
1: SAI3 peripheral clocks enabled during CSleep mode (default after reset)

The peripheral clocks of the SAI3 are: the kernel clock selected by SAI23SEL and provided to sai_a_ker_ck and sai_b_ker_ck inputs, and the rcc_pclk2 bus interface clock.

Bit 23 **SAI2LPEN**: SAI2 Peripheral Clocks Enable During CSleep Mode

Set and reset by software.

0: SAI2 peripheral clocks disabled during CSleep mode
1: SAI2 peripheral clocks enabled during CSleep mode (default after reset)

The peripheral clocks of the SAI2 are: the kernel clock selected by SAI23SEL and provided to sai_a_ker_ck and sai_b_ker_ck inputs, and the rcc_pclk2 bus interface clock.
Bit 22 **SAI1LPEN**: SAI1 Peripheral Clocks Enable During CSleep Mode
Set and reset by software.
0: SAI1 peripheral clocks disabled during CSleep mode
1: SAI1 peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the SAI1 are: the kernel clock selected by SAI1SEL and provided to sai_a_ker_ck and sai_b_ker_ck inputs, and the rcc_pclk2 bus interface clock.

Bit 21 Reserved, must be kept at reset value.

Bit 20 **SPI5LPEN**: SPI5 Peripheral Clocks Enable During CSleep Mode
Set and reset by software.
0: SPI5 peripheral clocks disabled during CSleep mode
1: SPI5 peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the SPI5 are: the kernel clock selected by SPI45SEL and provided to spi_ker_ck input, and the rcc_pclk2 bus interface clock.

Bit 19 Reserved, must be kept at reset value.

Bit 18 **TIM17LPEN**: TIM17 peripheral clock enable during CSleep mode
Set and reset by software.
0: TIM17 peripheral clock disabled during CSleep mode
1: TIM17 peripheral clock enabled during CSleep mode (default after reset)

Bit 17 **TIM16LPEN**: TIM16 peripheral clock enable during CSleep mode
Set and reset by software.
0: TIM16 peripheral clock disabled during CSleep mode
1: TIM16 peripheral clock enabled during CSleep mode (default after reset)

Bit 16 **TIM15LPEN**: TIM15 peripheral clock enable during CSleep mode
Set and reset by software.
0: TIM15 peripheral clock disabled during CSleep mode
1: TIM15 peripheral clock enabled during CSleep mode (default after reset)

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **SPI4LPEN**: SPI4 Peripheral Clocks Enable During CSleep Mode
Set and reset by software.
0: SPI4 peripheral clocks disabled during CSleep mode
1: SPI4 peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the SPI4 are: the kernel clock selected by SPI45SEL and provided to spi_ker_ck input, and the rcc_pclk2 bus interface clock.

Bit 12 **SPI1LPEN**: SPI1 Peripheral Clocks Enable During CSleep Mode
Set and reset by software.
0: SPI1 peripheral clocks disabled during CSleep mode
1: SPI1 peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the SPI1 are: the kernel clock selected by I2S123SRC and provided to spi_ker_ck input, and the rcc_pclk2 bus interface clock.

Bits 11:6 Reserved, must be kept at reset value.

Bit 5 **USART6LPEN**: USART6 Peripheral Clocks Enable During CSleep Mode
Set and reset by software.
0: USART6 peripheral clocks disabled during CSleep mode
1: USART6 peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the USART6 are: the kernel clock selected by USART16SEL and provided to usart_ker_ck input, and the rcc_pclk2 bus interface clock.
Bit 4 **USART1LPEN**: USART1 Peripheral Clocks Enable During CSleep Mode
- Set and reset by software.
- 0: USART1 peripheral clocks disabled during CSleep mode
- 1: USART1 peripheral clocks enabled during CSleep mode (default after reset)

The peripheral clocks of the USART1 are: the kernel clock selected by USART16SEL and provided to `usart_ker_ck` inputs, and the `rcc_pclk2` bus interface clock.

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **TIM8LPEN**: TIM8 peripheral clock enable during CSleep mode
- Set and reset by software.
- 0: TIM8 peripheral clock disabled during CSleep mode
- 1: TIM8 peripheral clock enabled during CSleep mode (default after reset)

Bit 0 **TIM1LPEN**: TIM1 peripheral clock enable during CSleep mode
- Set and reset by software.
- 0: TIM1 peripheral clock disabled during CSleep mode
- 1: TIM1 peripheral clock enabled during CSleep mode (default after reset)
7.7.57 RCC APB4 Sleep Clock Register (RCC_APB4LPENR)

This register can be accessed via two different offset address.

### Table 78. RCC_APB4LPENR address offset and reset value

<table>

| Bit 31:26 | Reserved, must be kept at reset value. |
| Bit 25:22 | Reserved, must be kept at reset value. |

**Bit 21** **SAI4LPEN**: SAI4 Peripheral Clocks Enable During CSleep Mode
- Set and reset by software.
- 0: SAI4 peripheral clocks disabled during CSleep mode
- 1: SAI4 peripheral clocks enabled during CSleep mode (default after reset)

The peripheral clocks of the SAI4 are: the kernel clocks selected by SAI4ASEL and SAI4BSEL, and provided to `sai_a_ker_ck` and `sai_b_ker_ck` inputs respectively, and the `rcc_pclk4` bus interface clock.

**Bit 20:17** Reserved, must be kept at reset value.

**Bit 16** **RTCAPBLPEN**: RTC APB Clock Enable During CSleep Mode
- Set and reset by software.
- 0: The register clock interface of the RTC (APB) is disabled during CSleep mode
- 1: The register clock interface of the RTC (APB) is enabled during CSleep mode (default after reset)

**Bit 15** **VREFLPEN**: VREF peripheral clock enable during CSleep mode
- Set and reset by software.
- 0: VREF peripheral clock disabled during CSleep mode
- 1: VREF peripheral clock enabled during CSleep mode (default after reset)

**Bit 14** **COMP12LPEN**: COMP1/2 peripheral clock enable during CSleep mode
- Set and reset by software.
- 0: COMP1/2 peripheral clock disabled during CSleep mode
- 1: COMP1/2 peripheral clock enabled during CSleep mode (default after reset)

**Bit 13** Reserved, must be kept at reset value.
Bit 12 **LPTIM5LPEN**: LPTIM5 Peripheral Clocks Enable During CSleep Mode
Set and reset by software.
0: LPTIM5 peripheral clocks disabled during CSleep mode
1: LPTIM5 peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the LPTIM5 are: the kernel clock selected by LPTIM345SEL and provided to
$lptim\_ker\_ck$ input, and the $rcc\_pclk4$ bus interface clock.

Bit 11 **LPTIM4LPEN**: LPTIM4 Peripheral Clocks Enable During CSleep Mode
Set and reset by software.
0: LPTIM4 peripheral clocks disabled during CSleep mode
1: LPTIM4 peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the LPTIM4 are: the kernel clock selected by LPTIM345SEL and provided to
$lptim\_ker\_ck$ input, and the $rcc\_pclk4$ bus interface clock.

Bit 10 **LPTIM3LPEN**: LPTIM3 Peripheral Clocks Enable During CSleep Mode
Set and reset by software.
0: LPTIM3 peripheral clocks disabled during CSleep mode
1: LPTIM3 peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the LPTIM3 are: the kernel clock selected by LPTIM345SEL and provided to
$lptim\_ker\_ck$ input, and the $rcc\_pclk4$ bus interface clock.

Bit 9 **LPTIM2LPEN**: LPTIM2 Peripheral Clocks Enable During CSleep Mode
Set and reset by software.
0: LPTIM2 peripheral clocks disabled during CSleep mode
1: LPTIM2 peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the LPTIM5 are: the kernel clock selected by LPTIM2SEL and provided to
$lptim\_ker\_ck$ input, and the $rcc\_pclk4$ bus interface clock.

Bit 8 Reserved, must be kept at reset value.

Bit 7 **I2C4LPEN**: I2C4 Peripheral Clocks Enable During CSleep Mode
Set and reset by software.
0: I2C4 peripheral clocks disabled during CSleep mode
1: I2C4 peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the I2C4 are: the kernel clock selected by I2C4SEL and provided to
$i2c\_ker\_ck$ input, and the $rcc\_pclk4$ bus interface clock.

Bit 6 Reserved, must be kept at reset value.

Bit 5 **SPI6LPEN**: SPI6 Peripheral Clocks Enable During CSleep Mode
Set and reset by software.
0: SPI6 peripheral clocks disabled during CSleep mode
1: SPI6 peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the SPI6 are: the kernel clock selected by SPI6SEL and provided to
$spi\_ker\_ck$ input, and the $rcc\_pclk4$ bus interface clock.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **LPUART1LPEN**: LPUART1 Peripheral Clocks Enable During CSleep Mode
Set and reset by software.
0: LPUART1 peripheral clocks disabled during CSleep mode
1: LPUART1 peripheral clocks enabled during CSleep mode (default after reset)
The peripheral clocks of the LPUART1 are: the kernel clock selected by LPUART1SEL and provided to
$luart\_ker\_ck$ input, and the $rcc\_pclk4$ bus interface clock.
Bit 2  Reserved, must be kept at reset value.

Bit 1  **SYSCFGLPEN**: SYSCFG peripheral clock enable during CSleep mode
    Set and reset by software.
    0: SYSCFG peripheral clock disabled during CSleep mode
    1: SYSCFG peripheral clock enabled during CSleep mode (default after reset)

Bit 0  Reserved, must be kept at reset value.
### 7.8 RCC register map

#### Table 79. RCC register map and reset values

| Offset | Register name | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

2. Available only on revision V devices.

Refer to Section 2.3 on page 126 for the register boundary addresses.
8 Clock recovery system (CRS)

8.1 Introduction

The clock recovery system (CRS) is an advanced digital controller acting on the internal fine-granularity trimmable RC oscillator HSI48. The CRS provides powerful means for oscillator output frequency evaluation, based on comparison with a selectable synchronization signal. It is capable of doing automatic adjustment of oscillator trimming based on the measured frequency error value, while keeping the possibility of a manual trimming.

The CRS is ideally suited to provide a precise clock to the USB peripheral. In such case, the synchronization signal can be derived from the start-of-frame (SOF) packet signalization on the USB bus, which is sent by a USB host at precise 1-ms intervals.

The synchronization signal can also be derived from the LSE oscillator output or it can be generated by user software.

8.2 CRS main features

- Selectable synchronization source with programmable prescaler and polarity:
  - USB2 SOF packet reception
  - LSE oscillator output
  - USB1 SOF packet reception
- Possibility to generate synchronization pulses by software
- Automatic oscillator trimming capability with no need of CPU action
- Manual control option for faster start-up convergence
- 16-bit frequency error counter with automatic error value capture and reload
- Programmable limit for automatic frequency error value evaluation and status reporting
- Maskable interrupts/events:
  - Expected synchronization (ESYNC)
  - Synchronization OK (SYNCKOK)
  - Synchronization warning (SYNCPWARN)
  - Synchronization or trimming error (ERR)
8.3 CRS functional description

8.3.1 CRS block diagram

Figure 62. CRS block diagram

8.4 CRS internal signals

Table 80 gives the list of CRS internal signals.

8.4.1 Synchronization input

The CRS synchronization (SYNC) source, selectable through the CRS_CFGR register, can be the signal from an external signal (SYNC), the LSE clock, the OTG HS1 SOF signal, or the OTG HS2 SOF signal. This source signal also has a configurable polarity and can then be divided by a programmable binary prescaler to obtain a synchronization signal in a suitable frequency range (usually around 1 kHz).

For more information on the CRS synchronization source configuration, refer to Section 8.7.2: CRS configuration register (CRS_CFGR).

It is also possible to generate a synchronization event by software, by setting the SWSYNC bit in the CRS_CR register.

8.4.2 Frequency error measurement

The frequency error counter is a 16-bit down/up counter which is reloaded with the RELOAD value on each SYNC event. It starts counting down till it reaches the zero value, where the ESYNC (expected synchronization) event is generated. Then it starts counting up to the OUTRANGE limit where it eventually stops (if no SYNC event is received) and generates a SYNCMISS event. The OUTRANGE limit is defined as the frequency error limit (FELIM field of the CRS_CFGR register) multiplied by 128.

When the SYNC event is detected, the actual value of the frequency error counter and its counting direction are stored in the FECAP (frequency error capture) field and in the FEDIR (frequency error direction) bit of the CRS_ISR register. When the SYNC event is detected during the downcounting phase (before reaching the zero value), it means that the actual frequency is lower than the target (and so, that the TRIM value should be incremented), while when it is detected during the upcounting phase it means that the actual frequency is higher (and that the TRIM value should be decremented).

8.4.3 Frequency error evaluation and automatic trimming

The measured frequency error is evaluated by comparing its value with a set of limits:

- **TOLERANCE LIMIT**, given directly in the FELIM field of the CRS_CFRGR register
- **WARNING LIMIT**, defined as 3 * FELIM value
- **OUTRANGE (error limit)**, defined as 128 * FELIM value

The result of this comparison is used to generate the status indication and also to control the automatic trimming which is enabled by setting the AUTOTRIMEN bit in the CRS_CR register:

- **When the frequency error is below the tolerance limit**, it means that the actual trimming value in the TRIM field is the optimal one and that then, no trimming action is necessary.
  - SYNCOK status indicated
  - TRIM value not changed in AUTOTRIM mode

- **When the frequency error is below the warning limit but above or equal to the tolerance limit**, it means that some trimming action is necessary but that adjustment by one trimming step is enough to reach the optimal TRIM value.
  - SYNCOK status indicated
  - TRIM value adjusted by one trimming step in AUTOTRIM mode

- **When the frequency error is above or equal to the warning limit but below the error limit**, it means that a stronger trimming action is necessary, and there is a risk that the optimal TRIM value will not be reached for the next period.
  - SYNCWARN status indicated
  - TRIM value adjusted by two trimming steps in AUTOTRIM mode

- **When the frequency error is above or equal to the error limit**, it means that the frequency is out of the trimming range. This can also happen when the SYNC input is not clean or when some SYNC pulse is missing (for example when one USB SOF is corrupted).
  - SYNCERR or SYNCMISS status indicated
  - TRIM value not changed in AUTOTRIM mode

**Note:** If the actual value of the TRIM field is so close to its limits that the automatic trimming would force it to overflow or underflow, then the TRIM value is set just to the limit and the TRIMOVF status is indicated.

In AUTOTRIM mode (AUTOTRIMEN bit set in the CRS_CR register), the TRIM field of CRS_CR is adjusted by hardware and is read-only.

8.4.4 CRS initialization and configuration

**RELOAD value**

The RELOAD value should be selected according to the ratio between the target frequency and the frequency of the synchronization source after prescaling. It is then decreased by one in order to reach the expected synchronization on the zero value. The formula is the following:

\[
\text{RELOAD} = \left(\frac{f_{\text{TARGET}}}{f_{\text{SYNC}}} \right) - 1
\]

The reset value of the RELOAD field corresponds to a target frequency of 48 MHz and a synchronization signal frequency of 1 kHz (SOF signal from USB).
FELIM value

The selection of the FELIM value is closely coupled with the HSI48 oscillator characteristics and its typical trimming step size. The optimal value corresponds to half of the trimming step size, expressed as a number of HSI48 oscillator clock ticks. The following formula can be used:

\[
FELIM = \frac{f_{TARGET}}{f_{SYNC}} \times \frac{\text{STEP}\%}{100\%} \times 2
\]

The result should be always rounded up to the nearest integer value in order to obtain the best trimming response. If frequent trimming actions are not wanted in the application, the trimming hysteresis can be increased by increasing slightly the FELIM value.

The reset value of the FELIM field corresponds to \( \frac{f_{TARGET}}{f_{SYNC}} = 48000 \) and to a typical trimming step size of 0.14%.

Caution: There is no hardware protection from a wrong configuration of the RELOAD and FELIM fields which can lead to an erratic trimming response. The expected operational mode requires proper setup of the RELOAD value (according to the synchronization source frequency), which is also greater than 128 * FELIM value (OUTRANGE limit).

8.5 CRS low-power modes

(TrimOVF, SYMMISS, SYMCERR)
8.7 **CRS registers**

Refer to *Section 1.2 on page 98* of the reference manual for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by words (32-bit).

8.7.1 **CRS control register (CRS_CR)**

Address offset: 0x00  
Reset value: 0x0000 2000

| Bit 31:14 | Reserved, must be kept at reset value. |
| Bit 13:8 | TRIM[5:0]: HSI48 oscillator smooth trimming  
These bits provide a user-programmable trimming value to the HSI48 oscillator. They can be programmed to adjust to variations in voltage and temperature that influence the frequency of the HSI48 oscillator.  
The default value is 32, which corresponds to the middle of the trimming interval. The trimming step is specified in the product datasheet. A higher TRIM value corresponds to a higher output frequency.  
When the AUTOTRIMEN bit is set, this field is controlled by hardware and is read-only. |
| Bit 7 | SWSYNC: Generate software SYNC event  
This bit is set by software in order to generate a software SYNC event. It is automatically cleared by hardware.  
0: No action  
1: A software SYNC event is generated. |
| Bit 6 | AUTOTRIMEN: Automatic trimming enable  
This bit enables the automatic hardware adjustment of TRIM bits according to the measured frequency error between two SYNC events. If this bit is set, the TRIM bits are read-only. The TRIM value can be adjusted by hardware by one or two steps at a time, depending on the measured frequency error value. Refer to *Section 8.4.3: Frequency error evaluation and automatic trimming* for more details.  
0: Automatic trimming disabled, TRIM bits can be adjusted by the user.  
1: Automatic trimming enabled, TRIM bits are read-only and under hardware control. |
| Bit 5 | CEN: Frequency error counter enable  
This bit enables the oscillator clock for the frequency error counter.  
0: Frequency error counter disabled  
1: Frequency error counter enabled  
When this bit is set, the CRS_CFGR register is write-protected and cannot be modified. |
| Bit 4 | Reserved, must be kept at reset value. |
8.7.2  **CRS configuration register (CRS_CFGR)**

This register can be written only when the frequency error counter is disabled (CEN bit is cleared in CRS_CR). When the counter is enabled, this register is write-protected.

**Address offset:** 0x04

**Reset value:** 0x2022 BB7F

- **SYNCPOL** *(rw)*: SYNC polarity selection
  This bit is set and cleared by software to select the input polarity for the SYNC signal source.
  0: SYNC active on rising edge (default)
  1: SYNC active on falling edge

- **SYNCSRC[1:0]** *(rw)*: SYNC signal source selection
  These bits are set and cleared by software to select the SYNC signal source.
  00: USB2 SOF selected as SYNC signal source
  01: LSE selected as SYNC signal source
  10: OTG HS1 SOF selected as SYNC signal source (default)
  11: Reserved
  
  *When using USB LPM (Link Power Management) and the device is in Sleep mode, the periodic USB SOF will not be generated by the host. No SYNC signal will therefore be provided to the CRS to calibrate the HSI48 oscillator on the run. To guarantee the required clock precision after waking up from Sleep mode, the LSE clock or the SYNC pin should be used as SYNC signal.*

**FECAP[15:0]**

FECAP is the frequency error counter value latched in the time of the last SYNC event. Refer to Section 8.4.3: Frequency error evaluation and automatic trimming for more details about FECAP usage.

**Bit 15 FEDIR:** Frequency error direction

FEDIR is the counting direction of the frequency error counter latched in the time of the last SYNC event. It shows whether the actual frequency is below or above the target.

0: Upcounting direction, the actual frequency is above the target.
1: Downcounting direction, the actual frequency is below the target.

**Bits 14:11 Reserved, must be kept at reset value.**

**Bit 10 TRIMOVF:** Trimming overflow or underflow

This flag is set by hardware when the automatic trimming tries to over- or under-flow the TRIM value. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.

0: No trimming error signaled
1: Trimming error signaled
Bit 9  **SYNCMISS**: SYNC missed  
This flag is set by hardware when the frequency error counter reached value $FELIM \times 128$ and no SYNC was detected, meaning either that a SYNC pulse was missed or that the frequency error is too big (internal frequency too high) to be compensated by adjusting the TRIM value, and that some other action should be taken. At this point, the frequency error counter is stopped (waiting for a next SYNC) and an interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.

0: No SYNC missed error signalized  
1: SYNC missed error signalized  

Bit 8 **SYNCERR**: SYNC error  
This flag is set by hardware when the SYNC pulse arrives before the ESYNC event and the measured frequency error is greater than or equal to $FELIM \times 128$. This means that the frequency error is too big (internal frequency too low) to be compensated by adjusting the TRIM value, and that some other action should be taken. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.

0: No SYNC error signalized  
1: SYNC error signalized  

Bits 7:4 Reserved, must be kept at reset value.  

Bit 3 **ESYNC**: Expected SYNC flag  
This flag is set by hardware when the frequency error counter reached a zero value. An interrupt is generated if the ESYNCIE bit is set in the CRS_CR register. It is cleared by software by setting the ESYNCC bit in the CRS_ICR register.

0: No expected SYNC signalized  
1: Expected SYNC signalized  

Bit 2 **ERRF**: Error flag  
This flag is set by hardware in case of any synchronization or trimming error. It is the logical OR of the TRIMOVF, SYNCMISS and SYNCERR bits. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software in reaction to setting the ERRC bit in the CRS_ICR register.

0: No synchronization or trimming error signalized  
1: Synchronization or trimming error signalized  

Bit 1 **SYNCWARNF**: SYNC warning flag  
This flag is set by hardware when the measured frequency error is greater than or equal to $FELIM \times 3$, but smaller than $FELIM \times 128$. This means that to compensate the frequency error, the TRIM value must be adjusted by two steps or more. An interrupt is generated if the SYNCWARNIE bit is set in the CRS_CR register. It is cleared by software by setting the SYNCWARNC bit in the CRS_ICR register.

0: No SYNC warning signalized  
1: SYNC warning signalized  

Bit 0 **SYNCKOF**: SYNC event OK flag  
This flag is set by hardware when the measured frequency error is smaller than $FELIM \times 3$. This means that either no adjustment of the TRIM value is needed or that an adjustment by one trimming step is enough to compensate the frequency error. An interrupt is generated if the SYNCKIE bit is set in the CRS_CR register. It is cleared by software by setting the SYNCC bit in the CRS_ICR register.

0: No SYNC event OK signalized  
1: SYNC event OK signalized
### 8.7.4 CRS interrupt flag clear register (CRS_ICR)

Bits 31:4 Reserved, must be kept at reset value.

**Bit 3 ESYNCC:** Expected SYNC clear flag  
Writing 1 to this bit clears the ESYNCF flag in the CRS_ISR register.

**Bit 2 ERRC:** Error clear flag  
Writing 1 to this bit clears TRIMOVF, SYNCMISS and SYNCERR bits and consequently also the ERRF flag in the CRS_ISR register.

**Bit 1 SYNCWARNC:** SYNC warning clear flag  
Writing 1 to this bit clears the SYNCWARNF flag in the CRS_ISR register.

**Bit 0 SYNCOKC:** SYNC event OK clear flag  
Writing 1 to this bit clears the SYNCOKF flag in the CRS_ISR register.
## 8.7.5 CRS register map

Table 83. CRS register map and reset values

| Offset | Register  | 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |

| 0x0C   | CRS_ICR  |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        |          |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |

Refer to Section 2.3 on page 126 for the register boundary addresses.
9  Hardware semaphore (HSEM)

9.1  Hardware semaphore introduction

The hardware semaphore block provides 32 (32-bit) register based semaphores. The semaphores can be used to ensure synchronization between different processes running on the core. The HSEM provides a non blocking mechanism to lock semaphores in an atomic way. The following functions are provided:

- Locking a semaphore can be done in two ways:
  - 2-step lock: by writing MASTERID and PROCID to the semaphore, followed by a Read check
  - 1-step lock: by reading the MASTERID from the semaphore
- Interrupt generation when a semaphore is freed
  - Each semaphore may generate an interrupt
- Semaphore clear protection
  - A semaphore will only be cleared when MASTERID and PROCID match
- Global semaphore clear per MASTERID

9.2  Hardware semaphore main features

The HSEM includes the following features:

- 32 (32-bit) semaphores
- 8-bit PROCID
- 4-bit MASTERID
- 1 interrupt line
- Lock indication
9.3 HSEM functional description

9.3.1 HSEM block diagram

As shown in Figure 64, the HSEM is based on three sub-blocks:

- The Semaphore block containing the semaphore status and IDs
- The Semaphore Interface block providing AHB access to the Semaphore via the HSEM_Rx and HSEM_RLRx registers
- The Interrupt interface block providing control for the interrupts via the HSEM_ISR, HSEM_IER, HSEM_MISR, and HSEM_ICR registers

![Figure 64. HSEM block diagram]

9.3.2 HSEM internal signals

<table>

</tr>
</tbody>
</table>
9.3.3 HSEM lock procedures

There are two lock procedures:

- 2-step (Write) lock
- 1-step (Read) lock

The semaphore is free when its lock bit is ‘0’, in this case the MASTERID and PROCID are also ‘0’. When the lock bit is ‘1’ the semaphore is locked and the MASTERID indicates which AHB bus master has locked it. The PROCID indicates which process of that AHB bus master has locked the semaphore.

When Write locking a semaphore, the MASTERID is taken from the bus master ID and the PROCID is taken from the Write data. When Read locking the semaphore, the MASTERID is taken from the AHB bus master ID, and the PROCID will be zero. There is no PROCID available with the 1-step (Read) lock.

The MASTERID is taken from the AHB bus master ID. The PROCID is written by the firmware of that AHB bus master. Each AHB bus master process must have a unique PROCID. PROCID is only available in the 2-step lock procedure.

The two procedures (1-step and 2-step) can be used concurrently.

Figure 65. Procedure state diagram

2-step (Write) lock procedure

The 2-step lock procedure consists in a Write to lock the semaphore, followed by a Read to check if the lock has been successful, carried out from the HSEM_Rx register

- Write semaphore with PROCID and MASTERID, and LOCK bit = 1
  (Lock will be put in place when semaphore is free at Write time)
- Read-back the semaphore
  (FW checks lock status, if PROCID and MASTERID match, then lock is confirmed).
- Else retry (the semaphore has been locked by another AHB bus master or process)

A semaphore can only be locked when it is free.
A semaphore can be locked when the PROCID is ‘0’.
Consecutive write attempts with the lock bit = 1 to a locked semaphore are ignored.
1-step (Read) lock procedure

The 1-step procedure consists in a Read to lock and check the semaphore in a single step from the HSEM_RLRx register.

- Read Lock semaphore with MASTERID.
- If Read MASTERID matches and PROCID = 0, then lock is put in place (if MASTERID matches and PROCID is not '0', this means that another process from the same MASTERID has locked the semaphore with a 2-step (Write) procedure).
- Else retry (the semaphore has been locked by another AHB bus master or process)

A semaphore can only be locked when it is free. When Read locking a free semaphore the PROCID will be '0'. Read locking a locked semaphore will return the MASTERID and PROCID that locked it. All Read locks, including the first one which locks the semaphore, will return the MASTERID that locks or has locked the semaphore.

If multiple processes of the same AHB bus master use the 1-step procedure, all processes using the same semaphore will read the same status. When only one process locks the semaphore, each process of that AHB bus master will read the semaphore as locked by itself with the MASTERID.

9.3.4 HSEM Write/Read/ReadLock register address

For each semaphore, two AHB register addresses are provided, separated in two banks of 0x80.

In the first register address bank the semaphore can be written (locked/cleared) and read through the HSEM_Rx registers.

In the second register address bank the semaphore can be read (locked) through the HSEM_RLRx registers.

9.3.5 HSEM Clear procedures

Clearing a semaphore is a protected process, to prevent accidental clearing by a AHB bus master or by a process that does not have the semaphore lock right. The semaphore Clear procedure consists in writing to the semaphore with the corresponding MASTERID and PROCID and the lock bit = 0. When cleared, the semaphore lock bit, the MASTERID, and the PROCID are all '0'.

When cleared, an interrupt may be generated to signal the event. To this end, the semaphore interrupt shall be enabled.

The Clear procedure consists in a Write to the semaphore HSEM_Rx registers

- Write semaphore with PROCID and MASTERID, lock bit = 0
- If PROCID and MASTERID match, semaphore is freed, and an interrupt may be generated when enabled
- Else Write is ignored, semaphore remains locked and no interrupt is generated (the semaphore is locked by another AHB bus master or process)

If multiple processes of the same AHB bus master use the 1-step lock procedure (PROCID = 0), all processes using the same semaphore will clear the semaphore also for the other processes of that AHB bus master.
9.3.6 HSEM MASTERID semaphore clear

All semaphores locked by a AHB bus master can be cleared all at once by using the HSEM_CR register.

The procedure to clear all semaphores locked by a AHB bus master is the following:
- Write MASTERID and correct KEY value. All locked semaphore with a matching MASTERID are cleared (set to free), and may generate an interrupt when enabled.

This procedure may be used in case of an incorrect functioning AHB bus master, where the AHB bus master can free the locked semaphores by writing the MASTERID into the HSEM_CR register with the correct KEY value. This will clear all locked semaphores with a matching MASTERID.

An interrupt may be generated for the semaphore(s) that become free. To this end, the semaphore interrupt shall be enabled in the HSEM_IER registers.

9.3.7 HSEM interrupts

The hsem_int_it interrupt line allows each of the semaphores to generate an interrupt.

This interrupt line provides the following features:
- Interrupt enable per semaphore
- Interrupt clear per semaphore
- Interrupt status per semaphore
- Masked interrupt status per semaphore

With the Interrupt enable (HSEM_IER) the semaphores affecting the interrupt line can be enabled. Disabled (masked) semaphore interrupts will not set the masked interrupt status for that semaphore, and will not generate an interrupt on the interrupt line.

The Interrupt clear (HSEM_ICR) will clear the Interrupt status and Masked interrupt status of the associated semaphore for the interrupt line.

The Interrupt status (HSEM_ISR) mirrors the semaphore Interrupt status of the interrupt line before the Enable.

The Masked interrupt status (HSEM_MISR) only mirrors the semaphore Interrupt status of the enabled semaphore interrupts on the interrupt line. All Masked interrupt status of the enabled semaphore need to be cleared in order to clear the interrupt line.
Figure 66. Interrupt state diagram

Semaphore x locked

WRITE (MASTERID & PROCID & LOCK = 0)

Interrupt Semaphore x Status = 1

No

Yes

Interrupt Semaphore x Enabled

Interrupt Semaphore x MaskedStatus = 1 & Interrupt x generated

Semaphore x free
The procedure to get an interrupt when a semaphore becomes free is described hereafter.

**Try to lock the semaphore x**
- If the semaphore lock is obtained, no interrupt is needed.
- If the semaphore lock fails:
  Clear pending semaphore x interrupt status for the interrupt line hsem_int_it in HSEM_ICR.
  Re-try to lock the semaphore x again:
    - If the semaphore lock is obtained, no interrupt is needed (semaphore has been freed between first try to lock it and clear semaphore interrupt status).
    - If the semaphore lock fails, enable the semaphore x interrupt for the interrupt line hsem_int_it in HSEM_IER.

**On the semaphore x free interrupt, try to lock the semaphore x**
- If the semaphore lock is obtained:
  disable the semaphore x interrupt for the interrupt line hsem_int_it in HSEM_IER, and clear pending semaphore x interrupt status for the interrupt line hsem_int_it in HSEM_ICR.
- If the semaphore x lock fails:
  Clear pending semaphore x interrupt status for the interrupt line hsem_int_it in HSEM_ICR.
  Try again to lock the semaphore x:
    - If the semaphore lock is obtained (semaphore has been freed between first try to lock and semaphore interrupt status clear):
      Disable the semaphore interrupt for the interrupt line hsem_int_it in HSEM_IER.
    - If the semaphore lock failed, wait for semaphore free interrupt.

**Note:** *An interrupt will not lock the semaphore. After an interrupt either the AHB bus master or the process still have to perform the lock procedure to lock the semaphore.*

### 9.3.8 AHB bus master ID verification

The HSEM allows only authorized AHB bus master IDs to lock and unlock semaphores.

- The AHB bus master 2-step lock Write access to the semaphore HSEM_Rx register is checked against the valid bus master IDs.
  - Accesses from unauthorized AHB bus master IDs are discarded and will not lock the semaphore.
- The AHB bus master 1-step lock Read access from the semaphore HSEM_RLRx register is checked against the valid bus master IDs.
  - An unauthorized AHB bus master ID read from HSEM_RLRx will return the following Read data depending on the semaphore status:
    - when the semaphore is free it will return all `0`'s
    - when the semaphore has been locked before it will return the HSEM_RLRx data.
- The MASTERID semaphore clear Write access to the HSEM_CR register is checked against the valid bus master IDs.
  - Accesses from unauthorized AHB bus master IDs are discarded and will not clear the MASTERID semaphore.
Table 85 details the relation between bus master/CPU and MASTERID.

Table 85. Authorized AHB bus master ID

| Bus master 0 (CPU) | MASTERID = 3 |

Note: Accesses from unauthorized AHB bus master IDs to other registers are granted.
9.4 **HSEM registers**

Registers shall be accessed using Word format. Byte and Half Word access are ignored and will have no effect on the semaphores. Byte and Half Word Read accesses will always return 0. Byte and Half Word accesses will not generate a bus error.

9.4.1 **HSEM register semaphore x (HSEM_Rx)**

Address offset: 0x000 + 0x4 * x (x = 0 to 31)

Reset value: 0x0000 0000

The HSEM_Rx shall be used to perform a 2-step Write lock and Read back. Only Write accesses with authorized AHB bus master IDs are granted. Write accesses with unauthorized AHB bus master IDs are discarded.

Bit 31 **LOCK**: Lock indication.

This bit can be written and read by firmware.

- 0: On Write free semaphore (only when MASTERID and PROCID match), on Read semaphore is free.
- 1: On Write try to lock semaphore, on Read semaphore is locked.

Bits 30:12 **Reserved**, must be kept at reset value.

Bits 11:8 **MASTERID[3:0]**: Semaphore MASTERID.

Written by firmware, when the semaphore is free and the LOCK bit is at the same time written to 1, the MASTERID will be written only when the bus ID of the AHB bus master writing the semaphore matches.

When the semaphore is cleared (LOCK bit written to 0 and AHB bus master ID matched MASTERID), the MASTERID will be cleared to 0.

When the semaphore is cleared (LOCK bit written to 0 and AHB bus master ID does not match MASTERID), the MASTERID will not be affected.

Write when LOCK bit is already 1 (semaphore locked), the MASTERID will not be affected.

A Read will return the stored MASTERID value.

Bits 7:0 **PROCID[7:0]**: Semaphore PROCID.

Written by firmware, when the semaphore is free and the lock bit is written to 1, the PROCID will be set to the written data.

When the semaphore is cleared, (LOCK bit written to 0), the PROCID will be cleared to 0.

Write when LOCK bit is already 1 (semaphore locked), the PROCID will not be affected.

A Read will return the programmed PROCID value.
9.4.2 HSEM read lock register semaphore x (HSEM_RLRx)

Address offset: 0x080 + 0x004 * x (x = 0 to 31)
Reset value: 0x0000 0000

Accesses the same physical bits as HSEM_Rx. The HSEM_RLRx shall be used to perform a 1-step Read lock. Only Read accesses with authorized AHB bus master IDs are granted. Read accesses with unauthorized AHB bus master IDs are discarded.

Bit 31 LOCK: Lock indication.
This bit is read only by firmware at this address. A Read with a valid bus master ID will always return 1.
When the semaphore is free and the firmware performs a Read, hardware will set the semaphore to locked.
When the semaphore is locked and the firmware performs a Read the LOCK bit is not effected.
0: Semaphore is free.
1: Semaphore is locked.

Bits 30:12 Reserved, must be kept at reset value.

Bits 11:8 MASTERID[3:0]: Semaphore MASTERID.
This field is read only by firmware at this address.
On a Read, when the semaphore is free, hardware will set the MASTERID to the AHB bus master ID reading the semaphore. The MASTERID of the AHB bus master locking the semaphore will be read.
On a Read when the semaphore is locked, will return the MASTERID of the AHB bus master that has locked the semaphore.

Bits 7:0 PROCID[7:0]: Semaphore processor ID.
This field is read only by firmware at this address.
On a Read when the semaphore is free will return 0.
On a Read when the semaphore is locked will return the processor ID of the process that has locked the semaphore.

10 General-purpose I/Os (GPIO)

10.1 Introduction
Each general-purpose I/O port has four 32-bit configuration registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR and GPIOx_PUPDR), two 32-bit data registers (GPIOx_IDR and GPIOx_ODR) and a 32-bit set/reset register (GPIOx_BSRR). In addition all GPIOs have a 32-bit locking register (GPIOx_LCKR) and two 32-bit alternate function selection registers (GPIOx_AFRH and GPIOx_AFRL).

10.2 GPIO main features
- Output states: push-pull or open drain + pull-up/down
- Output data from output data register (GPIOx_ODR) or peripheral (alternate function output)
- Speed selection for each I/O
- Input states: floating, pull-up/down, analog
- Input data to input data register (GPIOx_IDR) or peripheral (alternate function input)
- Bit set and reset register (GPIOx_BSRR) for bitwise write access to GPIOx_ODR
- Locking mechanism (GPIOx_LCKR) provided to freeze the I/O port configurations
- Analog function
- Alternate function selection registers
- Fast toggle capable of changing every two clock cycles
- Highly flexible pin multiplexing allows the use of I/O pins as GPIOs or as one of several peripheral functions

10.3 GPIO functional description
Subject to the specific hardware characteristics of each I/O port listed in the datasheet, each port bit of the general-purpose I/O (GPIO) ports can be individually configured by software in several modes:
- Input floating
- Input pull-up
- Input-pull-down
- Analog
- Output open-drain with pull-up or pull-down capability
- Output push-pull with pull-up or pull-down capability
- Alternate function push-pull with pull-up or pull-down capability
- Alternate function open-drain with pull-up or pull-down capability

Each I/O port bit is freely programmable, however the I/O port registers have to be accessed as 32-bit words, half-words or bytes. The purpose of the GPIOx_BSRR and GPIOx_BRR registers is to allow atomic read/modify accesses to any of the GPIOx_ODR registers. In this way, there is no risk of an IRQ occurring between the read and the modify access.
Figure 67 and Figure 68 show the basic structures of a standard and a 5-Volt tolerant I/O port bit, respectively. Table 87 gives the possible port bit configurations.

Figure 67. Basic structure of an I/O port bit

Figure 68. Basic structure of a 5-Volt tolerant I/O port bit

1. \( V_{DD_{FT}} \) is a potential specific to five-volt tolerant I/Os and different from \( V_{DD} \).

1. GP = general-purpose, PP = push-pull, PU = pull-up, PD = pull-down, OD = open-drain, AF = alternate function.
10.3.1 General-purpose I/O (GPIO)

During and just after reset, the alternate functions are not active and most of the I/O ports are configured in input floating mode.

The debug pins are in AF pull-up/pull-down after reset:
- PA15: JTDI in pull-up
- PA14: JTCK/SWCLK in pull-down
- PA13: JTMS/SWDAT in pull-up
- PB4: NJTRST in pull-up
- PB3: JTD0 in floating state

When the pin is configured as output, the value written to the output data register (GPIOx_ODR) is output on the I/O pin. It is possible to use the output driver in push-pull mode or open-drain mode (only the low level is driven, high level is HI-Z).

The input data register (GPIOx_IDR) captures the data present on the I/O pin at every AHB clock cycle.

All GPIO pins have weak internal pull-up and pull-down resistors, which can be activated or not depending on the value in the GPIOx_PUPDR register.

10.3.2 I/O pin alternate function multiplexer and mapping

The device I/O pins are connected to on-board peripherals/modules through a multiplexer that allows only one peripheral alternate function (AF) connected to an I/O pin at a time. In this way, there can be no conflict between peripherals available on the same I/O pin.

Each I/O pin has a multiplexer with up to sixteen alternate function inputs (AF0 to AF15) that can be configured through the GPIOx_AFRL (for pin 0 to 7) and GPIOx_AFRH (for pin 8 to 15) registers:
- After reset the multiplexer selection is alternate function 0 (AF0). The I/Os are configured in alternate function mode through GPIOx_MODER register.
- The specific alternate function assignments for each pin are detailed in the device datasheet.
- Cortex-M7 with FPU EVENTOUT is mapped on AF15

In addition to this flexible I/O multiplexing architecture, each peripheral has alternate functions mapped onto different I/O pins to optimize the number of peripherals available in smaller packages.

To use an I/O in a given configuration, the user has to proceed as follows:
- **Debug function**: after each device reset these pins are assigned as alternate function pins immediately usable by the debugger host
- **System function**: MCOx pins have to be configured in alternate function mode.
- **GPIO**: configure the desired I/O as output, input or analog in the GPIOx_MODER register.
- **Peripheral alternate function**:
  - Connect the I/O to the desired AFx in one of the GPIOx_AFRL or GPIOx_AFRH register.
  - Select the type, pull-up/pull-down and output speed via the GPIOx_OTYPER, GPIOx_PUPDR and GPIOx_OSPEEDER registers, respectively.
– Configure the desired I/O as an alternate function in the GPIOx_MODER register.

• Additional functions:
  – For the ADC and DAC, configure the desired I/O in analog mode in the GPIOx_MODER register and configure the required function in the ADC and DAC registers.
  – For the additional functions like RTC_OUT, RTC_TS, RTC_TAMPx, WKUPx and oscillators, configure the required function in the related RTC, PWR and RCC registers. These functions have priority over the configuration in the standard GPIO registers. For details about I/O control by the RTC, refer to Section 45.3: RTC functional description on page 1907.

  • EVENTOUT
  – Configure the I/O pin used to output the core EVENTOUT signal by connecting it to AF15.

Refer to the “Alternate function mapping” table in the device datasheet for the detailed mapping of the alternate function I/O pins.

10.3.3 I/O port control registers

Each of the GPIO ports has four 32-bit memory-mapped control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR) to configure up to 16 I/Os. The GPIOx_MODER register is used to select the I/O mode (input, output, AF, analog). The GPIOx_OTYPER and GPIOx_OSPEEDR registers are used to select the output type (push-pull or open-drain) and speed. The GPIOx_PUPDR register is used to select the pull-up/pull-down whatever the I/O direction.

10.3.4 I/O port data registers

Each GPIO has two 16-bit memory-mapped data registers: input and output data registers (GPIOx_IDR and GPIOx_ODR). GPIOx_ODR stores the data to be output, it is read/write accessible. The data input through the I/O are stored into the input data register (GPIOx_IDR), a read-only register.

See Section 10.4.5: GPIO port input data register (GPIOx_IDR) (x = A to K) and Section 10.4.6: GPIO port output data register (GPIOx_ODR) (x = A to K) for the register descriptions.

10.3.5 I/O data bitwise handling

The bit set reset register (GPIOx_BSRR) is a 32-bit register which allows the application to set and reset each individual bit in the output data register (GPIOx_ODR). The bit set reset register has twice the size of GPIOx_ODR.

To each bit in GPIOx_ODR, correspond two control bits in GPIOx_BSRR: BS(i) and BR(i). When written to 1, bit BS(i) sets the corresponding ODR(i) bit. When written to 1, bit BR(i) resets the ODR(i) corresponding bit.

Writing any bit to 0 in GPIOx_BSRR does not have any effect on the corresponding bit in GPIOx_ODR. If there is an attempt to both set and reset a bit in GPIOx_BSRR, the set action takes priority.

Using the GPIOx_BSRR register to change the values of individual bits in GPIOx_ODR is a “one-shot” effect that does not lock the GPIOx_ODR bits. The GPIOx_ODR bits can always
be accessed directly. The GPIOx_BSRR register provides a way of performing atomic bitwise handling.

There is no need for the software to disable interrupts when programming the GPIOx_ODR at bit level: it is possible to modify one or more bits in a single atomic AHB write access.

10.3.6 GPIO locking mechanism

It is possible to freeze the GPIO control registers by applying a specific write sequence to the GPIOx_LCKR register. The frozen registers are GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL and GPIOx_AFRH.

To write the GPIOx_LCKR register, a specific write / read sequence has to be applied. When the right LOCK sequence is applied to bit 16 in this register, the value of LCKR[15:0] is used to lock the configuration of the I/Os (during the write sequence the LCKR[15:0] value must be the same). When the LOCK sequence has been applied to a port bit, the value of the port bit can no longer be modified until the next MCU reset or peripheral reset. Each GPIOx_LCKR bit freezes the corresponding bit in the control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL and GPIOx_AFRH.

The LOCK sequence (refer to Section 10.4.8: GPIO port configuration lock register (GPIOx_LCKR) (x = A to K)) can only be performed using a word (32-bit long) access to the GPIOx_LCKR register due to the fact that GPIOx_LCKR bit 16 has to be set at the same time as the [15:0] bits.

For more details refer to LCKR register description in Section 10.4.8: GPIO port configuration lock register (GPIOx_LCKR) (x = A to K).

10.3.7 I/O alternate function input/output

Two registers are provided to select one of the alternate function inputs/outputs available for each I/O. With these registers, the user can connect an alternate function to some other pin as required by the application.

This means that a number of possible peripheral functions are multiplexed on each GPIO using the GPIOx_AFRL and GPIOx_AFRH alternate function registers. The application can thus select any one of the possible functions for each I/O. The AF selection signal being common to the alternate function input and alternate function output, a single channel is selected for the alternate function input/output of a given I/O.

To know which functions are multiplexed on each GPIO pin, refer to the device datasheet.

10.3.8 External interrupt/wakeup lines

All ports have external interrupt capability. To use external interrupt lines, the port must be configured in input mode.

Refer to Section 19: Extended interrupt and event controller (EXTI) and to Section 19.3: EXTI functional description.
10.3.9 Input configuration

When the I/O port is programmed as input:

- The output buffer is disabled
- The Schmitt trigger input is activated
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle
- A read access to the input data register provides the I/O state

*Figure 69* shows the input configuration of the I/O port bit.

![Figure 69. Input floating/pull up/pull down configurations](image)

10.3.10 Output configuration

When the I/O port is programmed as output:

- The output buffer is enabled:
  - Open drain mode: A "0" in the Output register activates the N-MOS whereas a "1" in the Output register leaves the port in Hi-Z (the P-MOS is never activated)
  - Push-pull mode: A "0" in the Output register activates the N-MOS whereas a "1" in the Output register activates the P-MOS
- The Schmitt trigger input is activated
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle
- A read access to the input data register gets the I/O state
- A read access to the output data register gets the last written value

*Figure 70* shows the output configuration of the I/O port bit.
10.3.11 I/O compensation cell

This cell is used to control the I/O commutation slew rate \( \frac{t_{\text{fall}}}{t_{\text{rise}}} \) to reduce the I/O noise on power supply.

The cell is split into two blocks:

- The first block provides an optimal code for the current PVT. The code stored in this block can be read when the READY flag of the SYSCFG_CCSR is set.
- The second block controls the I/O slew rate. The user selects the code to be applied and programs it by software.

The I/O compensation cell features 2 voltage ranges: 1.62 to 2.0 V and 2.7 to 3.6 V.

10.3.12 Alternate function configuration

When the I/O port is programmed as alternate function:

- The output buffer can be configured in open-drain or push-pull mode
- The output buffer is driven by the signals coming from the peripheral (transmitter enable and data)
- The Schmitt trigger input is activated
- The weak pull-up and pull-down resistors are activated or not depending on the value in the GPIOx_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle
- A read access to the input data register gets the I/O state

*Figure 71* shows the Alternate function configuration of the I/O port bit.
10.3.13 Analog configuration

When the I/O port is programmed as analog configuration:

- The output buffer is disabled
- The Schmitt trigger input is deactivated, providing zero consumption for every analog value of the I/O pin. The output of the Schmitt trigger is forced to a constant value (0).
- The weak pull-up and pull-down resistors are disabled by hardware
- Read access to the input data register gets the value “0”

*Figure 72* shows the high-impedance, analog-input configuration of the I/O port bits.

Some pins/balls are directly connected to PA0_C, PA1_C, PC2_C and PC3_C ADC analog inputs (see *Figure 73*): there is a direct path between Pxy_C and Pxy pins/balls, through an
analog switch (refer to Section 11.3.1: SYSCFG peripheral mode configuration register (SYSCFG_PMCR) for details on how to configure analog switches).

Figure 73. Analog inputs connected to ADC inputs

1. VDD_FT is a potential specific to 5V tolerant I/Os. It is distinct from VDD.

10.3.14 Using the HSE or LSE oscillator pins as GPIOs

When the HSE or LSE oscillator is switched OFF (default state after reset), the related oscillator pins can be used as normal GPIOs.

When the HSE or LSE oscillator is switched ON (by setting the HSEON or LSEON bit in the RCC_CSR register) the oscillator takes control of its associated pins and the GPIO configuration of these pins has no effect.

When the oscillator is configured in a user external clock mode, only the OSC_IN or OSC32_IN pin is reserved for clock input and the OSC_OUT or OSC32_OUT pin can still be used as normal GPIO.

10.3.15 Using the GPIO pins in the backup supply domain

The PC13/PC14/PC15/Pi8 GPIO functionality is lost when the core supply domain is powered off (when the device enters Standby mode). In this case, if their GPIO configuration is not bypassed by the RTC configuration, these pins are set in an analog input mode.
10.4 GPIO registers

This section gives a detailed description of the GPIO registers.

For a summary of register bits, register address offsets and reset values, refer to Table 88.

The peripheral registers can be written in word, half word or byte mode.

10.4.1 GPIO port mode register (GPIOx_MODER) (x = A to K)

Address offset: 0x00

Reset value:
- 0xABFF FFFF for port A
- 0xFFFF FEBF for port B
- 0xFFFF FFFF for other ports

#### Bits 31:0 PUPDR[15:0][1:0]: Port x configuration I/O pin y (y = 15 to 0)

These bits are written by software to configure the I/O pull-up or pull-down

- 00: No pull-up, pull-down
- 01: Pull-up
- 10: Pull-down
- 11: Reserved
10.4.5  GPIO port input data register (GPIOx_IDR) (x = A to K)

Address offset: 0x10
Reset value: 0x0000 XXXX

Bits 31:16 Reserved, must be kept at reset value.
Bits 15:0  IDR[15:0]: Port x input data I/O pin y (y = 15 to 0)
These bits are read-only. They contain the input value of the corresponding I/O port.

10.4.6  GPIO port output data register (GPIOx_ODR) (x = A to K)

Address offset: 0x14
Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.
Bits 15:0  ODR[15:0]: Port output data I/O pin y (y = 15 to 0)
These bits can be read and written by software.
Note: For atomic bit set/reset, the ODR bits can be individually set and/or reset by writing to the GPIOx_BSRR or GPIOx_BRR registers (x = A..F).

10.4.7  GPIO port bit set/reset register (GPIOx_BSRR) (x = A to K)

Address offset: 0x18
Reset value: 0x0000 0000

528/3289   RM0433 Rev 6
10.4.8 GPIO port configuration lock register (GPIOx_LCKR)

This register is used to lock the configuration of the port bits when a correct write sequence is applied to bit 16 (LCKk). The value of bits [15:0] is used to lock the configuration of the GPIO. During the write sequence, the value of LCKR[15:0] must not change. When the LOCK sequence has been applied on a port bit, the value of this port bit can no longer be modified until the next MCU reset or peripheral reset.

Note: A specific write sequence is used to write to the GPIOx_LCKR register. Only word access (32-bit long) is allowed during this locking sequence.

Each lock bit freezes a specific configuration register (control and alternate function registers).

Address offset: 0x1C

Reset value: 0x0000 0000

Refer to Section 2.3 on page 126 for the register boundary addresses.
11 System configuration controller (SYSCFG)

11.1 Introduction

The devices feature a set of configuration registers. The objectives of this section is to describe in details the system configuration controller.

11.2 SYSCFG main features

The system configuration controller main functions are the following:
- Analog switch configuration management
- I2C Fm+ configuration
- Selection of the Ethernet PHY interface.
- Management of the external interrupt line connection to the GPIOs
- Management of the I/O compensation cell
- Getting readout protection and Flash memory bank swap informations
- Management of boot sequences and boot addresses
- Management BOR reset level
- Management of Flash memory secured and protected sector status
- Management Flash memory write protections status
- Management of DTCM secured section status
- Management of independent watchdog behavior (hardware or software / freeze)
- Reset generation in Stop and Standby mode
- Secure mode enabling/disabling status.

On STM32H750xB devices, only the statuses of Bank 1 option bytes are applicable.

11.3 SYSCFG registers

11.3.1 SYSCFG peripheral mode configuration register (SYSCFG_PMCR)

Address offset: 0x04
Reset value: 0x0000 0000

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **PC3SO**: PC3 Switch Open
This bit controls the analog switch between PC3 and PC3_C (dual pad)
0: Analog switch closed (pads are connected through the analog switch)
1: Analog switch open (2 separated pads)

Bit 26 **PC2SO**: PC2 Switch Open
This bit controls the analog switch between PC2 and PC2_C (dual pad)
0: Analog switch closed (pads are connected through the analog switch)
1: Analog switch open (2 separated pads)

Bit 25 **PA1SO**: PA1 Switch Open
This bit controls the analog switch between PA1 and PA1_C (dual pad)
0: Analog switch closed (pads are connected through the analog switch)
1: Analog switch open (2 separated pads)

Bit 24 **PA0SO**: PA0 Switch Open
This bit controls the analog switch between PA0 and PA0_C (dual pad)
0: Analog switch closed (pads are connected through the analog switch)
1: Analog switch open (2 separated pads)

Bits 23:21 **EPIS[2:0]**: Ethernet PHY Interface Selection
These bits select the Ethernet PHY interface.
000: MII 001: Reserved 010: Reserved 011: Reserved 100: RMII 101: Reserved 110: Reserved 111: Reserved

Bits 20:10 Reserved, must be kept at reset value.

Bit 9 **BOOSTVDSEL**: Analog switch supply voltage selection (V_DD/V_DDA/booster)
To avoid current consumption due to booster activation when V_DDA < 2.7 V and V_DD > 2.7 V, V_DD can be selected as supply voltage for analog switches. In this case, the BOOSTE bit should be cleared to avoid unwanted power consumption. When both V_DD < 2.7 V and V_DDA < 2.7 V, the booster is still needed to obtain full AC performances from I/O analog switches.
0: V_DD selected as analog switch supply voltage (when BOOSTE bit is cleared)
1: V_DD selected as analog switch supply voltage

*Note: This bit is available only on devices revision X and higher.*

Bit 8 **BOOSTE**: Booster Enable
This bit enables the booster to reduce the total harmonic distortion of the analog switch when the supply voltage is lower than 2.7 V.
Activating the booster allows to guaranty the analog switch AC performance when the supply voltage is below 2.7 V: in this case, the analog switch performance is the same on the full voltage range.
0: Booster disabled
1: Booster enabled

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **AXISRAM**: D1 AXI-SRAM double ECC error lock bit

This bit is set by software and cleared only by a system reset. It can be used to enable and lock the AXI-SRAM double ECC error flag connection to TIM1/8/15/16/17 and HRTIMER Break inputs.

0: AXI-SRAM double ECC error flag disconnected from TIM1/8/15/16/17/HRTIMER Break inputs
1: AXI-SRAM double ECC error flag connected to TIM1/8/15/16/17/HRTIMER Break inputs.

Bit 14 **ITCM**: D1 ITCM double ECC error lock bit

This bit is set by software and cleared only by a system reset. It can be used to enable and lock the ITCM double ECC error flag connection to TIM1/8/15/16/17 and HRTIMER Break inputs.

0: ITCM double ECC error flag disconnected from TIM1/8/15/16/17/HRTIMER Break inputs
1: ITCM double ECC error flag connected to TIM1/8/15/16/17/HRTIMER Break inputs.

Bit 13 **DTCM**: D1 DTCM double ECC error lock bit

This bit is set by software and cleared only by a system reset. It can be used to enable and lock the DTCM double ECC error flag connection to TIM1/8/15/16/17 and HRTIMER Break inputs.

0: DTCM double ECC error flag disconnected from TIM1/8/15/16/17/HRTIMER Break inputs
1: DTCM double ECC error flag connected to TIM1/8/15/16/17/HRTIMER Break inputs.

Bit 12 **SRAM1L**: D2 SRAM1 double ECC error lock bit

This bit is set by software and cleared only by a system reset. It can be used to enable and lock the D2 SRAM1 double ECC error flag connection to TIM1/8/15/16/17 and HRTIMER Break inputs.

0: D2 SRAM1 double ECC error flag disconnected from TIM1/8/15/16/17/HRTIMER Break inputs
1: D2 SRAM1 double ECC error flag connected to TIM1/8/15/16/17/HRTIMER Break inputs.
Bit 11 **SRAM2L**: D2 SRAM2 double ECC error lock bit
This bit is set by software and cleared only by a system reset. It can be used to enable and lock the D2 SRAM2 double ECC error flag connection to TIM1/8/15/16/17 and HRTIMER Break inputs.
0: D2 SRAM2 double ECC error flag disconnected from TIM1/8/15/16/17/HRTIMER Break inputs
1: D2 SRAM2 double ECC error flag connected to TIM1/8/15/16/17/HRTIMER Break inputs

Bit 10 **SRAM3L**: D2 SRAM3 double ECC error lock bit
This bit is set by software and cleared only by a system reset. It can be used to enable and lock the D2 SRAM3 double ECC error flag connection to TIM1/8/15/16/17 and HRTIMER Break inputs.
0: D2 SRAM3 double ECC error flag disconnected from TIM1/8/15/16/17/HRTIMER Break inputs
1: D2 SRAM3 double ECC error flag connected to TIM1/8/15/16/17/HRTIMER Break inputs

Bit 9 **SRAM4L**: D3 SRAM4 double ECC error lock bit
This bit is set by software and cleared only by a system reset. It can be used to enable and lock the D3 SRAM4 double ECC error flag connection to TIM1/8/15/16/17 and HRTIMER Break inputs.
0: D3 SRAM4 double ECC error flag disconnected from TIM1/8/15/16/17/HRTIMER Break inputs
1: D3 SRAM4 double ECC error flag connected to TIM1/8/15/16/17/HRTIMER Break inputs

Bit 8 Reserved, must be kept at reset value.

Bit 7 **BKRAML**: Backup SRAM double ECC error lock bit
This bit is set by software and cleared only by a system reset. It can be used to enable and lock the Backup SRAM double ECC error flag connection to TIM1/8/15/16/17 and HRTIMER Break inputs.
0: Backup SRAM double ECC error flag disconnected from TIM1/8/15/16/17/HRTIMER Break inputs
1: Backup SRAM double ECC error flag connected to TIM1/8/15/16/17/HRTIMER Break inputs

Bit 6 **CM7L**: Arm® Cortex®-M7 LOCKUP (HardFault) output enable bit
This bit is set by software and cleared only by a system reset. It can be used to enable and lock the connection of the Arm® Cortex®-M7 LOCKUP (HardFault) output to TIM1/8/15/16/17 and HRTIMER Break inputs.
0: Arm® Cortex®-M7 LOCKUP output disconnected from TIM1/8/15/16/17/HRTIMER Break inputs
1: Arm® Cortex®-M7 LOCKUP output connected to TIM1/8/15/16/17/HRTIMER Break inputs

Bits 5:4 Reserved, must be kept at reset value.
Bit 3  **FLASHL**: FLASH double ECC error lock bit  
This bit is set by software and cleared only by a system reset. It can be used to enable and lock the FLASH double ECC error flag connection to TIM1/8/15/16/17 and HRTIMER Break inputs.
0: FLASH double ECC error flag disconnected from TIM1/8/15/16/17/HRTIMER Break inputs  
1: FLASH double ECC error flag connected to TIM1/8/15/16/17/HRTIMER Break inputs

Bit 2  **PVDL**: PVD lock enable bit  
This bit is set by software and cleared only by a system reset. It can be used to enable and lock the PVD connection to TIM1/8/15/16/17 and HRTIMER Break inputs, as well as the PVDE and PLS[2:0] in the PWR_CR1 register.
0: PVD signal disconnected from TIM1/8/15/16/17/HRTIMER Break inputs  
1: PVD signal connected to TIM1/8/15/16/17/HRTIMER Break inputs

Bits 1:0  Reserved, must be kept at reset value.
### 11.3.7 SYSCFG compensation cell control/status register (SYSCFG_CCCSR)

Address offset: 0x20

Reset value: 0x0000 0000

Refer to Section 10.3.11: I/O compensation cell for a detailed description of I/O compensation mechanism.

</table>

Bits 31:17 Reserved, must be kept at reset value.

**Bit 16 HSLV:** High-speed at low-voltage
- This bit is written by software to optimize the I/O speed when the product voltage is low.
- This bit is active only if IO_HSLV user option bit is set. It must be used only if the product supply voltage is below 2.7 V. Setting this bit when VDD is higher than 2.7 V might be destructive.
- 0: No I/O speed optimization
- 1: I/O speed optimization

Bits 15:9 Reserved, must be kept at reset value.

**Bit 8 READY:** Compensation cell ready flag
- This bit provides the status of the compensation cell.
- 0: I/O compensation cell not ready
- 1: I/O compensation cell ready

*Note:* The CSI clock is required for the compensation cell to work properly. The compensation cell ready bit (READY) is not set if the CSI clock is not enabled.

Bits 7:2 Reserved, must be kept at reset value.

**Bit 1 CS:** Code selection
- This bit selects the code to be applied for the I/O compensation cell.
- 0: Code from the cell (available in the SYSCFG_CCVR)
- 1: Code from the SYSCFG compensation cell code register (SYSCFG_CCCR)

**Bit 0 EN:** Enable
- This bit enables the I/O compensation cell.
- 0: I/O compensation cell disabled
- 1: I/O compensation cell enabled
11.3.8 SYSCFG compensation cell value register (SYSCFG_CCVR)

</table>

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 **PCV[3:0]**: PMOS compensation value

This value is provided by the cell and can be used by the CPU to compute an I/O compensation cell code for PMOS transistors. This code is applied to the I/O compensation cell when the CS bit of the SYSCFG_CCCSR is reset.

Bits 3:0 **NCV[3:0]**: NMOS compensation value

This value is provided by the cell and can be used by the CPU to compute an I/O compensation cell code for NMOS transistors. This code is applied to the I/O compensation cell when the CS bit of the SYSCFG_CCCSR is reset.

11.3.9 SYSCFG compensation cell code register (SYSCFG_CCCR)

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 **PCC[3:0]**: PMOS compensation code

These bits are written by software to define an I/O compensation cell code for PMOS transistors. This code is applied to the I/O compensation cell when the CS bit of the SYSCFG_CCCSR is set.

Bits 3:0 **NCC[3:0]**: NMOS compensation code

These bits are written by software to define an I/O compensation cell code for NMOS transistors. This code is applied to the I/O compensation cell when the CS bit of the SYSCFG_CCCSR is set.
### 11.3.10 SYSCFG power control register (SYSCFG_PWRCR)

</tbody>
</table>

Bits 31:1 Reserved, must be kept at reset value.

**Bit 0 ODEN**: Overdrive enable, this bit allows to activate the LDO regulator overdrive mode.  
This bit must be written only in VOS1 voltage scaling mode.  
0: Overdrive mode disabled  
1: Overdrive mode enabled (the LDO generates VOS0 for V\textsubscript{CORE})  

*Note*: VOS0 must be activated only in VOS1 mode. It must be disabled by software before entering low-power mode (execution of WFE/WFI instruction).

### 11.3.11 SYSCFG package register (SYSCFG_PKGR)

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **RDP[7:0]**: Readout protection
- These bits indicate the readout protection level.
- 0xAA: Level 0 (no protection)
- 0xCC: Level 2 (Flash memory readout protected, full debug features, boot from SRAM and boundary scan disabled)
- Other configurations: Level 1 (Flash memory readout protected, limited debug features and boundary scan enabled)

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **BKS**: Bank Swap
- This bit indicates Flash memory bank mapping.
- 0: Flash memory bank addresses are inverted
- 1: Flash memory banks are mapped to their original addresses

Bits 31:28: Reserved, must be kept at reset value.

Bits 27:16 **PA_BEG_2[11:0]:** Protected area start address for bank 2

Start address for bank 2 protected area.

Bits 15:8: Reserved, must be kept at reset value.

Bits 7:0 **WRPS_2[7:0]:** Write protection for flash bank 2

WRPN[i] bit indicates if the sector i of the Flash memory bank 2 is protected.

0: Write protection is active on sector i

1: Write protection is not active on sector i

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **IWDG1M**: Independent Watchdog 1 mode  
This bit indicates the control mode of the Independent Watchdog 1 (IWDG1).  
0: IWDG1 controlled by hardware  
1: IWDG1 controlled by software

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **SA_END_2[11:0]**: Secured area end address for bank 2  
End address for bank 2 secured area.

### 11.3.23 SYSCFG user register 12 (SYSCFG_UR12)

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **SECURE**: Secure mode  
This bit indicates the Secure mode status.  
0: Secure mode disabled  
1: Secure mode enabled

Bits 15:0 Reserved, must be kept at reset value.
11.3.24 SYSTEM configuration controller (SYSCFG)

Address offset: 0x334
Reset value: 0x000X 000X

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 D1SBRST: D1 Standby reset
This bit indicates if a reset is generated when D1 domain enters DStandby mode.
0: A reset is generated by entering D1 Standby mode
1: D1 Standby mode is entered without reset generation

Bits 15:2 Reserved, must be kept at reset value.

Bits 1:0 SDRS[1:0]: Secured DTCM RAM Size
These bits indicate the size of the secured DTCM RAM.
00: 2 Kbytes
01: 4 Kbytes
10: 8 Kbytes
11: 16 Kbytes
11.3.25  SYSCFG user register 14 (SYSCFG_UR14)

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:1  Reserved, must be kept at reset value.

Bit 0  **D1STPRST**: D1 Stop Reset

- This bit indicates if a reset is generated when D1 domain enters in DStop mode.
- 0: A reset is generated entering D1 Stop mode
- 1: D1 Stop mode is entered without reset generation
11.3.26 SYSCFG user register 15 (SYSCFG_UR15)

Address offset: 0x33C
Reset value: 0x000X 000X

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **FZIWDGSTB**: Freeze independent watchdog in Standby mode
This bit indicates if the independent watchdog is frozen in Standby mode.
0: Independent Watchdog frozen in Standby mode
1: Independent Watchdog running in Standby mode

Bits 15:0 Reserved, must be kept at reset value.
11.3.27 SYSCFG user register 16 (SYSCFG_UR16)

Address offset: 0x340
Reset value: 0x0000 000X

<table>

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **PKP**: Private key programmed
This bit indicates if the device private key is programmed.
0: Private key not programmed
1: Private key programmed

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **FZIWGDSTP**: Freeze independent watchdog in Stop mode
This bit indicates if the independent watchdog is frozen in Stop mode.
0: Independent Watchdog frozen in Stop mode
1: Independent Watchdog running in Stop mode

11.3.28 SYSCFG user register 17 (SYSCFG_UR17)

Address offset: 0x344
Reset value: 0x0000 000X

Refer to *Section 2.3 on page 126* for the register boundary addresses.
12 Block interconnect

12.1 Peripheral interconnect

12.1.1 Introduction

Several peripherals have direct connections between them.

This enables autonomous communication and synchronization between peripherals, thus saving CPU resources and power consumption.

These hardware connections remove software latency, allow the design of a predictable system and result in a reduction of the number of pins and GPIOs.

12.1.2 Connection overview

There are several types of connections.

- Asynchronous connections (A)
  The source output signal is sampled by the destination clock, leading to introduction of a possible jitter in the latency between the source output event and the destination event detection

- Synchronous connections (S)
  Both source and destination are synchronous (they run on the same clock), and the latency from the source to the destination is deterministic. No jitter is introduced.

- Immediate connections (I)
  Either the source or the destination is an analog signal.

- Break/fault connection for TIM/HRTIM outputs (B)
  The source output signal disables the timer outputs through a pure combinational logic path, without any latency.

1. Letters in the table correspond to the type of connection described in Section 12.1.2: Connection overview.
2. comp1_out and comp2_out are connected to the inputs of an OR gate. The output of this OR gate is connected to the lptim2_in1_mux3 input.
12.2 **Wakeup from low power modes**

The Extended interrupt and event controller module (EXTI) allows to wake up the system from Stop mode and/or a CPU from CStop mode. Wakeup events are coming from peripherals.

These events are handled by the EXTI either as Configurable events (C), or as Direct events (D). See **Type** column in *Table 93*. Refer to *Section 19: Extended interrupt and event controller (EXTI)* for further details.

Three types of peripheral output signals are connected to the EXTI input events:

- The wake up signals. These signals can be generated by the peripheral without any bus interface clock, they are referred to as xxx_wkup in *Table 93*. Some peripherals do not have this capability.

- The interrupt signals. These signals can be generated only if the peripheral bus interface clock is running. These interrupt signals are generally directly connected to the NVIC of CPU. They are referred to as xxx_it.

- The signals, i.e. the pulses generated by the peripheral. Once a peripheral has generated a signal, no action (flag clearing) is required at peripheral level.

Each EXTI input event has a different wakeup capability or possible target (see **Target** column in *Table 93*):

- CPU wakeup (**CPU**): the input event can be enabled to wake up the CPU

- CPU and D3 domain wakeup for autonomous Run mode (**ANY**): the input event can be enabled to wake up the CPU or the D3 domain only for an autonomous Run mode phase.

</table>

1. The source peripheral needs its bus clock in order to generate the event. This is either PCLK4 or HCLK4 in D3 domain, PCLK3 in D1 domain.
2. The source peripheral signal is not connected to the NVIC.
The Extended Interrupt and Event Controller (EXTI) module event inputs able to wake up the D3 domain for autonomous Run mode have a pending request logic that can be cleared by 4 different input sources (Table 94). Refer to Section 19: Extended interrupt and event controller (EXTI) for further details.

12.3 DMA

In D1 domain, the MDMA allows the memory to transfer data. It can be triggered by software or by hardware, according to the connections described in Section 12.3.1.

DMA Multiplexer in D2 domain (DMAMUX1) allows to map any peripheral DMA request to any stream of the DMA1 or the DMA2. In addition to this, The DMAMUX provides two other functionalities:

- It's possible to synchronize a peripheral DMA request with a timer, with an external pin or with a DMA transfer complete of another stream.
- DMA requests can be generated on a stream by the DMAMUX1 itself. This event can be triggered by a timer, by an external pin event, or by a DMA transfer complete of another stream. The number of DMA requests generated is configurable.

The connections on DMAMUX1 and DMA1/DMA2 are described in Section 16: DMA request multiplexer (DMAMUX), Section 14: Direct memory access controller (DMA) and Section 15: Basic direct memory access controller (BDMA).

DMA Multiplexer in D3 domain (DMAMUX2) has the same functionality of DMAMUX1, it is connected to the basic DMA (BDMA).

The connections on DMAMUX2 and BDMA are described in Section 12.3.3: DMAMUX2, BDMA (D3 domain). Refer to Section 12.3.3: DMAMUX2, BDMA (D3 domain) and Section 15: Basic direct memory access controller (BDMA) for more details.

13 MDMA controller (MDMA)

13.1 MDMA introduction

The master direct memory access (MDMA) is used in order to provide high-speed data transfer between memory and memory or between peripherals and memory. Data can be quickly moved by the MDMA without any CPU action. This keeps the CPU resources free for other operations.

The MDMA controller provides a master AXI interface for main memory and peripheral registers access (system access port) and a master AHB interface only for Cortex-M7 TCM memory access (TCM access port).

The MDMA works in conjunction with the standard DMA controllers (DMA1 or DMA2). It offers up to 16 channels, each dedicated to manage memory access requests from one of the DMA stream memory buffer or other peripherals (w/ integrated FIFO).

13.2 MDMA main features

- AXI/AHB master bus architecture, one dedicated to main memory/peripheral accesses and one dedicated to Cortex-M7 AHBS port (only for TCM accesses).
- 16 channels
- Up to 32 hardware trigger sources
- Each channel request can be selected among any of the request sources. This selection is software-configurable and allows several peripherals to initiate DMA requests. The trigger selection can be automatically changed at the end of one block transfer.
- All the channels are identical and can be connected either to a standard DMA or a peripheral request (acknowledge by data read/write) system
- Each channel also supports software trigger
- One 256-level memory buffer, split in two 128-level first-in, first-out (FIFO), that will be used to store temporary the data to be transferred (in burst or single transfer mode), for 1 or 2 consecutive buffers. The FIFO will store the data that will be transferred during the current channel block transfer (up to the block transfer size). The 2nd FIFO can be used for the next buffer to be transferred, either for the same channel or for the next channel transfer.
- The priorities between the DMA channels are software-programmable (4 levels consisting of very high, high, medium, low) or hardware in case of equality (channel 0 has priority over channel 1, etc.)
- Independent source and destination transfer width (byte, half-word, word, double-word): when the data widths of the source and destination are not equal, the MDMA can pack/unpack the necessary data to optimize the bandwidth.
- The size and address increment for both source and destination can be independently selected.
Note: Based on this separation, some more advanced packing/unpacking operations are available at software level. As an example, 2 x 16-bit data blocks can be interleaved together using two MDMA channels, in the destination memory, by simply programming the 2 channels with an increment step of 4 bytes and a data size of 16-bit + a start address shifted by 2 between the 2 channels.

- Incrementing, decrementing or non incrementing/fixed addressing for source and destination
- Data packing/unpacking is always done respecting the little endian convention: lower address in a data entity (double word, word or half word) contains always the lowest significant byte. This is independent of the address increment/decrement mode of both source and destination.
- Supports incremental burst transfers. The size of the burst is software-configurable, up to 128 bytes. For larger data sizes the burst length is limited, as to respect the maximum 128 bytes data burst size (e.g. 16x64-bit or 32x32-bit).
- For the TCM memory accesses, the burst access is only allowed when the increment and data size are identical and lower than or equal to 32-bit.
- 5 event flags (MDMA Channel Transfer Complete, MDMA Block Transfer complete, MDMA Block Repeat Transfer Complete, MDMA buffer transfer Complete, MDMA Transfer Error) are available and can generate interrupts.
13.3 MDMA functional description

13.3.1 MDMA block diagram

Figure 74 shows the block diagram of the MDMA.

13.3.3 MDMA overview

The MDMA controller performs a direct memory transfer: as an AXI/AHB master, it can take the control of the AXI/AHB bus matrix to initiate AXI/AHB transactions.

It can carry out the following transactions:

- memory-to-memory (software triggered)
- peripheral-to-memory
- memory-to-peripheral

For the last two transaction types, the memory can also be replaced by a memory-mapped peripheral, which has no control over the MDMA flow. When these types of transaction are used and the request is coming from a standard DMA (DMA1 or DMA2), the peripheral register access is replaced by a memory access to the memory buffer used by this DMA.

Note: Non-incrementing/decrementing mode will not be used for memory accesses.

The source and destination are simply defined by the address (peripherals being memory mapped also).

The AHB slave port is used to program the MDMA controller (it supports 8/16/32-bit accesses).

The size of the data array to be transferred for a single request will be one of the following:

1. The buffer transfer size
2. The block size
3. Repeated block
4. Complete channel data (until the linked list pointer for the channel is null)

The choice of the size is done through the TRGM[1:0] (Trigger mode) selection field.

The user must choose one of them based on the data array size available (usually in the DMA1/2 memory buffer) and the “real time” requirements for other MDMA channels (knowing that a buffer transfer is the minimum data aggregate to be transferred by the MDMA without doing a new arbitration between MDMA channel requests).

For each channel, there are three key data array sizes:

1. Burst size: this is the length of the data transfer which can be performed in burst mode. This burst length defines the maximum transfer length which cannot be interrupted at bus arbitration level and can block other masters from accessing the bus.
2. Buffer transfer size: this is the length of the data array to be transferred, on a channel, before checking for MDMA requests on other channels. This is the data array transfer lengths which cannot be interrupted at MDMA level (from other channel requests).
3. Block size: this value has two meanings which can be used together:
   a) main: this is length of the data block which is described in a block structure of the MDMA linked list (corresponds to one entry in the linked list)
   b) selectable: when TRGM[1:0] equals 01, this is the length of the data array which is transferred on a single MDMA request activation (for the respective channel)
13.3.4 MDMA channel

Each of the DMA controller channel provides a unidirectional transfer link between a source and a destination.

Each channel can perform:

- Single block transfer: one block is transferred. At the end of the block, the DMA channel is disabled and an End of Channel Transfer interrupt is generated.
- Repeated block transfer: a number of blocks is transferred before disabling the channel
- Linked list transfer: when the transfer of the current data block (or last block in a repeat) is completed, a new block control structure is loaded from memory and a new block transfer is started.

The minimum amount of data to be transferred for each request (buffer size, up to 128-bytes) is programmable. The total amount of data in a block, is programmable up to 64 Kbytes. This value is decremented after each transfer. When this counter reaches 0, the end of the block is reached and an action is taken based on the repeat counter (for repeated block transfer) and/or linked list structure value.

Note: If the block length is not a multiple of the buffer length, the last buffer transfer in the block will be shorter, covering the remaining bytes to be transferred in the current block.

If the link structure address points to a valid memory address, the MDMA will reload the whole channel descriptor structure register contents from memory at this address. Then, a new block transfer will then be executed (on the next MDMA channel request) based on this information.

If the link structure address is 0x0, at the end of the current/repeated block transfer, the MDMA channel will be disabled and the end of channel transfer interrupt will be generated.

13.3.5 Source, destination and transfer modes

Both the source and destination transfers can address peripherals and memories in the entire 4-Gbyte area, at addresses comprised between 0x0000 0000 and 0xFFFF FFFF.

The source/destination addresses can be fixed (e.g. FIFO/single data register peripherals) or incremented/decremented. The transfer can be done in single access or in burst mode (programmable).

13.3.6 Pointer update

The source and destination memory pointers can optionally be automatically post-incremented/decremented or kept constant after each transfer depending on the SINC[1:0] and DINC[1:0] bits in the MDMA_CxCR register.

Disabling the increment mode is useful when the peripheral source or destination data are accessed through a single register/FIFO mode.

If the increment/decrement mode is enabled, the address of the next data transfer will be the address of the previous one incremented/decrement by 1, 2, 4 or 8 depending on the increment size programmed in the SINCOS[1:0] or DINCOS[1:0] bits in the MDMA_CxCR register.

In order to optimize the packing operation, the increment offset size and the data size are programmable independently.
13.3.7 MDMA buffer transfer

This is the minimum logical amount of data (up to 128 bytes) which is transferred on an MDMA request event, on one channel.

An MDMA buffer transfer consists of a sequence of a given number of data transfers (done as single or burst data transfers). The number of data items to be transferred and their width (8-bit, 16-bit, 32-bit or 64-bit) are software programmable. The length of the burst used for data transfers is also programmable, independently.

After an event requiring a data array to be transferred, the DMA/peripheral sends a request signal to the MDMA controller. The MDMA controller serves the request depending on the channel priorities.

The request is acknowledged by writing the mask data value to the address given mask address, when these registers are set.

If the mask address register is not set (0x00 value), the request can be reset by simply reading/writing the data to the peripheral. In this case, if the request is done by a destination peripheral, the write must be set as non bufferable, in order to avoid a false new MDMA request.

The total amount of data to be transferred, on the current channel, following a MDMA request, is determined by the TRGM[1:0] field.

If TRGM[1:0] equals 00, a single buffer will be transferred, then the MDMA will wait for another request on the same channel.

**Note:** In this case, the hardware request for the currently active channel (data in the FIFO) will not be considered again until the end of the write phase for this channel. In this case, even if the channel would still be active at the end of the read phase, another channel (even with lower priority) could start the read phase. Because of this, lower priority channels can be interleaved with current channel transfer.

If TRGM[1:0] is different from 00 (multiple buffers need to be transferred), the mdma_strx for the current channel remains active (internally memorized) until the whole transfer defined by TRGM (block, repeated block or whole channel/linked list data) is completed. However, after transferring an individual buffer, the MDMA will enter in a new arbitration phase (between new external requests and internally memorized ones). If no other higher priority, channel request is active, a new buffer transfer will be started for the same channel.

**Note:** When TRGM[1:0] is different from 00, a larger array of data will be transferred for a single request. But, as the channel arbitration is done after each buffer transfer, no higher level MDMA requests would be blocked for the more than a buffer transfer period, on any lower priority channel.
13.3.8 Request arbitration

An arbiter manages the MDMA channel requests based on their priority. When MDMA is idle and after the end of each buffer transfer, all MDMA requests (hardware or software) are checked for all enabled channels.

Priorities are managed in two stages:

- **Software**: each stream priority can be configured in the MDMA_CxCR register. There are four levels:
  - Very high priority
  - High priority
  - Medium priority
  - Low priority

- **Hardware**: at hardware level, the channel priority is fixed. If two requests have the same software priority level, the channel with the lower number takes priority over the stream with the higher number. For example, Channel 2 takes priority over Channel 4 when they have the same software priority level.

13.3.9 FIFO

A FIFO structure is used to temporarily store data coming from the source before writing them to the destination. There is a central FIFO structure which is used for all channels.

In order to maximize data bandwidth and bus usage, the following mechanisms are used, allowing multiple read/write operation to be executed in parallel.

- During a buffer transfer, as soon as the FIFO contains enough data for a destination burst transfer, the write operation will start.
- When the complete data for a buffer transfer has been read into the FIFO, the arbitration procedure will be started. Following that, the next buffer data to be transferred can be read to the FIFO.

When an active channel is disabled due to an error, during a buffer transfer, the remaining data in the internal FIFO will be discarded.
13.3.10 Block transfer

A block is a “contiguous” array of data, up to 64 Kbytes, which is transferred by successive buffer transfers.

Each block of data is defined by the start address and the block length. When a block transfer is completed, one of the following three actions can be executed:

- The block is part of a repeated block transfer: the block length is reloaded and new block start address is computed (based on the information in the MDMA_CxBRUR register)
- It is a single block or the last block in a repeated block transfer: the next block information is loaded from the memory (using the linked list address information, from the MDMA_CxLAR)
- It is the last block which needs to be transferred for the current MDMA channel (MDMA_CxLAR = 0): the channel is disabled and no further MDMA requests will be accepted for this channel

13.3.11 Block repeat mode

The block repeat mode allows to repeat a block transfer, with different start addresses for source and destination.

When the repeat block mode is active (repeat counter non 0), at the end of the current block transfer, the block parameters will be updated (the BNDT value reloaded and SAR/DAR values updated according to BRSUM/BRDUM configuration), and the repeat counter decremented by 1.

When the repeat block counter reaches 0, this last block will be treated as a single block transfer.

13.3.12 Linked list mode

The Linked list mode allows to load a new MDMA configuration (CxTCR, CxBNDTR, CxSAR, CxDAR, CxBRUR, CxLAR, CxTBR, CxMAR and CxMDR registers), from the address given in the CxLAR register. This address must address a memory mapped on the AXI system bus.

Following this operation, the channel is ready to accept new requests, as defined in the block/repeated block modes above, or continue the transfer if TRGM[1:0] equals 11.

The trigger source can be automatically changed, when loading the CxTBR value.

The TRGM and SWRM values must not be changed when TRGM[1:0] equals 11.

13.3.13 MDMA transfer completion

Different events can generate an end of transfer by setting the CTCIF bit in the status register (MDMA_CxISR):

- The MDMA_CxBNDTR counter has reached zero, the Block Repeat Counter is 0 and the Link list pointer address is 0
- The channel is disabled before the end of transfer (by clearing the EN bit in the MDMA_CxCR register) and all the remaining data have been transferred from the FIFO to the destination
13.3.14 MDMA transfer suspension

At any time, a MDMA transfer can be suspended in order to be restarted later on or to be definitively disabled before the end of the MDMA transfer.

There are two cases:

- The channel is disabled, with no later-on restart from the point where it was stopped. There is no particular action to do, besides clearing the EN bit in the MDMA_CxCR register to disable the channel. The stream can take time to be disabled (on going buffer transfer is completed first). The transfer complete interrupt flag is set in order to indicate the end of transfer. The value of the EN bit in MDMA_CxCR is now 0 to confirm the channel interruption. The MDMA_CxNDTR register contains the number of remaining data items at the moment when the channel was stopped so that the software can determine how many data items have been transferred before the channel was interrupted.

- The channel is suspended before the number of remaining bytes to be transferred in the MDMA_CxBNDTR register reaches 0. The aim is to restart the transfer later by re-enabling the channel. The channel transfer complete interrupt flag CTCIF is set in order to indicate the end of transfer. If the MDMA_CxBNDTR, SAR and DAR registers are not modified by software, the transfer will continue when the channel is re-enabled. CTCIF must also be reset before restarting the channel.

\textit{Note:} If the completed buffer is the last of the block, the configuration registers are also updated before disabling the channel, in order to be correctly prepared for a soft restart.

\textit{Note:} Before reprogramming the channel, software must wait the CTCIF register is set, in order to guarantee that any ongoing operation has been completed.

13.3.15 Error management

The MDMA controller can detect the following errors:

The transfer error interrupt flag (TEIF) is set when:

- A bus error occurs during a MDMA read or a write access
- The address alignment does not correspond to the data size
- The block size is not a multiple of the data size (for source and/or destination): this error is activated on the last transfer and the error address points to the last transfer (which cannot be done)

13.4 MDMA interrupts

For each MDMA channel, an interrupt can be produced on the following events:

- Channel Transfer Completed
- Block-Transfer Completed
- Block-Transfer Repeat Completed
- buffer Transfer Completed
- Transfer Error

Separate interrupt enable control bits are available for flexibility as shown in \textit{Table 99}.
Table 99. MDMA interrupt requests

<table>
<thead>
<tr>
<th>Interrupt event</th>
<th>Event flag</th>
<th>Enable control bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Channel Transfer Completed</td>
<td>CTCIF</td>
<td>CTCIE</td>
</tr>
<tr>
<td>Block-Transfer Repeat completed</td>
<td>BTRIF</td>

</tr>
<tr>
<td>Block-Transfer completed</td>
<td>BTIF</td>
<td>BTIE</td>
</tr>
<tr>
<td>Buffer Transfer Completed</td>
<td>TCIF</td>
<td>TCIE</td>
</tr>
<tr>
<td>Transfer Error</td>
<td>TEIF</td>
<td>TEIE</td>
</tr>
</tbody>
</table>

Note: Before setting an Enable control bit to 1, the corresponding event flag should be cleared, otherwise an interrupt might be immediately generated, if the bit is already set.

Note: When at least one interrupt flag and the respective enable control bit are set, the channel interrupt bit is set in the GISR. The Interrupt output is also activated. This will generate an interrupt if the respective interrupt channel is enabled in the NVIC.

13.5 MDMA registers

The MDMA registers can be accessed in word/half-word or byte format.

13.5.1 MDMA global interrupt/status register (MDMA_GISR0)

Address offset: 0x00

Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 GIF[15:0]: Channel x global interrupt flag (x=0..15)

This bit is set and reset by hardware. It is a logical OR of all the Channel x interrupt flags (CTCIF, BTIF, BRTIF, TEIF) which are enabled in the interrupt mask register (CTCIE, BTIE, BRTIE, TEIE)

0: No interrupt generated by channel x
1: Interrupt generated by channel x
### MDMA channel x interrupt/status register (MDMA_CxISR)

Address offset: $0x40 + 0x40 \cdot x$, ($x = 0$ to $15$)

Reset value: $0x0000 \ 0000$

| r | r | r | r | r | r | r | r | r | r | r | r | r |

Bits 31:12 are reserved, must be kept at reset value.

- **Bit 11 BSE**: Block Size Error
  - These bits are set by hardware, when the block size is not an integer multiple of the data size either for source or destination. TED will indicate whether the problem is on the source or destination.
  - It is cleared by software writing 1 to the CTEIF bit in the MDMA_IFCRy register.
  - 0: No block size error.
  - 1: Programmed block size is not an integer multiple of the data size.

- **Bit 10 ASE**: Address/Size Error
  - These bits are set by hardware, when the programmed address is not aligned with the data size. TED will indicate whether the problem is on the source or destination.
  - It is cleared by software writing 1 to the CTEIF bit in the MDMA_IFCRy register.
  - 0: No address/size error.
  - 1: Programmed address is not coherent with the data size.

- **Bit 9 TEMD**: Transfer Error Mask Data
  - These bits are set by hardware, in case of a transfer error while writing the Mask Data. It is cleared by software writing 1 to the CTEIF bit in the MDMA_IFCRy register.
  - 0: No mask write access error.
  - 1: The last transfer error on the channel was a related to a write of the Mask Data.

- **Bit 8 TELD**: Transfer Error Link Data
  - These bits are set by hardware, in case of a transfer error while reading the block link data structure. It is cleared by software writing 1 to the CTEIF bit in the MDMA_IFCRy register.
  - 0: No link data read access error.
  - 1: The last transfer error on the channel was a related to a read of the Link Data structure.

- **Bit 7 TED**: Transfer Error Direction
  - These bits are set and cleared by hardware, in case of an MDMA data transfer error.
  - 0: The last transfer error on the channel was a related to a read access.
  - 1: The last transfer error on the channel was a related to a write access.
Bits 6:0 **TEA[6:0]: Transfer Error Address**

These bits are set and cleared by hardware, in case of an MDMA data transfer error. It is used in conjunction with TED.

This field indicates the 7 LSBits of the address which generated a transfer/access error. It can be used by software to retrieve the failing address, by adding this value (truncated to the buffer transfer length size) to the current SAR/DAR value.

**Note:** The SAR/DAR current value doesn’t reflect this last address due to the FIFO management system. The SAR/DAR are only updated at the end of a (buffer) transfer (of TLEN+1 bytes).

**Note:** It is not set in case of a link data error.
13.5.5 MDMA channel x control register (MDMA_CxCR)

This register is used to control the concerned channel.

Address offset: 0x4C + 0x40 * x, (x = 0 to 15)

Reset value: 0x0000 0000

<table>

</tbody>
</table>

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 SWRQ: Software Request
Writing 1 into this bit sets the CRQA in MDMA_ISRy register, activating the request on Channel x

Note: Either the whole CxCR register or the 8-bit/16-bit register at Address offset: 0x4E + 0x40 * channel number can be used for SWRQ activation.
In case of a software request, acknowledge is not generated (neither hardware signal, nor CxMAR write access).

Bit 15 Reserved, must be kept at reset value.

Bit 14 WEX: Word Endianess exchange
This bit is set and cleared by software.
0: Little endianess preserved for words
1: word order exchanged in double word
When this bit is set, the word order in the destination double word is reversed: higher address word contains the data read from the lower address of the source.
If destination is not a double word, do not care of the value of this bit.
This bit is protected and can be written only if EN is 0.

Bit 13 HEX: Half word Endianess exchange
This bit is set and cleared by software.
0: Little endianess preserved for half words
1: half-word order exchanged in each word
When this bit is set, the half-word order in each destination word is reversed: higher address half-word contains the data read from the lower address of the source.
If destination length is shorter than word, do not care of the value of this bit.
This bit is protected and can be written only if EN is 0.

Bit 12 BEX: Byte Endianess exchange
This bit is set and cleared by software.
0: Little endianess preserved for bytes
1: byte order exchanged in each half-word
When this bit is set, the byte order in each destination Half Word is reversed: higher address word contains the data read from the lower address of the source.
If destination is byte, do not care of the value of this bit.
This bit is protected and can be written only if EN is 0.

Bits 11:9 Reserved, must be kept at reset value.
Bit 8  Reserved, must be kept at reset value.

Bits 7:6  **PL[1:0]:** Priority level
These bits are set and cleared by software.
00: Low
01: Medium
10: High
11: Very high
These bits are protected and can be written only if EN is 0.

Bit 5  **TCIE:** buffer Transfer Complete interrupt enable
This bit is set and cleared by software.
0: TC interrupt disabled
1: TC interrupt enabled

Bit 4  **BTIE:** Block Transfer interrupt enable
This bit is set and cleared by software.
0: BT complete interrupt disabled
1: BT complete interrupt enabled

Bit 3  **BRTIE:** Block Repeat transfer interrupt enable
This bit is set and cleared by software.
0: BT interrupt disabled
1: BT interrupt enabled

Bit 2  **CTCIE:** Channel Transfer Complete interrupt enable
This bit is set and cleared by software.
0: TC interrupt disabled
1: TC interrupt enabled

Bit 1  **TEIE:** Transfer error interrupt enable
This bit is set and cleared by software.
0: TE interrupt disabled
1: TE interrupt enabled

Bit 0  **EN:** Channel enable / flag channel ready when read low
This bit is set and cleared by software.
0: Channel disabled
1: Channel enabled
This bit can be cleared by hardware:
– on a MDMA end of transfer (stream ready to be configured)
– if a transfer error occurs on the AHB/AXI master buses (bus error/hard fault)
– if another error condition is encountered (data alignment, block/data size incompatibility)

When this bit is reset by software, the ongoing buffer transfer (if any) will be completed. All status/configuration registers will keep their current values. If the channel is re enabled without writing these registers, the channel will continue from the point where it was interrupted. When this bit is read as 0, the software is allowed to program the configuration registers. It is forbidden to write these registers when the EN bit is read as 1 (writes are ignored).

**Note:** *When this bit is reset by software, it is recommended to wait for the CTCIF = 1, in order to ensure that any ongoing buffer transfer has been completed, before reprogramming the channel.*
13.5.6 MDMA channel x transfer configuration register (MDMA_CxTCR)

This register is used to configure the concerned channel. In Linked List mode, at the end of a block (single or last block in repeated block transfer mode), this register will be loaded from memory (from address given by current LAR[31:0] + 0x00).

Address offset: 0x50 + 0x40 * x, (x = 0 to 15)
Reset value: 0x0000 0000

</tbody>
</table>
Bits 27:26 **PAM[1:0]: Padding/Alignement Mode**

These bits are set and cleared by software.

Case 1: Source data size smaller than destination data size - 3 options are valid.
- 00: Right Aligned, padded with 0s (default)
- 01: Right Aligned, Sign extended
- 10: Left Aligned (padded with 0s)
- 11: Reserved

Case 2: Source data size larger than destination data size.
- 00: Right Aligned - only the LSBs part of the Source is written to the destination address
- 10: Left Aligned - only the MSBs part of the Source is written to the destination address
The remainder part is discarded.

When PKE = 1 or DSIZE=SSIZE, these bits are ignored.
These bits are protected and can be written only if EN is 0

Bit 25 **PKE: Pack Enable**

This bit is set and cleared by software.
- 0: The source data is written to the destination as is.
- 1: The source data is packed/unpacked into the destination data size. All data are right aligned, in Little Endian mode.

This bit is protected and can be written only if EN is 0

Bits 24:18 **TLEN[6:0]: buffer Transfer Length (number of bytes - 1)**

These bits are set and cleared by software.
The value of TLEN+1 represents the number of bytes to be transferred in a single transfer.
The Transfer Length MUST be a multiple of the data size (for both Source and Destination)

*Note*: When the source/destination sizes are different and padding/truncation is used, the TLEN+1 refers to the source data array size.
These bits are protected and can be written only if EN is 0
DBURST value must be programmed in order to ensure that the burst size will be lower than the Transfer Size.

Bits 17:15 **DBURST[2:0]: Destination burst transfer configuration**

These bits are set and cleared by software.
- 000: single transfer
- N: burst of 2^N beats

These bits are protected and can be written only if EN is 0
DBURST value must be programmed as to ensure that the burst size will be lower than the Transfer Length. If this is not ensured, the result is unpredictable.

*Note*: When the destination bus is TCM/AHB (DBUS=1) and DINCOS=11 or DINC=00 or DINCOS=DSIZE, DBURST must be programmed to 000 (single transfer), else the result is unpredictable.

*Note*: When the destination bus is system/AXI bus (DBUS=0) and DINC=00, DBURST must be maximum 100 (burst of 16), else the result is unpredictable.
Bits 14:12 **SBURST[2:0]**: Source burst transfer configuration
These bits are set and cleared by software.
- 000: single transfer
- N: burst of \(2^N\) beats

These bits are protected and can be written only if EN is 0.
SBURST value must be programmed as to ensure that the burst size will be lower than the transfer length. If this is not ensured, the result is unpredictable.

**Note:** When the source bus is TCM (SBUS=1) and SINCOS=11 or SINC = 00 or SINCOS=SSIZE, SBURST must be programmed to 000 (single transfer), else the result is unpredictable.

**Note:** When the source bus is system/AXI bus (SBUS=0) and SINC=00, SBURST must be maximum 100 (burst of 16), else the result is unpredictable.

Bits 11:10 **DINCOS[1:0]**: Destination increment offset size
These bits are set and cleared by software.
- 00: byte (8-bit)
- 01: half-word (16-bit)
- 10: word (32-bit)
- 11: Double-Word (64-bit)

This bits have no meaning if bit DINC[1:0] = ‘00’.
These bits are protected and can be written only if EN = ‘0’.
If DINCOS < DSIZE and DINC /= 00, the result will be unpredictable.
If destination is AHB and DBURST != 000, destination address must be aligned with DINCOS size, else the result is unpredictable.

Bits 9:8 **SINCOS[1:0]**: Source increment offset size
These bits are set and cleared by software.
- 00: byte (8-bit)
- 01: half-word (16-bit)
- 10: word (32-bit)
- 11: Double-Word (64-bit)

This bits have no meaning if bit SINC[1:0] = ‘00’.
These bits are protected and can be written only if EN = ‘0’.
If SINCOS < SSIZE and SINC /= 00, the result will be unpredictable.
If source is TCM/AHB and SBURST /= 000, source address must be aligned with SINCOS size, else the result is unpredictable.

Bits 7:6 **DSIZE[1:0]**: Destination data size
These bits are set and cleared by software.
- 00: byte (8-bit)
- 01: half-word (16-bit)
- 10: word (32-bit)
- 11: Double-Word (64-bit)

These bits are protected and can be written only if EN is 0.

**Note:** If a value of 11 is programmed for the TCM access/AHB port, a transfer error will occur (TEIF bit set)
If DINCOS < DSIZE and DINC /= 00, the result will be unpredictable.

**Note:** DSIZE = 11 (double-word) is forbidden when destination is TCM/AHB bus (DBUS=1).
13.5.7 MDMA channel x block number of data register (MDMA_CxBNDTR)

In Linked List mode, at the end of a block (single or last block in repeated block transfer mode), this register will be loaded from memory (from address given by current LAR[31:0] + 0x04).

Address offset: 0x54 + 0x40 * x, (x = 0 to 15)

Reset value: 0x0000 0000

| BNDT[15:0] |
| rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 5:4 **SSIZE[1:0]**: Source data size
- These bits are set and cleared by software.
  - 00: Byte (8-bit)
  - 01: Half-word (16-bit)
  - 10: Word (32-bit)
  - 11: Double-Word (64-bit)

  These bits are protected and can be written only if EN is 0

  **Note:** If a value of 11 is programmed for the TCM access/AHB port, a transfer error will occur (TEIF bit set)

  If SINCOS < SSIZE and SINC /= 00, the result will be unpredictable.

  **Note:** SSIZE = 11 (double-word) is forbidden when source is TCM/AHB bus (SBUS=1).

Bits 3:2 **DINC[1:0]**: Destination increment mode
- These bits are set and cleared by software.
  - 00: Destination address pointer is fixed
  - 10: Destination address pointer is incremented after each data transfer (increment is done according to DINCOS)
  - 11: Destination address pointer is decremented after each data transfer (decrement is done according to DINCOS)

  These bits are protected and can be written only if EN is 0

  **Note:** When destination is AHB (DBUS=1), DINC = 00 is forbidden.

Bits 1:0 **SINC[1:0]**: Source increment mode
- These bits are set and cleared by software.
  - 00: Source address pointer is fixed
  - 10: Source address pointer is incremented after each data transfer (increment is done according to SINCOS)
  - 11: Source address pointer is decremented after each data transfer (decrement is done according to SINCOS)

  These bits are protected and can be written only if EN is 0

  **Note:** When source is AHB (SBUS=1), SINC = 00 is forbidden.
Bits 31:20 **BRC[11:0]: Block Repeat Count**

This field contains the number of repetitions of the current block (0 to 4095). When the channel is enabled, this register is read-only, indicating the remaining number of blocks, excluding the current one. This register decrements after each complete block transfer. Once the last block transfer has completed, this register can either stay at zero or be reloaded automatically from memory (in Linked List mode - i.e. Link Address valid).

These bits are protected and can be written only if EN is 0.

Bit 19 **BRDUM: Block Repeat Destination address Update Mode**

0: At the end of a Block transfer, the DAR register will be updated by adding the DUV to the current DAR value (current Destination Address)

1: At the end of a block transfer, the DAR register will be updated by subtracting the DUV from the current DAR value (current Destination Address)

These bits are protected and can be written only if EN is 0.

Bit 18 **BRSUM: Block Repeat Source address Update Mode**

0: At the end of a block transfer, the SAR register will be updated by adding the SUV to the current SAR value (current Source Address)

1: At the end of a block transfer, the SAR register will be updated by subtracting the SUV from the current SAR value (current Source Address)

These bits are protected and can be written only if EN is 0.

Bit 17 **Reserved, must be kept at reset value.**

Bits 16:0 **BNDT[16:0]: Block Number of data bytes to transfer**

Number of bytes to be transferred (0 up to 65536) in the current block. When the channel is enabled, this register is read-only, indicating the remaining data items to be transmitted. During the channel activity, this register decrements, indicating the number of data items remaining in the current block.

Once the block transfer has completed, this register can either stay at zero or be reloaded automatically with the previously programmed value if the channel is configured in block Repeat mode.

If the value of this register is zero, no transaction can be served even if the stream is enabled.

These bits are protected and can be written only if EN is 0.

**Note:** 1: If the BNDT value is not an integer multiple of the TLEN+1 value, the last transfer will be shorter and contain only the remaining data in the Block.

**Note:** 2: The size of the block must be a multiple of the source and destination data size. If this is not true, an error will be set and the no data will be written.
13.5.8 MDMA channel x source address register (MDMA_CxSAR)

In Linked List mode, at the end of a Block (single or last Block in repeated Block transfer mode), this register will be loaded from memory (from address given by current LAR[31:0] + 0x08).

Address offset: 0x58 + 0x40 * x, (x = 0 to 15)

Reset value: 0x0000 0000

Bits 31:0 SAR[31:0]: Source address

These bits represent the base address of the peripheral data register from/to which the data will be read. They must be aligned with the SSIZE (e.g. SAR[1:0] = 00 when SSIZE=10), but may be unaligned with the SINCOS.

When source is TCM/AHB, if address is not aligned with SINCOS, access must be programmed as single (SBURST=000).

These bits are write-protected and can be written only when bit EN = ‘0’ in the DMA_SxCR register.

During the channel activity, this register is updated, reflecting the current address from which the data will be read next.

When the block repeat mode is active, when a block transfer is completed, the source address is updated by adding/subtracting the SAU value to the current value (already updated after the last transfer in the block).

When the Linked List mode is active, at the end of a block (repeated or not) transfer, the SAR value will be loaded from memory (from address LSA + m)

13.5.9 MDMA channel x destination address register (MDMA_CxDAR)

In Linked List mode, at the end of a block (single or last block in repeated block transfer mode), this register will be loaded from memory (from address given by current LAR[31:0] + 0x0C).

Address offset: 0x5C + 0x40 * x, (x = 0 to 15)

Reset value: 0x0000 0000

DAR[15:0]
Bits 31:0 **DAR[31:0]: Destination address**

Base address of the destination address to which the data will be written.

These bits are write-protected and can be written only when bit EN = '0' in the DMA_SxCR register.

Must be aligned with the DSIZE (e.g. DAR[0] = 0 when DSIZE=01), but may be unaligned with the DINCOS.

When destination is AHB, if address is not aligned with DINCOS, access must be programmed as single (DBURST=000).

During the channel activity, this register is updated, reflecting the current address to which the data will be written next.

When the block repeat mode is active, when a block transfer is completed, the Destination address is updated by adding/subtracting the DAU value to the current value (after the last transfer in the block).

When the Linked List mode is active, at the end of a block (repeated or not) transfer, the DAR value will be loaded from memory (from address LSA + m)
MDMA channel x block repeat address update register (MDMA_CxBRUR)

In Linked List mode, at the end of a block (single or last block in repeated block transfer mode), this register will be loaded from memory (from address given by current LAR[31:0] + 0x10).

Address offset: 0x60 + 0x40 * x, (x = 0 to 15)

Reset value: 0x0000 0000

</tbody>
</table>

Bits 31:16 **DUV[15:0]**: Destination address Update Value

This value is used to update (by addition or subtraction) the current destination address at the end of a block transfer. Must be an integer multiple of DSIZE, in order to keep DAR aligned to DSIZE (e.g. DAR[1:0] = 00 when DSIZE=10).

If this value is 0, the next repetition of the block transfer will continue to the next address.

When the block repeat mode is not active (BRC=0), this field is ignored.

These bits are write-protected and can be written only when bit EN = '0' in the MDMA_CxCR register.

**Note:** This field must be programmed to 0 when DINC[1:0] = 00.

Bits 15:0 **SUV[15:0]**: Source address Update Value

This value is used to update (by addition or subtraction) the current source address at the end of a block transfer. Must be an integer multiple of SSIZE, in order to keep SAR aligned to SSIZE (e.g. SAR[1:0] = 00 when SSIZE=10).

If this value is 0, the next repetition of the block transfer will continue from the next address.

When the block repeat mode is not active (BRC=0), this field is ignored.

These bits are write-protected and can be written only when bit EN = '0' in the MDMA_CxCR register.

**Note:** This field must be programmed to 0 when SINC[1:0] = 00.
13.5.11 MDMA channel x link address register (MDMA_CxLAR)

In Linked List mode, at the end of a block (single or last block in repeated block transfer mode), this register will be loaded from memory (from address given by current LAR[31:0] + 0x14).

*Note:* The new value is only taken into account after all registers are updated, for the next end of block.

Address offset: 0x64 + 0x40 * x, (x = 0 to 15)

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bits 31:0</th>
<th>LAR[31:0]: Link Address Register</th>
</tr>
</thead>
</table>
| At the end of a (repeated) block Transfer, the current channel configuration registers (CxTCR, CxBDTR, CxSAR, CxDR, CxBRUR, CxMAR, CxMDR and the CxLAR register itself) are loaded with the data structure found at this address.
| If the value of this register is 0, no register update will take place, the channel will be disabled and the CTCIF will be set, indicating the end of the transfer for this channel. These bits are write-protected and can be written only when bit EN = '0' in the MDMA_CxCR register.
| The channel configuration (LAR address) must be in the AXI address space.
| LAR value must be aligned at a Double Word address, i.e. LAR[2:0] = 0x0 |
13.5.12 MDMA channel x trigger and bus selection register (MDMA_CxTBR)

In Linked List mode, at the end of a block (single or last block in repeated block transfer mode), this register will be loaded from memory (from address given by current LAR[31:0] + 0x18).

Address offset: 0x68 + 0x40 * x, (x = 0 to 15)

Reset value: 0x0000 0000

| Bit 31:18 Reserved, must be kept at reset value. |
| Bit 17 **DBUS**: Destination BUS select |
| 0: The system/AXI bus is used as destination (write operation) on channel x. |
| 1: The AHB bus/TCM is used as destination (write operation) on channel x. |
| This bit is protected and can be written only if EN is 0. |
| Bit 16 **SBUS**: Source BUS select |
| 0: The system/AXI bus is used as source (read operation) on channel x. |
| 1: The AHB bus/TCM is used as source (read operation) on channel x. |
| This bit is protected and can be written only if EN is 0. |
| Bits 15:6 Reserved, must be kept at reset value. |
| Bits 5:0 **TSEL[5:0]**: Trigger Selection |
| This bit field selects the hardware trigger (RQ) input for channel x. The ACK is sent on the ACK output having the same index value. |
| When SWRM bit is set (software request selected), this bit field is ignored. |
| These bits are write-protected and can be written only when bit EN = '0' in the MDMA_CxCR register. |

*Note: If multiple channels are triggered by the same event (have the same TSEL value), all of them will be triggered in parallel. However, only the channel with the lowest index will acknowledge the request.*
13.5.13 MDMA channel x mask address register (MDMA_CxMAR)

In Linked List mode, at the end of a block (single or last block in repeated block transfer mode), this register will be loaded from memory (from address given by current LAR[31:0] + 0x20).

Address offset: 0x70 + 0x40 * x, (x = 0 to 15)
Reset value: 0x0000 0000

14 Direct memory access controller (DMA)

14.1 DMA introduction

Direct memory access (DMA) is used in order to provide high-speed data transfer between peripherals and memory and between memory and memory. Data can be quickly moved by DMA without any CPU action. This keeps CPU resources free for other operations.

The DMA controller combines a powerful dual AHB master bus architecture with independent FIFO to optimize the bandwidth of the system, based on a complex bus matrix architecture.

The two DMA controllers (DMA1 and DMA2) have 16 streams in total (8 for each controller), each dedicated to managing memory access requests from one or more peripherals.

Each DMA stream is driven by one DMAMUX1 output channel (request). Any DMAMUX1 output request can be individually programmed in order to select the DMA request source signal, from any of the 115 available request input signals.

Refer to the Section 16.3: DMAMUX implementation for more information about the DMA requests and streams mapping.

Each DMA controller has an arbiter for handling the priority between DMA requests.

14.2 DMA main features

The main DMA features are:

- Dual AHB master bus architecture, one dedicated to memory accesses and one dedicated to peripheral accesses
- AHB slave programming interface supporting only 32-bit accesses
- 8 streams for each DMA controller, up to 115 channels (requests) per stream
- Four-word depth 32 first-in, first-out memory buffers (FIFOs) per stream, that can be used in FIFO mode or direct mode:
  - FIFO mode: with threshold level software selectable between 1/4, 1/2 or 3/4 of the FIFO size
  - Direct mode: each DMA request immediately initiates a transfer from/to the memory. When it is configured in direct mode (FIFO disabled), to transfer data in memory-to-peripheral mode, the DMA preloads only one data from the memory to the internal FIFO to ensure an immediate data transfer as soon as a DMA request is triggered by a peripheral.
- Each stream can be configured to be:
  - a regular channel that supports peripheral-to-memory, memory-to-peripheral and memory-to-memory transfers
  - a double buffer channel that also supports double buffering on the memory side
- Priorities between DMA stream requests are software-programmable (4 levels consisting of very high, high, medium, low) or hardware in case of equality (for example, request 0 has priority over request 1)
- Each stream also supports software trigger for memory-to-memory transfers
Each stream request can be selected among up to 115 possible channel requests. This selection is software-configurable by the DMAMUX1 and allows 107 peripherals to initiate DMA requests.

The number of data items to be transferred can be managed either by the DMA controller or by the peripheral:

- DMA flow controller: the number of data items to be transferred is software-programmable from 1 to 65535
- Peripheral flow controller: the number of data items to be transferred is unknown and controlled by the source or the destination peripheral that signals the end of the transfer by hardware

Independent source and destination transfer width (byte, half-word, word): when the data widths of the source and destination are not equal, the DMA automatically packs/unpacks the necessary transfers to optimize the bandwidth. This feature is only available in FIFO mode.

Incrementing or non-incrementing addressing for source and destination.

Supports incremental burst transfers of 4, 8 or 16 beats. The size of the burst is software-configurable, usually equal to half the FIFO size of the peripheral.

Each stream supports circular buffer management.

5 event flags (DMA half transfer, DMA transfer complete, DMA transfer error, DMA FIFO error, direct mode error) logically ORed together in a single interrupt request for each stream.
14.3 DMA functional description

14.3.1 DMA block diagram

14.3.3 DMA overview

The DMA controller performs direct memory transfer: as an AHB master, it can take the control of the AHB bus matrix to initiate AHB transactions.

It carries out the following transactions:
- peripheral-to-memory
- memory-to-peripheral
- memory-to-memory

The DMA controller provides two AHB master ports: the AHB memory port, intended to be connected to memories and the AHB peripheral port, intended to be connected to peripherals. However, to allow memory-to-memory transfers, the AHB peripheral port must also have access to the memories.

The AHB slave port is used to program the DMA controller (it supports only 32-bit accesses).

14.3.4 DMA transactions

A DMA transaction consists of a sequence of a given number of data transfers. The number of data items to be transferred and their width (8-bit, 16-bit or 32-bit) are software-programmable.

Each DMA transfer consists of three operations:
- a loading from the peripheral data register or a location in memory, addressed through the DMA_SxPAR or DMA_SxM0AR register
- a storage of the data loaded to the peripheral data register or a location in memory addressed through the DMA_SxPAR or DMA_SxM0AR register
- a post-decrement of the DMA_SxNDTR register, containing the number of transactions that still have to be performed

After an event, the peripheral sends a request signal to the DMA controller. The DMA controller serves the request depending on the channel priorities. As soon as the DMA controller accesses the peripheral, an Acknowledge signal is sent to the peripheral by the DMA controller. The peripheral releases its request as soon as it gets the Acknowledge signal from the DMA controller. Once the request has been deasserted by the peripheral, the DMA controller releases the Acknowledge signal. If there are more requests, the peripheral can initiate the next transaction.

14.3.5 DMA request mapping

The DMA request mapping from peripherals to DMA streams is described in Section 16.3.2: DMAMUX1 mapping.
14.3.6 Arbiter

An arbiter manages the 8 DMA stream requests based on their priority for each of the two AHB master ports (memory and peripheral ports) and launches the peripheral/memory access sequences.

Priorities are managed in two stages:
- Software: each stream priority can be configured in the DMA_SxCR register. There are four levels:
  - Very high priority
  - High priority
  - Medium priority
  - Low priority
- Hardware: If two requests have the same software priority level, the stream with the lower number takes priority over the stream with the higher number. For example, stream 2 takes priority over stream 4.

14.3.7 DMA streams

Each of the 8 DMA controller streams provides a unidirectional transfer link between a source and a destination.

Each stream can be configured to perform:
- Regular type transactions: memory-to-peripherals, peripherals-to-memory or memory-to-memory transfers
- Double-buffer type transactions: double buffer transfers using two memory pointers for the memory (while the DMA is reading/writing from/to a buffer, the application can write/read to/from the other buffer).

The amount of data to be transferred (up to 65535) is programmable and related to the source width of the peripheral that requests the DMA transfer connected to the peripheral AHB port. The register that contains the amount of data items to be transferred is decremented after each transaction.

14.3.8 Source, destination and transfer modes

Both source and destination transfers can address peripherals and memories in the entire 4 Gbytes area, at addresses comprised between 0x0000 0000 and 0xFFFF FFFF.

The direction is configured using the DIR[1:0] bits in the DMA_SxCR register and offers three possibilities: memory-to-peripheral, peripheral-to-memory or memory-to-memory transfers. Table 102 describes the corresponding source and destination addresses.

<table>
<thead>
<tr>

</tbody>
</table>
When the data width (programmed in the PSIZE or MSIZE bits in the DMA_SxCR register) is a half-word or a word, respectively, the peripheral or memory address written into the DMA_SxPAR or DMA_SxM0AR/M1AR registers has to be aligned on a word or half-word address boundary, respectively.

**Peripheral-to-memory mode**

*Figure 76* describes this mode.

When this mode is enabled (by setting the bit EN in the DMA_SxCR register), each time a peripheral request occurs, the stream initiates a transfer from the source to fill the FIFO.

When the threshold level of the FIFO is reached, the contents of the FIFO are drained and stored into the destination.

The transfer stops once the DMA_SxNDTR register reaches zero, when the peripheral requests the end of transfers (in case of a peripheral flow controller) or when the EN bit in the DMA_SxCR register is cleared by software.

In direct mode (when the DMDIS value in the DMA_SxFCR register is ‘0’), the threshold level of the FIFO is not used: after each single data transfer from the peripheral to the FIFO, the corresponding data are immediately drained and stored into the destination.

The stream has access to the AHB source or destination port only if the arbitration of the corresponding stream is won. This arbitration is performed using the priority defined for each stream using the PL[1:0] bits in the DMA_SxCR register.

*Figure 76. Peripheral-to-memory mode*

1. For double-buffer mode.
Memory-to-peripheral mode

Figure 77 describes this mode.

When this mode is enabled (by setting the EN bit in the DMA_SxCR register), the stream immediately initiates transfers from the source to entirely fill the FIFO.

Each time a peripheral request occurs, the contents of the FIFO are drained and stored into the destination. When the level of the FIFO is lower than or equal to the predefined threshold level, the FIFO is fully reloaded with data from the memory.

The transfer stops once the DMA_SxNDTR register reaches zero, when the peripheral requests the end of transfers (in case of a peripheral flow controller) or when the EN bit in the DMA_SxCR register is cleared by software.

In direct mode (when the DMDIS value in the DMA_SxFCR register is '0'), the threshold level of the FIFO is not used. Once the stream is enabled, the DMA preloads the first data to transfer into an internal FIFO. As soon as the peripheral requests a data transfer, the DMA transfers the preloaded value into the configured destination. It then reloads again the empty internal FIFO with the next data to be transfer. The preloaded data size corresponds to the value of the PSIZE bitfield in the DMA_SxCR register.

The stream has access to the AHB source or destination port only if the arbitration of the corresponding stream is won. This arbitration is performed using the priority defined for each stream using the PL[1:0] bits in the DMA_SxCR register.

Figure 77. Memory-to-peripheral mode

1. For double-buffer mode.
Memory-to-memory mode

The DMA channels can also work without being triggered by a request from a peripheral. This is the memory-to-memory mode, described in Figure 78.

When the stream is enabled by setting the Enable bit (EN) in the DMA_SxCR register, the stream immediately starts to fill the FIFO up to the threshold level. When the threshold level is reached, the FIFO contents are drained and stored into the destination.

The transfer stops once the DMA_SxNDTR register reaches zero or when the EN bit in the DMA_SxCR register is cleared by software.

The stream has access to the AHB source or destination port only if the arbitration of the corresponding stream is won. This arbitration is performed using the priority defined for each stream using the PL[1:0] bits in the DMA_SxCR register.

Note: When memory-to-memory mode is used, the circular and direct modes are not allowed.

![Figure 78. Memory-to-memory mode](image.png)

1. For double-buffer mode.

14.3.9 Pointer incrementation

Peripheral and memory pointers can optionally be automatically post-incremented or kept constant after each transfer depending on the PINC and MINC bits in the DMA_SxCR register.

Disabling the increment mode is useful when the peripheral source or destination data is accessed through a single register.

If the increment mode is enabled, the address of the next transfer is the address of the previous one incremented by 1 (for bytes), 2 (for half-words) or 4 (for words) depending on the data width programmed in the PSIZE or MSIZE bits in the DMA_SxCR register.
In order to optimize the packing operation, it is possible to fix the increment offset size for the peripheral address whatever the size of the data transferred on the AHB peripheral port. The PINCOS bit in the DMA_SxCR register is used to align the increment offset size with the data size on the peripheral AHB port, or on a 32-bit address (the address is then incremented by 4). The PINCOS bit has an impact on the AHB peripheral port only.

If the PINCOS bit is set, the address of the following transfer is the address of the previous one incremented by 4 (automatically aligned on a 32-bit address), whatever the PSIZE value. The AHB memory port, however, is not impacted by this operation.

### 14.3.10 Circular mode

The circular mode is available to handle circular buffers and continuous data flows (e.g. ADC scan mode). This feature can be enabled using the CIRC bit in the DMA_SxCR register.

When the circular mode is activated, the number of data items to be transferred is automatically reloaded with the initial value programmed during the stream configuration phase, and the DMA requests continue to be served.

**Note:** In the circular mode, it is mandatory to respect the following rule in case of a burst mode configured for memory:

\[
\text{DMA}_x\text{NDTR} = \text{Multiple of } ((\text{Mburst beat}) \times (\text{Msize})/(\text{Psize})), \text{ where:}
\]

- \((\text{Mburst beat}) = 4, 8 \text{ or } 16 \text{ (depending on the MBURST bits in the DMA_SxCR register)}\)
- \((\text{Msize})/(\text{Psize}) = 1, 2, 4, 1/2 \text{ or } 1/4 \text{ (Msize and Psize represent the MSIZE and PSIZE bits in the DMA_SxCR register. They are byte dependent)}\)
- \(\text{DMA}_x\text{NDTR} = \text{Number of data items to transfer on the AHB peripheral port}\)

For example: \(\text{Mburst beat} = 8 \text{ (INCR8), MSIZE = '00' (byte) and PSIZE = '01' (half-word), in this case: } \text{DMA}_x\text{NDTR must be a multiple of } (8 \times 1/2 = 4)\).

If this formula is not respected, the DMA behavior and data integrity are not guaranteed.

**NDTR must also be a multiple of the Peripheral burst size multiplied by the peripheral data size, otherwise this could result in a bad DMA behavior.**

### 14.3.11 Double-buffer mode

This mode is available for all the DMA1 and DMA2 streams.

The double-buffer mode is enabled by setting the DBM bit in the DMA_SxCR register.

A double-buffer stream works as a regular (single buffer) stream with the difference that it has two memory pointers. When the double-buffer mode is enabled, the circular mode is automatically enabled (CIRC bit in DMA_SxCR is not relevant) and at each end of transaction, the memory pointers are swapped.

In this mode, the DMA controller swaps from one memory target to another at each end of transaction. This allows the software to process one memory area while the second memory area is being filled/used by the DMA transfer. The double-buffer stream can work in both directions (the memory can be either the source or the destination) as described in **Table 103: Source and destination address registers in double-buffer mode (DBM = 1).**
Note: In double-buffer mode, it is possible to update the base address for the AHB memory port on-the-fly (DMA_SxM0AR or DMA_SxM1AR) when the stream is enabled, by respecting the following conditions:

- When the CT bit is ‘0’ in the DMA_SxCR register, the DMA_SxM1AR register can be written. Attempting to write to this register while CT = ‘1’ sets an error flag (TEIF) and the stream is automatically disabled.
- When the CT bit is ‘1’ in the DMA_SxCR register, the DMA_SxM0AR register can be written. Attempting to write to this register while CT = ‘0’, sets an error flag (TEIF) and the stream is automatically disabled.

To avoid any error condition, it is advised to change the base address as soon as the TCIF flag is asserted because, at this point, the targeted memory must have changed from memory 0 to 1 (or from 1 to 0) depending on the value of CT in the DMA_SxCR register in accordance with one of the two above conditions.

For all the other modes (except the double-buffer mode), the memory address registers are write-protected as soon as the stream is enabled.

### Table 103. Source and destination address registers in double-buffer mode (DBM = 1)

1. When the double-buffer mode is enabled, the circular mode is automatically enabled. Since the memory-to-memory mode is not compatible with the circular mode, when the double-buffer mode is enabled, it is not allowed to configure the memory-to-memory mode.

### 14.3.12 Programmable data width, packing/unpacking, endianness

The number of data items to be transferred has to be programmed into DMA_SxNDTR (number of data items to transfer bit, NDT) before enabling the stream (except when the flow controller is the peripheral, PFCTRL bit in DMA_SxCR is set).

When using the internal FIFO, the data widths of the source and destination data are programmable through the PSIZE and MSIZE bits in the DMA_SxCR register (can be 8-, 16- or 32-bit).

When PSIZE and MSIZE are not equal:

- The data width of the number of data items to transfer, configured in the DMA_SxNDTR register is equal to the width of the peripheral bus (configured by the PSIZE bits in the DMA_SxCR register). For instance, in case of peripheral-to-memory, memory-to-peripheral or memory-to-memory transfers and if the PSIZE[1:0] bits are configured for half-word, the number of bytes to be transferred is equal to $2 \times NDT$.
- The DMA controller only copes with little-endian addressing for both source and destination. This is described in Table 104: Packing/unpacking and endian behavior (bit PINC = MINC = 1).

This packing/unpacking procedure may present a risk of data corruption when the operation is interrupted before the data are completely packed/unpacked. So, to ensure data coherence, the stream may be configured to generate burst transfers: in this case, each
group of transfers belonging to a burst are indivisible (refer to Section 14.3.13: Single and burst transfers).

In direct mode (DMDIS = 0 in the DMA_SxFCR register), the packing/unpacking of data is not possible. In this case, it is not allowed to have different source and destination transfer data widths: both are equal and defined by the PSIZE bits in the DMA_SxFCR register. MSIZE bits are not relevant.

</tbody>
</table>

Note: Peripheral port may be the source or the destination (it could also be the memory source in the case of memory-to-memory transfer).

PSIZE, MSIZE and NDT[15:0] have to be configured so as to ensure that the last transfer will not be incomplete. This can occur when the data width of the peripheral port (PSIZE bits) is lower than the data width of the memory port (MSIZE bits). This constraint is summarized in Table 105.
14.3.13 Single and burst transfers

The DMA controller can generate single transfers or incremental burst transfers of 4, 8 or 16 beats.

The size of the burst is configured by software independently for the two AHB ports by using the MBURST[1:0] and PBURST[1:0] bits in the DMA_SxCR register.

The burst size indicates the number of beats in the burst, not the number of bytes transferred.

To ensure data coherence, each group of transfers that form a burst are indivisible: AHB transfers are locked and the arbiter of the AHB bus matrix does not degrant the DMA master during the sequence of the burst transfer.

Depending on the single or burst configuration, each DMA request initiates a different number of transfers on the AHB peripheral port:

- When the AHB peripheral port is configured for single transfers, each DMA request generates a data transfer of a byte, half-word or word depending on the PSIZE[1:0] bits in the DMA_SxCR register
- When the AHB peripheral port is configured for burst transfers, each DMA request generates 4, 8 or 16 beats of byte, half word or word transfers depending on the PBURST[1:0] and PSIZE[1:0] bits in the DMA_SxCR register.

The same as above has to be considered for the AHB memory port considering the MBURST and MSIZE bits.

In direct mode, the stream can only generate single transfers and the MBURST[1:0] and PBURST[1:0] bits are forced by hardware.

The address pointers (DMA_SxPAR or DMA_SxM0AR registers) must be chosen so as to ensure that all transfers within a burst block are aligned on the address boundary equal to the size of the transfer.

The burst configuration has to be selected in order to respect the AHB protocol, where bursts **must not** cross the 1 Kbyte address boundary because the minimum address space that can be allocated to a single slave is 1 Kbyte. This means that the 1 Kbyte address boundary **must not** be crossed by a burst block transfer, otherwise an AHB error is generated, that is not reported by the DMA registers.

14.3.14 FIFO

FIFO structure

The FIFO is used to temporarily store data coming from the source before transmitting them to the destination.

Each stream has an independent 4-word FIFO and the threshold level is software-configurable between 1/4, 1/2, 3/4 or full.

To enable the use of the FIFO threshold level, the direct mode must be disabled by setting the DMDIS bit in the DMA_SxFCR register.

The structure of the FIFO differs depending on the source and destination data widths, and is described in Figure 79: FIFO structure.

Figure 79. FIFO structure

![FIFO Structure Diagram]
FIFO threshold and burst configuration

Caution is required when choosing the FIFO threshold (bits FTH[1:0] of the DMA_SxFCR register) and the size of the memory burst (MBURST[1:0] of the DMA_SxCR register): The content pointed by the FIFO threshold must exactly match an integer number of memory burst transfers. If this is not in the case, a FIFO error (flag FEIFx of the DMA_HISR or DMA_LISR register) is generated when the stream is enabled, then the stream is automatically disabled. The allowed and forbidden configurations are described in Table 106. The forbidden configurations are highlighted in gray in the table.

In all cases, the burst size multiplied by the data size must not exceed the FIFO size (data size can be: 1 (byte), 2 (half-word) or 4 (word)).

Incomplete burst transfer at the end of a DMA transfer may happen if one of the following conditions occurs:

- For the AHB peripheral port configuration: the total number of data items (set in the DMA_SxNDTR register) is not a multiple of the burst size multiplied by the data size.
- For the AHB memory port configuration: the number of remaining data items in the FIFO to be transferred to the memory is not a multiple of the burst size multiplied by the data size.

In such cases, the remaining data to be transferred is managed in single mode by the DMA, even if a burst transaction is requested during the DMA stream configuration.

Note: When burst transfers are requested on the peripheral AHB port and the FIFO is used (DMDIS = 1 in the DMA_SxCR register), it is mandatory to respect the following rule to avoid permanent underrun or overrun conditions, depending on the DMA stream direction:

If \( (PBURST \times PSIZE) = FIFO\_SIZE \) (4 words), \( FIFO\_Threshold = 3/4 \) is forbidden with \( PSIZE = 1, 2 \) or 4 and \( PBURST = 4, 8 \) or 16.

This rule ensures that enough FIFO space at a time is free to serve the request from the peripheral.
**FIFO flush**

The FIFO can be flushed when the stream is disabled by resetting the EN bit in the DMA_SxCR register and when the stream is configured to manage peripheral-to-memory or memory-to-memory transfers. If some data are still present in the FIFO when the stream is disabled, the DMA controller continues transferring the remaining data to the destination (even though stream is effectively disabled). When this flush is completed, the transfer complete status bit (TCIFx) in the DMA_LISR or DMA_HISR register is set.

The remaining data counter DMA_SxNDTR keeps the value in this case to indicate how many data items are currently available in the destination memory.

Note that during the FIFO flush operation, if the number of remaining data items in the FIFO to be transferred to memory (in bytes) is less than the memory data width (for example 2 bytes in FIFO while MSIZE is configured to word), data is sent with the data width set in the MSIZE bit in the DMA_SxCR register. This means that memory is written with an undesired value. The software may read the DMA_SxNDTR register to determine the memory area that contains the good data (start address and last address).

If the number of remaining data items in the FIFO is lower than a burst size (if the MBURST bits in DMA_SxCR register are set to configure the stream to manage burst on the AHB memory port), single transactions are generated to complete the FIFO flush.

**Direct mode**

By default, the FIFO operates in direct mode (DMDIS bit in the DMA_SxFCR is reset) and the FIFO threshold level is not used. This mode is useful when the system requires an immediate and single transfer to or from the memory after each DMA request.

When the DMA is configured in direct mode (FIFO disabled), to transfer data in memory-to-peripheral mode, the DMA preloads one data from the memory to the internal FIFO to ensure an immediate data transfer as soon as a DMA request is triggered by a peripheral.

To avoid saturating the FIFO, it is recommended to configure the corresponding stream with a high priority.

This mode is restricted to transfers where:

- the source and destination transfer widths are equal and both defined by the PSIZE[1:0] bits in DMA_SxCR (MSIZE[1:0] bits are not relevant)
- burst transfers are not possible (PBURST[1:0] and MBURST[1:0] bits in DMA_SxCR are don’t care)

Direct mode must not be used when implementing memory-to-memory transfers.

### 14.3.15 DMA transfer completion

Different events can generate an end of transfer by setting the TCIFx bit in the DMA_LISR or DMA_HISR status register:

- In DMA flow controller mode:
  - The DMA_SxNDTR counter has reached zero in the memory-to-peripheral mode.
  - The stream is disabled before the end of transfer (by clearing the EN bit in the DMA_SxCR register) and (when transfers are peripheral-to-memory or memory-
to-memory) all the remaining data have been flushed from the FIFO into the memory.

- In Peripheral flow controller mode:
  - The last external burst or single request has been generated from the peripheral and (when the DMA is operating in peripheral-to-memory mode) the remaining data have been transferred from the FIFO into the memory.
  - The stream is disabled by software, and (when the DMA is operating in peripheral-to-memory mode) the remaining data have been transferred from the FIFO into the memory.

**Note:** The transfer completion is dependent on the remaining data in FIFO to be transferred into memory only in the case of peripheral-to-memory mode. This condition is not applicable in memory-to-peripheral mode.

If the stream is configured in noncircular mode, after the end of the transfer (that is when the number of data to be transferred reaches zero), the DMA is stopped (EN bit in DMA_SxCR register is cleared by Hardware) and no DMA request is served unless the software reprograms the stream and re-enables it (by setting the EN bit in the DMA_SxCR register).

### 14.3.16 DMA transfer suspension

At any time, a DMA transfer can be suspended to be restarted later on or to be definitively disabled before the end of the DMA transfer.

There are two cases:

- The stream disables the transfer with no later-on restart from the point where it was stopped. There is no particular action to do, except to clear the EN bit in the DMA_SxCR register to disable the stream. The stream may take time to be disabled (ongoing transfer is completed first). The transfer complete interrupt flag (TCIF in the DMA_LISR or DMA_HISR register) is set in order to indicate the end of transfer. The value of the EN bit in DMA_SxCR is now '0' to confirm the stream interruption. The DMA_SxNDTR register contains the number of remaining data items at the moment when the stream was stopped so that the software can determine how many data items have been transferred before the stream was interrupted.

- The stream suspends the transfer before the number of remaining data items to be transferred in the DMA_SxNDTR register reaches 0. The aim is to restart the transfer later by re-enabling the stream. In order to restart from the point where the transfer was stopped, the software has to read the DMA_SxNDTR register after disabling the stream by writing the EN bit in DMA_SxCR register (and then checking that it is at '0') to know the number of data items already collected. Then:
  - The peripheral and/or memory addresses have to be updated in order to adjust the address pointers.
  - The SxNDTR register has to be updated with the remaining number of data items to be transferred (the value read when the stream was disabled).
  - The stream may then be re-enabled to restart the transfer from the point it was stopped.

**Note:** A transfer complete interrupt flag (TCIF in DMA_LISR or DMA_HISR) is set to indicate the end of transfer due to the stream interruption.
14.3.17 Flow controller

The entity that controls the number of data to be transferred is known as the flow controller. This flow controller is configured independently for each stream using the PFCTRL bit in the DMA_SxCR register.

The flow controller can be:

- The DMA controller: in this case, the number of data items to be transferred is programmed by software into the DMA_SxNDTR register before the DMA stream is enabled.
- The peripheral source or destination: this is the case when the number of data items to be transferred is unknown. The peripheral indicates by hardware to the DMA controller when the last data are being transferred. This feature is only supported for peripherals that are able to signal the end of the transfer.

When the peripheral flow controller is used for a given stream, the value written into the DMA_SxNDTR has no effect on the DMA transfer. Actually, whatever the value written, it will be forced by hardware to 0xFFFF as soon as the stream is enabled, to respect the following schemes:

- Anticipated stream interruption: EN bit in DMA_SxCR register is reset to 0 by the software to stop the stream before the last data hardware signal (single or burst) is sent by the peripheral. In such a case, the stream is switched off and the FIFO flush is triggered in the case of a peripheral-to-memory DMA transfer. The TCIFx flag of the corresponding stream is set in the status register to indicate the DMA completion. To know the number of data items transferred during the DMA transfer, read the DMA_SxNDTR register and apply the following formula:
  \[ \text{Number of data transferred} = 0xFFFF - \text{DMA_SxNDTR} \]

- Normal stream interruption due to the reception of a last data hardware signal: the stream is automatically interrupted when the peripheral requests the last transfer (single or burst) and when this transfer is complete. the TCIFx flag of the corresponding stream is set in the status register to indicate the DMA transfer completion. To know the number of data items transferred, read the DMA_SxNDTR register and apply the same formula as above.

- The DMA_SxNDTR register reaches 0: the TCIFx flag of the corresponding stream is set in the status register to indicate the forced DMA transfer completion. The stream is automatically switched off even though the last data hardware signal (single or burst) has not been yet asserted. The already transferred data is not lost. This means that a maximum of 65535 data items can be managed by the DMA in a single transaction, even in peripheral flow control mode.

Note: When configured in memory-to-memory mode, the DMA is always the flow controller and the PFCTRL bit is forced to 0 by hardware.

The circular mode is forbidden in the peripheral flow controller mode.
14.3.18  Summary of the possible DMA configurations

Table 107 summarizes the different possible DMA configurations. The forbidden
configurations are highlighted in gray in the table.

14.3.19  Stream configuration procedure

The following sequence must be followed to configure a DMA stream x (where x is the
stream number):

1. If the stream is enabled, disable it by resetting the EN bit in the DMA_SxCR register,
then read this bit in order to confirm that there is no ongoing stream operation. Writing
this bit to 0 is not immediately effective since it is actually written to 0 once all the
current transfers are finished. When the EN bit is read as 0, this means that the stream
is ready to be configured. It is therefore necessary to wait for the EN bit to be cleared
before starting any stream configuration. All the stream dedicated bits set in the status
register (DMA_LISR and DMA_HISR) from the previous data block DMA transfer must
be cleared before the stream can be re-enabled.

2. Set the peripheral port register address in the DMA_SxPAR register. The data is moved
from/ to this address to/ from the peripheral port after the peripheral event.

3. Set the memory address in the DMA_SxMA0R register (and in the DMA_SxMA1R
register in the case of a double-buffer mode). The data is written to or read from this
memory after the peripheral event.

4. Configure the total number of data items to be transferred in the DMA_SxNDTR
register. After each peripheral event or each beat of the burst, this value is
decrementd.

5. Use DMAMUX1 to route a DMA request line to the DMA channel.

6. If the peripheral is intended to be the flow controller and if it supports this feature, set
the PFCTRL bit in the DMA_SxCR register.

7. Configure the stream priority using the PL[1:0] bits in the DMA_SxCR register.

8. Configure the FIFO usage (enable or disable, threshold in transmission and reception)
9. Configure the data transfer direction, peripheral and memory incremented/fixed mode, single or burst transactions, peripheral and memory data widths, circular mode, double-buffer mode and interrupts after half and/or full transfer, and/or errors in the DMA_SxCR register.

10. Activate the stream by setting the EN bit in the DMA_SxCR register.

As soon as the stream is enabled, it can serve any DMA request from the peripheral connected to the stream.

Once half the data have been transferred on the AHB destination port, the half-transfer flag (HTIF) is set and an interrupt is generated if the half-transfer interrupt enable bit (HTIE) is set. At the end of the transfer, the transfer complete flag (TCIF) is set and an interrupt is generated if the transfer complete interrupt enable bit (TCIE) is set.

**Warning:** To switch off a peripheral connected to a DMA stream request, it is mandatory to, first, switch off the DMA stream to which the peripheral is connected, then to wait for EN bit = 0. Only then can the peripheral be safely disabled.

### 14.3.20 Error management

The DMA controller can detect the following errors:

- **Transfer error**: the transfer error interrupt flag (TEIFx) is set when:
  - a bus error occurs during a DMA read or a write access
  - a write access is requested by software on a memory address register in double-buffer mode whereas the stream is enabled and the current target memory is the one impacted by the write into the memory address register (refer to Section 14.3.11: Double-buffer mode)

- **FIFO error**: the FIFO error interrupt flag (FEIFx) is set if:
  - a FIFO underrun condition is detected
  - a FIFO overrun condition is detected (no detection in memory-to-memory mode because requests and transfers are internally managed by the DMA)
  - the stream is enabled while the FIFO threshold level is not compatible with the size of the memory burst (refer to Table 106: FIFO threshold configurations)

- **Direct mode error**: the direct mode error interrupt flag (DMEIFx) can only be set in the peripheral-to-memory mode while operating in direct mode and when the MINC bit in the DMA_SxCR register is cleared. This flag is set when a DMA request occurs while the previous data have not yet been fully transferred into the memory (because the memory bus was not granted). In this case, the flag indicates that 2 data items were transferred successively to the same destination address, which could be an issue if the destination is not able to manage this situation.

In direct mode, the FIFO error flag can also be set under the following conditions:

- **In the peripheral-to-memory mode**, the FIFO can be saturated (overrun) if the memory bus is not granted for several peripheral requests.
- **In the memory-to-peripheral mode**, an underrun condition may occur if the memory bus has not been granted before a peripheral request occurs.
If the TEIFx or the FEIFx flag is set due to incompatibility between burst size and FIFO threshold level, the faulty stream is automatically disabled through a hardware clear of its EN bit in the corresponding stream configuration register (DMA_SxCR).

If the DMEIFx or the FEIFx flag is set due to an overrun or underrun condition, the faulty stream is not automatically disabled and it is up to the software to disable or not the stream by resetting the EN bit in the DMA_SxCR register. This is because there is no data loss when this kind of errors occur.

When the stream's error interrupt flag (TEIF, FEIF, DMEIF) in the DMA_LISR or DMA_HISR register is set, an interrupt is generated if the corresponding interrupt enable bit (TEIE, FEIE, DMIE) in the DMA_SxCR or DMA_SxFCR register is set.

**Note:** When a FIFO overrun or underrun condition occurs, the data is not lost because the peripheral request is not acknowledged by the stream until the overrun or underrun condition is cleared. If this acknowledge takes too much time, the peripheral itself may detect an overrun or underrun condition of its internal buffer and data might be lost.

### 14.4 DMA interrupts

For each DMA stream, an interrupt can be produced on the following events:

- Half-transfer reached
- Transfer complete
- Transfer error
- FIFO error (overrun, underrun or FIFO level error)
- Direct mode error

Separate interrupt enable control bits are available for flexibility as shown in Table 108.

<table>
<thead>
<tr>
<th>Interrupt event</th>
<th>Event flag</th>
<th>Enable control bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Half-transfer</td>

Bits 31:28, 15:12 Reserved, must be kept at reset value.

Bits 27, 21, 11, 5 **TCIF[3:0]**: stream x transfer complete interrupt flag (x = 3..0)
This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA_LIFCR register.
0: no transfer complete event on stream x
1: a transfer complete event occurred on stream x

Bits 26, 20, 10, 4 **HTIF[3:0]**: stream x half transfer interrupt flag (x = 3..0)
This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA_LIFCR register.
0: no half transfer event on stream x
1: a half transfer event occurred on stream x

Bits 25, 19, 9, 3 **TEIF[3:0]**: stream x transfer error interrupt flag (x = 3..0)
This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA_LIFCR register.
0: no transfer error on stream x
1: a transfer error occurred on stream x

Bits 24, 18, 8, 2 **DMEIF[3:0]**: stream x direct error interrupt flag (x = 3..0)
This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA_LIFCR register.
0: No direct mode error on stream x
1: a direct mode error occurred on stream x

Bits 23, 17, 7, 1 Reserved, must be kept at reset value.

Bits 22, 16, 6, 0 **FEIF[3:0]**: stream x FIFO error interrupt flag (x = 3..0)
This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA_LIFCR register.
0: no FIFO error event on stream x
1: a FIFO error event occurred on stream x

Bits 31:28, 15:12 Reserved, must be kept at reset value.

Bits 27, 21, 11, 5 **TCIF[7:4]:** stream x transfer complete interrupt flag (x = 7..4)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA_HIFCR register.

0: no transfer complete event on stream x
1: a transfer complete event occurred on stream x

Bits 26, 20, 10, 4 **HTIF[7:4]:** stream x half transfer interrupt flag (x = 7..4)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA_HIFCR register.

0: no half transfer event on stream x
1: a half transfer event occurred on stream x

Bits 25, 19, 9, 3 **TEIF[7:4]:** stream x transfer error interrupt flag (x = 7..4)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA_HIFCR register.

0: no transfer error on stream x
1: a transfer error occurred on stream x

Bits 24, 18, 8, 2 **DMEIF[7:4]:** stream x direct mode error interrupt flag (x = 7..4)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA_HIFCR register.

0: no direct mode error on stream x
1: a direct mode error occurred on stream x

Bits 23, 17, 7, 1 Reserved, must be kept at reset value.

Bits 22, 16, 6, 0 **FEIF[7:4]:** stream x FIFO error interrupt flag (x = 7..4)

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in the DMA_HIFCR register.

0: no FIFO error event on stream x
1: a FIFO error event occurred on stream x
**14.5.3 DMA low interrupt flag clear register (DMA_LIFCR)**

Bits 31:25 MBURST[1:0]: memory burst transfer configuration
These bits are set and cleared by software.
00: single transfer
01: INCR4 (incremental burst of 4 beats)
10: INCR8 (incremental burst of 8 beats)
11: INCR16 (incremental burst of 16 beats)
These bits are protected and can be written only if EN is ‘0’.
In direct mode, these bits are forced to 0x0 by hardware as soon as bit EN= ‘1’.

Bits 24:23 PBURST[1:0]: peripheral burst transfer configuration
These bits are set and cleared by software.
00: single transfer
01: INCR4 (incremental burst of 4 beats)
10: INCR8 (incremental burst of 8 beats)
11: INCR16 (incremental burst of 16 beats)
These bits are protected and can be written only if EN is ‘0’.
In direct mode, these bits are forced to 0x0 by hardware.

Bit 20 Reserved, must be kept at reset value.

Bit 19 CT: current target (only in double-buffer mode)
This bit is set and cleared by hardware. It can also be written by software.
0: current target memory is Memory 0 (addressed by the DMA_SxM0AR pointer)
1: current target memory is Memory 1 (addressed by the DMA_SxM1AR pointer)
This bit can be written only if EN is ‘0’ to indicate the target memory area of the first transfer.
Once the stream is enabled, this bit operates as a status flag indicating which memory area is the current target.
Bit 18 **DBM**: double-buffer mode

This bit is set and cleared by software.

- 0: no buffer switching at the end of transfer
- 1: memory target switched at the end of the DMA transfer

This bit is protected and can be written only if EN is ‘0’.

Bits 17:16 **PL[1:0]**: priority level

These bits are set and cleared by software.

- 00: low
- 01: medium
- 10: high
- 11: very high

These bits are protected and can be written only if EN is ‘0’.

Bit 15 **PINCOS**: peripheral increment offset size

This bit is set and cleared by software.

- 0: The offset size for the peripheral address calculation is linked to the PSIZE
- 1: The offset size for the peripheral address calculation is fixed to 4 (32-bit alignment).

This bit has no meaning if bit PINC = ‘0’.

This bit is protected and can be written only if EN = ‘0’.

This bit is forced low by hardware when the stream is enabled (bit EN = ‘1’) if the direct mode is selected or if PBURST are different from ‘00’.

Bits 14:13 **MSIZE[1:0]**: memory data size

These bits are set and cleared by software.

- 00: byte (8-bit)
- 01: half-word (16-bit)
- 10: word (32-bit)
- 11: reserved

These bits are protected and can be written only if EN is ‘0’.

In direct mode, MSIZE is forced by hardware to the same value as PSIZE as soon as bit EN = ‘1’.

Bits 12:11 **PSIZE[1:0]**: peripheral data size

These bits are set and cleared by software.

- 00: byte (8-bit)
- 01: half-word (16-bit)
- 10: word (32-bit)
- 11: reserved

These bits are protected and can be written only if EN is ‘0’.

Bit 10 **MINC**: memory increment mode

This bit is set and cleared by software.

- 0: memory address pointer is fixed
- 1: memory address pointer is incremented after each data transfer (increment is done according to MSIZE)

This bit is protected and can be written only if EN is ‘0’.

Bit 9 **PINC**: peripheral increment mode

This bit is set and cleared by software.

- 0: peripheral address pointer is fixed
- 1: peripheral address pointer is incremented after each data transfer (increment is done according to PSIZE)

This bit is protected and can be written only if EN is ‘0’.
Bit 8  **CIRC**: circular mode
This bit is set and cleared by software and can be cleared by hardware.
0: circular mode disabled
1: circular mode enabled
When the peripheral is the flow controller (bit PFCTRL = 1) and the stream is enabled (bit EN = 1), then this bit is automatically forced by hardware to 0.
It is automatically forced by hardware to 1 if the DBM bit is set, as soon as the stream is enabled (bit EN = ‘1’).

Bits 7:6  **DIR[1:0]**: data transfer direction
These bits are set and cleared by software.
00: peripheral-to-memory
01: memory-to-peripheral
10: memory-to-memory
11: reserved
These bits are protected and can be written only if EN is ‘0’.

Bit 5  **PFCTRL**: peripheral flow controller
This bit is set and cleared by software.
0: DMA is the flow controller
1: The peripheral is the flow controller
This bit is protected and can be written only if EN is ‘0’.
When the memory-to-memory mode is selected (bits DIR[1:0]=10), then this bit is automatically forced to 0 by hardware.

Bit 4  **TCIE**: transfer complete interrupt enable
This bit is set and cleared by software.
0: TC interrupt disabled
1: TC interrupt enabled

Bit 3  **HTIE**: half transfer interrupt enable
This bit is set and cleared by software.
0: HT interrupt disabled
1: HT interrupt enabled

Bit 2  **TEIE**: transfer error interrupt enable
This bit is set and cleared by software.
0: TE interrupt disabled
1: TE interrupt enabled

Bit 1  **DMEIE**: direct mode error interrupt enable
This bit is set and cleared by software.
0: DME interrupt disabled
1: DME interrupt enabled
Bit 0 **EN**: stream enable / flag stream ready when read low
This bit is set and cleared by software.
0: stream disabled
1: stream enabled
This bit may be cleared by hardware:
- on a DMA end of transfer (stream ready to be configured)
- if a transfer error occurs on the AHB master buses
- when the FIFO threshold on memory AHB port is not compatible with the size of the burst
When this bit is read as 0, the software is allowed to program the configuration and FIFO bits registers. It is forbidden to write these registers when the EN bit is read as 1.

**Note**: Before setting EN bit to ‘1’ to start a new transfer, the event flags corresponding to the stream in DMA_LISR or DMA_HISR register must be cleared.

### 14.5.6 DMA stream x number of data register (DMA_SxNDTR)

Address offset: 0x14 + 0x18 * x, (x = 0 to 7)

**NDT[15:0]**

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **NDT[15:0]**: number of data items to transfer (0 up to 65535)
This register can be written only when the stream is disabled. When the stream is enabled, this register is read-only, indicating the remaining data items to be transmitted. This register decrements after each DMA transfer.

Once the transfer is completed, this register can either stay at zero (when the stream is in normal mode) or be reloaded automatically with the previously programmed value in the following cases:
- when the stream is configured in circular mode.
- when the stream is enabled again by setting EN bit to ‘1’.
If the value of this register is zero, no transaction can be served even if the stream is enabled.
14.5.7 DMA stream x peripheral address register (DMA_SxPAR)
Address offset: 0x18 + 0x18 * x, (x = 0 to 7)
Reset value: 0x0000 0000

Bits 31:0 PAR[31:0]: peripheral address
Base address of the peripheral data register from/to which the data is read/written.
These bits are write-protected and can be written only when bit EN = '0' in the DMA_SxCR register.

14.5.8 DMA stream x memory 0 address register (DMA_SxM0AR)
Address offset: 0x1C + 0x18 * x, (x = 0 to 7)
Reset value: 0x0000 0000

Bits 31:0 M0A[31:0]: memory 0 address
Base address of memory area 0 from/to which the data is read/written.
These bits are write-protected. They can be written only if:
– the stream is disabled (bit EN = '0' in the DMA_SxCR register) or
– the stream is enabled (EN='1' in DMA_SxCR register) and bit CT = '1' in the DMA_SxCR register (in double-buffer mode).

14.5.9 DMA stream x memory 1 address register (DMA_SxM1AR)
Address offset: 0x20 + 0x18 * x, (x = 0 to 7)
Reset value: 0x0000 0000
Bits 31:0 **M1A[31:0]**: memory 1 address (used in case of double-buffer mode)
Base address of memory area 1 from/to which the data is read/written.
This register is used only for the double-buffer mode.
These bits are write-protected. They can be written only if:
- the stream is disabled (bit EN= ’0’ in the DMA_SxCR register) or
- the stream is enabled (EN=’1’ in DMA_SxCR register) and bit CT = ’0’ in the DMA_SxCR register.

### 14.5.10 DMA stream x FIFO control register (DMA_SxFCR)

</table>

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **FEIE**: FIFO error interrupt enable
This bit is set and cleared by software.
0: FE interrupt disabled
1: FE interrupt enabled

Bit 6 Reserved, must be kept at reset value.

Bits 5:3 **FS[2:0]**: FIFO status
These bits are read-only.
000: 0 < fifo_level < 1/4
001: 1/4 ≤ fifo_level < 1/2
010: 1/2 ≤ fifo_level < 3/4
011: 3/4 ≤ fifo_level < full
100: FIFO is empty
101: FIFO is full
others: no meaning
These bits are not relevant in the direct mode (DMDIS bit is zero).

Bit 2 **DMDIS**: direct mode disable
This bit is set and cleared by software. It can be set by hardware.
0: direct mode enabled
1: direct mode disabled
This bit is protected and can be written only if EN is ’0’.
This bit is set by hardware if the memory-to-memory mode is selected (DIR bit in DMA_SxCR are “10”) and the EN bit in the DMA_SxCR register is ’1’ because the direct mode is not allowed in the memory-to-memory configuration.
Bits 1:0 **FTH[1:0]**: FIFO threshold selection

These bits are set and cleared by software.

- **00**: 1/4 full FIFO
- **01**: 1/2 full FIFO
- **10**: 3/4 full FIFO
- **11**: full FIFO

These bits are not used in the direct mode when the DMIS value is zero. These bits are protected and can be written only if EN is ‘0’. 
### 14.5.11 DMA register map

Table 109 summarizes the DMA registers.

| Offset | Register name | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|--------|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|

15 Basic direct memory access controller (BDMA)

15.1 Introduction

The basic direct memory access (BDMA) controller is a bus master and system peripheral. The BDMA is used to perform programmable data transfers between memory-mapped peripherals and/or memories, upon the control of an off-loaded CPU.

The BDMA controller features a single AHB master architecture.

There is one instance of BDMA with 8 channels.

Each channel is dedicated to managing memory access requests from one or more peripherals. The BDMA includes an arbiter for handling the priority between DMA requests.

15.2 BDMA main features

- Single AHB master
- Peripheral-to-memory, memory-to-peripheral, memory-to-memory and peripheral-to-peripheral data transfers
- Access to D3 domain SRAM and AHB/APB peripherals (BDMA)
- All BDMA channels independently configurable:
  - Each channel is associated either with a DMA request signal coming from a peripheral, or with a software trigger in memory-to-memory transfers. This configuration is done by software.
  - Priority between the requests is programmable by software (4 levels per channel: very high, high, medium, low) and by hardware in case of equality (such as request to channel 1 has priority over request to channel 2).
  - Transfer size of source and destination are independent (byte, half-word, word), emulating packing and unpacking. Source and destination addresses must be aligned on the data size.
  - Support of transfers from/to peripherals to/from memory with circular buffer management
  - Programmable number of data to be transferred: 0 to $2^{16} - 1$
- Generation of an interrupt request per channel. Each interrupt request is caused from any of the three DMA events: transfer complete, half transfer, or transfer error.

15.3 BDMA implementation

15.3.1 BDMA

BDMA is implemented with the hardware configuration parameters shown in Table 110.

<table>
<thead>

<tr>
<td>Number of channels (double-buffer)</td>
<td>8</td>
</tr>
</tbody>
</table>
15.3.2 BDMA request mapping

The BDMA controller is connected to DMA requests from the AHB/APB peripherals through the DMAMUX peripheral.

For the mapping of the different requests, refer to the Section 16.3: DMAMUX implementation.

15.4 BDMA functional description

15.4.1 BDMA block diagram

The BDMA block diagram is shown in Figure 80.

Figure 80. BDMA block diagram

The BDMA controller performs direct memory transfer by sharing the AHB system bus with other system masters. The bus matrix implements round-robin scheduling. DMA requests may stop the CPU access to the system bus for a number of bus cycles, when CPU and BDMA target the same destination (memory or peripheral).

The BDMA controller is connected to DMA requests from the AHB/APB peripherals through the DMAMUX peripheral.

According to its configuration through the AHB slave interface, the BDMA controller arbitrates between the DMA channels and their associated received requests. The BDMA controller also schedules the DMA data transfers over the single AHB port master.

The BDMA controller generates an interrupt per channel to the interrupt controller.

15.4.3 BDMA transfers

The software configures the BDMA controller at channel level, in order to perform a block transfer, composed of a sequence of AHB bus transfers.

A BDMA block transfer may be requested from a peripheral, or triggered by the software in case of memory-to-memory transfer.

After an event, the following steps of a single BDMA transfer occur:

1. The peripheral sends a single DMA request signal to the BDMA controller.
2. The BDMA controller serves the request, depending on the priority of the channel associated to this peripheral request.
3. As soon as the BDMA controller grants the peripheral, an acknowledge is sent to the peripheral by the BDMA controller.
4. The peripheral releases its request as soon as it gets the acknowledge from the BDMA controller.
5. Once the request is de-asserted by the peripheral, the BDMA controller releases the acknowledge.

The peripheral may order a further single request and initiate another single BDMA transfer.

The request/acknowledge protocol is used when a peripheral is either the source or the destination of the transfer. For example, in case of memory-to-peripheral transfer, the peripheral initiates the transfer by driving its single request signal to the BDMA controller. The BDMA controller reads then a single data in the memory and writes this data to the peripheral.

For a given channel x, a BDMA block transfer consists of a repeated sequence of:

- a single BDMA transfer, encapsulating two AHB transfers of a single data, over the BDMA AHB bus master:
  - a single data read (byte, half-word or word) from the peripheral data register or a location in the memory, addressed through an internal current peripheral/memory address register.
  - The start address used for the first single transfer is the base address of the peripheral or memory, and is programmed in the BDMA_CPARx or BDMA_CM0/1ARx register.
  - a single data write (byte, half-word or word) to the peripheral data register or a location in the memory, addressed through an internal current peripheral/memory address register.
The start address used for the first transfer is the base address of the peripheral or memory, and is programmed in the BDMA_CPARx or BDMA_CM0/1ARx register.

- post-decrementing of the programmed BDMA_CNDTRx register

This register contains the remaining number of data items to transfer (number of AHB ‘read followed by write’ transfers).

This sequence is repeated until BDMA_CNDTRx is null.

**Note:** *The AHB master bus source/destination address must be aligned with the programmed size of the transferred single data to the source/destination.*

### 15.4.4 BDMA arbitration

The BDMA arbiter manages the priority between the different channels.

When an active channel x is granted by the arbiter (hardware requested or software triggered), a single BDMA transfer is issued (such as an AHB ‘read followed by write’ transfer of a single data). Then, the arbiter considers again the set of active channels and selects the one with the highest priority.

The priorities are managed in two stages:

- **software:** priority of each channel is configured in the BDMA_CCRx register, to one of the four different levels:
  - very high
  - high
  - medium
  - low

- **hardware:** if two requests have the same software priority level, the channel with the lowest index gets priority. For example, channel 2 gets priority over channel 4.

When a channel x is programmed for a block transfer in memory-to-memory mode, re-arbitration is considered between each single BDMA transfer of this channel x. Whenever there is another concurrent active requested channel, the BDMA arbiter automatically alternates and grants the other highest-priority requested channel, which may be of lower priority than the memory-to-memory channel.

### 15.4.5 BDMA channels

Each channel may handle a BDMA transfer between a peripheral register located at a fixed address, and a memory address. The amount of data items to transfer is programmable. The register that contains the amount of data items to transfer is decremented after each transfer.

A DMA channel is programmed at block transfer level.

**Programmable data sizes**

The transfer sizes of a single data (byte, half-word, or word) to the peripheral and memory are programmable through, respectively, the PSIZE[1:0] and MSIZE[1:0] fields of the BDMA_CCRx register.

**Pointer incrementation**

The peripheral and memory pointers may be automatically incremented after each transfer, depending on the PINC and MINC bits of the BDMA_CCRx register.
If the **incremented mode** is enabled (PINC or MINC set to 1), the address of the next transfer is the address of the previous one incremented by 1, 2 or 4, depending on the data size defined in PSIZE[1:0] or MSIZE[1:0]. The first transfer address is the one programmed in the BDMA_CPARx or BDMA_CM0/1ARx register. During transfers, these registers keep the initially programmed value. The current transfer addresses (in the current internal peripheral/memory address register) are not accessible by software.

If the channel x is configured in **non-circular mode**, no DMA request is served after the last data transfer (once the number of single data to transfer reaches zero). The DMA channel must be disabled in order to reload a new number of data items into the BDMA_CNDTRx register.

**Note:** *If the channel x is disabled, the BDMA registers are not reset. The DMA channel registers (BDMA_CCRx, BDMA_CPARx and BDMA_CM0ARx) retain the initial values programmed during the channel configuration phase.*

In **circular mode**, after the last data transfer, the BDMA_CNDTRx register is automatically reloaded with the initially programmed value. The current internal address registers are reloaded with the base address values from the BDMA_CPARx and BDMA_CM0/1ARx registers.

**Channel configuration procedure**

The following sequence is needed to configure a DMA channel x:

1. Set the peripheral register address in the BDMA_CPARx register.
   The data is moved from/to this address to/from the memory after the peripheral event, or after the channel is enabled in memory-to-memory mode.

2. Set the memory address in the BDMA_CM0ARx register.
   The data is written to/read from the memory after the peripheral event or after the channel is enabled in memory-to-memory mode.

3. Configure the total number of data to transfer in the BDMA_CNDTRx register.
   After each data transfer, this value is decremented.

4. Configure the parameters listed below in the BDMA_CCRx register:
   - the channel priority
   - the data transfer direction
   - the circular mode
   - the double-buffer mode
   - the peripheral and memory incremented mode
   - the peripheral and memory data size
   - the interrupt enable at half and/or full transfer and/or transfer error

5. Activate the channel by setting the EN bit in the BDMA_CCRx register.

A channel, as soon as enabled, may serve any BDMA request from the peripheral connected to this channel, or may start a memory-to-memory block transfer.

**Note:** *The two last steps of the channel configuration procedure may be merged into a single access to the BDMA_CCRx register, to configure and enable the channel.*

**Channel state and disabling a channel**

A channel x in active state is an enabled channel (read BDMA_CCRx.EN = 1). An active channel x is a channel that must have been enabled by the software (BDMA_CCRx.EN set
to 1) and afterwards with no occurred transfer error (BDMA_ISR.TEIFx = 0). In case there is a transfer error, the channel is automatically disabled by hardware (BDMA_CCRx.EN = 0).

The three following use cases may happen:

- **Suspend and resume a channel**
  
  This corresponds to the two following actions:
  
  - An active channel is disabled by software (writing BDMA_CCRx.EN = 0 whereas BDMA_CCRx.EN = 1).
  - The software enables the channel again (BDMA_CCRx.EN set to 1) without reconfiguring the other channel registers (such as BDMA_CNDTRx, BDMA_CPARx and BDMA_CM0/1ARx).

  This case is not supported by the BDMA hardware, that does not guarantee that the remaining data transfers are performed correctly.

- **Stop and abort a channel**
  
  If the application does not need any more the channel, this active channel can be disabled by software. The channel is stopped and aborted but the BDMA_CNDTRx register content may not correctly reflect the remaining data transfers versus the aborted source and destination buffer/register.

- **Abort and restart a channel**
  
  This corresponds to the software sequence: disable an active channel, then reconfigure the channel and enable it again.

  This is supported by the hardware if the following conditions are met:
  
  - The application guarantees that, when the software is disabling the channel, a DMA data transfer is not occurring at the same time over its master port. For example, the application can first disable the peripheral in DMA mode, in order to ensure that there is no pending hardware DMA request from this peripheral.
  - The software must operate separated write accesses to the same BDMA_CCRx register: First disable the channel. Second reconfigure the channel for a next block transfer including the BDMA_CCRx if a configuration change is needed. There are read-only BDMA_CCRx register fields when BDMA_CCRx.EN=1. Finally enable again the channel.

When a channel transfer error occurs, the EN bit of the BDMA_CCRx register is cleared by hardware. This EN bit can not be set again by software to re-activate the channel x, until the TEIFx bit of the BDMA_CxISR register is set.

**Circular mode (in memory-to-peripheral/peripheral-to-memory transfers)**

The circular mode is available to handle circular buffers and continuous data flows (such as ADC scan mode). This feature is enabled using the CIRC bit in the BDMA_CCRx register.

**Note:** The circular mode must not be used in memory-to-memory mode. Before enabling a channel in circular mode (CIRC = 1), the software must clear the MEM2MEM bit of the BDMA_CCRx register. When the circular mode is activated, the amount of data to transfer is automatically reloaded with the initial value programmed during the channel configuration phase, and the DMA requests continue to be served.

In order to stop a circular transfer, the software needs to stop the peripheral from generating DMA requests (such as quit the ADC scan mode), before disabling the DMA channel. The software must explicitly program the BDMA_CNDTRx value before starting/enabling a transfer, and after having stopped a circular transfer.
Memory-to-memory mode

The BDMA channels may operate without being triggered by a request from a peripheral. This mode is called memory-to-memory mode, and is initiated by software.

If the MEM2MEM bit in the BDMA_CCRx register is set, the channel, if enabled, initiates transfers. The transfer stops once the BDMA_CNDTRx register reaches zero.

Note: The memory-to-memory mode must not be used in circular mode. Before enabling a channel in memory-to-memory mode (MEM2MEM = 1), the software must clear the CIRC bit of the BDMA_CCRx register.

Double-buffer mode (in memory-to-peripheral and peripheral-to-memory transfers)

The BDMA channels can operate in double-buffer mode.

The difference compared to a regular operation is that the BDMA controller toggles between two memory address pointers at the end of each BDMA transfer, thus accessing two memory areas in an alternate way. This allows the software to access one of the two memory areas while the BDMA controller accesses the other one. The double-buffer mode transfer operates in both directions, so the target memory can be either the source or the destination.

The double-buffer mode is configured by setting both the DBM and CIRC bits of the BDMA_CCRx register.

Note: The double-buffer mode must not be used in memory-to-memory mode. Before enabling a channel in double-buffer mode (DBM = 1), the software has to configure appropriately the MEM2MEM bit (MEM2MEM = 0).

The steps described below allow the configuration of a BDMA channel x in double-buffer mode:

• Set the DBM and CIRC bits and clear the MEM2MEM bit of the BDMA_CCRx register. The circular mode is then activated for the swap mechanism to occur.
• Configure the second memory address register BDMA_CM1ARx.
• Continue with the regular channel configuration procedure, and lastly, activate the channel by setting the EN bit of the BDMA_CCRx register. The first BDMA transfer target memory of the corresponding BDMA channel x, is given by the CT bit of the BDMA_CCRx register.

Note: Independently from the value of DBM bit of the BDMA_CCRx register, if CT = 1, the memory address pointer for the BDMA transfer is defined by BDMA_CM1ARx, and not by BDMA_CM0ARx.

Peripheral-to-peripheral mode

Any BDMA channel can operate in peripheral-to-peripheral mode:

• when the hardware request from a peripheral is selected to trigger the BDMA channel
  This peripheral is the BDMA initiator and paces the data transfer from/to this peripheral to/from a register belonging to another memory-mapped peripheral (this one being not configured in DMA mode).
• when no peripheral request is selected and connected to the BDMA channel
  The software configures a register-to-register transfer by setting the MEM2MEM bit of the BDMA_CCRx register.
Programming transfer direction, assigning source/destination

The value of the DIR bit of the BDMA_CCRx register sets the direction of the transfer, and consequently, it identifies the source and the destination, regardless the source/destination type (peripheral or memory):

- **DIR = 1** defines typically a memory-to-peripheral transfer. More generally, if DIR = 1:
  - The source attributes are defined by the BDMA_MARx register, the MSIZE[1:0] field and MINC bit of the BDMA_CCRx register. Regardless of their usual naming, these ‘memory’ register, field and bit are used to define the source peripheral in peripheral-to-peripheral mode.
  - The destination attributes are defined by the BDMA_PARx register, the PSIZE[1:0] field and PINC bit of the BDMA_CCRx register. Regardless of their usual naming, these ‘peripheral’ register, field and bit are used to define the destination memory in memory-to-memory mode.

- **DIR = 0** defines typically a peripheral-to-memory transfer. More generally, if DIR = 0:
  - The source attributes are defined by the BDMA_PARx register, the PSIZE[1:0] field and PINC bit of the BDMA_CCRx register. Regardless of their usual naming, these ‘peripheral’ register, field and bit are used to define the source memory in memory-to-memory mode.
  - The destination attributes are defined by the BDMA_MARx register, the MSIZE[1:0] field and MINC bit of the BDMA_CCRx register. Regardless of their usual naming, these ‘memory’ register, field and bit are used to define the destination peripheral in peripheral-to-peripheral mode.

### 15.4.6 BDMA data width, alignment and endianness

When PSIZE[1:0] and MSIZE[1:0] are not equal, the BDMA controller performs some data alignments as described in *Table 112*.

<table>

</table>
Addressing AHB peripherals not supporting byte/half-word write transfers

When the BDMA controller initiates an AHB byte or half-word write transfer, the data are duplicated on the unused lanes of the AHB master 32-bit data bus (HWDATA[31:0]).

When the AHB slave peripheral does not support byte or half-word write transfers and does not generate any error, the BDMA controller writes the 32 HWDATA bits as shown in the two examples below:

- To write the half-word 0xABCD, the BDMA controller sets the HWDATA bus to 0xABCDABCD with a half-word data size (HSIZE = HalfWord in AHB master bus).
- To write the byte 0xAB, the BDMA controller sets the HWDATA bus to 0xABABABAB with a byte data size (HSIZE = Byte in the AHB master bus).

Assuming the AHB/APB bridge is an AHB 32-bit slave peripheral that does not take into account the HSIZE data, any AHB byte or half-word transfer is changed into a 32-bit APB transfer as described below:

- An AHB byte write transfer of 0xB0 to one of the 0x0, 0x1, 0x2 or 0x3 addresses, is converted to an APB word write transfer of 0x0000B0B0B0 to the 0x0 address.
- An AHB half-word write transfer of 0xB1B0 to the 0x0 or 0x2 addresses, is converted to an APB word write transfer of 0xB1B0B1B0 to the 0x0 address.

15.4.7 BDMA error management

A BDMA transfer error is generated when reading from or writing to a reserved address space. When a BDMA transfer error occurs during a BDMA read or write access, the faulty channel x is automatically disabled through a hardware clear of its EN bit in the corresponding BDMA_CCRx register.
The TEIFx bit of the BDMA_ISR register is set. An interrupt is then generated if the TEIE bit of the BDMA_CCRx register is set.

The EN bit of the BDMA_CCRx register can not be set again by software (channel x re-activated) until the TEIFx bit of the BDMA_ISR register is cleared (by setting the CTEIFx bit of the BDMA_IFCR register).

When the software is notified with a transfer error over a channel which involves a peripheral, the software has first to stop this peripheral in DMA mode, in order to disable any pending or future DMA request. Then software may normally reconfigure both BDMA and the peripheral in DMA mode for a new transfer.

### 15.5 BDMA interrupts

An interrupt can be generated on a half transfer, transfer complete or transfer error for each DMA channel x. Separate interrupt enable bits are available for flexibility.

<table>

### 15.6 BDMA registers

Refer to Section 1.2 for a list of abbreviations used in register descriptions.

The BDMA registers have to be accessed by words (32-bit).

#### 15.6.1 BDMA interrupt status register (BDMA_ISR)

Address offset: 0x00

Reset value: 0x0000 0000

Every status bit is cleared by hardware when the software sets the corresponding clear bit or the corresponding global clear bit CGIFx, in the BDMA_IFCR register.
Bit 31  **TEIF7**: transfer error (TE) flag for channel 7  
0: no TE event  
1: a TE event occurred  

Bit 30  **HTIF7**: half transfer (HT) flag for channel 7  
0: no HT event  
1: a HT event occurred  

Bit 29  **TCIF7**: transfer complete (TC) flag for channel 7  
0: no TC event  
1: a TC event occurred  

Bit 28  **GIF7**: global interrupt flag for channel 7  
0: no TE, HT or TC event  
1: a TE, HT or TC event occurred  

Bit 27  **TEIF6**: transfer error (TE) flag for channel 6  
0: no TE event  
1: a TE event occurred  

Bit 26  **HTIF6**: half transfer (HT) flag for channel 6  
0: no HT event  
1: a HT event occurred  

Bit 25  **TCIF6**: transfer complete (TC) flag for channel 6  
0: no TC event  
1: a TC event occurred  

Bit 24  **GIF6**: global interrupt flag for channel 6  
0: no TE, HT or TC event  
1: a TE, HT or TC event occurred  

Bit 23  **TEIF5**: transfer error (TE) flag for channel 5  
0: no TE event  
1: a TE event occurred  

Bit 22  **HTIF5**: half transfer (HT) flag for channel 5  
0: no HT event  
1: a HT event occurred  

Bit 21  **TCIF5**: transfer complete (TC) flag for channel 5  
0: no TC event  
1: a TC event occurred  

Bit 20  **GIF5**: global interrupt flag for channel 5  
0: no TE, HT or TC event  
1: a TE, HT or TC event occurred  

Bit 19  **TEIF4**: transfer error (TE) flag for channel 4  
0: no TE event  
1: a TE event occurred  

Bit 18  **HTIF4**: half transfer (HT) flag for channel 4  
0: no HT event  
1: a HT event occurred
Bit 17  **TCIF4**: transfer complete (TC) flag for channel 4
   0: no TC event
   1: a TC event occurred

Bit 16  **GIF4**: global interrupt flag for channel 4
   0: no TE, HT or TC event
   1: a TE, HT or TC event occurred

Bit 15  **TEIF3**: transfer error (TE) flag for channel 3
   0: no TE event
   1: a TE event occurred

Bit 14  **HTIF3**: half transfer (HT) flag for channel 3
   0: no HT event
   1: a HT event occurred

Bit 13  **TCIF3**: transfer complete (TC) flag for channel 3
   0: no TC event
   1: a TC event occurred

Bit 12  **GIF3**: global interrupt flag for channel 3
   0: no TE, HT or TC event
   1: a TE, HT or TC event occurred

Bit 11  **TEIF2**: transfer error (TE) flag for channel 2
   0: no TE event
   1: a TE event occurred

Bit 10  **HTIF2**: half transfer (HT) flag for channel 2
   0: no HT event
   1: a HT event occurred

Bit 9   **TCIF2**: transfer complete (TC) flag for channel 2
   0: no TC event
   1: a TC event occurred

Bit 8   **GIF2**: global interrupt flag for channel 2
   0: no TE, HT or TC event
   1: a TE, HT or TC event occurred

Bit 7   **TEIF1**: transfer error (TE) flag for channel 1
   0: no TE event
   1: a TE event occurred

Bit 6   **HTIF1**: half transfer (HT) flag for channel 1
   0: no HT event
   1: a HT event occurred

Bit 5   **TCIF1**: transfer complete (TC) flag for channel 1
   0: no TC event
   1: a TC event occurred

Bit 4   **GIF1**: global interrupt flag for channel 1
   0: no TE, HT or TC event
   1: a TE, HT or TC event occurred

Bit 3   **TEIF0**: transfer error (TE) flag for channel 0
   0: no TE event
   1: a TE event occurred
15.6.2 BDMA interrupt flag clear register (BDMA_IFCR)

Address offset: 0x04

Reset value: 0x0000 0000

Setting the global clear bit CGIFx of the channel x in this BDMA_IFCR register, causes the BDMA hardware to clear the corresponding GIFx bit and any individual flag among TEIFx, HTIFx, TCIFx, in the BDMA_ISR register.

Setting any individual clear bit among CTEIFx, CHTIFx, CTCIFx in this BDMA_IFCR register, causes the BDMA hardware to clear the corresponding individual flag and the global flag GIFx in the BDMA_ISR register, provided that none of the two other individual flags is set.

Writing 0 into any flag clear bit has no effect.

15.6.3 BDMA channel x configuration register (BDMA_CCRx)

Address offset: 0x08 + 0x14 * x, (x = 0 to 7)
Reset value: 0x0000 0000

The register fields/bits CT, DBM, MEM2MEM, PL[1:0], MSIZE[1:0], PSIZE[1:0], MINC, PINC, and DIR are read-only when EN = 1.
The states of MEM2MEM and CIRC bits must not be both high at the same time.
Bits 31:17  Reserved, must be kept at reset value.

Bit 16  **CT**: current target memory of DMA transfer in double-buffer mode
        This bit is toggled by hardware at the end of each channel transfer in double-buffer mode.
        0: memory 0 (addressed by the BDMA_CM0AR pointer)
        1: memory 1 (addressed by the BDMA_CM1AR pointer)
        **Note:** this bit is set and cleared by software.
        *It must not be written when the channel is enabled (EN = 1).*
        *It is read-only when the channel is enabled (EN = 1).*

Bit 15  **DBM**: double-buffer mode
        This bit must be set only in memory-to-peripheral and peripheral-to-memory transfers (MEM2MEM=0). The CIRC bit must also be set in double buffer mode.
        0: disabled (no memory address switch at the end of the BDMA transfer)
        1: enabled (memory address switched at the end of the BDMA transfer)
        **Note:** this bit is set and cleared by software.
        *It must not be written when the channel is enabled (EN = 1).*
        *It is not read-only when the channel is enabled (EN = 1).*

Bit 14  **MEM2MEM**: memory-to-memory mode
        0: disabled
        1: enabled
        **Note:** this bit is set and cleared by software.
        *It must not be written when the channel is enabled (EN = 1).*
        *It is read-only when the channel is enabled (EN = 1).*

Bits 13:12  **PL[1:0]**: priority level
        00: low
        01: medium
        10: high
        11: very high
        **Note:** this field is set and cleared by software.
        *It must not be written when the channel is enabled (EN = 1).*
        *It is read-only when the channel is enabled (EN = 1).*

Bits 11:10  **MSIZE[1:0]**: memory size
        Defines the data size of each DMA transfer to the identified memory.
        In memory-to-memory mode, this field identifies the memory source if DIR = 1 and the memory destination if DIR = 0.
        In peripheral-to-peripheral mode, this field identifies the peripheral source if DIR = 1 and the peripheral destination if DIR = 0.
        00: 8 bits
        01: 16 bits
        10: 32 bits
        11: reserved
        **Note:** this field is set and cleared by software.
        *It must not be written when the channel is enabled (EN = 1).*
        *It is read-only when the channel is enabled (EN = 1).*
Bits 9:8 **PSIZE[1:0]**: peripheral size

Defines the data size of each DMA transfer to the identified peripheral.

In memory-to-memory mode, this field identifies the memory destination if DIR = 1 and the memory source if DIR = 0.

In peripheral-to-peripheral mode, this field identifies the peripheral destination if DIR = 1 and the peripheral source if DIR = 0.

00: 8 bits
01: 16 bits
10: 32 bits
11: reserved

Note: this field is set and cleared by software.

It must not be written when the channel is enabled (EN = 1).

It is read-only when the channel is enabled (EN = 1).

Bit 7 **MINC**: memory increment mode

Defines the increment mode for each DMA transfer to the identified memory.

In memory-to-memory mode, this field identifies the memory source if DIR = 1 and the memory destination if DIR = 0.

In peripheral-to-peripheral mode, this field identifies the peripheral source if DIR = 1 and the peripheral destination if DIR = 0.

0: disabled
1: enabled

Note: this bit is set and cleared by software.

It must not be written when the channel is enabled (EN = 1).

It is read-only when the channel is enabled (EN = 1).

Bit 6 **PINC**: peripheral increment mode

Defines the increment mode for each DMA transfer to the identified peripheral.

In memory-to-memory mode, this field identifies the memory destination if DIR = 1 and the memory source if DIR = 0.

In peripheral-to-peripheral mode, this field identifies the peripheral destination if DIR = 1 and the peripheral source if DIR = 0.

0: disabled
1: enabled

Note: this bit is set and cleared by software.

It must not be written when the channel is enabled (EN = 1).

It is read-only when the channel is enabled (EN = 1).

Bit 5 **CIRC**: circular mode

0: disabled
1: enabled

Note: this bit is set and cleared by software.

It must not be written when the channel is enabled (EN = 1).

It is not read-only when the channel is enabled (EN = 1).
Basic direct memory access controller (BDMA)

Bit 4 **DIR**: data transfer direction
This bit must be set only in memory-to-peripheral and peripheral-to-memory modes.
- 0: read from peripheral
  - Source attributes are defined by PSIZE and PINC, plus the BDMA_CPARx register.
  - This is still valid in a memory-to-memory mode.
  - Destination attributes are defined by MSIZE and MINC, plus the BDMA_CM0/1ARx register. This is still valid in a peripheral-to-peripheral mode.
- 1: read from memory
  - Destination attributes are defined by PSIZE and PINC, plus the BDMA_CPARx register. This is still valid in a memory-to-memory mode.
  - Source attributes are defined by MSIZE and MINC, plus the BDMA_CM0/1ARx register. This is still valid in a peripheral-to-peripheral mode.

*Note:* this bit is set and cleared by software.
- *It must not be written when the channel is enabled (EN = 1).*
- *It is read-only when the channel is enabled (EN = 1).*

Bit 3 **TEIE**: transfer error interrupt enable
- 0: disabled
- 1: enabled

*Note:* this bit is set and cleared by software.
- *It must not be written when the channel is enabled (EN = 1).*
- *It is not read-only when the channel is enabled (EN = 1).*

Bit 2 **HTIE**: half transfer interrupt enable
- 0: disabled
- 1: enabled

*Note:* this bit is set and cleared by software.
- *It must not be written when the channel is enabled (EN = 1).*
- *It is not read-only when the channel is enabled (EN = 1).*

Bit 1 **TCIE**: transfer complete interrupt enable
- 0: disabled
- 1: enabled

*Note:* this bit is set and cleared by software.
- *It must not be written when the channel is enabled (EN = 1).*
- *It is not read-only when the channel is enabled (EN = 1).*

Bit 0 **EN**: channel enable
When a channel transfer error occurs, this bit is cleared by hardware. It can not be set again by software (channel x re-activated) until the TEIFx bit of the BDMA_ISR register is cleared (by setting the CTEIFx bit of the BDMA_IFCR register).
- 0: disabled
- 1: enabled

*Note:* this bit is set and cleared by software.
15.6.4 BDMA channel x number of data to transfer register (BDMA_CNDTRx)

Address offset: 0xOC + 0x14 * x, (x = 0 to 7)
Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.
Bits 15:0 **NDT[15:0]**: number of data to transfer (0 to $2^{16} - 1$)
This field is updated by hardware when the channel is enabled:
- It is decremented after each single BDMA 'read followed by write' transfer, indicating the remaining amount of data items to transfer.
- It is kept at zero when the programmed amount of data to transfer is reached, if the channel is not in circular mode (CIRC = 0 in the BDMA_CCRx register).
- It is reloaded automatically by the previously programmed value, when the transfer is complete, if the channel is in circular mode (CIRC = 1).
If this field is zero, no transfer can be served whatever the channel status (enabled or not).

**Note:** this field is set and cleared by software.
It must not be written when the channel is enabled (EN = 1).
It is read-only when the channel is enabled (EN = 1).

15.6.5 BDMA channel x peripheral address register (BDMA_CPARx)

Address offset: 0x10 + 0x14 * x, (x = 0 to 7)
Reset value: 0x0000 0000
Bits 31:0  **PA[31:0]**: peripheral address

- It contains the base address of the peripheral data register from/to which the data will be read/written.
- When PSIZE[1:0] = 01 (16 bits), bit 0 of PA[31:0] is ignored. Access is automatically aligned to a half-word address.
- When PSIZE = 10 (32 bits), bits 1 and 0 of PA[31:0] are ignored. Access is automatically aligned to a word address.
- In memory-to-memory mode, this register identifies the memory destination address if DIR = 1 and the memory source address if DIR = 0.
- In peripheral-to-peripheral mode, this register identifies the peripheral destination address if DIR = 1 and the peripheral source address if DIR = 0.

*Note:* this register is set and cleared by software.

*It must not be written when the channel is enabled (EN = 1).*

*It is not read-only when the channel is enabled (EN = 1).*

### 15.6.6  BDMA channel x memory 0 address register (BDMA_CM0ARx)

Address offset: 0x14 + 0x14 * x, (x = 0 to 7)

Reset value: 0x0000 0000

Bits 31:0  **MA[31:0]**: peripheral address

- It contains the base address of the memory from/to which the data will be read/written.
- When MSIZE[1:0] = 01 (16 bits), bit 0 of MA[31:0] is ignored. Access is automatically aligned to a half-word address.
- When MSIZE = 10 (32 bits), bits 1 and 0 of MA[31:0] are ignored. Access is automatically aligned to a word address.
- In memory-to-memory mode, this register identifies the memory source address if DIR = 1 and the memory destination address if DIR = 0.
- In peripheral-to-peripheral mode, this register identifies the peripheral source address if DIR = 1 and the peripheral destination address if DIR = 0.

*Note:* this register is set and cleared by software.

*It must not be written when the channel is enabled (EN = 1).*

*It is not read-only when the channel is enabled (EN = 1).*
15.6.7 BDMA channel x memory 1 address register (BDMA_CM1ARx)

Address offset: 0x18 + 0x14 * x, (x = 0 to 7)
Reset value: 0x0000 0000

Refer to Section 2.3 on page 126 for the register boundary addresses.
16 DMA request multiplexer (DMAMUX)

16.1 Introduction

A peripheral indicates a request for DMA transfer by setting its DMA request signal. The DMA request is pending until it is served by the DMA controller that generates a DMA acknowledge signal, and the corresponding DMA request signal is de-asserted.

In this document, the set of control signals required for the DMA request/acknowledge protocol is not explicitly shown or described, and it is referred to as DMA request line.

The DMAMUX request multiplexer enables routing a DMA request line between the peripherals and the DMA controllers of the product. The routing function is ensured by a programmable multi-channel DMA request line multiplexer. Each channel selects a unique DMA request line, unconditionally or synchronously with events from its DMAMUX synchronization inputs. The DMAMUX may also be used as a DMA request generator from programmable events on its input trigger signals.

The number of DMAMUX instances and their main characteristics are specified in Section 16.3.1.

The assignment of DMAMUX request multiplexer inputs to the DMA request lines from peripherals and to the DMAMUX request generator outputs, the assignment of DMAMUX request multiplexer outputs to DMA controller channels, and the assignment of DMAMUX synchronizations and trigger inputs to internal and external signals depend on the product implementation, and are detailed in Section 16.3.2.
16.2 DMAMUX main features

- Up to 16-channel programmable DMA request line multiplexer output
- Up to 8-channel DMA request generator
- Up to 32 trigger inputs to DMA request generator
- Up to 16 synchronization inputs
- Per DMA request generator channel:
  - DMA request trigger input selector
  - DMA request counter
  - Event overrun flag for selected DMA request trigger input
- Per DMA request line multiplexer channel output:
  - Up to 107 input DMA request lines from peripherals
  - One DMA request line output
  - Synchronization input selector
  - DMA request counter
  - Event overrun flag for selected synchronization input
  - One event output, for DMA request chaining

16.3 DMAMUX implementation

16.3.1 DMAMUX1 and DMAMUX2 instantiation

The product integrates two instances of DMA request multiplexer:
- DMAMUX1 for DMA1 and DMA2 (D2 domain)
- DMAMUX2 for BDMA (D3 domain)

DMAMUX1 and DMAMUX2 are instantiated with the hardware configuration parameters listed in the following table.

<table>
<thead>
<tr>
<th>Feature</th>
<th>DMAMUX1</th>
<th>DMAMUX2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of DMAMUX output request channels</td>
<td>16</td>
<td>8</td>
</tr>
<tr>
<td>Number of DMAMUX request generator channels</td>
<td>8</td>
<td>8</td>
</tr>
<tr>
<td>Number of DMAMUX request trigger inputs</td>
<td>8</td>
<td>32</td>
</tr>
<tr>
<td>Number of DMAMUX synchronization inputs</td>
<td>8</td>
<td>16</td>
</tr>
<tr>
<td>Number of DMAMUX peripheral request inputs</td>
<td>107</td>
<td>12</td>
</tr>
</tbody>
</table>

16.3.2 DMAMUX1 mapping

The mapping of resources to DMAMUX1 is hardwired.

DMAMUX1 is used with the DMA1 and DMA2 in D2 domain:
- DMAMUX1 channels 0 to 7 are connected to DMA1 channels 0 to 7
- DMAMUX1 channels 8 to 15 are connected to DMA2 channels 0 to 7

16.4 DMAMUX functional description

16.4.1 DMAMUX block diagram

Figure 81 shows the DMAMUX block diagram.

Figure 81. DMAMUX block diagram

DMAMUX features two main sub-blocks: the request line multiplexer and the request line generator.

The implementation assigns:

- DMAMUX request multiplexer sub-block inputs (dmamux_reqx) from peripherals (dmamux_req_inx) and from channels of the DMAMUX request generator sub-block (dmamux_req_genx)
- DMAMUX request outputs to channels of DMA controllers (dmamux_req_outx)
- Internal or external signals to DMA request trigger inputs (dmamux_trgx)
- Internal or external signals to synchronization inputs (dmamux_syncx)
16.4.2 DMAMUX signals

*Table 122* lists the DMAMUX signals.

16.4.3 DMAMUX channels

A DMAMUX channel is a DMAMUX request multiplexer channel that may include, depending on the selected input of the request multiplexer, an additional DMAMUX request generator channel.

A DMAMUX request multiplexer channel is connected and dedicated to one single channel of DMA controller(s).

**Channel configuration procedure**

The following sequence should be followed to configure both a DMAMUX x channel and the related DMA channel y:

1. Set and configure completely the DMA channel y, except enabling the channel y.
2. Set and configure completely the related DMAMUX y channel.
3. Last, activate the DMA channel y by setting the EN bit in the DMA y channel register.

16.4.4 DMAMUX request line multiplexer

The DMAMUX request multiplexer with its multiple channels ensures the actual routing of DMA request/acknowledge control signals, named DMA request lines.

Each DMA request line is connected in parallel to all the channels of the DMAMUX request line multiplexer.

A DMA request is sourced either from the peripherals or from the DMAMUX request generator.

The DMAMUX request line multiplexer channel x selects the DMA request line number as configured by the DMAPREQ_ID field in the DMAMUX_CxCR register.
Note: The null value in the field DMAREQ_ID corresponds to no DMA request line selected. It is not allowed to configure a same non-null DMAREQ_ID to two different channels of the DMAMUX request line multiplexer.

On top of the DMA request selection, the synchronization mode and/or the event generation may be configured and enabled, if required.

**Synchronization mode and channel event generation**

Each DMAMUX request line multiplexer channel x can be individually synchronized by setting the synchronization enable (SE) bit in the DMAMUX_CxCR register.

DMAMUX has multiple synchronization inputs. The synchronization inputs are connected in parallel to all the channels of the request multiplexer.

The synchronization input is selected via the SYNC_ID field in the DMAMUX_CxCR register of a given channel x.

When a channel is in this synchronization mode, the selected input DMA request line is propagated to the multiplexer channel output, once is detected a programmable rising/falling edge on the selected input synchronization signal, via the SPOL[1:0] field of the DMAMUX_CxCR register.

Additionally, there is a programmable DMA request counter, internally to the DMAMUX request multiplexer, which may be used for the channel request output generation and also possibly for an event generation. An event generation on the channel x output is enabled through the EGE bit (event generation enable) of the DMAMUX_CxCR register.

As shown in Figure 83, upon the detected edge of the synchronization input, the pending selected input DMA request line is connected to the DMAMUX multiplexer channel x output.

*Note:* If a synchronization event occurs while there is no pending selected input DMA request line, it will be discarded. The following asserted input request lines will not be connected to the DMAMUX multiplexer channel output until a synchronization event occurs again.

From this point on, each time the connected DMAMUX request is served by the DMA controller (a served request is de-asserted), the DMAMUX request counter is decremented. At its underrun, the DMA request counter is automatically loaded with the value in NBREQ field of the DMAMUX_CxCR register and the input DMA request line is disconnected from the multiplexer channel x output.

Thus, the number of DMA requests transferred to the multiplexer channel x output following a detected synchronization event, is equal to the value in NBREQ field, plus one.

*Note:* The NBREQ field value shall only be written by software when both synchronization enable bit SE and event generation enable EGE bit of the corresponding multiplexer channel x are disabled.
If EGE is enabled, the multiplexer channel generates a channel event, as a pulse of one AHB clock cycle, when its DMA request counter is automatically reloaded with the value of the programmed NBREQ field, as shown in Figure 82 and Figure 83.
Note: If EGE is enabled and NBREQ = 0, an event is generated after each served DMA request.

Note: A synchronization event (edge) is detected if the state following the edge remains stable for more than two AHB clock cycles.

Upon writing into DMAMUX_CxCR register, the synchronization events are masked during three AHB clock cycles.

Synchronization overrun and interrupt

If a new synchronization event occurs before the request counter underrun (the internal request counter programmed via the NBREQ field of the DMAMUX_CxCR register), the synchronization overrun flag bit SOFx is set in the DMAMUX_CSR status register.

Note: The request multiplexer channel x synchronization shall be disabled (DMAMUX_CxCR.SE = 0) at the completion of the use of the related channel of the DMA controller. Else, upon a new detected synchronization event, there will be a synchronization overrun due to the absence of a DMA acknowledge (that is, no served request) received from the DMA controller.

The overrun flag SOFx is reset by setting the associated clear synchronization overrun flag bit CSOFx in the DMAMUX_CFR register.

Setting the synchronization overrun flag generates an interrupt if the synchronization overrun interrupt enable bit SOIE is set in the DMAMUX_CxCR register.

16.4.5 DMAMUX request generator

The DMAMUX request generator produces DMA requests following trigger events on its DMA request trigger inputs.

The DMAMUX request generator has multiple channels. DMA request trigger inputs are connected in parallel to all channels.

The outputs of DMAMUX request generator channels are inputs to the DMAMUX request line multiplexer.

Each DMAMUX request generator channel x has an enable bit GE (generator enable) in the corresponding DMAMUX_RGxCR register.

The DMA request trigger input for the DMAMUX request generator channel x is selected through the SIG_ID (trigger signal ID) field in the corresponding DMAMUX_RGxCR register.

Trigger events on a DMA request trigger input can be rising edge, falling edge or either edge. The active edge is selected through the GPOL (generator polarity) field in the corresponding DMAMUX_RGxCR register.

Upon the trigger event, the corresponding generator channel starts generating DMA requests on its output. Each time the DMAMUX generated request is served by the connected DMA controller (a served request is de-asserted), a built-in (inside the DMAMUX request generator) DMA request counter is decremented. At its underrun, the request generator channel stops generating DMA requests and the DMA request counter will be automatically reloaded to its programmed value upon the next trigger event.

Thus, the number of DMA requests generated after the trigger event is GNBREQ + 1.
Note: The GNBREQ field value shall only be written by software when the enable GE bit of the corresponding generator channel x is disabled.

A trigger event (edge) is detected if the state following the edge remains stable for more than two AHB clock cycles.

Upon writing into DMAMUX_RGxCR register, the trigger events are masked during three AHB clock cycles.

Trigger overrun and interrupt

If a new DMA request trigger event occurs before the DMAMUX request generator counter underrun (the internal counter programmed via the GNBREQ field of the DMAMUX_RGxCR register), and if the request generator channel x was enabled via GE, then the request trigger event overrun flag bit OFx is asserted by the hardware in the status DMAMUX_RGSR register.

Note: The request generator channel x shall be disabled (DMAMUX_RGxCR.GE = 0) at the completion of the usage of the related channel of the DMA controller. Else, upon a new detected trigger event, there will be a trigger overrun due to the absence of an acknowledge (that is, no served request) received from the DMA.

The overrun flag OFx is reset by setting the associated clear overrun flag bit COFx in the DMAMUX_RGCFR register.

Setting the DMAMUX request trigger overrun flag generates an interrupt if the DMA request trigger event overrun interrupt enable bit OIE is set in the DMAMUX_RGxCR register.

16.5 DMAMUX interrupts

An interrupt can be generated upon:
- a synchronization event overrun in each DMA request line multiplexer channel
- a trigger event overrun in each DMA request generator channel

For each case, per-channel individual interrupt enable, status and clear flag register bits are available.

<table>

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:24 **SYNC_ID[2:0]**: Synchronization identification
Selects the synchronization input (see Table 118: DMAMUX1: assignment of synchronization inputs to resources).

Bits 23:19 **NBREQ[4:0]**: Number of DMA requests minus 1 to forward
Defines the number of DMA requests to forward to the DMA controller after a synchronization event, and/or the number of DMA requests before an output event is generated.
This field shall only be written when both SE and EGE bits are low.

Bits 18:17 **SPOL[1:0]**: Synchronization polarity
Defines the edge polarity of the selected synchronization input:
00: no event, i.e. no synchronization nor detection.
01: rising edge
10: falling edge
11: rising and falling edge

Bit 16 **SE**: Synchronization enable
0: synchronization disabled
1: synchronization enabled

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **EGE**: Event generation enable
0: event generation disabled
1: event generation enabled

Bit 8 **SOIE**: Synchronization overrun interrupt enable
0: interrupt disabled
1: interrupt enabled
Bit 7  Reserved, must be kept at reset value.

Bits 6:0  **DMAREQ_ID[6:0]: DMA request identification**
Selects the input DMA request. See the DMAMUX table about assignments of multiplexer inputs to resources.

### 16.6.2  **DMAMUX2 request line multiplexer channel x configuration register (DMAMUX2_CxCR)**

**Address offset**: 0x000 + 0x04 * x, where x = 0 to 7

**Reset value**: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31-29</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits 28:24</td>
<td><strong>SYNC_ID[4:0]: Synchronization identification</strong></td>
</tr>
</tbody>
</table>
Selects the synchronization input. (C.f. table: DMAMUX- assignments of synchronization inputs to resources)

| Bits 23:19 | **NBREQ[4:0]: Number of DMA requests minus 1 to forward** |
Defines the number of DMA requests to forward to the DMA controller after a synchronization event, and/or the number of DMA requests before an output event is generated. This field shall only be written when both SE and EGE bits are low.

| Bits 18:17 | **SPOL[1:0]: Synchronization polarity** |
Defines the edge polarity of the selected synchronization input:
00: no event, i.e. no synchronization nor detection.
01: rising edge
10: falling edge
11: rising and falling edges

| Bit 16 | **SE: Synchronization enable** |
0: synchronization disabled
1: synchronization enabled

| Bits 15:10 | Reserved, must be kept at reset value. |

| Bit 9 | **EGE: Event generation enable** |
0: event generation disabled
1: event generation enabled

| Bit 8 | **SOIE: Synchronization overrun interrupt enable** |
0: interrupt disabled
1: interrupt enabled

| Bits 7:5 | Reserved, must be kept at reset value. |

| Bits 4:0 | **DMAREQ_ID[4:0]: DMA request identification** |
Selects the input DMA request. C.f. the DMAMUX table about assignments of multiplexer inputs to resources. |
### 16.6.3 DMAMUX1 request line multiplexer interrupt channel status register (DMAMUX1_CSR)

Address offset: 0x080

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>

<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **SOF[15:0]**: Synchronization overrun event flag

The flag is set when a synchronization event occurs on a DMA request line multiplexer channel x, while the DMA request counter value is lower than NBREQ.

The flag is cleared by writing 1 to the corresponding CSOFx bit in DMAMUX_CFR register.

For DMAMUX2_CFR bits 15:8 are reserved.

### 16.6.4 DMAMUX2 request line multiplexer interrupt channel status register (DMAMUX2_CSR)

Address offset: 0x080

Reset value: 0x0000 0000

<table>

</tr>
</thead>
</table>

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **SOF[7:0]**: Synchronization overrun event flag

The flag is set when a new synchronization event occurs on a DMA request line multiplexer channel x before the request counter underrun (the internal request counter programmed via the NBREQ field of the DMAMUX_CxCR register).

The flag is cleared by writing 1 to the corresponding CSOFx bit in DMAMUX2_CFR register.
16.6.5  **DMAMUX1 request line multiplexer interrupt clear flag register**  
(DMAMUX1_CFR)

Address offset: 0x084
Reset value: 0x0000 0000

Bits 31:8  Reserved, must be kept at reset value.

Bits 7:0  **CSOF[7:0]**: Clear synchronization overrun event flag

Writing 1 in each bit clears the corresponding overrun flag SOFx in the DMAMUX2_CSR register.
16.6.7 DMAMUX1 request generator channel x configuration register (DMAMUX1_RGxCR)

Address offset: 0x100 + 0x04 * x (x = 0 to 7)
Reset value: 0x0000 0000

| Bits 31:24 | Reserved, must be kept at reset value. |
| Bits 23:19 | **GNBREQ[4:0]**: Number of DMA requests to be generated (minus 1) |
|            | Defines the number of DMA requests to be generated after a trigger event. The actual number of generated DMA requests is GNBREQ + 1. |
|            | **Note**: This field shall only be written when GE bit is disabled. |
| Bits 18:17 | **GPOL[1:0]**: DMA request generator trigger polarity |
|            | Defines the edge polarity of the selected trigger input |
|            | 00: no event. I.e. none trigger detection nor generation. |
|            | 01: rising edge |
|            | 10: falling edge |
|            | 11: rising and falling edge |
| Bit 16     | **GE**: DMA request generator channel x enable |
|            | 0: DMA request generator channel x disabled |
|            | 1: DMA request generator channel x enabled |
| Bits 15:9  | Reserved, must be kept at reset value. |
| Bit 8      | **OIE**: Trigger overrun interrupt enable |
|            | 0: interrupt on a trigger overrun event occurrence is disabled |
|            | 1: interrupt on a trigger overrun event occurrence is enabled |
| Bits 7:3   | Reserved, must be kept at reset value. |
| Bits 2:0   | **SIG_ID[2:0]**: Signal identification |
|            | Selects the DMA request trigger input used for the channel x of the DMA request generator |

16.6.8 DMAMUX2 request generator channel x configuration register (DMAMUX2_RGxCR)

Address offset: 0x100 + 0x04 * (x-0) (x = 0 to 7)
Reset value: 0x0000 0000

**Bits 31:24**  
Reserved, must be kept at reset value.

**Bits 23:19**  
**GNBREQ[4:0]:** Number of DMA requests to be generated (minus 1)  
Defines the number of DMA requests to be generated after a trigger event. The actual number of generated DMA requests is GNBREQ+1.  
*Note:* This field shall only be written when GE bit is disabled.

**Bits 18:17**  
**GPOL[1:0]:** DMA request generator trigger polarity  
Defines the edge polarity of the selected trigger input  
00: no event. I.e. none trigger detection nor generation.  
01: rising edge  
10: falling edge  
11: rising and falling edge

**Bit 16**  
**GE:** DMA request generator channel x enable  
0: DMA request generator channel x disabled  
1: DMA request generator channel x enabled

**Bits 15:9**  
Reserved, must be kept at reset value.

**Bit 8**  
**OIE:** Trigger overrun interrupt enable  
0: interrupt on a trigger overrun event occurrence is disabled  
1: interrupt on a trigger overrun event occurrence is enabled

**Bits 7:5**  
Reserved, must be kept at reset value.

**Bits 4:0**  
**SIG_ID[4:0]:** Signal identification  
Selects the DMA request trigger input used for the channel x of the DMA request generator

---

|        | Reset value            |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 0x148 -| Reserved               |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

1. For DMAMUX2 bits 6:5 are reserved.
2. For DMAMUX2 bits 28:24 correspond to SYNC_ID[4:0].
3. Only applies to DMAMUX1. For DMAMUX2 the word is reserved.
4. For DMAMUX2 bits 15:8 are reserved.
5. Valid for DMAMUX1. For DMAMUX2 bits 4:0 are for SIG_ID[4:0].

Refer to Section 2.3 on page 126 for the register boundary addresses.
17 Chrom-Art Accelerator™ controller (DMA2D)

17.1 DMA2D introduction

The Chrom-Art Accelerator™ (DMA2D) is a specialized DMA dedicated to image manipulation. It can perform the following operations:

- Filling a part or the whole of a destination image with a specific color
- Copying a part or the whole of a source image into a part or the whole of a destination image
- Copying a part or the whole of a source image into a part or the whole of a destination image with a pixel format conversion
- Blending a part and/or two complete source images with different pixel format and copy the result into a part or the whole of a destination image with a different color format.

All the classical color coding schemes are supported from 4-bit up to 32-bit per pixel with indexed or direct color mode, including block based YCbCr to handle JPEG decoder output. The DMA2D has its own dedicated memories for CLUTs (color look-up tables).

17.2 DMA2D main features

The main DMA2D features are:

- Single AXI master bus architecture.
- AHB slave programming interface supporting 8/16/32-bit accesses (except for CLUT accesses which are 32-bit).
- User programmable working area size
- User programmable offset for sources and destination areas
- User programmable sources and destination addresses on the whole memory space
- Up to 2 sources with blending operation
- Alpha value can be modified (source value, fixed value or modulated value)
- User programmable source and destination color format
- Up to 11 color formats supported from 4-bit up to 32-bit per pixel with indirect or direct color coding
- Block based (8x8) YCbCr support with 4:4:4, 4:2:2 and 4:2:0 chroma sub-sampling factors
- 2 internal memories for CLUT storage in indirect color mode
- Automatic CLUT loading or CLUT programming via the CPU
- User programmable CLUT size
- Internal timer to control AXI bandwidth
- 6 operating modes: register-to-memory, memory-to-memory, memory-to-memory with pixel format conversion, memory-to-memory with pixel format conversion and blending, memory-to-memory with pixel format conversion, blending and fixed color foreground,
and memory-to memory with pixel format conversion, blending and fixed color background.

- Area filling with a fixed color
- Copy from an area to another
- Copy with pixel format conversion between source and destination images
- Copy from two sources with independent color format and blending
- Output buffer byte swapping to support refresh of displays through parallel interface
- Abort and suspend of DMA2D operations
- Watermark interrupt on a user programmable destination line
- Interrupt generation on bus error or access conflict
- Interrupt generation on process completion

### 17.3 DMA2D functional description

#### 17.3.1 General description

The DMA2D controller performs direct memory transfer. As an AXI master, it can take the control of the AXI bus matrix to initiate AXI transactions.

The DMA2D can operate in the following modes:

- Register-to-memory
- Memory-to-memory
- Memory-to-memory with Pixel Format Conversion
- Memory-to-memory with Pixel Format Conversion and Blending
- Memory-to-memory with pixel format conversion, blending and fixed color foreground

The AHB slave port is used to program the DMA2D controller.

The block diagram of the DMA2D is shown in Figure 84: DMA2D block diagram.
17.4 DMA2D pins and internal signals

Table 125 lists the DMA2D internal signals.

17.4.1 DMA2D control

The DMA2D controller is configured through the DMA2D Control Register (DMA2D_CR) which allows selecting:

The user application can perform the following operations:
- Select the operating mode
- Enable/disable the DMA2D interrupt
- Start/suspend/abort ongoing data transfers

17.4.2 DMA2D foreground and background FIFOs

The DMA2D foreground (FG) FG FIFO and background (BG) FIFO fetch the input data to be copied and/or processed.

The FIFOs fetch the pixels according to the color format defined in their respective pixel format converter (PFC).

They are programmed through a set of control registers:
- DMA2D foreground memory address register (DMA2D_FGMAR)
- DMA2D foreground offset register (DMA2D_FGOR)
- DMA2D background memory address register (DMA2D_BGMAR)
- DMA2D background offset register (DMA2D_BGBOR)
- DMA2D number of lines register (number of lines and pixel per lines) (DMA2D_NLR)

When the DMA2D operates in register-to-memory mode, none of the FIFOs is activated.
When the DMA2D operates in memory-to-memory mode (no pixel format conversion nor blending operation), only the FG FIFO is activated and acts as a buffer.
When the DMA2D operates in memory-to-memory operation with pixel format conversion (no blending operation), the BG FIFO is not activated.

17.4.3 DMA2D foreground and background pixel format converter (PFC)

DMA2D foreground pixel format converter (PFC) and background pixel format converter perform the pixel format conversion to generate a 32-bit per pixel value. The PFC can also modify the alpha channel.

The first stage of the converter converts the color format. The original color format of the foreground pixel and background pixels are configured through the CM[3:0] bits of the DMA2D_FGPFCCR and DMA2D_BGPFCCR, respectively.

The supported input formats are given in Table 126: Supported color mode in input.

<table>
<thead>
<tr>
<th>CM[3:0]</th>
<th>Color mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>
<td>ARGB8888</td>
</tr>
<tr>
<td>0001</td>
<td>RGB888</td>
</tr>
<tr>
<td>0010</td>
<td>RGB565</td>
</tr>
<tr>
<td>0011</td>
<td>ARGB1555</td>
</tr>
<tr>
<td>0100</td>
<td>ARGB4444</td>
</tr>
</tbody>
</table>
The color format are coded as follows:

- **Alpha value field:** transparency
  0xFF value corresponds to an opaque pixel and 0x00 to a transparent one.
- **R field for Red**
- **G field for Green**
- **B field for Blue**
- **L field: luminance**
  This field is the index to a CLUT to retrieve the three/four RGB/ARGB components.

If the original format was direct color mode, then the extension to 8-bit per channel is performed by copying the MSBs into the LSBs. This ensures a perfect linearity of the conversion.

If the original format does not include an alpha channel, the alpha value is automatically set to 0xFF (opaque).

If the original format is indirect color mode, a CLUT is required and each pixel format converter is associated with a 256 entry 32-bit CLUT.

For the specific alpha mode A4 and A8, no color information is stored nor indexed. The color to be used for the image generation is fixed and is defined in the DMA2D_FGCOLR for foreground pixels and in the DMA2D_BGCOLR register for background pixels.

The order of the fields in the system memory is defined in Table 127: Data order in memory.

### Table 126. Supported color mode in input

<table>
<thead>
<tr>
<th>CM[3:0]</th>
<th>Color mode</th>

</tr>
<tr>
<td>1010</td>
<td>A4</td>
</tr>
<tr>
<td>1011</td>
<td>YCbCr (only for foreground)</td>
</tr>
</tbody>
</table>
The 24-bit RGB888 aligned on 32-bit is supported through the ARGB8888 mode.

Once the 32-bit value is generated, the alpha channel can be modified according to the AM[1:0] field of the DMA2D_FGPFCCR/DMA2D_BGPFCCR registers as shown in Table 128: Alpha mode configuration.

The alpha channel can be:
- kept as it is (no modification),
- replaced by the ALPHA[7:0] value of DMA2D_FGPFCCR/DMA2D_BGPFCCR,
- or replaced by the original alpha value multiplied by the ALPHA[7:0] value of DMA2D_FGPFCCR/DMA2D_BGPFCCR divided by 255.

Note: To support the alternate format, the incoming alpha value can be inverted setting the AI bit of the DMA2D_FGPFCCR/DMA2D_BGPFCCR registers. This applies also to the Alpha value stored in the DMA2D_FGPFCCR/DMA2D_BGPFCCR and in the CLUT.

The R and B fields can also be swapped setting the RBS bit of the DMA2D_FGPFCCR/DMA2D_BGPFCCR registers. This applies also to the RGB order used in the CLUT and in the DMA2D_FGCOLR/DMA2D_BGCOLR registers.
17.4.4 DMA2D foreground and background CLUT interface

The CLUT interface manages the CLUT memory access and the automatic loading of the CLUT.

Three kinds of accesses are possible:

- CLUT read by the PFC during pixel format conversion operation
- CLUT accessed through the AHB slave port when the CPU is reading or writing data into the CLUT
- CLUT written through the AXI master port when an automatic loading of the CLUT is performed

The CLUT memory loading can be done in two different ways:

- Automatic loading
  The following sequence should be followed to load the CLUT:
  a) Program the CLUT address into the DMA2D_FGCMAR register (foreground CLUT) or DMA2D_BGCMAR register (background CLUT)
  b) Program the CLUT size in the CS[7:0] field of the DMA2D_FGPFCCR register (foreground CLUT) or DMA2D_BGPFCCR register (background CLUT).
  c) Set the START bit of the DMA2D_FGPFCCR register (foreground CLUT) or DMA2D_BGPFCCR register (background CLUT) to start the transfer. During this automatic loading process, the CLUT is not accessible by the CPU. If a conflict occurs, a CLUT access error interrupt is raised assuming CAEIE is set to ‘1’ in DMA2D_CR.

- Manual loading
  The application has to program the CLUT manually through the DMA2D AHB slave port to which the local CLUT memory is mapped. The foreground CLUT is located at address offset 0x0400 and the background CLUT at address offset 0x0800.

The CLUT format can be 24 or 32 bits. It is configured through the CCM bit of the DMA2D_FGPFCCR register (foreground CLUT) or DMA2D_BGPFCCR register (background CLUT) as shown in Table 129: Supported CLUT color mode.

Table 129. Supported CLUT color mode

<table>
<thead>
<tr>
<th>CCM</th>
<th>CLUT color mode</th>

</tbody>
</table>
17.4.5 DMA2D blender

The DMA2D blender blends the source pixels by pair to compute the resulting pixel. The blending is performed according to the following equation:

\[ \alpha_{\text{Mult}} = \frac{\alpha_{\text{FG}} \cdot \alpha_{\text{BG}}}{255} \]
\[ \alpha_{\text{OUT}} = \alpha_{\text{FG}} + \alpha_{\text{BG}} - \alpha_{\text{Mult}} \]

\[ C_{\text{OUT}} = \frac{C_{\text{FG}} \cdot \alpha_{\text{FG}} + C_{\text{BG}} \cdot \alpha_{\text{BG}} - C_{\text{BG}} \cdot \alpha_{\text{Mult}}}{\alpha_{\text{OUT}}} \quad \text{with } C = \text{R or G or B} \]

Division is rounded to the nearest lower integer

No configuration register is required by the blender. The blender usage depends on the DMA2D operating mode defined in MODE[1:0] field of the DMA2D_CR register.

17.4.6 DMA2D output PFC

The output PFC performs the pixel format conversion from 32 bits to the output format defined in the CM[2:0] field of the DMA2D output pixel format converter configuration register (DMA2D_OPFCCR).

The supported output formats are given in Table 131: Supported color mode in output

<table>
<thead>
<tr>
<th>CM[2:0]</th>
<th>Color mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>ARGB8888</td>
</tr>
<tr>
<td>001</td>
<td>RGB888</td>
</tr>
<tr>
<td>010</td>
<td>RGB565</td>
</tr>
<tr>
<td>011</td>
<td>ARGB1555</td>
</tr>
<tr>
<td>100</td>
<td>ARGB4444</td>
</tr>
</tbody>
</table>

Note: To support the alternate format, the calculated alpha value can be inverted setting the AI bit of the DMA2D_OPFCCR registers. This applies also to the Alpha value used in the DMA2D_OCOLR.

The R and B fields can also be swapped setting the RBS bit of the DMA2D_OPFCCR registers. This applies also to the RGB order used in the DMA2D_OCOLR.
17.4.7 DMA2D output FIFO

The output FIFO programs the pixels according to the color format defined in the output PFC.

The destination area is defined through a set of control registers:
- DMA2D output memory address register (DMA2D_OMAR)
- DMA2D output offset register (DMA2D_OOR)
- DMA2D number of lines register (number of lines and pixel per lines) (DMA2D_NLR)

If the DMA2D operates in register-to-memory mode, the configured output rectangle is filled by the color specified in the DMA2D output color register (DMA2D_OCOLR) which contains a fixed 32-bit, 24-bit or 16-bit value. The format is selected by the CM[2:0] field of the DMA2D_OPFCCR register.

The data are stored into the memory in the order defined in Table 132: Data order in memory

Table 132. Data order in memory

<table>
<thead>
<tr>
<th>Color mode</th>
<th>@ + 3</th>
<th>@ + 2</th>
<th>@ + 1</th>
<th>@ + 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARGB8888</td>
<td>A0[7:0]</td>
<td>R0[7:0]</td>
<td>G0[7:0]</td>
<td>B0[7:0]</td>
</tr>
<tr>
<td>RGB888</td>
<td>B0[7:0]</td>
<td>R0[7:0]</td>
<td>G0[7:0]</td>
<td>B0[7:0]</td>
</tr>
<tr>
<td>RGB565</td>
<td>G0[7:0]</td>
<td>B0[7:0]</td>
<td>R0[7:0]</td>
<td>G0[7:0]</td>
</tr>
</tbody>
</table>

The RGB888 aligned on 32-bit is supported through the ARGB8888 mode.

17.4.8 DMA2D output FIFO byte reordering

The output FIFO bytes can be reordered to support display frame buffer update through a parallel interface (F(S)MC) directly from the DMA2D.

The reordering of bytes can be done using:
- RBS bit to swap red and blue component
- SB bit to swap byte two by two in the output FIFO

When the byte swapping is activated (SB field of the DMA2D_OPFCR is set), the number of pixel per line (PL field of the DMA2D_NLR) must be even and the output memory address (MA field of the DMA2D_OMAR) must be even, and the output line offset computed in bytes (resulting from LOM field of DMA2D_CR and LO field of DMA2D_OOR values) must be even. If not a configuration error will be detected.
16-bit mode (RGB565)

This mode is supported without byte reordering by the DMA2D.

**Figure 85. Intel 8080 16-bit mode (RGB565)**

16/24-bit mode (RGB888)

This mode needs data reordering.
1. The red and the blue have to be swapped (setting the RBS bit)
2. The MSB and the LSB bytes of an half-word as to be swapped (setting the SB bit)

**Figure 86. Intel 8080 18/24-bit mode (RGB888)**

17.4.9 DMA2D AXI master port timer

An 8-bit timer is embedded into the AXI master port to provide an optional limitation of the bandwidth on the crossbar.

This timer is clocked by the AXI clock and counts a dead time between two consecutive accesses. This limits the bandwidth usage.

The timer enabling and the dead time value are configured through the AXI master port timer configuration register (DMA2D_AMPTCR).

17.4.10 DMA2D transactions

DMA2D transactions consist of a sequence of a given number of data transfers. The number of data and the width can be programmed by software.

Each DMA2D data transfer is composed of up to 4 steps:

1. Data loading from the memory location pointed by the DMA2D_FGMAR register and pixel format conversion as defined in DMA2D_FGCR.
2. Data loading from a memory location pointed by the DMA2D_BGMAR register and pixel format conversion as defined in DMA2D_BGCR.
3. Blending of all retrieved pixels according to the alpha channels resulting of the PFC operation on alpha values.
4. Pixel format conversion of the resulting pixels according to the DMA2D_OCR register and programming of the data to the memory location addressed through the DMA2D_OMAR register.

17.4.11 DMA2D configuration

Both source and destination data transfers can target peripherals and memories in the whole 4-Gbyte memory area, at addresses ranging between 0x0000 0000 and 0xFFFF FFFF.

The DMA2D can operate in any of the four following modes selected through MODE[1:0] bits of the DMA2D_CR register:
- Register-to-memory
- Memory-to-memory
- Memory-to-memory with PFC
- Memory-to-memory with PFC and blending
- Memory-to-memory with PFC, blending and fixed FG color

Register-to-memory

The register-to-memory mode is used to fill a user defined area with a predefined color. The color format is set in the DMA2D_OPFCCR.

The DMA2D does not perform any data fetching from any source. It just writes the color defined in the DMA2D_OCOLR register to the area located at the address pointed by the DMA2D_OMAR and defined in the DMA2D_NLR and DMA2D_OOR.

Memory-to-memory

In memory-to-memory mode, the DMA2D does not perform any graphical data transformation. The foreground input FIFO acts as a buffer and the data are transferred from the source memory location defined in DMA2D_FGMAR to the destination memory location pointed by DMA2D_OMAR.

The color mode programmed in the CM[3:0] bits of the DMA2D_FGPFCCR register defines the number of bits per pixel for both input and output.

The size of the area to be transferred is defined by the DMA2D_NLR and DMA2D_FGOR registers for the source, and by DMA2D_NLR and DMA2D_OOR registers for the destination.

Memory-to-memory with PFC

In this mode, the DMA2D performs a pixel format conversion of the source data and stores them in the destination memory location.

The size of the areas to be transferred are defined by the DMA2D_NLR and DMA2D_FGOR registers for the source, and by DMA2D_NLR and DMA2D_OOR registers for the destination.

Data are fetched from the location defined in the DMA2D_FGMAR register and processed by the foreground PFC. The original pixel format is configured through the DMA2D_FGPFCCR register.

If the original pixel format is direct color mode, then the color channels are all expanded to 8 bits.

If the pixel format is indirect color mode, the associated CLUT has to be loaded into the CLUT memory.

The CLUT loading can be done automatically by following the sequence below:
1. Set the CLUT address into the DMA2D_FGCMAR.
2. Set the CLUT size in the CS[7:0] bits of the DMA2D_FGPFCCR register.
3. Set the CLUT format (24 or 32 bits) in the CCM bit of the DMA2D_FGPFCCR register.
4. Start the CLUT loading by setting the START bit of the DMA2D_FGPFCCR register.

Once the CLUT loading is complete, the CTCIF flag of the DMA2D_IFR register is raised, and an interrupt is generated if the CTCIE bit is set in DMA2D_CR. The automatic CLUT loading process cannot work in parallel with classical DMA2D transfers.

The CLUT can also be filled by the CPU or by any other master through the AHB port. The access to the CLUT is not possible when a DMA2D transfer is ongoing and uses the CLUT (indirect color format).

In parallel to the color conversion process, the alpha value can be added or changed depending on the value programmed in the DMA2D_FGPFCCR register. If the original image does not have an alpha channel, a default alpha value of 0xFF is automatically added to obtain a fully opaque pixel. The alpha value can be modified according to the AM[1:0] bits of the DMA2D_FGPFCCR register:
- It can be unchanged.
- It can be replaced by the value defined in the ALPHA[7:0] value of the DMA2D_FGPFCCR register.
- It can be replaced by the original value multiplied by the ALPHA[7:0] value of the DMA2D_FGPFCCR register divided by 255.

The resulting 32-bit data are encoded by the OUT PFC into the format specified by the CM[2:0] field of the DMA2D_OPFCCR register. The output pixel format cannot be the indirect mode since no CLUT generation process is supported.

The processed data are written into the destination memory location pointed by DMA2D_OMAR.

**Memory-to-memory with PFC and blending**

In this mode, 2 sources are fetched in the foreground FIFO and background FIFO from the memory locations defined by DMA2D_FGMAR and DMA2D_BGMAR.

The two pixel format converters have to be configured as described in the memory-to-memory mode. Their configurations can be different as each pixel format converter are independent and have their own CLUT memory.

Once each pixel has been converted into 32 bits by their respective PFCs, they are blended according to the equation below:

\[
\begin{align*}
C_{OUT} & = \frac{C_{FG}a_{FG} + C_{BG}a_{BG} - C_{BG}a_{Mult}}{a_{OUT}} \\
\text{with } C & = R \text{ or } G \text{ or } B
\end{align*}
\]

\[
\text{Division are rounded to the nearest lower integer}
\]
The resulting 32-bit pixel value is encoded by the output PFC according to the specified output format, and the data are written into the destination memory location pointed by DMA2D_OMAR.

**Memory-to-memory with PFC, blending and fixed color FG**

In this mode, only 1 source is fetched in the background FIFO from the memory location defined by DMA2D_BGMAR.

The value of the foreground color is given by the DMA2D_FGCOLR register and the alpha value is set to 0xFF (opaque).

The alpha value can be replaced or modified according to the AM[1:0] and ALPHA[7:0] fields of the DMA2D_FGPFCCR.

The two pixel format converters have to be configured as described in the memory-to-memory mode. Their configurations can be different as each pixel format converter are independent and have their own CLUT memory.

Once each pixel has been converted into 32 bits by their respective PFCs, they are blended together, and the resulting 32-bit pixel value is encoded by the output PFC according to the specified output format, and the data are written into the destination memory location pointed by DMA2D_OMAR.

**Memory-to-memory with PFC, blending and fixed color BG**

In this mode, only 1 source is fetched in the foreground FIFO from the memory location defined by DMA2D_FGMAR.

The value of the background color is given by the DMA2D_BGCOLOR register and the alpha value is set to 0xFF (opaque).

The alpha value can be replaced or modified according to the AM[1:0] and ALPHA[7:0] fields of the DMA2D_BGPFCR.

The two pixel format converters have to be configured as described in the memory-to-memory mode. Their configurations can be different as each pixel format converter are independent and have their own CLUT memory.

Once each pixel has been converted into 32 bits by their respective PFCs, they are blended together, and the resulting 32-bit pixel value is encoded by the output PFC according to the specified output format, and the data are written into the destination memory location pointed by DMA2D_OMAR.

**Configuration error detection**

The DMA2D checks that the configuration is correct before any transfer. The configuration error interrupt flag is set by hardware when a wrong configuration is detected when a new transfer/automatic loading starts. An interrupt is then generated if the CEIE bit of the DMA2D_CR is set.
The wrong configurations that can be detected are listed below:

- Foreground CLUT automatic loading: MA bits of DMA2D_FGCMAR are not aligned with CCM of DMA2D_FGPFCCR.
- Background CLUT automatic loading: MA bits of DMA2D_BGCMAR are not aligned with CCM of DMA2D_BGPFCCR.
- Memory transfer (except in register-to-memory mode and except in memory-to-memory mode with blending and fixed color FG): MA bits of DMA2D_FGMAR are not aligned with CM of DMA2D_FGPFCCR.
- Memory transfer (except in register-to-memory mode and except in memory-to-memory mode with blending and fixed color FG): CM bits of DMA2D_FGPFCCR are invalid.
- Memory transfer (except in register-to-memory mode and except in memory-to-memory mode with blending and fixed color FG): PL bits of DMA2D_NLR are odd while CM of DMA2D_FGPFCCR is A4 or L4.
- Memory transfer (except in register-to-memory mode and except in memory-to-memory mode with blending and fixed color FG): LO bits of DMA2D_FGOR are odd while CM of DMA2D_FGPFCCR is A4 or L4 and LOM bit of the DMA2D_CR is pixel mode.
- Memory transfer (only in blending mode and except in memory-to-memory mode with blending and fixed color FG): MA bits of DMA2D_BGMAR are not aligned with the CM of DMA2D_BGPFCCR.
- Memory transfer: (only in blending mode and in blending with fixed color FG mode) CM bits of DMA2D_BGPFCCR are invalid.
- Memory transfer (only in blending mode and in blending with fixed color FG mode): PL bits of DMA2D_NLR odd while CM of DMA2D_BGPFCCR is A4 or L4.
- Memory transfer (only in blending mode and in blending with fixed color FG mode): LO bits of DMA2D_BGOR are odd while CM of DMA2D_BGPFCCR is A4 or L4 and LOM bit of the DMA2D_CR is pixel mode.
- Memory transfer (except in memory to memory mode): MA bits of DMA2D_OMAR are not aligned with CM bits of DMA2D_OPFCCR.
- Memory transfer (except in memory to memory mode): CM bits of DMA2D_OPFCCR are invalid.
- Memory transfer with byte swapping: PL bits of DMA2D_NLR are odd or MA bits of the DMA2D_OMAR are odd or LO in bytes (resulting from LOM bit of the DMA2D_CR and LO bits of DMA2D_OOR values) are odd while SB bit of DMA2D_OPFCCR is set.
- Memory transfer: NL bits of DMA2D_NLR = 0.
- Memory transfer: PL bits of DMA2D_NLR = 0.
- Memory transfer: MODE bits of DMA2D_CR are invalid.
- YCbCr format: when a CLUT loading starts setting the START bit of the DMA2D_FGPFCCR.
- YCbCr format: when the memory-to-memory mode is selected.
- YCbCr format: when YCbCr4:4:4 is selected and the sum of the number of pixel (PL) and the line offset LO is not a multiple of 8 pixels.
- YCbCr format: when YCbCr4:2:2 or YCbCr4:2:0 is selected and the sum of the number of pixel (PL) and the line offset LO is not a multiple of 16 pixels.
17.4.12 **YCbCr support**

The DMA2D foreground plane can support 8x8 block based YCbCr as output by the JPEG decoder with different chroma sub-sampling factors:

The memory organization follows the standard JFIF rules:
- Each of the three color component must be coded on 8-bit
- Each component must be arranged by blocks of 8x8 (64 bytes) called MCU

Depending of the chroma sub-sampling factor the MCU must be arranged in the memory as described in Table 135: **MCU order in memory**.

<table>
<thead>
<tr>
<th>Sub-sampling</th>
<th>@</th>
<th>@ + 64</th>
<th>@ + 128</th>
<th>@+192</th>
<th>@+256</th>
<th>@ + 320</th>
</tr>
</thead>
<tbody>
<tr>
<td>4:4:4</td>
<td>Y1</td>
<td>Cb1</td>
<td>Cr1</td>
<td>Y2</td>
<td>Cb2</td>
<td>Cr2</td>
</tr>
<tr>
<td>4:2:2</td>
<td>Y1</td>
<td>Y2</td>
<td>Cb12</td>
<td>Cr12</td>
<td>Y3</td>
<td>Y4</td>
</tr>
<tr>
<td>4:2:0</td>
<td>Y1</td>
<td>Y2</td>
<td>Y3</td>
<td>Y4</td>
<td>Cb1234</td>
<td>Cr1234</td>
</tr>
</tbody>
</table>

The chroma sub-sampling factor is configured through the CSS field of the DMA2D_FGPFCCR register.

Once the DMA2D has started with the foreground configured in YCbCr color mode, the first 2 chroma MCU are loaded in the foreground CLUT. Once the chroma MCU are loaded, the DMA2D performs the loading of the Y MCU as for a classical color mode.

17.4.13 **DMA2D transfer control (start, suspend, abort and completion)**

Once the DMA2D is configured, the transfer can be launched by setting the START bit of the DMA2D_CR register. Once the transfer is completed, the START bit is automatically reset and the TCIF flag of the DMA2D_ISR register is raised. An interrupt can be generated if the TCIE bit of the DMA2D_CR is set.

The user application can suspend the DMA2D at any time by setting the SUSP bit of the DMA2D_CR register. The transaction can then be aborted by setting the ABORT bit of the DMA2D_CR register or can be restarted by resetting the SUSP bit of the DMA2D_CR register.

The user application can abort at any time an ongoing transaction by setting the ABORT bit of the DMA2D_CR register. In this case, the TCIF flag is not raised.

Automatic CLUT transfers can also be aborted or suspended by using their own START bits in the DMA2D_FGPFCCR and DMA2D_BGPFCCR registers.

17.4.14 **Watermark**

A watermark can be programmed to generate an interrupt when the last pixel of a given line has been written to the destination memory area.

The line number is defined in the LW[15:0] field of the DMA2D_LWR register.

When the last pixel of this line has been transferred, the TWIF flag of the DMA2D_ISR register is raised and an interrupt is generated if the TWIE bit of the DMA2D_CR is set.
17.4.15 Error management

Two kind of errors can be triggered:

- AXI master port errors signaled by the TEIF flag of the DMA2D_ISR register.
- Conflicts caused by CLUT access (CPU trying to access the CLUT while a CLUT loading or a DMA2D transfer is ongoing) signaled by the CAEIF flag of the DMA2D_ISR register.

Both flags are associated to their own interrupt enable flag in the DMA2D_CR register to generate an interrupt if need be (TEIE and CAEIE).

17.4.16 AXI dead time

To limit the AXI bandwidth usage, a dead time between two consecutive AXI accesses can be programmed.

This feature can be enabled by setting the EN bit in the DMA2D_AMTCR register.

The dead time value is stored in the DT[7:0] field of the DMA2D_AMTCR register. This value represents the guaranteed minimum number of cycles between two consecutive transactions on the AXI bus.

The update of the dead time value while the DMA2D is running will be taken into account for the next AXI transfer.

17.5 DMA2D interrupts

An interrupt can be generated on the following events:

- Configuration error
- CLUT transfer complete
- CLUT access error
- Transfer watermark reached
- Transfer complete
- Transfer error

Separate interrupt enable bits are available for flexibility.

Bit 9 **TCIE**: Transfer complete interrupt enable
   This bit is set and cleared by software.
   0: TC interrupt disable
   1: TC interrupt enable

Bit 8 **TEIE**: Transfer error interrupt enable
   This bit is set and cleared by software.
   0: TE interrupt disable
   1: TE interrupt enable

Bit 7 Reserved, must be kept at reset value.

Bit 6 **LOM**: Line Offset Mode
   This bit configures how is expressed the line offset (pixels or bytes) for the foreground, background and output.
   This bit is set and cleared by software. It cannot be modified while a transfer is ongoing.
   0: Line offsets are expressed in pixels
   1: Line offsets are expressed in bytes

Bits 5:3 Reserved, must be kept at reset value.

Bit 2 **ABORT**: Abort
   This bit can be used to abort the current transfer. This bit is set by software and is automatically reset by hardware when the START bit is reset.
   0: No transfer abort requested
   1: Transfer abort requested

Bit 1 **SUSP**: Suspend
   This bit can be used to suspend the current transfer. This bit is set and reset by software. It is automatically reset by hardware when the START bit is reset.
   0: Transfer not suspended
   1: Transfer suspended

Bit 0 **START**: Start
   This bit can be used to launch the DMA2D according to the parameters loaded in the various configuration registers. This bit is automatically reset by the following events:
   - At the end of the transfer
   - When the data transfer is aborted by the user application by setting the ABORT bit in DMA2D_CR
   - When a data transfer error occurs
   - When the data transfer has not started due to a configuration error or another transfer operation already ongoing (automatic CLUT loading).

```

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 \textbf{LO}[15:0]: Line offset

The line offset used for the foreground image, expressed in pixel when the LOM bit is reset and in byte when the LOM bit is set.

When expressed in pixels, only \textbf{LO}[13:0] bits are considered, \textbf{LO}[15:14] bits are ignored.

This value is used for the address generation. It is added at the end of each line to determine the starting address of the next line.

These bits can only be written when data transfers are disabled. Once the data transfer has started, they become read-only.

If the image format is 4-bit per pixel, the line offset must be even.
17.6.6  DMA2D background memory address register (DMA2D_BGMAR)

Address offset: 0x0014
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bits 31:16</th>
<th>MA[31:16]</th>
<th>rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw</th>

<td>14</td>
<td>13 12 11 10 9 8 7 6 5 4 3 2 1 0</td>
</tr>
</tbody>
</table>

Bits 31:0  MA[31:0]: Memory address
Address of the data used for the background image. This register can only be written when data transfers are disabled. Once a data transfer has started, this register is read-only.
The address alignment must match the image format selected e.g. a 32-bit per pixel format must be 32-bit aligned, a 16-bit per pixel format must be 16-bit aligned and a 4-bit per pixel format must be 8-bit aligned.

17.6.7  DMA2D background offset register (DMA2D_BGOR)

Address offset: 0x0018
Reset value: 0x0000 0000

<table>
<thead>

</table>
Bits 15:8 **CS[7:0]: CLUT size**

These bits define the size of the CLUT used for the foreground image. Once the CLUT transfer has started, this field is read-only.

The number of CLUT entries is equal to CS[7:0] + 1.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **START: Start**

This bit can be set to start the automatic loading of the CLUT. It is automatically reset:
- at the end of the transfer
- when the transfer is aborted by the user application by setting the ABORT bit in DMA2D_CR
- when a transfer error occurs
- when the transfer has not started due to a configuration error or another transfer operation already ongoing (data transfer or automatic background CLUT transfer).

Bit 4 **CCM: CLUT color mode**

This bit defines the color format of the CLUT. It can only be written when the transfer is disabled. Once the CLUT transfer has started, this bit is read-only.

0: ARGB8888
1: RGB888

Bits 3:0 **CM[3:0]: Color mode**

These bits define the color format of the foreground image. They can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 31:24 **ALPHA[7:0]:** Alpha value

These bits define a fixed alpha channel value which can replace the original alpha value or be multiplied with the original alpha value according to the alpha mode selected with bits AM[1: 0]. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **RBS:** Red Blue Swap

This bit allows to swap the R & B to support BGR or ABGR color formats. Once the transfer has started, this bit is read-only.

0: Regular mode (RGB or ARGB)
1: Swap mode (BGR or ABGR)

Bit 20 **AI:** Alpha Inverted

This bit inverts the alpha value. Once the transfer has started, this bit is read-only.

0: Regular alpha
1: Inverted alpha

Bits 19:18 Reserved, must be kept at reset value.

Bits 17:16 **AM[1:0]:** Alpha mode

These bits define which alpha channel value to be used for the background image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

00: No modification of the foreground image alpha channel value
01: Replace original background image alpha channel value by ALPHA[7: 0]
10: Replace original background image alpha channel value by ALPHA[7:0] multiplied with original alpha channel value
others: meaningless

Bits 15:8 **CS[7:0]:** CLUT size

These bits define the size of the CLUT used for the BG. Once the CLUT transfer has started, this field is read-only.
The number of CLUT entries is equal to CS[7:0] + 1.

Bits 7:6 Reserved, must be kept at reset value.
Bit 5 **START**: Start
This bit is set to start the automatic loading of the CLUT. This bit is automatically reset:
- at the end of the transfer
- when the transfer is aborted by the user application by setting the ABORT bit in the DMA2D_CR
- when a transfer error occurs
- when the transfer has not started due to a configuration error or another transfer operation already ongoing (data transfer or automatic BackGround CLUT transfer).

Bit 4 **CCM**: CLUT Color mode
These bits define the color format of the CLUT. This register can only be written when the transfer is disabled. Once the CLUT transfer has started, this bit is read-only.
- 0: ARGB8888
- 1: RGB888

Bits 3:0 **CM[3:0]**: Color mode
These bits define the color format of the foreground image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

ARGB8888 or RGB888 color mode

Bits 31:24 ALPHA[7:0]: Alpha channel value in ARGB8888 mode otherwise reserved
These bits define the alpha channel of the output color. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 23:16 RED[7:0]: Red value in ARGB8888 or RGB888 mode otherwise reserved
These bits define the red value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 15:8 GREEN[7:0]: Green value in ARGB8888 or RGB888
These bits define the green value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 7:0 BLUE[7:0]: Blue value in ARGB8888 or RGB888
These bits define the blue value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

RGB565 color mode

Bits 15:11 RED[4:0]: Red value in RGB565 mode
These bits define the red value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 12:5 GREEN[5:0]: Green value in RGB565 mode
These bits define the green value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 4:0 BLUE[4:0]: Blue value in RGB565 mode
These bits define the blue value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

ARGB1555 color mode

Bit 15 A: Alpha channel value in ARGB1555 mode
This bit defines the alpha channel of the output color. This bit can only be written when data transfers are disabled. Once the transfer has started, it is read-only.

Bits 14:10 RED[4:0]: Red value in ARGB1555 mode
These bits define the red value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 9:5 GREEN[4:0]: Green value in ARGB1555 mode
These bits define the green value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 4:0 BLUE[4:0]: Blue value in ARGB1555 mode
These bits define the blue value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

ARGB4444 color mode

Bits 15:12 ALPHA[3:0]: Alpha channel value in ARGB4444
This bit defines the alpha channel of the output color. This bit can only be written when data transfers are disabled. Once the transfer has started, it is read-only.
17.6.16 DMA2D output memory address register (DMA2D_OMAR)

Address offset: 0x003C
Reset value: 0x0000 0000

<table>
<thead>

</tr>
</tbody>
</table>

Bits 31:0 MA[31:0]: Memory address
Address of the data used for the output FIFO. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

The address alignment must match the image format selected e.g. a 32-bit per pixel format must be 32-bit aligned and a 16-bit per pixel format must be 16-bit aligned.

17.6.17 DMA2D output offset register (DMA2D_OOR)

Address offset: 0x0040
Reset value: 0x0000 0000

<table>

Bits 31:0 LO[15:0]: Memory offset
These bits define the memory offset of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.
Bits 31:16  Reserved, must be kept at reset value.

Bits 15:0  **LO[15:0]: Line offset**

The line offset used for the output expressed in pixel when the LOM bit is reset and in byte when the LOM bit is set.

When expressed in pixels, only LO[13:0] is considered, LO[15:14] are ignored.

This value is used for the address generation. It is added at the end of each line to determine the starting address of the next line.

These bits can only be written when data transfers are disabled. Once data transfer has started, they become read-only.

### 17.6.18 DMA2D number of line register (DMA2D_NLR)

</tbody>
</table>

Bits 31:30  Reserved, must be kept at reset value.

Bits 29:16  **PL[13:0]: Pixel per lines**

Number of pixels per lines of the area to be transferred. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

If any of the input image format is 4-bit per pixel, pixel per lines must be even.

Bits 15:0  **NL[15:0]: Number of lines**

Number of lines of the area to be transferred. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

### 17.6.19 DMA2D line watermark register (DMA2D_LWR)

17.6.20 DMA2D AXI master timer configuration register (DMA2D_AMTCR)

Address offset: 0x004C
Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 LW[15:0]: Line watermark
These bits allow to configure the line watermark for interrupt generation.
An interrupt is raised when the last pixel of the watermarked line has been transferred.
These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

17.6.21 DMA2D foreground CLUT (DMA2D_FGCLUT[y])

Address offset: 0x0400 + 4*y, y=0..255
Reset value: 0xXXXX XXXX

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 DT[7:0]: Dead time
Dead time value in the AXI clock cycle inserted between two consecutive accesses on
the AXI master port. These bits represent the minimum guaranteed number of cycles
between two consecutive AXI accesses.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 EN: Enable
Enables the dead time functionality.

Bit 15:0 LW[15:0]: Line watermark
These bits allow to configure the line watermark for interrupt generation.
An interrupt is raised when the last pixel of the watermarked line has been transferred.
These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.
17.6.22 DMA2D background CLUT (DMA2D_BGCLUT[y])

Address offset: 0x0800 + 4*y, y=0..255
Reset value: 0xXXXX XXXX

<table>

Bits 31:24 ALPHA<y>[7:0]: Alpha <y>
Alpha value for index <y> for the background.

Bits 23:16 RED<y>[7:0]: Red <y>
Red value for index <y> for the background.

Bits 15:8 GREEN<y>[7:0]: Green <y>
Green value for index <y> for the background.

Bits 7:0 BLUE<y>[7:0]: Blue <y>
Blue value for index <y> for the background.
### 17.6.23 DMA2D register map

The following table summarizes the DMA2D registers. Refer to Section 2.3 on page 126 for the DMA2D register base address.

Refer to Section 2.3 on page 126 for the register boundary addresses.
18 Nested Vectored Interrupt Controllers

18.1 NVIC features

The NVIC includes the following features:

- up to 150 maskable interrupt channels for STM32H7xxx (not including the 16 interrupt lines of Cortex®-M7 with FPU)
- 16 programmable priority levels (4 bits of interrupt priority are used)
- low-latency exception and interrupt handling
- power management control
- implementation of system control registers

The NVIC and the processor core interface are closely coupled, which enables low latency interrupt processing and efficient processing of late arriving interrupts.

All interrupts, including the core exceptions, are managed by the NVIC.

For more information on exceptions and NVIC programming, refer to PM0253 programming manual for Cortex®-M7.

18.1.1 SysTick calibration value register

The SysTick calibration value (SYST_CALIB) is fixed to 0x3E8. It provides a reference timebase of 1 ms based when the SysTick clock frequency is 1 MHz. To match the 1 ms timebase whatever the application frequency, the SysTick reload value must be programmed as follows in the SYST_RVR register:

- The SysTick clock source is the 100 MHz CPU clock (HCLK):

  reload value = \( \left( \frac{F_{HCLK} \times SYST\_CALIB}}{1} \right) - 1 \)

- or the SysTick clock source is an external clock:

  reload value = \( \left( \frac{F_{HCLK}}{8} \times SYST\_CALIB} \right) - 1 \)

where \( F_{HCLK} \) refers to the AHB frequency expressed in MHz.

For example, to achieve a timebase of 1 ms when the SysTick clock source is the 100 MHz HCLK:

\[
\text{reload value} = (100 \times SYST\_CALIB} \right) - 1 = 0x1869F
\]
18.1.2 Interrupt and exception vectors

The exception vectors connected to the NVIC are the following: reset, NMI, HardFault, MemManage, Bus Fault, UsageFault, SVCall, DebugMonitor, PendSV, SysTick.

1. When different signals are connected to the same NVIC interrupt line, they are OR-ed.
19 Extended interrupt and event controller (EXTI)

The Extended Interrupt and event controller (EXTI) manages wakeup through configurable and direct event inputs. It provides wakeup requests to the Power Control, and generates interrupt requests to the CPU NVIC and to the D3 domain DMAMUX2, and events to the CPU event input.

The EXTI wakeup requests allow the system to be woken up from Stop mode, and the CPU to be woken up from CStop mode.

Both the interrupt request and event request generation can also be used in Run modes.

19.1 EXTI main features

The EXTI main features are the following:

- All Event inputs allow the CPU to wakeup and to generate a CPU interrupt and/or CPU event
- Some Event inputs allow the user to wakeup the D3 domain for autonomous Run mode and generate an interrupt to the D3 domain, i.e. the DMAMUX2

The asynchronous event inputs are classified in 2 groups:

- Configurable events (signals from I/Os or peripherals able to generate a pulse), they have the following features:
  - Selectable active trigger edge
  - Interrupt pending status register bit
  - Individual Interrupt and Event generation mask
  - SW trigger possibility
  - Configurable System D3 domain wakeup events have a D3 Pending mask and status register and may have a D3 interrupt signal.
- Direct events (interrupt and wakeup sources from other peripherals, requiring to be cleared in the peripheral), they feature
  - Fixed rising edge active trigger
  - No interrupt pending status register bit in the EXTI (the interrupt pending status is provided by the peripheral generating the event)
  - Individual Interrupt and Event generation mask
  - No SW trigger possibility
  - Direct system D3 domain wakeup events have a D3 Pending mask and status register and may have a D3 interrupt signal

19.2 EXTI block diagram

As shown in Figure 87, the EXTI consists of a Register block accessed via an APB interface, an Event input Trigger block, and a Masking block.

The Register block contains all EXTI registers.

The Event input trigger block provides Event input edge triggering logic.
The Masking block provides the Event input distribution to the different wakeup, interrupt
and event outputs, and their masking.

Figure 87. EXTI block diagram

19.2.1 EXTI connections between peripherals, CPU, and D3 domain

The peripherals able to generate wakeup events when the system is in Stop mode or the
CPU is in CStop mode are connected to an EXTI Configurable event input or Direct Event
input:

- Peripheral signals that generate a pulse are connected to an EXTI Configurable Event
  input. For these events the EXTI provides a CPU status pending bit that has to be
  cleared.
- Peripheral Interrupt and Wakeup sources that have to be cleared in the peripheral are
  connected to an EXTI Direct Event input. There is no CPU status pending bit within the
  EXTI. The Interrupt or Wakeup is cleared by the CPU in the peripheral.

The Event inputs able to wakeup D3 for autonomous Run mode are provided with a D3
domain pending request function, that has to be cleared. This clearing request is taken care
of by the signal selected by the Pending clear selection.

The CPU interrupts are connected to their respective CPU NVIC, and, similarly, the CPU
event is connected to the CPU rxev input.

The EXTI Wakeup signals are connected to the PWR block, and are used to wakeup the D3
domain and/or the CPU.

The D3 domain interrupts allow the system to trigger events for D3 domain autonomous
Run mode operation.
19.3 EXTI functional description

Depending on the EXTI Event input type and wakeup target(s), different logic implementations are used. The applicable features are controlled from register bits:

- Active trigger edge enable, by EXTI rising trigger selection register (EXTI_RTSR1), EXTI rising trigger selection register (EXTI_RTSR2), EXTI rising trigger selection register (EXTI_RTSR3), and EXTI falling trigger selection register (EXTI_FTSR1), EXTI falling trigger selection register (EXTI_FTSR2), EXTI falling trigger selection register (EXTI_FTSR3)
- Software trigger, by EXTI software interrupt event register (EXTI_SWIER1), EXTI software interrupt event register (EXTI_SWIER2), EXTI software interrupt event register (EXTI_SWIER3)
- CPU Interrupt enable, by EXTI interrupt mask register (EXTI_CPUIMR1), EXTI interrupt mask register (EXTI_CPUIMR2), EXTI interrupt mask register (EXTI_CPUIMR3)
- CPU Event enable, by EXTI event mask register (EXTI_CPUEMR1), EXTI event mask register (EXTI_CPUEMR2), EXTI event mask register (EXTI_CPUEMR3)
- D3 domain wakeup pending, by EXTI D3 pending mask register (EXTI_D3PMR1), EXTI D3 pending mask register (EXTI_D3PMR2), EXTI D3 pending mask register (EXTI_D3PMR3)

2. Waking-up D3 domain for autonomous Run mode, and/or CPU.
19.3.1 EXTI Configurable event input CPU wakeup

*Figure 89* is a detailed representation of the logic associated with Configurable Event inputs which will always wake up the CPU.

*Figure 88. Configurable event triggering logic CPU wakeup*

The Software interrupt event register allows the system to trigger Configurable events by software, writing the EXTI software interrupt event register (EXTI_SWIER1), the EXTI software interrupt event register (EXTI_SWIER2), or the EXTI software interrupt event register (EXTI_SWIER3) register bit.

The rising edge EXTI rising trigger selection register (EXTI_RTSR1), EXTI rising trigger selection register (EXTI_RTSR2), EXTI rising trigger selection register (EXTI_RTSR3), and falling edge EXTI falling trigger selection register (EXTI_FTSR1), EXTI falling trigger selection register (EXTI_FTSR2), EXTI falling trigger selection register (EXTI_FTSR3) selection registers allow the system to enable and select the Configurable event active trigger edge or both edges.

The devices feature dedicated interrupt mask registers, namely EXTI interrupt mask register (EXTI_CPUIMR1) and EXTI interrupt mask register (EXTI_CPUIMR2), EXTI interrupt mask register (EXTI_CPUIMR3), and EXTI pending register (EXTI_CPUPR1), EXTI pending register (EXTI_CPUPR2), EXTI pending register (EXTI_CPUPR3) for Configurable events pending request registers. The CPU pending register will only be set for an unmasked CPU interrupt. Each event provides a individual CPU interrupt to the CPU NVIC. The Configurable events interrupts need to be acknowledged by software in the EXTI_CPUPR register.
The devices feature dedicated event mask registers, i.e. EXTI event mask register (EXTI_CPUEMR1), EXTI event mask register (EXTI_CPUEMR2), and EXTI event mask register (EXTI_CPUEMR3). The enabled event then generates an event on the CPU. All events for a CPU are OR-ed together into a single CPU event signal. The CPU Pending register (EXTI_CPUPR) will not be set for an unmasked CPU event.

When a CPU interrupt or CPU event is enabled, the Asynchronous edge detection circuit is reset by the clocked Delay and Rising edge detect pulse generator. This guarantees that the CPU clock is woken up before the Asynchronous edge detection circuit is reset.

*Note:* A detected Configurable event, enabled by the CPU, is only cleared when the CPU wakes up.

### 19.3.2 EXTI configurable event input Any wakeup

*Figure 89* is a detailed representation of the logic associated with Configurable Event inputs that can wakeup D3 domain for autonomous Run mode and/or CPU (“Any” target). It provides the same functionality as the Configurable event input CPU wakeup, with additional functionality to wake up the D3 domain independently.

When all CPU interrupts and CPU events are disabled, the Asynchronous edge detection circuit is reset by the D3 domain clocked Delay and Rising edge detect pulse generator. This guarantees that the D3 domain clock is woken up before the Asynchronous edge detection circuit is reset.

<table>
<thead>
<tr>
<th>EXTI_C1IMR</th>
<th>EXTI_C1EMR</th>
<th>Asynchronous Edge detector reset by</th>
</tr>
</thead>
<tbody>
<tr>
<td>Both = 0</td>
<td></td>
<td>D3 domain clock rising edge detect pulse generator</td>
</tr>
<tr>
<td>At least one = 1</td>
<td></td>
<td>CPU clock rising edge detect pulse generator</td>
</tr>
</tbody>
</table>
The event triggering logic for “Any” target has additional D3 Pending mask register `EXTI D3 pending mask register (EXTI_D3PMR1)`, `EXTI D3 pending mask register (EXTI_D3PMR2)`, `EXTI D3 pending mask register (EXTI_D3PMR3)` and D3 Pending request logic. The D3 Pending request logic will only be set for unmasked D3 Pending events. The D3 Pending request logic keeps the D3 domain in Run mode until the D3 Pending request logic is cleared by the selected D3 domain pendclear source.
19.3.3 EXTI direct event input CPU wakeup

*Figure 90* is a detailed representation of the logic associated with Direct Event inputs waking up the CPU.

Direct events only provide CPU interrupt enable and CPU event enable functionality.

1. The CPU interrupt for asynchronous Direct Event inputs (peripheral Wakeup signals) is synchronized with the CPU clock. The synchronous Direct Event inputs (peripheral interrupt signals), after the asynchronous edge detection, are directly sent to the CPU interrupt without resynchronization.
19.3.4 EXTI direct event input Any wakeup

Figure 91 is a detailed representation of the logic associated with Direct Event inputs waking up D3 domain for autonomous Run mode and/or CPU, ("Any" target). It provides the same functionality as the Direct event input CPU wakeup, plus additional functionality to wakeup the D3 domain independently.

1. The CPU interrupt and D3 domain interrupt for asynchronous Direct Event inputs (peripheral Wakeup signals) are synchronized, respectively, with the CPU clock and the D3 domain clock. The synchronous Direct Event inputs (peripheral interrupt signals), after the asynchronous edge detection, are directly sent to the CPU interrupt and the D3 domain interrupt without resynchronization in the EXTI.
19.3.5 EXTI D3 pending request clear selection

Event inputs able to wake up D3 domain for autonomous Run mode have D3 Pending request logic that can be cleared by the selected D3 pendclear source. For each D3 Pending request a D3 domain pendclear source can be selected from four different inputs. *Figure 92* is a detailed representation of the logic selecting the D3 pendclear source.

*Figure 92. D3 domain Pending request clear logic*

The D3 Pending request clear selection registers *EXTI D3 pending clear selection register low (EXTI_D3PCR1L), EXTI D3 pending clear selection register high (EXTI_D3PCR1H), EXTI D3 pending clear selection register low (EXTI_D3PCR2L), EXTI D3 pending clear selection register high (EXTI_D3PCR2H), EXTI D3 pending clear selection register low (EXTI_D3PCR3L) and EXTI D3 pending clear selection register high (EXTI_D3PCR3H)* allow the system to select the source to reset the D3 Pending request.

19.4 EXTI event input mapping

For the sixteen GPIO Event inputs the associated IOPORT pin has to be selected in the SYSCFG register SYSCFG_EXTICRn. The same pin from each IOPORT maps to the corresponding EXTI Event input.

The wakeup capabilities of each Event input are detailed in *Table 141*. An Event input can either wake up the CPU, and in the case of “Any” can also wake up D3 domain for autonomous Run mode.

The EXTI Event inputs with a connection to the CPU NVIC are indicated in the *Connection to NVIC* column. For the EXTI events not having a connection to the NVIC, the peripheral interrupt is directly connected to the NVIC in parallel with the connection to the EXTI.

All EXTI Event inputs are OR-ed together and connected to the CPU event input (rxev).

</tbody>
</table>
The Direct event inputs are enabled in the respective peripheral generating the event. The Configurable events are enabled by enabling at least one of the trigger edges. When in Stop mode an event will always wake up the D3 domain. In system Run and Stop modes an event will always generate an associated D3 domain interrupt. An event will only wake up the CPU when the event associated CPU interrupt is unmasked and/or the CPU event is unmasked.

For Configurable event inputs, when the enabled edge(s) occur on the event input, an event request is generated. When the associated CPU interrupt is unmasked, the corresponding pending PRx bit in EXTI_CPUPR is set and the CPU interrupt signal is activated. EXTI_CPUPR PRx pending bit shall be cleared by software writing it to ‘1’. This will clear the CPU interrupt.

For Direct event inputs, when enabled in the associated peripheral, an event request is generated on the rising edge only. There is no corresponding CPU pending bit. When the associated CPU interrupt is unmasked the corresponding CPU interrupt signal is activated.

### Table 141. EXTI Event input mapping (continued)

</tr>
</tbody>
</table>

1. Only for Event inputs that allow the system to wakeup D3 domain for autonomous Run mode (Any target).
2. For Event inputs that will always wake up CPU.

For Configurable event inputs, when the enabled edge(s) occur on the event input, an event request is generated. When the associated CPU interrupt is unmasked, the corresponding pending PRx bit in EXTI_CPUPR is set and the CPU interrupt signal is activated. EXTI_CPUPR PRx pending bit shall be cleared by software writing it to ‘1’. This will clear the CPU interrupt.

For Direct event inputs, when enabled in the associated peripheral, an event request is generated on the rising edge only. There is no corresponding CPU pending bit. When the associated CPU interrupt is unmasked the corresponding CPU interrupt signal is activated.
The CPU event has to be unmasked to generate an event. When the enabled edge(s) occur on the Event input a CPU event pulse is generated. There is no CPU Event pending bit.

Both a CPU interrupt and a CPU event may be enabled on the same Event input. They will both trigger the same Event input condition(s).

For the Configurable Event inputs an event input request can be generated by software when writing a ‘1’ in the software interrupt/event register EXTI_SWIER.

Whenever an Event input is enabled and a CPU interrupt and/or CPU event is unmasked, the Event input will also generate a D3 domain wakeup next to the CPU wakeup.

Some Event inputs are able to wakeup the D3 domain autonomous Run mode, in this case the CPU interrupt and CPU event are masked, preventing the CPU to be woken up. Two D3 domain autonomous Run mode wakeup mechanisms are supported:

- D3 domain wakeup without pending (EXTI_D3PMR = 0)
  - On a Configurable Event input this mechanism will wake up D3 domain and clear the D3 domain wakeup signal automatically after the Delay + Rising Edge detect Pulse generator.
  - On a Direct Event input this mechanism will wake up D3 domain and clear the D3 domain wakeup signal after the Direct Event input signal is cleared.
- D3 domain wakeup with pending (EXTI_D3PMR = 1)
  - On a Configurable Event input this mechanism will wake up D3 domain and clear the D3 domain wakeup signal after the Delay + Rising Edge detect Pulse generator and when the D3 Pending request is cleared.
  - On a Direct Event input this mechanism will wake up D3 domain and clear the D3 domain wakeup signal after the Direct Event input signal is cleared and when the D3 Pending request is cleared.

19.5.1 EXTI CPU interrupt procedure

- Unmask the Event input interrupt by setting the corresponding mask bits in the EXTI_CPUIMR register.
- For Configurable Event inputs, enable the event input by setting either one or both the corresponding trigger edge enable bits in EXTI_RTSR and EXTI_FTSR registers.
- Enable the associated trigger source in the CPU NVIC or use the SEVONPEND, so that an interrupt coming from the CPU interrupt signal is detectable by the CPU after a WFI/WFE instruction.
  - For Configurable event inputs the associated EXTI pending bit needs to be cleared.

19.5.2 EXTI CPU event procedure

- Unmask the Event input by setting the corresponding mask bits of the EXTI_CPUEMR register.
- For Configurable Event inputs, enable the event input by setting either one or both the corresponding trigger edge enable bits in EXTI_RTSR and EXTI_FTSR registers.
- The CPU event signal is detected by the CPU after a WFE instruction.
  - For Configurable event inputs there is no EXTI pending bit to clear.
19.5.3 EXTI CPU wakeup procedure

- Unmask the Event input by setting at least one of the corresponding mask bits in the EXTI_CPUIMR and/or EXTI_CPUEMR registers. The CPU wakeup is generated at the same time as the unmasked CPU interrupt and/or CPU event.
- For Configurable Event inputs, enable the event input by setting either one or both the corresponding trigger edge enable bits in EXTI_RTSR and EXTI_FTSR registers.
- Direct Events will automatically generate a CPU wakeup.

19.5.4 EXTI D3 domain wakeup for autonomous Run mode procedure

- Mask the Event input for waking up the CPU, by clearing both the corresponding mask bits in the EXTI_CPUIMR and/or EXTI_CPUEMR registers.
- For Configurable Event inputs, enable the event input by setting either one or both the corresponding trigger edge enable bits in EXTI_RTSR and EXTI_FTSR registers.
- Direct Events will automatically generate a D3 domain wakeup.
- Select the D3 domain wakeup mechanism in EXTI_D3PMR.
  - When D3 domain wakeup without pending (EXTI_PMR = 0) is selected, the Wakeup will be cleared automatically following the clearing of the Event input.
  - When D3 domain wakeup with pending (EXTI_PMR = 1) is selected the Wakeup needs to be cleared by a selected D3 domain pendclear source. A pending D3 domain wakeup signal can also be cleared by FW clearing the associated EXTI_D3PMR register bit.
- After the D3 domain wakeup a D3 domain interrupt is generated.
  - Configurable Event inputs will generate a pulse on D3 domain interrupt.
  - Direct Event inputs will activate the D3 domain interrupt until the event input is cleared in the peripheral.

19.5.5 EXTI software interrupt/event trigger procedure

Any of the Configurable Event inputs can be triggered from the software interrupt/event register (the associated CPU interrupt and/or CPU event shall be enabled by their respective procedure).

- Enable the Event input by setting at least one of the corresponding edge trigger bits in the EXTI_RTSR and/or EXTI_FTSR registers.
- Unmask the software interrupt/event trigger by setting at least one of the corresponding mask bits in the EXTI_CPUIMR and/or EXTI_CPUEMR registers.
- Trigger the software interrupt/event by writing "1" to the corresponding bit in the EXTI_SWIER register.
- The Event input may be disabled by clearing the EXTI_RTSR and EXTI_FTSR register bits.

Note: An edge on the Configurable event input will also trigger an interrupt/event.
A software trigger can be used to set the D3 Pending request logic, keeping the D3 domain in Run until the D3 Pending request logic is cleared.
19.6 EXTI registers

Every register can only be accessed with 32-bit (word). A byte or half-word cannot be read or written.

19.6.1 EXTI rising trigger selection register (EXTI_RTSR1)

Bits 8:4 Reserved, must be kept at reset value.

Bits 3:2 **MRx:** D3 Pending Mask on Event input x+32
0: D3 Pending request from Line x+32 is masked. Writing this bit to 0 will also clear the D3 Pending request.
1: D3 Pending request from Line x+32 is unmasked. The D3 domain pending signal when triggered will keep D3 domain wakeup active until cleared.

Bits 1:0 Reserved, must be kept at reset value.

Refer to *Section 2.3 on page 126* for the register boundary addresses.
20 **Cyclic redundancy check calculation unit (CRC)**

20.1 **Introduction**

The CRC (cyclic redundancy check) calculation unit is used to get a CRC code from 8-, 16- or 32-bit data word and a generator polynomial.

Among other applications, CRC-based techniques are used to verify data transmission or storage integrity. In the scope of the functional safety standards, they offer a means of verifying the Flash memory integrity. The CRC calculation unit helps compute a signature of the software during runtime, to be compared with a reference signature generated at link time and stored at a given memory location.

20.2 **CRC main features**

- Uses CRC-32 (Ethernet) polynomial: 0x4C11DB7
  \[ X^{32} + X^{26} + X^{23} + X^{16} + X^{12} + X^{11} + X^{10} + X^9 + X^7 + X^5 + X^4 + X^2 + X + 1 \]
- Alternatively, uses fully programmable polynomial with programmable size (7, 8, 16, 32 bits)
- Handles 8-, 16-, 32-bit data size
- Programmable CRC initial value
- Single input/output 32-bit data register
- Input buffer to avoid bus stall during calculation
- CRC computation done in 4 AHB clock cycles (HCLK) for the 32-bit data size
- General-purpose 8-bit register (can be used for temporary storage)
- Reversibility option on I/O data
20.3 CRC functional description

20.3.1 CRC block diagram

The CRC calculation unit has a single 32-bit read/write data register (CRC_DR). It is used to input new data (write access), and holds the result of the previous CRC calculation (read access).

Each write operation to the data register creates a combination of the previous CRC value (stored in CRC_DR) and the new one. CRC computation is done on the whole 32-bit data word or byte by byte depending on the format of the data being written.

The CRC_DR register can be accessed by word, right-aligned half-word and right-aligned byte. For the other registers only 32-bit access is allowed.

The duration of the computation depends on data width:
- 4 AHB clock cycles for 32-bit
- 2 AHB clock cycles for 16-bit
- 1 AHB clock cycles for 8-bit

An input buffer allows to immediately write a second data without waiting for any wait states due to the previous CRC calculation.

The data size can be dynamically adjusted to minimize the number of write accesses for a given number of bytes. For instance, a CRC for 5 bytes can be computed with a word write followed by a byte write.

20.3.3 CRC operation

The CRC calculation unit has a single 32-bit read/write data register (CRC_DR). It is used to input new data (write access), and holds the result of the previous CRC calculation (read access).

Each write operation to the data register creates a combination of the previous CRC value (stored in CRC_DR) and the new one. CRC computation is done on the whole 32-bit data word or byte by byte depending on the format of the data being written.

The CRC_DR register can be accessed by word, right-aligned half-word and right-aligned byte. For the other registers only 32-bit access is allowed.

The duration of the computation depends on data width:
- 4 AHB clock cycles for 32-bit
- 2 AHB clock cycles for 16-bit
- 1 AHB clock cycles for 8-bit

An input buffer allows to immediately write a second data without waiting for any wait states due to the previous CRC calculation.

The data size can be dynamically adjusted to minimize the number of write accesses for a given number of bytes. For instance, a CRC for 5 bytes can be computed with a word write followed by a byte write.
The input data can be reversed, to manage the various endianness schemes. The reversing operation can be performed on 8 bits, 16 bits and 32 bits depending on the REV_IN[1:0] bits in the CRC_CR register.

For example: input data 0x1A2B3C4D is used for CRC calculation as:

- 0x58D43CB2 with bit-reversal done by byte
- 0xD458B23C with bit-reversal done by half-word
- 0xB23CD458 with bit-reversal done on the full word

The output data can also be reversed by setting the REV_OUT bit in the CRC_CR register.

The operation is done at bit level: for example, output data 0x11223344 is converted into 0x22CC4488.

The CRC calculator can be initialized to a programmable value using the RESET control bit in the CRC_CR register (the default value is 0xFFFFFFFF).

The initial CRC value can be programmed with the CRC_INIT register. The CRC_DR register is automatically initialized upon CRC_INIT register write access.

The CRC_IDR register can be used to hold a temporary value related to CRC calculation. It is not affected by the RESET bit in the CRC_CR register.

**Polynomial programmability**

The polynomial coefficients are fully programmable through the CRC_POL register, and the polynomial size can be configured to be 7, 8, 16 or 32 bits by programming the POLYSIZE[1:0] bits in the CRC_CR register. Even polynomials are not supported.

If the CRC data is less than 32-bit, its value can be read from the least significant bits of the CRC_DR register.

To obtain a reliable CRC calculation, the change on-fly of the polynomial value or size can not be performed during a CRC calculation. As a result, if a CRC calculation is ongoing, the application must either reset it or perform a CRC_DR read before changing the polynomial.

The default polynomial value is the CRC-32 (Ethernet) polynomial: 0x4C11DB7.

Refer to Section 2.3 on page 126 for the register boundary addresses.
21 Flexible memory controller (FMC)

The Flexible memory controller (FMC) includes three memory controllers:
- The NOR/PSRAM memory controller
- The NAND memory controller
- The Synchronous DRAM (SDRAM/Mobile LPSDR SDRAM) controller

21.1 FMC main features

The FMC functional block makes the interface with: synchronous and asynchronous static memories, SDRAM memories, and NAND flash memory. Its main purposes are:
- to translate AXI transactions into the appropriate external device protocol
- to meet the access time requirements of the external memory devices

All external memories share the addresses, data and control signals with the controller. Each external device is accessed by means of a unique Chip Select. The FMC performs only one access at a time to an external device.

The main features of the FMC controller are the following:
- Interface with static-memory mapped devices including:
  - Static random access memory (SRAM)
  - NOR Flash memory/OneNAND Flash memory
  - PSRAM (4 memory banks)
  - NAND Flash memory with ECC hardware to check up to 8 Kbytes of data
- Interface with synchronous DRAM (SDRAM/Mobile LPSDR SDRAM) memories
- Burst mode support for faster access to synchronous devices such as NOR Flash memory, PSRAM and SDRAM
- Programmable continuous clock output for asynchronous and synchronous accesses
- 8-, 16- or 32-bit wide data bus
- Independent Chip Select control for each memory bank
- Independent configuration for each memory bank
- Write enable and byte lane select outputs for use with PSRAM, SRAM and SDRAM devices
- External asynchronous wait control
- Write FIFO with 16 x32-bit depth
  The Write FIFO is common to all memory controllers and consists of:
  - a Write Data FIFO which stores the data to be written to the memory
  - a Write Address FIFO which stores the address (up to 28 bits) plus the data size (up to 2 bits). When operating in Burst mode, only the start address is stored except when crossing a page boundary (for PSRAM and SDRAM). In this case, the burst is broken into two FIFO entries.
- Cacheable Read FIFO with 6 x64-bit depth (6 x14-bit address tag) for SDRAM controller.

At startup the FMC pins must be configured by the user application. The FMC I/O pins which are not used by the application can be used for other purposes.
The FMC registers that define the external device type and associated characteristics are set at boot time and do not change until the next reset or power-up. However, only a few bits can be changed on-the-fly:

- ECCEN and PBKEN bits in the FMC_PCR register
- IFS, IRS and ILS bits in the FMC_SR register
- MODE[2:0], CTB1/CTB2, NRFS and MRD bits in the FMC_SDCMR register
- REIE and CRE bits in the FMC_SDRTR register.

Follow the below sequence to modify parameters while the FMC is enabled:
1. First disable the FMC controller to prevent further accesses to any memory controller while the register is modified.
2. Update all required configurations.
3. Enable the FMC controller again.

When the SDRAM controller is used, if the SDCLK Clock ratio or refresh rate has to be modified after initialization phase, the following procedure must be followed.
1. Put the SDRAM device in Self-refresh mode.
2. Disable the FMC controller by resetting the FMCEN bit in the FMC_BCR1 register.
3. Update the required parameters.
4. Enable the FMC controller once all parameters have been updated.
5. Then, send the Clock Configuration Enable command to exit Self-fresh mode.

### 21.2 FMC block diagram

The FMC consists of the following main blocks:
- The NOR Flash/PSRAM/SRAM controller
- The NAND controller
- The SDRAM controller
- The AXI interface
- The AHB interface (including the FMC configuration registers)

The block diagram is shown in the figure below.

21.4 AHB interface

The AHB slave interface allows internal CPUs to configure the FMC registers.

The AHB clock (fmc_hclk) is the reference clock for the FMC register accesses.

21.5 AXI interface

The AXI slave interface allows internal CPUs and other bus master peripherals to access the external memories.

AXI transactions are translated into the external device protocol. As the AXI data bus is 64-bit wide, the AXI transactions might be split into several consecutive 32-, 16- or 8-bit accesses according to data size accesses. The FMC Chip Select (FMC_NEx) does not toggle between consecutive accesses except in case of accesses in Mode D when the Extended mode is enabled.

The FMC generates an AXI slave error when one of the following conditions is met:

- Reading or writing to an FMC bank (Bank 1 to 4) which is not enabled.
- Reading or writing to the NOR Flash bank while the FACCEN bit is reset in the FMC_BCRx register.
- Writing to a write protected SDRAM bank (WP bit set in the SDRAM_SDCRx register).
- Violation of the SDRAM address range (access to reserved address range)
- Attempting to read/write access from/to SDRAM bank when it is not yet initialized

The FMC generates an AXI decoder error when ADDR[31:28] address bits are not supported by the FMC bank base address following the BMAP[1:0] bits configuration.

The kernel clock for the FMC controller is the asynchronous fmc_ker_ck clock (refer to Section 7: Reset and Clock Control (RCC) for fmc_ker_ck clock source selection).
21.5.1 Supported memories and transactions

General transaction rules

The requested AXI transaction data size can be 8-, 16-, 32- or 64-bit wide whereas the accessed external device has a fixed data width. The AXI transaction size depends on memory region MPU attributes. This may lead to inconsistent transfers.

Therefore, some simple transaction rules can be followed, depending on AXI transaction size versus memory data size:

- AXI transaction size and memory data size are equal to prevent issues from occurring.

- AXI transaction size is greater than the memory size:
  - In this case, the FMC splits the AXI transaction into smaller consecutive memory accesses to meet the external data width.
  - The memory region MPU attribute must be configured as “Device” or “strongly-ordered” in order to prevent issues on devices that do not have the byte select feature. As an example, if byte accesses are performed to 16-bit memories with the MPU attribute set to “Normal memory”, the AXI transaction size is 64 bits and the FMC splits the transaction into four consecutive accesses while only one access is expected instead of four.

- AXI transaction size is smaller than the memory size:
  - The transfer may or not be consistent depending on the type of external device:
    - Accesses to devices that have the byte select feature (SRAM, ROM, PSRAM, SDRAM)
      - In this case, the FMC allows read/write transactions and accesses the right data through its NBL[3:0] byte lanes.
      - Bytes to be written are addressed by NBL[3:0].
      - All memory bytes are read (NBL[3:0] are driven low during read transaction) and the useless ones are discarded.
    - Accesses to devices that do not have the byte select feature (NOR and NAND Flash memories)
      - This situation occurs when a byte access is requested to a 16-bit wide Flash memory. Since the device cannot be accessed in Byte mode (only 16-bit words can be read/written from/to the Flash memory), write transactions are not allowed while read transactions are allowed (the controller reads the entire 16-bit memory word and uses only the required byte).

Wrap support for NOR Flash/PSRAM and SDRAM

The synchronous memories must be configured in Linear burst mode of undefined length as not all masters can issue wrap transactions.

If a master generates a wrap transaction:

- The read is split into two linear burst transactions.
- The write is split into two linear burst transactions if the write FIFO is enabled and into several linear burst transactions if the write FIFO is disabled.

Configuration registers

The FMC can be configured through a set of registers. Refer to Section 21.7.6, for a detailed description of the NOR Flash/PSRAM controller registers. Refer to Section 21.8.7,
for a detailed description of the NAND Flash registers and to Section 21.9.5 for a detailed description of the SDRAM controller registers.

21.6 External device address mapping

From the FMC point of view, the external memory is divided into fixed-size banks of 256 Mbytes each (see Figure 95):

- Bank 1 is used to address up to 4 NOR Flash memory or PSRAM devices. This bank is split into 4 NOR/PSRAM subbanks with 4 dedicated Chip Selects, as follows:
  - Bank 1 - NOR/PSRAM 1
  - Bank 1 - NOR/PSRAM 2
  - Bank 1 - NOR/PSRAM 3
  - Bank 1 - NOR/PSRAM 4
- Bank 2 is used for SDRAM device, SDRAM bank 1 or SDRAM bank 2 depending on BMAP bits configuration.
- Bank 3 is used to address NAND Flash memory devices. The MPU memory attribute for this space must be reconfigured by software to Device.
- Bank 5 and 6 are used to address SDRAM devices (1 device per bank).

For each bank the type of memory to be used can be configured by the user application through the Configuration register.
The FMC bank mapping can be modified through the BMAP[1:0] bits in the FMC_BCR1 register. Table 147 shows the configuration to swap the NOR/PSRAM bank with SDRAM banks or remap the SDRAM bank2, thus allowing to access the SDRAM banks at two different address mapping.

Table 147. FMC bank mapping options

<table>
<thead>
<tr>
<th>Start -End address</th>

<td>SDRAM bank2</td>
<td>SDRAM bank2</td>
</tr>
</tbody>
</table>
21.6.1 NOR/PSRAM address mapping

ADDR[27:26] bits are used to select one of the four memory banks as shown in Table 148.

<table>
<thead>
<tr>
<th>ADDR[27:26]</th>
<th>Selected bank</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Bank 1 - NOR/PSRAM 1</td>
</tr>
<tr>
<td>01</td>
<td>Bank 1 - NOR/PSRAM 2</td>
</tr>
<tr>
<td>10</td>
<td>Bank 1 - NOR/PSRAM 3</td>
</tr>
<tr>
<td>11</td>
<td>Bank 1 - NOR/PSRAM 4</td>
</tr>
</tbody>
</table>

1. ADDR are internal address lines that are translated to external memory.

The ADDR[25:0] bits contain the external memory address. Since ADDR is a byte address whereas the memory is addressed at word level, the address actually issued to the memory varies according to the memory data width, as shown in the following table.

Table 149. NOR/PSRAM External memory address

<table>
<thead>
<tr>
<th>Memory width</th>
<th>Data address issued to the memory</th>
<th>Maximum memory capacity (bits)</th>
</tr>
</thead>
<tbody>
<tr>
<td>8-bit</td>
<td>ADDR[25:0]</td>
<td>64 Mbytes x 8 = 512 Mbit</td>
</tr>
<tr>
<td>16-bit</td>
<td>ADDR[25:1] &gt;&gt; 1</td>
<td>64 Mbytes/2 x 16 = 512 Mbit</td>
</tr>
<tr>
<td>32-bit</td>
<td>ADDR[25:2] &gt;&gt; 2</td>
<td>64 Mbytes/4 x 32 = 512 Mbit</td>
</tr>
</tbody>
</table>

1. In case of a 16-bit external memory width, the FMC will internally use ADDR[25:1] to generate the address for external memory FMC_A[24:0]. In case of a 32-bit memory width, the FMC will internally use ADDR[25:2] to generate the external address. Whatever the external memory width, FMC_A[0] should be connected to external memory address A[0].

21.6.2 NAND Flash memory address mapping

The NAND bank is divided into memory areas as indicated in Table 150.

<table>
<thead>
<tr>
<th>Start address</th>
<th>End address</th>
<th>FMC bank</th>
<th>Memory space</th>
<th>Timing register</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x8800 0000</td>
<td>0xBFFFF FFFF</td>
<td>Bank 3 - NAND Flash</td>
<td>Attribute</td>
<td>FMC_PATT (0x8C)</td>
</tr>
<tr>
<td>0x8000 0000</td>
<td>0x83FFFF FFFF</td>
<td>Common</td>
<td>FMC_PMEM (0x88)</td>
<td></td>
</tr>
</tbody>
</table>

For NAND Flash memory, the common and attribute memory spaces are subdivided into three sections (see in Table 151 below) located in the lower 256 Kbytes:
- Data section (first 64 Kbytes in the common/attribute memory space)
- Command section (second 64 Kbytes in the common / attribute memory space)
- Address section (next 128 Kbytes in the common / attribute memory space)
The application software uses the 3 sections to access the NAND Flash memory:

- **To send a command to NAND Flash memory**, the software must write the command value to any memory location in the command section.

- **To specify the NAND Flash address that must be read or written**, the software must write the address value to any memory location in the address section. Since an address can be 4 or 5 bytes long (depending on the actual memory size), several consecutive write operations to the address section are required to specify the full address.

- **To read or write data**, the software reads or writes the data from/to any memory location in the data section.

Since the NAND Flash memory automatically increments addresses, there is no need to increment the address of the data section to access consecutive memory locations.

### 21.6.3 SDRAM address mapping

Two SDRAM banks are available as indicated in Table 152.

#### Table 151. NAND bank selection

<table>
<thead>

<tr>
<td>SDRAM Bank2</td>
<td>FMC_SDCR2</td>
<td>FMC_SDTR2</td>
</tr>
</tbody>
</table>

Table 153 shows SDRAM mapping for a 13-bit row and an 11-bit column configuration.

#### Table 153. SDRAM address mapping

<table>
<thead>
<tr>
<th>Memory width(1)</th>
<th>Internal bank</th>
<th>Row address</th>
<th>Column address(2)</th>
<th>Maximum memory capacity (Mbytes)</th>
</tr>
</thead>
</table>

1. When interfacing with a 16-bit memory, the FMC internally uses the ADDR[11:1] internal address lines to generate the external address. When interfacing with a 32-bit memory, the FMC internally uses ADDR[12:2] lines to generate the external address. Whatever the memory width, FMC_A[0] has to be connected to the external memory address A[0].

2. The AutoPrecharge is not supported. FMC_A[10] must be connected to the external memory address A[10] but it will be always driven low.
The ADDR[27:0] bits are translated into an external SDRAM address depending on the SDRAM controller configuration:

- Data size: 8, 16 or 32 bits
- Row size: 11, 12 or 13 bits
- Column size: 8, 9, 10 or 11 bits
- Number of internal banks: two or four internal banks

The following tables show the SDRAM address mapping versus the SDRAM controller configuration.

**Table 154. SDRAM address mapping with 8-bit data bus width**

| Row size configuration | ADDR (Internal Address Lines) | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|------------------------|-------------------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 11-bit row size        | Res.                          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | Res. |

</tbody>
</table>

1. BANK[1:0] are the Bank Address BA[1:0]. When only 2 internal banks are used, BA1 must always be set to '0'.
2. Access to Reserved space (Res.) generates an AXI Slave error.
3. BM0: is the byte mask for 16-bit access.
### 21.7 NOR Flash/PSRAM controller

The FMC generates the appropriate signal timings to drive the following types of memories:

- **Asynchronous SRAM and ROM**
  - 8 bits
  - 16 bits
  - 32 bits

- **PSRAM (Cellular RAM)**
  - Asynchronous mode
  - Burst mode for synchronous accesses with configurable option to split burst access when crossing boundary page for CRAM 1.5.
  - Multiplexed or non-multiplexed

- **NOR Flash memory**
  - Asynchronous mode
  - Burst mode for synchronous accesses
  - Multiplexed or non-multiplexed
The FMC outputs a unique Chip Select signal, NE[4:1], per bank. All the other signals (addresses, data and control) are shared.

The FMC supports a wide range of devices through a programmable timings among which:

- Programmable wait states (up to 15)
- Programmable bus turnaround cycles (up to 15)
- Programmable output enable and write enable delays (up to 15)
- Independent read and write timings and protocol to support the widest variety of memories and timings
- Programmable continuous clock (FMC_CLK) output.

The FMC output Clock (FMC_CLK) is a sub-multiple of the fmc_ker_ck clock. It can be delivered to the selected external device either during synchronous accesses only or during asynchronous and synchronous accesses depending on the CCKEN bit configuration in the FMC_BCR1 register:

- If the CCLKEN bit is reset, the FMC generates the clock (FMC_CLK) only during synchronous accesses (Read/write transactions).
- If the CCLKEN bit is set, the FMC generates a continuous clock during asynchronous and synchronous accesses. To generate the FMC_CLK continuous clock, Bank 1 must be configured in Synchronous mode (see Section 21.7.6: NOR/PSRAM controller registers). Since the same clock is used for all synchronous memories, when a continuous output clock is generated and synchronous accesses are performed, the AXI data size has to be the same as the memory data width (MWID) otherwise the FMC_CLK frequency will be changed depending on AXI data transaction (refer to Section 21.7.5: Synchronous transactions for FMC_CLK divider ratio formula).

The size of each bank is fixed and equal to 64 Mbytes. Each bank is configured through dedicated registers (see Section 21.7.6: NOR/PSRAM controller registers).

The programmable memory parameters include access times (see Table 157) and support for wait management (for PSRAM and NOR Flash memory accessed in Burst mode).

</tbody>
</table>
21.7.3 General timing rules

Signal synchronization is performed as follows:
- All controller output signals change on the rising edge of the fmc_ker_ck clock.
- In Synchronous read and write modes, all output signals change on the rising edge of fmc_ker_ck clock. Whatever the CLKDIV value, all outputs change as follows:
  - NOEL/NWEL/ NEL/NADVL/ NADVH /NBLL/ Address valid outputs change on the falling edge of FMC_CLK clock.
  - NOEH/ NWEH / NEH/ NOEH/NBLH/ Address invalid outputs change on the rising edge of FMC_CLK clock.

21.7.4 NOR Flash/PSRAM controller asynchronous transactions

Asynchronous transactions on static memories (NOR Flash memory, PSRAM, SRAM) are performed as follows:
- Signals are synchronized by the internal clock. This clock is not issued to the memory.
- The FMC always samples the data before de-asserting the Chip Select signal. This guarantees that the memory data hold timing constraint is met (minimum Chip Enable high to data transition is usually 0 ns)
- If the Extended mode is enabled (EXTMOD bit is set in the FMC_BCRx register), up to four extended modes (A, B, C and D) are available. It is possible to mix A, B, C and D modes for read and write operations. For example, read operation can be performed in mode A and write in mode B.
- If the Extended mode is disabled (EXTMOD bit is reset in the FMC_BCRx register), the FMC can operate in Mode1 or Mode2 as follows:
  - Mode 1 is the default mode when SRAM/PSRAM memory type is selected (MTYP = 0x0 or 0x01 in the FMC_BCRx register)
  - Mode 2 is the default mode when NOR memory type is selected (MTYP = 0x10 in the FMC_BCRx register).

1. NBL[1:0] are also driven by AXI write strobes.
Mode 1 - SRAM/PSRAM (CRAM)

The next figures show the read and write transactions for the supported modes followed by the required configuration of FMC_BCRx, and FMC_BTRx/FMC_BWTRx registers.

**Figure 96. Mode 1 read access waveforms**
The fmc_ker_ck cycle at the end of the write transaction helps guarantee the address and data hold time after the NWE rising edge. Due to the presence of this fmc_ker_ck cycle, the DATAST value must be greater than zero (DATAST > 0).

WAIT management in asynchronous accesses

If the asynchronous memory asserts the WAIT signal to indicate that it is not yet ready to accept or to provide data, the ASYNCWAIT bit has to be set in FMC_BCRx register.

If the WAIT signal is active (high or low depending on the WAITPOL bit), the second access phase (Data setup phase), programmed by the DATAST bits, is extended until WAIT becomes inactive. Unlike the data setup phase, the first access phases (Address setup and Address hold phases), programmed by the ADDSET and ADDHLD bits, are not WAIT sensitive and so they are not prolonged.

The data setup phase must be programmed so that WAIT can be detected 4 fmc_ker_ck cycles before the end of the memory transaction. The following cases must be considered:

1. The memory asserts the WAIT signal aligned to NOE/NWE which toggles:
   \[
   \text{DATAST} \geq (4 \times \text{FMC_CLK}) + \text{max\_wait\_assertion\_time}
   \]

2. The memory asserts the WAIT signal aligned to NEx (or NOE/NWE not toggling):
   if
   \[
   \text{max\_wait\_assertion\_time} > \text{address\_phase} + \text{hold\_phase}
   \]
   then:

   \[
   \text{DATAST} \geq (4 \times \text{FMC_CLK}) + (\text{max\_wait\_assertion\_time} - \text{address\_phase} - \text{hold\_phase})
   \]
   otherwise

   \[
   \text{DATAST} \geq (4 \times \text{FMC_CLK})
   \]
   where max\_wait\_assertion\_time is the maximum time taken by the memory to assert the WAIT signal once NEx/NOE/NWE is low.

*Figure 109* and *Figure 110* show the number of fmc_ker_ck clock cycles that are added to the memory access phase after WAIT is released by the asynchronous memory (independently of the above cases).

Figure 110. Asynchronous wait during a write access waveforms

1. NWAIT polarity depends on WAITPOL bit setting in FMC_BCRx register.
21.7.5 Synchronous transactions

The memory clock, FMC_CLK, is a sub-multiple of fmc_ker_ck. It depends on the value of CLKDIV and the MWID/AXI data size, following the formula given below:

\[
\text{FMC_CLK divider ratio} = \max(\text{CLKDIV} + 1, \text{MWID} \times \text{AXI data size})
\]

If MWID is 16 or 8-bit, the FMC_CLK divider ratio is always defined by the programmed CLKDIV value.

If MWID is 32-bit, the FMC_CLK divider ratio depends also on AXI data size.

Example:

- If CLKDIV=1, MWID = 32 bits, AXI data size=8 bits, FMC_CLK=fmc_ker_ck/4.
- If CLKDIV=1, MWID = 16 bits, AXI data size=8 bits, FMC_CLK=fmc_ker_ck/2.

NOR Flash memories specify a minimum time from NADV assertion to FMC_CLK high. To meet this constraint, the FMC does not issue the clock to the memory during the first internal clock cycle of the synchronous access (before NADV assertion). This guarantees that the rising edge of the memory clock occurs in the middle of the NADV low pulse.

For some PSRAM memories which must be configured to Synchronous mode, during the BCR register writing, the memory attribute space must be configured to device or strongly-ordered. Once PSRAM BCR register is configured, the memory attribute of PSRAM address space can be programmed to cacheable.

Data latency versus NOR memory latency

The data latency is the number of cycles to wait before sampling the data. The DATLAT value must be consistent with the latency value specified in the NOR Flash configuration register. The FMC does not include the clock cycle when NADV is low in the data latency count.

Caution: Some NOR Flash memories include the NADV Low cycle in the data latency count, so that the exact relation between the NOR Flash latency and the FMC DATLAT parameter can be either:

- NOR Flash latency = (DATLAT + 2) FMC_CLK clock cycles
- or NOR Flash latency = (DATLAT + 3) FMC_CLK clock cycles

Some recent memories assert NWAIT during the latency phase. In such cases DATLAT can be set to its minimum value. As a result, the FMC samples the data and waits long enough to evaluate if the data are valid. Thus the FMC detects when the memory exits latency and real data are processed.

Other memories do not assert NWAIT during latency. In this case the latency must be set correctly for both the FMC and the memory, otherwise invalid data are mistaken for good data, or valid data are lost in the initial phase of the memory access.
Single-burst transfer

When the selected bank is configured in Burst mode for synchronous accesses, if for example a single-burst transaction is requested on 16-bit memories, the FMC performs a burst transaction of length 1 (if the AXI transfer is 16 bits), or length 2 (if the AXI transfer is 32 bits) and de-assert the Chip Select signal when the last data is strobed.

Such transfers are not the most efficient in terms of cycles compared to asynchronous read operations. Nevertheless, a random asynchronous access would first require to re-program the memory access mode, which would altogether last longer.

Cross boundary page for Cellular RAM 1.5

Cellular RAM 1.5 does not allow burst access to cross the page boundary. The FMC controller allows to split automatically the burst access when the memory page size is reached by configuring the CPSIZE bits in the FMC_BCR1 register following the memory page size.

Wait management

For synchronous NOR Flash memories, NWAIT is evaluated after the programmed latency period, which corresponds to (DATLAT+2) FMC_CLK clock cycles.

If NWAIT is active (low level when WAITPOL = 0, high level when WAITPOL = 1), wait states are inserted until NWAIT is inactive (high level when WAITPOL = 0, low level when WAITPOL = 1).

When NWAIT is inactive, the data is considered valid either immediately (bit WAITCFG = 1) or on the next clock edge (bit WAITCFG = 0).

During wait-state insertion via the NWAIT signal, the controller continues to send clock pulses to the memory, keeping the Chip Select and output enable signals valid. It does not consider the data as valid.

In Burst mode, there are two timing configurations for the NOR Flash NWAIT signal:

- The Flash memory asserts the NWAIT signal one data cycle before the wait state (default after reset).
- The Flash memory asserts the NWAIT signal during the wait state

The FMC supports both NOR Flash wait state configurations, for each Chip Select, thanks to the WAITCFG bit in the FMC_BCRx registers (x = 0..3).
1. Byte lane outputs (NBL are not shown; for NOR access, they are held high, and, for PSRAM (CRAM) access, they are held low.

21.7.6 **NOR/PSRAM controller registers**

**SRAM/NOR-Flash chip-select control registers for bank x (FMC_BCRx)**

- **Address offset:** $8 \times (x - 1)$, $(x = 1$ to $4)$
- **Reset value:** Block 1: $0x0000$ 30DB
- **Reset value:** Block 2: $0x0000$ 30D2
- **Reset value:** Block 3: $0x0000$ 30D2
- **Reset value:** Block 4: $0x0000$ 30D2

This register contains the control information of each memory bank, used for SRAMs, PSRAM and NOR Flash memories.

### Bit 31 **FMCEN**: FMC controller Enable
- This bit enables/disables the FMC controller.
  - 0: Disable the FMC controller
  - 1: Enable the FMC controller

*Note:* The FMCEN bit of the FMC_BCR2..4 registers is don’t care. It is only enabled through the FMC_BCR1 register.

### Bits 30:26 **Reserved**, must be kept at reset value.

### Bits 25:24 **BMAP[1:0]**: FMC bank mapping
- These bits allow different remap or swap of the FMC NOR/PSRAM and SDRAM banks (refer to Table 147).
  - 00: Default mapping (refer to Figure 95 and Table 147).
  - 01: NOR/PSRAM bank and SDRAM bank 1/bank2 are swapped.
  - 10: SDRAM Bank2 remapped on FMC bank2 and still accessible at default mapping
  - 11: Reserved.

*Note:* The BMAP bits of the FMC_BCR2..4 registers are don’t care. It is only enabled through the FMC_BCR1 register.

### Bits 23:22 **Reserved**, must be kept at reset value.
Bit 21 **WFDIS**: Write FIFO Disable
This bit disables the Write FIFO used by the FMC controller.
0: Write FIFO enabled (Default after reset)
1: Write FIFO disabled

*Note: The WFDIS bit of the FMC_BCR2..4 registers is don’t care. It is only enabled through the FMC_BCR1 register.*

Bit 20 **CCLKEN**: Continuous Clock Enable
This bit enables the FMC_CLK clock output to external memory devices.
0: The FMC_CLK is only generated during the synchronous memory access (read/write transaction). The FMC_CLK clock ratio is specified by the programmed CLKDIV value in the FMC_BCRx register (default after reset).
1: The FMC_CLK is generated continuously during asynchronous and synchronous access.
The FMC_CLK clock is activated when the CCLKEN is set.

*Note: The CCLKEN bit of the FMC_BCR2..4 registers is don’t care. It is only enabled through the FMC_BCR1 register. Bank 1 must be configured in Synchronous mode to generate the FMC_CLK continuous clock.*

If CCLKEN bit is set, the FMC_CLK clock ratio is specified by CLKDIV value in the FMC_BTR1 register. CLKDIV in FMC_BWTR1 is don’t care.

If the Synchronous mode is used and CCLKEN bit is set, the synchronous memories connected to other banks than Bank 1 are clocked by the same clock (the CLKDIV value in the FMC_BTR2..4 and FMC_BWTR2..4 registers for other banks has no effect.)

Bit 19 **CBURSTWR**: Write burst enable
For PSRAM (CRAM) operating in Burst mode, the bit enables synchronous accesses during write operations. The enable bit for synchronous read accesses is the BURSTEN bit in the FMC_BCRx register.
0: Write operations are always performed in Asynchronous mode
1: Write operations are performed in Synchronous mode.

Bits 18:16 **CPSIZE[2:0]**: CRAM Page Size
These are used for Cellular RAM 1.5 which does not allow burst access to cross the address boundaries between pages. When these bits are configured, the FMC controller splits automatically the burst access when the memory page size is reached (refer to memory datasheet for page size).
000: No burst split when crossing page boundary (default after reset).
001: 128 bytes
010: 256 bytes
100: 1024 bytes
Other configuration: reserved.

Bit 15 **ASYNCWAIT**: Wait signal during asynchronous transfers
This bit enables/disables the FMC to use the wait signal even during an asynchronous protocol.
0: NWAIT signal is not taken in to account when running an asynchronous protocol (default after reset)
1: NWAIT signal is taken in to account when running an asynchronous protocol
Bit 14 **EXTMOD**: Extended mode enable.
- This bit enables the FMC to program the write timings for asynchronous accesses inside the FMC_BWTR register, thus resulting in different timings for read and write operations.
  0: values inside FMC_BWTR register are not taken into account (default after reset)
  1: values inside FMC_BWTR register are taken into account

*Note:* When the Extended mode is disabled, the FMC can operate in Mode1 or Mode2 as follows:
- Mode 1 is the default mode when the SRAM/PSRAM memory type is selected (MTYP = 0x0 or 0x01)
- Mode 2 is the default mode when the NOR memory type is selected (MTYP = 0x10).

Bit 13 **WAITEN**: Wait enable bit
- This bit enables/disables wait-state insertion via the NWAIT signal when accessing the memory in Synchronous mode.
  0: NWAIT signal is disabled (its level not taken into account, no wait state inserted after the programmed Flash latency period)
  1: NWAIT signal is enabled (its level is taken into account after the programmed latency period to insert wait states if asserted) (default after reset)

Bit 12 **WREN**: Write enable bit
- This bit indicates whether write operations are enabled/disabled in the bank by the FMC:
  0: Write operations are disabled in the bank by the FMC, an AXI slave error is reported,
  1: Write operations are enabled for the bank by the FMC (default after reset).

Bit 11 **WAITCFG**: Wait timing configuration
- The NWAIT signal indicates whether the data from the memory are valid or if a wait state must be inserted when accessing the memory in Synchronous mode. This configuration bit determines if NWAIT is asserted by the memory one clock cycle before the wait state or during the wait state:
  0: NWAIT signal is active one data cycle before wait state (default after reset),
  1: NWAIT signal is active during wait state (not used for PSRAM).

Bit 10 Reserved, must be kept at reset value.

Bit 9 **WAITPOL**: Wait signal polarity bit
- This bit defines the polarity of the wait signal from memory used for either in Synchronous or Asynchronous mode:
  0: NWAIT active low (default after reset),
  1: NWAIT active high.

Bit 8 **BURSTEN**: Burst enable bit
- This bit enables/disables synchronous accesses during read operations. It is valid only for synchronous memories operating in Burst mode:
  0: Burst mode disabled (default after reset). Read accesses are performed in Asynchronous mode.
  1: Burst mode enable. Read accesses are performed in Synchronous mode.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **FACCE**: Flash access enable
- This bit enables NOR Flash memory access operations.
  0: Corresponding NOR Flash memory access is disabled
  1: Corresponding NOR Flash memory access is enabled (default after reset)
Bits 5:4 **MWID[1:0]: Memory data bus width**
Defines the external memory device width, valid for all type of memories.
- 00: 8 bits
- 01: 16 bits (default after reset)
- 10: 32 bits
- 11: reserved

Bits 3:2 **MTYP[1:0]: Memory type**
These bits define the type of external memory attached to the corresponding memory bank:
- 00: SRAM (default after reset for Bank 2...4)
- 01: PSRAM (CRAM)
- 10: NOR Flash/OneNAND Flash (default after reset for Bank 1)
- 11: reserved

Bit 1 **MUXEN: Address/data multiplexing enable bit**
When this bit is set, the address and data values are multiplexed on the data bus, valid only with NOR and PSRAM memories:
- 0: Address/Data non-multiplexed
- 1: Address/Data multiplexed on databus (default after reset)

Bit 0 **MBKEN: Memory bank enable bit**
This bit enables the memory bank. After reset Bank 1 is enabled, all others are disabled.
Accessing a disabled bank causes an ERROR on AXI bus.
- 0: Corresponding memory bank is disabled
- 1: Corresponding memory bank is enabled
SRAM/NOR-Flash chip-select timing registers for bank x (FMC_BTRx)

Address offset: 0x04 + 8 * (x - 1), (x = 1 to 4)

Reset value: 0x0FFF FFFF

This register contains the control information of each memory bank, used for SRAMs, PSRAM and NOR Flash memories. If the EXTMOD bit is set in the FMC_BCRx register, then this register is partitioned for write and read access, that is, 2 registers are available: one to configure read accesses (this register) and one to configure write accesses (FMC_BWTRx registers).

Bits 31:30  Reserved, must be kept at reset value.

Bits 29:28  ACCMOD[1:0]: Access mode

These bits specify the Asynchronous access modes as shown in the timing diagrams. They are taken into account only when the EXTMOD bit in the FMC_BCRx register is 1.

00: access mode A
01: access mode B
10: access mode C
11: access mode D

Bits 27:24  DATLAT[3:0]: (see note below bit descriptions): Data latency for synchronous memory

For synchronous access with read/write Burst mode enabled (BURSTEN / CBURSTRW bits set), these bits define the number of memory clock cycles (+2) to issue to the memory before reading/writing the first data:

This timing parameter is not expressed in fmc_ker_ck periods, but in FMC_CLK periods.

For asynchronous access, this value is don’t care.

0000: Data latency of 2 FMC_CLK clock cycles for first burst access
1111: Data latency of 17 FMC_CLK clock cycles for first burst access (default value after reset)

Bits 23:20  CLKDIV[3:0]: Clock divide ratio (for FMC_CLK signal)

These bits define the period of FMC_CLK clock output signal, expressed in number of fmc_ker_ck cycles:

0000: Reserved
0001: FMC_CLK period = 2 × fmc_ker_ck periods
0010: FMC_CLK period = 3 × fmc_ker_ck periods
1111: FMC_CLK period = 16 × fmc_ker_ck periods (default value after reset)

In asynchronous NOR Flash, SRAM or PSRAM accesses, this value is don’t care.

Note: Refer to Section 21.7.5: Synchronous transactions for FMC_CLK divider ratio formula)
Bits 19:16 **BUSTURN**: Bus turnaround phase duration

These bits are written by software to add a delay at the end of a write-to-read (and read-to-write) transaction. This delay allows to match the minimum time between consecutive transactions ($t_{EHEL}$ from NEx high to NEx low) and the maximum time needed by the memory to free the data bus after a read access ($t_{EHQZ}$). The programmed bus turnaround delay is inserted between an asynchronous read (muxed or mode D) or write transaction and any other asynchronous/synchronous read or write to or from a static bank. The bank can be the same or different in case of read, in case of write the bank can be different except for muxed or mode D.

In some cases, whatever the programmed BUSTURN values, the bus turnaround delay is fixed as follows:

- The bus turnaround delay is not inserted between two consecutive asynchronous write transfers to the same static memory bank except for muxed and D modes.
- There is a bus turnaround delay of 1 FMC clock cycle between:
  - Two consecutive asynchronous read transfers to the same static memory bank except for muxed and D modes.
  - An asynchronous read to an asynchronous or synchronous write to any static bank or dynamic bank except for muxed and D modes.
  - An asynchronous (modes 1, 2, A, B or C) read and a read from another static bank.
- There is a bus turnaround delay of 2 FMC clock cycle between:
  - Two consecutive synchronous writes (burst or single) to the same bank.
  - A synchronous write (burst or single) access and an asynchronous write or read transfer to or from static memory bank (the bank can be the same or different for the case of read).
  - Two consecutive synchronous reads (burst or single) followed by any synchronous/asynchronous read or write from/to another static memory bank.
- There is a bus turnaround delay of 3 FMC clock cycle between:
  - Two consecutive synchronous writes (burst or single) to different static bank.
  - A synchronous write (burst or single) access and a synchronous read from the same or a different bank.

0000: BUSTURN phase duration = 0 fmc_ker_ck clock cycle added
...
1111: BUSTURN phase duration = 15 x fmc_ker_ck clock cycles added (default value after reset)

Bits 15:8 **DATAST**: Data-phase duration

These bits are written by software to define the duration of the data phase (refer to Figure 96 to Figure 108), used in asynchronous accesses:

0000 0000: Reserved
0000 0001: DATAST phase duration = 1 x fmc_ker_ck clock cycles
0000 0010: DATAST phase duration = 2 x fmc_ker_ck clock cycles
...
1111 1111: DATAST phase duration = 255 x fmc_ker_ck clock cycles (default value after reset)

For each memory type and access mode data-phase duration, please refer to the respective figure (Figure 96 to Figure 108).

Example: Mode1, write access, DATAST = 1: Data-phase duration = DATAST+1 = 1 x fmc_ker_ck clock cycles.

Note: In synchronous accesses, this value is don’t care.
Bits 7:4 **ADDHLD**: Address-hold phase duration
These bits are written by software to define the duration of the *address hold* phase (refer to *Figure 96* to *Figure 108*), used in mode D or multiplexed accesses:
- 0000: Reserved
- 0001: ADDHLD phase duration = 1 × fmc_ker_ck clock cycle
- 0010: ADDHLD phase duration = 2 × fmc_ker_ck clock cycle
- ... 1111: ADDHLD phase duration = 15 × fmc_ker_ck clock cycles (default value after reset)

For each access mode address-hold phase duration, please refer to the respective figure (*Figure 96* to *Figure 108*).

*Note:* In synchronous accesses, this value is not used, the address hold phase is always 1 memory clock period duration.

Bits 3:0 **ADDSET**: Address setup phase duration
These bits are written by software to define the duration of the *address setup* phase (refer to *Figure 96* to *Figure 108*), used in SRAMs, ROMs and asynchronous NOR Flash:
- 0000: ADDSET phase duration = 0 × fmc_ker_ck clock cycle
- ... 1111: ADDSET phase duration = 15 × fmc_ker_ck clock cycles (default value after reset)

For each access mode address setup phase duration, please refer to the respective figure (refer to *Figure 96* to *Figure 108*).

*Note:* In synchronous accesses, this value is don't care.
In Muxed mode or Mode D, the minimum value for ADDSET is 1.
In mode 1 and PSRAM memory, the minimum value for ADDSET is 1.

*Note:* **PSRAMs (CRAMs)** have a variable latency due to internal refresh. Therefore these memories issue the NWAIT signal during the whole latency phase to extend the latency as needed.

On PSRAMs (CRAMs) the filled DATLAT must be set to 0, so that the FMC exits its latency phase soon and starts sampling NWAIT from memory, then starts to read or write when the memory is ready.

This method can be used also with the latest generation of synchronous Flash memories that issue the NWAIT signal, unlike older Flash memories (check the datasheet of the specific Flash memory being used).
SRAM/NOR-Flash write timing registers for bank x (FMC_BWTRx)

Address offset: 0x104 + 8 * (x - 1), (x = 1 to 4)

Reset value: 0xFFFF FFFF

This register contains the control information of each memory bank. It is used for SRAMs, PSRAMs and NOR Flash memories. When the EXTMOD bit is set in the FMC_BCRx register, then this register is active for write access.

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

Bits 31:30  Reserved, must be kept at reset value.

Bits 29:28  ACCMOD: Access mode.
These bits specify the asynchronous access modes as shown in the next timing diagrams. These bits are taken into account only when the EXTMOD bit in the FMC_BCRx register is 1.
- 00: access mode A
- 01: access mode B
- 10: access mode C
- 11: access mode D

Bits 27:20  Reserved, must be kept at reset value.

Bits 19:16  BUSTURN: Bus turnaround phase duration
These bits are written by software to add a delay at the end of a write transaction to match the minimum time between consecutive transactions (t_{EHEL} from ENx high to ENx low):
(BUSTURN + 1) fmc_ker_ck period ≥ t_{EHELmin}

The programmed bus turnaround delay is inserted between an asynchronous write transfer and any other asynchronous /synchronous read or write transfer to or from a static bank. The bank can be the same or different in case of read, in case of write the bank can be different expect for muxed or mode D.

In some cases, whatever the programmed BUSTURN values, the bus turnaround delay is fixed as follows:
- The bus turnaround delay is not inserted between two consecutive asynchronous write transfers to the same static memory bank except for muxed and D modes.
- There is a bus turnaround delay of 2 FMC clock cycle between:
  - Two consecutive synchronous writes (burst or single) to the same bank.
  - A synchronous write (burst or single) transfer and an asynchronous write or read transfer to or from static memory bank.
- There is a bus turnaround delay of 3 FMC clock cycle between:
  - Two consecutive synchronous writes (burst or single) transfer and a synchronous read from the same or a different bank.

0000: BUSTURN phase duration = 0 fmc_ker_ck clock cycle added
... 1111: BUSTURN phase duration = 15 fmc_ker_ck clock cycles added (default value after reset)
Bits 15:8 **DATAST**: Data-phase duration.
These bits are written by software to define the duration of the data phase (refer to Figure 96 to Figure 108), used in asynchronous SRAM, PSRAM and NOR Flash memory accesses:
- 0000 0000: Reserved
- 0000 0001: DATAST phase duration = 1 × fmc_ker_ck clock cycles
- 0000 0010: DATAST phase duration = 2 × fmc_ker_ck clock cycles
... 
- 1111 1111: DATAST phase duration = 255 × fmc_ker_ck clock cycles (default value after reset)

Bits 7:4 **ADDHLD**: Address-hold phase duration.
These bits are written by software to define the duration of the address hold phase (refer to Figure 96 to Figure 108), used in asynchronous multiplexed accesses:
- 0000: Reserved
- 0001: ADDHLD phase duration = 1 × fmc_ker_ck clock cycle
- 0010: ADDHLD phase duration = 2 × fmc_ker_ck clock cycle
... 
- 1111: ADDHLD phase duration = 15 × fmc_ker_ck clock cycles (default value after reset)

*Note: In synchronous NOR Flash accesses, this value is not used, the address hold phase is always 1 Flash clock period duration.*

Bits 3:0 **ADDSET**: Address setup phase duration.
These bits are written by software to define the duration of the address setup phase in fmc_ker_ck cycles (refer to Figure 96 to Figure 108), used in asynchronous accesses:
- 0000: ADDSET phase duration = 0 × fmc_ker_ck clock cycle
... 
- 1111: ADDSET phase duration = 15 × fmc_ker_ck clock cycles (default value after reset)

*Note: In synchronous accesses, this value is not used, the address setup phase is always 1 Flash clock period duration. In muxed mode, the minimum ADDSET value is 1.*
21.8  NAND Flash controller

The FMC generates the appropriate signal timings to drive 8- and 16-bit NAND Flash memories.

The NAND bank is configured through dedicated registers (Section 21.8.7). The programmable memory parameters include access timings (shown in Table 183) and ECC configuration.

### Table 183. Programmable NAND Flash access parameters

The NAND Flash memory bank is managed through a set of registers:

- Control register: FMC_PCR
- Interrupt status register: FMC_SR
- ECC register: FMC_ECCR
- Timing register for Common memory space: FMC_PMEM
- Timing register for Attribute memory space: FMC_PATT

Each timing configuration register contains three parameters used to define the number of fmc_ker_ck cycles for the three phases of any NAND Flash access, plus one parameter that defines the timing to start driving the data bus when a write access is performed. Figure 114 shows the timing parameter definitions for common memory accesses, knowing that Attribute memory space access timings are similar.
21.8.4 NAND Flash operations

The command latch enable (CLE) and address latch enable (ALE) signals of the NAND Flash memory device are driven by address signals from the FMC controller. This means that to send a command or an address to the NAND Flash memory, the CPU has to perform a write to a specific address in its memory space.

A typical page read operation from the NAND Flash device requires the following steps:

1. Program and enable the corresponding memory bank by configuring the FMC_PCR and FMC_PMEM (and for some devices, FMC_PATT, see Section 21.8.5: NAND Flash prewait feature) registers according to the characteristics of the NAND Flash memory (PWID bits for the data bus width of the NAND Flash memory, PWAITEN = 0 or 1 as needed, see Section 21.6.2: NAND Flash memory address mapping for timing configuration).

2. The CPU performs a byte write to the common memory space, with data byte equal to one Flash command byte (for example 0x00 for Samsung NAND Flash devices). The LE input of the NAND Flash memory is active during the write strobe (low pulse on NWE), thus the written byte is interpreted as a command by the NAND Flash memory. Once the command is latched by the memory device, it does not need to be written again for the following page read operations.

3. The CPU can send the start address (STARTAD) for a read operation by writing four bytes (or three for smaller capacity devices), STARTAD[7:0], STARTAD[16:9], STARTAD[24:17] and finally STARTAD[25] (for 64 Mb x 8 bit NAND Flash memories) in the common memory or attribute space. The ALE input of the NAND Flash device is active during the write strobe (low pulse on NWE), thus the written bytes are interpreted as the start address for read operations. Using the attribute memory space makes it possible to use a different timing configuration of the FMC, which can be used...
to implement the prewait functionality needed by some NAND Flash memories (see details in Section 21.8.5: NAND Flash prewait feature).

4. The controller waits for the NAND Flash memory to be ready (R/NB signal high), before starting a new access to the same or another memory bank. While waiting, the controller holds the NCE signal active (low).

5. The CPU can then perform byte read operations from the common memory space to read the NAND Flash page (data field + Spare field) byte by byte.

6. The next NAND Flash page can be read without any CPU command or address write operation. This can be done in three different ways:
   – by simply performing the operation described in step 5
   – a new random address can be accessed by restarting the operation at step 3
   – a new command can be sent to the NAND Flash device by restarting at step 2

21.8.5 NAND Flash prewait feature

Some NAND Flash devices require that, after writing the last part of the address, the controller waits for the R/NB signal to go low. (see Figure 115).

Figure 115. Access to non ‘CE don’t care’ NAND-Flash

1. CPU wrote byte 0x00 at address 0x7001 0000.
2. CPU wrote byte A7–A0 at address 0x7002 0000.
3. CPU wrote byte A16–A9 at address 0x7002 0000.
4. CPU wrote byte A24–A17 at address 0x7002 0000.
5. CPU wrote byte A25 at address 0x8802 0000; FMC performs a write access using FMC_PATT2 timing definition, where ATTHOLD ≥ 7 (providing that (7+1) × fmc_ker_ck = 112 ns > tWB max). This guarantees that NCE remains low until R/NB goes low and high again (only requested for NAND Flash memories where NCE is not don’t care).
When this function is required, it can be performed by programming the MEMHOLD value to meet the tWB timing. However, any CPU read access to NAND Flash memory has a hold delay of (MEMHOLD + 1) fmc_ker_ck cycles, and any CPU write access has a hold delay of (MEMHOLD) fmc_ker_ck cycles that is inserted between the rising edge of the NWE signal and the next access.

To cope with this timing constraint, the attribute memory space can be used by programming its timing register with an ATTHOLD value that meets the tWB timing, and by keeping the MEMHOLD value at its minimum value. The CPU must then use the common memory space for all NAND Flash read and write accesses, except when writing the last address byte to the NAND Flash device, where the CPU must write to the attribute memory space.

21.8.6 Computation of the error correction code (ECC) in NAND Flash memory

The FMC controller includes an error correction code computation hardware block. It reduces the host CPU workload when processing the ECC by software. The ECC block is associated with NAND bank.

The ECC algorithm implemented in the FMC can perform 1-bit error correction and 2-bit error detection per 256, 512, 1 024, 2 048, 4 096 or 8 192 bytes read or written from/to the NAND Flash memory. It is based on the Hamming coding algorithm and consists in calculating the row and column parity.

The ECC modules monitor the NAND Flash data bus and read/write signals (NCE and NWE) each time the NAND Flash memory bank is active.

The ECC operates as follows:

- When accessing NAND Flash bank, the data present on the D[15:0] bus is latched and used for ECC computation.
- When accessing any other address in NAND Flash memory, the ECC logic is idle, and does not perform any operation. As a result, write operations to define commands or addresses to the NAND Flash memory are not taken into account for ECC computation.

Once the desired number of bytes has been read/written from/to the NAND Flash memory by the host CPU, the FMC_ECCR registers must be read to retrieve the computed value. Once read, they should be cleared by resetting the ECCEN bit to ‘0’. To compute a new data block, the ECCEN bit must be set to one in the FMC_PCR registers.
Execute below the sequence to perform an ECC computation:

1. Enable the ECCEN bit in the FMC_PCR register.
2. Write data to the NAND Flash memory page. While the NAND page is written, the ECC block computes the ECC value.
3. Wait until the ECC code is ready (FIFO empty).
4. Read the ECC value available in the FMC_ECCR register and store it in a variable.
5. Clear the ECCEN bit and then enable it in the FMC_PCR register before reading back the written data from the NAND page. While the NAND page is read, the ECC block computes the ECC value.
6. Read the new ECC value available in the FMC_ECCR register.
7. If the two ECC values are the same, no correction is required, otherwise there is an ECC error and the software correction routine returns information on whether the error can be corrected or not.

### 21.8.7 NAND Flash controller registers

Bits 31:20  Reserved, must be kept at reset value.

Bits 19:17  **ECCPS**: ECC page size.

These bits define the page size for the extended ECC:

- 000: 256 bytes
- 001: 512 bytes
- 010: 1024 bytes
- 011: 2048 bytes
- 100: 4096 bytes
- 101: 8192 bytes

Bits 16:13  **TAR**: ALE to RE delay.

These bits set time from ALE low to RE low in number of fmc_ker_ck clock cycles.

Time is: \( t_{ar} = (TAR + SET + 2) \times fmc_ker_ck \) where \( fmc_ker_ck \) is the FMC clock period

- 0000: 1 x fmc_ker_ck cycle (default)
- 1111: 16 x fmc_ker_ck cycles

**Note**: Set is MEMSET or ATTSET according to the addressed space.
FIFO status and interrupt register (FMC_SR)

Address offset: 0x84
Reset value: 0x0000 0040

This register contains information about the FIFO status and interrupt. The FMC features a FIFO that is used when writing to memories to transfer up to 16 words of data.

This is used to quickly write to the FIFO and free the AXI bus for transactions to peripherals other than the FMC, while the FMC is draining its FIFO into the memory. One of these register bits indicates the status of the FIFO, for ECC purposes.

The ECC is calculated while the data are written to the memory. To read the correct ECC, the software must consequently wait until the FIFO is empty.
Flexible memory controller (FMC)

Bits 31:7  Reserved, must be kept at reset value.

Bit 6  **FEMPT**: FIFO empty.
       Read-only bit that provides the status of the FIFO
       0: FIFO not empty
       1: FIFO empty

Bit 5  **IFEN**: Interrupt falling edge detection enable bit
       0: Interrupt falling edge detection request disabled
       1: Interrupt falling edge detection request enabled

Bit 4  **ILEN**: Interrupt high-level detection enable bit
       0: Interrupt high-level detection request disabled
       1: Interrupt high-level detection request enabled

Bit 3  **IREN**: Interrupt rising edge detection enable bit
       0: Interrupt rising edge detection request disabled
       1: Interrupt rising edge detection request enabled

Bit 2  **IFS**: Interrupt falling edge status
       The flag is set by hardware and reset by software.
       0: No interrupt falling edge occurred
       1: Interrupt falling edge occurred

   *Note: If this bit is written by software to 1 it will be set.*

Bit 1  **ILS**: Interrupt high-level status
       The flag is set by hardware and reset by software.
       0: No Interrupt high-level occurred
       1: Interrupt high-level occurred

Bit 0  **IRS**: Interrupt rising edge status
       The flag is set by hardware and reset by software.
       0: No interrupt rising edge occurred
       1: Interrupt rising edge occurred

   *Note: If this bit is written by software to 1 it will be set.*
Common memory space timing register (FMC_PMEM)

Address offset: Address: 0x88
Reset value: 0xFCFC FCFC

The FMC_PMEM read/write register contains the timing information for NAND Flash memory bank. This information is used to access either the common memory space of the NAND Flash for command, address write access and data read/write access.

Attribute memory space timing registers (FMC_PATT)

Address offset: 0x8C
Reset value: 0xFCFC FCFC

The FMC_PATT read/write register contains the timing information for NAND Flash memory bank. It is used for 8-bit accesses to the attribute memory space of the NAND Flash for the last address write access if the timing must differ from that of previous accesses (for Ready/Busy management, refer to Section 21.8.5: NAND Flash prewait feature).

ECC result registers (FMC_ECCR)

Address offset: 0x94

Reset value: 0x0000 0000

This register contain the current error correction code value computed by the ECC computation modules of the FMC NAND controller. When the CPU reads/writes the data from a NAND Flash memory page at the correct address (refer to Section 21.8.6: Computation of the error correction code (ECC) in NAND Flash memory), the data read/written from/to the NAND Flash memory are processed automatically by the ECC computation module. When X bytes have been read (according to the ECCPS field in the FMC_PCR registers), the CPU must read the computed ECC value from the FMC_ECC registers. It then verifies if these computed parity data are the same as the parity value recorded in the spare area, to determine whether a page is valid, and, to correct it otherwise. The FMC_ECCR register should be cleared after being read by setting the ECCEN bit to ‘0’. To compute a new data block, the ECCEN bit must be set to ‘1’.

21.9 SDRAM controller

21.9.1 SDRAM controller main features

The main features of the SDRAM controller are the following:

- Two SDRAM banks with independent configuration
- 8-bit, 16-bit, 32-bit data bus width
- 13-bits Address Row, 11-bits Address Column, 4 internal banks: 4x16Mx32bit (256 MB), 4x16Mx16bit (128 MB), 4x16Mx8bit (64 MB)
- Word, half-word, byte access
- SDRAM clock can be fmc_ker_ck/2 or fmc_ker_ck/3
- Automatic row and bank boundary management
- Multibank ping-pong access
- Programmable timing parameters
- Automatic Refresh operation with programmable Refresh rate
- Self-refresh mode
- Power-down mode
- SDRAM power-up initialization by software
- CAS latency of 1,2,3
- Cacheable Read FIFO with depth of 6 lines x32-bit (6 x14-bit address tag)

21.9.2 SDRAM External memory interface signals

At startup, the SDRAM I/O pins used to interface the FMC SDRAM controller with the external SDRAM devices must configured by the user application. The SDRAM controller I/O pins which are not used by the application, can be used for other purposes.

21.9.3 SDRAM controller functional description

All SDRAM controller outputs (signals, address and data) change on the falling edge of the memory clock (FMC_SDCLK).

SDRAM initialization

The initialization sequence is managed by software. If the two banks are used, the initialization sequence must be generated simultaneously to Bank 1 and Bank 2 by setting the Target Bank bits CTB1 and CTB2 in the FMC_SDCMR register:

1. Program the memory device features into the FMC_SDCRx register. The SDRAM clock frequency, RBURST and RPIPE must be programmed in the FMC_SDCR1 register.
2. Program the memory device timing into the FMC_SDTRx register. The TRP and TRC timings must be programmed in the FMC_SDTR1 register.
3. Set MODE bits to ‘001’ and configure the Target Bank bits (CTB1 and/or CTB2) in the FMC_SDCMR register to start delivering the clock to the memory (SDCKE is driven high).
4. Wait during the prescribed delay period. Typical delay is around 100 μs (refer to the SDRAM datasheet for the required delay after power-up).
5. Set MODE bits to ‘010’ and configure the Target Bank bits (CTB1 and/or CTB2) in the FMC_SDCMR register to issue a “Precharge All” command.
6. Set MODE bits to ‘011’, and configure the Target Bank bits (CTB1 and/or CTB2) as well as the number of consecutive Auto-refresh commands (NRFS) in the FMC_SDCMR register. Refer to the SDRAM datasheet for the number of Auto-refresh commands that should be issued. Typical number is 8.
7. Configure the MRD field, set the MODE bits to ‘100’, and configure the Target Bank bits (CTB1 and/or CTB2) in the FMC_SDCMR register to issue a “Load Mode Register” command and program the SDRAM device. In particular the Burst Length (BL) has to be set to ‘1’) and the CAS latency has to be selected. If the Mode Register is not the same for both SDRAM banks, this step has to be repeated twice, once for each bank and the Target Bank bits set accordingly. For mobile SDRAM devices, the MRD field is also used to configure the extended mode register while issuing the Load Mode Register.
8. Program the refresh rate in the FMC_SDRTR register
   The refresh rate corresponds to the delay between refresh cycles. Its value must be adapted to SDRAM devices.

At this stage the SDRAM device is ready to accept commands. If a system reset occurs during an ongoing SDRAM access, the data bus might still be driven by the SDRAM device. Therefore the SDRAM device must be first reinitialized after reset before issuing any new access by the NOR Flash/PSRAM/SRAM or NAND Flash controller.

Note: If two SDRAM devices are connected to the FMC, all the accesses performed at the same time to both devices by the Command Mode register (Load Mode Register command) are issued using the timing parameters configured for SDRAM Bank 1 (TMRD and TRAS timings) in the FMC_SDTR1 register.
**SDRAM controller write cycle**

The SDRAM controller accepts single and burst write requests and translates them into single memory accesses. In both cases, the SDRAM controller keeps track of the active row for each bank to be able to perform consecutive write accesses to different banks (Multibank ping-pong access).

Before performing any write access, the SDRAM bank write protection must be disabled by clearing the WP bit in the FMC_SDCRx register.

*Figure 116. Burst write SDRAM access waveforms*

The SDRAM controller always checks the next access:
- If the next access is in the same row or in another active row, the write operation is carried out,
- if the next access targets another row (not active), the SDRAM controller generates a precharge command, activates the new row and initiates a write command.
SDRAM controller read cycle

The SDRAM controller accepts single and burst read requests and translates them into single memory accesses. In both cases, the SDRAM controller keeps track of the active row in each bank to be able to perform consecutive read accesses in different banks (Multibank ping-pong access).

Figure 117. Burst read SDRAM access

The FMC SDRAM controller features a Cacheable read FIFO (6 lines x 32 bits). It is used to store data read in advance during the CAS latency period (up to 3 memory clock cycles, programmed FMC_SDCRx) and during the RPIPE delay when set to 2xfmc_ker_ck clock cycles as configured in FMC_SDCR1) following this formula: CAS Latency + 1 + (RPIPE DIV2). The RBURST bit must be set in the FMC_SDCR1 register to anticipate the next read access.

Examples:
- CAS=3, RPIPE= 2xfmc_ker_ck. In this case, 5 data (not committed) are stored in the FIFO (4 data during CAS latency and 1 data during RPIPE delay)
- CAS=3, RPIPE= 1xfmc_ker_ck. In this case, 4 data (not committed) are stored in the FIFO (4 data during CAS latency)

The read FIFO features a 14-bit address tag to each line to identify its content: 11 bits for the column address, 2 bits to select the internal bank and the active row, and 1 bit to select the SDRAM device

When the end of the row is reached in advance during an burst read transaction, the data read in advance (not committed) are not stored in the read FIFO. For single read access, data are correctly stored in the FIFO.
Each time a read request occurs, the SDRAM controller checks:

- If the address matches one of the address tags, data are directly read from the FIFO and the corresponding address tag/line content is cleared and the remaining data in the FIFO are compacted to avoid empty lines.
- Otherwise, a new read command is issued to the memory and the FIFO is updated with new data. If the FIFO is full, the older data are lost.

**Figure 118. Logic diagram of Read access with RBURST bit set (CAS=2, RPIPE=0)**

During a write access or a Precharge command, the read FIFO is flushed and ready to be filled with new data.

After the first read request, if the current access was not performed to a row boundary, the SDRAM controller anticipates the next read access during the CAS latency period and the RPIPE delay (if configured). This is done by incrementing the memory address. The following condition must be met:

- RBURST control bit should be set to ‘1’ in the FMC_SDCR1 register.
The address management depends on the next AXI request:

- **Next request is sequential (Burst access)**
  
  In this case, the SDRAM controller increments the address.

- **Next request is not sequential**
  
  - If the new read request targets the same row or another active row, the new address is passed to the memory and the master is stalled for the CAS latency period, waiting for the new data from memory.
  
  - If the new read request does not target an active row, the SDRAM controller generates a Precharge command, activates the new row, and initiates a read command.

If the RBURST is reset, the read FIFO is not used.

**Row and bank boundary management**

When a read or write access crosses a row boundary, if the next read or write access is sequential and the current access was performed to a row boundary, the SDRAM controller executes the following operations:

1. Precharge of the active row,
2. Activation of the new row
3. Start of a read/write command.

At a row boundary, the automatic activation of the next row is supported for all columns and data bus width configurations.

If necessary, the SDRAM controller inserts additional clock cycles between the following commands:

- Between Precharge and Active commands to match TRP parameter (only if the next access is in a different row in the same bank),
- Between Active and Read commands to match the TRCD parameter.

These parameters are defined into the FMC_SDTRx register.

Refer to Figure 116 and Figure 117 for read and burst write access crossing a row boundary.
Figure 119. Read access crossing row boundary

Figure 120. Write access crossing row boundary
If the next access is sequential and the current access crosses a bank boundary, the SDRAM controller activates the first row in the next bank and initiates a new read/write command. Two cases are possible:

- If the current bank is not the last one, the active row in the new bank must be precharged. At a bank boundary, the automatic activation of the next row is supported for all rows/columns and data bus width configuration.

- If the current bank is the last one, the automatic activation of the next row is supported only when addressing 13-bit rows, 11-bit columns, 4 internal banks and 32-bit data bus SDRAM devices. Otherwise, the SDRAM address range is violated and an AXI slave error is generated.

- In case of 13-bit row address, 11-bit column address, 4 internal banks and bus width 32-bit SDRAM memories, at boundary bank, the SDRAM controller continues to read/write from the second SDRAM device (assuming it has been initialized):
  a) The SDRAM controller activates the first row (after precharging the active row, if there is already an active row in the first internal bank, and initiates a new read/write command.
  b) If the first row is already activated, the SDRAM controller just initiates a read/write command.

**SDRAM controller refresh cycle**

The Auto-refresh command is used to refresh the SDRAM device content. The SDRAM controller periodically issues auto-refresh commands. An internal counter is loaded with the COUNT value in the register FMC_SDRTR. This value defines the number of memory clock cycles between the refresh cycles (refresh rate). When this counter reaches zero, an internal pulse is generated.

If a memory access is ongoing, the auto-refresh request is delayed. However, if the memory access and the auto-refresh requests are generated simultaneously, the auto-refresh request takes precedence.

If the memory access occurs during an auto-refresh operation, the request is buffered and processed when the auto-refresh is complete.

If a new auto-refresh request occurs while the previous one was not served, the RE (Refresh Error) bit is set in the Status register. An Interrupt is generated if it has been enabled (REIE = ‘1’).

If SDRAM lines are not in idle state (not all row are closed), the SDRAM controller generates a PALL (Precharge ALL) command before the auto-refresh.

If the Auto-refresh command is generated by the FMC_SDCMR Command Mode register (Mode bits = ‘011’), a PALL command (Mode bits = ‘010’) must be issued first.
21.9.4 **Low-power modes**

Two low-power modes are available:

- **Self-refresh mode**
  
  The auto-refresh cycles are performed by the SDRAM device itself to retain data without external clocking.

- **Power-down mode**
  
  The auto-refresh cycles are performed by the SDRAM controller.

**Self-refresh mode**

This mode is selected by setting the MODE bits to ‘101’ and by configuring the Target Bank bits (CTB1 and/or CTB2) in the FMC_SDCMR register.

The SDRAM clock stops running after a TRAS delay and the internal refresh timer stops counting only if one of the following conditions is met:

- A Self-refresh command is issued to both devices
- One of the devices is not activated (SDRAM bank is not initialized).

Before entering Self-Refresh mode, the SDRAM controller automatically issues a PALL command.

If the Write data FIFO is not empty, all data are sent to the memory before activating the Self-refresh mode and the BUSY status flag remains set.

In Self-refresh mode, all SDRAM device inputs become don’t care except for SDCKE which remains low.

The SDRAM device must remain in Self-refresh mode for a minimum period of time of TRAS and can remain in Self-refresh mode for an indefinite period beyond that. To guarantee this minimum period, the BUSY status flag remains high after the Self-refresh activation during a TRAS delay.

As soon as an SDRAM device is selected, the SDRAM controller generates a sequence of commands to exit from Self-refresh mode. After the memory access, the selected device remains in Normal mode.

To exit from Self-refresh, the MODE bits must be set to ‘000’ (Normal mode) and the Target Bank bits (CTB1 and/or CTB2) must be configured in the FMC_SDCMR register.
Figure 121. Self-refresh mode

- SDCLK
- SDCKE
- COMMAND: PRECHARGE, NOP, AUTO REFRESH, NOP or COMMAND INHERIT, AUTO REFRESH
- DOM/DOML/DOMU
- A0-A9
- A11, A12
- A10
- Data[31:0]: Hi-Z

Precharge all active banks → Enter Self-refresh mode
CLK stable prior to existing Self-refresh mode
Exit Self-refresh mode (restart refresh timebase)
Power-down mode

This mode is selected by setting the MODE bits to ‘110’ and by configuring the Target Bank bits (CTB1 and/or CTB2) in the FMC_SDCMR register.

Figure 122. Power-down mode

If the Write data FIFO is not empty, all data are sent to the memory before activating the Power-down mode.

As soon as an SDRAM device is selected, the SDRAM controller exits from the Power-down mode. After the memory access, the selected SDRAM device remains in Normal mode.

During Power-down mode, all SDRAM device input and output buffers are deactivated except for the SDCKE which remains low.

The SDRAM device cannot remain in Power-down mode longer than the refresh period and cannot perform the Auto-refresh cycles by itself. Therefore, the SDRAM controller carries out the refresh operation by executing the operations below:
1. Exit from Power-down mode and drive the SDCKE high
2. Generate the PALL command only if a row was active during Power-down mode
3. Generate the auto-refresh command
4. Drive SDCKE low again to return to Power-down mode.

To exit from Power-down mode, the MODE bits must be set to ‘000’ (Normal mode) and the Target Bank bits (CTB1 and/or CTB2) must be configured in the FMC_SDCMR register.
21.9.5 SDRAM controller registers

SDRAM Control registers for SDRAM memory bank x (FMC_SDCRx)

Address offset: 0x140 + 4*(x - 1), (x = 1 to 2)

Reset value: 0x0000 02D0

This register contains the control parameters for each SDRAM memory bank.

| Bit 31:15 | Reserved, must be kept at reset value. |
| Bit 14:13 | RPIPE[1:0]: Read pipe |
|           | These bits define the delay, in fmc_ker_ck clock cycles, for reading data after CAS latency. |
|           | 00: No fmc_ker_ck clock cycle delay |
|           | 01: One fmc_ker_ck clock cycle delay |
|           | 10: Two fmc_ker_ck clock cycle delay |
|           | 11: reserved. |
| Note:     | The corresponding bits in the FMC_SDCR2 register is read only. |
| Bit 12    | RBURST: Burst read |
|           | This bit enables Burst read mode. The SDRAM controller anticipates the next read commands during the CAS latency and stores data in the Read FIFO. |
|           | 0: single read requests are not managed as bursts |
|           | 1: single read requests are always managed as bursts |
| Note:     | The corresponding bit in the FMC_SDCR2 register is read only. |
| Bits 11:10| SDCLK[1:0]: SDRAM clock configuration |
|           | These bits define the SDRAM clock period for both SDRAM banks and allow disabling the clock before changing the frequency. In this case the SDRAM must be re-initialized. |
|           | 00: SDCLK clock disabled |
|           | 01: Reserved |
|           | 10: SDCLK period = 2 x fmc_ker_ck periods |
|           | 11: SDCLK period = 3 x fmc_ker_ck periods |
| Note:     | The corresponding bits in the FMC_SDCR2 register is read only. |
| Bit 9     | WP: Write protection |
|           | This bit enables Write mode access to the SDRAM bank. |
|           | 0: Write accesses allowed |
|           | 1: Write accesses ignored |
Bits 8:7 **CAS[1:0]:** CAS Latency
This bits sets the SDRAM CAS latency in number of memory clock cycles
- 00: reserved.
- 01: 1 cycle
- 10: 2 cycles
- 11: 3 cycles

Bit 6 **NB:** Number of internal banks
This bit sets the number of internal banks.
- 0: Two internal Banks
- 1: Four internal Banks

Bits 5:4 **MWID[1:0]:** Memory data bus width.
These bits define the memory device width.
- 00: 8 bits
- 01: 16 bits
- 10: 32 bits
- 11: reserved.

Bits 3:2 **NR[1:0]:** Number of row address bits
These bits define the number of bits of a row address.
- 00: 11 bit
- 01: 12 bits
- 10: 13 bits
- 11: reserved.

Bits 1:0 **NC[1:0]:** Number of column address bits
These bits define the number of bits of a column address.
- 00: 8 bits
- 01: 9 bits
- 10: 10 bits
- 11: 11 bits.

_Note:_ Before modifying the RBURST or RPIPE settings or disabling the SDCLK clock, the user must first send a PALL command to make sure ongoing operations are complete.

**SDRAM Timing registers for SDRAM memory bank x (FMC_SDTRx)**
Address offset: 0x148 + 4 * (x - 1), (x = 1 to 2)
Reset value: 0x0FFF FFFF
This register contains the timing parameters of each SDRAM bank

Bits 31:28  Reserved, must be kept at reset value.

Bits 27:24  **TRCD[3:0]**: Row to column delay
These bits define the delay between the Activate command and a Read/Write command in number of memory clock cycles.

- 0000: 1 cycle
- 0001: 2 cycles
- ...
- 1111: 16 cycles

Bits 23:20  **TRP[3:0]**: Row precharge delay
These bits define the delay between a Precharge command and another command in number of memory clock cycles. The TRP timing is only configured in the FMC_SDTR1 register. If two SDRAM devices are used, the TRP must be programmed with the timing of the slowest device.

- 0000: 1 cycle
- 0001: 2 cycles
- ...
- 1111: 16 cycles

*Note: The corresponding bits in the FMC_SDTR2 register are don't care.*

Bits 19:16  **TWR[3:0]**: Recovery delay
These bits define the delay between a Write and a Precharge command in number of memory clock cycles.

- 0000: 1 cycle
- 0001: 2 cycles
- ...
- 1111: 16 cycles

*Note: TWR must be programmed to match the write recovery time (tWR) defined in the SDRAM datasheet, and to guarantee that:

\[ TWR \geq TRAS - TRCD \]

Example: TRAS = 4 cycles, TRCD = 2 cycles. So, TWR >= 2 cycles. TWR must be programmed to 0x1.

- If two SDRAM devices are used, the FMC_SDTR1 and FMC_SDTR2 must be programmed with the same TWR timing corresponding to the slowest SDRAM device.
- If only one SDRAM device is used, the TWR timing must be kept at reset value (0xF) for the not used bank.

Bits 15:12  **TRC[3:0]**: Row cycle delay
These bits define the delay between the Refresh command and the Activate command, as well as the delay between two consecutive Refresh commands. It is expressed in number of memory clock cycles. The TRC timing is only configured in the FMC_SDTR1 register. If two SDRAM devices are used, the TRC must be programmed with the timings of the slowest device.

- 0000: 1 cycle
- 0001: 2 cycles
- ...
- 1111: 16 cycles

*Note: TRC must match the TRC and TRFC (Auto Refresh period) timings defined in the SDRAM device datasheet.*

*Note: The corresponding bits in the FMC_SDTR2 register are don't care.*
Bits 11:8 **TRAS[3:0]: Self refresh time**
These bits define the minimum Self-refresh period in number of memory clock cycles.
0000: 1 cycle
0001: 2 cycles
....
1111: 16 cycles

**Note:** If two SDRAM devices are used, the FMC_SDTR1 and FMC_SDTR2 must be programmed with the same TXSR timing corresponding to the slowest SDRAM device.

Bits 7:4 **TXSR[3:0]: Exit Self-refresh delay**
These bits define the delay from releasing the Self-refresh command to issuing the Activate command in number of memory clock cycles.
0000: 1 cycle
0001: 2 cycles
....
1111: 16 cycles

**Note:** If two SDRAM devices are used, the FMC_SDTR1 and FMC_SDTR2 must be programmed with the same TXSR timing corresponding to the slowest SDRAM device.

Bits 3:0 **TMRD[3:0]: Load Mode Register to Active**
These bits define the delay between a Load Mode Register command and an Active or Refresh command in number of memory clock cycles.
0000: 1 cycle
0001: 2 cycles
....
1111: 16 cycles

**SDRAM Command mode register (FMC_SDCMR)**
Address offset: 0x150
Reset value: 0x0000 0000

This register contains the command issued when the SDRAM device is accessed. This register is used to initialize the SDRAM device, and to activate the Self-refresh and the Power-down modes. As soon as the MODE field is written, the command will be issued only to one or to both SDRAM banks according to CTB1 and CTB2 command bits. This register is the same for both SDRAM banks.

Bits 31:23 Reserved, must be kept at reset value.
Bits 22:9 **MRD[13:0]**: Mode Register definition

This 14-bit field defines the SDRAM Mode Register content. The Mode Register is programmed using the Load Mode Register command. The MRD[13:0] bits are also used to program the extended mode register for mobile SDRAM.

Bits 8:5 **NRFS[3:0]**: Number of Auto-refresh

These bits define the number of consecutive Auto-refresh commands issued when MODE = ‘011’.

- 0000: 1 Auto-refresh cycle
- 0001: 2 Auto-refresh cycles
- ....
- 1110: 15 Auto-refresh cycles
- 1111: 16 Auto-refresh cycles

Bit 4 **CTB1**: Command Target Bank 1

This bit indicates whether the command will be issued to SDRAM Bank 1 or not.

- 0: Command not issued to SDRAM Bank 1
- 1: Command issued to SDRAM Bank 1

Bit 3 **CTB2**: Command Target Bank 2

This bit indicates whether the command will be issued to SDRAM Bank 2 or not.

- 0: Command not issued to SDRAM Bank 2
- 1: Command issued to SDRAM Bank 2

Bits 2:0 **MODE[2:0]**: Command mode

These bits define the command issued to the SDRAM device.

- 000: Normal Mode
- 001: Clock Configuration Enable
- 010: PALL (“All Bank Precharge”) command
- 011: Auto-refresh command
- 100: Load Mode Register
- 101: Self-refresh command
- 110: Power-down command
- 111: Reserved

Note: When a command is issued, at least one Command Target Bank bit (CTB1 or CTB2) must be set otherwise the command will be ignored.

Note: If two SDRAM banks are used, the Auto-refresh and PALL command must be issued simultaneously to the two devices with CTB1 and CTB2 bits set otherwise the command will be ignored.

Note: If only one SDRAM bank is used and a command is issued with it's associated CTB bit set, the other CTB bit of the unused bank must be kept to 0.

**SDRAM refresh timer register (FMC_SDRTR)**

Address offset: 0x154

Reset value: 0x0000 0000

This register sets the refresh rate in number of SDCLK clock cycles between the refresh cycles by configuring the Refresh Timer Count value.

\[
\text{Refresh rate} = (\text{COUNT} + 1) \times \text{SDRAM clock frequency}
\]

\[
\text{COUNT} = (\text{SDRAM refresh period}/ \text{Number of rows}) - 20
\]
Below an example of refresh rate calculation:

\[
\text{Refresh rate} = 64 \text{ ms}/(8196 \text{ rows}) = 7.81 \mu \text{s}
\]

where 64 ms is the SDRAM refresh period.

\[
7.81 \mu \text{s} \times 60 \text{MHz} = 468.6
\]

The refresh rate must be increased by 20 SDRAM clock cycles (as in the above example) to obtain a safe margin if an internal refresh request occurs when a read request has been accepted. It corresponds to a COUNT value of '0000111000000' (448).

This 13-bit field is loaded into a timer which is decremented using the SDRAM clock. This timer generates a refresh pulse when zero is reached. The COUNT value must be set at least to 41 SDRAM clock cycles.

As soon as the FMC_SDRTR register is programmed, the timer starts counting. If the value programmed in the register is '0', no refresh is carried out. This register must not be reprogrammed after the initialization procedure to avoid modifying the refresh rate.

Each time a refresh pulse is generated, this 13-bit COUNT field is reloaded into the counter.

If a memory access is in progress, the Auto-refresh request is delayed. However, if the memory access and Auto-refresh requests are generated simultaneously, the Auto-refresh takes precedence. If the memory access occurs during a refresh operation, the request is buffered to be processed when the refresh is complete.

This register is common to SDRAM bank 1 and bank 2.

Bits 31: 15 Reserved, must be kept at reset value.

Bit 14 **REIE**: RES Interrupt Enable

0: Interrupt is disabled
1: An Interrupt is generated if RE = 1

Bits 13:1 **COUNT[12:0]**: Refresh Timer Count

This 13-bit field defines the refresh rate of the SDRAM device. It is expressed in number of memory clock cycles. It must be set at least to 41 SDRAM clock cycles (0x29).

Refresh rate = (COUNT + 1) x SDRAM frequency clock

COUNT = (SDRAM refresh period / Number of rows) - 20

Bit 0 **CRE**: Clear Refresh error flag

This bit is used to clear the Refresh Error Flag (RE) in the Status Register.

0: no effect
1: Refresh Error flag is cleared

**Note:** The programmed COUNT value must not be equal to the sum of the following timings: TWR+TRP+TRC+TRCD+4 memory clock cycles.

Refer to Section 2.3 on page 126 for the register boundary addresses.
22 Quad-SPI interface (QUADSPI)

22.1 Introduction

The QUADSPI is a specialized communication interface targeting single, dual or quad SPI Flash memories. It can operate in any of the three following modes:

- indirect mode: all the operations are performed using the QUADSPI registers
- status polling mode: the external Flash memory status register is periodically read and an interrupt can be generated in case of flag setting
- memory-mapped mode: the external Flash memory is mapped to the device address space and is seen by the system as if it was an internal memory

Both throughput and capacity can be increased two-fold using dual-flash mode, where two Quad-SPI Flash memories are accessed simultaneously.

22.2 QUADSPI main features

- Three functional modes: indirect, status-polling, and memory-mapped
- Dual-flash mode, where 8 bits can be sent/received simultaneously by accessing two Flash memories in parallel.
- SDR and DDR support
- Fully programmable opcode for both indirect and memory mapped mode
- Fully programmable frame format for both indirect and memory mapped mode
- Integrated FIFO for reception and transmission
- 8, 16, and 32-bit data accesses are allowed
- MDMA trigger generation for FIFO threshold and transfer complete
- Interrupt generation on FIFO threshold, timeout, operation complete, and access error

22.3.3 QUADSPI command sequence

The QUADSPI communicates with the Flash memory using commands. Each command can include 5 phases: instruction, address, alternate byte, dummy, data. Any of these phases can be configured to be skipped, but at least one of the instruction, address, alternate byte, or data phase must be present.

nCS falls before the start of each command and rises again after each command finishes.
**Instruction phase**

During this phase, an 8-bit instruction, configured in INSTRUCTION field of QUADSPI_CCR[7:0] register, is sent to the Flash memory, specifying the type of operation to be performed.

Though most Flash memories can receive instructions only one bit at a time from the IO0/SO signal (single SPI mode), the instruction phase can optionally send 2 bits at a time (over IO0/IO1 in dual SPI mode) or 4 bits at a time (over IO0/IO1/IO2/IO3 in quad SPI mode). This can be configured using the IMODE[1:0] field of QUADSPI_CCR[9:8] register.

When IMODE = 00, the instruction phase is skipped, and the command sequence starts with the address phase, if present.

**Address phase**

In the address phase, 1-4 bytes are sent to the Flash memory to indicate the address of the operation. The number of address bytes to be sent is configured in the ADSIZE[1:0] field of QUADSPI_CCR[13:12] register. In indirect and automatic-polling modes, the address bytes to be sent are specified in the ADDRESS[31:0] field of QUADSPI_AR register, while in memory-mapped mode the address is given directly via the AXI (from the Cortex® or from a DMA).

The address phase can send 1 bit at a time (over SO in single SPI mode), 2 bits at a time (over IO0/IO1 in dual SPI mode), or 4 bits at a time (over IO0/IO1/IO2/IO3 in quad SPI mode). This can be configured using the ADMODE[1:0] field of QUADSPI_CCR[11:10] register.

When ADMODE = 00, the address phase is skipped, and the command sequence proceeds directly to the next phase, if any.

**Alternate-bytes phase**

In the alternate-bytes phase, 1-4 bytes are sent to the Flash memory, generally to control the mode of operation. The number of alternate bytes to be sent is configured in the ABSIZE[1:0] field of QUADSPI_CCR[17:16] register. The bytes to be sent are specified in the QUADSPI_ABR register.

The alternate-bytes phase can send 1 bit at a time (over SO in single SPI mode), 2 bits at a time (over IO0/IO1 in dual SPI mode), or 4 bits at a time (over IO0/IO1/IO2/IO3 in quad SPI mode). This can be configured using the ABMODE[1:0] field of QUADSPI_CCR[15:14] register.
When ABMODE = 00, the alternate-bytes phase is skipped, and the command sequence proceeds directly to the next phase, if any.

There may be times when only a single nibble needs to be sent during the alternate-byte phase rather than a full byte, such as when dual-mode is used and only two cycles are used for the alternate bytes. In this case, firmware can use quad-mode (ABMODE = 11) and send a byte with bits 7 and 3 of ALTERNATE set to ‘1’ (keeping the IO3 line high), and bits 6 and 2 set to ‘0’ (keeping the IO2 line low). In this case the upper two bits of the nibble to be sent are placed in bits 4:3 of ALTERNATE while the lower two bits are placed in bits 1 and 0. For example, if the nibble 2 (0010) is to be sent over IO0/IO1, then ALTERNATE should be set to 0x8A (1000_1010).

**Dummy-cycles phase**

In the dummy-cycles phase, 1-31 cycles are given without any data being sent or received, in order to allow the Flash memory the time to prepare for the data phase when higher clock frequencies are used. The number of cycles given during this phase is specified in the DCYC[4:0] field of QUADSPI_CCR[22:18] register. In both SDR and DDR modes, the duration is specified as a number of full CLK cycles.

When DCYC is zero, the dummy-cycles phase is skipped, and the command sequence proceeds directly to the data phase, if present.

The operating mode of the dummy-cycles phase is determined by DMODE.

In order to assure enough “turn-around” time for changing the data signals from output mode to input mode, there must be at least one dummy cycle when using dual or quad mode to receive data from the Flash memory.

**Data phase**

During the data phase, any number of bytes can be sent to, or received from the Flash memory.

In indirect and automatic-polling modes, the number of bytes to be sent/received is specified in the QUADSPI_DLR register.

In indirect write mode the data to be sent to the Flash memory must be written to the QUADSPI_DR register, while in indirect read mode the data received from the Flash memory is obtained by reading from the QUADSPI_DR register.

In memory-mapped mode, the data which is read is sent back directly over the AXI to the Cortex or to a DMA.

The data phase can send/receive 1 bit at a time (over SO/SI in single SPI mode), 2 bits at a time (over IO0/IO1 in dual SPI mode), or 4 bits at a time (over IO0/IO1/IO2/IO3 in quad SPI mode). This can be configured using the ABMODE[1:0] field of QUADSPI_CCR[15:14] register.

When DMODE = 00, the data phase is skipped, and the command sequence finishes immediately by raising nCS. This configuration must only be used in only indirect write mode.
22.3.4 QUADSPI signal interface protocol modes

Single SPI mode

Legacy SPI mode allows just a single bit to be sent/received serially. In this mode, data is sent to the Flash memory over the SO signal (whose I/O shared with IO0). Data received from the Flash memory arrives via SI (whose I/O shared with IO1).

The different phases can each be configured separately to use this single bit mode by setting the IMODE/ADMODE/ABMODE/DMODE fields (in QUADSPI_CCR) to 01.

In each phase which is configured in single mode:
- IO0 (SO) is in output mode
- IO1 (SI) is in input mode (high impedance)
- IO2 is in output mode and forced to ‘0’ (to deactivate the “write protect” function)
- IO3 is in output mode and forced to ‘1’ (to deactivate the “hold” function)

This is the case even for the dummy phase if DMODE = 01.

Dual SPI mode

In dual SPI mode, two bits are sent/received simultaneously over the IO0/IO1 signals.

The different phases can each be configured separately to use dual SPI mode by setting the IMODE/ADMODE/ABMODE/DMODE fields of QUADSPI_CCR register to 10.

In each phase which is configured in dual mode:
- IO0/IO1 are at high-impedance (input) during the data phase for read operations, and outputs in all other cases
- IO2 is in output mode and forced to ‘0’
- IO3 is in output mode and forced to ‘1’

In the dummy phase when DMODE = 01, IO0/IO1 are always high-impedance.

Quad SPI mode

In quad SPI mode, four bits are sent/received simultaneously over the IO0/IO1/IO2/IO3 signals.

The different phases can each be configured separately to use quad SPI mode by setting the IMODE/ADMODE/ABMODE/DMODE fields of QUADSPI_CCR register to 11.

In each phase which is configured in quad mode, IO0/IO1/IO2/IO3 are all are at high-impedance (input) during the data phase for read operations, and outputs in all other cases.

In the dummy phase when DMODE = 11, IO0/IO1/IO2/IO3 are all high-impedance.

IO2 and IO3 are used only in Quad SPI mode. If none of the phases are configured to use Quad SPI mode, then the pins corresponding to IO2 and IO3 can be used for other functions even while QUADSPI is active.

SDR mode

By default, the DDRM bit (QUADSPI_CCR[31]) is 0 and the QUADSPI operates in single data rate (SDR) mode.

In SDR mode, when the QUADSPI is driving the IO0/SO, IO1, IO2, IO3 signals, these signals transition only with the falling edge of CLK.
When receiving data in SDR mode, the QUADSPI assumes that the Flash memories also send the data using CLK’s falling edge. By default (when SSHIFT = 0), the signals are sampled using the following (rising) edge of CLK.

**DDR mode**

When the DDRM bit (QUADSPI_CCR[31]) is set to 1, the QUADSPI operates in double data rate (DDR) mode.

In DDR mode, when the QUADSPI is driving the IO0/SO, IO1, IO2, IO3 signals in the address/alternate-byte/data phases, a bit is sent on each of the falling and rising edges of CLK.

The instruction phase is not affected by DDRM. The instruction is always sent using CLK’s falling edge.

When receiving data in DDR mode, the QUADSPI assumes that the Flash memories also send the data using both rising and falling CLK edges. When DDRM = 1, firmware must clear SSHIFT bit (bit 4 of QUADSPI.CR). Thus, the signals are sampled one half of a CLK cycle later (on the following, opposite edge).

**Figure 126. An example of a DDR command in quad mode**

**Dual-flash mode**

When the DFM bit (bit 6 of QUADSPI.CR) is 1, the QUADSPI is in dual-flash mode, where two external quad SPI Flash memories (FLASH 1 and FLASH 2) are used in order to send/receive 8 bits (or 16 bits in DDR mode) every cycle, effectively doubling the throughput as well as the capacity.

Each of the Flash memories use the same CLK and optionally the same nCS signals, but each have separate IO0, IO1, IO2, and IO3 signals.

Dual-flash mode can be used in conjunction with single-bit, dual-bit, and quad-bit modes, as well as with either SDR or DDR mode.

The Flash memory size, as specified in FSIZE[4:0] (QUADSPI_DCR[20:16]), should reflect the total Flash memory capacity, which is double the size of one individual component.

If address X is even, then the byte which the QUADSPI gives for address X is the byte at the address X/2 of FLASH 1, and the byte which the QUADSPI gives for address X+1 is the byte at the address X/2 of FLASH 2. In other words, bytes at even addresses are all stored in FLASH 1 and bytes at odd addresses are all stored in FLASH 2.
When reading the Flash memories status registers in dual-flash mode, twice as many bytes should be read compared to doing the same read in single-flash mode. This means that if each Flash memory gives 8 valid bits after the instruction for fetching the status register, then the QUADSPI must be configured with a data length of 2 bytes (16 bits), and the QUADSPI will receive one byte from each Flash memory. If each Flash memory gives a status of 16 bits, then the QUADSPI must be configured to read 4 bytes to get all the status bits of both Flash memories in dual-flash mode. The least-significant byte of the result (in the data register) is the least-significant byte of FLASH 1 status register, while the next byte is the least-significant byte of FLASH 2 status register. Then, the third byte of the data register is FLASH 1 second byte, while the forth byte is FLASH 2 second byte (in the case that the Flash memories have 16-bit status registers).

An even number of bytes must always be accessed in dual-flash mode. For this reason, bit 0 of the data length field (QUADSPI_DLR[0]) is stuck at 1 when DRM = 1.

In dual-flash mode, the behavior of FLASH 1 interface signals are basically the same as in normal mode. FLASH 2 interface signals have exactly the same waveforms as FLASH 1 during the instruction, address, alternate-byte, and dummy-cycles phases. In other words, each Flash memory always receives the same instruction and the same address. Then, during the data phase, the BK1_IOx and BK2_IOx buses are both transferring data in parallel, but the data that are sent to (or received from) FLASH 1 are distinct from those of FLASH 2.

22.3.5 QUADSPI indirect mode

When in indirect mode, commands are started by writing to QUADSPI registers and data is transferred by writing or reading the data register, in the same way as for other communication peripherals.

When FMODE = 00 (QUADSPI_CCR[27:26]), the QUADSPI is in indirect write mode, where bytes are sent to the Flash memory during the data phase. Data are provided by writing to the data register (QUADSPI_DR).

When FMODE = 01, the QUADSPI is in indirect read mode, where bytes are received from the Flash memory during the data phase. Data are recovered by reading QUADSPI_DR.

The number of bytes to be read/written is specified in the data length register (QUADSPI_DLR). If QUADSPI_DLR = 0xFFFF_FFFF (all 1’s), then the data length is considered undefined and the QUADSPI simply continues to transfer data until the end of Flash memory (as defined by FSIZE) is reached. If no bytes are to be transferred, DMODE (QUADSPI_CCR[25:24]) should be set to 00.

If QUADSPI_DLR = 0xFFFF_FFFF and FSIZE = 0x1F (max value indicating a 4GB Flash memory), then in this special case the transfers continue indefinitely, stopping only after an abort request or after the QUADSPI is disabled. After the last memory address is read (at address 0xFFFF_FFFF), reading continues with address = 0x0000_0000.

When the programmed number of bytes to be transmitted or received is reached, TCF is set and an interrupt is generated if TCIE = 1. In the case of undefined number of data, the TCF is set when the limit of the external SPI memory is reached according to the Flash memory size defined in the QUADSPI_CR.
Triggering the start of a command

Essentially, a command starts as soon as firmware gives the last information that is necessary for this command. Depending on the QUADSPI configuration, there are three different ways to trigger the start of a command in indirect mode. The commands starts immediately after:

1. a write is performed to INSTRUCTION[7:0] (QUADSPI_CCR), if no address is necessary (when ADMODE = 00) and if no data needs to be provided by the firmware (when FMODE = 01 or DMODE = 00)
2. a write is performed to ADDRESS[31:0] (QUADSPI_AR), if an address is necessary (when ADMODE != 00) and if no data needs to be provided by the firmware (when FMODE = 01 or DMODE = 00)
3. a write is performed to DATA[31:0] (QUADSPI_DR), if an address is necessary (when ADMODE != 00) and if data needs to be provided by the firmware (when FMODE = 00 and DMODE != 00)

 Writes to the alternate byte register (QUADSPI_ABR) never trigger the communication start. If alternate bytes are required, they must be programmed before.

As soon as a command is started, the BUSY bit (bit 5 of QUADSPI_SR) is automatically set.

FIFO and data management

In indirect mode, data go through a 32-byte FIFO which is internal to the QUADSPI. FLEVEL[5:0] (QUADSPI_SR[13:8]) indicates how many bytes are currently being held in the FIFO.

In indirect write mode (FMODE = 00), firmware adds data to the FIFO when it writes QUADSPI_DR. Word writes add 4 bytes to the FIFO, halfword writes add 2 bytes, and byte writes add only 1 byte. If firmware adds too many bytes to the FIFO (more than is indicated by DL[31:0]), the extra bytes are flushed from the FIFO at the end of the write operation (when TCF is set).

Byte/halfword accesses to QUADSPI_DR must be done only to the least significant byte/halfword of the 32-bit register.

FTHRES[3:0] is used to define a FIFO threshold. When the threshold is reached, the FTF (FIFO threshold flag) is set. In indirect read mode, FTF is set when the number of valid bytes to be read from the FIFO is above the threshold. FTF is also set if there are data in the FIFO after the last byte is read from the Flash memory, regardless of the FTHRES setting. In indirect write mode, FTF is set when the number of empty bytes in the FIFO is above the threshold.

If FTIE = 1, there is an interrupt when FTF is set. FTF is cleared by HW as soon as the threshold condition is no longer true (after enough data has been transferred by the CPU or DMA).

In indirect read mode when the FIFO becomes full, the QUADSPI temporarily stops reading bytes from the Flash memory to avoid an overrun. Note that the reading of the Flash memory does not restart until 4 bytes become vacant in the FIFO (when FLEVEL ≤ 11). Thus, when FTHRES ≥ 13, the application must take care to read enough bytes to assure that the QUADSPI starts retrieving data from the Flash memory again. Otherwise, the FTF flag stays at '0' as long as 11 < FLEVEL < FTHRES.
22.3.6 QUADSPI status flag polling mode

In automatic-polling mode, the QUADSPI periodically starts a command to read a defined number of status bytes (up to 4). The received bytes can be masked to isolate some status bits and an interrupt can be generated when the selected bits have a defined value.

The accesses to the Flash memory begin in the same way as in indirect read mode: if no address is required (AMODE = 00), accesses begin as soon as the QUADSPI_CCR is written. Otherwise, if an address is required, the first access begins when QUADSPI_AR is written. BUSY goes high at this point and stays high even between the periodic accesses.

The contents of MASK[31:0] (QUADSPI_PSMAR) are used to mask the data from the Flash memory in automatic-polling mode. If the MASK[n] = 0, then bit n of the result is masked and not considered. If MASK[n] = 1, and the content of bit[n] is the same as MATCH[n] (QUADSPI_PSMAR), then there is a match for bit n.

If the polling match mode bit (PMM, bit 23 of QUADSPI_CR) is 0, then “AND” match mode is activated. This means status match flag (SMF) is set only when there is a match on all of the unmasked bits.

If PMM = 1, then “OR” match mode is activated. This means SMF is set if there is a match on any of the unmasked bits.

An interrupt is called when SMF is set if SMIE = 1.

If the automatic-polling-mode-stop (APMS) bit is set, operation stops and BUSY goes to 0 as soon as a match is detected. Otherwise, BUSY stays at ‘1’ and the periodic accesses continue until there is an abort or the QUADSPI is disabled (EN = 0).

The data register (QUADSPI_DR) contains the latest received status bytes (the FIFO is deactivated). The content of the data register is not affected by the masking used in the matching logic. The FTF status bit is set as soon as a new reading of the status is complete, and FTF is cleared as soon as the data is read.

22.3.7 QUADSPI memory-mapped mode

When configured in memory-mapped mode, the external SPI device is seen as an internal memory.

It is forbidden to access QUADSPI Flash bank area before having properly configured and enabled the QUADSPI peripheral.

No more than 256MB can addressed even if the Flash memory capacity is larger.

If an access is made to an address outside of the range defined by FSIZE but still within the 256MB range, then a bus error is given. The effect of this error depends on the bus master that attempted the access:

- If it is the Cortex® CPU, bus fault exception is generated when enabled (or a hard fault exception when bus fault is disabled)
- If it is a DMA, a DMA transfer error is generated and the corresponding DMA channel is automatically disabled.

Byte, halfword, and word access types are all supported.

Support for execute in place (XIP) operation is implemented, where the QUADSPI anticipates the next access and load in advance the byte at the following address. If the subsequent access is indeed made at a continuous address, the access will be completed faster since the value is already prefetched.
By default, the QUADSPI never stops its prefetch operation, keeping the previous read operation active with nCS maintained low, even if no access to the Flash memory occurs for a long time. Since Flash memories tend to consume more when nCS is held low, the application might want to activate the timeout counter (TCEN = 1, bit 3 of QUADSPI_CR) so that nCS is released after a period of TIMEOUT[15:0] (QUADSPI_LPTR) cycles have elapsed without any access since when the FIFO becomes full with prefetch data.

BUSY goes high as soon as the first memory-mapped access occurs. Because of the prefetch operations, BUSY does not fall until there is a timeout, there is an abort, or the peripheral is disabled.

**22.3.8 QUADSPI Free running clock mode**

When configured in Free running clock mode, the QUADSPI peripheral continuously outputs the clock for test and calibration purposes.

Free running clock mode is entered as soon as the Free running clock mode bit (FRCM) is set in the QUADSPI communication configuration register (QUADSPI_CCR). It is exited by setting the ABORT bit of the QUADSPI control register (QUADSPI_CR).

When the QUADSPI operates in Free running clock mode:
- the clock is running continuously,
- nCS stays High (external device deselected),
- data lines are released (High-Z),
- the BUSY flag of the QUADSPI status register (QUADSPI_SR) is set.

**22.3.9 QUADSPI Flash memory configuration**

The device configuration register (QUADSPI_DCR) can be used to specify the characteristics of the external SPI Flash memory.

The FSIZE[4:0] field defines the size of external memory using the following formula:

\[
\text{Number of bytes in Flash memory} = 2^{(\text{FSIZE}+1)}
\]

FSIZE+1 is effectively the number of address bits required to address the Flash memory. The Flash memory capacity can be up to 4GB (addressed using 32 bits) in indirect mode, but the addressable space in memory-mapped mode is limited to 256MB.

If DFM = 1, FSIZE indicates the total capacity of the two Flash memories together.

When the QUADSPI executes two commands, one immediately after the other, it raises the chip select signal (nCS) high between the two commands for only one CLK cycle by default. If the Flash memory requires more time between commands, the chip select high time (CSHT) field can be used to specify the minimum number of CLK cycles (up to 8) that nCS must remain high.

The clock mode (CKMODE) bit indicates the CLK signal logic level in between commands (when nCS = 1).

**22.3.10 QUADSPI delayed data sampling**

By default, the QUADSPI samples the data driven by the Flash memory one half of a CLK cycle after the Flash memory drives the signal.
In case of external signal delays, it may be beneficial to sample the data later. Using the SSHIFT bit (bit 4 of QUADSPI_CR), the sampling of the data can be shifted by half of a CLK cycle.

Clock shifting is not supported in DDR mode: the SSHIFT bit must be clear when DDRM bit is set.

**22.3.11 QUADSPI configuration**

The QUADSPI configuration is done in two phases:

- QUADSPI IP configuration
- QUADSPI Flash memory configuration

Once configured and enabled, the QUADSPI can be used in one of its three operating modes: indirect mode, status-polling mode, or memory-mapped mode.

**QUADSPI IP configuration**

The QUADSPI IP is configured using the QUADSPI_CR. The user shall configure the clock prescaler division factor and the sample shifting settings for the incoming data.

DDR mode can be set through the DDRM bit. Once enabled, the address and the alternate bytes are sent on both clock edges and the data are sent/received on both clock edges. Regardless of the DDRM bit setting, instructions are always sent in SDR mode.

FIFO level for either MDMA trigger generation or interrupt generation is programmed in the FTHRES bits.

If timeout counter is needed, the TCEN bit can be set and the timeout value programmed in the QUADSPI_LPTR register.

Dual-flash mode can be activated by setting DFM to 1.

**QUADSPI Flash memory configuration**

The parameters related to the targeted external Flash memory are configured through the QUADSPI_DCR register. The user shall program the Flash memory size in the FSIZE bits, the Chip Select minimum high time in the CSHT bits, and the functional mode (Mode 0 or Mode 3) in the MODE bit.

**22.3.12 QUADSPI usage**

The operating mode is selected using FMODE[1:0] (QUADSPI_CCR[27:26]).

**Indirect mode procedure**

When FMODE is programmed to 00, indirect write mode is selected and data can be sent to the Flash memory. With FMODE = 01, indirect read mode is selected where data can be read from the Flash memory.
When the QUADSPI is used in indirect mode, the frames are constructed in the following way:

1. Specify a number of data bytes to read or write in the QUADSPI_DLR.
2. Specify the frame format, mode and instruction code in the QUADSPI_CCR.
3. Specify optional alternate byte to be sent right after the address phase in the QUADSPI_ABR.
4. Specify the operating mode in the QUADSPI_CR.
5. Specify the targeted address in the QUADSPI_AR.
6. Read/Write the data from/to the FIFO through the QUADSPI_DR.

When writing the control register (QUADSPI_CR) the user specifies the following settings:

- The enable bit (EN) set to ‘1’
- Timeout counter enable bit (TCEN)
- Sample shift setting (SSSHIFT)
- FIFO threshold level (FTRHES) to indicate when the FTF flag should be set
- Interrupt enables
- Automatic polling mode parameters: match mode and stop mode (valid when FMODE = 11)
- Clock prescaler

When writing the communication configuration register (QUADSPI_CCR) the user specifies the following parameters:

- The instruction byte through the INSTRUCTION bits
- The way the instruction has to be sent through the IMODE bits (1/2/4 lines)
- The way the address has to be sent through the ADMODE bits (None/1/2/4 lines)
- The address size (8/16/24/32-bit) through the ADSIZE bits
- The way the alternate bytes have to be sent through the ABMODE (None/1/2/4 lines)
- The alternate bytes number (1/2/3/4) through the ABSIZE bits
- The presence or not of dummy bytes through the DBMODE bit
- The number of dummy bytes through the DCYC bits
- The way the data have to be sent/received (None/1/2/4 lines) through the DMODE bits

If neither the address register (QUADSPI_AR) nor the data register (QUADSPI_DR) need to be updated for a particular command, then the command sequence starts as soon as QUADSPI_CCR is written. This is the case when both ADMODE and DMODE are 00, or if just ADMODE = 00 when in indirect read mode (FMODE = 01).

When an address is required (ADMODE is not 00) and the data register does not need to be written (when FMODE = 01 or DMODE = 00), the command sequence starts as soon as the address is updated with a write to QUADSPI_AR.

In case of data transmission (FMODE = 00 and DMODE! = 00), the communication start is triggered by a write in the FIFO through QUADSPI_DR.
Status flag polling mode

The status flag polling mode is enabled setting the FMODE field (QUADSPI_CCR[27:26]) to 10. In this mode, the programmed frame will be sent and the data retrieved periodically.

The maximum amount of data read in each frame is 4 bytes. If more data is requested in QUADSPI_DLR, it will be ignored and only 4 bytes will be read.

The periodicity is specified in the QUADSPI_PISR register.

Once the status data has been retrieved, it can internally be processed i order to:
- set the status match flag and generate an interrupt if enabled
- stop automatically the periodic retrieving of the status bytes

The received value can be masked with the value stored in the QUADSPI_PSMKR and ORed or ANDed with the value stored in the QUADSPI_PSMAR.

In case of match, the status match flag is set and an interrupt is generated if enabled, and the QUADSPI can be automatically stopped if the AMPS bit is set.

In any case, the latest retrieved value is available in the QUADSPI_DR.

Memory-mapped mode

In memory-mapped mode, the external Flash memory is seen as internal memory but with some latency during accesses. Only read operations are allowed to the external Flash memory in this mode.

Memory-mapped mode is entered by setting the FMODE to 11 in the QUADSPI_CCR register.

The programmed instruction and frame is sent when a master is accessing the memory mapped space.

The FIFO is used as a prefetch buffer to anticipate linear reads. Any access to QUADSPI_DR in this mode returns zero.

The data length register (QUADSPI_DLR) has no meaning in memory-mapped mode.

22.3.13 Sending the instruction only once

Some Flash memories (e.g. Winbound) might provide a mode where an instruction must be sent only with the first command sequence, while subsequent commands start directly with the address. One can take advantage of such a feature using the SIOO bit (QUADSPI_CCR[28]).

SIOO is valid for all functional modes (indirect, automatic polling, and memory-mapped). If the SIOO bit is set, the instruction is sent only for the first command following a write to QUADSPI_CCR. Subsequent command sequences skip the instruction phase, until there is a write to QUADSPI_CCR.

SIOO has no effect when IMODE = 00 (no instruction).
22.3.14 QUADSPI error management

An error can be generated in the following case:

- In indirect mode or status flag polling mode when a wrong address has been programmed in the QUADSPI_AR (according to the Flash memory size defined by FSIZE[4:0] in the QUADSPI_DCR): this will set the TEF and an interrupt is generated if enabled.
- Also in indirect mode, if the address plus the data length exceeds the Flash memory size, TEF will be set as soon as the access is triggered.
- In memory-mapped mode, when an out of range access is done by a master or when the QUADSPI is disabled: this will generate a bus error as a response to the faulty bus master request.
- When a master is accessing the memory mapped space while the memory mapped mode is disabled: this will generate a bus error as a response to the faulty bus master request.

22.3.15 QUADSPI busy bit and abort functionality

Once the QUADSPI starts an operation with the Flash memory, the BUSY bit is automatically set in the QUADSPI_SR.

In indirect mode, the BUSY bit is reset once the QUADSPI has completed the requested command sequence and the FIFO is empty.

In automatic-polling mode, BUSY goes low only after the last periodic access is complete, due to a match when APMS = 1, or due to an abort.

After the first access in memory-mapped mode, BUSY goes low only on a timeout event or on an abort.

Any operation can be aborted by setting the ABORT bit in the QUADSPI_CR. Once the abort is completed, the BUSY bit and the ABORT bit are automatically reset, and the FIFO is flushed.

Note: Some Flash memories might misbehave if a write operation to a status registers is aborted.

22.3.16 nCS behavior

By default, nCS is high, deselecting the external Flash memory. nCS falls before an operation begins and rises as soon as it finishes.

When CKMODE = 0 (“mode0”, where CLK stays low when no operation is in progress) nCS falls one CLK cycle before an operation first rising CLK edge, and nCS rises one CLK cycle after the operation final rising CLK edge, as shown in Figure 127.

Figure 127. nCS when CKMODE = 0 (T = CLK period)
When CKMODE=1 (“mode3”, where CLK goes high when no operation is in progress) and DDRM=0 (SDR mode), nCS still falls one CLK cycle before an operation first rising CLK edge, and nCS rises one CLK cycle after the operation final rising CLK edge, as shown in Figure 128.

**Figure 128. nCS when CKMODE = 1 in SDR mode (T = CLK period)**

When CKMODE = 1 (“mode3”) and DDRM = 1 (DDR mode), nCS falls one CLK cycle before an operation first rising CLK edge, and nCS rises one CLK cycle after the operation final active rising CLK edge, as shown in Figure 129. Because DDR operations must finish with a falling edge, CLK is low when nCS rises, and CLK rises back up one half of a CLK cycle afterwards.

**Figure 129. nCS when CKMODE = 1 in DDR mode (T = CLK period)**

When the FIFO stays full in a read operation or if the FIFO stays empty in a write operation, the operation stalls and CLK stays low until firmware services the FIFO. If an abort occurs when an operation is stalled, nCS rises just after the abort is requested and then CLK rises one half of a CLK cycle later, as shown in Figure 130.

**Figure 130. nCS when CKMODE = 1 with an abort (T = CLK period)**
When not in dual-flash mode (DFM = 0), only FLASH 1 is accessed and thus the BK2\textunderscore nCS stays high. In dual-flash mode, BK2\textunderscore nCS behaves exactly the same as BK1\textunderscore nCS. Thus, if there is a FLASH 2 and if the application always stays in dual-flash mode, then FLASH 2 may use BK1\textunderscore nCS and the pin outputting BK2\textunderscore nCS can be used for other functions.

### 22.4 QUADSPI interrupts

An interrupt can be produced on the following events:
- Timeout
- Status match
- FIFO threshold
- Transfer complete
- Transfer error

Separate interrupt enable bits are available for flexibility.

**PRESCALER[7:0]**

- This field defines the scaler factor for generating CLK based on the quadspi_ker_ck clock (value+1).
- 0: $F_{CLK} = F_{quadspi_ker_ck}$, quadspi_ker_ck clock used directly as QUADSPI CLK (prescaler bypassed)
- 1: $F_{CLK} = F_{quadspi_ker_ck}/2$
- 2: $F_{CLK} = F_{quadspi_ker_ck}/3$
- ... 255: $F_{CLK} = F_{quadspi_ker_ck}/256$
- For odd clock division factors, CLK's duty cycle is not 50%. The clock signal remains low one cycle longer than it stays high.
- This field can be modified only when BUSY = 0.

**Bit 23 PMM:** Polling match mode

- This bit indicates which method should be used for determining a "match" during automatic polling mode.
- 0: AND match mode. SMF is set if all the unmasked bits received from the Flash memory match the corresponding bits in the match register.
- 1: OR match mode. SMF is set if any one of the unmasked bits received from the Flash memory matches its corresponding bit in the match register.
- This bit can be modified only when BUSY = 0.

**Bit 22 APMS:** Automatic poll mode stop

- This bit determines if automatic polling is stopped after a match.
- 0: Automatic polling mode is stopped only by abort or by disabling the QUADSPI.
- 1: Automatic polling mode stops as soon as there is a match.
- This bit can be modified only when BUSY = 0.

**Bit 21 Reserved, must be kept at reset value.**

**Bit 20 TOIE:** TimeOut interrupt enable

- This bit enables the TimeOut interrupt.
- 0: Interrupt disable
- 1: Interrupt enabled
Bit 19 **SMIE**: Status match interrupt enable
   This bit enables the status match interrupt.
   0: Interrupt disable
   1: Interrupt enabled

Bit 18 **FTIE**: FIFO threshold interrupt enable
   This bit enables the FIFO threshold interrupt.
   0: Interrupt disabled
   1: Interrupt enabled

Bit 17 **TCIE**: Transfer complete interrupt enable
   This bit enables the transfer complete interrupt.
   0: Interrupt disabled
   1: Interrupt enabled

Bit 16 **TEIE**: Transfer error interrupt enable
   This bit enables the transfer error interrupt.
   0: Interrupt disabled
   1: Interrupt enabled

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **FTHRES[4:0]** FIFO threshold level
   Defines, in indirect mode, the threshold number of bytes in the FIFO that will cause the FIFO threshold flag (FTF, QUADSPI_SR[2]) to be set.
   In indirect write mode (FMODE = 00):
   0: FTF is set if there are 1 or more free bytes available to be written to in the FIFO
   1: FTF is set if there are 2 or more free bytes available to be written to in the FIFO
   ...
   31: FTF is set if there are 32 free bytes available to be written to in the FIFO
   In indirect read mode (FMODE = 01):
   0: FTF is set if there are 1 or more valid bytes that can be read from the FIFO
   1: FTF is set if there are 2 or more valid bytes that can be read from the FIFO
   ...
   31: FTF is set if there are 32 valid bytes that can be read from the FIFO

Bit 7 **FSEL**: Flash memory selection
   This bit selects the Flash memory to be addressed in single flash mode (when DFM = 0).
   0: FLASH 1 selected
   1: FLASH 2 selected
   This bit can be modified only when BUSY = 0.
   This bit is ignored when DFM = 1.

Bit 6 **DFM**: Dual-flash mode
   This bit activates dual-flash mode, where two external Flash memories are used simultaneously to double throughput and capacity.
   0: Dual-flash mode disabled
   1: Dual-flash mode enabled
   This bit can be modified only when BUSY = 0.

Bit 5 Reserved, must be kept at reset value.
Bit 4 **SShift**: Sample shift

By default, the QUADSPI samples data 1/2 of a CLK cycle after the data is driven by the Flash memory. This bit allows the data to be sampled later in order to account for external signal delays.
- 0: No shift
- 1: 1/2 cycle shift

Firmware must assure that SShift = 0 when in DDR mode (when DDRM = 1).
This field can be modified only when BUSY = 0.

Bit 3 **TCEN**: Timeout counter enable

This bit is valid only when memory-mapped mode (FMODE = 11) is selected. Activating this bit causes the chip select (nCS) to be released (and thus reduces consumption) if there has not been an access after a certain amount of time, where this time is defined by TIMEOUT[15:0] (QUADSPI_LPTR).

Enable the timeout counter.
By default, the QUADSPI never stops its prefetch operation, keeping the previous read operation active with nCS maintained low, even if no access to the Flash memory occurs for a long time. Since Flash memories tend to consume more when nCS is held low, the application might want to activate the timeout counter (TCEN = 1, bit 3 of QUADSPI_CR) so that nCS is released after a period of TIMEOUT[15:0] (QUADSPI_LPTR) cycles have elapsed without an access since when the FIFO becomes full with prefetch data.
- 0: Timeout counter is disabled, and thus the chip select (nCS) remains active indefinitely after an access in memory-mapped mode.
- 1: Timeout counter is enabled, and thus the chip select is released in memory-mapped mode after TIMEOUT[15:0] cycles of Flash memory inactivity.
This bit can be modified only when BUSY = 0.

Bit 2 **Reserved**

Bit 1 **ABORT**: Abort request

This bit aborts the on-going command sequence. It is automatically reset once the abort is complete.
This bit stops the current transfer.
In polling mode or memory-mapped mode, this bit also reset the APM bit or the DM bit.
- 0: No abort requested
- 1: Abort requested

Bit 0 **EN**: Enable

Enable the QUADSPI.
- 0: QUADSPI is disabled
- 1: QUADSPI is enabled

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **FSIZE[4:0]**: Flash memory size  
This field defines the size of external memory using the following formula:  
Number of bytes in Flash memory = 2^(FSIZE+1)  
FSIZE+1 is effectively the number of address bits required to address the Flash memory. The Flash memory capacity can be up to 4GB (addressed using 32 bits) in indirect mode, but the addressable space in memory-mapped mode is limited to 256MB.  
If DFM = 1, FSIZE indicates the total capacity of the two Flash memories together.  
This field can be modified only when BUSY = 0.

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:8 **CSHT[2:0]**: Chip select high time  
CSHT+1 defines the minimum number of CLK cycles which the chip select (nCS) must remain high between commands issued to the Flash memory.  
0: nCS stays high for at least 1 cycle between Flash memory commands  
1: nCS stays high for at least 2 cycles between Flash memory commands  
...  
7: nCS stays high for at least 8 cycles between Flash memory commands  
This field can be modified only when BUSY = 0.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **CKMODE**: Mode 0 / mode 3  
This bit indicates the level that CLK takes between commands (when nCS = 1).  
0: CLK must stay low while nCS is high (chip select released). This is referred to as mode 0.  
1: CLK must stay high while nCS is high (chip select released). This is referred to as mode 3.  
This field can be modified only when BUSY = 0.

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:8 FLEVEL[5:0]: FIFO level
This field gives the number of valid bytes which are being held in the FIFO. FLEVEL = 0 when the FIFO is empty, and 32 when it is full. In memory-mapped mode and in automatic status polling mode, FLEVEL is zero.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 BUSY: Busy
This bit is set when an operation is on going. This bit clears automatically when the operation with the Flash memory is finished and the FIFO is empty.

Bit 4 TOF: Timeout flag
This bit is set when timeout occurs. It is cleared by writing 1 to CTOF.

Bit 3 SMF: Status match flag
This bit is set in automatic polling mode when the unmasked received data matches the corresponding bits in the match register (QUADSPI_PSMAR). It is cleared by writing 1 to CSMF.

Bit 2 FTF: FIFO threshold flag
In indirect mode, this bit is set when the FIFO threshold has been reached, or if there is any data left in the FIFO after reads from the Flash memory are complete. It is cleared automatically as soon as threshold condition is no longer true.
In automatic polling mode this bit is set every time the status register is read, and the bit is cleared when the data register is read.

Bit 1 TCF: Transfer complete flag
This bit is set in indirect mode when the programmed number of data has been transferred or in any mode when the transfer has been aborted. It is cleared by writing 1 to CTCF.

Bit 0 TEF: Transfer error flag
This bit is set in indirect mode when an invalid address is being accessed in indirect mode. It is cleared by writing 1 to CTEF.

</tbody>
</table>
Bits 31:0 DL[31:0]: Data length
Number of data to be retrieved (value+1) in indirect and status-polling modes. A value no greater than 3 (indicating 4 bytes) should be used for status-polling mode. All 1s in indirect mode means undefined length, where QUADSPI will continue until the end of memory, as defined by FSIZE.
0x0000_0000: 1 byte is to be transferred
0x0000_0001: 2 bytes are to be transferred
0x0000_0002: 3 bytes are to be transferred
0x0000_0003: 4 bytes are to be transferred
...
0xFFFF_FFFD: 4,294,967,294 (4G-2) bytes are to be transferred
0xFFFF_FFFE: 4,294,967,295 (4G-1) bytes are to be transferred
0xFFFF_FFFF: undefined length -- all bytes until the end of Flash memory (as defined by FSIZE) are to be transferred. Continue reading indefinitely if FSIZE = 0x1F.
DL[0] is stuck at ‘1’ in dual-flash mode (DFM = 1) even when ‘0’ is written to this bit, thus assuring that each access transfers an even number of bytes.
This field has no effect when in memory-mapped mode (FMODE = 10).
This field can be written only when BUSY = 0.

22.5.6 QUADSPI communication configuration register (QUADSPI_CCR)
Address offset: 0x0014
Reset value: 0x0000 0000

</table>

Bit 31 DDRM: Double data rate mode
This bit sets the DDR mode for the address, alternate byte and data phase:
0: DDR Mode disabled
1: DDR Mode enabled
This field can be written only when BUSY = 0.

Bit 30 DHHC: DDR hold
Delay the data output by 1/4 of the QUADSPI output clock cycle in DDR mode:
0: Delay the data output using analog delay
1: Delay the data output by 1/4 of a QUADSPI output clock cycle.
This feature is only active in DDR mode.
This field can be written only when BUSY = 0.

Bit 29 FRCM: Free Running Clock Mode
When this bit is set, the QUADSPI peripheral enters Free running clock mode regardless of the FMODE bits.
0: Normal mode
1: Free running clock mode
This bit can be written only when BUSY = 0.
Bit 28 **SIOO**: Send instruction only once mode

See **Section 22.3.13: Sending the instruction only once on page 883**. This bit has no effect when IMODE = 00.
0: Send instruction on every transaction
1: Send instruction only for the first command
This field can be written only when BUSY = 0.

Bits 27:26 **FMODE[1:0]**: Functional mode

This field defines the QUADSPI functional mode of operation.
00: Indirect write mode
01: Indirect read mode
10: Automatic polling mode
11: Memory-mapped mode
This field can be written only when BUSY = 0.

Bits 25:24 **DMODE[1:0]**: Data mode

This field defines the data phase’s mode of operation:
00: No data
01: Data on a single line
10: Data on two lines
11: Data on four lines
This field also determines the dummy phase mode of operation.
This field can be written only when BUSY = 0.

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **DCYC[4:0]**: Number of dummy cycles

This field defines the duration of the dummy phase. In both SDR and DDR modes, it specifies a number of CLK cycles (0-31).
This field can be written only when BUSY = 0.

Bits 17:16 **ABSIZE[1:0]**: Alternate bytes size

This bit defines alternate bytes size:
00: 8-bit alternate byte
01: 16-bit alternate bytes
10: 24-bit alternate bytes
11: 32-bit alternate bytes
This field can be written only when BUSY = 0.

Bits 15:14 **ABMODE[1:0]**: Alternate bytes mode

This field defines the alternate-bytes phase mode of operation:
00: No alternate bytes
01: Alternate bytes on a single line
10: Alternate bytes on two lines
11: Alternate bytes on four lines
This field can be written only when BUSY = 0.

Bits 13:12 **ADSIZE[1:0]**: Address size

This bit defines address size:
00: 8-bit address
01: 16-bit address
10: 24-bit address
11: 32-bit address
This field can be written only when BUSY = 0.
Bits 11:10 **ADMODE[1:0]**: Address mode
   This field defines the address phase mode of operation:
   00: No address
   01: Address on a single line
   10: Address on two lines
   11: Address on four lines
   This field can be written only when BUSY = 0.

Bits 9:8 **IMODE[1:0]**: Instruction mode
   This field defines the instruction phase mode of operation:
   00: No instruction
   01: Instruction on a single line
   10: Instruction on two lines
   11: Instruction on four lines
   This field can be written only when BUSY = 0.

Bits 7:0 **INSTRUCTION[7:0]**: Instruction
   Instruction to be send to the external SPI device.
   This field can be written only when BUSY = 0.

Bits 31:0 **ADDRESS[31:0]**: Address
   Address to be send to the external Flash memory
   Writes to this field are ignored when BUSY = 0 or when FMODE = 11 (memory-mapped mode).
   In dual flash mode, ADDRESS[0] is automatically stuck to ‘0’ as the address should always be even
22.5.8 QUADSPI alternate bytes registers (QUADSPI_ABR)

<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 31:0 DATA[31:0]: Data
Data to be sent/received to/from the external SPI device.
In indirect write mode, data written to this register is stored on the FIFO before it is sent to the Flash memory during the data phase. If the FIFO is too full, a write operation is stalled until the FIFO has enough space to accept the amount of data being written.
In indirect read mode, reading this register gives (via the FIFO) the data which was received from the Flash memory. If the FIFO does not have as many bytes as requested by the read operation and if BUSY=1, the read operation is stalled until enough data is present or until the transfer is complete, whichever happens first.
In automatic polling mode, this register contains the last data read from the Flash memory (without masking).
Word, halfword, and byte accesses to this register are supported. In indirect write mode, a byte write adds 1 byte to the FIFO, a halfword write 2, and a word write 4. Similarly, in indirect read mode, a byte read removes 1 byte from the FIFO, a halfword read 2, and a word read 4. Accesses in indirect mode must be aligned to the bottom of this register: a byte read must read DATA[7:0] and a halfword read must read DATA[15:0].
22.5.10 QUADSPI polling status mask register (QUADSPI _PSMKR)

Address offset: 0x0024
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>

<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 31: Mask to be applied to the status bytes received in polling mode.
For bit n:
0: Bit n of the data received in automatic polling mode is masked and its value is not considered in the matching logic
1: Bit n of the data received in automatic polling mode is unmasked and its value is considered in the matching logic
This field can be written only when BUSY = 0.

22.5.11 QUADSPI polling status match register (QUADSPI _PSMAR)

Address offset: 0x0028
Reset value: 0x0000 0000

</tr>
</tbody>
</table>

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 INTERVAL[15:0]: Polling interval
Number of CLK cycles between to read during automatic polling phases.
This field can be written only when BUSY = 0.

22.5.13 QUADSPI low-power timeout register (QUADSPI_LPTR)

Address offset: 0x0030
Reset value: 0x0000 0000

<table>
<thead>

<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 TIMEOUT[15:0]: Timeout period
After each access in memory-mapped mode, the QUADSPI prefetches the subsequent bytes and holds these bytes in the FIFO. This field indicates how many CLK cycles the QUADSPI waits after the FIFO becomes full until it raises nCS, putting the Flash memory in a lower-consumption state.
This field can be written only when BUSY = 0.
### 22.5.14 QUADSPI register map

#### Table 193. QUADSPI register map and reset values

| Offset  | Register name | Offset | Register name | Offset | Register name | Offset | Register name | Offset | Register name | Offset | Register name | Offset | Register name | Offset | Register name | Offset | Register name | Offset | Register name | Offset | Register name |

Refer to Section 2.3 on page 126 for the register boundary addresses.
23 Delay block (DLYB)

23.1 Introduction

The delay block (DLYB) is used to generate an output clock which is dephased from the input clock. The phase of the output clock must be programmed by the user application. The output clock is then used to clock the data received by another peripheral such as an SDMMC or Quad-SPI interface.

The delay is voltage- and temperature-dependent, which may require the application to reconfigure and recenter the output clock phase with the receive data.

23.2 DLYB main features

The delay block has the following features:
- Input clock frequency ranging from 25 to 208 MHz
- Up to 12 oversampling phases.

23.3 DLYB functional description

23.3.1 DLYB diagram

The delay block includes the following sub-blocks:
- Register interface block providing AHB access to the Delay Block registers.
- Delay line supporting the unit delays.
- Delay line length sampling
- Output clock selection multiplexer

23.3.3 General description

The delay block is enabled by setting the DEN bit in the DLYB_CR register (see Section 23.4.1: DLYB control register (DLYB_CR)). The length sampler is enabled through the SEN bit in DLYB_CR register.

When the delay block is enabled, the delay added by a unit delay is defined by the UNIT bits in DLYB_CFGR register (see Section 23.4.2: DLYB configuration register (DLYB_CFGR)). Note that the UNIT bits can be programmed only when the output clock is disabled (SEN = ‘1’).

When the delay block is enabled, the output clock phase is selected through the SEL bit in DLYB_CFGR register. Note that SEL can be programmed only when the output clock is disabled (SEN = ‘1’).

Before dephasing the output clock, the delay line length shall be configured to one input clock period. The delay line length can be configured by enabling the length sampler through the SEN bit, which gives access to the delay line length (LNG bits) and Length valid flag (LNGF) in DLYB_CFGR.

Once the delay line length has been configured, a dephased output clock can be selected by the output clock multiplexer. This is done through SEL bits. The output clock is only available on the selected phase when SEN is set to ‘0’.

</tbody>
</table>

1. The unit delay can only be changed when SEN = ‘1’.
2. The output clock phase can only be changed when SEN = ‘1’.
23.3.4 Delay line length configuration procedure

LNG bits are used to determine the delay line length with respect to the input clock period. The length shall be configured so that one full input clock period is covered by the delay line length.

To configure the delay line length to one period of the Input clock, follow the sequence below:

1. Enable the delay block by setting DEN bit to ‘1’.
2. Enable the length sampling by setting SEN bit to ‘1’.
3. Enable all delay cells by setting SEL bits to 12.
4. For UNIT = 0 to 127 (this step must be repeated until the delay line length is configured):
   a) Update the UNIT value and wait till the length flag LNGF is set to ‘1’.
   b) Read LNG bits.
      If (LNG[10:0] > 0) and (LNG[11] or LNG[10] = 0), the delay line length is configured to one input clock period.
5. Determine how many unit delays (N) span one input clock period.
   – For N = 10 to 0:
     If LNG[N] = ‘1’, the number of unit delays spanning the input clock period = N.
6. Disable the length sampling by clearing SEN to ‘0’.

23.3.5 Output clock phase configuration procedure

When the delay line length is configured to one input clock period, the output clock phase can be selected between the unit delays spanning one Input clock period.

Follow the steps below to select the output clock phase:

1. Disable the output clock and enable the access to the phase selection SEL bits by setting SEN bit to ‘1’.
2. Program SEL bits with the desired output clock phase value.
3. Enable the output clock on the selected phase by clearing SEN to ‘0’.
23.4 DLYB registers

All registers can be accessed in word, half-word and byte access.

23.4.1 DLYB control register (DLYB_CR)

Address offset: 0x000

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th></th>
<th>31</th>
<th>30</th>

<td></td>
</tr>
</tbody>
</table>

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **SEN**: Sampler length enable bit

0: Sampler length and register access to UNIT and SEL disabled, output clock enabled.
1: Sampler length and register access to UNIT and SEL enabled, output clock disabled.

Bit 0 **DEN**: Delay block enable bit

0: Delay block disabled.
1: Delay block enabled.

23.4.2 DLYB configuration register (DLYB_CFGCR)

Address offset: 0x004

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th></th>
<th>31</th>
<th>30</th>

</tr>
</tbody>
</table>

Bit 31 **LNGF**: Length valid flag

This flag indicates when the delay line length value contained in LNG bits is valid after UNIT bits changed.

0: Length value in LNG is not valid.
1: Length value in LNG is valid.

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:16 **LNG[11:0]**: Delay line length value

These bits reflect the 12 unit delay values sampled at the rising edge of the input clock.
The value is only valid when LNGF = ‘1’.
Bit 15  Reserved, must be kept at reset value.

Bits 14:8  **UNIT[6:0]**: Delay Defines the delay of a Unit delay cell.
These bits can only be written when SEN = ‘1’.
Unit delay = Initial delay + UNIT x delay step

Bits 7:4  Reserved, must be kept at reset value.

Bits 3:0  **SEL[3:0]**: Select the phase for the Output clock.
These bits can only be written when SEN = ‘1’.
Output clock phase = Input clock + SEL x Unit delay

### 23.4.3  DLYB register map

Refer to Section 2.3 on page 126 for the register boundary addresses.
24 Analog-to-digital converters (ADC)

24.1 Introduction

This section describes the ADC implementation:

- ADC1 and ADC2 are tightly coupled and can operate in dual mode (ADC1 is master).
- ADC3 is instantiated separately.

Each ADC consists of a 16-bit successive approximation analog-to-digital converter.

Each ADC has up to 20 multiplexed channels. A/D conversion of the various channels can be performed in single, continuous, scan or discontinuous mode. The result of the ADC is stored in a left-aligned or right-aligned 32-bit data register.

The ADCs are mapped on the AHB bus to allow fast data handling.

The analog watchdog features allow the application to detect if the input voltage goes outside the user-defined high or low thresholds.

A built-in hardware oversampler allows to improve analog performances while off-loading the related computational burden from the CPU.

An efficient low-power mode is implemented to allow very low consumption at low frequency.
24.2 ADC main features

- High-performance features
  - Up to 2x ADCs which can operate in dual mode
  - 16, 14, 12, 10 or 8-bit configurable resolution
  - ADC conversion time is independent from the AHB bus clock frequency
  - Faster conversion time by lowering resolution
  - Can manage Single-ended or differential inputs (programmable per channels)
  - AHB slave bus interface to allow fast data handling
  - Self-calibration (both offset and linearity)
  - Channel-wise programmable sampling time
  - Up to four injected channels (analog inputs assignment to regular or injected channels is fully configurable)
  - Hardware assistant to prepare the context of the injected channels to allow fast context switching
  - Data alignment with in-built data coherency
  - Data can be managed by GP-DMA for regular channel conversions with FIFO
  - Data can be routed to DFSDM for post processing
  - 4 dedicated data registers for the injected channels

- Oversampler
  - 32-bit data register
  - Oversampling ratio adjustable from 2 to 1024x
  - Programmable data right and left shift

- Low-power features
  - Speed adaptive low-power mode to reduce ADC consumption when operating at low frequency
  - Allows slow bus frequency application while keeping optimum ADC performance
  - Provides automatic control to avoid ADC overrun in low AHB bus clock frequency application (auto-delayed mode)

- Each ADC features an external analog input channel
  - Up to 6 fast channels from dedicated GPIO pads
  - Up to 14 slow channels from dedicated GPIO pads

- In addition, there are 5 internal dedicated channels
  - The internal reference voltage ($V_{REFIN}$), connected to ADC3
  - The internal temperature sensor ($V_{SENSE}$), connected to ADC3
  - The $V_{BAT}$ monitoring channel ($V_{BAT}/4$), connected to ADC3
  - The internal DAC channel 1 and channel 2, connected to ADC2

- Start-of-conversion can be initiated:
  - by software for both regular and injected conversions
  - by hardware triggers with configurable polarity (internal timers events or GPIO input events) for both regular and injected conversions

- Conversion modes
  - Each ADC can convert a single channel or can scan a sequence of channels
– Single mode converts selected inputs once per trigger
– Continuous mode converts selected inputs continuously
– Discontinuous mode
- Dual ADC mode for ADC1 and 2
- Interrupt generation at ADC ready, the end of sampling, the end of conversion (regular or injected), end of sequence conversion (regular or injected), analog watchdog 1, 2 or 3 or overrun events
- 3 analog watchdogs per ADC
- ADC input range: $V_{REF-} \leq V_{IN} \leq V_{REF+}$

*Figure 132* shows the block diagram of one ADC.

24.4.3 Clocks

Dual clock domain architecture

The dual clock-domain architecture means that the ADCs clock is independent from the AHB bus clock.

The input clock is the same for the three ADCs and can be selected between two different clock sources (see Figure 133: ADC clock scheme):

1. The ADC clock can be a specific clock source, named adc_ker_ck_input which is independent and asynchronous with the AHB clock.
   It can be configured in the RCC (refer to RCC Section for more information on how to generate the ADC clock (adc_ker_ck_input) dedicated clock).
   To select this scheme, CKMODE[1:0] bits of the ADCx_CCR register must be reset.

2. The ADC clock can be derived from the AHB clock of the ADC bus interface, divided by a programmable factor (1, 2 or 4). In this mode, a programmable divider factor can be selected (/1, 2 or 4 according to bits CKMODE[1:0]).
   To select this scheme, CKMODE[1:0] bits of the ADCx_CCR register must be different from “00”.

   Note: For option 2), a prescaling factor of 1 (CKMODE[1:0]=01) can be used only if the AHB prescaler is set to 1 (HPRE[3:0] = 0xx in RCC_CFGR register).

Option 1) has the advantage of reaching the maximum ADC clock frequency whatever the AHB clock scheme selected. The ADC clock can eventually be divided by the following ratio: 1, 2, 4, 6, 8, 10, 12, 16, 32, 64, 128, 256; using the prescaler configured with bits PRESC[3:0] in the ADCx_CCR register.

Option 2) has the advantage of bypassing the clock domain resynchronizations. This can be useful when the ADC is triggered by a timer and if the application requires that the ADC is precisely triggered without any uncertainty (otherwise, an uncertainty of the trigger instant is added by the resynchronizations between the two clock domains).

The clock configured through CKMODE[1:0] bits must be compliant with the operating frequency specified in the product datasheet.
1. Refer to the RCC section to see how adc_hclk and adc_ker_ck_input can be generated.
Clock ratio constraint between ADC clock and AHB clock

There are generally no constraints to be respected for the ratio between the ADC clock and the AHB clock except if some injected channels are programmed. In this case, it is mandatory to respect the following ratio:

- \( \frac{F_{\text{adc\_hclk}}}{F_{\text{adc\_ker\_ck}}} \geq 4 \) if the resolution of all channels are 16-bit, 14-bit, 12-bit or 10-bit
- \( \frac{F_{\text{adc\_hclk}}}{F_{\text{adc\_ker\_ck}}} \geq 3 \) if there are some channels with resolutions equal to 8-bit (and none with lower resolutions)

BOOST bit control

There is ADC boost control bit, BOOST, in the ADC_CR register.

This bit must be set when the ADC clock is more than 20 MHz. When ADC clock is less than 20 MHz, this bit can be cleared to save power.
24.4.4 ADC1/2/3 connectivity

ADC1 and ADC2 are tightly coupled and share some external channels as described in the following figures.

ADC3 is instantiated separately, but some inputs are shared with ADC1 and ADC2.

Figure 134. ADC1 connectivity

1. ADCx_IN Ny signal can only be used when the corresponding ADC input channel is configured as differential mode.
Figure 135. ADC2 connectivity

1. ADCx_INNy signal can only be used when the corresponding ADC input channel is configured as differential mode.
ADCx_INNy signal can only be used when the corresponding ADC input channel is configured as differential mode.
24.4.5 Slave AHB interface

The ADCs implement an AHB slave port for control/status register and data access. The features of the AHB interface are listed below:

- Word (32-bit) accesses
- Single cycle response
- Response to all read/write accesses to the registers with zero wait states.

The AHB slave interface does not support split/retry requests, and never generates AHB errors.

24.4.6 ADC deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)

By default, the ADC is in deep-power-down mode where its supply is internally switched off to reduce the leakage currents (the reset state of bit DEEPPWD is 1 in the ADC_CR register).

To start ADC operations, it is first needed to exit deep-power-down mode by clearing bit DEEPPWD=0.

Then, it is mandatory to enable the ADC internal voltage regulator by setting the bit ADVREGEN=1 into ADC_CR register. The software must wait for the startup time of the ADC voltage regulator ($T_{ADCVREG\_STUP}$) before launching a calibration or enabling the ADC. This delay must be implemented by software.

For the startup time of the ADC voltage regulator, please refer to device datasheet for $T_{ADCVREG\_STUP}$ parameter.

After ADC operations are complete, the ADC can be disabled (ADEN=0). It is possible to save power by also disabling the ADC voltage regulator. This is done by writing bit ADVREGEN=0.

Then, to save more power by reducing the leakage currents, it is also possible to re-enter in ADC deep-power-down mode by setting bit DEEPPWD=1 into ADC_CR register. This is particularly interesting before entering Stop mode.

**Note:** Writing DEEPPWD=1 automatically disables the ADC voltage regulator and bit ADVREGEN is automatically cleared.

**Note:** When the internal voltage regulator is disabled (ADVREGEN=0), the internal analog calibration is kept.

In ADC deep-power-down mode (DEEPPWD=1), the internal analog calibration is lost and it is necessary to either relaunch a calibration or apply again the calibration factor which was previously saved (refer to Section 24.4.8: Calibration (ADCAL, ADCALDIFF, ADCALLIN, ADC_CALFACT)).
24.4.7 Single-ended and differential input channels

Channels can be configured to be either single-ended input or differential input by writing into bits DIFSEL[19:0] in the ADC_DIFSEL register. This configuration must be written while the ADC is disabled (ADEN=0).

In single-ended input mode, the analog voltage to be converted for channel “i” is the difference between the external voltage $V_{INP}[i]$ (positive input) and $V_{REF}$ (negative input).

In differential input mode, the analog voltage to be converted for channel “i” is the difference between the external voltage $V_{INP}[i]$ (positive input) and $V_{INN}[i]$ (negative input).

The output data for the differential mode is an unsigned data. When $V_{INP}[i]$ is $V_{REF}$, $V_{INN}[i]$ is $V_{REF}$, the output data is 0x0000 (16-bit resolution mode), when $V_{INP}[i]$ is $V_{REF}$, $V_{INN}[i]$ is $V_{REF}$, the output data is 0xFFFF.

When ADC is configured as differential mode, both input should be biased at $V_{REF}$ / 2 voltage.

The input signal are supposed to be differential (common mode voltage should be fixed).

For a complete description of how the input channels are connected for each ADC, refer to Figure 134: ADC1 connectivity to Figure 136: ADC3 connectivity.

Caution: When configuring the channel “i” in differential input mode, its negative input voltage is connected to $V_{INN}[i]$. As a consequence, channel “i+n”, which is connected to $V_{INN}[i]$, should not be converted at same time by different ADCs. Some channels are shared between ADC1/ADC2: this can make the channel on the other ADC unusable.

24.4.8 Calibration (ADCAL, ADCALDIF, ADCALLIN, ADC_CALFACT)

Each ADC provides an automatic calibration procedure which drives all the calibration sequence including the power-on/off sequence of the ADC. During the procedure, the ADC calculates a calibration factor which is 11-bits of offset or 160-bits of linearity and which is applied internally to the ADC until the next ADC power-off. During the calibration procedure, the application must not use the ADC and must wait until calibration is complete.

Calibration is preliminary to any ADC operation. It removes the systematic errors which may vary from chip to chip and allows to compensate offset and linearity deviation.

The calibration factor for the offset to be applied for single-ended input conversions is different from the factor to be applied for differential input conversions:

- Write ADCALDIF=0 before launching a calibration which will be applied for single-ended input conversions.
- Write ADCALDIF=1 before launching a calibration which will be applied for differential input conversions.
The linearity correction must be done once only, regardless of single / differential configuration.

- Write ADCALLIN=1 before launching a calibration which will run the linearity calibration same time as the offset calibration.
- Write ADCALLIN=0 before launching a calibration which will not run the linearity calibration but only the offset calibration.

The calibration is then initiated by software by setting bit ADCAL=1. Calibration can only be initiated when the ADC is disabled (when ADEN=0). ADCAL bit stays at 1 during all the calibration sequence. It is then cleared by hardware as soon the calibration completes. At this time, the associated calibration factor is stored internally in the analog ADC and also in the bits CALFACT_S[10:0] or CALFACT_D[10:0] of ADC_CALFACT register (depending on single-ended or differential input calibration). The 160-bit linearity calibration factor can be accessed using the ADC_CALFACT2 register with ADEN set to 1.

The internal analog calibration is kept if the ADC is disabled (ADEN=0). However, if the ADC is disabled for extended periods, then it is recommended that a new calibration cycle is run before re-enabling the ADC.

The internal analog calibration is lost each time the power of the ADC is removed (example, when the product enters in STANDBY or VBAT mode). In this case, to avoid spending time recalibrating the ADC, it is possible to re-write the calibration factor into the ADC_CALFACT and ADC_CALFACT2 register without recalibrating, supposing that the software has previously saved the calibration factor delivered during the previous calibration.

The calibration factor can be written if the ADC is enabled but not converting (ADEN=1 and ADSTART=0 and JADSTART=0). Then, at the next start of conversion, the calibration factor will automatically be injected into the analog ADC. This loading is transparent and does not add any cycle latency to the start of the conversion. It is recommended to recalibrate when VREF+ voltage changed more than 10%.

Refer to the datasheets for the clock cycle requirement for both linear and offset calibration.

**Software procedure to calibrate the ADC**

1. Ensure DEEPPWD=0, ADVREGEN=1 and check that the ADC voltage regulator startup time has elapsed.
2. Ensure that ADEN=0.
3. Select the input mode for this calibration by setting ADCALDIF=0 (Single-ended input) or ADCALDIF=1 (Differential input). Select if Linearity calibration enable or not by ADCALLIN=1(enabled) or ADCALLIN=0(disabled).
4. Set ADCAL=1.
5. Wait until ADCAL=0.
6. The offset calibration factor can be read from ADC_CALFACT register.
7. The linearity calibration factor can be read from ADC_CALFACT2 register, following the procedure described in Section : Linearity calibration reading procedure (ADEN must be set to 1 prior to accessing ADC_CALFACT2 register).
Software procedure to re-inject a calibration factor into the ADC

1. Ensure ADEN=1 and ADSTART=0 and JADSTART=0 (ADC enabled and no conversion is ongoing).
2. Write CALFACT_S and CALFACT_D with the new offset calibration factors.
3. Write LINCALFACT bits with the new linearity calibration factors, following the procedure described in Section: Linearity calibration writing procedure.
4. When a conversion is launched, the calibration factor will be injected into the analog ADC only if the internal analog calibration factor differs from the one stored in bits CALFACT_S for single-ended input channel or bits CALFACT_D for differential input channel.
Converting single-ended and differential analog inputs with a single ADC

If the ADC is supposed to convert both differential and single-ended inputs, two calibrations must be performed, one with ADCALDIF=0 and one with ADCALDIF=1. The procedure is the following:

1. Disable the ADC.
2. Calibrate the ADC in single-ended input mode (with ADCALDIF=0) and Linearity calibration enable (with ADCALLIN=1). This updates the registers CALFACT_S[10:0] and LINCALFACT[159:0].
3. Calibrate the ADC in Differential input modes (with ADCALDIF=1) and Linearity calibration disable (with ADCALLIN=0). This updates the register CALFACT_D[10:0].
4. Enable the ADC, configure the channels and launch the conversions. Each time there is a switch from a single-ended to a differential inputs channel (and vice-versa), the calibration will automatically be injected into the analog ADC.

Linearity calibration reading procedure

Once the calibration is done (ADCAL bit cleared by hardware) with ADCALLIN=1, the 160-bit linearity correction factor can be read using the ADC_CALFACT2 30-bit registers (6 read accesses are necessary).

The six LINCALRDYW1..6 control/status bits in ADC_CR are set when the calibration is complete. When ADEN is set to 1, clearing one of these bits launches the transfer of part of the linearity factor into the LINCALFACT[29:0] of the ADC_CALFACT2 register. The bit will be reset by hardware when the ADC_CALFACT2 register can be read (software must poll the bit until it is cleared). The complete procedure is as following:
1. Ensure DEEPPWD=0, ADVREGEN=1 and that the ADC voltage regulator startup time has elapsed.
2. Set ADEN = 1 and wait until ADRDY=1.
4. Poll LINCALRDYW6 bit until returned value is zero, indicating linearity correction bits[159:150] are available in ADC_CALFACT2[29:0].
5. Read ADC_CALFACT2[29:0].
7. Poll LINCALRDYW5 bit until returned value is zero, indicating linearity correction bits[149:120] are available in ADC_CALFACT2[29:0].
8. Read ADC_CALFACT2[29:0].
10. Poll LINCALRDYW4 bit until returned value is zero, indicating linearity correction bits[119:90] are available in ADC_CALFACT2[29:0].
11. Read ADC_CALFACT2[29:0].
13. Poll LINCALRDYW3 bit until returned value is zero, indicating linearity correction bits[89:60] are available in ADC_CALFACT2[29:0].
14. Read ADC_CALFACT2[29:0].
15. Clear LINCALRDYW2 bit.
16. Poll LINCALRDYW2 bit until returned value is zero, indicating linearity correction bits[59:30] are available in ADC_CALFACT2[29:0].
17. Read ADC_CALFACT2[29:0].
18. Clear LINCALRDYW1 bit.
19. Poll LINCALRDYW1 bit until returned value is zero, indicating linearity correction bits[29:0] are available in ADC_CALFACT2[29:0].
20. Read ADC_CALFACT2[29:0].

Note: The software is allowed to toggle a single LINCALRDYWx bit at once (other bits left unchanged), otherwise causing unexpected behavior.

The software can access the linearity calibration factor by writing LINCALRDYW1..6 bits only when ADEN=1 and ADSTART=0 and JADSTART=0 (ADC enabled and no conversion is ongoing).
Linearity calibration writing procedure

The six LINCALRDYW1..6 control/status bits in ADC_CR are reset when the calibration has not yet been done or a new linearity calibration factor have been rewritten. It is possible to force directly a linearity calibration factor or re-inject it using the following procedure:

1. Ensure DEEPPWD=0, ADVREGEN=1 and that ADC voltage regulator startup time has elapsed.
2. Set ADEN = 1 and wait until ADRDY=1.
3. Write ADC_CALFACT2[9:0] with previously saved linearity correction factor bits[159:150].
4. Set LINCALRDYW6 bit.
5. Poll LINCALRDYW6 bit until returned value is one, indicating linearity correction bits[159:150] have been effectively written.
6. Write ADC_CALFACT2[29:0] with previously saved linearity correction factor bits[149:120].
7. Set LINCALRDYW5 bit.
8. Poll LINCALRDYW5 bit until returned value is one, indicating linearity correction bits[149:120] have been effectively written.
9. Write ADC_CALFACT2[29:0] with previously saved linearity correction factor bits[119:90].
10. Set LINCALRDYW4 bit.
11. Poll LINCALRDYW4 bit until returned value is one, indicating linearity correction bits[119:90] have been effectively written.
12. Write ADC_CALFACT2[29:0] with previously saved linearity correction factor bits[89:60].
13. Set LINCALRDYW3 bit.
14. Poll LINCALRDYW3 bit until returned value is one, indicating linearity correction bits[89:60] have been effectively written.
15. Write ADC_CALFACT2[29:0] with previously saved linearity correction factor bits[59:30].
17. Poll LINCALRDYW2 bit until returned value is one, indicating linearity correction bits[59:30] have been effectively written.
18. Write ADC_CALFACT2[29:0] with previously saved linearity correction factor bits[29:0].
19. Set LINCALRDYW1 bit.
20. Poll LINCALRDYW1 bit until returned value is one, indicating linearity correction bits[29:0] have been effectively written.

Note: The software is allowed to toggle a single LINCALRDYWx bit at once (other bits left unchanged), otherwise causing unexpected behavior.
The software is allowed to update the linearity calibration factor by writing LINCALRDYW1..6 bits only when ADEN=1 and ADSTART=0 and JADSTART=0 (ADC enabled and no conversion is ongoing).
24.4.9 ADC on-off control (ADEN, ADDIS, ADRDY)

First of all, follow the procedure explained in Section 24.4.6: ADC deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN).

Once DEEPPWD=0 and ADVREGEN=1, the ADC can be enabled and the ADC needs a stabilization time of $t_{STAB}$ before it starts converting accurately, as shown in Figure 140. Two control bits enable or disable the ADC:

- ADEN=1 enables the ADC. The flag ADRDY will be set once the ADC is ready for operation.
- ADDIS=1 disables the ADC. ADEN and ADDIS are then automatically cleared by hardware as soon as the analog ADC is effectively disabled.

Regular conversion can then start either by setting ADSTART=1 (refer to Section 24.4.19: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN)) or when an external trigger event occurs, if triggers are enabled.

Injected conversions start by setting JADSTART=1 or when an external injected trigger event occurs, if injected triggers are enabled.

Software procedure to enable the ADC

1. Clear the ADRDY bit in the ADC_ISR register by writing ‘1’.
2. Set ADEN=1.
3. Wait until ADRDY=1 (ADRDY is set after the ADC startup time). This can be done using the associated interrupt (setting ADRDYIE=1).
4. Clear the ADRDY bit in the ADC_ISR register by writing ‘1’ (optional).

Software procedure to disable the ADC

1. Check that both ADSTART=0 and JADSTART=0 to ensure that no conversion is ongoing. If required, stop any regular and injected conversion ongoing by setting ADSTP=1 and JADSTP=1 and then wait until ADSTP=0 and JADSTP=0.
2. Set ADDIS=1.
3. If required by the application, wait until ADEN=0, until the analog ADC is effectively disabled (ADDIS will automatically be reset once ADEN=0).

Figure 140. Enabling / Disabling the ADC
24.4.10 Constraints when writing the ADC control bits

The software can write the RCC control bits to configure and enable the ADC clock (refer to RCC Section), the control bits DIFSEL in the ADC_DIFSEL register, ADCx_CCR register and the control bits ADCAL and ADEN in the ADC_CR register, only if the ADC is disabled (ADEN must be equal to 0).

The software is then allowed to write the control bits ADSTART, JADSTART and ADDIS of the ADC_CR register only if the ADC is enabled and there is no pending request to disable the ADC (ADEN must be equal to 1 and ADDIS to 0).

For all the other control bits of the ADC_CFRG, ADC_SMPRy, ADC_TRy, ADC_SQRy, ADC_JDRy, ADC_OFRy and ADC_IER registers:

- For control bits related to configuration of regular conversions, the software is allowed to write them only if the ADC is enabled (ADEN=1) and if there is no regular conversion ongoing (ADSTART must be equal to 0).
- For control bits related to configuration of injected conversions, the software is allowed to write them only if the ADC is enabled (ADEN=1) and if there is no injected conversion ongoing (JADSTART must be equal to 0).

The software can write ADSTP or JADSTP control bits in the ADC_CR register only if the ADC is enabled and eventually converting and if there is no pending request to disable the ADC (ADSTART or JADSTART must be equal to 1 and ADDIS to 0).

The software can write the register ADC_JSQR at any time, when the ADC is enabled (ADEN=1).

The software is allowed to write the ADC_JSQR register only when JADSTART is cleared to 0 (no injected conversion is ongoing) unless the context queue is enabled (JQDIS=0 in ADC_CFGR register).

Note: There is no hardware protection to prevent these forbidden write accesses and ADC behavior may become in an unknown state. To recover from this situation, the ADC must be disabled (clear ADEN=0 as well as all the bits of ADC_CR register).

24.4.11 Channel selection (SQRx, JSQRx)

There are up to 20 multiplexed channels per ADC:

- 6 fast analog inputs coming from Analog PADs and GPIO pads (ADCx_INP/INN[0..5])
- Up to 14 slow analog inputs coming from GPIO pads (ADCx_INP/INN[6..19]).
- The ADCs are connected to 5 internal analog inputs:
  - the internal temperature sensor (VSENSE) is connected to ADC3 VINP/VINN[18]
  - the internal reference voltage (VREFINT) is connected to ADC3 VINP/VINN[19]
  - the VBAT monitoring channel (VBAT/4) is connected to ADC3 VINP/VINN[17]
  - DAC internal channel 1, connected to ADC2 VINP/VINN[16]

It is possible to organize the conversions in two groups: regular and injected. A group consists of a sequence of conversions that can be done on any channel and in any order. For instance, it is possible to implement the conversion sequence in the following order: ADCx_INP/INN3, ADCx_INP/INN8, ADCx_INP/INN2, ADCx_INP/INN2, ADCx_INP/INN0, ADCx_INP/INN2, ADCx_INP/INN2, ADCx_INP/INN15.

- A regular group is composed of up to 16 conversions. The regular channels and their order in the conversion sequence must be selected in the ADC_SQRy registers. The
total number of conversions in the regular group must be written in the L[3:0] bits in the ADC_SQR1 register.

- An **injected group** is composed of up to 4 conversions. The injected channels and their order in the conversion sequence must be selected in the ADC_JSQR register. The total number of conversions in the injected group must be written in the L[1:0] bits in the ADC_JSQR register.

ADC_SQRy registers must not be modified while regular conversions can occur. For this, the ADC regular conversions must be first stopped by writing ADSTP=1 (refer to Section 24.4.18: Stopping an ongoing conversion (ADSTP, JADSTP)).

The software is allowed to modify on-the-fly the ADC_JSQR register when JADSTART is set to 1 only when the context queue is enabled (JQDIS=0 in ADC_CFGR register).

**Temperature sensor, VREFINT and VBAT internal channels**

The temperature sensor VSENSE is connected to channel ADC3 VINP[18].

The internal reference voltage VREFINT is connected to ADC3 VINP[19].

The VBAT channel is connected to channel ADC3 VINP[17].

*Note: To convert one of the internal analog channels, the corresponding analog sources must first be enabled by programming VREFEN, VSENSEEN or VBATEN bits in the ADCx_CCR registers.*

### 24.4.12 Channel preselection register (ADC_PCSEL)

For each channel selected through SQRx or JSQRx, the corresponding ADC_PCSEL bit must be previously configured.

This ADC_PCSEL bit controls the analog switch integrated in the IO level. The ADC input MUX selects the ADC input according to the SQRx and JSQRx with very high speed, the analog switch integrated in the IO cannot react as fast as ADC mux do. To avoid the delay on analog switch control on IO, it is necessary to pre select the input channels which will be selected in the SQRx, JSQRx.

The selection is based on the VINP[i] of the each ADC input. If ADC1 will convert the ADC123_INP2(VINP[2]) as differential mode, ADC123_INP6(VINP[6]) also need to be selected in ADC_PCSEL.

Some I/Os are connected to several VINP[i] of the ADCx. The control inputs of the analog switch are ORed with the corresponding ADC_PCSEL register bits.

### 24.4.13 Channel-wise programmable sampling time (SMPR1, SMPR2)

Before starting a conversion, the ADC must establish a direct connection between the voltage source under measurement and the embedded sampling capacitor of the ADC. This sampling time must be enough for the input voltage source to charge the embedded capacitor to the input voltage level.
Each channel can be sampled with a different sampling time which is programmable using the SMP[2:0] bits in the ADC_SMPR1 and ADC_SMPR2 registers. It is therefore possible to select among the following sampling time values:

- SMP = 000: 1.5 ADC clock cycles
- SMP = 001: 2.5 ADC clock cycles
- SMP = 010: 8.5 ADC clock cycles
- SMP = 011: 16.5 ADC clock cycles
- SMP = 100: 32.5 ADC clock cycles
- SMP = 101: 64.5 ADC clock cycles
- SMP = 110: 387.5 ADC clock cycles
- SMP = 111: 810.5 ADC clock cycles

The total conversion time is calculated as follows:

\[ T_{\text{CONV}} = \text{Sampling time} + 7.5 \text{ ADC clock cycles} \]

Example:

With \( F_{\text{adc,ker,ck}} = 24 \text{ MHz} \) and a sampling time of 1.5 ADC clock cycles (14-bit mode):

\[ T_{\text{CONV}} = (1.5 + 7.5) \text{ ADC clock cycles} = 9 \text{ ADC clock cycles} = 0.375 \mu\text{s} \] (14 bit mode for fast channels)

The ADC notifies the end of the sampling phase by setting the status bit EOSMP (only for regular conversion).

**Constraints on the sampling time for fast and slow channels**

For each channel, SMP[2:0] bits must be programmed to respect a minimum sampling time as specified in the ADC characteristics section of the datasheets.

**I/O analog switches voltage booster**

The I/O analog switches resistance increases when the \( V_{\text{DDA}} \) voltage is too low. This requires to have the sampling time adapted accordingly (cf datasheet for electrical characteristics). This resistance can be minimized at low \( V_{\text{DDA}} \) by enabling an internal voltage booster with BOOSTE bit in the SYSCFG_PMCR register.

### 24.4.14 Single conversion mode (CONT=0)

In Single conversion mode, the ADC performs once all the conversions of the channels. This mode is started with the CONT bit at 0 by either:

- Setting the ADSTART bit in the ADC_CR register (for a regular channel, with software trigger selected)
- Setting the JADSTART bit in the ADC_CR register (for an injected channel, with software trigger selected)
- External hardware trigger event (for a regular or injected channel)

ADSTART bit or JADSTART bit must be set before triggering an external event.

Inside the regular sequence, after each conversion is complete:

- The converted data are stored into the 32-bit ADC_DR register
- The EOC (end of regular conversion) flag is set
- An interrupt is generated if the EOCIE bit is set
Inside the injected sequence, after each conversion is complete:
- The converted data are stored into one of the four 32-bit ADC_JDRy registers
- The JEOC (end of injected conversion) flag is set
- An interrupt is generated if the JEOCIE bit is set

After the regular sequence is complete:
- The EOS (end of regular sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

After the injected sequence is complete:
- The JEOS (end of injected sequence) flag is set
- An interrupt is generated if the JEOSIE bit is set

Then the ADC stops until a new external regular or injected trigger occurs or until bit
ADSTART or JADSTART is set again.

*Note:* To convert a single channel, program a sequence with a length of 1.

### 24.4.15 Continuous conversion mode (CONT=1)

This mode applies to regular channels only.

In continuous conversion mode, when a software or hardware regular trigger event occurs,
the ADC performs once all the regular conversions of the channels and then automatically
re-starts and continuously converts each conversions of the sequence. This mode is started
with the CONT bit at 1 either by external trigger or by setting the ADSTART bit in the
ADC_CR register.

Inside the regular sequence, after each conversion is complete:
- The converted data are stored into the 32-bit ADC_DR register
- The EOC (end of conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

After the sequence of conversions is complete:
- The EOS (end of sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

Then, a new sequence restarts immediately and the ADC continuously repeats the
conversion sequence.

*Note:* To convert a single channel, program a sequence with a length of 1.

It is not possible to have both discontinuous mode and continuous mode enabled: it is
forbidden to set both DISCEN=1 and CONT=1.

Injected channels cannot be converted continuously. The only exception is when an injected
channel is configured to be converted automatically after regular channels in continuous
mode (using JAUTO bit), refer to Auto-injection mode section.)
24.4.16 Starting conversions (ADSTART, JADSTART)

Software starts ADC regular conversions by setting ADSTART=1.

When ADSTART is set, the conversion starts:
- Immediately: if EXTEN = 0x0 (software trigger)
- At the next active edge of the selected regular hardware trigger: if EXTEN /= 0x0

Software starts ADC injected conversions by setting JADSTART=1.

When JADSTART is set, the conversion starts:
- Immediately, if JEXTEN = 0x0 (software trigger)
- At the next active edge of the selected injected hardware trigger: if JEXTEN /= 0x0

Note: In auto-injection mode (JAUTO=1), use ADSTART bit to start the regular conversions followed by the auto-injected conversions (JADSTART must be kept cleared).

ADSTART and JADSTART also provide information on whether any ADC operation is currently ongoing. It is possible to re-configure the ADC while ADSTART=0 and JADSTART=0 are both true, indicating that the ADC is idle.

ADSTART is cleared by hardware:
- In single mode with software trigger (CONT=0, EXTEN=0x0)
  - at any end of conversion sequence (EOS =1)
- In discontinuous mode with software trigger (CONT=0, DISCEN=1, EXTEN=0x0)
  - at end of conversion (EOC=1)
- In all other cases (CONT=x, EXTEN=x)
  - after execution of the ADSTP procedure asserted by the software.

Note: In continuous mode (CONT=1), ADSTART is not cleared by hardware with the assertion of EOS because the sequence is automatically relaunched.

When a hardware trigger is selected in single mode (CONT=0 and EXTEN /=0x00), ADSTART is not cleared by hardware with the assertion of EOS to help the software which does not need to reset ADSTART again for the next hardware trigger event. This ensures that no further hardware triggers are missed.

JADSTART is cleared by hardware:
- in single mode with software injected trigger (JEXTEN=0x0)
  - at any end of injected conversion sequence (JEOS assertion) or at any end of sub-group processing if JDISCEN=1
- in all cases (JEXTEN=x)
  - after execution of the JADSTP procedure asserted by the software.

Note: When the software trigger is selected, ADSTART bit should not be set if the EOC flag is still high.
24.4.17 **Timing**

The elapsed time between the start of a conversion and the end of conversion is the sum of the configured sampling time plus the successive approximation time depending on data resolution:

\[
T_{\text{CONV}} = T_{\text{SMPL}} + T_{\text{SAR}} = [1.5 \text{ ms}] + 7.5 \times T_{\text{adc, ker, ck}}
\]

\[
T_{\text{CONV}} = T_{\text{SMPL}} + T_{\text{SAR}} = 62.5 \text{ ns} + 312.5 \text{ ns} \times 14\text{bit} = 375.0 \text{ ns (for } F_{\text{adc, ker, ck}} = 24 \text{ MHz)}
\]

![Figure 141. Analog to digital conversion time](image)

1. \(T_{\text{SMPL}}\) depends on \(\text{SMP}[2:0]\)
2. \(T_{\text{SAR}}\) depends on \(\text{RES}[2:0]\)

24.4.18 **Stopping an ongoing conversion (ADSTP, JADSTP)**

The software can decide to stop regular conversions ongoing by setting \(\text{ADSTP}=1\) and injected conversions ongoing by setting \(\text{JADSTP}=1\).

Stopping conversions will reset the ongoing ADC operation. Then the ADC can be reconfigured (ex: changing the channel selection or the trigger) ready for a new operation.

Note that it is possible to stop injected conversions while regular conversions are still operating and vice-versa. This allows, for instance, re-configuration of the injected conversion sequence and triggers while regular conversions are still operating (and vice-versa).

When the \(\text{ADSTP}\) bit is set by software, any ongoing regular conversion is aborted with partial result discarded (\(\text{ADC}_{\text{DR}}\) register is not updated with the current conversion).

When the \(\text{JADSTP}\) bit is set by software, any ongoing injected conversion is aborted with partial result discarded (\(\text{ADC}_{\text{JDRy}}\) register is not updated with the current conversion). The scan sequence is also aborted and reset (meaning that relaunching the ADC would re-start a new sequence).

Once this procedure is complete, bits \(\text{ADSTP}/\text{ADSTART}\) (in case of regular conversion), or \(\text{JADSTP}/\text{JADSTART}\) (in case of injected conversion) are cleared by hardware and the software must poll \(\text{ADSTART}\) (or \(\text{JADSTART}\)) until the bit is reset before assuming the ADC is completely stopped.
**Note:** In auto-injection mode (JAUTO=1), setting ADSTP bit aborts both regular and injected conversions (JADSTP must not be used).

24.4.19 Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN)

A conversion or a sequence of conversions can be triggered either by software or by an external event (e.g. timer capture, input pins). If the EXTEN[1:0] control bits (for a regular conversion) or JEXTEN[1:0] bits (for an injected conversion) are different from 0b00, then external events are able to trigger a conversion with the selected polarity.

When the Injected Queue is enabled (bit JQDIS=0), injected software triggers are not possible.

The regular trigger selection is effective once software has set bit ADSTART=1 and the injected trigger selection is effective once software has set bit JADSTART=1.

Any hardware triggers which occur while a conversion is ongoing are ignored.
- If bit ADSTART=0, any regular hardware triggers which occur are ignored.
- If bit JADSTART=0, any injected hardware triggers which occur are ignored.

Table 200 provides the correspondence between the EXTEN[1:0] and JEXTEN[1:0] values and the trigger polarity.

<table>
<thead>
<tr>

<tr>
<td></td>
<td>– If JQDIS=0 (Queue enabled), Hardware and software trigger detection disabled</td>
</tr>
<tr>
<td>01</td>
<td>Hardware Trigger with detection on the rising edge</td>
</tr>
<tr>
<td>10</td>
<td>Hardware Trigger with detection on the falling edge</td>
</tr>
<tr>
<td>11</td>
<td>Hardware Trigger with detection on both the rising and falling edges</td>
</tr>
</tbody>
</table>

Note: The polarity of the injected trigger can be anticipated and changed on-the-fly when the queue is enabled (JQDIS=0). Refer to Section 24.4.22: Queue of context for injected conversions.

The EXTSEL[4:0] and JEXTSEL[4:0] control bits select which out of 21 possible events can trigger conversion for the regular and injected groups.

A regular group conversion can be interrupted by an injected trigger.
Note: The regular trigger selection cannot be changed on-the-fly.
The injected trigger selection can be anticipated and changed on-the-fly. Refer to Section 24.4.22: Queue of context for injected conversions on page 937.

Each ADC master shares the same input triggers with its ADC slave as described in Figure 144.

Figure 144. Triggers are shared between ADC master and ADC slave

Table 202 and Table 203 give all the possible external triggers of the three ADCs for regular and injected conversion.

</table>

To use triggered injection, the JAUTO bit in the ADC_CFG register must be cleared.

1. Start the conversion of a group of regular channels either by an external trigger or by setting the ADSTART bit in the ADC_CR register.
2. If an external injected trigger occurs, or if the JADSTART bit in the ADC_CR register is set during the conversion of a regular group of channels, the current conversion is
reset and the injected channel sequence switches are launched (all the injected channels are converted once).

3. Then, the regular conversion of the regular group of channels is resumed from the last interrupted regular conversion.

4. If a regular event occurs during an injected conversion, the injected conversion is not interrupted but the regular sequence is executed at the end of the injected sequence. Figure 145 shows the corresponding timing diagram.

**Note:** When using triggered injection, one must ensure that the interval between trigger events is longer than the injection sequence. For instance, if the sequence length is 20 ADC clock cycles (that is two conversions with a sampling time of 1.5 clock periods), the minimum interval between triggers must be 21 ADC clock cycles.

**Auto-injection mode**

If the JAUTO bit in the ADC_CFGR register is set, then the channels in the injected group are automatically converted after the regular group of channels. This can be used to convert a sequence of up to 20 conversions programmed in the ADC_SQRy and ADC_JSQR registers.

In this mode, the ADSTART bit in the ADC_CR register must be set to start regular conversions, followed by injected conversions (JADSTART must be kept cleared). Setting the ADSTP bit aborts both regular and injected conversions (JADSTP bit must not be used).

In this mode, external trigger on injected channels must be disabled.

If the CONT bit is also set in addition to the JAUTO bit, regular channels followed by injected channels are continuously converted.

**Note:** It is not possible to use both the auto-injected and discontinuous modes simultaneously.

When the DMA is used for exporting regular sequencer’s data in JAUTO mode, it is necessary to program it in circular mode (CIRC bit set in DMA_CCRx register). If the CIRC bit is reset (single-shot mode), the JAUTO sequence will be stopped upon DMA Transfer Complete event.
24.4.21 Discontinuous mode (DISCEN, DISCNUM, JDISCEN)

Regular group mode

This mode is enabled by setting the DISCEN bit in the ADC_CFGR register.

It is used to convert a short sequence (sub-group) of \( n \) conversions \( (n \leq 8) \) that is part of the sequence of conversions selected in the ADC_SQRy registers. The value of \( n \) is specified by writing to the DISCNUM[2:0] bits in the ADC_CFGR register.

When an external trigger occurs, it starts the next \( n \) conversions selected in the ADC_SQR registers until all the conversions in the sequence are done. The total sequence length is defined by the L[3:0] bits in the ADC_SQR1 register.

Example:
- **DISCEN=1, n=3**, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10, 11
  - 1st trigger: channels converted are 1, 2, 3 (an EOC event is generated at each conversion).
  - 2nd trigger: channels converted are 6, 7, 8 (an EOC event is generated at each conversion).
  - 3rd trigger: channels converted are 9, 10, 11 (an EOC event is generated at each conversion) and an EOS event is generated after the conversion of channel 11.
  - 4th trigger: channels converted are 1, 2, 3 (an EOC event is generated at each conversion).
  - ...
- **DISCEN=0**, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10, 11
