  - 1st trigger: the complete sequence is converted: channel 1, then 2, 3, 6, 7, 8, 9, 10 and 11. Each conversion generates an EOC event and the last one also generates an EOS event.
  - all the next trigger events will relaunch the complete sequence.
**Note:** When a regular group is converted in discontinuous mode, no rollover occurs (the last subgroup of the sequence can have less than \(n\) conversions).

When all subgroups are converted, the next trigger starts the conversion of the first subgroup. In the example above, the 4th trigger reconverts the channels 1, 2 and 3 in the 1st subgroup.

It is not possible to have both discontinuous mode and continuous mode enabled. In this case (if \(\text{DISCEN}=1\), \(\text{CONT}=1\)), the ADC behaves as if continuous mode was disabled.

**Injected group mode**

This mode is enabled by setting the JDISCEN bit in the ADC_CFGR register. It converts the sequence selected in the ADC_JSQR register, channel by channel, after an external injected trigger event. This is equivalent to discontinuous mode for regular channels where ‘\(n\)’ is fixed to 1.

When an external trigger occurs, it starts the next channel conversions selected in the ADC_JSQR registers until all the conversions in the sequence are done. The total sequence length is defined by the JL[1:0] bits in the ADC_JSQR register.

Example:
- JDISCEN=1, channels to be converted = 1, 2, 3
  - 1st trigger: channel 1 converted (a JEOC event is generated)
  - 2nd trigger: channel 2 converted (a JEOC event is generated)
  - 3rd trigger: channel 3 converted and a JEOC event + a JEOS event are generated
  - ...

**Note:** When all injected channels have been converted, the next trigger starts the conversion of the first injected channel. In the example above, the 4th trigger reconverts the 1st injected channel 1.

It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

**24.4.22 Queue of context for injected conversions**

A queue of context is implemented to anticipate up to 2 contexts for the next injected sequence of conversions. JQDIS bit of ADC_CFGR register must be reset to enable this feature. Only hardware-triggered conversions are possible when the context queue is enabled.

This context consists of:
- Configuration of the injected triggers (bits JEXTEN[1:0] and JEXTSEL[4:0] in ADC_JSQR register)
- Definition of the injected sequence (bits JSQx[4:0] and JL[1:0] in ADC_JSQR register)
All the parameters of the context are defined into a single register ADC_JSQR and this register implements a queue of 2 buffers, allowing the bufferization of up to 2 sets of parameters:

- The JSQR register can be written at any moment even when injected conversions are ongoing.
- Each data written into the JSQR register is stored into the Queue of context.
- At the beginning, the Queue is empty and the first write access into the JSQR register immediately changes the context and the ADC is ready to receive injected triggers.
- Once an injected sequence is complete, the Queue is consumed and the context changes according to the next JSQR parameters stored in the Queue. This new context is applied for the next injected sequence of conversions.
- A Queue overflow occurs when writing into register JSQR while the Queue is full. This overflow is signaled by the assertion of the flag JQOVF. When an overflow occurs, the write access of JSQR register which has created the overflow is ignored and the queue of context is unchanged. An interrupt can be generated if bit JQOVFIE is set.

Two possible behaviors are possible when the Queue becomes empty, depending on the value of the control bit JQM of register ADC_CFGR:

- If JQM=0, the Queue is empty just after enabling the ADC, but then it can never be empty during run operations: the Queue always maintains the last active context and any further valid start of injected sequence will be served according to the last active context.
- If JQM=1, the Queue can be empty after the end of an injected sequence or if the Queue is flushed. When this occurs, there is no more context in the queue and hardware triggers are disabled. Therefore, any further hardware injected triggers are ignored until the software re-writes a new injected context into JSQR register.

- Reading JSQR register returns the current JSQR context which is active at that moment. When the JSQR context is empty, JSQR is read as 0x0000.
- The Queue is flushed when stopping injected conversions by setting JADSTP=1 or when disabling the ADC by setting ADDIS=1:
  - If JQM=0, the Queue is maintained with the last active context.
  - If JQM=1, the Queue becomes empty and triggers are ignored.

**Note:** When configured in discontinuous mode (bit JDISCEN=1), only the last trigger of the injected sequence changes the context and consumes the Queue. The 1st trigger only consumes the queue but others are still valid triggers as shown by the discontinuous mode example below (length = 3 for both contexts):

- 1st trigger, discontinuous. Sequence 1: context 1 consumed, 1st conversion carried out
- 2nd trigger, disc. Sequence 1: 2nd conversion.
- 3rd trigger, discontinuous. Sequence 1: 3rd conversion.
- 4th trigger, discontinuous. Sequence 2: context 2 consumed, 1st conversion carried out.
- 5th trigger, discontinuous. Sequence 2: 2nd conversion.
- 6th trigger, discontinuous. Sequence 2: 3rd conversion.

**Note:** When queue of context enabled (bit JQDIS=0), only hardware trigger can be used.
Behavior when changing the trigger or sequence context

The Figure 146 and Figure 147 show the behavior of the context Queue when changing the sequence or the triggers.

**Figure 146. Example of JSQR queue of context (sequence change)**

1. Parameters:
P1: sequence of 3 conversions, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 1
P3: sequence of 4 conversions, hardware trigger 1

**Figure 147. Example of JSQR queue of context (trigger change)**

1. Parameters:
P1: sequence of 2 conversions, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 2
P3: sequence of 4 conversions, hardware trigger 1
Queue of context: Behavior when a queue overflow occurs

The Figure 148 and Figure 149 show the behavior of the context Queue if an overflow occurs before or during a conversion.

**Figure 148. Example of JSQR queue of context with overflow before conversion**

1. Parameters:
   - P1: sequence of 2 conversions, hardware trigger 1
   - P2: sequence of 1 conversion, hardware trigger 2
   - P3: sequence of 3 conversions, hardware trigger 1
   - P4: sequence of 4 conversions, hardware trigger 1

**Figure 149. Example of JSQR queue of context with overflow during conversion**

1. Parameters:
   - P1: sequence of 2 conversions, hardware trigger 1
   - P2: sequence of 1 conversion, hardware trigger 2
   - P3: sequence of 3 conversions, hardware trigger 1
   - P4: sequence of 4 conversions, hardware trigger 1
It is recommended to manage the queue overflows as described below:

- After each P context write into JSQR register, flag JQOVF shows if the write has been ignored or not (an interrupt can be generated).
- Avoid Queue overflows by writing the third context (P3) only once the flag JEOS of the previous context P2 has been set. This ensures that the previous context has been consumed and that the queue is not full.

Queue of context: Behavior when the queue becomes empty

*Figure 150* and *Figure 151* show the behavior of the context Queue when the Queue becomes empty in both cases JQM=0 or 1.

**Figure 150. Example of JSQR queue of context with empty queue (case JQM=0)**

<table>
<thead>
<tr>
<th>Write JSQR</th>
<th>P1</th>
<th>P2</th>
<th>P3</th>
<th>The queue is not empty and maintains P2 because JQM=0</th>
</tr>
</thead>

<td>P1</td>
<td>P2</td>
<td>P3</td>
</tr>
<tr>
<td>ADC state</td>
<td>RDY</td>
<td>Conversion1</td>
<td>RDY</td>
<td>Conversion1</td>
</tr>
</tbody>
</table>

1. Parameters:
   - P1: sequence of 1 conversion, hardware trigger 1
   - P2: sequence of 1 conversion, hardware trigger 1
   - P3: sequence of 1 conversion, hardware trigger 1

**Note:** When writing P3, the context changes immediately. However, because of internal resynchronization, there is a latency and if a trigger occurs just after or before writing P3, it can happen that the conversion is launched considering the context P2. To avoid this situation, the user must ensure that there is no ADC trigger happening when writing a new context that applies immediately.
## Flushing the queue of context

The figures below show the behavior of the context Queue in various situations when the queue is flushed.

### Figure 151. Example of JSQR queue of context with empty queue (case JQM=1)

</tbody>
</table>

Queue of context: Starting the ADC with an empty queue

The following procedure must be followed to start ADC operation with an empty queue, in case the first context is not known at the time the ADC is initialized. This procedure is only applicable when JQM bit is reset:

1. **Parameters:**
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

2. Write a dummy JSQR with JEXTEN not equal to 0 (otherwise triggering a software conversion)
3. Set JADSTART
4. Set JADSTP
5. Wait until JADSTART is reset
6. Set JADSTART.

**Disabling the queue**

It is possible to disable the queue by setting bit JQDIS=1 into the ADC_CFRGR register.

Queue of context: Programming of the register ADC_JSQR

When the injected conversion queue of context is enabled (JQDIS=0), the ADC_JSQR must be programmed at one register write access. As JL[1:0] register define the number of the injected sequence, corresponding JSQ1 to JSQ4 must be written at same time. If ADC_JSQR is reprogrammed before the injected conversion start, reprogrammed data is put on the queue. When queue of context is empty, ADC_JSQR read back as 0x0000.

Register access should not use the `read modify write` sequence.

When ADC_JSQR is programmed when already 2 contexts are queued, it will raise JQOVF flag and generate the interrupt.
24.4.23 Programmable resolution (RES) - fast conversion mode

It is possible to perform faster conversion by reducing the ADC resolution.

The resolution can be configured to be either 16, 14, 12, 10, 8 bits by programming the control bits RES[1:0]. Figure 162, Figure 163, Figure 164 and Figure 165 show the conversion result format with respect to the resolution as well as to the data alignment.

Lower resolution allows faster conversion time for applications where high-data precision is not required. It reduces the conversion time spent by the successive approximation steps according to Table 204.

<table>
<thead>

</tbody>
</table>

24.4.24 End of conversion, end of sampling phase (EOC, JEOC, EOSMP)

The ADC notifies the application for each end of regular conversion (EOC) event and each injected conversion (JEOC) event.

The ADC sets the EOC flag as soon as a new regular conversion data is available in the ADC_DR register. An interrupt can be generated if bit EOCIE is set. EOC flag is cleared by the software either by writing 1 to it or by reading ADC_DR.

The ADC sets the JEOC flag as soon as a new injected conversion data is available in one of the ADC_JDRy register. An interrupt can be generated if bit JEOCIE is set. JEOC flag is cleared by the software either by writing 1 to it or by reading the corresponding ADC_JDRy register.

The ADC also notifies the end of Sampling phase by setting the status bit EOSMP (for regular conversions only). EOSMP flag is cleared by software by writing 1 to it. An interrupt can be generated if bit EOSMPIE is set.

24.4.25 End of conversion sequence (EOS, JEOS)

The ADC notifies the application for each end of regular sequence (EOS) and for each end of injected sequence (JEOS) event.

The ADC sets the EOS flag as soon as the last data of the regular conversion sequence is available in the ADC_DR register. An interrupt can be generated if bit EOSIE is set. EOS flag is cleared by the software either by writing 1 to it.

The ADC sets the JEOS flag as soon as the last data of the injected conversion sequence is complete. An interrupt can be generated if bit JEOSIE is set. JEOS flag is cleared by the software either by writing 1 to it.

Data management

Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, RSHIFT, SSATE)

Data and alignment

At the end of each regular conversion channel (when EOC event occurs), the result of the converted data is stored into the ADC_DR data register which is 32 bits wide.

At the end of each injected conversion channel (when JEOC event occurs), the result of the converted data is stored into the corresponding ADC_JDRy data register which is 32 bits wide.

The OVSS[3:0] and LSHIFT[3:0] bitfields in the ADC_CFGR2 register selects the alignment of the data stored after conversion. Data can be right- or left-aligned as shown in Figure 162, Figure 163, Figure 164 and Figure 165.

Note: The data can be re-aligned in normal and in oversampling mode.
Offset

An offset $y$ ($y=1, 2, 3, 4$) can be applied to a channel by programming a value different from 0 in OFFSET$y[25:0]$ bitfield into ADC_OFR$y$ register. The channel to which the offset will be applied is programmed into the bits OFFSET$y_{-}CH[4:0]$ of ADC_OFR$y$ register. In this case, the converted value is decreased by the user-defined offset written in the bits OFFSET$y[25:0]$. The result may be a negative value so the read data is signed and the SEXT bit represents the extended sign value.

The offset value should be lower than the max conversion value (ex. 16bit mode, offset value max is 0xFFFF).

The offset correction is also supported in oversampling mode. For the oversampling mode, offset is subtracted before OVSS right shift applied.

Table 205 describes how the comparison is performed for all the possible resolutions for analog watchdog 1, 2, 3.

</tbody>
</table>

When reading data from ADC_DR (regular channel) or from ADC_JDR$y$ (injected channel, $y=1,2,3,4$), the offset compensation is disabled when ADC_OFR$y$[25:0] bitfield is reset. Otherwise, the offset for ADC_OFR$y$(30:26) channel is enabled.

Figure 162, Figure 163, Figure 164 and Figure 165 show alignments for signed and unsigned data together with corresponding OVSS and LSHIFT values.

Signed 32-bit format
Signed 16-bit format
Signed 8-bit format
16-bit and 8-bit signed format management: RSHIFTx, SSATE

The offset correction sign-extends the data format, resulting in an unsigned 16-bit conversion being extended to 17-bit signed format, for instance.

Three options are offered for formatting 8-bit and 16-bit conversion results.
For each offset correction channel 1 to 4, a RSHIFT1..4 bit in the ADC_CFGR2 register allows to have the result right-shifted 1-bit and have it fitting a standard 8 or 16-bit format.

Another option is to have the result saturated to the 16-bit and 8-bit signed formats, for the following cases only: RES[2:0] = 000 (16-bit format) and RES[2:0] = 111 (8-bit format).

This mode is enabled with the SSATE bit in the ADC_OFRy register.

The table below summarizes the 3 available use case for 16-bit format.

When oversampling mode is active, the SSATE and RSHIFT1..4 bits are not supported.
ADC overrun (OVR, OVRMOD)

The overrun flag (OVR) notifies of a buffer overrun event, when the regular converted data was not read (by the CPU or the DMA) before new converted data became available.

The OVR flag is set if the EOC flag is still 1 at the time when a new conversion completes. An interrupt can be generated if bit OVRIE=1.

When an overrun condition occurs, the ADC is still operating and can continue to convert unless the software decides to stop and reset the sequence by setting bit ADSTP=1.

OVR flag is cleared by software by writing 1 to it.

It is possible to configure if data is preserved or overwritten when an overrun event occurs by programming the control bit OVRMOD:

- OVRMOD=0: The overrun event preserves the data register from being overrun: the old data is maintained and the new conversion is discarded and lost. If OVR remains at 1, any further conversions will occur but the result data will be also discarded.
- OVRMOD=1: The data register is overwritten with the last conversion result and the previous unread data is lost. If OVR remains at 1, any further conversions will operate normally and the ADC_DR register will always contain the latest converted data.

**Figure 166. Example of overrun (OVR)**

Note: There is no overrun detection on the injected channels since there is a dedicated data register for each of the four injected channels.

**Managing a sequence of conversion without using the DMA**

If the conversions are slow enough, the conversion sequence can be handled by the software. In this case the software must use the EOC flag and its associated interrupt to handle each data. Each time a conversion is complete, EOC is set and the ADC_DR register can be read. OVRMOD should be configured to 0 to manage overrun events as an error.
Managing conversions without using the DMA and without overrun

It may be useful to let the ADC convert one or more channels without reading the data each time (if there is an analog watchdog for instance). In this case, the OVRMOD bit must be configured to 1 and OVR flag should be ignored by the software. An overrun event will not prevent the ADC from continuing to convert and the ADC_DR register will always contain the latest conversion.

Managing conversions using the DMA

Since converted channel values are stored into a unique data register, it is useful to use DMA for conversion of more than one channel. This avoids the loss of the data already stored in the ADC_DR register.

When the DMA mode is enabled (DMNGT bit = 01 or 11 in the ADC_CFGFR register in single ADC mode or MDMA different from 0b00 in dual ADC mode), a DMA request is generated after each conversion of a channel. This allows the transfer of the converted data from the ADC_DR register to the destination location selected by the software.

Despite this, if an overrun occurs (OVR=1) because the DMA could not serve the DMA transfer request in time, the ADC stops generating DMA requests and the data corresponding to the new conversion is not transferred by the DMA. Which means that all the data transferred to the RAM can be considered as valid.

Depending on the configuration of OVRMOD bit, the data is either preserved or overwritten (refer to Section : ADC overrun (OVR, OVRMOD)).

The DMA transfer requests are blocked until the software clears the OVR bit.

Two different DMA modes are proposed depending on the application use and are configured with bit DMNGT of the ADC_CFGFR register in single ADC mode, or with bit DAMDF of the ADCx_CCR register in dual ADC mode:

- **DMA one shot mode (DMNGT = 01)**
  - This mode is suitable when the DMA is programmed to transfer a fixed number of data.

- **DMA circular mode (DMNGT = 11)**
  - This mode is suitable when programming the DMA in circular mode.

**DMA one shot mode (DMNGT=01)**

In this mode, the ADC generates a DMA transfer request each time a new conversion data is available and stops generating DMA requests once the DMA has reached the last DMA transfer (when DMA_EOT interrupt occurs - refer to DMA paragraph) even if a conversion has been started again.

When the DMA transfer is complete (all the transfers configured in the DMA controller have been done):

- The content of the ADC data register is frozen.
- Any ongoing conversion is aborted with partial result discarded.
- No new DMA request is issued to the DMA controller. This avoids generating an overrun error if there are still conversions which are started.
- Scan sequence is stopped and reset.
- The DMA is stopped.
DMA circular mode (DMNGT=11)
In this mode, the ADC generates a DMA transfer request each time a new conversion data is available in the data register, even if the DMA has reached the last DMA transfer. This allows configuring the DMA in circular mode to handle a continuous analog input data stream.

DMA with FIFO
The output data register has 8 stage FIFO. Two different DMA requests are generated parallel. When a data is available, “SREQ single request” generated, when 4 data are available, “BREQ burst request” generated. DMA2 can be programmed either single transfer mode or incremental burst mode(4 beats), according to this mode, correct request line is selected by the DMA2. Please refer to the DMA2 chapter for further information.

24.4.28 Managing conversions using the DFSDM
The ADC conversion results can be transferred directly to the Digital Filter for Sigma Delta Modulators (DFSDM).
In this case, the DMNGT[1:0] bits must be set to 10.
The ADC transfers 16 least significant bits of the regular data register data to the DFSDM, which in turns will reset the EOC flag once the transfer is effective.
The data format must be 16-bit signed:
ADC_DR[31:16] = don’t care
ADC_DR[15] = sign
ADC_DR[14:0] = data
Any value above 16-bit signed format will be truncated.

24.4.29 Dynamic low-power features

Auto-delayed conversion mode (AUTDLY)
The ADC implements an auto-delayed conversion mode controlled by the AUTDLY configuration bit. Auto-delayed conversions are useful to simplify the software as well as to optimize performance of an application clocked at low frequency where there would be risk of encountering an ADC overrun.
When AUTDLY=1, a new conversion can start only if all the previous data of the same group has been treated:
• For a regular conversion: once the ADC_DR register has been read or if the EOC bit has been cleared (see Figure 167).
• For an injected conversion: when the JEOS bit has been cleared (see Figure 168).
This is a way to automatically adapt the speed of the ADC to the speed of the system which will read the data.
The delay is inserted after each regular conversion (whatever DISCEN=0 or 1) and after each sequence of injected conversions (whatever JDISCEN=0 or 1).

Note: There is no delay inserted between each conversions of the injected sequence, except after the last one.
During a conversion, a hardware trigger event (for the same group of conversions) occurring during this delay is ignored.

Note: This is not true for software triggers where it remains possible during this delay to set the bits ADSTART or JADSTART to re-start a conversion: it is up to the software to read the data before launching a new conversion.

No delay is inserted between conversions of different groups (a regular conversion followed by an injected conversion or conversely):

- If an injected trigger occurs during the automatic delay of a regular conversion, the injected conversion starts immediately (see Figure 168).
- Once the injected sequence is complete, the ADC waits for the delay (if not ended) of the previous regular conversion before launching a new regular conversion (see Figure 170).

The behavior is slightly different in auto-injected mode (JAUTO=1) where a new regular conversion can start only when the automatic delay of the previous injected sequence of conversion has ended (when JEOS has been cleared). This is to ensure that the software can read all the data of a given sequence before starting a new sequence (see Figure 171).

To stop a conversion in continuous auto-injection mode combined with autodelay mode (JAUTO=1, CONT=1 and AUTDLY=1), follow the following procedure:

1. Wait until JEOS=1 (no more conversions are restarted)
2. Clear JEOS,
3. Set ADSTP=1
4. Read the regular data.

If this procedure is not respected, a new regular sequence can re-start if JEOS is cleared after ADSTP has been set.

In AUTDLY mode, a hardware regular trigger event is ignored if it occurs during an already ongoing regular sequence or during the delay that follows the last regular conversion of the sequence. It is however considered pending if it occurs after this delay, even if it occurs during an injected sequence of the delay that follows it. The conversion then starts at the end of the delay of the injected sequence.

In AUTDLY mode, a hardware injected trigger event is ignored if it occurs during an already ongoing injected sequence or during the delay that follows the last injected conversion of the sequence.

24.4.30 Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTRy, AWD_LTRy, AWDy)

The three AWD analog watchdogs monitor whether some channels remain within a configured voltage range (window).

![Analog watchdog guarded area](image)

**AWDx flag and interrupt**

An interrupt can be enabled for each of the 3 analog watchdogs by setting AWDyIE in the ADC_IER register (x=1,2,3).

AWDy (y=1,2,3) flag is cleared by software by writing 1 to it.

The ADC conversion result is compared to the lower and higher thresholds before alignment.

**Description of analog watchdog 1**

The AWD analog watchdog 1 is enabled by setting the AWD1EN bit in the ADC_CFGR register. This watchdog monitors whether either one selected channel or all enabled channels\(^{(1)}\) remain within a configured voltage range (window).

*Table 208* shows how the ADC_CFGRy registers should be configured to enable the analog watchdog on one or more channels.

1. Selected by the AWDyCH[4:0] bits. The channels must also be programmed to be converted in the appropriate regular or injected sequence.

The AWD1 analog watchdog status bit is set if the analog voltage converted by the ADC is below a lower threshold or above a higher threshold.
These thresholds are programmed in bits HTR1[25:0] of the ADC_HTR1 register and LTR1[25:0] of the ADC_LTR1 register for the analog watchdog 1.

The threshold can be up to 26-bits (16-bit resolution with oversampling, OSVR[9:0]=1024). When converting data with a resolution of less than 16 bits (according to bits RES[2:0]), the LSBs of the programmed thresholds must be kept cleared, the internal comparison being performed on the full 16-bit converted data (left aligned to the half-word boundary).

*Table 209* describes how the comparison is performed for all the possible resolutions for analog watchdog 1,2,3.

</tbody>
</table>

1. The watchdog comparison is performed on the raw converted data before any alignment calculation and before applying any offsets (the data which is compared is not signed).

### Description of analog watchdog 2 and 3

The second and third analog watchdogs are more flexible and can guard several selected channels by programming the corresponding bits in AWDCHy[19:0] (y=2,3).

The corresponding watchdog is enabled when any bit of AWDCHy[19:0] (y=2,3) is set. The threshold can be up to 26-bits (16-bit resolution with oversampling, OSVR[9:0]=1024) and are programmed with the ADC_HTR2, ADC_LTR2, ADC_LTR3, and ADC_HTR3 registers.

When converting data with a resolution of less than 16 bits (according to bits RES[2:0]), the LSBs of the programmed thresholds must be kept cleared, the internal comparison being performed on the full 16-bit converted data (left aligned to the half-word boundary).

### ADCx_AWDy_OUT signal output generation

Each analog watchdog is associated to an internal hardware signal ADCx_AWDy_OUT (x=ADC number, y=watchdog number) which is directly connected to the ETR input (external trigger) of some on-chip timers. Refer to the on-chip timers section to understand how to select the ADCx_AWDy_OUT signal as ETR.
ADCx_AWDy_OUT is activated when the associated analog watchdog is enabled:

- ADCx_AWDy_OUT is set when a guarded conversion is outside the programmed thresholds.
- ADCx_AWDy_OUT is reset after the end of the next guarded conversion which is inside the programmed thresholds (It remains at 1 if the next guarded conversions are still outside the programmed thresholds).
- ADCx_AWDy_OUT is also reset when disabling the ADC (when setting ADDIS=1).

Note: AWDx flag is set by hardware and reset by software: AWDy flag has no influence on the generation of ADCy_AWDx_OUT.

Note: AWDx flag is set by hardware and reset by software: AWDy flag has no influence on the generation of ADCy_AWDx_OUT (ex: ADCy_AWDy_OUT can toggle while AWDx flag remains at 1 if the software did not clear the flag).

24.4.31 Oversampler

The oversampling unit performs data preprocessing to offload the CPU. It is able to handle multiple conversions and average them into a single data with increased data width, up to 26-bit (16-bit values and OSVR[9:0] = 1024).

It provides a result with the following form, where \( N \) and \( M \) can be adjusted:

\[
\text{Result} = \frac{1}{M} \times \sum_{n=0}^{n=N-1} \text{Conversion}(t_n)
\]

It allows to perform by hardware the following functions: averaging, data rate reduction, SNR improvement, basic filtering.
The oversampling ratio $N$ is defined using the OSVR[9:0] bits in the ADC_CFRG2 register, and can range from 2x to 1024x. The division coefficient $M$ consists of a right bit shift up to 10 bits, and is defined using the OVSS[3:0] bits in the ADC_CFRG2 register.

The summation unit can yield a result up to 26 bits (1024 x 16-bit results), which can be left or right shifted. When right shifting is selected, it is rounded to the nearest value using the least significant bits left apart by the shifting, before being transferred into the ADC_DR data register.

The Table 177 gives a numerical example of the processing, from a raw 26-bit accumulated data to the final 16-bit result.

There are no changes for conversion timings in oversampled mode: the sample time is maintained equal during the whole oversampling sequence. A new data is provided every $N$ conversions, with an equivalent delay equal to $N \times T_{CONV} = N \times (t_{SMPL} + t_{SAR})$. The flags are set as follow:

- the end of the sampling phase (EOSMP) is set after each sampling phase
- the end of conversion (EOC) occurs once every $N$ conversions, when the oversampled result is available
- the end of sequence (EOS) occurs once the sequence of oversampled data is completed (i.e. after $N \times$ sequence length conversions total)
Single ADC operating modes support when oversampling

In oversampling mode, most of the ADC operating modes are maintained:

- Single or continuous mode conversions
- ADC conversions start either by software or with triggers
- ADC stop during a conversion (abort)
- Data read via CPU or DMA with overrun detection
- Low-power modes (AUTDLY)
- Programmable resolution: in this case, the reduced conversion values (as per RES[2:0] bits in ADC_CFGR register) are accumulated, truncated, rounded and shifted in the same way as 16-bit conversions are

Note: The alignment mode is not available when working with oversampled data. The data are always provided right-aligned.

Offset correction is not supported in oversampling mode.

Analog watchdog

The analog watchdog functionality is maintained (AWDSGL and AWDEN bits), with the following difference:

- the RES[2:0] bits are ignored, comparison is always done on using the full 26-bit values HTRx[25:0] and LTRx[25:0]
- the comparison is performed on the oversampled accumulated value before shifting

Note: Care must be taken when using high shifting values, this will reduce the comparison range. For instance, if the oversampled result is shifted by 4 bits, thus yielding a 12-bit data right-aligned, the effective analog watchdog comparison can only be performed on 8 bits. The comparison is done between ADC_DR[11:4] and HT[0:7] / LT[0:7], and HT[11:8] / LT[11:8] must be kept reset.

Triggered mode

The averager can also be used for basic filtering purpose. Although not a very powerful filter (slow roll-off and limited stop band attenuation), it can be used as a notch filter to reject constant parasitic frequencies (typically coming from the mains or from a switched mode power supply). For this purpose, a specific discontinuous mode can be enabled with TROVS bit in ADC_CFGR2, to be able to have an oversampling frequency defined by a user and independent from the conversion time itself.

The Figure 178 below shows how conversions are started in response to triggers during discontinuous mode.

If the TROVS bit is set, the content of the DISCEN bit is ignored and considered as 1.
Injected and regular sequencer management when oversampling

In oversampling mode, it is possible to have differentiated behavior for injected and regular sequencers. The oversampling can be enabled for both sequencers with some limitations if they have to be used simultaneously (this is related to a unique accumulation unit).

Oversampling regular channels only

The regular oversampling mode bit ROVSM defines how the regular oversampling sequence is resumed if it is interrupted by injected conversion:

- in continued mode, the accumulation re-starts from the last valid data (prior to the conversion abort request due to the injected trigger). This ensures that oversampling will be completed whatever the injection frequency (providing at least one regular conversion can be completed between triggers);
- in resumed mode, the accumulation re-starts from 0 (previous conversions results are ignored). This mode allows to guarantee that all data used for oversampling were converted back-to-back within a single timeslot. Care must be taken to have a injection trigger period above the oversampling period length. If this condition is not respected, the oversampling cannot be completed and the regular sequencer will be blocked.

The Figure 179 gives examples for a 4x oversampling ratio.
Oversampling Injected channels only

The Injected oversampling mode bit JOVSE enables oversampling solely for conversions in the injected sequencer.

Oversampling regular and Injected channels

It is possible to have both ROVSE and JOVSE bits set. In this case, the regular oversampling mode is forced to resumed mode (ROVSM bit ignored), as represented on Figure 180 below.
Triggered regular oversampling with injected conversions

It is possible to have triggered regular mode with injected conversions. In this case, the injected mode oversampling mode must be disabled, and the ROVSM bit is ignored (resumed mode is forced). The JOVSE bit must be reset. The behavior is represented on Figure 181 below.

Autoinjected mode

It is possible to oversample auto-injected sequences and have all conversions results stored in registers to save a DMA resource. This mode is available only with both regular and injected oversampling active: JAUTO = 1, ROVSE = 1 and JOVSE = 1, other combinations are not supported. The ROVSM bit is ignored in auto-injected mode. The Figure 182 below shows how the conversions are sequenced.

Dual ADC modes support when oversampling

It is possible to have oversampling enabled when working in dual ADC configuration, for the injected simultaneous mode and regular simultaneous mode. In this case, the two ADCs must be programmed with the very same settings (including oversampling).

All other dual ADC modes are not supported when either regular or injected oversampling is enabled (ROVSE = 1 or JOVSE = 1).
Combined modes summary

The Table 210 below summarizes all combinations, including modes not supported.

24.4.32 Dual ADC modes

In devices with two ADCs or more, dual ADC modes can be used (see Figure 183):

- ADC1 and ADC2 can be used together in dual mode (ADC1 is master)

In dual ADC mode the start of conversion is triggered alternately or simultaneously by the ADCx master to the ADC slave, depending on the mode selected by the bits DUAL[4:0] in the ADCx_CCR register.

Four possible modes are implemented:

- Injected simultaneous mode
- Regular simultaneous mode
- Interleaved mode
- Alternate trigger mode

It is also possible to use these modes combined in the following ways:

- Injected simultaneous mode + Regular simultaneous mode
- Regular simultaneous mode + Alternate trigger mode
- Injected simultaneous mode + Interleaved mode

In dual ADC mode (when bits DUAL[4:0] in ADCx_CCR register are not equal to zero), the bits CONT, AUTDLY, DISCEN, DISCNUM[2:0], JDISCEN, JQM, JAUTO of the ADC_CFGR register are shared between the master and slave ADC: the bits in the slave ADC are always equal to the corresponding bits of the master ADC.

To start a conversion in dual mode, the user must program the bits EXTEN, EXTSEL, JEXTEN, JEXTSEL of the master ADC only, to configure a software or hardware trigger,
and a regular or injected trigger. (the bits EXTEN[1:0] and JEXTEN[1:0] of the slave ADC are don’t care).

In regular simultaneous or interleaved modes: once the user sets bit ADSTART or bit ADSTP of the master ADC, the corresponding bit of the slave ADC is also automatically set. However, bit ADSTART or bit ADSTP of the slave ADC is not necessary cleared at the same time as the master ADC bit.

In injected simultaneous or alternate trigger modes: once the user sets bit JADSTART or bit JADSTP of the master ADC, the corresponding bit of the slave ADC is also automatically set. However, bit JADSTART or bit JADSTP of the slave ADC is not necessary cleared at the same time as the master ADC bit.

In dual ADC mode, the converted data of the master and slave ADC can be read in parallel, by reading the ADC common data register (ADCx_CDR). The status bits can be also read in parallel by reading the dual-mode status register (ADCx_CSR).
1. External triggers also exist on slave ADC but are not shown for the purposes of this diagram.

2. The ADC common data register (ADCx_CDR) contains both the master and slave ADC regular converted data.
Injected simultaneous mode

This mode is selected by programming bits DUAL[4:0]=00101

This mode converts an injected group of channels. The external trigger source comes from the injected group multiplexer of the master ADC (selected by the JEXTSEL[4:0] bits in the ADC_JSQR register).

**Note:** Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).

In simultaneous mode, one must convert sequences with the same length and inside a sequence, the N-th conversion in master ans slave must be configured with the same sampling time.

Regular conversions can be performed on one or all ADCs. In that case, they are independent of each other and are interrupted when an injected event occurs. They are resumed at the end of the injected conversion group.

- At the end of injected sequence of conversion event (JEOS) on the master ADC, the converted data is stored into the master ADC_JDRy registers and a JEOS interrupt is generated (if enabled)
- At the end of injected sequence of conversion event (JEOS) on the slave ADC, the converted data is stored into the slave ADC_JDRy registers and a JEOS interrupt is generated (if enabled)
- If the duration of the master injected sequence is equal to the duration of the slave injected one (like in Figure 184), it is possible for the software to enable only one of the two JEOS interrupt (ex: master JEOS) and read both converted data (from master ADC_JDRy and slave ADC_JDRy registers).

![Figure 184. Injected simultaneous mode on 4 channels: dual ADC mode](image)

If JDISCEN=1, each simultaneous conversion of the injected sequence requires an injected trigger event to occur.

This mode can be combined with AUTDLY mode:

- Once a simultaneous injected sequence of conversions has ended, a new injected trigger event is accepted only if both JEOS bits of the master and the slave ADC have been cleared (delay phase). Any new injected trigger events occurring during the ongoing injected sequence and the associated delay phase are ignored.
- Once a regular sequence of conversions of the master ADC has ended, a new regular trigger event of the master ADC is accepted only if the master data register (ADC_DR) has been read. Any new regular trigger events occurring for the master ADC during the ongoing regular sequence and the associated delay phases are ignored. There is the same behavior for regular sequences occurring on the slave ADC.
Regular simultaneous mode with independent injected

This mode is selected by programming bits DUAL[4:0] = 00110.

This mode is performed on a regular group of channels. The external trigger source comes from the regular group multiplexer of the master ADC (selected by the EXTSEL[4:0] bits in the ADC_CFGR register). A simultaneous trigger is provided to the slave ADC.

In this mode, independent injected conversions are supported. An injection request (either on master or on the slave) will abort the current simultaneous conversions, which are re-started once the injected conversion is completed.

Note: Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).

In regular simultaneous mode, one must convert sequences with the same length and inside a sequence, the N-th conversion in master ans slave must be configured with the same sampling time.

Software is notified by interrupts when it can read the data:

- At the end of each conversion event (EOC) on the master ADC, a master EOC interrupt is generated (if EOCIE is enabled) and software can read the ADC_DR of the master ADC.
- At the end of each conversion event (EOC) on the slave ADC, a slave EOC interrupt is generated (if EOCIE is enabled) and software can read the ADC_DR of the slave ADC.
- If the duration of the master regular sequence is equal to the duration of the slave one (like in Figure 185), it is possible for the software to enable only one of the two EOC interrupt (ex: master EOC) and read both converted data from the Common Data register (ADCx_CDR).

It is also possible to read the regular data using the DMA. Two methods are possible:

- Using two DMA channels (one for the master and one for the slave). In this case bits DAMDF[1:0] must be kept cleared:
  - Configure the DMA master ADC channel to read ADC_DR from the master. DMA requests are generated at each EOC event of the master ADC.
  - Configure the DMA slave ADC channel to read ADC_DR from the slave. DMA requests are generated at each EOC event of the slave ADC.
- Configuring Dual ADC mode data format DAMDF[1:0] bits, which leaves one DMA channel free for other uses:
  - Configure DAMDF[1:0]=0b10 or 0b11 (depending on resolution).
  - A single DMA channel is used (the one of the master). Configure the DMA master ADC channel to read the common ADC register (ADCx_CDR)
  - A single DMA request is generated each time both master and slave EOC events have occurred. At that time, the slave ADC converted data is available in the upper half-word of the ADCx_CDR 32-bit register and the master ADC converted data is available in the lower half-word of ADCx_CCR register.
  - both EOC flags are cleared when the DMA reads the ADCx_CCR register.

Note: When DAMDF[1:0]=0b10 or 0b11, the user must program the same number of conversions in the master’s sequence as in the slave’s sequence. Otherwise, the remaining conversions will not generate a DMA request.
If DISCEN=1 then each “n” simultaneous conversions of the regular sequence require a regular trigger event to occur (“n” is defined by DISCNUM).

This mode can be combined with AUTDLY mode:

- Once a simultaneous conversion of the sequence has ended, the next conversion in the sequence is started only if the common data register, ADCx_CDR (or the regular data register of the master ADC) has been read (delay phase).
- Once a simultaneous regular sequence of conversions has ended, a new regular trigger event is accepted only if the common data register (ADCx_CDR) has been read (delay phase). Any new regular trigger events occurring during the ongoing regular sequence and the associated delay phases are ignored.

It is possible to use the DMA to handle data in regular simultaneous mode combined with AUTDLY mode, assuming that multi-DMA mode is used: bits DAMDF must be set to 0b10 or 0b11.

When regular simultaneous mode is combined with AUTDLY mode, it is mandatory for the user to ensure that:

- The number of conversions in the master’s sequence is equal to the number of conversions in the slave’s.
- For each simultaneous conversions of the sequence, the length of the conversion of the slave ADC is inferior to the length of the conversion of the master ADC. Note that the length of the sequence depends on the number of channels to convert and the sampling time and the resolution of each channels.

**Note:** This combination of regular simultaneous mode and AUTDLY mode is restricted to the use case when only regular channels are programmed: it is forbidden to program injected channels in this combined mode.

**Interleaved mode with independent injected**

This mode is selected by programming bits DUAL[4:0] = 00111.

This mode can be started only on a regular group (usually one channel). The external trigger source comes from the regular channel multiplexer of the master ADC.

After an external trigger occurs:

- The master ADC starts immediately.
- The slave ADC starts after a delay of several-ADC clock cycles after the sampling phase of the master ADC has complete.

The minimum delay which separates 2 conversions in interleaved mode is configured in the DELAY bits in the ADCx_CCR register. This delay starts to count after the end of the sampling phase of the master conversion. This way, an ADC cannot start a conversion if the
complementary ADC is still sampling its input (only one ADC can sample the input signal at a given time).

- The minimum possible DELAY is 1 to ensure that there is at least one cycle time between the opening of the analog switch of the master ADC sampling phase and the closing of the analog switch of the slave ADC sampling phase.
- The maximum DELAY is equal to the number of cycles corresponding to the selected resolution. However the user must properly calculate this delay to ensure that an ADC does not start a conversion while the other ADC is still sampling its input.

If the CONT bit is set on both master and slave ADCs, the selected regular channels of both ADCs are continuously converted.

The software is notified by interrupts when it can read the data at the end of each conversion event (EOC) on the slave ADC. A slave and master EOC interrupts are generated (if EOCIE is enabled) and the software can read the ADC_DR of the slave/master ADC.

**Note:** It is possible to enable only the EOC interrupt of the slave and read the common data register (ADCx_CDR). But in this case, the user must ensure that the duration of the conversions are compatible to ensure that inside the sequence, a master conversion is always followed by a slave conversion before a new master conversion restarts. It is recommended to use the MDMA mode.

It is also possible to have the regular data transferred by DMA. In this case, individual DMA requests on each ADC cannot be used and it is mandatory to use the MDMA mode, as following:

- Configure DAMDF[1:0]=0b10 or 0b11 (depending on resolution).
- A single DMA channel is used (the one of the master). Configure the DMA master ADC channel to read the common ADC register (ADCx_CDR).
- A single DMA request is generated each time both master and slave EOC events have occurred. At that time, the slave ADC converted data is available in the upper half-word of the ADCx_CDR 32-bit register and the master ADC converted data is available in the lower half-word of ADCx_CCR register.
- Both EOC flags are cleared when the DMA reads the ADCx_CCR register.

**Figure 186. Interleaved mode on 1 channel in continuous conversion mode: dual ADC mode**
If DISCEN=1, each “n” simultaneous conversions (“n” is defined by DISCNUM) of the regular sequence require a regular trigger event to occur.

In this mode, injected conversions are supported. When injection is done (either on master or on slave), both the master and the slave regular conversions are aborted and the sequence is re-started from the master (see Figure 188 below).

**Figure 188. Interleaved conversion with injection**

**Alternate trigger mode**

This mode is selected by programming bits DUAL[4:0] = 01001.

This mode can be started only on an injected group. The source of external trigger comes from the injected group multiplexer of the master ADC.

This mode is only possible when selecting hardware triggers: JEXTEN must not be 0x0.
Injected discontinuous mode disabled (JDISCEN=0 for both ADC)

1. When the 1st trigger occurs, all injected master ADC channels in the group are converted.
2. When the 2nd trigger occurs, all injected slave ADC channels in the group are converted.
3. And so on.

A JEOS interrupt, if enabled, is generated after all injected channels of the master ADC in the group have been converted.

A JEOS interrupt, if enabled, is generated after all injected channels of the slave ADC in the group have been converted.

JEOC interrupts, if enabled, can also be generated after each injected conversion.

If another external trigger occurs after all injected channels in the group have been converted then the alternate trigger process restarts by converting the injected channels of the master ADC in the group.

**Figure 189. Alternate trigger: injected group of each ADC**

*Note:* Regular conversions can be enabled on one or all ADCs. In this case the regular conversions are independent of each other. A regular conversion is interrupted when the ADC has to perform an injected conversion. It is resumed when the injected conversion is finished.

The time interval between 2 trigger events must be greater than or equal to 1 ADC clock period. The minimum time interval between 2 trigger events that start conversions on the same ADC is the same as in the single ADC mode.
 Injected discontinuous mode enabled (JDISCEN=1 for both ADC)

If the injected discontinuous mode is enabled for both master and slave ADCs:

- When the 1st trigger occurs, the first injected channel of the master ADC is converted.
- When the 2nd trigger occurs, the first injected channel of the slave ADC is converted.
- And so on.

A JEOS interrupt, if enabled, is generated after all injected channels of the master ADC in the group have been converted.

A JEOS interrupt, if enabled, is generated after all injected channels of the slave ADC in the group have been converted.

JEOC interrupts, if enabled, can also be generated after each injected conversions.

If another external trigger occurs after all injected channels in the group have been converted then the alternate trigger process restarts.

**Figure 190. Alternate trigger: 4 injected channels (each ADC) in discontinuous mode**

Combined regular/injected simultaneous mode

This mode is selected by programming bits DUAL[4:0] = 00001.

It is possible to interrupt the simultaneous conversion of a regular group to start the simultaneous conversion of an injected group.

*Note:* The sequences must be converted with the same length, the N-th conversion in master and slave mode must be configured with the same sampling time inside a given sequence, or the interval between triggers has to be longer than the long conversion time of the 2 sequences. If the above conditions are not respected, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

Combined regular simultaneous + alternate trigger mode

This mode is selected by programming bits DUAL[4:0]=00010.

It is possible to interrupt the simultaneous conversion of a regular group to start the alternate trigger conversion of an injected group. **Figure 191** shows the behavior of an alternate trigger interrupting a simultaneous regular conversion.

The injected alternate conversion is immediately started after the injected event. If a regular conversion is already running, in order to ensure synchronization after the injected conversion.
conversion, the regular conversion of all (master/slave) ADCs is stopped and resumed synchronously at the end of the injected conversion.

**Note:** The sequences must be converted with the same length, the N-th conversion in master and slave mode must be configured with the same sampling time inside a given sequence, or the interval between triggers has to be longer than the long conversion time of the 2 sequences. If the above conditions are not respected, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

**Figure 191. Alternate + regular simultaneous**

If a trigger occurs during an injected conversion that has interrupted a regular conversion, the alternate trigger is served. **Figure 192** shows the behavior in this case (note that the 6th trigger is ignored because the associated alternate conversion is not complete).

**Figure 192. Case of trigger occurring during injected conversion**

**Combined injected simultaneous plus interleaved**

This mode is selected by programming bits DUAL[4:0]=00011

It is possible to interrupt an interleaved conversion with a simultaneous injected event. In this case the interleaved conversion is interrupted immediately and the simultaneous injected conversion starts. At the end of the injected sequence the interleaved conversion is resumed. When the interleaved regular conversion resumes, the first regular conversion which is performed is always the master’s one. **Figure 193, Figure 194** and **Figure 195** show the behavior using an example.

**Caution:** In this mode, it is mandatory to use the Common Data Register to read the regular data with a single read access. On the contrary, master-slave data coherency is not guaranteed.
Figure 193. Interleaved single channel CH0 with injected sequence CH11, CH12

Figure 194. Two Interleaved channels (CH1, CH2) with injected sequence CH11, CH12
- case 1: Master interrupted first

Figure 195. Two Interleaved channels (CH1, CH2) with injected sequence CH11, CH12
- case 2: Slave interrupted first
DMA requests in dual ADC mode

In all dual ADC modes, it is possible to use two DMA channels (one for the master, one for the slave) to transfer the data, like in single mode (refer to Figure 196:DMA Requests in regular simultaneous mode when DAMDF=0b00).

Figure 196. DMA Requests in regular simultaneous mode when DAMDF=0b00

In simultaneous regular and interleaved modes, it is also possible to save one DMA channel and transfer both data using a single DMA channel. For this DAMDF bits must be configured in the ADCx_CCR register:

- **DAMDF=0b10, 32-bit format**: A single DMA request is generated alternatively when either the master or slave EOC events have occurred. At that time, the data items are alternatively available in the ADCx_CDR2 32-bit register. This mode is used in interleaved mode and in regular simultaneous mode when resolution is above 16-bit.
  
  **Example:**
  
  Interleaved dual mode: a DMA request is generated each time a new 32-bit data is available:
  
  1st DMA request: ADCx_CDR2[31:0] = MST_ADC_DR[31:0]
  
  2nd DMA request: ADCx_CDR2[31:0] = SLV_ADC_DR[31:0]

- **DAMDF=0b10, 16-bit format**: A single DMA request is generated each time both master and slave EOC events have occurred. At that time, two data items are available and the 32-bit register ADCx_CDR contains the two half-words representing two ADC-
converted data items. The slave ADC data take the upper half-word and the master ADC data take the lower half-word.

This mode is used in interleaved mode and in regular simultaneous mode when resolution is ranging from 10 to 16-bit. Any value above 16-bit in the master or the slave converter will be truncated to the least 16 significant bits.

**Example:**

Interleaved dual mode: a DMA request is generated each time 2 data items are available:

1st DMA request: ADCx_CDR[31:0] = SLV_ADC_DR[15:0] | MST_ADC_DR[15:0]
2nd DMA request: ADCx_CDR[31:0] = SLV_ADC_DR[15:0] | MST_ADC_DR[15:0]

**Figure 197. DMA requests in regular simultaneous mode when DAMDF=0b10**

**Figure 198. DMA requests in interleaved mode when DAMDF=0b10**
When using Multi ADC mode, the user must take care to configure properly the duration of the master and slave conversions so that a DMA request is generated and served for reading both data (master + slave) before a new conversion is available.

- **DAMDF=0b11**: This mode is similar to the DAMDF=0b10. The only differences are that on each DMA request (two data items are available), two bytes representing two ADC converted data items are transferred as a half-word. This mode is used in interleaved and regular simultaneous mode when the result is 8-bit. A new DMA request is issued when 4 new 8-bit values are available.

**Example:**

Interleaved dual mode: a DMA request is generated each time 4 data items are available (t0, t1,... are corresponding to the consecutive sampling instants)

1st DMA request:

\[
\begin{align*}
ADCx\_CDR[7:0] &= MST\_ADC\_DR[7:0]_{t0} \\
ADCx\_CDR[15:8] &= SLV\_ADC\_DR[7:0]_{t0} \\
ADCx\_CDR[23:16] &= MST\_ADC\_DR[7:0]_{t1} \\
ADCx\_CDR[31:24] &= SLV\_ADC\_DR[7:0]_{t1}
\end{align*}
\]

2nd DMA request:

\[
\begin{align*}
ADCx\_CDR[7:0] &= MST\_ADC\_DR[7:0]_{t2} \\
ADCx\_CDR[15:8] &= SLV\_ADC\_DR[7:0]_{t2} \\
ADCx\_CDR[23:16] &= MST\_ADC\_DR[7:0]_{t3} \\
ADCx\_CDR[31:24] &= SLV\_ADC\_DR[7:0]_{t3}
\end{align*}
\]

**Overrun detection**

In dual ADC mode (when DUAL[4:0] is not equal to b00000), if an overrun is detected on one of the ADCs, the DMA requests are no longer issued to ensure that all the data transferred to the RAM are valid (this behavior occurs whatever the DAMDF configuration). It may happen that the EOC bit corresponding to one ADC remains set because the data register of this ADC contains valid data.

**Overrun detection**

In dual ADC mode (when DUAL[4:0] is not equal to b00000), if an overrun is detected on one of the ADCs, the DMA requests are no longer issued to ensure that all the data transferred to the RAM are valid (this behavior occurs whatever the DAMDF configuration). It may happen that the EOC bit corresponding to one ADC remains set because the data register of this ADC contains valid data.

**Overrun detection**

In dual ADC mode (when DUAL[4:0] is not equal to b00000), if an overrun is detected on one of the ADCs, the DMA requests are no longer issued to ensure that all the data transferred to the RAM are valid (this behavior occurs whatever the DAMDF configuration). It may happen that the EOC bit corresponding to one ADC remains set because the data register of this ADC contains valid data.

**DMA one shot mode/ DMA circular mode when Multi ADC mode is selected**

When DAMDF mode is selected (0b10 or 0b11), bit DMNGT[1:0]=0b10 in the master ADC’s ADCx\_CCR register must also be configured to select between DMA one shot mode and circular mode, as explained in section *Section: Managing conversions using the DMA*.

**Stopping the conversions in dual ADC modes**

The user must set the control bits ADSTP/JADSTP of the master ADC to stop the conversions of both ADC in dual ADC mode. The other ADSTP control bit of the slave ADC has no effect in dual ADC mode.

Once both ADC are effectively stopped, the bits ADSTART/JADSTART of the master and slave ADCs are both cleared by hardware.

**DFSDM mode in dual ADC mode interleaved mode**

In dual ADC interleaved modes, the ADC conversion results can be transferred directly to the Digital Filter for Sigma Delta Modulators (DFSDM).
This mode is enabled by setting the bits DMNGT[1:0] = 0b10 in the master ADC’s ADC_CONFIG register.

The ADC transfers alternatively the 16 least significant bits of the regular data register from the master and the slave converter to a single channel of the DFSDM.

The data format must be 16-bit signed:
ADC_DR[31:16] = 0x0000
ADC_DR[15] = sign
ADC_DR[14:0] = data

Any value above 16-bit signed format in any converter will be truncated.

**DFSDM mode in dual ADC simultaneous mode**

The dual mode is not required to use DFSDM in dual ADC simultaneous mode since conversion data will be treated by each individual channel. Single mode with same trigger source results in simultaneous conversion with DFSDM interface.

### 24.4.33 Temperature sensor

The temperature sensor can measure the junction temperature (T_J) of the device in the –40 to 125 °C temperature range.

The temperature sensor is internally connected to ADC3 VINP[18] input channel which is used to convert the sensor’s output voltage to a digital value. The sampling time for the temperature sensor’s analog pin must be greater than the stabilization time specified in the product datasheet.

When not in use, the sensor can be put in power-down mode.

*Figure 199* shows the block diagram of the temperature sensor.

*Figure 199. Temperature sensor channel block diagram*

---

*Note:* The VSENSEEN bit must be set to enable the conversion of internal channel ADC3 VINP[18] (temperature sensor, VSENSE).
**Reading the temperature**

To use the sensor:

1. Select the ADC3 V INP[18] input channels (with the appropriate sampling time).
2. Program with the appropriate sampling time (refer to electrical characteristics section of the device datasheet).
3. Set the VSENSEEN bit in the ADCx_CCR register to wake up the temperature sensor from power-down mode.
4. Start the ADC conversion.
5. Read the resulting VSENSE data in the ADC data register.
6. Calculate the actual temperature using the following formula:

   \[
   \text{Temperature (in } ^\circ\text{C}) = \frac{110 \ ^\circ\text{C} - 30 \ ^\circ\text{C}}{\text{TS\_CAL2} - \text{TS\_CAL1}} \times (\text{TS\_DATA} - \text{TS\_CAL1}) + 30 \ ^\circ\text{C}
   \]

   Where:
   - TS\_CAL2 is the temperature sensor calibration value acquired at 110°C
   - TS\_CAL1 is the temperature sensor calibration value acquired at 30°C
   - TS\_DATA is the actual temperature sensor output value converted by ADC

   Refer to the device datasheet for more information about TS\_CAL1 and TS\_CAL2 calibration points.

**Note:** The sensor has a startup time after waking from power-down mode before it can output VSENSE at the correct level. The ADC also has a startup time after power-on, so to minimize the delay, the ADEN and SENSEEN bits should be set at the same time.

**24.4.34 V\text{BAT} supply monitoring**

The VBATEN bit in the ADCx_CCR register is used to switch to the battery voltage. As the V\text{BAT} voltage could be higher than V\text{DDA}, to ensure the correct operation of the ADC, the V\text{BAT} pin is internally connected to a bridge divider by 4. This bridge is automatically enabled when VBATEN is set, to connect V\text{BAT}/4 to the ADC3 V INP[17] input channels. As a consequence, the converted digital value is one fourth of the V\text{BAT} voltage. To prevent any unwanted consumption on the battery, it is recommended to enable the bridge divider only when needed, for ADC conversion.

Refer to the electrical characteristics of the device datasheet for the sampling time value to be applied when converting the V\text{BAT}/4 voltage.

*Figure 200* shows the block diagram of the V\text{BAT} sensing feature.
24.4.35 Monitoring the internal voltage reference

The internal voltage reference can be monitored to have a reference point for evaluating the ADC $V_{REF+}$ voltage level.

The internal voltage reference is internally connected to the input channel ADC3 $V_{INP[19]}$. The sampling time for this channel must be greater than the stabilization time specified in the product datasheet. Figure 200 shows the block diagram of the $V_{REFINT}$ sensing feature.

Note: The VBATEN bit must be set to enable the conversion of internal channels ADC3 $V_{INP[17]}$ ($V_{BAT}/4$).

Note: The VREFEN bit into ADCx_CUR register must be set to enable the conversion of internal channels ADC3 $V_{INP[19]}$ ($V_{REFINT}$).
Calculating the actual $V_{DDA}$ voltage using the internal reference voltage

The power supply voltage applied to the device may be subject to variations or not precisely known. When $V_{DDA}$ is connected to $V_{REF+}$, it is possible to compute the actual $V_{DDA}$ voltage using the embedded internal reference voltage ($V_{REFINT}$). $V_{REFINT}$ and its calibration data acquired by the ADC during the manufacturing process at $V_{DDA} = 3.3$ V can be used to evaluate the actual $V_{DDA}$ voltage level.

The following formula gives the actual $V_{DDA}$ voltage supplying the device:

$$V_{REF+} = 3.3 \, V \times V_{REFINT\text{CAL}} / V_{REFINT\text{DATA}}$$

Where:

- $V_{REFINT\text{CAL}}$ is the $V_{REFINT}$ calibration value
- $V_{REFINT\text{DATA}}$ is the actual $V_{REFINT}$ output value converted by ADC

Converting a supply-relative ADC measurement to an absolute voltage value

The ADC is designed to deliver a digital value corresponding to the ratio between $V_{REF+}$ and the voltage applied on the converted channel.

For most applications $V_{DDA}$ value is unknown and ADC converted values are right-aligned. In this case, it is necessary to convert this ratio into a voltage independent from $V_{DDA}$:

$$V_{\text{CHANNEL}x} = \frac{V_{REF+}}{\text{FULL\_SCALE}} \times \text{ADC\_DATA}$$

By replacing $V_{REF+}$ by the formula provided above, the absolute voltage value is given by the following formula

$$V_{\text{CHANNEL}x} = 3.3 \, V \times \frac{V_{REFINT\text{CAL}} \times \text{ADC\_DATA}}{V_{REFINT\text{DATA}} \times \text{FULL\_SCALE}}$$

For applications where $V_{DDA}$ is known and ADC converted values are right-aligned, the absolute voltage value can be obtained by using the following formula:

$$V_{\text{CHANNEL}x} = \frac{V_{DDA}}{\text{FULL\_SCALE}} \times \text{ADC\_DATA}$$

Where:

- $V_{REFINT\text{CAL}}$ is the $V_{REFINT}$ calibration value
- $\text{ADC\_DATA}$ is the value measured by the ADC on channel $x$ (right-aligned)
- $V_{REFINT\text{DATA}}$ is the actual $V_{REFINT}$ output value converted by the ADC
- $\text{FULL\_SCALE}$ is the maximum digital value of the ADC output. For example with 16-bit resolution, it will be $2^{16} - 1 = 65535$ or with 8-bit resolution, $2^8 - 1 = 255$.

Note: If ADC measurements are done using an output format other than 16-bit right-aligned, all the parameters must first be converted to a compatible format before the calculation is done.
24.5 ADC interrupts

For each ADC, an interrupt can be generated:

- After ADC power-up, when the ADC is ready (flag ADRDY)
- On the end of any conversion for regular groups (flag EOC)
- On the end of a sequence of conversion for regular groups (flag EOS)
- On the end of any conversion for injected groups (flag JEOC)
- On the end of a sequence of conversion for injected groups (flag JEOS)
- When an analog watchdog detection occurs (flag AWD1, AWD2 and AWD3)
- When the end of sampling phase occurs (flag EOSMP)
- When the data overrun occurs (OVR flag)
- When the injected sequence context queue overflows (flag JQOVF)

Separate interrupt enable bits are available for flexibility.

Bits 31:11 Reserved, must be kept at reset value.

- **Bit 10 JQOVF**: Injected context queue overflow
  - This bit is set by hardware when an Overflow of the Injected Queue of Context occurs. It is cleared by software writing 1 to it. Refer to Section 24.4.22: Queue of context for injected conversions for more information.
  - 0: No injected context queue overflow occurred (or the flag event was already acknowledged and cleared by software)
  - 1: Injected context queue overflow has occurred

- **Bit 9 AWD3**: Analog watchdog 3 flag
  - This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT3[7:0] and HT3[7:0] of ADC_TR3 register. It is cleared by software writing 1 to it.
  - 0: No analog watchdog 3 event occurred (or the flag event was already acknowledged and cleared by software)
  - 1: Analog watchdog 3 event occurred

- **Bit 8 AWD2**: Analog watchdog 2 flag
  - This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT2[7:0] and HT2[7:0] of ADC_TR2 register. It is cleared by software writing 1 to it.
  - 0: No analog watchdog 2 event occurred (or the flag event was already acknowledged and cleared by software)
  - 1: Analog watchdog 2 event occurred

- **Bit 7 AWD1**: Analog watchdog 1 flag
  - This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT1[11:0] and HT1[11:0] of ADC_TR1 register. It is cleared by software, writing 1 to it.
  - 0: No analog watchdog 1 event occurred (or the flag event was already acknowledged and cleared by software)
  - 1: Analog watchdog 1 event occurred

- **Bit 6 JEOS**: Injected channel end of sequence flag
  - This bit is set by hardware at the end of the conversions of all injected channels in the group. It is cleared by software writing 1 to it.
  - 0: Injected conversion sequence not complete (or the flag event was already acknowledged and cleared by software)
  - 1: Injected conversions complete
Bit 5  **JEOC**: Injected channel end of conversion flag
This bit is set by hardware at the end of each injected conversion of a channel when a new data is available in the corresponding ADC_JDRy register. It is cleared by software writing 1 to it or by reading the corresponding ADC_JDRy register.
0: Injected channel conversion not complete (or the flag event was already acknowledged and cleared by software)
1: Injected channel conversion complete

Bit 4  **OVR**: ADC overrun
This bit is set by hardware when an overrun occurs on a regular channel, meaning that a new conversion has completed while the EOC flag was already set. It is cleared by software writing 1 to it.
0: No overrun occurred (or the flag event was already acknowledged and cleared by software)
1: Overrun has occurred

Bit 3  **EOS**: End of regular sequence flag
This bit is set by hardware at the end of the conversions of a regular sequence of channels. It is cleared by software writing 1 to it.
0: Regular Conversions sequence not complete (or the flag event was already acknowledged and cleared by software)
1: Regular Conversions sequence complete

Bit 2  **EOC**: End of conversion flag
This bit is set by hardware at the end of each regular conversion of a channel when a new data is available in the ADC_DR register. It is cleared by software writing 1 to it or by reading the ADC_DR register.
0: Regular channel conversion not complete (or the flag event was already acknowledged and cleared by software)
1: Regular channel conversion complete

Bit 1  **EOSMP**: End of sampling flag
This bit is set by hardware during the conversion of any channel (only for regular channels), at the end of the sampling phase.
0: not at the end of the sampling phase (or the flag event was already acknowledged and cleared by software)
1: End of sampling phase reached

Bit 0  **ADRDY**: ADC ready
This bit is set by hardware after the ADC has been enabled (bit ADEN=1) and when the ADC reaches a state where it is ready to accept conversion requests.
It is cleared by software writing 1 to it.
0: ADC not yet ready to start conversion (or the flag event was already acknowledged and cleared by software)
1: ADC is ready to start conversion
24.6.2 ADC interrupt enable register (ADC_IER)

</table>

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **JQOVFIE**: Injected context queue overflow interrupt enable
This bit is set and cleared by software to enable/disable the Injected Context Queue Overflow interrupt.
0: Injected Context Queue Overflow interrupt disabled
1: Injected Context Queue Overflow interrupt enabled. An interrupt is generated when the JQOVF bit is set.

*Note: The software is allowed to write this bit only when JADSTART=0 (which ensures that no injected conversion is ongoing).*

Bit 9 **AWD3IE**: Analog watchdog 3 interrupt enable
This bit is set and cleared by software to enable/disable the analog watchdog 2 interrupt.
0: Analog watchdog 3 interrupt disabled
1: Analog watchdog 3 interrupt enabled

*Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

Bit 8 **AWD2IE**: Analog watchdog 2 interrupt enable
This bit is set and cleared by software to enable/disable the analog watchdog 2 interrupt.
0: Analog watchdog 2 interrupt disabled
1: Analog watchdog 2 interrupt enabled

*Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

Bit 7 **AWD1IE**: Analog watchdog 1 interrupt enable
This bit is set and cleared by software to enable/disable the analog watchdog 1 interrupt.
0: Analog watchdog 1 interrupt disabled
1: Analog watchdog 1 interrupt enabled

*Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

Bit 6 **JEOSIE**: End of injected sequence of conversions interrupt enable
This bit is set and cleared by software to enable/disable the end of injected sequence of conversions interrupt.
0: JEOS interrupt disabled
1: JEOS interrupt enabled. An interrupt is generated when the JEOS bit is set.

*Note: The software is allowed to write this bit only when JADSTART=0 (which ensures that no injected conversion is ongoing).*
Bit 5  **JEOCIE**: End of injected conversion interrupt enable
This bit is set and cleared by software to enable/disable the end of an injected conversion interrupt.
0: JEOC interrupt disabled.
1: JEOC interrupt enabled. An interrupt is generated when the JEOC bit is set.
*Note: The software is allowed to write this bit only when JADSTART is cleared to 0 (no injected conversion is ongoing).*

Bit 4  **OVRIE**: Overrun interrupt enable
This bit is set and cleared by software to enable/disable the Overrun interrupt of a regular conversion.
0: Overrun interrupt disabled
1: Overrun interrupt enabled. An interrupt is generated when the OVR bit is set.
*Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bit 3  **EOSIE**: End of regular sequence of conversions interrupt enable
This bit is set and cleared by software to enable/disable the end of regular sequence of conversions interrupt.
0: EOS interrupt disabled
1: EOS interrupt enabled. An interrupt is generated when the EOS bit is set.
*Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bit 2  **EOCIE**: End of regular conversion interrupt enable
This bit is set and cleared by software to enable/disable the end of a regular conversion interrupt.
0: EOC interrupt disabled
1: EOC interrupt enabled. An interrupt is generated when the EOC bit is set.
*Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bit 1  **EOSMPIE**: End of sampling flag interrupt enable for regular conversions
This bit is set and cleared by software to enable/disable the end of the sampling phase interrupt for regular conversions.
0: EOSMP interrupt disabled.
1: EOSMP interrupt enabled. An interrupt is generated when the EOSMP bit is set.
*Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bit 0  **ADRDYIE**: ADC ready interrupt enable
This bit is set and cleared by software to enable/disable the ADC Ready interrupt.
0: ADRDY interrupt disabled
1: ADRDY interrupt enabled. An interrupt is generated when the ADRDY bit is set.
*Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*
24.6.3  ADC control register (ADC_CR)

</table>
Bit 27  **LINCALRDYW6**: Linearity calibration ready Word 6

This control / status bit allows to read/write the 6th linearity calibration factor.

When the linearity calibration is complete, this bit is set. A bit clear will launch the transfer of the linearity factor 6 into the LINCALFACT[29:0] of the ADC_CALFACT2 register. The bit will be reset by hardware when the ADC_CALFACT2 register can be read (software must poll the bit until it is cleared).

When the LINCALRDYW6 bit is reset, a new linearity factor 6 value can be written into the LINCALFACT[29:0] of the ADC_CALFACT2 register. A bit set will launch the linearity factor 6 update and the bit will be effectively set by hardware once the update will be done (software must poll the bit until it is set to indicate the write is effective).

**Note:** ADC_CALFACT2[29:10] contains 0. ADC_CALFACT2[9:0] corresponds linearity correction factor bits[159:150].

The software is allowed to toggle this bit only if the LINCALRDYW5, LINCALRDYW4, LINCALRDYW3, LINCALRDYW2 and LINCALRDYW1 bits are left unchanged, see chapter 24.4.8: Calibration (ADCAL, ADCALDIF, ADCALLIN, ADC_CALFACT) for details.

The software is allowed to update the linearity calibration factor by writing LINCALRDYWx only when ADEN=1 and ADSTART=0 and JADSTART=0 (ADC enabled and no conversion is ongoing)

Bit 26  **LINCALRDYW5**: Linearity calibration ready Word 5

Refer to LINCALRDYW6 description.

**Note:** ADC_CALFACT2[29:0] corresponds linearity correction factor bits[149:120].

The software is allowed to toggle this bit only if the LINCALRDYW6, LINCALRDYW5, LINCALRDYW3, LINCALRDYW2 and LINCALRDYW1 bits are left unchanged.

Bit 25  **LINCALRDYW4**: Linearity calibration ready Word 4

Refer to LINCALRDYW6 description.

**Note:** ADC_CALFACT2[29:0] correspond linearity correction factor bits[119:90].

The software is allowed to toggle this bit only if the LINCALRDYW6, LINCALRDYW5, LINCALRDYW3, LINCALRDYW2 and LINCALRDYW1 bits are left unchanged.

Bit 24  **LINCALRDYW3**: Linearity calibration ready Word 3

Refer to LINCALRDYW6 description.

**Note:** ADC_CALFACT2[29:0] corresponds linearity correction factor bits[89:60].

The software is allowed to toggle this bit only if the LINCALRDYW6, LINCALRDYW5, LINCALRDYW4, LINCALRDYW2 and LINCALRDYW1 bits are left unchanged.

Bit 23  **LINCALRDYW2**: Linearity calibration ready Word 2

Refer to LINCALRDYW6 description.

**Note:** ADC_CALFACT2[29:0] corresponds linearity correction factor bits[59:30].

The software is allowed to toggle this bit only if the LINCALRDYW6, LINCALRDYW5, LINCALRDYW4, LINCALRDYW3 and LINCALRDYW1 bits are left unchanged.

Bit 22  **LINCALRDYW1**: Linearity calibration ready Word 1

Refer to LINCALRDYW6 description.

**Note:** ADC_CALFACT2[29:0] corresponds linearity correction factor bits[29:0].

The software is allowed to toggle this bit only if the LINCALRDYW6, LINCALRDYW5, LINCALRDYW4, LINCALRDYW3 and LINCALRDYW2 bits are left unchanged.

**Bits 21:17**  Reserved, must be kept at reset value.
Bit 16 ADCALLIN: Linearity calibration
This bit is set and cleared by software to enable the Linearity calibration.
0: Writing ADCAL will launch a calibration without the Linearity calibration.
1: Writing ADCAL will launch a calibration with the Linearity calibration.

Note: The software is allowed to write this bit only when the ADC is disabled and is not calibrating (ADCAL=0, JADSTART=0, JADSTP=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 BOOST: Boost mode control
This bit is set and cleared by software to enable/disable the Boost mode.
0: Boost mode off. Used when ADC clock < 20 MHz to save power at lower clock frequency.
1: Boost mode on. Must be used when ADC clock > 20 MHz.

Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

When dual mode is enabled (bits DAMDF of ADCx_CCR register are not equal to zero), the bit BOOST of the slave ADC is no more writable and its content must be equal to the master ADC BOOST bit.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 JADSTP: ADC stop of injected conversion command
This bit is set by software to stop and discard an ongoing injected conversion (JADSTP Command).
It is cleared by hardware when the conversion is effectively discarded and the ADC injected sequence and triggers can be re-configured. The ADC is then ready to accept a new start of injected conversions (JADSTART command).
0: No ADC stop injected conversion command ongoing
1: Write 1 to stop injected conversions ongoing. Read 1 means that an ADSTP command is in progress.

Note: The software is allowed to set JADSTP only when JADSTART=1 and ADDIS=0 (ADC is enabled and eventually converting an injected conversion and there is no pending request to disable the ADC).

In auto-injection mode (JAUTO=1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP).

Bit 4 ADSTP: ADC stop of regular conversion command
This bit is set by software to stop and discard an ongoing regular conversion (ADSTP Command).
It is cleared by hardware when the conversion is effectively discarded and the ADC regular sequence and triggers can be re-configured. The ADC is then ready to accept a new start of regular conversions (ADSTART command).
0: No ADC stop regular conversion command ongoing
1: Write 1 to stop regular conversions ongoing. Read 1 means that an ADSTP command is in progress.

Note: The software is allowed to set ADSTP only when ADSTART=1 and ADDIS=0 (ADC is enabled and eventually converting a regular conversion and there is no pending request to disable the ADC).

In auto-injection mode (JAUTO=1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP).

In dual ADC regular simultaneous mode and interleaved mode, the bit ADSTP of the master ADC must be used to stop regular conversions. The other ADSTP bit is inactive.
Bit 3  JADSTART: ADC start of injected conversion

This bit is set by software to start ADC conversion of injected channels. Depending on the configuration bits JEXTEN, a conversion will start immediately (software trigger configuration) or once an injected hardware trigger event occurs (hardware trigger configuration).

It is cleared by hardware:

- in single conversion mode when software trigger is selected (JEXTSEL=0x0): at the assertion of the End of Injected Conversion Sequence (JEOS) flag.
- in all cases: after the execution of the JADSTP command, at the same time that JADSTP is cleared by hardware.

0: No ADC injected conversion is ongoing.
1: Write 1 to start injected conversions. Read 1 means that the ADC is operating and eventually converting an injected channel.

Note: The software is allowed to set JADSTART only when ADEN=1 and ADDIS=0 (ADC is enabled and there is no pending request to disable the ADC).

In auto-injection mode (JAUTO=1), regular and auto-injected conversions are started by setting bit ADSTART (JADSTART must be kept cleared)
Bit 2 **ADSTART**: ADC start of regular conversion

This bit is set by software to start ADC conversion of regular channels. Depending on the configuration bits EXTEN, a conversion will start immediately (software trigger configuration) or once a regular hardware trigger event occurs (hardware trigger configuration).

It is cleared by hardware:
- in single conversion mode (CONT=0, DISCEN=0) when software trigger is selected (EXTEN=0x0): at the assertion of the End of Regular Conversion Sequence (EOS) flag.
- In discontinuous conversion mode (CONT=0, DISCEN=1), when the software trigger is selected (EXTEN=0x0): at the end of conversion (EOC) flag.
- in all other cases: after the execution of the ADSTP command, at the same time that ADSTP is cleared by hardware.

0: No ADC regular conversion is ongoing.
1: Write 1 to start regular conversions. Read 1 means that the ADC is operating and eventually converting a regular channel.

*Note: The software is allowed to set ADSTART only when ADEN=1 and ADDIS=0 (ADC is enabled and there is no pending request to disable the ADC)*

In auto-injection mode (JAUTO=1), regular and auto-injected conversions are started by setting bit ADSTART (JADSTART must be kept cleared)

Bit 1 **ADDIS**: ADC disable command

This bit is set by software to disable the ADC (ADDIS command) and put it into power-down state (OFF state).

It is cleared by hardware once the ADC is effectively disabled (ADEN is also cleared by hardware at this time).

0: no ADDIS command ongoing
1: Write 1 to disable the ADC. Read 1 means that an ADDIS command is in progress.

*Note: The software is allowed to set ADDIS only when ADEN=1 and both ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing)*

Bit 0 **ADEN**: ADC enable control

This bit is set by software to enable the ADC. The ADC will be effectively ready to operate once the flag ADRDY has been set.

It is cleared by hardware when the ADC is disabled, after the execution of the ADDIS command.

0: ADC is disabled (OFF state)
1: Write 1 to enable the ADC.

*Note: The software is allowed to set ADEN only when all bits of ADC_CR registers are 0 (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0) except for bit ADVREGEN which must be 1 (and the software must have wait for the startup time of the voltage regulator)*

Bit 31  **ADCAL**: ADC calibration  
This bit is set by software to start the calibration of the ADC. Program first the bit ADCALDIF to determine if this calibration applies for single-ended or differential inputs mode.  
It is cleared by hardware after calibration is complete.  
0: Calibration complete  
1: Write 1 to calibrate the ADC. Read at 1 means that a calibration in progress.  
*Note:* The software is allowed to launch a calibration by setting ADCAL only when ADEN=0.  
The software is allowed to update the calibration factor by writing ADC_CALFACT only when ADEN=1 and ADSTART=0 and JADSTART=0 (ADC enabled and no conversion is ongoing).

Bit 30  **ADCALDIF**: Differential mode for calibration  
This bit is set and cleared by software to configure the single-ended or differential inputs mode for the calibration.  
0: Writing ADCAL will launch a calibration in Single-ended inputs Mode.  
1: Writing ADCAL will launch a calibration in Differential inputs Mode.  
*Note:* The software is allowed to write this bit only when the ADC is disabled and is not calibrating (ADCAL=0, JADSTART=0, JADSTP=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

Bit 29  **DEEPPWD**: Deep-power-down enable  
This bit is set and cleared by software to put the ADC in deep-power-down mode.  
0: ADC not in deep-power-down  
1: ADC in deep-power-down (default reset state)  
*Note:* The software is allowed to write this bit only when the ADC is disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

Bit 28  **ADVREGEN**: ADC voltage regulator enable  
This bit is set by software to enable the ADC voltage regulator.  
Before performing any operation such as launching a calibration or enabling the ADC, the ADC voltage regulator must first be enabled and the software must wait for the regulator start-up time.  
0: ADC Voltage regulator disabled  
1: ADC Voltage regulator enabled.  
For more details about the ADC voltage regulator enable and disable sequences, refer to Section 24.4.6: ADC deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN).  
The software can program this bitfield only when the ADC is disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

Bit 27  **LINCALRDYW6**: Linearity calibration ready Word 6  
This control / status bit allows to read/write the 6th linearity calibration factor.  
When the linearity calibration is complete, this bit is set. A bit clear will launch the transfer of the linearity factor 6 into the LINCALFACT[29:0] of the ADC_CALFACT2 register. The bit will be reset by hardware when the ADC_CALFACT2 register can be read (software must poll the bit until it is cleared).  
When the LINCALRDYW6 bit is reset, a new linearity factor 6 value can be written into the LINCALFACT[29:0] of the ADC_CALFACT2 register. A bit set will launch the linearity factor 6 update and the bit will be effectively set by hardware once the update will be done (software must poll the bit until it is set to indicate the write is effective).  
*Note:* ADC_CALFACT2[29:10] contains 0. ADC_CALFACT2[9:0] corresponds linearity correction factor bits[159:150].  
The software is allowed to toggle this bit only if the LINCALRDYW5, LINCALRDYW4, LINCALRDYW3, LINCALRDYW2 and LINCALRDYW1 bits are left unchanged, see chapter 24.4.8: Calibration (ADCAL, ADCALDIF, ADCALIN, ADC_CALFACT) for details.  
The software is allowed to update the linearity calibration factor by writing LINCALRDYW6 only when ADEN=1 and ADSTART=0 and JADSTART=0 (ADC enabled and no conversion is ongoing).
Bit 26 **LINCALRDYW5**: Linearity calibration ready Word 5  
Refer to LINCALRDYW6 description.  
*Note:* ADC_CALFACT2[29:0] corresponds linearity correction factor bits[149:120].  
The software is allowed to toggle this bit only if the LINCALRDYW6, LINCALRDYW5, LINCALRDYW3, LINCALRDYW2 and LINCALRDYW1 bits are left unchanged.

Bit 25 **LINCALRDYW4**: Linearity calibration ready Word 4  
Refer to LINCALRDYW6 description.  
*Note:* ADC_CALFACT2[29:0] correspond linearity correction factor bits[119:90].  
The software is allowed to toggle this bit only if the LINCALRDYW6, LINCALRDYW5, LINCALRDYW3, LINCALRDYW2 and LINCALRDYW1 bits are left unchanged.

Bit 24 **LINCALRDYW3**: Linearity calibration ready Word 3  
Refer to LINCALRDYW6 description.  
*Note:* ADC_CALFACT2[29:0] correspond linearity correction factor bits[89:60].  
The software is allowed to toggle this bit only if the LINCALRDYW6, LINCALRDYW5, LINCALRDYW4, LINCALRDYW3 and LINCALRDYW1 bits are left unchanged.

Bit 23 **LINCALRDYW2**: Linearity calibration ready Word 2  
Refer to LINCALRDYW6 description.  
*Note:* ADC_CALFACT2[29:0] correspond linearity correction factor bits[59:30].  
The software is allowed to toggle this bit only if the LINCALRDYW6, LINCALRDYW5, LINCALRDYW4, LINCALRDYW3, LINCALRDYW2 and LINCALRDYW1 bits are left unchanged.

Bit 22 **LINCALRDYW1**: Linearity calibration ready Word 1  
Refer to LINCALRDYW6 description.  
*Note:* ADC_CALFACT2[29:0] correspond linearity correction factor bits[29:0].  
The software is allowed to toggle this bit only if the LINCALRDYW6, LINCALRDYW5, LINCALRDYW4, LINCALRDYW3 and LINCALRDYW2 bits are left unchanged.

Bits 21:17 Reserved, must be kept at reset value.

Bit 16 **ADCALLIN**: Linearity calibration  
This bit is set and cleared by software to enable the Linearity calibration.  
0: Writing ADCAL will launch a calibration without the Linearity calibration.  
1: Writing ADCAL will launch a calibration with the Linearity calibration.  
*Note:* The software is allowed to write this bit only when the ADC is disabled and is not calibrating (ADCAL=0, JADSTART=0, JADSTP=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:8 **BOOST[1:0]**: Boost mode control  
This bitfield is set and cleared by software to enable/disable the Boost mode.  
00: used when ADC clock ≤ 6.25 MHz  
01: used when 6.25 MHz < ADC clock frequency ≤ 12.5 MHz  
10: used when 12.5 MHz < ADC clock ≤ 25.0 MHz  
11: used when 25.0 MHz < ADC clock ≤ 50.0 MHz  
*Note:* The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).  
When dual mode is enabled (bits DAMDF of ADCx_CCR register are not equal to zero), the BOOST bitfield of the slave ADC is no more writable and its content must be equal to the master ADC BOOST bitfield.

Bits 7:6 Reserved, must be kept at reset value.
Bit 5  JADSTP: ADC stop of injected conversion command

This bit is set by software to stop and discard an ongoing injected conversion (JADSTP Command). It is cleared by hardware when the conversion is effectively discarded and the ADC injected sequence and triggers can be re-configured. The ADC is then ready to accept a new start of injected conversions (JADSTART command).

0: No ADC stop injected conversion command ongoing
1: Write 1 to stop injected conversions ongoing. Read 1 means that an ADSTP command is in progress.

Note: The software is allowed to set JADSTP only when JADSTART=1 and ADDIS=0 (ADC is enabled and eventually converting an injected conversion and there is no pending request to disable the ADC).

In auto-injection mode (JAUTO=1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP).

Bit 4  ADSTP: ADC stop of regular conversion command

This bit is set by software to stop and discard an ongoing regular conversion (ADSTP Command). It is cleared by hardware when the conversion is effectively discarded and the ADC regular sequence and triggers can be re-configured. The ADC is then ready to accept a new start of regular conversions (ADSTART command).

0: No ADC stop regular conversion command ongoing
1: Write 1 to stop regular conversions ongoing. Read 1 means that an ADSTP command is in progress.

Note: The software is allowed to set ADSTP only when ADSTART=1 and ADDIS=0 (ADC is enabled and eventually converting a regular conversion and there is no pending request to disable the ADC).

In auto-injection mode (JAUTO=1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP).

In dual ADC regular simultaneous mode and interleaved mode, the bit ADSTP of the master ADC must be used to stop regular conversions. The other ADSTP bit is inactive.

Bit 3  JADSTART: ADC start of injected conversion

This bit is set by software to start ADC conversion of injected channels. Depending on the configuration bits JEXTEN, a conversion will start immediately (software trigger configuration) or once an injected hardware trigger event occurs (hardware trigger configuration).

It is cleared by hardware:

– in single conversion mode when software trigger is selected (JEXTSEL=0x0): at the assertion of the End of Injected Conversion Sequence (JEOS) flag.
– in all cases: after the execution of the JADSTP command, at the same time that JADSTP is cleared by hardware.

0: No ADC injected conversion is ongoing.
1: Write 1 to start injected conversions. Read 1 means that the ADC is operating and eventually converting an injected channel.

Note: The software is allowed to set JADSTART only when ADEN=1 and ADDIS=0 (ADC is enabled and there is no pending request to disable the ADC).

In auto-injection mode (JAUTO=1), regular and auto-injected conversions are started by setting bit ADSTART (JADSTART must be kept cleared).
Bit 2  **ADSTART**: ADC start of regular conversion

This bit is set by software to start ADC conversion of regular channels. Depending on the configuration bits EXTen, a conversion will start immediately (software trigger configuration) or once a regular hardware trigger event occurs (hardware trigger configuration).

It is cleared by hardware:
- in single conversion mode (CONT=0, DISCEN=0) when software trigger is selected (EXTen=0x0): at the assertion of the End of Regular Conversion Sequence (EOS) flag.
- In discontinuous conversion mode (CONT=0, DISCEN=1), when the software trigger is selected (EXTen=0x0): at the end of conversion (EOC) flag.
- in all other cases: after the execution of the ADSTP command, at the same time that ADSTP is cleared by hardware.

0: No ADC regular conversion is ongoing.
1: Write 1 to start regular conversions. Read 1 means that the ADC is operating and eventually converting a regular channel.

*Note:* The software is allowed to set ADSTART only when ADEN=1 and ADDIS=0 (ADC is enabled and there is no pending request to disable the ADC)

In auto-injection mode (JAUTO=1), regular and auto-injected conversions are started by setting bit ADSTART (JADSTART must be kept cleared)

Bit 1  **ADDIS**: ADC disable command

This bit is set by software to disable the ADC (ADDIS command) and put it into power-down state (OFF state).

It is cleared by hardware once the ADC is effectively disabled (ADEN is also cleared by hardware at this time).

0: no ADDIS command ongoing
1: Write 1 to disable the ADC. Read 1 means that an ADDIS command is in progress.

*Note:* The software is allowed to set ADDIS only when ADEN=1 and both ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing)

Bit 0  **ADEN**: ADC enable control

This bit is set by software to enable the ADC. The ADC will be effectively ready to operate once the flag ADRDY has been set.

It is cleared by hardware when the ADC is disabled, after the execution of the ADDIS command.

0: ADC is disabled (OFF state)
1: Write 1 to enable the ADC.

*Note:* The software is allowed to set ADEN only when all bits of ADC_CR registers are 0 (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0) except for bit ADVREGEN which must be 1 (and the software must have wait for the startup time of the voltage regulator)
24.6.4 ADC configuration register (ADC_CFGR)

Address offset: 0x0C
Reset value: 0x8000 0000

Bit 31 **JQDIS**: Injected Queue disable

These bits are set and cleared by software to disable the Injected Queue mechanism:
0: Injected Queue enabled
1: Injected Queue disabled

*Note:* The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no regular nor injected conversion is ongoing).

A set or reset of JQDIS bit causes the injected queue to be flushed and the JSQR register is cleared.

Bits 30:26 **AWD1CH[4:0]**: Analog watchdog 1 channel selection

These bits are set and cleared by software. They select the input channel to be guarded by the analog watchdog.

00000: ADC analog input channel-0 monitored by AWD1
00001: ADC analog input channel-1 monitored by AWD1
......
10010: ADC analog input channel-19 monitored by AWD1
others: Reserved, must not be used

*Note:* The channel selected by AWD1CH must be also selected into the SQRi or JSQRi registers. The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

Bit 25 **JAUTO**: Automatic injected group conversion

This bit is set and cleared by software to enable/disable automatic injected group conversion after regular group conversion.
0: Automatic injected group conversion disabled
1: Automatic injected group conversion enabled

*Note:* The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no regular nor injected conversion is ongoing).

When dual mode is enabled (DAMDF bits in ADCx_CCR register are not equal to zero), the bit JAUTO of the slave ADC is no more writable and its content is equal to the bit JAUTO of the master ADC.

Bit 24 **JAWD1EN**: Analog watchdog 1 enable on injected channels

This bit is set and cleared by software
0: Analog watchdog 1 disabled on injected channels
1: Analog watchdog 1 enabled on injected channels

*Note:* The software is allowed to write this bit only when JADSTART=0 (which ensures that no injected conversion is ongoing).
Bit 23 **AWD1EN**: Analog watchdog 1 enable on regular channels

- This bit is set and cleared by software.
- 0: Analog watchdog 1 disabled on regular channels
- 1: Analog watchdog 1 enabled on regular channels

*Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bit 22 **AWD1SGL**: Enable the watchdog 1 on a single channel or on all channels

- This bit is set and cleared by software to enable the analog watchdog on the channel identified by the AWD1CH[4:0] bits or on all the channels.
- 0: Analog watchdog 1 enabled on all channels
- 1: Analog watchdog 1 enabled on a single channel

*Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

Bit 21 **JQM**: JSQR queue mode

- This bit is set and cleared by software.
- It defines how an empty Queue is managed.
- 0: JSQR Mode 0: The Queue is never empty and maintains the last written configuration into JSQR.
- 1: JSQR Mode 1: The Queue can be empty and when this occurs, the software and hardware triggers of the injected sequence are both internally disabled just after the completion of the last valid injected sequence.

Refer to Section 24.4.22: Queue of context for injected conversions for more information.

*Note: The software is allowed to write this bit only when JADSTART=0 (which ensures that no injected conversion is ongoing).*

When dual mode is enabled (DAMDF bits in ADCx_CCR register are not equal to zero), the bit JQM of the slave ADC is no more writable and its content is equal to the bit JQM of the master ADC.

Bit 20 **JDISCEN**: Discontinuous mode on injected channels

- This bit is set and cleared by software to enable/disable discontinuous mode on the injected channels of a group.
- 0: Discontinuous mode on injected channels disabled
- 1: Discontinuous mode on injected channels enabled

*Note: The software is allowed to write this bit only when JADSTART=0 (which ensures that no injected conversion is ongoing).*

It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

When dual mode is enabled (bits DAMDF of ADCx_CCR register are not equal to zero), the bit JDISCEN of the slave ADC is no more writable and its content is equal to the bit JDISCEN of the master ADC.

Bits 19:17 **DISCNUM[2:0]**: Discontinuous mode channel count

- These bits are written by software to define the number of regular channels to be converted in discontinuous mode, after receiving an external trigger.
- 000: 1 channel
- 001: 2 channels
- ...
- 111: 8 channels

*Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

When dual mode is enabled (DAMDF bits in ADCx_CCR register are not equal to zero), the bits DISCNUM[2:0] of the slave ADC are no more writable and their content is equal to the bits DISCNUM[2:0] of the master ADC.
Bit 16 **DISCEN**: Discontinuous mode for regular channels

This bit is set and cleared by software to enable/disable Discontinuous mode for regular channels.

- 0: Discontinuous mode for regular channels disabled
- 1: Discontinuous mode for regular channels enabled

**Note:** It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN=1 and CONT=1.

It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).

When dual mode is enabled (DAMDF bits in ADCx_CCR register are not equal to zero), the bit DISCEN of the slave ADC is no more writable and its content is equal to the bit DISCEN of the master ADC.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **AUTDLY**: Delayed conversion mode

This bit is set and cleared by software to enable/disable the Auto Delayed Conversion mode.

- 0: Auto-delayed conversion mode off
- 1: Auto-delayed conversion mode on

**Note:** The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

When dual mode is enabled (DAMDF bits in ADCx_CCR register are not equal to zero), the bit AUTDLY of the slave ADC is no more writable and its content is equal to the bit AUTDLY of the master ADC.

Bit 13 **CONT**: Single / continuous conversion mode for regular conversions

This bit is set and cleared by software. If it is set, regular conversion takes place continuously until it is cleared.

- 0: Single conversion mode
- 1: Continuous conversion mode

**Note:** It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN=1 and CONT=1.

The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).

When dual mode is enabled (DAMDF bits in ADCx_CCR register are not equal to zero), the bit CONT of the slave ADC is no more writable and its content is equal to the bit CONT of the master ADC.

Bit 12 **OVRMOD**: Overrun Mode

This bit is set and cleared by software and configure the way data overrun is managed.

- 0: ADC_DR register is preserved with the old data when an overrun is detected.
- 1: ADC_DR register is overwritten with the last conversion result when an overrun is detected.

**Note:** The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bits 11:10 **EXTEN[1:0]**: External trigger enable and polarity selection for regular channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of a regular group.

- 00: Hardware trigger detection disabled (conversions can be launched by software)
- 01: Hardware trigger detection on the rising edge
- 10: Hardware trigger detection on the falling edge
- 11: Hardware trigger detection on both the rising and falling edges

**Note:** The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).
Bits 9:5 **EXTSEL[4:0]**: External trigger selection for regular group

These bits select the external event used to trigger the start of conversion of a regular group:

- 00000: Event 0
- 00001: Event 1
- 00010: Event 2
- 00011: Event 3
- 00100: Event 4
- 00101: Event 5
- 00110: Event 6
- 00111: Event 7
- ...
- 11111: Event 31

*Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bits 4:2 **RES[2:0]**: Data resolution

These bits are written by software to select the resolution of the conversion.

- 000: 16 bits
- 001: 14 bits
- 010: 12 bits
- 011: 10 bits
- 100: 8-bit on devices revision Y
- 111: 8-bit on devices revision V
- Others: Reserved.

*Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

Bits 1:0 **DMNGT[1:0]**: Data Management configuration

This bit is set and cleared by software to select how ADC interface output data are managed.

- 00: Regular conversion data stored in DR only
- 01: DMA One Shot Mode selected
- 10: DFSDM mode selected
- 11: DMA Circular Mode selected

*Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

In dual-ADC modes, this bit is not relevant and replaced by control bit DAMDF of the ADCx_CCR register.
24.6.5 ADC configuration register 2 (ADC_CFGR2)

Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no conversion is ongoing).

Bits 15 Reserved, must be kept at reset value.

Bit 14 RSHIFT4: Right-shift data after Offset 4 correction
Refer to RSHIFT1 description.
Bit 13 **RSHIFT3**: Right-shift data after Offset 3 correction
Refer to RSHIFT1 description

Bit 12 **RSHIFT2**: Right-shift data after Offset 2 correction
Refer to RSHIFT1 description

Bit 11 **RSHIFT1**: Right-shift data after Offset 1 correction
This bitfield is set and cleared by software to right-shift 1-bit data after offset1 correction. This bit can only be used for 8-bit and 16-bit data format (see Section: Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, RSHIFT, SSATE) for details).
0: Right-shifting disabled
1: Data is right-shifted 1-bit.

Bit 10 **ROVSM**: Regular Oversampling mode
This bit is set and cleared by software to select the regular oversampling mode.
0: Continued mode: When injected conversions are triggered, the oversampling is temporary stopped and continued after the injection sequence (oversampling buffer is maintained during injected sequence)
1: Resumed mode: When injected conversions are triggered, the current oversampling is aborted and resumed from start after the injection sequence (oversampling buffer is zeroed by injected sequence start)

Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no conversion is ongoing).

Bit 9 **TROVS**: Triggered Regular Oversampling
This bit is set and cleared by software to enable triggered oversampling
0: All oversampled conversions for a channel are done consecutively following a trigger
1: Each oversampled conversion for a channel needs a new trigger

Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no conversion is ongoing).

Bits 8:5 **OVSS[3:0]**: Oversampling right shift
This bitfield is set and cleared by software to define the right shifting applied to the raw oversampling result.
0000: No right shift
0001: Shift right 1-bit
0010: Shift right 2-bits
0011: Shift right 3-bits

1001: Shift right 9-bits
1010: Shift right 10-bits
1011: Shift right 11-bits
Others: Reserved.

Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no conversion is ongoing).
Bits 4:2 Reserved, must be kept at reset value.

Bit 1  **JOVSE**: Injected Oversampling Enable
This bit is set and cleared by software to enable injected oversampling.
- 0: Injected Oversampling disabled
- 1: Injected Oversampling enabled

**Note:** The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing)

Bit 0  **ROVSE**: Regular Oversampling Enable
This bit is set and cleared by software to enable regular oversampling.
- 0: Regular Oversampling disabled
- 1: Regular Oversampling enabled

**Note:** The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing)

```
|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 31| 30| 29| 28| 27| 26| 25| 24| 23| 22| 21| 20| 19| 18| 17| 16| 15| 14| 13| 12| 11| 10|  9|  8|  7|  6|  5|  4|  3|  2|  1|  0|
```

- **Bits 31:20**: Reserved, must be kept at reset value.
- **Bits 19:0**: ADC_PCSEL[19:0]: Channel x (VinP[x]) preselection (x = 0 to 19)
  - These bits are written by software to preselect the input channel at I/O instance to be converted.
  - 0: Input Channel x (VinP[x]) is not preselected for conversion, the ADC conversion result with this channel shows wrong result.
  - 1: Input Channel x (VinP[x]) is preselected for conversion
  - Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

24.6.9 ADC watchdog threshold register 1 (ADC_LTR1)

Address offset: 0x20
Reset value: 0x0000 0000

```
|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 31| 30| 29| 28| 27| 26| 25| 24| 23| 22| 21| 20| 19| 18| 17| 16| 15| 14| 13| 12| 11| 10|  9|  8|  7|  6|  5|  4|  3|  2|  1|  0|
```

- **Bits 31:26**: Reserved, must be kept at reset value.
- **Bits 25:0**: ADC_LTR1[25:0]: Analog watchdog 1 lower threshold
  - These bits are written by software to define the lower threshold for the analog watchdog 1.
  - Refer to Section 24.4.30: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTRy, AWD_LTRy, AWDy)
  - Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).
24.6.10 ADC watchdog threshold register 1 (ADC_HTR1)

Address offset: 0x24
Reset value: 0x03FF FFFF

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ4[4:0]**: 4th conversion in regular sequence
These bits are written by software with the channel number (0..19) assigned as the 4th in the regular conversion sequence.

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ3[4:0]**: 3rd conversion in regular sequence
These bits are written by software with the channel number (0..19) assigned as the 3rd in the regular conversion sequence.

*Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ2[4:0]**: 2nd conversion in regular sequence
These bits are written by software with the channel number (0..19) assigned as the 2nd in the regular conversion sequence.

*Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ1[4:0]**: 1st conversion in regular sequence
These bits are written by software with the channel number (0..19) assigned as the 1st in the regular conversion sequence.

*Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bits 5:4 Reserved, must be kept at reset value.

Bits 3:0 **L[3:0]**: Regular channel sequence length
These bits are written by software to define the total number of conversions in the regular channel conversion sequence.

0000: 1 conversion
0001: 2 conversions
...
1111: 16 conversions

*Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

<td></td>
</tr>
</tbody>
</table>
Bits 8:7 **JEXTEN[1:0]**: External Trigger Enable and Polarity Selection for injected channels
These bits are set and cleared by software to select the external trigger polarity and enable the trigger of an injected group.
00: If JQDIS=0 (queue enabled), Hardware and software trigger detection disabled
00: If JQDIS=1 (queue disabled), Hardware trigger detection disabled (conversions can be launched by software)
01: Hardware trigger detection on the rising edge
10: Hardware trigger detection on the falling edge
11: Hardware trigger detection on both the rising and falling edges

*Note:* The software is allowed to write these bits only when JADSTART is cleared to 0 (no injected conversion is ongoing).

If JQM=1 and if the Queue of Context becomes empty, the software and hardware triggers of the injected sequence are both internally disabled (refer to **Section 24.4.22: Queue of context for injected conversions**)

Bits 6:2 **JEXTSEL[4:0]**: External Trigger Selection for injected group
These bits select the external event used to trigger the start of conversion of an injected group:
00000: Event 0
00001: Event 1
00010: Event 2
00011: Event 3
00100: Event 4
00101: Event 5
00110: Event 6
00111: Event 7
...
11111: Event 31:

*Note:* The software is allowed to write these bits only when JADSTART is cleared to 0 (no injected conversion is ongoing).

Bits 1:0 **JL[1:0]**: Injected channel sequence length
These bits are written by software to define the total number of conversions in the injected channel conversion sequence.
00: 1 conversion
01: 2 conversions
10: 3 conversions
11: 4 conversions

*Note:* The software is allowed to write these bits only when JADSTART is cleared to 0 (no injected conversion is ongoing).
24.6.17  ADC injected channel y offset register (ADC_OFRy)

</tr>
</tbody>
</table>

Bit 31  **SSATE**: Signed saturation Enable
This bit is written by software to enable or disable the Signed saturation feature.
This bit can be enabled only for 8-bit and 16-bit data format (see Section : Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, RSHIFT, SSATE) for details).
0: Offset is subtracted maintaining data integrity and extending result size (9-bit and 17-bit signed format).
1: Offset is subtracted and result is saturated to maintain result size.

**Note**: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

Bits 30:26  **OFFSETy_CH[4:0]**: Channel selection for the Data offset y
These bits are written by software to define the channel to which the offset programmed into bits OFFSETy[25:0] will apply.

**Note**: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

Bits 25:0  **OFFSETy[25:0]**: Data offset y for the channel programmed into bits OFFSETy_CH[4:0]
These bits are written by software to define the offset y to be subtracted from the raw converted data when converting a channel (can be regular or injected). The channel to which applies the data offset y must be programmed in the bits OFFSETy_CH[4:0]. The conversion result can be read from in the ADC_DR (regular conversion) or from in the ADC_JDRyi registers (injected conversion).

When OFFSETy[25:0] bitfield is reset, the offset compensation is disabled.

**Note**: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

If several offset (OFFSETy) point to the same channel, only the offset with the lowest x value is considered for the subtraction.

Ex: If OFFSET1.CH[4:0]=4 and OFFSET2.CH[4:0]=4, this is OFFSET1[25:0] which is subtracted when converting channel 4.
24.6.18 ADC injected channel y data register (ADC_JDRy)

Address offset: 0x80 + 0x04 * (y-1), (y= 1 to 4)
Reset value: 0x0000 0000

<table>

</tbody>
</table>

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 AWD2CH[19:0]: Analog watchdog 2 channel selection
These bits are set and cleared by software. They enable and select the input channels to be guarded by the analog watchdog 2.
AWD2CH[i] = 0: ADC analog input channel-i is not monitored by AWD2
AWD2CH[i] = 1: ADC analog input channel-i is monitored by AWD2
When AWD2CH[19:0] = 000...0, the analog Watchdog 2 is disabled

Note: The channels selected by AWD2CH must be also selected into the SQRI or JSQRI registers.
The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

  These bits are set and cleared by software. They enable and select the input channels to be guarded by the analog watchdog 3.  
  - AWD3CH[i] = 0: ADC analog input channel-i is not monitored by AWD3  
  - AWD3CH[i] = 1: ADC analog input channel-i is monitored by AWD3  
  When AWD3CH[19:0] = 000...0, the analog Watchdog 3 is disabled  
  **Note:** The channels selected by AWD3CH must be also selected into the SQRI or JSQRi registers. The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

**LTR2[25:16]**
- Bits 31:26: Reserved, must be kept at reset value.
- Bits 25:0 **LTR2[25:0]:** Analog watchdog 2 lower threshold  
  These bits are written by software to define the lower threshold for the analog watchdog 2.  
  Refer to Section 24.4.30: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTRY, AWD_LTRY, AWDy).  
  **Note:** The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).
24.6.22  ADC watchdog higher threshold register 2 (ADC_HTR2)

Address offset: 0xB4
Reset value: 0x03FF FFFF

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 HTR2[25:0]: Analog watchdog 2 higher threshold
These bits are written by software to define the higher threshold for the analog watchdog 2.
Refer to Section 24.4.30: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTRy, AWD_LTRY, AWDy).
Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

24.6.23  ADC watchdog lower threshold register 3 (ADC_LTR3)

Address offset: 0xB8
Reset value: 0x0000 0000

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:0 LTR3[25:0]: Analog watchdog 3 lower threshold
These bits are written by software to define the lower threshold for the analog watchdog 3.
Refer to Section 24.4.30: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTRy, AWD_LTRy, AWDy)
Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).
24.6.24 ADC watchdog higher threshold register 3 (ADC_HTR3)

Address offset: 0xBC
Reset value: 0x03FF FFFF

Bits 31:26 Reserved, must be kept at reset value.
Bits 25:0 **HTR3[25:0]**: Analog watchdog 3 higher threshold
These bits are written by software to define the higher threshold for the analog watchdog 3. Refer to **Section 24.4.30: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTRY, AWD_LTRY, AWDy)**

**Note:** The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

24.6.25 ADC differential mode selection register (ADC_DIFSEL)

Address offset: 0xC0
Reset value: 0x0000 0000

Bits 31:20 Reserved, must be kept at reset value.
Bits 19:0 **DIFSEL[19:0]**: Differential mode for channels 19 to 0
These bits are set and cleared by software. They allow to select if a channel is configured as single ended or differential mode.

**DIFSEL[i] = 0:** ADC analog input channel-i is configured in single ended mode
**DIFSEL[i] = 1:** ADC analog input channel-i is configured in differential mode

**Note:** The software is allowed to write these bits only when the ADC is disabled (ADCAL=0, JADSTART=0, JADSTP=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).
24.6.26 ADC calibration factors register (ADC_CALFACT)

Address offset: 0xC4
Reset value: 0x0000 0000

<table>

</tbody>
</table>

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:16 CALFACT_D[10:0]: Calibration Factors in differential mode
These bits are written by hardware or by software.
Once a differential inputs calibration is complete, they are updated by hardware with the calibration factors.
Software can write these bits with a new calibration factor. If the new calibration factor is different from the current one stored into the analog ADC, it will then be applied once a new differential calibration is launched.

Note: The software is allowed to write these bits only when ADEN=1, ADSTART=0 and JADSTART=0 (ADC is enabled and no calibration is ongoing and no conversion is ongoing).

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:0 CALFACT_S[10:0]: Calibration Factors in Single-Ended mode
These bits are written by hardware or by software.
Once a single-ended inputs calibration is complete, they are updated by hardware with the calibration factors.
Software can write these bits with a new calibration factor. If the new calibration factor is different from the current one stored into the analog ADC, it will then be applied once a new single-ended calibration is launched.

Note: The software is allowed to write these bits only when ADEN=1, ADSTART=0 and JADSTART=0 (ADC is enabled and no calibration is ongoing and no conversion is ongoing).

LINCALFACT[15:0]

rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |
Bits 31:30  Reserved, must be kept at reset value.

Bits 29:0  **LINCALFACT[29:0]**: Linearity Calibration Factor

- These bits are written by hardware or by software.
- They hold 30-bit out of the 160-bit linearity calibration factor.
- Once a single-ended inputs calibration is complete, they are updated by hardware with the calibration factors.
- Software can write these bits with a new calibration factor. If the new calibration factor is different from the current one stored into the analog ADC, it will then be applied once a new single-ended calibration is launched.

**Note:** The software is allowed to write these bits only when ADEN=1, ADSTART=0 and JADSTART=0 (ADC is enabled and no calibration is ongoing and no conversion is ongoing).
24.7 ADC common registers

These registers define the control and status registers common to master and slave ADCs:

24.7.1 ADC x common status register (ADCx_CSR) (x=1/2 or 3)

Address offset: 0x00
Reset value: 0x0000 0000

The address offset is relative to the master ADC base address + 0x300.

This register provides an image of the status bits of the different ADCs. Nevertheless it is read-only and does not allow to clear the different status bits. Instead each status bit must be cleared by writing 0 to it in the corresponding ADC_ISR register.

ADC1 and ADC2 are controlled by the same interface, while ADC3 is controlled separately.

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 JQOVF_SLV: Injected Context Queue Overflow flag of the slave ADC
This bit is a copy of the JQOVF bit in the corresponding ADCx+1_ISR register.

Bit 25 AWD3_SLV: Analog watchdog 3 flag of the slave ADC
This bit is a copy of the AWD3 bit in the corresponding ADCx+1_ISR register.

Bit 24 AWD2_SLV: Analog watchdog 2 flag of the slave ADC
This bit is a copy of the AWD2 bit in the corresponding ADCx+1_ISR register.

Bit 23 AWD1_SLV: Analog watchdog 1 flag of the slave ADC
This bit is a copy of the AWD1 bit in the corresponding ADCx+1_ISR register.

Bit 22 JEOS_SLV: End of injected sequence flag of the slave ADC
This bit is a copy of the JEOS bit in the corresponding ADCx+1_ISR register.

Bit 21 JEOC_SLV: End of injected conversion flag of the slave ADC
This bit is a copy of the JEOC bit in the corresponding ADCx+1_ISR register.

Bit 20 OVR_SLV: Overrun flag of the slave ADC
This bit is a copy of the OVR bit in the corresponding ADCx+1_ISR register.

Bit 19 EOS_SLV: End of regular sequence flag of the slave ADC
This bit is a copy of the EOS bit in the corresponding ADCx+1_ISR register.

Bit 18 EOC_SLV: End of regular conversion of the slave ADC
This bit is a copy of the EOC bit in the corresponding ADCx+1_ISR register.

Bit 17 EOSMP_SLV: End of Sampling phase flag of the slave ADC
This bit is a copy of the EOSMP2 bit in the corresponding ADCx+1_ISR register.
Bit 16 **ADRDY_SLV**: Slave ADC ready  
This bit is a copy of the ADRDY bit in the corresponding ADCx+1_ISR register.

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 **JQOVF_MST**: Injected Context Queue Overflow flag of the master ADC  
This bit is a copy of the JQOVF bit in the corresponding ADC_ISR register.

Bit 9 **AWD3_MST**: Analog watchdog 3 flag of the master ADC  
This bit is a copy of the AWD3 bit in the corresponding ADC_ISR register.

Bit 8 **AWD2_MST**: Analog watchdog 2 flag of the master ADC  
This bit is a copy of the AWD2 bit in the corresponding ADC_ISR register.

Bit 7 **AWD1_MST**: Analog watchdog 1 flag of the master ADC  
This bit is a copy of the AWD1 bit in the corresponding ADC_ISR register.

Bit 6 **JEOS_MST**: End of injected sequence flag of the master ADC  
This bit is a copy of the JEOS bit in the corresponding ADC_ISR register.

Bit 5 **JEOC_MST**: End of injected conversion flag of the master ADC  
This bit is a copy of the JEOC bit in the corresponding ADC_ISR register.

Bit 4 **OVR_MST**: Overrun flag of the master ADC  
This bit is a copy of the OVR bit in the corresponding ADC_ISR register.

Bit 3 **EOS_MST**: End of regular sequence flag of the master ADC  
This bit is a copy of the EOS bit in the corresponding ADC_ISR register.

Bit 2 **EOC_MST**: End of regular conversion of the master ADC  
This bit is a copy of the EOC bit in the corresponding ADC_ISR register.

Bit 1 **EOSMP_MST**: End of Sampling phase flag of the master ADC  
This bit is a copy of the EOSMP bit in the corresponding ADC_ISR register.

Bit 0 **ADRDY_MST**: Master ADC ready  
This bit is a copy of the ADRDY bit in the corresponding ADC_ISR register.
## 24.7.2 ADC x common control register (ADCx_CCR) (x=1/2 or 3)

Address offset: 0x08  
Reset value: 0x0000 0000  
The address offset is relative to the master ADC base address + 0x300.

ADC1 and ADC2 are controlled by the same interface, while ADC3 is controlled separately.

</tr>
</tbody>
</table>
Bits 21:18 **PRESC[3:0]:** ADC prescaler

These bits are set and cleared by software to select the frequency of the clock to the ADC. The clock is common for all the ADCs.

- 0000: input ADC clock not divided
- 0001: input ADC clock divided by 2
- 0010: input ADC clock divided by 4
- 0011: input ADC clock divided by 6
- 0100: input ADC clock divided by 8
- 0101: input ADC clock divided by 10
- 0110: input ADC clock divided by 12
- 0111: input ADC clock divided by 16
- 1000: input ADC clock divided by 32
- 1001: input ADC clock divided by 64
- 1010: input ADC clock divided by 128
- 1011: input ADC clock divided by 256
- Others: Reserved.

*Note:* The software is allowed to write these bits only when the ADC is disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0). The ADC prescaler value is applied only when CKMODE[1:0] = 0b00.

Bits 17:16 **CKMODE[1:0]:** ADC clock mode

These bits are set and cleared by software to define the ADC clock scheme (which is common to both master and slave ADCs):

- 00: CK_ADCx (x=1 to 3) (Asynchronous clock mode), generated at product level (refer to Section Reset and Clock Control (RCC))
- 01: adc_hclk/1 (Synchronous clock mode). This configuration must be enabled only if the AHB clock prescaler is set to 1 (HPRE[3:0] = 0xxx in RCC_CFGR register) and if the system clock has a 50% duty cycle.
- 10: adc_hclk/2 (Synchronous clock mode)
- 11: adc_hclk/4 (Synchronous clock mode)

In all synchronous clock modes, there is no jitter in the delay from a timer trigger to the start of a conversion.

*Note:* The software is allowed to write these bits only when the ADCs are disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

Bits 15:14 **DAMDF[1:0]:** Dual ADC Mode Data Format

This bit-field is set and cleared by software. It specifies the data format in the common data register ADCx_CDR.

- 00: Dual ADC mode without data packing (ADCx_CDR and ADCx_CDR2 registers not used).
- 01: Reserved.
- 10: Data formatting mode for 32 down to 10-bit resolution
- 11: Data formatting mode for 8-bit resolution

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bits 13:12 Reserved, must be kept at reset value.
Bits 11:8 **DELAY[3:0]**: Delay between 2 sampling phases

These bits are set and cleared by software. These bits are used in dual interleaved modes.

Refer to Table 212 for the value of ADC resolution versus DELAY bits values.

*Note:* The software is allowed to write these bits only when the ADCs are disabled
(ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DUAL[4:0]**: Dual ADC mode selection

These bits are written by software to select the operating mode.

All the ADCs independent:
00000: Independent mode

00001 to 01001: Dual mode, master and slave ADCs working together

00001: Combined regular simultaneous + injected simultaneous mode

00010: Combined regular simultaneous + alternate trigger mode

00011: Combined Interleaved mode + injected simultaneous mode

00100: Reserved.

00101: Injected simultaneous mode only

00110: Regular simultaneous mode only

00111: Interleaved mode only

01001: Alternate trigger mode only

All other combinations are reserved and must not be programmed

*Note:* The software is allowed to write these bits only when the ADCs are disabled
(ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

**RDATA_SLV[15:0]**

Bits 31:16 **RDATA_SLV[15:0]**: Regular data of the slave ADC
In dual mode, these bits contain the regular data of the slave ADC. Refer to Section 24.4.32: Dual ADC modes.
The data alignment is applied as described in Section: Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, RSHIFT, SSATE).

Bits 15:0 **RDATA_MST[15:0]**: Regular data of the master ADC.
In dual mode, these bits contain the regular data of the master ADC. Refer to Section 24.4.32: Dual ADC modes.
The data alignment is applied as described in Section: Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, RSHIFT, SSATE).
In MDMA=0b11 mode, bits 15:8 contains SLV_ADC_DR[7:0], bits 7:0 contains MST_ADC_DR[7:0].

24.7.4 ADC x common regular data register for 32-bit dual mode
(ADCx_CDR2) (x=1/2 or 3)

Address offset: 0x10
Reset value: 0x0000 0000

The address offset is relative to the master ADC base address + 0x300.
ADC1 and ADC2 are controlled by the same interface, while ADC3 is controlled separately.

**Table 214. ADC register map and reset values for each ADC (offset=0x000 for master ADC, 0x100 for slave ADC) (continued)**

1. Revision Y devices feature only one BOOST bit.
Refer to Section 2.3 on page 126 for the register boundary addresses.
25 **Digital-to-analog converter (DAC)**

**25.1 Introduction**

The DAC module is a 12-bit, voltage output digital-to-analog converter. The DAC can be configured in 8- or 12-bit mode and may be used in conjunction with the DMA controller. In 12-bit mode, the data could be left- or right-aligned. The DAC features two output channels, each with its own converter. In dual DAC channel mode, conversions could be done independently or simultaneously when both channels are grouped together for synchronous update operations. An input reference pin, \( V_{REF+} \) (shared with others analog peripherals) is available for better resolution. An internal reference can also be set on the same input. Refer to **voltage reference buffer (VREFBUF)** section.

The DAC_OUTPUT pin can be used as general purpose input/output (GPIO) when the DAC output is disconnected from output pad and connected to on chip peripheral. The DAC output buffer can be optionally enabled to allow a high drive output current. An individual calibration can be applied on each DAC output channel. The DAC output channels support a low power mode, the Sample and Hold mode.

**25.2 DAC main features**

The DAC main features are the following (see **Figure 202: Dual-channel DAC block diagram**)

- One DAC interface, maximum two output channels
- Left or right data alignment in 12-bit mode
- Synchronized update capability
- Noise-wave and Triangular-wave generation
- Dual DAC channel for independent or simultaneous conversions
- DMA capability for each channel including DMA underrun error detection
- External triggers for conversion
- DAC output channel buffered/unbuffered modes
- Buffer offset calibration
- Each DAC output can be disconnected from the DAC_OUTPUT pin
- DAC output connection to on chip peripherals
- Sample and Hold mode for low power operation in Stop mode
- Input voltage reference from \( V_{REF+} \) pin or internal VREFBUF reference

**Figure 202** shows the block diagram of a DAC channel and **Table 217** gives the pin description.

25.4 DAC functional description

25.4.1 DAC block diagram

Figure 202. Dual-channel DAC block diagram

1. MODEEx bits in the DAC_MCR control the output mode and allow switching between the Normal mode in buffer/unbuffered configuration and the Sample and Hold mode.

2. Refer to Section 25.3: DAC implementation for channel2 availability.
25.4.2 DAC pins and internal signals

The DAC includes:

- Up to two output channels
- The DAC_OUTx can be disconnected from the output pin and used as an ordinary GPIO
- The dac_outx can use an internal pin connection to on-chip peripherals such as comparator, operational amplifier and ADC (if available).
- DAC output channel buffered or non buffered
- Sample and Hold block and registers operational in Stop mode, using LSI clock source for static conversion

The DAC includes up to two separate output channels. Each output channel can be connected to on-chip peripherals such as comparator, operational amplifier and ADC (if available). In this case, the DAC output channel can be disconnected from the DAC_OUTx output pin and the corresponding GPIO can be used for another purpose.

The DAC output can be buffered or not. The Sample and Hold block and its associated registers can run in Stop mode using the LSI clock source.

**25.4.3 DAC channel enable**

Each DAC channel can be powered on by setting its corresponding ENx bit in the DAC_CR register. The DAC channel is then enabled after a tWAKEUP startup time.

*Note:*  
The ENx bit enables the analog DAC channel x only. The DAC channel x digital interface is enabled even if the ENx bit is reset.

**25.4.4 DAC data format**

Depending on the selected configuration mode, the data have to be written into the specified register as described below:

- **Single DAC channel**
  
  There are three possibilities:
  
  - 8-bit right alignment: the software has to load data into the DAC_DHR8Rx[7:0] bits (stored into the DHRx[11:4] bits)
  - 12-bit left alignment: the software has to load data into the DAC_DHR12Lx [15:4] bits (stored into the DHRx[11:0] bits)
  - 12-bit right alignment: the software has to load data into the DAC_DHR12Rx [11:0] bits (stored into the DHRx[11:0] bits)

Depending on the loaded DAC_DHRyyyx register, the data written by the user is shifted and stored into the corresponding DHRx (data holding register, which are internal non-memory-mapped registers). The DHRx register is then loaded into the DORx register either automatically, by software trigger or by an external event trigger.

- **Dual DAC channels (when available)**
  
  There are three possibilities:
  
  - 8-bit right alignment: data for DAC channel 1 to be loaded into the DAC_DHR8RD [7:0] bits (stored into the DHR1[11:4] bits) and data for DAC channel 2 to be loaded into the DAC_DHR8RD [15:8] bits (stored into the DHR2[11:4] bits)
  - 12-bit left alignment: data for DAC channel 1 to be loaded into the DAC_DHR12LD [15:4] bits (stored into the DHR1[11:0] bits) and data for DAC channel 2 to be loaded into the DAC_DHR12LD [31:20] bits (stored into the DHR2[11:0] bits)
  - 12-bit right alignment: data for DAC channel 1 to be loaded into the DAC_DHR12RD [11:0] bits (stored into the DHR1[11:0] bits) and data for DAC channel 2 to be loaded into the DAC_DHR12RD [27:16] bits (stored into the DHR2[11:0] bits)

Depending on the loaded DAC_DHRyyyD register, the data written by the user is shifted and stored into DHR1 and DHR2 (data holding registers, which are internal non-memory-mapped registers). The DHR1 and DHR2 registers are then loaded into the DAC_DOR1.
and DOR2 registers, respectively, either automatically, by software trigger or by an external event trigger.

25.4.5 DAC conversion

The DAC_DORx cannot be written directly and any data transfer to the DAC channel must be performed by loading the DAC_DHRx register (write operation to DAC_DHR8Rx, DAC_DHR12Lx, DAC_DHR12Rx, DAC_DHR8RD, DAC_DHR12RD or DAC_DHR12LD).

Data stored in the DAC_DHRx register are automatically transferred to the DAC_DORx register after one dac_pclk clock cycle, if no hardware trigger is selected (TENx bit in DAC_CR register is reset). However, when a hardware trigger is selected (TENx bit in DAC_CR register is set) and a trigger occurs, the transfer is performed three dac_pclk clock cycles after the trigger signal.

When DAC_DORx is loaded with the DAC_DHRx contents, the analog output voltage becomes available after a time tSETTLING that depends on the power supply voltage and the analog output load.

Figure 205. Timing diagram for conversion with trigger disabled TEN = 0

25.4.6 DAC output voltage

Digital inputs are converted to output voltages on a linear conversion between 0 and VREF+.

The analog output voltages on each DAC channel pin are determined by the following equation:

\[
\text{DAC output} = \frac{V_{\text{REF}} \times \text{DOR}}{4096}
\]
25.4.7 DAC trigger selection

If the TENx control bit is set, conversion can then be triggered by an external event (timer counter, external interrupt line). The TSELx[3:0] control bits determine which out of 16 possible events will trigger conversion as shown in bits TSEL1[3:0] and TSEL2[3:0] in Table 219: DAC trigger selection.

Each time a DAC interface detects a rising edge on the selected trigger source (refer to the table below), the last data stored into the DAC_DHRx register are transferred into the DAC_DORx register. The DAC_DORx register is updated three dac_pclk cycles after the trigger occurs.

If the software trigger is selected, the conversion starts once the SWTRIG bit is set. SWTRIG is reset by hardware once the DAC_DORx register has been loaded with the DAC_DHRx register contents.

**Note:** *TSELx[3:0] bit cannot be changed when the ENx bit is set.*

*When software trigger is selected, the transfer from the DAC_DHRx register to the DAC_DORx register takes only one dac_pclk clock cycle.*

25.4.8 DMA requests

Each DAC channel has a DMA capability. Two DMA channels are used to service DAC channel DMA requests.

When an external trigger (but not a software trigger) occurs while the DMAENx bit is set, the value of the DAC_DHRx register is transferred into the DAC_DORx register when the transfer is complete, and a DMA request is generated.

In dual mode, if both DMAENx bits are set, two DMA requests are generated. If only one DMA request is needed, only the corresponding DMAENx bit should be set. In this way, the application can manage both DAC channels in dual mode by using one DMA request and a unique DMA channel.

As DAC_DHRx to DAC_DORx data transfer occurred before the DMA request, the very first data has to be written to the DAC_DHRx before the first trigger event occurs.

DMA underrun

The DAC DMA request is not queued so that if a second external trigger arrives before the acknowledgment for the first external trigger is received (first request), then no new request is issued and the DMA channelx underrun flag DMAUDRx in the DAC_SR register is set, reporting the error condition. The DAC channelx continues to convert old data.

The software should clear the DMAUDRx flag by writing 1, clear the DMAEN bit of the used DMA stream and re-initialize both DMA and DAC channelx to restart the transfer correctly. The software should modify the DAC trigger conversion frequency or lighten the DMA workload to avoid a new DMA underrun. Finally, the DAC conversion could be resumed by enabling both DMA data transfer and conversion trigger.

For each DAC channelx, an interrupt is also generated if its corresponding DMAUDRIEx bit in the DAC_CR register is enabled.

25.4.9 Noise generation

In order to generate a variable-amplitude pseudonoise, an LFSR (linear feedback shift register) is available. DAC noise generation is selected by setting WAVEx[1:0] to 01”. The preloaded value in LFSR is 0xAAA. This register is updated three dac_pclk clock cycles after each trigger event, following a specific calculation algorithm.
The LFSR value, that may be masked partially or totally by means of the MAMPx[3:0] bits in the DAC_CR register, is added up to the DAC_DHRx contents without overflow and this value is then transferred into the DAC_DORx register.

If LFSR is 0x0000, a ‘1’ is injected into it (antilock-up mechanism).

It is possible to reset LFSR wave generation by resetting the WAVEx[1:0] bits.

*Note:* The DAC trigger must be enabled for noise generation by setting the TENx bit in the DAC_CR register.
25.4.10 Triangle-wave generation

It is possible to add a small-amplitude triangular waveform on a DC or slowly varying signal. DAC triangle-wave generation is selected by setting WAVEx[1:0] to 10. The amplitude is configured through the MAMPx[3:0] bits in the DAC_CR register. An internal triangle counter is incremented three dac_pclk clock cycles after each trigger event. The value of this counter is then added to the DAC_DHRx register without overflow and the sum is transferred into the DAC_DORx register. The triangle counter is incremented as long as it is less than the maximum amplitude defined by the MAMPx[3:0] bits. Once the configured amplitude is reached, the counter is decremented down to 0, then incremented again and so on.

It is possible to reset triangle wave generation by resetting the WAVEx[1:0] bits.

Figure 208. DAC triangle wave generation

Figure 209. DAC conversion (SW trigger enabled) with triangle wave generation

Note: The DAC trigger must be enabled for triangle wave generation by setting the TENx bit in the DAC_CR register. The MAMPx[3:0] bits must be configured before enabling the DAC, otherwise they cannot be changed.
25.4.11 DAC channel modes

Each DAC channel can be configured in Normal mode or Sample and Hold mode. The output buffer can be enabled to allow a high drive capability. Before enabling output buffer, the voltage offset needs to be calibrated. This calibration is performed at the factory (loaded after reset) and can be adjusted by software during application operation.

Normal mode

In Normal mode, there are four combinations, by changing the buffer state and by changing the DAC_OUTx pin interconnections.

To enable the output buffer, the MODEx[2:0] bits in DAC_MCR register should be:

- 000: DAC is connected to the external pin
- 001: DAC is connected to external pin and to on-chip peripherals

To disable the output buffer, the MODEx[2:0] bits in DAC_MCR register should be:

- 010: DAC is connected to the external pin
- 011: DAC is connected to on-chip peripherals

Sample and Hold mode

In sample and Hold mode, the DAC core converts data on a triggered conversion, and then holds the converted voltage on a capacitor. When not converting, the DAC cores and buffer are completely turned off between samples and the DAC output is tri-stated, therefore reducing the overall power consumption. A new stabilization period, which value depends on the buffer state, is required before each new conversion.

In this mode, the DAC core and all corresponding logic and registers are driven by the low-speed clock (LSI) in addition to the dac_pclk clock, allowing to use the DAC channels in deep low power modes such as Stop mode.

The sample/hold mode operations can be divided into 3 phases:

1. Sample phase: the sample/hold element is charged to the desired voltage. The charging time depends on capacitor value (internal or external, selected by the user). The sampling time is configured with the TSAMPLEx[9:0] bits in DAC_SHSRx register. During the write of the TSAMPLEx[9:0] bits; the BWSTx bit in DAC_SR register is set to 1 to synchronize between both clocks domains (APB and low speed clock) and allowing the software to change the value of sample phase during the DAC channel operation

2. Hold phase: the DAC output channel is tri-stated, the DAC core and the buffer are turned off, to reduce the current consumption. The hold time is configured with the THOLDx[9:0] bits in DAC_SHHR register

3. Refresh phase: the refresh time is configured with the TREFRESHx[7:0] bits in DAC_SHRR register

The timings for the three phases above are in units of LSI clocks. As an example, to configure a sample time of 350 µs, a hold time of 2 ms and a refresh time of 100 µs assuming LSI ~32 KHz is selected:

- 12 cycles are required for sample phase: TSAMPLEx[9:0] = 11,
- 62 cycles are required for hold phase: THOLDx[9:0] = 62,
- and 4 cycles are required for refresh period: TREFRESHx[7:0] = 4.
In this example, the power consumption is reduced by almost a factor of 15 versus Normal modes.

The formulas to compute the right sample and refresh timings are described in the table below, the Hold time depends on the leakage current.

### Table 220. Sample and refresh timings

<table>
<thead>
<tr>
<th>Buffer State</th>
<th>$t_{SAMP}^{(1)(2)}$</th>
<th>$t_{REFRESH}^{(2)(3)}$</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable</td>
<td>$7 \mu s + (10 \times R_{BON} \times C_{SH})$</td>
<td>$7 \mu s + (R_{BON} \times C_{SH}) \times \ln(2 \times N_{LSB})$</td>
</tr>
<tr>
<td>Disable</td>
<td>$3 \mu s + (10 \times R_{BOFF} \times C_{SH})$</td>
<td>$3 \mu s + (R_{BOFF} \times C_{SH}) \times \ln(2 \times N_{LSB})$</td>
</tr>
</tbody>
</table>

1. In the above formula the settling to the desired code value with ½ LSB or accuracy requires 10 constant time for 12 bits resolution. For 8 bits resolution, the settling time is 7 constant time.
2. $C_{SH}$ is the capacitor in Sample and Hold mode.
3. The tolerated voltage drop during the hold phase “$V_d$” is represented by the number of LSBs after the capacitor discharging with the output leakage current. The settling back to the desired value with ½ LSB error accuracy requires $\ln(2 \times N_{LSB})$ constant time of the DAC.

**Example of the sample and refresh time calculation with output buffer on**

The values used in the example below are provided as indication only. Please refer to the product datasheet for product data.

$C_{SH} = 100 \text{nF}$

$V_{DDA} = 3.0 \text{V}$

**Sampling phase:**

$t_{SAMP} = 7 \mu s + (10 \times 2000 \times 100 \times 10^{-9}) = 2.007 \text{ms}$

(where $R_{BON} = 2 \text{k}\Omega$)

**Refresh phase:**

$t_{REFRESH} = 7 \mu s + (2000 \times 100 \times 10^{-9}) \times \ln(2 \times 10) = 606.1 \mu s$

(where $N_{LSB} = 10$ (10 LSB drop during the hold phase))

**Hold phase:**

$D_v = i_{\text{leak}} \times t_{\text{hold}} / C_{SH} = 0.0073 \text{V}$ (10 LSB of 12 bit at 3 V)

$i_{\text{leak}} = 150 \text{nA}$ (worst case on the IO leakage on all the temperature range)

$t_{\text{hold}} = 0.0073 \times 100 \times 10^{-9} / (150 \times 10^{-9}) = 4.867 \text{ms}$
Like in Normal mode, the Sample and Hold mode has different configurations.

To enable the output buffer, the MODEx[2:0] bits in DAC_MCR register should be:

- 100: DAC is connected to the external pin
- 101: DAC is connected to external pin and to on chip peripherals

To disabled the output buffer, The MODEx[2:0] bits in DAC_MCR register should be:

- 110: DAC is connected to external pin and to on chip peripherals
- 111: DAC is connected to on chip peripherals

When MODEx[2:0] bits in DAC_MCR register is equal to 111. An internal capacitor, C_{Lint} will hold the voltage output of the DAC Core and then drive it to on-chip peripherals.

All Sample and Hold phases are interruptible and any change in DAC_DHRx will trigger immediately a new sample phase.

25.4.12 DAC channel buffer calibration

The transfer function for an N-bit digital-to-analog converter (DAC) is:

\[ V_{\text{out}} = \left( \frac{D}{2^N - 1} \right) \times G \times V_{\text{ref}} + V_{\text{OS}} \]

Where \( V_{\text{OUT}} \) is the analog output, \( D \) is the digital input, \( G \) is the gain, \( V_{\text{ref}} \) is the nominal full-scale voltage, and \( V_{\text{os}} \) is the offset voltage. For an ideal DAC channel, \( G = 1 \) and \( V_{\text{os}} = 0 \).

Due to output buffer characteristics, the voltage offset may differ from part-to-part and introduce an absolute offset error on the analog output. To compensate the \( V_{\text{os}} \), a calibration is required by a trimming technique.

The calibration is only valid when the DAC channelx is operating with buffer enabled (MODEx[2:0] = 000b or 001b or 100b or 101b). If applied in other modes when the buffer is off, it has no effect. During the calibration:

- The buffer output will be disconnected from the pin internal/external connections and put in tristate mode (HiZ).
- The buffer will act as a comparator, to sense the middle-code value 0x800 and compare it to VREF+/2 signal through an internal bridge, then toggle its output signal to 0 or 1 depending on the comparison result (CAL_FLAGx bit).

Two calibration techniques are provided:

- Factory trimming (always enabled)
  The DAC buffer offset is factory trimmed. The default value of OTRIMx[4:0] bits in DAC_CCR register is the factory trimming value and it is loaded once DAC digital interface is reset.

- User trimming
  The user trimming can be done when the operating conditions differ from nominal factory trimming conditions and in particular when \( V_{\text{DD}}/V_{\text{DDA}} \) voltage, temperature, VREF+ values change and can be done at any point during application by software.

Note: Refer to the datasheet for more details of the Nominal factory trimming conditions

In addition, when \( V_{\text{DD}}/V_{\text{DDA}} \) is removed (example the device enters in STANDBY or VBAT modes) the calibration is required.

The steps to perform a user trimming calibration are as below:

<table>
<thead>
<tr>
<th>MODEx[2:0]</th>
<th>Mode</th>
<th>Buffer</th>
<th>Output connections</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 0 0</td>
<td>Sample and Hold mode</td>
<td>Enabled</td>
<td>Connected to external pin</td>
</tr>
<tr>
<td>1 0 1</td>
<td>Sample and Hold mode</td>
<td>Connected to external pin and to on chip peripherals (ex, comparators)</td>
<td></td>
</tr>
<tr>
<td>1 1 0</td>
<td>Sample and Hold mode</td>
<td>Disabled</td>
<td>Connected to external pin and to on chip peripherals (ex, comparators)</td>
</tr>
<tr>
<td>1 1 1</td>
<td>Sample and Hold mode</td>
<td>Disabled</td>
<td>Connected to on chip peripherals (ex, comparators)</td>
</tr>
</tbody>
</table>
1. If the DAC channel is active, write 0 to ENx bit in DAC_CR to disable the channel.
2. Select a mode where the buffer is enabled, by writing to DAC_MCR register, MODEx[2:0] = 000b or 001b or 100b or 101b.
3. Start the DAC channelx calibration, by setting the CENx bit in DAC_CR register to 1.
4. Apply a trimming algorithm:
   a) Write a code into OTRIMx[4:0] bits, starting by 00000b.
   b) Wait for tTRIM delay.
   c) Check if CAL_FLAGx bit in DAC_SR is set to 1.
   d) If CAL_FLAGx is set to 1 the trimming code OTRIMx[4:0] is found and will be used during operation to compensate the output value, else increment OTRIMx[4:0] and repeat sub-steps from (a) to (d) again.

The software algorithm may use either a successive approximation or dichotomy techniques to compute and set the content of OTRIMx[4:0] bits in a faster way.

The commutation/toggle of CAL_FLAGx bit indicates that the offset is correctly compensated and the corresponding trim code must be kept in the OTRIMx[4:0] bits in DAC_CCR register.

Note: A tTRIM delay must be respected between the write to the OTRIMx[4:0] bits and the read of the CAL_FLAGx bit in DAC_SR register in order to get a correct value. This parameter is specified into datasheet electrical characteristics section.

If the VDD/VDDA, VREF+ and temperature conditions will not change during the device operation while it enters more often in standby and VBAT mode, the software may store the OTRIMx[4:0] bits found in the first user calibration in the flash or in back-up registers. then to load/write them directly when the device power is back again thus avoiding to wait for a new calibration time.

When CENx bit is set, it is not allowed to set ENx bit.

25.4.13 Dual DAC channel conversion modes (if available)

To efficiently use the bus bandwidth in applications that require the two DAC channels at the same time, three dual registers are implemented: DHR8RD, DHR12RD and DHR12LD. A unique register access is then required to drive both DAC channels at the same time. For the wave generation, no accesses to DHRxxxD registers are required. As a result, two output channels can be used either independently or simultaneously.

11 conversion modes are possible using the two DAC channels and these dual registers. All the conversion modes can nevertheless be obtained using separate DHRx registers if needed.

All modes are described in the paragraphs below.

Independent trigger without wave generation

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).
When a DAC channel1 trigger arrives, the DHR1 register is transferred into DAC_DOR1 (three dac_pclk clock cycles later).

When a DAC channel2 trigger arrives, the DHR2 register is transferred into DAC_DOR2 (three dac_pclk clock cycles later).

**Independent trigger with single LFSR generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and the same LFSR mask value in the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_pclk clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel2 trigger arrives, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_pclk clock cycles later). Then the LFSR2 counter is updated.

**Independent trigger with different LFSR generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and set different LFSR masks values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_pclk clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel2 trigger arrives, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_pclk clock cycles later). Then the LFSR2 counter is updated.

**Independent trigger with single triangle generation**

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and the same maximum amplitude value in the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the DAC channel1 triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_pclk clock cycles later). The DAC channel1 triangle counter is then updated.

When a DAC channel2 trigger arrives, the DAC channel2 triangle counter, with the same triangle amplitude, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_pclk clock cycles later). The DAC channel2 triangle counter is then updated.

**Independent trigger with different triangle generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1[ and TSEL2 bits.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and set different maximum amplitude values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the DAC channel1 triangle counter, with a triangle amplitude configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_pclk clock cycles later). The DAC channel1 triangle counter is then updated.

When a DAC channel2 trigger arrives, the DAC channel2 triangle counter, with a triangle amplitude configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_pclk clock cycles later). The DAC channel2 triangle counter is then updated.

**Simultaneous software start**

To configure the DAC in this conversion mode, the following sequence is required:

- Load the dual DAC channel data to the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

In this configuration, one dac_pclk clock cycle later, the DHR1 and DHR2 registers are transferred into DAC_DOR1 and DAC_DOR2, respectively.

**Simultaneous trigger without wave generation**

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Load the dual DAC channel data to the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DHR1 and DHR2 registers are transferred into DAC_DOR1 and DAC_DOR2, respectively (after three dac_pclk clock cycles).

**Simultaneous trigger with single LFSR generation**

1. To configure the DAC in this conversion mode, the following sequence is required:
2. Set the two DAC channel trigger enable bits TEN1 and TEN2.
3. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
4. Configure the two DAC channel WAVEx[1:0] bits as 01 and the same LFSR mask value in the MAMPx[3:0] bits.
5. Load the dual DAC channel data to the desired DHR register (DHR12RD, DHR12LD or DHR8RD).

When a trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_pclk clock cycles later). The LFSR1 counter is then updated. At the same time, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_pclk clock cycles later). The LFSR2 counter is then updated.

**Simultaneous trigger with different LFSR generation**

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and set different LFSR mask values using the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_pclk clock cycles later). The LFSR1 counter is then updated. At the same time, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_pclk clock cycles later). The LFSR2 counter is then updated.

**Simultaneous trigger with single triangle generation**

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and the same maximum amplitude value using the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DAC channel1 triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_pclk clock cycles later). The DAC channel1 triangle counter is then updated.

At the same time, the DAC channel2 triangle counter, with the same triangle amplitude, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_pclk clock cycles later). The DAC channel2 triangle counter is then updated.

**Simultaneous trigger with different triangle generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and set different maximum amplitude values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DAC channel1 triangle counter, with a triangle amplitude configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three APB clock cycles later). Then the DAC channel1 triangle counter is updated.

At the same time, the DAC channel2 triangle counter, with a triangle amplitude configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three dac_pclk clock cycles later). Then the DAC channel2 triangle counter is updated.
25.5 DAC low-power modes

Table 222. Effect of low-power modes on DAC

</tbody>
</table>
Bits 27:24 **MAMP2[3:0]**: DAC channel 2 mask/amplitude selector

These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.

0000: Unmask bit 0 of LFSR/ triangle amplitude equal to 1
0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3
0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7
0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15
0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31
0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63
0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127
0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255
1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511
1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023
1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047
≥ 1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095

*Note:* These bits are available only on dual-channel DACs. Refer to Section 25.3: DAC implementation.

Bits 23:22 **WAVE2[1:0]**: DAC channel 2 noise/triangle wave generation enable

These bits are set/reset by software.

00: Wave generation disabled
01: Noise wave generation enabled
1x: Triangle wave generation enabled

*Note:* Only used if bit TEN2 = 1 (DAC channel 2 trigger enabled)

These bits are available only on dual-channel DACs. Refer to Section 25.3: DAC implementation.

Bits 21:18 **TSEL2[3:0]**: DAC channel 2 trigger selection

These bits select the external event used to trigger DAC channel 2.

Refer to the trigger selection tables for the details on trigger configuration and mapping.

*Note:* Only used if bit TEN2 = 1 (DAC channel 2 trigger enabled).

These bits are available only on dual-channel DACs. Refer to Section 25.3: DAC implementation.

Bit 17 **TEN2**: DAC channel 2 trigger enable

This bit is set and cleared by software to enable/disable DAC channel 2 trigger

0: DAC channel 2 trigger disabled and data written into the DAC_DHR2 register are transferred one dac_pclk clock cycle later to the DAC_DOR2 register
1: DAC channel 2 trigger enabled and data from the DAC_DHR2 register are transferred three dac_pclk clock cycles later to the DAC_DOR2 register

*Note:* When software trigger is selected, the transfer from the DAC_DHR2 register to the DAC_DOR2 register takes only one dac_pclk clock cycle.

These bits are available only on dual-channel DACs. Refer to Section 25.3: DAC implementation.

Bit 16 **EN2**: DAC channel 2 enable

This bit is set and cleared by software to enable/disable DAC channel 2.

0: DAC channel 2 disabled
1: DAC channel 2 enabled

*Note:* These bits are available only on dual-channel DACs. Refer to Section 25.3: DAC implementation.

Bit 15 Reserved, must be kept at reset value.
Bit 14  **CEN1**: DAC channel1 calibration enable
This bit is set and cleared by software to enable/disable DAC channel1 calibration, it can be written only if bit EN1=0 into DAC_CR (the calibration mode can be entered/exit only when the DAC channel is disabled) Otherwise, the write operation is ignored.
0: DAC channel1 in Normal operating mode
1: DAC channel1 in calibration mode

Bit 13  **DMAUDRIE1**: DAC channel1 DMA Underrun Interrupt enable
This bit is set and cleared by software.
0: DAC channel1 DMA Underrun Interrupt disabled
1: DAC channel1 DMA Underrun Interrupt enabled

Bit 12  **DMAEN1**: DAC channel1 DMA enable
This bit is set and cleared by software.
0: DAC channel1 DMA mode disabled
1: DAC channel1 DMA mode enabled

Bits 11:8  **MAMP1[3:0]**: DAC channel1 mask/amplitude selector
These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.
- 0000: Unmask bit0 of LFSR/ triangle amplitude equal to 1
- 0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3
- 0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7
- 0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15
- 0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31
- 0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63
- 0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127
- 0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255
- 1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511
- 1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023
- 1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047
- 1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095

Bits 7:6  **WAVE1[1:0]**: DAC channel1 noise/triangle wave generation enable
These bits are set and cleared by software.
- 00: wave generation disabled
- 01: Noise wave generation enabled
- 1x: Triangle wave generation enabled
Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).
Bits 5:2 **TSEL[3:0]**: DAC channel1 trigger selection

These bits select the external event used to trigger DAC channel1.

Refer to the trigger selection tables for the details on trigger configuration and mapping.

*Note: Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).*

Bit 1 **TEN1**: DAC channel1 trigger enable

This bit is set and cleared by software to enable/disable DAC channel1 trigger.

0: DAC channel1 trigger disabled and data written into the DAC_DHR1 register are transferred one dac_pclk clock cycle later to the DAC_DOR1 register.

1: DAC channel1 trigger enabled and data from the DAC_DHR1 register are transferred three dac_pclk clock cycles later to the DAC_DOR1 register.

*Note: When software trigger is selected, the transfer from the DAC_DHR1 register to the DAC_DOR1 register takes only one dac_pclk clock cycle.*

Bit 0 **EN1**: DAC channel1 enable

This bit is set and cleared by software to enable/disable DAC channel1.

0: DAC channel1 disabled

1: DAC channel1 enabled

### 25.7.2 DAC software trigger register (DAC_SWTRGR)

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **SWTRIG2**: DAC channel2 software trigger

This bit is set by software to trigger the DAC in software trigger mode.

0: No trigger

1: Trigger

*Note: This bit is cleared by hardware (one dac_pclk clock cycle later) once the DAC_DHR2 register value has been loaded into the DAC_DOR2 register.

This bit is available only on dual-channel DACs. Refer to Section 25.3: DAC implementation.*

Bit 0 **SWTRIG1**: DAC channel1 software trigger

This bit is set by software to trigger the DAC in software trigger mode.

0: No trigger

1: Trigger

*Note: This bit is cleared by hardware (one dac_pclk clock cycle later) once the DAC_DHR1 register value has been loaded into the DAC_DOR1 register.*

Bit 31 **BWST2**: DAC channel2 busy writing sample time flag  
This bit is systematically set just after Sample and Hold mode enable. It is set each time the software writes the register DAC_SHSR2. It is cleared by hardware when the write operation of DAC_SHSR2 is complete. (It takes about 3 LSI periods of synchronization).  
0: There is no write operation of DAC_SHSR2 ongoing; DAC_SHSR2 can be written  
1: There is a write operation of DAC_SHSR2 ongoing; DAC_SHSR2 cannot be written  
*Note:* This bit is available only on dual-channel DACs. Refer to Section 25.3: DAC implementation.

Bit 30 **CAL_FLAG2**: DAC channel2 calibration offset status  
This bit is set and cleared by hardware  
0: calibration trimming value is lower than the offset correction value  
1: calibration trimming value is equal or greater than the offset correction value  
*Note:* This bit is available only on dual-channel DACs. Refer to Section 25.3: DAC implementation.

Bit 29 **DMAUDR2**: DAC channel2 DMA underrun flag  
This bit is set by hardware and cleared by software (by writing it to 1).  
0: No DMA underrun error condition occurred for DAC channel2  
1: DMA underrun error condition occurred for DAC channel2 (the currently selected trigger is driving DAC channel2 conversion at a frequency higher than the DMA service capability rate).  
*Note:* This bit is available only on dual-channel DACs. Refer to Section 25.3: DAC implementation.

Bit 28 Reserved, must be kept at reset value.

Bit 27 Reserved, must be kept at reset value.

Bits 26:16 Reserved, must be kept at reset value.

Bit 15 **BWST1**: DAC channel1 busy writing sample time flag  
This bit is systematically set just after Sample and Hold mode enable and is set each time the software writes the register DAC_SHSR1. It is cleared by hardware when the write operation of DAC_SHSR1 is complete. (It takes about 3 LSI periods of synchronization).  
0: There is no write operation of DAC_SHSR1 ongoing; DAC_SHSR1 can be written  
1: There is a write operation of DAC_SHSR1 ongoing; DAC_SHSR1 cannot be written  

Bit 14 **CAL_FLAG1**: DAC channel1 calibration offset status  
This bit is set and cleared by hardware  
0: calibration trimming value is lower than the offset correction value  
1: calibration trimming value is equal or greater than the offset correction value  

Bit 13 **DMAUDR1**: DAC channel1 DMA underrun flag  
This bit is set by hardware and cleared by software (by writing it to 1).  
0: No DMA underrun error condition occurred for DAC channel1  
1: DMA underrun error condition occurred for DAC channel1 (the currently selected trigger is driving DAC channel1 conversion at a frequency higher than the DMA service capability rate)

Bit 12 Reserved, must be kept at reset value.

Bit 11 Reserved, must be kept at reset value.

Bits 10:0 Reserved, must be kept at reset value.
### 25.7.15 DAC calibration control register (DAC_CCR)

Address offset: 0x38  
Reset value: 0x00XX 00XX

<table>
<thead>
<tr>
<th>Bits 31:21</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
</table>
| Bits 20:16 | OTRIM2\[4:0\]: DAC channel2 offset trimming value  
These bits are available only on dual-channel DACs. Refer to Section 25.3: DAC implementation. |
| Bits 15:5  | Reserved, must be kept at reset value.  
Bits 4:0 OTRIM1\[4:0\]: DAC channel1 offset trimming value |

### 25.7.16 DAC mode control register (DAC_MCR)

Address offset: 0x3C  
Reset value: 0x0000 0000

| Bits 31:26 | Reserved, must be kept at reset value.  
Bit 25 Reserved, must be kept at reset value.  
Bit 24 Reserved, must be kept at reset value.  
Bits 23:19 Reserved, must be kept at reset value. |
Bits 18:16 **MODE2[2:0]**: DAC channel2 mode

These bits can be written only when the DAC is disabled and not in the calibration mode (when bit EN2=0 and bit CEN2 =0 in the DAC_CR register). If EN2=1 or CEN2 =1 the write operation is ignored.

They can be set and cleared by software to select the DAC channel2 mode:

- DAC channel2 in Normal mode
  - 000: DAC channel2 is connected to external pin with Buffer enabled
  - 001: DAC channel2 is connected to external pin and to on chip peripherals with buffer enabled
  - 010: DAC channel2 is connected to external pin with buffer disabled
  - 011: DAC channel2 is connected to on chip peripherals with Buffer disabled

- DAC channel2 in Sample and Hold mode
  - 100: DAC channel2 is connected to external pin with Buffer enabled
  - 101: DAC channel2 is connected to external pin and to on chip peripherals with Buffer enabled
  - 110: DAC channel2 is connected to external pin and to on chip peripherals with Buffer disabled
  - 111: DAC channel2 is connected to on chip peripherals with Buffer disabled

*Note: This register can be modified only when EN2=0.*

Refer to Section 25.3: DAC implementation for the availability of DAC channel2.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:10 Reserved, must be kept at reset value.

Bit 9 Reserved, must be kept at reset value.

Bit 8 Reserved, must be kept at reset value.

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **MODE1[2:0]**: DAC channel1 mode

These bits can be written only when the DAC is disabled and not in the calibration mode (when bit EN1=0 and bit CEN1 =0 in the DAC_CR register). If EN1=1 or CEN1 =1 the write operation is ignored.

They can be set and cleared by software to select the DAC channel1 mode:

- DAC channel1 in Normal mode
  - 000: DAC channel1 is connected to external pin with Buffer enabled
  - 001: DAC channel1 is connected to external pin and to on chip peripherals with Buffer enabled
  - 010: DAC channel1 is connected to external pin with Buffer disabled
  - 011: DAC channel1 is connected to on chip peripherals with Buffer disabled

- DAC channel1 in sample & hold mode
  - 100: DAC channel1 is connected to external pin with Buffer enabled
  - 101: DAC channel1 is connected to external pin and to on chip peripherals with Buffer enabled
  - 110: DAC channel1 is connected to external pin and to on chip peripherals with Buffer disabled
  - 111: DAC channel1 is connected to on chip peripherals with Buffer disabled

*Note: This register can be modified only when EN1=0.*
25.7.17 DAC channel1 sample and hold sample time register (DAC_SHSR1)

Address offset: 0x40
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
<th>Access</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:10</td>
<td>Reserved, must be kept at reset value.</td>
<td>rw</td>
</tr>
<tr>
<td>9:0</td>
<td>TSAMPLE1[9:0]: DAC channel1 sample time (only valid in Sample and Hold mode)</td>
<td>rw</td>
</tr>
</tbody>
</table>

These bits can be written when the DAC channel1 is disabled or also during normal operation. In the latter case, the write can be done only when BWST1 of DAC_SR register is low, if BWST1=1, the write operation is ignored.

Note: It represents the number of LSI clocks to perform a sample phase. Sampling time = (TSAMPLE1[9:0] + 1) x LSI clock period.

25.7.18 DAC channel2 sample and hold sample time register (DAC_SHSR2)

This register is available only on dual-channel DACs. Refer to Section 25.3: DAC implementation.

Address offset: 0x44
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bits</th>

26 Voltage reference buffer (VREFBUF)

26.1 Introduction

The STM32H742, STM32H743/753 and STM32H750 devices embed a voltage reference buffer which can be used as voltage reference for ADCs, DACs and also as voltage reference for external components through the VREF+ pin.

26.2 VREFBUF functional description

The internal voltage reference buffer supports four voltages\(^{(a)}\), which are configured with VRS bits in the VREFBUF_CSR register:

- VRS = 000: around 2.5 V.
- VRS = 001: around 2.048 V.
- VRS = 010: around 1.8 V.
- VRS = 011: around 1.5 V.

The internal voltage reference can be configured in four different modes depending on ENVR and HIZ bits configuration. These modes are provided in the table below:

<table>
<thead>
<tr>
<th>ENVR</th>
<th>HIZ</th>
<th>VREF buffer configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>VREFBUF buffer OFF:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VREF+ pin pulled-down to VSSA</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>External voltage reference mode (default value):</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VREFBUF buffer OFF</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VREF+ pin input mode</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>Internal voltage reference mode:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VREFBUF buffer ON</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VREF+ pin connected to VREFBUF buffer output</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Hold mode:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VREFBUF buffer OFF</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VREF+ pin floating. The voltage is held with the external capacitor</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VRR detection disabled and VRR bit keeps last state</td>
</tr>
</tbody>
</table>

After enabling the VREFBUF by setting ENVR bit and clearing HIZ bit in the VREFBUF_CSR register, the user must wait until VRR bit is set, meaning that the voltage reference output has reached its expected value.

---

\(a\). The minimum \(V_{DDA}\) voltage depends on VRS setting, refer to the product datasheet.

Bits 31:7  Reserved, must be kept at reset value.

Bits 6:4  VRS[2:0]: Voltage reference scale
These bits select the value generated by the voltage reference buffer.
000: Voltage reference set to 2.5 V
001: Voltage reference set to 2.048 V
010: Voltage reference set to 1.8 V
011: Voltage reference set to 1.5 V
Others: Reserved

Bit 3  VRR: Voltage reference buffer ready
0: the voltage reference buffer output is not ready.
1: the voltage reference buffer output reached the requested level.

Bit 2  Reserved, must be kept at reset value.

Bit 1  HIZ: High impedance mode
This bit controls the analog switch to connect or not the VREF+ pin.
0: VREF+ pin is internally connected to the voltage reference buffer output.
1: VREF+ pin is high impedance.
Refer to Table 225: VREF buffer modes for the mode descriptions depending on ENVR bit configuration.

Bit 0  ENVR: Voltage reference buffer mode enable
This bit is used to enable the voltage reference buffer mode.
0: Internal voltage reference mode disable (external voltage reference mode).
1: Internal voltage reference mode (reference buffer enable or hold mode) enable.
26.3.2  VREFBUF calibration control register (VREFBUF_CCR)

Refer to Section 2.3 on page 126 for the register boundary addresses.
27 Comparator (COMP)

27.1 Introduction
The device embeds two ultra-low-power comparator channels (COMP1 and COMP2). They can be used for a variety of functions including:
- wake up from low-power mode triggered by an analog signal
- analog signal conditioning
- cycle-by-cycle current control loop when combined with a PWM output from a timer

27.2 COMP main features
- Selectable inverting analog inputs:
  - I/O pins (different for either channel)
  - DAC Channel1 and Channel2 outputs
  - internal reference voltage and three sub multiple values (1/4, 1/2, 3/4) provided by scaler (buffered voltage divider)
- Two I/O pins per channel selectable as non-inverting analog inputs
- Programmable hysteresis
- Programmable speed / consumption
- Mapping of outputs to I/Os
- Redirection of outputs to timer inputs for triggering:
  - capture events
  - OCREF_CLR events (for cycle-by-cycle current control)
  - break events for fast PWM shutdowns
- Blanking of comparator outputs
- Window comparator
- Interrupt generation capability with wake up from Sleep and Stop modes (through the EXTI controller)
- Direct interrupt output to the CPU
27.3 COMP functional description

27.3.1 COMP block diagram

The block diagram of the comparators is shown in Figure 211: Comparator functional block diagram.

Figure 211. Comparator functional block diagram

27.3.2 COMP pins and internal signals

The I/Os used as comparator inputs must be configured in analog mode in the GPIO registers.

The comparator outputs can be connected to the I/Os through their alternate functions. Refer to the product datasheet.
The outputs can also be internally redirected to a variety of timer inputs for the following purposes:

- emergency shut-down of PWM signals, using BKIN and BKIN2 inputs
- cycle-by-cycle current control, using ETR inputs of timers
- input capture for timing measurements

The comparator output can be routed simultaneously internally and to the I/O pins.

</tr>
</tbody>
</table>
27.3.3 COMP reset and clocks

The clock comp_pclk provided by the clock controller is synchronous with the APB clock.

**Note:** Important: The polarity selection logic and the output redirection to the port works independently from the APB clock. This allows the comparator to work even in Stop mode. The interrupt line, connected to the NVIC of CPU, requires the APB clock (comp_pclk) to work. In absence of the APB clock, the interrupt signal comp_it cannot be generated.

27.3.4 Comparator LOCK mechanism

The comparators can be used for safety purposes, such as over-current or thermal protection. For applications with specific functional safety requirements, the comparator configuration can be protected against undesired alteration that could happen, for example, at program counter corruption.

For this purpose, the comparator configuration registers can be write-protected (read-only).

Upon configuring a comparator channel, its LOCK bit is set to 1. This causes the whole register set of the comparator channel, as well as the common COMP_OR register, to become read-only, the LOCK bit inclusive.

The write protection can only be removed through the MCU reset.

The COMP_OR register is locked by the LOCK bit of COMP_CFGR1 OR COMP_CFGR2.

27.3.5 Window comparator

The purpose of the window comparator is to monitor the analog voltage and check that it is comprised within the specified voltage range defined by lower and upper thresholds.

The window comparator requires both COMP channels. The monitored analog voltage is connected to their non-inverting (plus) inputs and the upper and lower threshold voltages are connected to the inverting (minus) input of either comparator, respectively. The non-inverting input of the COMP channel 2 can be connected internally with the non-inverting input of the COMP channel 1 by enabling WINMODE bit. This can save the input pins of COMP channel 2 for other purposes. See Figure 211: Comparator functional block diagram.

27.3.6 Hysteresis

The comparator includes a programmable hysteresis to avoid spurious output transitions in case of noisy signals. The hysteresis can be disabled if it is not needed (for instance when exiting from low-power mode) to be able to force the hysteresis value using external components.
27.3.7 Comparator output blanking function

The purpose of the blanking function is to prevent the current regulation to trip upon short current spikes at the beginning of the PWM period (typically the recovery current in power switches anti parallel diodes). It uses a blanking window defined with a timer output compare signal. Refer to the register description for selectable blanking signals. The blanking signal gates the internal comparator output such as to clean the comp_out from spurious pulses due to current spikes, as depicted in Figure 213 (the COMP channel number is not represented).

Figure 213. Comparator output blanking
27.3.8 Comparator output on GPIOs

The COMP1_OUT and COMP2_OUT outputs of the comparator channels are mapped to GPIOs through the AFOP field of the COMP_OR register, bits [10:0], and through the GPIO alternate function.

</tr>
<tr>
<td>PK2</td>
<td>AF10, AF11 (can be used as timer break in)</td>
</tr>
</tbody>
</table>
The assignment to GPIOs for both comparator channel outputs must be done before locking registers of any channel, because the common COMP_OR register is locked when locking the registers of either comparator channel.

### 27.3.9 Comparator output redirection

The outputs of either COMP channel can be redirected to timer break inputs (TIMx_BKIN or TIMx_BKIN2), as shown in Figure 214. For that end, the COMP channel output is connected to one of GPIOs programmable in alternate function as timer break input. See Table 229 and Table 230. The selected GPIO(s) must be set in open drain mode. The COMP output passes through the GPIO to the timer break input. With a pull-up resistor, the selected GPIO can be used as timer break input logic OR-ed with the comparator output.

![Figure 214. Output redirection](image)

### 27.3.10 COMP power and speed modes

The power consumption of the COMP channels versus propagation delay can be adjusted to have the optimum trade-off for a given application.

The bits PWRMODE[1:0] in COMP_CFRx registers can be programmed as follows:

- 00: High speed / full power
- 01: Medium speed / medium power
- 10: Medium speed / medium power
- 11: Very-low speed / ultra-low-power
27.4 COMP low-power modes

Table 231. Comparator behavior in the low-power modes

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect on the comparators. Comparator interrupts cause the device to exit the Sleep mode.</td>
</tr>
<tr>
<td>Stop</td>
<td>No effect on the comparators. Comparator interrupts cause the device to exit the Stop mode.</td>
</tr>
</tbody>
</table>

Note: The comparators cannot be used to exit the device from Sleep or Stop mode when the internal reference voltage is switched off.

27.5 COMP interrupts

There are two ways to use the comparator as interrupt source.

The comparator outputs are internally connected to the Extended interrupt and event controller. Each comparator has its own EXTI line and can generate either interrupts or events to make the device exit low-power modes.

The comparators also provide an interrupt line to the NVIC of CPU. This functionality is used when the CPU is active to handle low latency interrupt. It requires APB clock running.

27.5.1 Interrupt through EXTI block

Refer to Interrupt and events section for more details.

Sequence to enable the COMPx interrupt through EXTI block:
1. Configure the EXTI line, receiving the comp_wkup signal, in interrupt mode, select the rising, falling or either-edge sensitivity and enable the EXTI line.
2. Configure and enable the NVIC IRQ channel mapped to the corresponding EXTI lines.
3. Enable the COMPx.

Table 232. Interrupt control bits

</tbody>
</table>
27.5.2 Interrupt through NVIC of the CPU

Sequence to enable the COMPx interrupt through NVIC of the CPU:
1. Configure and enable the NVIC IRQ channel mapped to the comp_it line.
2. Configure and enable the ITEN in COMP_CFGRx.
3. Enable the COMPx.

Note: It is mandatory to enable APB clock to use this interrupt. If clock is not enabled, interrupt is not generated.

27.6 SCALER function

The scaler block is available to provide the different voltage reference levels to the comparator inputs. It is based on an amplifier driving a resistor bridge. The amplifier input is connected to the internal voltage reference.

The amplifier and the resistor bridge can be enabled separately. The amplifier is enabled by the SCALEN bits of the COMP_CFGRx registers. The resistor bridge is enabled by the BRGEN bits of the COMP_CFGRx registers.

When the resistor divided voltage is not used, the resistor bridge can be disconnected in order to reduce the consumption. When it is disconnected, the 1/4 VREF_COMP, 1/2 VREF_COMP and 3/4 VREF_COMP levels are equal to VREF_COMP.

Table 233. Interrupt control bits

Bit 31 **LOCK**: Lock bit
This bit is set by software and cleared by a hardware system reset. It locks the whole content of the COMP channel 1 configuration register COMP_CFRG1[31:0], and COMP_OR register

0: COMP_CFRG1[31:0] register is read/write
1: COMP_CFRG1[31:0] and COMP_OR registers are read-only

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:24 **BLANKING[3:0]**: COMP channel 1 blanking source selection bits

Bits of this field are set and cleared by software (only if LOCK not set).
The field selects the input source for COMP channel 1 output blanking:
0000: No blanking
0001: comp_blk1
0010: comp_blk2
0011: comp_blk3
0100: comp_blk4
0101: comp_blk5
0110: comp_blk6
All other values: reserved

Bits 23:21 Reserved, must be kept at reset value.

Bit 20 **INPSEL**: COMP channel 1 non-inverting input selection bit
This bit is set and cleared by software (only if LOCK not set).
0: COMP1_INP1 (PB0)
1: COMP1_InP2 (PB2)

Bit 19 Reserved, must be kept at reset value.
Bits 18:16 **INMSEL[2:0]**: COMP channel 1 inverting input selection field
These bits are set and cleared by software (only if LOCK not set). They select which input is connected to the input minus of COMP channel 1.

- 000 = 1/4 \(V_{REF\_COMP}\)
- 001 = 1/2 \(V_{REF\_COMP}\)
- 010 = 3/4 \(V_{REF\_COMP}\)
- 011 = \(V_{REF\_COMP}\)
- 100 = comp_inm1 (DAC channel 1 output)
- 101 = comp_inm2 (DAC channel 2 output)
- 110 = COMP1_INM1 (PB1)
- 111 = COMP1_INM2 (PC4)

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **PWRMODE[1:0]**: Power Mode of the COMP channel 1
These bits are set and cleared by software (only if LOCK not set). They control the power/speed of the COMP channel 1.

- 00: High speed / full power
- 01: Medium speed / medium power
- 10: Medium speed / medium power
- 11: Ultra low power / ultra-low-power

Bits 11:10 Reserved, must be kept at reset value.

Bits 9:8 **HYST[1:0]**: COMP channel 1 hysteresis selection bits
These bits are set and cleared by software (only if LOCK not set). They select the Hysteresis voltage of the COMP channel 1.

- 00: No hysteresis
- 01: Low hysteresis
- 10: Medium hysteresis
- 11: High hysteresis

Bit 7 Reserved, must be kept at reset value.

Bit 6 **ITEN**: COMP channel 1 interrupt enable
This bit is set and cleared by software (only if LOCK not set). This bit enable the interrupt generation of the COMP channel 1.

- 0: Interrupt generation disabled for COMP channel 1
- 1: Interrupt generation enabled for COMP channel 1

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **POLARITY**: COMP channel 1 polarity selection bit
This bit is set and cleared by software (only if LOCK not set). It inverts COMP channel 1 polarity.

- 0: COMP channel 1 output is not inverted
- 1: COMP channel 1 output is inverted
Comparator (COMP) RM0433

27.7.5 Comparator configuration register 2 (COMP_CFGR2)

The COMP_CFGR2 is the COMP channel 2 configuration register.

Address offset: 0x10

System reset value: 0x0000 0000

<table>
<thead>
<tr>

</table>
Bit 31  **LOCK**: Lock bit
This bit is set by software and cleared by a hardware system reset. It locks the whole content of the COMP channel 2 configuration register COMP_CFGR2[31:0], and COMP_OR register
0: COMP_CFGR2[31:0] register is read/write
1: COMP_CFGR2[31:0] and COMP_OR registers are read-only

Bits 30:28  Reserved, must be kept at reset value.

Bits 27:24  **BLANKING[3:0]**: COMP channel 2 blanking source selection bits
These bits are set and cleared by software (only if LOCK not set). These bits select which timer output controls the COMP channel 2 output blanking.

0000: No blanking
0001: TIM1 OC5 selected as blanking source
0010: TIM2 OC3 selected as blanking source
0011: TIM3 OC3 selected as blanking source
0100: TIM3 OC4 selected as blanking source
0101: TIM8 OC5 selected as blanking source
0110: TIM15 OC1 selected as blanking source
All other values: reserved

Bits 23:21  Reserved, must be kept at reset value.

Bit 20  **INPSEL**: COMP channel 2 non-inverting input selection bit
This bit is set and cleared by software (only if LOCK not set).
0: COMP2_INP1 (PE9)
1: COMP2_INP2 (PE11)

Bit 19  Reserved, must be kept at reset value.

Bits 18:16  **INMSEL[2:0]**: COMP channel 2 inverting input selection field
These bits are set and cleared by software (only if LOCK not set). They select which input is connected to the input minus of COMP channel 2.

000 = 1/4 VREF_COMP
001 = 1/2 VREF_COMP
010 = 3/4 VREF_COMP
011 = VREF_COMP
100 = comp_inm1 (DAC channel 1 output)
101 = comp_inm2 (DAC channel 2 output)
110 = COMP2_INM1 (PE10)
111 = COMP2_INM2 (PE7)

Bits 15:14  Reserved, must be kept at reset value.

Bits 13:12  **PWRMODE[1:0]**: Power Mode of the COMP channel 2
These bits are set and cleared by software (only if LOCK not set). They control the power/speed of the COMP channel 2.

00: High speed / full power
01: Medium speed / medium power
10: Medium speed / medium power
11: Ultra low power / ultra-low-power

Bits 11:10  Reserved, must be kept at reset value.
Bits 9:8 **HYST[1:0]**: COMP channel 2 hysteresis selection bits
These bits are set and cleared by software (only if LOCK not set). They select the Hysteresis voltage of the COMP channel 2.
- 00: No hysteresis
- 01: Low hysteresis
- 10: Medium hysteresis
- 11: High hysteresis

Bit 7 Reserved, must be kept at reset value.

Bit 6 **ITEN**: COMP channel 2 interrupt enable
This bit is set and cleared by software (only if LOCK not set). This bit enable the interrupt generation of the COMP channel 2.
- 0: Interrupt generation disabled for COMP channel 2
- 1: Interrupt generation enabled for COMP channel 2

Bit 5 Reserved, must be kept at reset value.

Bit 4 **WINMODE**: Window comparator mode selection bit
This bit is set and cleared by software (only if LOCK not set). This bit selects the window mode of the comparators. If set, the non-inverting input of COMP channel 2 is connected to the non-inverting input of the COMP channel 1.
Depending on the bit value, the non-inverting input of COMP channel 2 is connected to:
- 0: COMP2_INP input selector
- 1: Non-inverting input comp1_inp of COMP channel 1

Bit 3 **POLARITY**: COMP channel 2 polarity selection bit
This bit is set and cleared by software (only if LOCK not set). It inverts COMP channel 2 polarity.
- 0: COMP channel 2 output is not inverted
- 1: COMP channel 2 output is inverted

Bit 2 **SCALEN**: Voltage scaler enable bit
This bit is set and cleared by software (only if LOCK not set). This bit enables the $V_{REFINT}$ scaler for the COMP channels.
- 0: $V_{REFINT}$ scaler disabled (if SCALEN bit of COMP_CFGR1 register is also low)
- 1: $V_{REFINT}$ scaler enabled

Bit 1 **BRGEN**: Scaler bridge enable
This bit is set and cleared by software (only if LOCK not set). This bit enables the bridge of the scaler.
- 0: Scaler resistor bridge disabled (if BRGEN bit of COMP_CFGR1 register is also low)
- 1: Scaler resistor bridge enabled
If SCALEN is set and BRGEN is reset, all four scaler outputs provide the same level $V_{REF,COMP}$ (similar to $V_{REFINT}$).
If SCALEN and BRGEN are set, the four scaler outputs provide $V_{REF,COMP}$, $3/4 V_{REF,COMP}$, $1/2 V_{REF,COMP}$ and $1/4 V_{REF,COMP}$ levels, respectively.

Bit 0 **EN**: COMP channel 2 enable bit
This bit is set and cleared by software (only if LOCK not set). It enables the COMP channel 2.
- 0: Disable
- 1: Enable
### COMP register map

The following table summarizes the comparator registers.

#### Table 234. COMP register map and reset values

| Offset | Register name | 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |

Refer to Section 2.3 on page 126 for the register boundary addresses.
28 Operational amplifiers (OPAMP)

28.1 Introduction

The devices embed two operational amplifiers with two inputs and one output each. The three I/Os can be connected to the external pins, thus enabling any type of external interconnections. The operational amplifiers can be configured internally as a follower, as an amplifier with a non-inverting gain ranging from 2 to 16 or with inverting gain ranging from -1 to -15.

Refer to Section 28.3.3: Signal routing for detailed information on OPAMP input and output connection to internal peripherals.

28.2 OPAMP main features

- Rail-to-rail input and output voltage range
- Low input bias current (down to 1 nA)
- Low input offset voltage (1.5 mV after calibration, 10 mV with factory calibration)
- 7 MHz gain bandwidth
- High-speed mode to achieve a better slew rate

Note: Refer to the product datasheet for detailed OPAMP characteristics.

28.3 OPAMP functional description

The OPAMP has several modes.

Each OPAMP can be individually enabled, when disabled the output is high-impedance. When enabled, it can be in calibration mode, all input and output of the OPAMP are then disconnected, or in functional mode.

There are two functional modes, the high-speed mode and the normal mode. In functional mode the inputs and output of the OPAMP are connected as described in Section 28.3.3: Signal routing.

28.3.1 OPAMP reset and clocks

The operational amplifier clock is necessary for accessing the registers. When the application does not need to have read or write access to those registers, the clock can be switched off using the peripheral clock enable register (see OPAMPEN bit in Section 7.7.45: RCC APB1 Clock Register (RCC_APB1LENR)).

The bit OPAEN enables and disables the OPAMP operation. The OPAMP registers configurations should be changed before enabling the OPAEN bit in order to avoid spurious effects on the output.

When the output of the operational amplifier is no more needed the operational amplifier can be disabled to save power. All the configurations previously set (including the calibration) are maintained while OPAMP is disabled.
28.3.2 Initial configuration

The default configuration of the operational amplifier is a functional mode where the three input/outputs are connected to external pins. In the default mode the operational amplifier uses the factory trimming values for its offset calibration. See electrical characteristics section of the datasheet for factory trimming conditions, usually the temperature is 30 °C and the voltage is 3 V. The trimming values can be adjusted, see Section 28.3.5: Calibration for changing the trimming values. The default configuration uses the normal mode, which provides the standard performance. The bit OPAHSM can be set in order to switch the operational amplifier to high-speed mode for a better slew rate. Both normal and high-speed mode characteristics are defined in Section: Electrical characteristics of the datasheet.

As soon as the OPAEN bit in OPAMPx_CSR register is set, the operational amplifier is functional. The two input pins and the output pin are connected as defined in Section 28.3.3: Signal routing and the default connection settings can be changed.

Note: The inputs and output pins must be configured in analog mode (default state) in the corresponding GPIOx_MODER register.

28.3.3 Signal routing

The routing for the operational amplifier pins is determined by OPAMPx_CSR register.

The connections of the two operational amplifiers (OPAMP1 and OPAMP2) are described in the table below.

<table>
<thead>
<tr>
<th>Table 235. Operational amplifier possible connections</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Signal</strong></td>
</tr>
<tr>
<td>OPAMP1_VINM</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>OPAMP1_VINP</td>
</tr>
<tr>

</tr>
<tr>
<td>OPAMP2_VINM</td>
</tr>
<tr>
<td>OPAMP2_VINP</td>
</tr>
<tr>
<td>OPAMP2_VOUT(1)</td>
</tr>
</tbody>
</table>

1. Both OPAMP1_VOUT and OPAMP2_VOUT are not available on all packages. In this case, the unused I/O should not be activated since is internally set to a fixed configuration.
28.3.4 OPAMP modes

The operational amplifier inputs and outputs are all accessible on terminals. The amplifiers can be used in multiple configuration environments:

- Standalone mode (external gain setting mode)
- Follower configuration mode
- PGA modes

Note: The amplifier output pin is directly connected to the output pad to minimize the output impedance. When the amplifier is enabled, it cannot be used as a general purpose I/O, even if the amplifier is configured as a PGA and only connected to the internal channel.

The impedance of the signal must be maintained below a level which avoids the input leakage to create significant artifacts (due to a resistive drop in the source). Please refer to the electrical characteristics section in the datasheet for further details.

Standalone mode (external gain setting mode)

The procedure to use the OPAMP in standalone mode is presented hereafter.

Starting from the default value of OPAMPx_CSR, and the default state of GPIOx_MODER, as soon as the OPAEN bit is set, the two input pins and the output pin are connected to the operational amplifier.

This default configuration uses the factory trimming values and operates in normal mode (highest performance). The behavior of the OPAMP can be changed as follows:

- OPAHSM can be set to "operational amplifier high-speed" mode in order to have high slew rate.
- USERTRIM can be set to modify the trimming values for input offsets.
Follower configuration mode

The procedure to use the OPAMP in follower mode is presented hereafter.

- configure VM_SEL bits as “opamp_out connected to OPAMPx_VINM input”, 11
- configure VP_SEL bits as “GPIO connected to OPAMPx_VINP”, 00
- As soon as the OPAEN bit is set, the voltage on pin OPAMPx_VINP is buffered to pin OPAMPx_VOUT.

Note: The pin corresponding to OPAMPx_VINM is free for another usage.

The signal on the OPAMP1 output is also seen as an ADC input. As a consequence, the OPAMP configured in follower mode can be used to perform impedance adaptation on input signals before feeding them to the ADC input, assuming the input signal frequency is compatible with the operational amplifier gain bandwidth specification.

Figure 217. Follower configuration
Programmable gain amplifier mode

The procedure to use the OPAMP as programmable gain amplifier is presented hereafter.

- configure VM_SEL bits as “Feedback resistor is connected to OPAMPx_VINM input”, 10
- configure PGA_GAIN bits as “internal Gain 2, 4, 8 or 16”, 0000 to 0011
- configure VP_SEL bits as “GPIO connected to OPAMPx_VINP”, 00

As soon as the OPAEN bit is set, the voltage on pin OPAMPx_VINP is amplified by the selected gain and visible on pin OPAMPx_VOUT.

Note: To avoid saturation, the input voltage should stay below $V_{DDA}$ divided by the selected gain.

Figure 218. PGA mode, internal gain setting (x2/x4/x8/x16), inverting input not used
Programmable gain amplifier mode with external filtering

The procedure to use the OPAMP to amplify the amplitude of an input signal, with an external filtering, is presented hereafter.

- configure VM_SEL bits as “Feedback resistor is connected to OPAMPx_VINM input”, 10
- configure PGA_GAIN bits as “internal Gain 2, 4, 8 or 16 with filtering on INM0”, 0100 to 0111
- configure VP_SEL bits as “GPIO connected to OPAMPx_VINP”.

Any external connection on INM can be used in parallel with the internal PGA, for example a capacitor can be connected between opamp_out and INM for filtering purpose (see datasheet for the value of resistors used in the PGA resistor network).

Figure 219. PGA mode, internal gain setting (x2/x4/x8/x16), inverting input used for filtering

1. The gain depends on the cut-off frequency.
Programmable gain amplifier, non-inverting with external bias or inverting mode

The procedure to use the OPAMP to amplify the amplitude of an input signal with bias voltage for non-inverting mode or inverting mode.

- configure VM_SEL bits as “Feedback resistor is connected to OPAMPx_VINM input”,
- configure PGA_GAIN bits as “Inverting gain=-1,-3,-7,-15/ Non-inverting gain =2,4,8,16 with INM0”, 1000 to 1011
- configure VP_SEL bits as “GPIO connected to OPAMPx_VINP”.

*Figure 220. PGA mode, non-inverting gain setting (x2/x4/x8/x16) or inverting gain setting (x-1/x-3/x-7/x-15)*

*Figure 221. Example configuration*
Programmable gain amplifier, non-inverting with external bias or inverting mode with filtering

The procedure to use the OPAMP to amplify the amplitude of an input signal with bias voltage for non-inverting mode or inverting mode with filtering

- configure VM_SEL bits as “Feedback resistor is connected to OPAMPx_VINM input”, 10
- configure PGA_GAIN bits as “Inverting gain=-1,-3,-7,-15/ Non-inverting gain =2,4,8,16 with INM0, INM1 node for filtering”, 1100 to 1111
- configure VP_SEL bits as “GPIO connected to OPAMPx_VINP”.

Any external connection on VM1 can be used in parallel with the internal PGA, for example a capacitor can be connected between opamp_out and VM1 for filtering purpose (see datasheet for the value of resistors used in the PGA resistor network).

Figure 222. PGA mode, non-inverting gain setting (x2/x4/x8/x16) or inverting gain setting (x-1/x-3/x-7/x-15) with filtering

Figure 223. Example configuration
28.3.5 Calibration

The OPAMP interface continuously sends trimmed offset values to the operational amplifiers. At startup, the trimming values are initialized with the preset ‘factory’ trimming value.

Each operational amplifier can be trimmed by the user. Specific registers allow to have different trimming values for normal mode and for high-speed mode.

The aim of the calibration is to cancel as much as possible the OPAMP inputs offset voltage. The calibration circuitry allows to reduce the input offset voltage to less than +/-1.5 mV within stable voltage and temperature conditions.

For each operational amplifier and each mode two trimming value needs to be trimmed, one for N differential pair and one for P differential pair.

There are two registers for trimming the offsets for each operational amplifiers, one for normal mode (OPAMPx _OTR) and one high-speed mode (OPAMPx _HSOTR). Each register is composed of five bits for P differential pair trimming and five bits for N differential pair trimming. These are the ‘user’ values.

The user is able to switch from ‘factory’ values to ‘user’ trimmed values using the USERTRIM bit in the OPAMPx _CSR register. This bit is reset at startup and so the ‘factory’ value are applied by default to the OPAMP option registers.

User is liable to change the trimming values in calibration or in functional mode.

The offset trimming registers are typically configured after the calibration operation is initialized by setting bit CALON to 1. When CALON = 1 the inputs of the operational amplifier are disconnected from the functional environment.

- Setting CALSEL to 01 initializes the offset calibration for the P differential pair (low voltage reference used).
- Resetting CALSEL to 11 initializes the offset calibration for the N differential pair (high voltage reference used).

When CALON = 1, the bit CALOUT will reflect the influence of the trimming value selected by CALSEL and OPAHSM. The software should increment the TRIMOFFSETN bits in the OPAMP control register from 0x00 to the first value that causes the CALOUT bit to change from 1 to 0 in the OPAMP register. If the CALOUT bit is reset, the offset is calibrated correctly and the corresponding trimming value must be stored. The CALOUT flag needs up to 1 ms after the trimming value is changed to become steady (see tOFFTRIMmax delay specification in the electrical characteristics section of the datasheet).

**Note:** The closer the trimming value is to the optimum trimming value, the longer it takes to stabilize (with a maximum stabilization time remaining below 1 ms in any case).

</tr>
</tbody>
</table>
Calibration procedure

Here are the steps to perform a full calibration of either one of the operational amplifiers:

1. Set the OPAEN bit in OPAMPx_CSR to 1 to enable the operational amplifier.
2. Set the USERTRIM bit in the OPAMPx_CSR register to 1.
3. Choose a calibration mode (refer to Table 236: Operating modes and calibration). The steps 3 to 4 will have to be repeated 4 times. For the first iteration select
   - Normal mode and N differential pair
   The above calibration mode correspond to OPAHSM=0 and CALSEL=11 in the OPAMPx_CSR register.
4. Increment TRIMOFFSETN[4:0] in OPAMPx_OTR starting from 00000b until CALOUT changes to 0 in OPAMPx_CSR.

Note: Between the write to the OPAMPx_OTR register and the read of the CALOUT value, make sure to wait for the \( t_{\text{OFFTRIM}} \) delay specified in the electrical characteristics section of the datasheet, to get the correct CALOUT value.

The commutation means that the is correctly compensated and that the corresponding trim code must be saved in the OPAMPx_OTR register.

Repeat steps 3 to 4 for:
- Normal mode and P differential pair, CALSEL=01
- High-speed mode and N differential pair
- High-speed mode and P differential pair

If a mode is not used, it is not necessary to perform the corresponding calibration.

All operational amplifier can be calibrated at the same time.

Note: During the whole calibration phase the external connection of the operational amplifier output must not pull up or down currents higher than 500 µA.
28.4 OPAMP low-power modes

Table 237. Effect of low-power modes on the OPAMP

</tbody>
</table>

28.5 OPAMP PGA gain

When OPAMP is configured as PGA mode, it can select the gain of x2, x4, x8, x16 for non-inverting mode and x-1, x-3, x-7, x-15 for inverting mode.

When OPAMP is configured as non-inverting mode, the Gain error can be refer to the product datasheet. When it is configured as inverting mode, Gain factor is defined not only the on chip feedback resistor but also the signal source output impedance. If signal source output impedance is not negligible compared to the input feedback resistance of PGA, it will create the gain error. Please refer to the PGA resistance value in the product datasheet.

28.6 OPAMP registers

28.6.1 OPAMP1 control/status register (OPAMP1_CSR)

Address: 0x00
Reset value: 0x0000 0000

<table>

</tr>
</tbody>
</table>

Bit 31 Reserved, must be kept at reset value.

Bit 30 CALOUT: Operational amplifier calibration output
OPAMP output status flag. During the calibration mode, OPAMP is used as comparator.
0: Non-inverting < inverting
1: Non-inverting > inverting

Bit 29 TSTREF: OPAMP calibration reference voltage output control (reserved for test)
0: INTVREF of OPAMP is not output
1: INTVREF of OPAMP is output

Bits 28:19 Reserved, must be kept at reset value.
Bit 18 **USERTRIM**: User trimming enable
This bit allows to switch from ‘factory’ AOP offset trimmed values to ‘user’ AOP offset trimmed values
This bit is active for both mode normal and high-power.
0: ‘factory’ trim code used
1: ‘user’ trim code used

Bits 17:14 **PGA_GAIN**: Operational amplifier Programmable amplifier gain value
0000: Non-inverting internal Gain 2, VREF- referenced
0001: Non-inverting internal Gain 4, VREF- referenced
0010: Non-inverting internal Gain 8, VREF- referenced
0011: Non-inverting internal Gain 16, VREF- referenced
0100: Non-inverting internal Gain 2 with filtering on INM0, VREF- referenced
0101: Non-inverting internal Gain 4 with filtering on INM0, VREF- referenced
0110: Non-inverting internal Gain 8 with filtering on INM0, VREF- referenced
0111: Non-inverting internal Gain 16 with filtering on INM0, VREF- referenced
1000: Inverting gain=-1/ Non-inverting gain =2 with INM0 node for input or bias
1001: Inverting gain=-3/ Non-inverting gain =4 with INM0 node for input or bias
1010: Inverting gain=-7/ Non-inverting gain =8 with INM0 node for input or bias
1011: Inverting gain=-15/ Non-inverting gain =16 with INM0 node for input or bias
1100: Inverting gain=-1/ Non-inverting gain =2 with INM0 node for input or bias, INM1 node for filtering
1101: Inverting gain=-3/ Non-inverting gain =4 with INM0 node for input or bias, INM1 node for filtering
1110: Inverting gain=-7/ Non-inverting gain =8 with INM0 node for input or bias, INM1 node for filtering
1111: Inverting gain=-15/ Non-inverting gain =16 with INM0 node for input or bias, INM1 node for filtering

Bits 13:12 **CALSEL**: Calibration selection
It is used to select the offset calibration bus used to generate the internal reference voltage when CALON = 1 or FORCE_VP= 1.
00: 0.033*VDDA applied on OPAMP inputs
01: 0.1*VDDA applied on OPAMP inputs (for PMOS calibration)
10: 0.5*VDDA applied on OPAMP inputs
11: 0.9*VDDA applied on OPAMP inputs (for NMOS calibration)

Bit 11 **CALON**: Calibration mode enabled
0: Normal mode
1: Calibration mode (all switches opened by HW)

Bits 10:9 Reserved, must be kept at reset value.

Bit 8 **OPAHS**: Operational amplifier high-speed mode
The operational amplifier must be disable to change this configuration.
0: operational amplifier in normal mode
1: operational amplifier in high-speed mode

Bit 7 Reserved, must be kept at reset value.

        0: Non-inverting < inverting
        1: Non-inverting > inverting

Bit 29  **TSTREF**: OPAMP calibration reference voltage output control (reserved for test)
        0: INTVREF of OPAMP is not output
        1: INTVREF of OPAMP is output

Bits 28:19  Reserved, must be kept at reset value.

Bit 18  **USERTRIM**: User trimming enable
        This bit allows to switch from ‘factory’ AOP offset trimmed values to ‘user’ AOP offset trimmed values
        This bit is active for both mode normal and high-power.
        0: ‘factory’ trim code used
        1: ‘user’ trim code used

Bits 17:14  **PGA_GAIN**: Operational amplifier Programmable amplifier gain value
            0000: Non-inverting internal Gain 2, VREF- referenced
            0001: Non-inverting internal Gain 4, VREF- referenced
            0010: Non-inverting internal Gain 8, VREF- referenced
            0011: Non-inverting internal Gain 16, VREF- referenced
            0100: Non-inverting internal Gain 2 with filtering on INM0, VREF- referenced
            0101: Non-inverting internal Gain 4 with filtering on INM0, VREF- referenced
            0110: Non-inverting internal Gain 8 with filtering on INMINM0, VREF- referenced
            0111: Non-inverting internal Gain 16 with filtering on INM0, VREF- referenced
            1000: Inverting gain=-1/ Non-inverting gain =2 with INM0 node for input or bias
            1001: Inverting gain=-3/ Non-inverting gain =4 with INM0 node for input or bias
            1010: Inverting gain=-7/ Non-inverting gain =8 with INM0 node for input or bias
            1011: Inverting gain=-15/ Non-inverting gain =16 with INM0 node for input or bias
            1100: Inverting gain=-1/ Non-inverting gain =2 with INM0 node for input or bias, INM1 node for filtering
            1101: Inverting gain=-3/ Non-inverting gain =4 with INM0 node for input or bias, INM1 node for filtering
            1110: Inverting gain=-7/ Non-inverting gain =8 with INM0 node for input or bias, INM1 node for filtering
            1111: Inverting gain=-15/ Non-inverting gain =16 with INM0 node for input or bias, INM1 node for filtering

Bits 13:12  **CALSEL**: Calibration selection
            It is used to select the offset calibration bus used to generate the internal reference voltage when CALON = 1 or FORCE_VP= 1.
            00: 0.033*VDDA applied on OPAMP inputs
            01: 0.1*VDDA applied on OPAMP inputs (for PMOS calibration)
            10: 0.5*VDDA applied on OPAMP inputs
            11: 0.9*VDDA applied on OPAMP inputs (for NMOS calibration)

Bit 11  **CALON**: Calibration mode enabled
        0: Normal mode
        1: Calibration mode (all switches opened by HW)

Bits 10:9  Reserved, must be kept at reset value.
Bit 8 **OPAHSM**: Operational amplifier high-speed mode
The operational amplifier must be disable to change this configuration.
  0: operational amplifier in normal mode
  1: operational amplifier in high-speed mode

Bit 7 Reserved, must be kept at reset value.

Bits 6:5 **VM_SEL**: Inverting input selection
  00: INM0 connected to OPAMP INM input
  01: INM1 connected to OPAMP INM input
  10: Feedback resistor is connected to OPAMP INM input (PGA mode), Inverting input selection is depends on the PGA_GAIN setting
  11: opamp_out connected to OPAMP INM input (Follower mode)

Bit 4 Reserved, must be kept at reset value.

Bits 3:2 **VP_SEL**: Non inverted input selection
  00: GPIO connected to OPAMPx_VINP
  01: DAC connected to OPAMPx_VINP
  10: Reserved
  11: Reserved

Bit 1 **FORCE_VP**: Force internal reference on VP (reserved for test)
  0: Normal operating mode. Non-inverting input connected to inputs.
  1: Calibration verification mode: Non-inverting input connected to calibration reference voltage.

Bit 0 **OPAEN**: Operational amplifier Enable
  0: operational amplifier disabled
  1: operational amplifier enabled

Note: *If OPAMP2 is unconnected in a specific package, it must remain disabled (keep OPAMP2_CSR register default value).*

29 Digital filter for sigma delta modulators (DFSDM)

29.1 Introduction

Digital filter for sigma delta modulators (DFSDM) is a high-performance module dedicated to interface external ΣΔ modulators. It is featuring up to 8 external digital serial interfaces (channels) and up to 4 digital filters with flexible Sigma Delta stream digital processing options to offer up to 24-bit final ADC resolution. DFSDM also features optional parallel data stream input from internal ADC peripherals or from device memory.

An external ΣΔ modulator provides digital data stream of converted analog values from the external ΣΔ modulator analog input. This digital data stream is sent into a DFSDM input channel through a serial interface. DFSDM supports several standards to connect various ΣΔ modulator outputs: SPI interface and Manchester coded 1-wire interface (both with adjustable parameters). DFSDM module supports the connection of up to 8 multiplexed input digital serial channels which are shared with up to 4 DFSDM modules. DFSDM module also supports alternative parallel data inputs from up to 8 internal 16-bit data channels (from internal ADCs or from device memory).

DFSDM is converting an input data stream into a final digital data word which represents an analog input value on a ΣΔ modulator analog input. The conversion is based on a configurable digital process: the digital filtering and decimation of the input serial data stream.

The conversion speed and resolution are adjustable according to configurable parameters for digital processing: filter type, filter order, length of filter, integrator length. The maximum output data resolution is up to 24 bits. There are two conversion modes: single conversion mode and continuous mode. The data can be automatically stored in a system RAM buffer through DMA, thus reducing the software overhead.

A flexible timer triggering system can be used to control the start of conversion of DFSDM. This timing control is capable of triggering simultaneous conversions or inserting a programmable delay between conversions.

DFSDM features an analog watchdog function. Analog watchdog can be assigned to any of the input channel data stream or to final output data. Analog watchdog has its own digital filtering of input data stream to reach the required speed and resolution of watched data.

To detect short-circuit in control applications, there is a short-circuit detector. This block watches each input channel data stream for occurrence of stable data for a defined time duration (several 0’s or 1’s in an input data stream).

An extremes detector block watches final output data and stores maximum and minimum values from the output data values. The extremes values stored can be restarted by software.

Two power modes are supported: normal mode and stop mode.
29.2 DFSDM main features

- Up to 8 multiplexed input digital serial channels:
  - configurable SPI interface to connect various ΣΔ modulators
  - configurable Manchester coded 1 wire interface support
  - clock output for ΣΔ modulator(s)
- Alternative inputs from up to 8 internal digital parallel channels:
  - inputs with up to 16 bit resolution
  - internal sources: ADCs data or memory (CPU/DMA write) data streams
- Adjustable digital signal processing:
  - $\text{Sinc}^x$ filter: filter order/type (1..5), oversampling ratio (up to 1..1024)
  - integrator: oversampling ratio (1..256)
- Up to 24-bit output data resolution:
  - right bit-shifter on final data (0..31 bits)
- Signed output data format
- Automatic data offset correction (offset stored in register by user)
- Continuous or single conversion
- Start-of-conversion synchronization with:
  - software trigger
  - internal timers
  - external events
  - start-of-conversion synchronously with first DFSDM filter (DFSDM_FLT0)
- Analog watchdog feature:
  - low value and high value data threshold registers
  - own configurable $\text{Sinc}^x$ digital filter (order = 1..3, oversampling ratio = 1..32)
  - input from output data register or from one or more input digital serial channels
  - continuous monitoring independently from standard conversion
- Short-circuit detector to detect saturated analog input values (bottom and top ranges):
  - up to 8-bit counter to detect 1..256 consecutive 0’s or 1’s on input data stream
  - monitoring continuously each channel (8 serial channel transceiver outputs)
- Break generation on analog watchdog event or short-circuit detector event
- Extremes detector:
  - store minimum and maximum values of output data values
  - refreshed by software
- DMA may be used to read the conversion data
- Interrupts: end of conversion, overrun, analog watchdog, short-circuit, channel clock absence
- “regular” or “injected” conversions:
  - “regular” conversions can be requested at any time or even in continuous mode without having any impact on the timing of “injected” conversions
29.3 DFSDM implementation

This section describes the configuration implemented in DFSDMx.

29.4.3 DFSDM reset and clocks

DFSDM on-off control

The DFSDM interface is globally enabled by setting DFSDMEN=1 in the DFSDM_CH0CFGR1 register. Once DFSDM is globally enabled, all input channels (y=0..7) and digital filters DFSDM_FLTx (x=0..3) start to work if their enable bits are set (channel enable bit CHEN in DFSDM_CHyCFGR1 and DFSDM_FLTx enable bit DFEN in DFSDM_FLTxCR1).

Digital filter x DFSDM_FLTx (x=0..3) is enabled by setting DFEN=1 in the DFSDM_FLTxCR1 register. Once DFSDM_FLTx is enabled (DFEN=1), both Sincx digital filter unit and integrator unit are reinitialized.

By clearing DFEN, any conversion which may be in progress is immediately stopped and DFSDM_FLTx is put into stop mode. All register settings remain unchanged except DFSDM_FLTxAWSR and DFSDM_FLTxISR (which are reset).

Channel y (y=0..7) is enabled by setting CHEN=1 in the DFSDM_CHyCFGR1 register. Once the channel is enabled, it receives serial data from the external ΣΔ modulator or parallel internal data sources (ADCs or CPU/DMA wire from memory).

DFSDM must be globally disabled (by DFSDMEN=0 in DFSDM_CH0CFGR1) before stopping the system clock to enter in the STOP mode of the device.
DFSDM clocks

The internal DFSDM clock f_{DFSDMCLK}, which is used to drive the channel transceivers, digital processing blocks (digital filter, integrator) and next additional blocks (analog watchdog, short-circuit detector, extremes detector, control block) is generated by the RCC block and is derived from the system clock SYSCLK or peripheral clock PCLK2 (see DFSDMSEL bit description in ). The DFSDM clock is automatically stopped in stop mode (if DFEN = 0 for all DFSDM_FLTx, x=0..3).

The DFSDM serial channel transceivers can receive an external serial clock to sample an external serial data stream. The internal DFSDM clock must be at least 4 times faster than the external serial clock if standard SPI coding is used, and 6 times faster than the external serial clock if Manchester coding is used.

DFSDM can provide one external output clock signal to drive external $\Sigma\Delta$ modulator(s) clock input(s). It is provided on CKOUT pin. This output clock signal must be in the range specified in given device datasheet and is derived from DFSDM clock or from audio clock (see CKOUTSRC bit in DFSDM_CH0CFGR1 register) by programmable divider in the range 2 - 256 (CKOUTDIV in DFSDM_CH0CFGR1 register). Audio clock source is SAI1 clock selected by SAI1SEL[1:0] field in RCC configuration (see ).

29.4.4 Serial channel transceivers

There are 8 multiplexed serial data channels which can be selected for conversion by each filter or Analog watchdog or Short-circuit detector. Those serial transceivers receive data stream from external $\Sigma\Delta$ modulator. Data stream can be sent in SPI format or Manchester coded format (see SITP[1:0] bits in DFSDM_CHyCFGR1 register). The channel is enabled for operation by setting CHEN=1 in DFSDM_CHyCFGR1 register.

Channel inputs selection

Serial inputs (data and clock signals) from DATINy and CKINy pins can be redirected from the following channel pins. This serial input channel redirection is set by CHINSEL bit in DFSDM_CHyCFGR1 register.

Channel redirection can be used to collect audio data from PDM (pulse density modulation) stereo microphone type. PDM stereo microphone has one data and one clock signal. Data signal provides information for both left and right audio channel (rising clock edge samples for left channel and falling clock edge samples for right channel).

Configuration of serial channels for PDM microphone input:
- PDM microphone signals (data, clock) will be connected to DFSDM input serial channel y (DATINy, CKOUT) pins.
- Channel y will be configured: CHINSEL = 0 (input from given channel pins: DATINy, CKINy).
- Channel (y-1) (modulo 8) will be configured: CHINSEL = 1 (input from the following channel ((y-1)+1) pins: DATINy, CKINy).
- Channel y: SITP[1:0] = 0 (rising edge to strobe data) => left audio channel on channel y.
- Channel (y-1): SITP[1:0] = 1 (falling edge to strobe data) => right audio channel on channel y-1.
- Two DFSDM filters will be assigned to channel y and channel (y-1) (to filter left and right channels from PDM microphone).
Output clock generation

A clock signal can be provided on CKOUT pin to drive external ΣΔ modulator clock inputs. The frequency of this CKOUT signal is derived from DFSDM clock or from audio clock (see CKOUTSRC bit in DFSDM_CH0CFGR1 register) divided by a predivider (see CKOUTDIV bits in DFSDM_CH0CFGR1 register). If the output clock is stopped, then CKOUT signal is set to low state (output clock can be stopped by CKOUTDIV=0 in DFSDM_CHyCFGR1 register or by DFSDMEN=0 in DFSDM_CH0CFGR1 register). The output clock stopping is performed:

- 4 system clocks after DFSDMEN is cleared (if CKOUTSRC=0)
- 1 system clock and 3 audio clocks after DFSDMEN is cleared (if CKOUTSRC=1)

Before changing CKOUTSRC the software has to wait for CKOUT being stopped to avoid glitch on CKOUT pin. The output clock signal frequency must be in the range 0 - 20 MHz.
SPI data input format operation

In SPI format, the data stream is sent in serial format through data and clock signals. Data signal is always provided from DATINy pin. A clock signal can be provided externally from CKINy pin or internally from a signal derived from the CKOUT signal source.

In case of external clock source selection (SPICKSEL[1:0]=0) data signal (on DATINy pin) is sampled on rising or falling clock edge (of CKINy pin) according SITP[1:0] bits setting (in DFSDM_CHyCFGR1 register).

Internal clock sources - see SPICKSEL[1:0] in DFSDM_CHyCFGR1 register:

- **CKOUT signal:**
  - For connection to external ΣΔ modulator which uses directly its clock input (from CKOUT) to generate its output serial communication clock.
  - Sampling point: on rising/falling edge according SITP[1:0] setting.

- **CKOUT/2 signal (generated on CKOUT rising edge):**
  - For connection to external ΣΔ modulator which divides its clock input (from CKOUT) by 2 to generate its output serial communication clock (and this output clock change is active on each clock input rising edge).
  - Sampling point: on each second CKOUT falling edge.

- **CKOUT/2 signal (generated on CKOUT falling edge):**
  - For connection to external ΣΔ modulator which divides its clock input (from CKOUT) by 2 to generate its output serial communication clock (and this output clock change is active on each clock input falling edge).
  - Sampling point: on each second CKOUT rising edge.

Note: An internal clock source can only be used when the external ΣΔ modulator uses CKOUT signal as a clock input (to have synchronous clock and data operation).

Internal clock source usage can save CKINy pin connection (CKINy pins can be used for other purpose).

The clock source signal frequency must be in the range 0 - 20 MHz for SPI coding and less than $f_{DFSDMCLK}/4$.

Manchester coded data input format operation

In Manchester coded format, the data stream is sent in serial format through DATINy pin only. Decoded data and clock signal are recovered from serial stream after Manchester decoding. There are two possible settings of Manchester codings (see SITP[1:0] bits in DFSDM_CHyCFGR1 register):

- signal rising edge = log 0; signal falling edge = log 1
- signal rising edge = log 1; signal falling edge = log 0

The recovered clock signal frequency for Manchester coding must be in the range 0 - 10 MHz and less than $f_{DFSDMCLK}/6$.

To correctly receive Manchester coded data, the CKOUTDIV divider (in DFSDM_CH0CFGR1 register) must be set with respect to expected Manchester data rate according formula:

$$((\text{CKOUTDIV} + 1) \times T_{SYSLCLK}) < T_{\text{Manchester clock}} < (2 \times \text{CKOUTDIV} \times T_{SYSLCLK})$$

Clock absence detection

Channels serial clock inputs can be checked for clock absence/presence to ensure the correct operation of conversion and error reporting. Clock absence detection can be enabled or disabled on each input channel \( y \) by bit CKABEN in DFSDM\_CHyCFGR1 register. If enabled, then this clock absence detection is performed continuously on a given channel. A clock absence flag is set (CKABF\([y] = 1\)) and an interrupt can be invoked (if CKABIE\(=1\)) in case of an input clock error (see CKABF\([7:0]\) in DFSDM\_FLT0ISR register and CKABEN in DFSDM\_CHyCFGR1). After a clock absence flag clearing (by CLRCKABF in DFSDM\_FLT0ICR register), the clock absence flag is refreshed. Clock absence status bit CKABF\([y]\) is set also by hardware when corresponding channel \( y \) is disabled (if CHEN\([y] = 0\) then CKABF\([y]\) is held in set state).

When a clock absence event has occurred, the data conversion (and/or analog watchdog and short-circuit detector) provides incorrect data. The user should manage this event and discard given data while a clock absence is reported.

The clock absence feature is available only when the system clock is used for the CKOUT signal (CKOUTSRC\(=0\) in DFSDM\_CH0CFGR1 register).

When the transceiver is not yet synchronized, the clock absence flag is set and cannot be cleared by CLRCKABF\([y]\) bit (in DFSDM\_FLT0ICR register). The software sequence concerning clock absence detection feature should be:

- Enable given channel by CHEN = 1
- Try to clear the clock absence flag (by CLRCKABF = 1) until the clock absence flag is really cleared (CKABF = 0). At this time, the transceiver is synchronized (signal clock is valid) and is able to receive data.
- Enable the clock absence feature CKABEN = 1 and the associated interrupt CKABIE = 1 to detect if the SPI clock is lost or Manchester data edges are missing.

If SPI data format is used, then the clock absence detection is based on the comparison of an external input clock with an output clock generation (CKOUT signal). The external input clock signal into the input channel must be changed at least once per 8 signal periods of CKOUT signal (which is controlled by CKOUTDIV field in DFSDM\_CH0CFGR1 register).

**Figure 227. Clock absence timing diagram for SPI**

If Manchester data format is used, then the clock absence means that the clock recovery is unable to perform from Manchester coded signal. For a correct clock recovery, it is first necessary to receive data with 1 to 0 or 0 to 1 transition (see Figure 229 for Manchester synchronization).
The detection of a clock absence in Manchester coding (after a first successful synchronization) is based on changes comparison of coded serial data input signal with output clock generation (CKOUT signal). There must be a voltage level change on DATINy pin during 2 periods of CKOUT signal (which is controlled by CKOUTDIV bits in DFSDM_CH0CFGR1 register). This condition also defines the minimum data rate to be able to correctly recover the Manchester coded data and clock signals.

The maximum data rate of Manchester coded data must be less than the CKOUT signal. So to correctly receive Manchester coded data, the CKOUTDIV divider must be set according the formula:

\[(\text{CKOUTDIV}\times\text{TSYSCLK}) < T_{\text{Manchester clock}} < (2 \times \text{CKOUTDIV}\times\text{TSYSCLK})\]

A clock absence flag is set (CKABF[y] = 1) and an interrupt can be invoked (if CKABIE=1) in case of an input clock recovery error (see CKABF[7:0] in DFSDM_FLT0ISR register and CKABEN in DFSDM_CHyCFGR1). After a clock absence flag clearing (by CLRCKABF in DFSDM_FLT0ICR register), the clock absence flag is refreshed.

**Figure 228. Clock absence timing diagram for Manchester coding**
Manchester/SPI code synchronization

The Manchester coded stream must be synchronized the first time after enabling the channel (CHEN=1 in DFSDM_CHyCFGR1 register). The synchronization ends when a data transition from 0 to 1 or from 1 to 0 (to be able to detect valid data edge) is received. The end of the synchronization can be checked by polling CKABF[y]=0 for a given channel after it has been cleared by CLRCKABF[y] in DFSDM_FLT0ICR, following the software sequence detailed hereafter:

CKABF[y] flag is cleared by setting CLRCKABF[y] bit. If channel y is not yet synchronized the hardware immediately set the CKABF[y] flag. Software is then reading back the CKABF[y] flag and if it is set then perform again clearing of this flag by setting CLRCKABF[y] bit. This software sequence (polling of CKABF[y] flag) continues until CKABF[y] flag is set (signalizing that Manchester stream is synchronized). To be able to synchronize/receive Manchester coded data the CKOUTDIV divider (in DFSDM_CH0CFGR1 register) must be set with respect to expected Manchester data rate according the formula below.

\[
((\text{CKOUTDIV} + 1) \times T_{\text{SYSCLK}}) < T_{\text{Manchester clock}} < (2 \times \text{CKOUTDIV} \times T_{\text{SYSCLK}})
\]

SPI coded stream is synchronized after first detection of clock input signal (valid rising/falling edge).

Note: When the transceiver is not yet synchronized, the clock absence flag is set and cannot be cleared by CLRCKABF[y] bit (in DFSDM_FLT0ICR register).
External serial clock frequency measurement

The measuring of a channel serial clock input frequency provides a real data rate from an external ΣΔ modulator, which is important for application purposes.

An external serial clock input frequency can be measured by a timer counting DFSDM clocks (fDFSDMCLK) during one conversion duration. The counting starts at the first input data clock after a conversion trigger (regular or injected) and finishes by last input data clock before conversion ends (end of conversion flag is set). Each conversion duration (time between first serial sample and last serial sample) is updated in counter CNVCNT[27:0] in register DFSDM_FLTxCNVTIMR when the conversion finishes (JEOCF=1 or REOCF=1). The user can then compute the data rate according to the digital filter settings (FORD, FOSR, IOSR, FAST). The external serial frequency measurement is stopped only if the filter is bypassed (FOSR=0, only integrator is active, CNVCNT[27:0]=0 in DFSDM_FLTxCNVTIMR register).

In case of parallel data input (Section 29.4.6: Parallel data inputs) the measured frequency is the average input data rate during one conversion.
Note: When conversion is interrupted (e.g. by disabling/enabling the selected channel) the interruption time is also counted in CNVCNT[27:0]. Therefore it is recommended to not interrupt the conversion for correct conversion duration result.

Conversion times:

injected conversion or regular conversion with FAST = 0 (or first conversion if FAST=1):

for Sinc^x filters (x=1..5):
\[ t = \frac{CNVCNT/f_{DFSDMCLK}}{FOSR * (IOSR-1 + FORD)} / f_{CKIN} \]

for FastSinc filter:
\[ t = \frac{CNVCNT/f_{DFSDMCLK}}{FOSR * (IOSR-1 + 4) + 2} / f_{CKIN} \]

regular conversion with FAST = 1 (except first conversion):

for Sinc^x and FastSinc filters:
\[ t = \frac{CNVCNT/f_{DFSDMCLK}}{FOSR * IOSR} / f_{CKIN} \]

in case if FOSR = FOSR[9:0]+1 = 1 (filter bypassed, active only integrator):
\[ t = \frac{IOSR}{f_{CKIN}} \] (but CNVCNT=0)

where:
- \( f_{CKIN} \) is the channel input clock frequency (on given channel CKINy pin) or input data rate (in case of parallel data input)
- \( FOSR \) is the filter oversampling ratio: \( FOSR = FOSR[9:0]+1 \) (see DFSDM_FLTxFCR register)
- \( IOSR \) is the integrator oversampling ratio: \( IOSR = IOSR[7:0]+1 \) (see DFSDM_FLTxFCR register)
- \( FORD \) is the filter order: \( FORD = FORD[2:0] \) (see DFSDM_FLTxFCR register)

Channel offset setting

Each channel has its own offset setting (in register) which is finally subtracted from each conversion result (injected or regular) from a given channel. Offset correction is performed after the data right bit shift. The offset is stored as a 24-bit signed value in OFFSET[23:0] field in DFSDM_CHyCFGR2 register.

Data right bit shift

To have the result aligned to a 24-bit value, each channel defines a number of right bit shifts which will be applied on each conversion result (injected or regular) from a given channel. The data bit shift number is stored in DTRBS[4:0] bits in DFSDM_CHyCFGR2 register.

The right bit-shift is rounding the result to nearest integer value. The sign of shifted result is maintained, in order to have valid 24-bit signed format of result data.
29.4.5 Configuring the input serial interface

The following parameters must be configured for the input serial interface:

- **Output clock predivider.** There is a programmable predivider to generate the output clock from DFSDM clock (2 - 256). It is defined by CKOUTDIV[7:0] bits in DFSDM_CH0CFGR1 register.

- **Serial interface type and input clock phase.** Selection of SPI or Manchester coding and sampling edge of input clock. It is defined by SITP [1:0] bits in DFSDM_CHyCFGR1 register.

- **Input clock source.** External source from CKINy pin or internal from CKOUT pin. It is defined by SPICKSEL[1:0] field in DFSDM_CHyCFGR1 register.

- **Final data right bit-shift.** Defines the final data right bit shift to have the result aligned to a 24-bit value. It is defined by DTRBS[4:0] in DFSDM_CHyCFGR2 register.

- **Channel offset per channel.** Defines the analog offset of a given serial channel (offset of connected external ΣΔ modulator). It is defined by OFFSET[23:0] bits in DFSDM_CHyCFGR2 register.

- **short-circuit detector and clock absence per channel enable.** To enable or disable the short-circuit detector (by SCDEN bit) and the clock absence monitoring (by CKABEN bit) on a given serial channel in register DFSDM_CHyCFGR1.

- **Analog watchdog filter and short-circuit detector threshold settings.** To configure channel analog watchdog filter parameters and channel short-circuit detector parameters. Configurations are defined in DFSDM_CHyAWSCDR register.

29.4.6 Parallel data inputs

Each input channel provides a register for 16-bit parallel data input (besides serial data input). Each 16-bit parallel input can be sourced from internal data sources only:

- internal ADC results\(^{(a)}\)
- direct CPU/DMA writing.

The selection for using serial or parallel data input for a given channel is done by field DATMPX[1:0] of DFSDM_CHyCFGR1 register. In DATMPX[1:0] is also defined the parallel data source: internal ADC\(^{(a)}\) or direct write by CPU/DMA.

Each channel contains a 32-bit data input register DFSDM_CHyDATINR in which it can be written a 16-bit data. Data are in 16-bit signed format. Those data can be used as input to the digital filter which is accepting 16-bit parallel data.

If serial data input is selected (DATMPX[1:0] = 0), the DFSDM_CHyDATINR register is write protected.

**Input from internal ADC\(^{(a)}\)**

In case of ADC data parallel input (DATMPX[1:0]=1) the ADC[y+1] result is assigned to channel y input (ADC1 is filling DFSDM_CHDATIN0R register, ADC2 is filling DFSDM_CHDATIN1R register, ... , ADC8 is filling DFSDM_CHDATIN7R register). End of conversion event from ADC[y+1] causes update of channel y data (parallel data from ADC[y+1] are put as next sample to digital filter). Data from ADC[y+1] is written into DFSDM_CHyDATINR register (field INDAT0[15:0]) when end of conversion event occurred.

\(^{(a)}\) ADC1 and ADC2 only.
The setting of data packing mode (DATPACK[1:0] in the DFSDM_CHyCFGR1 register) has no effect in case of ADC data input.

Note: Extension of ADC specification: in case the internal ADC is configured in interleaved mode (e.g. ADC1 together with ADC2 - see ADC specification) then each result from ADC1 or from ADC2 will come to the same 16-bit bus - to the bus of ADC1 - which is coming into DFSDM channel 0 (fixed connection). So there will be double input data rate into DFSDM channel 0 (even samples come from ADC1 and odd samples from ADC2). Channel 1 associated with ADC2 will be free.

Input from memory (direct CPU/DMA write)

The direct data write into DFSDM_CHyDATINR register by CPU or DMA (DATMPX[1:0]=2) can be used as data input in order to process digital data streams from memory or peripherals.

Data can be written by CPU or DMA into DFSDM_CHyDATINR register:

1. **CPU data write:**
   - Input data are written directly by CPU into DFSDM_CHyDATINR register.

2. **DMA data write:**
   - The DMA should be configured in memory-to-memory transfer mode to transfer data from memory buffer into DFSDM_CHyDATINR register. The destination memory address is the address of DFSDM_CHyDATINR register. Data are transferred at DMA transfer speed from memory to DFSDM parallel input.
   - This DMA transfer is different from DMA used to read DFSDM conversion results. Both DMA can be used at the same time - first DMA (configured as memory-to-memory transfer) for input data writings and second DMA (configured as peripheral-to-memory transfer) for data results reading.

The accesses to DFSDM_CHyDATINR can be either 16-bit or 32-bit wide, allowing to load respectively one or two samples in one write operation. 32-bit input data register (DFSDM_CHyDATINR) can be filled with one or two 16-bit data samples, depending on the data packing operation mode defined in field DATPACK[1:0] of DFSDM_CHyCFGR1 register:

1. **Standard mode (DATPACK[1:0]=0):**
   - Only one sample is stored in field INDAT0[15:0] of DFSDM_CHyDATINR register which is used as input data for channel y. The upper 16 bits (INDAT1[15:0]) are ignored and write protected. The digital filter must perform one input sampling (from INDAT0[15:0]) to empty data register after it has been filled by CPU/DMA. This mode is used together with 16-bit CPU/DMA access to DFSDM_CHyDATINR register to load one sample per write operation.

2. **Interleaved mode (DATPACK[1:0]=1):**
   - DFSDM_CHyDATINR register is used as a two sample buffer. The first sample is stored in INDAT0[15:0] and the second sample is stored in INDAT1[15:0]. The digital filter must perform two input samplings from channel y to empty DFSDM_CHyDATINR register. This mode is used together with 32-bit CPU/DMA access to DFSDM_CHyDATINR register to load two samples per write operation.

3. **Dual mode (DATPACK[1:0]=2):**
   - Two samples are written into DFSDM_CHyDATINR register. The data INDAT0[15:0] is for channel y, the data in INDAT1[15:0] is for channel y+1. The data in INDAT1[15:0] is automatically copied INDAT0[15:0] of the following (y+1) channel data register.
The digital filters must perform two samplings - one from channel \( y \) and one from channel \( (y+1) \) - in order to empty DFSDM_CHyDATINR registers.

Dual mode setting (DATPACK[1:0]=2) is available only on even channel numbers \( (y = 0, 2, 4, 6) \). If odd channel \( (y = 1, 3, 5, 7) \) is set to Dual mode then both INDAT0[15:0] and INDAT1[15:0] parts are write protected for this channel. If even channel is set to Dual mode then the following odd channel must be set into Standard mode (DATPACK[1:0]=0) for correct cooperation with even channels.

See Figure 230 for DFSDM_CHyDATINR registers data modes and assignments of data samples to channels.

</tbody>
</table>

The write into DFSDM_CHyDATINR register to load one or two samples must be performed after the selected input channel (channel \( y \)) is enabled for data collection (starting conversion for channel \( y \)). Otherwise written data are lost for next processing.

For example: for single conversion and interleaved mode, do not start writing pair of data samples into DFSDM_CHyDATINR before the single conversion is started (any data present in the DFSDM_CHyDATINR before starting a conversion is discarded).

### 29.4.7 Channel selection

There are 8 multiplexed channels which can be selected for conversion using the injected channel group and/or using the regular channel.

The **injected channel group** is a selection of any or all of the 8 channels. JCHG[7:0] in the DFSDM_FLT\texttt{X}JCHGR register selects the channels of the injected group, where JCHG[y]=1 means that channel \( y \) is selected.

Injected conversions can operate in scan mode (JSCAN=1) or single mode (JSCAN=0). In scan mode, each of the selected channels is converted, one after another. The lowest channel (channel 0, if selected) is converted first, followed immediately by the next higher channel until all the channels selected by JCHG[7:0] have been converted. In single mode (JSCAN=0), only one channel from the selected channels is converted, and the channel selection is moved to the next channel. Writing to JCHG[7:0] if JSCAN=0 resets the channel selection to the lowest selected channel.
Injected conversions can be launched by software or by a trigger. They are never interrupted by regular conversions.

The **regular channel** is a selection of just one of the 8 channels. RCH[2:0] in the DFSDM_FLTxCR1 register indicates the selected channel.

Regular conversions can be launched only by software (not by a trigger). A sequence of continuous regular conversions is temporarily interrupted when an injected conversion is requested.

Performing a conversion on a disabled channel (CHEN=0 in DFSDM_CHyCFGR1 register) causes that the conversion will never end - because no input data is provided (with no clock signal). In this case, it is necessary to enable a given channel (CHEN=1 in DFSDM_CHyCFGR1 register) or to stop the conversion by DFEN=0 in DFSDM_FLTxCR1 register.

### 29.4.8 Digital filter configuration

DFSDM contains a Sinc\(x\) type digital filter implementation. This Sinc\(x\) filter performs an input digital data stream filtering, which results in decreasing the output data rate (decimation) and increasing the output data resolution. The Sinc\(x\) digital filter is configurable in order to reach the required output data rates and required output data resolution. The configurable parameters are:

- Filter order/type: (see FORD[2:0] bits in DFSDM_FLTxFCR register):
  - FastSinc
  - Sinc\(^1\)
  - Sinc\(^2\)
  - Sinc\(^3\)
  - Sinc\(^4\)
  - Sinc\(^5\)

- Filter oversampling/decimation ratio (see FOSR[9:0] bits in DFSDM_FLTxFCR register):
  - FOSR = 1-1024 - for FastSinc filter and Sinc\(x\) filter \(x = FORD = 1..3\)
  - FOSR = 1-215 - for Sinc\(x\) filter \(x = FORD = 4\)
  - FOSR = 1-73 - for Sinc\(x\) filter \(x = FORD = 5\)

The filter has the following transfer function (impulse response in H domain):

- Sinc\(x\) filter type: \(H(z) = \frac{(1 - z^{-\text{FOSR}})^x}{1 - z^{-1}}\)

- FastSinc filter type: \(H(z) = \frac{(1 - z^{-\text{FOSR}})^2}{1 - z^{-1}} \cdot (1 + z^{-2 \cdot \text{FOSR}})\)
Figure 231. Example: Sinc$^3$ filter response

For more information about Sinc filter type properties and usage, it is recommended to study the theory about digital filters (more resources can be downloaded from internet).

29.4.9 Integrator unit

The integrator performs additional decimation and a resolution increase of data coming from the digital filter. The integrator simply performs the sum of data from a digital filter for a given number of data samples from a filter.

The integrator oversampling ratio parameter defines how many data counts will be summed to one data output from the integrator. IOSR can be set in the range 1-256 (see IOSR[7:0] bits description in DFSDM_FLTxFCR register).

29.4.10 Analog watchdog

The analog watchdog purpose is to trigger an external signal (break or interrupt) when an analog signal reaches or crosses given maximum and minimum threshold values. An interrupt/event/break generation can then be invoked.

Each analog watchdog will supervise serial data receiver outputs (after the analog watchdog filter on each channel) or data output register (current injected or regular conversion result) according to AWFSEL bit setting (in DFSDM_FLTxCR1 register). The input channels to be monitored or not by the analog watchdog x will be selected by AWDCH[7:0] in DFSDM_FLTxCR2 register.

Analog watchdog conversions on input channels are independent from standard conversions. In this case, the analog watchdog uses its own filters and signal processing on each input channel independently from the main injected or regular conversions. Analog watchdog conversions are performed in a continuous mode on the selected input channels in order to watch channels also when main injected or regular conversions are paused (RCIP = 0, JCIP = 0).

There are high and low threshold registers which are compared with given data values (set by AWHT[23:0] bits in DFSDM_FLTxAWHTR register and by AWLT[23:0] bits in DFSDM_FLTxAWLTR register).
There are 2 options for comparing the threshold registers with the data values

- **Option1**: in this case, the input data are taken from final output data register (AWFSEL=0). This option is characterized by:
  - high input data resolution (up to 24-bits)
  - slow response time - inappropriate for fast response applications like overcurrent detection
  - for the comparison the final data are taken after bit shifting and offset data correction
  - final data are available only after main regular or injected conversions are performed
  - can be used in case of parallel input data source (DATMPX[1:0] ≠ 0 in DFSDM_CHyCFGR1 register)

- **Option2**: in this case, the input data are taken from any serial data receivers output (AWFSEL=1). This option is characterized by:
  - input serial data are processed by dedicated analog watchdog Sinc^x channel filters with configurable oversampling ratio (1..32) and filter order (1..3) (see AWFOSR[4:0] and AWFORD[1:0] bits setting in DFSDM_CHyAWSCDR register)
  - lower resolution (up to 16-bit)
  - fast response time - appropriate for applications which require a fast response like overcurrent/overvoltage detection
  - data are available in continuous mode independently from main regular or injected conversions activity

In case of input channels monitoring (AWFSEL=1), the data for comparison to threshold is taken from channels selected by AWDCH[7:0] field (DFSDM_FLTxCR2 register). Each of the selected channels filter result is compared to one threshold value pair (AWHT[23:0] / AWLT[23:0]). In this case, only higher 16 bits (AWHT[23:8] / AWLT[23:8]) define the 16-bit threshold compared with the analog watchdog filter output because data coming from the analog watchdog filter is up to a 16-bit resolution. Bits AWHT[7:0] / AWLT[7:0] are not taken into comparison in this case (AWFSEL=1).

Parameters of the analog watchdog filter configuration for each input channel are set in DFSDM_CHyAWSCDR register (filter order AWFORD[1:0] and filter oversampling ratio AWFOSR[4:0]).

Each input channel has its own comparator which compares the analog watchdog data (from analog watchdog filter) with analog watchdog threshold values (AWHT/AWLT). When several channels are selected (field AWCH[7] field of DFSDM_FLTxCR2 register), several comparison requests may be received simultaneously. In this case, the channel request with the lowest number is managed first and then continuing to higher selected channels. For each channel, the result can be recorded in a separate flag (fields AWHTF[7:0], AWLTF[7:0] of DFSDM_FLTxAWSR register). Each channel request is executed in 8 DFSDM clock cycles. So, the bandwidth from each channel is limited to 8 DFSDM clock cycles (if AWCH[7:0] = 0xFF). Because the maximum input channel sampling clock frequency is the DFSDM clock frequency divided by 4, the configuration AWFOSR = 0 (analog watchdog filter is bypassed) cannot be used for analog watchdog feature at this input clock speed. Therefore user must properly configure the number of watched channels and analog watchdog filter parameters with respect to input sampling clock speed and DFSDM frequency.
Analog watchdog filter data for given channel y is available for reading by firmware on field WDATA[15:0] in DFSDM_CHyWDATR register. That analog watchdog filter data is converted continuously (if CHEN=1 in DFSDM_CHyCFGR1 register) with the data rate given by the analog watchdog filter setting and the channel input clock frequency.

The analog watchdog filter conversion works like a regular Fast Continuous Conversion without the integrator. The number of serial samples needed for one result from analog watchdog filter output (at channel input clock frequency f_{CKIN}):  

- first conversion:
  - for Sinc^x filters (x=1..5): number of samples = \( [F_{OSR} \times F_{ORD} + F_{ORD} + 1] \)
  - for FastSinc filter: number of samples = \( [F_{OSR} \times 4 + 2 + 1] \)

- next conversions:
  - for Sinc^x and FastSinc filters: number of samples = \( [F_{OSR} \times I_{OSR}] \)

where:

- \( F_{OSR} \) ...... filter oversampling ratio: \( F_{OSR} = AWFOSR[4:0]+1 \) (see DFSDM_CHyAWSCDR register)
- \( F_{ORD} \) ...... the filter order: \( F_{ORD} = AWFORD[1:0] \) (see DFSDM_CHyAWSCDR register)

In case of output data register monitoring (AWFSEL=0), the comparison is done after a right bit shift and an offset correction of final data (see OFFSET[23:0] and DTRBS[4:0] fields in DFSDM_CHyCFGR2 register). A comparison is performed after each injected or regular end of conversion for the channels selected by AWDCH[7:0] field (in DFSDM_FLTxCBxCR2 register).

The status of an analog watchdog event is signalized in DFSDM_FLTxAWSR register where a given event is latched. AWHTF\[y\]=1 flag signalizes crossing AWHT[23:0] value on channel y. AWLTF\[y\]=1 flag signalizes crossing AWLT[23:0] value on channel y. Latched events in DFSDM_FLTxAWSR register are cleared by writing ‘1’ into the corresponding clearing bit CLR\_AWHTF[y] or CLR\_AWLTF[y] in DFSDM_FLTxAFCFR register.

The global status of an analog watchdog is signalized by the AWDF flag bit in DFSDM_FLT\_xISR register (it is used for the fast detection of an interrupt source). AWDF=1 signals that at least one watchdog occurred (AWHTF\[y\]=1 or AWLTF\[y\]=1 for at least one channel). AWDF bit is cleared when all AWHTF\[7:0\] and AWLTF\[7:0\] are cleared.

An analog watchdog event can be assigned to break output signal. There are four break outputs to be assigned to a high or low threshold crossing event (dfsdm_break[3:0]). The break signal assignment to a given analog watchdog event is done by BKAWH[3:0] and BKAWL[3:0] fields in DFSDM_FLTxAWHTR and DFSDM_FLTxAWLTR register.

### 29.4.11 Short-circuit detector

The purpose of a short-circuit detector is to signalize with a very fast response time if an analog signal reached saturated values (out of full scale ranges) and remained on this value given time. This behavior can detect short-circuit or open circuit errors (e.g. overcurrent or overvoltage). An interrupt/event/break generation can be invoked.

Input data into a short-circuit detector is taken from channel transceiver outputs.

There is an upcounting counter on each input channel which is counting consecutive 0’s or 1’s on serial data receiver outputs. A counter is restarted if there is a change in the data stream received - 1 to 0 or 0 to 1 change of data signal. If this counter reaches a short-circuit threshold register value (SCDT[7:0] bits in DFSDM_CHyAWSCDR register), then a short-
circuit event is invoked. Each input channel has its short-circuit detector. Any channel can be selected to be continuously monitored by setting the SCDEN bit (in DFSDM_CHyCFGR1 register) and it has its own short-circuit detector settings (threshold value in SCDT[7:0] bits, status bit SCDF[7:0], status clearing bits CLRSCDF[7:0]). Status flag SCDF[y] is cleared also by hardware when corresponding channel y is disabled (CHEN[y] = 0).

On each channel, a short-circuit detector event can be assigned to break output signal dfsdm_break[3:0]. There are four break outputs to be assigned to a short-circuit detector event. The break signal assignment to a given channel short-circuit detector event is done by BKSCD[3:0] field in DFSDM_CHyAWSCDR register.

Short circuit detector cannot be used in case of parallel input data channel selection (DATMPX[1:0] ≠ 0 in DFSDM_CHyCFGR1 register).

Four break outputs are totally available (shared with the analog watchdog function).

### 29.4.12 Extreme detector

The purpose of an extremes detector is to collect the minimum and maximum values of final output data words (peak to peak values).

If the output data word is higher than the value stored in the extremes detector maximum register (EXMAX[23:0] bits in DFSDM_FLTxEXMAX register), then this register is updated with the current output data word value and the channel from which the data is stored is in EXMAXCH[2:0] bits (in DFSDM_FLTxEXMAX register).

If the output data word is lower than the value stored in the extremes detector minimum register (EXMIN[23:0] bits in DFSDM_FLTxEXMIN register), then this register is updated with the current output data word value and the channel from which the data is stored is in EXMINCH[2:0] bits (in DFSDM_FLTxEXMIN register).

The minimum and maximum register values can be refreshed by software (by reading given DFSDM_FLTxEXMAX or DFSDM_FLTxEXMIN register). After refresh, the extremes detector minimum data register DFSDM_FLTxEXMIN is filled with 0x7FFFFFF (maximum positive value) and the extremes detector maximum register DFSDM_FLTxEXMAX is filled with 0x8000000 (minimum negative value).

The extremes detector performs a comparison after a right bit shift and an offset data correction. For each extremes detector, the input channels to be considered into computing the extremes value are selected in EXCH[7:0] bits (in DFSDM_FLTxCR2 register).

### 29.4.13 Data unit block

The data unit block is the last block of the whole processing path: External ΣΔ modulators - Serial transceivers - Sinc filter - Integrator - Data unit block.

The output data rate depends on the serial data stream rate, and filter and integrator settings. The maximum output data rate is:

\[
\text{Datarate} \left[ \frac{\text{samples}}{\text{s}} \right] = \frac{f_{\text{CKIN}}}{F_{\text{OSR}} \cdot (1 - 1 + F_{\text{ORD}})} + \frac{f_{\text{CKIN}}}{(1 + 4 + 2 + 1)}
\]

...FAST = 0, Sincx filter

\[
\text{Datarate} \left[ \frac{\text{samples}}{\text{s}} \right] = \frac{f_{\text{CKIN}}}{F_{\text{OSR}} \cdot (1 - 1 + 4) + (2 + 1)}
\]

...FAST = 0, FastSinc filter
or

\[
\text{Datarate} \left[ \frac{\text{samples}}{\text{s}} \right] = \frac{f_{\text{CKIN}}}{F_{\text{OSR}} \cdot I_{\text{OSR}}} \quad \text{...FAST} = 1
\]

Maximum output data rate in case of parallel data input:

\[
\text{Datarate} \left[ \frac{\text{samples}}{\text{s}} \right] = \frac{f_{\text{DATAIN RATE}}}{F_{\text{OSR}} \cdot (I_{\text{OSR}} - 1 + F_{\text{ORD}}) + (F_{\text{ORD}} + 1)} \quad \text{...FAST} = 0, \text{ Sincx filter}
\]

or

\[
\text{Datarate} \left[ \frac{\text{samples}}{\text{s}} \right] = \frac{f_{\text{DATAIN RATE}}}{F_{\text{OSR}} \cdot (I_{\text{OSR}} - 1 + 4) + (2 + 1)} \quad \text{...FAST} = 0, \text{ FastSinc filter}
\]

or

\[
\text{Datarate} \left[ \frac{\text{samples}}{\text{s}} \right] = \frac{f_{\text{DATAIN RATE}}}{F_{\text{OSR}} \cdot I_{\text{OSR}}} \quad \text{...FAST} = 1 \text{ or any filter bypass case (F_{\text{OSR}} = 1)}
\]

where: \( f_{\text{DATAIN RATE}} \) = input data rate from ADC or from CPU/DMA

The right bit-shift of final data is performed in this module because the final data width is 24-bit and data coming from the processing path can be up to 32 bits. This right bit-shift is configurable in the range 0-31 bits for each selected input channel (see DTRBS[4:0] bits in DFSDM.CHyCFGR2 register). The right bit-shift is rounding the result to nearest integer value. The sign of shifted result is maintained - to have valid 24-bit signed format of result data.

In the next step, an offset correction of the result is performed. The offset correction value (OFFSET[23:0] stored in register DFSDM.CHyCFGR2) is subtracted from the output data for a given channel. Data in the OFFSET[23:0] field is set by software by the appropriate calibration routine.

Due to the fact that all operations in digital processing are performed on 32-bit signed registers, the following conditions must be fulfilled not to overflow the result:

\[
\begin{align*}
\text{FOSR} & \quad \text{FORD} \quad \text{IOSR} \leq 2^{31} \quad \text{... for Sincx filters, x = 1..5)} \\
2 \cdot \text{FOSR} & \quad \text{2 . IOSR} \quad \leq 2^{31} \quad \text{... for FastSinc filter)}
\end{align*}
\]

Note: In case of filter and integrator bypass (IOSR[7:0]=0, FOSR[9:0]=0), the input data rate \( f_{\text{DATAIN RATE}} \) must be limited to be able to read all output data:

\[
f_{\text{DATAIN RATE}} \leq f_{\text{APB}}
\]

where \( f_{\text{APB}} \) is the bus frequency to which the DFSDM peripheral is connected.

### 29.4.14 Signed data format

Each DFSDM input serial channel can be connected to one external \( \Sigma \Delta \) modulator. An external \( \Sigma \Delta \) modulator can have 2 differential inputs (positive and negative) which can be used for a differential or single-ended signal measurement.

A \( \Sigma \Delta \) modulator output is always assumed in a signed format (a data stream of zeros and ones from a \( \Sigma \Delta \) modulator represents values -1 and +1).
Signed data format in registers: Data is in a signed format in registers for final output data, analog watchdog, extremes detector, offset correction. The msb of output data word represents the sign of value (two's complement format).

29.4.15 Launching conversions

Injected conversions can be launched using the following methods:

- Software: writing ‘1’ to JSWSTART in the DFSDM_FLTxCR1 register.
- Trigger: JEXTSEL[4:0] selects the trigger signal while JEXTEN activates the trigger and selects the active edge at the same time (see the DFSDM_FLTxCR1 register).
- Synchronous with DFSDM_FLT0 if JSYNC=1: for DFSDM_FLTx (x>0), an injected conversion is automatically launched when in DFSDM_FLT0; the injected conversion is started by software (JSWSTART=1 in DFSDM_FLT0CR2 register). Each injected conversion in DFSDM_FLTx (x>0) is always executed according to its local configuration settings (JSCAN, JCHG, etc.).

If the scan conversion is enabled (bit JSCAN=1) then, each time an injected conversion is triggered, all of the selected channels in the injected group (JCHG[7:0] bits in DFSDM_FLTxJCHGR register) are converted sequentially, starting with the lowest channel (channel 0, if selected).

If the scan conversion is disabled (bit JSCAN=0) then, each time an injected conversion is triggered, only one of the selected channels in the injected group (JCHG[7:0] bits in DFSDM_FLTxJCHGR register) is converted and the channel selection is then moved to the next selected channel. Writing to the JCHG[7:0] bits when JSCAN=0 sets the channel selection to the lowest selected injected channel.

Only one injected conversion can be ongoing at a given time. Thus, any request to launch an injected conversion is ignored if another request for an injected conversion has already been issued but not yet completed.

Regular conversions can be launched using the following methods:

- Software: by writing ‘1’ to RSWSTART in the DFSDM_FLTxCR1 register.
- Synchronous with DFSDM_FLT0 if RSYNC=1: for DFSDM_FLTx (x>0), a regular conversion is automatically launched when in DFSDM_FLT0; a regular conversion is started by software (RSWSTART=1 in DFSDM_FLT0CR2 register). Each regular conversion in DFSDM_FLTx (x>0) is always executed according to its local configuration settings (RCONT, RCH, etc.).

Only one regular conversion can be pending or ongoing at a given time. Thus, any request to launch a regular conversion is ignored if another request for a regular conversion has already been issued but not yet completed. A regular conversion can be pending if it was interrupted by an injected conversion or if it was started while an injected conversion was in progress. This pending regular conversion is then delayed and is performed when all injected conversion are finished. Any delayed regular conversion is signalized by RPEND bit in DFSDM_FLTxRDATAR register.

29.4.16 Continuous and fast continuous modes

Setting RCONT in the DFSDM_FLTxCR1 register causes regular conversions to execute in continuous mode. RCONT=1 means that the channel selected by RCH[2:0] is converted repeatedly after ‘1’ is written to RSWSTART.
The regular conversions executing in continuous mode can be stopped by writing ‘0’ to RCONT. After clearing RCONT, the on-going conversion is stopped immediately.

In continuous mode, the data rate can be increased by setting the FAST bit in the DFSDM_FLTxCR1 register. In this case, the filter does not need to be refilled by new fresh data if converting continuously from one channel because data inside the filter is valid from previously sampled continuous data. The speed increase depends on the chosen filter order. The first conversion in fast mode (FAST=1) after starting a continuous conversion by RSWSTART=1 takes still full time (as when FAST=0), then each subsequent conversion is finished in shorter intervals.

Conversion time in continuous mode:
- if FAST = 0 (or first conversion if FAST=1):
  for Sinc\(x\) filters:
  \[
  t = \frac{\text{CNVCNT}}{f_{\text{DFSDMCLK}}} = \frac{[\text{FOSR} \times (\text{IOSR}-1 + \text{FORD}) + \text{FORD}]}{f_{\text{CKIN}}}
  \]
  for FastSinc filter:
  \[
  t = \frac{\text{CNVCNT}}{f_{\text{DFSDMCLK}}} = \frac{[\text{FOSR} \times (\text{IOSR}-1 + 4) + 2]}{f_{\text{CKIN}}}
  \]
- if FAST = 1 (except first conversion):
  for Sinc\(x\) and FastSinc filters:
  \[
  t = \frac{\text{CNVCNT}}{f_{\text{DFSDMCLK}}} = \frac{[\text{FOSR} \times \text{IOSR}]}{f_{\text{CKIN}}}
  \]
  in case FOSR = FOSR[9:0]+1 = 1 (filter bypassed, only integrator active):
  \[
  t = \frac{\text{IOSR}}{f_{\text{CKIN}}} \quad (... \text{but } \text{CNVCNT}=0)
  \]

Continuous mode is not available for injected conversions. Injected conversions can be started by timer trigger to emulate the continuous mode with precise timing.

If a regular continuous conversion is in progress (RCONT=1) and if a write access to DFSDM_FLTxCR1 register requesting regular continuous conversion (RCONT=1) is performed, then regular continuous conversion is restarted from the next conversion cycle (like new regular continuous conversion is applied for new channel selection - even if there is no change in DFSDM_FLTxCR1 register).

29.4.17 Request precedence

An injected conversion has a higher precedence than a regular conversion. A regular conversion which is already in progress is immediately interrupted by the request of an injected conversion; this regular conversion is restarted after the injected conversion finishes.

An injected conversion cannot be launched if another injected conversion is pending or already in progress: any request to launch an injected conversion (either by JSWSTART or by a trigger) is ignored as long as bit JCIP is ‘1’ (in the DFSDM_FLTxISR register).

Similarly, a regular conversion cannot be launched if another regular conversion is pending or already in progress: any request to launch a regular conversion (using RSWSTART) is ignored as long as bit RCIP is ‘1’ (in the DFSDM_FLTxISR register).

However, if an injected conversion is requested while a regular conversion is already in progress, the regular conversion is immediately stopped and an injected conversion is launched. The regular conversion is then restarted and this delayed restart is signalized in bit RPEND.

Injected conversions have precedence over regular conversions in that a injected conversion can temporarily interrupt a sequence of continuous regular conversions. When
the sequence of injected conversions finishes, the continuous regular conversions start again if RCONT is still set (and RPEND bit will signalize the delayed start on the first regular conversion result).

Precedence also matters when actions are initiated by the same write to DFSDM, or if multiple actions are pending at the end of another action. For example, suppose that, while an injected conversion is in process (JCIP=1), a single write operation to DFSDM_FLTxCR1 writes ‘1’ to RSWSTART, requesting a regular conversion. When the injected sequence finishes, the precedence dictates that the regular conversion is performed next and its delayed start is signalized in RPEND bit.

29.4.18 Power optimization in run mode

In order to reduce the consumption, the DFSDM filter and integrator are automatically put into idle when not used by conversions (RCIP=0, JCIP=0).

29.5 DFSDM interrupts

In order to increase the CPU performance, a set of interrupts related to the CPU event occurrence has been implemented:

- **End of injected conversion interrupt:**
  - enabled by JEOCIE bit in DFSDM_FLTxCR2 register
  - indicated in JEOCF bit in DFSDM_FLTxISR register
  - cleared by reading DFSDM_FLTxJDATAR register (injected data)
  - indication of which channel end of conversion occurred, reported in JDATACH[2:0] bits in DFSDM_FLTxJDATAR register

- **End of regular conversion interrupt:**
  - enabled by REOCIE bit in DFSDM_FLTxCR2 register
  - indicated in REOCF bit in DFSDM_FLTxISR register
  - cleared by reading DFSDM_FLTxRDATAR register (regular data)
  - indication of which channel end of conversion occurred, reported in RDATACH[2:0] bits in DFSDM_FLTxRDATAR register

- **Data overrun interrupt for injected conversions:**
  - occurred when injected converted data were not read from DFSDM_FLTxJDATAR register (by CPU or DMA) and were overwritten by a new injected conversion
  - enabled by JOVRIE bit in DFSDM_FLTxCR2 register
  - indicated in JOVRF bit in DFSDM_FLTxISR register
  - cleared by writing ‘1’ into CLRJOVRF bit in DFSDM_FLTxICR register

- **Data overrun interrupt for regular conversions:**
  - occurred when regular converted data were not read from DFSDM_FLTxRDATAR register (by CPU or DMA) and were overwritten by a new regular conversion
  - enabled by ROVRIE bit in DFSDM_FLTxCR2 register
  - indicated in ROVRF bit in DFSDM_FLTxISR register
  - cleared by writing ‘1’ into CLRROVRF bit in DFSDM_FLTxICR register

- **Analog watchdog interrupt:**
occurred when converted data (output data or data from analog watchdog filter - according to AWFSEL bit setting in DFSDMFLTxC1R1 register) crosses over/under high/low thresholds in DFSDMFLTxAWHTR / DFSDMFLTxAWLTR registers
– enabled by AWDIE bit in DFSDMFLTxC2R register (on selected channels AWDC[7:0])
– indicated in AWDF bit in DFSDMFLTxISR register
– separate indication of high or low analog watchdog threshold error by AWHTF[7:0] and AWLTF[7:0] fields in DFSDMFLTxAWSR register
– cleared by writing ‘1’ into corresponding CLRAWHTF[7:0] or CLRAWLTF[7:0] bits in DFSDMFLTxAWer

• Short-circuit detector interrupt:
  – occurred when the number of stable data crosses over thresholds in DFSDMChyAWS CDCR register
  – enabled by SCDIE bit in DFSDMFLTxC2R register (on channel selected by SCDEN bit in DFSDMChyCFGR1 register)
  – indicated in SCD[7:0] bits in DFSDMFLTxISR register (which also reports the channel on which the short-circuit detector event occurred)
  – cleared by writing ‘1’ into the corresponding CLRSCDF[7:0] bit in DFSDMFLTxCICR register

• Channel clock absence interrupt:
  – occurred when there is clock absence on CKINy pin (see Clock absence detection in Section 29.4.4: Serial channel transceivers)
  – enabled by CKABIE bit in DFSDMFLTxC2R register (on channels selected by CKABEN bit in DFSDMChyCFGR1 register)
  – indicated in CKABF[y] bit in DFSDMFLTxISR register
  – cleared by writing ‘1’ into CLRCKABF[y] bit in DFSDMFLTxCICR register

29.6 **DFSDM DMA transfer**

To decrease the CPU intervention, conversions can be transferred into memory using a DMA transfer. A DMA transfer for injected conversions is enabled by setting bit JDMAEN=1 in DFSDM_FLTxCR1 register. A DMA transfer for regular conversions is enabled by setting bit RDMAEN=1 in DFSDM_FLTxCR1 register.

*Note:* With a DMA transfer, the interrupt flag is automatically cleared at the end of the injected or regular conversion (JEOCF or REOCF bit in DFSDM_FLTxISR register) because DMA is reading DFSDM_FLTxDATAR or DFSDM_FLTxDATAR register.

29.7 **DFSDM channel y registers (y=0..7)**

29.7.1 **DFSDM channel y configuration register (DFSDM_CHyCFGR1)**

This register specifies the parameters used by channel y.

Address offset: 0x00 + 0x20 * y, (y = 0 to 7)

Reset value: 0x0000 0000

</tbody>
</table>
Bits 23:16 **CKOUTDIV[7:0]**: Output serial clock divider
- 0: Output clock generation is disabled (CKOUT signal is set to low state)
- 1-255: Defines the division of system clock for the serial clock output for CKOUT signal in range 2-256 (Divider = CKOUTDIV+1).
CKOUTDIV also defines the threshold for a clock absence detection.
This value can only be modified when DFSDMEN=0 (in DFSDM_CH0CFGR1 register).
If DFSDMEN=0 (in DFSDM_CH0CFGR1 register) then CKOUT signal is set to low state (setting is performed one DFSDM clock cycle after DFSDMEN=0).

*Note: CKOUTDIV is present only in DFSDM_CH0CFGR1 register (channel y=0)*

Bits 15:14 **DATPACK[1:0]**: Data packing mode in DFSDM_CHyDATINR register.
- 0: Standard: input data in DFSDM_CHyDATINR register are stored only in INDAT0[15:0]. To empty DFSDM_CHyDATINR register one sample must be read by the digital filter from channel y.
- 1: Interleaved: input data in DFSDM_CHyDATINR register are stored as two samples:
  - first sample in INDAT0[15:0] (assigned to channel y)
  - second sample INDAT1[15:0] (assigned to channel y)
To empty DFSDM_CHyDATINR register, two samples must be read by the digital filter from channel y (INDAT0[15:0] part is read as first sample and then INDAT1[15:0] part is read as next sample).
- 2: Dual: input data in DFSDM_CHyDATINR register are stored as two samples:
  - first sample INDAT0[15:0] (assigned to channel y)
  - second sample INDAT1[15:0] (assigned to channel y+1)
To empty DFSDM_CHyDATINR register first sample must be read by the digital filter from channel y and second sample must be read by another digital filter from channel y+1. Dual mode is available only on even channel numbers (y = 0, 2, 4, 6), for odd channel numbers (y = 1, 3, 5, 7) DFSDM_CHyDATINR is write protected. If an even channel is set to dual mode then the following odd channel must be set into standard mode (DATPACK[1:0]=0) for correct cooperation with even channel.
- 3: Reserved
This value can be modified only when CHEN=0 (in DFSDM_CHyCFGR1 register).

Bits 13:12 **DATMPX[1:0]**: Input data multiplexer for channel y
- 0: Data to channel y are taken from external serial inputs as 1-bit values. DFSDM_CHyDATINR register is write protected.
- 1: Data to channel y are taken from internal analog to digital converter ADCy+1 output register update as 16-bit values (if ADCy+1 is available). Data from ADCs are written into INDAT0[15:0] part of DFSDM_CHyDATINR register.
- 2: Data to channel y are taken from internal DFSDM_CHyDATINR register by direct CPU/DMA write.
  There can be written one or two 16-bit data samples according DATPACK[1:0] bit field setting.
- 3: Reserved

*Note: This value can be modified only when CHEN=0 (in DFSDM_CHyCFGR1 register).*

*Note: DATMPX[1:0] = 1 is supported only by ADC1 and ADC2.*

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **CHINSEL**: Channel inputs selection
- 0: Channel inputs are taken from pins of the same channel y.
- 1: Channel inputs are taken from pins of the following channel (channel (y+1) modulo 8).
This value can be modified only when CHEN=0 (in DFSDM_CHyCFGR1 register).

Bit 7 **CHEN**: Channel y enable
- 0: Channel y disabled
- 1: Channel y enabled
If channel y is enabled, then serial data receiving is started according to the given channel setting.
Bit 6 **CKABEN**: Clock absence detector enable on channel y
   0: Clock absence detector disabled on channel y
   1: Clock absence detector enabled on channel y

Bit 5 **SCDEN**: Short-circuit detector enable on channel y
   0: Input channel y will not be guarded by the short-circuit detector
   1: Input channel y will be continuously guarded by the short-circuit detector

Bit 4 Reserved, must be kept at reset value.

Bits 3:2 **SPICSEL[1:0]**: SPI clock select for channel y
   0: clock coming from external CKINy input - sampling point according SITP[1:0]
   1: clock coming from internal CKOUT output - sampling point according SITP[1:0]
   2: clock coming from internal CKOUT - sampling point on each second CKOUT falling edge.
      For connection to external ΣΔ modulator which divides its clock input (from CKOUT) by 2 to
      generate its output serial communication clock (and this output clock change is active on each
      clock input rising edge).
   3: clock coming from internal CKOUT output - sampling point on each second CKOUT rising edge.
      For connection to external ΣΔ modulator which divides its clock input (from CKOUT) by 2 to
      generate its output serial communication clock (and this output clock change is active on each
      clock input falling edge).
      This value can be modified only when CHEN=0 (in DFSDM_CHyCFGR1 register).

Bits 1:0 **SITP[1:0]**: Serial interface type for channel y
   00: SPI with rising edge to strobe data
   01: SPI with falling edge to strobe data
   10: Manchester coded input on DATINy pin: rising edge = logic 0, falling edge = logic 1
   11: Manchester coded input on DATINy pin: rising edge = logic 1, falling edge = logic 0
      This value can only be modified when CHEN=0 (in DFSDM_CHyCFGR1 register).

**29.7.2 DFSDM channel y configuration register (DFSDM_CHyCFGR2)**

This register specifies the parameters used by channel y.

Address offset: 0x04 + 0x20 * y, (y = 0 to 7)

Reset value: 0x0000 0000
Bits 31:8 **OFFSET[23:0]**: 24-bit calibration offset for channel y
For channel y, OFFSET is applied to the results of each conversion from this channel. This value is set by software.

Bits 7:3 **DTRBS[4:0]**: Data right bit-shift for channel y
0-31: Defines the shift of the data result coming from the integrator - how many bit shifts to the right will be performed to have final results. Bit-shift is performed before offset correction. The data shift is rounding the result to nearest integer value. The sign of shifted result is maintained (to have valid 24-bit signed format of result data).
This value can be modified only when CHEN=0 (in DFSDM_CHyCFG1 register).

Bits 2:0 Reserved, must be kept at reset value.

### 29.7.3 DFSDM channel y analog watchdog and short-circuit detector register (DFSDM_CHyAWSCDR)

Short-circuit detector and analog watchdog settings for channel y.
Address offset: 0x08 + 0x20 * y, (y = 0 to 7)
Reset value: 0x0000 0000

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:22 **AWFORD[1:0]**: Analog watchdog Sinc filter order on channel y
0: FastSinc filter type
1: Sinc1 filter type
2: Sinc2 filter type
3: Sinc3 filter type
Sincx filter type transfer function:

\[
H(z) = \left(1 - \frac{\text{FOSR}}{z^{-1}}\right)^x
\]

FastSinc filter type transfer function:

\[
H(z) = \left(1 - \frac{\text{FOSR}}{z^{-1}}\right)^2 \cdot (1 + z^{-1})^{(2 \cdot \text{FOSR})}
\]

This bit can be modified only when CHEN=0 (in DFSDM_CHyCFG1 register).

Bit 21 Reserved, must be kept at reset value.

Bits 20:16 **AWFOSR[4:0]**: Analog watchdog filter oversampling ratio (decimation rate) on channel y
0 - 31: Defines the length of the Sinc type filter in the range 1 - 32 (AWFOSR + 1). This number is also the decimation ratio of the analog data rate.
This bit can be modified only when CHEN=0 (in DFSDM_CHyCFG1 register).

*Note: If AWFOSR = 0 then the filter has no effect (filter bypass).*
**29.7.4 DFSDM channel y watchdog filter data register (DFSDM_CHyWDATR)**

This register contains the data resulting from the analog watchdog filter associated to the input channel y.

Address offset: 0x0C + 0x20 * y, (y = 0 to 7)

Reset value: 0x0000 0000

Bits 31:16 **INDAT1[15:0]:** Input data for channel y or channel y+1

Input parallel channel data to be processed by the digital filter if DATMPX[1:0]=1 or DATMPX[1:0]=2. Data can be written by CPU/DMA (if DATMPX[1:0]=2) or directly by internal ADC (if DATMPX[1:0]=1).

If DATPACK[1:0]=0 (standard mode)

INDAT0[15:0] is write protected (not used for input sample).

If DATPACK[1:0]=1 (interleaved mode)

Second channel y data sample is stored into INDAT1[15:0]. First channel y data sample is stored into INDAT0[15:0]. Both samples are read sequentially by DFSDM_FLTx filter as two channel y data samples.

If DATPACK[1:0]=2 (dual mode).

For even y channels: sample in INDAT1[15:0] is automatically copied into INDAT0[15:0] of channel (y+1).

For odd y channels: INDAT1[15:0] is write protected.

See Section 29.4.6: Parallel data inputs for more details.

INDAT0[15:1] is in the 16-bit signed format.

Bits 15:0 **INDAT0[15:0]:** Input data for channel y

Input parallel channel data to be processed by the digital filter if DATMPX[1:0]=1 or DATMPX[1:0]=2. Data can be written by CPU/DMA (if DATMPX[1:0]=2) or directly by internal ADC (if DATMPX[1:0]=1).

If DATPACK[1:0]=0 (standard mode)

Channel y data sample is stored into INDAT0[15:0].

If DATPACK[1:0]=1 (interleaved mode)

First channel y data sample is stored into INDAT0[15:0]. Second channel y data sample is stored into INDAT1[15:0]. Both samples are read sequentially by DFSDM_FLTx filter as two channel y data samples.

If DATPACK[1:0]=2 (dual mode).

For even y channels: Channel y data sample is stored into INDAT0[15:0].

For odd y channels: INDAT0[15:0] is write protected.

See Section 29.4.6: Parallel data inputs for more details.

INDAT0[15:0] is in the 16-bit signed format.
Bit 31  Reserved, must be kept at reset value.

Bit 30  **AWFSEL**: Analog watchdog fast mode select
0: Analog watchdog on data output value (after the digital filter). The comparison is done after offset correction and shift
1: Analog watchdog on channel transceivers value (after watchdog filter)

Bit 29  **FAST**: Fast conversion mode selection for regular conversions
0: Fast conversion mode disabled
1: Fast conversion mode enabled
When converting a regular conversion in continuous mode, having enabled the fast mode causes each conversion (except the first) to execute faster than in standard mode. This bit has no effect on conversions which are not continuous.
This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).
if FAST=0 (or first conversion in continuous mode if FAST=1):
\[ t = \frac{[FOSR \times (IOSR-1 + FORD) + FORD]}{f_{CKIN}} \]  
... for Sinc\(x\) filters
\[ t = \frac{[FOSR \times (IOSR-1 + 4) + 2]}{f_{CKIN}} \]  
... for FastSinc filter
if FAST=1 in continuous mode (except first conversion):
\[ t = \frac{[FOSR \times IOSR]}{f_{CKIN}} \]
in case if FOSR = FOSR[9:0]+1 = 1 (filter bypassed, active only integrator):
\[ t = \frac{IOSR}{f_{CKIN}} \]
... \(but \ CNVCNT=0\)
where: \(f_{CKIN}\) is the channel input clock frequency (on given channel CKINy pin) or input data rate in case of parallel data input.

Bits 28:27  Reserved, must be kept at reset value.

Bits 26:24  **RCH[2:0]**: Regular channel selection
0: Channel 0 is selected as the regular channel
1: Channel 1 is selected as the regular channel
...
7: Channel 7 is selected as the regular channel
Writing these bits when RCIP=1 takes effect when the next regular conversion begins. This is especially useful in continuous mode (when RCONT=1). It also affects regular conversions which are pending (due to ongoing injected conversion).

Bits 23:22  Reserved, must be kept at reset value.

Bit 21  **RDMAEN**: DMA channel enabled to read data for the regular conversion
0: The DMA channel is not enabled to read regular data
1: The DMA channel is enabled to read regular data
This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).

Bit 20  Reserved, must be kept at reset value.

Bit 19  **RSYNC**: Launch regular conversion synchronously with DFSDM_FLT0
0: Do not launch a regular conversion synchronously with DFSDM_FLT0
1: Launch a regular conversion in this DFSDM_FLTx at the very moment when a regular conversion is launched in DFSDM_FLT0
This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).

Bit 18  **RCONT**: Continuous mode selection for regular conversions
0: The regular channel is converted just once for each conversion request
1: The regular channel is converted repeatedly after each conversion request
Writing ‘0’ to this bit while a continuous regular conversion is already in progress stops the continuous mode immediately.
Bit 17 **RSWSTART**: Software start of a conversion on the regular channel
- 0: Writing ‘0’ has no effect
- 1: Writing ‘1’ makes a request to start a conversion on the regular channel and causes RCIP to become ‘1’. If RCIP=1 already, writing to RSWSTART has no effect. Writing ‘1’ has no effect if RSYNC=1.
- This bit is always read as ‘0’.

Bits 16:15 Reserved, must be kept at reset value.

Bits 14:13 **JEXTEN[1:0]**: Trigger enable and trigger edge selection for injected conversions
- 00: Trigger detection is disabled
- 01: Each rising edge on the selected trigger makes a request to launch an injected conversion
- 10: Each falling edge on the selected trigger makes a request to launch an injected conversion
- 11: Both rising edges and falling edges on the selected trigger make requests to launch injected conversions
- This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).

Bits 12:8 **JEXTSEL[4:0]**: Trigger signal selection for launching injected conversions
- 0x0-0x1F: Trigger inputs selected by the following table (internal or external trigger).
- This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).

*Note:* synchronous trigger has latency up to one $f_{DFSDMCLK}$ clock cycle (with deterministic jitter), asynchronous trigger has latency 2-3 $f_{DFSDMCLK}$ clock cycles (with jitter up to 1 cycle).

DFSDM_FLTx
- 0x00 dfsdm_jtrg0
- 0x01 dfsdm_jtrg1
- ...
- 0x1E dfsdm_jtrg30
- 0x1F dfsdm_jtrg31
- Refer to Table 242: DFSDM triggers connection.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **JDMAEN**: DMA channel enabled to read data for the injected channel group
- 0: The DMA channel is not enabled to read injected data
- 1: The DMA channel is enabled to read injected data
- This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).

Bit 4 **JSCAN**: Scanning conversion mode for injected conversions
- 0: One channel conversion is performed from the injected channel group and next the selected channel from this group is selected.
- 1: The series of conversions for the injected group channels is executed, starting over with the lowest selected channel.
- This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).
- Writing JCHG if JSCAN=0 resets the channel selection to the lowest selected channel.

Bit 3 **JSYNC**: Launch an injected conversion synchronously with the DFSDM_FLT0 JSWSTART trigger
- 0: Do not launch an injected conversion synchronously with DFSDM_FLT0
- 1: Launch an injected conversion in this DFSDM_FLTx at the very moment when an injected conversion is launched in DFSDM_FLT0 by its JSWSTART trigger
- This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).
Bit 2 Reserved, must be kept at reset value.

Bit 1 **JSWSTART**: Start a conversion of the injected group of channels
- 0: Writing ‘0’ has no effect.
- 1: Writing ‘1’ makes a request to convert the channels in the injected conversion group, causing JCIP to become ‘1’ at the same time. If JCIP=1 already, then writing to JSWSTART has no effect.
Writing ‘1’ has no effect if JSYNC=1.
This bit is always read as ‘0’.

Bit 0 **DFEN**: DFSDMFLTx enable
- 0: DFSDMFLTx is disabled. All conversions of given DFSDMFLTx are stopped immediately and all DFSDMFLTx functions are stopped.
- 1: DFSDMFLTx is enabled. If DFSDMFLTx is enabled, then DFSDMFLTx starts operating according to its setting.
Data which are cleared by setting DFEN=0:
- register DFSDMFLTxISR is set to the reset state
- register DFSDMFLTxAWSR is set to the reset state

29.8.2 DFSDM filter x control register 2 (DFSDMFLTxCr2)

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **AWDCH[7:0]**: Analog watchdog channel selection
These bits select the input channel to be guarded continuously by the analog watchdog.
- AWDCH[y] = 0: Analog watchdog is disabled on channel y
- AWDCH[y] = 1: Analog watchdog is enabled on channel y

Bits 15:8 **EXCH[7:0]**: Extremes detector channel selection
These bits select the input channels to be taken by the Extremes detector.
- EXCH[y] = 0: Extremes detector does not accept data from channel y
- EXCH[y] = 1: Extremes detector accepts data from channel y

Bit 7 Reserved, must be kept at reset value.

Bit 6 **CKABIE**: Clock absence interrupt enable
- 0: Detection of channel input clock absence interrupt is disabled
- 1: Detection of channel input clock absence interrupt is enabled
Please see the explanation of CKABF[7:0] in DFSDMFLTxCrISR.

Note: **CKABIE is present only in DFSDMFLT0Cr2 register (filter x=0)**
Bit 5 **SCDIE**: Short-circuit detector interrupt enable
- 0: short-circuit detector interrupt is disabled
- 1: short-circuit detector interrupt is enabled

Please see the explanation of SCDF[7:0] in DFSDM_FLTxISR.
*Note: SCDIE is present only in DFSDM_FLT0CR2 register (filter x=0)*

Bit 4 **AWDIE**: Analog watchdog interrupt enable
- 0: Analog watchdog interrupt is disabled
- 1: Analog watchdog interrupt is enabled

Please see the explanation of AWDF in DFSDM_FLTxISR.

Bit 3 **ROVRIE**: Regular data overrun interrupt enable
- 0: Regular data overrun interrupt is disabled
- 1: Regular data overrun interrupt is enabled

Please see the explanation of ROVRF in DFSDM_FLTxISR.

Bit 2 **JOVRIE**: Injected data overrun interrupt enable
- 0: Injected data overrun interrupt is disabled
- 1: Injected data overrun interrupt is enabled

Please see the explanation of JOVRF in DFSDM_FLTxISR.

Bit 1 **REOCIE**: Regular end of conversion interrupt enable
- 0: Regular end of conversion interrupt is disabled
- 1: Regular end of conversion interrupt is enabled

Please see the explanation of REOCF in DFSDM_FLTxISR.

Bit 0 **JEOCIE**: Injected end of conversion interrupt enable
- 0: Injected end of conversion interrupt is disabled
- 1: Injected end of conversion interrupt is enabled

Please see the explanation of JEOCF in DFSDM_FLTxISR.

### Bits 31:24 SCDF[7:0]: Short-circuit detector flag
- **SCDF[y] = 0**: No short-circuit detector event occurred on channel y.
- **SCDF[y] = 1**: The short-circuit detector counter reaches, on channel y, the value programmed in the DFSDM_CHyAWSCDR registers.

  This bit is set by hardware. It can be cleared by software using the corresponding CLRSCDF[y] bit in the DFSDM_FLT0ISR register. SCDF[y] is cleared also by hardware when CHEN[y] = 0 (given channel is disabled).

  **Note**: SCDF[7:0] is present only in DFSDM_FLT0ISR register (filter x=0)

### Bits 23:16 CKABF[7:0]: Clock absence flag
- **CKABF[y] = 0**: Clock signal on channel y is present.
- **CKABF[y] = 1**: Clock signal on channel y is not present.

  Given y bit is set by hardware when clock absence is detected on channel y. It is held at CKABF[y] = 1 state by hardware when CHEN=0 (see DFSDM_CHyCFGR1 register). It is held at CKABF[y] = 1 state by hardware when the transceiver is not yet synchronized. It can be cleared by software using the corresponding CLRCKABF[y] bit in the DFSDM_FLT0ISR register.

  **Note**: CKABF[7:0] is present only in DFSDM_FLT0ISR register (filter x=0)

### Bit 15 Reserved, must be kept at reset value.

### Bit 14 RCIP: Regular conversion in progress status
- **0**: No request to convert the regular channel has been issued.
- **1**: The conversion of the regular channel is in progress or a request for a regular conversion is pending.

  A request to start a regular conversion is ignored when RCIP=1.

### Bit 13 JCIP: Injected conversion in progress status
- **0**: No request to convert the injected channel group (neither by software nor by trigger) has been issued.
- **1**: The conversion of the injected channel group is in progress or a request for a injected conversion is pending, due either to ‘1’ being written to JSWSTART or to a trigger detection.

  A request to start an injected conversion is ignored when JCIP=1.

### Bits 12:5 Reserved, must be kept at reset value.

### Bit 4 AWDF: Analog watchdog
- **0**: No Analog watchdog event occurred.
- **1**: The analog watchdog block detected voltage which crosses the value programmed in the DFSDM_FLTxAWLTR or DFSDM_FLTxAWHTR registers.

  This bit is set by hardware. It is cleared by software by clearing all source flag bits AWHTF[7:0] and AWLTF[7:0] in DFSDM_FLTxAWSR register (by writing ‘1’ into the clear bits in DFSDM_FLTxAWCFR register).

### Bit 3 ROVRF: Regular conversion overrun flag
- **0**: No regular conversion overrun has occurred.
- **1**: A regular conversion overrun has occurred, which means that a regular conversion finished while REOCF was already ‘1’. RDATAR is not affected by overruns.

  This bit is set by hardware. It can be cleared by software using the CLRROVRF bit in the DFSDM_FLT0ISR register.
Bit 2 JOVRF: Injected conversion overrun flag
0: No injected conversion overrun has occurred
1: An injected conversion overrun has occurred, which means that an injected conversion finished while JEOCF was already ‘1’. JDATAR is not affected by overruns
This bit is set by hardware. It can be cleared by software using the CLRJOVRF bit in the DFSDM_FLT0ISR register.

Bit 1 REOCF: End of regular conversion flag
0: No regular conversion has completed
1: A regular conversion has completed and its data may be read
This bit is set by hardware. It is cleared when the software or DMA reads DFSDM_FLT0RDATAR.

Bit 0 JEOCF: End of injected conversion flag
0: No injected conversion has completed
1: An injected conversion has completed and its data may be read
This bit is set by hardware. It is cleared when the software or DMA reads DFSDM_FLT0JDATAR.

Note: For each of the flag bits, an interrupt can be enabled by setting the corresponding bit in DFSDM_FLTxCR2. If an interrupt is called, the flag must be cleared before exiting the interrupt service routine.

All the bits of DFSDM_FLTxISR are automatically reset when DFEN=0.

### 29.8.4 DFSDM filter x interrupt flag clear register (DFSDM_FLT0ICR)

Address offset: 0x10C + 0x80 * x, (x = 0 to 3)
Reset value: 0x0000 0000

</tbody>
</table>

**JCHG[7:0]**: Injected channel group selection  

JCHG[y]=0: channel y is not part of the injected group  
JCHG[y]=1: channel y is part of the injected group  
If JSCAN=1, each of the selected channels is converted, one after another. The lowest channel (channel 0, if selected) is converted first and the sequence ends at the highest selected channel.  
If JSCAN=0, then only one channel is converted from the selected channels, and the channel selection is moved to the next channel. Writing JCHG, if JSCAN=0, resets the channel selection to the lowest selected channel.  
At least one channel must always be selected for the injected group. Writes causing all JCHG bits to be zero are ignored.  

### 29.8.6 DFSDM filter x control register (DFSDM_FLTxCBFCR)  

Address offset: 0x114 + 0x80 * x, (x = 0 to 3)  
Reset value: 0x0000 0000

**FORD[2:0]**  

**FOSR[9:0]**  

**IOSR[7:0]**
**29.8.7 DFSDM filter x data register for injected group (DFSDMFLTxJDATAR)**

Address offset: 0x118 + 0x80 * x, (x = 0 to 3)

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>r r r r r r r r r r r r</td>
<td>Res. Res. Res. Res.</td>
<td>r r r r r r r r r r</td>
</tr>
</tbody>
</table>

**Bits 31:29 FORD[2:0]:** Sinc filter order

- 0: FastSinc filter type
- 1: Sinc\(^1\) filter type
- 2: Sinc\(^2\) filter type
- 3: Sinc\(^3\) filter type
- 4: Sinc\(^4\) filter type
- 5: Sinc\(^5\) filter type
- 6-7: Reserved

Sinc\(^x\) filter type transfer function:

\[
H(z) = \left(\frac{1 - z^{-FOSR}}{1 - z^{-1}}\right)^x
\]

FastSinc filter type transfer function:

\[
H(z) = \left(\frac{1 - z^{-2 \cdot FOSR}}{1 - z^{-1}}\right)^2 \cdot \left(1 + z^{-2 \cdot FOSR}\right)
\]

This bit can only be modified when DFEN=0 (DFSDMFLTxCR1).

**Bits 28:26:** Reserved, must be kept at reset value.

**Bits 25:16 FOSR[9:0]:** Sinc filter oversampling ratio (decimation rate)

0 - 1023: Defines the length of the Sinc type filter in the range 1 - 1024 (FOSR = FOSR[9:0] +1). This number is also the decimation ratio of the output data rate from filter.

This bit can only be modified when DFEN=0 (DFSDMFLTxCR1)

*Note: If FOSR = 0, then the filter has no effect (filter bypass).*

**Bits 15:8:** Reserved, must be kept at reset value.

**Bits 7:0 IOSR[7:0]:** Integrator oversampling ratio (averaging length)

0 - 255: The length of the Integrator in the range 1 - 256 (IOSR + 1). Defines how many samples from Sinc filter will be summed into one output data sample from the integrator. The output data rate from the integrator will be decreased by this number (additional data decimation ratio).

This bit can only be modified when DFEN=0 (DFSDMFLTxCR1)

*Note: If IOSR = 0, then the Integrator has no effect (Integrator bypass).*
Note: DMA may be used to read the data from this register. Half-word accesses may be used to read only the MSBs of conversion data. Reading this register also clears JEOCF in DFSDM_FLTxISR. Thus, the firmware must not read this register if DMA is activated to read data from this register.

29.8.8 DFSDM filter x data register for the regular channel (DFSDM_FLTxRDATAR)

Address offset: 0x11C + 0x80 * x, (x = 0 to 3)
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bits 31:8</th>
<th>JDATA[23:0]: Injected group conversion data</th>

</tbody>
</table>

Note: When conversion is interrupted (e.g. by disable/enable selected channel) the timer counts also this interruption time.

Bits 31:4 **CNVCNT[27:0]**: 28-bit timer counting conversion time \( t = CNVCNT[27:0] / f_{DFSDMCLK} \)

The timer has an input clock from DFSDM clock (system clock \( f_{DFSDMCLK} \)). Conversion time measurement is started on each conversion start and stopped when conversion finishes (interval between first and last serial sample). Only in case of filter bypass (FOSR[9:0] = 0) is the conversion time measurement stopped and CNVCNT[27:0] = 0. The counted time is:

- if FAST=0 (or first conversion in continuous mode if FAST=1):
  \[ t = \left( F_{OSR} \times (I_{OSR}-1 + F_{ORD}) + F_{ORD} \right) / f_{CKIN} \]
  for Sinc^6 filters
  \[ t = \left( F_{OSR} \times (I_{OSR}-1 + 4) + 2 \right) / f_{CKIN} \]
  for FastSinc filter

- if FAST=1 in continuous mode (except first conversion):
  \[ t = \left( F_{OSR} \times I_{OSR} \right) / f_{CKIN} \]

- in case if FOSR = FOSR[9:0]+1 = 1 (filter bypassed, active only integrator):
  \[ CNVCNT = 0 \] (counting is stopped, conversion time: \( t = I_{OSR} / f_{CKIN} \))

where: 
- \( f_{CKIN} \) is the channel input clock frequency (on given channel CKINy pin) or input data rate in case of parallel data input (from internal ADC or from CPU/DMA write)

Note: When conversion is interrupted (e.g. by disable/enable selected channel) the timer counts also this interruption time.

Bits 3:0 Reserved, must be kept at reset value.

Table 247. DFSDM register map and reset values (continued)
30 Digital camera interface (DCMI)

30.1 DCMI introduction

The digital camera is a synchronous parallel interface able to receive a high-speed data flow from an external 8-, 10-, 12- or 14-bit CMOS camera module. It supports different data formats: YCbCr4:2:2/RGB565 progressive video and compressed data (JPEG).

This interface is for use with black & white cameras, X24 and X5 cameras, and it is assumed that all preprocessing like resizing is performed in the camera module.

30.2 DCMI main features

- 8-, 10-, 12- or 14-bit parallel interface
- Embedded/external line and frame synchronization
- Continuous or snapshot mode
- Crop feature
- Supports the following data formats:
  - 8/10/12/14-bit progressive video: either monochrome or raw bayer
  - YCbCr 4:2:2 progressive video
  - RGB 565 progressive video
  - Compressed data: JPEG

30.3 DCMI clocks

The digital camera interface uses two clock domains, DCMI_PIXCLK and HCLK. The signals generated with DCMI_PIXCLK are sampled on the rising edge of HCLK once they are stable. An enable signal is generated in the HCLK domain, to indicate that data coming from the camera are stable and can be sampled. The maximum DCMI_PIXCLK period must be higher than 2.5 HCLK periods.

30.4 DCMI functional overview

The digital camera interface is a synchronous parallel interface that can receive high-speed data flows. It consists of up to 14 data lines (D13-D0) and a pixel clock line (DCMI_PIXCLK). The pixel clock has a programmable polarity, so that data can be captured on either the rising or the falling edge of the pixel clock.

The data are packed into a 32-bit data register (DCMI_DR) and then transferred through a general-purpose DMA channel. The image buffer is managed by the DMA, not by the camera interface.

The data received from the camera can be organized in lines/frames (raw YUB/RGB/Bayer modes) or can be a sequence of JPEG images. To enable JPEG image reception, the JPEG bit (bit 3 of DCMI_CR register) must be set.
The data flow is synchronized either by hardware using the optional DCMI_HSYNC (horizontal synchronization) and DCMI_VSYNC (vertical synchronization) signals or by synchronization codes embedded in the data flow.

### 30.4.1 DCMI block diagram

*Figure 232* shows the DCMI block diagram.

</tbody>
</table>

30.4.3 DMA interface

The DMA interface is active when the CAPTURE bit in the DCMI_CR register is set. A DMA request is generated each time the camera interface receives a complete 32-bit data block in its register.

30.4.4 DCMI physical interface

The interface is composed of 11/13/15/17 inputs. Only the Slave mode is supported.

The camera interface can capture 8-bit, 10-bit, 12-bit or 14-bit data depending on the EDM[1:0] bits in the DCMI_CR register. If less than 14 bits are used, the unused input pins must be connected to ground.

Table 249 shows the DCMI pins.

<table>
<thead>
<tr>

</tr>
<tr>
<td>DCMI_VSYNC</td>
<td>Digital input</td>
<td>Vertical synchronization</td>
</tr>
</tbody>
</table>

The data are synchronous with DCMI_PIXCLK and change on the rising/falling edge of the pixel clock depending on the polarity.

The DCMI_HSYNC signal indicates the start/end of a line.

The DCMI_VSYNC signal indicates the start/end of a frame.
1. The capture edge of DCMI_PIXCLK is the falling edge, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.

2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.

8-bit data

When EDM[1:0] in DCMI_CR are programmed to “00” the interface captures 8 LSBs at its input (DCMI_D[0:7]) and stores them as 8-bit data. The DCMI_D[13:8] inputs are ignored. In this case, to capture a 32-bit word, the camera interface takes four pixel clock cycles.

The first captured data byte is placed in the LSB position in the 32-bit word and the 4th captured data byte is placed in the MSB position in the 32-bit word. *Table 250* gives an example of the positioning of captured data bytes in two 32-bit words.

<table>
<thead>
<tr>
<th>Byte address</th>
<th>31:24</th>
<th>23:16</th>
<th>15:8</th>
<th>7:0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>$D_{n+3}[7:0]$</td>
<td>$D_{n+2}[7:0]$</td>
<td>$D_{n+1}[7:0]$</td>
<td>$D_n[7:0]$</td>
</tr>
<tr>
<td>4</td>
<td>$D_{n+7}[7:0]$</td>
<td>$D_{n+6}[7:0]$</td>
<td>$D_{n+5}[7:0]$</td>
<td>$D_{n+4}[7:0]$</td>
</tr>
</tbody>
</table>

10-bit data

When EDM[1:0] in DCMI_CR are programmed to “01”, the camera interface captures 10-bit data at its input DCMI_D[0:9] and stores them as the 10 least significant bits of a 16-bit word. The remaining most significant bits in the DCMI_DR register (bits 11 to 15) are cleared to zero. So, in this case, a 32-bit data word is made up every two pixel clock cycles.

The first captured data are placed in the LSB position in the 32-bit word and the 2nd captured data are placed in the MSB position in the 32-bit word as shown in *Table 251*.

<table>
<thead>
<tr>
<th>Byte address</th>
<th>31:26</th>
<th>25:16</th>
<th>15:10</th>
<th>9:0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>

</tr>
<tr>
<td>4</td>
<td>0</td>
<td>$D_{n+3}[9:0]$</td>
<td>0</td>
<td>$D_{n+2}[9:0]$</td>
</tr>
</tbody>
</table>
12-bit data

When EDM[1:0] in DCMI_CR are programmed to “10”, the camera interface captures the 12-bit data at its input DCMI_D[0..11] and stores them as the 12 least significant bits of a 16-bit word. The remaining most significant bits are cleared to zero. So, in this case a 32-bit data word is made up every two pixel clock cycles.

The first captured data are placed in the LSB position in the 32-bit word and the 2nd captured data are placed in the MSB position in the 32-bit word as shown in Table 252.

<table>
<thead>
<tr>
<th>Byte address</th>

<td>0</td>
<td>D_{n}[11:0]</td>
</tr>
<tr>
<td>4</td>
<td>0</td>
<td>D_{n+3}[11:0]</td>
<td>0</td>
<td>D_{n+2}[11:0]</td>
</tr>
</tbody>
</table>

14-bit data

When EDM[1:0] in DCMI_CR are programmed to “11”, the camera interface captures the 14-bit data at its input DCMI_D[0..13] and stores them as the 14 least significant bits of a 16-bit word. The remaining most significant bits are cleared to zero. So, in this case a 32-bit data word is made up every two pixel clock cycles.

The first captured data are placed in the LSB position in the 32-bit word and the 2nd captured data are placed in the MSB position in the 32-bit word as shown in Table 253.

<table>

</tr>
<tr>
<td>4</td>
<td>0</td>
<td>D_{n+3}[13:0]</td>
<td>0</td>
<td>D_{n+2}[13:0]</td>
</tr>
</tbody>
</table>

30.4.5 Synchronization

The digital camera interface supports embedded or hardware (DCMI_HSYNC and DCMI_VSYNC) synchronization. When embedded synchronization is used, it is up to the digital camera module to make sure that the 0x00 and 0xFF values are used ONLY for synchronization (not in data). Embedded synchronization codes are supported only for the 8-bit parallel data interface width (that is, in the DCMI_CR register, the EDM[1:0] bits should be cleared to “00”).

For compressed data, the DCMI supports only the hardware synchronization mode. In this case, DCMI_VSYNC is used as a start/end of the image, and DCMI_HSYNC is used as a Data Valid signal. Figure 235 shows the corresponding timing diagram.
Hardware synchronization mode

In hardware synchronization mode, the two synchronization signals (DCMI_HSYNC/DCMI_VSYNC) are used.

Depending on the camera module/mode, data may be transmitted during horizontal/vertical synchronization periods. The DCMI_HSYNC/DCMI_VSYNC signals act like blanking signals since all the data received during DCMI_HSYNC/DCMI_VSYNC active periods are ignored.

In order to correctly transfer images into the DMA/RAM buffer, data transfer is synchronized with the DCMI_VSYNC signal. When the hardware synchronization mode is selected, and capture is enabled (CAPTURE bit set in DCMI_CR), data transfer is synchronized with the deactivation of the DCMI_VSYNC signal (next start of frame).

Transfer can then be continuous, with successive frames transferred by DMA to successive buffers or the same/circular buffer. To allow the DMA management of successive frames, a VSIF (Vertical synchronization interrupt flag) is activated at the end of each frame.

Embedded data synchronization mode

In this synchronization mode, the data flow is synchronized using 32-bit codes embedded in the data flow. These codes use the 0x00/0xFF values that are not used in data anymore. There are 4 types of codes, all with a 0xFF0000XY format. The embedded synchronization codes are supported only in 8-bit parallel data width capture (in the DCMI_CR register, the EDM[1:0] bits should be programmed to “00”). For other data widths, this mode generates unpredictable results and must not be used.
Note: Camera modules can have 8 such codes (in interleaved mode). For this reason, the interleaved mode is not supported by the camera interface (otherwise, every other half-frame would be discarded).

- **Mode 2**
  Four embedded codes signal the following events
  - Frame start (FS)
  - Frame end (FE)
  - Line start (LS)
  - Line end (LE)

  The XY values in the 0xFF0000XY format of the four codes are programmable (see Section 30.7.7: DCMI embedded synchronization code register (DCMI_ESCR)).

  A 0xFF value programmed as a “frame end” means that all the unused codes are interpreted as valid frame end codes.

  In this mode, once the camera interface has been enabled, the frame capture starts after the first occurrence of the frame end (FE) code followed by a frame start (FS) code.

- **Mode 1**
  An alternative coding is the camera mode 1. This mode is ITU656 compatible.

  The codes signal another set of events:
  - SAV (active line) - line start
  - EAV (active line) - line end
  - SAV (blanking) - end of line during interframe blanking period
  - EAV (blanking) - end of line during interframe blanking period

  This mode can be supported by programming the following codes:
  - FS ≤ 0xFF
  - FE ≤ 0xFF
  - LS ≤ SAV (active)
  - LE ≤ EAV (active)

  An embedded unmask code is also implemented for frame/line start and frame/line end codes. Using it, it is possible to compare only the selected unmasked bits with the programmed code. You can therefore select a bit to compare in the embedded code and detect a frame/line start or frame/line end. This means that there can be different codes for the frame/line start and frame/line end with the unmasked bit position remaining the same.

**Example**

FS = 0xA5

Unmask code for FS = 0x10

In this case the frame start code is embedded in the bit 4 of the frame start code.
30.4.6 Capture modes

This interface supports two types of capture: snapshot (single frame) and continuous grab.

**Snapshot mode (single frame)**

In this mode, a single frame is captured (CM = ‘1’ in the DCMI_CR register). After the CAPTURE bit is set in DCMI_CR, the interface waits for the detection of a start of frame before sampling the data. The camera interface is automatically disabled (CAPTURE bit cleared in DCMI_CR) after receiving the first complete frame. An interrupt is generated (IT_FRAME) if it is enabled.

In case of an overrun, the frame is lost and the CAPTURE bit is cleared.

**Continuous grab mode**

In this mode (CM bit = ‘0’ in DCMI_CR), once the CAPTURE bit has been set in DCMI_CR, the grabbing process starts on the next DCMI_VSYNC or embedded frame start depending on the mode. The process continues until the CAPTURE bit is cleared in DCMI_CR. Once the CAPTURE bit has been cleared, the grabbing process continues until the end of the current frame.
1. Here, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.
2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.

In continuous grab mode, you can configure the FCRC bits in DCMI_CR to grab all pictures, every second picture or one out of four pictures to decrease the frame capture rate.

Note: In the hardware synchronization mode (ESS = '0' in DCMI_CR), the IT_VSYNC interrupt is generated (if enabled) even when CAPTURE = '0' in DCMI.CR so, to reduce the frame capture rate even further, the IT_VSYNC interrupt can be used to count the number of frames between 2 captures in conjunction with the Snapshot mode. This is not allowed by embedded data synchronization mode.

30.4.7 Crop feature

With the crop feature, the camera interface can select a rectangular window from the received image. The start (upper left corner) coordinates and size (horizontal dimension in number of pixel clocks and vertical dimension in number of lines) are specified using two 32-bit registers (DCMI_CWSTRT and DCMI_CWSIZE). The size of the window is specified in number of pixel clocks (horizontal dimension) and in number of lines (vertical dimension).

These registers specify the coordinates of the starting point of the capture window as a line number (in the frame, starting from 0) and a number of pixel clocks (on the line, starting from 0), and the size of the window as a line number and a number of pixel clocks. The CAPCNT value can only be a multiple of 4 (two least significant bits are forced to 0) to allow the correct transfer of data through the DMA.
If the DCMI_VSYNC signal goes active before the number of lines is specified in the DCMI_CWSIZE register, then the capture stops and an IT_FRAME interrupt is generated when enabled.

**Figure 239. Data capture waveforms**

1. Here, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.
2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.

### 30.4.8 JPEG format

To allow JPEG image reception, it is necessary to set the JPEG bit in the DCMI_CR register. JPEG images are not stored as lines and frames, so the DCMI_VSYNC signal is used to start the capture while DCMI_HSYNC serves as a data enable signal. The number of bytes in a line may not be a multiple of 4, you should therefore be careful when handling this case since a DMA request is generated each time a complete 32-bit word has been constructed from the captured data. When an end of frame is detected and the 32-bit word to be transferred has not been completely received, the remaining data are padded with ‘0s’ and a DMA request is generated.

The crop feature and embedded synchronization codes cannot be used in the JPEG format.

### 30.4.9 FIFO

**Input mode**

A four-word FIFO is implemented to manage data rate transfers on the AHB. The DCMI features a simple FIFO controller with a read pointer incremented each time the camera interface reads from the AHB, and a write pointer incremented each time the camera interface writes to the FIFO. There is no overrun protection to prevent the data from being overwritten if the AHB interface does not sustain the data transfer rate.

In case of overrun or errors in the synchronization signals, the FIFO is reset and the DCMI interface waits for a new start of frame.
30.5 Data format description

30.5.1 Data formats

Three types of data are supported:

- 8/10/12/14-bit progressive video: either monochrome or raw Bayer format
- YCbCr 4:2:2 progressive video
- RGB565 progressive video. A pixel coded in 16 bits (5 bits for blue, 5 bits for red, 6 bits for green) takes two clock cycles to be transferred.

Compressed data: JPEG

For B&W, YCbCr or RGB data, the maximum input size is 2048 × 2048 pixels. No limit in JPEG compressed mode.

For monochrome, RGB & YCbCr, the frame buffer is stored in raster mode. 32-bit words are used. Only the little endian format is supported.

![Pixel raster scan order](ai15848)

30.5.2 Monochrome format

Characteristics:

- Raster format
- 8 bits per pixel

*Table 254* shows how the data are stored.

30.5.3  RGB format

Characteristics:
- Raster format
- RGB
- Interleaved: one buffer: R, G & B interleaved: BRGBRGRBG, etc.
- Optimized for display output

The RGB planar format is compatible with standard OS frame buffer display formats. Only 16 BPP (bits per pixel): RGB565 (2 pixels per 32-bit word) is supported. The 24 BPP (palletized format) and grayscale formats are not supported. Pixels are stored in a raster scan order, that is from top to bottom for pixel rows, and from left to right within a pixel row. Pixel components are R (red), G (green) and B (blue). All components have the same spatial resolution (4:4:4 format). A frame is stored in a single part, with the components interleaved on a pixel basis.

*Table 255* shows how the data are stored.

<table>
<thead>
<tr>
<th>Byte address</th>
<th>31:27</th>

<td>Blue n + 3</td>
<td>Red n + 2</td>
<td>Green n + 2</td>
<td>Blue n + 2</td>
</tr>
</tbody>
</table>

30.5.4  YCbCr format

Characteristics:
- Raster format
- YCbCr 4:2:2
- Interleaved: one Buffer: Y, Cb & Cr interleaved: CbYCrYCbYCr, etc.

Pixel components are Y (luminance or “luma”), Cb and Cr (chrominance or “chroma” blue and red). Each component is encoded in 8 bits. Luma and chroma are stored together (interleaved) as shown in *Table 256*.

<table>
<thead>
<tr>
<th>Byte address</th>
<th>31:24</th>
<th>23:16</th>
<th>15:8</th>
<th>7:0</th>

<td>Cb n</td>
</tr>
<tr>
<td>4</td>
<td>Y n + 3</td>
<td>Cr n + 2</td>
<td>Y n + 2</td>
<td>Cb n + 2</td>
</tr>
</tbody>
</table>

30.5.5  YCbCr format - Y only

Characteristics:
- Raster format
- YCbCr 4:2:2
- The buffer only contains Y information - monochrome image

Pixel components are Y (luminance or “luma”), Cb and Cr (chrominance or “chroma” blue and red). In this mode, the chroma information is dropped. Only Luma component of each...
pixel, encoded in 8 bits, is stored as shown in Table 257.

The result is a monochrome image having the same resolution as the original YCbCr data.

### Table 257. Data storage in YCbCr progressive video format - Y extraction mode

</table>

#### 30.5.6 Half resolution image extraction

This is a modification of the previous reception modes, being applicable to monochrome, RGB or Y extraction modes.

This mode allows to only store a half resolution image. It is selected through OELS and LSM control bits.

#### 30.6 DCMI interrupts

Five interrupts are generated. All interrupts are maskable by software. The global interrupt (dcmi_it) is the OR of all the individual interrupts. Table 258 gives the list of all interrupts.

### Table 258. DCMI interrupts

</tbody>
</table>

#### 30.7 DCMI register description

All DCMI registers have to be accessed as 32-bit words, otherwise a bus error occurs.

#### 30.7.1 DCMI control register (DCMI_CR)

Address offset: 0x00
Reset value: 0x0000 0000
Digital camera interface (DCMI)

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **OELS**: Odd/Even Line Select (Line Select Start)

This bit works in conjunction with LSM field (LSM = 1)

0: Interface captures first line after the frame start, second one being dropped
1: Interface captures second line from the frame start, first one being dropped

Bit 19 **LSM**: Line Select mode

0: Interface captures all received lines
1: Interface captures one line out of two.

Bit 18 **OEBS**: Odd/Even Byte Select (Byte Select Start)

This bit works in conjunction with BSM field (BSM ≠ 00)

0: Interface captures first data (byte or double byte) from the frame/line start, second one being dropped
1: Interface captures second data (byte or double byte) from the frame/line start, first one being dropped

Bits 17:16 **BSM[1:0]**: Byte Select mode

00: Interface captures all received data
01: Interface captures every other byte from the received data
10: Interface captures one byte out of four
11: Interface captures two bytes out of four

*Note*: This mode only work for EDM[1:0]=00. For all other EDM values, this bit field must be programmed to the reset value.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **ENABLE**: DCMI enable

0: DCMI disabled
1: DCMI enabled

*Note*: The DCMI configuration registers should be programmed correctly before enabling this Bit

Bits 13:12 Reserved, must be kept at reset value.

Bits 11:10 **EDM[1:0]**: Extended data mode

00: Interface captures 8-bit data on every pixel clock
01: Interface captures 10-bit data on every pixel clock
10: Interface captures 12-bit data on every pixel clock
11: Interface captures 14-bit data on every pixel clock

Bits 9:8 **FCRC[1:0]**: Frame capture rate control

These bits define the frequency of frame capture. They are meaningful only in Continuous grab mode. They are ignored in snapshot mode.

00: All frames are captured
01: Every alternate frame captured (50% bandwidth reduction)
10: One frame in 4 frames captured (75% bandwidth reduction)
11: reserved
Bit 7 **VSPOL:** Vertical synchronization polarity
This bit indicates the level on the DCMI_VSYNC pin when the data are not valid on the parallel interface.
0: DCMI_VSYNC active low
1: DCMI_VSYNC active high

Bit 6 **HSPOL:** Horizontal synchronization polarity
This bit indicates the level on the DCMI_HSYNC pin when the data are not valid on the parallel interface.
0: DCMI_HSYNC active low
1: DCMI_HSYNC active high

Bit 5 **PCKPOL:** Pixel clock polarity
This bit configures the capture edge of the pixel clock
0: Falling edge active.
1: Rising edge active.

Bit 4 **ESS:** Embedded synchronization select
0: Hardware synchronization data capture (frame/line start/stop) is synchronized with the DCMI_HSYNC/DCMI_VSYNC signals.
1: Embedded synchronization data capture is synchronized with synchronization codes embedded in the data flow.

*Note: Valid only for 8-bit parallel data. HSPOL/VSPOL are ignored when the ESS bit is set.*
This bit is disabled in JPEG mode.

Bit 3 **JPEG:** JPEG format
0: Uncompressed video format
1: This bit is used for JPEG data transfers. The DCMI_HSYNC signal is used as data enable. The crop and embedded synchronization features (ESS bit) cannot be used in this mode.

Bit 2 **CROP:** Crop feature
0: The full image is captured. In this case the total number of bytes in an image frame should be a multiple of 4
1: Only the data inside the window specified by the crop register will be captured. If the size of the crop window exceeds the picture size, then only the picture size is captured.

Bit 1 **CM:** Capture mode
0: Continuous grab mode - The received data are transferred into the destination memory through the DMA. The buffer location and mode (linear or circular buffer) is controlled through the system DMA.
1: Snapshot mode (single frame) - Once activated, the interface waits for the start of frame and then transfers a single frame through the DMA. At the end of the frame, the CAPTURE bit is automatically reset.
Bit 0 CAPTURE: Capture enable
0: Capture disabled.
1: Capture enabled.
The camera interface waits for the first start of frame, then a DMA request is generated to transfer the received data into the destination memory.
In snapshot mode, the CAPTURE bit is automatically cleared at the end of the 1st frame received.
In continuous grab mode, if the software clears this bit while a capture is ongoing, the bit will be effectively cleared after the frame end.
Note: The DMA controller and all DCMI configuration registers should be programmed correctly before enabling this bit.
### 30.7.2 DCMI status register (DCMI_SR)

Address offset: 0x04  
Reset value: 0x0000 0000

</table>

Bits 31:3 Reserved, must be kept at reset value.

- **Bit 2 FNE**: FIFO not empty  
  This bit gives the status of the FIFO  
  1: FIFO contains valid data  
  0: FIFO empty

- **Bit 1 VSYNC**:  
  This bit gives the state of the DCMI_VSYNC pin with the correct programmed polarity.  
  When embedded synchronization codes are used, the meaning of this bit is the following:  
  0: active frame  
  1: synchronization between frames  
  In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in DCMI_CR is set.

- **Bit 0 HSYNC**:  
  This bit gives the state of the DCMI_HSYNC pin with the correct programmed polarity.  
  When embedded synchronization codes are used, the meaning of this bit is the following:  
  0: active line  
  1: synchronization between lines  
  In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in DCMI_CR is set.
### 30.7.3 DCMI raw interrupt status register (DCMI_RIS)

Address offset: 0x08

<td>This bit is cleared by writing a ‘1’ to the FRAME_ISC bit in DCMI_ICR.</td>
<td></td>
</tr>
</tbody>
</table>

DCMI_RIS gives the raw interrupt status and is accessible in read only. When read, this register returns the status of the corresponding interrupt before masking with the DCMI_IER register value.
30.7.4  DCMI interrupt enable register (DCMI_IER)

Address offset: 0x0C
Reset value: 0x0000 0000

The DCMI_IER register is used to enable interrupts. When one of the DCMI_IER bits is set, the corresponding interrupt is enabled. This register is accessible in both read and write.

| Bit | Bit 31:5 Reserved, must be kept at reset value. |
| Bit 4 | LINE_IE: Line interrupt enable |
| | 0: No interrupt generation when the line is received |
| | 1: An interrupt is generated when a line has been completely received |
| Bit 3 | VSYNC_IE: DCMI_VSYNC interrupt enable |
| | 0: No interrupt generation |
| | 1: An interrupt is generated on each DCMI_VSYNC transition from the inactive to the active state |
| | The active state of the DCMI_VSYNC signal is defined by the VSPOL bit. |
| Bit 2 | ERR_IE: Synchronization error interrupt enable |
| | 0: No interrupt generation |
| | 1: An interrupt is generated if the embedded synchronization codes are not received in the correct order. |
| | Note: This bit is available only in embedded synchronization mode. |
| Bit 1 | OVR_IE: Overrun interrupt enable |
| | 0: No interrupt generation |
| | 1: An interrupt is generated if the DMA was not able to transfer the last data before new data (32-bit) are received. |
| Bit 0 | FRAME_IE: Capture complete interrupt enable |
| | 0: No interrupt generation |
| | 1: An interrupt is generated at the end of each received frame/crop window (in crop mode). |
30.7.5 DCMI masked interrupt status register (DCMI_MIS)

This DCMI_MIS register is a read-only register. When read, it returns the current masked status value (depending on the value in DCMI_IER) of the corresponding interrupt. A bit in this register is set if the corresponding enable bit in DCMI_IER is set and the corresponding bit in DCMI_RIS is set.

Address offset: 0x10
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31-5</th>

</thead>
<tbody>
<tr>
<td>31-5</td>
<td>r</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 LINE_MIS: Line masked interrupt status
This bit gives the status of the masked line interrupt
0: No interrupt generation when the line is received
1: An Interrupt is generated when a line has been completely received and the LINE_IE bit is set in DCMI_IER.

Bit 3 VSYNC_MIS: VSYNC masked interrupt status
This bit gives the status of the masked VSYNC interrupt
0: No interrupt is generated on DCMI_VSYNC transitions
1: An interrupt is generated on each DCMI_VSYNC transition from the inactive to the active state and the VSYNC_IE bit is set in DCMI_IER.
The active state of the DCMI_VSYNC signal is defined by the VSPOL bit.

Bit 2 ERR_MIS: Synchronization error masked interrupt status
This bit gives the status of the masked synchronization error interrupt
0: No interrupt is generated on a synchronization error
1: An interrupt is generated if the embedded synchronization codes are not received in the correct order and the ERR_IE bit in DCMI_IER is set.
Note: This bit is available only in embedded synchronization mode.

Bit 1 OVR_MIS: Overrun masked interrupt status
This bit gives the status of the masked overflow interrupt
0: No interrupt is generated on overrun
1: An interrupt is generated if the DMA was not able to transfer the last data before new data (32-bit) are received and the OVR_IE bit is set in DCMI_IER.

Bit 0 FRAME_MIS: Capture complete masked interrupt status
This bit gives the status of the masked capture complete interrupt
0: No interrupt is generated after a complete capture
1: An interrupt is generated at the end of each received frame/crop window (in crop mode) and the FRAME_IE bit is set in DCMI_IER.
### 30.7.6 DCMI interrupt clear register (DCMI_ICR)

The DCMI_ICR register is write-only. Writing a ‘1’ into a bit of this register clears the corresponding bit in the DCMI_RIS and DCMI_MIS registers. Writing a ‘0’ has no effect.

- **Bits 31:5** Reserved, must be kept at reset value.
- **Bit 4** **LINE_ICSC**: line interrupt status clear
  Writing a ‘1’ into this bit clears LINE_RIS in the DCMI_RIS register
- **Bit 3** **VSYNC_ICSC**: Vertical Synchronization interrupt status clear
  Writing a ‘1’ into this bit clears the VSYNC_RIS bit in DCMI_RIS
- **Bit 2** **ERR_ICSC**: Synchronization error interrupt status clear
  Writing a ‘1’ into this bit clears the ERR_RIS bit in DCMI_RIS
  **Note**: This bit is available only in embedded synchronization mode.
- **Bit 1** **OVR_ICSC**: Overrun interrupt status clear
  Writing a ‘1’ into this bit clears the OVR_RIS bit in DCMI_RIS
- **Bit 0** **FRAME_ICSC**: Capture complete interrupt status clear
  Writing a ‘1’ into this bit clears the FRAME_RIS bit in DCMI_RIS

Bits 31:24 **FEC[7:0]**: Frame end delimiter code  
This byte specifies the code of the frame end delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, FEC.  
If FEC is programmed to 0xFF, all the unused codes (0xFF0000XY) are interpreted as frame end delimiters.

Bits 23:16 **LEC[7:0]**: Line end delimiter code  
This byte specifies the code of the line end delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, LEC.

Bits 15:8 **LSC[7:0]**: Line start delimiter code  
This byte specifies the code of the line start delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, LSC.

Bits 7:0 **FSC[7:0]**: Frame start delimiter code  
This byte specifies the code of the frame start delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, FSC.  
If FSC is programmed to 0xFF, no frame start delimiter is detected. But, the 1st occurrence of LSC after an FEC code will be interpreted as a start of frame delimiter.
### 30.7.8 DCMI embedded synchronization unmask register (DCMI_ESUR)

**Bits 31:24** **FEU[7:0]: Frame end delimiter unmask**

This byte specifies the mask to be applied to the code of the frame end delimiter.
0: The corresponding bit in the FEC byte in DCMI_ESCR is masked while comparing the frame end delimiter with the received data.
1: The corresponding bit in the FEC byte in DCMI_ESCR is compared while comparing the frame end delimiter with the received data

**Bits 23:16** **LEU[7:0]: Line end delimiter unmask**

This byte specifies the mask to be applied to the code of the line end delimiter.
0: The corresponding bit in the LEC byte in DCMI_ESCR is masked while comparing the line end delimiter with the received data.
1: The corresponding bit in the LEC byte in DCMI_ESCR is compared while comparing the line end delimiter with the received data

**Bits 15:8** **LSU[7:0]: Line start delimiter unmask**

This byte specifies the mask to be applied to the code of the line start delimiter.
0: The corresponding bit in the LSC byte in DCMI_ESCR is masked while comparing the line start delimiter with the received data.
1: The corresponding bit in the LSC byte in DCMI_ESCR is compared while comparing the line start delimiter with the received data

**Bits 7:0** **FSU[7:0]: Frame start delimiter unmask**

This byte specifies the mask to be applied to the code of the frame start delimiter.
0: The corresponding bit in the FSC byte in DCMI_ESCR is masked while comparing the frame start delimiter with the received data.
1: The corresponding bit in the FSC byte in DCMI_ESCR is compared while comparing the frame start delimiter with the received data

Refer to *Section 2.3 on page 126* for the register boundary addresses.
31 LCD-TFT display controller (LTDC)

31.1 Introduction

The LCD-TFT (liquid crystal display - thin film transistor) display controller provides a parallel digital RGB (red, green, blue) and signals for horizontal, vertical synchronization, pixel clock and data enable as output to interface directly to a variety of LCD and TFT panels.

31.2 LTDC main features

- 24-bit RGB parallel pixel output; 8 bits-per-pixel (RGB888)
- 2 display layers with dedicated FIFO (64x64-bit)
- Color look-up table (CLUT) up to 256 color (256x24-bit) per layer
- Programmable timings for different display panels
- Programmable background color
- Programmable polarity for HSYNC, VSYNC and data enable
- Up to 8 input color formats selectable per layer
  - ARGB8888
  - RGB888
  - RGB565
  - ARGB1555
  - ARGB4444
  - L8 (8-bit luminance or CLUT)
  - AL44 (4-bit alpha + 4-bit luminance)
  - AL88 (8-bit alpha + 8-bit luminance)
- Pseudo-random dithering output for low bits per channel
  - Dither width 2-bits for red, green, blue
- Flexible blending between two layers using alpha value (per pixel or constant)
- Color keying (transparency color)
- Programmable window position and size
- Supports thin film transistor (TFT) color displays
- AXI master interface with burst of 16 double-words
- Up to 4 programmable interrupt events

31.3 LTDC functional description

31.3.1 LTDC block diagram

The block diagram of the LTDC is shown in Figure 241: LTDC block diagram.
Layer FIFO: One FIFO 64x64-bit per layer.

PFC: pixel format converter, performing the pixel format conversion from the selected input pixel format of a layer to words.

AXI interface: for data transfer from memories to the FIFO.

Blending, dithering unit and timings generator: Refer to Section 31.4.1 and Section 31.4.2.

### 31.3.2 LCD-TFT internal signals

*Table 260* gives the list of LCD-TFT internal signals.

<table>
<thead>
<tr>

</tr>
<tr>
<td>LCD_B[7:0]</td>
<td>O</td>
<td>Data: 8-bit blue data</td>
</tr>
</tbody>
</table>

The LTDC-TFT controller pins must be configured by the user application. The unused pins can be used for other purposes.

For LTDC outputs up to 24-bit (RGB888), if less than 8 bpp are used to output for example RGB565 or RGB666 to interface on 16- or 18-bit displays, the RGB display data lines must be connected to the MSB of the LCD-TFT controller RGB data lines. As an example, in the case of an LCD-TFT controller interfacing with a RGB565 16-bit display, the LCD display R[4:0], G[5:0] and B[4:0] data lines pins must be connected to LCD-TFT controller LCD_R[7:3], LCD_G[7:2] and LCD_B[7:3].

31.3.4 LTDC reset and clocks

The LCD-TFT controller peripheral uses 3 clock domains:

- **AXI clock domain (ltdc_aclk)**
  This domain contains the LCD-TFT AXI master interface for data transfer from the memories to the Layer FIFO and the frame buffer configuration register.

- **APB clock domain (ltdc_pclk):**
  This domain contains the global configuration registers and the interrupt register.

- **Pixel clock domain (LCD_CLK)**
  This domain contains the pixel data generation, the layer configuration register as well as the LCD-TFT interface signal generator. The LCD_CLK output should be configured following the panel requirements. The LCD_CLK is generated from a specific PLL output (refer to the reset and clock control section).

Table 262 summarizes the clock domain for each register.
Table 262. Clock domain for each register

</tr>
<tr>
<td>Register write access duration</td>
<td>6 x ltdc_pclk + 5 x ltdc_aclk</td>
</tr>
</tbody>
</table>
The LCD controller can be reset by setting the corresponding bit in the RCC_APBRSTR register. It resets the three clock domains.

31.4 LTDC programmable parameters

The LCD-TFT controller provides flexible configurable parameters. It can be enabled or disabled through the LTDC_GCR register.

31.4.1 LTDC global configuration parameters

Synchronous timings

*Figure 242* presents the configurable timing parameters generated by the synchronous timings generator block presented in the block diagram *Figure 241*. It generates the horizontal and vertical synchronization timings panel signals, the pixel clock and the data enable signals.

![LCD-TFT synchronous timings](MSv19674V1)

**Note:** The HBP and HFP are respectively the horizontal back porch and front porch period. The VBP and the VFP are respectively the vertical back porch and front porch period.
The LCD-TFT programmable synchronous timings are:

- **HSYNC and VSYNC width**: horizontal and vertical synchronization width, configured by programming a value of $\text{HSYNC width} - 1$ and $\text{VSYNC width} - 1$ in the LTDC_SSCR register.

- **HBP and VBP**: horizontal and vertical synchronization back porch width, configured by programming the accumulated value $\text{HSYNC width} + \text{HBP} - 1$ and the accumulated value $\text{VSYNC width} + \text{VBP} - 1$ in the LTDC_BPCR register.

- **Active width and active height**: the active width and active height are configured by programming the accumulated value $\text{HSYNC width} + \text{HBP} + \text{active width} - 1$ and the accumulated value $\text{VSYNC width} + \text{VBP} + \text{active height} - 1$ in the LTDC_AWCR register.

- **Total width**: the total width is configured by programming the accumulated value $\text{HSYNC width} + \text{HBP} + \text{active width} + \text{HFP} - 1$ in the LTDC_TWCR register. The HFP is the horizontal front porch period.

- **Total height**: the total height is configured by programming the accumulated value $\text{VSYNC height} + \text{VBP} + \text{active height} + \text{VFP} - 1$ in the LTDC_TWCR register. The VFP is the vertical front porch period.

**Note:** When the LTDC is enabled, the timings generated start with $X/Y=0/0$ position as the first horizontal synchronization pixel in the vertical synchronization area and following the back porch, active data display area and the front porch.

When the LTDC is disabled, the timing generator block is reset to $X=\text{total width} - 1$, $Y=\text{total height} - 1$ and held the last pixel before the vertical synchronization phase and the FIFO are flushed. Therefore only blanking data is output continuously.

**Example of synchronous timings configuration**

TFT-LCD timings (must be extracted from panel datasheet):

- horizontal and vertical synchronization width: $0xA$ pixels and $0x2$ lines
- horizontal and vertical back porch: $0x14$ pixels and $0x2$ lines
- active width and active height: $0x140$ pixels, $0xF0$ lines ($320 \times 240$)
- horizontal front porch: $0xA$ pixels
- vertical front porch: $0x4$ lines

The programmed values in the LTDC timings registers are:

- **LTDC_SSCR register**: to be programmed to $0x00090001$. (H$\text{SW}[11:0]$ is $0x9$ and V$\text{SH}[10:0]$ is $0x1$)
- **LTDC_BPCR register**: to be programmed to $0x001D0003$ (A$\text{HBP}[11:0]$ is $0x1D(0xA+0x13)$ and A$\text{VBP}[10:0]$ is $0x3(0x2 + 0x1)$).
- **LTDC_AWCR register**: to be programmed to $0x015D00F3$ (A$\text{AW}[11:0]$ is $0x15D(0xA+0x14 +0x13F)$ and A$\text{AH}[10:0]$ is $0xF3(0x2 +0x2 +0xEF)$).
- **LTDC_TWCR register**: to be programmed to $0x00000167$ (TOTAL$\text{W}[11:0]$ is $0x167(0xA+0x14 +0x140 +0x9)$).
- **LTDC_THCR register**: to be programmed to $0x000000F7$ (TOTAL$\text{H}[10:0]$ is $0xF7(0x2 +0x2 +0xF0 +3)$)

**Programmable polarity**

The horizontal and vertical synchronization, data enable and pixel clock output signals polarity can be programmed to active high or active low through the LTDC_GCR register.
Background color
A constant background color (RGB888) can be programmed through the LTDC_BCCR register. It is used for blending with the bottom layer.

Dithering
The dithering pseudo-random technique using an LFSR is used to add a small random value (threshold) to each pixel color channel (R, G or B) value, thus rounding up the MSB in some cases when displaying a 24-bit data on 18-bit display. Thus the Dithering technique is used to round data which is different from one frame to the other.

The dithering pseudo-random technique is the same as comparing LSBs against a threshold value and adding a 1 to the MSB part only, if the LSB part is >= the threshold. The LSBs are typically dropped once dithering was applied.

The width of the added pseudo-random value is 2 bits for each color channel: 2 bits for red, 2 bits for green, and 2 bits for blue.

Once the LCD-TFT controller is enabled, the LFSR starts running with the first active pixel and it is kept running even during blanking periods and when dithering is switched off. If the LTDC is disabled, the LFSR is reset.

The dithering can be switched On and Off on the fly through the LTDC_GCR register.

Reload shadow registers
Some configuration registers are shadowed. The shadow registers values can be reloaded immediately to the active registers when writing to these registers or at the beginning of the vertical blanking period following the configuration in the LTDC_SRCR register. If the immediate reload configuration is selected, the reload should be only activated when all new registers have been written.

The shadow registers should not be modified again before the reload has been done. Reading from the shadow registers returns the actual active value. The new written value can only be read after the reload has taken place.

A register reload interrupt can be generated if enabled in the LTDC_IER register.

The shadowed registers are all the layer1 and layer2 registers except the LTDC_LxCLUTWR register.

Interrupt generation event
Refer to Section 31.5: LTDC interrupts for interrupt configuration.

31.4.2 Layer programmable parameters
Up to two layers can be enabled, disabled and configured separately. The layer display order is fixed and it is bottom up. If two layers are enabled, the layer2 is the top displayed window.

Windowing
Every layer can be positioned and resized and it must be inside the active display area.

The window position and size are configured through the top-left and bottom-right X/Y positions and the internal timing generator that includes the synchronous, back porch size and the active data area. Refer to LTDC_LxWHPCR and LTDC_WVPCR registers.
The programmable layer position and size defines the first/last visible pixel of a line and the first/last visible line in the window. It allows to display either the full image frame or only a part of the image frame. Refer to Figure 243.

- The first and the last visible pixel in the layer are set by configuring the WHSTPOS[11:0] and WHSPPOS[11:0] in the LTDC_LxWHPCR register.
- The first and the last visible lines in the layer are set by configuring the WVSTPOS[10:0] and WVSPPOS[10:0] in the LTDC_LxWVPCR register.

**Figure 243. Layer window programmable parameters**

**Pixel input format**

The programmable pixel format is used for the data stored in the frame buffer of a layer. Up to 8 input pixel formats can be configured for every layer through the LTDC_LxPFCR register.

The pixel data is read from the frame buffer and then transformed to the internal 8888 (ARGB) format as follows: components having a width of less than 8 bits get expanded to 8 bits by bit replication. The selected bit range is concatenated multiple times until it is longer than 8 bits. Of the resulting vector, the 8 MSB bits are chosen. Example: 5 bits of an RGB565 red channel become (bit positions): 43210432 (the 3 LSBs are filled with the 3 MSBs of the 5 bits).

*Table 264* describes the pixel data mapping depending on the selected format.

</table>
Color look-up table (CLUT)

The CLUT can be enabled at run-time for every layer through the LTDC_LxCR register and it is only useful in case of indexed color when using the L8, AL44 and AL88 input pixel format.

First, the CLUT has to be loaded with the R, G and B values that replace the original R, G, B values of that pixel (indexed color). Each color (RGB value) has its own address which is the position within the CLUT.

The R, G and B values and their own respective address are programmed through the LTDC_LxCLUTWR register.

- In case of L8 and AL88 input pixel format, the CLUT has to be loaded by 256 colors. The address of each color is configured in the CLUTADD bits in the LTDC_LxCLUTWR register.
- In case of AL44 input pixel format, the CLUT has to be only loaded by 16 colors. The address of each color must be filled by replicating the 4-bit L channel to 8-bit as follows:
  - L0 (indexed color 0), at address 0x00
  - L1, at address 0x11
  - L2, at address 0x22
  - .....         
  - L15, at address 0xFF

Color frame buffer address

Every layer has a start address for the color frame buffer configured through the LTDC_LxCFBAR register.

When a layer is enabled, the data is fetched from the color frame buffer.

Color frame buffer length

Every layer has a total line length setting for the color frame buffer in bytes and a number of lines in the frame buffer configurable in the LTDC_LxCFBLR and LTDC_LxCFBLNR register respectively.

The line length and the number of lines settings are used to stop the prefetching of data to the layer FIFO at the end of the frame buffer.

- If it is set to less bytes than required, a FIFO underrun interrupt is generated if it has been previously enabled.
- If it is set to more bytes than actually required, the useless data read from the FIFO is discarded. The useless data is not displayed.

Color frame buffer pitch

Every layer has a configurable pitch for the color frame buffer, which is the distance between the start of one line and the beginning of the next line in bytes. It is configured through the LTDC_LxCFBLR register.
Layer blending

The blending is always active and the two layers can be blended following the blending factors configured through the LTDC_LxBFCR register.

The blending order is fixed and it is bottom up. If two layers are enabled, first the Layer1 is blended with the Background color, then the layer2 is blended with the result of blended color of layer1 and the background. Refer to Figure 244.

**Figure 244. Blending two layers with background**

![Layer blending diagram](image)

Default color

Every layer can have a default color in the format ARGB which is used outside the defined layer window or when a layer is disabled.

The default color is configured through the LTDC_LxDCCR register.

The blending is always performed between the two layers even when a layer is disabled. To avoid displaying the default color when a layer is disabled, keep the blending factors of this layer in the LTDC_LxBFCR register to their reset value.

Color keying

A color key (RGB) can be configured to be representative for a transparent pixel.

If the color keying is enabled, the current pixels (after format conversion and before CLUT respectively blending) are compared to the color key. If they match for the programmed RGB value, all channels (ARGB) of that pixel are set to 0.

The color key value can be configured and used at run-time to replace the pixel RGB value.

The color keying is enabled through the LTDC_LxCKCR register.

The color keying is configured through the LTDC_LxCKCR register. The programmed value depends on the pixel format as it is compared to current pixel after pixel format conversion to ARGB888.

**Example**: if the a mid-yellow color (50% red + 50% green) is used as the transparent color key:

- In RGB565, the mid-yellow color is 0x8400. Set the LTDC_LxCKCR to 0x848200.
- In ARGB8888, the mid-yellow color is 0x808000, set LTDC_LxCKCR to 0x808000.
- In all CLUT-based color modes (L8, AL88, AL44), set one of the palette entry to the mid-yellow color 0x808000 and set the LTDC_LxCKCR to 0x808000.
31.5 **LTDC interrupts**

The LTDC provides four maskable interrupts logically ORed to two interrupt vectors.

The interrupt sources can be enabled or disabled separately through the LTDC_IER register. Setting the appropriate mask bit to 1 enables the corresponding interrupt.

The two interrupts are generated on the following events:
- Line interrupt: generated when a programmed line is reached. The line interrupt position is programmed in the LTDC_LIPCR register.
- Register reload interrupt: generated when the shadow registers reload was performed during the vertical blanking period.
- FIFO underrun interrupt: generated when a pixel is requested from an empty layer FIFO.
- Transfer error interrupt: generated when an AXI bus error occurs during data transfer.

Those interrupts events are connected to the NVIC controller as described in Figure 245.

**Figure 245. Interrupt events**

31.6 LTDC programming procedure

- Enable the LTDC clock in the RCC register.
- Configure the required pixel clock following the panel datasheet.
- Configure the synchronous timings: VSYNC, HSYNC, vertical and horizontal back porch, active data area and the front porch timings following the panel datasheet as described in the Section 31.4.1: LTDC global configuration parameters.
- Configure the synchronous signals and clock polarity in the LTDC_GCR register.
- If needed, configure the background color in the LTDC_BCCR register.
- Configure the needed interrupts in the LTDC_IER and LTDC_LIPCR register.
- Configure the layer1/2 parameters by:
  - programming the layer window horizontal and vertical position in the LTDC_LxWHPCR and LTDC_WVPCR registers. The layer window must be in the active data area.
  - programming the pixel input format in the LTDC_LxPFCR register
  - programming the color frame buffer start address in the LTDC_LxCFBAR register
  - programming the line length and pitch of the color frame buffer in the LTDC_LxCFBLR register
  - programming the number of lines of the color frame buffer in the LTDC_LxCFBLNR register
  - if needed, loading the CLUT with the RGB values and its address in the LTDC_LxCFUTWR register
  - If needed, configuring the default color and the blending factors respectively in the LTDC_LxDCCR and LTDC_LxBFCR registers
- Enable layer1/2 and if needed the CLUT in the LTDC_LxCR register.
- If needed, enable dithering and color keying respectively in the LTDC_GCR and LTDC_LxCKCR registers. They can be also enabled on the fly.
- Reload the shadow registers to active register through the LTDC_SRCR register.
- Enable the LCD-TFT controller in the LTDC_GCR register.
- All layer parameters can be modified on the fly except the CLUT. The new configuration has to be either reloaded immediately or during vertical blanking period by configuring the LTDC_SRCR register.

Note: All layer’s registers are shadowed. Once a register is written, it must not be modified again before the reload has been done. Thus, a new write to the same register overrides the previous configuration if not yet reloaded.
31.7 LTDC registers

31.7.1 LTDC synchronization size configuration register (LTDC_SSCR)

This register defines the number of horizontal synchronization pixels minus 1 and the number of vertical synchronization lines minus 1. Refer to Figure 242 and Section 31.4: LTDC programmable parameters for an example of configuration.

Address offset: 0x08
Reset value: 0x0000 0000

| Bits 31:28 | Reserved, must be kept at reset value. |
| Bits 27:16 | HSW[11:0]: horizontal synchronization width (in units of pixel clock period) These bits define the number of Horizontal Synchronization pixel minus 1. |
| Bits 15:11 | Reserved, must be kept at reset value. |
| Bits 10:0  | VSH[10:0]: vertical synchronization height (in units of horizontal scan line) These bits define the vertical Synchronization height minus 1. It represents the number of horizontal synchronization lines. |

31.7.2 LTDC back porch configuration register (LTDC_BPCR)

This register defines the accumulated number of horizontal synchronization and back porch pixels minus 1 (HSYNC width + HBP - 1) and the accumulated number of vertical synchronization and back porch lines minus 1 (VSYNC height + VBP - 1). Refer to Figure 242 and Section 31.4: LTDC programmable parameters for an example of configuration.

Address offset: 0x0C
Reset value: 0x0000 0000

| Bits 31:28 | Reserved, must be kept at reset value. |
| Bits 27:16 | AHBP[11:0]: horizontal back porch configuration (in units of pixel clock period) These bits define the number of Horizontal Back Porch pixels minus 1. |
| Bits 15:11 | Reserved, must be kept at reset value. |
| Bits 10:0  | AVBP[10:0]: vertical back porch configuration (in units of horizontal scan line) These bits define the number of Horizontal Back Porch lines. |
31.7.3 LTDC active width configuration register (LTDC_AWCR)

This register defines the accumulated number of horizontal synchronization, back porch and active pixels minus 1 \( (\text{HSYNC width} + \text{HBP} + \text{active width} - 1) \) and the accumulated number of vertical synchronization, back porch lines and active lines minus 1 \( (\text{VSYNC height} + \text{BVBP} + \text{active height} - 1) \). Refer to Figure 242 and Section 31.4: LTDC programmable parameters for an example of configuration.

Address offset: 0x10

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 \( \text{AAW}[11:0] \): accumulated active width (in units of pixel clock period)

These bits define the accumulated active width which includes the horizontal synchronization, horizontal back porch and active pixels minus 1. The active width is the number of pixels in active display area of the panel scan line. Refer to device datasheet for maximum active width supported following maximum pixel clock.

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:0 \( \text{AAH}[10:0] \): accumulated active height (in units of horizontal scan line)

These bits define the accumulated height which includes the vertical synchronization, vertical back porch and the active height lines minus 1. The active height is the number of active lines in the panel. Refer to device datasheet for maximum active height supported following maximum pixel clock.
### 31.7.4 LTDC total width configuration register (LTDC_TWCR)

This register defines the accumulated number of horizontal synchronization, back porch, active and front porch pixels minus 1 \((HSYNC \text{ width} + \text{HBP} + \text{active width} + \text{HFP} - 1)\) and the accumulated number of vertical synchronization, back porch lines, active and front lines minus 1 \((VSYNC \text{ height} + \text{BVBP} + \text{active height} + \text{VFP} - 1)\). Refer to Figure 242 and Section 31.4: LTDC programmable parameters for an example of configuration.

Bit 31 **HSPOL**: horizontal synchronization polarity
   This bit is set and cleared by software.
   0: horizontal synchronization polarity is active low.
   1: horizontal synchronization polarity is active high.

Bit 30 **VSPOL**: vertical synchronization polarity
   This bit is set and cleared by software.
   0: vertical synchronization is active low.
   1: vertical synchronization is active high.

Bit 29 **DEPOL**: not data enable polarity
   This bit is set and cleared by software.
   0: not data enable polarity is active low.
   1: not data enable polarity is active high.

Bit 28 **PCPOL**: pixel clock polarity
   This bit is set and cleared by software.
   0: pixel clock polarity is active low.
   1: pixel clock is active high.

Bits 27:17 Reserved, must be kept at reset value.

Bit 16 **DEN**: dither enable
   This bit is set and cleared by software.
   0: dither disable
   1: dither enable

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **DRW[2:0]**: dither red width
   These bits return the Dither Red Bits.

Bit 11 Reserved, must be kept at reset value.

Bits 10:8 **DGW[2:0]**: dither green width
   These bits return the dither green bits.

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **DBW[2:0]**: dither blue width
   These bits return the dither blue bits.

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **LTDCEN**: LCD-TFT controller enable
   This bit is set and cleared by software.
   0: LTDC disable
   1: LTDC enable
31.7.6 LTDC shadow reload configuration register (LTDC_SSRCR)

This register allows to reload either immediately or during the vertical blanking period, the shadow registers values to the active registers. The shadow registers are all Layer1 and Layer2 registers except the LTDC_L1CLUTWR and the LTDC_L2CLUTWR.

Address offset: 0x24
Reset value: 0x0000 0000

<table>

Bits 31:4 Reserved, must be kept at reset value.

**Bit 3 RRIE:** register reload interrupt enable

This bit is set and cleared by software.

0: register reload interrupt disable
1: register reload interrupt enable

**Bit 2 TERRIE:** transfer error interrupt enable

This bit is set and cleared by software.

0: transfer error interrupt disable
1: transfer error interrupt enable

**Bit 1 FUIE:** FIFO underrun interrupt enable

This bit is set and cleared by software.

0: FIFO underrun interrupt disable
1: FIFO underrun interrupt enable

**Bit 0 LIE:** line interrupt enable

This bit is set and cleared by software.

0: line interrupt disable
1: line interrupt enable
31.7.9 LTDC interrupt status register (LTDC_ISR)

This register returns the interrupt status flag.

Address offset: 0x38

Reset value: 0x0000 0000

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 RRIF: register reload interrupt flag
0: no register reload interrupt generated
1: register reload interrupt generated when a vertical blanking reload occurs (and the first line after the active area is reached)

Bit 2 TERRIF: transfer error interrupt flag
0: no transfer error interrupt generated
1: transfer error interrupt generated when a bus error occurs

Bit 1 FUIF: FIFO underrun interrupt flag
0: no FIFO underrun interrupt generated.
1: FIFO underrun interrupt generated, if one of the layer FIFOs is empty and pixel data is read from the FIFO

Bit 0 LIF: line interrupt flag
0: no line interrupt generated
1: line interrupt generated when a programmed line is reached

31.7.10 LTDC Interrupt Clear Register (LTDC_ICR)

Address offset: 0x3C

Reset value: 0x0000 0000

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 CRRIF: clear register reload interrupt flag
0: no register reload interrupt cleared
1: register reload interrupt cleared

Bit 2 CTERRIF: clear transfer error interrupt flag
0: no transfer error interrupt cleared
1: transfer error interrupt cleared

Bit 1 CFUIF: clear FIFO underrun interrupt flag
0: no FIFO underrun interrupt cleared
1: FIFO underrun interrupt cleared

Bit 0 CLIF: clear line interrupt flag
0: no line interrupt cleared
1: line interrupt cleared when a programmed line is reached
31.7.11 LTDC line interrupt position configuration register (LTDC_LIPCR)

This register defines the position of the line interrupt. The line value to be programmed depends on the timings parameters. Refer to Figure 242.

Address offset: 0x40
Reset value: 0x0000 0000

| Bits 31:11 | Reserved, must be kept at reset value.
| Bit 10:0 | LIPOS[10:0]: line interrupt position
| These bits configure the line interrupt position.

</table>
31.7.13  **LTDC current display status register (LTDC_CDSR)**

This register returns the status of the current display phase which is controlled by the HSYNC, VSYNC, and horizontal/vertical DE signals.

Example: if the current display phase is the vertical synchronization, the VSYNCS bit is set (active high). If the current display phase is the horizontal synchronization, the HSYNCS bit is active high.

Address offset: 0x48

Reset value: 0x0000 000F

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>CXPOS[15:0]</td>

<td>horizontal data enable display status</td>
</tr>
<tr>
<td>0</td>
<td>VDES</td>
<td>vertical data enable display status</td>
</tr>
</tbody>
</table>

Bits 31:4  Reserved, must be kept at reset value.

Bit 3  **HSYNCS**: horizontal synchronization display status

0: active low
1: active high

Bit 2  **VSYNCS**: vertical synchronization display status

0: active low
1: active high

Bit 1  **HDES**: horizontal data enable display status

0: active low
1: active high

Bit 0  **VDES**: vertical data enable display status

0: active low
1: active high

**Note**: The returned status does not depend on the configured polarity in the LTDC_GCR register, instead it returns the current active display phase.

31.7.14  **LTDC layer x control register (LTDC_LxCR)**

Address offset: 0x84 + 0x80 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000
31.7.15 LTDC layer x window horizontal position configuration register (LTDC_LxWHPCR)

This register defines the horizontal position (first and last pixel) of the layer 1 or 2 window.

The first visible pixel of a line is the programmed value of AHBP[11:0] bits + 1 in the LTDC_BPCR register.

The last visible pixel of a line is the programmed value of AAW[11:0] bits in the LTDC_AWCR register.

Address offset: 0x88 + 0x80 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 CLUTEN: color look-up table enable
This bit is set and cleared by software.
0: color look-up table disable
1: color look-up table enable
The CLUT is only meaningful for L8, AL44 and AL88 pixel format. Refer to Color look-up table (CLUT)

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 COLKEN: color keying enable
This bit is set and cleared by software.
0: color keying disable
1: color keying enable

Bit 0 LEN: layer enable
This bit is set and cleared by software.
0: layer disable
1: layer enable

Example:
The LTDC_BPCR register is configured to 0x000E0005 (AHBP[11:0] is 0xE) and the LTDC_AWCR register is configured to 0x028E01E5 (AAW[11:0] is 0x28E). To configure the horizontal position of a window size of 630x460, with horizontal start offset of 5 pixels in the active data area:
1. layer window first pixel, WHSTPOS[11:0], must be programmed to 0x14 (0xE+1+0x5)
2. layer window last pixel, WHSPPOS[11:0], must be programmed to 0x28A.

31.7.16 LTDC layer x window vertical position configuration register (LTDC_LxWVPCR)
This register defines the vertical position (first and last line) of the layer1 or 2 window.
The first visible line of a frame is the programmed value of AVBP[10:0] bits + 1 in the register LTDC_BPCR register.
The last visible line of a frame is the programmed value of AAH[10:0] bits in the LTDC_AWCR register.

Address offset: 0x8C + 0x80 * (x - 1), (x = 1 to 2)
Reset value: 0x0000 0000

| Bits 31:27 Reserved, must be kept at reset value. |
| Bits 26:16 WVSTPOS[10:0]: window vertical start position |
| Bits 15:11 Reserved, must be kept at reset value. |
| Bits 10:0 WVSTPOS[10:0]: window vertical start position |

| Bits 31:27 Reserved, must be kept at reset value. |
| Bits 26:16 WVSTPOS[10:0]: window vertical start position |
| Bits 15:11 Reserved, must be kept at reset value. |
| Bits 10:0 WVSTPOS[10:0]: window vertical start position |
Example:
The LTDC_BPCR register is configured to 0x000E0005 (AVBP[10:0] is 0x5) and the LTDC_AWCR register is configured to 0x028E01E5 (AAH[10:0] is 0x1E5).

To configure the vertical position of a window size of 630x460, with vertical start offset of 8 lines in the active data area:
1. layer window first line: WVSTPOS[10:0] must be programmed to 0xE (0x5 + 1 + 0x8).
2. layer window last line: WVSTPOS[10:0] must be programmed to 0x1DA.

31.7.17 LTDC layer x color keying configuration register (LTDC_LxCKCR)
This register defines the color key value (RGB), that is used by the color keying.
Address offset: 0x90 + 0x80 * (x - 1), (x = 1 to 2)
Reset value: 0x0000 0000

Bits 23:16  CKRED[7:0]: color key red value
Bits 15:8   CKGREEN[7:0]: color key green value
Bits 7:0    CKBLUE[7:0]: color key blue value

31.7.18 LTDC layer x pixel format configuration register (LTDC_LxPFCR)
This register defines the pixel format that is used for the stored data in the frame buffer of a layer. The pixel data is read from the frame buffer and then transformed to the internal format 8888 (ARGB).
Address offset: 0x94 + 0x80 * (x - 1), (x = 1 to 2)
Reset value: 0x0000 0000

Bits 23:16  PF[2:0]: pixel format value
31.7.19  LTDC layer x constant alpha configuration register
(LTDC_LxCACR)

This register defines the constant alpha value (divided by 255 by hardware), that is used in
the alpha blending. Refer to LTDC_LxBFCR register.

Address offset: 0x98 + 0x80 * (x - 1), (x = 1 to 2)
Reset value: 0x0000 00FF

</tbody>
</table>

Bits 31:8  Reserved, must be kept at reset value.

Bits 7:0  const[7:0]: constant alpha

These bits configure the constant alpha used for blending. The constant alpha is divided by
255 by hardware.

Example: if the programmed constant alpha is 0xFF, the constant alpha value is
255 / 255 = 1.
31.7.20 LTDC layer x default color configuration register (LTDC_LxDCCR)

This register defines the default color of a layer in the format ARGB. The default color is used outside the defined layer window or when a layer is disabled. The reset value of 0x00000000 defines a transparent black color.

Address offset: 0x9C + 0x80 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

<table>

<td>DCBLUE[7:0]: default color blue</td>
<td>These bits configure the default blue value.</td>
</tr>
</tbody>
</table>
31.7.21  LTDC layer x blending factors configuration register (LTDC_LxBFCR)

This register defines the blending factors F1 and F2.

The general blending formula is: $BC = BF1 \times C + BF2 \times Cs$

- $BC =$ blended color
- $BF1 =$ blend factor 1
- $C =$ current layer color
- $BF2 =$ blend factor 2
- $Cs =$ subjacent layers blended color

Address offset: 0xA0 + 0x80 * (x - 1), (x = 1 to 2)
Reset value: 0x0000 0607

</tbody>
</table>

Bits 31:11  Reserved, must be kept at reset value.

Bits 10:8  **BF1[2:0]:** blending factor 1

These bits select the blending factor F1.

- 000: reserved
- 001: reserved
- 010: reserved
- 011: reserved
- 100: constant alpha
- 101: reserved
- 110: pixel alpha x constant alpha
- 111: reserved

Bits 7:3  Reserved, must be kept at reset value.

Bits 2:0  **BF2[2:0]:** blending factor 2

These bits select the blending factor F2

- 000: reserved
- 001: reserved
- 010: reserved
- 011: reserved
- 100: reserved
- 101: 1 - constant alpha
- 110: reserved
- 111: 1 - (pixel alpha x constant alpha)
Note: The constant alpha value, is the programmed value in the LxCACR register divided by 255 by hardware.

Example: Only layer1 is enabled, BF1 configured to constant alpha. BF2 configured to 1 - constant alpha. The constant alpha programmed in the LxCACR register is 240 (0xF0). Thus, the constant alpha value is 240/255 = 0.94. C: current layer color is 128. Cs: background color is 48. Layer1 is blended with the background color.

BC = constant alpha x C + (1 - Constant Alpha) x Cs = 0.94 x 128 + (1- 0.94) x 48 = 123.

31.7.22 LTDC layer x color frame buffer address register (LTDC_LxCFBAR)

This register defines the color frame buffer start address which has to point to the address where the pixel data of the top left pixel of a layer is stored in the frame buffer.

Address offset: 0xAC + 0x80 * (x - 1), (x = 1 to 2)
Reset value: 0x0000 0000

31.7.23 LTDC layer x color frame buffer length register (LTDC_LxCFBLR)

This register defines the color frame buffer line length and pitch.

Address offset: 0xB0 + 0x80 * (x - 1), (x = 1 to 2)
Reset value: 0x0000 0000
Example:

- A frame buffer having the format RGB565 (2 bytes per pixel) and a width of 256 pixels (total number of bytes per line is 256 \* 2 = 512), where pitch = line length requires a value of 0x02000207 to be written into this register.

- A frame buffer having the format RGB888 (3 bytes per pixel) and a width of 320 pixels (total number of bytes per line is 320 \* 3 = 960), where pitch = line length requires a value of 0x03C003C7 to be written into this register.

### 31.7.24 LTDC layer x color frame buffer line number register (LTDC\_LxCFBLNR)

This register defines the number of lines in the color frame buffer.

Address offset: 0xB4 + 0x80 \* (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

<table>

<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:0 **CFBLNR[10:0]:** frame buffer line number

These bits define the number of lines in the frame buffer that corresponds to the active high width.

**Note:**

The number of lines and line length settings define how much data is fetched per frame for every layer. If it is configured to less bytes than required, a FIFO underrun interrupt will be generated if enabled.

The start address and pitch settings on the other hand define the correct start of every line in memory.
31.7.25  LTDC layer x CLUT write register (LTDC_LxCLUTWR)

This register defines the CLUT address and the RGB value.

Address offset: 0xC4 + 0x80 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

Note: The CLUT write register should only be configured during blanking period or if the layer is disabled. The CLUT can be enabled or disabled in the LTDC_LxCR register. The CLUT is only meaningful for L8, AL44 and AL88 pixel format.
### 31.7.26 LTDC register map

The following table summarizes the LTDC registers. Refer to the register boundary addresses table for the LTDC register base address.

#### Table 266. LTDC register map and reset values

| Offset | Register name   | 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |

32 JPEG codec (JPEG)

32.1 Introduction

The hardware 8-bit JPEG codec encodes uncompressed image data stream or decodes JPEG-compressed image data stream. It also fully manages JPEG headers.

32.2 JPEG codec main features

- High-speed fully-synchronous operation
- Configurable as encoder or decoder
- Single-clock-per-pixel encode/decode
- RGB, YCbCr, YCMK and BW (grayscale) image color space support
- 8-bit depth per image component at encode/decode
- JPEG header generator/parser with enable/disable
- Four programmable quantization tables
- Single-clock Huffman coding and decoding
- Fully-programmable Huffman tables (two AC and two DC)
- Fully-programmable minimum coded unit (MCU)
- Concurrent input and output data stream interfaces
32.3 JPEG codec block functional description

32.3.1 General description

The block diagram of the JPEG codec is shown in Figure 246: JPEG codec block diagram.

Table 267 lists the JPEG internal signals.

32.3.3 JPEG decoding procedure

The JPEG codec can decode a JPEG stream as defined in the ISO/IEC 10918-1 specification.

It can optionally parse the JPEG header and update accordingly the JPEG codec registers, the quantization tables and the Huffman tables.

The JPEG codec is configured in decode mode setting the DE bit (decode enable) of the JPEG_CONFR1 register.

The JPEG decode starts by setting the START bit of the JPEG_CONFR0 register.

The JPEG codec requests data for its input FIFO through generating one of:

- MDMA trigger
- interrupts

**Interrupt or MDMA trigger generation for input FIFO**

Input FIFO can be managed using interrupts or MDMA triggers through two flags according to the FIFO state:

- Input FIFO not full flag: a 32-bit value can be written in.
- Input FIFO threshold flag: 8 words (32 bytes) can be written in.

The interrupt or MDMA trigger generation is independent of the START bit of the JPEG_CONFR0 register. The input FIFO flags are generated regardless of the state of the JPEG codec kernel.

 Writes are ignored if the input FIFO is full.

At the end of the decoding process, extra bytes may remain in the input FIFO and/or an interrupt request / MDMA trigger may be pending. The FIFO can be flushed by setting the IFF bit (Input FIFO Flush) of the JPEG_CR register.

Prior to flushing the FIFO:

- The interrupts for the input FIFO must be disabled to prevent unwanted interrupt request upon flushing the FIFO.
- The MDMA channel must be stopped to prevent unwanted MDMA trigger.

The consequence of not flushing the FIFO at the end of the decoding process is that any remaining data is taken into the next JPEG decoding.

**Header parsing**

The header parsing can be activated setting the HDR bit of the JPEG_CONFR1 register.

The JPEG header parser supports all markers relevant to the JPEG baseline algorithm indicated in Annex B of the ISO/IEC 10918-1.
When parsing a supported marker, the JPEG header parser extracts the required parameters and stores them in shadow registers. At the end of the parsing the JPEG codec registers are updated.

If a DQT marker segment is located, quantization data associated with it is written into the quantization table memory.

If a DHT marker segment is located, the Huffman table data associated with it is converted into three different table formats (HuffMin, HuffBase and HuffSymb) and stored in their respective memories.

Once the parsing operation is completed, the HPDF (header parsing done flag) bit of the JPEG_SR register is set. An interrupt is generated if the EHPIE (end of header parsing interrupt enable) bit of the JPEG_CR register is set.

**JPEG decoding**

Once the JPEG header is parsed or JPEG codec registers and memories are properly programmed, the incoming data stream is decoded and the resulting MCUs are sent to the output FIFO.

When decoding two images successively, the START bit of the JPEG_CONFR0 register must be set again (even if already 1) after the header processing of the second image is completed.

**Interrupt or MDMA trigger generation for output FIFO**

The output FIFO can be managed using interrupts or MDMA triggers through two flags according to the FIFO state:

- Output FIFO not empty flag: a 32-bit value can be read out.
- Output FIFO Threshold flag: 8 words (32 bytes) can be read out.

Reads return 0 if the output FIFO is empty.

In case of abort of the JPEG codec operations by resetting the START bit of the JPEG_CONFR0 register, the output FIFO can be flushed. If the FIFO needs to be flushed, it shall be done by software setting the FF bit (FIFO flush) of the JPEG_CR register.

Prior to flushing the FIFO:

- The interrupts for the output FIFO must be disabled to prevent unwanted interrupt request upon flushing the FIFO.
- The MDMA channel must be stopped to prevent unwanted MDMA trigger.

The output FIFO must be flushed at the end of processing before any JPEG configuration change.

**32.3.4 JPEG encoding procedure**

The JPEG codec can encode a JPEG stream as defined in the ISO/IEC 10918-1 specification.

It can optionally generate the JPEG Header.

The JPEG codec is configured in encode mode resetting the DE bit (decode enable) of the JPEG_CONFR1 register.
The configuration used for encoding the JPEG must be loaded in the JPEG codec:

- JPEG codec configuration registers
- quantization tables
- Huffman tables

The JPEG codec is started setting the START bit of the JPEG_CONFR0 register.

Once the JPEG codec has been started, it request data for its input FIFO generating one of:

- MDMA trigger
- interrupts

**Interrupt or MDMA trigger generation for input FIFO**

Input FIFO can be managed using interrupts or MDMA triggers through two flags according to the FIFO state:

- Input FIFO not full flag: a 32-bit value can be written in.
- Input FIFO threshold flag: 8 words (32 bytes) can be written in.

The interrupt or MDMA trigger generation is independent of the START bit of the JPEG_CONFR0 register. The input FIFO flags are generated regardless of the state of the JPEG codec kernel.

Writes are ignored if the input FIFO is full.

At the end of the encoding process, extra bytes may remain in the input FIFO and/or an interrupt request / MDMA trigger may be pending. The FIFO can be flushed by setting the IFF bit (input FIFO flush) of the JPEG_CR register.

Prior to flushing the FIFO:

- The interrupts for the input FIFO must be disabled to prevent unwanted interrupt request upon flushing the FIFO.
- The MDMA channel must be stopped to prevent unwanted MDMA trigger.

The consequence of not flushing the FIFO at the end of the encoding process is that any remaining data is taken into the next JPEG encoding.

**JPEG encoding**

Once the JPEG header generated, the incoming MCUs are encoded and the resulting data stream sent to the output FIFO.

**Interrupt or MDMA trigger generation for output FIFO**

Output FIFO can be managed using interrupts or MDMA triggers through two flags according to the FIFO state:

- Output FIFO not empty flag: a 32-bit value can be read out.
- Output FIFO threshold flag: 8 words (32 bytes) can be read out.

Reads return 0 if the output FIFO is empty.

In case of abort of the JPEG codec operations by resetting the START bit of the JPEG_CONFR0 register, the output FIFO can be flushed. The FIFO can be flushed by setting the FF bit (FIFO flush) of the JPEG_CR register.
Prior to flushing the FIFO:

- The interrupts for the output FIFO must be disabled to prevent unwanted interrupt request upon flushing the FIFO.
- The MDMA channel must be stopped to prevent unwanted MDMA trigger.

The output FIFO must be flushed at the end of processing before any JPEG configuration change.

The EOCF bit (end of conversion flag) of the JPEG_SR register can only be cleared when the output FIFO is empty.

Clearing either of the HDR bit (header processing) of the JPEG_CONFR1 register and the JCEN bit (JPEG codec enable) of the JPEG_CR register is allowed only when the EOCF bit of the JPEG_SR register is cleared.

### 32.4 JPEG codec interrupts

An interrupt can be produced on the following events:

- input FIFO threshold reached
- input FIFO not full
- output FIFO threshold reached
- output FIFO not empty
- end of conversion
- header parsing done

Separate interrupt enable bits are available for flexibility.

<table>

## 32.5 JPEG codec registers

### 32.5.1 JPEG codec control register (JPEG_CONFR0)

Address offset: 0x0000  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bits 31:16</th>
<th>YSIZE[15:0]: Y Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>15 14 13</td>
<td>HDR NS[1:0] COLSPACE[1:0] DE</td>
</tr>
<tr>
<td>8 7 6</td>
<td>RES NF[1:0]</td>
</tr>
<tr>
<td>3 2 1 0</td>
<td>START</td>
</tr>
</tbody>
</table>

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **START**: Start  
This bit start or stop the encoding or decoding process.  
0: Stop/abort  
1: Start  
Reads always return 0.

### 32.5.2 JPEG codec configuration register 1 (JPEG_CONFR1)

Address offset: 0x0004  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bits 31:16</th>
<th>YSIZE[15:0]: Y Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>15 14 13</td>
<td>HDR NS[1:0] COLSPACE[1:0] DE</td>
</tr>
<tr>
<td>8 7 6</td>
<td>RES NF[1:0]</td>
</tr>
<tr>
<td>3 2 1 0</td>
<td>START</td>
</tr>
</tbody>
</table>

Bits 31:16 **YSIZE[15:0]: Y Size**  
This field defines the number of lines in source image.

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **HDR**: Header processing  
This bit enables the header processing (generation/parsing).  
0: Disable  
1: Enable

Bits 7:6 **NS[1:0]: Number of components for scan**  
This field defines the number of components minus 1 for scan header marker segment.
Bits 5:4  **COLSPACE[1:0]**: Color space
This filed defines the number of quantization tables minus 1 to insert in the output stream.
- 00: Grayscale (1 quantization table)
- 01: YUV (2 quantization tables)
- 10: RGB (3 quantization tables)
- 11: CMYK (4 quantization tables)

Bit 3  **DE**: Codec operation as coder or decoder
This bit selects the code or decode process
- 0: Code
- 1: Decode

Bit 2  Reserved, must be kept at reset value.

Bits 1:0  **NF[1:0]**: Number of color components
This field defines the number of color components minus 1.
- 00: Grayscale (1 color component)
- 01: - (2 color components)
- 10: YUV or RGB (3 color components)
- 11: CMYK (4 color components)

### 32.5.3  JPEG codec configuration register 2 (JPEG_CONFR2)

**Address offset**: 0x0008  
**Reset value**: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>

<td>nw</td>
<td>nw</td>
</tr>
</tbody>
</table>

Bits 31:26  Reserved, must be kept at reset value.

Bits 25:0  **NMCU[25:0]**: Number of MCUs
For encoding: this field defines the number of MCU units minus 1 to encode.  
For decoding: this field indicates the number of complete MCU units minus 1 to be decoded (this field is updated after the JPEG header parsing). If the decoded image size has not a X or Y size multiple of 8 or 16 (depending on the sub-sampling process), the resulting incomplete or empty MCU must be added to this value to get the total number of MCUs generated.
32.5.4 JPEG codec configuration register 3 (JPEG_CONFR3)

Address offset: 0x000C
Reset value: 0x0000 0000

<table>
<thead>
<tr>

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **HSF[3:0]**: Horizontal sampling factor
Horizontal sampling factor for component i.

Bits 11:8 **VSF[3:0]**: Vertical sampling factor
Vertical sampling factor for component i.

Bits 7:4 **NB[3:0]**: Number of blocks
Number of data units minus 1 that belong to a particular color in the MCU.
Bits 3:2 \( QT[1:0] \): Quantization table
Selects quantization table used for component i.
- 00: Quantization table 0
- 01: Quantization table 1
- 10: Quantization table 2
- 11: Quantization table 3

Bit 1 \( HA \): Huffman AC
Selects the Huffman table for encoding AC coefficients.
- 0: Not selected
- 1: Selected

Bit 0 \( HD \): Huffman DC
Selects the Huffman table for encoding DC coefficients.
- 0: Not selected
- 1: Selected

### 32.5.6 JPEG control register (JPEG_CR)

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 \( OFF \): Output FIFO flush
This bit flushes the output FIFO.
- 0: No effect
- 1: Output FIFO is flushed
Reads always return 0.

Bit 13 \( IFF \): Input FIFO flush
This bit flushes the input FIFO.
- 0: No effect
- 1: Input FIFO is flushed
Reads always return 0.

Bits 12:7 Reserved, must be kept at reset value.

Bit 6 \( HPDIE \): Header parsing done interrupt enable
This bit enables interrupt generation upon the completion of the header parsing operation.
- 0: Disabled
- 1: Enabled
Bit 5 **EOCIE**: End of conversion interrupt enable
   This bit enables interrupt generation at the end of conversion.
   0: Disabled
   1: Enabled

Bit 4 **OFNEIE**: Output FIFO not empty interrupt enable
   This bit enables interrupt generation when the output FIFO is not empty.
   0: Disabled
   1: Enabled

Bit 3 **OFTIE**: Output FIFO threshold interrupt enable
   This bit enables interrupt generation when the output FIFO reaches a threshold.
   0: Disabled
   1: Enabled

Bit 2 **IFNFIE**: Input FIFO not full interrupt enable
   This bit enables interrupt generation when the input FIFO is not empty.
   0: Disabled
   1: Enabled

Bit 1 **IFTIE**: Input FIFO threshold interrupt enable
   This bit enables interrupt generation when the input FIFO reaches a threshold.
   0: Disabled
   1: Enabled

Bit 0 **JCEN**: JPEG core enable
   This bit enables the JPEG codec core.
   0: Disabled (internal registers are reset).
   1: Enabled (internal registers are accessible).

1240/3289 RM0433 Rev 6
Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **COF**: Codec operation flag
This bit flags code/decode operation in progress.
- 0: Not in progress
- 1: In progress

Bit 6 **HPDF**: Header parsing done flag
In decode mode, this bit flags the completion of header parsing and updating internal registers.
- 0: Not completed
- 1: Completed

Bit 5 **EOCF**: End of conversion flag
This bit flags the completion of encode/decode process and data transfer to the output FIFO.
- 0: Not completed
- 1: Completed

Bit 4 **OFNFF**: Output FIFO not empty flag
This bit flags that data is available in the output FIFO.
- 0: Empty (data not available)
- 1: Not empty (data available)

Bit 3 **OFTF**: Output FIFO threshold flag
This bit flags that the amount of data in the output FIFO reaches or exceeds a threshold.
- 0: Below threshold
- 1: At or above threshold

Bit 2 **IFNFF**: Input FIFO not full flag
This bit flags that the input FIFO is not full (data can be written).
- 0: Full
- 1: Not full

Bit 1 **IFTF**: Input FIFO threshold flag
This bit flags that the amount of data in the input FIFO is below a threshold.
- 0: At or above threshold
- 1: Below threshold

Bit 0 Reserved, must be kept at reset value.

8-bit quantization coefficient.

Bits 15:8 QCOEF<4*y+1>[7:0]: Quantization coefficient 4*y+1
8-bit quantization coefficient.

Bits 7:0 QCOEF<4*y>[7:0]: Quantization coefficient 4*y
8-bit quantization coefficient.

32.5.12 JPEG Huffman min (JPEG_HUFFMIN[4*y+x])
Address offset: 0x0150 + 16*y + 4*x, x = 0..3 and y = 0..3
Reset value: 0xXXXX XXXX
This memory stores the minimum Huffman values used internally by the JPEG decoder. The memory content is written by hardware during the header parsing.
- DATA0: Min AC0 value
- DATA1: Min DC0 value
- DATA2: Min AC1 value
- DATA3: Min DC1 value
32.5.13 JPEG Huffman base (JPEG_HUFFBASE[y])

Address offset: 0x0190 + 4*y, y = 0..31
Reset value: 0xXXXX XXXX

This memory stores the base Huffman values used internally by the JPEG decoder. The memory content is written by hardware during the header parsing:

- DATA0 to DATA15: Base AC0 value
- DATA16 to DATA31: Base DC0 value
- DATA32 to DATA47: Base AC1 value
- DATA48 to DATA63: Base DC1 value

Bits 31:0 \(\text{DATA}<y>[99:0]\): Minimum Huffman value
100-bit minimum Huffman value used internally by the JPEG decoder.

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:16 \(\text{DATA}<2*y+1>[8:0]\): DATA 2*y+1
Base Huffman value.

Bits 15:9 Reserved, must be kept at reset value.

Bits 8:0 \(\text{DATA}<2*y>[8:0]\): DATA 2*y
Base Huffman value.
32.5.14 JPEG Huffman symbol (JPEG_HUFFSYMB[y])

Address offset: 0x0210 + 4*y, y = 0..83
Reset value: 0xXXXX XXXX

This memory stores the Huffman symbols used internally by the JPEG decoder. The memory content is written by hardware during the header parsing:

- DATA0 to DATA161: AC0 symbols
- DATA162 to DATA173: DC0 and DC1 symbols
- DATA174 to DATA335: AC1 symbols

32.5.15 JPEG DHT memory (JPEG_DHTMEM[y])

Address offset: 0x0360 + 4*y, y = 0..102
Reset value: 0xXXXX XXXX

For encoding process with header generation, this memory stores the DHT marker segment AC and DC Huffman tables in the ISO/IEC specification format:

- DATA0 to DATA27: DC Huffman table0
- DATA28 to DATA205: AC Huffman table0
- DATA206 to DATA233: DC Huffman table1
- DATA234 to DATA411: AC Huffman table1
32.5.16 JPEG Huffman encoder ACx (JPEG_HUFFENC_ACx[y])

Address offset: 0x0500 + 220*x + 4*y, x=0..1, y = 0..87

Reset value: 0xXXXX XXXX

This memory defines the Huffman codes used during the encoding process of AC components.

| Bits 31:24 | DATA<4*y+3>[7:0]: Huffman table data 4*y+3 |
| Bits 23:16 | DATA<4*y+2>[7:0]: Huffman table data 4*y+2 |
| Bits 15:8  | DATA<4*y+1>[7:0]: Huffman table data 4*y+1 |
| Bits 7:0   | DATA<4*y>[7:0]: Huffman table data 4*y   |

### 32.5.17 JPEG Huffman encoder DCx (JPEG_HUFFENC_DCx[y])

Address offset: 0x07C0 + 220*x + 4*y, x=0..1, y = 0..7

Reset value: 0xXXXX XXXX

This memory defines the Huffman codes used during the encoding process of DC components.
Bits 31:28  Reserved, must be kept at reset value.

Bits 27:24  **HLEN<2*y+1>[3:0]**: Huffman length 2\(^y\)+1
Number of bits in the Huffman code **HCODE<2*y+1>** minus 1.

Bits 23:16  **HCODE<2*y+1>[7:0]**: Huffman code 2\(^y\)+1
8 least significant bits of the Huffman code.
If the Huffman code is less than 8 bits long, the unused bits must be 0.

Bits 15:12  Reserved, must be kept at reset value.

Bits 11:8  **HLEN<2*y>[3:0]**: Huffman length 2\(^y\)
Number of bits in the Huffman code **HCODE<2*y>** minus 1.

Bits 7:0  **HCODE<2*y>[7:0]**: Huffman code 2\(^y\)
8 least significant bits of the Huffman code.
If the Huffman code is less than 8 bits long, the unused bits must be 0.
### 32.5.18 JPEG codec register map

The following table summarizes the JPEG codec registers. Refer to the register boundary addresses table for the JPEG codec register base address.

Refer to Section 2.3 on page 126 for the register boundary addresses.
33 True random number generator (RNG)

33.1 Introduction

The RNG is a true random number generator that provides full entropy outputs to the application as 32-bit samples. It is composed of a live entropy source (analog) and an internal conditioning component.

The RNG can be used to construct a NIST compliant Deterministic Random Bit Generator (DRBG), acting as a live entropy source.

The RNG true random number generator has been tested using German BSI statistical tests of AIS-31 (T0 to T8).

33.2 RNG main features

- The RNG delivers 32-bit true random numbers, produced by an analog entropy source processed by a high quality conditioning stage.
- It produces four 32-bit random samples every $16 \times \frac{f_{\text{AHB}}}{f_{\text{RNG}}}$ AHB clock cycles, if value is higher than 213 cycles (213 cycles otherwise).
- It allows embedded continuous basic health tests with associated error management
  – Includes too low sampling clock detection and repetition count tests.
- It can be disabled to reduce power consumption.
- It has an AMBA AHB slave peripheral, accessible through 32-bit word single accesses only (else for write accesses an AHB bus error is generated). Warning! any write not equal to 32 bits might corrupt the register content.
33.3 **RNG functional description**

33.3.1 **RNG block diagram**

*Figure 247* shows the RNG block diagram.

33.3.3 Random number generation

The true random number generator (RNG) delivers truly random data through its AHB interface at deterministic intervals. The RNG implements the entropy source model pictured on Figure 248, and provides three main functions to the application:

- Collects the bitstring output of the entropy source box
- Obtains samples of the noise source for validation purpose
- Collects error messages from continuous health tests

Figure 248. Entropy source model

The main components of the RNG are:

- A source of physical randomness (analog noise sources)
- A digitization stage for those analog noise sources
- A stage delivering a cryptographically conditioned noise source
- Output buffers, for both entropy source output (buffered) and noise source samples (also buffered)
- A health monitoring block performing tests on the whole entropy source

All those components are detailed below.

Noise source

The noise source is the component that contains the non-deterministic, entropy-providing activity that is ultimately responsible for the uncertainty associated with the bitstring output by the entropy source. It is composed of:

- Two analog noise sources, each based on three XORed free-running ring oscillator outputs. It is possible to disable those analog oscillators to save power, as described in Section 33.3.8: RNG low-power usage.
- A sampling stage of these outputs clocked by a dedicated clock input (rng_clk), delivering a 2-bit raw data output.
This noise source sampling is independent to the AHB interface clock frequency (\texttt{rng_hclk}).

\textbf{Note:} In Section 33.6: RNG entropy source validation recommended RNG clock frequencies are given.

**Post processing**

The sample values obtained from a true random noise source consist of 2-bit bitstrings. Because this noise source output is biased, the RNG implements a post-processing component that reduces that bias to a tolerable level.

More specifically, for each of the two noise source bits the RNG takes half of the bits from the sampled noise source, and half of the bits from inverted sampled noise source. Thus, if the source generates more ‘1’ than ‘0’ (or the opposite), it is filtered

**Conditioning**

The conditioning component in the RNG is a deterministic function that increases the entropy rate of the resulting fixed-length bitstrings output (128-bit).

\textbf{Note:} The latency during the RNG initialization is described in Section 33.5: RNG processing time.

Also note that post-processing computations are triggered when at least 32 bits of raw data has been received and when output FIFO needs a refill. Thus the RNG output entropy is maximum when the RNG 128-bit FIFO is emptied by application after 64 RNG clock cycles.

The times required between two random number generations, and between the RNG initialization and availability of first sample are described in Section 33.5: RNG processing time.

The conditioning component is clocked by the faster AHB clock.

**Output buffer**

A data output buffer can store up to four 32-bit words which have been output from the conditioning component. When four words have been read from the output FIFO through the \texttt{RNG\_DR} register, the content of the 128-bit conditioning output register is pushed into the output FIFO, and a new conditioning round is automatically started. Four new words are added to the conditioning output register 213 AHB clock cycles later.

Whenever a random number is available through the \texttt{RNG\_DR} register the \texttt{DRDY} flag transitions from ‘0’ to ‘1’. This flag remains high until output buffer becomes empty after reading four words from the \texttt{RNG\_DR} register.

\textbf{Note:} When interrupts are enabled an interrupt is generated when this data ready flag transitions from ‘0’ to ‘1’. Interrupt is then cleared automatically by the RNG as explained above.
Health checks

This component ensures that the entire entropy source (with its noise source) starts then operates as expected, obtaining assurance that failures are caught quickly and with a high probability and reliability.

The RNG implements the following health check features to the value recommended for register: RNG_HCTR (in Section 33.6.2).

1. the Continuous health tests, running indefinitely on the output of the noise source
   - Repetition count test, flagging an error when:
     a) One of the noise source has provided more than 64 consecutive bits at a constant value ("0" or "1"), or more than 32 consecutive occurrence of two bits patterns ("01" or "10")
     b) Both noise sources have delivered more than 32 consecutive bits at a constant value ("0" or "1"), or more than 16 consecutive occurrence of two bits patterns ("01" or "10")

2. Vendor specific continuous test
   - Real-time "too slow" sampling clock detector, flagging an error when one RNG clock cycle is smaller than AHB clock cycle divided by 32.

The CECS and SECS status bits in the RNG_SR register indicate when an error condition is detected, as detailed in Section 33.3.7: Error management.

Note: An interrupt can be generated when an error is detected.

33.3.4 RNG initialization

The RNG simplified state machine is pictured on Figure 249

After enabling the RNG (RNGEN=1 in RNG_CR) the following chain of events occurs:

1. The analog noise source is enabled, and logic immediately starts sampling the analog output, filling 128-bit conditioning shift register
2. The conditioning logic is enabled and post-processing context is initialized using two 128 noise source bits.
3. The conditioning stage internal input data buffer is filled again with 128-bit and one conditioning round is performed. The output buffer is then filled with post processing result.
4. The output buffer is refilled automatically according to the RNG usage.
The associated initialization time can be found in Section 33.5: RNG processing time.

**Figure 249. RNG initialization overview**

33.3.5 RNG operation

**Normal operations**

To run the RNG using interrupts the following steps are recommended:

1. Enable the interrupts by setting the IE bit in the RNG_CR register. At the same time enable the RNG by setting the bit RNGEN=1.

2. An interrupt is now generated when a random number is ready or when an error occurs. Therefore at each interrupt, check that:
   - No error occurred. The SEIS and CEIS bits should be set to 0 in the RNG_SR register.
   - A random number is ready. The DRDY bit must be set to 1 in the RNG_SR register.
   - If above two conditions are true the content of the RNG_DR register can be read up to four consecutive times. If valid data is available in the conditioning output buffer, four additional words can be read by the application (in this case the DRDY bit will still be high). If one or both of above conditions are false, the RNG_DR register must not be read. If an error occurred error recovery sequence described in Section 33.3.7 shall be used.
To run the RNG in polling mode following steps are recommended:
1. Enable the random number generation by setting the RNGEN bit to “1” in the RNG_CR register.
2. Read the RNG_SR register and check that:
   – No error occurred (the SEIS and CEIS bits should be set to 0)
   – A random number is ready (the DRDY bit should be set to 1)
3. If above conditions are true read the content of the RNG_DR register up to four consecutive times. If valid data is available in the conditioning output buffer four additional words can be read by the application (in this case the DRDY bit will still be high). If one or both of above conditions are false, the RNG_DR register must not be read. If an error occurred error recovery sequence described in Section 33.3.7 shall be used.

Note: When data is not ready (DRDY=“0”) RNG_DR returns zero.

Low-power operations
If the power consumption is a concern to the application, low-power strategies can be used, as described in Section 33.3.8: RNG low-power usage.

Software post-processing
No specific software post-processing/conditioning is required to meet AIS-31 approvals. If a NIST approved DRBG with 128 bits of security strength is required an approved random generator software must be built around the RNG true random number generator.

Built-in health check functions are described in Section 33.3.3: Random number generation.

33.3.6 RNG clocking
The RNG runs on two different clocks: the AHB bus clock and a dedicated RNG clock.

The AHB clock is used to clock the AHB banked registers and conditioning component. The RNG clock is used for noise source sampling. Recommended clock configurations are detailed in Section 33.6: RNG entropy source validation.

Note: When the CED bit in the RNG_CR register is set to “0”, the RNG clock frequency should be higher than AHB clock frequency divided by 32, otherwise the clock checker will always flag a clock error (CECS=1 in the RNG_SR register).

See Section 33.3.1: RNG block diagram for details (AHB and RNG clock domains).

33.3.7 Error management
In parallel to random number generation an health check block verifies the correct noise source behavior and the frequency of the RNG source clock as detailed in this section. Associated error state is also described.

Clock error detection
When the clock error detection is enabled (CED = 0) and if the RNG clock frequency is too low, the RNG sets to “1” both the CEIS and CECS bits to indicate that a clock error occurred. In this case, the application should check that the RNG clock is configured correctly (see Section 33.3.6: RNG clocking) and then it must clear the CEIS bit interrupt flag. The CECS bit is automatically cleared when clocking condition is normal.
Note: The clock error has no impact on generated random numbers, i.e. application can still read RNG_DR register.

CEIS is set only when CECS is set to “1” by RNG.

Noise source error detection

When a noise source (or seed) error occurs, the RNG stops generating random numbers and sets to “1” both SEIS and SECS bits to indicate that a seed error occurred. If a value is available in the RNG_DR register, it must not be used as it may not have enough entropy. If the error was detected during the initialization phase the whole initialization sequence will be automatically restarted by the RNG.

The following sequence shall be used to fully recover from a seed error after the RNG initialization:
1. Clear the SEIS bit by writing it to “0”.
2. Read out 12 words from the RNG_DR register, and discard each of them in order to clean the pipeline.
3. Confirm that SEIS is still cleared. Random number generation is back to normal.

33.3.8 RNG low-power usage

If power consumption is a concern, the RNG can be disabled as soon as the DRDY bit is set to “1” by setting the RNGEN bit to “0” in the RNG_CR register. As the post-processing logic and the output buffer remain operational while RNGEN=’0’ following features are available to software:

- If there are valid words in the output buffer four random numbers can still be read from the RNG_DR register.
- If there are valid bits in the conditioning output internal register four additional random numbers can be still be read from the RNG_DR register. If it is not the case the RNG must be re-enabled by the application until at least 32 new bits have been collected from the noise source and a complete conditioning round has been done. It corresponds to 16 RNG clock cycles to sample new bits, and 216 AHB clock cycles to run a conditioning round.

When disabling the RNG the user deactivates all the analog seed generators, whose power consumption is given in the datasheet electrical characteristics section. The user also gates all the logic clocked by the RNG clock. Note that this strategy is adding latency before a random sample is available on the RNG_DR register, because of the RNG initialization time.

If the RNG block is disabled during initialization (i.e. well before the DRDY bit rises for the first time), the initialization sequence will resume from where it was stopped when RNGEN bit is set to “1”.

33.4 RNG interrupts

In the RNG an interrupt can be produced on the following events:

- Data ready flag
- Seed error, see Section 33.3.7: Error management
- Clock error, see Section 33.3.7: Error management

Dedicated interrupt enable control bits are available as shown in Table 271.
The user can enable or disable the above interrupt sources individually by changing the mask bits or the general interrupt control bit IE in the RNG_CR register. The status of the individual interrupt sources can be read from the RNG_SR register.

Note: Interrupts are generated only when RNG is enabled.

### 33.5 RNG processing time

The conditioning stage can produce four 32-bit random numbers every $16 \times \frac{f_{AHB}}{f_{RNG}}$ clock cycles, if the value is higher than 213 cycles (213 cycles otherwise).

More time is needed for the first set of random numbers after the device exits reset (see Section 33.3.4: RNG initialization). Indeed, after enabling the RNG for the first time, random data is first available after either:

- 128 RNG clock cycles + 426 AHB cycles, if $f_{AHB} < f_{\text{threshold}}$
- 192 RNG clock cycles + 213 AHB cycles, if $f_{AHB} \geq f_{\text{threshold}}$

With $f_{\text{threshold}} = \left(213 \times f_{RNG}\right)/64$

### 33.6 RNG entropy source validation

#### 33.6.1 Introduction

In order to assess the amount of entropy available from the RNG, STMicroelectronics has tested the peripheral using German BSI AIS-31 statistical tests (T0 to T8). The results can be provided on demand or the customer can reproduce the tests.

#### 33.6.2 Validation conditions

STMicroelectronics has tested the RNG true random number generator in the following conditions:

- RNG clock rng_clk= 48 MHz (CED bit = ‘0’ in RNG_CR register) and rng_clk = 400 kHz (CED bit = ‘1’ in RNG_CR register).

#### 33.6.3 Data collection

In order to run statistical tests it is required to collect samples from the entropy source at raw data level as well as at the output of the entropy source.

Contact STMicroelectronics if above samples need to be retrieved for your product.

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **CED**: Clock error detection

0: Clock error detection is enable
1: Clock error detection is disable

The clock error detection cannot be enabled nor disabled on-the-fly when the RNG is enabled, i.e. to enable or disable CED the RNG must be disabled.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **IE**: Interrupt Enable

0: RNG Interrupt is disabled
1: RNG Interrupt is enabled. An interrupt is pending as soon as DRDY='1', SEIS='1' or CEIS='1' in the RNG_SR register.

Bit 2 **RNGEN**: True random number generator enable

0: True random number generator is disabled. Analog noise sources are powered off and logic clocked by the RNG clock is gated.
1: True random number generator is enabled.

Bits 1:0 Reserved, must be kept at reset value.
### 33.7.2 RNG status register (RNG_SR)

</tr>
</tbody>
</table>
| 6 | SEIS: Seed error interrupt status | 0: No faulty sequence detected  
1: At least one faulty sequence has been detected. See SECS bit description for details. | |
| 5 | CEIS: Clock error interrupt status | 0: The RNG clock is correct (fRNGCLK > fHCLK/32)  
1: The RNG has been detected too slow (fRNGCLK < fHCLK/32) | |
| 4:3 | Reserved, must be kept at reset value. | | |
| 2 | SECS: Seed error current status | 0: No faulty sequence has currently been detected. If the SEIS bit is set, this means that a faulty sequence was detected and the situation has been recovered.  
1: At least one of the following faulty sequence has been detected:  
  - One of the noise source has provided more than 64 consecutive bits at a constant value ("0" or "1"), or more than 32 consecutive occurrence of two bit patterns ("01" or "10")  
  - Both noise sources have delivered more than 32 consecutive bits at a constant value ("0" or "1"), or more than 16 consecutive occurrence of two bit patterns ("01" or "10") | |
| 1 | CECS: Clock error current status | 0: The RNG clock is correct (fRNGCLK > fHCLK/32). If the CEIS bit is set, this means that a slow clock was detected and the situation has been recovered.  
1: The RNG clock is too slow (fRNGCLK < fHCLK/32). | Note: CECS bit is valid only if the CED bit in the RNG_CR register is set to 0. |
| 0 | DRDY: Data Ready | 0: The RNG_DR register is not yet valid, no random data is available.  
1: The RNG_DR register contains valid random data. | Once the output buffer becomes empty (after reading the RNG_DR register), this bit returns to 0 until a new random value is generated.  
Note: The DRDY bit can rise when the peripheral is disabled (RNGEN=0 in the RNG_CR register). If IE=1 in the RNG_CR register, an interrupt is generated when DRDY=1. |
### 33.7.3 RNG data register (RNG_DR)

Address offset: 0x008  
Reset value: 0x0000 0000

The RNG_DR register is a read-only register that delivers a 32-bit random value when read. After being read this register delivers a new random value after 216 periods of AHB clock if the output FIFO is empty.

The content of this register is valid when DRDY=1, even if RNGEN=0.

34 Cryptographic processor (CRYP)

34.1 Introduction

The cryptographic processor (CRYP) can be used both to encrypt and decrypt data using the DES, Triple-DES or AES algorithms. It is a fully compliant implementation of the following standards:

- The data encryption standard (DES) and Triple-DES (TDES) as defined by Federal Information Processing Standards Publication (FIPS PUB 46-3, Oct 1999), and the American National Standards Institute (ANSI X9.52)
- The advanced encryption standard (AES) as defined by Federal Information Processing Standards Publication (FIPS PUB 197, Nov 2001)

Multiple key sizes and chaining modes are supported:

- DES/TDES chaining modes ECB and CBC, supporting standard 56-bit keys with 8-bit parity per key
- AES chaining modes ECB, CBC, CTR, GCM, GMAC, CCM for key sizes of 128, 192 or 256 bits

The CRYP is a 32-bit AHB peripheral. It supports DMA transfers for incoming and outgoing data (two DMA channels are required). The peripheral also includes input and output FIFOs (each 8 words deep) for better performance.

The CRYP peripheral provides hardware acceleration to AES and DES cryptographic algorithms packaged in STM32 cryptographic library.

34.2 CRYP main features

- Compliant implementation of the following standards:
  - NIST FIPS publication 46-3, Data Encryption Standard (DES)
  - ANSI X9.52, Triple Data Encryption Algorithm Modes of Operation
  - NIST FIPS publication 197, Advanced Encryption Standard (AES)
- AES symmetric block cipher implementation
  - 128-bit data block processing
  - Support for 128-, 192- and 256-bit cipher key lengths
  - Encryption and decryption with multiple chaining modes: Electronic Code Book (ECB), Cipher Block Chaining (CBC), Counter mode (CTR), Galois Counter Mode (GCM), Galois Message Authentication Code mode (GMAC) and Counter with CBC-MAC (CCM).
  - 14 (respectively 18) clock cycles for processing one 128-bit block of data with a 128-bit (respectively 256-bit) key in AES-ECB mode
  - Integrated key scheduler with its key derivation stage (ECB or CBC decryption only)
- DES/TDES encryption/decryption implementation
  - 64-bit data block processing
  - Support for 64-, 128- and 192-bit cipher key lengths (including parity)
  - Encryption and decryption with support of ECB and CBC chaining modes
– Direct implementation of simple DES algorithms (a single key K1 is used)
– 16 (respectively 64) clock cycles for processing one 64-bit block of data in DES
  (respectively TDES) ECB mode
– Software implementation of ciphertext stealing

• Features common to DES/TDES and AES
  – AMBA AHB slave peripheral, accessible through 32-bit word single accesses only
    (otherwise an AHB bus error is generated, and write accesses are ignored)
  – 256-bit register for storing the cryptographic key (8x 32-bit registers)
  – 128-bit registers for storing initialization vectors (4x 32-bit)
  – 1x32-bit INPUT buffer associated with an internal IN FIFO of eight 32-bit words,
    corresponding to four incoming DES blocks or two AES blocks
  – 1x32-bit OUTPUT buffer associated with an internal OUT FIFO of eight 32-bit
    words, corresponding to four processed DES blocks or two AES blocks
  – Automatic data flow control supporting direct memory access (DMA) using two
    channels (one for incoming data, one for processed data). Single and burst
    transfers are supported.
  – Data swapping logic to support 1-, 8-, 16- or 32-bit data
  – Possibility for software to suspend a message if the cryptographic processor
    needs to process another message with higher priority (suspend/resume
    operation)

34.3.3 CRYP DES/TDES cryptographic core

Overview

The DES/Triple-DES cryptographic core consists of three components:
- The DES Algorithm (DEA core)
- Multiple keys (one for the DES algorithm, one to three for the TDES algorithm)
- The initialization vector, which is used only in CBC mode

The DES/Triple-DES cryptographic core provides two operating modes:
- **ALGODIR=0**: Plaintext encryption using the key stored in the CRYP_Kx registers.
- **ALGODIR=1**: Ciphertext decryption using the key stored in the CRYP_Kx registers.

The operating mode is selected by programming the ALGODIR bit in the CRYP_CR register.

Typical data processing

Typical usage of the cryptographic processor in DES modes can be found in Section 34.3.10: CRYP DES/TDES basic chaining modes (ECB, CBC).

Note: The outputs of the intermediate DEA stages are never revealed outside the cryptographic boundary, with the exclusion of the IV registers in CBC mode.

DES keying and chaining modes

The TDES allows three different keying options:
- **Three independent keys**
  The first option specifies that all the keys are independent, that is, K1, K2 and K3 are independent. FIPS PUB 46-3 – 1999 (and ANSI X9.52 – 1998) refers to this option as the Keying Option 1 and, to the TDES as 3-key TDES.
- **Two independent keys**
  The second option specifies that K1 and K2 are independent and K3 is equal to K1, that is, K1 and K2 are independent, K3 = K1. FIPS PUB 46-3 – 1999 (and ANSI X9.52
Three equal keys
The third option specifies that K1, K2 and K3 are equal, that is:
K1 = K2 = K3
FIPS PUB 46-3 – 1999 (and ANSI X9.52 – 1998) refers to the third option as the Keying Option 3. This “1-key” TDES is equivalent to single DES.

The following chaining algorithms are supported by the DES hardware and can be selected through the ALGOMODE bits in the CRYP_CR register:

- Electronic Code Book (ECB)
- Cipher Block Chaining (CBC)

These modes are described in details in Section 34.3.10: CRYP DES/TDES basic chaining modes (ECB, CBC).

34.3.4 CRYP AES cryptographic core

Overview
The AES cryptographic core consists of the following components:
- The AES Algorithm (AEA core)
- The Multiplier over a binary Galois field (GF2mul)
- The key information
- The initialization vector (IV) or Nonce information
- Chaining algorithms logic (XOR, feedback/counter, mask)

The AES core works on 128-bit data blocks of (four words) with 128-, 192- or 256-bit key lengths. Depending on the chaining mode, the peripheral requires zero or one 128-bit initialization vector (IV).

The cryptographic peripheral features two operating modes:
- ALGODIR=0: Plaintext encryption using the key stored in the CRYP_Kx registers.
- ALGODIR=1: Ciphertext decryption using the key stored in the CRYP_Kx registers.
  When ECB and CBC chaining modes are selected, an initial key derivation process is automatically performed by the cryptographic peripheral.

The operating mode is selected by programming the ALGODIR bit in the CRYP_CR register.

Typical data processing
A description of cryptographic processor typical usage in AES mode can be found in Section 34.3.11: CRYP AES basic chaining modes (ECB, CBC).

Note: The outputs of the intermediate AEA stages is never revealed outside the cryptographic boundary, with the exclusion of the IV registers.
AES chaining modes

The following chaining algorithms are supported by the cryptographic processor and can be selected through the ALGOMODE bits in the CRYP_CR register:

- Electronic Code Book (ECB)
- Cipher Block Chaining (CBC)
- Counter Mode (CTR)
- Galois/Counter Mode (GCM)
- Galois Message Authentication Code mode (GMAC)
- Counter with CBC-MAC (CCM)

A quick introduction on these chaining modes can be found in the following subsections.

For detailed instructions, refer to Section 34.3.11: CRYP AES basic chaining modes (ECB, CBC) and onward.

AES Electronic CodeBook (ECB)

![Figure 251. AES-ECB mode overview](image)

ECB is the simplest operating mode. There are no chaining operations, and no special initialization stage. The message is divided into blocks and each block is encrypted or decrypted separately.

**Note:** For decryption, a special key scheduling is required before processing the first block.
AES Cipher block chaining (CBC)

 CBC operating mode chains the output of each block with the input of the following block. To make each message unique, an initialization vector is used during the first block processing.

Note: For decryption, a special key scheduling is required before processing the first block.
AES Counter mode (CTR)

The CTR mode uses the AES core to generate a key stream; these keys are then XORed with the plaintext to obtain the ciphertext as specified in NIST Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation.

Note: Unlike ECB and CBC modes, no key scheduling is required for the CTR decryption, since in this chaining scheme the AES core is always used in encryption mode for producing the counter blocks.
AES Galois/Counter mode (GCM)

Figure 254. AES-GCM mode overview

In Galois/Counter mode (GCM), the plaintext message is encrypted, while a message authentication code (MAC) is computed in parallel, thus generating the corresponding ciphertext and its MAC (also known as authentication tag). It is defined in NIST Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.

GCM mode is based on AES in counter mode for confidentiality. It uses a multiplier over a fixed finite field for computing the message authentication code. It requires an initial value and a particular 128-bit block at the end of the message.

AES Galois Message Authentication Code (GMAC)

Figure 255. AES-GMAC mode overview
Galois Message Authentication Code (GMAC) allows authenticating a message and generating the corresponding message authentication code (MAC). It is defined in NIST Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.

GMAC is similar to Galois/Counter mode (GCM), except that it is applied on a message composed only by clear-text authenticated data (i.e. only header, no payload).

**AES Counter with CBC-MAC (CCM)**

In Counter with Cipher Block Chaining-Message Authentication Code (CCM), the plaintext message is encrypted while a message authentication code (MAC) is computed in parallel, thus generating the corresponding ciphertext and the corresponding MAC (also known as tag). It is described by NIST in Special Publication 800-38C, Recommendation for Block Cipher Modes of Operation - The CCM Mode for Authentication and Confidentiality.

CCM mode is based on AES in counter mode for confidentiality and it uses CBC for computing the message authentication code. It requires an initial value.

Like GCM CCM chaining mode, AES-CCM mode can be applied on a message composed only by cleartext authenticated data (i.e. only header, no payload). Note that this way of using CCM is not called CMAC (it is not similar to GCM/GMAC), and its usage is not recommended by NIST.

---

**Figure 256. AES-CCM mode overview**

In Counter with Cipher Block Chaining-Message Authentication Code (CCM), the plaintext message is encrypted while a message authentication code (MAC) is computed in parallel, thus generating the corresponding ciphertext and the corresponding MAC (also known as tag). It is described by NIST in Special Publication 800-38C, Recommendation for Block Cipher Modes of Operation - The CCM Mode for Authentication and Confidentiality.
34.3.5  CRYP procedure to perform a cipher operation

Introduction

To understand how the cryptographic peripheral operates, a typical cipher operation is described below. For the detailed peripheral usage according to the cipher mode, refer to the specific section, e.g. Section 34.3.11: CRYP AES basic chaining modes (ECB, CBC).

The flowcharts shown in Figure 257 and Figure 258 describe the way STM32 cryptographic library implements DES (respectively AES) algorithm. The cryptographic processor accelerates the execution of the following cryptographic algorithms:

- AES-128, AES-192, AES-256 bit in the following modes: ECB, CBC, CTR, CCM, GCM
- DES, TripleDES in the following modes: ECB, CBC

**CRYP initialization**

1. Initialize the cryptographic processor. The order of operations is not important except for AES-ECB and AES-CBC decryption, where the key preparation requires a specific sequence.
   
   a) Disable the cryptographic processor by setting to 0 the CRYPEN bit in the CRYP_CR register.
   
   b) Configure the key size (128-, 192- or 256-bit, in the AES only) with the KEYSIZE bits in the CRYP_CR register.
   
   c) Write the symmetric key into the CRYP_Kx L/R registers (2 to 8 registers to be written depending on the algorithm).
   
   d) Configure the data type (1-, 8-, 16- or 32-bit), with the DATATYPE bits in the CRYP_CR register.
   
   e) In case of decryption in AES-ECB or AES-CBC mode, prepare the key that has been written. First configure the key preparation mode by setting the ALGOMODE bits to 0b111 in the CRYP_CR register. Then write the CRYPEN bit to 1: the BUSY
bit is set automatically. Wait until BUSY returns to 0 (CRYPEN is automatically cleared as well): the key is prepared for decryption.

f) Configure the algorithm and chaining with the ALGOMODE bits in the CRYP_Cr
   register.

g) Configure the direction (encryption/decryption) through the ALGODIR bit in the
   CRYP_CR register.

h) When it is required (e.g. CBC or CTR chaining modes), write the initialization
   vectors into the CRYP_IVxL/R register.

2. Flush the IN and OUT FIFOs by writing the FFLUSH bit to 1 in the CRYP_CR register.

Preliminary warning for all cases

If the ECB or CBC mode is selected and data are not a multiple of 64 bits (for DES) or 128 bits (for AES), the second and the last block management is more complex than the sequences below. Refer to Section 34.3.8: CRYP stealing and data padding for more details.

Appending data using the CPU in polling mode

1. Enable the cryptographic processor by setting to 1 the CRYPEN bit in the CRYP_CR
   register.

2. Write data in the IN FIFO (one block or until the FIFO is full).

3. Repeat the following sequence until the second last block of data has been processed:
   a) Wait until the not-empty-flag OFNE is set to 1, then read the OUT FIFO (one block
      or until the FIFO is empty).
   b) Wait until the not-full-flag IFNF is set to 1, then write the IN FIFO (one block or until
      the FIFO is full) except if it is the last block.

4. The BUSY bit is set automatically by the cryptographic processor. At the end of the
   processing, the BUSY bit returns to 0 and both FIFOs are empty (IN FIFO empty flag
   IFEM=1 and OUT FIFO not empty flag OFNE=0).

5. If the next processing block is the last block, the CPU must pad (when applicable) the
   data with zeroes to obtain a complete block

6. When the operation is complete, the cryptographic processor can be disabled by
   clearing the CRYPEN bit in CRYP_CR register.

Appending data using the CPU in interrupt mode

1. Enable the interrupts by setting the INIM and OUTIM bits in the CRYP_IMSCR register.

2. Enable the cryptographic processor by setting to 1 the CRYPEN bit in the CRYP_CR
   register.

3. In the interrupt service routine that manages the input data:
   a) If the last block is being loaded, the CPU must pad (when applicable) the data with
      zeroes to have a complete block. Then load the block into the IN FIFO.
   b) If it is not the last block, load the data into the IN FIFO. You can load only one
      block (2 words for DES, 4 words for AES), or load data until the FIFO is full.
   c) In all cases, after the last word of data has been written, disable the interrupt by
      clearing the INIM interrupt mask.

4. In the interrupt service routine that manages the input data:
a) Read the output data from the OUT FIFO. You can read only one block (2 words for DES, 4 words for AES), or read data until the FIFO is empty.

b) When the last word has been read, INIM and BUSY bits are set to 0 and both FIFOs are empty (IFEM=1 and OFNE=0). You can disable the interrupt by clearing the OUTIM bit, and disable the peripheral by clearing the CRYPEN bit.

c) If you read the last block of cleartext data (i.e. decryption), optionally discard the data that is not part of message/payload.

### Appending data using the DMA

1. Prepare the last block of data by optionally padding it with zeroes to have a complete block.
2. Configure the DMA controller to transfer the input data from the memory and transfer the output data from the peripheral to the memory, as described in Section 34.3.19: CRYP DMA interface. The DMA should be configured to set an interrupt on transfer completion to indicate that the processing is complete.
3. Enable the cryptographic processor by setting to 1 the CRYPEN bit in CRYP_CR register, then enable the DMA IN and OUT requests by setting to 1 the DIEN and DOEN bits in the CRYP_DMACR register.
4. All the transfers and processing are managed by the DMA and the cryptographic processor. The DMA interrupt indicates that the processing is complete. Both FIFOs are normally empty and BUSY flag is set 0.

**Caution:** It is important that DMA controller empties the cryptographic processor output FIFO before filling up the cryptographic processor input FIFO. To achieve this, the DMA controller should be configured so that the transfer from the cryptographic peripheral to the memory has a higher priority than the transfer from the memory to the cryptographic peripheral.

### 34.3.6 CRYP busy state

The cryptographic processor is busy and processing data (BUSY set to 1 in CRYP_SR register) when all the conditions below are met:
- CRYPEN = 1 in CRYP_CR register.
- There are enough data in the input FIFO (at least two words for the DES or TDES algorithm mode, four words for the AES algorithm mode).
- There is enough free-space in the output FIFO (at least two word locations for DES, four for AES).

Write operations to the CRYP_Kx(L/R)R key registers, to the CRYP_IVx(L/R)R initialization registers, or to bits [9:2] of the CRYP_CR register, are ignored when cryptographic processor is busy (i.e. the registers are not modified). It is thus not possible to modify the configuration of the cryptographic processor while it is processing a data block.

It is possible to clear the CRYPEN bit while BUSY bit is set to 1. In this case the ongoing DES/TDES or AES processing first completes (i.e. the word results are written to the output FIFO) before the BUSY bit is cleared by hardware.

**Note:** If the application needs to suspend a message to process another one with a higher priority, refer to Section 34.3.9: CRYP suspend/resume operations

When a block is being processed in DES or TDES mode, if the output FIFO becomes full and the input FIFO contains at least one new block, then the new block is popped off the
input FIFO and the BUSY bit remains high until there is enough space to store this new block into the output FIFO.

34.3.7 Preparing the CRYP AES key for decryption

When performing an AES ECB or CBC decryption, the AES key has to be prepared, i.e. a complete key schedule of encryption is required before performing the decryption. In other words, the key in the last round of encryption must be used as the first round key for decryption.

This preparation is not required in any other AES modes than AES ECB or CBC decryption.

If the application software stores somehow the initial key prepared for decryption, the key scheduling operation can be performed only once for all the data to be decrypted with a given cipher key.

**Note:** The latency of the key preparation operation is 14, 16 or 18 clock cycles depending on the key size (128-, 192- or 256-bit).

The CRYP key preparation process is performed as follow:

1. Write the encryption key to K0...K3 key registers.
2. Program ALGOMODE bits to 0b111 in CRYP_CR. Writing this value when CRYPEN is set to 1 immediately starts an AES round for key preparation. The BUSY bit in the CRYP_SR register is set to 1.
3. When the key processing is complete, the resulting key is copied back into the K0...K3 key registers, and the BUSY bit is cleared.

**Note:** As the CRYPEN bitfield is reset by hardware at the end of the key preparation, the application software must set it again for the next operation.

34.3.8 CRYP stealing and data padding

When using DES or AES algorithm in ECB or CBC modes to manage messages that are not multiple of the block size (64 bits for DES, 128 bits for AES), use ciphertext stealing techniques such as those described in NIST Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation: Three Variants of Ciphertext Stealing for CBC Mode. Since the cryptographic processor does not implement such techniques, the last two blocks must be handled in a special way by the application.

**Note:** Ciphertext stealing techniques are not documented in this reference manual.

Similarly, when the AES algorithm is used in other modes than ECB or CBC, incomplete input data blocks (i.e. block shorter than 128 bits) have to be padded with zeroes by the application prior to encryption (i.e. extra bits should be appended to the trailing end of the data string). After decryption, the extra bits have to be discarded. The cryptographic processor does not implement automatic data padding operation to the last block, so the application should follow the recommendation given in Section 34.3.5: CRYP procedure to perform a cipher operation to manage messages that are not multiple of 128 bits.

**Note:** Padding data are swapped in a similar way as normal data, according to the DATATYPE field in CRYP_CR register (see Section 34.3.16: CRYP data registers and data swapping for details).
With this version of cryptographic processor, a special workaround is required in order to properly compute authentication tags while doing a **GCM encryption** or a **CCM decryption** with the last block of payload size **inferior to 128 bits**. This workaround is described below:

- During GCM encryption payload phase and before inserting a last plaintext block smaller than 128 bits, the application has to follow the below sequence:
  a) Disable the peripheral by setting the CRYPEN bit to 0 in CRYP_CR.
  b) Load CRYP_IV1R register content in a temporary variable. Decrement the value by 1 and reinsert the result in CRYP_IV1R register.
  c) Change the AES mode to CTR mode by writing the ALGOMODE bitfield to 0b0110 in the CRYP_CR register.
  a) Set the CRYPEN bit to 1 in CRYP_CR to enable again the peripheral.
  b) Pad the last block (smaller than 128 bits) with zeros to have a complete block of 128 bits, then write it into CRYP_DIN register.
  c) Upon encryption completion, read the 128-bit generated ciphertext from the CRYP_DOUT register and store it as intermediate data.
  d) Change again the AES mode to GCM mode by writing the ALGOMODE bitfield to 0b1000 in the CRYP_CR register.
  e) Select Final phase by writing the GCM_CCMPH bitfield to 0b11 in the CRYP_CR register.
  f) In the intermediate data, set to 0 the bits corresponding to the padded bits of the last payload block then insert the resulting data to CRYP_DIN register.
  g) When the operation is complete, read data from CRYP_DOUT. These data have to be discarded.
  h) Apply the normal Final phase as described in **Section 34.3.13: CRYP AES Galois/counter mode (GCM)**.

- During CCM decryption payload phase and before inserting a last ciphertext block smaller than 128 bits, the application has to follow the below sequence:
  a) To disable the peripheral, set the CRYPEN bit to 0 in CRYP_CR.
  b) Load CRYP_IV1R in a temporary variable (named here IV1temp).
  c) Load CRYP_CSGCMCCM0R, CRYP_CSGCMCCM1R, CRYP_CSGCMCCM2R, and CRYP_CSGCMCCM3R register contents from LSB to MSB in 128-bit temporary variable (named here temp1).
  d) Load in CRYP_IV1R the content previously stored in IV1temp.
  e) Change the AES mode to CTR mode by writing the ALGOMODE bitfield to 0b0110 in the CRYP_CR register.
  a) Set the CRYPEN bit to 1 in CRYP_CR to enable again the peripheral.
  b) Pad the last block (smaller than 128 bits) with zeros to have a complete block of 128 bits, then write it to CRYP_DIN register.
  c) Upon decryption completion, read the 128-bit generated data from DOUT register, and store them as intermediate data (here named intdata_o).
  d) Save again CRYP_CSGCMCCM0R, CRYP_CSGCMCCM1R, CRYP_CSGCMCCM2R, and CRYP_CSGCMCCM3R register contents, from LSB to MSB, in a new 128-bit temporary variable (named here temp2).
  e) Change again the AES mode to CCM mode by writing the ALGOMODE bitfield to 0b1001 in the CRYP_CR register.
f) Select the header phase by writing the GCM_CCMPH bitfield to 0b01 in the CRYP_CR register.

g) In the intermediate data (intdata_o which was generated with CTR), set to 0 the bits corresponding to the padded bits of the last payload block, XOR with temp1, XOR with temp2, and insert the resulting data into CRYP_DIN register. In other words:
\[
\text{CRYP_DIN} = (\text{intdata_o AND mask}) \text{ XOR temp1 XOR temp2.}
\]
h) Wait for operation completion.
i) Apply the normal Final phase as described in Section 34.3.15: CRYP AES Counter with CBC-MAC (CCM).

### 34.3.9 CRYP suspend/resume operations

A message can be suspended if another message with a higher priority has to be processed. When this highest priority message has been sent, the suspended message can be resumed in both encryption or decryption mode.

Suspend/resume operations do not break the chaining operation and the message processing can be resumed as soon as cryptographic processor is enabled again to receive the next data block.

*Figure 259* gives an example of suspend.resume operation: message 1 is suspended in order to send a higher priority message (message 2), which is shorter than message 1 (AES algorithm).

*Figure 259. Example of suspend mode management*

A detailed description of suspend/resume operations can be found in each AES mode section.
34.3.10 CRYP DES/TDES basic chaining modes (ECB, CBC)

Overview

FIPS PUB 46-3 – 1999 (and ANSI X9.52-1998) provides a thorough explanation of the processing involved in the four operation modes supplied by the DES computing core: TDES-ECB encryption, TDES-ECB decryption, TDES-CBC encryption and TDES-CBC decryption. This section only gives a brief explanation of each mode.

DES/TDES-ECB encryption

Figure 260 illustrates the encryption in DES and TDES Electronic CodeBook (DES/TDES-ECB) mode. This mode is selected by writing in ALGOMODE to 0b000 and ALGODIR to 0 in CRYP_CR.

Figure 260. DES/TDES-ECB mode encryption

1. K: key; C: cipher text; I: input block; O: output block; P: plain text.

A 64-bit plaintext data block (P) is used after bit/byte/half-word as the input block (I). The input block is processed through the DEA in the encrypt state using K1. The output of this process is fed back directly to the input of the DEA where the DES is performed in the decrypt state using K2. The output of this process is fed back directly to the input of the DEA where the DES is performed in the encrypt state using K3. The resultant 64-bit output block (O) is used, after bit/byte/half-word swapping, as ciphertext (C) and it is pushed into the OUT FIFO.

Note: For more information on data swapping, refer to Section 34.3.16: CRYP data registers and data swapping.

Detailed DES/TDES encryption sequence can be found in Section 34.3.5: CRYP procedure to perform a cipher operation.
DES/TDES-ECB mode decryption

Figure 261 illustrates the decryption in DES and TDES Electronic CodeBook (DES/TDES-ECB) mode. This mode is selected by writing ALGOMODE to 0b000 and ALGODIR to 1 in CRYP_CR.

Figure 261. DES/TDES-ECB mode decryption

A 64-bit ciphertext block (C) is used, after bit/byte/half-word swapping, as the input block (I). The keying sequence is reversed compared to that used in the encryption process. The input block is processed through the DEA in the decrypt state using K3. The output of this process is fed back directly to the input of the DEA where the DES is performed in the encrypt state using K2. The new result is directly fed to the input of the DEA where the DES is performed in the decrypt state using K1. The resultant 64-bit output block (O), after bit/byte/half-word swapping, produces the plaintext (P).

Note: For more information on data swapping refer to Section 34.3.16: CRYP data registers and data swapping.

Detailed DES/TDES encryption sequence can be found in Section 34.3.5: CRYP procedure to perform a cipher operation.
DES/TDES-CBC encryption

*Figure 262* illustrates the encryption in DES and TDES Cipher Block Chaining (DES/TDES-ECB) mode. This mode is selected by writing in ALGOMODE to 0b001 and ALGODIR to 0 in CRYP_CR.

This mode begins by dividing a plaintext message into 64-bit data blocks. In TCBC encryption, the first input block (I1), obtained after bit/byte/half-word swapping, is formed by exclusive-ORing the first plaintext data block (P1) with a 64-bit initialization vector IV (I1 = IV ⊕ P1). The input block is processed through the DEA in the encrypt state using K1. The output of this process is fed back directly to the input of the DEA, which performs the DES in the decrypt state using K2. The output of this process is fed directly to the input of the DEA, which performs the DES in the encrypt state using K3. The resultant 64-bit output block (O1) is used directly as the ciphertext (C1), that is, C1 = O1.

This first ciphertext block is then exclusive-ORed with the second plaintext data block to produce the second input block, (I2) = (C1 ⊕ P2). Note that I2 and P2 now refer to the second block. The second input block is processed through the TDEA to produce the second ciphertext block.

This encryption process continues to “chain” successive cipher and plaintext blocks together until the last plaintext block in the message is encrypted.

If the message does not consist of an integral number of data blocks, then the final partial data block should be encrypted in a manner specified for the application.
Note: For more information on data swapping refer to Section 34.3.16: CRYP data registers and data swapping.

Detailed DES/TDES encryption sequence can be found in Section 34.3.5: CRYP procedure to perform a cipher operation.

**DES/TDES-CBC decryption**

*Figure 262* illustrates the decryption in DES and TDES Cipher Block Chaining (DES/TDES-ECB) mode. This mode is selected by writing ALGOMODE to 0b001 and ALGODIR to 1 in CRYP_CR.

### Figure 263. DES/TDES-CBC mode decryption

In this mode the first ciphertext block (C1) is used directly as the input block (I1). The keying sequence is reversed compared to that used for the encrypt process. The input block is processed through the DEA in the decrypt state using K3. The output of this process is fed directly to the input of the DEA where the DES is processed in the encrypt state using K2. This resulting value is directly fed to the input of the DEA where the DES is processed in the decrypt state using K1. The resulting output block is exclusive-ORed with the IV (which must be the same as that used during encryption) to produce the first plaintext block (P1 = O1 ⊕ IV).

The second ciphertext block is then used as the next input block and is processed through the TDEA. The resulting output block is exclusive-ORed with the first ciphertext block to produce the second plaintext data block (P2 = O2 ⊕ C1). Note that P2 and O2 refer to the second block of data.
The DES/TDES-CBC decryption process continues in this manner until the last complete ciphertext block has been decrypted.

Ciphertext representing a partial data block must be decrypted in a manner specified for the application.

Note: For more information on data swapping refer to Section 34.3.16: CRYP data registers and data swapping.

Detailed DES/TDES encryption sequence can be found in Section 34.3.5: CRYP procedure to perform a cipher operation.

DES/TDES suspend/resume operations in ECB/CBC modes

Before interrupting the current message, the user application must respect the following steps:

1. If DMA is used, stop the DMA transfers to the IN FIFO by clearing to 0 the DIEN bit in the CRYP_DMACR register.
2. Wait until both the IN and the OUT FIFOs are empty (IFEM=1 and OFNE=0 in the CRYP_SR) and the BUSY bit is cleared. Alternatively, as the input FIFO can contain up to four unprocessed DES blocks, the application could decide for real-time reason to interrupt the cryptographic processing without waiting for the IN FIFO to be empty. In this case, the alternative is:
   a) Wait until OUT FIFO is empty (OFNE=0).
   b) Read back the data loaded in the IN FIFO that have not been processed and save them in the memory until the IN FIFO is empty.
3. If DMA is used stop the DMA transfers from the OUT FIFO by clearing to 0 the DOEN bit in the CRYP_DMACR register.
4. Disable the cryptographic processor by setting the CRYPEN bit to 0 in CRYP_CR, then save the current configuration (bits [9:2] in the CRYP_CR register). If CBC mode is selected, save the initialization vector registers, since CRYP_IVx registers have changed from initial values during the data processing.

Note: Key registers do not need to be saved as the original key value is known by the application.

5. If DMA is used, save the DMA controller status (such as the pointers to IN and OUT data transfers, number of remaining bytes).

To resume message processing, the user application must respect the following sequence:

1. If DMA is used, reconfigure the DMA controller to complete the rest of the FIFO IN and FIFO OUT transfers.
2. Make sure the cryptographic processor is disabled by reading the CRYPEN bit in CRYP_CR (it must be 0).
3. Configure again the cryptographic processor with the initial setting in CRYP_CR, as well as the key registers using the saved configuration.
4. If the CBC mode is selected, restore CRYP_IVx registers using the saved configuration.
5. Optionally, write the data that were saved during context saving into the IN FIFO.
6. Enable the cryptographic processor by setting the CRYPEN bit to 1.
7. If DMA is used, enable again DMA requests for the cryptographic processor, by setting to 1 the DIEN and DOEN bits in the CRYP_DMACR register.
34.3.11 CRYP AES basic chaining modes (ECB, CBC)

Overview

FIPS PUB 197 (November 26, 2001) provides a thorough explanation of the processing involved in the four basic operation modes supplied by the AES computing core: AES-ECB encryption, AES-ECB decryption, AES-CBC encryption and AES-CBC decryption. This section only gives a brief explanation of each mode.

AES ECB encryption

*Figure 264* illustrates the AES Electronic codebook (AES-ECB) mode encryption. This mode is selected by writing ALGOMODE to 0b100 and ALGODIR to 0 in CRYP_CR.

In this mode a 128-bit plaintext data block (P) is used after bit/byte/half-word swapping as the input block (I). The input block is processed through the AEA in the encrypt state using the 128, 192 or 256-bit key. The resultant 128-bit output block (O) is used after bit/byte/half-word swapping as ciphertext (C). It is then pushed into the OUT FIFO.

For more information on data swapping refer to *Section 34.3.16: CRYP data registers and data swapping.*
AES ECB decryption

*Figure 265* illustrates the AES Electronic codebook (AES-ECB) mode decryption. This mode is selected by writing in ALGOMODE to 0b100 and ALGODIR to 1 in CRYP.CR.

**Figure 265. AES-ECB mode decryption**

1. K: key; C: cipher text; I: input block; O: output block; P: plain text.
2. If Key size = 128 => Key = [K₃ K₂].
   - If Key size = 192 => Key = [K₃ K₂ K₁]
   - If Key size = 256 => Key = [K₃ K₂ K₁ K₀].

To perform an AES decryption in ECB mode, the secret key has to be prepared (it is necessary to execute the complete key schedule for encryption) by collecting the last round key, and using it as the first round key for the decryption of the ciphertext. This preparation phase is computed by the AES core. Refer to *Section 34.3.7: Preparing the CRYP AES key for decryption* for more details on how to prepare the key.

When the key preparation is complete, the decryption proceed as follow: a 128-bit ciphertext block (C) is used after bit/byte/half-word swapping as the input block (I). The keying sequence is reversed compared to that of the encryption process. The resultant 128-bit output block (O), after bit/byte or half-word swapping, produces the plaintext (P). The AES-CBC decryption process continues in this manner until the last complete ciphertext block has been decrypted.

For more information on data swapping refer to *Section 34.3.16: CRYP data registers and data swapping.*
AES CBC encryption

Figure 266 illustrates the AES Cipher block chaining (AES-CBC) mode encryption. This mode is selected by writing ALGOMODE to 0b101 and ALGODIR to 0 in CRYP_CR.

Figure 266. AES-CBC mode encryption

1. K: key; C: cipher text; I: input block; O: output block; Ps: plain text before swapping (when decoding) or after swapping (when encoding); P: plain text; IV: Initialization vectors.

2. IVx=[[IVxR IVxL][2]].

3. If Key size = 128 => Key = [K3 K2],
   If Key size = 192 => Key = [K3 K2 K1],
   If Key size = 256 => Key = [K3 K2 K1 K0].

In this mode the first input block (I1) obtained after bit/byte/half-word swapping is formed by exclusive-ORing the first plaintext data block (P1) with a 128-bit initialization vector IV (I1 = IV ⊕ P1). The input block is processed through the AEA in the encrypt state using the 128-, 192- or 256-bit key (K0...K3). The resultant 128-bit output block (O1) is used directly as ciphertext (C1), that is, C1 = O1. This first ciphertext block is then exclusive-ORed with the second plaintext data block to produce the second input block, (I2) = (C1 ⊕ P2). Note that I2 and P2 now refer to the second block. The second input block is processed through the AEA to produce the second ciphertext block. This encryption process continues to “chain” successive cipher and plaintext blocks together until the last plaintext block in the message is encrypted.

If the message does not consist of an integral number of data blocks, then the final partial data block should be encrypted in a manner specified for the application, as explained in Section 34.3.8: CRYP stealing and data padding.

For more information on data swapping, refer to Section 34.3.16: CRYP data registers and data swapping.
AES CBC decryption

Figure 267 illustrates the AES Cipher block chaining (AES-CBC) mode decryption. This mode is selected by writing ALGOMODE to 0b101 and ALGODIR to 1 in CRYP_CR.

Figure 267. AES-CBC mode decryption

1. K: key; C: cipher text; I: input block; O: output block; Ps: plain text before swapping (when decoding) or after swapping (when encoding); P: plain text; IV: Initialization vectors.

2. IVx=[[IVxR IVxL], R=right, L=left.

3. If Key size = 128 => Key = [K3 K2],
   If Key size = 192 => Key = [K3 K2 K1],
   If Key size = 256 => Key = [K3 K2 K1 K0].

In CBC mode, like in ECB mode, the secret key must be prepared to perform an AES decryption. Refer to Section 34.3.7: Preparing the CRYP AES key for decryption for more details on how to prepare the key.

When the key preparation process is complete, the decryption proceeds as follow: the first 128-bit ciphertext block (C1) is used directly as the input block (I1). The input block is processed through the AEA in the decrypt state using the 128-, 192- or 256-bit key. The resulting output block is exclusive-ORed with the 128-bit initialization vector IV (which must be the same as that used during encryption) to produce the first plaintext block (P1 = O1 ⊕ IV).

The second ciphertext block is then used as the next input block and is processed through the AEA. The resulting output block is exclusive-ORed with the first ciphertext block to produce the second plaintext data block (P2 = O2 ⊕ C1). Note that P2 and O2 refer to the second block of data. The AES-CBC decryption process continues in this manner until the last complete ciphertext block has been decrypted.
Ciphertext representing a partial data block must be decrypted in a manner specified for the application, as explained in Section 34.3.8: CRYP stealing and data padding.

For more information on data swapping, refer to Section 34.3.16: CRYP data registers and data swapping.

AES suspend/resume operations in ECB/CBC modes

Before interrupting the current message, the user application must respect the following sequence:

1. If DMA is used, stop the DMA transfers to the IN FIFO by clearing to 0 the DIEN bit in the CRYP_DMACR register.
2. Wait until both the IN and the OUT FIFOs are empty (IFEM=1 and OFNE=0 in the CRYP_SR) and the BUSY bit is cleared.
3. If DMA is used, stop the DMA transfers from the OUT FIFO by clearing to 0 the DOEN bit in the CRYP_DMACR register.
4. Disable the CRYP by setting the CRYPEN bit to 0 in CRYP_CR, then save the current configuration (bits [9:2] in the CRYP_CR register). If ECB mode is not selected, save the initialization vector registers, because CRYP_IVx registers have changed from initial values during the data processing.

Note: Key registers do not need to be saved as the original key value is known by the application.
5. If DMA is used, save the DMA controller status (such as pointers to IN and OUT data transfers, number of remaining bytes).

To resume message processing, the user application must respect the following sequence:

1. If DMA is used, reconfigure the DMA controller to complete the rest of the FIFO IN and FIFO OUT transfers.
2. Make sure the cryptographic processor is disabled by reading the CRYPEN bit in CRYP_CR (it must be set to 0).
3. Configure the cryptographic processor again with the initial setting in CRYP_CR, as well as the key registers using the saved configuration.
4. For AES-ECB or AES-CBC decryption, the key must be prepared again, as described in Section 34.3.7: Preparing the CRYP AES key for decryption.
5. If ECB mode is not selected, restore CRYP_IVx registers using the saved configuration.
6. Enable the cryptographic processor by setting the CRYPEN bit to 1.
7. If DMA is used, enable again the DMA requests from the cryptographic processor, by setting DIEN and DOEN bits to 1 in the CRYP_DMACR register.
34.3.12 CRYP AES counter mode (AES-CTR)

Overview

The AES counter mode (CTR) uses the AES block as a key stream generator. The generated keys are then XORed with the plaintext to obtain the ciphertext.

CTR chaining is defined in NIST Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation. A typical message construction in CTR mode is given in Figure 268.

**Figure 268. Message construction for the Counter mode**

The structure of this message is as below:

- A 16-byte Initial Counter Block (ICB), composed of three distinct fields:
  - A nonce: a 32-bit, single-use value (i.e. a new nonce should be assigned to each new communication).
  - The initialization vector (IV): a 64-bit value that must be unique for each execution of the mode under a given key.
  - The counter: a 32-bit big-endian integer that is incremented each time a block has been processed. The initial value of the counter should be set to 1.

- The plaintext (P) is both authenticated and encrypted as ciphertext C, with a known length. This length can be non-multiple of 16 bytes, in which case a plaintext padding is required.
AES CTR processing

*Figure 269* (respectively *Figure 270*) describes the AES-CTR encryption (respectively decryption) process implemented within this peripheral. This mode is selected by writing in ALGOMODE bitfield to 0b110 in CRYP_CR.

*Figure 269. AES-CTR mode encryption*

1. K: key; C: cipher text; I: input Block; o: output block; Ps: plain text before swapping (when decoding) or after swapping (when encoding); Cs: cipher text after swapping (when decoding) or before swapping (when encoding); P: plain text; IV: Initialization vectors.
In CTR mode, the output block is XORed with the subsequent input block before it is input to the algorithm. Initialization vectors in the peripheral must be initialized as shown on Table 274.

Table 274. Counter mode initialization vector

<table>
<thead>
<tr>
<th>CRYP_IV1R[31:0]</th>
<th>CRYP_IV1L[31:0]</th>
<th>CRYP_IV0R[31:0]</th>

</tr>
</thead>
<tbody>
<tr>
<td>nonce</td>
<td>IV[63:32]</td>
<td>IV[31:0]</td>
<td>32-bit counter= 0x1</td>
</tr>
</tbody>
</table>

Unlike in CBC mode, which uses the CRYP_IVx registers only once when processing the first data block, in CTR mode IV registers are used for processing each data block, and the peripheral increments the least significant 32 bits (leaving the other most significant 96 bits unchanged).

CTR decryption does not differ from CTR encryption, since the core always encrypts the current counter block to produce the key stream that will be XORed with the plaintext or cipher as input. Thus when ALGOMODE is set to 0b110, ALGODIR is don't care.

Note: In this mode the key must NOT be prepared for decryption.
The following sequence must be used to perform an encryption or a decryption in CTR chaining mode:

1. Make sure the cryptographic processor is disabled by clearing the CRYPEN bit in the CRYP_CR register.
2. Configure CRYP_CR as follows:
   a) Program ALGOMODE bits to 0b110 to select CTR mode.
   b) Configure the data type (1, 8, 16 or 32 bits) through the DATATYPE bits.
3. Initialize the key registers (128, 192 and 256 bits) in CRYP_KEYRx as well as the initialization vector (IV) as described in Table 274.
4. Flush the IN and OUT FIFOs by writing the FFLUSH bit to 1 in the CRYP_CR register.
5. If it is the last block, optionally pad the data with zeros to have a complete block.
6. Append data in the cryptographic processor and read the result. The three possible scenarios are described in Section 34.3.5: CRYP procedure to perform a cipher operation.
7. Repeat the previous step until the second last block is processed. For the last block, execute the two previous steps. For this last block, the driver must discard the data that is not part of the data when the last block size is less than 16 bytes.

Suspend/resume operations in CTR mode

Like for the CBC mode, it is possible to interrupt a message to send a higher priority message, and resume the message which was interrupted. Detailed CBC sequence can be found in Section 34.3.11: CRYP AES basic chaining modes (ECB, CBC).

Note: Like for CBC mode, IV registers must be reloaded during the resume operation.
34.3.13 CRYP AES Galois/counter mode (GCM)

Overview

The AES Galois/counter mode (GCM) allows encrypting and authenticating the plaintext, and generating the correspondent ciphertext and tag (also known as message authentication code). To ensure confidentiality, GCM algorithm is based on AES counter mode. It uses a multiplier over a fixed finite field to generate the tag.

GCM chaining is defined in NIST Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC. A typical message construction in GCM mode is given in Figure 271.

Figure 271. Message construction for the Galois/counter mode

The structure of this message is defined as below:

- A 16-byte Initial Counter Block (ICB), composed of two distinct fields:
  - The initialization vector (IV): a 96-bit value that must be unique for each execution of the mode under a given key. Note that the GCM standard supports IV that are shorter than 96-bit, but in this case strict rules apply.
  - The counter: a 32-bit big-endian integer that is incremented each time a block has been processed. According to NIST specification, the counter value is 0x2 when processing the first block of payload.

- The authenticated header A (also knows as Additional Authentication Data) has a known length Len(A) that can be non-multiple of 16 bytes and cannot exceed \(2^{64}-1\) bits. This part of the message is only authenticated, not encrypted.

- The plaintext message (P) is both authenticated and encrypted as ciphertext C, with a known length Len(P) that can be non-multiple of 16 bytes, and cannot exceed \(2^{32}-2\) blocks of 128-bits.

Note: GCM standard specifies that ciphertext C has same bit length as the plaintext P.

- When a part of the message (AAD or P) has a length which is non-multiple of 16 bytes, a special padding scheme is required.

- The last block is composed of the length of A (on 64 bits) and the length of ciphertext C (on 64 bits) as shown in Table 275.
AES GCM processing

This mode is selected by writing ALGOMODE bitfield to 0b110 in CRYP_CR.

The mechanism for the confidentiality of the plaintext in GCM mode is a variation of the Counter mode, with a particular 32-bit incrementing function that generates the necessary sequence of counter blocks.

CRYP_IV registers are used for processing each data block. The cryptographic processor automatically increments the 32 least significant bits of the counter block. The first counter block (CB1) written by the application is equal to the Initial Counter Block incremented by one (see Table 276).

**Note:** In this mode the key must NOT be prepared for decryption.

The authentication mechanism in GCM mode is based on a hash function, called $GF2mul$, that performs multiplication by a fixed parameter, called the hash subkey (H), within a binary Galois field.

To process a GCM message, the driver must go through four phases, which are described in the following subsections.

- The Init phase: the peripheral prepares the GCM hash subkey (H) and performs the IV processing.
- The Header phase: the peripheral processes the Additional Authenticated Data (AAD), with hash computation only.
- The Payload phase: the peripheral processes the plaintext (P) with hash computation, keystream encryption and data XORing. It operates in a similar way for ciphertext (C).
- The Final phase: the peripheral generates the authenticated tag (T) using the data last block.

Table 275. GCM last block definition

Table 276. GCM mode IV registers initialization
1. **GCM init phase**
   During this first step, the GCM hash subkey (H) is calculated and saved internally to be used for processing all the blocks. It is recommended to follow the sequence below:
   a) Make sure the cryptographic processor is disabled by clearing the CRYPEN bit in the CRYP_CR register.
   b) Select the GCM chaining mode by programming ALGOMODE bits to 0b01000 in CRYP_CR.
   c) Configure GCM_CCMPH bits to 0b00 in CRYP_CR to indicate that the init phase is ongoing.
   d) Initialize the key registers (128, 192 and 256 bits) in CRYP_KEYRx as well as the initialization vector (IV) as defined in Table 276.
   e) Set CRYPEN bit to 1 to start the calculation of the hash key.
   f) Wait for the CRYPEN bit to be cleared to 0 by the cryptographic processor, before moving on to the next phase.

2. **GCM header phase**
   The below sequence shall be performed after the GCM init phase. It must be complete before jumping to the payload phase. The sequence is identical for encryption and decryption.
   g) Set the GCM_CCMPH bits to 0b01 in CRYP_CR to indicate that the header phase is ongoing.
   h) Set the CRYPEN bit to 1 to start accepting data.
   i) If it is the last block of additional authenticated data, optionally pad the data with zeros to have a complete block.
   j) Append additional authenticated data in the cryptographic processor. The three possible scenarios are described in Section 34.3.5: CRYP procedure to perform a cipher operation.
   k) Repeat the previous step until the second last additional authenticated data block is processed. For the last block, execute the two previous steps. Once all the additional authenticated data have been supplied, wait until the BUSY flag is cleared before moving on to the next phase.

*Note:* This phase can be skipped if there is no additional authenticated data, i.e. Len(A)=0.

In header and payload phases, CRYPEN bit is not automatically cleared by the cryptographic processor.
3. **GCM payload phase (encryption or decryption)**

When the payload size is not null, this sequence must be executed after the GCM header phase. During this phase, the encrypted/decrypted payload is stored in the CRYP_DOUT register.

l) Set the CRYPEN bit to 0.

m) Configure GCM_CCMPH to 0b10 in the CRYP_CR register to indicate that the payload phase is ongoing.

n) Select the algorithm direction (0 for encryption, 1 for decryption) through the ALGODIR bit in CRYP_CR.

o) Set the CRYPEN bit to 1 to start accepting data.

p) If it is the last block of cleartext or plaintext, optionally pad the data with zeros to have a complete block. For encryption, refer to Section 34.3.8: CRYP stealing and data padding for more details.

q) Append payload data in the cryptographic processor, and read the result. The three possible scenarios are described in Section 34.3.5: CRYP procedure to perform a cipher operation.

r) Repeat the previous step until the second last plaintext block is encrypted or until the last block of ciphertext is decrypted. For the last block of plaintext (encryption only), execute the two previous steps. For the last block, the driver must discard the bits that are not part of the cleartext or the ciphertext when the last block size is less than 16 bytes. Once all payload data have been supplied, wait until the BUSY flag is cleared.

Note: This phase can be skipped if there is no payload data, i.e. Len(C)=0 (see GMAC mode).

4. **GCM final phase**

In this last step, the cryptographic processor generates the GCM authentication tag and stores it in CRYP_DOUT register.

s) Configure GCM_CCMPH[1:0] to 0b11 in CRYP_CR to indicate that the Final phase is ongoing. Set the ALGODIR bit to 0 in the same register.

t) Write the input to the CRYP_DIN register four times. The input must be composed of the length in bits of the additional authenticated data (coded on 64 bits) concatenated with the length in bits of the payload (coded of 64 bits), as show in Table 275.

Note: In this final phase data have to be swapped according to the DATATYPE programmed in CRYP_CR register.

u) Wait until the OFNE flag (FIFO output not empty) is set to 1 in the CRYP_SR register.

v) Read the CRYP_DOUT register four times: the output corresponds to the authentication tag.

w) Disable the cryptographic processor (CRYPEN bit = 0 in CRYP_CR)

x) If an authenticated decryption is being performed, compare the generated tag with the expected tag passed with the message.
Suspend/resume operations in GCM mode

Before interrupting the current message in header or payload phase, the user application must respect the following sequence:

1. If DMA is used, stop DMA transfers to the IN FIFO by clearing to 0 the DIEN bit in the CRYP_DMACR register.
2. Wait until both the IN and the OUT FIFOs are empty (IFEM=1 and OFNE=0 in the CRYP_SR register) and the BUSY bit is cleared.
3. If DMA is used, stop DMA transfers from the OUT FIFO by clearing to 0 the DOEN bit in the CRYP_DMACR register.
4. Disable the cryptographic processor by setting the CRYPEN bit to 0 in CRYP_CR, then save the current configuration (bits [9:2], bits [17:16] and bits 19 of the CRYP_CR register). In addition, save the initialization vector registers, since CRYP_IVx registers have changed from their initial values during data processing.

Note: Key registers do not need to be saved as original their key value is known by the application.

5. Save context swap registers: CRYP_CSGCMCCM0..7R and CRYP_CSGCM0..7R
6. If DMA is used, save the DMA controller status (pointers to IN and OUT data transfers, number of remaining bytes, etc.).

To resume message processing, the user must respect the following sequence:

1. If DMA is used, reconfigure the DMA controller to complete the rest of the FIFO IN and FIFO OUT transfers.
2. Make sure the cryptographic processor is disabled by reading the CRYPEN bit in CRYP_CR (it must be 0).
3. Configure again the cryptographic processor with the initial setting in CRYP_CR, as well as the key registers using the saved configuration.
4. Restore context swap registers: CRYP_CSGCMCCM0..7R and CRYP_CSGCM0..7R
5. Restore CRYP_IVx registers using the saved configuration.
6. Enable the cryptographic processor by setting the CRYPEN bit to 1.
7. If DMA is used, enable again cryptographic processor DMA requests by setting to 1 the DIEN and DOEN bits in the CRYP_DMACR register.

Note: In Header phase, DMA OUT FIFO transfer is not used.
34.3.14 CRYP AES Galois message authentication code (GMAC)

Overview

The Galois message authentication code (GMAC) allows authenticating a plaintext and generating the corresponding tag information (also known as message authentication code). It is based on GCM algorithm, as defined in NIST Special Publication 800-38D, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.

A typical message construction in GMAC mode is given in Figure 272.

Figure 272. Message construction for the Galois Message Authentication Code mode

![Diagram of GMAC message construction]

AES GMAC processing

This mode is selected by writing ALGOMODE bitfield to 0b110 in CRYP_CR.

GMAC algorithm corresponds to the GCM algorithm applied on a message composed only of an header. As a consequence, all steps and settings are the same as in GCM mode, except that the payload phase (3) is not used.

Suspend/resume operations in GMAC

GMAC is exactly the same as GCM algorithm except that only header phase (2) can be interrupted.
34.3.15 CRYP AES Counter with CBC-MAC (CCM)

Overview

The AES Counter with Cipher Block Chaining-Message Authentication Code (CCM) algorithm allows encrypting and authenticating the plaintext, and generating the correspondent ciphertext and tag (also known as message authentication code). To ensure confidentiality, CCM algorithm is based on AES counter mode. It uses Cipher Block Chaining technique to generate the message authentication code. This is commonly called CBC-MAC.

Note: NIST does not approve this CBC-MAC as an authentication mode outside of the context of the CCM specification.

CCM chaining is specified in NIST Special Publication 800-38C, Recommendation for Block Cipher Modes of Operation - The CCM Mode for Authentication and Confidentiality. A typical message construction in CCM mode is given in Figure 273.

Figure 273. Message construction for the Counter with CBC-MAC mode

The structure of this message is as below:

- One 16-byte first authentication block (called B0 by the standard), composed of three distinct fields:
  - Q: a bit string representation of the byte length of P (Plen)
  - A nonce (N): single-use value (i.e. a new nonce should be assigned to each new communication). Size of nonce Nlen + size of Plen shall be equal to 15 bytes.
  - Flags: most significant byte containing four flags for control information, as specified by the standard. It contains two 3-bit strings to encode the values t (MAC length expressed in bytes) and q (plaintext length such as Plen<2^q bytes). Note that the counter blocks range associated to q is equal to 2^{q+4}, i.e. if q maximum value is 8, the counter blocks used in cipher shall be on 60 bits.

Note: The cryptographic peripheral can only manage padded plaintext/ciphertext messages of length Plen < 2^{36} +1 bytes.
• 16-bytes blocks (B) associated to the Associated Data (A).
  This part of the message is only authenticated, not encrypted. This section has a
  known length, \( ALen \), that can be a non-multiple of 16 bytes (see Figure 273). The
  standard also states that, on the MSB bits of the first message block (B1), the
  associated data length expressed in bytes (a) must be encoded as defined below:
  \( ALen \), that can be a non-multiple of 16 bytes (see Figure 273). The
  standard also states that, on the MSB bits of the first message block (B1), the
  associated data length expressed in bytes (a) must be encoded as defined below:
  – If \( 0 < a < 2^{16} - 2^8 \), then it is encoded as \([a]_{16}\), i.e. two bytes.
  – If \( 2^{16} - 2^8 < a < 2^{32} \), then it is encoded as \(0xff \| 0xfe \| [a]_{32}\), i.e. six bytes.
  – If \( 2^{32} < a < 2^{64} \), then it is encoded as \(0xff \| 0xff \| [a]_{64}\), i.e. ten bytes.
• 16-byte blocks (B) associated to the plaintext message (P), which is both authenticated
  and encrypted as ciphertext C, with a known length of \( Plen \). This length can be a non-
  multiple of 16 bytes (see Figure 273) but cannot exceed \( 2^{32} \) blocks of 128-bit.
• The encrypted MAC (T) of length \( Tlen \) appended to the ciphertext C of overall length
  \( Clen \).
• When a part of the message (A or P) has a length which is a non-multiple of 16 bytes, a
  special padding scheme is required.

Note: CCM chaining mode can also be used with associated data only (i.e. no payload).

As an example, the C.1 section in NIST Special Publication 800-38C gives the following:

\[
\begin{align*}
N: & \quad 10111213 \quad 141516 \quad (Nlen= 56 \text{ bits or } 0x7 \text{ bytes}) \\
A: & \quad 00010203 \quad 04050607 \quad (Alen= 64 \text{ bits or } 0x8 \text{ bytes}) \\
P: & \quad 001223 \quad (Plen= 32 \text{ bits i.e. } Q= 0x4 \text{ bytes}) \\
T: & \quad 07141516 \quad (Tlen= 32 \text{ bytes or } t= 4) \\
B0: & \quad 4f101112 \quad 13141516 \quad 00000000 \quad 00000004 \\
B1: & \quad 00080001 \quad 02030405 \quad 06070000 \quad 00000000 \\
B2: & \quad 001223 \quad 00000000 \quad 00000000 \quad 00000000 \\
CTR0: & \quad 0710111213 \quad 141516 \quad 00000000 \quad 00000000 \\
CTR1: & \quad 0710111213 \quad 141516 \quad 00000000 \quad 00000001 \\
\end{align*}
\]

The usage of control blocks CTRx is explained in the following section. The generation of
CTR0 from the first block (B0) must be managed by software.
AES CCM processing

This mode is selected by writing ALGOMODE bitfield to 0b1001 in CRYP_CR.

The data input to the generation-encryption process are a valid nonce, a valid payload string, and a valid associated data string, all properly formatted. The CBC chaining mechanism is applied to the formatted data to generate a MAC, whose length is known. Counter mode encryption, which requires a sufficiently long sequence of counter blocks as input, is applied to the payload string and separately to the MAC. The resulting data, called the ciphertext C, is the output of the generation-encryption process on plaintext P.

CRYP_IV registers are used for processing each data block. The cryptographic processor automatically increments the CTR counter with a bit length defined by the first block (B0). The first counter written by application, CTR1, is equal to B0 with the first 5 bits zeroed and the most significant bits containing P byte length also zeroed, then incremented by one (see Table 277).

**Table 277. CCM mode IV registers initialization**

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

**Note:** In this mode, the key must NOT be prepared for decryption.

To process a CCM message, the driver must go through four phases, which are described below:

- The Init phase: the peripheral processes the first block and prepares the first counter block.
- The Header phase: the peripheral processes the Associated data (A), with hash computation only.
- The Payload phase: the peripheral processes the plaintext (P), with hash computation, counter block encryption and data XORing. It operates in a similar way for ciphertext (C).
- The Final phase: the peripheral generates the message authentication code (MAC).
1. **CCM init phase**

In this first step, the first block (B0) of the CCM message is programmed into the CRYP_DIN register. During this phase, the CRYP_DOUT register does not contain any output data. It is recommended to follow the sequence below:

a) Make sure that the cryptographic processor is disabled by clearing the CRYPEN bit in the CRYP_CR register.

b) Select the CCM chaining mode by programming the ALGOMODE bits to 0b01001 in the CRYP_CR register.

c) Configure the GCM_CCMPH bits to 0b00 in CRYP_CR to indicate that we are in the init phase.

d) Initialize the key registers (128, 192 and 256 bits) in CRYP_KEYRx as well as the initialization vector (IV) with CTR1 information, as defined in Table 277.

e) Set the CRYPEN bit to 1 in CRYP_CR to start accepting data.

f) Write the B0 packet into CRYP_DIN register, then wait for the CRYPEN bit to be cleared to 0 by the cryptographic processor before moving on to the next phase.

**Note:** In this init phase data have to be swapped according to the DATATYPE programmed in CRYP_CR register.

2. **CCM header phase**

The below sequence shall be performed after the CCM Init phase. It must be complete before jumping to the payload phase. The sequence is identical for encryption and decryption. During this phase, the CRYP_DOUT register does not contain any output data.

g) Set the GCM_CCMPH bit to 0b01 in CRYP_CR to indicate that the header phase is ongoing.

h) Set the CRYPEN bit to 1 to start accepting data.

i) If it is the last block of associated data, optionally pad the data with zeros to have a complete block.

j) Append the associated data in the cryptographic processor. The three possible scenarios are described in Section 34.3.5: CRYP procedure to perform a cipher operation.

k) Repeat the previous step until the second last associated data block is processed. For the last block, execute the two previous steps. Once all the additional authenticated data have been supplied, wait until the BUSY flag is cleared.

**Note:** This phase can be skipped if there is no associated data (Alen=0).

**Note:** The first block of the associated data B1 must be formatted with the associated data length. This task must be managed by the driver.
3. **CCM payload phase (encryption or decryption)**

When the payload size is not null, this sequence must be performed after the CCM header phase. During this phase, the encrypted/decrypted payload is stored in the CRYP_DOUT register.

- l) Set the CRYPEN bit to 0.
- m) Configure GCM_CCMPH bits to 0b10 in CRYP_CR to indicate that the payload phase is ongoing.
- n) Select the algorithm direction (0 for encryption, 1 for decryption) through the ALGODIR bit in CRYP_CR.
- o) Set the CRYPEN bit to 1 to start accepting data.
- p) If it is the last block of cleartext, optionally pad the data with zeros to have a complete block (encryption only). For decryption, refer to Section 34.3.8: CRYP stealing and data padding for more details.
- q) Append payload data in the cryptographic processor, and read the result. The three possible scenarios are described in Section 34.3.5: CRYP procedure to perform a cipher operation.
- r) Repeat the previous step until the second last plaintext block is encrypted or until the last block of ciphertext is decrypted. For the last block of plaintext (encryption only), execute the two previous steps. For the last block of ciphertext (decryption only), the driver must discard the data that is not part of the cleartext when the last block size is less than 16 bytes. Once all payload data have been supplied, wait until the BUSY flag is cleared.

**Note:** This phase can be skipped if there is no payload data, i.e. Plen=0 or Clen=Tlen

**Note:** Do not forget to remove LSB\_Tlen(C) encrypted tag information when decrypting ciphertext C.

4. **CCM final phase**

In this last step, the cryptographic processor generates the CCM authentication tag and stores it in the CRYP_DOUT register.

- s) Configure GCM_CCMPH[1:0] bits to 0b11 in CRYP_CR to indicate that the final phase is ongoing and set the ALGODIR bit to 0 in the same register.
- t) Load in CRYP_DIN, the CTR0 information which is described in Table 277 with bit[0] set to 0.

**Note:** In this final phase, data have to be swapped according to the DATATYPE programmed in CRYP_CR register.

- u) Wait until the OFNE flag (FIFO output not empty) is set to 1 in the CRYP_SR register.
- v) Read the CRYP_DOUT register four times: the output corresponds to the encrypted CCM tag.
- w) Disable the cryptographic processor (CRYPEN bit set to 0 in CRYP_CR)
- x) If an authenticated decryption is being performed, compare the generated encrypted tag with the encrypted tag padded in the ciphertext, i.e. LSB\_Tlen(C)= MSB\_Tlen(CRYP_DOUT data).
**Suspend/resume operations in CCM mode**

Before interrupting the current message in payload phase, the user application must respect the following sequence:

1. If DMA is used, stop the DMA transfers to the IN FIFO by clearing to 0 the DIEN bit in the CRYP_DMACR register.
2. Wait until both the IN and the OUT FIFOs are empty (IFEM=1 and OFNE=0 in the CRYP_SR register) and the BUSY bit is cleared.
3. If DMA is used, stop the DMA transfers from the OUT FIFO by clearing to 0 the DOEN bit in the CRYP_DMACR register.
4. Disable the cryptographic processor by setting the CRYPEN bit to 0 in CRYP_CR, then save the current configuration (bits [9:2], bits [17:16] and bits 19 in the CRYP_CR register). In addition, save the initialization vector registers, since CRYP_IVx registers have changed from their initial values during the data processing.

**Note:** *Key registers do not need to be saved as their original key value is known by the application.*

5. Save context swap registers: CRYP_CSGCMCCM0..7R
6. If DMA is used, save the DMA controller status (pointers for IN and OUT data transfers, number of remaining bytes, etc.).

To resume message processing, the user application must respect the following sequence:

1. If DMA is used, reconfigure the DMA controller to complete the rest of the FIFO IN and FIFO OUT transfers.
2. Make sure the cryptographic processor is disabled by reading the CRYPEN bit in CRYP_CR (must be 0).
3. Configure the cryptographic processor again with the initial setting in CRYP_CR and key registers using the saved configuration.
4. Restore context swap registers: CRYP_CSGCMCCM0..7R
5. Restore CRYP_IVx registers using the saved configuration.
6. Enable the cryptographic processor by setting the CRYPEN bit to 1.
7. If DMA is used, enable again cryptographic processor DMA requests by setting to 1 the DIEN and DOEN bits in the CRYP_DMACR register.

**Note:** *In Header phase DMA OUT FIFO transfer is not used.*
34.3.16 CRYP data registers and data swapping

Introduction

The CRYP_DIN register is the 32-bit wide data input register of the peripheral. It is used to enter into the input FIFO up to four 64-bit blocks (TDES) or two 128-bit blocks (AES) of plaintext (when encrypting) or ciphertext (when decrypting), one 32-bit word at a time.

The first word written into the FIFO is the LSB of the input block. The MSB of the input block is written at the end. CRYP_DIN data endianness can be described as below when DATATYPE="00" (no data swapping):

- In the DES/TDES modes
  Bit 1 (leftmost bit) of the data block corresponds to the MSB (bit 31) of the first word entered into the FIFO, bit 64 (rightmost bit) corresponds to the LSB (bit 0) of the second word entered into the FIFO.

- In the AES mode
  Bit 0 (leftmost bit) of the data block corresponds to the MSB (bit 31) of the first word written into the FIFO, bit 127 (rightmost bit) corresponds to the LSB (bit 0) of the 4th word written into the FIFO.

Similarly CRYP_DOUT register is the 32-bit wide data out register of the peripheral. It is a read-only register that is used to retrieve from the output FIFO up to four 64-bit blocks (TDES) or two 128-bit blocks (AES) of plaintext (when encrypting) or ciphertext (when decrypting), one 32-bit word at a time.

Like for the input data, the LSB of the output block is the first word read from the output FIFO. The MSB of the output block is read at the end. CRYP_DOUT data endianness can be described as below when DATATYPE="00" (no data swapping):

- In the DES/TDES modes
  Bit 1 (leftmost bit) of the data block corresponds to the MSB (bit 31) of the first word read from the FIFO, bit 64 (rightmost bit) corresponds to the LSB (bit 0) of the second word read from the FIFO.

- In the AES mode
  Bit 0 (leftmost bit) of the data block corresponds to the MSB (bit 31) of the first word read from the FIFO, bit 127 (rightmost bit) corresponds to the LSB (bit 0) of the 4th word read from the FIFO.
DES/TDES data swapping feature

Depending on the type of data to be processed (e.g. byte swapping when data are ASCII text stream), a bit, byte, half-word or no swapping operation must be done on the data read from the input FIFO before entering the little-endian DES processing core. The same swapping must be performed on the data produced by the little-endian DES processing core before they are written to the output FIFO.

*Figure 274* shows how the DES processing core 64-bit data block M1...64 is constructed from two consecutive 32-bit words popped into IN FIFO by the driver. This is done according to the DATATYPE bitfield in the CRYP_CR register.

**Note:** The same swapping is performed between the IN FIFO and the CRYP data block, and between the CRYP data block and the OUT FIFO.

*Figure 274.* 64-bit block construction according to the data type (IN FIFO)

**Note:** The CRYP Key registers (CRYP_Kx(L/R)) and initialization registers (CRYP_IVx(L/R)) are not sensitive to the swap mode selected. They have a fixed little-endian configuration (refer to Section 34.3.17 and Section 34.3.18, respectively).

A typical example of data swapping is given in *Table 278.*

AES data swapping feature

Depending on the type of data to be processed (e.g., byte swapping when data are ASCII text stream), a bit, byte, half-word or no swapping operation must be done on data read from the input FIFO before entering the little-endian AES processing core. The same swapping must be performed on the data produced by the little-endian AES processing core before they are written to the output FIFO.

*Figure 275* shows how the AES processing core 128-bit data block P0..127 is constructed from four consecutive 32-bit words written by the driver to the CRYP_DIN register. This is done according to the DATATYPE bitfield in the CRYP control register (CRYP_CR).

**Note:** The same swapping is performed between the CRYP_DIN and the CRYP data block, and between the CRYP data block and the CRYP_DOUT.

*Figure 275. 128-bit block construction according to the data type*
Note: The swapping operation concerns only the CRYP_DOUT and CRYP_DIN registers. The CRYP_KxL/KxR and CRYP_IVxL/IVxR registers are not sensitive to the swap mode selected. They have a fixed little-endian configuration (refer to Section 34.3.17 and Section 34.3.18).

Typical examples of data swapping are given in Table 279.

34.3.17  CRYP key registers

The CRYP_Kx registers are used to store the encryption or decryption keys. They are organized as eight registers in a little-endian configuration, as shown in Table 280.

Table 280. Key registers CRYP_KxR/LR endianness (TDES K1/2/3 and AES 128/192/256-bit keys)

<table>
<thead>
<tr>
<th></th>
<th></th>

<td>k[64:95]</td>
<td>k[96:127]</td>
</tr>
<tr>
<td>-</td>
<td>-</td>
<td>-</td>
<td>-</td>
<td>k[0:31]</td>
<td>k[32:63]</td>
<td>k[64:95]</td>
<td>k[96:127]</td>
</tr>
</tbody>
</table>

Note: DES/TDES keys include 8-bit parity information that are not used by the cryptographic processor. In other words, bits 8, 16, 24, 32, 40, 48, 56 and 64 of each 64-bit key value Kx[1:64] are not used.
Keys are considered as four 64-bit data items. They therefore do not have the same data format and representation in system memory as plaintext or ciphertext data.

Any write operation to the CRYP_Kx(L/R) registers when the BUSY bit is set to 1 in the CRYP_SR register is disregarded (i.e., register content not modified). Thus, the software must check that the BUSY equals 0 before modifying key registers.

Key registers are not affected by the data swapping feature controlled by DATATYPE value in CRYP_CR register.

Refer to Section 34.6: CRYP registers for a detailed description of CRYP_Kx(L/R) registers.

### 34.3.18 CRYP initialization vector registers

The CRYP_IVxL/IVxR registers are used to store the initialization vector or the nonce, depending on the chaining mode selected. When used, these registers are updated by the core after each computation round of the TDES or AES core.

They are organized as four registers in a little-endian configuration, as shown in Table 281.

**Table 281. Initialization vector registers CRYP_IVxR endianness**

<table>
<thead>
<tr>
<th>CRYP_IV1R[31:0]</th>
<th>CRYP_IV1L[31:0]</th>
<th>CRYP_IV0R[31:0]</th>
<th>CRYP_IV0L[31:0]</th>
</tr>
</thead>
</table>

Initialization vector registers are considered as two 64-bit data items. They therefore do not have the same data format and representation in system memory as plaintext or ciphertext data.

Any write operation to the CRYP_IV0...1(L/R) registers when the BUSY bit is set to 1 in the CRYP_SR register is disregarded (i.e., register content not modified). Therefore, the software must check that the BUSY equals 0 in the CRYP_SR register before modifying initialization vectors.

Reading the CRYP_IV0...1(L/R) register returns the latest counter value (useful for managing suspend mode) except for CCM/GCM.

**Note:** In DES/TDES mode, only CRYP_IV0x are used.

Initialization vector registers are not affected by the data swapping feature controlled by DATATYPE value in CRYP_CR register.

Refer to Section 34.6: CRYP registers for a detailed description of CRYP_IVxL/IVxR registers.
34.3.19 CRYP DMA interface

The cryptographic processor provides an interface to connect to the DMA (Direct Memory Access) controller. The DMA operation is controlled through the CRYP DMA control register (CRYP_DMACR).

Data input using DMA

DMA can be enabled for writing data into the cryptographic peripheral by setting the DIEN bit in the CRYP_DMACR register. When this bit is set, the cryptographic processor initiates a DMA request during the INPUT phase each time it requires a word to be written to the CRYP_DIN register.

Table 282 shows the recommended configuration to transfer data from memory to cryptographic processor through the DMA controller.

Table 282. Cryptographic processor configuration for memory-to-peripheral DMA transfers

<td>Fixed address of CRYP_DIN shall be used (no increment).</td>
</tr>
</tbody>
</table>

Data output using DMA

To enable the DMA for reading data from AES peripheral, set the DOEN bit in the CRYP_DMACR register. When this bit is set, the cryptographic processor initiates a DMA request during the OUTPUT phase each time it requires a word to be read from the CRYP_DOUT register.

Table 283 shows the recommended configuration to transfer data from cryptographic processor to memory through the DMA controller.
When AES is used, the cryptographic processor manages two DMA transfer requests through cryp_in_dma and cryp_out_dma internal input/output signals, which are asserted:

- for IN FIFO: every time a block has been read from FIFO by CRYP,
- for OUT FIFO: every time a block has been written into the FIFO by the cryptographic processor.

When DES is used, the cryptographic processor manages two DMA transfer requests through cryp_in_dma and cryp_out_dma internal input/output signals, which are asserted:

- for IN FIFO: every time two blocks have been read from FIFO by the cryptographic processor
- for OUT FIFO: every time a word has been written into the FIFO by the cryptographic processor (single transfer). Note that a burst transfer is also triggered when two blocks have been written into the FIFO.

All request signals are de-asserted if the cryptographic peripheral is disabled or the DMA enable bit is cleared (DIEN bit for the IN FIFO and DOEN bit for the OUT FIFO in the CRYP_DMACR register).

Caution: It is important that DMA controller empties the cryptographic peripheral output FIFO before filling up the CRYP input FIFO. To achieve it, the DMA controller should be configured so that it can handle the cyclic nature of the cryptographic operations efficiently.
that the transfer from the peripheral to the memory has a higher priority than the transfer from the memory to the peripheral.

For more detailed information on DMA operations, refer to Section 34.3.5: CRYP procedure to perform a cipher operation.

34.3.20 CRYP error management

No error flags are generated by the cryptographic processor.

34.4 CRYP interrupts

Overview

There are two individual maskable interrupt sources generated by the cryptographic processor to signal the following events:

- Input FIFO empty or not full
- Output FIFO full or not empty

These two sources are combined into a single interrupt signal which is the only interrupt signal from the CRYP peripheral that drives the NVIC (nested vectored interrupt controller). The interrupt logic is summarized on Figure 276.

**Figure 276. CRYP interrupt mapping diagram**

![Diagram of CRYP interrupt mapping](MSv43722V1)

You can enable or disable CRYP interrupt sources individually by changing the mask bits in the CRYP_IMSCR register. Setting the appropriate mask bit to 1 enables the interrupt.

The status of the individual maskable interrupt sources can be read either from the CRYP_RISR register, for raw interrupt status, or from the CRYP_MISR register for masked interrupt status. The status of the individual source of event flags can be read from the CRYP_SR register.

*Table 284* gives a summary of the available features.
The output FIFO service interrupt is asserted when there is one or more (32-bit word) data items in the output FIFO. This interrupt is cleared by reading data from the output FIFO until there is no valid (32-bit) word left (that is when the interrupt follows the state of the output FIFO not empty flag OFNE).

The output FIFO service interrupt OUTMIS is NOT enabled with the CRYP enable bit. Consequently, disabling the CRYP will not force the OUTMIS signal low if the output FIFO is not empty.

**Output FIFO service interrupt - OUTMIS**

The input FIFO service interrupt is asserted when there are less than four words in the input FIFO. It is cleared by performing write operations to the input FIFO until it holds four or more words.

The input FIFO service interrupt INMIS is enabled with the CRYP enable bit. Consequently, when CRYP is disabled, the INMIS signal is low even if the input FIFO is empty.

**Input FIFO service interrupt - INMIS**

Bits 31:20 Reserved, must be kept at reset value.

Bit 18 Reserved, must be kept at reset value.

Bits 17:16 **GCM_CCMPH[1:0]**: GCM or CCM Phase selection

This bitfield has no effect if GCM, GMAC or CCM algorithm is not selected in ALGOMODE field.

- 00: Init phase
- 01: Header phase
- 10: Payload phase
- 11: Final phase

Bit 15 **CRYPEN**: CRYP processor Enable

- 0: Cryptographic processor peripheral is disabled
- 1: Cryptographic processor peripheral is enabled

This bit is automatically cleared by hardware when the key preparation process ends (ALGOMODE= 0b111) or after GCM/GMAC or CCM init phase.

Bit 14 **FFLUSH**: CRYP FIFO Flush

- 0: No FIFO flush
- 1: FIFO flush enabled

When CRYPEN = 0, writing this bit to 1 flushes the IN and OUT FIFOs (i.e. read and write pointers of the FIFOs are reset). Writing this bit to 0 has no effect.

When CRYPEN = 1, writing this bit to 0 or 1 has no effect.

Reading this bit always returns 0.

FFLUSH bit has to be set only when BUSY=0. If not, the FIFO is flushed, but the block being processed may be pushed into the output FIFO just after the flush operation, resulting in a non-empty FIFO condition.

Bits 13:10 Reserved, must be kept at reset value.
Bits 9:8 **KEYSIZE[1:0]**: Key Size selection (AES mode only)

This bitfield defines the bit-length of the key used for the AES cryptographic core. This bitfield is ‘don’t care’ in the DES or TDES modes.

- 00: 128-bit key length
- 01: 192-bit key length
- 10: 256-bit key length
- 11: Reserved, do not use this value

Writing KEYSIZE bits while BUSY=1 has no effect. These bits can only be configured when BUSY=0.

Bits 7:6 **DATATYPE[1:0]**: Data Type selection

This bitfield defines the format of data written in CRYP_DIN or read from CRYP_DOUT registers. For more details refer to Section 34.3.16: CRYP data registers and data swapping.

- 00: 32-bit data. No swapping for each word. First word pushed into the IN FIFO (or popped off the OUT FIFO) forms bits 1...32 of the data block, the second word forms bits 33...64 etc.
- 01: 16-bit data, or half-word. Each word pushed into the IN FIFO (or popped off the OUT FIFO) is considered as 2 half-words, which are swapped with each other.
- 10: 8-bit data, or bytes. Each word pushed into the IN FIFO (or popped off the OUT FIFO) is considered as 4 bytes, which are swapped with each other.
- 11: bit data, or bit-string. Each word pushed into the IN FIFO (or popped off the OUT FIFO) is considered as 32 bits (1st bit of the string at position 0), which are swapped with each other.

Writing DATATYPE bits while BUSY=1 has no effect. These bits can only be configured when BUSY=0.

Bits 19, 5:3 **ALGOMODE[3:0]**: Algorithm mode

Below definition includes the bit 19:

- 0000: TDES-ECB (triple-DES Electronic Codebook).
- 0001: TDES-CBC (triple-DES Cipher Block Chaining).
- 0011: DES-CBC (simple DES Cipher Block Chaining).
- 0100: AES-ECB (AES Electronic Codebook).
- 0101: AES-CBC (AES Cipher Block Chaining).
- 0110: AES-CTR (AES Counter Mode).
- 0111: AES key preparation for ECB or CBC decryption.
- 1000: AES-GCM (Galois Counter Mode) and AES-GMAC (Galois Message Authentication Code mode).
- 1001: AES-CCM (Counter with CBC-MAC).

Writing ALGOMODE bits while BUSY=1 has no effect. These bits can only be configured when BUSY=0.

Bit 2 **ALGODIR**: Algorithm Direction

- 0: Encrypt
- 1: Decrypt

Writing ALGODIR bit while BUSY=1 has no effect. It can only be configured when BUSY=0.

Bits 1:0 Reserved, must be kept at reset value.
### 34.6.2 CRYP status register (CRYP_SR)

Address offset: 0x04
Reset value: 0x0000 0003

<table>
<thead>
<tr>
<th>Bit</th>
<th>Reset Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-5</td>
<td>Reserved</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
</tbody>
</table>

#### Bit 4 \textbf{BUSY}: Busy bit

- **0**: The CRYP core is not processing any data. The reason is:
  - either that the CRYP core is disabled (CRYPEN=0 in the CRYP_CR register) and the last processing has completed,
  - or the CRYP core is waiting for enough data in the input FIFO or enough free space in the output FIFO (that is in each case at least 2 words in the DES, 4 words in the AES).
- **1**: The CRYP core is currently processing a block of data or a key preparation is ongoing (AES ECB or CBC decryption only).

#### Bit 3 \textbf{OFFU}: Output FIFO full flag

- **0**: Output FIFO is not full
- **1**: Output FIFO is full

#### Bit 2 \textbf{OFNE}: Output FIFO not empty flag

- **0**: Output FIFO is empty
- **1**: Output FIFO is not empty

#### Bit 1 \textbf{IFNF}: Input FIFO not full flag

- **0**: Input FIFO is full
- **1**: Input FIFO is not full

#### Bit 0 \textbf{IFEM}: Input FIFO empty flag

- **0**: Input FIFO is not empty
- **1**: Input FIFO is empty

### 34.6.3 CRYP data input register (CRYP_DIN)

Address offset: 0x08
Reset value: 0x0000 0000

The CRYP_DIN register is the data input register. It is 32-bit wide. It is used to enter into the input FIFO up to four 64-bit blocks (TDES) or two 128-bit blocks (AES) of plaintext (when encrypting) or ciphertext (when decrypting), one 32-bit word at a time.

To fit different data sizes, the data can be swapped after processing by configuring the DATATYPE bits in the CRYP_CR register. Refer to Section 34.3.16: CRYP data registers and data swapping for more details.
When CRYP_DIN register is written to the data are pushed into the input FIFO.

- If CRYPEN = 1, when at least two 32-bit words in the DES/TDES mode have been pushed into the input FIFO (four words in the AES mode), and when at least two words are free in the output FIFO (four words in the AES mode), the CRYP engine starts an encrypting or decrypting process.

When CRYP_DIN register is read:

- If CRYPEN = 0, the FIFO is popped, and then the data present in the Input FIFO are returned, from the oldest one (first reading) to the newest one (last reading). The IFEM flag must be checked before each read operation to make sure that the FIFO is not empty.
- If CRYPEN = 1, an undefined value is returned.

Note: *After the CRYP_DIN register has been read once or several times, the FIFO must be flushed by setting the FFLUSH bit prior to processing new data.*

---

### 34.6.4 CRYP data output register (CRYP_DOUT)

**Address offset:** 0x0C  
**Reset value:** 0x0000 0000

The CRYP_DOUT register is the data output register. It is read-only and 32-bit wide. It is used to retrieve from the output FIFO up to four 64-bit blocks (TDES) or two 128-bit blocks (AES) of plaintext (when encrypting) or ciphertext (when decrypting), one 32-bit word at a time.

To fit different data sizes, the data can be swapped after processing by configuring the DATATYPE bits in the CRYP_CR register. Refer to *Section 34.3.16: CRYP data registers and data swapping* for more details.

When CRYP_DOUT register is read, the last data entered into the output FIFO (pointed to by the read pointer) is returned.
34.6.5 CRYP DMA control register (CRYP_DMACR)

Address offset: 0x10
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>

<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:0 DATAOUT[31:0]: Data Output
On read returns output FIFO content (pointed to by read pointer), else returns an undefined value.
On write, no effect.

Bit 1 DOEN: DMA Output Enable
When this bit is set, DMA requests are automatically generated by the peripheral during the output data phase.
0: DMA for outgoing data transfer is disabled
1: DMA for outgoing data transfer is enabled

Bit 0 DIEN: DMA Input Enable
When this bit is set, DMA requests are automatically generated by the peripheral during the input data phase.
0: DMA for incoming data transfer is disabled
1: DMA for incoming data transfer is enabled

34.6.6 CRYP interrupt mask set/clear register (CRYP_IMSCR)

Address offset: 0x14
Reset value: 0x0000 0000

The CRYP_IMSCR register is the interrupt mask set or clear register. It is a read/write register. When a read operation is performed, this register gives the current value of the mask applied to the relevant interrupt. Writing 1 to the particular bit sets the mask, thus enabling the interrupt to be read. Writing 0 to this bit clears the corresponding mask. All the bits are cleared to 0 when the peripheral is reset.
34.6.7 **CRYP raw interrupt status register (CRYP_RISR)**

Address offset: 0x18  
Reset value: 0x0000 0001  
The CRYP_RISR register is the raw interrupt status register. It is a read-only register. When a read operation is performed, this register gives the current raw status of the corresponding interrupt, i.e. the interrupt information without taking CRYP_IMSCR mask into account. Write operations have no effect.

**Bits 31:2**  
Reserved, must be kept at reset value.

**Bit 1 OUTIM:** Output FIFO service interrupt mask  
0: Output FIFO service interrupt is masked  
1: Output FIFO service interrupt is not masked

**Bit 0 INIM:** Input FIFO service interrupt mask  
0: Input FIFO service interrupt is masked  
1: Input FIFO service interrupt is not masked

### 34.6.8 **CRYP masked interrupt status register (CRYP_MISR)**

Address offset: 0x1C  
Reset value: 0x0000 0000  
The CRYP_MISR register is the masked interrupt status register. It is a read-only register. When a read operation is performed, this register gives the current masked status of the corresponding interrupt, i.e. the interrupt information taking CRYP_IMSCR mask into account. Write operations have no effect.

<table>

| 0        | INRIS: Input FIFO service raw interrupt status  
This bit gives the input FIFO interrupt information without taking CRYP_IMSCR corresponding mask into account.  
0: Raw interrupt not pending  
1: Raw interrupt pending |
34.6.9 CRYP key register 0L (CRYP_K0LR)

Address offset: 0x20
Reset value: 0x0000 0000

CRYP key registers contain the cryptographic keys.

- In DES/TDES mode, the keys are 64-bit binary values (number from left to right, that is the leftmost bit is bit 1) and named K1, K2 and K3 (K0 is not used). Each key consists of 56 information bits and 8 parity bits.

- In AES mode, the key is considered as a single 128, 192 or 256 bits long sequence $K_0K_1K_2...K_{127/191/255}$. The AES key is entered into the registers as follows:
  - for AES-128: $K_0...K_{127}$ corresponds to $b_{127}...b_0$ ($b_{255}...b_{128}$ are not used),
  - for AES-192: $K_0...K_{191}$ corresponds to $b_{191}...b_0$ ($b_{255}...b_{192}$ are not used),
  - for AES-256: $K_0...K_{255}$ corresponds to $b_{255}...b_0$.

In all cases key bit $K_0$ is the leftmost bit in CRYP inner memory and register bit $b_0$ is the rightmost bit in corresponding CRYP_KxLR key register.

For more information refer to Section 34.3.17: CRYP key registers.

Note: Write accesses to these registers are disregarded when the cryptographic processor is busy (bit BUSY = 1 in the CRYP_SR register)
34.6.10  CRYP key register 0R (CRYP_K0RR)

Address offset: 0x24
Reset value: 0x0000 0000

Refer to Section 34.6.9: CRYP key register 0L (CRYP_K0LR) for details.

Bits 31:0  **K[255:224]**: AES key bit x (x= 255 to 224)

Note: This register is not used in DES mode

In DES mode, K192 corresponds to key K1 bit 1 and K160 corresponds to key K1 bit 32.

34.6.11  CRYP key register 1L (CRYP_K1LR)

Address offset: 0x28
Reset value: 0x0000 0000

Refer to Section 34.6.9: CRYP key register 0L (CRYP_K0LR) for details.

Bits 31:0 $K_{[31:0]}$: AES key bit $x$ ($x = 31$ to $0$)
In DES mode $K_{31}$ corresponds to key $K_3$ bit 33 and $K_{0}$ corresponds to key $K_3$ bit 64.
34.6.17 CRYP initialization vector register 0L (CRYP_IV0LR)

Address offset: 0x40
Reset value: 0x0000 0000

The CRYP_IV0...1(L/R)R are the left-word and right-word registers for the initialization vector (64 bits for DES/TDES and 128 bits for AES). For more information refer to Section 34.3.18: CRYP initialization vector registers.

IV0 is the leftmost bit whereas IV63 (DES, TDES) or IV127 (AES) are the rightmost bits of the initialization vector. IV1(L/R)R is used only in the AES. Only CRYP_IV0(L/R) is used in DES/TDES.

Note: Write access to these registers are disregarded when the cryptographic processor is busy (bit BUSY = 1 in the CRYP_SR register).

34.6.18 CRYP initialization vector register 0R (CRYP_IV0RR)

Address offset: 0x44
Reset value: 0x0000 0000

Refer to Section 34.6.17: CRYP initialization vector register 0L (CRYP_IV0LR) for details.
34.6.19 Cryptographic processor (CRYP) RM0433

CRYP initialization vector register 1L (CRYP_IV1LR)

Address offset: 0x48
Reset value: 0x0000 0000

Refer to Section 34.6.17: CRYP initialization vector register 0L (CRYP_IV0LR) for details.

| Bits 31:0 | IV[64:95]: Initialization vector bit x (x= 64 to 95) |
| Note: This register is not used in DES mode |

34.6.20 CRYP initialization vector register 1R (CRYP_IV1RR)

Address offset: 0x4C
Reset value: 0x0000 0000

Refer to Section 34.6.17: CRYP initialization vector register 0L (CRYP_IV0LR) for details.

| Bits 31:0 | IV[96:127]: Initialization vector bit x (x= 96 to 127) |
| Note: This register is not used in DES mode |

34.6.21 CRYP context swap GCM-CCM registers (CRYP_CSGCMCCMxR)

Address offset: 0x050 + x* 0x4 (x=0 to 7)
Reset value: 0x0000 0000

These registers contain the complete internal register states of the CRYP processor when the GCM/GMAC or CCM algorithm is selected. They are useful when a context swap has to be performed because a high-priority task needs the cryptographic processor while it is already in use by another task.

When such an event occurs, the CRYP_CSGCMCCM0..7R and CRYP_CSGCM0..7R (in GCM/GMAC mode) or CRYP_CSGCMCCM0..7R (in CCM mode) registers have to be read and the values retrieved have to be saved in the system memory space. The cryptographic processor can then be used by the preemptive task. Then when the cryptographic computation is complete, the saved context can be read from memory and written back into the corresponding context swap registers.
34.6.22 **CRYP context swap GCM registers (CRYP_CSGCMxR)**

Address offset: 0x070 + x*0x4 (x=0 to 7)

Reset value: 0x0000 0000

Please refer to *Section 34.6.21: CRYP context swap GCM-CCM registers (CRYP_CSGMCCMCCR)* for details.

Refer to Section 2.3 on page 126 for the register boundary addresses.
35 Hash processor (HASH)

35.1 Introduction

The hash processor is a fully compliant implementation of the secure hash algorithm (SHA-1, SHA-224, SHA-256), the MD5 (message-digest algorithm 5) hash algorithm and the HMAC (keyed-hash message authentication code) algorithm suitable for a variety of applications. HMAC is suitable for applications requiring message authentication.

The hash processor computes FIPS (Federal Information Processing Standards) approved digests of length of 160, 224, 256 bits, for messages of up to \((2^{61} - 1)\) bits. It also computes 128 bits digests for the MD5 algorithm.

35.2 HASH main features

- Suitable for data authentication applications, compliant with:
  - Federal Information Processing Standards Publication FIPS PUB 180-4, Secure Hash Standard (SHA-1 and SHA-2 family)
  - Internet Engineering Task Force (IETF) Request For Comments RFC 1321 MD5 Message-Digest Algorithm
- Corresponding 32-bit words of the digest from consecutive message blocks are added to each other to form the digest of the whole message
  - Automatic 32-bit words swapping to comply with the internal little-endian representation of the input bit-string
  - Word swapping supported: bits, bytes, half-words and 32-bit words
- Automatic padding to complete the input bit string to fit digest minimum block size of 512 bits \((16 \times 32\) bits)
- Single 32-bit input register associated to an internal input FIFO of sixteen 32-bit words, corresponding to one block size
- Fast computation of SHA-1, SHA-224, SHA-256, and MD5
  - 82 (respectively 66) clock cycles for processing one 512-bit block of data using SHA-1 (respectively SHA-256) algorithm
  - 66 clock cycles for processing one 512-bit block of data using MD5 algorithm
- AHB slave peripheral, accessible through 32-bit word accesses only (else an AHB error is generated)
- \(8 \times 32\)-bit words (H0 to H7) for output message digest
- Automatic data flow control with support of direct memory access (DMA) using one channel. Fixed burst of 4 supported.
- Interruptible message digest computation, on a per-32-bit word basis
  - Re-loadable digest registers
  - Hashing computation suspend/resume mechanism, including using DMA
35.3 HASH functional description

35.3.1 HASH block diagram

*Figure 277* shows the block diagram of the hash processor.

35.3.3 About secure hash algorithms

The hash processor is a fully compliant implementation of the secure hash algorithm defined by FIPS PUB 180-4 standard and the IETF RFC1321 publication (MD5).

With each algorithm, the HASH computes a condensed representation of a message or data file. More specifically, when a message of any length below $2^{64}$ bits is provided on input, the SHA-1, SHA-224, SHA-256 and MD5 processing core produces respectively a 160-bit, 224 bit, 256-bit and 128-bit output string called a message digest. The message digest can then be processed with a digital signature algorithm in order to generate or verify the signature for the message.

Signing the message digest rather than the message often improves the efficiency of the process because the message digest is usually much smaller in size than the message. The verifier of a digital signature has to use the same hash algorithm as the one used by the creator of the digital signature.

The SHA-2 functions supported by the hash processor are qualified as “secure” because it is computationally infeasible to find a message that corresponds to a given message digest (SHA-1 is no more qualified as secure since February 2017), or to find two different messages that produce the same message digest. Any change to a message in transit will, with very high probability, result in a different message digest, and the signature will fail to verify.

35.3.4 Message data feeding

The message (or data file) to be processed by the HASH should be considered as a bit string. Per FIPS PUB 180-1 and 180-2 standards this message bit string grows from left to right, with hexadecimal words expressed in “big-endian” convention, so that within each word, the most significant bit is stored in the left-most bit position. For example message string “abc” with a bit string representation of "01100001 01100010 01100011" is represented by a 32-bit word 0x00636261, and 8-bit words 0x61626300.

Data are entered into the HASH one 32-bit word at a time, by writing them into the HASH_DIN register. The current contents of the HASH_DIN register are transferred to the 16 words input FIFO (IN FIFO) each time the register is written with new data. Hence HASH_DIN and the input FIFO form a seventeen 32-bit words length FIFO (named the IN buffer).

In accordance to the kind of data to be processed (e.g. byte swapping when data are ASCII text stream) there must be a bit, byte, half-word or no swapping operation to be performed on data from the input FIFO before entering the little-endian hash processing core. Figure 278 shows how the hash processing core 32-bit data block M0...31 is constructed from one 32-bit words popped into IN FIFO by the driver, according to the DATATYPE bitfield in the HASH control register (HASH_CR).

HASH_DIN data endianness when bit swapping is disabled (DATATYPE=“00”) can be described as following: the least significant bit of the message has to be at MSB position in the first word entered into the hash processor, the 32nd bit of the bit string has to be at MSB position in the second word entered into the hash processor and so on.
Figure 278. Message data swapping feature

DATATYPE "00": no swapping

DATATYPE "01": 16-bit or half-word swapping

DATATYPE "10": 8-bit or byte swapping

DATATYPE "11": bit swapping

MSv41984V1
35.3.5 Message digest computing

The hash processor sequentially processes 512-bit blocks when computing the message digest. Thus, each time $16 \times 32$-bit words ($= 512$ bits) have been written to the hash processor by the DMA or the CPU, the HASH automatically starts computing the message digest. This operation is known as 'partial digest computation'.

As described in Section 35.3.4: Message data feeding, the message to be processed is entered into the HASH 32-bit word at a time, writing to the HASH_DIN register to fill the input FIFO. In order to perform the hash computation on this data below sequence shall be used by the application.

1. Initialize the hash processor using the HASH_CR register:
   - Select the right algorithm using ALGO field. If needed program the correct swapping operation on the message input words using DATATYPE bitfield in HASH_CR.
   - Set MODE=1 and select the key length using LKEY if HMAC mode has been selected.
   - Update NBLW to define the number of valid bits in last word if it is different from 32 bits. If it is the case automatic padding could be applied by the HASH.

2. Complete the initialization by setting to 1 the INIT bit in HASH_CR. Also set the bit DMAE to 1 if data are transferred via DMA.

Caution: When programming step 2, it is important to set up before or at the same time the correct configuration values (ALGO, DATATYPE, HMAC mode, key length, NBLW).

3. Start filling data by writing to HASH_DIN register, unless data are automatically transferred via DMA. Note that the processing of a block can start only once the last value of the block has entered the IN FIFO. The way the partial or final digest computation is managed depends on the way data are fed into the processor:
   a) When data are filled by software:
      - The partial digest computation is triggered when the software writes an additional word to the HASH_DIN register (actually the first word of the next block). Once the processor is ready again (DINIS=1 in HASH_SR), the software can write new data to HASH_DIN. This mechanism avoids the introduction of wait states by the HASH.
      - The final digest computation is triggered when the last block is entered and the software writes the DCAL bit to 1. If the message length is not an exact multiple of 512 bits, the NBLW field in HASH_STR register must be written prior to writing DCAL bit (see Section 35.3.6 for details).
   b) When data are filled by DMA as a single DMA transfer (MDMAT bit="0"):
      - The partial digest computation is triggered automatically each time the FIFO is full.
      - The final digest computation is triggered automatically when the last block has been transferred to the HASH_DIN register (DCAL bit is set to 1 by hardware). If the message length is not an exact multiple of 512 bits, the NBLW field in HASH_STR register must be written prior to enabling the DMA (see Section 35.3.6 for details).
   c) When data are filled using multiple DMA transfers (MDMAT bit="1"):
      - The partial digest computations are triggered as for single DMA transfers. However the final digest computation is not triggered automatically when the last block has been transferred to the HASH_DIN register (DCAL bit is not set to 1 by hardware). It allows the hash processor to receive a new DMA transfer as part of
this digest computation. To launch the final digest computation, the software must set MDMAT bit to 0 before the last DMA transfer in order to trigger the final digest computation as it is done for single DMA transfers (see description before).

4. Once computed, the digest can be read from the output registers as described in Table 289.

For more information about HMAC detailed instructions, refer to Section 35.3.7: HMAC operation.

#### 35.3.6 Message padding

#### Overview

When computing a condensed representation of a message, the process of feeding data into the hash processor (with automatic partial digest computation every 512-bit block) loops until the last bits of the original message are written to the HASH_DIN register.

As the length (number of bits) of a message can be any integer value, the last word written to the hash processor may have a valid number of bits between 1 and 32. This number of valid bits in the last word, NBLW, has to be written to the HASH_STR register, so that message padding is correctly performed before the final message digest computation.

#### Padding processing

Detailed padding sequences with DMA is enabled or disabled are described in Section 35.3.5: Message digest computing.

#### Padding example

As specified by Federal Information Processing Standards PUB 180-1 and PUB 180-2, message padding consists in appending a “1” followed by k “0”s, itself followed by a 64-bit integer that is equal to the length L in bits of the message. These three padding operations generate a padded message of length \( L + 1 + k + 64 \), which by construction is a multiple of 512 bits.

For the hash processor, the “1” is added to the last word written to the HASH_DIN register at the bit position defined by the NBLW bitfield, and the remaining upper bits are cleared (“0”s).
Example from FIPS PUB180-2

Let us assume that the original message is the ASCII binary-coded form of “abc”, of length $L = 24$:

```
byte 0     byte 1     byte 2     byte 3
01100001 01100010 01100011 UUUUUUUU
```

NBLW has to be loaded with the value 24: a “1” is appended at bit location 24 in the bit string (starting counting from left to right in the above bit string), which corresponds to bit 31 in the HASH_DIN register (little-endian convention):

```
01100001 01100010 01100011 1UUUUUUU
```

Since $L = 24$, the number of bits in the above bit string is 25, and 423 “0” bits are appended, making now 448 bits.

This gives in hexadecimal (byte words in big-endian format):

```
61626380 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 0000018
```

The message length value, $L$, in two-word format (that is 00000000 00000018) is appended. Hence the final padded message in hexadecimal (byte words in big-endian format):

```
61626380 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 0000018
```

If the hash processor is programmed to swap byte within HASH_DIN input register (DATATYPE=10 in HASH_CR), the above message has to be entered by following below the sequence:

1. $0xUU636261$ is written to the HASH_DIN register (where ‘U’ means don’t care).
2. $0x18$ is written to the HASH_STR register (the number of valid bits in the last word written to the HASH_DIN register is 24, as the original message length is 24 bits).
3. $0x10$ is written to the HASH_STR register to start the message padding (described above) and then perform the digest computation.
4. The hash computing is complete with the message digest available in the HASH_HRx registers ($x = 0...4$) for the SHA-1 algorithm. For this FIPS example, the expected value is as follows:

```
HASH_H0 = 0xA9993E36
HASH_H1 = 0x4706816A
HASH_H2 = 0x8E9A5171
HASH_H3 = 0x7850C26C
HASH_H4 = 0x9CD0D89D
```
35.3.7 HMAC operation

Overview
As specified by Internet Engineering Task Force RFC2104, HMAC: keyed-hashing for message authentication, the HMAC algorithm is used for message authentication by irreversibly binding the message being processed to a key chosen by the user. The algorithm consists of two nested hash operations:

\[
\text{HMAC}(\text{message}) = \text{Hash}((\text{key} \mid \text{pad}) \oplus [0x5C]_n \mid \text{Hash}((\text{key} \mid \text{pad}) \oplus [0x36]_n \mid \text{message}))
\]

where:
- \([X]_n\) represents a repetition of \(X\) \(n\) times, where \(n\) equal to the size of the underlying hash function data block that is 512 bits for SHA-1, SHA224, SHA-256, MD5 hash algorithms (i.e. \(n=64\)).
- \(\text{pad}\) is a sequence of zeroes needed to extend the key to the length \(n\) defined above. If the key length is greater than \(n\), the application shall first hash the key using Hash() function and then use the resultant byte string as the actual key to HMAC.
- \(\mid\) represents the concatenation operator.

HMAC processing
Four different steps are required to compute the HMAC:

1. The block is initialized by writing the INIT bit to 1 with the MODE bit at 1 and the ALGO bits set to the value corresponding to the desired algorithm. The LKEY bit must also be set to 1 if the key being used is longer than 64 bytes. In this case, as required by HMAC specifications, the hash processor will use the hash of the key instead of the real key.
2. The key to be used for the inner hash function must be provided to the hash processor:
   The key loading operation follows the same mechanism as the message bit string loading, i.e. write key data into \(\text{HASH\_DIN}\) and complete the transfer by writing to \(\text{HASH\_STR}\) register.

   \(\text{Note: Endianness details can be found in Section 35.3.4: Message data feeding.}\)

3. Once the last key word has been entered and computation has started, the hash processor elaborates the inner key material. Once this operation has completed, it is ready to accept the message bit string as described in Section 35.3.4: Message data feeding.

4. After the final hash round, the hash processor returns “ready” to indicate that it is ready to receive the key to be used for the outer hash function (normally, this key is the same as the one used for the inner hash function). When the last word of the key is entered and computation starts, the HMAC result can be found in the \(\text{HASH\_H0...HASH\_H7}\) registers.

   \(\text{Note: The computation latency of the HMAC primitive depends on the lengths of the keys and message, as described in Section 35.5: HASH processing time.}\)

HMAC example
Below is an example of HMAC SHA-1 algorithm (ALGO=”00” and MODE=”1” in HASH\_CR) as specified by NIST.

Let us assume that the original message is the ASCII binary-coded form of "Sample message for keylen=blocklen", of length \(L = 34\) bytes. If the HASH is programmed in
no swapping mode (DATATYPE=00 in HASH_CR), the following data must be loaded sequentially into HASH_DIN register:

1. **Inner hash key** input (length=64, i.e. no padding), specified by NIST. As key length=64, LKEY bit is set to 0 in HASH_CR register

   00010203 04050607 08090A0B 0C0D0E0F 10111213 14151617
   18191A1B 1C1D1E1F 20212223 24252627 28292A2B 2C2D2E2F
   30313233 34353637 38393A3B 3C3D3E3F

2. **Message** input (length=34, i.e. padding required). HASH_STR must be set to 0x20 to start message padding and inner hash computation (see 'U' as don’t care)

   53616D70 6C65206D 65737361 67652066 6F72206B 65796C65
   6E3D626C 6F636B6C 6EUUUU

3. **Outer hash key** input (length=64, i.e. no padding). A key identical to the inner hash key is entered here.

4. **Final outer hash computing** is then performed by the HASH. The HMAC SHA-1 digest result is available in the HASH_HRx registers (x = 0...4), as shown below:

   HASH_H0 = 0xFD596EE
   HASH_H1 = 0x7D553C
   HASH_H2 = 0xFF4E72D
   HASH_H3 = 0x266DFD19
   HASH_H4 = 0x2366DA29
35.3.8 Context swapping

Overview

It is possible to interrupt a hash/HMAC operation to perform another processing with a higher priority. The interrupted process completes later when the higher-priority task has been processed, as shown in Figure 279.

Figure 279. HASH save/restore mechanism

To do so, the context of the interrupted task must be saved from the HASH registers to memory, and then be restored from memory to the HASH registers.

The procedures where the data flow is controlled by software or by DMA are described below.
Data loaded by software

When the DMA is not used to load the message into the hash processor, the context can be saved only when no block processing is ongoing. This means that the user application must wait until DINIS = 1 (last block processed and input FIFO empty) or NBW ≠ 0 (FIFO not full and no processing ongoing). The detailed procedure is described below.

- **Current context saving**
  Before interrupting the current message digest calculation, the application must store the contents of the following registers into memory:
  - HASH_IMR
  - HASH_STR
  - HASH_CR
  - HASH_CSR0 to HASH_CSR53

- **Current context restoring**
  To resume processing the interrupted message, the application must respect the following steps:
  a) Write the following registers with the values saved in memory: HASH_IMR, HASH_STR and HASH_CR.
  b) Initialize the hash processor by setting the INIT bit in the HASH_CR register.
  c) Write the HASH_CSR0 to HASH_CSR53 registers with the values saved in memory.
  d) Restart the processing from the point where it has been interrupted.

Data loaded by DMA

When the DMA is used to load the message into the hash processor, it is not possible to predict if a DMA transfer is ongoing. The user application must thus stop DMA transfers, then wait until the hash processor is ready before interrupting the current message digest calculation. The detailed procedure is described below.

- **Current context saving**
  Before interrupting the current message digest calculation using DMA, the application must respect the following steps:
  a) Clear the DMAE bit to disable the DMA interface.
  b) Wait until the current DMA transfer is complete (wait for DMAS = 0 in the HASH_SR register). Note that the block may or may not have been totally transferred to the HASH.
  c) Disable the corresponding channel in the DMA controller.
  d) Wait until the hash processor is ready (no block is being processed), that is wait for DINIS = 1

- **Current context restoring**
  To resume processing the interrupted message using DMA, the application must respect the following steps:
  a) Reconfigure the DMA controller so that it proceeds with the transfer of the message up to the end if it is not interrupted again.
  b) Restart the processing from the point where it was interrupted by setting the DMAE bit.
Note: If the context swapping does not involve HMAC operations, the HASH_CSR38 to HASH_CSR53 registers do not need to be saved and restored.

If the context swapping occurs between two blocks (the last block was completely processed and the next block has not yet been pushed into the IN FIFO, NBW = 000 in the HASH_CR register), the HASH_CSR22 to HASH_CSR37 registers do not need to be saved and restored.

35.3.9 HASH DMA interface

The hash processor provides an interface to connect to the DMA controller. This DMA can be used to write data to the HASH by setting the DMAE bit in the HASH_CR register. When this bit is set, the HASH asserts the burst request signal to the DMA controller when there is enough free words in the FIFO to support a burst of four words.

Once four 32-bit words have been received, the HASH automatically restarts this process, checks the FIFO size, and asserts a new request if the FIFO status allow a burst reception. For more information refer to Section 35.3.5: Message digest computing.

Before starting the DMA transfer, the software must program the number of valid bits in the last word that will be copied into HASH_DIN register. This is done by writing in HASH_STR register the following value:

\[
NBLW = \text{Len}(\text{Message}) \mod 32
\]

where \(x \mod 32\) gives the remainder of \(x\) divided by 32.

DMAS bit in HASH_SR register provides information on the DMA interface activity. This bit is set with DMAE and cleared when DMAE is cleared to 0 and no DMA transfer is ongoing.

Note: No interrupt is associated to DMAS bit.

35.3.10 HASH error management

No error flags are generated by the HASH hardware.

35.4 HASH interrupts

Two individual maskable interrupt sources are generated by the hash processor to signal the following events:

- Digest calculation completion (DCIS)
- Data input buffer ready (DINIS)

Both interrupt sources are connected to the same global interrupt request signal, as shown on Figure 280.

Figure 280. HASH interrupt mapping diagram
The above interrupt sources can be enabled or disabled individually by changing the mask bits in the HASH_IMR register. Setting the appropriate mask bit to 1 enables the interrupt.

The status of the individual interrupt events can be read from the HASH_SR register. **Table 290** gives a summary of the available features.

<table>
<thead>
<tr>

<td></td>
<td></td>
</tr>
</tbody>
</table>

1. The time required to load the 16 words of the block into the processor must be added to this value.

The time required to process the last block of a message (or of a key in HMAC) can be longer. This time depends on the length of the last block and the size of the key (in HMAC mode).

Compared to the processing of an intermediate block, it can be increased by the factor below:

- **1 to 2.5** for a hash message
- **~2.5** for an HMAC input-key
- **1 to 2.5** for an HMAC message
- **~2.5** for an HMAC output key in case of a short key
- **3.5 to 5** for an HMAC output key in case of a long key
35.6 HASH registers

The HASH core is associated with several control and status registers and five message digest registers. All these registers are accessible through 32-bit word accesses only, else an AHB2 error is generated.

35.6.1 HASH control register (HASH_CR)

Address offset: 0x00
Reset value: 0x0000 0000

| Bit 31-19 | Reserved, must be kept at reset value. |
| Bit 17    | Reserved, must be kept at reset value. |
| Bit 16    | **LKEY:** Long key selection<br>This bit selects between short key (≤ 64 bytes) or long key (> 64 bytes) in HMAC mode.<br>0: Short key (≤ 64 bytes)<br>1: Long key (> 64 bytes)<br>Note: This selection is only taken into account when the INIT bit is set and MODE= 1. Changing this bit during a computation has no effect. |
| Bit 15    | Reserved, must be kept at reset value. |
| Bit 14    | Reserved, must be kept at reset value. |
| Bit 13    | **MDMAT:** Multiple DMA Transfers<br>This bit is set when hashing large files when multiple DMA transfers are needed.<br>0: DCAL is automatically set at the end of a DMA transfer.<br>1: DCAL is not automatically set at the end of a DMA transfer. |
| Bit 12    | **DINNE:** DIN not empty<br>This bit is set when the HASH_DIN register holds valid data (that is after being written at least once). It is cleared when either the INIT bit (initialization) or the DCAL bit (completion of the previous message processing) is written to 1.<br>0: No data are present in the data input buffer<br>1: The input buffer contains at least one word of data |

![Register Configuration Table](image-url)
Bits 11:8 **NBW[3:0]:** Number of words already pushed

This bitfield reflects the number of words in the message that have already been pushed into the IN FIFO. NBW increments (+1) when a write access is performed to the HASH_DIN register while DINNE = 1.

It goes to zero when the INIT bit is written to 1 or when a digest calculation starts (DCAL written to 1 or DMA end of transfer).

**If the DMA is not used**

0000 and DINNE=0: no word has been pushed into the DIN buffer, i.e. both HASH_DIN register and IN FIFO are empty.

0000 and DINNE=1: one word has been pushed into the DIN buffer, i.e. HASH_DIN register contains one word and IN FIFO is empty.

0001: two words have been pushed into the DIN buffer, i.e. HASH_DIN register and the IN FIFO contain one word each.

... 

1111: 16 words have been pushed into the DIN buffer.

**If the DMA is used**

NBW is the exact number of words that have been pushed into the IN FIFO by the DMA.

Bits 18, 7 **ALGO[1:0]:** Algorithm selection

These bits selects the SHA-1, SHA-224, SHA-256 or the MD5 algorithm:

00: SHA-1 algorithm selected

01: MD5 algorithm selected

10: SHA-224 algorithm selected

11: SHA-256 algorithm selected

*Note: This selection is only taken into account when the INIT bit is set. Changing this bit during a computation has no effect.*

Bit 6 **MODE:** Mode selection

This bit selects the HASH or HMAC mode for the selected algorithm:

0: Hash mode selected

1: HMAC mode selected. LKEY must be set if the key being used is longer than 64 bytes.

*Note: This selection is only taken into account when the INIT bit is set. Changing this bit during a computation has no effect.*

Bits 5:4 **DATATYPE[1:0]:** Data type selection

These bits define the format of the data entered into the HASH_DIN register:

00: 32-bit data. The data written to HASH_DIN are directly used by the hash processing, without reordering.

01: 16-bit data or half-word. The data written to HASH_DIN are considered as two half-words, and are swapped before being used by the hash processing.

10: 8-bit data or bytes. The data written to HASH_DIN are considered as four bytes, and are swapped before being used by the hash processing.

11: bit data or bit-string. The data written to HASH_DIN are considered as 32 bits (1st bit of the string at position 0), and are swapped before being used by the hash processing (first bit of the string at position 31).
Bit 3  **DMAE**: DMA enable
0: DMA transfers disabled
1: DMA transfers enabled. A DMA request is sent as soon as the hash core is ready to receive data.
After this bit is set it is cleared by hardware while the last data of the message is written to the hash processor.
Setting this bit to 0 while a DMA transfer is on-going is not aborting this current transfer. Instead, the DMA interface of the HASH remains internally enabled until the transfer is complete or INIT is written to 1.
Setting INIT bit to 1 does not clear DMAE bit.

Bit 2  **INIT**: Initialize message digest calculation
Writing this bit to 1 resets the hash processor core, so that the HASH is ready to compute the message digest of a new message.
Writing this bit to 0 has no effect. Reading this bit always return 0.

Bits 1:0  Reserved, must be kept at reset value.
35.6.2 HASH data input register (HASH_DIN)

Address offset: 0x04
Reset value: 0x0000 0000

HASH_DIN is the data input register. It is 32-bit wide. This register is used to enter the message by blocks of 512 bits. When the HASH_DIN register is programmed, the value presented on the AHB databus is ‘pushed’ into the hash core and the register takes the new value presented on the AHB databus. To get a correct message format, the DATATYPE bits must have been previously configured in the HASH_CR register.

When a block of 16 words has been written to the HASH_DIN register, an intermediate digest calculation is launched:
- by writing new data into the HASH_DIN register (the first word of the next block) if the DMA is not used (intermediate digest calculation),
- automatically if the DMA is used.

When the last block has been written to the HASH_DIN register, the final digest calculation (including padding) is launched:
- by writing the DCAL bit to 1 in the HASH_STR register (final digest calculation),
- automatically if the DMA is used and MDMAT bit is set to 0.

When a digest calculation (intermediate or final) is ongoing and a new write access to the HASH_DIN register is performed, wait-states are inserted on the AHB2 bus until the hash calculation completes.

When the HASH_DIN register is read, the last word written to this location is accessed (zero after reset).

<tr>
<td>Writing this register pushes the current register content into the IN FIFO, and the register takes the new value presented on the AHB databus.</td>
</tr>
</tbody>
</table>
35.6.3 HASH start register (HASH_STR)

Address offset: 0x08
Reset value: 0x0000 0000

The HASH_Str register has two functions:
- It is used to define the number of valid bits in the last word of the message entered in the hash processor (that is the number of valid least significant bits in the last data written to the HASH_DIN register)
- It is used to start the processing of the last block in the message by writing the DCAL bit to 1

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>
<th>23</th>
<th>22</th>
<th>21</th>
<th>20</th>
<th>19</th>
<th>18</th>
<th>17</th>
<th>16</th>
</tr>
</thead>
</table>

Bits 31:9  Reserved, must be kept at reset value.

Bit 8  DCAL: Digest calculation
Writing this bit to 1 starts the message padding, using the previously written value of NBLW, and starts the calculation of the final message digest with all data words written to the IN FIFO since the INIT bit was last written to 1.
Reading this bit returns 0.

Bits 7:5  Reserved, must be kept at reset value.

Bits 4:0  NBLW[4:0]: Number of valid bits in the last word
When the last word of the message bit string is written in HASH_DIN register, the hash processor takes only the valid bits specified as below, after internal data swapping:
- 0x00: All 32 bits of the last data written are valid message bits i.e. M[31:0]
- 0x01: Only one bit of the last data written (after swapping) is valid i.e. M[0]
- 0x02: Only two bits of the last data written (after swapping) are valid i.e. M[1:0]
- 0x03: Only three bits of the last data written (after swapping) are valid i.e. M[2:0]
... 0x1F: Only 31 bits of the last data written (after swapping) are valid i.e. M[30:0]
The above mechanism is valid only if DCAL=0. If NBLW bits are written while DCAL is set to 1, the NBLW bitfield remains unchanged. In other words it is not possible to configure NBLW and set DCAL at the same time.
Reading NBLW bits returns the last value written to NBLW.
35.6.4 HASH digest registers

These registers contain the message digest result named as follows:

- HASH_HR0, HASH_HR1, HASH_HR2, HASH_HR3 and HASH_HR4 registers return the SHA-1 digest result.
  - HASH_HR5 to HASH_HR7 registers are not used, and they are read as zero.
- HASH_HR0, HASH_HR1, HASH_HR2 and HASH_HR3 registers return A, B, C and D (respectively), as defined by MD5.
  - HASH_HR4 to HASH_HR7 registers are not used, and they are read as zero.
- HASH_HR0 to HASH_HR6 registers return the SHA-224 digest result.
  - HASH_HR7 register is not used, and it is read as zero.
- HASH_HR0 to HASH_HR7 registers return the SHA-256 digest result.

In all cases, the digest most significant bit is stored in HASH_HR0[31] and it is not used.

If a read access to one of these registers is performed while the hash core is calculating an intermediate digest or a final message digest (that is when the DCAL bit has been written to 1), then the read operation is stalled until the hash calculation completes.

**Note:** When starting a digest computation for a new bit stream (by writing the INIT bit to 1), these registers are forced to their reset values.

HASH_HR0, HASH_HR1, HASH_HR2, HASH_HR3 and HASH_HR4 mapping are duplicated in two memory regions.

**HASH digest register x (HASH_HRx)**

Address offset: 0x0C + 0x04 * x (x=0 to 4)

Reset value: 0x0000 0000

#### Bits 31:4
Reserved, must be kept at reset value.

#### Bit 3 **BUSY**

- 0: No block is currently being processed
- 1: The hash core is processing a block of data

#### Bit 2 **DMAS**

This bit provides information on the DMA interface activity. It is set with DMAE=0 and no DMA transfer is ongoing. No interrupt is associated with this bit.

- 0: DMA interface is disabled (DMAE=0) and no transfer is ongoing
- 1: DMA interface is enabled (DMAE=1) or a transfer is ongoing

#### Bit 1 **DCIS**

Digest calculation completion interrupt status

- 0: No digest available in the HASH_HRx registers
- 1: Digest calculation complete, a digest is available in the HASH_HRx registers. An interrupt is generated if the DCIE bit is set in the HASH_IMR register.

#### Bit 0 **DINIS**

Data input interrupt status

- 0: Less than 16 locations are free in the input buffer
- 1: A new block can be entered into the input buffer. An interrupt is generated if the DINIE bit is set in the HASH_IMR register.
35.6.7 HASH context swap registers

These registers contain the complete internal register states of the hash processor. They are useful when a context swap has to be done because a high-priority task needs to use the hash processor while it is already used by another task.

When such an event occurs, the HASH_CSRx registers have to be read and the read values have to be saved in the system memory space. Then the hash processor can be used by the preemptive task, and when the hash computation is complete, the saved context can be read from memory and written back into the HASH_CSRx registers.

HASH_CSRx registers can be read only when DINIS equals to 1, otherwise zeroes are returned.

**HASH context swap register 0 (HASH_CSR0)**

Address offset: 0x0F8
Reset value: 0x0000 0002

Refer to *Section 2.3 on page 126* for the register boundary addresses.
36 High-Resolution Timer (HRTIM)

36.1 Introduction

The high-resolution timer can generate up to 10 digital signals with highly accurate timings. It is primarily intended to drive power conversion systems such as switch mode power supplies or lighting systems, but can be of general purpose usage, whenever a very fine timing resolution is expected.

Its modular architecture allows to generate either independent or coupled waveforms. The wave-shape is defined by self-contained timings (using counters and compare units) and a broad range of external events, such as analog or digital feedbacks and synchronization signals. This allows to produce a large variety of control signal (PWM, phase-shifted, constant Ton,...) and address most of conversion topologies.

For control and monitoring purposes, the timer has also timing measure capabilities and links to built-in ADC and DAC converters. Last, it features light-load management mode and is able to handle various fault schemes for safe shut-down purposes.
36.2 Main features

- Multiple timing units
  - Full-resolution available on all outputs, possibility to adjust duty-cycle, frequency and pulse width in triggered one-pulse mode
  - 6 16-bit timing units (each one with an independent counter and 4 compare units)
  - 10 outputs that can be controlled by any timing unit, up to 32 set/reset sources per channel
  - Modular architecture to address either multiple independent converters with 1 or 2 switches or few large multi-switch topologies
- Up to 10 external events, available for any timing unit
  - Programmable polarity and edge sensitivity
  - 5 events with a fast asynchronous mode
  - 5 events with a programmable digital filter
  - Spurious events filtering with blanking and windowing modes
- Multiple links to built-in analog peripherals
  - 4 triggers to ADC converters
  - 3 triggers to DAC converters
  - 3 comparators for analog signal conditioning
- Versatile protection scheme
  - 5 fault inputs can be combined and associated to any timing unit
  - Programmable polarity, edge sensitivity, and programmable digital filter
  - dedicated delayed protections for resonant converters
- Multiple HRTIM instances can be synchronized with external synchronization inputs/outputs
- Versatile output stage
  - Full-resolution Deadtime insertion
  - Programmable output polarity
  - Chopper mode
- Burst mode controller to handle light-load operation synchronously on multiple converters
- 7 interrupt vectors, each one with up to 14 sources
- 6 DMA requests with up to 14 sources, with a burst mode for multiple registers update
36.3 Functional description

36.3.1 General description

The HRTIM can be partitioned into several sub entities:
- The master timer
- The timing units (Timer A to Timer E)
- The output stage
- The burst mode controller
- An external event and fault signal conditioning logic that is shared by all timers
- The system interface

The master timer is based on a 16-bit up counter. It can set/reset any of the 10 outputs via 4 compare units and it provides synchronization signals to the 5 timer units. Its main purpose is to have the timer units controlled by a unique source. An interleaved buck converter is a typical application example where the master timer manages the phase-shifts between the multiple units.

The timer units are working either independently or coupled with the other timers including the master timer. Each timer contains the controls for two outputs. The outputs set/reset events are triggered either by the timing units compare registers or by events coming from the master timer, from the other timers or from external events.

The output stage has several duties
- Addition of deadtime when the 2 outputs are configured in complementary PWM mode
- Addition of a carrier frequency on top of the modulating signal
- Management of fault events, by asynchronously asserting the outputs to a predefined safe level

The burst mode controller can take over the control of one or multiple timers in case of light-load operation. The burst length and period can be programmed, as well as the idle state of the outputs.

The external event and fault signal conditioning logic includes:
- The input selection MUXes (for instance for selecting a digital input or an on-chip source for a given external event channel)
- Polarity and edge-sensitivity programming
- Digital filtering (for 5 channels out of 10)

The system interface allows the HRTIM to interact with the rest of the MCU:
- Interrupt requests to the CPU
- DMA controller for automatic accesses to/from the memories, including an HRTIM specific burst mode
- Triggers for the ADC and DAC converters

The HRTIM registers are split into 7 groups:
- Master timer registers
- Timer A to Timer E registers
- Common registers for features shared by all timer units
Note: As a writing convention, references to the 5 timing units in the text and in registers are generalized using the “x” letter, where x can be any value from A to E.

The block diagram of the timer is shown in Figure 281.

### 36.3.3 Clocks

The HRTIM must be supplied by the $t_{\text{HRTIM}}$ system clock to offer a full resolution. All clocks present in the HRTIM are derived from this reference clock.

#### Definition of terms

- $f_{\text{HRTIM}}$: main HRTIM clock ($hrtim\_ker\_ck$). All subsequent clocks are derived and synchronous with this source.
- $f_{\text{DTG}}$: deadtime generator clock. For convenience, only the $t_{\text{DTG}}$ period ($t_{\text{DTG}} = 1/f_{\text{DTG}}$) is used in this document.
- $f_{\text{CHPFRQ}}$: chopper stage clock source.
- $f_{\text{1STPW}}$: clock source defining the length of the initial pulse in chopper mode. For convenience, only the $t_{\text{1STPW}}$ period ($t_{\text{1STPW}} = 1/f_{\text{1STPW}}$) is used in this document.
- $f_{\text{BRST}}$: burst mode controller counter clock.
- $f_{\text{SAMPLING}}$: clock needed to sample the fault or the external events inputs.
- $f_{\text{FLTS}}$: clock derived from $f_{\text{HRTIM}}$ which is used as a source for $f_{\text{SAMPLING}}$ to filter fault events.
- $f_{\text{EEVS}}$: clock derived from $f_{\text{HRTIM}}$ which is used as a source for $f_{\text{SAMPLING}}$ to filter external events.
- $f_{\text{pclk}}$ ($hrtim\_pclk$): APB bus clock, needed for register read/write accesses.

Timer clock and prescaler

Each timer in the HRTIM has its own individual clock prescaler, which allows you to adjust the timer resolution. (See Table 294).

 Initialization

At start-up, it is mandatory to initialize first the prescaler bitfields before writing the compare and period registers. Once the timer is enabled (MCEN or TxCEN bit set in the HRTIM_MCR register), the prescaler cannot be modified.

When multiple timers are enabled, the prescalers are synchronized with the prescaler of the timer that was started first.

**Warning:** It is possible to have different prescaling ratios in the master and TIMA.E timers only if the counter and output behavior does not depend on other timers’ information and signals. It is mandatory to configure identical prescaling ratios in these timers when one of the following events is propagated from one timing unit (or master timer) to another: output set/reset event, counter reset event, update event, external event filter or capture triggers. Prescaler factors not equal will yield to unpredictable results.

Deadtime generator clock

The deadtime prescaler is supplied by \( f_{HRTIM} / \left(8 / 2^{DTPRSC[2:0]}\right) \), programmed with DTPRSC[2:0] bits in the HRTIM_DTxR register.

\( t_{DTG} \) ranges from 2.5 ns to 20 ns for \( f_{HRTIM} = 400 \text{ MHz} \).

---

<td>10 ns</td>
<td>1.5 kHz</td>
</tr>
</tbody>
</table>

1. CKPSC[2:0] values from 000 to 100 are reserved.
Chopper stage clock

The chopper stage clock source $f_{CHPFRQ}$ is derived from $f_{HRTIM}$ with a division factor ranging from 16 to 256, so that $1.56 \text{ MHz} \leq f_{CHPFRQ} \leq 25 \text{ MHz}$ for $f_{HRTIM} = 400 \text{ MHz}$.

$t_{1STPW}$ is the length of the initial pulse in chopper mode, programmed with the $\text{STRPW}[3:0]$ bits in the $\text{HRTIM\_CHPxR}$ register, as follows:

$$t_{1STPW} = (\text{STRPW}[3:0]+1) \times 16 \times t_{HRTIM}.$$ 

It uses $f_{HRTIM} / 16$ as clock source (25 MHz for $f_{HRTIM} = 400 \text{ MHz}$).

Burst Mode Prescaler

The burst mode controller counter clock $f_{BRST}$ can be supplied by several sources, among which one is derived from $f_{HRTIM}$.

In this case, $f_{BRST}$ ranges from $f_{HRTIM}$ to $f_{HRTIM} / 32768$ (12.2 kHz for $f_{HRTIM} = 400 \text{ MHz}$).

Fault input sampling clock

The fault input noise rejection filter has a time constant defined with $f_{SAMPLING}$ which can be either $f_{HRTIM}$ or $f_{FLTS}$.

$f_{FLTS}$ is derived from $f_{HRTIM}$ and ranges from 400 MHz to 50 MHz for $f_{HRTIM} = 400 \text{ MHz}$.

External Event input sampling clock

The fault input noise rejection filter has a time constant defined with $f_{SAMPLING}$ which can be either $f_{HRTIM}$ or $f_{EEVS}$.

$f_{EEVS}$ is derived from $f_{HRTIM}$ and ranges from 400 MHz to 50 MHz for $f_{HRTIM} = 400 \text{ MHz}$.
36.3.4 Timer A..E timing units

The HRTIM embeds 5 identical timing units made of a 16-bit up-counter with an auto-reload mechanism to define the counting period, 4 compare and 2 capture units, as per Figure 282. Each unit includes all control features for 2 outputs, so that it can operate as a standalone timer.

Figure 282. Timer A..E overview

The period and compare values must be within a lower and an upper limit related to the high-resolution implementation and listed in Table 295:

- The minimum value must be greater than or equal to 3 periods of the \( f_{\text{HRTIM}} \) clock
- The maximum value must be less than or equal to \( 0xFFFF - 1 \) periods of the \( f_{\text{HRTIM}} \) clock

Note: A compare value greater than the period register value will not generate a compare match event.

Table 295. Period and Compare registers min and max values

Counter operating mode

Timer A..E can operate in continuous (free-running) mode or in single-shot manner where counting is started by a reset event, using the CONT bit in the HRTIM_TIMxCR control register. An additional RETRIG bit allows you to select whether the single-shot operation is retriggerable or non-retriggerable. Details of operation are summarized on Table 296 and on Figure 283 and Figure 284.

</tr>
</tbody>
</table>

The TxEN bit can be cleared at any time to disable the timer and stop the counting.

Figure 283. Continuous timer operation

![Continuous mode (CONT = 1, RETRIG = X) (MS32259V1)](image-url)
A counter roll-over event is generated when the counter goes back to 0 after having reached the period value set in the HRTIM_PERxR register in continuous mode.

This event is used for multiple purposes in the HRTIM:

- To set/reset the outputs
- To trigger the register content update (transfer from preload to active)
- To trigger an IRQ or a DMA request
- To serve as a burst mode clock source or a burst start trigger
- as an ADC trigger
- To decrement the repetition counter

If the initial counter value is above the period value when the timer is started, or if a new period is set while the counter is already above this value, the counter is not reset: it will overflow at the maximum period value and the repetition counter will not decrement.
Timer reset

The reset of the timing unit counter can be triggered by up to 30 events that can be selected simultaneously in the HRTIM_RSTxR register, among the following sources:

- The timing unit: Compare 2, Compare 4 and Update (3 events)
- The master timer: Reset and Compare 1..4 (5 events)
- The external events EXTEVNT1..10 (10 events)
- All other timing units (e.g. Timer B..E for timer A): Compare 1, 2 and 4 (12 events)

Several events can be selected simultaneously to handle multiple reset sources. In this case, the multiple reset requests are ORed. When 2 counter reset events are generated within the same \(f_{HRTIM}\) clock cycle, the last counter reset is taken into account.

Additionally, it is possible to do a software reset of the counter using the TxRST bits in the HRTIM_CR2 register. These control bits are grouped into a single register to allow the simultaneous reset of several counters.

The reset requests are taken into account only once the related counters are enabled (TxCEN bit set).

When the \(f_{HRTIM}\) clock prescaling ratio is above 1, the counter reset event is delayed to the next active edge of the prescaled clock. This allows to maintain a jitterless waveform generation when an output transition is synchronized to the reset event (typically a constant \(T_{on}\) time converter).

*Figure 285* shows how the reset is handled for a clock prescaling ratio of 4 (\(f_{HRTIM}\) divided by 4).

Figure 285. Timer reset resynchronization (prescaling ratio above 32)

![Diagram showing timer reset resynchronization](image-url)
**Repetition counter**

A common software practice is to have an interrupt generated when the period value is reached, so that the maximum amount of time is left for processing before the next period begins. The main purpose of the repetition counter is to adjust the period interrupt rate and off-load the CPU by decoupling the switching frequency and the interrupt frequency.

The timing units have a repetition counter. This counter cannot be read, but solely programmed with an auto-reload value in the HRTIM_REPxR register.

The repetition counter is initialized with the content of the HRTIM_REPxR register when the timer is enabled (TXCEN bit set). Once the timer has been enabled, any time the counter is cleared, either due to a reset event or due to a counter roll-over, the repetition counter is decreased. When it reaches zero, a REP interrupt or a DMA request is issued if enabled (REPIE and REPDE bits in the HRTIM_DIER register).

If the HRTIM_REPxR register is set to 0, an interrupt is generated for each and every period. For any value above 0, a REP interrupt is generated after (HRTIM_REPxR + 1) periods. *Figure 286* presents the repetition counter operation for various values, in continuous mode.

*Figure 286. Repetition rate vs HRTIM_REPxR content in continuous mode*

The repetition counter can also be used when the counter is reset before reaching the period value (variable frequency operation) either in continuous or in single-shot mode (*Figure 287* here-below). The reset causes the repetition counter to be decremented, at the exception of the very first start following counter enable (TxCEN bit set).
A reset or start event from the hrtim_in_sync[3:1] source causes the repetition to be decremented as any other reset. However, in SYNCIN-started single-shot mode (SYNCSTRTx bit set in the HRTIM_TIMxCR register), the repetition counter will be decremented only on the 1st reset event following the period. Any subsequent reset will not alter the repetition counter until the counter is re-started by a new request on hrtim_in_sync[3:1] inputs.

**Set / reset crossbar**

A “set” event corresponds to a transition to the output active state, while a “reset” event corresponds to a transition to the output inactive state.

The polarity of the waveform is defined in the output stage to accommodate positive or negative logic external components: an active level corresponds to a logic level 1 for a positive polarity (POLx = 0), and to a logic level 0 for a negative polarity (POLx = 1).

Each of the timing units handles the set/reset crossbar for two outputs. These 2 outputs can be set, reset or toggled by up to 32 events that can be selected among the following sources:

- The timing unit: Period, Compare 1..4, register update (6 events)
- The master timer: Period, Compare 1..4, HRTIM synchronization (6 events)
- All other timing units (e.g. Timer B..E for timer A): TIMEVNT1..9 (9 events described in Table 297)
- The external events EXTEVNT1..10 (10 events)
- A software forcing (1 event)

The event sources are ORed and multiple events can be simultaneously selected. Each output is controlled by two 32-bit registers, one coding for the set (HRTIM_SETxyR) and another one for the reset (HRTIM_RSTxyR), where x stands for the timing unit: A..E and y stands for the output 1 or 2 (e.g. HRTIM_SETA1R, HRTIM_RSTC2R,…).

If the same event is selected for both set and reset, it will toggle the output. It is not possible to toggle the output state more than one time per $\tau_{HRTIM}$ period: in case of two consecutive toggling events within the same cycle, only the first one is considered.

The set and reset requests are taken into account only once the counter is enabled (TxCEN bit set), except if the software is forcing a request to allow the prepositioning of the outputs at timer start-up.
Table 297 summarizes the events from other timing units that can be used to set and reset the outputs. The number corresponds to the timer events (such as TIMEVNTx) listed in the register, and empty locations are indicating non-available events.

For instance, Timer A outputs can be set or reset by the following events: Timer B Compare1, 2 and 4, Timer C Compare 2 and 3,... and Timer E Compare 3 will be listed as TIMEVNT8 in HRTIM_SETA1R.

Figure 288 represents how a PWM signal is generated using two compare events.

Figure 288. Compare events action on outputs: set on compare 1, reset on compare 2

Register setting: HRTIM_SETA1R = 0x0000 0008, HRTIM_RSTA1R = 0x0000 0010

MSv39607V1
Set/Reset on Update events

Half mode

This mode aims at generating square signal with fixed 50% duty cycle and variable frequency (typically for converters using resonant topologies). It allows to have the duty cycle automatically forced to half of the period value when a new period is programmed.

This mode is enabled by writing HALF bit to 1 in the HRTIM_TIMxCR register. When the HRTIM_PERxR register is written, it causes an automatic update of the Compare 1 value with HRTIM_PERxR/2 value.

The output on which a square wave is generated must be programmed to have one transition on CMP1 event, and one transition on the period event, as follows:
- HRTIM_SETxyR = 0x0000 0008, HRTIM_RSTxyR = 0x0000 0004, or
- HRTIM_SETxyR = 0x0000 0004, HRTIM_RSTxyR = 0x0000 0008

The HALF mode overrides the content of the HRTIM_CMP1xR register. The access to the HRTIM_PERxR register only causes Compare 1 internal register to be updated. The user-accessible HRTIM_CMP1xR register is not updated with the HRTIM_PERxR / 2 value.

When the preload is enabled (PREEN = 1, MUDIS, TxUDIS), Compare 1 active register is refreshed on the Update event. If the preload is disabled (PREEN= 0), Compare 1 active register is updated as soon as HRTIM_PERxR is written.

The period must be greater than or equal to 6 periods of the fHRTIM clock when the HALF mode is enabled.

Capture

The timing unit has the capability to capture the counter value, triggered by internal and external events. The purpose is to:
- measure events arrival timings or occurrence intervals
- update Compare 2 and Compare 4 values in auto-delayed mode (see Auto-delayed mode).

The capture is done with fHRTIM resolution.

The timer has 2 capture registers: HRTIM_CPT1xR and HRTIM_CPT2xR. The capture triggers are programmed in the HRTIM_CPT1xCR and HRTIM_CPT2xCR registers.

The capture of the timing unit counter can be triggered by up to 28 events that can be selected simultaneously in the HRTIM_CPT1xCR and HRTIM_CPT2xCR registers, among the following sources:
- The external events, EXTEVNT1..10 (10 events)
- All other timing units (e.g. Timer B..E for timer A): Compare 1, 2 and output 1 set/reset events (16 events)
- The timing unit: Update (1 event)
- A software capture (1 event)

Several events can be selected simultaneously to handle multiple capture triggers. In this case, the concurrent trigger requests are ORed. The capture can generate an interrupt or a DMA request when CPTxIE and CPTxDE bits are set in the HRTIM_TIMxDIER register.

Over-capture is not prevented by the circuitry: a new capture is triggered even if the previous value was not read, or if the capture flag was not cleared.
Auto-delayed mode

This mode allows to have compare events generated relatively to capture events, so that for instance an output change can happen with a programmed timing following a capture. In this case, the compare match occurs independently from the timer counter value. It enables the generation of waveforms with timings synchronized to external events without the need of software computation and interrupt servicing.

As long as no capture is triggered, the content of the HRTIM_CMPxR register is ignored (no compare event is generated when the counter value matches the Compare value. Once the capture is triggered, the compare value programmed in HRTIM_CMPxR is summed with the captured counter value in HRTIM_CPTxyR, and it updates the internal auto-delayed compare register, as seen on Figure 290. The auto-delayed compare register is internal to the timing unit and cannot be read. The HRTIM_CMPxR preload register is not modified after the calculation.

This feature is available only for Compare 2 and Compare 4 registers. Compare 2 is associated with capture 1, while Compare 4 is associated with capture 2. HRTIM_CMP2xR and HRTIM_CMP4xR Compares cannot be programmed with a value below $3 \times T_{\text{HRTIM}}$ clock periods, as in the regular mode.
The auto-delayed Compare is only valid from the capture up to the period event: once the counter has reached the period value, the system is re-armed with Compare disabled until a capture occurs.

DELCMP2[1:0] and DELCMP4[1:0] bits in HRTIM_TIMxCR register allow to configure the auto-delayed mode as follows:

- **00**
  Regular compare mode: HRTIM_CMP2xR and HRTIM_CMP4xR register contents are directly compared with the counter value.

- **01**
  Auto-delayed mode: Compare 2 and Compare 4 values are recomputed and used for comparison with the counter after a capture 1/2 event.
• 1X

Auto-delayed mode with timeout: Compare 2 and Compare 4 values are recomputed and used for comparison with the counter after a capture 1/2 event or after a Compare 1 match (DELCMPx[1:0]= 10) or a Compare 3 match (DELCMPx[1:0]= 11) to have a timeout function if capture 1/2 event is missing.

When the capture occurs, the comparison is done with the (HRTIM_CMP2/4xR + HRTIM_CPT1/2xR) value. If no capture is triggered within the period, the behavior depends on the DELCMPx[1:0] value:
• DELCMPx[1:0] = 01: the compare event is not generated
• DELCMPx[1:0] = 10 or 11: the comparison is done with the sum of the 2 compares (for instance HRTIM_CMP2xR + HRTIM_CMP1xR). The captures are not taken into account if they are triggered after CMPx + CMP1 (resp. CMPx + CMP3).

The captures are enabled again at the beginning of the next PWM period.

If the result of the auto-delayed summation is above 0xFFFF (overflow), the value is ignored and no compare event will be generated until a new period is started.

**Note:** DELCMPx[1:0] bitfield must be reset when reprogrammed from one value to the other to reinitialize properly the auto-delayed mechanism, for instance:
• DELCMPx[1:0] = 10
• DELCMPx[1:0] = 00
• DELCMPx[1:0] = 11

As an example, Figure 291 shows how the following signal can be generated:
• Output set when the counter is equal to Compare 1 value
• Output reset 4 cycles after a falling edge on a given external event

**Note:** To simplify the figure, the external event signal is shown without any resynchronization delay; practically, there is a delay of 1 to 2 \( f_{\text{HRTIM}} \) clock periods between the falling edge and the capture event due to an internal resynchronization stage which is necessary to process external input signals.

![Figure 291. Auto-delayed compare](attachment:image.png)

A regular compare channel (e.g. Compare 1) is used for the output set: as soon as the counter matches the content of the compare register, the output goes to its active state.
A delayed compare is used for the output reset: the compare event can be generated only if a capture event has occurred. No event is generated when the counter matches the delayed compare value (counter = 4). Once the capture event has been triggered by the external event, the content of the capture register is summed to the delayed compare value to have the new compare value. In the example, the auto-delayed value 4 is summed to the capture equal to 7 to give a value of 12 in the auto-delayed compare register. From this time on, the compare event can be generated and will happen when the counter is equal to 12, causing the output to be reset.

**Overcapture management in auto-delayed mode**

Overcapture is prevented when the auto-delayed mode is enabled (DELCMPx[1:0] = 01, 10, 11).

When multiple capture requests occur within the same counting period, only the first capture is taken into account to compute the auto-delayed compare value. A new capture is possible only:
- Once the auto-delayed compare has matched the counter value (compare event)
- Once the counter has rolled over (period)
- Once the timer has been reset

**Changing auto-delayed compare values**

When the auto-delayed compare value is preloaded (PREEN bit set), the new compare value is taken into account on the next coming update event (for instance on the period event), regardless of when the compare register was written and if the capture occurred (see *Figure 291*, where the delay is changed when the counter rolls over).

When the preload is disabled (PREEN bit reset), the new compare value is taken into account immediately, even if it is modified after the capture event has occurred, as per the example below:

1. At t1, DELCMP2 = 1.
2. At t2, CMP2_act = 0x40 => comparison disabled
3. At t3, a capture event occurs capturing the value CPTR1 = 0x20. => comparison enabled, compare value = 0x60
4. At t4, CMP2_act = 0x100 (before the counter reached value CPTR1 + 0x40) => comparison still enabled, new compare value = 0x120
5. At t5, the counter reaches the period value => comparison disabled, cmp2_act = 0x100

Similarly, if the CMP1(CMP3) value changes while DELCMPx = 10 or 11, and preload is disabled:

1. At t1, DELCMP2 = 2.
2. At t2, CMP2_act = 0x40 => comparison disabled
3. At t3, CMP3 event occurs - CMP3_act = 0x50 before capture 1 event occurs => comparison enabled, compare value = 0x90
4. At t4, CMP3_act = 0x100 (before the counter reached value 0x90) => comparison still enabled, Compare 2 event will occur at = 0x140
Push-pull mode

This mode primarily aims at driving converters using push-pull topologies. It also needs to be enabled when the delayed idle protection is required, typically for resonant converters (refer to Section 36.3.9: Delayed Protection).

The push-pull mode is enabled by setting PSHPLL bit in the HRTIM_TIMxCR register.

It applies the signals generated by the crossbar to output 1 and output 2 alternatively, on the period basis, maintaining the other output to its inactive state. The redirection rate (push-pull frequency) is defined by the timer’s period event, as shown on Figure 292. The push-pull period is twice the timer counting period.

**Figure 292. Push-pull mode block diagram**

The push-pull mode is only available when the timer operates in continuous mode: the counter must not be reset once it has been enabled (TxCEN bit set). It is necessary to disable the timer to stop a push-pull operation and to reset the counter before re-enabling it.

The signal shape is defined using HRTIM_SETxyR and HRTIM_RSTxyR for both outputs. It is necessary to have HRTIM_SETx1R = HRTIM_SETx2R and HRTIM_RSTx1R = HRTIM_RSTx2R to have both outputs with identical waveforms and to achieve a balanced operation. Still, it is possible to have different programming on both outputs for other uses.

**Note:** The push-pull operation cannot be used when a deadtime is enabled (mutually exclusive functions).

The CPPSAT status bit in HRTIM_TIMxISR indicates on which output the signal is currently active. CPPSTAT is reset when the push-pull mode is disabled.

In the example given on Figure 293, the timer internal waveform is defined as follows:

- Output set on period event
- Output reset on Compare 1 match event
Deadtime

A deadtime insertion unit allows to generate a couple of complementary signals from a single reference waveform, with programmable delays between active state transitions. This is commonly used for topologies using half-bridges or full bridges. It simplifies the software: only 1 waveform is programmed and controlled to drive two outputs.

The Dead time insertion is enabled by setting DTEN bit in HRTIM_OUTxR register. The complementary signals are built based on the reference waveform defined for output 1, using HRTIM_SETx1R and HRTIM_RSTx1R registers: HRTIM_SETx2R and HRTIM_RSTx2R registers are not significant when DTEN bit is set.

Note: The deadtime cannot be used simultaneously with the push-pull mode.

Two deadtimes can be defined in relationship with the rising edge and the falling edge of the reference waveform, as in Figure 294.

Figure 293. Push-pull mode example

Figure 294. Complementary outputs with deadtime insertion
Negative deadtime values can be defined when some control overlap is required. This is done using the deadtime sign bits (SDTFx and SDTRx bits in HRTIM_DTxR register).

Figure 295 shows complementary signal waveforms depending on respective signs.

Figure 295. Deadtime insertion vs deadtime sign (1 indicates negative deadtime)

The deadtime values are defined with DTFx[8:0] and DTRx[8:0] bitfields and based on a specific clock prescaled according to DTPRSC[2:0] bits, as follows:

\[ t_{DTx} = \pm \times t_{DTG} \]

where \( x \) is either R or F and \( t_{DTG} = (2^{(\text{DTPRSC}[2:0])}) \times t_{HRTIM} \).

Table 298 gives the resolution and maximum absolute values depending on the prescaler value.

*Figure 296* to *Figure 299* present how the deadtime generator behaves for reference waveforms with pulsewidth below the deadtime values, for all deadtime configurations.

**Figure 296. Complementary outputs for low pulse width (SDTRx = SDTFx = 0)**

**Figure 297. Complementary outputs for low pulse width (SDTRx = SDTFx = 1)**

**Figure 298. Complementary outputs for low pulse width (SDTRx = 0, SDTFx = 1)**
Figure 299. Complementary outputs for low pulse width (SDTRx = 1, SDTFx=0)

For safety purposes, it is possible to prevent any spurious write into the deadtime registers by locking the sign and/or the value of the deadtime using DTFLKx, DTRLKx, DTFSLKx and DTRSLKx. Once these bits are set, the related bits and bitfields are becoming read only until the next system reset.

**Caution:** DTEN bit must not be changed in the following cases:
- When the timer is enabled (TxEN bit set)
- When the timer outputs are set/reset by another timer (while TxEN is reset)

Otherwise, an unpredictable behavior would result.

It is therefore necessary to disable the timer (TxCEN bit reset) and have the corresponding outputs disabled.

*For the particular case where DTEN must be set while the burst mode is enabled with a deadtime upon entry (BME = 1, DIDL = 1, IDLEM = 1), it is necessary to force the two outputs in their IDLES state by software commands (SST, RST bits) before setting DTEN bit. This is to avoid any side effect resulting from a burst mode entry that would happen immediately before a deadtime enable.*
36.3.5 Master timer

The main purpose of the master timer is to provide common signals to the 5 timing units, either for synchronization purpose or to set/reset outputs. It does not have direct control over any outputs, but still can be used indirectly by the set/reset crossbars. 

*Figure 300* provides an overview of the master timer.

---

**Figure 300. Master timer overview**

The master timer is based on the very same architecture as the timing units, with the following differences:

- It does not have outputs associated with, nor output related control
- It does not have its own crossbar unit, nor push-pull or deadtime mode
- It can only be reset by the external synchronization circuitry
- It does not have a capture unit, nor the auto-delayed mode
- It does not include external event blanking and windowing circuitry
- It has a limited set of interrupt / DMA requests: Compare 1..4, repetition, register update and external synchronization event.

The master timer control register includes all the timer enable bits, for the master and Timer A..E timing units. This allows to have all timer synchronously started with a single write access.

It also handles the external synchronization for the whole HRTIM timer (see *Section 36.3.17: Synchronizing the HRTIM with other timers or HRTIM instances*), with both MCU internal and external (inputs/outputs) resources.
Master timer control registers are mapped with the same offset as the timing units’ registers.

### 36.3.6 Set/reset events priorities and narrow pulses management

This section describes how the output waveform is generated when several set and/or reset requests are occurring within 3 consecutive \( t_{\text{HRTIM}} \) periods.

An arbitration is performed during each \( t_{\text{HRTIM}} \) period, in 2 steps:

1. For each active event, the desired output transition is determined (set, reset or toggle).
2. A predefined arbitration is performed among the active events (from highest to lowest priority \( \text{CMP4} \rightarrow \text{CMP3} \rightarrow \text{CMP2} \rightarrow \text{CMP1} \rightarrow \text{PER} \), see Concurrent set request / Concurrent reset requests.

When set and reset requests from two different sources are simultaneous, the reset action has the highest priority.

Concurrent set request / Concurrent reset requests

When multiple sources are selected for a set event, an arbitration is performed when the set requests occur within the same \( f_{\text{HRTIM}} \) clock period.

In case of multiple requests from adjacent timers (\( \text{TIMEVNT1}..9 \)), the request which occurs first is taken into account. The arbitration is done in 2 steps, depending on the source (from the highest to the lowest priority): \( \text{CMP4} \rightarrow \text{CMP3} \rightarrow \text{CMP2} \rightarrow \text{CMP1} \).

If multiple requests from the master timer occur within the same \( f_{\text{HRTIM}} \) clock period, a predefined arbitration is applied and a single request will be taken into account (from the highest to the lowest priority):

\begin{align*}
\text{MSTCMP4} \rightarrow \text{MSTCMP3} \rightarrow \text{MSTCMP2} \rightarrow \text{MSTCMP1} \rightarrow \text{MSTCMPER}
\end{align*}

When multiple requests internal to the timer occur within the same \( f_{\text{HRTIM}} \) clock period, a predefined arbitration is applied and the requests are taken with the following priority, whatever the effective timing (from highest to lowest):

\begin{align*}
\text{CMP4} \rightarrow \text{CMP3} \rightarrow \text{CMP2} \rightarrow \text{CMP1} \rightarrow \text{PER}
\end{align*}

**Note:** Practically, this is of a primary importance only when using auto-delayed Compare 2 and Compare 4 simultaneously (i.e. when the effective set/reset cannot be determined a priori because it is related to an external event). In this case, the highest priority signal must be affected to the CMP4 event.

Last, the highest priority is given to non timing-related: \( \text{EXTEVNT1}..10 \), RESYNC (coming from \( \text{SYNC} \) event if \( \text{SYNCRSTx} \) or \( \text{SYNCSTRTx} \) is set or from a software reset), update and software set (SST).

As a summary, in case of simultaneous events, the effective set (reset) event will be arbitrated between:

- Any \( \text{TIMEVNT1}..9 \) event
- A single source from the master (as per the fixed arbitration given above)
- A single source from the timer
- The “non timing-related events”.

The same arbitration principle applies for concurrent reset requests. In this case, the reset request has the highest priority.
A set or reset event occurring within the prescaler clock cycle is delayed to the next active edge of the prescaled clock (as for a counter reset), even if the arbitration is still performed every $t_{\text{HRTIM}}$ cycle.

If a reset event is followed by a set event within the same prescaler clock cycle, the latest event will be considered.

### 36.3.7 External events global conditioning

The HRTIM timer can handle events not generated within the timer, referred to as “external event”. These external events come from multiple sources, either on-chip or off-chip:

- built-in comparators,
- digital input pins (typically connected to off-chip comparators and zero-crossing detectors),
- on-chip events for other peripheral (ADC’s analog watchdogs and general purpose timer trigger outputs).

The external events conditioning circuitry allows to select the signal source for a given channel (with a 4:1 multiplexer) and to convert it into an information that can be processed by the crossbar unit (for instance, to have an output reset triggered by a falling edge detection on an external event channel).

Up to 10 external event channels can be conditioned and are available simultaneously for any of the 5 timers. This conditioning is common to all timers, since this is usually dictated by external components (such as a zero-crossing detector) and environmental conditions (typically the filter set-up will be related to the applications noise level and signature). *Figure 301* presents an overview of the conditioning logic for a single channel.
The 10 external events are initialized using the HRTIM_EECR1 and HRTIM_EECR2 registers:

- to select up to 4 sources with the EExSRC[1:0] bits,
- to select the sensitivity with EExSNS[1:0] bits, to be either level-sensitive or edge-sensitive (rising, falling or both),
- to select the polarity, in case of a level sensitivity, with EExPOL bit,
- to have a low latency mode, with EExFAST bits (see Latency to external events), for external events 1 to 5.

**Note:** The external events used as triggers for reset, capture, burst mode, ADC triggers and delayed protection are edge-sensitive even if EESNS bit is reset (level-sensitive selection): if POL = 0 the trigger is active on external event rising edge, while if POL = 1 the trigger is active on external event falling edge.

The external events are discarded as long as the counters are disabled (TxCEN bit reset) to prevent any output state change and counter reset, except if they are used as ADC triggers.

Additionally, it is possible to enable digital noise filters, for external events 6 to 10, using EExF[3:0] bits in the HRTIM_EECR3 register.

A digital filter is made of a counter in which a number N of valid samples is needed to validate a transition on the output. If the input value changes before the counter has.
reached the value N, the counter is reset and the transition is discarded (considered as a spurious event). If the counter reaches N, the transition is considered as valid and transmitted as a correct external event. Consequently, the digital filter adds a latency to the external events being filtered, depending on the sampling clock and on the filter length (number of valid samples expected).

The sampling clock is either the \( f_{\text{HRTIM}} \) clock or a specific prescaled clock \( f_{\text{EEVS}} \) derived from \( f_{\text{HRTIM}} \), defined with EEVSD[1:0] bits in HRTIM_EECR3 register.

**Table 299** summarizes the available sources and features associated with each of the 10 external events channels.

1. OPAMP1_VOUT can be used as High-resolution timer internal event source. In this case, OPAMP1_VOUT (PC4) pin must be configured in input mode. The data from the GPIO pin is redirected to the HRTIM external events through the pin Schmitt trigger. If OPAMP1 is disabled, PC4 pin, configured in input mode, can be used as HRTIM external events.

### Latency to external events

The external event conditioning gives the possibility to adjust the external event processing time (and associated latency) depending on performance expectations:

- A regular operating mode, in which the external event is resampled with the clock before acting on the output crossbar. This adds some latency but gives access to all crossbar functionalities. It enables the generation of an externally triggered high-resolution pulse.
- A fast operating mode, in which the latency between the external event and the action on the output is minimized. This mode is convenient for ultra-fast over-current protections, for instance.

EExFAST bits in the HRTIM_EECR1 register allow to define the operating for channels 1 to 5. This influences the latency and the jitter present on the output pulses, as summarized in the table below.
The EExFAST mode is only available with level-sensitive programming (EExSNS[1:0] = 00); the edge-sensitivity cannot be programmed.

It is possible to apply event filtering to external events (both blanking and windowing with EExFLTR[3:0] != 0000, see Section 36.3.8). In this case, EExLTCHx bit must be reset: the postponed mode is not supported, neither the windowing timeout feature.

**Note:** The external event configuration (source and polarity) must not be modified once the related EExFAST bit is set.

A fast external event cannot be used to toggle an output: if must be enabled either in HRTIM_SETxyR or HRTIM_RSTxyR registers, not in both.

When a set and a reset event - from 2 independent fast external events - occur simultaneously, the reset has the highest priority in the crossbar and the output becomes inactive.

When EExFAST bit is set, the output cannot be changed during the 11 $f_{HRTIM}$ clock periods following the external event.

*Figure 302* and *Figure 303* give practical examples of the reaction time to external events, for output set/reset and counter reset.

  - EExFAST = 0: 2-3 cycles delay.
  - EExFAST = 1: 5-6 cycles delay total.
36.3.8 **External event filtering in timing units**

Once conditioned, the 10 external events are available for all timing units. They can be used directly and are active as soon as the timing unit counter is enabled (TxCEN bit set).

They can also be filtered to have an action limited in time, usually related to the counting period. Two operations can be performed:

- blanking, to mask external events during a defined time period,
- windowing, to enable external events only during a defined time period.

These modes are enabled using HRTIM_EExFLTR[3:0] bits in the HRTIM_EEFxR1 and HRTIM_EEFxR2 registers. Each of the 5 TimerA..E timing units has its own programmable filter settings for the 10 external events.

**Blanking mode**

In event blanking mode (see Figure 304), the external event is ignored if it happens during a given blanking period. This is convenient, for instance, to avoid a current limit to trip on switching noise at the beginning of a PWM period. This mode is active for EExFLTR[3:0] bitfield values ranging from 0001 to 1100.

![Figure 304. Event blanking mode](image)

In event postpone mode, the external event is not taken into account immediately but is memorized (latched) and generated as soon as the blanking period is completed, as shown on Figure 305. This mode is enabled by setting EExLTX bit in HRTIM_EEFxR1 and HRTIM_EEFxR2 registers.

![Figure 305. Event postpone mode](image)
The blanking signal comes from several sources:

- the timer itself: the blanking lasts from the counter reset to the compare match (EExFLTR[3:0] = 0001 to 0100 for Compare 1 to Compare 4)
- from other timing units (EExFLTR[3:0] = 0101 to 1100): the blanking lasts from the selected timing unit counter reset to one of its compare match, or can be fully programmed as a waveform on Tx2 output. In this case, events are masked as long as the Tx2 signal is inactive (it is not necessary to have the output enabled, the signal is taken prior to the output stage).

The EEXFLTR[3:0] configurations from 0101 to 1100 are referred to as TIMFLTR1 to TIMFLTR8 in the bit description, and differ from one timing unit to the other. Table 301 gives the 8 available options per timer: CMPx refers to blanking from counter reset to compare match, Tx2 refers to the timing unit TIMx output 2 waveform defined with HRTIM_SETx2 and HRTIM_RSTx2 registers. For instance, Timer B (TIMFLTR6) is Timer C output 2 waveform.

- POL = 1 (L), LTCH = 1

* A high level denotes a continuous event generation after blanking
Windowing mode

In event windowing mode, the event is taken into account only if it occurs within a given time window, otherwise it is ignored. This mode is active for EEFLTR[3:0] ranging from 1101 to 1111.

Figure 308. Event windowing mode

EExLTCH bit in EEFxR1 and EEFxR2 registers allows to latch the signal, if set to 1: in this case, an event is accepted if it occurs during the window but is delayed at the end of it.

- If EExLTCH bit is reset and the signal occurs during the window, it is passed through directly.
- If EExLTCH bit is reset and no signal occurs, a timeout event is generated at the end of the window.

A use case of the windowing mode is to filter synchronization signals. The timeout generation allows to force a default synchronization event, when the expected synchronization event is lacking (for instance during a converter start-up).

There are 3 sources for each external event windowing, coded as follows:

- 1101 and 1110: the windowing lasts from the counter reset to the compare match (respectively Compare 2 and Compare 3)
- 1111: the windowing is related to another timing unit and lasts from its counter reset to its Compare 2 match. The source is described as TIMWIN in the bit description and is given in Table 302. As an example, the external events in timer B can be filtered by a window starting from timer A counter reset to timer A Compare 2.

Table 302. Windowing signals mapping per timer (EEFLTR[3:0] = 1111)

<table>
<thead>
<tr>
<th>Destination</th>

<td>Timer A CMP2</td>
<td>Timer D CMP2</td>
<td>Timer C CMP2</td>
<td>Timer D CMP2</td>
</tr>
</tbody>
</table>

Note: The timeout event generation is not supported if the external event is programmed in fast mode.

Figure 309 and Figure 310 present how the events are generated for the various edge and level sensitivities, as well as depending on EExLTCH bit setting. Timeout events are specifically mentioned for clarity reasons.
Figure 309. External trigger windowing with edge-sensitive trigger

Figure 310. External trigger windowing, level sensitive triggering

* A high level denotes continuous event generation after windowing
36.3.9 Delayed Protection

The HRTIM features specific protection schemes, typically for resonant converters when it is necessary to shut down the PWM outputs in a delayed manner, either once the active pulse is completed or once a push-pull period is completed. These features are enabled with DLYPRTEN bit in the HRTIM.OUTxR register, and are using specific external event channels.

Delayed Idle

In this mode, the active pulse is completed before the protection is activated. The selected external event causes the output to enter in idle mode at the end of the active pulse (defined by an output reset event in HRTIM_RSTx1R or HRTIM_RSTx2R).

Once the protection is triggered, the idle mode is permanently maintained but the counter continues to run, until the output is re-enabled. Tx1OEN and Tx2OEN bits are not affected by the delayed idle entry. To exit from delayed idle and resume operation, it is necessary to overwrite Tx1OEN and Tx2OEN bits to 1. The output state will change on the first transition to an active state following the output enable command.

Note: The delayed idle mode cannot be exited immediately after having been entered, before the active pulse is completed: it is mandatory to make sure that the outputs are in idle state before resuming the run mode. This can be done by waiting up to the next period, for instance, or by polling the O1CPY and/or O2CPY status bits in the TIMxISR register.

The delayed idle mode can be applied to a single output (DLYPRT[2:0] = x00 or x01) or to both outputs (DLYPRT[2:0] = x10).

An interrupt or a DMA request can be generated in response to a Delayed Idle mode entry. The DLYPRT flag in HRTIM_TIMxISR is set as soon as the external event arrives, independently from the end of the active pulse on output.

When the Delayed Idle mode is triggered, the output states can be determined using O1STAT and O2STAT in HRTIM_TIMxISR. Both status bits are updated even if the delayed idle is applied to a single output. When the push-pull mode is enabled, the IPPSTAT flag in HRTIM_TIMxISR indicates during which period the delayed protection request occurred.

This mode is available whatever the timer operating mode (regular, push-pull, deadtime). It is available with 2 external events only:

- hrtim_evt6 and hrtim_evt7 for Timer A, B and C
- hrtim_evt8 and hrtim_evt9 for Timer D and E

The delayed protection mode can be triggered only when the counter is enabled (TxCEN bit set). It remains active even if the TxEN bit is reset, until the TxYOEN bits are set.
The delayed idle mode has a higher priority than the burst mode: any burst mode exit request is discarded once the delayed idle protection has been triggered. On the contrary, if the delayed protection is exited while the burst mode is active, the burst mode will be resumed normally and the output will be maintained in the idle state until the burst mode exits. Figure 312 gives an overview of these different scenarios.
The same priorities are applied when the delayed burst mode entry is enabled (DIDL bit set), as shown on Figure 313 below.
Balanced Idle

Only available in push-pull mode, it allows to have balanced pulsewidth on the two outputs when one of the active pulse is shortened due to a protection. The pulsewidth, which was terminated earlier than programmed, is copied on the alternate output and the two outputs are then put in idle state, until the normal operation is resumed by software. This mode is enabled by writing x11 in DLYPRT[2:0] bitfield in HRTIM_OUTxR.

This mode is available with 2 external events only:
- hrtim_evt6 and hrtim_evt7 for Timer A, B and C
- hrtim_evt8 and hrtim_evt9 for Timer D and E
When the balanced Idle mode is enabled, the selected external event triggers a capture of the counter value into the Compare 4 active register (this value is not user-accessible). The push-pull is maintained for one additional period so that the shorten pulse can be repeated: a new output reset event is generated while the regular output set event is maintained.
The Idle mode is then entered and the output takes the level defined by IDLESx bits in the HRTIM_OUTxR register. The balanced idle mode entry is indicated by the DLYPRT flag, while the IPPSTAT flag indicates during which period the external event occurred, to determine the sequence of shorten pulses (HRTIM_CHA1 then HRTIM_CHA2 or vice versa).

The timer operation is not interrupted (the counter continues to run).

To enable the balanced idle mode, it is necessary to have the following initialization:

- timer operating in continuous mode (CONT = 1)
- Push-pull mode enabled
- HRTIM_CMP4xR must be set to 0 and the content transferred into the active register (for instance by forcing a software update)
- DELCMP4[1:0] bit field must be set to 00 (auto-delayed mode disabled)
- DLYPRT[2:0] = x11 (delayed protection enable)

**Note:** The HRTIM_CMP4xR register must not be written during a balanced idle operation. The CMP4 event is reserved and cannot be used for another purpose.

In balanced idle mode, it is recommended to avoid multiple external events or software-based reset events causing an output reset. If such an event arrives before a balanced idle request within the same period, it will cause the output pulses to be unbalanced (1st pulse length defined by the external event or software reset, while the 2nd pulse is defined by the balanced idle mode entry).

The minimum pulsewidth that can be handled in balanced idle mode is 4 f_{HRTIM} clock periods.

If the capture occurs before the counter has reached this minimum value, the current pulse is extended up to 4 f_{HRTIM} clock periods before being copied into the secondary output. In any case, the pulsewidths are always balanced.

Tx1OEN and Tx2OEN bits are not affected by the balanced idle entry. To exit from balanced idle and resume the operation, it is necessary to overwrite Tx1OEN and Tx2OEN bits to 1 simultaneously. The output state will change on the first active transition following the output enable.

It is possible to resume operation similarly to the delayed idle entry. For instance, if the external event arrives while output 1 is active (delayed idle effective after output 2 pulse), the re-start sequence can be initiated for output 1 first. To do so, it is necessary to poll CPPSTAT bit in the HRTIM_TIMxISR register. Using the above example (IPPSTAT flag equal to 0), the operation will be resumed when CPPSTAT bit is 0.

In order to have a specific re-start sequence, it is possible to poll the CPPSTAT to know which output will be active first. This allows, for instance, to re-start with the same sequence as the idle entry sequence: if EEV arrives during output 1 active, the re-start sequence will be initiated when the output 1 is active (CPPSTAT = 0).

**Note:** The balanced idle mode must not be disabled while a pulse balancing sequence is ongoing. It is necessary to wait until the CMP4 flag is set, thus indicating that the sequence is completed, to reset the DLYPRTE bit.

The balanced idle protection mode can be triggered only when the counter is enabled (Tx1CEN bit set). It remains active even if the Tx1CEN bit is reset, until Tx2OEN bits are set.
Balanced idle can be used together with the burst mode under the following conditions:

- TxBM bit must be reset (counter clock maintained during the burst, see Section 36.3.13),
- No balanced idle protection must be triggered while the outputs are in a burst idle state.

The balanced idle mode has a higher priority than the burst mode: any burst mode exit request is discarded once the balanced idle protection has been triggered. On the contrary, if the delayed protection is exited while the burst mode is active, the burst mode will be resumed normally.

Note: Although the output state is frozen in idle mode, a number of events are still generated on the auxiliary outputs (see Section 36.3.16) during the idle period following the delayed protection:
- Output set/reset interrupt or DMA requests
- External event filtering based on output signal
- Capture events triggered by set/reset

36.3.10 Register preload and update management

Most of HRTIM registers are buffered and can be preloaded if needed. Typically, this allows to prevent the waveforms from being altered by a register update not synchronized with the active events (set/reset).

When the preload mode is enabled, accessed registers are shadow registers. Their content is transferred into the active register after an update request, either software or synchronized with an event.

By default, PREEN bits in HRTIM_MCR and HRTIM_TIMxCR registers are reset and the registers are not preloaded: any write directly updates the active registers. If PREEN bit is reset while the timer is running and preload was enabled, the content of the preload registers is directly transferred into the active registers.

Each timing unit and the master timer have their own PREEN bit. If PRREN is set, the preload registers are enabled and transferred to the active register only upon an update event.

There are two options to initialize the timer when the preload feature is needed:

- Enable PREEN bit at the very end of the timer initialization to have the preload registers transferred into the active registers before the timer is enabled (by setting MCEN and TxCEN bits).
- enable PREEN bit at any time during the initialization and force a software update immediately before starting.

Table 303 lists the registers which can be preloaded, together with a summary of available update events.
The master timer has 4 update options:

1. **Software**: writing 1 into MSWU bit in HRTIM_CR2 forces an immediate update of the registers. In this case, any pending hardware update request is cancelled.

2. **Update done when the master counter rolls over and the master repetition counter is equal to 0**. This is enabled when MREPU bit is set in HRTIM_MCR.

3. **Update done once Burst DMA is completed** (see Section 36.3.21 for details). This is enabled when BRSTDMA[1:0] = 01 in HRTIM_MCR. It is possible to have both MREPU=1 and BRSTDMA=01.

   **Note**: The update can take place immediately after the end of the burst sequence if SWU bit is set (i.e. forced update mode). If SWU bit is reset, the update will be done on the next update event following the end of the burst sequence.

4. **Update done when the master counter rolls over following a Burst DMA completion**. This is enabled when BRSTDMA[1:0] = 10 in HRTIM_MCR.

   An interrupt or a DMA request can be generated by the master update event.

<td></td>
</tr>
</tbody>
</table>
Each timer (TIMA..E) can also have the update done as follows:

- By software: writing 1 into TxSWU bit in HRTIM_CR2 forces an immediate update of the registers. In this case, any pending hardware update request is canceled.
- Update done when the counter rolls over and the repetition counter is equal to 0. This is enabled when TxREPU bit is set in HRTIM_TIMxCR.
- Update done when the counter is reset or rolls over in continuous mode. This is enabled when TxRSTU bit is set in HRTIM_TIMxCR. This is used for a timer operating in single-shot mode, for instance.
- Update done once a Burst DMA is completed. This is enabled when UPDGAT[3:0] = 0001 in HRTIM_TIMxCR.
- Update done on an update event following a Burst DMA completion (the event can be enabled with TxREPU, MSTU or TxU). This is enabled when UPDGAT[3:0] = 0010 in HRTIM_TIMxCR.
- Update done when receiving a request on the update enable input 1..3. This is enabled when UPDGAT[3:0] = 0011, 0100, 0101 in HRTIM_TIMxCR.
- Update done on the update event following a request on the update enable input 1..3 (the event can be enabled with TxREPU, MSTU or TxU). This is enabled when UPDGAT[3:0] = 0110, 0111, 1000 in HRTIM_TIMxCR.
- Update done synchronously with any other timer or master update (for instance TIMA can be updated simultaneously with TIMB). This is used for converters requiring several timers, and is enabled by setting bits MSTU and TxU in HRTIM_TIMxCR register.

The update enable inputs 1..3 allow to have an update event synchronized with on-chip events coming from the general-purpose timers. These inputs are rising-edge sensitive. Table 304 lists the connections between update enable inputs and the on-chip sources.

### Table 304. Update enable inputs and sources

<table>
<thead>
<tr>
<th>Update enable input</th>
<th>Update source</th>
</tr>
</thead>
<tbody>
<tr>
<td>Update enable input 1</td>
<td>TIM16_OC</td>
</tr>
<tr>
<td>Update enable input 2</td>
<td>TIM17_OC</td>
</tr>
<tr>
<td>Update enable input 3</td>
<td>TIM6_TRGO</td>
</tr>
</tbody>
</table>

This allows to synchronize low frequency update requests with high-frequency signals (for instance an update on the counter roll-over of a 100 kHz PWM that has to be done at a 100 Hz rate).

**Note:** The update events are synchronized to the prescaler clock when CKPSC[2:0] > 5.

An interrupt or a DMA request can be generated by the Timx update event.

MUDIS and TxUDIS bits in the HRTIM_CR1 register allow to temporarily disable the transfer from preload to active registers, whatever the selected update event. This allows to modify several registers in multiple timers. The regular update event takes place once these bits are reset.

MUDIS and TxUDIS bits are all grouped in the same register. This allows the update of multiple timers (not necessarily synchronized) to be disabled and resumed simultaneously.
The following example is a practical use case. A first power converter is controlled with the master, TIMB and TIMC. TIMB and TIMC must be updated simultaneously with the master timer repetition event. A second converter works in parallel with TIMA, TIMD and TIME, and TIMD, TIME must be updated with TIMA repetition event.

**First converter**

In HRTIM_MCR, MREPU bit is set: the update will occur at the end of the master timer counter repetition period. In HRTIM_TIMBCR and HRTIM_TIMCCR, MSTU bits are set to have TIMB and TIMC timers updated simultaneously with the master timer.

When the power converter set-point has to be adjusted by software, MUDIS, TBUDIS and TCUDIS bits of the HRTIM_CR register must be set prior to write accessing registers to update the values (for instance the compare values). From this time on, any hardware update request is ignored and the preload registers can be accessed without any risk to have them transferred into the active registers. Once the software processing is over, MUDIS, TBUDIS and TCUDIS bits must be reset. The transfer from preload to active registers will be done as soon as the master repetition event occurs.

**Second converter**

In HRTIM_TIMACR, TAREPU bit is set: the update will occur at the end of the Timer A counter repetition period. In HRTIM_TIMDCR and HRTIM_TIMECR, TAU bits are set to have TIMD and TIME timers updated simultaneously with Timer A.

When the power converter set-point has to be adjusted by software, TAUDIS, TDUDIS and TEUDIS bits of the HRTIM_CR register must be set prior to write accessing the registers to update the values (for instance the compare values). From this time on, any hardware update request is ignored and the preload registers can be accessed without any risk to have them transferred into the active registers. Once the software processing is over, TAUDIS, TDUDIS and TEUDIS bits can be reset: the transfer from preload to active registers will be done as soon as the Timer A repetition event occurs.

**36.3.11 Events propagation within or across multiple timers**

The HRTIM offers many possibilities for cascading events or sharing them across multiple timing units, including the master timer, to get full benefits from its modular architecture. These are key features for converters requiring multiple synchronized outputs.

This section summarizes the various options and specifies whether and how an event is propagated within the HRTIM.

**TIMx update triggered by the Master timer update**

The sources listed in Table 305 are generating a master timer update. The table indicates if the source event can be used to trigger a simultaneous update in any of TIMx timing units.

Operating condition: MSTU bit is set in HRTIM_TIMxCR register.
The sources listed in Table 306 are generating a TIMy update. The table indicates if the given event can be used to trigger a simultaneous update in another or multiple TIMx timers.

Operating condition: TyU bit set in HRTIM_TIMyCR register (source = TIMy and destination = TIMx).

36.3.12 Output management

Each timing unit controls a pair of outputs. The outputs have three operating states:

- **RUN:** this is the main operating mode, where the output can take the active or inactive level as programmed in the crossbar unit.
- **IDLE:** this state is the default operating state after an HRTIM reset, when the outputs are disabled by software or during a burst mode operation (where outputs are temporary disabled during a normal operating mode; refer to Section 36.3.13 for more details). It is either permanently active or inactive.
- **FAULT:** this is the safety state, entered in case of a shut-down request on FAULTx inputs. It can be permanently active, inactive or Hi-Z.

The output status is indicated by TxyOEN bit in HRTIM_OENR register and TxyODS bit in HRTIM_ODSR register, as in Table 309.

</table>

TxyOEN bit is both a control and a status bit: it must be set by software to have the output in RUN mode. It is cleared by hardware when the output goes back in IDLE or FAULT mode. When TxyOEN bit is cleared, TxyODS bit indicates whether the output is in the IDLE or FAULT state. A third bit in the HRTIM_ODISR register allows to disable the output by software.
Figure 315. Output management overview

Figure 316 summarizes the bit values for the three states and how the transitions are triggered. Faults can be triggered by any external or internal fault source, as listed in Section 36.3.15, while the Idle state can be entered when the burst mode or delayed protections are active.

Figure 316. HRTIM output states and transitions

The FAULT and IDLE levels are defined as active or inactive. Active (or inactive) refers to the level on the timer output that causes a power switch to be closed (or opened for an inactive state).

The IDLE state has the highest priority: the transition FAULT → IDLE is possible even if the FAULT condition is still valid, triggered by ODIS bit set.

The FAULT state has priority over the RUN state: if TxyOEN bit is set simultaneously with a Fault event, the FAULT state will be entered. The condition is given on the transition IDLE →
FAULT, as in Figure 316: fault protection needs to be enabled (FAULTx[1:0] bits = 01, 10, 11) and the Txy OEN bit set with a fault active (or during a breakpoint if DBG_HRTIM_STOP = 1).

The output polarity is programmed using POLx bits in HRTIM_OUTxR. When POLx = 0, the polarity is positive (output active high), while it is active low in case of a negative polarity (POLx = 1). Practically, the polarity is defined depending on the power switch to be driven (PMOS vs. NMOS) or on a gate driver polarity.

The output level in the FAULT state is configured using FAULTx[1:0] bits in HRTIM_OUTxR, for each output, as follows:
- 00: output never enters the fault state and stays in RUN or IDLE state
- 01: output at active level when in FAULT
- 10: output at inactive level when in FAULT
- 11: output is tri-stated when in FAULT. The safe state must be forced externally with pull-up or pull-down resistors, for instance.

Note: FAULTx[1:0] bits must not be changed as long as the outputs are in FAULT state.

The level of the output in IDLE state is configured using IDLESx bit in HRTIM_OUTxR, as follows:
- 0: output at inactive level when in IDLE
- 1: output at active level when in IDLE

When TxyOEN bit is set to enter the RUN state, the output is immediately connected to the crossbar output. If the timer clock is stopped, the level will either be inactive (after an HRTIM reset) or correspond to the RUN level (when the timer was stopped and the output disabled).

During the HRTIM initialization, the output level can be prepositioned prior to have it in RUN mode, using the software forced output set and reset in the HRTIM_SETx1R and HRTIM_RSTx1R registers.

36.3.13 Burst mode controller

The burst mode controller allows to have the outputs alternatively in IDLE and RUN state, by hardware, so as to skip some switching periods with a programmable periodicity and duty cycle.

Burst mode operation is of common use in power converters when operating under light loads. It can significantly increase the efficiency of the converter by reducing the number of transitions on the outputs and the associated switching losses.

When operating in burst mode, one or a few pulses are outputs followed by an idle period equal to several counting periods, typically, where no output pulses are produced, as shown in the example on Figure 317.
The burst mode controller consists of:
- A counter that can be clocked by various sources, either within or outside the HRTIM (typically the end of a PWM period).
- A comparison register to define the number of idle periods: HRTIM_BMCMP.
- A period register to define the burst repetition rate (corresponding to the sum of the idle and run periods): HRTIM_BMPER.

The burst mode controller is able to take over the control of any of the 10 PWM outputs. The state of each output during a burst mode operation is programmed using IDLESx and IDLEMx bits in the HRTIM_OUTxR register, as in Table 310.

<table>
<thead>
<tr>
<th>IDLEMx</th>
<th>IDLESx</th>
<th>Output state during burst mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>X</td>
<td>No action: the output is not affected by the burst mode operation.</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>Output inactive during the burst</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Output active during the burst</td>
</tr>
</tbody>
</table>

Note: IDLEMx bit must not be changed while the burst mode is active.

The burst mode controller only acts on the output stage. A number of events are still generated during the idle period:
- Output set/reset interrupt or DMA requests
- External event filtering based on Tx2 output signal
- Capture events triggered by output set/reset

During the burst mode, neither start not reset events are generated on the HRTIM_SCOUT output, even if TxBM bit is set.
Operating mode

It is necessary to have the counter enabled (TxCEN bit set) before using the burst mode on a given timing unit. The burst mode is enabled with BME bit in the HRTIM_BMCR register.

It can operate in continuous or single-shot mode, using BMOM bit in the HRTIM_BMCR register. The continuous mode is enabled when BMOM = 1. The Burst operation is maintained until BMSTAT bit in HRTIM_BMCR is reset to terminate it.

In single-shot mode (BMOM = 0), the idle sequence is executed once, following the burst mode trigger, and the normal timer operation is resumed immediately after.

The duration of the idle and run periods is defined with a burst mode counter and 2 registers. The HRTIM_BMCMPR register defines the number of counts during which the selected timer(s) are in an idle state (idle period). HRTIM_BMPER defines the overall burst mode period (sum of the idle and run periods). Once the initial burst mode trigger has occurred, the idle period length is HRTIM_BMCMPR+1, the overall burst period is

HRTIM_BMPER+1.

Note: The burst mode period must not be less than or equal to the deadtime duration defined with DTRx[8:0] and DTFx[8:0] bitfields.

The counters of the timing units and the master timer can be stopped and reset during the burst mode operation. HRTIM_BMCR holds 6 control bits for this purpose: MTBM (master) and TABM..TEBM for Timer A..E.

When MTBM or TxBM bit is reset, the counter clock is maintained. This allows to keep a phase relationship with other timers in multiphase systems, for instance.

When MTBM or TxBM bit is set, the corresponding counter is stopped and maintained in reset state during the burst idle period. This allows to have the timer restarting a full period when exiting from idle. If SYNCSRC[1:0] = 00 or 10 (synchronization output on the master start or timer A start), a pulse is sent on the HRTIM_SCOUT output when exiting the burst mode.

Note: TxBM bit must not be set when the balanced idle mode is active (DLYPRT[1:0] = 0x11).

Burst mode clock

The burst mode controller counter can be clocked by several sources, selected with BMCLK[3:0] bits in the HRTIM_BMCR register:

- BMCLK[3:0] = 0000 to 0101: Master timer and TIMA..E reset/roll-over events. This allows to have burst mode idle and run periods aligned with the timing unit counting period (both in free-running and counter reset mode).
- BMCLK[3:0] = 0110 to 1001: The clocking is provided by the general purpose timers, as in Table 311. In this case, the burst mode idle and run periods are not necessarily aligned with timing unit counting period (a pulse on the output may be interrupted, resulting a waveform with modified duty cycle for instance.
- BMCLK[3:0] = 1010: The \( f_{\text{HRTIM}} \) clock prescaled by a factor defined with BMPRSC[3:0] bits in HRTIM_BMCR register. In this case, the burst mode idle and run periods are not necessarily aligned with the timing unit counting period (a pulse on the output may be interrupted, resulting in a waveform with a modified duty cycle, for instance.
The pulsewidth on TIMxx OC output must be at least $N f_{HRTIM}$ clock cycles long to be detected by the HRTIM burst mode controller.

**Burst mode triggers**

To trigger the burst operation, 32 sources are available and are selected using the HRTIM_BMTRGR register:

- Software trigger (set by software and reset by hardware)
- 6 Master timer events: repetition, reset/roll-over, Compare 1 to 4
- 5 x 4 events from timers A..E: repetition, reset/roll-over, Compare 1 and 2
- hrtim_evt7 (including TIMA event filtering) and hrtim_evt8 (including TIMD event filtering)
- Timer A period following hrtim_evt7 (including TIMA event filtering)
- Timer D period following hrtim_evt8 (including TIMD event filtering)
- On-chip events coming from other general purpose timer (hrtim_bm_trg output:TIM7_TRGO output)

These sources can be combined to have multiple concurrent triggers.

Burst mode is not re-triggerable. In continuous mode, new triggers are ignored until the burst mode is terminated, while in single-shot mode, the triggers are ignored until the current burst completion including run periods (HRTIM_BMPER+1 cycles). This is also valid for software trigger (the software bit is reset by hardware even if it is discarded).

*Figure 318* shows how the burst mode is started in response to an external event, either immediately or on the timer period following the event.

*Figure 318. Burst mode trigger on external event*
For TAEVEV7 and TDEEV8 combined triggers (trigger on a Timer period following an external event), the external event detection is always active, regardless of the burst mode programming and the on-going burst operation:

- When the burst mode is enabled (BME=1) or the trigger is enabled (TAEVEV7 or TDEEV8 bit set in the BMTRG register) in between the external event and the timer period event, the burst is triggered.
- The single-shot burst mode is re-triggered even if the external event occurs before the burst end (as long as the corresponding period happens after the burst).

**Note:** TAEVEV7 and TDEEV8 triggers are valid only after a period event. If the counter is reset before the period event, the pending hrtim_evt7/8 event is discarded.

**Burst mode delayed entry**

By default, the outputs are taking their idle level (as per IDLES1 and IDLES2 setting) immediately after the burst mode trigger.

It is also possible to delay the burst mode entry and force the output to an inactive state during a programmable period before the output takes its idle state. This is useful when driving two complementary outputs, one of them having an active idle state, to avoid a deadtime violation as shown on Figure 319. This prevents any risk of shoot through current in half-bridges, but causes a delayed response to the burst mode entry.
The delayed burst entry mode is enabled with DIDLx bit in the HRTIM_OUTxR register (one enable bit per output). It forces a deadtime insertion before the output takes its idle state. Each TIMx output has its own deadtime value:
- DTRx[8:0] on output 1 when DIDL1 = 1
- DTFx[8:0] on output 2 when DIDL2 = 1

DIDLx bits can be set only if one of the outputs has an active idle level during the burst mode (IDLES = 1) and only when positive deadtimes are used (SDTR/SDTF set to 0).

**Note:** The delayed burst entry mode uses deadtime generator resources. Consequently, when any of the 2 DIDLx bits is set and the corresponding timing unit uses the deadtime insertion (DTEN bit set in HRTIM_OUTxR), it is not possible to use the timerx output 2 as a filter for external events (Tx2 filtering signal is not available).

When durations defined by DTRx[8:0] and DTFx[8:0] are lower than 3 f_{HRTIM} clock cycle periods, the limitations related to the narrow pulse management listed in Section 36.3.6 must be applied.

When the burst mode entry arrives during the regular deadtime, it is aborted and a new deadtime is re-started corresponding to the inactive period, as on Figure 320.
Burst mode exit

The burst mode exit is either forced by software (in continuous mode) or once the idle period is elapsed (in single-shot mode). In both cases, the counter is re-started immediately (if it was hold in a reset state with MTBM or TxBM bit = 1), but the effective output state transition from the idle to active mode only happens after the programmed set/reset event.

A burst period interrupt is generated in single-shot and continuous modes when BMPERIE enable bit is set in the HRTIM_IER register. This interrupt can be used to synchronize the burst mode exit with a burst period in continuous burst mode.

*Figure 321* shows how a normal operation is resumed when the deadtime is enabled. Although the burst mode exit is immediate, this is only effective on the first set event on any of the complementary outputs.

Two different cases are presented:

1. The burst mode ends while the signal is inactive on the crossbar output waveform. The active state is resumed on Tx1 and Tx2 on the set event for the Tx1 output, and the Tx2 output does not take the complementary level on burst exit.

2. The burst mode ends while the crossbar output waveform is active: the activity is resumed on the set event of Tx2 output, and Tx1 does not take the active level immediately on burst exit.
The behavior described above is slightly different when the push-pull mode is enabled. The push-pull mode forces an output reset at the beginning of the period if the output is inactive, or symmetrically forces an active level if the output was high during the preceding period. Consequently, an output with an active idle state can be reset at the time the burst mode is exited even if no transition is explicitly programmed. For symmetrical reasons, an output can be set at the time the burst mode is exited even if no transition is explicitly programmed, in case it was active when it entered in idle state.

**Burst mode registers preloading and update**

BMPREN bit (Burst mode Preload Enable) allows to have the burst mode compare and period registers preloaded (HRTIM_BMCMP and HRTIM_BMPER).

When BMPREN is set, the transfer from preload to active register happens:
- when the burst mode is enabled (BME = 1),
- at the end of the burst mode period.

A write into the HRTIM_BMPER period register disables the update temporarily, until the HRTIM_BMCMP compare register is written, to ensure the consistency of the two registers when they are modified.
If the compare register only needs to be changed, a single write is necessary. If the period only needs to be changed, it is also necessary to re-write the compare to have the new values taken into account.

When BMPREN bits is reset, the write access into BMCMPR and BMPER directly updates the active register. In this case, it is necessary to consider when the update is done during the overall burst period, for the 2 cases below:

a) Compare register update

If the new compare value is above the current burst mode counter value, the new compare is taken into account in the current period.

If the new compare value is below the current burst mode counter value, the new compare is taken into account in the next burst period in continuous mode, and ignored in single-shot mode (no compare match will occur and the idle state will last until the end of the idle period).

b) Period register update

If the new period value is above the current burst mode counter value, the change is taken into account in the current period.

Note: If the new period value is below the current burst mode counter value, the new period will not be taken into account, the burst mode counter will overflow (at 0xFFFF) and the change will be effective in the next period. In single-shot mode, the counter will roll over at 0xFFFF and the burst mode will re-start for another period up to the new programmed value.

Burst mode emulation using a compound register

The burst mode controller only controls one or a set of timers for a single converter. When the burst mode is necessary for multiple independent timers, it is possible to emulate a simple burst mode controller using the DMA and the HRTIM_CMP1CxR compound register, which holds aliases of both the repetition and the Compare 1 registers.

This is applicable to a converter which only requires a simple PWM (typically a buck converter), where the duty cycle only needs to be updated. In this case, the CMP1 register is used to reset the output (and define the duty cycle), while it is set on the period event.

In this case, a single 32-bit write access in CMP1CxR is sufficient to define the duty cycle (with the CMP1 value) and the number of periods during which this duty cycle is maintained (with the repetition value). To implement a burst mode, it is then only necessary to transfer by DMA (upon repetition event) two 32-bit data in continuous mode, organized as follows:

\[ \text{CMPC1xR} = \{\text{REP}_\text{Run}; \text{CMP1} = \text{Duty}_\text{Cycle}\}, \{\text{REP}_\text{Idle}; \text{CMP1} = 0\} \]

For instance, the values:

\{0x0003 0000\}: CMP1 = 0 for 3 periods
\{0x0001 0800\}: CMP1 = 0x0800 for 1 period

will provide a burst mode with 2 periods active every 6 PWM periods, as shown on Figure 322.
36.3.14 Chopper

A high-frequency carrier can be added on top of the timing unit output signals to drive isolation transformers. This is done in the output stage before the polarity insertion, as shown on Figure 323, using CHP1 and CHP2 bits in the HRTIM_OUTxR register, to enable chopper on outputs 1 and 2, respectively.

Figure 323. Carrier frequency signal insertion
The chopper parameters can be adjusted using the HRIM_CHPxR register, with the possibility to define a specific pulselwidth at the beginning of the pulse, to be followed by a carrier frequency with programmable frequency and duty cycle, as in Figure 324.

CARFRQ[3:0] bits define the frequency, ranging from 156 MHz to 25 MHz (for \( f_{HRTIM} = 400 \text{ MHz} \)) following the formula \( F_{CHPFRQ} = f_{HRTIM} / (16 \times (\text{CARFRQ}[3:0]+1)) \).

The duty cycle can be adjusted by 1/8 step with CARDTY[2:0], from 0/8 up to 7/8 duty cycle. When CARDTY[2:0] = 000 (duty cycle = 0/8), the output waveform only contains the starting pulse following the rising edge of the reference waveform, without any added carrier.

The pulselwidth of the initial pulse is defined using the STRPW[3:0] bitfield as follows: \( t_{1STPW} = (\text{STRPW}[3:0]+1) \times 16 \times t_{HRTIM} \) and ranges from 40 ns to 0.63 \( \mu \text{s} \) (for \( f_{HRTIM}=400 \text{ MHz} \)).

The carrier frequency parameters are defined based on the \( f_{HRTIM} \) frequency, and are not dependent from the CKPSC[2:0] setting.

In chopper mode, the carrier frequency and the initial pulselwidth are combined with the reference waveform using an AND function. A synchronization is performed at the end of the initial pulse to have a repetitive signal shape.

The chopping signal is stopped at the end of the output waveform active state, without waiting for the current carrier period to be completed. It can thus contain shorter pulses than programmed.

Figure 324. HRTIM outputs with Chopper mode enabled

![Fig324](MS32335V1)

Note: CHP1 and CHP2 bits must be set prior to the output enable done with TxyOEN bits in the HRTIM_OENR register.

CARFRQ[2:0], CARDTY[2:0] and STRPW[3:0] bitfields cannot be modified while the chopper mode is active (at least one of the two CHPx bits is set).

36.3.15 Fault protection

The HRTIMER has a versatile fault protection circuitry to disable the outputs in case of an abnormal operation. Once a fault has been triggered, the outputs take a predefined safe state. This state is maintained until the output is re-enabled by software. In case of a permanent fault request, the output will remain in its fault state, even if the software attempts to re-enable them, until the fault source disappears.

The HRTIM has 5 FAULT input channels; all of them are available and can be combined for each of the 5 timing units, as shown on Figure 325.
Figure 325. Fault protection circuitry (FAULT1 fully represented, FAULT2..5 partially)

Each fault channel is fully configurable using HRTIM_FLTINR1 and HRTIM_FLTINR2 registers before being routed to the timing units. FLTxSRC bit selects the source of the Fault signal, that can be either a digital input or an internal event (built-in comparator output).

Table 312 summarizes the available sources for each of the 10 faults channels:

<table>
<thead>
<tr>

</tbody>
</table>

The polarity of the signal can be selected to define the active level, using the FLTxP polarity bit in HRTIM_FLTINRx registers. If FLTxP = 0, the signal is active at low level; if FLTxP = 1, it is active when high.

The fault information can be filtered after the polarity setting. If FLTxF[3:0] bitfield is set to 0000, the signal is not filtered and will act asynchronously, independently from the f_HRTIM clock. For all other FLTxF[3:0] bitfield values, the signal is digitally filtered. The digital filter is made of a counter in which a number N of valid samples is needed to validate a transition on the output. If the input value changes before the counter has reached the value N, the counter is reset and the transition is discarded (considered as a spurious event). If the counter reaches N, the transition is considered as valid and transmitted as a correct external
event. Consequently, the digital filter adds a latency to the external events being filtered, depending on the sampling clock and on the filter length (number of valid samples expected). Figure 326 shows how a spurious fault signal is filtered.

Figure 326. Fault signal filtering (FLTxF[3:0]= 0010: f\textsubscript{SAMPLING} = f\textsubscript{HRTIM}, N = 4)

The filtering period ranges from 2 cycles of the f\textsubscript{HRTIM} clock up to 8 cycles of the f\textsubscript{FLTS} clock divided by 32. f\textsubscript{FLTS} is defined using FLTSD[1:0] bits in the HRTIM\_FLTINR2 register. Table 313 summarizes the sampling rate and the filter length. A jitter of 1 sampling clock period must be subtracted from the filter length to take into account the uncertainty due to the sampling and have the effective filtering.

Table 313. Sampling rate and filter length vs FLTFxF[3:0] and clock setting

</tbody>
</table>
System fault input (hrtim_sys_flt)
This fault is provided by the MCU Class B circuitry (see the System configuration controller (SYSCFG) section for details) and corresponds to a system fault coming from:

- the Clock Security System
- the SRAM parity checker
- the Cortex®-M7-lockup signal
- the PVD detector

This input overrides the FAULT inputs and disables all outputs having FAULTy[1:0] = 01, 10, 11.

For each FAULT channel, a write-once FLTxLCK bit in the HRTIM_FLTxR register allows to lock FLTxE, FLTxP, FLTxSRC, FLTxF[3:0] bits (it renders them read-only), for functional safety purpose. If enabled, the fault conditioning set-up is frozen until the next HRTIM or system reset.

Once the fault signal is conditioned as explained above, it is routed to the timing units. For any of them, the 5 fault channels are enabled using bits FLT1EN to FLT5EN in the HRTIM_FLTxR register, and they can be selected simultaneously (the sysfault is automatically enabled as long as the output is protected by the fault mechanism). This allows to have, for instance:

- One fault channel simultaneously disabling several timing units
- Multiple fault channels being ORed to disable a single timing unit

A write-once FLTLCK bit in the HRTIM_FLTxR register allows to lock FLTxEN bits (it renders them read-only) until the next reset, for functional safety purpose. If enabled, the timing unit fault-related set-up is frozen until the next HRTIM or system reset.

For each of the timers, the output state during a fault is defined with FAULT1[1:0] and FAULT2[1:0] bits in the HRTIM_OUTxR register (see Section 36.3.12).

36.3.16 Auxiliary outputs
Timer A to E have auxiliary outputs in parallel with the regular outputs going to the output stage. They provide the following internal status, events and signals:

- SETxy and RSTxy status flags, together with the corresponding interrupts and DMA requests
- Capture triggers upon output set/reset
- External event filters following a Tx2 output copy (see details in Section 36.3.8)
The auxiliary outputs are taken either before or after the burst mode controller, depending on the HRTIM operating mode. An overview is given on Figure 327.

**Figure 327. Auxiliary outputs**

By default, the auxiliary outputs are copies of outputs Tx1 and Tx2. The exceptions are:

- The delayed idle and the balanced idle protections, when the deadtime is disabled (DTEN = 0). When the protection is triggered, the auxiliary outputs are maintained and follow the signal coming out of the crossbar. On the contrary, if the deadtime is enabled (DTEN = 1), both main and auxiliary outputs are forced to an inactive level.

- The burst mode (TCEN=1, IDLEMx=1); there are 2 cases:
  a) If DTEN=0 or DIDLx=0, the auxiliary outputs are not affected by the burst mode entry and continue to follow the reference signal coming out of the crossbar (see Figure 328).
  b) If the deadtime is enabled (DTEN=1) together with the delayed burst mode entry (DIDLx=1), the auxiliary outputs have the same behavior as the main outputs. They are forced to the IDLES level after a deadtime duration, then they keep this level during all the burst period. When the burst mode is terminated, the IDLES level is maintained until a transition occurs to the opposite level, similarly to the main output.
The signal on the auxiliary output can be slightly distorted when exiting from the burst mode or when re-enabling the outputs after a delayed protection, if this happens during a deadtime. In this case, the deadtime applied to the auxiliary outputs is extended so that the deadtime on the main outputs is respected. *Figure 329* gives some examples.

**Figure 328. Auxiliary and main outputs during burst mode (DIDLx = 0)**

![Diagram of auxiliary and main outputs during burst mode](image1)

**Figure 329. Deadtime distortion on auxiliary output when exiting burst mode**

![Diagram of deadtime distortion on auxiliary output](image2)
### 36.3.17 Synchronizing the HRTIM with other timers or HRTIM instances

The HRTIM provides options for synchronizing multiple HRTIM instances, as a master unit (generating a synchronization signal) or as a slave (waiting for a trigger to be synchronized). This feature can also be used to synchronize the HRTIM with other timers, either external or on-chip. The synchronization circuitry is controlled inside the master timer.

#### Synchronization output

This section explains how the HRTIM must be configured to synchronize external resources and act as a master unit.

Four events can be selected as the source to be sent to the synchronization output. This is done using SYNCSRC[1:0] bits in the HRTIM_MCR register, as follows:

- **00**: Master timer Start
  This event is generated when MCEN bit is set or when the timer is re-started after having reached the period value in single-shot mode. It is also generated on a reset which occurs during the counting (when CONT or RETRIG bits are set).

- **01**: Master timer Compare 1 event

- **10**: Timer A start
  This event is generated when TACEN bit is set or when the counter is reset and re-starts counting in response to this reset. The following counter reset events are not propagated to the synchronization output: counter roll-over in continuous mode, and discarded reset request in single-shot non-retriggerable mode. The reset is only taken into account when it occurs during the counting (CONT or RETRIG bits are set).

- **11**: Timer A Compare 1 event

SYNCSRC[1:0] bits in the HRTIM_MCR register specify how the synchronization event is generated.

The synchronization pulses are generated on the HRTIM_SCOUT output pin, with SYNCSRC[1:0] = 1x. SYNCSRC[0] bit specifies the polarity of the synchronization signal. If SYNCSRC[0] = 0, the HRTIM_SCOUT pin has a low idle level and issues a positive pulse of 16 \(f_{HRTIM}\) clock cycles length for the synchronization). If SYNCSRC[0] = 1, the idle level is high and a negative pulse is generated.

**Note:** The synchronization pulse is followed by an idle level of 16 \(f_{HRTIM}\) clock cycles during which any new synchronization request is discarded. Consequently, the maximum synchronization frequency is \(f_{HRTIM}/32\).

The idle level on the HRTIM_SCOUT pin is applied as soon as the SYNCSRC[1:0] bits are enabled (i.e. the bitfield value is different from 00).

The synchronization output initialization procedure must be done prior to the configuration of the MCU outputs and counter enable, in the following order:

1. SYNCSRC[1:0] and SYNCSRC[1:0] bitfield configuration in HRTIM_MCR
2. HRTIM_SCOUT pin configuration (see the General-purpose I/Os section)
3. Master or Timer A counter enable (MCEN or TACEN bit set)

When the synchronization input mode is enabled and starts the counter (using SYNCTRTM/SYNCTRTx bits) simultaneously with the synchronization output mode (SYNCSRC[1:0] = 00 or 10), the output pulse is generated only when the counter is starting or is reset while running. Any reset request clearing the counter without causing it to start will not affect the synchronization output.
Synchronization input

The HRTIM can be synchronized by external sources, as per the programming of the SYNCIN[1:0] bits in the HRTIM_MCR register:

- 00: synchronization input is disabled
- 01: reserved configuration
- 10: the on-chip TIM1 general purpose timer (TIM1 TRGO output)
- 11: a positive pulse on the HRTIM_SCIN input pin

This bitfield cannot be changed once the destination timer (master timer or timing unit) is enabled (MCEN and/or TxCEN bit set).

The HRTIM_SCIN input is rising-edge sensitive. The timer behavior is defined with the following bits present in HRTIM_MCR and HRTIM_TIMxCR registers (see Table 314 for details):

- Synchronous start: the incoming signal starts the timer’s counter (SYNCSTRTM and/or SYNCRSTx bits set). TxCEN (MCEN) bits must be set to have the timer enabled and the counter ready to start. In continuous mode, the counter will not start until the synchronization signal is received.
- Synchronous reset: the incoming signal resets the counter (SYNCRSTM and/or SYNCRSTx bits set). This event decrements the repetition counter as any other reset event.

The synchronization events are taken into account only once the related counters are enabled (MCEN or TxCEN bit set). A synchronization request triggers a SYNC interrupt.

Note: A synchronized start event resets the counter if the current counter value is above the active period value.

The effect of the synchronization event depends on the timer operating mode, as summarized in Table 314.

36.3.18 ADC triggers

The ADCs can be triggered by the master and the 5 timing units.

4 independent triggers are available to start both the regular and the injected sequencers of the 2 ADCs. Up to 32 events can be combined (ORed) for each trigger output, in registers HRTIM_ADC1R to HRTIM_ADC4R, as shown on Figure 331. Triggers 1/3 and 2/4 are using the same source set.

The external events can be used as a trigger. They are taken right after the conditioning defined in HRTIM_EECRx registers, and are not depending on EEFxR1 and EEFxR2 register settings.

Multiple triggering is possible within a single switching period by selecting several sources simultaneously. A typical use case is for a non-overlapping multiphase converter, where all phases can be sampled in a row using a single ADC trigger output.
HRTIM_ADC1R to HRTIM_ADC4R registers are preloaded and can be updated synchronously with the timer they are related to. The update source is defined with ADxUSRC[2:0] bits in the HRTIM_CR1 register.

For instance, if ADC trigger 1 outputs Timer A CMP2 events (HRTIM_ADC1R = 0x0000 0400), HRTIM_ADC1R will be typically updated simultaneously with Timer A (AD1USRC[2:0] = 001).

When the preload is disabled (PREEN bit reset) in the source timer, the HRTIM_ADCxR registers are not preloaded either: a write access will result in an immediate update of the trigger source.

### 36.3.19 DAC triggers

The HRTIMER allows to have the embedded DACs updated synchronously with the timer updates.

The update events from the master timer and the timer units can generate DAC update triggers on any of the 3 hrtim_dac_trgx outputs.

**Note:** Each timer has its own DAC-related control register.

DACSYNC[1:0] bits of the HRTIM_MCR and HRTIM_TIMxCR registers are programmed as follows:

- 00: No update generated
- 01: Update generated on hrtim_dac_trg1
- 10: Update generated on hrtim_dac_trg2
- 11: Update generated on hrtim_dac_trg3

An output pulse of 1 fHRTIM clock periods is generated on the hrtim_dac_trgx output.
When DACSYNC[1:0] bits are enabled in multiple timers, the hrtim_dac_trgx output will consist of an OR of all timers’ update events. For instance, if DACSYNC = 1 in timer A and in timer B, the update event in timer A will be ORed with the update event in timer B to generate a DAC update trigger on the corresponding hrtim_dac_trgx output, as shown on Figure 332.

**Figure 332. Combining several updates on a single hrtim_dac_trgx output**

hrtim_dac_trgx pins are connected to the DACs as follows:

- hrtim_dac_trg1: DAC1_CH1 trigger input 9 (TSEL1[2:0] = 1001 in DAC_CR of DAC1 peripheral)
- hrtim_dac_trg2: DAC1_CH2 trigger input 10 (TSEL1[2:0] = 1010 in DAC_CR of DAC1 peripheral)
- hrtim_dac_trg3: not connected
36.3.20 **HRTIM Interrupts**

7 interrupts can be generated by the master timer:
- Master timer registers update
- Synchronization event received
- Master timer repetition event
- Master Compare 1 to 4 event

14 interrupts can be generated by each timing unit:
- Delayed protection triggered
- Counter reset or roll-over event
- Output 1 and output 2 reset (transition active to inactive)
- Output 1 and output 2 set (transition inactive to active)
- Capture 1 and 2 events
- Timing unit registers update
- Repetition event
- Compare 1 to 4 event

8 global interrupts are generated for the whole HRTIM:
- System fault and Fault 1 to 5 (regardless of the timing unit attribution)
- Burst mode period completed

The interrupt requests are grouped in 7 vectors as follows:
- hrtim_mst_it: Master timer interrupts (Master Update, Sync Input, Repetition, MCMP1..4) and global interrupt except faults (Burst mode period)
- hrtim_tima_it: TIMA interrupts
- hrtim_timb_it: TIMB interrupts
- hrtim_timc_it: TIMC interrupts
- hrtim_timd_it: TIMD interrupts
- hrtim_time_it: TIME interrupts
- hrtim_fault_it: Dedicated vector all fault interrupts to allow high-priority interrupt handling

*Table 315* is a summary of the interrupt requests, their mapping and associated control, and status bits.

36.3.21 DMA

Most of the events able to generate an interrupt can also generate a DMA request, even both simultaneously. Each timer (master, TIMA...E) has its own DMA enable register.

The individual DMA requests are ORed into 6 channels as follows:
- 1 channel for the master timer
- 1 channel per timing unit

Note: Before disabling a DMA channel (DMA enable bit reset in TIMxDIER), it is necessary to disable first the DMA controller.

Table 316 is a summary of the events with their associated DMA enable bits.

Burst DMA transfers

In addition to the standard DMA requests, the HRTIM features a DMA burst controller to have multiple registers updated with a single DMA request. This allows to:

- update multiple data registers with one DMA channel only,
- reprogram dynamically one or several timing units, for converters using multiple timer outputs.

The burst DMA feature is only available for one DMA channel, but any of the 6 channels can be selected for burst DMA transfers.

The principle is to program which registers are to be written by DMA. The master timer and TIMA..E have the burst DMA update register, where most of their control and data registers are associated with a selection bit: HRTIM_BDMUPR, HRTIM_BDTAUPR to HRTIM_BDTEUPR (this is applicable only for registers with write accesses). A redirection mechanism allows to forward the DMA write accesses to the HRTIM registers automatically, as shown on Figure 333.

**Figure 333. DMA burst overview**

When the DMA trigger occurs, the HRTIM generates multiple 32-bit DMA requests and parses the update register. If the control bit is set, the write access is redirected to the associated register. If the bit is reset, the register update is skipped and the register parsing is resumed until a new bit set is detected, to trigger a new request. Once the 6 update registers (HRTIM_BDMUPR, 5x HRTIM_BDTxUPR) are parsed, the burst is completed and the system is ready for another DMA trigger (see the flowchart on Figure 334).

**Note:** Any trigger occurring while the burst is on-going is discarded, except if it occurs during the very last data transfer.

The burst DMA mode is permanently enabled (there is no enable bit). A burst DMA operation is started by the first write access into the HRTIM_BDMADR register.
It is only necessary to have the DMA controller pointing to the HRTIM_BDMADR register as the destination, in the memory, to the peripheral configuration with the peripheral increment mode disabled (the HRTIM handles internally the data re-routing to the final destination register).

To re-initialize the burst DMA mode if it was interrupted during a transaction, it is necessary to write at least to one of the 6 update registers.

Several options are available once the DMA burst is completed, depending on the register update strategy.

If the PREEN bit is reset (preload disabled), the value written by the DMA is immediately transferred into the active register and the registers are updated sequentially, following the DMA transaction pace.

When the preload is enabled (PREEN bit set), there are 3 use cases:

1. The update is done independently from DMA burst transfers (UPDGAT[3:0] = 0000 in HRTIM_TIMxCR and BRSTDMA[1:0] = 00 in HRTIM_MCR). In this case, and if it is necessary to have all transferred data taken into account simultaneously, the user must check that the DMA burst is completed before the update event takes place. On the contrary, if the update event happens while the DMA transfer is on-going, only part of the registers will be loaded and the complete register update will require 2 consecutive update events.

2. The update is done when the DMA burst transfer is completed (UPDGAT[3:0] = 0000 in HRTIM_TIMxCR and BRSTDMA[1:0] = 01 in HRTIM_MCR). This mode guarantees that all new register values are transferred simultaneously. This is done independently
from the counter value and can be combined with regular update events, if necessary (for instance, an update on a counter reset when TxRSTU is set).

3. The update is done on the update event following the DMA burst transfer completion (UPDGAT[3:0] = 0010 in HRTIM_TIMxCR and BRSTDMA[1:0] = 10 in HRTIM_MCR). This mode guarantees both a coherent update of all transferred data and the synchronization with regular update events, with the timer counter. In this case, if a regular update request occurs while the transfer is on-going, it will be discarded and the effective update will happen on the next coming update request.

The chronogram on Figure 335 presents the active register content for 3 cases: PREEN=0, UPDGAT[3:0] = 0001 and UPDGAT[3:0] = 0001 (when PREEN = 1).

Figure 335. Registers update following DMA burst transfer

36.3.22 HRTIM initialization

This section describes the recommended HRTIM initialization procedure, including other related MCU peripherals.

The HRTIM clock source must be enabled in the Reset and Clock control unit (RCC).

The HRTIM control registers can be initialized as per the power converter topology and the timing units use case. All inputs have to be configured (source, polarity, edge-sensitivity).
The HRTIM outputs must be set up eventually, with the following sequence:

- the polarity must be defined using POLx bits in HRTIM_OUTxR
- the FAULT and IDLE states must be configured using FAULTx[1:0] and IDLESx bits in HRTIM_OUTxR

The HRTIM outputs are ready to be connected to the MCU I/Os. In the GPIO controller, the selected HRTIM I/Os have to be configured as per the alternate function mapping table in the product datasheet.

From this point on, the HRTIM controls the outputs, which are in the IDLE state.

The outputs are configured in RUN mode by setting TxyOEN bits in the HRTIM_OENR register. The 2 outputs are in the inactive state until the first valid set/reset event in RUN mode. Any output set/reset event (except software requests using SST, SRT) are ignored as long as TxCEN bit is reset, as well as burst mode requests (IDLEM bit value is ignored). Similarly, any counter reset request coming from the burst mode controller is ignored (if TxBM bit is set).

**Note:** When the deadtime insertion is enabled (DTEN bit set), it is necessary to force the output state by software, using SST and RST bits, to have the outputs in a complementary state as soon as the RUN mode is entered.

The HRTIM operation can eventually be started by setting TxCEN or MCEN bits in HRTIM_MCR.

If the HRTIM peripheral is reset with the Reset and Clock Controller, the HRTIM outputs are put in IDLE mode with a low level. It is recommended to first disconnect the HRTIMER from the outputs (using the GPIO controller) before performing a peripheral reset.

### 36.3.23 Debug

When a microcontroller enters the debug mode (Cortex®-M7 core halted), the TIMx counter either continues to work normally or stops, depending on DBG_HRTIM_STOP configuration bit in DBG module:

- **DBG_HRTIM_STOP = 0**: no behavior change, the HRTIM continues to operate.
- **DBG_HRTIM_STOP = 1**: all HRTIM timers, including the master, are stopped. The outputs in RUN mode enter the FAULT state if FAULTx[1:0] = 01, 10, 11, or keep their current state if FAULTx[1:0] = 00. The outputs in idle state are maintained in this state. This is permanently maintained even if the MCU exits the halt mode. This allows to maintain a safe state during the execution stepping. The outputs can be enabled again by settings TxyOEN bit (requires the use of the debugger).

**Timer behavior during MCU halt when DBG_HRTIM_STOP = 1**

The set/reset crossbar, the dead-time and push-pull unit, the idle/balanced fault detection and all the logic driving the normal output in RUN mode are not affected by debug. The output will keep on toggling internally, so as to retrieve regular signals of the outputs when TxyOEN will be set again (during or after the MCU halt). Associated triggers and filters are also following internal waveforms when the outputs are disabled.

FAULT inputs and events (any source) are enabled during the MCU halt.

Fault status bits can be set and TxyOEN bits reset during the MCU halt if a fault occurs at that time (TxyOEN and TxyODS are not affected by DBG_HRTIM_STOP bit state).
Synchronization, counter reset, start and reset-start events are discarded in debug mode, as well as capture events. This is to keep all related registers stable as long as the MCU is halted.

The counter stops counting when a breakpoint is reached. However, the counter enable signal is not reset; consequently no start event will be emitted when exiting from debug. All counter reset and capture triggers are disabled, as well as external events (ignored as long as the MCU is halted). The outputs SET and RST flags are frozen, except in case of forced software set/reset. A level-sensitive event is masked during the debug but will be active again as soon as the debug will be exited. For edge-sensitive events, if the signal is maintained active during the MCU halt, a new edge is not generated when exiting from debug.

The update events are discarded. This prevents any update trigger on hrtim_upd_en[3:1] inputs. DMA triggers are disabled. The burst mode circuit is frozen: the triggers are ignored and the burst mode counter stopped.

### 36.4 Application use cases

#### 36.4.1 Buck converter

Buck converters are of common use as step-down converters. The HRTIM can control up to 10 buck converters with 6 independent switching frequencies.

The converter usually operates at a fixed frequency and the Vin/Vout ratio depends on the duty cycle D applied to the power switch:

\[ V_{out} = D \times V_{in} \]

The topology is given on Figure 336 with the connection to the ADC for voltage reading.

![Figure 336. Buck converter topology](image)

*Figure 337 presents the management of two converters with identical frequency PWM signals. The outputs are defined as follows:

- HRTIM_CHA1 set on period, reset on CMP1
- HRTIM_CHA2 set on CMP3, reset on PER

The ADC is triggered twice per period, precisely in the middle of the ON time, using CMP2 and CMP4 events.*
Timers A..E provide either 10 buck converters coupled by pairs (both with identical switching frequencies) or 6 completely independent converters (each of them having a different switching frequency), using the master timer as the 6th time base.

36.4.2 Buck converter with synchronous rectification

Synchronous rectification allows to minimize losses in buck converters, by means of a FET replacing the freewheeling diode. Synchronous rectification can be turned on or off on the fly depending on the output current level, as shown on Figure 338.

The main difference vs. a single-switch buck converter is the addition of a deadtime for an almost complementary waveform generation on HRTIM_CHA2, based on the reference waveform on HRTIM_CHA1 (see Figure 339).
36.4.3 Multiphase converters

Multiphase techniques can be applied to multiple power conversion topologies (buck, flyback). Their main benefits are:

- Reduction of the current ripple on the input and output capacitors
- Reduced EMI
- Higher efficiency at light load by dynamically changing the number of phases (phase shedding)

The HRTIM is able to manage multiple converters. The number of converters that can be controlled depends on the topologies and resources used (including the ADC triggers):

- 5 buck converters with synchronous rectification (SR), using the master timer and the 5 timers
- 4 buck converters (without SR), using the master timer and 2 timers
- ...

*Figure 341* presents the topology of a 3-phase interleaved buck converter.
The master timer is responsible for the phase management: it defines the phase relationship between the converters by resetting the timers periodically. The phase-shift is 360° divided by the number of phases, 120° in the given example.

The duty cycle is then programmed into each of the timers. The outputs are defined as follows:

- HRTIM_CHA1 set on master timer period, reset on TACMP1
- HRTIM_CHB1 set on master timer MCMP1, reset on TBCMP1
- HRTIM_CHC1 set on master timer MCMP2, reset on TCCMP1

The ADC trigger can be generated on TxCMP2 compare event. Since all ADC trigger sources are phase-shifted because of the converter topology, it is possible to have all of them combined into a single ADC trigger to save ADC resources (for instance 1 ADC regular channel for the full multi-phase converter).
### 36.4.4 Transition mode Power Factor Correction

The basic operating principle is to build up current into an inductor during a fixed Ton time. This current will then decay during the Toff time, and the period will be re-started when it becomes null. This is detected using a Zero Crossing Detection circuitry (ZCD), as shown on Figure 342. With a constant Ton time, the peak current value in the inductor is proportional to the rectified AC input voltage, which provides the power factor correction.

![Figure 342. Transition mode PFC](MS32348V2)

![Figure 341. 3-phase interleaved buck converter control](MS32349V3)
This converter is operating with a constant Ton time and a variable frequency due the Toff time variation (depending on the input voltage). It must also include some features to operate when no zero-crossing is detected, or to limit the Ton time in case of over-current (OC). The OC feedback is usually conditioned with the built-in comparator and routed onto an external event input.

*Figure 343* presents the waveform during the various operating modes, with the following parameters defined:

- **Ton Min**: masks spurious overcurrent (freewheeling diode recovery current), represented as OC blanking
- **Ton Max**: practically, the converter set-point. It is defined by CMP1
- **Toff Min**: limits the frequency when the current limit is close to zero (demagnetization is very fast). It is defined with CMP2.
- **Toff Max**: prevents the system to be stuck if no ZCD occurs. It is defined with CMP4 in auto-delayed mode.

Both Toff values are auto-delayed since the value must be relative to the output falling edge.

*Figure 343. Transition mode PFC waveforms*
36.5 HRTIM registers

36.5.1 HRTIM Master Timer Control Register (HRTIM_MCR)

Address offset: 0x0000h

Bits 31:30 **BRSTDMA[1:0]: Burst DMA Update**

These bits define how the update occurs relatively to a burst DMA transaction.
00: Update done independently from the DMA burst transfer completion
01: Update done when the DMA burst transfer is completed
10: Update done on master timer roll-over following a DMA burst transfer completion. This mode only works in continuous mode.
11: reserved

Bit 29 **MREPU: Master Timer Repetition update**

This bit defines whether an update occurs when the master timer repetition period is completed (either due to roll-over or reset events). MREPU can be set only if BRSTDMA[1:0] = 00 or 01.
0: Update on repetition disabled
1: Update on repetition enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 **PREEN: Preload enable**

This bit enables the registers preload mechanism and defines whether the write accesses to the memory mapped registers are done into HRTIM active or preload registers.
0: Preload disabled: the write access is directly done into the active register
1: Preload enabled: the write access is done into the preload register

Bits 26:25 **DACSYNC[1:0]: DAC Synchronization**

A DAC synchronization event can be enabled and generated when the master timer update occurs. These bits are defining on which output the DAC synchronization is sent (refer to Section 36.3.19: DAC triggers for connections details).
00: No DAC trigger generated
01: Trigger generated on hrtim_dac_trg1
10: Trigger generated on hrtim_dac_trg2
11: Trigger generated on hrtim_dac_trg3

Bits 24:22 Reserved, must be kept at reset value.

Bit 21 **TECEN: Timer E counter enable**

This bit starts the Timer E counter.
0: Timer E counter disabled
1: Timer E counter enabled

**Note:** This bit must not be changed within a minimum of 8 cycles of f_HRTIM clock.
Bit 20 **TDCEN**: Timer D counter enable
This bit starts the Timer D counter.
0: Timer D counter disabled
1: Timer D counter enabled
*Note*: This bit must not be changed within a minimum of 8 cycles of $f_{HRTIM}$ clock.

Bit 19 **TCCEN**: Timer C counter enable
This bit starts the Timer C counter.
0: Timer C counter disabled
1: Timer C counter enabled
*Note*: This bit must not be changed within a minimum of 8 cycles of $f_{HRTIM}$ clock.

Bit 18 **TBCEN**: Timer B counter enable
This bit starts the Timer B counter.
0: Timer B counter disabled
1: Timer B counter enabled
*Note*: This bit must not be changed within a minimum of 8 cycles of $f_{HRTIM}$ clock.

Bit 17 **TACEN**: Timer A counter enable
This bit starts the Timer A counter.
0: Timer A counter disabled
1: Timer A counter enabled
*Note*: This bit must not be changed within a minimum of 8 cycles of $f_{HRTIM}$ clock.

Bit 16 **MCEN**: Master timer counter enable
This bit starts the Master timer counter.
0: Master counter disabled
1: Master counter enabled
*Note*: This bit must not be changed within a minimum of 8 cycles of $f_{HRTIM}$ clock.

Bits 15:14 **SYNCSRC[1:0]**: Synchronization source
These bits define the source and event to be sent on the synchronization outputs SYNCOU[2:1]
00: Master timer Start
01: Master timer Compare 1 event
10: Timer A start/reset
11: Timer A Compare 1 event

Bits 13:12 **SYNCOU[1:0]**: Synchronization output
These bits define the routing and conditioning of the synchronization output event.
00: disabled
01: Reserved.
10: Positive pulse on HRTIM_SCOUT output (16x $f_{HRTIM}$ clock cycles)
11: Negative pulse on HRTIM_SCOUT output (16x $f_{HRTIM}$ clock cycles)
*Note*: This bitfield must not be modified once the counter is enabled (TxCEN bit set)

Bit 11 **SYNCRSTM**: Synchronization Starts Master
This bit enables the Master timer start when receiving a synchronization input event:
0: No effect on the Master timer
1: A synchronization input event starts the Master timer

Bit 10 **SYNCSTRM**: Synchronization Resets Master
This bit enables the Master timer reset when receiving a synchronization input event:
0: No effect on the Master timer
1: A synchronization input event resets the Master timer
**Bits 9:8  **SYNCIN[1:0]  **Synchronization input  
These bits are defining the synchronization input source.
00: disabled. HRTIM is not synchronized and runs in standalone mode.
01: Reserved.
10: Internal event: the HRTIM is synchronized with the on-chip timer (see *Synchronization input*).
11: External event (input pin). A positive pulse on HRTIM_SCIN input triggers the HRTIM.  
*Note: This parameter cannot be changed once the impacted timers are enabled.*

**Bits 7:6  **Reserved, must be kept at reset value.

**Bit 5  **HALF:  **Half mode  
This bit enables the half duty-cycle mode: the HRTIM_MCMP1xR active register is automatically updated with HRTIM_MPER/2 value when HRTIM_MPER register is written.
0: Half mode disabled
1: Half mode enabled

**Bit 4  **RETRIG:  **Re-triggerable mode  
This bit defines the behavior of the master timer counter in single-shot mode.
0: The timer is not re-triggerable: a counter reset can be done only if the counter is stopped (period elapsed)
1: The timer is re-triggerable: a counter reset is done whatever the counter state (running or stopped)

**Bit 3  **CONT:  **Continuous mode  
0: The timer operates in single-shot mode and stops when it reaches the MPER value
1: The timer operates in continuous (free-running) mode and rolls over to zero when it reaches the MPER value

**Bits 2:0  **CKPSC[2:0]:  **Clock prescaler  
These bits define the master timer clock prescaler ratio.
The counter clock equivalent frequency ($f_{\text{COUNTER}}$) is equal to $f_{\text{HRCK}} / 2^{(\text{CKPSC}[2:0]-5)}$.
The prescaling ratio cannot be modified once the timer is enabled.
000: Reserved
001: Reserved
010: Reserved
011: Reserved
100: Reserved
101: $f_{\text{COUNTER}} = f_{\text{HRTIM}}$
110: $f_{\text{COUNTER}} = f_{\text{HRTIM}} / 2$
111: $f_{\text{COUNTER}} = f_{\text{HRTIM}} / 4$

#### Bit 6 MUPD: Master Update Interrupt Flag
This bit is set by hardware when the Master timer registers are updated.
- 0: No Master Update interrupt occurred
- 1: Master Update interrupt occurred

#### Bit 5 SYNC: Sync Input Interrupt Flag
This bit is set by hardware when a synchronization input event is received.
- 0: No Sync input interrupt occurred
- 1: Sync input interrupt occurred

#### Bit 4 MREP: Master Repetition Interrupt Flag
This bit is set by hardware when the Master timer repetition period has elapsed.
- 0: No Master Repetition interrupt occurred
- 1: Master Repetition interrupt occurred

#### Bit 3 MCMP4: Master Compare 4 Interrupt Flag
Refer to MCMP1 description

#### Bit 2 MCMP3: Master Compare 3 Interrupt Flag
Refer to MCMP1 description

#### Bit 1 MCMP2: Master Compare 2 Interrupt Flag
Refer to MCMP1 description

#### Bit 0 MCMP1: Master Compare 1 Interrupt Flag
This bit is set by hardware when the Master timer counter matches the value programmed in the master Compare 1 register.
- 0: No Master Compare 1 interrupt occurred
- 1: Master Compare 1 interrupt occurred
36.5.3 HRTIM Master Timer Interrupt Clear Register (HRTIM_MICR)

<tr>
<td>Bits 26:25 DACSYNC[1:0]: DAC Synchronization A DAC synchronization event is generated when the timer update occurs. These bits are defining on which output the DAC synchronization is sent (refer to Section 36.3.19: DAC triggers for connections details). 00: No DAC trigger generated 01: Trigger generated on hrtim_dac_trg1 10: Trigger generated on hrtim_dac_trg2 11: Trigger generated on hrtim_dac_trg3</td>
<td></td>
</tr>
</tbody>
</table>
Bit 24 **MSTU**: Master Timer update  
Register update is triggered by the master timer update.  
0: Update by master timer disabled  
1: Update by master timer enabled

Bit 23 In HRTIM_TIMACR, HRTIM_TIMBCR, HRTIM_TIMCCR, HRTIM_TIMDCR:  
**TEU**: Timer E update  
Register update is triggered by the timer E update  
0: Update by timer E disabled  
1: Update by timer E enabled

In HRTIM_TIMECR:  
Reserved, must be kept at reset value

Bit 22 In HRTIM_TIMACR, HRTIM_TIMBCR, HRTIM_TIMCCR, HRTIM_TIMDCR, HRTIM_TIMECR:  
**TDU**: Timer D update  
Register update is triggered by the timer D update  
0: Update by timer D disabled  
1: Update by timer D enabled

In HRTIM_TIMDCR:  
Reserved, must be kept at reset value

Bit 21 In HRTIM_TIMACR, HRTIM_TIMBCR, HRTIM_TIMCCR, HRTIM_TIMDCR, HRTIM_TIMECR:  
**TCU**: Timer C update  
Register update is triggered by the timer C update  
0: Update by timer C disabled  
1: Update by timer C enabled

In HRTIM_TIMCCR:  
Reserved, must be kept at reset value

Bit 20 In HRTIM_TIMACR, HRTIM_TIMBCR, HRTIM_TIMCCR, HRTIM_TIMDCR, HRTIM_TIMECR:  
**TBU**: Timer B update  
Register update is triggered by the timer B update  
0: Update by timer B disabled  
1: Update by timer B enabled

In HRTIM_TIMBCR:  
Reserved, must be kept at reset value

Bit 19 In HRTIM_TIMBCR, HRTIM_TIMCCR, HRTIM_TIMDCR, HRTIM_TIMECR:  
**TAU**: Timer A update  
Register update is triggered by the timer A update  
0: Update by timer A disabled  
1: Update by timer A enabled

In HRTIM_TIMACR:  
Reserved, must be kept at reset value
Bit 18  \textbf{TxRSTU}: Timer x reset update
Register update is triggered by Timerx counter reset or roll-over to 0 after reaching the period value in continuous mode.
0: Update by timer x reset / roll-over disabled
1: Update by timer x reset / roll-over enabled

Bit 17  \textbf{TxREPU}: Timer x Repetition update
Register update is triggered when the counter rolls over and HRTIM\_REP\_x = 0
0: Update on repetition disabled
1: Update on repetition enabled

Bit 16 Reserved, must be kept at reset value.

Bits 15:14  \textbf{DELCMP4}[1:0]: CMP4 auto-delayed mode
This bitfield defines whether the compare register is behaving in standard mode (compare match issued as soon as counter equal compare), or in auto-delayed mode (see \textit{Auto-delayed mode}).
00: CMP4 register is always active (standard compare mode)
01: CMP4 value is recomputed and is active following a capture 2 event
10: CMP4 value is recomputed and is active following a capture 2 event, or is recomputed and active after Compare 1 match (timeout function if capture 2 event is missing)
11: CMP4 value is recomputed and is active following a capture event, or is recomputed and active after Compare 3 match (timeout function if capture event is missing)
\textbf{Note}: This bitfield must not be modified once the counter is enabled (\textit{TxCEN} bit set)

Bits 13:12  \textbf{DELCMP2}[1:0]: CMP2 auto-delayed mode
This bitfield defines whether the compare register is behaving in standard mode (compare match issued as soon as counter equal compare), or in auto-delayed mode (see \textit{Auto-delayed mode}).
00: CMP2 register is always active (standard compare mode)
01: CMP2 value is recomputed and is active following a capture 1 event
10: CMP2 value is recomputed and is active following a capture 1 event, or is recomputed and active after Compare 1 match (timeout function if capture event is missing)
11: CMP2 value is recomputed and is active following a capture 1 event, or is recomputed and active after Compare 3 match (timeout function if capture event is missing)
\textbf{Note}: This bitfield must not be modified once the counter is enabled (\textit{TxCEN} bit set)

Bit 11  \textbf{SYNCSTRTx}: Synchronization Starts Timer x
This bit defines the Timer x behavior following the synchronization event:
0: No effect on Timer x
1: A synchronization input event starts the Timer x

Bit 10  \textbf{SYNCRSTx}: Synchronization Resets Timer x
This bit defines the Timer x behavior following the synchronization event:
0: No effect on Timer x
1: A synchronization input event resets the Timer x

Bits 9:7 Reserved, must be kept at reset value.

Bit 6  \textbf{PSHPLL}: Push-Pull mode enable
This bit enables the push-pull mode.
0: Push-Pull mode disabled
1: Push-Pull mode enabled
\textbf{Note}: This bitfield must not be modified once the counter is enabled (\textit{TxCEN} bit set)
Bit 5  **HALF: Half mode enable**
This bit enables the half duty-cycle mode: the HRTIM_CMP1xR active register is automatically updated with HRTIM_PERxR/2 value when HRTIM_PERxR register is written.
0: Half mode disabled
1: Half mode enabled

Bit 4  **RETRIG: Re-triggerable mode**
This bit defines the counter behavior in single shot mode.
0: The timer is not re-triggerable: a counter reset is done if the counter is stopped (period elapsed in single-shot mode or counter stopped in continuous mode)
1: The timer is re-triggerable: a counter reset is done whatever the counter state.

Bit 3  **CONT: Continuous mode**
This bit defines the timer operating mode.
0: The timer operates in single-shot mode and stops when it reaches TIMxPER value
1: The timer operates in continuous mode and rolls over to zero when it reaches TIMxPER value

**Bits 2:0 CKPSCx[2:0]: HRTIM Timer x Clock prescaler**
These bits define the master timer clock prescaler ratio.
The counter clock equivalent frequency (fCOUNTER) is equal to fHRCK / 2^{(CKPSC[2:0]-5)}.
The prescaling ratio cannot be modified once the timer is enabled.
000: Reserved
001: Reserved
010: Reserved
011: Reserved
100: Reserved
101: fCOUNTER = fHRTIM
110: fCOUNTER = fHRTIM / 2
111: fCOUNTER = fHRTIM / 4
### 36.5.13 HRTIM Timerx Interrupt Status Register (HRTIM_TIMxISR)

Address offset: 0x0004h (this offset address is relative to timer x base address)
Reset value: 0x0000 0000

| Bit 31:22 | Reserved, must be kept at reset value. |
| Bit 21   | **O2CPY**: Output 2 Copy |
|          | This status bit is a raw copy of the output 2 state, before the output stage (chopper, polarity). It allows to check the current output state before re-enabling the output after a delayed protection. |
|          | 0: Output 2 is inactive  |
|          | 1: Output 2 is active   |
| Bit 20   | **O1CPY**: Output 1 Copy |
|          | This status bit is a raw copy of the output 1 state, before the output stage (chopper, polarity). It allows to check the current output state before re-enabling the output after a delayed protection. |
|          | 0: Output 1 is inactive  |
|          | 1: Output 1 is active   |
| Bit 19   | **O2STAT**: Output 2 Status |
|          | This status bit indicates the output 2 state when the delayed idle protection was triggered. This bit is updated upon any new delayed protection entry. This bit is not updated in balanced idle. |
|          | 0: Output 2 was inactive  |
|          | 1: Output 2 was active   |
| Bit 18   | **O1STAT**: Output 1 Status |
|          | This status bit indicates the output 1 state when the delayed idle protection was triggered. This bit is updated upon any new delayed protection entry. This bit is not updated in balanced idle. |
|          | 0: Output 1 was inactive  |
|          | 1: Output 1 was active   |
| Bit 17   | **IPPSTAT**: Idle Push Pull Status |
|          | This status bit indicates on which output the signal was applied, in push-pull mode balanced fault mode or delayed idle mode, when the protection was triggered (whatever the output state, active or inactive). |
|          | 0: Protection occurred when the output 1 was active and output 2 forced inactive |
|          | 1: Protection occurred when the output 2 was active and output 1 forced inactive |
| Bit 16   | **CPPSTAT**: Current Push Pull Status |
|          | This status bit indicates on which output the signal is currently applied, in push-pull mode. It is only significant in this configuration. |
|          | 0: Signal applied on output 1 and output 2 forced inactive |
|          | 1: Signal applied on output 2 and output 1 forced inactive |
| Bit 15   | Reserved |
| Bit 14   | **DLYPRT**: Delayed Protection Flag |
|          | This bit indicates delayed idle or the balanced idle mode entry. |
Bit 13  **RST**: Reset and/or roll-over Interrupt Flag  
This bit is set by hardware when the timer x counter is reset or rolls over in continuous mode.  
0: No TIMx counter reset/roll-over interrupt occurred  
1: TIMx counter reset/roll-over interrupt occurred

Bit 12  **RSTx2**: Output 2 Reset Interrupt Flag  
Refer to RSTx1 description

Bit 11  **SETx2**: Output 2 Set Interrupt Flag  
Refer to SETx1 description

Bit 10  **RSTx1**: Output 1 Reset Interrupt Flag  
This bit is set by hardware when the Tx1 output is reset (goes from active to inactive mode).  
0: No Tx1 output reset interrupt occurred  
1: Tx1 output reset interrupt occurred

Bit 9  **SETx1**: Output 1 Set Interrupt Flag  
This bit is set by hardware when the Tx1 output is set (goes from inactive to active mode).  
0: No Tx1 output set interrupt occurred  
1: Tx1 output set interrupt occurred

Bit 8  **CPT2**: Capture2 Interrupt Flag  
Refer to CPT1 description

Bit 7  **CPT1**: Capture1 Interrupt Flag  
This bit is set by hardware when the timer x capture 1 event occurs.  
0: No timer x Capture 1 reset interrupt occurred  
1: Timer x output 1 reset interrupt occurred

Bit 6  **UPD**: Update Interrupt Flag  
This bit is set by hardware when the timer x update event occurs.  
0: No timer x update interrupt occurred  
1: Timer x update interrupt occurred

Bit 5  Reserved, must be kept at reset value.

Bit 4  **REP**: Repetition Interrupt Flag  
This bit is set by hardware when the timer x repetition period has elapsed.  
0: No timer x repetition interrupt occurred  
1: Timer x repetition interrupt occurred

Bit 3  **CMP4**: Compare 4 Interrupt Flag  
Refer to CMP1 description

Bit 2  **CMP3**: Compare 3 Interrupt Flag  
Refer to CMP1 description

Bit 1  **CMP2**: Compare 2 Interrupt Flag  
Refer to CMP1 description

Bit 0  **CMP1**: Compare 1 Interrupt Flag  
This bit is set by hardware when the timer x counter matches the value programmed in the  
Compare 1 register.  
0: No Compare 1 interrupt occurred  
1: Compare 1 interrupt occurred
### HRTIM Timerx Interrupt Clear Register (HRTIM_TIMxICR)

**Bit 31** Res.

**Bit 30** DLYPR TDE: Delayed Protection DMA request Enable
- This bit is set and cleared by software to enable/disable DMA requests on delayed protection.
  - 0: Delayed protection DMA request disabled
  - 1: Delayed protection DMA request enabled

**Bit 29** RSTDE: Reset/roll-over DMA request Enable
- This bit is set and cleared by software to enable/disable DMA requests on timer x counter reset or roll-over in continuous mode.
  - 0: Timer x counter reset/roll-over DMA request disabled
  - 1: Timer x counter reset/roll-over DMA request enabled

**Bit 28** RSTx2DE: Output 2 Reset DMA request Enable
- Refer to RSTx1DE description

**Bit 27** SETx2DE: Output 2 Set DMA request Enable
- Refer to SETx1DE description

**Bit 26** RSTx1DE: Output 1 Reset DMA request Enable
- This bit is set and cleared by software to enable/disable Tx1 output reset DMA requests.
  - 0: Tx1 output reset DMA request disabled
  - 1: Tx1 output reset DMA request enabled

**Bit 25** SETx1DE: Output 1 Set DMA request Enable
- This bit is set and cleared by software to enable/disable Tx1 output set DMA requests.
  - 0: Tx1 output set DMA request disabled
  - 1: Tx1 output set DMA request enabled

**Bit 24** CPT2DE: Capture 2 DMA request Enable
- Refer to CPT1DE description

**Bit 23** CPT1DE: Capture 1 DMA request Enable
- This bit is set and cleared by software to enable/disable Capture 1 DMA requests.
  - 0: Capture 1 DMA request disabled
  - 1: Capture 1 DMA request enabled

**Bit 22** UPDDE: Update DMA request Enable
- This bit is set and cleared by software to enable/disable DMA requests on update event.
  - 0: Update DMA request disabled
  - 1: Update DMA request enabled
Bit 21 Reserved, must be kept at reset value.

Bit 20 **REPDE**: Repetition DMA request Enable
- This bit is set and cleared by software to enable/disable DMA requests on repetition event.
  - 0: Repetition DMA request disabled
  - 1: Repetition DMA request enabled

Bit 19 **CMP4DE**: Compare 4 DMA request Enable
- Refer to CMP1DE description

Bit 18 **CMP3DE**: Compare 3 DMA request Enable
- Refer to CMP1DE description

Bit 17 **CMP2DE**: Compare 2 DMA request Enable
- Refer to CMP1DE description

Bit 16 **CMP1DE**: Compare 1 DMA request Enable
- This bit is set and cleared by software to enable/disable the Compare 1 DMA requests.
  - 0: Compare 1 DMA request disabled
  - 1: Compare 1 DMA request enabled

Bit 15 Reserved

Bit 14 **DLYPRTIE**: Delayed Protection Interrupt Enable
- This bit is set and cleared by software to enable/disable interrupts on delayed protection.
  - 0: Delayed protection interrupts disabled
  - 1: Delayed protection interrupts enabled

Bit 13 **RSTIE**: Reset/roll-over Interrupt Enable
- This bit is set and cleared by software to enable/disable interrupts on timer x counter reset or roll-over in continuous mode.
  - 0: Timer x counter reset/roll-over interrupt disabled
  - 1: Timer x counter reset/roll-over interrupt enabled

Bit 12 **RSTx2IE**: Output 2 Reset Interrupt Enable
- Refer to RSTx1IE description

Bit 11 **SETx2IE**: Output 2 Set Interrupt Enable
- Refer to SETx1IE description

Bit 10 **RSTx1IE**: Output 1 Reset Interrupt Enable
- This bit is set and cleared by software to enable/disable Tx1 output reset interrupts.
  - 0: Tx1 output reset interrupts disabled
  - 1: Tx1 output reset interrupts enabled

Bit 9 **SETx1IE**: Output 1 Set Interrupt Enable
- This bit is set and cleared by software to enable/disable Tx1 output set interrupts.
  - 0: Tx1 output set interrupts disabled
  - 1: Tx1 output set interrupts enabled

Bit 8 **CPT2IE**: Capture Interrupt Enable
- Refer to CPT1IE description

Bit 7 **CPT1IE**: Capture Interrupt Enable
- This bit is set and cleared by software to enable/disable Capture 1 interrupts.
  - 0: Capture 1 interrupts disabled
  - 1: Capture 1 interrupts enabled
Bit 6 **UPDIE**: Update Interrupt Enable
   This bit is set and cleared by software to enable/disable update event interrupts.
   0: Update interrupts disabled
   1: Update interrupts enabled

Bit 5 Reserved, must be kept at reset value.

Bit 4 **REPIE**: Repetition Interrupt Enable
   This bit is set and cleared by software to enable/disable repetition event interrupts.
   0: Repetition interrupts disabled
   1: Repetition interrupts enabled

Bit 3 **CMP4IE**: Compare 4 Interrupt Enable
   Refer to CMP1IE description

Bit 2 **CMP3IE**: Compare 3 Interrupt Enable
   Refer to CMP1IE description

Bit 1 **CMP2IE**: Compare 2 Interrupt Enable
   Refer to CMP1IE description

Bit 0 **CMP1IE**: Compare 1 Interrupt Enable
   This bit is set and cleared by software to enable/disable the Compare 1 interrupts.
   0: Compare 1 interrupt disabled
   1: Compare 1 interrupt enabled
36.5.16 HRTIM Timerx Counter Register (HRTIM_CNTxR)

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 PERx[15:0]: Timerx Period value
This register holds timer x period value.
This register holds either the content of the preload register or the content of the active register if preload is disabled.
The period value must be above or equal to 3 periods of the \( f_{HRTIM} \) clock.
The maximum value is 0x0000 FFDF.

1464/3289 RM0433 Rev 6
### 36.5.18 HRTIM Timerx Repetition Register (HRTIM_REPxR)

Address offset: 0x18h (this offset address is relative to timer x base address)

Reset value: 0x0000 0000

<table>
<thead>
<tr>

Bits 31:24 Reserved, must be kept at reset value.

- **Bits 23:16 REPx[7:0]: Timerx Repetition value (aliased from HRTIM_REPx register)**
  This bitfield is an alias from the REPx[7:0] bitfield in the HRTIMx_REPxR register.

- **Bits 15:0 CMP1x[15:0]: Timerx Compare 1 value**
  This bitfield is an alias from the CMP1x[15:0] bitfield in the HRTIMx_CMP1xR register.

### 36.5.21 HRTIM Timerx Compare 2 Register (HRTIM_CMP2xR)

Address offset: 0x24h (this offset address is relative to timer x base address)

Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

- **Bits 15:0 CMP2x[15:0]: Timerx Compare 2 value**
  This register holds the Compare 2 value.
  This register holds either the content of the preload register or the content of the active register if preload is disabled.
  The compare value must be above or equal to 3 periods of the f_HRTIM clock.
  This register can behave as an auto-delayed compare register, if enabled with DELCMP2[1:0] bits in HRTIM_TIMxCR.
### 36.5.22 HRTIM Timerx Compare 3 Register (HRTIM_CMP3xR)

Address offset: 0x28h (this offset address is relative to timer x base address)

Reset value: 0x0000 0000

</table>

**CMP3x[15:0]**  

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **CMP3x[15:0]: Timerx Compare 3 value**  
This register holds the Compare 3 value.
This register holds either the content of the preload register or the content of the active register if preload is disabled.
The compare value must be above or equal to 3 periods of the $f_{HRTIM}$ clock.

### 36.5.23 HRTIM Timerx Compare 4 Register (HRTIM_CMP4xR)

Address offset: 0x2Ch (this offset address is relative to timer x base address)

Reset value: 0x0000 0000

<table>
<thead>

</table>

**CMP4x[15:0]**  

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **CMP4x[15:0]: Timerx Compare 4 value**  
This register holds the Compare 4 value.
This register holds either the content of the preload register or the content of the active register if preload is disabled.
The compare value must be above or equal to 3 periods of the $f_{HRTIM}$ clock.
This register can behave as an auto-delayed compare register, if enabled with DELCMP4[1:0] bits in HRTIM_TIMxCR.
### 36.5.24 HRTIM Timerx Capture 1 Register (HRTIM_CPT1xR)

Address offset: 0x30h (this offset address is relative to timer x base address)

Reset value: 0x0000 0000

<table>
<thead>
<tr>

</thead>
<tbody>
<tr>
<td>f</td>
</tr>
</tbody>
</table>

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **CPT1x[15:0]: Timerx Capture 1 value**

This register holds the counter value when the capture 1 event occurred.

### 36.5.25 HRTIM Timerx Capture 2 Register (HRTIM_CPT2xR)

Address offset: 0x34h (this offset address is relative to timer x base address)

Reset value: 0x0000 0000

<table>
<thead>

<td>rw</td>
<td></td>
</tr>
<tr>
<td>24</td>
<td>DTRx[8:0]</td>
<td>Deadtime Rising value</td>
<td>rw</td>
<td></td>
</tr>
</tbody>
</table>

### Bit 31 DTFLKx: Deadtime Falling Lock
- This write-once bit prevents the deadtime (sign and value) to be modified, if enabled.
  - 0: Deadtime falling value and sign is writable
  - 1: Deadtime falling value and sign is read-only

*Note: This bit is not preloaded*

### Bit 30 DTFSLKx: Deadtime Falling Sign Lock
- This write-once bit prevents the sign of falling deadtime to be modified, if enabled.
  - 0: Deadtime falling sign is writable
  - 1: Deadtime falling sign is read-only

*Note: This bit is not preloaded*

### Bit 29:26 Reserved, must be kept at reset value.

### Bit 25 SDTFx: Sign Deadtime Falling value
- This register determines whether the deadtime is positive (signals not overlapping) or negative (signals overlapping).
  - 0: Positive deadtime on falling edge
  - 1: Negative deadtime on falling edge

### Bits 24:16 DTFx[8:0]: Deadtime Falling value
- This register holds the value of the deadtime following a falling edge of reference PWM signal.
  \[ t_{DTF} = DTFx[8:0] \times t_{DTG} \]

### Bit 15 DTRLKx: Deadtime Rising Lock
- This write-once bit prevents the deadtime (sign and value) to be modified, if enabled
  - 0: Deadtime rising value and sign is writable
  - 1: Deadtime rising value and sign is read-only

*Note: This bit is not preloaded*

### Bit 14 DTRSLKx: Deadtime Rising Sign Lock
- This write-once bit prevents the sign of deadtime to be modified, if enabled
  - 0: Deadtime rising sign is writable
  - 1: Deadtime rising sign is read-only

*Note: This bit is not preloaded*

### Bit 13 Reserved, must be kept at reset value.
Bits 12:10  **DTPRSC[2:0]: Deadtime Prescaler**  
This register holds the value of the deadtime clock prescaler.  
\[ t_{\text{DTG}} = (2^{(\text{DTPRSC[2:0]-3})}) \times t_{\text{HRTIM}} \]  
000: Reserved  
001: Reserved  
010: Reserved  
011: \( t_{\text{DTG}} = t_{\text{HRTIM}} \)  
100: \( t_{\text{DTG}} = t_{\text{HRTIM}} \times 2 \)  
101: \( t_{\text{DTG}} = t_{\text{HRTIM}} \times 4 \)  
110: \( t_{\text{DTG}} = t_{\text{HRTIM}} \times 8 \)  
111: \( t_{\text{DTG}} = t_{\text{HRTIM}} \times 16 \)  
This bitfield is read-only as soon as any of the lock bit is enabled (DTFLKs, DTFSLKx, DTRLKx, DTRSLKx).

Bit 9  **SDTRx: Sign Deadtime Rising value**  
This register determines whether the deadtime is positive or negative (overlapping signals)  
0: Positive deadtime on rising edge  
1: Negative deadtime on rising edge

Bits 8:0  **DTRx[8:0]: Deadtime Rising value**  
This register holds the value of the deadtime following a rising edge of reference PWM signal.  
\[ t_{\text{DTR}} = \text{DTRx}[8:0] \times t_{\text{DTG}} \]
## 36.5.27 HRTIM Timerx Output1 Set Register (HRTIM_SETx1R)

   Refer to TIMEVNT1 description

Bit 13 **TIMEVNT2**: *Timer Event 2*
   Refer to TIMEVNT1 description

Bit 12 **TIMEVNT1**: *Timer Event 1*
   Timers event 1 forces the output to its active state (refer to Table 297 for Timer Events assignments)

Bit 11 **MSTCMP4**: *Master Compare 4*
   Master Timer Compare 4 event forces the output to its active state.

Bit 10 **MSTCMP3**: *Master Compare 3*
   Master Timer Compare 3 event forces the output to its active state.

Bit 9 **MSTCMP2**: *Master Compare 2*
   Master Timer Compare 2 event forces the output to its active state.

Bit 8 **MSTCMP1**: *Master Compare 1*
   Master Timer compare 1 event forces the output to its active state.

Bit 7 **MSTPER**: *Master Period*
   The master timer counter roll-over in continuous mode, or to the master timer reset in single-shot mode forces the output to its active state.

Bit 6 **CMP4**: *Timer x Compare 4*
   Timer A compare 4 event forces the output to its active state.

Bit 5 **CMP3**: *Timer x Compare 3*
   Timer A compare 3 event forces the output to its active state.

Bit 4 **CMP2**: *Timer x Compare 2*
   Timer A compare 2 event forces the output to its active state.

Bit 3 **CMP1**: *Timer x Compare 1*
   Timer A compare 1 event forces the output to its active state.

Bit 2 **PER**: *Timer x Period*
   Timer A Period event forces the output to its active state.

Bit 1 **RESYNC**: *Timer A resynchronization*
   Timer A reset event coming solely from software or SYNC input forces the output to its active state.
   *Note*: *Other timer reset are not affecting the output when RESYNC=1*

Bit 0 **SST**: *Software Set trigger*
   This bit forces the output to its active state. This bit can only be set by software and is reset by hardware.
   *Note*: *This bit is not preloaded*

Bit 5  Reserved, must be kept at reset value.

Bits 4:1  **EE1FLTR[3:0]**: *External Event 1 filter*

  0000: No filtering
  0001: Blanking from counter reset/roll-over to Compare 1
  0010: Blanking from counter reset/roll-over to Compare 2
  0011: Blanking from counter reset/roll-over to Compare 3
  0100: Blanking from counter reset/roll-over to Compare 4
  0101: Blanking from another timing unit: TIMFLTR1 source (see Table 301 for details)
  0110: Blanking from another timing unit: TIMFLTR2 source (see Table 301 for details)
  0111: Blanking from another timing unit: TIMFLTR3 source (see Table 301 for details)
  1000: Blanking from another timing unit: TIMFLTR4 source (see Table 301 for details)
  1001: Blanking from another timing unit: TIMFLTR5 source (see Table 301 for details)
  1010: Blanking from another timing unit: TIMFLTR6 source (see Table 301 for details)
  1011: Blanking from another timing unit: TIMFLTR7 source (see Table 301 for details)
  1100: Blanking from another timing unit: TIMFLTR8 source (see Table 301 for details)
  1101: Windowing from counter reset/roll-over to Compare 2
  1110: Windowing from counter reset/roll-over to Compare 3
  1111: Windowing from another timing unit: TIMWIN source (see Table 302 for details)

*Note: Whenever a compare register is used for filtering, the value must be strictly above 0.*

  *This bitfield must not be modified once the counter is enabled (TxCEN bit set)*

Bit 0  **EE1LTCH**: *External Event 1 latch*

  0: Event 1 is ignored if it happens during a blank, or passed through during a window.
  1: Event 1 is latched and delayed till the end of the blanking or windowing period.

*Note: A timeout event is generated in window mode (EE1FLTR[3:0]=1101, 1110, 1111) if EE1LTCH = 0, except if the External event is programmed in fast mode (EExFAST = 1).*

  *This bitfield must not be modified once the counter is enabled (TxCEN bit set)*

Bit 31 Reserved, must be kept at reset value.

Bit 30 **TECPM4**: Timer E Compare 4
The timer A counter is reset upon timer E Compare 4 event.

Bit 29 **TECMP2**: Timer E Compare 2
The timer A counter is reset upon timer E Compare 2 event.

Bit 28 **TECMP1**: Timer E Compare 1
The timer A counter is reset upon timer E Compare 1 event.

Bit 27 **TDCMP4**: Timer D Compare 4
The timer A counter is reset upon timer D Compare 4 event.

Bit 26 **TDCMP2**: Timer D Compare 2
The timer A counter is reset upon timer D Compare 2 event.

Bit 25 **TDCMP1**: Timer D Compare 1
The timer A counter is reset upon timer D Compare 1 event.

Bit 24 **TCCMP4**: Timer C Compare 4
The timer A counter is reset upon timer C Compare 4 event.

Bit 23 **TCCMP2**: Timer C Compare 2
The timer A counter is reset upon timer C Compare 2 event.

Bit 22 **TCCMP1**: Timer C Compare 1
The timer A counter is reset upon timer C Compare 1 event.

Bit 21 **TBCMP4**: Timer B Compare 4
The timer A counter is reset upon timer B Compare 4 event.

Bit 20 **TBCMP2**: Timer B Compare 2
The timer A counter is reset upon timer B Compare 2 event.

Bit 19 **TBCMP1**: Timer B Compare 1
The timer A counter is reset upon timer B Compare 1 event.

Bit 18 **EXTEVNT10**: External Event
The timer A counter is reset upon external event 10.

Bit 17 **EXTEVNT9**: External Event 9
The timer A counter is reset upon external event 9.
Bit 16 **EXTEVNT8**: *External Event 8*
The timer A counter is reset upon external event 8.

Bit 15 **EXTEVNT7**: *External Event 7*
The timer A counter is reset upon external event 7.

Bit 14 **EXTEVNT6**: *External Event 6*
The timer A counter is reset upon external event 6.

Bit 13 **EXTEVNT5**: *External Event 5*
The timer A counter is reset upon external event 5.

Bit 12 **EXTEVNT4**: *External Event 4*
The timer A counter is reset upon external event 4.

Bit 11 **EXTEVNT3**: *External Event 3*
The timer A counter is reset upon external event 3.

Bit 10 **EXTEVNT2**: *External Event 2*
The timer A counter is reset upon external event 2.

Bit 9 **EXTEVNT1**: *External Event 1*
The timer A counter is reset upon external event 1.

Bit 8 **MSTCMP4**: *Master compare 4*
The timer A counter is reset upon master timer Compare 4 event.

Bit 7 **MSTCMP3**: *Master compare 3*
The timer A counter is reset upon master timer Compare 3 event.

Bit 6 **MSTCMP2**: *Master compare 2*
The timer A counter is reset upon master timer Compare 2 event.

Bit 5 **MSTCMP1**: *Master compare 1*
The timer A counter is reset upon master timer Compare 1 event.

Bit 4 **MSTPER**: *Master timer Period*
The timer A counter is reset upon master timer period event.

Bit 3 **CMP4**: *Timer A compare 4 reset*
The timer A counter is reset upon Timer A Compare 4 event.

Bit 2 **CMP2**: *Timer A compare 2 reset*
The timer A counter is reset upon Timer A Compare 2 event.

Bit 1 **UPDT**: *Timer A Update reset*
The timer A counter is reset upon update event.

Bit 0 **Reserved, must be kept at reset value.**

#### Bit 31  **TECMP2**: Timer E Compare 2
- Refer to TACMP1 description
- Note: This bit is reserved for Timer E

#### Bit 30  **TECMP1**: Timer E Compare 1
- Refer to TACMP1 description
- Note: This bit is reserved for Timer E

#### Bit 29  **TE1RST**: Timer E output 1 Reset
- Refer to TA1RST description
- Note: This bit is reserved for Timer E

#### Bit 28  **TE1SET**: Timer E output 1 Set
- Refer to TA1SET description
- Note: This bit is reserved for Timer E

#### Bit 27  **TDCMP2**: Timer D Compare 2
- Refer to TACMP1 description
- Note: This bit is reserved for Timer D

#### Bit 26  **TDCMP1**: Timer D Compare 1
- Refer to TACMP1 description
- Note: This bit is reserved for Timer D

#### Bit 25  **TD1RST**: Timer D output 1 Reset
- Refer to TA1RST description
- Note: This bit is reserved for Timer D

#### Bit 24  **TD1SET**: Timer D output 1 Set
- Refer to TA1SET description
- Note: This bit is reserved for Timer D

#### Bit 23  **TCCMP2**: Timer C Compare 2
- Refer to TACMP1 description
- Note: This bit is reserved for Timer C
Bit 22 **TCCMP1**: Timer C Compare 1  
Refer to TACMP1 description  
*Note: This bit is reserved for Timer C*

Bit 21 **TC1RST**: Timer C output 1 Reset  
Refer to TA1RST description  
*Note: This bit is reserved for Timer C*

Bit 20 **TC1SET**: Timer C output 1 Set  
Refer to TA1SET description  
*Note: This bit is reserved for Timer C*

Bit 19 **TBCMP2**: Timer B Compare 2  
Refer to TACMP1 description  
*Note: This bit is reserved for Timer B*

Bit 18 **TBCMP1**: Timer B Compare 1  
Refer to TACMP1 description  
*Note: This bit is reserved for Timer B*

Bit 17 **TB1RST**: Timer B output 1 Reset  
Refer to TA1RST description  
*Note: This bit is reserved for Timer B*

Bit 16 **TB1SET**: Timer B output 1 Set  
Refer to TA1SET description  
*Note: This bit is reserved for Timer B*

Bit 15 **TACMP2**: Timer A Compare 2  
Timer A Compare 2 triggers Capture 2.  
*Note: This bit is reserved for Timer A*

Bit 14 **TACMP1**: Timer A Compare 1  
Timer A Compare 1 triggers Capture 2.  
*Note: This bit is reserved for Timer A*

Bit 13 **TA1RST**: Timer B output 1 Reset  
Capture 2 is triggered by HRTIM_CHA1 output active to inactive transition.  
*Note: This bit is reserved for Timer A*

Bit 12 **TA1SET**: Timer B output 1 Set  
Capture 2 is triggered by HRTIM_CHA1 output inactive to active transition.  
*Note: This bit is reserved for Timer A*

Bit 11 **EXEV10CPT**: External Event 10 Capture  
Refer to EXEV1CPT description

Bit 10 **EXEV9CPT**: External Event 9 Capture  
Refer to EXEV1CPT description

Bit 9 **EXEV8CPT**: External Event 8 Capture  
Refer to EXEV1CPT description

Bit 8 **EXEV7CPT**: External Event 7 Capture  
Refer to EXEV1CPT description

Bit 7 **EXEV6CPT**: External Event 6 Capture  
Refer to EXEV1CPT description
Bit 6  **EXEV5CPT**: *External Event 5 Capture*
Refer to EXEV1CPT description

Bit 5  **EXEV4CPT**: *External Event 4 Capture*
Refer to EXEV1CPT description

Bit 4  **EXEV3CPT**: *External Event 3 Capture*
Refer to EXEV1CPT description

Bit 3  **EXEV2CPT**: *External Event 2 Capture*
Refer to EXEV1CPT description

Bit 2  **EXEV1CPT**: *External Event 1 Capture*
The External event 1 triggers the Capture 2.

Bit 1  **UPDCPT**: *Update Capture*
The update event triggers the Capture 2.

Bit 0  **SWCPT**: *Software Capture*
This bit forces the Capture 2 by software. This bit is set only, reset by hardware
36.5.37  HRTIM Timerx Output Register (HRTIM_OUTxR)

Address offset: 0x64h (this offset address is relative to timer x base address)
Reset value: 0x0000 0000

Bits 31:24  Reserved, must be kept at reset value.

Bit 23  **DIDL2: Output 2 Deadtime upon burst mode Idle entry**
This bit can delay the idle mode entry by forcing a deadtime insertion before switching the outputs to their idle state. This setting only applies when entering in idle state during a burst mode operation.

0: The programmed Idle state is applied immediately to the Output 2
1: Deadtime (inactive level) is inserted on output 2 before entering the idle mode. The deadtime value is set by DTFx[8:0].

*Note: This parameter cannot be changed once the timer x is enabled.*

Bit 22  **CHP2: Output 2 Chopper enable**
This bit enables the chopper on output 2
0: Output signal is not altered
1: Output signal is chopped by a carrier signal

*Note: This parameter cannot be changed once the timer x is enabled.*

Bits 21:20  **FAULT2[1:0]: Output 2 Fault state**
These bits select the output 2 state after a fault event
00: No action: the output is not affected by the fault input and stays in run mode.
01: Active
10: Inactive
11: High-Z

*Note: This parameter cannot be changed once the timer x is enabled (TxCEN bit set), if FLTENx bit is set or if the output is in FAULT state.*

Bit 19  **IDLES2: Output 2 Idle State**
This bit selects the output 2 idle state
0: Inactive
1: Active

*Note: This parameter must be set prior to have the HRTIM controlling the outputs.*

Bit 18  **IDLEM2: Output 2 Idle mode**
This bit selects the output 2 idle mode
0: No action: the output is not affected by the burst mode operation
1: The output is in idle state when requested by the burst mode controller.

*Note: This bit is preloaded and can be changed during run-time, but must not be changed while the burst mode is active.*
Bit 17 **POL2**: *Output 2 polarity*

This bit selects the output 2 polarity

0: positive polarity (output active high)
1: negative polarity (output active low)

*Note: This parameter cannot be changed once the timer x is enabled.*

Bits 16:12 Reserved, must be kept at reset value.

Bits 12:10 **DLYPRT[2:0]**: *Delayed Protection*

These bits define the source and outputs on which the delayed protection schemes are applied.

In **HRTIM_OUTAR, HRTIM_OUTBR, HRTIM_OUTCR**:

000: Output 1 delayed Idle on external Event 6
001: Output 2 delayed Idle on external Event 6
010: Output 1 and output 2 delayed Idle on external Event 6
011: Balanced Idle on external Event 6
100: Output 1 delayed Idle on external Event 7
101: Output 2 delayed Idle on external Event 7
110: Output 1 and output 2 delayed Idle on external Event 7
111: Balanced Idle on external Event 7

In **HRTIM_OUTDR, HRTIM_OUTER**:

000: Output 1 delayed Idle on external Event 8
001: Output 2 delayed Idle on external Event 8
010: Output 1 and output 2 delayed Idle on external Event 8
011: Balanced Idle on external Event 8
100: Output 1 delayed Idle on external Event 9
101: Output 2 delayed Idle on external Event 9
110: Output 1 and output 2 delayed Idle on external Event 9
111: Balanced Idle on external Event 9

*Note: This bitfield must not be modified once the delayed protection is enabled (DLYPRTEN bit set)*

Bit 9 **DLYPRTEN**: *Delayed Protection Enable*

This bit enables the delayed protection scheme

0: No action
1: Delayed protection is enabled, as per DLYPRT[2:0] bits

*Note: This parameter cannot be changed once the timer x is enabled (TxEN bit set).*

Bit 8 **DTEN**: *Deadtime enable*

This bit enables the deadtime insertion on output 1 and output 2

0: Output 1 and output 2 signals are independent.
1: Deadtime is inserted between output 1 and output 2 (reference signal is output 1 signal generator)

*Note: This parameter cannot be changed once the timer is operating (TxEN bit set) or if its outputs are enabled and set/reset by another timer.*

Bit 7 **DIDL1**: *Output 1 Deadtime upon burst mode Idle entry*

This bit can delay the idle mode entry by forcing a deadtime insertion before switching the outputs to their idle state. This setting only applies when entering the idle state during a burst mode operation.

0: The programmed Idle state is applied immediately to the Output 1
1: Deadtime (inactive level) is inserted on output 1 before entering the idle mode. The deadtime value is set by DTRx[8:0].

*Note: This parameter cannot be changed once the timer x is enabled.*

*DIDL=1 can be set only if one of the outputs is active during the burst mode (IDLES=1), and with positive deadtimes (SDTR/SDTF set to 0).*
Bit 6 **CHP1**: Output 1 Chopper enable
   - This bit enables the chopper on output 1
   - 0: Output signal is not altered
   - 1: Output signal is chopped by a carrier signal
   *Note: This parameter cannot be changed once the timer x is enabled.*

Bits 5:4 **FAULT1[1:0]**: Output 1 Fault state
   - These bits select the output 1 state after a fault event
   - 00: No action: the output is not affected by the fault input and stays in run mode.
   - 01: Active
   - 10: Inactive
   - 11: High-Z
   *Note: This parameter cannot be changed once the timer x is enabled (TxCEN bit set), if FLTENx bit is set or if the output is in FAULT state.*

Bit 3 **IDLES1**: Output 1 Idle State
   - This bit selects the output 1 idle state
   - 0: Inactive
   - 1: Active
   *Note: This parameter must be set prior to HRTIM controlling the outputs.*

Bit 2 **IDLEM1**: Output 1 Idle mode
   - This bit selects the output 1 idle mode
   - 0: No action: the output is not affected by the burst mode operation
   - 1: The output is in idle state when requested by the burst mode controller.
   *Note: This bit is preloaded and can be changed during runtime, but must not be changed while burst mode is active.*

Bit 1 **POL1**: Output 1 polarity
   - This bit selects the output 1 polarity
   - 0: positive polarity (output active high)
   - 1: negative polarity (output active low)
   *Note: This parameter cannot be changed once the timer x is enabled.*

Bit 0 Reserved
36.5.38 HRTIM Timerx Fault Register (HRTIM_FLTxR)

Bit 31 **FLTLCK**: Fault sources Lock
- 0: FLT1EN..FLT5EN bits are read/write
- 1: FLT1EN..FLT5EN bits are read only
  The FLTLCK bit is write-once. Once it has been set, it cannot be modified till the next system reset.

Bits 30:5 Reserved, must be kept at reset value.

Bit 4 **FLT5EN**: Fault 5 enable
- 0: Fault 5 input ignored
- 1: Fault 5 input is active and can disable HRTIM outputs.

Bit 3 **FLT4EN**: Fault 4 enable
- 0: Fault 4 input ignored
- 1: Fault 4 input is active and can disable HRTIM outputs.

Bit 2 **FLT3EN**: Fault 3 enable
- 0: Fault 3 input ignored
- 1: Fault 3 input is active and can disable HRTIM outputs.

Bit 1 **FLT2EN**: Fault 2 enable
- 0: Fault 2 input ignored
- 1: Fault 2 input is active and can disable HRTIM outputs.

Bit 0 **FLT1EN**: Fault 1 enable
- 0: Fault 1 input ignored
- 1: Fault 1 input is active and can disable HRTIM outputs.

Bit 2 **TBUDIS**: Timer B Update Disable
   Refer to TAUDIS description

Bit 1 **TAUDIS**: Timer A Update Disable
   This bit is set and cleared by software to enable/disable an update event generation temporarily on Timer A.
   0: update enabled. The update occurs upon generation of the selected source.
   1: update disabled. The updates are temporarily disabled to allow the software to write multiple registers that have to be simultaneously taken into account.

Bit 0 **MUDIS**: Master Update Disable
   This bit is set and cleared by software to enable/disable an update event generation temporarily.
   0: update enabled.
   1: update disabled. The updates are temporarily disabled to allow the software to write multiple registers that have to be simultaneously taken into account.

  Refer to TA1OEN description

- **Bit 3 TB2OEN**: Timer B Output 2 Enable  
  Refer to TA1OEN description

- **Bit 2 TB1OEN**: Timer B Output 1 Enable  
  Refer to TA1OEN description

- **Bit 1 TA2OEN**: Timer A Output 2 Enable  
  Refer to TA1OEN description

- **Bit 0 TA1OEN**: Timer A Output 1 (HRTIM_CHA1) Enable  
  Setting this bit enables the Timer A output 1. Writing “0” has no effect.  
  Reading the bit returns the output enable/disable status.  
  This bit is cleared asynchronously by hardware as soon as the timer-related fault input(s) is (are) active.  
  0: output HRTIM_CHA1 disabled. The output is either in Fault or Idle state.  
  1: output HRTIM_CHA1 enabled  
  **Note**: The disable status corresponds to both idle and fault states. The output disable status is given by TA1ODS bit in the HRTIM_ODSR register.

| Bit 1     | **TA2ODS**: Timer A Output 2 disable status  
|           | Refer to TA1ODS description             |
| Bit 0     | **TA1ODS**: Timer A Output 1 disable status  
|           | Reading the bit returns the output disable status. It is not significant when the output is active (Tx1OEN or Tx2OEN = 1).  
|           | 0: output HRTIM_CHA1 disabled, in Idle state.  
|           | 1: output HRTIM_CHA1 disabled, in Fault state. |
36.5.47  HRTIM Burst Mode Control Register (HRTIM_BMCR)

Address offset: 0x3A0h
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>BMSTAT: Burst Mode Status</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>This bit gives the current operating state.</td>
</tr>
<tr>
<td></td>
<td>0: Normal operation</td>
</tr>
<tr>
<td></td>
<td>1: Burst operation on-going. Writing this bit to 0 causes a burst mode early termination.</td>
</tr>
</tbody>
</table>

Bits 30:22  Reserved, must be kept at reset value.

Bit 21  TEBM: Timer E Burst Mode
Refer to TABM description

Bit 20  TDBM: Timer D Burst Mode
Refer to TABM description

Bit 19  TCBM: Timer C Burst Mode
Refer to TABM description

Bit 18  TBBM: Timer B Burst Mode
Refer to TABM description

Bit 17  TABM: Timer A Burst Mode
This bit defines how the timer behaves during a burst mode operation. This bitfield cannot be changed while the burst mode is enabled.
0: Timer A counter clock is maintained and the timer operates normally
1: Timer A counter clock is stopped and the counter is reset

Note: This bit must not be set when the balanced idle mode is active (DLYPRT[2:0] = 0x11)

Bit 16  MTBM: Master Timer Burst Mode
This bit defines how the timer behaves during a burst mode operation. This bitfield cannot be changed while the burst mode is enabled.
0: Master Timer counter clock is maintained and the timer operates normally
1: Master Timer counter clock is stopped and the counter is reset

Bits 15:11  Reserved, must be kept at reset value.

Bit 10  BMPREN: Burst Mode Preload Enable
This bit enables the registers preload mechanism and defines whether a write access into a preloadable register (HRTIM_BMCMPR, HRTIM_BMPER) is done into the active or the preload register.
0: Preload disabled: the write access is directly done into active registers
1: Preload enabled: the write access is done into preload registers
Bits 9:6 **BMPRSC[3:0]: Burst Mode Prescaler**
Defines the prescaling ratio of the \( f_{HRTIM} \) clock for the burst mode controller. This bitfield cannot be changed while the burst mode is enabled.
- 0000: Clock not divided
- 0001: Division by 2
- 0010: Division by 4
- 0011: Division by 8
- 0100: Division by 16
- 0101: Division by 32
- 0110: Division by 64
- 0111: Division by 128
- 1000: Division by 256
- 1001: Division by 512
- 1010: Division by 1024
- 1011: Division by 2048
- 1100: Division by 4096
- 1101: Division by 8192
- 1110: Division by 16384
- 1111: Division by 32768

Bits 5:2 **BMCLK[3:0]: Burst Mode Clock source**
This bitfield defines the clock source for the burst mode counter. It cannot be changed while the burst mode is enabled (refer to Table 311 for on-chip events 1..4 connections details).
- 0000: Master timer counter reset/roll-over
- 0001: Timer A counter reset/roll-over
- 0010: Timer B counter reset/roll-over
- 0011: Timer C counter reset/roll-over
- 0100: Timer D counter reset/roll-over
- 0101: Timer E counter reset/roll-over
- 0110: On-chip Event 1 (hrtim_bm_ck1), acting as a burst mode counter clock
- 0111: On-chip Event 2 (hrtim_bm_ck2) acting as a burst mode counter clock
- 1000: On-chip Event 3 (hrtim_bm_ck3) acting as a burst mode counter clock
- 1001: On-chip Event 4 (hrtim_bm_ck4) acting as a burst mode counter clock
- 1010: Prescaled \( f_{HRTIM} \) clock (as per BMPRSC[3:0] setting)
Other codes reserved

Bit 1 **BMOM: Burst Mode operating mode**
This bit defines if the burst mode is entered once or if it is continuously operating.
- 0: Single-shot mode
- 1: Continuous operation

Bit 0 **BME: Burst Mode enable**
This bit starts the burst mode controller which becomes ready to receive the start trigger.
Writing this bit to 0 causes a burst mode early termination.
- 0: Burst mode disabled
- 1: Burst mode enabled

**Bit 31 OCHPEV: On-chip Event**  
A rising edge on an on-chip Event (see Section: Burst mode triggers) triggers a burst mode entry.

**Bit 30 EEV8: External Event 8 (TIMD filters applied)**  
The external event 8 conditioned by TIMD filters is starting the burst mode operation.

**Bit 29 EEV7: External Event 7 (TIMA filters applied)**  
The external event 7 conditioned by TIMA filters is starting the burst mode operation.

**Bit 28 TDEEV8: Timer D period following External Event 8**  
The timer D period following an external event 8 (conditioned by TIMD filters) is starting the burst mode operation.

**Bit 27 TAEVEV: Timer A period following External Event 7**  
The timer A period following an external event 7 (conditioned by TIMA filters) is starting the burst mode operation.

**Bit 26 TECMP2: Timer E Compare 2 event**  
Refer to TACMP1 description

**Bit 25 TECMP1: Timer E Compare 1 event**  
Refer to TACMP1 description

**Bit 24 TEREP: Timer E repetition**  
Refer to TAREP description

**Bit 23 TERST: Timer E counter reset or roll-over**  
Refer to TARST description

**Bit 22 TDCMP2: Timer D Compare 2 event**  
Refer to TACMP1 description

**Bit 21 TDCMP1: Timer D Compare 1 event**  
Refer to TACMP1 description

**Bit 20 TDREP: Timer D repetition**  
Refer to TAREP description

**Bit 19 TDRST: Timer D reset or roll-over**  
Refer to TARST description

**Bit 18 TCCMP2: Timer C Compare 2 event**  
Refer to TACMP1 description

---

1502/3289  
RM0433 Rev 6
Bit 17 **TCCMP1**: *Timer C Compare 1 event*
   Refer to TACMP1 description

Bit 16 **TCREP**: *Timer C repetition*
   Refer to TAREP description

Bit 15 **TCRST**: *Timer C reset or roll-over*
   Refer to TARST description

Bit 14 **TBCMP2**: *Timer B Compare 2 event*
   Refer to TACMP1 description

Bit 13 **TBCMP1**: *Timer B Compare 1 event*
   Refer to TACMP1 description

Bit 12 **TBREP**: *Timer B repetition*
   Refer to TAREP description

Bit 11 **TBRST**: *Timer B reset or roll-over*
   Refer to TARST description

Bit 10 **TACMP2**: *Timer A Compare 2 event*
   Refer to TACMP1 description

Bit 9 **TACMP1**: *Timer A Compare 1 event*
   The timer A compare 1 event is starting the burst mode operation.

Bit 8 **TAREP**: *Timer A repetition*
   The Timer A repetition event is starting the burst mode operation.

Bit 7 **TARST**: *Timer A reset or roll-over*
   The Timer A reset or roll-over event is starting the burst mode operation.

Bit 6 **MSTCMP4**: *Master Compare 4*
   Refer to MSTCMP1 description

Bit 5 **MSTCMP3**: *Master Compare 3*
   Refer to MSTCMP1 description

Bit 4 **MSTCMP2**: *Master Compare 2*
   Refer to MSTCMP1 description

Bit 3 **MSTCMP1**: *Master Compare 1*
   The master timer Compare 1 event is starting the burst mode operation.

Bit 2 **MSTREP**: *Master repetition*
   The master timer repetition event is starting the burst mode operation.

Bit 1 **MSTRST**: *Master reset or roll-over*
   The master timer reset and roll-over event is starting the burst mode operation.

Bit 0 **SW**: *Software start*
   This bit is set by software and automatically reset by hardware.
   When set, It starts the burst mode operation immediately.
   This bit is not active if the burst mode is not enabled (BME bit is reset).
36.5.49 HRTIM Burst Mode Compare Register (HRTIM_BMCMPR)

Address offset: 0x3A8h
Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **BMCMP[15:0]: Burst mode compare value**
- Defines the number of periods during which the selected timers are in idle state.
- This register holds either the content of the preload register or the content of the active register if the preload is disabled.
- **Note:** BMCMP[15:0] cannot be set to 0x0000 when using the fHRTIM clock without a prescaler as the burst mode clock source (BMCLK[3:0] = 1010 and BMPRESC[3:0] = 0000).

36.5.50 HRTIM Burst Mode Period Register (HRTIM_BMPER)

Address offset: 0x3ACb
Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **BMPER[15:0]: Burst mode Period**
- Defines the burst mode repetition period.
- This register holds either the content of the preload register or the content of the active register if preload is disabled.
- **Note:** The BMPER[15:0] must not be null when the burst mode is enabled.
### 36.5.51 HRTIM Timer External Event Control Register 1 (HRTIM_EECR1)

</tbody>
</table>
Bits 7:6  **EE2SRC[1:0]: External Event 2 Source**
Refer to EE1SRC[1:0] description

Bit 5  **EE1FAST**: *External Event 1 Fast mode*
0: External Event 1 is re-synchronized by the HRTIM logic before acting on outputs, which adds a
\( f_{\text{HRTIM}} \) clock-related latency
1: External Event 1 is acting asynchronously on outputs (low latency mode)

*Note*: *This bit must not be modified once the counter in which the event is used is enabled (TxCEN bit set)*

Bits 4:3  **EE1SNS[1:0]: External Event 1 Sensitivity**
00: On active level defined by EE1POL bit
01: Rising edge, whatever EE1POL bit value
10: Falling edge, whatever EE1POL bit value
11: Both edges, whatever EE1POL bit value

Bit 2  **EE1POL**: *External Event 1 Polarity*
This bit is only significant if EE1SNS[1:0] = 00.
0: External event is active high
1: External event is active low

*Note*: *This parameter cannot be changed once the timer x is enabled. It must be configured prior to setting EE1FAST bit.*

Bits 1:0  **EE1SRC[1:0]: External Event 1 Source**
00: hrtimEvt11
01: hrtimEvt12
10: hrtimEvt13
11: hrtimEvt14

*Note*: *This parameter cannot be changed once the timer x is enabled. It must be configured prior to setting EE1FAST bit.*

  Refer to ADC3TBRST description
- **Bit 18** ADC3TBPER: ADC trigger 3 on Timer B Period  
  Refer to ADC3TAPER description
- **Bit 17** ADC3TBC4: ADC trigger 3 on Timer B Compare 4  
  Refer to ADC3TAC2 description
Bit 16 **ADC3TBC3**: ADC trigger 3 on Timer B Compare 3
Refer to ADC3TAC2 description

Bit 15 **ADC3TBC2**: ADC trigger 3 on Timer B Compare 2
Refer to ADC3TAC2 description

Bit 14 **ADC3TARST**: ADC trigger 3 on Timer A Reset and counter roll-over
This bit enables the generation of an ADC Trigger upon Timer A reset and roll-over event, on ADC Trigger 1 output.

Bit 13 **ADC3TAPER**: ADC trigger 3 on Timer A Period
This bit enables the generation of an ADC Trigger upon Timer A period event, on ADC Trigger 3 output (hrtim_adc_trg3).

Bit 12 **ADC3TAC4**: ADC trigger 3 on Timer A Compare 4
Refer to ADC3TAC2 description

Bit 11 **ADC3TAC3**: ADC trigger 3 on Timer A Compare 3
Refer to ADC3TAC2 description

Bit 10 **ADC3TAC2**: ADC trigger 3 on Timer A Compare 2
This bit enables the generation of an ADC Trigger upon Timer A Compare 2 event, on ADC Trigger 3 output (hrtim_adc_trg3).

Bit 9 **ADC3EEV5**: ADC trigger 3 on External Event 5
Refer to ADC3EEV1 description

Bit 8 **ADC3EEV4**: ADC trigger 3 on External Event 4
Refer to ADC3EEV1 description

Bit 7 **ADC3EEV3**: ADC trigger 3 on External Event 3
Refer to ADC3EEV1 description

Bit 6 **ADC3EEV2**: ADC trigger 3 on External Event 2
Refer to ADC3EEV1 description

Bit 5 **ADC3EEV1**: ADC trigger 3 on External Event 1
This bit enables the generation of an ADC Trigger upon External event 1, on ADC Trigger 3 output (hrtim_adc_trg3).

Bit 4 **ADC3MPER**: ADC trigger 3 on Master Period
This bit enables the generation of an ADC Trigger upon Master timer period event, on ADC Trigger 3 output (hrtim_adc_trg3).

Bit 3 **ADC3MC4**: ADC trigger 3 on Master Compare 4
Refer to ADC3MC1 description

Bit 2 **ADC3MC3**: ADC trigger 3 on Master Compare 3
Refer to ADC3MC1 description

Bit 1 **ADC3MC2**: ADC trigger 3 on Master Compare 2
Refer to ADC3MC1 description

Bit 0 **ADC3MC1**: ADC trigger 3 on Master Compare 1
This bit enables the generation of an ADC Trigger upon Master Compare 1 event, on ADC Trigger 3 output (hrtim_adc_trg3).
36.5.57  HRTIM ADC Trigger 4 Register (HRTIM_ADC4R)

Address offset: 0x3C8h
Reset value: 0x0000 0000

Bit 31  **ADC4TERST**: ADC trigger 4 on Timer E Reset and counter roll-over  \(^{(1)}\)
       Refer to ADC4TCRST description

Bit 30  **ADC4TEC4**: ADC trigger 4 on Timer E Compare 4
       Refer to ADC4TAC2 description

Bit 29  **ADC4TEC3**: ADC trigger 4 on Timer E Compare 3
       Refer to ADC4TAC2 description

Bit 28  **ADC4TEC2**: ADC trigger 4 on Timer E Compare 2
       Refer to ADC4TAC2 description

Bit 27  **ADC4TDRST**: ADC trigger 4 on Timer D Reset and counter roll-over  \(^{(1)}\)
       Refer to ADC4TCRST description

Bit 26  **ADC4TDPER**: ADC trigger 4 on Timer D Period
       Refer to ADC4TAPER description

Bit 25  **ADC4TDC4**: ADC trigger 4 on Timer D Compare 4
       Refer to ADC4TAC2 description

Bit 24  **ADC4TDC3**: ADC trigger 4 on Timer D Compare 3
       Refer to ADC4TAC2 description

Bit 23  **ADC4TDC2**: ADC trigger 2 on Timer D Compare 2
       Refer to ADC4TAC2 description

Bit 22  **ADC4TCRST**: ADC trigger 4 on Timer C Reset and counter roll-over  \(^{(1)}\)
       This bit enables the generation of an ADC Trigger upon Timer C reset and roll-over event, on ADC Trigger 4 output (hrtim_adc_trg4).

Bit 21  **ADC4TPER**: ADC trigger 4 on Timer C Period
       Refer to ADC4TAPER description

Bit 20  **ADC4TCC4**: ADC trigger 4 on Timer C Compare 4
       Refer to ADC4TAC2 description

Bit 19  **ADC4TCC3**: ADC trigger 4 on Timer C Compare 3
       Refer to ADC4TAC2 description

Bit 18  **ADC4TCC2**: ADC trigger 4 on Timer C Compare 2
       Refer to ADC4TAC2 description
Bit 17 **ADC4TBPER**: ADC trigger 4 on Timer B Period  
Refer to ADC4TAPER description

Bit 16 **ADC4TBC4**: ADC trigger 4 on Timer B Compare 4  
Refer to ADC4TAC2 description

Bit 15 **ADC4TBC3**: ADC trigger 4 on Timer B Compare 3  
Refer to ADC4TAC2 description

Bit 14 **ADC4TBC2**: ADC trigger 4 on Timer B Compare 2  
Refer to ADC4TAC2 description

Bit 13 **ADC4TAPER**: ADC trigger 4 on Timer A Period  
This bit enables the generation of an ADC Trigger upon Timer A event, on ADC Trigger 4 output (hrtim_adc_trg4).

Bit 12 **ADC4TAC4**: ADC trigger 4 on Timer A Compare 4  
Refer to ADC4TAC2 description

Bit 11 **ADC4TAC3**: ADC trigger 4 on Timer A Compare 3  
Refer to ADC4TAC2 description

Bit 10 **ADC4TAC2**: ADC trigger 4 on Timer A Compare 2  
This bit enables the generation of an ADC Trigger upon Timer A Compare 2, on ADC Trigger 4 output (hrtim_adc_trg4).

Bit 9 **ADC4EEV10**: ADC trigger 4 on External Event 10  
This bit enables the generation of an ADC Trigger upon external event 6, on ADC Trigger 4 output (hrtim_adc_trg4).

Bit 8 **ADC4EEV9**: ADC trigger 4 on External Event 9  
Refer to ADC4EEV6 description

Bit 7 **ADC4EEV8**: ADC trigger 4 on External Event 8  
Refer to ADC4EEV6 description

Bit 6 **ADC4EEV7**: ADC trigger 4 on External Event 7  
Refer to ADC4EEV6 description

Bit 5 **ADC4EEV6**: ADC trigger 4 on External Event 6  
This bit enables the generation of an ADC Trigger upon external event 6, on ADC Trigger 4 output (hrtim_adc_trg4).

Bit 4 **ADC4MPER**: ADC trigger 4 on Master Period  
This bit enables the generation of an ADC Trigger upon Master period event, on ADC Trigger 4 output (hrtim_adc_trg4).

Bit 3 **ADC4MC4**: ADC trigger 4 on Master Compare 4  
Refer to ADC4MC1 description

Bit 2 **ADC4MC3**: ADC trigger 4 on Master Compare 3  
Refer to ADC4MC1 description

Bit 1 **ADC4MC2**: ADC trigger 4 on Master Compare 2  
Refer to ADC4MC1 description

Bit 0 **ADC4MC1**: ADC trigger 4 on Master Compare 1  
This bit enables the generation of an ADC Trigger upon Master Compare 1 event, on ADC Trigger 4 output (hrtim_adc_trg4).

1. These triggers are differing from HRTIM_ADC1R/HRTIM_ADC3R to HRTIM_ADC2R/HRTIM_ADC4R.

    Refer to FLT5E description in HRTIMFLTINR2 register
36.5.59  HRTIM Fault Input Register 2 (HRTIM_FLTINR2)

Address offset: 0x3D4h
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:26</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
</tbody>
</table>
| 25:24 | **FLTSD[1:0]**: Fault Sampling clock division  
This bitfield indicates the division ratio between the timer clock frequency (f_{HRTIM}) and the fault signal sampling clock (f_{FLTS}) used by the digital filters.  
00: f_{FLTS}=f_{HRTIM}  
01: f_{FLTS}=f_{HRTIM} / 2  
10: f_{FLTS}=f_{HRTIM} / 4  
11: f_{FLTS}=f_{HRTIM} / 8  
**Note:** This bitfield must be written prior to any of the FLTxE enable bits. |
| 23:8 | Reserved, must be kept at reset value. |
| 7 | **FLT5LCK**: Fault 5 Lock  
The FLT5LCK bit modifies the write attributes of the fault programming bit, so that they can be protected against spurious write accesses.  
This bit is write-once. Once it has been set, it cannot be modified till the next system reset.  
0: FLT5E, FLT5P, FLT5SRC, FLT5F[3:0] bits are read/write.  
1: FLT5E, FLT5P, FLT5SRC, FLT5F[3:0] bits can no longer be written (read-only mode) |
Bits 6:3  **FLT5[3:0]: Fault 5 filter**  
This bitfield defines the frequency used to sample FLT5 input and the length of the digital filter applied to FLT5. The digital filter is made of an event counter in which N events are needed to validate a transition on the output:

- 0000: No filter, FLT5 acts asynchronously
- 0001: $f_{SAMPLING} = f_{HRTIM}$, $N = 2$
- 0010: $f_{SAMPLING} = f_{HRTIM}$, $N = 4$
- 0011: $f_{SAMPLING} = f_{HRTIM}$, $N = 8$
- 0100: $f_{SAMPLING} = f_{FLTS/2}$, $N = 6$
- 0101: $f_{SAMPLING} = f_{FLTS/2}$, $N = 8$
- 0110: $f_{SAMPLING} = f_{FLTS/4}$, $N = 6$
- 0111: $f_{SAMPLING} = f_{FLTS/4}$, $N = 8$
- 1000: $f_{SAMPLING} = f_{FLTS/8}$, $N = 6$
- 1001: $f_{SAMPLING} = f_{FLTS/8}$, $N = 8$
- 1010: $f_{SAMPLING} = f_{FLTS/16}$, $N = 5$
- 1011: $f_{SAMPLING} = f_{FLTS/16}$, $N = 6$
- 1100: $f_{SAMPLING} = f_{FLTS/32}$, $N = 5$
- 1101: $f_{SAMPLING} = f_{FLTS/32}$, $N = 6$
- 1110: $f_{SAMPLING} = f_{FLTS/32}$, $N = 8$
- 1111: $f_{SAMPLING} = f_{FLTS/32}$, $N = 8$

*Note:* This bitfield can be written only when FLT5E enable bit is reset.  
This bitfield cannot be modified when FLT5LOCK has been programmed.

Bit 2  **FLT5SRC:** Fault 5 source  
This bit selects the FAULT5 input source (refer to Table 312 for connection details).

- 0: Fault 1 input is HRTIM_FLT5 input pin
- 1: Fault 1 input is hrtim_in_flt5 signal

*Note:* This bitfield can be written only when FLT5E enable bit is reset

Bit 1  **FLT5P:** Fault 5 polarity  
This bit selects the FAULT5 input polarity.

- 0: Fault 5 input is active low
- 1: Fault 5 input is active high

*Note:* This bitfield can be written only when FLT5E enable bit is reset

Bit 0  **FLT5E:** Fault 5 enable  
This bit enables the global FAULT5 input circuitry.

- 0: Fault 5 input disabled
- 1: Fault 5 input enabled
### HRTIM Burst DMA Master timer update Register (HRTIM_BDMUPR)

Address offset: 0x3D8h

Reset value: 0x0000 0000

| Bit 31:10 Reserved, must be kept at reset value. |
| Bit 9 | MCMP4: MCMP4R register update enable |
| Bit 8 | MCMP3: MCMP3R register update enable |
| Bit 7 | MCMP2: MCMP2R register update enable |
| Bit 6 | MCMP1: MCMP1R register update enable |
| Bit 5 | MREP: MREP register update enable |
| Bit 4 | MPER: MPER register update enable |
| Bit 3 | MCNT: MCNTR register update enable |
| Bit 2 | MDIER: MDIER register update enable |
| Bit 1 | MICR: MICR register update enable |
| Bit 0 | MCR: MCR register update enable |

This bit defines if the master timer MCR register is part of the list of registers to be updated by the Burst DMA.

- 0: MCR register is not updated by Burst DMA accesses
- 1: MCR register is updated by Burst DMA accesses
### 36.5.61  HRTIM Burst DMA Timer update Register (HRTIM_BDTxUPR)

Bits 31:0  **BDMADR[31:0]**: Burst DMA Data register  
Write accesses to this register triggers:
  - the copy of the data value into the registers enabled in BDTxUPR and BDMUPR register bits  
  - the increment of the register pointer to the next location to be filled
# 36.5.63 HRTIM register map

The tables below summarize the HRTIM registers mapping. The address offsets in Table 318 and Table 319 are referred to in the base address offsets given in Table 317.

## Table 317. RTIM global register map

37 Advanced-control timers (TIM1/TIM8)

37.1 TIM1/TIM8 introduction

The advanced-control timers (TIM1/TIM8) consist of a 16-bit auto-reload counter driven by a programmable prescaler.

It may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM, complementary PWM with dead-time insertion).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The advanced-control (TIM1/TIM8) and general-purpose (TIMy) timers are completely independent, and do not share any resources. They can be synchronized together as described in Section 37.3.26: Timer synchronization.

37.2 TIM1/TIM8 main features

TIM1/TIM8 timer features include:

- 16-bit up, down, up/down auto-reload counter.
- 16-bit programmable prescaler allowing dividing (also “on the fly”) the counter clock frequency either by any factor between 1 and 65536.
- Up to 6 independent channels for:
  - Input Capture (but channels 5 and 6)
  - Output Compare
  - PWM generation (Edge and Center-aligned Mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time
- Synchronization circuit to control the timer with external signals and to interconnect several timers together.
- Repetition counter to update the timer registers only after a given number of cycles of the counter.
- 2 break inputs to put the timer’s output signals in a safe user selectable configuration.
- Interrupt/DMA generation on the following events:
  - Update: counter overflow/underflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
- Supports incremental (quadrature) encoder and Hall-sensor circuitry for positioning purposes
- Trigger input for external clock or cycle-by-cycle current management
Figure 344. Advanced-control timer block diagram

Notes:
- Preload registers transferred to active registers on U event according to control bit
- Event
- Interrupt & DMA output

1. See Figure 387: Break and Break2 circuitry overview for details
37.3 TIM1/TIM8 functional description

37.3.1 Time-base unit

The main block of the programmable advanced-control timer is a 16-bit counter with its related auto-reload register. The counter can count up, down or both up and down. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:
- Counter register (TIMx_CNT)
- Prescaler register (TIMx_PSC)
- Auto-reload register (TIMx_ARR)
- Repetition counter register (TIMx_RCR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow (or underflow when downcounting) and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detailed for each configuration.

The counter is clocked by the prescaler output CK_CNT, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the counter starts counting 1 clock cycle after setting the CEN bit in the TIMx_CR1 register.

Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 345* and *Figure 346* give some examples of the counter behavior when the prescaler ratio is changed on the fly:
Figure 345. Counter timing diagram with prescaler division change from 1 to 2

Figure 346. Counter timing diagram with prescaler division change from 1 to 4
37.3.2 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

If the repetition counter is used, the update event (UEV) is generated after upcounting is repeated for the number of times programmed in the repetition counter register (TIMx_RCR) + 1. Else the update event is generated at each counter overflow.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register,
- The auto-reload shadow register is updated with the preload value (TIMx_ARR),
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

Figure 351. Counter timing diagram, update event when ARPE=0 (TIMx_ARR not preloaded)

Figure 352. Counter timing diagram, update event when ARPE=1 (TIMx_ARR preloaded)
**Downcounting mode**

In downcounting mode, the counter counts from the auto-reload value (content of the TIMx_ARR register) down to 0, then restarts from the auto-reload value and generates a counter underflow event.

If the repetition counter is used, the update event (UEV) is generated after downcounting is repeated for the number of times programmed in the repetition counter register (TIMx_RCR) + 1. Else the update event is generated at each counter underflow.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV update event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter restarts from the current auto-reload value, whereas the counter of the prescaler restarts from 0 (but the prescale rate doesn’t change).

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register.
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that the auto-reload is updated before the counter is reloaded, so that the next period is the expected one.

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

Figure 355. Counter timing diagram, internal clock divided by 4

![Counter timing diagram, internal clock divided by 4](MS31186V1)

Figure 356. Counter timing diagram, internal clock divided by N

![Counter timing diagram, internal clock divided by N](MS31187V1)
Center-aligned mode (up/down counting)

In center-aligned mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register) – 1, generates a counter overflow event, then counts from the auto-reload value down to 1 and generates a counter underflow event. Then it restarts counting from 0.

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are not equal to ’00’. The Output compare interrupt flag of channels configured in output is set when: the counter counts down (Center aligned mode 1, CMS = "01"), the counter counts up (Center aligned mode 2, CMS = "10") the counter counts up and down (Center aligned mode 3, CMS = "11").

In this mode, the DIR direction bit in the TIMx_CR1 register cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event. In this case, the counter restarts counting from 0, as well as the counter of the prescaler.

The UEV update event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter continues counting up and down, based on the current auto-reload value.

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an UEV update event but without setting the UIF flag (thus no interrupt or
DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register)
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that if the update source is a counter overflow, the auto-reload is updated before the counter is reloaded, so that the next period is the expected one (the counter is loaded with the new value).

The following figures show some examples of the counter behavior for different clock frequencies.

**Figure 358. Counter timing diagram, internal clock divided by 1, TIMx_ARR = 0x6**

![Counter timing diagram](image)

37.3.3 Repetition counter

Section 37.3.1: Time-base unit describes how the update event (UEV) is generated with respect to the counter overflows/underflows. It is actually generated only when the repetition counter has reached zero. This can be useful when generating PWM signals.

This means that data are transferred from the preload registers to the shadow registers (TIMx_ARR auto-reload register, TIMx_PSC prescaler register, but also TIMx_CCRx capture/compare registers in compare mode) every N+1 counter overflows or underflows, where N is the value in the TIMx_RCR repetition counter register.

The repetition counter is decremented:

- At each counter overflow in upcounting mode,
- At each counter underflow in downcounting mode,
- At each counter overflow and at each counter underflow in center-aligned mode.

Although this limits the maximum number of repetition to 32768 PWM cycles, it makes it possible to update the duty cycle twice per PWM period. When refreshing compare registers only once per PWM period in center-aligned mode, maximum resolution is 2xTck, due to the symmetry of the pattern.

The repetition counter is an auto-reload type; the repetition rate is maintained as defined by the TIMx_RCR register value (refer to Figure 364). When the update event is generated by software (by setting the UG bit in TIMx_EGR register) or by hardware through the slave mode controller, it occurs immediately whatever the value of the repetition counter is and the repetition counter is reloaded with the content of the TIMx_RCR register.
In Center aligned mode, for odd values of RCR, the update event occurs either on the overflow or on the underflow depending on when the RCR register was written and when the counter was launched: if the RCR was written before launching the counter, the UEV occurs on the overflow. If the RCR was written after launching the counter, the UEV occurs on the underflow.

For example, for RCR = 3, the UEV is generated each 4th overflow or underflow event depending on when the RCR was written.

**UEV**: Update event: Preload registers transferred to active registers and update interrupt generated

**Update Event**: If the repetition counter underflow occurs when the counter is equal to the auto-reload value.
37.3.4 External trigger input

The timer features an external trigger input ETR. It can be used as:
- external clock (external clock mode 2, see Section 37.3.5)
- trigger for the slave mode (see Section 37.3.26)
- PWM reset input for cycle-by-cycle current regulation (see Section 37.3.7)

Figure 365 below describes the ETR input conditioning. The input polarity is defined with the ETP bit in TIMxSMCR register. The trigger can be prescaled with the divider programmed by the ETPS[1:0] bitfield and digitally filtered with the ETF[3:0] bitfield.

The ETR input comes from multiple sources: input pins (default configuration), comparator outputs and analog watchdogs. The selection is done with the ETRSEL[3:0] bitfield.

Figure 365. External trigger input block

Figure 366. TIM1/TIM8 ETR input circuitry
37.3.5 Clock selection

The counter clock can be provided by the following clock sources:
- Internal clock (CK_INT)
- External clock mode1: external input pin
- External clock mode2: external trigger input ETR
- Encoder mode

Internal clock source (CK_INT)

If the slave mode controller is disabled (SMS=000), then the CEN, DIR (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK_INT.

Figure 367 shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

External clock source mode 1

This mode is selected when SMS=111 in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.
1. Codes ranging from 01000 to 11111 are reserved

For example, to configure the upcounter to count in response to a rising edge on the TI2 input, use the following procedure:

1. Select the proper TI2x source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Configure channel 2 to detect rising edges on the TI2 input by writing CC2S = ‘01’ in the TIMx_CCMR1 register.
3. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx_CCMR1 register (if no filter is needed, keep IC2F=0000).
4. Select rising edge polarity by writing CC2P=0 and CC2NP=0 in the TIMx_CCER register.
5. Configure the timer in external clock mode 1 by writing SMS=111 in the TIMx_SMCR register.
6. Select TI2 as the trigger input source by writing TS=00110 in the TIMx_SMCR register.
7. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

Note: The capture prescaler is not used for triggering, so the user does not need to configure it.

When a rising edge occurs on TI2, the counter counts once and the TIF flag is set.

The delay between the rising edge on TI2 and the actual clock of the counter is due to the resynchronization circuit on TI2 input.
External clock source mode 2

This mode is selected by writing ECE=1 in the TIMx_SMCR register.

The counter can count at each rising or falling edge on the external trigger input ETR.

The Figure 370 gives an overview of the external trigger input block.

Figure 370. External trigger input block

For example, to configure the upcounter to count each 2 rising edges on ETR, use the following procedure:

1. Refer to Figure 366: TIM1/TIM8 ETR input circuitry.
1. As no filter is needed in this example, write ETF[3:0]=0000 in the TIMx_SMCR register.
2. Set the prescaler by writing ETPS[1:0]=01 in the TIMx_SMCR register
3. Select rising edge detection on the ETR pin by writing ETP=0 in the TIMx_SMCR register
4. Enable external clock mode 2 by writing ECE=1 in the TIMx_SMCR register.
5. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

The counter counts once each 2 ETR rising edges.

The delay between the rising edge on ETR and the actual clock of the counter is due to the resynchronization circuit on the ETRP signal.

**Figure 371. Control circuit in external clock mode 2**

![Control circuit in external clock mode 2](image_url)
37.3.6 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing, and prescaler, except for channels 5 and 6) and an output stage (with comparator and output control).

*Figure 372 to Figure 375* give an overview of one Capture/Compare channel.

The input stage samples the corresponding Tlx input to generate a filtered signal TlxF. Then, an edge detector with polarity selection generates a signal (TlxFPx) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

*Figure 372. Capture/compare channel (example: channel 1 input stage)*

The output stage generates an intermediate waveform which is then used for reference: OCxRef (active high). The polarity acts at the end of the chain.
**Figure 373. Capture/compare channel 1 main circuit**

**Figure 374. Output stage of capture/compare channel (channel 1, idem ch. 2 and 3)**

1. OCxREF, where x is the rank of the complementary channel
1. Not available externally.

The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

37.3.7 Input capture mode

In Input capture mode, the Capture/Compare Registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCXIF flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx_SR register) is set. CCxIF can be
cleared by software by writing it to ‘0’ or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when written with ‘0’.

The following example shows how to capture the counter value in TIMx_CCR1 when TI1 input rises. To do this, use the following procedure:

1. Select the proper TI1x source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input: TIMx_CCR1 must be linked to the TI1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx_CCR1 register becomes read-only.
3. Program the appropriate input filter duration in relation with the signal connected to the timer (when the input is one of the TIx (ICxF bits in the TIMx_CCMRx register). Let’s imagine that, when toggling, the input signal is not stable during at most 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on TI1 when 8 consecutive samples with the new level have been detected (sampled at f_DTS frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.
4. Select the edge of the active transition on the TI1 channel by writing CC1P and CC1NP bits to 0 in the TIMx_CCER register (rising edge in this case).
5. Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to ‘00’ in the TIMx_CCMR1 register).
6. Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.
7. If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx_DIER register.

When an input capture occurs:
- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is set depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

Note: IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.

37.3.8 PWM input mode

This mode is a particular case of input capture mode. The procedure is the same except:
- Two ICx signals are mapped on the same TIx input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two TIxFP signals is selected as trigger input and the slave mode controller is configured in reset mode.
For example, the user can measure the period (in TIMx_CCR1 register) and the duty cycle (in TIMx_CCR2 register) of the PWM applied on TI1 using the following procedure (depending on CK_INT frequency and prescaler value):

1. Select the proper TI1x source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input for TIMx_CCR1: write the CC1S bits to 01 in the TIMx_CCMR1 register (TI1 selected).
3. Select the active polarity for TI1FP1 (used both for capture in TIMx_CCR1 and counter clear): write the CC1P and CC1NP bits to ‘0’ (active on rising edge).
4. Select the active input for TIMx_CCR2: write the CC2S bits to 10 in the TIMx_CCMR1 register (TI1 selected).
5. Select the active polarity for TI1FP2 (used for capture in TIMx_CCR2): write the CC2P and CC2NP bits to CC2P/CC2NP=’10’ (active on falling edge).
6. Select the valid trigger input: write the TS bits to 00101 in the TIMx_SMCR register (TI1FP1 selected).
7. Configure the slave mode controller in reset mode: write the SMS bits to 0100 in the TIMx_SMCR register.
8. Enable the captures: write the CC1E and CC2E bits to ‘1’ in the TIMx_CCER register.

### 37.3.9 Forced output mode

In output mode (CCxS bits = 00 in the TIMx_CCMRx register), each output compare signal (OCxREF and then OCx/OCxN) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (OCXREF/OCx) to its active level, user just needs to write 0101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus OCXREF is forced high (OCxREF is always active high) and OCx get opposite value to CCxP polarity bit.

For example: CCxP=0 (OCx active high) => OCx is forced to high level.

The OCxREF signal can be forced low by writing the OCxM bits to 0100 in the TIMx_CCMRx register.
Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the output compare mode section below.

37.3.10 Output compare mode

This function is used to control an output waveform or indicate when a period of time has elapsed. Channels 1 to 4 can be output, while Channel 5 and 6 are only available inside the device (for instance, for compound waveform generation or for ADC triggering).

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP bit in the TIMx_CCRER register). The output pin can keep its level (OCxM=0000), be set active (OCxM=0001), be set inactive (OCxM=0010) or can toggle (OCxM=0011) on match.
- Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCxIE bit in the TIMx_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx_DIER register, CCDS bit in the TIMx_CR2 register for the DMA request selection).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on OCxREF and OCx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One Pulse mode).

**Procedure**

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
   - Write OCxM = 0011 to toggle OCx output pin when CNT matches CCRx
   - Write OCxPE = 0 to disable preload register
   - Write CCxP = 0 to select active high polarity
   - Write CCxE = 1 to enable the output
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE=’0’, else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in Figure 378.
37.3.11 PWM mode

Pulse Width Modulation mode allows to generate a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per OCx output) by writing ‘0110’ (PWM mode 1) or ‘0111’ (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

OCx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. OCx output is enabled by a combination of the CCxE, CCxNE, MOE, OSSI and OSSR bits (TIMx_CCER and TIMx_BDTR registers). Refer to the TIMx_CCER register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CCRx ≤ TIMx_CNT or TIMx_CNT ≤ TIMx_CCRx (depending on the direction of the counter).

The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIMx_CR1 register.
PWM edge-aligned mode

- Upcounting configuration
  
  Upcounting is active when the DIR bit in the TIMx_CR1 register is low. Refer to the Upcounting mode on page 1535.

  In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is high as long as TIMx_CNT < TIMx_CCRx else it becomes low. If the compare value in TIMx_CCRx is greater than the auto-reload value (in TIMx_ARR) then OCxREF is held at ‘1’. If the compare value is 0 then OCxRef is held at ‘0’. Figure 379 shows some edge-aligned PWM waveforms in an example where TIMx_ARR=8.

  ![Figure 379. Edge-aligned PWM waveforms (ARR=8)](image)

- Downcounting configuration
  
  Downcounting is active when DIR bit in TIMx_CR1 register is high. Refer to the Downcounting mode on page 1539

  In PWM mode 1, the reference signal OCxRef is low as long as TIMx_CNT > TIMx_CCRx else it becomes high. If the compare value in TIMx_CCRx is greater than the auto-reload value in TIMx_ARR, then OCxREF is held at ‘1’. 0% PWM is not possible in this mode.

PWM center-aligned mode

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are different from ‘00’ (all the remaining configurations having the same effect on the OCxRef/OCx signals). The compare flag is set when the counter counts up, when it counts down or both when it counts up and down depending on the CMS bits configuration. The direction bit (DIR) in the
TIMx_CR1 register is updated by hardware and must not be changed by software. Refer to the *Center-aligned mode (up/down counting) on page 1542.*

*Figure 380* shows some center-aligned PWM waveforms in an example where:

- TIMx_ARR=8,
- PWM mode is the PWM mode 1,
- The flag is set when the counter counts down corresponding to the center-aligned mode 1 selected for CMS=01 in TIMx_CR1 register.

**Figure 380. Center-aligned PWM waveforms (ARR=8)**

Hints on using center-aligned mode

- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit.
in the TIMx_CR1 register. Moreover, the DIR and CMS bits must not be changed at the same time by the software.

- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:
  - The direction is not updated if a value greater than the auto-reload value is written in the counter (TIMx_CNT>TIMx_ARR). For example, if the counter was counting up, it continues to count up.
  - The direction is updated if 0 or the TIMx_ARR value is written in the counter but no Update Event UEV is generated.

- The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIMx_EGR register) just before starting the counter and not to write the counter while it is running.

### 37.3.12 Asymmetric PWM mode

Asymmetric mode allows two center-aligned PWM signals to be generated with a programmable phase shift. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and the phase-shift are determined by a pair of TIMx_CCRx register. One register controls the PWM during up-counting, the second during down counting, so that PWM is adjusted every half PWM cycle:

- OC1REFC (or OC2REFC) is controlled by TIMx_CCR1 and TIMx_CCR2
- OC3REFC (or OC4REFC) is controlled by TIMx_CCR3 and TIMx_CCR4

Asymmetric PWM mode can be selected independently on two channel (one OCx output per pair of CCR registers) by writing ‘1110’ (Asymmetric PWM mode 1) or ‘1111’ (Asymmetric PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

**Note:** The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

When a given channel is used as asymmetric PWM channel, its complementary channel can also be used. For instance, if an OC1REFC signal is generated on channel 1 (Asymmetric PWM mode 1), it is possible to output either the OC2REF signal on channel 2, or an OC2REFC signal resulting from asymmetric PWM mode 1.

*Figure 381* represents an example of signals that can be generated using Asymmetric PWM mode (channels 1 to 4 are configured in Asymmetric PWM mode 1). Together with the deadtime generator, this allows a full-bridge phase-shifted DC to DC converter to be controlled.
### 37.3.13 Combined PWM mode

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and delay are determined by the two TIMx_CCRx registers. The resulting signals, OCxREFC, are made of an OR or AND logical combination of two reference PWMs:

- OC1REFC (or OC2REFC) is controlled by TIMx_CCR1 and TIMx_CCR2
- OC3REFC (or OC4REFC) is controlled by TIMx_CCR3 and TIMx_CCR4

Combined PWM mode can be selected independently on two channels (one OCx output per pair of CCR registers) by writing ‘1100’ (Combined PWM mode 1) or ‘1101’ (Combined PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

When a given channel is used as combined PWM channel, its complementary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

**Note:** The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

**Figure 382** represents an example of signals that can be generated using Asymmetric PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2,
- Channel 2 is configured in PWM mode 1,
- Channel 3 is configured in Combined PWM mode 2,
- Channel 4 is configured in PWM mode 1.
37.3.14 Combined 3-phase PWM mode

Combined 3-phase PWM mode allows one to three center-aligned PWM signals to be generated with a single programmable signal ANDed in the middle of the pulses. The OC5REF signal is used to define the resulting combined signal. The 3-bits GC5C[3:1] in the TIMx_CCR5 allow selection on which reference signal the OC5REF is combined. The resulting signals, OCxREFC, are made of an AND logical combination of two reference PWMs:

- If GC5C1 is set, OC1REFC is controlled by TIMx_CCR1 and TIMx_CCR5
- If GC5C2 is set, OC2REFC is controlled by TIMx_CCR2 and TIMx_CCR5
- If GC5C3 is set, OC3REFC is controlled by TIMx_CCR3 and TIMx_CCR5

Combined 3-phase PWM mode can be selected independently on channels 1 to 3 by setting at least one of the 3-bits GC5C[3:1].
37.3.15 Complementary outputs and dead-time insertion

The advanced-control timers (TIM1/TIM8) can output two complementary signals and manage the switching-off and the switching-on instants of the outputs.

This time is generally known as dead-time and it has to be adjusted depending on the devices that are connected to the outputs and their characteristics (intrinsic delays of level-shifters, delays due to power switches...).

The polarity of the outputs (main output OCx or complementary OCxN) can be selected independently for each output. This is done by writing to the CCxP and CCxNP bits in the TIMx_CCER register.

The complementary signals OCx and OCxN are activated by a combination of several control bits: the CCxE and CCxNE bits in the TIMx_CCER register and the MOE, OISx, OISxN, OSSI and OSSR bits in the TIMx_BDTR and TIMx_CR2 registers. Refer to Table 324: Output control bits for complementary OCx and OCxN channels with break feature on page 1610 for more details. In particular, the dead-time is activated when switching to the idle state (MOE falling down to 0).
Dead-time insertion is enabled by setting both CCxE and CCxNE bits, and the MOE bit if the
break circuit is present. There is one 10-bit dead-time generator for each channel. From a
reference waveform OCxREF, it generates 2 outputs OCx and OCxN. If OCx and OCxN are
active high:

- The OCx output signal is the same as the reference signal except for the rising edge,
  which is delayed relative to the reference rising edge.
- The OCxN output signal is the opposite of the reference signal except for the rising
  edge, which is delayed relative to the reference falling edge.

If the delay is greater than the width of the active output (OCx or OCxN) then the
 corresponding pulse is not generated.

The following figures show the relationships between the output signals of the dead-time
generator and the reference signal OCxREF. (we suppose CCxP=0, CCxNP=0, MOE=1,
CCxE=1 and CCxNE=1 in these examples)

**Figure 384. Complementary output with dead-time insertion**

---

**Figure 385. Dead-time waveforms with delay greater than the negative pulse**

---
The dead-time delay is the same for each of the channels and is programmable with the DTG bits in the TIMx_BDTR register. Refer to Section 37.4.20: TIMx break and dead-time register (TIMx_BDTR)(x = 1, 8) for delay calculation.

**Re-directing OCxREF to OCx or OCxN**

In output mode (forced, output compare or PWM), OCxREF can be re-directed to the OCx output or to OCxN output by configuring the CCxE and CCxNE bits in the TIMx_CCER register.

This allows to send a specific waveform (such as PWM or static active level) on one output while the complementary remains at its inactive level. Other alternative possibilities are to have both outputs at inactive level or both outputs active and complementary with dead-time.

*Note:* When only OCxN is enabled (CCxE=0, CCxNE=1), it is not complemented and becomes active as soon as OCxREF is high. For example, if CCxNP=0 then OCxN=OCxRef. On the other hand, when both OCx and OCxN are enabled (CCxE=CCxNE=1) OCx becomes active when OCxREF is high whereas OCxN is complemented and becomes active when OCxREF is low.

### 37.3.16 Using the break function

The purpose of the break function is to protect power switches driven by PWM signals generated with the TIM1 and TIM8 timers. The two break inputs are usually connected to fault outputs of power stages and 3-phase inverters. When activated, the break circuitry shuts down the PWM outputs and forces them to a predefined safe state. A number of internal MCU events can also be selected to trigger an output shut-down.

The break features two channels. A break channel which gathers both system-level fault (clock failure, parity error,...) and application fault (from input pins and built-in comparator), and can force the outputs to a predefined level (either active or inactive) after a deadtime duration. A break2 channel which only includes application faults and is able to force the outputs to an inactive state.
The output enable signal and output levels during break are depending on several control bits:

- the MOE bit in TIMx_BDTR register allows to enable/disable the outputs by software and is reset in case of break or break2 event.
- the OSSI bit in the TIMx_BDTR register defines whether the timer controls the output in inactive state or releases the control to the GPIO controller (typically to have it in Hi-Z mode)
- the OISx and OISxN bits in the TIMx_CR2 register which are setting the output shut-down level, either active or inactive. The OCx and OCxN outputs cannot be set both to active level at a given time, whatever the OISx and OISxN values. Refer to Table 324: Output control bits for complementary OCx and OCxN channels with break feature on page 1610 for more details.

When exiting from reset, the break circuit is disabled and the MOE bit is low. The break functions can be enabled by setting the BKE and BK2E bits in the TIMx_BDTR register. The break input polarities can be selected by configuring the BKP and BK2P bits in the same register. BKE/BK2E and BKP/BK2P can be modified at the same time. When the BKE/BK2E and BKP/BK2P bits are written, a delay of 1 APB clock cycle is applied before the writing is effective. Consequently, it is necessary to wait 1 APB clock period to correctly read back the bit after the write operation.

Because MOE falling edge can be asynchronous, a resynchronization circuit has been inserted between the actual signal (acting on the outputs) and the synchronous control bit (accessed in the TIMx_BDTR register). It results in some delays between the asynchronous and the synchronous signals. In particular, if MOE is set to 1 whereas it was low, a delay must be inserted (dummy instruction) before reading it correctly. This is because the write acts on the asynchronous signal whereas the read reflects the synchronous signal.

The sources for break (BRK) channel are:

- An external source connected to one of the BKIN pin (as per selection done in the AFIO controller), with polarity selection and optional digital filtering
- An internal source:
  - the output from a comparator, with polarity selection and optional digital filtering
  - the analog watchdog output of the DFSDM1 peripheral
- A system break:
  - the Cortex®-M7 LOCKUP output
  - the PVD output
  - the SRAM parity error signal
  - a Flash ECC error
  - a clock failure event generated by the CSS detector

The sources for break2 (BRK2) are:

- An external source connected to one of the BKIN pin (as per selection done in the AFIO controller), with polarity selection and optional digital filtering
- An internal source coming from a comparator output.

Break events can also be generated by software using BG and B2G bits in the TIMx_EGR register. The software break generation using BG and B2G is active whatever the BKE and BK2E enable values.
All sources are ORed before entering the timer BRK or BRK2 inputs, as per Figure 387 below.

**Figure 387. Break and Break2 circuitry overview**

Note: An asynchronous (clockless) operation is only guaranteed when the programmable filter is disabled. If it is enabled, a fail safe clock mode (for example by using the internal PLL and/or the CSS) must be used to guarantee that break events are handled.
When one of the breaks occur (selected level on one of the break inputs):

- The MOE bit is cleared asynchronously, putting the outputs in inactive state, idle state or even releasing the control to the GPIO controller (selected by the OSSi bit). This feature is enabled even if the MCU oscillator is off.
- Each output channel is driven with the level programmed in the OISx bit in the TIMx_CR2 register as soon as MOE=0. If OSSi=0, the timer releases the output control (taken over by the GPIO controller), otherwise the enable output remains high.
- When complementary outputs are used:
  - The outputs are first put in inactive state (depending on the polarity). This is done asynchronously so that it works even if no clock is provided to the timer.
  - If the timer clock is still present, then the dead-time generator is reactivated in order to drive the outputs with the level programmed in the OISx and OISxN bits after a dead-time. Even in this case, OCx and OCxN cannot be driven to their active level together. Note that because of the resynchronization on MOE, the dead-time duration is slightly longer than usual (around 2 ck_timm clock cycles).
  - If OSSi=0, the timer releases the output control (taken over by the GPIO controller which forces a Hi-Z state), otherwise the enable outputs remain or become high as soon as one of the CCxE or CCxNE bits is high.
- The break status flag (SBIF, BIF and B2IF bits in the TIMx_SR register) is set. An interrupt is generated if the BIE bit in the TIMx_DIER register is set.
- If the AOE bit in the TIMx_BDTR register is set, the MOE bit is automatically set again at the next update event (UEV). As an example, this can be used to perform a regulation. Otherwise, MOE remains low until the application sets it to ‘1’ again. In this case, it can be used for security and the break input can be connected to an alarm from power drivers, thermal sensors or any security components.

Note: The break inputs are active on level. Thus, the MOE cannot be set while the break input is active (neither automatically nor by software). In the meantime, the status flag BIF and B2IF cannot be cleared.

In addition to the break input and the output management, a write protection has been implemented inside the break circuit to safeguard the application. It allows to freeze the configuration of several parameters (dead-time duration, OCx/OCxN polarities and state when disabled, OCxM configurations, break enable and polarity). The application can choose from 3 levels of protection selected by the LOCK bits in the TIMx_BDTR register. Refer to Section 37.4.20: TIMx break and dead-time register (TIMx_BDTR)(x = 1, 8). The LOCK bits can be written only once after an MCU reset.

Figure 388 shows an example of behavior of the outputs in response to a break.
Figure 388. Various output behavior in response to a break event on BRK (OSSI = 1)

- OCxREF
- OCx (OCxN not implemented, CCxP=0, OSx=1)
- OCx (OCxN not implemented, CCxP=0, OSx=0)
- OCx (OCxN not implemented, CCxP=1, OSx=1)
- OCx (OCxN not implemented, CCxP=1, OSx=0)
- OCx
- OCxN (CCxE=1, CCxP=0, OISx=0, CCxNE=1, CCxNP=0, OISxN=1)
- OCxN (CCxE=1, CCxP=0, OISx=1, CCxNE=1, CCxNP=1, OISxN=1)
- OCxN (CCxE=1, CCxP=0, OISx=0, CCxNE=0, CCxNP=0, OISxN=0)
- OCxN (CCxE=1, CCxP=0, CCxNE=0, CCxNP=0, OISx=OISxN=0 or OISx=OISxN=1)
The two break inputs have different behaviors on timer outputs:

- The BRK input can either disable (inactive state) or force the PWM outputs to a predefined safe state.
- BRK2 can only disable (inactive state) the PWM outputs.

The BRK has a higher priority than BRK2 input, as described in Table 321.

*Note:* BRK2 must only be used with OSSR = OSSI = 1.

### Table 321. Behavior of timer outputs versus BRK/BRK2 inputs

<table>
<thead>
<tr>
<th>BRK</th>
<th>BRK2</th>
<th>Timer outputs state</th>
<th>Typical use case</th>
</tr>
</thead>
</table>
| Active | X    | – Inactive then forced output state (after a deadtime)  
|       |      | – Outputs disabled if OSSI = 0 (control taken over by GPIO logic) | ON after deadtime insertion |
|      | Inactive | OFF | OFF |

*Figure 389* gives an example of OCx and OCxN output behavior in case of active signals on BRK and BRK2 inputs. In this case, both outputs have active high polarities (CCxP = CCxNP = 0 in TIMx_CCER register).

*Figure 389. PWM output state following BRK and BRK2 pins assertion (OSSI=1)*
### 37.3.17 Bidirectional break inputs

Beside regular digital break inputs and internal break events coming from the comparators, the timer 1 and 8 are featuring bidirectional break inputs/outputs combining the two sources, as represented on Figure 391.

The TIMx_BKINy_COMPz pins are combining the COMPz output (to be configured in open drain) and the Timerx’s TIMx_BKINy input. They allow to have:

- A global break information available for external MCUs or gate drivers shut down inputs, with a single-pin.

- An internal comparator and multiple external open drain comparators outputs ORed together and triggering a break event, when the multiple internal and external break inputs must be merged.

### 37.3.18 Clearing the OCxREF signal on an external event

The OCxREF signal of a given channel can be cleared when a high level is applied on the ocref_clr_int input (OCxCE enable bit in the corresponding TIMx_CCMRx register set to 1). OCxREF remains low until the next update event (UEV) occurs. This function can only be
used in Output compare and PWM modes. It does not work in Forced mode. The ocref_clr_int is connected to the ETRF signal (ETR after filtering).

When ETRF is chosen, ETR must be configured as follows:
1. The External Trigger Prescaler should be kept off: bits ETPS[1:0] of the TIMx_SMCR register set to '00'.
2. The external clock mode 2 must be disabled: bit ECE of the TIMx_SMCR register set to '0'.
3. The External Trigger Polarity (ETP) and the External Trigger Filter (ETF) can be configured according to the user needs.

*Figure 392* shows the behavior of the OCxREF signal when the ETRF Input becomes High, for both values of the enable bit OCxCE. In this example, the timer TIMx is programmed in PWM mode.

*Figure 392. Clearing TIMx OCxREF*

![Figure 392. Clearing TIMx OCxREF](image)

**Note:** In case of a PWM with a 100% duty cycle (if CCRx>ARR), then OCxREF is enabled again at the next counter overflow.
37.3.19 6-step PWM generation

When complementary outputs are used on a channel, preload bits are available on the OCxM, CCxE and CCxNE bits. The preload bits are transferred to the shadow bits at the COM commutation event. Thus one can program in advance the configuration for the next step and change the configuration of all the channels at the same time. COM can be generated by software by setting the COM bit in the TIMx_EGR register or by hardware (on TRGI rising edge).

A flag is set when the COM event occurs (COMIF bit in the TIMx_SR register), which can generate an interrupt (if the COMIE bit is set in the TIMx_DIER register) or a DMA request (if the COMDE bit is set in the TIMx_DIER register).

The Figure 393 describes the behavior of the OCx and OCxN outputs when a COM event occurs, in 3 different examples of programmed configurations.

![Figure 393. 6-step generation, COM example (OSSR=1)](image)
37.3.20 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:
- In upcounting: CNT < CCRx ≤ ARR (in particular, 0 < CCRx)
- In downcounting: CNT > CCRx

**Figure 394. Example of one pulse mode.**

For example one may want to generate a positive pulse on OC1 with a length of \( t_{\text{PULSE}} \) and after a delay of \( t_{\text{DELAY}} \) as soon as a positive edge is detected on the TI2 input pin.

Let’s use TI2FP2 as trigger 1:

1. Select the proper TI2x source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Map TI2FP2 to TI2 by writing CC2S='01' in the TIMx_CCMR1 register.
3. TI2FP2 must detect a rising edge, write CC2P='0' and CC2NP='0' in the TIMx_CCER register.
4. Configure TI2FP2 as trigger for the slave mode controller (TRGI) by writing TS=00110 in the TIMx_SMCR register.
5. TI2FP2 is used to start the counter by writing SMS to ‘110’ in the TIMx_SMCR register (trigger mode).
The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The \( t_{\text{DELAY}} \) is defined by the value written in the TIMx_CCR1 register.
- The \( t_{\text{PULSE}} \) is defined by the difference between the auto-reload value and the compare value (TIMx_ARR - TIMx_CCR1).
- Let's say one want to build a waveform with a transition from '0' to '1' when a compare match occurs and a transition from '1' to '0' when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing OC1M=111 in the TIMx_CCMR1 register. Optionally the preload registers can be enabled by writing OC1PE='1' in the TIMx_CCMR1 register and ARPE in the TIMx_CR1 register. In this case one has to write the compare value in the TIMx_CCR1 register, the auto-reload value in the TIMx_ARR register, generate an update by setting the UG bit and wait for external trigger event on TI2. CC1P is written to '0' in this example.

In our example, the DIR and CMS bits in the TIMx_CR1 register should be low.

Since only 1 pulse (Single mode) is needed, a 1 must be written in the OPM bit in the TIMx_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0). When OPM bit in the TIMx_CR1 register is set to '0', so the Repetitive Mode is selected.

**Particular case: OCx fast enable:**

In One-pulse mode, the edge detection on TIx input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay \( t_{\text{DELAY}} \) min we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx_CCMRx register. Then OCxRef (and OCx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

### 37.3.21 Retriggerable one pulse mode (OPM)

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with Non-retrigerrable one pulse mode described in Section 37.3.20:

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed

The timer must be in Slave mode, with the bits SMS[3:0] = ‘1000’ (Combined Reset + trigger mode) in the TIMx_SMCR register, and the OCxM[3:0] bits set to ‘1000’ or ‘1001’ for Retrigerrable OPM mode 1 or 2.

If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in Down-counting mode, CCRx must be above or equal to ARR.

**Note:** The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bit are not contiguous with the 3 least significant ones.

This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx_CR1.
37.3.22 Encoder interface mode

To select Encoder Interface mode write SMS=’001’ in the TIMx_SMCR register if the counter is counting on T12 edges only, SMS=’010’ if it is counting on T11 edges only and SMS=’011’ if it is counting on both T11 and T12 edges.

Select the T11 and T12 polarity by programming the CC1P and CC2P bits in the TIMx_CCER register. When needed, the input filter can be programmed as well. CC1NP and CC2NP must be kept low.

The two inputs T11 and T12 are used to interface to a quadrature encoder. Refer to Table 322. The counter is clocked by each valid transition on T11FP1 or T12FP2 (T11 and T12 after input filter and polarity selection, T11FP1=T11 if not filtered and not inverted, T12FP2=T12 if not filtered and not inverted) assuming that it is enabled (CEN bit in TIMx_CR1 register written to ‘1’). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the TIMx_CR1 register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (T11 or T12), whatever the counter is counting on T11 only, T12 only or both T11 and T12.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value in the TIMx_ARR register (0 to ARR or ARR down to 0 depending on the direction). So the TIMx_ARR must be configured before starting. In the same way, the capture, compare, repetition counter, trigger output features continue to work as normal. Encoder mode and External clock mode 2 are not compatible and must not be selected together.

Note: The prescaler must be set to zero when encoder mode is enabled

In this mode, the counter is modified automatically following the speed and the direction of the quadrature encoder and its content, therefore, always represents the encoder’s position. The count direction correspond to the rotation direction of the connected sensor. The table summarizes the possible combinations, assuming T11 and T12 do not switch at the same time.
A quadrature encoder can be connected directly to the MCU without external interface logic. However, comparators are normally be used to convert the encoder’s differential outputs to digital signals. This greatly increases noise immunity. The third encoder output which indicate the mechanical zero position, may be connected to an external interrupt input and trigger a counter reset.

The Figure 396 gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points. For this example we assume that the configuration is the following:

- CC1S='01' (TIMx_CCMR1 register, TI1FP1 mapped on TI1).
- CC2S='01' (TIMx_CCMR2 register, TI1FP2 mapped on TI2).
- CC1P='0' and CC1NP='0' (TIMx_CCER register, TI1FP1 non-inverted, TI1FP1=TI1).
- CC2P='0' and CC2NP='0' (TIMx_CCER register, TI1FP2 non-inverted, TI1FP2= TI2).
- SMS='011' (TIMx_SMCR register, both inputs are active on both rising and falling edges).
- CEN='1' (TIMx_CR1 register, Counter enabled).

**Figure 396. Example of counter operation in encoder interface mode.**

Figure 397 gives an example of counter behavior when TI1FP1 polarity is inverted (same configuration as above except CC1P='1').

Figure 397. Example of encoder interface mode with TI1FP1 polarity inverted.

The timer, when configured in Encoder Interface mode provides information on the sensor’s current position. Dynamic information can be obtained (speed, acceleration, deceleration) by measuring the period between two encoder events using a second timer configured in capture mode. The output of the encoder which indicates the mechanical zero can be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. This can be done by latching the counter value into a third input capture register if available (then the capture signal must be periodic and can be generated by another timer). when available, it is also possible to read its value through a DMA request.

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the update interrupt flag (UIF) into the timer counter register’s bit 31 (TIMxCNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. It eases the calculation of angular speed by avoiding race conditions caused, for instance, by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

There is no latency between the UIF and UIFCPY flag assertions.

In 32-bit timer implementations, when the IUFREMAP bit is set, bit 31 of the counter is overwritten by the UIFCPY flag upon read access (the counter’s most significant bit is only accessible in write mode).

37.3.23 UIF bit remapping

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the Update Interrupt Flag UIF into the timer counter register’s bit 31 (TIMxCNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. In particular cases, it can ease the calculations by avoiding race conditions, caused for instance by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

There is no latency between the UIF and UIFCPY flags assertion.
37.3.24 Timer input XOR function

The TI1S bit in the TIMx_CR2 register, allows the input filter of channel 1 to be connected to the output of an XOR gate, combining the three input pins TIMx_CH1, TIMx_CH2 and TIMx_CH3.

The XOR output can be used with all the timer input functions such as trigger or input capture. It is convenient to measure the interval between edges on two input signals, as per Figure 398 below.

Figure 398. Measuring time interval between edges on 3 signals

37.3.25 Interfacing with Hall sensors

This is done using the advanced-control timers (TIM1 or TIM8) to generate PWM signals to drive the motor and another timer TIMx (TIM2, TIM3, TIM4) referred to as “interfacing timer” in Figure 399. The “interfacing timer” captures the 3 timer input pins (CC1, CC2, CC3) connected through a XOR to the TI1 input channel (selected by setting the TI1S bit in the TIMx_CR2 register).

The slave mode controller is configured in reset mode; the slave input is TI1F_ED. Thus, each time one of the 3 inputs toggles, the counter restarts counting from 0. This creates a time base triggered by any change on the Hall inputs.

On the “interfacing timer”, capture/compare channel 1 is configured in capture mode, capture signal is TRC (See Figure 372: Capture/compare channel (example: channel 1 input stage) on page 1553). The captured value, which corresponds to the time elapsed between 2 changes on the inputs, gives information about motor speed.

The “interfacing timer” can be used in output mode to generate a pulse which changes the configuration of the channels of the advanced-control timer (TIM1 or TIM8) (by triggering a COM event). The TIM1 timer is used to generate PWM signals to drive the motor. To do this, the interfacing timer channel must be programmed so that a positive pulse is generated after a programmed delay (in output compare or PWM mode). This pulse is sent to the advanced-control timer (TIM1 or TIM8) through the TRGO output.
Example: one wants to change the PWM configuration of the advanced-control timer TIM1 after a programmed delay each time a change occurs on the Hall inputs connected to one of the TIMx timers.

- Configure 3 timer inputs ORed to the TI1 input channel by writing the TI1S bit in the TIMx_CR2 register to ‘1’,
- Program the time base: write the TIMx_ARR to the max value (the counter must be cleared by the TI1 change. Set the prescaler to get a maximum counter period longer than the time between 2 changes on the sensors,
- Program the channel 1 in capture mode (TRC selected): write the CC1S bits in the TIMx_CCMR1 register to ‘01’. The digital filter can also be programmed if needed,
- Program the channel 2 in PWM 2 mode with the desired delay: write the OC2M bits to ‘111’ and the CC2S bits to ‘00’ in the TIMx_CCMR1 register,
- Select OC2REF as trigger output on TRGO: write the MMS bits in the TIMx_CR2 register to ‘101’,

In the advanced-control timer TIM1, the right ITR input must be selected as trigger input, the timer is programmed to generate PWM signals, the capture/compare control signals are preloaded (CCPC=1 in the TIMx_CR2 register) and the COM event is controlled by the trigger input (CCUS=1 in the TIMx_CR2 register). The PWM control bits (CCxE, OCxM) are written after a COM event for the next step (this can be done in an interrupt subroutine generated by the rising edge of OC2REF).

The Figure 399 describes this example.
Figure 399. Example of Hall sensor interface
37.3.26 Timer synchronization

The TIMx timers are linked together internally for timer synchronization or chaining. They can be synchronized in several modes: Reset mode, Gated mode, and Trigger mode.

Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on TI1 input:

- Configure the channel 1 to detect rising edges on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx_CCMR1 register. Write CC1P=0 and CC1NP='0' in TIMx_CCER register to validate the polarity (and detect rising edges only).
- Configure the timer in reset mode by writing SMS=100 in TIMx_SMCR register. Select TI1 as the input source by writing TS=00101 in TIMx_SMCR register.
- Start the counter by writing CEN=1 in the TIMx_CR1 register.

The counter starts counting on the internal clock, then behaves normally until TI1 rising edge. When TI1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx_DIER register).

The following figure shows this behavior when the auto-reload register TIMx_ARR=0x36. The delay between the rising edge on TI1 and the actual reset of the counter is due to the resynchronization circuit on TI1 input.

Figure 400. Control circuit in reset mode
Slave mode: Gated mode

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when TI1 input is low:

- Configure the channel 1 to detect low levels on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S=01 in TIMx_CCMR1 register. Write CC1P=1 and CC1NP='0' in TIMx_CCER register to validate the polarity (and detect low level only).
- Configure the timer in gated mode by writing SMS=101 in TIMx_SMCR register. Select TI1 as the input source by writing TS=00101 in TIMx_SMCR register.
- Enable the counter by writing CEN=1 in the TIMx_CR1 register (in gated mode, the counter doesn’t start if CEN=0, whatever is the trigger input level).

The counter starts counting on the internal clock as long as TI1 is low and stops as soon as TI1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on TI1 and the actual stop of the counter is due to the resynchronization circuit on TI1 input.

Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on TI2 input:

- Configure the channel 2 to detect rising edges on TI2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC2S bits are configured to select the input capture source only, CC2S=01 in TIMx_CCMR1.
Advanced-control timers (TIM1/TIM8) RM0433

register. Write CC2P=1 and CC2NP=0 in TIMx_CCER register to validate the polarity (and detect low level only).

- Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select TI2 as the input source by writing TS=00110 in TIMx_SMCR register.

When a rising edge occurs on TI2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on TI2 and the actual start of the counter is due to the resynchronization circuit on TI2 input.

**Figure 402. Control circuit in trigger mode**

![Control circuit in trigger mode](image)

**Slave mode: Combined reset + trigger mode**

In this case, a rising edge of the selected trigger input (TRGI) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for one-pulse mode.

**Slave mode: external clock mode 2 + trigger mode**

The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the ETR signal is used as external clock input, and another input can be selected as trigger input (in reset mode, gated mode or trigger mode). It is recommended not to select ETR as TRGI through the TS bits of TIMx_SMCR register.

In the following example, the upcounter is incremented at each rising edge of the ETR signal as soon as a rising edge of TI1 occurs:
1. Configure the external trigger input circuit by programming the TIMx_SMCR register as follows:
   - ETF = 0000: no filter
   - ETPS=00: prescaler disabled
   - ETP=0: detection of rising edges on ETR and ECE=1 to enable the external clock mode 2.
2. Configure the channel 1 as follows, to detect rising edges on TI:
   - IC1F=0000: no filter.
   - The capture prescaler is not used for triggering and does not need to be configured.
   - CC1S=01 in TIMx_CCMR1 register to select only the input capture source
   - CC1P=0 and CC1NP='0' in TIMx_CCER register to validate the polarity (and detect rising edge only).
3. Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select TI1 as the input source by writing TS=00101 in TIMx_SMCR register.

A rising edge on TI1 enables the counter and sets the TIF flag. The counter then counts on ETR rising edges.

The delay between the rising edge of the ETR signal and the actual reset of the counter is due to the resynchronization circuit on ETRP input.

**Figure 403. Control circuit in external clock mode 2 + trigger mode**

**Note:** The clock of the slave peripherals (timer, ADC, ...) receiving the TRGO or the TRGO2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.
37.3.27 ADC synchronization

The timer can generate an ADC triggering event with various internal signals, such as reset, enable or compare events. It is also possible to generate a pulse issued by internal edge detectors, such as:

- Rising and falling edges of OC4ref
- Rising edge on OC5ref or falling edge on OC6ref

The triggers are issued on the TRGO2 internal line which is redirected to the ADC. There is a total of 16 possible events, which can be selected using the MMS2[3:0] bits in the TIMx_CR2 register.

An example of an application for 3-phase motor drives is given in Figure 383 on page 1565.

Note: The clock of the slave peripherals (timer, ADC, ...) receiving the TRGO or the TRGO2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

Note: The clock of the ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the timer.

37.3.28 DMA burst mode

The TIMx timers have the capability to generate multiple DMA requests upon a single event. The main purpose is to be able to re-program part of the timer multiple times without software overhead, but it can also be used to read several registers in a row, at regular intervals.

The DMA controller destination is unique and must point to the virtual register TIMx_DMAR. On a given timer event, the timer launches a sequence of DMA requests (burst). Each write into the TIMx_DMAR register is actually redirected to one of the timer registers.

The DBL[4:0] bits in the TIMx_DCR register set the DMA burst length. The timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address), i.e. the number of transfers (either in half-words or in bytes).

The DBA[4:0] bits in the TIMx_DCR registers define the DMA base address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register.

Example:

00000: TIMx_CR1
00001: TIMx_CR2
00010: TIMx_SMCR

As an example, the timer DMA burst feature is used to update the contents of the CCRx registers (x = 2, 3, 4) upon an update event, with the DMA transferring half words into the CCRx registers.
This is done in the following steps:

1. Configure the corresponding DMA channel as follows:
   - DMA channel peripheral address is the DMAR register address
   - DMA channel memory address is the address of the buffer in the RAM containing
     the data to be transferred by DMA into CCRx registers.
   - Number of data to transfer = 3 (See note below).
   - Circular mode disabled.
2. Configure the DCR register by configuring the DBA and DBL bit fields as follows:
   - DBL = 3 transfers, DBA = 0xE.
3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).
4. Enable TIMx
5. Enable the DMA channel

This example is for the case where every CCRx register to be updated once. If every CCRx register is to be updated twice for example, the number of data to transfer should be 6. Let's take the example of a buffer in the RAM containing data1, data2, data3, data4, data5 and data6. The data is transferred to the CCRx registers as follows: on the first update DMA request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is transferred to CCR3 and data6 is transferred to CCR4.

**Note:** A null value can be written to the reserved registers.

### 37.3.29 Debug mode

When the microcontroller enters debug mode (Cortex®-M7 with FPU core halted), the TIMx counter either continues to work normally or stops, depending on DBG_TIMx_STOP configuration bit in DBG module.

For safety purposes, when the counter is stopped (DBG_TIMx_STOP = 1), the outputs are disabled (as if the MOE bit was reset). The outputs can either be forced to an inactive state (OSSI bit = 1), or have their control taken over by the GPIO controller (OSSI bit = 0), typically to force a Hi-Z.

For more details, refer to Section 59.5.8: Microcontroller debug unit (DBGMCU). For safety purposes, when the counter is stopped (TIMx = 1 in DBGMCU_APB2FZ1), the outputs are disabled (as if the MOE bit was reset). The outputs can either be forced to an inactive state (OSSI bit = 1), or have their control taken over by the GPIO controller (OSSI bit = 0) to force them to Hi-Z.
37.4 TIM1/TIM8 registers

Refer to for a list of abbreviations used in register descriptions.

37.4.1 TIMx control register 1 (TIMx_CR1)(x = 1, 8)

Address offset: 0x00

Reset value: 0x0000

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 UIFREMAP: UIF status bit remapping
0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.
1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 CKD[1:0]: Clock division
This bit-field indicates the division ratio between the timer clock (CK_INT) frequency and the dead-time and sampling clock (tDTS) used by the dead-time generators and the digital filters (ETR, TIx),

00: tDTS=CK_INT
01: tDTS=2CK_INT
10: tDTS=4CK_INT
11: Reserved, do not program this value

Bit 7 ARPE: Auto-reload preload enable
0: TIMx_ARR register is not buffered
1: TIMx_ARR register is buffered

Bits 6:5 CMS[1:0]: Center-aligned mode selection
00: Edge-aligned mode. The counter counts up or down depending on the direction bit (DIR).
01: Center-aligned mode 1. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set only when the counter is counting down.
10: Center-aligned mode 2. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set only when the counter is counting up.
11: Center-aligned mode 3. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set both when the counter is counting up or down.

Note: It is not allowed to switch from edge-aligned mode to center-aligned mode as long as the counter is enabled (CEN=1)

Bit 4 DIR: Direction
0: Counter used as upcounter
1: Counter used as downcounter

Note: This bit is read only when the timer is configured in Center-aligned mode or Encoder mode.

*Note: External clock, gated mode and encoder mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.*
Bits 31:24: Reserved, must be kept at reset value.

Bits 23:20: **MMS2[3:0]: Master mode selection 2**

These bits allow the information to be sent to ADC for synchronization (TRGO2) to be selected. The combination is as follows:

- **0000: Reset** - the UG bit from the TIMx_EGR register is used as trigger output (TRGO2). If the reset is generated by the trigger input (slave mode controller configured in reset mode), the signal on TRGO2 is delayed compared to the actual reset.
- **0001: Enable** - the Counter Enable signal CNT_EN is used as trigger output (TRGO2). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between the CEN control bit and the trigger input when configured in Gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO2, except if the Master/Slave mode is selected (see the MSM bit description in TIMx_SMCR register).
- **0010: Update** - the update event is selected as trigger output (TRGO2). For instance, a master timer can then be used as a prescaler for a slave timer.
- **0011: Compare pulse** - the trigger output sends a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or compare match occurs (TRGO2).
- **0100: Compare** - OC1REF signal is used as trigger output (TRGO2)
- **0101: Compare** - OC2REF signal is used as trigger output (TRGO2)
- **0110: Compare** - OC3REF signal is used as trigger output (TRGO2)
- **0111: Compare** - OC4REF signal is used as trigger output (TRGO2)
- **1000: Compare** - OC5REF signal is used as trigger output (TRGO2)
- **1001: Compare** - OC6REF signal is used as trigger output (TRGO2)
- **1010: Compare Pulse** - OC4REF rising or falling edges generate pulses on TRGO2
- **1011: Compare Pulse** - OC5REF or OC6REF rising edges generate pulses on TRGO2
- **1100: Compare Pulse** - OC4REF rising or falling edges generate pulses on TRGO2
- **1101: Compare Pulse** - OC6REF falling edges generate pulses on TRGO2
- **1110: Compare Pulse** - OC5REF or OC6REF rising edges generate pulses on TRGO2
- **1111: Compare Pulse** - OC5REF rising or OC6REF falling edges generate pulses on TRGO2

*Note: The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.*

Bit 19: Reserved, must be kept at reset value.

Bit 18: **OIS6**: Output Idle state 6 (OC6 output)
Refer to OIS1 bit

Bit 17: Reserved, must be kept at reset value.

Bit 16: **OIS5**: Output Idle state 5 (OC5 output)
Refer to OIS1 bit

Bit 15: Reserved, must be kept at reset value.

Bit 14: **OIS4**: Output Idle state 4 (OC4 output)
Refer to OIS1 bit

Bit 13: **OIS3N**: Output Idle state 3 (OC3N output)
Refer to OIS1N bit

Bit 12: **OIS3**: Output Idle state 3 (OC3 output)
Refer to OIS1 bit
Bit 11 **OIS2N**: Output Idle state 2 (OC2N output)  
Refer to OIS1N bit

Bit 10 **OIS2**: Output Idle state 2 (OC2 output)  
Refer to OIS1 bit

Bit 9 **OIS1N**: Output Idle state 1 (OC1N output)  
0: OC1N=0 after a dead-time when MOE=0  
1: OC1N=1 after a dead-time when MOE=0  
*Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 8 **OIS1**: Output Idle state 1 (OC1 output)  
0: OC1=0 (after a dead-time if OC1N is implemented) when MOE=0  
1: OC1=1 (after a dead-time if OC1N is implemented) when MOE=0  
*Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 7 **TI1S**: TI1 selection  
0: The TIMx_CH1 pin is connected to TI1 input  
1: The TIMx_CH1, CH2 and CH3 pins are connected to the TI1 input (XOR combination)

Bits 6:4 **MMS[2:0]**: Master mode selection  
These bits allow to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows:  
000: **Reset** - the UG bit from the TIMx_EGR register is used as trigger output (TRGO). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on TRGO is delayed compared to the actual reset.  
001: **Enable** - the Counter Enable signal CNT_EN is used as trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enable. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO, except if the master/slave mode is selected (see the MSM bit description in TIMx_SMCR register).  
010: **Update** - The update event is selected as trigger output (TRGO). For instance a master timer can then be used as a prescaler for a slave timer.  
011: **Compare Pulse** - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred. (TRGO)  
100: **Compare** - OC1REF signal is used as trigger output (TRGO)  
101: **Compare** - OC2REF signal is used as trigger output (TRGO)  
110: **Compare** - OC3REF signal is used as trigger output (TRGO)  
111: **Compare** - OC4REF signal is used as trigger output (TRGO)  
*Note: The clock of the slave timer or ADC must be enable prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.*

Bit 3 **CCDS**: Capture/compare DMA selection  
0: CCx DMA request sent when CCx event occurs  
1: CCx DMA requests sent when update event occurs

### Bit 2 CCUS: Capture/compare control update selection

- **0**: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit only.
- **1**: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit or when an rising edge occurs on TRGI.

*Note: This bit acts only on channels that have a complementary output.*

### Bit 0 CCPC: Capture/compare preloaded control

- **0**: CCxE, CCxNE and OCxM bits are not preloaded.
- **1**: CCxE, CCxNE and OCxM bits are preloaded, after having been written, they are updated only when a commutation event (COM) occurs (COMG bit set or rising edge detected on TRGI, depending on the CCUS bit).

*Note: This bit acts only on channels that have a complementary output.*

### Bits 31:22 Reserved, must be kept at reset value.

### Bits 19:17 Reserved, must be kept at reset value.

### Bit 15 ETP: External trigger polarity

- **0**: ETR is non-inverted, active at high level or rising edge.
- **1**: ETR is inverted, active at low level or falling edge.

### Bit 14 ECE: External clock enable

- **0**: External clock mode 2 disabled.
- **1**: External clock mode 2 enabled. The counter is clocked by any active edge on the ETRF signal.

*Note: 1: Setting the ECE bit has the same effect as selecting external clock mode 1 with TRGI connected to ETRF (SMS=111 and TS=00111). 2: It is possible to simultaneously use external clock mode 2 with the following slave modes: reset mode, gated mode and trigger mode. Nevertheless, TRGI must not be connected to ETRF in this case (TS bits must not be 00111). 3: If external clock mode 1 and external clock mode 2 are enabled at the same time, the external clock input is ETRF.*
Bits 13:12 **ETPS[1:0]**: External trigger prescaler

External trigger signal ETRP frequency must be at most 1/4 of TIMxCLK frequency. A prescaler can be enabled to reduce ETRP frequency. It is useful when inputting fast external clocks.

- 00: Prescaler OFF
- 01: ETRP frequency divided by 2
- 10: ETRP frequency divided by 4
- 11: ETRP frequency divided by 8

Bits 11:8 **ETF[3:0]**: External trigger filter

This bit-field then defines the frequency used to sample ETRP signal and the length of the digital filter applied to ETRP. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

- 0000: No filter, sampling is done at fDTS
- 0001: fSAMPLING=fCK_INT, N=2
- 0010: fSAMPLING=fCK_INT, N=4
- 0011: fSAMPLING=fCK_INT, N=8
- 0100: fSAMPLING=fDTS/2, N=6
- 0101: fSAMPLING=fDTS/2, N=8
- 0110: fSAMPLING=fDTS/4, N=6
- 0111: fSAMPLING=fDTS/4, N=8
- 1000: fSAMPLING=fDTS/8, N=6
- 1001: fSAMPLING=fDTS/8, N=8
- 1010: fSAMPLING=fDTS/16, N=5
- 1011: fSAMPLING=fDTS/16, N=6
- 1100: fSAMPLING=fDTS/16, N=8
- 1101: fSAMPLING=fDTS/32, N=5
- 1110: fSAMPLING=fDTS/32, N=6
- 1111: fSAMPLING=fDTS/32, N=8

Bit 7 **MSM**: Master/slave mode

- 0: No action
- 1: The effect of an event on the trigger input (TRGI) is delayed to allow a perfect synchronization between the current timer and its slaves (through TRGO). It is useful if we want to synchronize several timers on a single external event.

Bits 21, 20, 6, 5, 4 **TS[4:0]**: Trigger selection

This bit-field selects the trigger input to be used to synchronize the counter.

- 00000: Internal Trigger 0 (ITR0)
- 00001: Internal Trigger 1 (ITR1)
- 00010: Internal Trigger 2 (ITR2)
- 00011: Internal Trigger 3 (ITR3)
- 00100: TI1 Edge Detector (TI1F_ED)
- 00101: Filtered Timer Input 1 (TI1FP1)
- 00110: Filtered Timer Input 2 (TI2FP2)
- 00111: External Trigger input (ETRF)

Others: Reserved

See Table 323: TIMx internal trigger connection on page 1596 for more details on ITRx meaning for each Timer.

**Note:** These bits must be changed only when they are not used (e.g. when SMS=000) to avoid wrong edge detections at the transition.

**Note:** The other bit is at position 16 in the same register

Bit 3 Reserved, must be kept at reset value.
Bits 16, 2, 1, 0  **SMS[3:0]**: Slave mode selection

When external signals are selected the active edge of the trigger signal (TRGI) is linked to the polarity selected on the external input (see Input Control register and Control Register description).

0000: Slave mode disabled - if CEN = ‘1’ then the prescaler is clocked directly by the internal clock.

0001: Encoder mode 1 - Counter counts up/down on TI1FP1 edge depending on TI2FP2 level.

0010: Encoder mode 2 - Counter counts up/down on TI2FP2 edge depending on TI1FP1 level.

0011: Encoder mode 3 - Counter counts up/down on both TI1FP1 and TI2FP2 edges depending on the level of the other input.

0100: Reset Mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter and generates an update of the registers.

0101: Gated Mode - The counter clock is enabled when the trigger input (TRGI) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

0110: Trigger Mode - The counter starts at a rising edge of the trigger TRGI (but it is not reset). Only the start of the counter is controlled.

0111: External Clock Mode 1 - Rising edges of the selected trigger (TRGI) clock the counter.

1000: Combined reset + trigger mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter, generates an update of the registers and starts the counter.

Codes above 1000: Reserved.

**Note**: The gated mode must not be used if Ti1F_ED is selected as the trigger input (TS=00100). Indeed, Ti1F_ED outputs 1 pulse for each transition on Ti1F, whereas the gated mode checks the level of the trigger signal.

**Note**: The clock of the slave peripherals (timer, ADC, ...) receiving the TRGO or the TRGO2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

---

Bits 31:18  Reserved, must be kept at reset value.

Bit 17  **CC6IF**: Compare 6 interrupt flag  
Refer to CC1IF description (Note: Channel 6 can only be configured as output)

Bit 16  **CC5IF**: Compare 5 interrupt flag  
Refer to CC1IF description (Note: Channel 5 can only be configured as output)

Bits 15:14  Reserved, must be kept at reset value.

Bit 13  **SBIF**: System Break interrupt flag  
This flag is set by hardware as soon as the system break input goes active. It can be  
cleared by software if the system break input is not active.  
This flag must be reset to re-start PWM operation.  
0: No break event occurred.  
1: An active level has been detected on the system break input. An interrupt is generated if  
BIE=1 in the TIMx_DIER register.

Bit 12  **CC4OF**: Capture/Compare 4 overcapture flag  
Refer to CC1OF description

Bit 11  **CC3OF**: Capture/Compare 3 overcapture flag  
Refer to CC1OF description

Bit 10  **CC2OF**: Capture/Compare 2 overcapture flag  
Refer to CC1OF description
Bit 9 **CC1OF**: Capture/Compare 1 overcapture flag
   This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to ‘0’.
   0: No overcapture has been detected.
   1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set

Bit 8 **B2IF**: Break 2 interrupt flag
   This flag is set by hardware as soon as the break 2 input goes active. It can be cleared by software if the break 2 input is not active.
   0: No break event occurred.
   1: An active level has been detected on the break 2 input. An interrupt is generated if BIE=1 in the TIMx_DIER register.

Bit 7 **BIF**: Break interrupt flag
   This flag is set by hardware as soon as the break input goes active. It can be cleared by software if the break input is not active.
   0: No break event occurred.
   1: An active level has been detected on the break input. An interrupt is generated if BIE=1 in the TIMx_DIER register.

Bit 6 **TIF**: Trigger interrupt flag
   This flag is set by hardware on trigger event (active edge detected on TRGI input when the slave mode controller is enabled in all modes but gated mode. It is set when the counter starts or stops when gated mode is selected. It is cleared by software.
   0: No trigger event occurred.
   1: Trigger interrupt pending.

Bit 5 **COMIF**: COM interrupt flag
   This flag is set by hardware on COM event (when Capture/compare Control bits - CCxE, CCxNE, OCxM - have been updated). It is cleared by software.
   0: No COM event occurred.
   1: COM interrupt pending.

Bit 4 **CC4IF**: Capture/Compare 4 interrupt flag
   Refer to CC1IF description

Bit 3 **CC3IF**: Capture/Compare 3 interrupt flag
   Refer to CC1IF description

Bit 2 **CC2IF**: Capture/Compare 2 interrupt flag
   Refer to CC1IF description

Bit 1 **CC1IF**: Capture/Compare 1 interrupt flag
   **If channel CC1 is configured as output**: This flag is set by hardware when the counter matches the compare value, with some exception in center-aligned mode (refer to the CMS bits in the TIMx_CR1 register description). It is cleared by software.
   0: No match.
   1: The content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the contents of TIMx_CCR1 are greater than the contents of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in upcounting and up/down-counting modes) or underflow (in downcounting mode)
   **If channel CC1 is configured as input**: This bit is set by hardware on a capture. It is cleared by software or by reading the TIMx_CCR1 register.
   0: No input capture occurred
   1: The counter value has been captured in TIMx_CCR1 register (An edge has been detected on IC1 which matches the selected polarity)
37.4.6 TIMx event generation register (TIMx_EGR)(x = 1, 8)

Address offset: 0x14
Reset value: 0x0000

| Bit 15:9 Reserved, must be kept at reset value. |
| Bit 8 B2G: Break 2 generation |
| This bit is set by software in order to generate an event, it is automatically cleared by hardware. |
| 0: No action |
| 1: A break 2 event is generated. MOE bit is cleared and B2IF flag is set. Related interrupt can occur if enabled. |

| Bit 7 BG: Break generation |
| This bit is set by software in order to generate an event, it is automatically cleared by hardware. |
| 0: No action |
| 1: A break event is generated. MOE bit is cleared and BIF flag is set. Related interrupt or DMA transfer can occur if enabled. |

| Bit 6 TG: Trigger generation |
| This bit is set by software in order to generate an event, it is automatically cleared by hardware. |
| 0: No action |
| 1: The TIF flag is set in TIMx_SR register. Related interrupt or DMA transfer can occur if enabled. |

| Bit 5 COMG: Capture/Compare control update generation |
| This bit can be set by software, it is automatically cleared by hardware. |
| 0: No action |
| 1: When CCPC bit is set, it allows to update CCxE, CCxNE and OCxM bits |

*Note: This bit acts only on channels having a complementary output.*

| Bit 4 CC4G: Capture/Compare 4 generation |
| Refer to CC1G description |

| Bit 3 CC3G: Capture/Compare 3 generation |
| Refer to CC1G description |
Bit 2  **CC2G**: Capture/Compare 2 generation  
Refer to CC1G description

Bit 1  **CC1G**: Capture/Compare 1 generation  
This bit is set by software in order to generate an event, it is automatically cleared by hardware.  
0: No action  
1: A capture/compare event is generated on channel 1:  
**If channel CC1 is configured as output:**  
CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled.  
**If channel CC1 is configured as input:**  
The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0  **UG**: Update generation  
This bit can be set by software, it is automatically cleared by hardware.  
0: No action  
1: Reinitialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected). The counter is cleared if the center-aligned mode is selected or if DIR=0 (upcounting), else it takes the auto-reload value (TIMx_ARR) if DIR=1 (downcounting).

### 37.4.7 TIMx capture/compare mode register 1 [alternate]  
(TIMx_CCMR1)(x = 1, 8)

Address offset: 0x18  
Reset value: 0x0000 0000  
The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (e.g. channel 1 in input capture mode and channel 2 in output compare mode).

#### Input capture mode:

Bits 31:25  Reserved, must be kept at reset value.

Bit 24 **OC2M[3]**: Output Compare 2 mode - bit 3
Refer to OC2M description on bits 14:12.

Bits 23:17  Reserved, must be kept at reset value.

Bit 16 **OC1M[3]**: Output Compare 1 mode - bit 3
Refer to OC1M description on bits 6:4

Bit 15 **OC2CE**: Output Compare 2 clear enable
Refer to OC1CE description.

Bits 14:12 **OC2M[2:0]**: Output Compare 2 mode
Refer to OC1M[2:0] description.

Bit 11 **OC2PE**: Output Compare 2 preload enable
Refer to OC1PE description.

Bit 10 **OC2FE**: Output Compare 2 fast enable
Refer to OC1FE description.

Bits 9:8 **CC2S[1:0]**: Capture/Compare 2 selection
This bit-field defines the direction of the channel (input/output) as well as the used input.
00: CC2 channel is configured as output
01: CC2 channel is configured as input, IC2 is mapped on TI2
10: CC2 channel is configured as input, IC2 is mapped on TI1
11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through the TS bit (TIMx_SMCR register)

*Note*: **CC2S bits are writable only when the channel is OFF (CC2E = ‘0’ in TIMx_CCER).**

Bit 7 **OC1CE**: Output Compare 1 clear enable
0: OC1Ref is not affected by the ETRF input
1: OC1Ref is cleared as soon as a High level is detected on ETRF input
Bits 6:4 **OC1M[2:0]: Output Compare 1 mode**

These bits define the behavior of the output reference signal OC1REF from which OC1 and OC1N are derived. OC1REF is active high whereas OC1 and OC1N active level depends on CC1P and CC1NP bits.

0000: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs.(this mode is used to generate a timing base).

0001: Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0010: Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0011: Toggle - OC1REF toggles when TIMx_CNT=TIMx_CCR1.

0010: Force inactive level - OC1REF is forced low.

0100: Force active level - OC1REF is forced high.

0101: PWM mode 1 - In upcounting, channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else inactive. In downcounting, channel 1 is inactive (OC1REF='0') as long as TIMx_CNT>TIMx_CCR1 else active (OC1REF='1').

0111: PWM mode 2 - In upcounting, channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else active. In downcounting, channel 1 is active as long as TIMx_CNT>TIMx_CCR1 else inactive.

1000: Retrigerrable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

1001: Retrigerrable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

1010: Combined PWM mode 1 - OC1REF has the same behavior as in PWM mode 1. OC1REFC is the logical OR between OC1REF and OC2REF.

1011: Combined PWM mode 2 - OC1REF has the same behavior as in PWM mode 2. OC1REFC is the logical AND between OC1REF and OC2REF.

1100: Asymmetric PWM mode 1 - OC1REF has the same behavior as in PWM mode 1. OC1REFC outputs OC1REF when the counter is counting up, OC2REF when it is counting down.

1110: Asymmetric PWM mode 2 - OC1REF has the same behavior as in PWM mode 2. OC1REFC outputs OC1REF when the counter is counting up, OC2REF when it is counting down.

Note: **These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S='00' (the channel is configured in output).**

Note: **In PWM mode, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.**

Note: **On channels having a complementary output, this bit field is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the OC1M active bits take the new value from the preloaded bits only when a COM event is generated.**
Bit 3 **OC1PE**: Output Compare 1 preload enable
- 0: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the
  new value is taken in account immediately.
- 1: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload
  register. TIMx_CCR1 preload value is loaded in the active register at each update event.

*Note:* 1: These bits can not be modified as long as LOCK level 3 has been programmed
(LOCK bits in TIMx_BDTR register) and CC1S=’00’ (the channel is configured in
output).
2: The PWM mode can be used without validating the preload register only in one
pulse mode (OPM bit set in TIMx_CR1 register). Else the behavior is not guaranteed.

Bit 2 **OC1FE**: Output Compare 1 fast enable
This bit is used to accelerate the effect of an event on the trigger in input on the CC output.
- 0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is
  ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is
  5 clock cycles.
- 1: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is
  set to the compare level independently from the result of the comparison. Delay to sample
  the trigger input and to activate CC1 output is reduced to 3 clock cycles. OCFE acts only if
  the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection
This bit-field defines the direction of the channel (input/output) as well as the used input.
- 00: CC1 channel is configured as output
- 01: CC1 channel is configured as input, IC1 is mapped on TI1
- 10: CC1 channel is configured as input, IC1 is mapped on TI2
- 11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if
  an internal trigger input is selected through TS bit (TIMx_SMCR register)

*Note:* CC1S bits are writable only when the channel is OFF (CC1E = ‘0’ in TIMx_CCER).

37.4.9 **TIMx capture/compare mode register 2 [alternate]**
(TIMx_CCMR2)(x = 1, 8)
Address offset: 0x1C
Reset value: 0x0000 0000
The same register can be used for input capture mode (this section) or for output compare
mode (next section). The direction of a channel is defined by configuring the corresponding
CCxS bits. All the other bits of this register have a different function for input capture and for
output compare modes. It is possible to combine both modes independently (e.g. channel 1
in input capture mode and channel 2 in output compare mode).

  Bit 24  **OC4M[3]**: Output Compare 4 mode - bit 3
          Refer to OC1M description.

Bits 23:17  Reserved, must be kept at reset value.

  Bit 16  **OC3M[3]**: Output Compare 3 mode - bit 3
          Refer to OC1M description.

  Bit 15  **OC4CE**: Output compare 4 clear enable
          Refer to OC1CE description.

Bits 14:12  **OC4M[2:0]**: Output compare 4 mode
          Refer to OC4M description.

  Bit 11  **OC4PE**: Output compare 4 preload enable
          Refer to OC1PE description.

  Bit 10  **OC4FE**: Output compare 4 fast enable
          Refer to OC1FE description.

Bits 9:8  **CC4S[1:0]**: Capture/Compare 4 selection
          This bit-field defines the direction of the channel (input/output) as well as the used input.
          00: CC4 channel is configured as output
          01: CC4 channel is configured as input, IC4 is mapped on TI4
          10: CC4 channel is configured as input, IC4 is mapped on TI3
          11: CC4 channel is configured as input, IC4 is mapped on TRC. This mode is working only if
          an internal trigger input is selected through TS bit (TIMx_SMCR register)

  **Note**: CC4S bits are writable only when the channel is OFF (CC4E = '0' in TIMx_CCER).

  Bit 7  **OC3CE**: Output compare 3 clear enable
          Refer to OC1CE description.

Bits 6:4  **OC3M[2:0]**: Output compare 3 mode
          Refer to OC1M description.

  Bit 3  **OC3PE**: Output compare 3 preload enable
          Refer to OC1PE description.

  Bit 2  **OC3FE**: Output compare 3 fast enable
          Refer to OC1FE description.

Bits 1:0  **CC3S[1:0]**: Capture/Compare 3 selection
          This bit-field defines the direction of the channel (input/output) as well as the used input.
          00: CC3 channel is configured as output
          01: CC3 channel is configured as input, IC3 is mapped on TI3
          10: CC3 channel is configured as input, IC3 is mapped on TI4
          11: CC3 channel is configured as input, IC3 is mapped on TRC. This mode is working only if
          an internal trigger input is selected through TS bit (TIMx_SMCR register)

  **Note**: CC3S bits are writable only when the channel is OFF (CC3E = '0' in TIMx_CCER).
37.4.11 TIMx capture/compare enable register (TIMx_CCER)(x = 1, 8)

Address offset: 0x20
Reset value: 0x0000 0000

Bits 31:22 Reserved, must be kept at reset value.
Bit 21 CC6P: Capture/Compare 6 output polarity
   Refer to CC1P description
Bit 20 CC6E: Capture/Compare 6 output enable
   Refer to CC1E description

Bits 19:18 Reserved, must be kept at reset value.
Bit 17 CC5P: Capture/Compare 5 output polarity
   Refer to CC1P description
Bit 16 CC5E: Capture/Compare 5 output enable
   Refer to CC1E description
Bit 15 CC4NP: Capture/Compare 4 complementary output polarity
   Refer to CC1NP description
Bit 14 Reserved, must be kept at reset value.
Bit 13 CC4P: Capture/Compare 4 output polarity
   Refer to CC1P description
Bit 12 CC4E: Capture/Compare 4 output enable
   Refer to CC1E description
Bit 11 CC3NP: Capture/Compare 3 complementary output polarity
   Refer to CC1NP description
Bit 10 CC3NE: Capture/Compare 3 complementary output enable
   Refer to CC1NE description
Bit 9 CC3P: Capture/Compare 3 output polarity
   Refer to CC1P description
Bit 8 CC3E: Capture/Compare 3 output enable
   Refer to CC1E description
Bit 7 CC2NP: Capture/Compare 2 complementary output polarity
   Refer to CC1NP description
Bit 6 CC2NE: Capture/Compare 2 complementary output enable
   Refer to CC1NE description
Bit 5 **CC2P**: Capture/Compare 2 output polarity
Refer to CC1P description

Bit 4 **CC2E**: Capture/Compare 2 output enable
Refer to CC1E description

Bit 3 **CC1NP**: Capture/Compare 1 complementary output polarity

**CC1 channel configured as output:**
0: OC1N active high.
1: OC1N active low.

**CC1 channel configured as input:**
This bit is used in conjunction with CC1P to define the polarity of TI1FP1 and TI2FP1. Refer to CC1P description.

*Note:* This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S="00" (channel configured as output).

On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1NP active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bit 2 **CC1NE**: Capture/Compare 1 complementary output enable

0: Off - OC1N is not active. OC1N level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.
1: On - OC1N signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.

On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1NE active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bit 1 **CC1P**: Capture/Compare 1 output polarity

**CC1 channel configured as output:**
0: OC1 active high
1: OC1 active low

**CC1 channel configured as input:** CC1NP/CC1P bits select the active polarity of TI1FP1 and TI2FP1 for trigger or capture operations.
00: non-inverted/rising edge. The circuit is sensitive to TIxFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode or encoder mode).
01: inverted/falling edge. The circuit is sensitive to TIxFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is inverted (trigger operation in gated mode or encoder mode).
10: reserved, do not use this configuration.
11: non-inverted/both edges/ The circuit is sensitive to both TIxFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode). This configuration must not be used in encoder mode.

*Note:* This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1P active bit takes the new value from the preloaded bit only when a Commutation event is generated.
Bit 0  **CC1E**: Capture/Compare 1 output enable

**CC1 channel configured as output:**
0: Off - OC1 is not active. OC1 level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and CC1NE bits.
1: On - OC1 signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and CC1NE bits.

**CC1 channel configured as input:** This bit determines if a capture of the counter value can actually be done into the input capture/compare register 1 (TIMx_CCR1) or not.
0: Capture disabled.
1: Capture enabled.

*On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1E active bit takes the new value from the preloaded bit only when a Commutation event is generated.*

### Table 324. Output control bits for complementary OCx and OCxN channels with break feature

</table>

**Note**: As the bits BK2P, BK2E, BKF[3:0], BKF[3:0], AOE, BKP, BKE, OSSI, OSSR and DTG[7:0] can be write-locked depending on the LOCK configuration, it can be necessary to configure all of them during the first write access to the TIMx_BDTR register.

Bits 31:26  Reserved, must be kept at reset value.

**Bit 25  BK2P**: Break 2 polarity

- 0: Break input BRK2 is active low
- 1: Break input BRK2 is active high

**Note**: This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

**Note**: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.
Bit 24 **BK2E**: Break 2 enable

This bit enables the complete break 2 protection (including all sources connected to bk_acth and BKIN sources, as per Figure 387: Break and Break2 circuitry overview).

- 0: Break2 function disabled
- 1: Break2 function enabled

**Note:** The BKIN2 must only be used with OSSR = OSSI = 1.

**Note:** This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

**Note:** Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bits 23:20 **BK2F[3:0]**: Break 2 filter

This bit-field defines the frequency used to sample BRK2 input and the length of the digital filter applied to BRK2. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

- 0000: No filter, BRK2 acts asynchronously
- 0001: \( f_{SAMPLING} = f_{CK} \), \( N = 2 \)
- 0010: \( f_{SAMPLING} = f_{CK} \), \( N = 4 \)
- 0011: \( f_{SAMPLING} = f_{CK} \), \( N = 8 \)
- 0100: \( f_{SAMPLING} = f_{DTS}/2 \), \( N = 6 \)
- 0101: \( f_{SAMPLING} = f_{DTS}/2 \), \( N = 8 \)
- 0110: \( f_{SAMPLING} = f_{DTS}/4 \), \( N = 6 \)
- 0111: \( f_{SAMPLING} = f_{DTS}/4 \), \( N = 8 \)
- 1000: \( f_{SAMPLING} = f_{DTS}/8 \), \( N = 6 \)
- 1001: \( f_{SAMPLING} = f_{DTS}/8 \), \( N = 8 \)
- 1010: \( f_{SAMPLING} = f_{DTS}/16 \), \( N = 5 \)
- 1011: \( f_{SAMPLING} = f_{DTS}/16 \), \( N = 6 \)
- 1100: \( f_{SAMPLING} = f_{DTS}/32 \), \( N = 5 \)
- 1101: \( f_{SAMPLING} = f_{DTS}/32 \), \( N = 6 \)
- 1110: \( f_{SAMPLING} = f_{DTS}/32 \), \( N = 8 \)

**Note:** This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 19:16 **BKF[3:0]**: Break filter

This bit-field defines the frequency used to sample BRK input and the length of the digital filter applied to BRK. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

- 0000: No filter, BRK acts asynchronously
- 0001: \( f_{SAMPLING} = f_{CK} \), \( N = 2 \)
- 0010: \( f_{SAMPLING} = f_{CK} \), \( N = 4 \)
- 0011: \( f_{SAMPLING} = f_{CK} \), \( N = 8 \)
- 0100: \( f_{SAMPLING} = f_{DTS}/2 \), \( N = 6 \)
- 0101: \( f_{SAMPLING} = f_{DTS}/2 \), \( N = 8 \)
- 0110: \( f_{SAMPLING} = f_{DTS}/4 \), \( N = 6 \)
- 0111: \( f_{SAMPLING} = f_{DTS}/4 \), \( N = 8 \)
- 1000: \( f_{SAMPLING} = f_{DTS}/8 \), \( N = 6 \)
- 1001: \( f_{SAMPLING} = f_{DTS}/8 \), \( N = 8 \)
- 1010: \( f_{SAMPLING} = f_{DTS}/16 \), \( N = 5 \)
- 1011: \( f_{SAMPLING} = f_{DTS}/16 \), \( N = 6 \)
- 1100: \( f_{SAMPLING} = f_{DTS}/32 \), \( N = 5 \)
- 1101: \( f_{SAMPLING} = f_{DTS}/32 \), \( N = 6 \)
- 1110: \( f_{SAMPLING} = f_{DTS}/32 \), \( N = 8 \)

**Note:** This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).
Bit 15 **MOE**: Main output enable

This bit is cleared asynchronously by hardware as soon as one of the break inputs is active (BRK or BRK2). It is set by software or automatically depending on the AOE bit. It is acting only on the channels which are configured in output.

0: In response to a break 2 event. OC and OCN outputs are disabled
In response to a break event or if MOE is written to 0: OC and OCN outputs are disabled or forced to idle state depending on the OSSI bit.
1: OC and OCN outputs are enabled if their respective enable bits are set (CCxE, CCxNE in TIMx_CCER register).

See OC/OCN enable description for more details (Section 37.4.11: TIMx capture/compare enable register (TIMx_CCER)(x = 1, 8)).

Bit 14 **AOE**: Automatic output enable

0: MOE can be set only by software
1: MOE can be set by software or automatically at the next update event (if none of the break inputs BRK and BRK2 is active)

*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 13 **BKP**: Break polarity

0: Break input BRK is active low
1: Break input BRK is active high

*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

*Note:* Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 12 **BKE**: Break enable

This bit enables the complete break protection (including all sources connected to bk_acth and BKIN sources, as per Figure 387: Break and Break2 circuitry overview).

0: Break function disabled
1: Break function enabled

*Note:* This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

*Note:* Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 11 **OSSR**: Off-state selection for Run mode

This bit is used when MOE=1 on channels having a complementary output which are configured as outputs. OSSR is not implemented if no complementary output is implemented in the timer.

See OC/OCN enable description for more details (Section 37.4.11: TIMx capture/compare enable register (TIMx_CCER)(x = 1, 8)).

0: When inactive, OC/OCN outputs are disabled (the timer releases the output control which is taken over by the GPIO logic, which forces a Hi-Z state).
1: When inactive, OC/OCN outputs are enabled with their inactive level as soon as CCxE=1 or CCxNE=1 (the output is still controlled by the timer).

*Note:* This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).
Bit 10 **OSSI**: Off-state selection for Idle mode

This bit is used when MOE=0 due to a break event or by a software write, on channels configured as outputs.

See OC/OCN enable description for more details (Section 37.4.11: TIMx capture/compare enable register (TIMx_CCER)(x = 1, 8)).

0: When inactive, OC/OCN outputs are disabled (the timer releases the output control which is taken over by the GPIO logic and which imposes a Hi-Z state).

1: When inactive, OC/OCN outputs are first forced with their inactive level then forced to their idle level after the deadtime. The timer maintains its control over the output.

Note: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 9:8 **LOCK[1:0]**: Lock configuration

These bits offer a write protection against software errors.

00: LOCK OFF - No bit is write protected.
01: LOCK Level 1 = DTG bits in TIMx_BDTR register, OISx and OISxN bits in TIMx_CR2 register and BKE/BKP/AOE bits in TIMx_BDTR register can no longer be written.
10: LOCK Level 2 = LOCK Level 1 + CC Polarity bits (CCxP/CCxNP bits in TIMx_CCER register, as long as the related channel is configured in output through the CCxS bits) as well as OSSR and OSSI bits can no longer be written.
11: LOCK Level 3 = LOCK Level 2 + CC Control bits (OCxM and OCxPE bits in TIMx_CCMRx registers, as long as the related channel is configured in output through the CCxS bits) can no longer be written.

Note: The LOCK bits can be written only once after the reset. Once the TIMx_BDTR register has been written, their content is frozen until the next reset.

Bits 7:0 **DTG[7:0]**: Dead-time generator setup

This bit-field defines the duration of the dead-time inserted between the complementary outputs. DT correspond to this duration.

DTG[7:5]=0xx => DT=DTG[7:0]x t_{d_{tg}} with t_{d_{tg}}=t_{DTS}.
DTG[7:5]=10x => DT=(64+DTG[5:0])x t_{d_{tg}} with T_{d_{tg}}=2x_{DTS}.
DTG[7:5]=110 => DT=(32+DTG[4:0])x t_{d_{tg}} with T_{d_{tg}}=8x_{DTS}.
DTG[7:5]=111 => DT=(32+DTG[4:0])x t_{d_{tg}} with T_{d_{tg}}=16x_{DTS}.

Example if T_{DTS}=125ns (8MHz), dead-time possible values are:
0 to 15875 ns by 125 ns steps,
16 us to 31750 ns by 250 ns steps,
32 us to 63us by 1 us steps,
64 us to 126 us by 2 us steps

Note: This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

### 37.4.21 TIMx DMA control register (TIMx_DCR)(x = 1, 8)

</tbody>
</table>

Bits 12:8 \(\text{DBL}[4:0]\): DMA burst length
This 5-bit vector defines the length of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address), i.e. the number of transfers. Transfers can be in half-words or in bytes (see example below).
00000: 1 transfer
00001: 2 transfers
00010: 3 transfers
...
10001: 18 transfers

Example: Let us consider the following transfer: \(\text{DBL} = 7\) bytes & \(\text{DBA} = \text{TIMx_CR1}\).
- If \(\text{DBL} = 7\) bytes and \(\text{DBA} = \text{TIMx_CR1}\) represents the address of the byte to be transferred, the address of the transfer should be given by the following equation:
\[(\text{TIMx_CR1 address}) + \text{DBA} + (\text{DMA index}), \text{where DMA index} = \text{DBL}\]
In this example, 7 bytes are added to \((\text{TIMx_CR1 address}) + \text{DBA}\), which gives us the address from/to which the data will be copied. In this case, the transfer is done to 7 registers starting from the following address: \((\text{TIMx_CR1 address}) + \text{DBA}\)

According to the configuration of the DMA Data Size, several cases may occur:
- If the DMA Data Size is configured in half-words, 16-bit data will be transferred to each of the 7 registers.
- If the DMA Data Size is configured in bytes, the data will also be transferred to 7 registers: the first register will contain the first MSB byte, the second register, the first LSB byte and so on. So with the transfer Timer, one also has to specify the size of data transferred by DMA.

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 \(\text{DBA}[4:0]\): DMA base address
This 5-bits vector defines the base-address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register.

Example:
00000: TIMx_CR1,
00001: TIMx_CR2,
00010: TIMx_SMCR,
...
37.4.23  **TIMx capture/compare mode register 3**

(TIMx_CCMR3)(x = 1, 8)

Address offset: 0x54

Reset value: 0x0000 0000

The channels 5 and 6 can only be configured in output.

**Output compare mode:**

Bits 31:18 Reserved, must be kept at reset value.

Bits 17:14 **ETRSEL[3:0]:** ETR source selection
These bits select the ETR input source.
0000: ETR input is connected to I/O
0001: COMP1 output
0010: COMP2 output
0011: ADC1 AWD1
0100: ADC1 AWD2
0101: ADC1 AWD3
0110: ADC3 AWD1
0111: ADC3 AWD2
1000: ADC3 AWD3
Others: Reserved

Note: These bits can not be modified as long as LOCK level 1 has been programmed (LOCK
bits in TIMx_BDTR register).

Bits 13:12 Reserved, must be kept at reset value.
Bit 11 **BKCMP2P**: BRK COMP2 input polarity
This bit selects the COMP2 input sensitivity. It must be programmed together with the BKP polarity bit.
0: COMP2 input is active high
1: COMP2 input is active low

*Note:* This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 10 **BKCMP1P**: BRK COMP1 input polarity
This bit selects the COMP1 input sensitivity. It must be programmed together with the BKP polarity bit.
0: COMP1 input is active high
1: COMP1 input is active low

*Note:* This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 9 **BKINP**: BRK BKIN input polarity
This bit selects the BKIN alternate function input sensitivity. It must be programmed together with the BKP polarity bit.
0: BKIN input is active high
1: BKIN input is active low

*Note:* This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 8 **BKDF1BK0E**: BRK dfsdm1_break[0] enable
This bit enables the dfsdm1_break[0] for the timer’s BRK input. dfsdm1_break[0] output is ‘ORed’ with the other BRK sources.
0: dfsdm1_break[0] input disabled
1: dfsdm1_break[0] input enabled

*Note:* This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 7:3 Reserved, must be kept at reset value.

Bit 2 **BKCMP2E**: BRK COMP2 enable
This bit enables the COMP2 for the timer’s BRK input. COMP2 output is ‘ORed’ with the other BRK sources.
0: COMP2 input disabled
1: COMP2 input enabled

*Note:* This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 1 **BKCMP1E**: BRK COMP1 enable
This bit enables the COMP1 for the timer’s BRK input. COMP1 output is ‘ORed’ with the other BRK sources.
0: COMP1 input disabled
1: COMP1 input enabled

*Note:* This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).
Bit 0 **BKINE**: BRK BKIN input enable

This bit enables the BKIN alternate function input for the timer’s BRK input. BKIN input is ‘ORed’ with the other BRK sources.

0: BKIN input disabled
1: BKIN input enabled

*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

**Note:** Refer to Figure 366: TIM1/TIM8 ETR input circuitry and to Figure 387: Break and Break2 circuitry overview.

**Bit 8 BK2DF1BK1E: BRK2 dfsdm1_break[1] enable**
- This bit enables the dfsdm1_break[1] for the timer’s BRK2 input. dfsdm1_break[1] output is 'ORed' with the other BRK2 sources.
- 0: dfsdm1_break[1] input disabled
- 1: dfsdm1_break[1] input enabled

**Note:** This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

**Bits 7:3:** Reserved, must be kept at reset value.

**Bit 2 BK2CMP2E: BRK2 COMP2 enable**
- This bit enables the COMP2 for the timer’s BRK2 input. COMP2 output is 'ORed' with the other BRK2 sources.
- 0: COMP2 input disabled
- 1: COMP2 input enabled

**Note:** This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

**Bit 1 BK2CMP1E: BRK2 COMP1 enable**
- This bit enables the COMP1 for the timer’s BRK2 input. COMP1 output is 'ORed' with the other BRK2 sources.
- 0: COMP1 input disabled
- 1: COMP1 input enabled

**Note:** This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

**Bit 0 BK2INE: BRK2 BKIN input enable**
- This bit enables the BKIN2 alternate function input for the timer’s BRK2 input. BKIN2 input is 'ORed' with the other BRK2 sources.
- 0: BKIN2 input disabled
- 1: BKIN2 input enabled

**Note:** This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).
Bits 17:14 **ETRSEL[3:0]**: ETR source selection

These bits select the ETR input source.

- 0000: ETR input is connected to I/O
- 0001: COMP1 output
- 0010: COMP2 output
- 0011: ADC2 AWD1
- 0100: ADC2 AWD2
- 0101: ADC2 AWD3
- 0110: ADC3 AWD1
- 0111: ADC3 AWD2
- 1000: ADC3 AWD3
- Others: Reserved

Note: These bits can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **BKCMP2P**: BRK COMP2 input polarity

This bit selects the COMP2 input sensitivity. It must be programmed together with the BKP polarity bit.

- 0: COMP2 input is active high
- 1: COMP2 input is active low

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 10 **BKCMP1P**: BRK COMP1 input polarity

This bit selects the COMP1 input sensitivity. It must be programmed together with the BKP polarity bit.

- 0: COMP1 input is active high
- 1: COMP1 input is active low

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 9 **BKINP**: BRK BKIN input polarity

This bit selects the BKIN alternate function input sensitivity. It must be programmed together with the BKP polarity bit.

- 0: BKIN input is active high
- 1: BKIN input is active low

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 8 **BKDF1BK2E**: BRK dfsdm1_break[2] enable

This bit enables the dfsdm1_break[2] for the timer’s BRK input. dfsdm1_break[2] output is 'ORed' with the other BRK sources.

- 0: dfsdm1_break[2] input disabled
- 1: dfsdm1_break[2] input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 7:3 Reserved, must be kept at reset value.
Bit 2 **BKCMP2E**: BRK COMP2 enable

This bit enables the COMP2 for the timer’s BRK input. COMP2 output is ‘ORed’ with the other BRK sources.

- 0: COMP2 input disabled
- 1: COMP2 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 1 **BKCMP1E**: BRK COMP1 enable

This bit enables the COMP1 for the timer’s BRK input. COMP1 output is ‘ORed’ with the other BRK sources.

- 0: COMP1 input disabled
- 1: COMP1 input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 0 **BKINE**: BRK BKIN input enable

This bit enables the BKIN alternate function input for the timer’s BRK input. BKIN input is ‘ORed’ with the other BRK sources.

- 0: BKIN input disabled
- 1: BKIN input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

---

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **BK2CMP2P**: BRK2 COMP2 input polarity

This bit selects the COMP2 input sensitivity. It must be programmed together with the BK2P polarity bit.

- 0: COMP2 input is active low
- 1: COMP2 input is active high

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*
Bit 10 **BK2CMP1P**: BRK2 COMP1 input polarity
This bit selects the COMP1 input sensitivity. It must be programmed together with the BK2P polarity bit.
- 0: COMP1 input is active low
- 1: COMP1 input is active high
*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 9 **BK2INP**: BRK2 BKIN2 input polarity
This bit selects the BKIN2 alternate function input sensitivity. It must be programmed together with the BK2P polarity bit.
- 0: BKIN2 input is active low
- 1: BKIN2 input is active high
*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 8 **BK2DF1BK3E**: BRK2 dfsdm1_break[3] enable
This bit enables the dfsdm1_break[3] for the timer’s BRK2 input. dfsdm1_break[3] output is ‘ORed’ with the other BRK2 sources.
- 0: dfsdm1_break[3] input disabled
- 1: dfsdm1_break[3] input enabled
*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 7:3 Reserved, must be kept at reset value.

Bit 2 **BK2CMP2E**: BRK2 COMP2 enable
This bit enables the COMP2 for the timer’s BRK2 input. COMP2 output is ‘ORed’ with the other BRK2 sources.
- 0: COMP2 input disabled
- 1: COMP2 input enabled
*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 1 **BK2CMP1E**: BRK2 COMP1 enable
This bit enables the COMP1 for the timer’s BRK2 input. COMP1 output is ‘ORed’ with the other BRK2 sources.
- 0: COMP1 input disabled
- 1: COMP1 input enabled
*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 0 **BK2INE**: BRK2 BKIN input enable
This bit enables the BKIN2 alternate function input for the timer’s BRK2 input. BKIN2 input is ‘ORed’ with the other BRK2 sources.
- 0: BKIN2 input disabled
- 1: BKIN2 input enabled
*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

*Note*: Refer to Figure 387: Break and Break2 circuitry overview.
### 37.4.30 TIM1 timer input selection register (TIM1_TISEL)

Address offset: 0x68  
Reset value: 0x0000 0000

|   |   |   |   |   |   |   |   | TIS[3:0] |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 31| 30| 29| 28| 27| 26| 25| 24| 23| 22| 21| 20| 19| 18| 17| 16|
| 31| 30| 29| 28| 27| 26| 25| 24| 23| 22| 21| 20| 19| 18| 17| 16|
| 15| 14| 13| 12| 11| 10| 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:24 **TIS[3:0]** selects TIS[0] to TIS[15] input

- 0000: TIM1_CH4 input
- Others: Reserved

Bits 23:20 Reserved, must be kept at reset value.

Bits 19:16 **TIS[3:0]** selects TIS[0] to TIS[15] input

- 0000: TIM1_CH3 input
- Others: Reserved

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **TIS[3:0]** selects TIS[0] to TIS[15] input

- 0000: TIM1_CH2 input
- Others: Reserved

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **TIS[3:0]** selects TIS[0] to TIS[15] input

- 0000: TIM1_CH1 input
- 0001: COMP1 output
- Others: Reserved

### 37.4.31 TIM8 timer input selection register (TIM8_TISEL)

Address offset: 0x68  
Reset value: 0x0000 0000

|   |   |   |   |   |   |   |   | TIS[3:0] |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 31| 30| 29| 28| 27| 26| 25| 24| 23| 22| 21| 20| 19| 18| 17| 16|
| 31| 30| 29| 28| 27| 26| 25| 24| 23| 22| 21| 20| 19| 18| 17| 16|
| 15| 14| 13| 12| 11| 10| 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:24 **TIS[3:0]** selects TIS[0] to TIS[15] input

- 0000: TIM8_CH4 input
- Others: Reserved
**Bits 23:20**  Reserved, must be kept at reset value.

**Bits 19:16**  **T13SEL[3:0]**: selects T13[0] to T13[15] input  
- 0000: TIM8.CH3 input  
- Others: Reserved

**Bits 15:12**  Reserved, must be kept at reset value.

**Bits 11:8**  **T12SEL[3:0]**: selects T12[0] to T12[15] input  
- 0000: TIM8.CH2 input  
- Others: Reserved

**Bits 7:4**  Reserved, must be kept at reset value.

**Bits 3:0**  **T11SEL[3:0]**: selects T11[0] to T11[15] input  
- 0000: TIM8.CH1 input  
- 0001: COMP2 output  
- Others: Reserved
37.4.32 TIM1 register map

TIM1 registers are mapped as 16-bit addressable registers as described in the table below:

TM0433 Rev 6 1633/3289
Refer to Section 2.3 on page 126 for the register boundary addresses.
38  General-purpose timers (TIM2/TIM3/TIM4/TIM5)

38.1  TIM2/TIM3/TIM4/TIM5 introduction

The general-purpose timers consist of a 16-bit/32-bit auto-reload counter driven by a programmable prescaler.

They may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare and PWM).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The timers are completely independent, and do not share any resources. They can be synchronized together as described in Section 38.3.19: Timer synchronization.

38.2  TIM2/TIM3/TIM4/TIM5 main features

General-purpose TIMx timer features include:

- 16-bit (TIM3, TIM4) or 32-bit (TIM2 and TIM5) up, down, up/down auto-reload counter.
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535.
- Up to 4 independent channels for:
  - Input capture
  - Output compare
  - PWM generation (Edge- and Center-aligned modes)
  - One-pulse mode output
- Synchronization circuit to control the timer with external signals and to interconnect several timers.
- Interrupt/DMA generation on the following events:
  - Update: counter overflow/underflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
- Supports incremental (quadrature) encoder and hall-sensor circuitry for positioning purposes
- Trigger input for external clock or cycle-by-cycle current management

38.3 TIM2/TIM3/TIM4/TIM5 functional description

38.3.1 Time-base unit

The main block of the programmable timer is a 16-bit/32-bit counter with its related auto-reload register. The counter can count up, down or both up and down but also down or both up and down. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:
- Counter Register (TIMx_CNT)
- Prescaler Register (TIMx_PSC)
- Auto-Reload Register (TIMx_ARR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow (or underflow when downcounting) and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detail for each configuration.

The counter is clocked by the prescaler output CK_CNT, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the actual counter enable signal CNT_EN is set 1 clock cycle after CEN.

Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit/32-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 405* and *Figure 406* give some examples of the counter behavior when the prescaler ratio is changed on the fly:
Figure 405. Counter timing diagram with prescaler division change from 1 to 2

Figure 406. Counter timing diagram with prescaler division change from 1 to 4
38.3.2 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

An Update event can be generated at each counter overflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller).

The UEV event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register)
- The auto-reload shadow register is updated with the preload value (TIMx_ARR)

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

Figure 407. Counter timing diagram, internal clock divided by 1
Figure 408. Counter timing diagram, internal clock divided by 2

Figure 409. Counter timing diagram, internal clock divided by 4
**Figure 410. Counter timing diagram, internal clock divided by N**

![Diagram with labels: CK_PSC, Timer clock = CK_CNT, Counter register, Counter overflow, Update event (UEV), Update interrupt flag (UIF)]

**Figure 411. Counter timing diagram, Update event when ARPE=0 (TIMx_ARR not preloaded)**

![Diagram with labels: CK_PSC, CEN, Timer clock = CK_CNT, Counter register, Counter overflow, Update event (UEV), Update interrupt flag (UIF), Auto-reload preload register, Write a new value in TIMx_ARR]
**Downcounting mode**

In downcounting mode, the counter counts from the auto-reload value (content of the TIMx_ARR register) down to 0, then restarts from the auto-reload value and generates a counter underflow event.

An Update event can be generated at each counter underflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller).

The UEV update event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter restarts from the current auto-reload value, whereas the counter of the prescaler restarts from 0 (but the prescale rate doesn’t change).

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that the auto-reload is updated before the counter is reloaded, so that the next period is the expected one.
The following figures show some examples of the counter behavior for different clock frequencies when TIMx.ARR=0x36.

**Figure 413. Counter timing diagram, internal clock divided by 1**

**Figure 414. Counter timing diagram, internal clock divided by 2**
Figure 415. Counter timing diagram, internal clock divided by 4

CK_PSC

Timer clock = CK_CNT

Counter register: 0001 0000 0000 0001

Counter underflow

Update event (UEV)

Update interrupt flag (UIF)

Figure 416. Counter timing diagram, internal clock divided by N

CK_PSC

Timer clock = CK_CNT

Counter register: 20 1F 00 36

Counter underflow

Update event (UEV)

Update interrupt flag (UIF)
Center-aligned mode (up/down counting)

In center-aligned mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register) – 1, generates a counter overflow event, then counts from the auto-reload value down to 1 and generates a counter underflow event. Then it restarts counting from 0.

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are not equal to ‘00’. The Output compare interrupt flag of channels configured in output is set when: the counter counts down (Center aligned mode 1, CMS = "01"), the counter counts up (Center aligned mode 2, CMS = "10") the counter counts up and down (Center aligned mode 3, CMS = "11").

In this mode, the direction bit (DIR from TIMx_CR1 register) cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event. In this case, the counter restarts counting from 0, as well as the counter of the prescaler.

The UEV update event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter continues counting up and down, based on the current auto-reload value.

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or
DMA request is sent). This is to avoid generating both update and capture interrupt when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that if the update source is a counter overflow, the auto-reload is updated before the counter is reloaded, so that the next period is the expected one (the counter is loaded with the new value).

The following figures show some examples of the counter behavior for different clock frequencies.

**Figure 418. Counter timing diagram, internal clock divided by 1, TIMx_ARR=0x6**

1. Here, center-aligned mode 1 is used (for more details refer to Section 38.4.1: TIMx control register 1 (TIMx_CR1)(x = 2 to 5) on page 1679).
1. Center-aligned mode 2 or 3 is used with an UIF on overflow.
Figure 421. Counter timing diagram, internal clock divided by N

Figure 422. Counter timing diagram, Update event with ARPE=1 (counter underflow)
38.3.3 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (CK_INT)
- External clock mode1: external input pin (TIx)
- External clock mode2: external trigger input (ETR)
- Internal trigger inputs (ITRx): using one timer as prescaler for another timer, for example, Timer X can be configured to act as a prescaler for Timer Y. Refer to "Using one timer as prescaler for another timer on page 1674 for more details.

Internal clock source (CK_INT)

If the slave mode controller is disabled (SMS=000 in the TIMx_SMCR register), then the CEN, DIR (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK_INT.

Figure 424 shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.
External clock source mode 1

This mode is selected when SMS=111 in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

1. Codes ranging from 01000 to 11111: ITRy.

For example, to configure the upcounter to count in response to a rising edge on the TI2 input, use the following procedure:

1. Select the proper TI2x source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Configure channel 2 to detect rising edges on the TI2 input by writing CC2S=’01 in the TIMx_CCMR1 register.
3. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx_CCMR1 register (if no filter is needed, keep IC2F=0000).
Note: The capture prescaler is not used for triggering, so it does not need to be configured.

4. Select rising edge polarity by writing CC2P=0 and CC2NP=0 in the TIMx_CCER register.
5. Configure the timer in external clock mode 1 by writing SMS=111 in the TIMx_SMCR register.
6. Select TI2 as the input source by writing TS=00110 in the TIMx_SMCR register.
7. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

When a rising edge occurs on TI2, the counter counts once and the TIF flag is set.

The delay between the rising edge on TI2 and the actual clock of the counter is due to the resynchronization circuit on TI2 input.

Figure 426. Control circuit in external clock mode 1

External clock source mode 2

This mode is selected by writing ECE=1 in the TIMx_SMCR register.

The counter can count at each rising or falling edge on the external trigger input ETR.

Figure 427 gives an overview of the external trigger input block.
For example, to configure the upcounter to count each 2 rising edges on ETR, use the following procedure:

1. Select the proper ETR source (internal or external) with the ETRSEL[3:0] bits in the TIMx_AF1 register.
2. As no filter is needed in this example, write ETF[3:0]=0000 in the TIMx_SMCR register.
3. Set the prescaler by writing ETPS[1:0]=01 in the TIMx_SMCR register.
4. Select rising edge detection on the ETR pin by writing ETP=0 in the TIMx_SMCR register.
5. Enable external clock mode 2 by writing ECE=1 in the TIMx_SMCR register.
6. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

The counter counts once each 2 ETR rising edges.

The delay between the rising edge on ETR and the actual clock of the counter is due to the resynchronization circuit on the ETRP signal. As a consequence, the maximum frequency which can be correctly captured by the counter is at most ¼ of TIMxCLK frequency. When the ETRP signal is faster, the user should apply a division of the external signal by a proper ETPS prescaler setting.
38.3.4 Capture/Compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

The following figure gives an overview of one Capture/Compare channel.

The input stage samples the corresponding TIx input to generate a filtered signal TIxF. Then, an edge detector with polarity selection generates a signal (TIxFPx) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

The output stage generates an intermediate waveform which is then used for reference: OCxRef (active high). The polarity acts at the end of the chain.
The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.
38.3.5 Input capture mode

In Input capture mode, the Capture/Compare Registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCxIF flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to 0 or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx_CCR1 when TI1 input rises. To do this, use the following procedure:

1. Select the proper TI1x source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input: TIMx_CCR1 must be linked to the TI1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx_CCR1 register becomes read-only.
3. Program the appropriate input filter duration in relation with the signal connected to the timer (when the input is one of the TIx (ICxF bits in the TIMx_CCMRx register). Let's imagine that, when toggling, the input signal is not stable during at most 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on TI1 when 8 consecutive samples with the new level have been detected (sampled at fDTS frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.
4. Select the edge of the active transition on the TI1 channel by writing the CC1P and CC1NP and CC1NP bits to 000 in the TIMx_CCER register (rising edge in this case).
5. Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to 00 in the TIMx_CCMR1 register).
6. Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.
7. If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx_DIER register.

When an input capture occurs:

- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

**Note:** IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.
38.3.6 **PWM input mode**

This mode is a particular case of input capture mode. The procedure is the same except:

- Two ICx signals are mapped on the same TIx input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two TIxFP signals is selected as trigger input and the slave mode controller is configured in reset mode.

For example, one can measure the period (in TIMx_CCR1 register) and the duty cycle (in TIMx_CCR2 register) of the PWM applied on TI1 using the following procedure (depending on CK_INT frequency and prescaler value):

1. Select the proper TI1x source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input for TIMx_CCR1: write the CC1S bits to 01 in the TIMx_CCMR1 register (TI1 selected).
3. Select the active polarity for TI1FP1 (used both for capture in TIMx_CCR1 and counter clear): write the CC1P to '0' and the CC1NP bit to '0' (active on rising edge).
4. Select the active input for TIMx_CCR2: write the CC2S bits to 10 in the TIMx_CCMR1 register (TI1 selected).
5. Select the active polarity for TI1FP2 (used for capture in TIMx_CCR2): write the CC2P bit to '1' and the CC2NP bit to '0' (active on falling edge).
6. Select the valid trigger input: write the TS bits to 00101 in the TIMx_SMCR register (TI1FP1 selected).
7. Configure the slave mode controller in reset mode: write the SMS bits to 100 in the TIMx_SMCR register.
8. Enable the captures: write the CC1E and CC2E bits to '1' in the TIMx_CCER register.

---

1. The PWM input mode can be used only with the TIMx_CH1/TIMx_CH2 signals due to the fact that only TI1FP1 and TI2FP2 are connected to the slave mode controller.
38.3.7 Forced output mode

In output mode (CCxS bits = 00 in the TIMx_CCMRx register), each output compare signal (OCxREF and then OCx) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (ocxref/OCx) to its active level, one just needs to write 101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus ocxref is forced high (OCxREF is always active high) and OCx get opposite value to CCxP polarity bit.

e.g.: CCxP=0 (OCx active high) => OCx is forced to high level.

ocxref signal can be forced low by writing the OCxM bits to 100 in the TIMx_CCMRx register.

Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the Output Compare Mode section.

38.3.8 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP bit in the TIMx_CCER register). The output pin can keep its level (OCxM=000), be set active (OCxM=001), be set inactive (OCxM=010) or can toggle (OCxM=011) on match.
- Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCxIE bit in the TIMx_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx_DIER register, CCDS bit in the TIMx_CR2 register for the DMA request selection).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on ocxref and OCx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

Procedure

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE and/or CCxDE bits if an interrupt and/or a DMA request is to be generated.
4. Select the output mode. For example, one must write OCxM=011, OCxPE=0, CCxP=0 and CCxE=1 to toggle OCx output pin when CNT matches CCRx, CCRx preload is not used, OCx is enabled and active high.
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.
The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE=0, else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in Figure 433.

**Figure 433. Output compare mode, toggle on OC1**

![Figure 433. Output compare mode, toggle on OC1](image)

### 38.3.9 PWM mode

Pulse width modulation mode allows to generate a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per OCx output) by writing 110 (PWM mode 1) or 111 (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

OCx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. OCx output is enabled by the CCxE bit in the TIMx_CCER register. Refer to the TIMx_CCERx register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CCRx ≤ TIMx_CNT or TIMx_CNT ≤ TIMx_CCRx (depending on the direction of the counter). However, to comply with the OCREF_CLR functionality (OCREF can be
cleared by an external event through the ETR signal until the next PWM period), the
OCREF signal is asserted only:
- When the result of the comparison or
- When the output compare mode (OCxM bits in TIMx_CCMRx register) switches from
  the "frozen" configuration (no comparison, OCxM='000) to one of the PWM modes
  (OCxM='110 or '111).

This forces the PWM by software while the timer is running.

The timer is able to generate PWM in edge-aligned mode or center-aligned mode
depending on the CMS bits in the TIMx_CR1 register.

**PWM edge-aligned mode**

Upcounting configuration

Upcounting is active when the DIR bit in the TIMx_CR1 register is low. Refer to *Upcounting
mode on page 1639.*

In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is
high as long as TIMx_CNT < TIMx_CCRx else it becomes low. If the compare value in
TIMx_CCRx is greater than the auto-reload value (in TIMx_ARR) then OCxREF is held at '1.
If the compare value is 0 then OCxREF is held at '0. *Figure 434* shows some edge-aligned
PWM waveforms in an example where TIMx_ARR=8.

![Figure 434. Edge-aligned PWM waveforms (ARR=8)](image-url)
**Downcounting configuration**

Downcounting is active when DIR bit in TIMx_CR1 register is high. Refer to *Downcounting mode on page 1642*.

In PWM mode 1, the reference signal ocxref is low as long as TIMx_CNT> TIMx_CCRx else it becomes high. If the compare value in TIMx_CCRx is greater than the auto-reload value in TIMx_ARR, then ocxref is held at 100%. PWM is not possible in this mode.

**PWM center-aligned mode**

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are different from ‘00 (all the remaining configurations having the same effect on the ocxref/OCx signals). The compare flag is set when the counter counts up, when it counts down or both when it counts up and down depending on the CMS bits configuration. The direction bit (DIR) in the TIMx_CR1 register is updated by hardware and must not be changed by software. Refer to *Center-aligned mode (up/down counting) on page 1645*.

*Figure 435* shows some center-aligned PWM waveforms in an example where:

- TIMx_ARR=8,
- PWM mode is the PWM mode 1,
- The flag is set when the counter counts down corresponding to the center-aligned mode 1 selected for CMS=01 in TIMx_CR1 register.
Hints on using center-aligned mode:

- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit in the TIMx_CR1 register. Moreover, the DIR and CMS bits must not be changed at the same time by the software.

- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:
  - The direction is not updated if a value greater than the auto-reload value is written in the counter (TIMx_CNT>TIMx_ARR). For example, if the counter was counting up, it continues to count up.
  - The direction is updated if 0 or the TIMx_ARR value is written in the counter but no Update Event UEV is generated.

- The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIMx_EGR register) just before starting the counter and not to write the counter while it is running.
38.3.10 Asymmetric PWM mode

Asymmetric mode allows two center-aligned PWM signals to be generated with a programmable phase shift. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and the phase-shift are determined by a pair of TIMx_CCRx registers. One register controls the PWM during up-counting, the second during down counting, so that PWM is adjusted every half PWM cycle:

- OC1REFC (or OC2REFC) is controlled by TIMx_CCR1 and TIMx_CCR2
- OC3REFC (or OC4REFC) is controlled by TIMx_CCR3 and TIMx_CCR4

Asymmetric PWM mode can be selected independently on two channels (one OCx output per pair of CCR registers) by writing ‘1110’ (Asymmetric PWM mode 1) or ‘1111’ (Asymmetric PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

**Note:** The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

When a given channel is used as asymmetric PWM channel, its secondary channel can also be used. For instance, if an OC1REFC signal is generated on channel 1 (Asymmetric PWM mode 1), it is possible to output either the OC2REF signal on channel 2, or an OC2REFC signal resulting from asymmetric PWM mode 2.

**Figure 436** shows an example of signals that can be generated using Asymmetric PWM mode (channels 1 to 4 are configured in Asymmetric PWM mode 1).

![Figure 436. Generation of 2 phase-shifted PWM signals with 50% duty cycle](image)

38.3.11 Combined PWM mode

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and delay are determined by the two TIMx_CCRx registers. The resulting signals, OCxREFC, are made of an OR or AND logical combination of two reference PWMs:

- OC1REFC (or OC2REFC) is controlled by TIMx_CCR1 and TIMx_CCR2
- OC3REFC (or OC4REFC) is controlled by TIMx_CCR3 and TIMx_CCR4

Combined PWM mode can be selected independently on two channels (one OCx output per pair of CCR registers) by writing ‘1100’ (Combined PWM mode 1) or ‘1101’ (Combined PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.
When a given channel is used as combined PWM channel, its secondary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

**Note:** The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

**Figure 437** shows an example of signals that can be generated using Asymmetric PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2,
- Channel 2 is configured in PWM mode 1,
- Channel 3 is configured in Combined PWM mode 2,
- Channel 4 is configured in PWM mode 1

**38.3.12 Clearing the OCxREF signal on an external event**

The OCxREF signal of a given channel can be cleared when a high level is applied on the ocref_clr_int input (OCxCE enable bit in the corresponding TIMx_CCMRx register set to 1). OCxREF remains low until the next update event (UEV) occurs. This function can only be used in Output compare and PWM modes. It does not work in Forced mode.

The ocref_clr_int is connected to the ETRF signal (ETR after filtering).
The OCxREF signal for a given channel can be reset by applying a high level on the ETRF input (OCxCE enable bit set to 1 in the corresponding TIMx_CCMRx register). OCxREF remains low until the next update event (UEV) occurs.

This function can be used only in the output compare and PWM modes. It does not work in forced mode.

For example, the OCxREF signal can be connected to the output of a comparator to be used for current handling. In this case, ETR must be configured as follows:

1. The external trigger prescaler should be kept off: bits ETPS[1:0] in the TIMx_SMCR register are cleared to 00.
2. The external clock mode 2 must be disabled: bit ECE in the TIM1_SMCR register is cleared to 0.
3. The external trigger polarity (ETP) and the external trigger filter (ETF) can be configured according to the application's needs.

*Figure 438* shows the behavior of the OCxREF signal when the ETRF input becomes high, for both values of the OCxCE enable bit. In this example, the timer TIMx is programmed in PWM mode.

*Figure 438. Clearing TIMx OCxREF*

![Figure 438. Clearing TIMx OCxREF](image)

**Note:** In case of a PWM with a 100% duty cycle (if CCRx>ARR), OCxREF is enabled again at the next counter overflow.
### 38.3.13 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- \( \text{CNT}<\text{CCR}_x \leq \text{ARR} \) (in particular, \( 0<\text{CCR}_x \)),

#### Figure 439. Example of one-pulse mode.

For example one may want to generate a positive pulse on OC1 with a length of \( t_{\text{PULSE}} \) and after a delay of \( t_{\text{DELAY}} \) as soon as a positive edge is detected on the TI2 input pin.

Let’s use TI2FP2 as trigger 1:

1. Select the proper TI2x source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Map TI2FP2 on TI2 by writing CC2S=01 in the TIMx_CCMR1 register.
3. TI2FP2 must detect a rising edge, write CC2P=0 and CC2NP='0' in the TIMx_CCER register.
4. Configure TI2FP2 as trigger for the slave mode controller (TRGI) by writing TS=00110 in the TIMx_SMCR register.
5. TI2FP2 is used to start the counter by writing SMS to '110 in the TIMx_SMCR register (trigger mode).
The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The $t_{\text{DELAY}}$ is defined by the value written in the TIMx_CCR1 register.
- The $t_{\text{PULSE}}$ is defined by the difference between the auto-reload value and the compare value (TIMx_ARR - TIMx_CCR1).
- Let’s say one want to build a waveform with a transition from ‘0 to ‘1 when a compare match occurs and a transition from ‘1 to ‘0 when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing OC1M=111 in the TIMx_CCMR1 register. Optionally the preload registers can be enabled by writing OC1PE=1 in the TIMx_CCMR1 register and ARPE in the TIMx_CR1 register. In this case one has to write the compare value in the TIMx_CCR1 register, the auto-reload value in the TIMx_ARR register, generate an update by setting the UG bit and wait for external trigger event on TI2. CC1P is written to ‘0 in this example.

In our example, the DIR and CMS bits in the TIMx_CR1 register should be low.

Since only 1 pulse (Single mode) is needed, a 1 must be written in the OPM bit in the TIMx_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0). When OPM bit in the TIMx_CR1 register is set to ‘0’, so the Repetitive Mode is selected.

**Particular case: OCx fast enable:**

In One-pulse mode, the edge detection on TIx input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay $t_{\text{DELAY min}}$ we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx_CCMRx register. Then OCxRef (and OCx) is forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

### 38.3.14 Retriggerable one pulse mode (OPM)

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with Non-retriggerable one pulse mode described in Section 38.3.13:

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed

The timer must be in Slave mode, with the bits SMS[3:0] = ‘1000’ (Combined Reset + trigger mode) in the TIMx_SMCR register, and the OCxM[3:0] bits set to ‘1000’ or ‘1001’ for Retriggerable OPM mode 1 or 2.

If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in Down-counting mode CCRx must be above or equal to ARR.

**Note:** *In retriggerable one pulse mode, the CCxIF flag is not significant.*

*The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.*

*This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx_CR1.*
**Encoder interface mode**

To select Encoder Interface mode write SMS=’001 in the TIMx_SMCR register if the counter is counting on TI2 edges only, SMS=010 if it is counting on TI1 edges only and SMS=011 if it is counting on both TI1 and TI2 edges.

Select the TI1 and TI2 polarity by programming the CC1P and CC2P bits in the TIMx_CCER register. CC1NP and CC2NP must be kept cleared. When needed, the input filter can be programmed as well. CC1NP and CC2NP must be kept low.

The two inputs TI1 and TI2 are used to interface to an incremental encoder. Refer to **Table 327**. The counter is clocked by each valid transition on TI1FP1 or TI2FP2 (TI1 and TI2 after input filter and polarity selection, TI1FP1=TI1 if not filtered and not inverted, TI2FP2=TI2 if not filtered and not inverted) assuming that it is enabled (CEN bit in TIMx_CR1 register written to ‘1’). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the TIMx_CR1 register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (TI1 or TI2), whatever the counter is counting on TI1 only, TI2 only or both TI1 and TI2.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value in the TIMx_ARR register (0 to ARR or ARR down to 0 depending on the direction). So the TIMx_ARR must be configured before starting. In the same way, the capture, compare, prescaler, trigger output features continue to work as normal.

In this mode, the counter is modified automatically following the speed and the direction of the quadrature encoder and its content, therefore, always represents the encoder’s position. The count direction correspond to the rotation direction of the connected sensor. The table summarizes the possible combinations, assuming TI1 and TI2 do not switch at the same time.
An external incremental encoder can be connected directly to the MCU without external interface logic. However, comparators are normally be used to convert the encoder’s differential outputs to digital signals. This greatly increases noise immunity. The third encoder output which indicate the mechanical zero position, may be connected to an external interrupt input and trigger a counter reset.

*Figure 441* gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points. For this example we assume that the configuration is the following:

- CC1S = 01 (TIMx_CCMR1 register, TI1FP1 mapped on TI1)
- CC2S = 01 (TIMx_CCMR2 register, TI2FP2 mapped on TI2)
- CC1P and CC1NP = ‘0’ (TIMx_CCER register, TI1FP1 noninverted, TI1FP1=TI1)
- CC2P and CC2NP = ‘0’ (TIMx_CCER register, TI2FP2 noninverted, TI2FP2=TI2)
- SMS = 011 (TIMx_SMCR register, both inputs are active on both rising and falling edges)
- CEN = 1 (TIMx_CR1 register, Counter is enabled)

*Figure 442* gives an example of counter behavior when TI1FP1 polarity is inverted (same configuration as above except CC1P=1).
The timer, when configured in Encoder Interface mode provides information on the sensor’s current position. Dynamic information can be obtained (speed, acceleration, deceleration) by measuring the period between two encoder events using a second timer configured in capture mode. The output of the encoder which indicates the mechanical zero can be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. This can be done by latching the counter value into a third input capture register if available (then the capture signal must be periodic and can be generated by another timer). When available, it is also possible to read its value through a DMA request generated by a Real-Time clock.

### 38.3.16 UIF bit remapping

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the update interrupt flag (UIF) into bit 31 of the timer counter register’s bit 31 (TIMx_CNT[31]). This allows to atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. It eases the calculation of angular speed by avoiding race conditions caused, for instance, by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the UIF and UIFCPY flag assertions.

In 32-bit timer implementations, when the IUFREMAP bit is set, bit 31 of the counter is overwritten by the UIFCPY flag upon read access (the counter’s most significant bit is only accessible in write mode).

### 38.3.17 Timer input XOR function

The TI1S bit in the TIM1xx_CR2 register, allows the input filter of channel 1 to be connected to the output of a XOR gate, combining the three input pins TIMx_CH1 to TIMx_CH3.

The XOR output can be used with all the timer input functions such as trigger or input capture.

An example of this feature used to interface Hall sensors is given in Section 37.3.25: Interfacing with Hall sensors on page 1581.
38.3.18 Timers and external trigger synchronization

The TIMx Timers can be synchronized with an external trigger in several modes: Reset mode, Gated mode and Trigger mode.

Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on TI1 input:

1. Configure the channel 1 to detect rising edges on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx_CCMR1 register. Write CC1P=0 and CC1NP=0 in TIMx_CCER register to validate the polarity (and detect rising edges only).

2. Configure the timer in reset mode by writing SMS=100 in TIMx_SMCR register. Select TI1 as the input source by writing TS=00101 in TIMx_SMCR register.

3. Start the counter by writing CEN=1 in the TIMx_CR1 register.

The counter starts counting on the internal clock, then behaves normally until TI1 rising edge. When TI1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx_DIER register).

The following figure shows this behavior when the auto-reload register TIMx_ARR=0x36. The delay between the rising edge on TI1 and the actual reset of the counter is due to the resynchronization circuit on TI1 input.

Figure 443. Control circuit in reset mode

Slave mode: Gated mode

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when TI1 input is low:
1. Configure the channel 1 to detect low levels on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S=01 in TIMx_CCMR1 register. Write CC1P=1 and CC1NP=0 in TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in gated mode by writing SMS=101 in TIMx_SMCR register. Select TI1 as the input source by writing TS=00101 in TIMx_SMCR register.

3. Enable the counter by writing CEN=1 in the TIMx_CR1 register (in gated mode, the counter doesn’t start if CEN=0, whatever is the trigger input level).

The counter starts counting on the internal clock as long as TI1 is low and stops as soon as TI1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on TI1 and the actual stop of the counter is due to the resynchronization circuit on TI1 input.

Note: The configuration “CCxP=CCxNP=1” (detection of both rising and falling edges) does not have any effect in gated mode because gated mode acts on a level and not on an edge.

Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on TI2 input:

1. Configure the channel 2 to detect rising edges on TI2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. CC2S bits are selecting the input capture source only, CC2S=01 in TIMx_CCMR1 register. Write
CC2P=1 and CC2NP=0 in TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select TI2 as the input source by writing TS=00110 in TIMx_SMCR register.

When a rising edge occurs on TI2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on TI2 and the actual start of the counter is due to the resynchronization circuit on TI2 input.

Figure 445. Control circuit in trigger mode

Slave mode: External Clock mode 2 + trigger mode

The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the ETR signal is used as external clock input, and another input can be selected as trigger input when operating in reset mode, gated mode or trigger mode. It is recommended not to select ETR as TRGI through the TS bits of TIMx_SMCR register.

In the following example, the upcounter is incremented at each rising edge of the ETR signal as soon as a rising edge of TI1 occurs:

1. Configure the external trigger input circuit by programming the TIMx_SMCR register as follows:
   - ETF = 0000: no filter
   - ETPS=00: prescaler disabled
   - ETP=0: detection of rising edges on ETR and ECE=1 to enable the external clock mode 2.

2. Configure the channel 1 as follows, to detect rising edges on TI:
   - IC1F=0000: no filter.
   - The capture prescaler is not used for triggering and does not need to be configured.
   - CC1S=01 in TIMx_CCMR1 register to select only the input capture source
   - CC1P=0 and CC1NP=0 in TIMx_CCER register to validate the polarity (and detect rising edge only).

3. Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select TI1 as the input source by writing TS=00101 in TIMx_SMCR register.
A rising edge on TI1 enables the counter and sets the TIF flag. The counter then counts on ETR rising edges.

The delay between the rising edge of the ETR signal and the actual reset of the counter is due to the resynchronization circuit on ETRP input.

**Figure 446. Control circuit in external clock mode 2 + trigger mode**

---

### 38.3.19 Timer synchronization

The TIMx timers are linked together internally for timer synchronization or chaining. When one Timer is configured in Master Mode, it can reset, start, stop or clock the counter of another Timer configured in Slave Mode.

**Figure 447: Master/Slave timer example** presents an overview of the trigger selection and the master mode selection blocks.

---

**Figure 447. Master/Slave timer example**
Using one timer as prescaler for another timer

For example, TIM3 can be configured to act as a prescaler for TIM2. Refer to Figure 447. To do this:

1. Configure TIM3 in master mode so that it outputs a periodic trigger signal on each update event UEV. If MMS=010 is written in the TIM3_CR2 register, a rising edge is output on TRGO each time an update event is generated.
2. To connect the TRGO output of TIM3 to TIM2, TIM2 must be configured in slave mode using ITR2 as internal trigger. This is selected through the TS bits in the TIM2_SMCR register (writing TS=00010).
3. Then the slave mode controller must be put in external clock mode 1 (write SMS=111 in the TIM2_SMCR register). This causes TIM2 to be clocked by the rising edge of the periodic TIM3 trigger signal (which correspond to the TIM3 counter overflow).
4. Finally both timers must be enabled by setting their respective CEN bits (TIMx_CR1 register).

Note: If OCx is selected on TIM3 as the trigger output (MMS=1xx), its rising edge is used to clock the counter of TIM2.

Using one timer to enable another timer

In this example, we control the enable of TIM2 with the output compare 1 of Timer 3. Refer to Figure 447 for connections. TIM2 counts on the divided internal clock only when OC1REF of TIM3 is high. Both counter clock frequencies are divided by 3 by the prescaler compared to CK_INT (f_{CK_CNT} = f_{CK_INT}/3).

1. Configure TIM3 master mode to send its Output Compare 1 Reference (OC1REF) signal as trigger output (MMS=100 in the TIM3_CR2 register).
2. Configure the TIM3 OC1REF waveform (TIM3_CCMR1 register).
3. Configure TIM2 to get the input trigger from TIM3 (TS=00010 in the TIM2_SMCR register).
4. Configure TIM2 in gated mode (SMS=101 in TIM2_SMCR register).
5. Enable TIM2 by writing ‘1 in the CEN bit (TIM2_CR1 register).
6. Start TIM3 by writing ‘1 in the CEN bit (TIM3_CR1 register).

Note: The counter 2 clock is not synchronized with counter 1, this mode only affects the TIM2 counter enable signal.

Figure 448. Gating TIM2 with OC1REF of TIM3

![Gating TIM2 with OC1REF of TIM3 diagram](image-url)
In the example in Figure 448, the TIM2 counter and prescaler are not initialized before being started. So they start counting from their current value. It is possible to start from a given value by resetting both timers before starting TIM3. Then any value can be written in the timer counters. The timers can easily be reset by software using the UG bit in the TIMx_EGR registers.

In the next example (refer to Figure 449), we synchronize TIM3 and TIM2. TIM3 is the master and starts from 0. TIM2 is the slave and starts from 0xE7. The prescaler ratio is the same for both timers. TIM2 stops when TIM3 is disabled by writing '0' to the CEN bit in the TIM3_CR1 register:

1. Configure TIM3 master mode to send its Output Compare 1 Reference (OC1REF) signal as trigger output (MMS=100 in the TIM3_CR2 register).
2. Configure the TIM3 OC1REF waveform (TIM3_CCMR1 register).
3. Configure TIM2 to get the input trigger from TIM3 (TS=00010 in the TIM2_SMCR register).
4. Configure TIM2 in gated mode (SMS=101 in TIM2_SMCR register).
5. Reset TIM3 by writing '1' in UG bit (TIM3_EGR register).
6. Reset TIM2 by writing '1' in UG bit (TIM2_EGR register).
7. Initialize TIM2 to 0xE7 by writing '0xE7' in the TIM2_CNT register.
8. Enable TIM2 by writing '1' in the CEN bit (TIM2_CR1 register).
9. Start TIM3 by writing '1' in the CEN bit (TIM3_CR1 register).
10. Stop TIM3 by writing '0' in the CEN bit (TIM3_CR1 register).

![Figure 449. Gating TIM2 with Enable of TIM3](image)

Using one timer to start another timer

In this example, we set the enable of Timer 2 with the update event of Timer 3. Refer to Figure 447 for connections. Timer 2 starts counting from its current value (which can be non-zero) on the divided internal clock as soon as the update event is generated by Timer 1. When Timer 2 receives the trigger signal its CEN bit is automatically set and the counter counts until we write '0' to the CEN bit in the TIM2_CR1 register. Both counter clock frequencies are divided by 3 by the prescaler compared to CK_INT ($f_{CK\_CNT} = f_{CK\_INT}/3$).
1. Configure TIM3 master mode to send its Update Event (UEV) as trigger output (MMS=010 in the TIM3_CR2 register).
2. Configure the TIM3 period (TIM3_ARR registers).
3. Configure TIM2 to get the input trigger from TIM3 (TS=00010 in the TIM2_SMCR register).
4. Configure TIM2 in trigger mode (SMS=110 in TIM2_SMCR register).
5. Start TIM3 by writing '1 in the CEN bit (TIM3_CR1 register).

As in the previous example, both counters can be initialized before starting counting. Figure 451 shows the behavior with the same configuration as in Figure 450 but in trigger mode instead of gated mode (SMS=110 in the TIM2_SMCR register).

Starting 2 timers synchronously in response to an external trigger

In this example, we set the enable of TIM3 when its TI1 input rises, and the enable of TIM2 with the enable of TIM3. Refer to Figure 447 for connections. To ensure the counters are
aligned, TIM3 must be configured in Master/Slave mode (slave with respect to TI1, master
with respect to TIM2):
1. Configure TIM3 master mode to send its Enable as trigger output (MMS=001 in the
   TIM3_CR2 register).
2. Configure TIM3 slave mode to get the input trigger from TI1 (TS=00100 in the
   TIM3_SMCR register).
3. Configure TIM3 in trigger mode (SMS=110 in the TIM3_SMCR register).
4. Configure the TIM3 in Master/Slave mode by writing MSM=1 (TIM3_SMCR register).
5. Configure TIM2 to get the input trigger from TIM3 (TS=00000 in the TIM2_SMCR
   register).
6. Configure TIM2 in trigger mode (SMS=110 in the TIM2_SMCR register).

When a rising edge occurs on TI1 (TIM3), both counters starts counting synchronously on
the internal clock and both TIF flags are set.

Note: In this example both timers are initialized before starting (by setting their respective UG
bits). Both counters starts from 0, but an offset can easily be inserted between them by
writing any of the counter registers (TIMx_CNT). One can see that the master/slave mode
insert a delay between CNT_EN and CK_PSC on TIM3.

Figure 452. Triggering TIM3 and TIM2 with TIM3 TI1 input

Note: The clock of the slave peripherals (timer, ADC, …) receiving the TRGO or the TRGO2
signals must be enabled prior to receive events from the master timer, and the clock
frequency (prescaler) must not be changed on-the-fly while triggers are received from the
master timer.

38.3.20 DMA burst mode

The TIMx timers have the capability to generate multiple DMA requests upon a single event.
The main purpose is to be able to re-program part of the timer multiple times without
software overhead, but it can also be used to read several registers in a row, at regular
intervals.
The DMA controller destination is unique and must point to the virtual register TIMx_DMAR. On a given timer event, the timer launches a sequence of DMA requests (burst). Each write into the TIMx_DMAR register is actually redirected to one of the timer registers.

The DBL[4:0] bits in the TIMx_DCR register set the DMA burst length. The timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address, i.e. the number of transfers (either in half-words or in bytes).

The DBA[4:0] bits in the TIMx_DCR registers define the DMA base address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register:

Example:

00000: TIMx_CR1
00001: TIMx_CR2
00010: TIMx_SMCR

As an example, the timer DMA burst feature is used to update the contents of the CCRx registers (x = 2, 3, 4) upon an update event, with the DMA transferring half words into the CCRx registers.

This is done in the following steps:
1. Configure the corresponding DMA channel as follows:
   – DMA channel peripheral address is the DMAR register address
   – DMA channel memory address is the address of the buffer in the RAM containing the data to be transferred by DMA into CCRx registers.
   – Number of data to transfer = 3 (See note below).
   – Circular mode disabled.
2. Configure the DCR register by configuring the DBA and DBL bit fields as follows:
   DBL = 3 transfers, DBA = 0xE.
3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).
4. Enable TIMx
5. Enable the DMA channel

This example is for the case where every CCRx register has to be updated once. If every CCRx register is to be updated twice for example, the number of data to transfer should be 6. Let's take the example of a buffer in the RAM containing data1, data2, data3, data4, data5 and data6. The data is transferred to the CCRx registers as follows: on the first update DMA request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is transferred to CCR3 and data6 is transferred to CCR4.

Note: A null value can be written to the reserved registers.

### 38.3.21 Debug mode

When the microcontroller enters debug mode (Cortex®-M7 with FPU core halted), the TIMx counter either continues to work normally or stops, depending on TIMx configuration bit in DBGMCU module. For more details, refer to Section 59.5.8: Microcontroller debug unit (DBGMCU).

For safety purposes, when the counter is stopped (TIMx = 1 in DBGMCU_APB1FZ2), the outputs are disabled.
38.4 TIM2/TIM3/TIM4/TIM5 registers

Refer to Section 1.2 for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

</table>
Bit 3  **OPM**: One-pulse mode

0: Counter is not stopped at update event
1: Counter stops counting at the next update event (clearing the bit CEN)

Bit 2  **URS**: Update request source

This bit is set and cleared by software to select the UEV event sources.
0: Any of the following events generate an update interrupt or DMA request if enabled.
These events can be:
- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller
1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1  **UDIS**: Update disable

This bit is set and cleared by software to enable/disable UEV event generation.
0: UEV enabled. The Update (UEV) event is generated by one of the following events:
- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller
Buffered registers are then loaded with their preload values.
1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0  **CEN**: Counter enable

0: Counter disabled
1: Counter enabled

*Note: External clock, gated mode and encoder mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.*

CEN is cleared automatically in one-pulse mode, when an update event occurs.

</thead>
</table>

1680/3289  RM0433 Rev 6
Bits 15:8  Reserved, must be kept at reset value.

Bit 7  **TI1S**: TI1 selection

0: The TIMx_CH1 pin is connected to TI1 input
1: The TIMx_CH1, CH2 and CH3 pins are connected to the TI1 input (XOR combination)

See also Section 37.3.25: Interfacing with Hall sensors on page 1581

Bits 6:4  **MMS[2:0]**: Master mode selection

These bits allow to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows:

000: **Reset** - the UG bit from the TIMx_EGR register is used as trigger output (TRGO). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on TRGO is delayed compared to the actual reset.

001: **Enable** - the Counter enable signal, CNT_EN, is used as trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode.

When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO, except if the master/slave mode is selected (see the MSM bit description in TIMx_SMCR register).

010: **Update** - The update event is selected as trigger output (TRGO). For instance a master timer can then be used as a prescaler for a slave timer.

011: **Compare Pulse** - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred.

(TRGO)

100: **Compare** - OC1REF signal is used as trigger output (TRGO)

101: **Compare** - OC2REF signal is used as trigger output (TRGO)

110: **Compare** - OC3REF signal is used as trigger output (TRGO)

111: **Compare** - OC4REF signal is used as trigger output (TRGO)

Note: The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

Bit 3  **CCDS**: Capture/compare DMA selection

0: CCx DMA request sent when CCx event occurs
1: CCx DMA requests sent when update event occurs

Bits 2:0  Reserved, must be kept at reset value.
### 38.4.3 TIMx slave mode control register (TIMx_SMCR)(x = 2 to 5)

Address offset: 0x08

Reset value: 0x0000 0000

| Bits 31:22 | Reserved, must be kept at reset value. |
| Bits 19:17 | Reserved, must be kept at reset value. |

#### Bit 16 SMS[3]: Slave mode selection - bit 3
- Refer to SMS description - bits 2:0.

#### Bit 15 ETP: External trigger polarity
- This bit selects whether ETR or \( \overline{ETR} \) is used for trigger operations
  - 0: \( \overline{ETR} \) is non-inverted, active at high level or rising edge
  - 1: \( \overline{ETR} \) is inverted, active at low level or falling edge

#### Bit 14 ECE: External clock enable
- This bit enables External clock mode 2.
  - 0: External clock mode 2 disabled
  - 1: External clock mode 2 enabled. The counter is clocked by any active edge on the ETRF signal.
- Setting the ECE bit has the same effect as selecting external clock mode 1 with TRGI connected to ETRF (SMS=111 and TS=00111).
- It is possible to simultaneously use external clock mode 2 with the following slave modes: reset mode, gated mode and trigger mode. Nevertheless, TRGI must not be connected to ETRF in this case (TS bits must not be 00111).
- If external clock mode 1 and external clock mode 2 are enabled at the same time, the external clock input is ETRF.

#### Bits 13:12 ETPS[1:0]: External trigger prescaler
- External trigger signal ETRP frequency must be at most 1/4 of CK_INT frequency. A prescaler can be enabled to reduce ETRP frequency. It is useful when inputting fast external clocks.
  - 00: Prescaler OFF
  - 01: ETRP frequency divided by 2
  - 10: ETRP frequency divided by 4
  - 11: ETRP frequency divided by 8
Bits 11:8 **ETF[3:0]**: External trigger filter

This bit-field then defines the frequency used to sample ETRP signal and the length of the digital filter applied to ETRP. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

- **0000**: No filter, sampling is done at f_{DTS}
- **0001**: f_{SAMPLING}=f_{CK, INT}, N=2
- **0010**: f_{SAMPLING}=f_{CK, INT}, N=4
- **0011**: f_{SAMPLING}=f_{CK, INT}, N=8
- **0100**: f_{SAMPLING}=f_{DTS}/2, N=6
- **0101**: f_{SAMPLING}=f_{DTS}/2, N=8
- **0110**: f_{SAMPLING}=f_{DTS}/4, N=6
- **0111**: f_{SAMPLING}=f_{DTS}/4, N=8
- **1000**: f_{SAMPLING}=f_{DTS}/8, N=6
- **1001**: f_{SAMPLING}=f_{DTS}/8, N=8
- **1010**: f_{SAMPLING}=f_{DTS}/16, N=5
- **1011**: f_{SAMPLING}=f_{DTS}/16, N=6
- **1100**: f_{SAMPLING}=f_{DTS}/16, N=8
- **1101**: f_{SAMPLING}=f_{DTS}/32, N=5
- **1110**: f_{SAMPLING}=f_{DTS}/32, N=6
- **1111**: f_{SAMPLING}=f_{DTS}/32, N=8

Bit 7 **MSM**: Master/Slave mode

- **0**: No action
- **1**: The effect of an event on the trigger input (TRGI) is delayed to allow a perfect synchronization between the current timer and its slaves (through TRGO). It is useful if we want to synchronize several timers on a single external event.
Bits 21, 20, 6, 5, 4  **TS[4:0]**: Trigger selection (see bits 21:20 for TS[4:3])

This bit-field selects the trigger input to be used to synchronize the counter.

- 00000: Internal Trigger 0 (ITR0)
- 00001: Internal Trigger 1 (ITR1)
- 00010: Internal Trigger 2 (ITR2)
- 00011: Internal Trigger 3 (ITR3)
- 00100: TI1 Edge Detector (TI1F_ED)
- 00101: Filtered Timer Input 1 (TI1FP1)
- 00110: Filtered Timer Input 2 (TI2FP2)
- 00111: External Trigger input (ETRF)
- 01000: Internal Trigger 4 (ITR4)
- 01001: Internal Trigger 5 (ITR5)
- 01010: Internal Trigger 6 (ITR6)
- 01011: Internal Trigger 7 (ITR7)
- 01100: Internal Trigger 8 (ITR8)
- Others: Reserved

See Table 328: TIMx internal trigger connection on page 1685 for more details on ITRx meaning for each Timer.

**Note:** These bits must be changed only when they are not used (e.g. when SMS=000) to avoid wrong edge detections at the transition.

Bit 3  Reserved, must be kept at reset value.

Bits 16, 2, 1, 0  **SMS[3:0]**: Slave mode selection

When external signals are selected the active edge of the trigger signal (TRGI) is linked to the polarity selected on the external input (see Input Control register and Control Register description.

- 0000: Slave mode disabled - if CEN = ‘1 then the prescaler is clocked directly by the internal clock.
- 0001: Encoder mode 1 - Counter counts up/down on TI1FP1 edge depending on TI2FP2 level.
- 0010: Encoder mode 2 - Counter counts up/down on TI2FP2 edge depending on TI1FP1 level.
- 0011: Encoder mode 3 - Counter counts up/down on both TI1FP1 and TI2FP2 edges depending on the level of the other input.
- 0100: Reset Mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter and generates an update of the registers.
- 0101: Gated Mode - The counter clock is enabled when the trigger input (TRGI) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.
- 0110: Trigger Mode - The counter starts at a rising edge of the trigger TRGI (but it is not reset). Only the start of the counter is controlled.
- 0111: External Clock Mode 1 - Rising edges of the selected trigger (TRGI) clock the counter.
- 1000: Combined reset + trigger mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter, generates an update of the registers and starts the counter.

**Note:** The gated mode must not be used if TI1F_ED is selected as the trigger input (TS=00100). Indeed, TI1F_ED outputs 1 pulse for each transition on TI1F, whereas the gated mode checks the level of the trigger signal.

**Note:** The clock of the slave peripherals (timer, ADC, ...) receiving the TRGO or the TRGO2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

0: CC2 interrupt disabled.
1: CC2 interrupt enabled.

Bit 1  **CC1IE**: Capture/Compare 1 interrupt enable
0: CC1 interrupt disabled.
1: CC1 interrupt enabled.

Bit 0  **UIE**: Update interrupt enable
0: Update interrupt disabled.
1: Update interrupt enabled.

Bits 15:13  Reserved, must be kept at reset value.

Bit 12  **CC4OF**: Capture/Compare 4 overcapture flag
refer to CC1OF description

Bit 11  **CC3OF**: Capture/Compare 3 overcapture flag
refer to CC1OF description

Bit 10  **CC2OF**: Capture/compare 2 overcapture flag
refer to CC1OF description

Bit 9  **CC1OF**: Capture/Compare 1 overcapture flag
This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to ‘0’.
0: No overcapture has been detected.
1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set

Bits 8:7  Reserved, must be kept at reset value.
Bit 6 **TIF**: Trigger interrupt flag
This flag is set by hardware on the TRG trigger event (active edge detected on TRGI input when the slave mode controller is enabled in all modes but gated mode. It is set when the counter starts or stops when gated mode is selected. It is cleared by software.
0: No trigger event occurred.
1: Trigger interrupt pending.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **CC4IF**: Capture/Compare 4 interrupt flag
Refer to CC1IF description

Bit 3 **CC3IF**: Capture/Compare 3 interrupt flag
Refer to CC1IF description

Bit 2 **CC2IF**: Capture/Compare 2 interrupt flag
Refer to CC1IF description

Bit 1 **CC1IF**: Capture/compare 1 interrupt flag
This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIMx_CCR1 register (input capture mode only).
0: No compare match / No input capture occurred
1: A compare match or an input capture occurred

If channel CC1 is configured as output: this flag is set when the content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the content of TIMx_CCR1 is greater than the content of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in down-counting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIMx_CR1 register for the full description.

If channel CC1 is configured as input: this bit is set when counter value has been captured in TIMx_CCR1 register (an edge has been detected on IC1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIMx_CCER).

Bit 0 **UIF**: Update interrupt flag
This bit is set by hardware on an update event. It is cleared by software.
0: No update occurred
1: Update interrupt pending. This bit is set by hardware when the registers are updated:
At overflow or underflow (for TIM2 to TIM4) and if UDIS=0 in the TIMx_CR1 register.
When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if URS=0 and UDIS=0 in the TIMx_CR1 register.
When CNT is reinitialized by a trigger event (refer to the synchro control register description), if URS=0 and UDIS=0 in the TIMx_CR1 register.

</table>
Bits 15:7 Reserved, must be kept at reset value.

Bit 6 **TG**: Trigger generation
   This bit is set by software in order to generate an event, it is automatically cleared by hardware.
   0: No action
   1: The TIF flag is set in TIMx_SR register. Related interrupt or DMA transfer can occur if enabled.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **CC4G**: Capture/compare 4 generation
   Refer to CC1G description

Bit 3 **CC3G**: Capture/compare 3 generation
   Refer to CC1G description

Bit 2 **CC2G**: Capture/compare 2 generation
   Refer to CC1G description

Bit 1 **CC1G**: Capture/compare 1 generation
   This bit is set by software in order to generate an event, it is automatically cleared by hardware.
   0: No action
   1: A capture/compare event is generated on channel 1:
      **If channel CC1 is configured as output:**
      CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled.
      **If channel CC1 is configured as input:**
      The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 **UG**: Update generation
   This bit can be set by software, it is automatically cleared by hardware.
   0: No action
   1: Re-initialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected). The counter is cleared if the center-aligned mode is selected or if DIR=0 (upcounting), else it takes the auto-reload value (TIMx_ARR) if DIR=1 (downcounting).
### 38.4.7 TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1) (x = 2 to 5)

Address offset: 0x18  
Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode.

**Input capture mode:**

<table>
<thead>
<tr>
<th>Bit 31-16</th>
<th>Bit 15-11</th>
<th>Bit 10-6</th>
<th>Bit 5-1</th>
<th>Bit 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 31:16: Reserved, must be kept at reset value.

Bits 15:12: **IC2F[3:0]:** Input capture 2 filter

Bits 11:10: **IC2PSC[1:0]:** Input capture 2 prescaler

Bits 9:8: **CC2S[1:0]:** Capture/compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input:

- 00: CC2 channel is configured as output.
- 01: CC2 channel is configured as input, IC2 is mapped on TI2.
- 10: CC2 channel is configured as input, IC2 is mapped on TI1.
- 11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

*Note: CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCER).*
Bits 7:4  **IC1F[3:0]**: Input capture 1 filter

This bit-field defines the frequency used to sample TI1 input and the length of the digital filter applied to TI1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

- 0000: No filter, sampling is done at fDTS
- 0001: $f_{SAMPLING}=f_{CK\_INT}$, N=2
- 0010: $f_{SAMPLING}=f_{CK\_INT}$, N=4
- 0011: $f_{SAMPLING}=f_{CK\_INT}$, N=8
- 0100: $f_{SAMPLING}=f_{DTS}/2$, N=6
- 0101: $f_{SAMPLING}=f_{DTS}/2$, N=8
- 0110: $f_{SAMPLING}=f_{DTS}/4$, N=6
- 0111: $f_{SAMPLING}=f_{DTS}/4$, N=8
- 1000: $f_{SAMPLING}=f_{DTS}/8$, N=6
- 1001: $f_{SAMPLING}=f_{DTS}/8$, N=8
- 1010: $f_{SAMPLING}=f_{DTS}/16$, N=5
- 1011: $f_{SAMPLING}=f_{DTS}/16$, N=6
- 1100: $f_{SAMPLING}=f_{DTS}/16$, N=8
- 1101: $f_{SAMPLING}=f_{DTS}/32$, N=5
- 1110: $f_{SAMPLING}=f_{DTS}/32$, N=6
- 1111: $f_{SAMPLING}=f_{DTS}/32$, N=8

Bits 3:2  **IC1PSC[1:0]**: Input capture 1 prescaler

This bit-field defines the ratio of the prescaler acting on CC1 input (IC1). The prescaler is reset as soon as CC1E=0 (TIMx_CCER register).

- 00: no prescaler, capture is done each time an edge is detected on the capture input
- 01: capture is done once every 2 events
- 10: capture is done once every 4 events
- 11: capture is done once every 8 events

Bits 1:0  **CC1S[1:0]**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

- 00: CC1 channel is configured as output
- 01: CC1 channel is configured as input, IC1 is mapped on TI1
- 10: CC1 channel is configured as input, IC1 is mapped on TI2
- 11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

*Note: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx_CCER).*
38.4.8 TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1) (x = 2 to 5)

Address offset: 0x18
Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode.

Output compare mode:

| Bits 31:25 | Reserved, must be kept at reset value. |
| Bits 23:17 | Reserved, must be kept at reset value. |
| Bit 15    | **OC2CE**: Output compare 2 clear enable |
| Bits 24, 14:12 | **OC2M[3:0]**: Output compare 2 mode |
|           | refer to OC1M description on bits 6:4 |
| Bit 11    | **OC2PE**: Output compare 2 preload enable |
| Bit 10    | **OC2FE**: Output compare 2 fast enable |
| Bits 9:8  | **CC2S[1:0]**: Capture/Compare 2 selection |
|           | This bit-field defines the direction of the channel (input/output) as well as the used input. |
| 00:       | CC2 channel is configured as output |
| 01:       | CC2 channel is configured as input, IC2 is mapped on TI2 |
| 10:       | CC2 channel is configured as input, IC2 is mapped on TI1 |
| 11:       | CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through the TS bit (TIMx_SMCR register) |
| **Note**: | **CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCR).** |
| Bit 7    | **OC1CE**: Output compare 1 clear enable |
| 0:       | OC1Ref is not affected by the ETRF input |
| 1:       | OC1Ref is cleared as soon as a High level is detected on ETRF input |
Bits 16, 6:4 \textbf{OC1M[3:0]: Output compare 1 mode}

These bits define the behavior of the output reference signal OC1REF from which OC1 and OC1N are derived. OC1REF is active high whereas OC1 and OC1N active level depends on CC1P and CC1NP bits.

0000: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs.(this mode is used to generate a timing base).

0001: Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0010: Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0011: Toggle - OC1REF toggles when TIMx_CNT=TIMx_CCR1.

0100: Force inactive level - OC1REF is forced low.

0101: Force active level - OC1REF is forced high.

0110: PWM mode 1 - In upcounting, channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else inactive. In downcounting, channel 1 is inactive as long as TIMx_CNT>TIMx_CCR1 else active (OC1REF=1).

0111: PWM mode 2 - In upcounting, channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else active. In downcounting, channel 1 is active as long as TIMx_CNT>TIMx_CCR1 else inactive.

1000: Retriggerable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

1001: Retriggerable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes active again at the next update.

1010: Reserved.

1011: Reserved.

1100: Combined PWM mode 1 - OC1REF has the same behavior as in PWM mode 1. OC1REFC is the logical OR between OC1REF and OC2REF.

1101: Combined PWM mode 2 - OC1REF has the same behavior as in PWM mode 2. OC1REFC is the logical AND between OC1REF and OC2REF.

1110: Asymmetric PWM mode 1 - OC1REF has the same behavior as in PWM mode 1. OC1REFC outputs OC1REF when the counter is counting up, OC2REF when it is counting down.

1111: Asymmetric PWM mode 2 - OC1REF has the same behavior as in PWM mode 2. OC1REFC outputs OC1REF when the counter is counting up, OC2REF when it is counting down.

\textbf{Note:} In \textit{PWM mode}, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.
Bit 3 **OC1PE**: Output compare 1 preload enable
0: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken in account immediately.
1: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded in the active register at each update event.

*Note: The PWM mode can be used without validating the preload register only in one-pulse mode (OPM bit set in TIMx_CR1 register). Else the behavior is not guaranteed.*

Bit 2 **OC1FE**: Output compare 1 fast enable
This bit is used to accelerate the effect of an event on the trigger in input on the CC output.
0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.
1: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection
This bit-field defines the direction of the channel (input/output) as well as the used input.
00: CC1 channel is configured as output.
01: CC1 channel is configured as input, IC1 is mapped on TI1.
10: CC1 channel is configured as input, IC1 is mapped on TI2.
11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

*Note: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx_CCER).*

### 38.4.9 **TIMx capture/compare mode register 2 [alternate] (TIMx_CCMR2)**

(x = 2 to 5)

Address offset: 0x1C

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode.

**Input capture mode:**

*Bits 31:16* Reserved, must be kept at reset value.

*Bits 15:12* **IC4F[3:0]**: Input capture 4 filter

*Bits 11:10* **IC4PSC[1:0]**: Input capture 4 prescaler
38.4.10 TIMx capture/compare mode register 2 [alternate] (TIMx_CCMR2) (x = 2 to 5)

Address offset: 0x1C
Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode.

Output compare mode:

Bits 31:25 Reserved, must be kept at reset value.
Bits 23:17 Reserved, must be kept at reset value.
Bit 15 OC4CE: Output compare 4 clear enable
Bits 24, 14:12 OC4M[3:0]: Output compare 4 mode
Refer to OC1M description (bits 6:4 in TIMx_CCMR1 register)
Bit 11 OC4PE: Output compare 4 preload enable
Bit 10 OC4FE: Output compare 4 fast enable
Bits 9:8 **CC4S[1:0]: Capture/Compare 4 selection**

This bit-field defines the direction of the channel (input/output) as well as the used input.

- **00**: CC4 channel is configured as output
- **01**: CC4 channel is configured as input, IC4 is mapped on TI4
- **10**: CC4 channel is configured as input, IC4 is mapped on TI3
- **11**: CC4 channel is configured as input, IC4 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

**Note**: **CC4S bits are writable only when the channel is OFF (CC4E = 0 in TIMx_CCER).**

Bit 7 **OC3CE**: Output compare 3 clear enable

Bits 16, 6:4 **OC3M[3:0]: Output compare 3 mode**

Refer to **OC1M** description (bits 6:4 in TIMx_CCMR1 register)

Bit 3 **OC3PE**: Output compare 3 preload enable

Bit 2 **OC3FE**: Output compare 3 fast enable

Bits 1:0 **CC3S[1:0]: Capture/Compare 3 selection**

This bit-field defines the direction of the channel (input/output) as well as the used input.

- **00**: CC3 channel is configured as output
- **01**: CC3 channel is configured as input, IC3 is mapped on TI3
- **10**: CC3 channel is configured as input, IC3 is mapped on TI4
- **11**: CC3 channel is configured as input, IC3 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

**Note**: **CC3S bits are writable only when the channel is OFF (CC3E = 0 in TIMx_CCER).**

### 38.4.11 **TIMx capture/compare enable register (TIMx_CCER)(x = 2 to 5)**

38.4.15 TIMx auto-reload register (TIMx_ARR)(x = 2 to 5)

Address offset: 0x2C
Reset value: 0xFFFF FFFF

| Bits 31:16 | ARR[31:16]: High auto-reload value (on TIM2 and TIM5) |
| Bits 15:0  | ARR[15:0]: Low Auto-reload value |

Bits 15:0 **PSC[15:0]:** Prescaler value
The counter clock frequency \( f_{CK\_CNT} \) is equal to \( f_{CK\_PSC} / (PSC[15:0] + 1) \).
PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in "reset mode").

38.4.16 TIMx capture/compare register 1 (TIMx_CCR1)(x = 2 to 5)

Address offset: 0x34
Reset value: 0x0000 0000

| Bits 31:16 | CCR1[31:16]: |
| Bits 15:0  | CCR1[15:0]: |

The counter is blocked while the auto-reload value is null.

Refer to the Section 38.3.1: Time-base unit on page 1637 for more details about ARR update and behavior.

ARR is the value to be loaded in the actual auto-reload register.

The counter is blocked while the auto-reload value is null.
38.4.17 TIMx capture/compare register 2 (TIMx_CCR2)(x = 2 to 5)

Address offset: 0x38
Reset value: 0x0000 0000

<table>

</table>

Bits 31:16 **CCR2[31:16]**: High Capture/Compare 2 value (on TIM2 and TIM5)

Bits 15:0 **CCR2[15:0]**: Low Capture/Compare 2 value

**If channel CC2 is configured as output:**
CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on OC2 output.

**If channel CC2 is configured as input:**
CCR2 is the counter value transferred by the last input capture 2 event (IC2). The TIMx_CCR2 register is read-only and cannot be programmed.

38.4.18 TIMx capture/compare register 3 (TIMx_CCR3)(x = 2 to 5)

Address offset: 0x3C
Reset value: 0x0000 0000
General-purpose timers (TIM2/TIM3/TIM4/TIM5) RM0433

38.4.19 TIMx capture/compare register 4 (TIMx_CCR4)(x = 2 to 5)

Address offset: 0x40

Reset value: 0x0000 0000

Bits 31:16 CCR3[31:16]: High Capture/Compare 3 value (on TIM2 and TIM5)

Bits 15:0 CCR3[15:0]: Low Capture/Compare value

If channel CC3 is configured as output:
CCR3 is the value to be loaded in the actual capture/compare 3 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIMx_CCMR2 register
(bit OC3PE). Else the preload value is copied in the active capture/compare 3 register when
an update event occurs.
The active capture/compare register contains the value to be compared to the counter
TIMx_CNT and signalled on OC3 output.

If channel CC3 is configured as input:
CCR3 is the counter value transferred by the last input capture 3 event (IC3). The
TIMx_CCR3 register is read-only and cannot be programmed.

Bits 31:16 CCR4[31:16]: High Capture/Compare 4 value (on TIM2 and TIM5)

Bits 15:0 CCR4[15:0]: Low Capture/Compare value

1. if CC4 channel is configured as output (CC4S bits):
CCR4 is the value to be loaded in the actual capture/compare 4 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIMx_CCMR2
register (bit OC4PE). Else the preload value is copied in the active capture/compare 4
register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter
TIMx_CNT and signalled on OC4 output.

2. if CC4 channel is configured as input (CC4S bits in TIMx_CCMR4 register):
CCR4 is the counter value transferred by the last input capture 4 event (IC4). The
TIMx_CCR4 register is read-only and cannot be programmed.
38.4.20 TIMx DMA control register (TIMx_DCR)(x = 2 to 5)

Address offset: 0x48
Reset value: 0x0000

</table>

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 DBL[4:0]: DMA burst length
This 5-bit vector defines the number of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address).
- 00000: 1 transfer,
- 00001: 2 transfers,
- 00010: 3 transfers,
- ...
- 10001: 18 transfers.

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 DBA[4:0]: DMA base address
This 5-bit vector defines the base-address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register.
Example:
- 00000: TIMx_CR1
- 00001: TIMx_CR2
- 00010: TIMx_SMCR
- ...
Example: Let us consider the following transfer: DBL = 7 transfers & DBA = TIMx_CR1. In this case the transfer is done to/from 7 registers starting from the TIMx_CR1 address.

38.4.21 TIMx DMA address for full transfer (TIMx_DMAR)(x = 2 to 5)

Address offset: 0x4C
Reset value: 0x0000

Bits 15:0 DMAB[15:0]: DMA register for burst accesses
A read or write operation to the DMAR register accesses the register located at the address (TIMx_CR1 address) + (DBA + DMA index) x 4
where TIMx_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIMx_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIMx_DCR).

39 General-purpose timers (TIM12/TIM13/TIM14)

39.1 TIM12/TIM13/TIM14 introduction

The TIM12/TIM13/TIM14 general-purpose timers consist in a 16-bit auto-reload counter driven by a programmable prescaler.

They may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The TIM12/TIM13/TIM14 timers are completely independent, and do not share any resources. They can be synchronized together as described in Section 39.3.17: Timer synchronization (TIM12).

39.2 TIM12/TIM13/TIM14 main features

39.2.1 TIM12 main features

The features of the TIM12 general-purpose timer include:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide the counter clock frequency by any factor between 1 and 65536 (can be changed “on the fly”)
- Up to 2 independent channels for:
  - Input capture
  - Output compare
  - PWM generation (edge-aligned mode)
  - One-pulse mode output
- Synchronization circuit to control the timer with external signals and to interconnect several timers together
- Interrupt generation on the following events:
  - Update: counter overflow, counter initialization (by software or internal trigger)
  - Trigger event (counter start, stop, initialization or count by internal trigger)
  - Input capture
  - Output compare
39.2.2 **TIM13/TIM14 main features**

The features of general-purpose timers TIM13/TIM14 include:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide the counter clock frequency by any factor between 1 and 65536 (can be changed “on the fly”)
- independent channel for:
  - Input capture
  - Output compare
  - PWM generation (edge-aligned mode)
  - One-pulse mode output
- Interrupt generation on the following events:
  - Update: counter overflow, counter initialization (by software)
  - Input capture
  - Output compare

39.3 TIM12/TIM13/TIM14 functional description

39.3.1 Time-base unit

The main block of the timer is a 16-bit up-counter with its related auto-reload register. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:
- Counter register (TIMx_CNT)
- Prescaler register (TIMx_PSC)
- Auto-reload register (TIMx_ARR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in details for each configuration.

The counter is clocked by the prescaler output CK_CNT, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the counter starts counting 1 clock cycle after setting the CEN bit in the TIMx_CR1 register.

Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 455* and *Figure 456* give some examples of the counter behavior when the prescaler ratio is changed on the fly.
Figure 455. Counter timing diagram with prescaler division change from 1 to 2

Figure 456. Counter timing diagram with prescaler division change from 1 to 4
39.3.2 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller on TIM12) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):
- The auto-reload shadow register is updated with the preload value (TIMx_ARR),
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

- Auto-reload preload register
- Write a new value in TIMx_ARR
39.3.3 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (CK_INT)
- External clock mode1 (for TIM12): external input pin (TIx)
- Internal trigger inputs (ITRx) (for TIM12): connecting the trigger output from another timer. For instance, another timer can be configured as a prescaler for TIM12. Refer to Section: Using one timer as prescaler for another timer for more details.

Internal clock source (CK_INT)

The internal clock source is the default clock source for TIM13/TIM14.

For TIM12, the internal clock source is selected when the slave mode controller is disabled (SMS=’000’). The CEN bit in the TIMx_CR1 register and the UG bit in the TIMx_EGR register are then used as control bits and can be changed only by software (except for UG which remains cleared). As soon as the CEN bit is programmed to 1, the prescaler is clocked by the internal clock CK_INT.

Figure 463 shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.
External clock source mode 1 (TIM12)

This mode is selected when SMS=’111’ in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

For example, to configure the upcounter to count in response to a rising edge on the TI2 input, use the following procedure:
1. Select the proper TI2[x] source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Configure channel 2 to detect rising edges on the TI2 input by writing CC2S = ‘01’ in the TIMx_CCMR1 register.
3. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx_CCMR1 register (if no filter is needed, keep IC2F='0000').
4. Select the rising edge polarity by writing CC2P='0' and CC2NP='0' in the TIMx_CCER register.
5. Configure the timer in external clock mode 1 by writing SMS='111' in the TIMx_SMCR register.
6. Select TI2 as the trigger input source by writing TS='110' in the TIMx_SMCR register.
7. Enable the counter by writing CEN='1' in the TIMx_CR1 register.

**Note:** The capture prescaler is not used for triggering, so it does not need to be configured.

When a rising edge occurs on TI2, the counter counts once and the TIF flag is set.

The delay between the rising edge on TI2 and the actual clock of the counter is due to the resynchronization circuit on TI2 input.

**Figure 465. Control circuit in external clock mode 1**

### 39.3.4 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

*Figure 466 to Figure 468* give an overview of one capture/compare channel.

The input stage samples the corresponding TIx input to generate a filtered signal TIxF. Then, an edge detector with polarity selection generates a signal (TIxFP) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).
The output stage generates an intermediate waveform which is then used for reference: OCxRef (active high). The polarity acts at the end of the chain.

**Figure 466. Capture/compare channel (example: channel 1 input stage)**

**Figure 467. Capture/compare channel 1 main circuit**
The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 39.3.5 Input capture mode

In Input capture mode, the Capture/Compare Registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCxIF flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to '0' or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx_CCR1 when TI1 input rises. To do this, use the following procedure:

1. Select the proper TI1[x] source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input: TIMx_CCR1 must be linked to the TI1 input, so write the CC1S bits to '01' in the TIMx_CCMR1 register. As soon as CC1S becomes different from '00', the channel is configured in input mode and the TIMx_CCR1 register becomes read-only.
3. Program the appropriate input filter duration in relation with the signal connected to the timer (by programming the ICxF bits in the TIMx_CCMRx register if the input is one of the TIx inputs). Let’s imagine that, when toggling, the input signal is not stable during at least 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on TI1 when 8 consecutive samples with the
new level have been detected (sampled at $f_{DTS}$ frequency). Then write IC1F bits to ‘0011’ in the TIMx_CCMR1 register.

4. Select the edge of the active transition on the TI1 channel by programming CC1P and CC1NP bits to ‘00’ in the TIMx_CCER register (rising edge in this case).

5. Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to ‘00’ in the TIMx_CCMR1 register).

6. Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.

7. If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register.

When an input capture occurs:

- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

Note: IC interrupt requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.

39.3.6 PWM input mode (only for TIM12)

This mode is a particular case of input capture mode. The procedure is the same except:

- Two ICx signals are mapped on the same TIx input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two TIxFP signals is selected as trigger input and the slave mode controller is configured in reset mode.

For example, one can measure the period (in TIMx_CCR1 register) and the duty cycle (in TIMx_CCR2 register) of the PWM applied on TI1 using the following procedure (depending on CK_INT frequency and prescaler value):
1. Select the proper TI1[x] source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input for TIMx_CCR1: write the CC1S bits to ‘01’ in the TIMx_CCMR1 register (TI1 selected).
3. Select the active polarity for TI1FP1 (used both for capture in TIMx_CCR1 and counter clear): program the CC1P and CC1NP bits to ‘00’ (active on rising edge).
4. Select the active input for TIMx_CCR2: write the CC2S bits to ‘10’ in the TIMx_CCMR1 register (TI1 selected).
5. Select the active polarity for TI1FP2 (used for capture in TIMx_CCR2): program the CC2P and CC2NP bits to ‘11’ (active on falling edge).
6. Select the valid trigger input: write the TS bits to ‘00101’ in the TIMx_SMCR register (TI1FP1 selected).
7. Configure the slave mode controller in reset mode: write the SMS bits to ‘100’ in the TIMx_SMCR register.
8. Enable the captures: write the CC1E and CC2E bits to ‘1’ in the TIMx_CCER register.

![Figure 469. PWM input mode timing](image)

1. The PWM input mode can be used only with the TIMx_CH1/TIMx_CH2 signals due to the fact that only TI1FP1 and TI2FP2 are connected to the slave mode controller.

### 39.3.7 Forced output mode

In output mode (CCxS bits = ‘00’ in the TIMx_CCMRx register), each output compare signal (OCxREF and then OCx) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (OCxREF/OCx) to its active level, one just needs to write ‘0101’ in the OCxM bits in the corresponding TIMx_CCMRx register. Thus OCxREF is forced high (OCxREF is always active high) and OCx get opposite value to CCxP polarity bit.

For example: CCxP=’0’ (OCx active high) => OCx is forced to high level.

The OCxREF signal can be forced low by writing the OCxM bits to ‘0100’ in the TIMx_CCMRx register.
Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt requests can be sent accordingly. This is described in the output compare mode section below.

### 39.3.8 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

1. Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP bit in the TIMx_CCER register). The output pin can keep its level (OCxM='0000'), be set active (OCxM='0001'), be set inactive (OCxM='0010') or can toggle (OCxM='0011') on match.
2. Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
3. Generates an interrupt if the corresponding interrupt mask is set (CCxIE bit in the TIMx_DIER register).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on OCxREF and OCx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

Procedure:

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
   - Write OCxM = ‘0011’ to toggle OCx output pin when CNT matches CCRx
   - Write OCxPE = ‘0’ to disable preload register
   - Write CCxP = ‘0’ to select active high polarity
   - Write CCxE = ‘1’ to enable the output
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE='0', else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in Figure 470.
39.3.9 PWM mode

Pulse Width Modulation mode allows to generate a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per OCx output) by writing ‘0110’ (PWM mode 1) or ‘0111’ (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxCE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

The OCx polarity is software programmable using the CCxE bit in the TIMx_CCER register. It can be programmed as active high or active low. The OCx output is enabled by the CCxE bit in the TIMx_CCER register. Refer to the TIMx_CCERx register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CNT ≤ TIMx_CCRx.

The timer is able to generate PWM in edge-aligned mode only since the counter is upcounting.

In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is high as long as TIMx_CNT < TIMx_CCRx else it becomes low. If the compare value in TIMx_CCRx is greater than the auto-reload value (in TIMx_ARR) then OCxREF is held at ‘1’. If the compare value is 0 then OCxRef is held at ‘0’. Figure 471 shows some edge-aligned PWM waveforms in an example where TIMx_ARR=8.
39.3.10 Combined PWM mode (TIM12 only)

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and delay are determined by the two TIMx_CCRx registers. The resulting signals, OCxREFC, are made of an OR or AND logical combination of two reference PWMs:

- OC1REFC (or OC2REFC) is controlled by the TIMx_CCR1 and TIMx_CCR2 registers

Combined PWM mode can be selected independently on two channels (one OCx output per pair of CCR registers) by writing '1100' (Combined PWM mode 1) or '1101' (Combined PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

When a given channel is used as a combined PWM channel, its complementary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

**Note:** The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

Figure 472 represents an example of signals that can be generated using combined PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2,
- Channel 2 is configured in PWM mode 1,
39.3.11 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be as follows:

\[ \text{CNT} < \text{CCR}x \leq \text{ARR} \] (in particular, \(0 < \text{CCR}x\))
For example one may want to generate a positive pulse on OC1 with a length of \( t_{\text{PULSE}} \) and after a delay of \( t_{\text{DELAY}} \) as soon as a positive edge is detected on the TI2 input pin.

Use TI2FP2 as trigger 1:
1. Select the proper TI2[x] source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Map TI2FP2 to TI2 by writing CC2S='01' in the TIMx_CCMR1 register.
3. TI2FP2 must detect a rising edge, write CC2P='0' and CC2NP='0' in the TIMx_CCER register.
4. Configure TI2FP2 as trigger for the slave mode controller (TRGI) by writing TS='00110' in the TIMx_SMCR register.
5. TI2FP2 is used to start the counter by writing SMS to '110' in the TIMx_SMCR register (trigger mode).

The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).
- The \( t_{\text{DELAY}} \) is defined by the value written in the TIMx_CCR1 register.
- The \( t_{\text{PULSE}} \) is defined by the difference between the auto-reload value and the compare value (TIMx_ARR - TIMx_CCR1).
- Let’s say one want to build a waveform with a transition from ‘0’ to ‘1’ when a compare match occurs and a transition from ‘1’ to ‘0’ when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing OC1M='0111' in the TIMx_CCMR1 register. Optionally the preload registers can be enabled by writing OC1PE='1' in the TIMx_CCMR1 register and ARPE in the TIMx_CR1 register. In this case one has to write the compare value in the TIMx_CCR1 register, the auto-reload value in the TIMx_ARR register, generate an update by setting the UG bit and wait for external trigger event on TI2. CC1P is written to ‘0’ in this example.

Since only 1 pulse (Single mode) is needed, a 1 must be written in the OPM bit in the TIMx_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0). When OPM bit in the TIMx_CR1 register is set to ‘0’, so the Repetitive Mode is selected.
Particular case: OCx fast enable

In One-pulse mode, the edge detection on TIx input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay \( t_{\text{DELAY min}} \) we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx_CCMRx register. Then OCxRef (and OCx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

39.3.12 Retriggerable one pulse mode (OPM) (TIM12 only)

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with non-retriggerable one pulse mode described in Section 39.3.11: One-pulse mode:

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed

The timer must be in Slave mode, with the bits SMS[3:0] = ‘1000’ (Combined Reset + trigger mode) in the TIMx_SMCR register, and the OCxM[3:0] bits set to ‘1000’ or ‘1001’ for retrigerrable OPM mode 1 or 2.

If the timer is configured in up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in down-counting mode, CCRx must be above or equal to ARR.

Note: The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bit are not contiguous with the 3 least significant ones.

This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx_CR1.

Figure 474. Retriggerable one pulse mode
39.3.13 UIF bit remapping

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the Update Interrupt Flag UIF into bit 31 of the timer counter register (TIMxCNT[31]). This allows to atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. In particular cases, it can ease the calculations by avoiding race conditions caused for instance by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

There is no latency between the assertions of the UIF and UIFCPY flags.

39.3.14 Timer input XOR function

The TI1S bit in the TIMx_CR2 register, allows the input filter of channel 1 to be connected to the output of a XOR gate, combining the two input pins TIMx_CH1 and TIMx_CH2.

The XOR output can be used with all the timer input functions such as trigger or input capture. It is useful for measuring the interval between the edges on two input signals, as shown in Figure 475.

![Figure 475. Measuring time interval between edges on 2 signals](image)

39.3.15 TIM12 external trigger synchronization

The TIM12 timer can be synchronized with an external trigger in several modes: Reset mode, Gated mode and Trigger mode.

**Slave mode: Reset mode**

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on TI1 input:

1. Configure the channel 1 to detect rising edges on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F='0000'). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = '01' in the TIMx_CCMap register.
Program CC1P and CC1NP to ‘00’ in TIMx_CCER register to validate the polarity (and detect rising edges only).

2. Configure the timer in reset mode by writing SMS=’100’ in TIMx_SMCR register. Select TI1 as the input source by writing TS=’00101’ in TIMx_SMCR register.

3. Start the counter by writing CEN=’1’ in the TIMx_CR1 register.

The counter starts counting on the internal clock, then behaves normally until TI1 rising edge. When TI1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request can be sent if enabled (depending on the TIE bit in TIMx_DIER register).

The following figure shows this behavior when the auto-reload register TIMx_ARR=0x36. The delay between the rising edge on TI1 and the actual reset of the counter is due to the resynchronization circuit on TI1 input.

**Figure 476. Control circuit in reset mode**

---

**Slave mode: Gated mode**

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when TI1 input is low:

1. Configure the channel 1 to detect low levels on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=’0000’). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S=’01’ in TIMx_CCMR1 register. Program CC1P=’1’ and CC1NP=’0’ in TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in gated mode by writing SMS=’101’ in TIMx_SMCR register. Select TI1 as the input source by writing TS=’00101’ in TIMx_SMCR register.

3. Enable the counter by writing CEN=’1’ in the TIMx_CR1 register (in gated mode, the counter doesn’t start if CEN=’0’, whatever is the trigger input level).

The counter starts counting on the internal clock as long as TI1 is low and stops as soon as TI1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.
The delay between the rising edge on TI1 and the actual stop of the counter is due to the resynchronization circuit on TI1 input.

**Slave mode: Trigger mode**

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on TI2 input:

1. Configure the channel 2 to detect rising edges on TI2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F='0000'). The capture prescaler is not used for triggering, so it does not need to be configured. The CC2S bits are configured to select the input capture source only, CC2S='01' in TIMx_CCMR1 register. Program CC2P='1' and CC2NP='0' in TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in trigger mode by writing SMS='110' in TIMx_SMCR register. Select TI2 as the input source by writing TS='00110' in TIMx_SMCR register.

When a rising edge occurs on TI2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on TI2 and the actual start of the counter is due to the resynchronization circuit on TI2 input.
### 39.3.16 Slave mode – combined reset + trigger mode

In this case, a rising edge of the selected trigger input (TRGI) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for one-pulse mode.
39.3.17 **Timer synchronization (TIM12)**

The TIM timers are linked together internally for timer synchronization or chaining. Refer to Section 38.3.19: Timer synchronization for details.

*Note:*  The clock of the slave timer must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

39.3.18 **Debug mode**

When the microcontroller enters debug mode (Cortex®-M7 with FPU core halted), the TIMx counter either continues to work normally or stops, depending on DBG_TIMx_STOP configuration bit in DBGMCU module. For more details, refer to Section 59.5.8: Microcontroller debug unit (DBGMCU).

39.4 **TIM12 registers**

Refer to Section 1.2 for a list of abbreviations used in register descriptions.

The peripheral registers have to be written by half-words (16 bits) or words (32 bits). Read accesses can be done by bytes (8 bits), half-words (16 bits) or words (32 bits).

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **T11S**: T11 selection

- 0: The TIM12_CH1 pin is connected to T11 input
- 1: The TIM12_CH1, CH2 pins are connected to the T11 input (XOR combination)

Bits 6:4 **MMS[2:0]**: Master mode selection

These bits allow to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows:

- 000: Reset - the UG bit from the TIMx_EGR register is used as trigger output (TRGO). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on TRGO is delayed compared to the actual reset.
- 001: Enable - the Counter Enable signal CNT_EN is used as trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic OR between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO, except if the master/slave mode is selected (see the MSM bit description in TIMx_SMCR register).
- 010: Update - The update event is selected as trigger output (TRGO). For instance a master timer can then be used as a prescaler for a slave timer.
- 011: Compare Pulse - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred.
- 100: Compare - OC1REF signal is used as trigger output (TRGO).
- 101: Compare - OC2REF signal is used as trigger output (TRGO).

Bits 3:0 Reserved, must be kept at reset value.

</tbody>
</table>

Bits 31:22 Reserved, must be kept at reset value.

Bits 19:17 Reserved, must be kept at reset value.

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **MSM**: Master/Slave mode

- 0: No action
- 1: The effect of an event on the trigger input (TRGI) is delayed to allow a perfect synchronization between the current timer and its slaves (through TRGO). It is useful in order to synchronize several timers on a single external event.
Bits 21, 20, 6, 5, 4 **TS[4:0]:** Trigger selection

This TS[4:0] bitfield selects the trigger input to be used to synchronize the counter.

- **00000:** Internal Trigger 0 (ITR0)
- **00001:** Internal Trigger 1 (ITR1)
- **00010:** Internal Trigger 2 (ITR2)
- **00011:** Internal Trigger 3 (ITR3)
- **00100:** TI1 Edge Detector (TI1F_ED)
- **00101:** Filtered Timer Input 1 (TI1FP1)
- **00110:** Filtered Timer Input 2 (TI2FP2)
- **Others:** Reserved

See Table 331: TIMx internal trigger connection on page 1738 for more details on the meaning of ITRx for each timer.

Note: These bits must be changed only when they are not used (e.g. when SMS='000') to avoid wrong edge detections at the transition.

Bit 3 Reserved, must be kept at reset value.

Bits 16, 2, 1, 0 **SMS[3:0]:** Slave mode selection

When external signals are selected the active edge of the trigger signal (TRGI) is linked to the polarity selected on the external input (see Input Control register and Control Register description.

- **0000:** Slave mode disabled - if CEN = ‘1’ then the prescaler is clocked directly by the internal clock.
- **0001:** Reserved
- **0010:** Reserved
- **0011:** Reserved
- **0100:** Reset Mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter and generates an update of the registers.
- **0101:** Gated Mode - The counter clock is enabled when the trigger input (TRGI) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.
- **0110:** Trigger Mode - The counter starts at a rising edge of the trigger TRGI (but it is not reset). Only the start of the counter is controlled.
- **0111:** External Clock Mode 1 - Rising edges of the selected trigger (TRGI) clock the counter.
- **1000:** Combined reset + trigger mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter, generates an update of the registers and starts the counter.
- **Others codes:** reserved.

Note: The gated mode must not be used if TI1F_ED is selected as the trigger input (TS='00100'). Indeed, TI1F_ED outputs 1 pulse for each transition on TI1F, whereas the gated mode checks the level of the trigger signal.

Note: The clock of the slave timer must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 CC2OF: Capture/compare 2 overcapture flag
Refer to CC1OF description

Bit 9 CC1OF: Capture/Compare 1 overcapture flag
This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to ‘0’.
0: No overcapture has been detected.
1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set

Bits 8:7 Reserved, must be kept at reset value.
General-purpose timers (TIM12/TIM13/TIM14)

Bits 15:7 Reserved, must be kept at reset value.

Bit 6 **TG**: Trigger generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: The TIF flag is set in the TIMx_SR register. Related interrupt can occur if enabled

Bits 5:3 Reserved, must be kept at reset value.
Bit 2  **CC2G**: Capture/compare 2 generation  
 refer to CC1G description

Bit 1  **CC1G**: Capture/compare 1 generation  
This bit is set by software to generate an event, it is automatically cleared by hardware.  
0: No action  
1: A capture/compare event is generated on channel 1:  
If channel CC1 is configured as output:  
the CC1IF flag is set, the corresponding interrupt is sent if enabled.  
If channel CC1 is configured as input:  
The current counter value is captured in the TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.  

Bit 0  **UG**: Update generation  
This bit can be set by software, it is automatically cleared by hardware.  
0: No action  
1: Re-initializes the counter and generates an update of the registers. The prescaler counter is also cleared and the prescaler ratio is not affected. The counter is cleared.

### 39.4.7 TIM12 capture/compare mode register 1 [alternate]  
(TIM12_CCMR1)

Address offset: 0x18  
Reset value: 0x0000 0000  
The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits in this register have different functions in input and output modes.

**Input capture mode:**

| Bit 31:16 Reserved, must be kept at reset value.  
| Bits 15:12  **IC2F[3:0]**: Input capture 2 filter  
| Bits 11:10  **IC2PSC[1:0]**: Input capture 2 prescaler  
| Bits 9:8  **CC2S[1:0]**: Capture/compare 2 selection  
| This bitfield defines the direction of the channel (input/output) as well as the used input.  
00: CC2 channel is configured as output  
01: CC2 channel is configured as input, IC2 is mapped on TI2  
10: CC2 channel is configured as input, IC2 is mapped on TI1  
11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode works only if an internal trigger input is selected through the TS bit (TIMx_SMCR register)  
*Note: The CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCER).*
39.4.8 TIM12 capture(compare) mode register 1 [alternate] (TIM12_CCMR1)

Address offset: 0x18

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the
corresponding CCxS bits. All the other bits in this register have different functions in input and output modes.

**Output compare mode:**

<table>

<td>OC1M[3]</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:25: Reserved, must be kept at reset value.

Bit 23:17: Reserved, must be kept at reset value.

Bit 15: Reserved, must be kept at reset value.

Bits 24, 14:12: **OC2M[3:0]:** Output compare 2 mode
Refer to OC1M[3:0] for bit description.

Bit 11: **OC2PE:** Output compare 2 preload enable

Bit 10: **OC2FE:** Output compare 2 fast enable

Bits 9:8: **CC2S[1:0]:** Capture/Compare 2 selection
This bitfield defines the direction of the channel (input/output) as well as the used input.
00: CC2 channel is configured as output
01: CC2 channel is configured as input, IC2 is mapped on TI2
10: CC2 channel is configured as input, IC2 is mapped on TI1
11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode works only if an internal trigger input is selected through the TS bit (TIMx_SMCR register)

*Note:* The CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCER).

Bit 7: Reserved, must be kept at reset value.
Bits 16, 6:4 **OC1M[3:0]**: Output compare 1 mode (refer to bit 16 for OC1M[3])

These bits define the behavior of the output reference signal OC1REF from which OC1 is derived. OC1REF is active high whereas the active level of OC1 depends on the CC1P.

- **0000**: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs. (this mode is used to generate a timing base).
- **0001**: Set channel 1 to active level on match. The OC1REF signal is forced high when the TIMx_CNT counter matches the capture/compare register 1 (TIMx_CCR1).
- **0010**: Set channel 1 to inactive level on match. The OC1REF signal is forced low when the TIMx_CNT counter matches the capture/compare register 1 (TIMx_CCR1).
- **0011**: Toggle - OC1REF toggles when TIMx_CNT=TIMx_CCR1.
- **0100**: Force inactive level - OC1REF is forced low.
- **0101**: Force active level - OC1REF is forced high.
- **0110**: PWM mode 1 - channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else it is inactive.
- **0111**: PWM mode 2 - channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else it is active.
- **1000**: Retrigerrable OPM mode 1 - The channel is active until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.
- **1001**: Retrigerrable OPM mode 2 - The channel is inactive until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update.
- **1010**: Reserved,
- **1011**: Reserved,
- **1100**: Combined PWM mode 1 - OC1REF has the same behavior as in PWM mode 1. OC1REFC is the logical OR between OC1REF and OC2REF.
- **1101**: Combined PWM mode 2 - OC1REF has the same behavior as in PWM mode 2. OC1REFC is the logical AND between OC1REF and OC2REF.
- **1110**: Reserved,
- **1111**: Reserved

Note: In PWM mode 1 or 2, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.
Bit 3 **OC1PE**: Output compare 1 preload enable  
0: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken into account immediately  
1: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded into the active register at each update event  
*Note:* The PWM mode can be used without validating the preload register only in one-pulse mode (OPM bit set in the TIMx_CR1 register). Else the behavior is not guaranteed.

Bit 2 **OC1FE**: Output compare 1 fast enable  
This bit is used to accelerate the effect of an event on the trigger in input on the CC output.  
0: CC1 behaves normally depending on the counter and CCR1 values even when the trigger is ON. The minimum delay to activate the CC1 output when an edge occurs on the trigger input is 5 clock cycles  
1: An active edge on the trigger input acts like a compare match on the CC1 output. Then, OC is set to the compare level independently of the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OC1FE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection  
This bitfield defines the direction of the channel (input/output) as well as the used input.  
00: CC1 channel is configured as output  
01: CC1 channel is configured as input, IC1 is mapped on TI1  
10: CC1 channel is configured as input, IC1 is mapped on TI2  
11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode works only if an internal trigger input is selected through the TS bit (TIMx_SMCR register)  
*Note:* The CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx_CCER).

### 39.4.9 TIM12 capture/compare enable register (TIM12_CCER)

Address offset: 0x20

```

Bits 15:8 Reserved, must be kept at reset value.  
Bit 7 **CC2NP**: Capture/Compare 2 output Polarity  
Refer to CC1NP description  
Bit 6 Reserved, must be kept at reset value.  
Bit 5 **CC2P**: Capture/Compare 2 output Polarity  
Refer to CC1P description  
Bit 4 **CC2E**: Capture/Compare 2 output enable  
Refer to CC1E description  
Bit 3 **CC1NP**: Capture/Compare 1 complementary output Polarity  
CC1 channel configured as output: CC1NP must be kept cleared  
CC1 channel configured as input: CC1NP is used in conjunction with CC1P to define TI1FP1/TI2FP1 polarity (refer to CC1P description).
Bit 2  Reserved, must be kept at reset value.

Bit 1  CC1P: Capture/Compare 1 output Polarity.

**CC1 channel configured as output:**
0: OC1 active high.
1: OC1 active low.

**CC1 channel configured as input:**
The CC1P and CC1NP bits select TI1FP1 polarity for capture operations.
00: non-inverted/rising edge
Circuit is sensitive to TI1FP1 rising edge (capture, trigger in reset, external clock or trigger mode), TI1FP1 is not inverted (trigger in gated mode, encoder mode).
01: inverted/falling edge
Circuit is sensitive to TI1FP1 falling edge (capture, trigger in reset, external clock or trigger mode), TI1FP1 is inverted (trigger in gated mode, encoder mode).
10: reserved, do not use this configuration.
11: noninverted/both edges
Circuit is sensitive to both TI1FP1 rising and falling edges (capture, trigger in reset, external clock or trigger mode), TI1FP1 is not inverted (trigger in gated mode). This configuration must not be used for encoder mode.

Bit 0  CC1E: Capture/Compare 1 output enable.

**CC1 channel configured as output:**
0: Off - OC1 is not active.
1: On - OC1 signal is output on the corresponding output pin.

**CC1 channel configured as input:**
This bit determines if a capture of the counter value can actually be done into the input capture/compare register 1 (TIMx_CCR1) or not.
0: Capture disabled.
1: Capture enabled.

### Table 332. Output control bit for standard OCx channels

<table>
<thead>
<tr>
<th>CCxE bit</th>
<th>OCx output state</th>
</tr>
</thead>
<tbody>
<tr>

Bits 15:0  **PSC[15:0]**: Prescaler value  
The counter clock frequency $f_{CK\_CNT}$ is equal to $f_{CK\_PSC} / (PSC[15:0] + 1)$.  
PSC contains the value to be loaded into the active prescaler register at each update event. (including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in “reset mode”).

### 39.4.12 TIM12 auto-reload register (TIM12_ARR)

Bits 15:0  **ARR[15:0]**: Auto-reload value  
ARR is the value to be loaded into the actual auto-reload register.  
Refer to the Section 39.3.1: Time-base unit on page 1713 for more details about ARR update and behavior.  
The counter is blocked while the auto-reload value is null.

### 39.4.13 TIM12 capture/compare register 1 (TIM12_CCR1)

Bits 15:0 CCR2[15:0]: Capture/Compare 2 value

- **If channel CC2 is configured as output:**
  - CCR2 is the value to be loaded into the actual capture/compare 2 register (preload value).
  - It is loaded permanently if the preload feature is not selected in the TIMx_CCMR2 register (OC2PE bit). Else the preload value is copied into the active capture/compare 2 register when an update event occurs.
  - The active capture/compare register contains the value to be compared to the TIMx_CNT counter and signaled on the OC2 output.

- **If channel CC2 is configured as input:**
  - CCR2 is the counter value transferred by the last input capture 2 event (IC2).

39.4.15 TIM12 timer input selection register (TIM12_TISEL)

Refer to *Section 2.3 on page 126* for the register boundary addresses.
39.5 TIM13/TIM14 registers

The peripheral registers have to be written by half-words (16 bits) or words (32 bits). Read accesses can be done by bytes (8 bits), half-words (16 bits) or words (32 bits).

39.5.1 TIMx control register 1 (TIMx_CR1)(x = 13 to 14)

Address offset: 0x00
Reset value: 0x0000

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **UiFREMAP**: UIF status bit remapping
0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.
1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division
This bit-field indicates the division ratio between the timer clock (CK_INT) frequency and sampling clock used by the digital filters (TIx),
00: tDTS = tCK_INT
01: tDTS = 2 × tCK_INT
10: tDTS = 4 × tCK_INT
11: Reserved

Bit 7 **ARPE**: Auto-reload preload enable
0: TIMx_ARR register is not buffered
1: TIMx_ARR register is buffered

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM**: One-pulse mode
0: Counter is not stopped on the update event
1: Counter stops counting on the next update event (clearing the CEN bit).
39.5.2 TIMx Interrupt enable register (TIMx_DIER)(x = 13 to 14)

Address offset: 0x0C
Reset value: 0x0000

</tr>
</tbody>
</table>

Bits 15:2 Reserved, must be kept at reset value.

Bit 1 CC1OF: Capture/Compare 1 overflow
0: No overflow
1: Overflow detected

Bit 0 UIF: Update interrupt flag
0: No update interrupt
1: Update interrupt pending
Bits 15:10  Reserved, must be kept at reset value.

Bit 9  **CC1OF**: Capture/Compare 1 overcapture flag
This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to ‘0’.
0: No overcapture has been detected.
1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set

Bits 8:2  Reserved, must be kept at reset value.

Bit 1  **CC1IF**: Capture/compare 1 interrupt flag
**If channel CC1 is configured as output:**
This flag is set by hardware when the counter matches the compare value. It is cleared by software.
0: No match.
1: The content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the contents of TIMx_CCR1 are greater than the contents of TIMx_ARR, the CC1IF bit goes high on the counter overflow.
If channel CC1 is configured as input:
This bit is set by hardware on a capture. It is cleared by software or by reading the TIMx_CCR1 register.
0: No input capture occurred.
1: The counter value has been captured in TIMx_CCR1 register (an edge has been detected on IC1 which matches the selected polarity).

Bit 0  **UIF**: Update interrupt flag
This bit is set by hardware on an update event. It is cleared by software.
0: No update occurred.
1: Update interrupt pending. This bit is set by hardware when the registers are updated:
– At overflow and if UDIS='0’ in the TIMx_CR1 register.
– When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if URS='0’ and UDIS='0’ in the TIMx_CR1 register.

### 39.5.4  **TIMx event generation register (TIMx_EGR)(x = 13 to 14)**

Address offset: 0x14

Reset value: 0x0000

<table>
<thead>
<tr>
<th>Bit 15</th>
<th>Bit 14</th>
<th>Bit 13</th>
<th>Bit 12</th>
<th>Bit 11</th>
<th>Bit 10</th>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>w</td>
</tr>
</tbody>
</table>

**w**
Bits 15:2 Reserved, must be kept at reset value.

Bit 1 \textbf{CC1G}: Capture/compare 1 generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: A capture/compare event is generated on channel 1:
\textbf{If channel CC1 is configured as output:}
CC1IF flag is set, corresponding interrupt or is sent if enabled.
\textbf{If channel CC1 is configured as input:}
The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 \textbf{UG}: Update generation
This bit can be set by software, it is automatically cleared by hardware.
0: No action
1: Re-initialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected). The counter is cleared.

### 39.5.5 TIMx capture/compare mode register 1 [alternate]
**(TIMx_CCMR1)(x = 13 to 14)**

Address offset: 0x18

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode.

#### Input capture mode:

Bits 31:8 Reserved, must be kept at reset value.

**Bits 7:4 IC1F[3:0]: Input capture 1 filter**
This bit-field defines the frequency used to sample TI1 input and the length of the digital filter applied to TI1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:
0000: No filter, sampling is done at \( f_{DTS} \), \( f_{SAMPLING} = f_{DTS}/8 \), \( N = 6 \)
0001: \( f_{SAMPLING} = f_{CK \_INT} \), \( N = 21001 \), \( f_{SAMPLING} = f_{DTS}/8 \), \( N = 8 \)
0010: \( f_{SAMPLING} = f_{CK \_INT} \), \( N = 41010 \), \( f_{SAMPLING} = f_{DTS}/16 \), \( N = 5 \)
0011: \( f_{SAMPLING} = f_{CK \_INT} \), \( N = 81011 \), \( f_{SAMPLING} = f_{DTS}/16 \), \( N = 6 \)
0100: \( f_{SAMPLING} = f_{DTS}/2 \), \( N = 61100 \), \( f_{SAMPLING} = f_{DTS}/16 \), \( N = 8 \)
0101: \( f_{SAMPLING} = f_{DTS}/2 \), \( N = 81101 \), \( f_{SAMPLING} = f_{DTS}/32 \), \( N = 5 \)
0110: \( f_{SAMPLING} = f_{DTS}/4 \), \( N = 61110 \), \( f_{SAMPLING} = f_{DTS}/32 \), \( N = 6 \)
0111: \( f_{SAMPLING} = f_{DTS}/4 \), \( N = 81111 \), \( f_{SAMPLING} = f_{DTS}/32 \), \( N = 8 \)
Bits 3:2 **IC1PSC[1:0]**: Input capture 1 prescaler
This bit-field defines the ratio of the prescaler acting on CC1 input (IC1).
The prescaler is reset as soon as CC1E='0' (TIMx_CCER register).
00: no prescaler, capture is done each time an edge is detected on the capture input
01: capture is done once every 2 events
10: capture is done once every 4 events
11: capture is done once every 8 events

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection
This bit-field defines the direction of the channel (input/output) as well as the used input.
00: CC1 channel is configured as output
01: CC1 channel is configured as input, IC1 is mapped on TI1
10: Reserved
11: Reserved

Note: **CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx_CCER).**

### 39.5.6 TIMx capture/compare mode register 1 [alternate]
(TIMx_CCMR1)(x = 13 to 14)

Address offset: 0x18

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode.

**Output compare mode:**

</tbody>
</table>
Bits 31:17 Reserved, must be kept at reset value.

Bits 15:7 Reserved, must be kept at reset value.

Bits 16, 6:4 **OC1M[3:0]**: Output compare 1 mode (refer to bit 16 for OC1M[3])

These bits define the behavior of the output reference signal OC1REF from which OC1 is derived. OC1REF is active high whereas OC1 active level depends on CC1P bit.

- **0000**: Frozen. The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs.
- **0001**: Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).
- **0010**: Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).
- **0011**: Toggle - OC1REF toggles when TIMx_CNT = TIMx_CCR1.
- **0100**: Force inactive level - OC1REF is forced low.
- **0101**: Force active level - OC1REF is forced high.
- **0110**: PWM mode 1 - Channel 1 is active as long as TIMx_CNT < TIMx_CCR1 else inactive.
- **0111**: PWM mode 2 - Channel 1 is inactive as long as TIMx_CNT < TIMx_CCR1 else active

Others: Reserved

**Note**: In PWM mode 1 or 2, the OCREF level changes when the result of the comparison changes or when the output compare mode switches from frozen to PWM mode.

Bit 3 **OC1PE**: Output compare 1 preload enable

- **0**: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken in account immediately.
- **1**: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded in the active register at each update event.

**Note**: The PWM mode can be used without validating the preload register only in one pulse mode (OPM bit set in TIMx_CR1 register). Else the behavior is not guaranteed.

Bit 2 **OC1FE**: Output compare 1 fast enable

This bit is used to accelerate the effect of an event on the trigger in input on the CC output.

- **0**: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.
- **1**: An active edge on the trigger input acts like a compare match on CC1 output. OC is then set to the compare level independently of the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OC1FE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

- **00**: CC1 channel is configured as output.
- **01**: CC1 channel is configured as input, IC1 is mapped on TI1.
- **10**: CC1 channel is configured as input, IC1 is mapped on TI2.
- **11**: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register).

**Note**: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx_CCER).
39.5.7 TIMx capture/compare enable register (TIMx_CCER)(x = 13 to 14)

Address offset: 0x20
Reset value: 0x0000

<table>

Bits 15:4 Reserved, must be kept at reset value.

Bit 3 CC1NP: Capture/Compare 1 complementary output Polarity.
- CC1 channel configured as output: CC1NP must be kept cleared.
- CC1 channel configured as input: CC1NP bit is used in conjunction with CC1P to define T1FP1 polarity (refer to CC1P description).

Bit 2 Reserved, must be kept at reset value.

Bit 1 CC1P: Capture/Compare 1 output Polarity.
- **CC1 channel configured as output:**
  - 0: OC1 active high
  - 1: OC1 active low
- **CC1 channel configured as input:**
  - The CC1P and CC1NP bits select T1FP1 polarity for capture operations.
  - 00: noninverted/rising edge
  - 01: inverted/falling edge
  - 10: reserved, do not use this configuration
  - 11: noninverted/both edges
  - Circuit is sensitive to both T1FP1 rising and falling edges (capture mode), T1FP1 is not inverted.

Bit 0 CC1E: Capture/Compare 1 output enable.
- **CC1 channel configured as output:**
  - 0: Off - OC1 is not active
  - 1: On - OC1 signal is output on the corresponding output pin
- **CC1 channel configured as input:**
  - This bit determines if a capture of the counter value can actually be done into the input capture/compare register 1 (TIMx_CCR1) or not.
  - 0: Capture disabled
  - 1: Capture enabled

<table>

<td></td>
</tr>
</tbody>
</table>

Bits 15:0 **PSC[15:0]**: Prescaler value
The counter clock frequency CK_CNT is equal to fCK_PSC / (PSC[15:0] + 1).
PSC contains the value to be loaded in the active prescaler register at each update event.
(including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in “reset mode”).

39.5.10 TIMx auto-reload register (TIMx_ARR)(x = 13 to 14)
Address offset: 0x2C
Reset value: 0xFFFF

<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 15:0 **ARR[15:0]**: Auto-reload value
ARR is the value to be loaded in the actual auto-reload register.
Refer to Section 39.3.1: Time-base unit on page 1713 for more details about ARR update and behavior.
The counter is blocked while the auto-reload value is null.
### 39.5.11 TIMx capture/compare register 1 (TIMx_CCR1) (x = 13 to 14)

Address offset: 0x34
Reset value: 0x0000

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>15</td>
<td>CCR1[15:0]</td>
<td>Capture/Compare 1 value</td>
</tr>
</tbody>
</table>

**If channel CC1 is configured as output:**
- CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).
- It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.
- The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on OC1 output.

**If channel CC1 is configured as input:**
- CCR1 is the counter value transferred by the last input capture 1 event (IC1).

### 39.5.12 TIM13 timer input selection register (TIM13_TISEL)

Address offset: 0x68

| 0x68   | TIM14_TISEL   |                |                |                |                |                |                |                |                |                |                |                |                |                |                |                |                |                |                |                |                |                |                |                |                |                |                |                |                |                | TISEL[3:0]      |
|        | Reset value   | 0              | 0              | 0              | 0              |                |                |                |                |                |                |                |                |                |                |                |                |                |                |                |                |                |                |                |                |                |                |                |                |                |

Refer to Section 2.3 on page 126 for the register boundary addresses.
40 General-purpose timers (TIM15/TIM16/TIM17)

40.1 TIM15/TIM16/TIM17 introduction

The TIM15/TIM16/TIM17 timers consist of a 16-bit auto-reload counter driven by a programmable prescaler.

They may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM, complementary PWM with dead-time insertion).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The TIM15/TIM16/TIM17 timers are completely independent, and do not share any resources. TIM15 can be synchronized as described in Section 40.4.21: Timer synchronization (TIM15).

40.2 TIM15 main features

TIM15 includes the following features:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535
- Up to 2 independent channels for:
  - Input capture
  - Output compare
  - PWM generation (edge mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time (for channel 1 only)
- Synchronization circuit to control the timer with external signals and to interconnect several timers together
- Repetition counter to update the timer registers only after a given number of cycles of the counter
- Break input to put the timer’s output signals in the reset state or a known state
- Interrupt/DMA generation on the following events:
  - Update: counter overflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
  - Break input (interrupt request)
40.3 TIM16/TIM17 main features

The TIM16/TIM17 timers include the following features:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide (also "on the fly") the counter clock frequency by any factor between 1 and 65535
- One channel for:
  - Input capture
  - Output compare
  - PWM generation (edge-aligned mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time
- Repetition counter to update the timer registers only after a given number of cycles of the counter
- Break input to put the timer’s output signals in the reset state or a known state
- Interrupt/DMA generation on the following events:
  - Update: counter overflow
  - Input capture
  - Output compare
  - Break input
1. The internal break event source can be:
   - A clock failure event generated by CSS. For further information on the CSS, refer to Section 7.5.3: Clock Security System (CSS)
   - A PVD output
   - SRAM parity error signal
   - Cortex®-M7 with FPÚ LOCKUP (Hardfault) output
   - COMP output

Notes:
- Preload registers transferred to active registers on U event according to control bit
- Event
- Interrupt & DMA output

40.4 **TIM15/TIM16/TIM17 functional description**

40.4.1 **Time-base unit**

The main block of the programmable advanced-control timer is a 16-bit upcounter with its related auto-reload register. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:
- Counter register (TIMx_CNT)
- Prescaler register (TIMx_PSC)
- Auto-reload register (TIMx_ARR)
- Repetition counter register (TIMx_RCR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detailed for each configuration.

The counter is clocked by the prescaler output CK_CNT, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the counter starts counting 1 clock cycle after setting the CEN bit in the TIMx_CR1 register.

**Prescaler description**

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 481* and *Figure 482* give some examples of the counter behavior when the prescaler ratio is changed on the fly:
Figure 481. Counter timing diagram with prescaler division change from 1 to 2

Figure 482. Counter timing diagram with prescaler division change from 1 to 4
40.4.2 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

If the repetition counter is used, the update event (UEV) is generated after upcounting is repeated for the number of times programmed in the repetition counter register (TIMx_RCR). Else the update event is generated at each counter overflow.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register,
- The auto-reload shadow register is updated with the preload value (TIMx_ARR),
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

40.4.3 Repetition counter

Section 40.4.1: Time-base unit describes how the update event (UEV) is generated with respect to the counter overflows. It is actually generated only when the repetition counter has reached zero. This can be useful when generating PWM signals.

This means that data are transferred from the preload registers to the shadow registers (TIMx_ARR auto-reload register, TIMx_PSC prescaler register, but also TIMx_CCRx capture/compare registers in compare mode) every N counter overflows, where N is the value in the TIMx_RCR repetition counter register.

The repetition counter is decremented at each counter overflow.

The repetition counter is an auto-reload type; the repetition rate is maintained as defined by the TIMx_RCR register value (refer to Figure 489). When the update event is generated by software (by setting the UG bit in TIMx_EGR register) or by hardware through the slave mode controller, it occurs immediately whatever the value of the repetition counter is and the repetition counter is reloaded with the content of the TIMx_RCR register.
40.4.4 Clock selection

The counter clock can be provided by the following clock sources:

- Internal clock (CK_INT)
- External clock mode 1: external input pin
- Internal trigger inputs (ITRx) (only for TIM15): using one timer as the prescaler for another timer, for example, TIM1 can be configured to act as a prescaler for TIM15.

Refer to Using one timer as prescaler for another timer on page 1674 for more details.

Internal clock source (CK_INT)

If the slave mode controller is disabled (SMS=000), then the CEN (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed.
only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK_INT.

*Figure 490* shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

**Figure 490. Control circuit in normal mode, internal clock divided by 1**

![Control circuit diagram](image)

**External clock source mode 1**

This mode is selected when SMS=111 in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

*Figure 491. TI2 external clock connection example*

![External clock connection diagram](image)

For example, to configure the upcounter to count in response to a rising edge on the TI2 input, use the following procedure:
1. Select the proper TI2[x] source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Configure channel 2 to detect rising edges on the TI2 input by writing CC2S = ‘01’ in the TIMx_CCMR1 register.
3. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx_CCMR1 register (if no filter is needed, keep IC2F=0000).
4. Select rising edge polarity by writing CC2P=0 in the TIMx_CCMR register.
5. Configure the timer in external clock mode 1 by writing SMS=111 in the TIMx_SMCR register.
6. Select TI2 as the trigger input source by writing TS=00110 in the TIMx_SMCR register.
7. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

Note: The capture prescaler is not used for triggering, so it does not need to be configured.

When a rising edge occurs on TI2, the counter counts once and the TIF flag is set.

The delay between the rising edge on TI2 and the actual clock of the counter is due to the resynchronization circuit on TI2 input.

**Figure 492. Control circuit in external clock mode 1**

40.4.5 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), a input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

*Figure 493 to Figure 496* give an overview of one Capture/Compare channel.

The input stage samples the corresponding TIx input to generate a filtered signal TIxF. Then, an edge detector with polarity selection generates a signal (TIxFPx) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).
The output stage generates an intermediate waveform which is then used for reference: OCxRef (active high). The polarity acts at the end of the chain.
The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 40.4.6 Input capture mode

In Input capture mode, the Capture/Compare Registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCXIF flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was
already high, then the over-capture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to ‘0’ or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx_CCR1 when TI1 input rises. To do this, use the following procedure:

1. Select the proper TI1x source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input: TIMx_CCR1 must be linked to the TI1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx_CCR1 register becomes read-only.
3. Program the appropriate input filter duration in relation with the signal connected to the timer (when the input is one of the TIx (ICxF bits in the TIMx_CCMRx register). Let’s imagine that, when toggling, the input signal is not stable during at least 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on TI1 when 8 consecutive samples with the new level have been detected (sampled at fDTS frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.
4. Select the edge of the active transition on the TI1 channel by writing CC1P bit to 0 in the TIMx_CCER register (rising edge in this case).
5. Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to ‘00’ in the TIMx_CCMR1 register).
6. Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.
7. If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx_DIER register.

When an input capture occurs:

- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

**Note:** IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.

### 40.4.7 PWM input mode (only for TIM15)

This mode is a particular case of input capture mode. The procedure is the same except:

- Two ICx signals are mapped on the same TIx input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two TIxFP signals is selected as trigger input and the slave mode controller is configured in reset mode.
For example, one can measure the period (in TIMx_CCR1 register) and the duty cycle (in TIMx_CCR2 register) of the PWM applied on TI1 using the following procedure (depending on CK_INT frequency and prescaler value):

1. Select the proper TI1[x] source (internal or external) with the TI1SEL[3:0] bits in the TIMx_TISEL register.
2. Select the active input for TIMx_CCR1: write the CC1S bits to 01 in the TIMx_CCMR1 register (TI1 selected).
3. Select the active polarity for TI1FP1 (used both for capture in TIMx_CCR1 and counter clear): write the CC1P and CC1NP bits to ‘0’ (active on rising edge).
4. Select the active input for TIMx_CCR2: write the CC2S bits to 10 in the TIMx_CCMR1 register (TI1 selected).
5. Select the active polarity for TI1FP2 (used for capture in TIMx_CCR2): write the CC2P and CC2NP bits to ‘1’ (active on falling edge).
6. Select the valid trigger input: write the TS bits to 00101 in the TIMx_SMCR register (TI1FP1 selected).
7. Configure the slave mode controller in reset mode: write the SMS bits to 100 in the TIMx_SMCR register.
8. Enable the captures: write the CC1E and CC2E bits to ‘1’ in the TIMx_CCER register.

![Figure 497. PWM input mode timing](image)

1. The PWM input mode can be used only with the TIMx_CH1/TIMx_CH2 signals due to the fact that only TI1FP1 and TI2FP2 are connected to the slave mode controller.

### 40.4.8 Forced output mode

In output mode (CCxS bits = 00 in the TIMx_CCMRx register), each output compare signal (OCxREF and then OCx/OCxN) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (OCXREF/OCx) to its active level, one just needs to write 101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus OCXREF is forced high (OCxREF is always active high) and OCx get opposite value to CCxP polarity bit.

For example: CCxP=0 (OCx active high) => OCx is forced to high level.

The OCXREF signal can be forced low by writing the OCxM bits to 100 in the TIMx_CCMRx register.
Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the output compare mode section below.

### 40.4.9 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP bit in the TIMx_CCER register). The output pin can keep its level (OCxM=000), be set active (OCxM=001), be set inactive (OCxM=010) or can toggle (OCxM=011) on match.
- Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCXIE bit in the TIMx_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx_DIER register, CCDS bit in the TIMx_CR2 register for the DMA request selection).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on OCxREF and OCx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

#### Procedure

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
   - Write OCxM = 011 to toggle OCx output pin when CNT matches CCRx
   - Write OCxPE = 0 to disable preload register
   - Write CCxP = 0 to select active high polarity
   - Write CCxE = 1 to enable the output
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE='0', else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in Figure 498.
40.4.10 PWM mode

Pulse Width Modulation mode allows to generate a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per OCx output) by writing '110' (PWM mode 1) or '111' (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

OCx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. OCx output is enabled by a combination of the CCxE, CCxNE, MOE, OSSI and OSSR bits (TIMx_CCER and TIMx_BDTR registers). Refer to the TIMx_CCER register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CCRx ≤ TIMx_CNT or TIMx_CNT ≤ TIMx_CCRx (depending on the direction of the counter).

The TIM15/TIM16/TIM17 are capable of upcounting only. Refer to Upcounting mode on page 1768.

In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is high as long as TIMx_CNT < TIMx_CCRx else it becomes low. If the compare value in TIMx_CCRx is greater than the auto-reload value (in TIMx_ARR) then OCxREF is held at...
‘1’. If the compare value is 0 then OCxRef is held at ‘0’. Figure 499 shows some edge-aligned PWM waveforms in an example where TIMx_ARR=8.

**40.4.11 Combined PWM mode (TIM15 only)**

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIMx_ARR register, the duty cycle and delay are determined by the two TIMx_CCRx registers. The resulting signals, OCxREFC, are made of an OR or AND logical combination of two reference PWMs:

- OC1REFC (or OC2REFC) is controlled by the TIMx_CCR1 and TIMx_CCR2 registers

Combined PWM mode can be selected independently on two channels (one OCx output per pair of CCR registers) by writing ‘1100’ (Combined PWM mode 1) or ‘1101’ (Combined PWM mode 2) in the OCxM bits in the TIMx_CCMRx register.

When a given channel is used as a combined PWM channel, its complementary channel must be configured in the opposite PWM mode (for instance, one in Combined PWM mode 1 and the other in Combined PWM mode 2).

**Note:** The OCxM[3:0] bit field is split into two parts for compatibility reasons, the most significant bit is not contiguous with the 3 least significant ones.

Figure 500 represents an example of signals that can be generated using Asymmetric PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2,
- Channel 2 is configured in PWM mode 1,
40.4.12 Complementary outputs and dead-time insertion

The TIM15/TIM16/TIM17 general-purpose timers can output one complementary signal and manage the switching-off and switching-on of the outputs.

This time is generally known as dead-time and it has to be adjusted depending on the devices that are connected to the outputs and their characteristics (intrinsic delays of level-shifters, delays due to power switches...)

The polarity of the outputs (main output OCx or complementary OCxN) can be selected independently for each output. This is done by writing to the CCxP and CCxNP bits in the TIMx_CCER register.

The complementary signals OCx and OCxN are activated by a combination of several control bits: the CCxE and CCxNE bits in the TIMx_CCER register and the MOE, OISx, OISxN, OSSI and OSSR bits in the TIMx_BDTR and TIMx_CR2 registers. Refer to Table 339: Output control bits for complementary OCx and OCxN channels with break feature (TIM16/17) on page 1835 for more details. In particular, the dead-time is activated when switching to the idle state (MOE falling down to 0).

Dead-time insertion is enabled by setting both CCxE and CCxNE bits, and the MOE bit if the break circuit is present. There is one 10-bit dead-time generator for each channel. From a
reference waveform OCxREF, it generates 2 outputs OCx and OCxN. If OCx and OCxN are active high:

- The OCx output signal is the same as the reference signal except for the rising edge, which is delayed relative to the reference rising edge.
- The OCxN output signal is the opposite of the reference signal except for the rising edge, which is delayed relative to the reference falling edge.

If the delay is greater than the width of the active output (OCx or OCxN) then the corresponding pulse is not generated.

The following figures show the relationships between the output signals of the dead-time generator and the reference signal OCxREF. (we suppose CCxP=0, CCxNP=0, MOE=1, CCxE=1 and CCxNE=1 in these examples)

**Figure 501. Complementary output with dead-time insertion.**

![Figure 501](MS31095V1)

**Figure 502. Dead-time waveforms with delay greater than the negative pulse.**

![Figure 502](MS31096V1)
The dead-time delay is the same for each of the channels and is programmable with the DTG bits in the TIMx_BDTR register. Refer to Section 40.6.14: TIMx break and dead-time register (TIMx_BDTR)(x = 16 to 17) on page 1838 for delay calculation.

Re-directing OCxREF to OCx or OCxN

In output mode (forced, output compare or PWM), OCxREF can be re-directed to the OCx output or to OCxN output by configuring the CCxE and CCxNE bits in the TIMx_CCER register.

This allows to send a specific waveform (such as PWM or static active level) on one output while the complementary remains at its inactive level. Other alternative possibilities are to have both outputs at inactive level or both outputs active and complementary with dead-time.

Note: When only OCxN is enabled (CCxE=0, CCxNE=1), it is not complemented and becomes active as soon as OCxREF is high. For example, if CCxNP=0 then OCxN=OCxRef. On the other hand, when both OCx and OCxN are enabled (CCxE=CCxNE=1) OCx becomes active when OCxREF is high whereas OCxN is complemented and becomes active when OCxREF is low.

40.4.13 Using the break function

The purpose of the break function is to protect power switches driven by PWM signals generated with the TIM15/TIM16/TIM17 timers. The break input is usually connected to fault outputs of power stages and 3-phase inverters. When activated, the break circuitry shuts down the PWM outputs and forces them to a predefined safe state.

The break channel gathers both system-level fault (clock failure, parity error,...) and application fault (from input pins and built-in comparator), and can force the outputs to a predefined level (either active or inactive) after a deadtime duration.
The output enable signal and output levels during break are depending on several control bits:

- the MOE bit in TIMx_BDTR register allows to enable /disable the outputs by software and is reset in case of break or break2 event.
- the OSSI bit in the TIMx_BDTR register defines whether the timer controls the output in inactive state or releases the control to the GPIO controller (typically to have it in Hi-Z mode)
- the OISx and OISxN bits in the TIMx_CR2 register which are setting the output shutdown level, either active or inactive. The OCx and OCxN outputs cannot be set both to active level at a given time, whatever the OISx and OISxN values. Refer to Table 337: Output control bits for complementary OCx and OCxN channels with break feature (TIM15) on page 1814 for more details.

When exiting from reset, the break circuit is disabled and the MOE bit is low. The break function is enabled by setting the BKE bit in the TIMx_BDTR register. The break input polarity can be selected by configuring the BKP bit in the same register. BKE and BKP can be modified at the same time. When the BKE and BKP bits are written, a delay of 1 APB clock cycle is applied before the writing is effective. Consequently, it is necessary to wait 1 APB clock period to correctly read back the bit after the write operation.

Because MOE falling edge can be asynchronous, a resynchronization circuit has been inserted between the actual signal (acting on the outputs) and the synchronous control bit (accessed in the TIMx_BDTR register). It results in some delays between the asynchronous and the synchronous signals. In particular, if MOE is set to 1 whereas it was low, a delay must be inserted (dummy instruction) before reading it correctly. This is because the write acts on the asynchronous signal whereas the read reflects the synchronous signal.

A programmable filter (BKF[3:0] bits in the TIMx_BDTR register allows to filter out spurious events.

The break can be generated from multiple sources which can be individually enabled and with programmable edge sensitivity, using the TIMx_OR2 register.

The sources for break (BRK) channel are:

- An external source connected to one of the BGIN pin (as per selection done in the AFIO controller), with polarity selection and optional digital filtering
- An internal source:
  - the output from a comparator, with polarity selection and optional digital filtering
  - the analog watchdog output of the DFSDM1 peripheral
  - A system break:
    - the Cortex®-M7 with FPU LOCKUP output
    - the PVD output
    - the SRAM parity error signal
    - a Flash ECC error
    - a clock failure event generated by the CSS detector
Caution: An asynchronous (clockless) operation is only guaranteed when the programmable filter is disabled. If it is enabled, a fail safe clock mode (example, using the internal PLL and/or the CSS) must be used to guarantee that break events are handled.

When a break occurs (selected level on the break input):

- The MOE bit is cleared asynchronously, putting the outputs in inactive state, idle state or even releasing the control to the AFIO controller (selected by the OSSi bit). This feature functions even if the MCU oscillator is off.
- Each output channel is driven with the level programmed in the OISx bit in the TIMx_CR2 register as soon as MOE=0. If OSSI=0, the timer releases the output control (taken over by the AFIO controller) else the enable output remains high.
- When complementary outputs are used:
  - The outputs are first put in reset state inactive state (depending on the polarity). This is done asynchronously so that it works even if no clock is provided to the timer.
  - If the timer clock is still present, then the dead-time generator is reactivated in order to drive the outputs with the level programmed in the OISx and OISxN bits after a dead-time. Even in this case, OCx and OCxN cannot be driven to their
active level together. Note that because of the resynchronization on MOE, the dead-time duration is a bit longer than usual (around 2 ck_tim clock cycles).

- If OSS1=0 then the timer releases the enable outputs (taken over by the AFIO controller which forces a Hi-Z state) else the enable outputs remain or become high as soon as one of the CCxE or CCxNE bits is high.

- The break status flag (BIF bit in the TIMx_SR register) is set. An interrupt can be generated if the BIE bit in the TIMx_DIER register is set.

- If the AOE bit in the TIMx_BDTR register is set, the MOE bit is automatically set again at the next update event UEV. This can be used to perform a regulation, for instance. Else, MOE remains low until it is written with 1 again. In this case, it can be used for security and the break input can be connected to an alarm from power drivers, thermal sensors or any security components.

Note: The break inputs is acting on level. Thus, the MOE cannot be set while the break input is active (neither automatically nor by software). In the meantime, the status flag BIF cannot be cleared.

The break can be generated by the BRK input which has a programmable polarity and an enable bit BKE in the TIMx_BDTR Register.

In addition to the break input and the output management, a write protection has been implemented inside the break circuit to safeguard the application. It allows to freeze the configuration of several parameters (dead-time duration, OCx/OCxN polarities and state when disabled, OCxM configurations, break enable and polarity). The protection can be selected among 3 levels with the LOCK bits in the TIMx_BDTR register. Refer to Section 40.6.14: TIMx break and dead-time register (TIMx_BDTR)(x = 16 to 17) on page 1838. The LOCK bits can be written only once after an MCU reset.

The Figure 505 shows an example of behavior of the outputs in response to a break.

40.4.14 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- $\text{CNT} < \text{CCR}_x \leq \text{ARR}$ (in particular, $0 < \text{CCR}_x$)
For example one may want to generate a positive pulse on OC1 with a length of $t_{\text{PULSE}}$ and after a delay of $t_{\text{DELAY}}$ as soon as a positive edge is detected on the TI2 input pin.

Let’s use TI2FP2 as trigger 1:
1. Select the proper TI2[x] source (internal or external) with the TI2SEL[3:0] bits in the TIMx_TISEL register.
2. Map TI2FP2 to TI2 by writing CC2S=’01’ in the TIMx_CCMR1 register.
3. TI2FP2 must detect a rising edge, write CC2P=’0’ and CC2NP=’0’ in the TIMx_CCER register.
4. Configure TI2FP2 as trigger for the slave mode controller (TRGI) by writing TS=’00110’ in the TIMx_SMCR register.
5. TI2FP2 is used to start the counter by writing SMS to ‘110’ in the TIMx_SMCR register (trigger mode).

The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The $t_{\text{DELAY}}$ is defined by the value written in the TIMx_CCR1 register.
- The $t_{\text{PULSE}}$ is defined by the difference between the auto-reload value and the compare value (TIMx_ARR - TIMx_CCR1).
- Let’s say one want to build a waveform with a transition from ‘0’ to ‘1’ when a compare match occurs and a transition from ‘1’ to ‘0’ when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing OC1M=11 in the TIMx_CCMR1 register. Optionally the preload registers can be enabled by writing OC1PE=’1’ in the TIMx_CCMR1 register and ARPE in the TIMx_CR1 register. In this case one has to write the compare value in the TIMx_CCR1 register, the auto-reload value in the TIMx_ARR register, generate an update by setting the UG bit and wait for external trigger event on TI2. CC1P is written to ‘0’ in this example.

Since only 1 pulse is needed, a 1 must be written in the OPM bit in the TIMx_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0).
Particular case: OCx fast enable

In One-pulse mode, the edge detection on TIx input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay $t_{\text{DELAY}\ \text{min}}$ we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx_CCMRx register. Then OCxRef (and OCx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

40.4.15 Retriggerable one pulse mode (OPM) (TIM15 only)

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with Non-retriggerable one pulse mode described in Section 40.4.14:

- The pulse starts as soon as the trigger occurs (no programmable delay)
- The pulse is extended if a new trigger occurs before the previous one is completed

The timer must be in Slave mode, with the bits SMS[3:0] = ‘1000’ (Combined Reset + trigger mode) in the TIMx_SMCR register, and the OCxM[3:0] bits set to ‘1000’ or ‘1001’ for Retrigerrable OPM mode 1 or 2.

If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in Down-counting mode, CCRx must be above or equal to ARR.

Note: The OCxM[3:0] and SMS[3:0] bit fields are split into two parts for compatibility reasons, the most significant bit are not contiguous with the 3 least significant ones.

This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIMx_CR1.

40.4.16 UIF bit remapping

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the Update Interrupt Flag UIF into bit 31 of the timer counter register (TIMxCNT[31]). This allows to
atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. In particular cases, it can ease the calculations by avoiding race conditions caused for instance by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

There is no latency between the assertions of the UIF and UIFCPY flags.
40.4.17 Timer input XOR function (TIM15 only)

The TI1S bit in the TIMx_CR2 register, allows the input filter of channel 1 to be connected to the output of a XOR gate, combining the two input pins TIMx_CH1 and TIMx_CH2.

The XOR output can be used with all the timer input functions such as trigger or input capture. It is useful for measuring the interval between the edges on two input signals, as shown in Figure 508.

Figure 508. Measuring time interval between edges on 2 signals
40.4.18 External trigger synchronization (TIM15 only)

The TIM timers are linked together internally for timer synchronization or chaining.

The TIM15 timer can be synchronized with an external trigger in several modes: Reset mode, Gated mode and Trigger mode.

Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on TI1 input:

1. Configure the channel 1 to detect rising edges on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx_CCMR1 register. Write CC1P='0' and CC1NP='0' in the TIMx_CCER register to validate the polarity (and detect rising edges only).

2. Configure the timer in reset mode by writing SMS=100 in TIMx_SMCR register. Select TI1 as the input source by writing TS=00101 in TIMx_SMCR register.

3. Start the counter by writing CEN=1 in the TIMx_CR1 register.

The counter starts counting on the internal clock, then behaves normally until TI1 rising edge. When TI1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx_DIER register).

The following figure shows this behavior when the auto-reload register TIMx_ARR=0x36. The delay between the rising edge on TI1 and the actual reset of the counter is due to the resynchronization circuit on TI1 input.

![Figure 509. Control circuit in reset mode](image-url)
Slave mode: Gated mode

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when TI1 input is low:

1. Configure the channel 1 to detect low levels on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S=01 in TIMx_CCMR1 register. Write CC1P=1 and CC1NP = ‘0’ in the TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in gated mode by writing SMS=101 in TIMx_SMCR register. Select TI1 as the input source by writing TS=00101 in TIMx_SMCR register.

3. Enable the counter by writing CEN=1 in the TIMx_CR1 register (in gated mode, the counter doesn’t start if CEN=0, whatever is the trigger input level).

The counter starts counting on the internal clock as long as TI1 is low and stops as soon as TI1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on TI1 and the actual stop of the counter is due to the resynchronization circuit on TI1 input.

Figure 510. Control circuit in gated mode

![Control circuit in gated mode diagram](MS31402V1)
Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on TI2 input:

1. Configure the channel 2 to detect rising edges on TI2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC2S bits are configured to select the input capture source only, CC2S=01 in TIMx_CCMR1 register. Write CC2P=’1’ and CC2NP=’0’ in the TIMx_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in trigger mode by writing SMS=110 in the TIMx_SMCR register. Select TI2 as the input source by writing TS=00110 in the TIMx_SMCR register.

When a rising edge occurs on TI2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on TI2 and the actual start of the counter is due to the resynchronization circuit on TI2 input.

40.4.19 Slave mode – combined reset + trigger mode

In this case, a rising edge of the selected trigger input (TRGI) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for one-pulse mode.

40.4.20 DMA burst mode

The TIMx timers have the capability to generate multiple DMA requests on a single event. The main purpose is to be able to re-program several timer registers multiple times without software overhead, but it can also be used to read several registers in a row, at regular intervals.

The DMA controller destination is unique and must point to the virtual register TIMx_DMAR. On a given timer event, the timer launches a sequence of DMA requests (burst). Each write into the TIMx_DMAR register is actually redirected to one of the timer registers.
The DBL[4:0] bits in the TIMx_DCR register set the DMA burst length. The timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address, i.e. the number of transfers (either in half-words or in bytes).

The DBA[4:0] bits in the TIMx_DCR registers define the DMA base address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register.

Example:

00000: TIMx_CR1,
00001: TIMx_CR2,
00010: TIMx_SMCR,

For example, the timer DMA burst feature could be used to update the contents of the CCRx registers (x = 2, 3, 4) on an update event, with the DMA transferring half words into the CCRx registers.

This is done in the following steps:

1. Configure the corresponding DMA channel as follows:
   – DMA channel peripheral address is the DMAR register address
   – DMA channel memory address is the address of the buffer in the RAM containing the data to be transferred by DMA into the CCRx registers.
   – Number of data to transfer = 3 (See note below).
   – Circular mode disabled.
2. Configure the DCR register by configuring the DBA and DBL bit fields as follows:
   – DBL = 3 transfers, DBA = 0xE.
3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).
4. Enable TIMx
5. Enable the DMA channel

This example is for the case where every CCRx register is to be updated once. If every CCRx register is to be updated twice for example, the number of data to transfer should be 6. Let’s take the example of a buffer in the RAM containing data1, data2, data3, data4, data5 and data6. The data is transferred to the CCRx registers as follows: on the first update DMA request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is transferred to CCR3 and data6 is transferred to CCR4.

Note: A null value can be written to the reserved registers.
40.4.21 Timer synchronization (TIM15)

The TIMx timers are linked together internally for timer synchronization or chaining. Refer to Section 38.3.19: Timer synchronization for details.

Note: The clock of the slave peripherals (timer, ADC, ...) receiving the TRGO or the TRGO2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

40.4.22 Debug mode

When the microcontroller enters debug mode (Cortex®-M7 with FPU core halted), the TIMx counter either continues to work normally or stops, depending on TIMx bit in DBGMCU module. For more details, refer to Section 59: Debug infrastructure.

For safety purposes, when the counter is stopped (TIMx = 1 in DBGMCU_APB2FZ1), the outputs are disabled (as if the MOE bit was reset). The outputs can either be forced to an inactive state (OSSI bit = 1), or have their control taken over by the GPIO controller (OSSI bit = 0) to force them to Hi-Z.
## 40.5 TIM15 registers

Refer to Section 1.2 for a list of abbreviations used in register descriptions.

### 40.5.1 TIM15 control register 1 (TIM15_CR1)

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **UIFREMAP**: UIF status bit remapping
   0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.
   1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division
   This bitfield indicates the division ratio between the timer clock (CK_INT) frequency and the
dead-time and sampling clock (tDTS) used by the dead-time generators and the digital filters
(TIx)
   00: tDTS = tCK_INT
   01: tDTS = 2*tCK_INT
   10: tDTS = 4*tCK_INT
   11: Reserved, do not program this value

Bit 7 **ARPE**: Auto-reload preload enable
   0: TIMx_ARR register is not buffered
   1: TIMx_ARR register is buffered

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM**: One-pulse mode
   0: Counter is not stopped at update event
   1: Counter stops counting at the next update event (clearing the bit CEN)
Bit 2 **URS**: Update request source  
This bit is set and cleared by software to select the UEV event sources.

- 0: Any of the following events generate an update interrupt if enabled. These events can be:
  - Counter overflow/underflow
  - Setting the UG bit
  - Update generation through the slave mode controller
- 1: Only counter overflow/underflow generates an update interrupt if enabled

Bit 1 **UDIS**: Update disable  
This bit is set and cleared by software to enable/disable UEV event generation.

- 0: UEV enabled. The Update (UEV) event is generated by one of the following events:
  - Counter overflow/underflow
  - Setting the UG bit
  - Update generation through the slave mode controller

Bit 0 **CEN**: Counter enable  
0: Counter disabled
1: Counter enabled

*Note: External clock and gated mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.*

### 40.5.2 TIM15 control register 2 (TIM15_CR2)

**Address offset: 0x04**

**Reset value: 0x0000**

</tr>
</tbody>
</table>
Bit 7 **TI1S**: TI1 selection

0: The TIMx_CH1 pin is connected to TI1 input
1: The TIMx_CH1, CH2 pins are connected to the TI1 input (XOR combination)

Bits 6:4 **MMS[2:0]**: Master mode selection

These bits allow to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows:

000: **Reset** - the UG bit from the TIMx_EGR register is used as trigger output (TRGO). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on TRGO is delayed compared to the actual reset.

001: **Enable** - the Counter Enable signal CNT_EN is used as trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic OR between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO, except if the master/slave mode is selected (see the MSM bit description in TIMx_SMCR register).

010: **Update** - The update event is selected as trigger output (TRGO). For instance a master timer can then be used as a prescaler for a slave timer.

011: **Compare Pulse** - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred (TRGO).

100: **Compare** - OC1REF signal is used as trigger output (TRGO).

101: **Compare** - OC2REF signal is used as trigger output (TRGO).

Bit 3 **CCDS**: Capture/compare DMA selection

0: CCx DMA request sent when CCx event occurs
1: CCx DMA request sent when update event occurs

Bit 2 **CCUS**: Capture/compare control update selection

0: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit only.
1: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit or when an rising edge occurs on TRGI.

*Note: This bit acts only on channels that have a complementary output.*

Bit 1 Reserved, must be kept at reset value.

Bit 0 **CCPC**: Capture/compare preloaded control

0: CCxE, CCxNE and OCxM bits are not preloaded
1: CCxE, CCxNE and OCxM bits are preloaded, after having been written, they are updated only when a commutation event (COM) occurs (COMG bit set or rising edge detected on TRGI, depending on the CCUS bit).

*Note: This bit acts only on channels that have a complementary output.*
### 40.5.3 TIM15 slave mode control register (TIM15_SMCR)

Address offset: 0x08  
Reset value: 0x0000 0000

</tbody>
</table>

Bits 31:22 Reserved, must be kept at reset value.  
Bits 19:17 Reserved, must be kept at reset value.  
Bits 15:8 Reserved, must be kept at reset value.  
Bit 7 **MSM**: Master/slave mode  
0: No action  
1: The effect of an event on the trigger input (TRGI) is delayed to allow a perfect synchronization between the current timer and its slaves (through TRGO). It is useful if we want to synchronize several timers on a single external event.  

Bits 21, 20, 6, 5, 4 **TS[4:0]**: Trigger selection  
This bit field selects the trigger input to be used to synchronize the counter.  
00000: Internal Trigger 0 (ITR0)  
00001: Internal Trigger 1 (ITR1)  
00010: Internal Trigger 2 (ITR2)  
00011: Internal Trigger 3 (ITR3)  
00100: TI1 Edge Detector (TI1F_ED)  
00101: Filtered Timer Input 1 (TI1FP1)  
00110: Filtered Timer Input 2 (TI2FP2)  
Other: Reserved  
See Table 336: TIMx Internal trigger connection on page 1804 for more details on ITRx meaning for each Timer.  
*Note: These bits must be changed only when they are not used (e.g. when SMS=000) to avoid wrong edge detections at the transition.*

Bit 3 Reserved, must be kept at reset value.
Bits 16, 2, 1, 0  **SMS[3:0]:** Slave mode selection

When external signals are selected the active edge of the trigger signal (TRGI) is linked to the polarity selected on the external input (see Input Control register and Control Register description.

0000: Slave mode disabled - if CEN = '1' then the prescaler is clocked directly by the internal clock.
0001: Reserved
0010: Reserved
0011: Reserved
0100: Reset Mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter and generates an update of the registers.
0101: Gated Mode - The counter clock is enabled when the trigger input (TRGI) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.
0110: Trigger Mode - The counter starts at a rising edge of the trigger TRGI (but it is not reset). Only the start of the counter is controlled.
0111: External Clock Mode 1 - Rising edges of the selected trigger (TRGI) clock the counter.
1000: Combined reset + trigger mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter, generates an update of the registers and starts the counter.
Other codes: reserved.

**Note:** The gated mode must not be used if **Ti1F_ED is selected as the trigger input (TS=00100).** Indeed, **Ti1F_ED outputs 1 pulse for each transition on Ti1F,** whereas the gated mode checks the level of the trigger signal.

**Note:** The clock of the slave peripherals (timer, ADC, ...) receiving the TRGO or the TRGO2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

<td></td>
<td></td>
</tr>
</tbody>
</table>
 Bits 15:11 Reserved, must be kept at reset value.

 Bit 10 **CC2OF**: Capture/Compare 2 overcapture flag
 Refer to CC1OF description

 Bit 9 **CC1OF**: Capture/Compare 1 overcapture flag
 This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to '0'.
 0: No overcapture has been detected
 1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set

 Bit 8 Reserved, must be kept at reset value.

 Bit 7 **BIF**: Break interrupt flag
 This flag is set by hardware as soon as the break input goes active. It can be cleared by software if the break input is not active.
 0: No break event occurred
 1: An active level has been detected on the break input

 Bit 6 **TIF**: Trigger interrupt flag
 This flag is set by hardware on trigger event (active edge detected on TRGI input when the slave mode controller is enabled in all modes but gated mode, both edges in case gated mode is selected). It is set when the counter starts or stops when gated mode is selected. It is cleared by software.
 0: No trigger event occurred
 1: Trigger interrupt pending

 Bit 5 **COMIF**: COM interrupt flag
 This flag is set by hardware on a COM event (once the capture/compare control bits –CCxE, CCxNE, OCxM– have been updated). It is cleared by software.
 0: No COM event occurred
 1: COM interrupt pending

 Bits 4:3 Reserved, must be kept at reset value.
Bit 2 **CC2IF**: Capture/Compare 2 interrupt flag

refer to **CC1IF** description

Bit 1 **CC1IF**: Capture/Compare 1 interrupt flag

*If channel CC1 is configured as output*: This flag is set by hardware when the counter matches the compare value. It is cleared by software.

0: No match.
1: The content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the contents of TIMx_CCR1 are greater than the contents of TIMx_ARR, the CC1IF bit goes high on the counter overflow.

*If channel CC1 is configured as input*: This bit is set by hardware on a capture. It is cleared by software or by reading the TIMx_CCR1 register.

0: No input capture occurred
1: The counter value has been captured in TIMx_CCR1 register (An edge has been detected on IC1 which matches the selected polarity)

Bit 0 **UIF**: Update interrupt flag

This bit is set by hardware on an update event. It is cleared by software.

0: No update occurred.
1: Update interrupt pending. This bit is set by hardware when the registers are updated:

– At overflow regarding the repetition counter value (update if repetition counter = 0) and if the UDIS=0 in the TIMx_CR1 register.
– When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if URS=0 and UDIS=0 in the TIMx_CR1 register.
– When CNT is reinitialized by a trigger event (refer to Section 40.5.3: TIM15 slave mode control register (TIM15_SMCR)), if URS=0 and UDIS=0 in the TIMx_CR1 register.

### 40.5.6 TIM15 event generation register (TIM15_EGR)

Address offset: 0x14

Reset value: 0x0000

<table>

</tbody>
</table>

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **BG**: Break generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action
1: A break event is generated. MOE bit is cleared and BIF flag is set. Related interrupt or DMA transfer can occur if enabled.

Bit 6 **TG**: Trigger generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action
1: The TIF flag is set in TIMx_SR register. Related interrupt or DMA transfer can occur if enabled
Bit 5 COMG: Capture/Compare control update generation
This bit can be set by software, it is automatically cleared by hardware.
0: No action
1: When the CCPC bit is set, it is possible to update the CCxE, CCxNE and OCxM bits

Note: This bit acts only on channels that have a complementary output.

Bits 4:3 Reserved, must be kept at reset value.

Bit 2 CC2G: Capture/Compare 2 generation
Refer to CC1G description

Bit 1 CC1G: Capture/Compare 1 generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: A capture/compare event is generated on channel 1:
If channel CC1 is configured as output:
CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled.
If channel CC1 is configured as input:
The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 UG: Update generation
This bit can be set by software, it is automatically cleared by hardware.
0: No action.
1: Reinitialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected).

40.5.7 TIM15 capture/compare mode register 1 [alternate]
(TIM15_CCMR1)
Address offset: 0x18
Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode.

**Input capture mode:**

</tbody>
</table>

Bits 31:25  Reserved, must be kept at reset value.

Bits 23:17  Reserved, must be kept at reset value.

Bit 15  Reserved, must be kept at reset value.

Bits 24, 14:12  **OC2M[3:0]**: Output Compare 2 mode

- Bit 11  **OC2PE**: Output Compare 2 preload enable
- Bit 10  **OC2FE**: Output Compare 2 fast enable

Bits 9:8  **CC2S[1:0]**: Capture/Compare 2 selection

- This bit-field defines the direction of the channel (input/output) as well as the used input.
  - 00: CC2 channel is configured as output.
  - 01: CC2 channel is configured as input, IC2 is mapped on TI2.
  - 10: CC2 channel is configured as input, IC2 is mapped on TI1.
  - 11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through the TS bit (TIMx_SMCR register)

  **Note**: CC2S bits are writable only when the channel is OFF (CC2E = ‘0’ in TIMx_CCER).

- Bit 7  Reserved, must be kept at reset value.
Bits 16, 6:4 **OC1M[3:0]: Output Compare 1 mode**

These bits define the behavior of the output reference signal OC1REF from which OC1 and OC1N are derived. OC1REF is active high whereas OC1 and OC1N active level depends on CC1P and CC1NP bits.

- **0000**: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs.
- **0001**: Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).
- **0010**: Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).
- **0011**: Toggle - OC1REF toggles when TIMx_CNT=TIMx_CCR1.
- **0100**: Force inactive level - OC1REF is forced low.
- **0101**: Force active level - OC1REF is forced high.
- **0110**: PWM mode 1 - Channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else inactive.
- **0111**: PWM mode 2 - Channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else active.
- **1000**: Retrigerrable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.
- **1001**: Retrigerrable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.
- **1010**: Reserved
- **1011**: Reserved
- **1100**: Combined PWM mode 1 - OC1REF has the same behavior as in PWM mode 1. OC1REFC is the logical OR between OC1REF and OC2REF.
- **1101**: Combined PWM mode 2 - OC1REF has the same behavior as in PWM mode 2. OC1REFC is the logical AND between OC1REF and OC2REF.
- **1110**: Reserved
- **1111**: Reserved

**Note:**
1. These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S=’00’ (the channel is configured in output).
2. In PWM mode, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.
3. On channels that have a complementary output, this bit field is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the OC1M active bits take the new value from the preloaded bits only when a COM event is generated.
40.5.9 TIM15 capture/compare enable register (TIM15_CCER)

Address offset: 0x20

Reset value: 0x0000

<table>
<thead>
<tr>
<th>Bit 15:8</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit 7</td>
<td>CC2NP: Capture/Compare 2 complementary output polarity</td>
</tr>
<tr>
<td>Refer to CC1NP description</td>
<td></td>
</tr>
<tr>
<td>Bit 6</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
<tr>
<td>Bit 5</td>
<td>CC2P: Capture/Compare 2 output polarity</td>
</tr>
<tr>
<td>Refer to CC1P description</td>
<td></td>
</tr>
<tr>
<td>Bit 4</td>
<td>CC2E: Capture/Compare 2 output enable</td>
</tr>
<tr>
<td>Refer to CC1E description</td>
<td></td>
</tr>
</tbody>
</table>
Bit 3  **CC1NP**: Capture/Compare 1 complementary output polarity

CC1 channel configured as output:
0: OC1N active high
1: OC1N active low

CC1 channel configured as input:
This bit is used in conjunction with CC1P to define the polarity of TI1FP1 and TI2FP1. Refer to CC1P description.

**Note:**
1. This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S="00" (the channel is configured in output).
2. On channels that have a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1NP active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bit 2  **CC1NE**: Capture/Compare 1 complementary output enable

0: Off - OC1N is not active. OC1N level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.
1: On - OC1N signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.

Bit 1  **CC1P**: Capture/Compare 1 output polarity

CC1 channel configured as output:
0: OC1 active high
1: OC1 active low

**CC1 channel configured as input:** The CC1NP/CC1P bits select the polarity of TI1FP1 and TI2FP1 for trigger or capture operations.
00: non-inverted/rising edge. The circuit is sensitive to TIxFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode).
01: inverted/falling edge. The circuit is sensitive to TIxFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is inverted (trigger operation in gated mode).
10: reserved, do not use this configuration.
11: non-inverted/both edges. The circuit is sensitive to both TIxFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode).

**Note:**
1. This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).
2. On channels that have a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1P active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bit 0  **CC1E**: Capture/Compare 1 output enable

**CC1 channel configured as output:**
0: Off - OC1 is not active. OC1 level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and CC1NE bits.
1: On - OC1 signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and CC1NE bits.

**CC1 channel configured as input:** This bit determines if a capture of the counter value can actually be done into the input capture/compare register 1 (TIMx_CCR1) or not.
0: Capture disabled
1: Capture enabled
### Table 337. Output control bits for complementary OCx and OCxN channels with break feature (TIM15)

<td></td>
</tr>
<tr>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

Bits 15:0 **PSC[15:0]**: Prescaler value
The counter clock frequency (CK_CNT) is equal to \( f_{\text{CK,PSC}} / (PSC[15:0] + 1) \).

PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in "reset mode").

40.5.12 TIM15 auto-reload register (TIM15_ARR)

Address offset: 0x2C
Reset value: 0xFFFF

<table>
<thead>
<tr>
<th>Bit 15</th>
<th>ARR15:0: Auto-reload value</th>

Bits 15:0 **CCR2[15:0]**: Capture/Compare 2 value

If channel CC2 is configured as output:
- CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value).
- It is loaded permanently if the preload feature is not selected in the TIMx_CCMR2 register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.
- The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signalled on OC2 output.

If channel CC2 is configured as input:
- CCR2 is the counter value transferred by the last input capture 2 event (IC2).

40.5.16 TIM15 break and dead-time register (TIM15_BDTR)

</tbody>
</table>

Note: As the BKF[3:0], AOE, BKP, BKE, OSSR, OSSI and DTG[7:0] bits may be write-locked depending on the LOCK configuration, it may be necessary to configure all of them during the first write access to the TIMx_BDTR register.
Bits 31:20  Reserved, must be kept at reset value.

Bits 19:16  **BKF[3:0]: Break filter**

This bit-field defines the frequency used to sample the BRK input signal and the length of the digital filter applied to BRK. The digital filter is made of an event counter in which N events are needed to validate a transition on the output:

- 0000: No filter, BRK acts asynchronously
- 0001: \( f_{\text{SAMPLING}} = f_{\text{CK_INT}} \), \( N=2 \)
- 0010: \( f_{\text{SAMPLING}} = f_{\text{CK_INT}} \), \( N=4 \)
- 0011: \( f_{\text{SAMPLING}} = f_{\text{CK_INT}} \), \( N=8 \)
- 0100: \( f_{\text{SAMPLING}} = f_{\text{DTS}} / 2 \), \( N=6 \)
- 0101: \( f_{\text{SAMPLING}} = f_{\text{DTS}} / 2 \), \( N=8 \)
- 0110: \( f_{\text{SAMPLING}} = f_{\text{DTS}} / 4 \), \( N=6 \)
- 0111: \( f_{\text{SAMPLING}} = f_{\text{DTS}} / 4 \), \( N=8 \)
- 1000: \( f_{\text{SAMPLING}} = f_{\text{DTS}} / 8 \), \( N=6 \)
- 1001: \( f_{\text{SAMPLING}} = f_{\text{DTS}} / 8 \), \( N=8 \)
- 1010: \( f_{\text{SAMPLING}} = f_{\text{DTS}} / 16 \), \( N=5 \)
- 1011: \( f_{\text{SAMPLING}} = f_{\text{DTS}} / 16 \), \( N=6 \)
- 1100: \( f_{\text{SAMPLING}} = f_{\text{DTS}} / 16 \), \( N=5 \)
- 1101: \( f_{\text{SAMPLING}} = f_{\text{DTS}} / 32 \), \( N=5 \)
- 1110: \( f_{\text{SAMPLING}} = f_{\text{DTS}} / 32 \), \( N=6 \)
- 1111: \( f_{\text{SAMPLING}} = f_{\text{DTS}} / 32 \), \( N=8 \)

**Note:** This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 15  **MOE:** Main output enable

This bit is cleared asynchronously by hardware as soon as the break input is active. It is set by software or automatically depending on the AOE bit. It is acting only on the channels which are configured in output.

- 0: OC and OCN outputs are disabled or forced to idle state depending on the OSSI bit.
- 1: OC and OCN outputs are enabled if their respective enable bits are set (CCxE, CCxNE in TIMx_CCER register)

See OC/OCN enable description for more details (*Section 40.5.9: TIM15 capture/compare enable register (TIM15_CCER) on page 1812*).

Bit 14  **AOE:** Automatic output enable

- 0: MOE can be set only by software
- 1: MOE can be set by software or automatically at the next update event (if the break input is not be active)

**Note:** This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 13  **BKP:** Break polarity

- 0: Break input BRK is active low
- 1: Break input BRK is active high

**Note:** 1: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

2: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 12  **BKE:** Break enable

- 0: Break inputs (BRK and CCS clock failure event) disabled
- 1: Break inputs (BRK and CCS clock failure event) enabled

This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

**Note:** Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.
Bit 11 **OSSR**: Off-state selection for Run mode

This bit is used when MOE=1 on channels that have a complementary output which are configured as outputs. OSSR is not implemented if no complementary output is implemented in the timer.

See OC/OCN enable description for more details (Section 40.5.9: TIM15 capture/compare enable register (TIM15_CCER) on page 1812).

0: When inactive, OC/OCN outputs are disabled (the timer releases the output control which is taken over by the AFIO logic, which forces a Hi-Z state)
1: When inactive, OC/OCN outputs are enabled with their inactive level as soon as CCxE=1 or CCxNE=1 (the output is still controlled by the timer).

*Note: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 10 **OSSI**: Off-state selection for Idle mode

This bit is used when MOE=0 on channels configured as outputs.

See OC/OCN enable description for more details (Section 40.5.9: TIM15 capture/compare enable register (TIM15_CCER) on page 1812).

0: When inactive, OC/OCN outputs are disabled (OC/OCN enable output signal=0)
1: When inactive, OC/OCN outputs are forced first with their idle level as soon as CCxE=1 or CCxNE=1. OC/OCN enable output signal=1)

*Note: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).*

Bits 9:8 **LOCK[1:0]**: Lock configuration

These bits offer a write protection against software errors.

00: LOCK OFF - No bit is write protected
01: LOCK Level 1 = DTG bits in TIMx_BDTR register, OISx and OISxN bits in TIMx_CR2 register and BKE/BKP/AOE bits in TIMx_BDTR register can no longer be written
10: LOCK Level 2 = LOCK Level 1 + CC Polarity bits (CCxP/CCxNP bits in TIMx_CCER register, as long as the related channel is configured in output through the CCxS bits) as well as OSSR and OSSI bits can no longer be written.
11: LOCK Level 3 = LOCK Level 2 + CC Control bits (OCxM and OCxPE bits in TIMx_CCMRx registers, as long as the related channel is configured in output through the CCxS bits) can no longer be written.

*Note: The LOCK bits can be written only once after the reset. Once the TIMx_BDTR register has been written, their content is frozen until the next reset.*

Bits 7:0 **DTG[7:0]**: Dead-time generator setup

This bit-field defines the duration of the dead-time inserted between the complementary outputs. DT correspond to this duration.

DTG[7:5]=0xx => DT=DTG[7:0]x t_dts with t_dts=tDTS
DTG[7:5]=10x => DT=(64+DTG[5:0])x t_dts with t_dts=2xTTS
DTG[7:5]=110 => DT=(32+DTG[4:0])x t_dts with t_dts=8xTTS
DTG[7:5]=111 => DT=(32+DTG[4:0])x t_dts with t_dts=16xTTS

Example if T_DTS=125ns (8MHz), dead-time possible values are:
0 to 15875 ns by 125 ns steps,
16 µs to 31750 ns by 250 ns steps,
32 µs to 63 µs by 1 µs steps,
64 µs to 126 µs by 2 µs steps

*Note: This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).*
40.5.17 TIM15 DMA control register (TIM15_DCR)

Address offset: 0x48
Reset value: 0x0000

| Bits 15:13 Reserved, must be kept at reset value. |
| Bits 12:8 **DBL[4:0]**: DMA burst length |
| This 5-bit field defines the length of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address). |
| 00000: 1 transfer, |
| 00001: 2 transfers, |
| 00010: 3 transfers, |
| ... |
| 10001: 18 transfers. |
| Bits 7:5 Reserved, must be kept at reset value. |
| Bits 4:0 **DBA[4:0]**: DMA base address |
| This 5-bit field defines the base-address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register. |
| Example: |
| 00000: TIMx_CR1, |
| 00001: TIMx_CR2, |
| 00010: TIMx_SMCR, |
| ... |

40.5.18 TIM15 DMA address for full transfer (TIM15_DMAR)

Address offset: 0x4C
Reset value: 0x0000

| Bits 15:0 **DMAB[15:0]**: DMA register for burst accesses |
| A read or write operation to the DMAR register accesses the register located at the address (TIMx_CR1 address) + (DBA + DMA index) x 4 |
| where TIMx_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIMx_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIMx_DCR). |
### 40.5.19 TIM15 alternate register 1 (TIM15_AF1)

Address offset: 0x60  
Reset value: 0x0000 0001

<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **UIFREMAP**: UIF status bit remapping
0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.
1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division
This bit-field indicates the division ratio between the timer clock (CK_INT) frequency and the
dead-time and sampling clock (tDTS) used by the dead-time generators and the digital filters
(TIx),
- 00: tDTS=CK_INT
- 01: tDTS=2×CK_INT
- 10: tDTS=4×CK_INT
- 11: Reserved, do not program this value

Bit 7 **ARPE**: Auto-reload preload enable
0: TIMx_ARR register is not buffered
1: TIMx_ARR register is buffered

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM**: One pulse mode
0: Counter is not stopped at update event
1: Counter stops counting at the next update event (clearing the bit CEN)

Bit 2 **URS**: Update request source
This bit is set and cleared by software to select the UEV event sources.
0: Any of the following events generate an update interrupt or DMA request if enabled.
These events can be:
- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller
1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.
Bit 1 **UDIS**: Update disable
This bit is set and cleared by software to enable/disable UEV event generation.
0: UEV enabled. The Update (UEV) event is generated by one of the following events:
– Counter overflow/underflow
– Setting the UG bit
– Update generation through the slave mode controller
Buffered registers are then loaded with their preload values.
1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable
0: Counter disabled
1: Counter enabled

**Note**: External clock and gated mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.

### 40.6.2 TIMx control register 2 (TIMx_CR2)(x = 16 to 17)

Address offset: 0x04
Reset value: 0x0000

</table>

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **OIS1N**: Output Idle state 1 (OC1N output)
0: OC1N=0 after a dead-time when MOE=0
1: OC1N=1 after a dead-time when MOE=0

**Note**: This bit cannot be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BKR register).

Bit 8 **OIS1**: Output Idle state 1 (OC1 output)
0: OC1=0 (after a dead-time if OC1N is implemented) when MOE=0
1: OC1=1 (after a dead-time if OC1N is implemented) when MOE=0

**Note**: This bit cannot be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BKR register).

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **CCDS**: Capture/compare DMA selection
0: CCx DMA request sent when CCx event occurs
1: CCx DMA requests sent when update event occurs

Bit 2 **CCUS**: Capture/compare control update selection
0: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit only.
1: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit or when an rising edge occurs on TRGI.

**Note**: This bit acts only on channels that have a complementary output.

Bit 1 Reserved, must be kept at reset value.
Bit 0 **CCPC**: Capture/compare preloaded control
- 0: CCxE, CCxNE and OCxM bits are not preloaded
- 1: CCxE, CCxNE and OCxM bits are preloaded, after having been written, they are updated only when COM bit is set.

*Note: This bit acts only on channels that have a complementary output.*

### 40.6.3 TIMx DMA/interrupt enable register (TIMx_DIER)(x = 16 to 17)

Address offset: 0x0C  
Reset value: 0x0000

</tbody>
</table>
Bit 0  **UIF**: Update interrupt flag
   This bit is set by hardware on an update event. It is cleared by software.
   0: No update occurred.
   1: Update interrupt pending. This bit is set by hardware when the registers are updated:
      – At overflow regarding the repetition counter value (update if repetition counter = 0)
        and if the UDIS=0 in the TIMx_CR1 register.
      – When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if
        URS=0 and UDIS=0 in the TIMx_CR1 register.

40.6.5  **TIMx event generation register (TIMx_EGR)(x = 16 to 17)**

Address offset: 0x14
Reset value: 0x0000

<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>

<td>CC1G</td>
<td>UG</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 15:8  Reserved, must be kept at reset value.

Bit 7  **BG**: Break generation
   This bit is set by software in order to generate an event, it is automatically cleared by
   hardware.
   0: No action.
   1: A break event is generated. MOE bit is cleared and BIF flag is set. Related interrupt or
   DMA transfer can occur if enabled.

Bit 6  Reserved, must be kept at reset value.

Bit 5  **COMG**: Capture/Compare control update generation
   This bit can be set by software, it is automatically cleared by hardware.
   0: No action
   1: When the CCPC bit is set, it is possible to update the CCxE, CCxNE and OCxM bits
   
   *Note*:  *This bit acts only on channels that have a complementary output.*

Bits 4:2  Reserved, must be kept at reset value.

Bit 1  **CC1G**: Capture/Compare 1 generation
   This bit is set by software in order to generate an event, it is automatically cleared by
   hardware.
   0: No action.
   1: A capture/compare event is generated on channel 1:
   
   **If channel CC1 is configured as output:**
   CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled.

   **If channel CC1 is configured as input:**
   The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set,
   the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the
   CC1IF flag was already high.

Bit 0  **UG**: Update generation
   This bit can be set by software, it is automatically cleared by hardware.
   0: No action.
   1: Reinitialize the counter and generates an update of the registers. Note that the prescaler
   counter is cleared too (anyway the prescaler ratio is not affected).
40.6.6 TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1) 
(x = 16 to 17)
Address offset: 0x18
Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode.

**Input capture mode:**

Bits 31:8 Reserved, must be kept at reset value.
Bits 7:4 **IC1F[3:0]**: Input capture 1 filter

This bit-field defines the frequency used to sample TI1 input and the length of the digital filter applied to TI1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

- **0000**: No filter, sampling is done at fDTS
- **0001**: f\_SAMPLING = f\_CK\_INT, N=2
- **0010**: f\_SAMPLING = f\_CK\_INT, N=4
- **0011**: f\_SAMPLING = f\_CK\_INT, N=8
- **0100**: f\_SAMPLING = f\_DTS/2, N=1
- **0101**: f\_SAMPLING = f\_DTS/2, N=2
- **0110**: f\_SAMPLING = f\_DTS/4, N=6
- **0111**: f\_SAMPLING = f\_DTS/4, N=8
- **1000**: f\_SAMPLING = f\_DTS/8, N=6
- **1001**: f\_SAMPLING = f\_DTS/8, N=8
- **1010**: f\_SAMPLING = f\_DTS/16, N=5
- **1011**: f\_SAMPLING = f\_DTS/16, N=6
- **1100**: f\_SAMPLING = f\_DTS/16, N=8
- **1101**: f\_SAMPLING = f\_DTS/32, N=5
- **1110**: f\_SAMPLING = f\_DTS/32, N=6
- **1111**: f\_SAMPLING = f\_DTS/32, N=8

Bits 3:2 **IC1PSC[1:0]**: Input capture 1 prescaler

This bit-field defines the ratio of the prescaler acting on CC1 input (IC1). The prescaler is reset as soon as CC1E='0' (TIMx\_CCER register).

- **00**: no prescaler, capture is done each time an edge is detected on the capture input.
- **01**: capture is done once every 2 events
- **10**: capture is done once every 4 events
- **11**: capture is done once every 8 events

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 Selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

- **00**: CC1 channel is configured as output
- **01**: CC1 channel is configured as input, IC1 is mapped on TI1
- **10**: CC1 channel is configured as input, IC1 is mapped on TI2
- **11**: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx\_SMCR register)

*Note: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIMx\_CCER).*

### 40.6.7 **TIMx capture/compare mode register 1 [alternate] (TIMx\_CCMR1)** (x = 16 to 17)

Address offset: 0x18

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode.

**Output compare mode:**
### General-purpose timers (TIM15/TIM16/TIM17)

#### Bits 31:17: Reserved, must be kept at reset value.

#### Bits 15:7: Reserved, must be kept at reset value.

**Bits 16, 6, 4** **OC1M[3:0]:** Output Compare 1 mode

These bits define the behavior of the output reference signal OC1REF from which OC1 and OC1N are derived. OC1REF is active high whereas OC1 and OC1N active level depends on CC1P and CC1NP bits.

- **0000:** Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs.
- **0001:** Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).
- **0010:** Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).
- **0011:** Toggle - OC1REF toggles when TIMx_CNT=TIMx_CCR1.
- **0100:** Force inactive level - OC1REF is forced low.
- **0101:** Force active level - OC1REF is forced high.
- **0110:** PWM mode 1 - Channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else inactive.
- **0111:** PWM mode 2 - Channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else active.
- **All other values:** Reserved

**Note:**
1. These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S='00' (the channel is configured in output).
2. In PWM mode 1 or 2, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.

**Bit 3** **OC1PE:** Output Compare 1 preload enable

- **0:** Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken in account immediately.
- **1:** Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded in the active register at each update event.

**Note:**
1. These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S='00' (the channel is configured in output).
2. The PWM mode can be used without validating the preload register only in one pulse mode (OPM bit set in TIMx_CR1 register). Else the behavior is not guaranteed.

**Bit 2** **OC1FE:** Output Compare 1 fast enable

This bit is used to accelerate the effect of an event on the trigger in input on the CC output.

- **0:** CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.
- **1:** An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently of the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OC1FE acts only if the channel is configured in PWM1 or PWM2 mode.
Bits 1:0 **CC1S[1:0]: Capture/Compare 1 selection**
This bit-field defines the direction of the channel (input/output) as well as the used input.
- 00: CC1 channel is configured as output
- 01: CC1 channel is configured as input, IC1 is mapped on TI1
- 10: CC1 channel is configured as input, IC1 is mapped on TI2
- 11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register).

*Note: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIMx_CCR).*

### 40.6.8 TIMx capture/compare enable register (TIMx_CCER)(x = 16 to 17)

**Address offset: 0x20**

**Reset value: 0x0000**

**Bits 15:4** Reserved, must be kept at reset value.

**Bit 3 CC1NP: Capture/Compare 1 complementary output polarity**
CC1 channel configured as output:
- 0: OC1N active high
- 1: OC1N active low
CC1 channel configured as input:
This bit is used in conjunction with CC1P to define the polarity of TI1FP1 and TI2FP1. Refer to the description of CC1P.

*Note: 1. This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S="00" (the channel is configured in output). 2. On channels that have a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1NP active bit takes the new value from the preloaded bit only when a commutation event is generated.*
Bit 2 **CC1NE**: Capture/Compare 1 complementary output enable
0: Off - OC1N is not active. OC1N level is then function of MOE, OSS1, OSSR, OIS1, OIS1N and CC1E bits.
1: On - OC1N signal is output on the corresponding output pin depending on MOE, OSS1, OSSR, OIS1, OIS1N and CC1E bits.

Bit 1 **CC1P**: Capture/Compare 1 output polarity

**CC1 channel configured as output:**
0: OC1 active high
1: OC1 active low

**CC1 channel configured as input:**
The CC1NP/CC1P bits select the polarity of TI1FP1 and TI2FP1 for trigger or capture operations.
00: Non-inverted/rising edge. The circuit is sensitive to TIxFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode).
01: Inverted/falling edge. The circuit is sensitive to TIxFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is inverted (trigger operation in gated mode).
10: Reserved, do not use this configuration.
1: Non-inverted/both edges. The circuit is sensitive to both TIxFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode).

**Note:**
1. This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).
2. On channels that have a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1P active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bit 0 **CC1E**: Capture/Compare 1 output enable

**CC1 channel configured as output:**
0: Off - OC1 is not active. OC1 level is then function of MOE, OSS1, OSSR, OIS1, OIS1N and CC1NE bits.
1: On - OC1 signal is output on the corresponding output pin depending on MOE, OSS1, OSSR, OIS1, OIS1N and CC1NE bits.

**CC1 channel configured as input:**
This bit determines if a capture of the counter value can actually be done into the input capture/compare register 1 (TIMx_CCR1) or not.
0: Capture disabled
1: Capture enabled

1. When both outputs of a channel are not used (control taken over by GPIO controller), the OISx, OISxN, CCxP and CCxNP bits must be kept cleared.

Note: The state of the external I/O pins connected to the complementary OCx and OCxN channels depends on the OCx and OCxN channel state and AFIO registers.

40.6.9 TIMx counter (TIMx_CNT)(x = 16 to 17)

Address offset: 0x24
Reset value: 0x0000 0000
40.6.10 TIMx prescaler (TIMx_PSC)(x = 16 to 17)

Address offset: 0x28

Bits 15:0 **PSC[15:0]**: Prescaler value
The counter clock frequency (CK_CNT) is equal to fCK_PSC / (PSC[15:0] + 1).
PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in "reset mode").

40.6.11 TIMx auto-reload register (TIMx_ARR)(x = 16 to 17)

</tr>
</tbody>
</table>

Bits 15:0 **ARR[15:0]**: Auto-reload value
ARR is the value to be loaded in the actual auto-reload register.
Refer to the Section 40.4.1: Time-base unit on page 1766 for more details about ARR update and behavior.
The counter is blocked while the auto-reload value is null.
40.6.12  TIMx repetition counter register (TIMx_RCR)(x = 16 to 17)

Address offset: 0x30
Reset value: 0x0000

<table>
<thead>
<tr>

<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

Bits 15:8  Reserved, must be kept at reset value.

Bits 7:0  **REP[7:0]: Repetition counter value**

These bits allow the user to set-up the update rate of the compare registers (i.e. periodic transfers from preload to active registers) when preload registers are enabled, as well as the update interrupt generation rate, if this interrupt is enabled. Each time the REP_CNT related downcounter reaches zero, an update event is generated and it restarts counting from REP value. As REP_CNT is reloaded with REP value only at the repetition update event U_RC, any write to the TIMx_RCR register is not taken in account until the next repetition update event. It means in PWM mode (REP+1) corresponds to the number of PWM periods in edge-aligned mode.

40.6.13  TIMx capture/compare register 1 (TIMx_CCR1)(x = 16 to 17)

Address offset: 0x34
Reset value: 0x00000

</tbody>
</table>

Bits 15:0  **CCR1[15:0]: Capture/Compare 1 value**

**If channel CC1 is configured as output:**  
CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs. The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on OC1 output.

**If channel CC1 is configured as input:**  
CCR1 is the counter value transferred by the last input capture 1 event (IC1).

**Note:** As the BKF[3:0], AOE, BKP, BKE, OSSR, OSSI and DTG[7:0] bits may be write-locked depending on the LOCK configuration, it may be necessary to configure all of them during the first write access to the TIMx_BDTR register.

Bits 31:20 Reserve, must be kept at reset value.

**Bits 19:16 BKF[3:0]: Break filter**

This bit-field defines the frequency used to sample BRK input and the length of the digital filter applied to BRK. The digital filter is made of an event counter in which N events are needed to validate a transition on the output:

- **0000:** No filter, BRK acts asynchronously
- **0001:** fSAMPLING = fCK_INT, N = 2
- **0010:** fSAMPLING = fCK_INT, N = 4
- **0011:** fSAMPLING = fCK_INT, N = 8
- **0100:** fSAMPLING = fDTS/2, N = 6
- **0101:** fSAMPLING = fDTS/2, N = 8
- **0110:** fSAMPLING = fDTS/4, N = 6
- **0111:** fSAMPLING = fDTS/4, N = 8
- **1000:** fSAMPLING = fDTS/8, N = 6
- **1001:** fSAMPLING = fDTS/8, N = 8
- **1010:** fSAMPLING = fDTS/16, N = 5
- **1011:** fSAMPLING = fDTS/16, N = 6
- **1100:** fSAMPLING = fDTS/16, N = 8
- **1101:** fSAMPLING = fDTS/32, N = 5
- **1110:** fSAMPLING = fDTS/32, N = 6
- **1111:** fSAMPLING = fDTS/32, N = 8

This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

**Bit 15 MOE: Main output enable**

This bit is cleared asynchronously by hardware as soon as the break input is active. It is set by software or automatically depending on the AOE bit. It is acting only on the channels which are configured in output.

- **0:** OC and OCN outputs are disabled or forced to idle state depending on the OSSI bit.
- **1:** OC and OCN outputs are enabled if their respective enable bits are set (CCxE, CCxNE in TIMx_CER register)

See OC/OCN enable description for more details (Section 40.6.8: TIMx capture/compare enable register (TIMx_CER)(x = 16 to 17) on page 1833).
Bit 14  **AOE**: Automatic output enable
0: MOE can be set only by software
1: MOE can be set by software or automatically at the next update event (if the break input is not be active)

*Note:*  This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 13  **BKP**: Break polarity
0: Break input BRK is active low
1: Break input BRK is active high

*Note:*  1. This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).
        2. Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 12  **BKE**: Break enable
0: Break inputs (BRK and CCS clock failure event) disabled
1: Break inputs (BRK and CCS clock failure event) enabled

*Note:*  1. This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).
        2. Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 11  **OSSR**: Off-state selection for Run mode
This bit is used when MOE=1 on channels that have a complementary output which are configured as outputs. OSSR is not implemented if no complementary output is implemented in the timer.

See OC/OCN enable description for more details (Section 40.6.8: TIMx capture/compare enable register (TIMx_CCER)(x = 16 to 17) on page 1833).
0: When inactive, OC/OCN outputs are disabled (the timer releases the output control which is taken over by the AFIO logic, which forces a Hi-Z state)
1: When inactive, OC/OCN outputs are enabled with their inactive level as soon as CCxE=1 or CCxNE=1 (the output is still controlled by the timer).

*Note:*  This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).
Bit 10 **OSSI**: Off-state selection for Idle mode

This bit is used when MOE=0 on channels configured as outputs.

See OC/OCN enable description for more details (Section 40.6.8: TIMx capture/compare enable register (TIMx_CCER)(x = 16 to 17) on page 1833).

0: When inactive, OC/OCN outputs are disabled (OC/OCN enable output signal=0)
1: When inactive, OC/OCN outputs are forced first with their idle level as soon as CCxEn=1 or CCxNE=1. OC/OCN enable output signal=1)

**Note**: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 9:8 **LOCK[1:0]**: Lock configuration

These bits offer a write protection against software errors.

00: LOCK OFF - No bit is write protected
01: LOCK Level 1 = DTG bits in TIMx_BDTR register, OISx and OISxN bits in TIMx_CR2 register and BKE/BKP/AOE bits in TIMx_BDTR register can no longer be written.
10: LOCK Level 2 = LOCK Level 1 + CC Polarity bits (CCxP/CCxNP bits in TIMx_CCER register, as long as the related channel is configured in output through the CCxS bits) as well as OSSR and OSSI bits can no longer be written.
11: LOCK Level 3 = LOCK Level 2 + CC Control bits (OCxM and OCxPE bits in TIMx_CCMRx registers, as long as the related channel is configured in output through the CCxS bits) can no longer be written.

**Note**: The LOCK bits can be written only once after the reset. Once the TIMx_BDTR register has been written, their content is frozen until the next reset.

Bits 7:0 **DTG[7:0]**: Dead-time generator setup

This bit-field defines the duration of the dead-time inserted between the complementary outputs. DT correspond to this duration.

DTG[7:5]=0xx => DT=DTG[7:0]x t_dig with t_dig=tDTS
DTG[7:5]=10x => DT=(64+DTG[5:0])x t_dig with t_dig=2x tDTS
DTG[7:5]=110 => DT=(32+DTG[4:0])x t_dig with t_dig=8x tDTS
DTG[7:5]=111 => DT=(32+DTG[4:0])x t_dig with t_dig=16x tDTS

Example if T_DTS=125ns (8MHz), dead-time possible values are:

0 to 15875 ns by 125 ns steps,
16 µs to 31750 ns by 250 ns steps,
32 µs to 63 µs by 1 µs steps,
64 µs to 126 µs by 2 µs steps

**Note**: This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

40.6.15 **TIMx DMA control register (TIMx_DCR)(x = 16 to 17)**

Address offset: 0x48

1840/3289 RM0433 Rev 6
Bits 15:13  Reserved, must be kept at reset value.

Bits 12:8  **DBL[4:0]: DMA burst length**
This 5-bit field defines the length of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address), i.e. the number of transfers. Transfers can be in half-words or in bytes (see example below).
- 00000: 1 transfer,
- 00001: 2 transfers,
- 00010: 3 transfers,
- ...
- 10001: 18 transfers.

Bits 7:5  Reserved, must be kept at reset value.

Bits 4:0  **DBA[4:0]: DMA base address**
This 5-bit field defines the base-address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register.
- Example:
  - 00000: TIMx_CR1,
  - 00001: TIMx_CR2,
  - 00010: TIMx_SMCR,
  - ...

**Example:** Let us consider the following transfer: DBL = 7 transfers and DBA = TIMx_CR1. In this case the transfer is done to/from 7 registers starting from the TIMx_CR1 address.

### 40.6.16  TIMx DMA address for full transfer (TIMx_DMAR)(x = 16 to 17)

Address offset: 0x4C

Reset value: 0x0000

<tbody>
<tr>
<td>rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw</td>
</tr>
</tbody>
</table>

Bits 15:0  **DMAB[15:0]: DMA register for burst accesses**
A read or write operation to the DMAR register accesses the register located at the address

(TIMx_CR1 address) + (DBA + DMA index) x 4

where TIMx_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIMx_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIMx_DCR).
### 40.6.17 TIM16 alternate function register 1 (TIM16_AF1)

Bits 31:12 Reserved, must be kept at reset value.

**Bit 11 BKCM P2P: BRK COMP2 input polarity**

This bit selects the COMP2 input sensitivity. It must be programmed together with the BKP polarity bit.

- **0**: COMP2 input is active low  
- **1**: COMP2 input is active high

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

**Bit 10 BKCM P1P: BRK COMP1 input polarity**

This bit selects the COMP1 input sensitivity. It must be programmed together with the BKP polarity bit.

- **0**: COMP1 input is active low  
- **1**: COMP1 input is active high

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

**Bit 9 BKINP: BRK B KIN input polarity**

This bit selects the B KIN alternate function input sensitivity. It must be programmed together with the BKP polarity bit.

- **0**: B KIN input is active low  
- **1**: B KIN input is active high

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

**Bit 8 BKDF1 BK2E: BRK dfsdm1_break[2] enable**

This bit enables the dfsdm1_break[2] for the timer's BRK input. dfsdm1_break[2] output is 'OREd' with the other BRK sources.

- **0**: dfsdm1_break[2] input disabled  
- **1**: dfsdm1_break[2] input enabled

*Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).*

Bits 7:3 Reserved, must be kept at reset value.

Refer to Section 2.3 on page 126 for the register boundary addresses.
41  Basic timers (TIM6/TIM7)

41.1  TIM6/TIM7 introduction

The basic timers TIM6 and TIM7 consist of a 16-bit auto-reload counter driven by a programmable prescaler.

They may be used as generic timers for time base generation but they are also specifically used to drive the digital-to-analog converter (DAC). In fact, the timers are internally connected to the DAC and are able to drive it through their trigger outputs.

The timers are completely independent, and do not share any resources.

41.2  TIM6/TIM7 main features

Basic timer (TIM6/TIM7) features include:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535
- Synchronization circuit to trigger the DAC
- Interrupt/DMA generation on the update event: counter overflow

![Figure 512. Basic timer block diagram](image-url)
41.3 TIM6/TIM7 functional description

41.3.1 Time-base unit

The main block of the programmable timer is a 16-bit upcounter with its related auto-reload register. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:

- Counter Register (TIMx_CNT)
- Prescaler Register (TIMx_PSC)
- Auto-Reload Register (TIMx_ARR)

The auto-reload register is preloaded. The preload register is accessed each time an attempt is made to write or read the auto-reload register. The contents of the preload register are transferred into the shadow register permanently or at each update event UEV, depending on the auto-reload preload enable bit (ARPE) in the TIMx_CR1 register. The update event is sent when the counter reaches the overflow value and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detail for each configuration.

The counter is clocked by the prescaler output CK_CNT, which is enabled only when the counter enable bit (CEN) in the TIMx_CR1 register is set.

Note that the actual counter enable signal CNT_EN is set 1 clock cycle after CEN.

Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as the TIMx_PSC control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 513* and *Figure 514* give some examples of the counter behavior when the prescaler ratio is changed on the fly.
Figure 513. Counter timing diagram with prescaler division change from 1 to 2

Figure 514. Counter timing diagram with prescaler division change from 1 to 4
41.3.2 Counting mode

The counter counts from 0 to the auto-reload value (contents of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

An update event can be generate at each counter overflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller).

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This avoids updating the shadow registers while writing new values into the preload registers. In this way, no update event occurs until the UDIS bit has been written to 0, however, the counter and the prescaler counter both restart from 0 (but the prescale rate does not change). In addition, if the URS (update request selection) bit in the TIMx_CR1 register is set, setting the UG bit generates an update event UEV, but the UIF flag is not set (so no interrupt or DMA request is sent).

When an update event occurs, all the registers are updated and the update flag (UIF bit in the TIMx_SR register) is set (depending on the URS bit):
- The buffer of the prescaler is reloaded with the preload value (contents of the TIMx_PSC register)
- The auto-reload shadow register is updated with the preload value (TIMx_ARR)

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR = 0x36.

Figure 517. Counter timing diagram, internal clock divided by 4
Figure 518. Counter timing diagram, internal clock divided by N

Figure 519. Counter timing diagram, update event when ARPE = 0 (TIMx_ARR not preloaded)
41.3.3 UIF bit remapping

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the Update Interrupt Flag UIF into the timer counter register’s bit 31 (TIMx_CNT[31]). This allows to atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. In particular cases, it can ease the calculations by avoiding race conditions caused for instance by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

There is no latency between the assertions of the UIF and UIFCPY flags.

41.3.4 Clock source

The counter clock is provided by the Internal clock (CK_INT) source.

The CEN (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except for UG that remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK_INT.

Figure 521 shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.
41.3.5 Debug mode

When the microcontroller enters the debug mode (Cortex®-M7 with FPU core - halted), the TIMx counter either continues to work normally or stops, depending on the DBG_TIMx_STOP configuration bit in the DBGMCU module. For more details, refer to Section 59.5.8: Microcontroller debug unit (DBGMCU).

41.4 TIM6/TIM7 registers

Refer to Section 1.2 on page 98 for a list of abbreviations used in register descriptions. The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

41.4.1 TIMx control register 1 (TIMx_CR1)(x = 6 to 7)

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **UIFREMAP**: UIF status bit remapping

0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.
1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.

Bits 10:8 Reserved, must be kept at reset value.
Bit 7 **ARPE**: Auto-reload preload enable
   0: TIMx_ARR register is not buffered.
   1: TIMx_ARR register is buffered.

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM**: One-pulse mode
   0: Counter is not stopped at update event
   1: Counter stops counting at the next update event (clearing the CEN bit).

Bit 2 **URS**: Update request source
   This bit is set and cleared by software to select the UEV event sources.
   0: Any of the following events generates an update interrupt or DMA request if enabled.
      These events can be:
      – Counter overflow/underflow
      – Setting the UG bit
      – Update generation through the slave mode controller
   1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1 **UDIS**: Update disable
   This bit is set and cleared by software to enable/disable UEV event generation.
   0: UEV enabled. The Update (UEV) event is generated by one of the following events:
      – Counter overflow/underflow
      – Setting the UG bit
      – Update generation through the slave mode controller
      Buffered registers are then loaded with their preload values.
   1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable
   0: Counter disabled
   1: Counter enabled

*Note: Gated mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware. CEN is cleared automatically in one-pulse mode, when an update event occurs.*

**Bits 15:7** Reserved, must be kept at reset value.

**Bits 6:4 MMS[2:0]: Master mode selection**

These bits are used to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows:

- **000: Reset** - the UG bit from the TIMx_EGR register is used as a trigger output (TRGO). If reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on TRGO is delayed compared to the actual reset.
- **001: Enable** - the Counter enable signal, CNT_EN, is used as a trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic OR between CEN control bit and the trigger input when configured in gated mode.
- **010: Update** - the update event is selected as a trigger output (TRGO). For instance a master timer can then be used as a prescaler for a slave timer.

**Note:** The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

**Bits 3:0** Reserved, must be kept at reset value.

### 41.4.3 TIMx DMA/Interrupt enable register (TIMx_DIER)(x = 6 to 7)

**Address offset:** 0x0C  
**Reset value:** 0x00000

<table>
<thead>
<tr>
<th>Bit 15</th>
<th>Bit 14</th>
<th>Bit 13</th>
<th>Bit 12</th>
<th>Bit 11</th>
<th>Bit 10</th>

<td>rw</td>
</tr>
</tbody>
</table>

**Bits 15:9** Reserved, must be kept at reset value.

**Bit 8 UDE:** Update DMA request enable

- 0: Update DMA request disabled.
- 1: Update DMA request enabled.

**Bits 7:1** Reserved, must be kept at reset value.

**Bit 0 UIE:** Update interrupt enable

- 0: Update interrupt disabled.
- 1: Update interrupt enabled.
### 41.4.4 TIMx status register (TIMx_SR)(x = 6 to 7)
Address offset: 0x10
Reset value: 0x0000

<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>

<th>9</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

Bits 15:1 Reserved, must be kept at reset value.

- **Bit 0** **UIF**: Update interrupt flag
  - This bit is set by hardware on an update event. It is cleared by software.
  - 0: No update occurred.
  - 1: Update interrupt pending. This bit is set by hardware when the registers are updated:
    - At overflow or underflow regarding the repetition counter value and if UDIS = 0 in the TIMx_CR1 register.
    - When CNT is reinitialized by software using the UG bit in the TIMx_EGR register, if URS = 0 and UDIS = 0 in the TIMx_CR1 register.

### 41.4.5 TIMx event generation register (TIMx_EGR)(x = 6 to 7)
Address offset: 0x14
Reset value: 0x0000

<table>
<thead>

<td>UG</td>
</tr>
</tbody>
</table>

Bits 15:1 Reserved, must be kept at reset value.

- **Bit 0** **UG**: Update generation
  - This bit can be set by software, it is automatically cleared by hardware.
  - 0: No action.
  - 1: Re-initializes the timer counter and generates an update of the registers. Note that the prescaler counter is cleared too (but the prescaler ratio is not affected).

### 41.4.6 TIMx counter (TIMx_CNT)(x = 6 to 7)

Refer to Section 2.3 on page 126 for the register boundary addresses.
42 Low-power timer (LPTIM)

42.1 Introduction

The LPTIM is a 16-bit timer that benefits from the ultimate developments in power consumption reduction. Thanks to its diversity of clock sources, the LPTIM is able to keep running in all power modes except for Standby mode. Given its capability to run even with no internal clock source, the LPTIM can be used as a “Pulse Counter” which can be useful in some applications. Also, the LPTIM capability to wake up the system from low-power modes, makes it suitable to realize “Timeout functions” with extremely low power consumption.

The LPTIM introduces a flexible clock scheme that provides the needed functionalities and performance, while minimizing the power consumption.

42.2 LPTIM main features

- 16 bit upcounter
- 3-bit prescaler with 8 possible dividing factors (1,2,4,8,16,32,64,128)
- Selectable clock
  - Internal clock sources: LSE, LSI, HSI or APB clock
  - External clock source over LPTIM input (working with no LP oscillator running, used by Pulse Counter application)
- 16 bit ARR autoreload register
- 16 bit compare register
- Continuous/One-shot mode
- Selectable software/hardware input trigger
- Programmable Digital Glitch filter
- Configurable output: Pulse, PWM
- Configurable I/O polarity
- Encoder mode

42.3 LPTIM implementation

Table 342 describes LPTIM implementation on STM32H742, STM32H743/753 and STM32H750 devices.

42.4.4 LPTIM reset and clocks

The LPTIM can be clocked using several clock sources. It can be clocked using an internal clock signal which can be chosen among APB, LSI, LSE or HSI sources through the Reset and Clock controller (RCC). Also, the LPTIM can be clocked using an external clock signal injected on its external Input1. When clocked with an external clock source, the LPTIM may run in one of these two possible configurations:

- The first configuration is when the LPTIM is clocked by an external signal but in the same time an internal clock signal is provided to the LPTIM either from APB or any other embedded oscillator including LSE, LSI and HSI.
- The second configuration is when the LPTIM is solely clocked by an external clock source through its external Input1. This configuration is the one used to realize Timeout function or Pulse counter function when all the embedded oscillators are turned off after entering a low-power mode.

Programming the CKSEL and COUNTMODE bits allows controlling whether the LPTIM will use an external clock source or an internal one.

When configured to use an external clock source, the CKPOL bits are used to select the external clock signal active edge. If both edges are configured to be active ones, an internal clock signal should also be provided (first configuration). In this case, the internal clock signal frequency should be at least four times higher than the external clock signal frequency.

42.4.5 Glitch filter

The LPTIM inputs, either external (mapped to GPIOs) or internal (mapped on the chip-level to other embedded peripherals, such as embedded comparators), are protected with digital filters that prevent any glitches and noise perturbations to propagate inside the LPTIM. This is in order to prevent spurious counts or triggers.

Before activating the digital filters, an internal clock source should first be provided to the LPTIM. This is necessary to guarantee the proper operation of the filters.
The digital filters are divided into two groups:

- The first group of digital filters protects the LPTIM external inputs. The digital filters sensitivity is controlled by the CKFLT bits.
- The second group of digital filters protects the LPTIM internal trigger inputs. The digital filters sensitivity is controlled by the TRGFLT bits.

**Note:** The digital filters sensitivity is controlled by groups. It is not possible to configure each digital filter sensitivity separately inside the same group.

The filter sensitivity acts on the number of consecutive equal samples that should be detected on one of the LPTIM inputs to consider a signal level change as a valid transition. Figure 525 shows an example of glitch filter behavior in case of a 2 consecutive samples programmed.

**Figure 525. Glitch filter timing diagram**

![Glitch filter timing diagram](image)

**Note:** In case no internal clock signal is provided, the digital filter must be deactivated by setting the CKFLT and TRGFLT bits to ‘0’. In that case, an external analog filter may be used to protect the LPTIM external inputs against glitches.

### 42.4.6 Prescaler

The LPTIM 16-bit counter is preceded by a configurable power-of-2 prescaler. The prescaler division ratio is controlled by the PRESC[2:0] 3-bit field. The table below lists all the possible division ratios:

<table>
<thead>
<tr>

<th>dividing factor</th>
</tr>
</thead>
<tbody>
<tr>
<td>111</td>
<td>/128</td>
</tr>
</tbody>
</table>
42.4.7 Trigger multiplexer

The LPTIM counter may be started either by software or after the detection of an active edge on one of the 8 trigger inputs.

TRIGEN[1:0] is used to determine the LPTIM trigger source:

- When TRIGEN[1:0] equals '00', the LPTIM counter is started as soon as one of the CNTSTRT or the SNGSTRT bits is set by software. The three remaining possible values for the TRIGEN[1:0] are used to configure the active edge used by the trigger inputs. The LPTIM counter starts as soon as an active edge is detected.
- When TRIGEN[1:0] is different than '00', TRIGSEL[2:0] is used to select which of the 8 trigger inputs is used to start the counter.

The external triggers are considered asynchronous signals for the LPTIM. So after a trigger detection, a two-counter-clock period latency is needed before the timer starts running due to the synchronization.

If a new trigger event occurs when the timer is already started it will be ignored (unless timeout function is enabled).

*Note:* The timer must be enabled before setting the SNGSTRT/CNTSTRT bits. Any write on these bits when the timer is disabled will be discarded by hardware.

42.4.8 Operating mode

The LPTIM features two operating modes:

- The Continuous mode: the timer is free running, the timer is started from a trigger event and never stops until the timer is disabled
- One-shot mode: the timer is started from a trigger event and stops when reaching the ARR value.

One-shot mode

To enable the one-shot counting, the SNGSTRT bit must be set.

A new trigger event will re-start the timer. Any trigger event occurring after the counter starts and before the counter reaches ARR will be discarded.

In case an external trigger is selected, each external trigger event arriving after the SNGSTRT bit is set, and after the counter register has stopped (contains zero value), will start the counter for a new one-shot counting cycle as shown in Figure 526.
- Set-once mode activated:

It should be noted that when the WAVE bit-field in the LPTIM_CFGR register is set, the Set-once mode is activated. In this case, the counter is only started once following the first trigger, and any subsequent trigger event is discarded as shown in Figure 527.

**Figure 527. LPTIM output waveform, Single counting mode configuration and Set-once mode activated (WAVE bit is set)**

In case of software start (TRIGEN[1:0] = ‘00’), the SNGSTRT setting will start the counter for one-shot counting.

**Continous mode**

To enable the continuous counting, the CNTSTRT bit must be set.

In case an external trigger is selected, an external trigger event arriving after CNTSTRT is set will start the counter for continuous counting. Any subsequent external trigger event will be discarded as shown in Figure 528.

In case of software start (TRIGEN[1:0] = ‘00’), setting CNTSTRT will start the counter for continuous counting.
SNGSTRT and CNTSTRT bits can only be set when the timer is enabled (The ENABLE bit is set to ‘1’). It is possible to change “on the fly” from One-shot mode to Continuous mode.

If the Continuous mode was previously selected, setting SNGSTRT will switch the LPTIM to the One-shot mode. The counter (if active) will stop as soon as it reaches ARR.

If the One-shot mode was previously selected, setting CNTSTRT will switch the LPTIM to the Continuous mode. The counter (if active) will restart as soon as it reaches ARR.

### 42.4.9 Timeout function

The detection of an active edge on one selected trigger input can be used to reset the LPTIM counter. This feature is controlled through the TIMOUT bit.

The first trigger event will start the timer, any successive trigger event will reset the counter and the timer will restart.

A low-power timeout function can be realized. The timeout value corresponds to the compare value; if no trigger occurs within the expected time frame, the MCU is waked-up by the compare match event.

### 42.4.10 Waveform generation

Two 16-bit registers, the LPTIM_ARR (autoreload register) and LPTIM_CMP (compare register), are used to generate several different waveforms on LPTIM output.

The timer can generate the following waveforms:

- The PWM mode: the LPTIM output is set as soon as the counter value in LPTIM_CNT exceeds the compare value in LPTIM_CMP. The LPTIM output is reset as soon as a match occurs between the LPTIM_ARR and the LPTIM_CNT registers.
- The One-pulse mode: the output waveform is similar to the one of the PWM mode for the first pulse, then the output is permanently reset.
- The Set-once mode: the output waveform is similar to the One-pulse mode except that the output is kept to the last signal level (depends on the output configured polarity).

The above described modes require that the LPTIM_ARR register value be strictly greater than the LPTIM_CMP register value.
The LPTIM output waveform can be configured through the WAVE bit as follow:

- Resetting the WAVE bit to ‘0’ forces the LPTIM to generate either a PWM waveform or a One pulse waveform depending on which bit is set: CNTSTRT or SNGSTRT.
- Setting the WAVE bit to ‘1’ forces the LPTIM to generate a Set-once mode waveform.

The WAVPOL bit controls the LPTIM output polarity. The change takes effect immediately, so the output default value will change immediately after the polarity is re-configured, even before the timer is enabled.

Signals with frequencies up to the LPTIM clock frequency divided by 2 can be generated. Figure 529 below shows the three possible waveforms that can be generated on the LPTIM output. Also, it shows the effect of the polarity change using the WAVPOL bit.

**Figure 529. Waveform generation**

![Waveform generation diagram](image)

### 42.4.11 Register update

The LPTIM.ARR register and LPTIM.CMP register are updated immediately after the APB bus write operation, or at the end of the current period if the timer is already started.

The PRELOAD bit controls how the LPTIM.ARR and the LPTIM.CMP registers are updated:

- When the PRELOAD bit is reset to ‘0’, the LPTIM.ARR and the LPTIM.CMP registers are immediately updated after any write access.
- When the PRELOAD bit is set to ‘1’, the LPTIM.ARR and the LPTIM.CMP registers are updated at the end of the current period, if the timer has been already started.

The LPTIM APB interface and the LPTIM kernel logic use different clocks, so there is some latency between the APB write and the moment when these values are available to the
counter comparator. Within this latency period, any additional write into these registers must be avoided.

The ARROK flag and the CMPOK flag in the LPTIM_ISR register indicate when the write operation is completed to respectively the LPTIM_ARR register and the LPTIM_CMP register.

After a write to the LPTIM_ARR register or the LPTIM_CMP register, a new write operation to the same register can only be performed when the previous write operation is completed. Any successive write before respectively the ARROK flag or the CMPOK flag be set, will lead to unpredictable results.

### 42.4.12 Counter mode

The LPTIM counter can be used to count external events on the LPTIM Input1 or it can be used to count internal clock cycles. The CKSEL and COUNTMODE bits control which source will be used for updating the counter.

In case the LPTIM is configured to count external events on Input1, the counter can be updated following a rising edge, falling edge or both edges depending on the value written to the CKPOL[1:0] bits.

The count modes below can be selected, depending on CKSEL and COUNTMODE values:

- **CKSEL = 0**: the LPTIM is clocked by an internal clock source
  - **COUNTMODE = 0**: The LPTIM is configured to be clocked by an internal clock source and the LPTIM counter is configured to be updated following each internal clock pulse.
  - **COUNTMODE = 1**: The LPTIM external Input1 is sampled with the internal clock provided to the LPTIM. Consequently, in order not to miss any event, the frequency of the changes on the external Input1 signal should never exceed the frequency of the internal clock provided to the LPTIM. Also, the internal clock provided to the LPTIM must not be prescaled (PRESC[2:0] = 000).

- **CKSEL = 1**: the LPTIM is clocked by an external clock source
  
  COUNTMODE value is don’t care.

  In this configuration, the LPTIM has no need for an internal clock source (except if the glitch filters are enabled). The signal injected on the LPTIM external Input1 is used as system clock for the LPTIM. This configuration is suitable for operation modes where no embedded oscillator is enabled.

  For this configuration, the LPTIM counter can be updated either on rising edges or falling edges of the input1 clock signal but not on both rising and falling edges.

  Since the signal injected on the LPTIM external Input1 is also used to clock the LPTIM kernel logic, there is some initial latency (after the LPTIM is enabled) before the counter is incremented. More precisely, the first five active edges on the LPTIM external Input1 (after LPTIM is enable) are lost.

### 42.4.13 Timer enable

The ENABLE bit located in the LPTIM_CR register is used to enable/disable the LPTIM kernel logic. After setting the ENABLE bit, a delay of two counter clock is needed before the LPTIM is actually enabled.
The LPTIM_CFGR and LPTIM_IER registers must be modified only when the LPTIM is disabled.

### 42.4.14 Timer counter reset

In order to reset the content of LPTIM_CNT register to zero, two reset mechanisms are implemented:

- The synchronous reset mechanism: the synchronous reset is controlled by the COUNTRST bit in the LPTIM_CR register. After setting the COUNTRST bit-field to '1', the reset signal is propagated in the LPTIM kernel clock domain. So it is important to note that a few clock pulses of the LPTIM kernel logic will elapse before the reset is taken into account. This will make the LPTIM counter count few extra pulses between the time when the reset is trigger and it become effective. Since the COUNTRST bit is located in the APB clock domain and the LPTIM counter is located in the LPTIM kernel clock domain, a delay of 3 clock cycles of the kernel clock is needed to synchronize the reset signal issued by the APB clock domain when writing '1' to the COUNTRST bit.

- The asynchronous reset mechanism: the asynchronous reset is controlled by the RSTARE bit located in the LPTIM_CR register. When this bit is set to '1', any read access to the LPTIM_CNT register will reset its content to zero. Asynchronous reset should be triggered within a timeframe in which no LPTIM core clock is provided. For example when LPTIM Input1 is used as external clock source, the asynchronous reset should be applied only when there is enough insurance that no toggle will occur on the LPTIM Input1.

It should be noted that to read reliably the content of the LPTIM_CNT register two successive read accesses must be performed and compared. A read access can be considered reliable when the value of the two read accesses is equal. Unfortunately when asynchronous reset is enabled there is no possibility to read twice the LPTIM_CNT register.

---

**Warning:** There is no mechanism inside the LPTIM that prevents the two reset mechanisms from being used simultaneously. So developer should make sure that these two mechanisms are used exclusively.

### 42.4.15 Encoder mode

This mode allows handling signals from quadrature encoders used to detect angular position of rotary elements. Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value programmed into the LPTIM_ARR register (0 up to ARR or ARR down to 0 depending on the direction). Therefore LPTIM_ARR must be configured before starting. From the two external input signals, Input1 and Input2, a clock signal is generated to clock the LPTIM counter. The phase between those two signals determines the counting direction.

The Encoder mode is only available when the LPTIM is clocked by an internal clock source. The signals frequency on both Input1 and Input2 inputs must not exceed the LPTIM internal clock frequency divided by 4. This is mandatory in order to guarantee a proper operation of the LPTIM.
Direction change is signaled by the two Down and Up flags in the LPTIM_ISR register. Also, an interrupt can be generated for both direction change events if enabled through the DOWNIE bit.

To activate the Encoder mode the ENC bit has to be set to ‘1’. The LPTIM must first be configured in Continuous mode.

When Encoder mode is active, the LPTIM counter is modified automatically following the speed and the direction of the incremental encoder. Therefore, its content always represents the encoder’s position. The count direction, signaled by the Up and Down flags, correspond to the rotation direction of the encoder rotor.

According to the edge sensitivity configured using the CKPOL[1:0] bits, different counting scenarios are possible. The following table summarizes the possible combinations, assuming that Input1 and Input2 do not switch at the same time.

<table>
<thead>
<tr>
<th>Active edge</th>
<th>Level on opposite signal (Input1 for Input2, Input2 for Input1)</th>
<th>Input1 signal</th>
<th>Input2 signal</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rising Edge</td>
<td>High, Down</td>
<td>No count</td>
<td>Up, No count</td>
</tr>
<tr>
<td></td>
<td>Low, Up</td>
<td>No count</td>
<td>Down, No count</td>
</tr>
<tr>
<td>Falling Edge</td>
<td>High, No count</td>
<td>Up,</td>
<td>No count, Down</td>
</tr>
<tr>
<td></td>
<td>Low, No count</td>
<td>Down, No count</td>
<td>Up</td>
</tr>
<tr>
<td>Both Edges</td>
<td>High, Down</td>
<td>Up,</td>
<td>Down, Up</td>
</tr>
<tr>
<td></td>
<td>Low, Up</td>
<td>Down, No count</td>
<td>Up</td>
</tr>
</tbody>
</table>

The following figure shows a counting sequence for Encoder mode where both-edge sensitivity is configured.

**Caution:** In this mode the LPTIM must be clocked by an internal clock source, so the CKSEL bit must be maintained to its reset value which is equal to ‘0’. Also, the prescaler division ratio must be equal to its reset value which is 1 (PRESC[2:0] bits must be ‘000’).
42.4.16 Debug mode

When the microcontroller enters debug mode (core halted), the LPTIM counter either continues to work normally or stops, depending on the DBG_LPTIM_STOP configuration bit in the DBG module.

42.5 LPTIM low-power modes

Table 357. Effect of low-power modes on the LPTIM

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect. LPTIM interrupts cause the device to exit Sleep mode.</td>

</tr>
</tbody>
</table>
42.6 LPTIM interrupts

The following events generate an interrupt/wake-up event, if they are enabled through the LPTIM_IER register:

- Compare match
- Auto-reload match (whatever the direction if encoder mode)
- External trigger event
- Autoreload register write completed
- Compare register write completed
- Direction change (encoder mode), programmable (up / down / both).

*Note:* If any bit in the LPTIM_IER register (Interrupt Enable Register) is set after that its corresponding flag in the LPTIM_ISR register (Status Register) is set, the interrupt is not asserted.

**Table 358. Interrupt events**

</tbody>
</table>

42.7 LPTIM registers

42.7.1 LPTIM interrupt and status register (LPTIM_ISR)

Address offset: 0x000

Reset value: 0x0000 0000
Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **DOWN**: Counter direction change up to down
In Encoder mode, DOWN bit is set by hardware to inform application that the counter direction has changed from up to down. DOWN flag can be cleared by writing 1 to the DOWNCF bit in the LPTIM_ICR register.

*Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Please refer to Section 42.3: LPTIM implementation.*

Bit 5 **UP**: Counter direction change down to up
In Encoder mode, UP bit is set by hardware to inform application that the counter direction has changed from down to up. UP flag can be cleared by writing 1 to the UPCF bit in the LPTIM_ICR register.

*Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Please refer to Section 42.3: LPTIM implementation.*

Bit 4 **ARROK**: Autoreload register update OK
ARROK is set by hardware to inform application that the APB bus write operation to the LPTIM_ARR register has been successfully completed. ARROK flag can be cleared by writing 1 to the ARROKCF bit in the LPTIM_ICR register.

Bit 3 **CMPOK**: Compare register update OK
CMPOK is set by hardware to inform application that the APB bus write operation to the LPTIM_CMP register has been successfully completed.

Bit 2 **EXTTRIG**: External trigger edge event
EXTTRIG is set by hardware to inform application that a valid edge on the selected external trigger input has occurred. If the trigger is ignored because the timer has already started, then this flag is not set. EXTTRIG flag can be cleared by writing 1 to the EXTTRIGCF bit in the LPTIM_ICR register.

Bit 1 **ARRM**: Autoreload match
ARRM is set by hardware to inform application that LPTIM_CNT register’s value reached the LPTIM_ARR register’s value. ARRM flag can be cleared by writing 1 to the ARRMCF bit in the LPTIM_ICR register.

Bit 0 **CMPM**: Compare match
The CMPM bit is set by hardware to inform application that LPTIM_CNT register value reached the LPTIM_CMP register’s value.

Bits 31:9 Reserved, must be kept at reset value.

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **DOWNCF**: Direction change to down clear flag
Writing 1 to this bit clears the DOWN flag in the LPTIM_ISR register.

Note: *If the LPTIM does not support encoder mode feature, this bit is reserved. Please refer to Section 42.3: LPTIM implementation.*

Bit 5 **UPCF**: Direction change to UP clear flag
Writing 1 to this bit clears the UP flag in the LPTIM_ISR register.

Note: *If the LPTIM does not support encoder mode feature, this bit is reserved. Please refer to Section 42.3: LPTIM implementation.*

Bit 4 **ARROKCF**: Autoreload register update OK clear flag
Writing 1 to this bit clears the ARROK flag in the LPTIM_ISR register

Bit 3 **CMPOKCF**: Compare register update OK clear flag
Writing 1 to this bit clears the CMPOK flag in the LPTIM_ISR register

Bit 2 **EXTTRIGCF**: External trigger valid edge clear flag
Writing 1 to this bit clears the EXTTRIG flag in the LPTIM_ISR register

Bit 1 **ARRMCF**: Autoreload match clear flag
Writing 1 to this bit clears the ARRM flag in the LPTIM_ISR register

Bit 0 **CMPMCF**: Compare match clear flag
Writing 1 to this bit clears the CMP flag in the LPTIM_ISR register

### 42.7.3 LPTIM interrupt enable register (LPTIM_IER)

Address offset: 0x008
Reset value: 0x0000 0000

*Bits 31:30* Reserved, must be kept at reset value.

*Bit 29* Reserved, must be kept at reset value.

*Bits 28:25* Reserved, must be kept at reset value.

*Bit 24** ENC**: Encoder mode enable
  - The ENC bit controls the Encoder mode
  - 0: Encoder mode disabled
  - 1: Encoder mode enabled

*Note:* If the LPTIM does not support encoder mode feature, this bit is reserved. Please refer to Section 42.3: LPTIM implementation.
Bit 23 **COUNTMODE**: counter mode enabled
The COUNTMODE bit selects which clock source is used by the LPTIM to clock the counter:
0: the counter is incremented following each internal clock pulse
1: the counter is incremented following each valid clock pulse on the LPTIM external Input1

Bit 22 **PRELOAD**: Registers update mode
The PRELOAD bit controls the LPTIM_ARR and the LPTIM_CMP registers update modality
0: Registers are updated after each APB bus write access
1: Registers are updated at the end of the current LPTIM period

Bit 21 **WAVPOL**: Waveform shape polarity
The WAVEPOL bit controls the output polarity
0: The LPTIM output reflects the compare results between LPTIM_ARR and LPTIM_CMP registers
1: The LPTIM output reflects the inverse of the compare results between LPTIM_ARR and LPTIM_CMP registers

Bit 20 **WAVE**: Waveform shape
The WAVE bit controls the output shape
0: Deactivate Set-once mode, PWM or One Pulse waveform depending on how the timer was started, CNTSTRT for PWM or SNGSTRT for One Pulse waveform.
1: Activate the Set-once mode

Bit 19 **TIMOUT**: Timeout enable
The TIMOUT bit controls the Timeout feature
0: A trigger event arriving when the timer is already started will be ignored
1: A trigger event arriving when the timer is already started will reset and restart the counter

Bits 18:17 **TRIGEN[1:0]**: Trigger enable and polarity
The TRIGEN bits controls whether the LPTIM counter is started by an external trigger or not. If the external trigger option is selected, three configurations are possible for the trigger active edge:
00: software trigger (counting start is initiated by software)
01: rising edge is the active edge
10: falling edge is the active edge
11: both edges are active edges

Bit 16 Reserved, must be kept at reset value.

Bits 15:13 **TRIGSEL[2:0]**: Trigger selector
The TRIGSEL bits select the trigger source that will serve as a trigger event for the LPTIM among the below 8 available sources:
000: lptim_ext_trig0
001: lptim_ext_trig1
010: lptim_ext_trig2
011: lptim_ext_trig3
100: lptim_ext_trig4
101: lptim_ext_trig5
110: lptim_ext_trig6
111: lptim_ext_trig7
See Section 42.4.3: LPTIM input and trigger mapping for details.

Bit 12 Reserved, must be kept at reset value.
Bits 11:9 **PRES**C[2:0]: Clock prescaler  
The PRES bits configure the prescaler division factor. It can be one among the following division factors:
- 000: /1  
- 001: /2  
- 010: /4  
- 011: /8  
- 100: /16  
- 101: /32  
- 110: /64  
- 111: /128  

Bit 8 Reserved, must be kept at reset value.

Bits 7:6 **TRGFL**T[1:0]: Configurable digital filter for trigger  
The TRGFLT value sets the number of consecutive equal samples that should be detected when a level change occurs on an internal trigger before it is considered as a valid level transition. An internal clock source must be present to use this feature.
- 00: any trigger active level change is considered as a valid trigger  
- 01: trigger active level change must be stable for at least 2 clock periods before it is considered as valid trigger.  
- 10: trigger active level change must be stable for at least 4 clock periods before it is considered as valid trigger.  
- 11: trigger active level change must be stable for at least 8 clock periods before it is considered as valid trigger.

Bit 5 Reserved, must be kept at reset value.
Bits 4:3 **CKFLT[1:0]:** Configurable digital filter for external clock

The CKFLT value sets the number of consecutive equal samples that should be detected when a level change occurs on an external clock signal before it is considered as a valid level transition. An internal clock source must be present to use this feature.

- 00: any external clock signal level change is considered as a valid transition
- 01: external clock signal level change must be stable for at least 2 clock periods before it is considered as valid transition.
- 10: external clock signal level change must be stable for at least 4 clock periods before it is considered as valid transition.
- 11: external clock signal level change must be stable for at least 8 clock periods before it is considered as valid transition.

Bits 2:1 **CKPOL[1:0]:** Clock Polarity

If LPTIM is clocked by an external clock source:

When the LPTIM is clocked by an external clock source, CKPOL bits is used to configure the active edge or edges used by the counter:

- 00: the rising edge is the active edge used for counting.
- 01: the falling edge is the active edge used for counting.
- 10: both edges are active edges. When both external clock signal edges are considered active ones, the LPTIM must also be clocked by an internal clock source with a frequency equal to at least four times the external clock frequency.
- 11: not allowed

Refer to Section 42.4.15: Encoder mode for more details about Encoder mode sub-modes.

Bit 0 **CKSEL:** Clock selector

The CKSEL bit selects which clock source the LPTIM will use:

- 0: LPTIM is clocked by internal clock source (APB clock or any of the embedded oscillators)
- 1: LPTIM is clocked by an external clock source through the LPTIM external Input1

Caution: The LPTIM_CFGR register must only be modified when the LPTIM is disabled (ENABLE bit reset to ‘0’).

42.7.5 **LPTIM control register (LPTIM_CR)**

Address offset: 0x010

Reset value: 0x0000 0000

</tbody>
</table>
```
Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **RSTARE**: Reset after read enable

This bit is set and cleared by software. When RSTARE is set to ‘1’, any read access to LPTIM_CNT register will asynchronously reset LPTIM_CNT register content.

**Caution:** This bitfield is write-only. This means that the bit cannot be read back to verify the value which has been written. As an example, if this bit is set to 1, attempting to read it back will return 0 even if the "Reset after read" function is enabled (due to the fact that this bitfield has previously been written to 1). To turn off the "Reset after read" or to make sure that it has already been turned off, this bit should be reset (by programming it to 0) even if it already contains 0.

Bit 3 **COUNTRST**: Counter reset

This bit is set by software and cleared by hardware. When set to ‘1’ this bit will trigger a synchronous reset of the LPTIM_CNT counter register. Due to the synchronous nature of this reset, it only takes place after a synchronization delay of 3 LPTimer core clock cycles (LPTimer core clock may be different from APB clock).

**Caution:** COUNTRST must never be set to ‘1’ by software before it is already cleared to ‘0’ by hardware. Software should consequently check that COUNTRST bit is already cleared to ‘0’ before attempting to set it to ‘1’.

Bit 2 **CNTSTRT**: Timer start in Continuous mode

This bit is set by software and cleared by hardware.

In case of software start (TRIGEN[1:0] = ‘00’), setting this bit starts the LPTIM in Continuous mode. If the software start is disabled (TRIGEN[1:0] different than ‘00’), setting this bit starts the timer in Continuous mode as soon as an external trigger is detected.

If this bit is set when a single pulse mode counting is ongoing, then the timer will not stop at the next match between the LPTIM_ARR and LPTIM_CNT registers and the LPTIM counter keeps counting in Continuous mode.

This bit can be set only when the LPTIM is enabled. It will be automatically reset by hardware.

Bit 1 **SNGSTRT**: LPTIM start in Single mode

This bit is set by software and cleared by hardware.

In case of software start (TRIGEN[1:0] = ‘00’), setting this bit starts the LPTIM in single pulse mode. If the software start is disabled (TRIGEN[1:0] different than ‘00’), setting this bit starts the LPTIM in single pulse mode as soon as an external trigger is detected.

If this bit is set when the LPTIM is in continuous counting mode, then the LPTIM will stop at the following match between LPTIM_ARR and LPTIM_CNT registers.

This bit can only be set when the LPTIM is enabled. It will be automatically reset by hardware.

Bit 0 **ENABLE**: LPTIM enable

The ENABLE bit is set and cleared by software.

0: LPTIM is disabled
1: LPTIM is enabled
42.7.6  LPTIM compare register (LPTIM_CMP)

</tbody>
</table>

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **CNT[15:0]:** Counter value

When the LPTIM is running with an asynchronous clock, reading the LPTIM_CNT register may return unreliable values. So in this case it is necessary to perform two consecutive read accesses and verify that the two returned values are identical.

It should be noted that for a reliable LPTIM_CNT register read access, two consecutive read accesses must be performed and compared. A read access can be considered reliable when the values of the two consecutive read accesses are equal.

42.7.9  LPTIM configuration register 2 (LPTIM_CFRG2)

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:4 **IN2SEL[1:0]:** LPTIM input 2 selection

The IN2SEL bits control the LPTIM Input 2 multiplexer, which connect LPTIM Input 2 to one of the available inputs.

00: lptim_in2_mux0
01: lptim_in2_mux1
10: lptim_in2_mux2
11: lptim_in2_mux3

For connection details refer to [Section 42.4.3: LPTIM input and trigger mapping](#).

**Note:** If the LPTIM does not support encoder mode feature, these bits are reserved. Please refer to [Section 42.3: LPTIM implementation](#).

Bits 3:2 Reserved, must be kept at reset value.
### 42.7.10 LPTIM3 configuration register 2 (LPTIM3_CFG2R)

**Address offset:** 0x024  
**Reset value:** 0x0000 0000

<table>

1. If LPTIM does not support encoder mode feature, this bit is reserved. Please refer to Section 42.3: LPTIM implementation.
43 System window watchdog (WWDG)

43.1 Introduction

The system window watchdog (WWDG) is used to detect the occurrence of a software fault, usually generated by external interference or by unforeseen logical conditions, which causes the application program to abandon its normal sequence. The watchdog circuit generates a reset on expiry of a programmed time period, unless the program refreshes the contents of the downcounter before the T6 bit becomes cleared. A reset is also generated if the 7-bit downcounter value (in the control register) is refreshed before the downcounter has reached the window register value. This implies that the counter must be refreshed in a limited window.

The WWDG clock is prescaled from the APB clock and has a configurable time-window that can be programmed to detect abnormally late or early application behavior. The WWDG is best suited for applications which require the watchdog to react within an accurate timing window.

43.2 WWDG main features

- Programmable free-running downcounter
- Conditional reset
  - Reset (if watchdog activated) when the downcounter value becomes lower than 0x40
  - Reset (if watchdog activated) if the downcounter is reloaded outside the window (see Figure 532)
- Early wakeup interrupt (EWI): triggered (if enabled and the watchdog activated) when the downcounter is equal to 0x40.

43.3 WWDG functional description

If the watchdog is activated (the WDGA bit is set in the WWDG_CR register) and when the 7-bit downcounter (T[6:0] bits) is decremented from 0x40 to 0x3F (T6 becomes cleared), it initiates a reset. If the software reloads the counter while the counter is greater than the value stored in the window register, then a reset is generated.

The application program must write in the WWDG_CR register at regular intervals during normal operation to prevent a reset. This operation must occur only when the counter value is lower than the window register value and higher than 0x3F. The value to be stored in the WWDG_CR register must be between 0xFF and 0xC0.

Refer to Figure 531 and to Section 43.3.2: WWDG internal signals for the WWDG block diagram.
43.3.1 **WWDG block diagram**

![WWDG block diagram](image)

43.3.2 **WWDG internal signals**

*Table 360* gives the list of WWDG internal signals.

43.3.3 **Enabling the watchdog**

*Table 360. WWDG internal input/output signals*

<table>
<thead>
<tr>

<td>Digital output</td>
<td>WWDG reset signal output</td>
</tr>
<tr>
<td>wwdg_it</td>
<td>Digital output</td>
<td>WWDG early interrupt output</td>
</tr>
</tbody>
</table>

The watchdog is always disabled after a reset. It is enabled by setting the WDGA bit in the WWDG_CR register, then it cannot be disabled again except by a reset.

43.3.4 **Controlling the downcounter**

This downcounter is free-running, counting down even if the watchdog is disabled. When the watchdog is enabled, the T6 bit must be set to prevent generating an immediate reset.

The T[5:0] bits contain the number of increments which represents the time delay before the watchdog produces a reset. The timing varies between a minimum and a maximum value due to the unknown status of the prescaler when writing to the WWDG_CR register (see *Figure 532*). The Configuration register (WWDG_CFR) contains the high limit of the window: To prevent a reset, the downcounter must be reloaded when its value is lower than the window register value and greater than 0x3F. *Figure 532* describes the window watchdog process.
Note: The T6 bit can be used to generate a software reset (the WDGA bit is set and the T6 bit is cleared).

43.3.5 Advanced watchdog interrupt feature

The early wakeup interrupt (EWI) can be used if specific safety operations or data logging must be performed before the actual reset is generated. The EWI interrupt is enabled by setting the EWI bit in the WWDG_CFR register. When the downcounter reaches the value 0x40, an EWI interrupt is generated and the corresponding interrupt service routine (ISR) can be used to trigger specific actions (such as communications or data logging), before resetting the device.

In some applications, the EWI interrupt can be used to manage a software system check and/or system recovery/graceful degradation, without generating a WWDG reset. In this case, the corresponding interrupt service routine (ISR) should reload the WWDG counter to avoid the WWDG reset, then trigger the required actions.

The EWI interrupt is cleared by writing '0' to the EWIF bit in the WWDG_SR register.

Note: When the EWI interrupt cannot be served, e.g. due to a system lock in a higher priority task, the WWDG reset is eventually generated.

43.3.6 How to program the watchdog timeout

Use the formula in Figure 532 to calculate the WWDG timeout.

Warning: When writing to the WWDG_CR register, always write 1 in the T6 bit to avoid generating an immediate reset.
Figure 532. Window watchdog timing diagram

The formula to calculate the timeout value is given by:

\[ t_{\text{WWDG}} = t_{\text{PCLK}} \times 4096 \times 2^{\text{WDGTB}[2:0]} \times (T[5:0] + 1) \] (ms)

where:
- \( t_{\text{WWDG}} \): WWDG timeout
- \( t_{\text{PCLK}} \): APB clock period measured in ms
- 4096: value corresponding to internal divider

As an example, let's assume APB frequency is equal to 48 MHz, WDGTB[2:0] is set to 3 and T[5:0] is set to 63:

\[ t_{\text{WWDG}} = \frac{1}{48000} \times 4096 \times 2^3 \times (63 + 1) = 43.69 \text{ ms} \]

Refer to the datasheet for the minimum and maximum values of the \( t_{\text{WWDG}} \).

43.3.7 Debug mode

When the CPU enters debug mode, WWDG1 counter either continues to work normally or stops, depending on DBGMCU_APB3LFZ1. For more details, refer to Section 59: Debug infrastructure.
43.4 WWDG registers

Refer to Section 1.2 on page 98 for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by halfwords (16-bit) or words (32-bit).

43.4.3 Status register (WWDG_SR)

Address offset: 0x008
Reset value: 0x0000 0000

```
01111111
```

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:11 **WDGTB[2:0]:** Timer base

The timebase of the prescaler can be modified as follows:
- 000: CK Counter Clock (PCLK div 4096) div 1
- 001: CK Counter Clock (PCLK div 4096) div 2
- 010: CK Counter Clock (PCLK div 4096) div 4
- 011: CK Counter Clock (PCLK div 4096) div 8
- 100: CK Counter Clock (PCLK div 4096) div 16
- 101: CK Counter Clock (PCLK div 4096) div 32
- 110: CK Counter Clock (PCLK div 4096) div 64
- 111: CK Counter Clock (PCLK div 4096) div 128

Bit 10 Reserved, must be kept at reset value.

Bit 9 **EWI:** Early wakeup interrupt

When set, an interrupt occurs whenever the counter reaches the value 0x40. This interrupt is only cleared by hardware after a reset.

Bits 8:7 Reserved, must be kept at reset value.

Bits 6:0 **W[6:0]:** 7-bit window value

These bits contain the window value to be compared with the downcounter.

43.4.4 WWDG register map

Bit 31:1 Reserved, must be kept at reset value.

Bit 0 **EWIF:** Early wakeup interrupt flag

This bit is set by hardware when the counter has reached the value 0x40. It must be cleared by software by writing '0'. Writing '1' has no effect. This bit is also set if the interrupt is not enabled.
Refer to *Section 2.3 on page 126* for the register boundary addresses.
44 Independent watchdog (IWDG)

44.1 Introduction

The devices feature an embedded watchdog peripheral that offers a combination of high safety level, timing accuracy and flexibility of use. The independent watchdog peripheral detects and solves malfunctions due to software failure, and triggers system reset when the counter reaches a given timeout value.

The independent watchdog (IWDG) is clocked by its own dedicated low-speed clock (LSI) and thus stays active even if the main clock fails.

The IWDG is best suited for applications that require the watchdog to run as a totally independent process outside the main application, but have lower timing accuracy constraints. For further information on the window watchdog, refer to Section 43 on page 1890.

44.2 IWDG main features

- Free-running downcounter
- Clocked from an independent RC oscillator (can operate in Standby and Stop modes)
- Conditional Reset
  - Reset (if watchdog activated) when the downcounter value becomes lower than 0x000
  - Reset (if watchdog activated) if the downcounter is reloaded outside the window

44.3 IWDG functional description

44.3.1 IWDG block diagram

*Figure 533* shows the functional blocks of the independent watchdog module.

*Figure 533. Independent watchdog block diagram*

1. The register interface is located in the $V_{DD}$ voltage domain. The watchdog function is located in the $V_{DD}$ voltage domain, still functional in Stop and Standby modes.
When the independent watchdog is started by writing the value 0x0000 CCCC in the **IWDG key register (IWDG_KR)**, the counter starts counting down from the reset value of 0xFFF. When it reaches the end of count value (0x000) a reset signal is generated (IWDG reset).

Whenever the key value 0x0000 AAAA is written in the **IWDG key register (IWDG_KR)**, the IWDG_RLR value is reloaded in the counter and the watchdog reset is prevented.

Once running, the IWDG cannot be stopped.

### 44.3.2 IWDG internal signals

*Table 362* gives the list of IWDG internal signals.

<table>
<thead>
<tr>
<th>Signal name</th>
<th>Signal type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lsi_ck</td>
<td>Digital input</td>
<td>LSI clock</td>
</tr>
<tr>
<td>iwdg1_out_rst</td>
<td>Digital output</td>
<td>IWDG1 reset signal output</td>
</tr>
</tbody>
</table>

### 44.3.3 Window option

The IWDG can also work as a window watchdog by setting the appropriate window in the **IWDG window register (IWDG_WINR)**.

If the reload operation is performed while the counter is greater than the value stored in the **IWDG window register (IWDG_WINR)**, then a reset is provided.

The default value of the **IWDG window register (IWDG_WINR)** is 0x0000 0FF, so if it is not updated, the window option is disabled.

As soon as the window value is changed, a reload operation is performed in order to reset the downcounter to the **IWDG reload register (IWDG_RLR)** value and ease the cycle number calculation to generate the next reload.

**Configuring the IWDG when the window option is enabled**

1. Enable the IWDG by writing 0x0000 CCCC in the **IWDG key register (IWDG_KR)**.
2. Enable register access by writing 0x0000 5555 in the **IWDG key register (IWDG_KR)**.
3. Write the IWDG prescaler by programming **IWDG prescaler register (IWDG_PR)** from 0 to 7.
4. Write the **IWDG reload register (IWDG_RLR)**.
5. Wait for the registers to be updated (IWDG_SR = 0x0000 0000).
6. Write to the **IWDG window register (IWDG_WINR)**. This automatically refreshes the counter value in the **IWDG reload register (IWDG_RLR)**.

**Note:** Writing the window value allows to refresh the Counter value by the RLR when IWDG status register (IWDG_SR) is set to 0x0000 0000.

**Configuring the IWDG when the window option is disabled**

When the window option it is not used, the IWDG can be configured as follows:
1. Enable the IWDG by writing 0x0000 CCCC in the **IWDG key register (IWDG_KR)**.
2. Enable register access by writing 0x0000 5555 in the **IWDG key register (IWDG_KR)**.
3. Write the prescaler by programming the **IWDG prescaler register (IWDG_PR)** from 0 to 7.
4. Write the **IWDG reload register (IWDG_RLR)**.
5. Wait for the registers to be updated (**IWDG_SR = 0x0000 0000**).
6. Refresh the counter value with IWDG_RLR (**IWDG_KR = 0x0000 AAAA**).

### 44.3.4 Hardware watchdog

If the “Hardware watchdog” feature is enabled through the device option bits, the watchdog is automatically enabled at power-on, and generates a reset unless the **IWDG key register (IWDG_KR)** is written by the software before the counter reaches end of count or if the downcounter is reloaded inside the window.

### 44.3.5 Low-power freeze

Depending on the IWDG_FZ_STOP and IWDG_FZ_STBY options configuration, the IWDG can continue counting or not during the Stop mode and the Standby mode, respectively. If the IWDG is kept running during Stop or Standby modes, it can wake up the device from this mode. Refer to **Section : User and read protection option bytes** for more details.

### 44.3.6 Register access protection

Write access to **IWDG prescaler register (IWDG_PR)**, **IWDG reload register (IWDG_RLR)** and **IWDG window register (IWDG_WINR)** is protected. To modify them, the user must first write the code 0x0000 5555 in the **IWDG key register (IWDG_KR)**. A write access to this register with a different value will break the sequence and register access will be protected again. This is the case of the reload operation (writing 0x0000 AAAA).

A status register is available to indicate that an update of the prescaler or the down-counter reload value or the window value is on going.

### 44.3.7 Debug mode

When the device enters Debug mode (core halted), the IWDG counter either continues to work normally or stops, depending on the configuration of the corresponding bit in DBGMCU freeze register.
44.4 IWDG registers

Refer to Section 1.2 on page 98 for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

44.4.1 IWDG key register (IWDG_KR)

Address offset: 0x00

Reset value: 0x0000 0000 (reset by Standby mode)

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 KEY[15:0]: Key value (write only, read 0x0000)

These bits must be written by software at regular intervals with the key value 0xAAAA, otherwise the watchdog generates a reset when the counter reaches 0.

Writing the key value 0x5555 to enable access to the IWDG_PR, IWDG_RLR and IWDG_WINR registers (see Section 44.3.6: Register access protection)

Writing the key value 0xC000 starts the watchdog (except if the hardware watchdog option is selected)
44.4.2  IWDG prescaler register (IWDG_PR)

Address offset: 0x04
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bits 31:3</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits 2:0</td>
<td>PR[2:0]: Prescaler divider</td>
</tr>
</tbody>
</table>

These bits are write access protected see Section 44.3.6: Register access protection. They are written by software to select the prescaler divider feeding the counter clock. PVU bit of the IWDG status register (IWDG_SR) must be reset in order to be able to change the prescaler divider.

000: divider /4
001: divider /8
010: divider /16
011: divider /32
100: divider /64
101: divider /128
110: divider /256
111: divider /256

Note: Reading this register returns the prescaler value from the VDD voltage domain. This value may not be up to date/valid if a write operation to this register is ongoing. For this reason the value read from this register is valid only when the PVU bit in the IWDG status register (IWDG_SR) is reset.
### 44.4.3 IWDG reload register (IWDG_RLR)

Address offset: 0x08

Reset value: 0x0000 0FFF (reset by Standby mode)

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **RL[11:0]:** Watchdog counter reload value

These bits are write access protected see *Register access protection*. They are written by software to define the value to be loaded in the watchdog counter each time the value 0xAAAA is written in the *IWDG key register (IWDG_KR)*. The watchdog counter counts down from this value. The timeout period is a function of this value and the clock prescaler. Refer to the datasheet for the timeout information.

The RVU bit in the *IWDG status register (IWDG_SR)* must be reset to be able to change the reload value.

**Note:** Reading this register returns the reload value from the VDD voltage domain. This value may not be up to date/valid if a write operation to this register is ongoing on it. For this reason the value read from this register is valid only when the RVU bit in the *IWDG status register (IWDG_SR)* is reset.
44.4.4  IWDG status register (IWDG_SR)

Address offset: 0x0C
Reset value: 0x0000 0000 (not reset by Standby mode)

Note: If several reload, prescaler, or window values are used by the application, it is mandatory to wait until RVU bit is reset before changing the reload value, to wait until PVU bit is reset before changing the prescaler value, and to wait until WVU bit is reset before changing the window value. However, after updating the prescaler and/or the reload/window value it is not necessary to wait until RVU or PVU or WVU is reset before continuing code execution except in case of low-power mode entry.
44.4.5  IWDG window register (IWDG_WINR)

Address offset: 0x10
Reset value: 0x0000 0FFF (reset by Standby mode)

</tbody>
</table>

Bits 31:12  Reserved, must be kept at reset value.

Bits 11:0  **WIN[11:0]**: Watchdog counter window value

These bits are write access protected, see Section 44.3.6, they contain the high limit of the window value to be compared with the downcounter.

To prevent a reset, the downcounter must be reloaded when its value is lower than the window register value and greater than 0x0

The WVU bit in the **IWDG status register (IWDG_SR)** must be reset in order to be able to change the reload value.

**Note:** Reading this register returns the reload value from the VDD voltage domain. This value may not be valid if a write operation to this register is ongoing. For this reason the value read from this register is valid only when the WVU bit in the **IWDG status register (IWDG_SR)** is reset.
44.4.6  IWDG register map

The following table gives the IWDG register map and reset values.

Table 363. IWDG register map and reset values

| Offset | Register name  | Register name  | Offset | Register name  | Offset | Register name  | Offset | Register name  | Offset | Register name  | Offset | Register name  | Offset | Register name  | Offset | Register name  | Offset | Register name  | Offset | Register name  | Offset | Register name  | Offset | Register name  | Offset | Register name  | Offset |

|        |                |                |        |                |        |                |        | RL[11:0]       |        |                |        |                |        |                |        |                |        |                |        |                |        |                |        |                |        |                |        |                |        |                |        |                |        |                |
|        |                |                |        |                |        |                |        |                |        |                |        |                |        |                |        |                |        |                |        |                |        |                |        |                |        |                |        |                |        |                |        |                |        |                |

Refer to Section 2.3 on page 126 for the register boundary addresses.
45 Real-time clock (RTC)

45.1 Introduction

The RTC provides an automatic wakeup to manage all low-power modes.

The real-time clock (RTC) is an independent BCD timer/counter. The RTC provides a time-of-day clock/calendar with programmable alarm interrupts.

The RTC includes also a periodic programmable wakeup flag with interrupt capability.

Two 32-bit registers contain the seconds, minutes, hours (12- or 24-hour format), day (day of week), date (day of month), month, and year, expressed in binary coded decimal format (BCD). The sub-seconds value is also available in binary format.

Compensations for 28-, 29- (leap year), 30-, and 31-day months are performed automatically. Daylight saving time compensation can also be performed.

Additional 32-bit registers contain the programmable alarm subseconds, seconds, minutes, hours, day, and date.

A digital calibration feature is available to compensate for any deviation in crystal oscillator accuracy.

After Backup domain reset, all RTC registers are protected against possible parasitic write accesses.

As long as the supply voltage remains in the operating range, the RTC never stops, regardless of the device status (Run mode, low-power mode or under reset).
45.2 RTC main features

The RTC unit main features are the following (see Figure 535: Detailed RTC block diagram):

- Calendar with subseconds, seconds, minutes, hours (12 or 24 format), day (day of week), date (day of month), month, and year.
- Daylight saving compensation programmable by software.
- Programmable alarm with interrupt function. The alarm can be triggered by any combination of the calendar fields.
- Automatic wakeup unit generating a periodic flag that triggers an automatic wakeup interrupt.
- Reference clock detection: a more precise second source clock (50 or 60 Hz) can be used to enhance the calendar precision.
- Accurate synchronization with an external clock using the subsecond shift feature.
- Digital calibration circuit (periodic counter correction): 0.95 ppm accuracy, obtained in a calibration window of several seconds.
- Time-stamp function for event saving
- Tamper detection event with configurable filter and internal pull-up
- Maskable interrupts/events:
  - Alarm A
  - Alarm B
  - Wakeup interrupt
  - Time-stamp
  - Tamper detection
- 32 backup registers.

45.3 RTC functional description

45.3.1 RTC block diagram

Figure 534. RTC block overview
Figure 535. Detailed RTC block diagram
The RTC includes:

- Two alarms
- Three tamper events from I/Os
  - Tamper detection erases the backup registers and the backup RAM.
  - In addition, the tamper detection forbids software access to the backup SRAM until its erase operation is finished. Refer to Section 45.3.15: Tamper detection
  - The tamper3 event detection is generated either by an event on I/O, or by an over or under voltage of the RTC power supply domain, or by an over or under temperature detection. These voltage and temperature monitor detections are enabled in the PWR control register 2 (PWR_CR2).
- One timestamp event from I/O
- Tamper event detection can generate a timestamp event
- Timestamp can be generated when a switch to VBAT occurs
- 32 x 32-bit backup registers
  - The backup registers (RTC_BKPxR) are implemented in the RTC domain that remains powered-on by VBAT when the VDD power is switched off.
- Output functions: RTC_OUT which selects one of the following two outputs:
  - RTC_CALIB: 512 Hz or 1Hz clock output (with an LSE frequency of 32.768 kHz). This output is enabled by setting the COE bit in the RTC_CR register.
  - RTC_ALARM: This output is enabled by configuring the OSEL[1:0] bits in the RTC_CR register which select the Alarm A, Alarm B or Wakeup outputs.
- Input functions:
  - RTC_TS: timestamp event
  - RTC_TAMP1: tamper1 event detection
  - RTC_TAMP2: tamper2 event detection
  - RTC_TAMP3: tamper3 event detection
  - RTC_REFIN: 50 or 60 Hz reference clock input

</table>
45.3.3 GPIOs controlled by the RTC

RTC_OUT, RTC_TS and RTC_TAMP1 are mapped on the same pin (PC13). PC13 pin configuration is controlled by the RTC, whatever the PC13 GPIO configuration, except for the RTC_ALARM output open-drain mode. The RTC functions mapped on PC13 are available in all low-power modes and in VBAT mode.

The output mechanism follows the priority order shown in Table 365.

<table>

In addition, it is possible to remap RTC_OUT on PB2 pin thanks to RTC_OUT_RMP bit. In this case it is mandatory to configure PB2 GPIO registers as alternate function with the correct type. The remap functions are shown in Table 366.

45.3.4 Clock and prescalers

The RTC clock source (RTCCLK) is selected through the clock controller among the LSE clock, the LSI oscillator clock, and the HSE clock. For more information on the RTC clock source configuration, refer to Section 7: Reset and Clock Control (RCC).

A programmable prescaler stage generates a 1 Hz clock which is used to update the calendar. To minimize power consumption, the prescaler is split into 2 programmable prescalers (see Figure 535: Detailed RTC block diagram):

- A 7-bit asynchronous prescaler configured through the PREDIV_A bits of the RTC_PRER register.
- A 15-bit synchronous prescaler configured through the PREDIV_S bits of the RTC_PRER register.

Note: When both prescalers are used, it is recommended to configure the asynchronous prescaler to a high value to minimize consumption.

The asynchronous prescaler division factor is set to 128, and the synchronous division factor to 256, to obtain an internal clock frequency of 1 Hz (ck_spre) with an LSE frequency of 32.768 kHz.

The minimum division factor is 1 and the maximum division factor is $2^{22}$.

This corresponds to a maximum input frequency of around 4 MHz.

$f_{ck\_apre}$ is given by the following formula:

$$ f_{ck\_apre} = \frac{f_{RTCCLK}}{PREDIV\_A + 1} $$

The $ck\_apre$ clock is used to clock the binary RTC_SSR subseconds downcounter. When it reaches 0, RTC_SSR is reloaded with the content of PREDIV_S.

$f_{ck\_spre}$ is given by the following formula:

$$ f_{ck\_spre} = \frac{f_{RTCCLK}}{(PREDIV\_S + 1) \times (PREDIV\_A + 1)} $$

The $ck\_spre$ clock can be used either to update the calendar or as timebase for the 16-bit wakeup auto-reload timer. To obtain short timeout periods, the 16-bit wakeup auto-reload timer can also run with the RTCCLK divided by the programmable 4-bit asynchronous prescaler (see Section 45.3.7: Periodic auto-wakeup for details).
45.3.5 **Real-time clock and calendar**

The RTC calendar time and date registers are accessed through shadow registers which are synchronized with PCLK (APB clock). They can also be accessed directly in order to avoid waiting for the synchronization duration.

- RTC_SSR for the subseconds
- RTC_TR for the time
- RTC_DR for the date

Every RTCCLK period, the current calendar value is copied into the shadow registers, and the RSF bit of RTC_ISR register is set (see Section 45.6.4: RTC initialization and status register (RTC_ISR)). The copy is not performed in Stop and Standby mode. When exiting these modes, the shadow registers are updated after up to 1 RTCCLK period.

When the application reads the calendar registers, it accesses the content of the shadow registers. It is possible to make a direct access to the calendar registers by setting the BYPSHAD control bit in the RTC_CR register. By default, this bit is cleared, and the user accesses the shadow registers.

When reading the RTC_SSR, RTC_TR or RTC_DR registers in BYPSHAD=0 mode, the frequency of the APB clock \(f_{APB}\) must be at least 7 times the frequency of the RTC clock \(f_{RTCCLK}\).

The shadow registers are reset by system reset.

45.3.6 **Programmable alarms**

The RTC unit provides programmable alarm: Alarm A and Alarm B. The description below is given for Alarm A, but can be translated in the same way for Alarm B.

The programmable alarm function is enabled through the ALRAE bit in the RTC_CR register. The ALRAF is set to 1 if the calendar subseconds, seconds, minutes, hours, date or day match the values programmed in the alarm registers RTC_ALRMASSR and RTC_ALRMAR. Each calendar field can be independently selected through the MSKx bits of the RTC_ALRMAR register, and through the MASKSSx bits of the RTC_ALRMASSR register. The alarm interrupt is enabled through the ALRAIE bit in the RTC_CR register.

**Caution:** If the seconds field is selected (MSK1 bit reset in RTC_ALRMAR), the synchronous prescaler division factor set in the RTC_PRER register must be at least 3 to ensure correct behavior.

Alarm A and Alarm B (if enabled by bits OSEL[1:0] in RTC_CR register) can be routed to the RTC_ALARM output. RTC_ALARM output polarity can be configured through bit POL the RTC_CR register.

45.3.7 **Periodic auto-wakeup**

The periodic wakeup flag is generated by a 16-bit programmable auto-reload down-counter. The wakeup timer range can be extended to 17 bits.

The wakeup function is enabled through the WUTE bit in the RTC_CR register.
The wakeup timer clock input can be:

- RTC clock (RTCCCLK) divided by 2, 4, 8, or 16.
  When RTCCCLK is LSE(32.768kHz), this allows to configure the wakeup interrupt period from 122 µs to 32 s, with a resolution down to 61 µs.
- ck_spre (usually 1 Hz internal clock)
  When ck_spre frequency is 1Hz, this allows to achieve a wakeup time from 1 s to around 36 hours with one-second resolution. This large programmable time range is divided in 2 parts:
  - from 1s to 18 hours when WUCKSEL[2:1] = 10
  - and from around 18h to 36h when WUCKSEL[2:1] = 11. In this last case 216 is added to the 16-bit counter current value. When the initialization sequence is complete (see Programming the wakeup timer on page 1915), the timer starts counting down. When the wakeup function is enabled, the down-counting remains active in low-power modes. In addition, when it reaches 0, the WUTF flag is set in the RTC_ISR register, and the wakeup counter is automatically reloaded with its reload value (RTC_WUTR register value).

The WUTF flag must then be cleared by software.

When the periodic wakeup interrupt is enabled by setting the WUTIE bit in the RTC_CR register, it can exit the device from low-power modes.

The periodic wakeup flag can be routed to the RTC_ALARM output provided it has been enabled through bits OSEL[1:0] of RTC_CR register. RTC_ALARM output polarity can be configured through the POL bit in the RTC_CR register.

System reset, as well as low-power modes (Sleep, Stop and Standby) have no influence on the wakeup timer.

45.3.8 RTC initialization and configuration

RTC register access

The RTC registers are 32-bit registers. The APB interface introduces 2 wait-states in RTC register accesses except on read accesses to calendar shadow registers when BYPSHAD=0.

RTC register write protection

After system reset, the RTC registers are protected against parasitic write access by clearing the DBP bit in the PWR_CR1 register (refer to the power control section). DBP bit must be set in order to enable RTC registers write access.

After Backup domain reset, all the RTC registers are write-protected. Writing to the RTC registers is enabled by writing a key into the Write Protection register, RTC_WPR.

The following steps are required to unlock the write protection on all the RTC registers except for RTC_TAMPCR, RTC_BKPxR, RTC_OR and RTC_ISR[13:8].
1. Write '0xCA' into the RTC_WPR register.
2. Write '0x53' into the RTC_WPR register.

Writing a wrong key reactivates the write protection.

The protection mechanism is not affected by system reset.
Calendar initialization and configuration

To program the initial time and date calendar values, including the time format and the prescaler configuration, the following sequence is required:

1. Set INIT bit to 1 in the RTC_ISR register to enter initialization mode. In this mode, the calendar counter is stopped and its value can be updated.
2. Poll INITF bit of in the RTC_ISR register. The initialization phase mode is entered when INITF is set to 1. It takes around 2 RTCCLK clock cycles (due to clock synchronization).
3. To generate a 1 Hz clock for the calendar counter, program both the prescaler factors in RTC_PRER register.
4. Load the initial time and date values in the shadow registers (RTC_TR and RTC_DR), and configure the time format (12 or 24 hours) through the FMT bit in the RTC_CR register.
5. Exit the initialization mode by clearing the INIT bit. The actual calendar counter value is then automatically loaded and the counting restarts after 4 RTCCLK clock cycles.

When the initialization sequence is complete, the calendar starts counting.

Note: After a system reset, the application can read the INITS flag in the RTC_ISR register to check if the calendar has been initialized or not. If this flag equals 0, the calendar has not been initialized since the year field is set at its Backup domain reset default value (0x00).

To read the calendar after initialization, the software must first check that the RSF flag is set in the RTC_ISR register.

Daylight saving time

The daylight saving time management is performed through bits SUB1H, ADD1H, and BKP of the RTC_CR register.

Using SUB1H or ADD1H, the software can subtract or add one hour to the calendar in one single operation without going through the initialization procedure.

In addition, the software can use the BKP bit to memorize this operation.

Programming the alarm

A similar procedure must be followed to program or update the programmable alarms. The procedure below is given for Alarm A but can be translated in the same way for Alarm B.

1. Clear ALRAE in RTC_CR to disable Alarm A.
2. Program the Alarm A registers (RTC_ALRMASSR/RTC_ALRMAR).
3. Set ALRAE in the RTC_CR register to enable Alarm A again.

Note: Each change of the RTC_CR register is taken into account after around 2 RTCCLK clock cycles due to clock synchronization.

Programming the wakeup timer

The following sequence is required to configure or change the wakeup timer auto-reload value (WUT[15:0] in RTC_WUTR):
1. Clear WUTE in RTC\_CR to disable the wakeup timer.
2. Poll WUTWF until it is set in RTC\_ISR to make sure the access to wakeup auto-reload counter and to WUCKSEL[2:0] bits is allowed. It takes around 2 RTCCCLK clock cycles (due to clock synchronization).
3. Program the wakeup auto-reload value WUT[15:0], and the wakeup clock selection (WUCKSEL[2:0] bits in RTC\_CR). Set WUTE in RTC\_CR to enable the timer again. The wakeup timer restarts down-counting. The WUTWF bit is cleared up to 2 RTCCCLK clock cycles after WUTE is cleared, due to clock synchronization.

45.3.9 Reading the calendar

When BYPSHAD control bit is cleared in the RTC\_CR register

To read the RTC calendar registers (RTC\_SSR, RTC\_TR and RTC\_DR) properly, the APB clock frequency ($f_{PCLK}$) must be equal to or greater than seven times the RTC clock frequency ($f_{RTCCCLK}$). This ensures a secure behavior of the synchronization mechanism.

If the APB clock frequency is less than seven times the RTC clock frequency, the software must read the calendar time and date registers twice. If the second read of the RTC\_TR gives the same result as the first read, this ensures that the data is correct. Otherwise a third read access must be done. In any case the APB clock frequency must never be lower than the RTC clock frequency.

The RSF bit is set in RTC\_ISR register each time the calendar registers are copied into the RTC\_SSR, RTC\_TR and RTC\_DR shadow registers. The copy is performed every RTCCCLK cycles. To ensure consistency between the 3 values, reading either RTC\_SSR or RTC\_TR locks the values in the higher-order calendar shadow registers until RTC\_DR is read. In case the software makes read accesses to the calendar in a time interval smaller than 1 RTCCCLK period: RSF must be cleared by software after the first calendar read, and then the software must wait until RSF is set before reading again the RTC\_SSR, RTC\_TR and RTC\_DR registers.

After waking up from low-power mode (Stop or Standby), RSF must be cleared by software. The software must then wait until it is set again before reading the RTC\_SSR, RTC\_TR and RTC\_DR registers.

The RSF bit must be cleared after wakeup and not before entering low-power mode.

After a system reset, the software must wait until RSF is set before reading the RTC\_SSR, RTC\_TR and RTC\_DR registers. Indeed, a system reset resets the shadow registers to their default values.

After an initialization (refer to Calendar initialization and configuration on page 1915): the software must wait until RSF is set before reading the RTC\_SSR, RTC\_TR and RTC\_DR registers.

After synchronization (refer to Section 45.3.11: RTC synchronization): the software must wait until RSF is set before reading the RTC\_SSR, RTC\_TR and RTC\_DR registers.

When the BYPSHAD control bit is set in the RTC\_CR register (bypass shadow registers)

Reading the calendar registers gives the values from the calendar counters directly, thus eliminating the need to wait for the RSF bit to be set. This is especially useful after exiting
from low-power modes (STOP or Standby), since the shadow registers are not updated during these modes.

When the BYPShAD bit is set to 1, the results of the different registers might not be coherent with each other if an RTCCLK edge occurs between two read accesses to the registers. Additionally, the value of one of the registers may be incorrect if an RTCCLK edge occurs during the read operation. The software must read all the registers twice, and then compare the results to confirm that the data is coherent and correct. Alternatively, the software can just compare the two results of the least-significant calendar register.

**Note:** While BYPShAD=1, instructions which read the calendar registers require one extra APB cycle to complete.

### 45.3.10 Resetting the RTC

The calendar shadow registers (RTC_SSR, RTC_TR and RTC_DR) and some bits of the RTC status register (RTC_ISR) are reset to their default values by all available system reset sources.

On the contrary, the following registers are reset to their default values by a Backup domain reset and are not affected by a system reset: the RTC current calendar registers, the RTC control register (RTC_CR), the prescaler register (RTC_PRER), the RTC calibration register (RTC_CALR), the RTC shift register (RTC_SHIFTR), the RTC timestamp registers (RTC_TSSSR, RTC_TSTR and RTC_TSDR), the RTC tamper configuration register (RTC_TAMPCR), the RTC backup registers (RTC_BKPxR), the wakeup timer register (RTC_WUTR), the Alarm A and Alarm B registers (RTC_ALRMASSR/RTC_ALRMAR and RTC_ALRMBSSR/RTC_ALRMBR), and the Option register (RTC_OR).

In addition, when it is clocked by the LSE, the RTC keeps on running under system reset if the reset source is different from the Backup domain reset one (refer to the RTC clock section of the Reset and clock controller for details on the list of RTC clock sources not affected by system reset). When a Backup domain reset occurs, the RTC is stopped and all the RTC registers are set to their reset values.

### 45.3.11 RTC synchronization

The RTC can be synchronized to a remote clock with a high degree of precision. After reading the sub-second field (RTC_SSR or RTC_TSSSR), a calculation can be made of the precise offset between the times being maintained by the remote clock and the RTC. The RTC can then be adjusted to eliminate this offset by “shifting” its clock by a fraction of a second using RTC_SHIFTR.

RTC_SSR contains the value of the synchronous prescaler counter. This allows one to calculate the exact time being maintained by the RTC down to a resolution of \( \frac{1}{(PREDIV_S + 1)} \) seconds. As a consequence, the resolution can be improved by increasing the synchronous prescaler value (PREDIV_S[14:0]). The maximum resolution allowed (30.52 μs with a 32768 Hz clock) is obtained with PREDIV_S set to 0x7FFF.

However, increasing PREDIV_S means that PREDIV_A must be decreased in order to maintain the synchronous prescaler output at 1 Hz. In this way, the frequency of the asynchronous prescaler output increases, which may increase the RTC dynamic consumption.

The RTC can be finely adjusted using the RTC shift control register (RTC_SHIFTR). Writing to RTC_SHIFTR can shift (either delay or advance) the clock by up to a second with a resolution of \( \frac{1}{(PREDIV_S + 1)} \) seconds. The shift operation consists of adding the
SUBFS[14:0] value to the synchronous prescaler counter SS[15:0]: this will delay the clock. If at the same time the ADD1S bit is set, this results in adding one second and at the same time subtracting a fraction of second, so this will advance the clock.

Caution: Before initiating a shift operation, the user must check that SS[15] = 0 in order to ensure that no overflow will occur.

As soon as a shift operation is initiated by a write to the RTC_SHIFTR register, the SHPF flag is set by hardware to indicate that a shift operation is pending. This bit is cleared by hardware as soon as the shift operation has completed.

Caution: This synchronization feature is not compatible with the reference clock detection feature: firmware must not write to RTC_SHIFTR when REFCKON=1.

45.3.12 RTC reference clock detection

The update of the RTC calendar can be synchronized to a reference clock, RTC_REFIN, which is usually the mains frequency (50 or 60 Hz). The precision of the RTC_REFIN reference clock should be higher than the 32.768 kHz LSE clock. When the RTC_REFIN detection is enabled (REFCKON bit of RTC_CR set to 1), the calendar is still clocked by the LSE, and RTC_REFIN is used to compensate for the imprecision of the calendar update frequency (1 Hz).

Each 1 Hz clock edge is compared to the nearest RTC_REFIN clock edge (if one is found within a given time window). In most cases, the two clock edges are properly aligned. When the 1 Hz clock becomes misaligned due to the imprecision of the LSE clock, the RTC shifts the 1 Hz clock a bit so that future 1 Hz clock edges are aligned. Thanks to this mechanism, the calendar becomes as precise as the reference clock.

The RTC detects if the reference clock source is present by using the 256 Hz clock (ck_apre) generated from the 32.768 kHz quartz. The detection is performed during a time window around each of the calendar updates (every 1 s). The window equals 7 ck_apre periods when detecting the first reference clock edge. A smaller window of 3 ck_apre periods is used for subsequent calendar updates.

Each time the reference clock is detected in the window, the synchronous prescaler which outputs the ck_spre clock is forced to reload. This has no effect when the reference clock and the 1 Hz clock are aligned because the prescaler is being reloaded at the same moment. When the clocks are not aligned, the reload shifts future 1 Hz clock edges a little for them to be aligned with the reference clock.

If the reference clock halts (no reference clock edge occurred during the 3 ck_apre window), the calendar is updated continuously based solely on the LSE clock. The RTC then waits for the reference clock using a large 7 ck_apre period detection window centered on the ck_spre edge.

When the RTC_REFIN detection is enabled, PREDIV_A and PREDIV_S must be set to their default values:

- PREDIV_A = 0x007F
- PREDIV_S = 0x00FF

Note: RTC_REFIN clock detection is not available in Standby mode.
45.3.13 RTC smooth digital calibration

The RTC frequency can be digitally calibrated with a resolution of about 0.954 ppm with a range from -487.1 ppm to +488.5 ppm. The correction of the frequency is performed using series of small adjustments (adding and/or subtracting individual RTCCLK pulses). These adjustments are fairly well distributed so that the RTC is well calibrated even when observed over short durations of time.

The smooth digital calibration is performed during a cycle of about $2^{20}$ RTCCLK pulses, or 32 seconds when the input frequency is 32768 Hz. This cycle is maintained by a 20-bit counter, cal_cnt[19:0], clocked by RTCCLK.

The smooth calibration register (RTC_CALR) specifies the number of RTCCLK clock cycles to be masked during the 32-second cycle:

- Setting the bit CALM[0] to 1 causes exactly one pulse to be masked during the 32-second cycle.
- Setting CALM[1] to 1 causes two additional cycles to be masked.
- Setting CALM[2] to 1 causes four additional cycles to be masked.
- and so on up to CALM[8] set to 1 which causes 256 clocks to be masked.

Note: CALM[8:0] (RTC_CALR) specifies the number of RTCCLK pulses to be masked during the 32-second cycle. Setting the bit CALM[0] to '1' causes exactly one pulse to be masked during the 32-second cycle at the moment when cal_cnt[19:0] is 0x80000; CALM[1]=1 causes two other cycles to be masked (when cal_cnt is 0x40000 and 0xC0000); CALM[2]=1 causes four other cycles to be masked (cal_cnt = 0x20000/0x60000/0xA0000/0xE0000); and so on up to CALM[8]=1 which causes 256 clocks to be masked (cal_cnt = 0xXX800).

While CALM allows the RTC frequency to be reduced by up to 487.1 ppm with fine resolution, the bit CALP can be used to increase the frequency by 488.5 ppm. Setting CALP to '1' effectively inserts an extra RTCCLK pulse every 211 RTCCLK cycles, which means that 512 clocks are added during every 32-second cycle.

Using CALM together with CALP, an offset ranging from -511 to +512 RTCCLK cycles can be added during the 32-second cycle, which translates to a calibration range of -487.1 ppm to +488.5 ppm with a resolution of about 0.954 ppm.

The formula to calculate the effective calibrated frequency (FCAL) given the input frequency (FRTCCLK) is as follows:

$$ FCAL = F_{RTCCLK} \times \left[1 + \frac{(CALP \times 512 - CALM)}{(2^{20} + CALM - CALP \times 512)}\right] $$

Calibration when PREDIV_A<3

The CALP bit can not be set to 1 when the asynchronous prescaler value (PREDIV_A bits in RTC_PRER register) is less than 3. If CALP was already set to 1 and PREDIV_A bits are set to a value less than 3, CALP is ignored and the calibration operates as if CALP was equal to 0.

To perform a calibration with PREDIV_A less than 3, the synchronous prescaler value (PREDIV_S) should be reduced so that each second is accelerated by 8 RTCCLK clock cycles, which is equivalent to adding 256 clock cycles every 32 seconds. As a result, between 255 and 256 clock pulses (corresponding to a calibration range from 243.3 to 244.1 ppm) can effectively be added during each 32-second cycle using only the CALM bits.

With a nominal RTCCLK frequency of 32768 Hz, when PREDIV_A equals 1 (division factor of 2), PREDIV_S should be set to 16379 rather than 16383 (4 less). The only other
interesting case is when PREDIV_A equals 0, PREDIV_S should be set to 32759 rather than 32767 (8 less).

If PREDIV_S is reduced in this way, the formula given the effective frequency of the calibrated input clock is as follows:

\[ F_{\text{CAL}} = F_{\text{RTCCLK}} \times \left[ 1 + \frac{256 - \text{CALM}}{220 + \text{CALM} - 256} \right] \]

In this case, CALM[7:0] equals 0x100 (the midpoint of the CALM range) is the correct setting if RTCCLK is exactly 32768.00 Hz.

**Verifying the RTC calibration**

RTC precision is ensured by measuring the precise frequency of RTCCLK and calculating the correct CALM value and CALP values. An optional 1 Hz output is provided to allow applications to measure and verify the RTC precision.

Measuring the precise frequency of the RTC over a limited interval can result in a measurement error of up to 2 RTCCLK clock cycles over the measurement period, depending on how the digital calibration cycle is aligned with the measurement period.

However, this measurement error can be eliminated if the measurement period is the same length as the calibration cycle period. In this case, the only error observed is the error due to the resolution of the digital calibration.

- By default, the calibration cycle period is 32 seconds.

Using this mode and measuring the accuracy of the 1 Hz output over exactly 32 seconds guarantees that the measure is within 0.477 ppm (0.5 RTCCLK cycles over 32 seconds, due to the limitation of the calibration resolution).

- CALW16 bit of the RTC_CALR register can be set to 1 to force a 16- second calibration cycle period.

In this case, the RTC precision can be measured during 16 seconds with a maximum error of 0.954 ppm (0.5 RTCCLK cycles over 16 seconds). However, since the calibration resolution is reduced, the long term RTC precision is also reduced to 0.954 ppm: CALM[0] bit is stuck at 0 when CALW16 is set to 1.

- CALW8 bit of the RTC_CALR register can be set to 1 to force a 8- second calibration cycle period.

In this case, the RTC precision can be measured during 8 seconds with a maximum error of 1.907 ppm (0.5 RTCCLK cycles over 8s). The long term RTC precision is also reduced to 1.907 ppm: CALM[1:0] bits are stuck at 00 when CALW8 is set to 1.

**Re-calibration on-the-fly**

The calibration register (RTC_CALR) can be updated on-the-fly while RTC_ISR/INITF=0, by using the follow process:

1. Poll the RTC_ISR/RECALPF (re-calibration pending flag).
2. If it is set to 0, write a new value to RTC_CALR, if necessary. RECALPF is then automatically set to 1
3. Within three ck_apre cycles after the write operation to RTC_CALR, the new calibration settings take effect.
45.3.14 **Time-stamp function**

Time-stamp is enabled by setting the TSE or ITSE bits of RTC_CR register to 1.

When TSE is set:

The calendar is saved in the time-stamp registers (RTC_TSSSR, RTC_TSTR, RTC_TSDR) when a time-stamp event is detected on the RTC_TS pin.

When ITSE is set:

The calendar is saved in the time-stamp registers (RTC_TSSSR, RTC_TSTR, RTC_TSDR) when an internal time-stamp event is detected. The internal timestamp event is generated by the switch to the VBAT supply.

When a time-stamp event occurs, due to internal or external event, the time-stamp flag bit (TSF) in RTC_ISR register is set. In case the event is internal, the ITSF flag is also set in RTC_ISR register.

By setting the TSIE bit in the RTC_CR register, an interrupt is generated when a time-stamp event occurs.

If a new time-stamp event is detected while the time-stamp flag (TSF) is already set, the time-stamp overflow flag (TSOVF) flag is set and the time-stamp registers (RTC_TSTR and RTC_TSDR) maintain the results of the previous event.

**Note:** TSF is set 2 ck_apre cycles after the time-stamp event occurs due to synchronization process.

*There is no delay in the setting of TSOVF. This means that if two time-stamp events are close together, TSOVF can be seen as ‘1’ while TSF is still ‘0’. As a consequence, it is recommended to poll TSOVF only after TSF has been set.*

**Caution:** If a time-stamp event occurs immediately after the TSF bit is supposed to be cleared, then both TSF and TSOVF bits are set. To avoid masking a time-stamp event occurring at the same moment, the application must not write ‘0’ into TSF bit unless it has already read it to ‘1’.

Optionally, a tamper event can cause a time-stamp to be recorded. See the description of the TAMPTS control bit in [Section 45.6.16: RTC tamper configuration register (RTC_TAMPCR)](https://example.com).

45.3.15 **Tamper detection**

The RTC_TAMPx input events can be configured either for edge detection, or for level detection with filtering.

The tamper detection can be configured for the following purposes:

- erase the RTC backup registers and backup SRAM (default configuration)
- generate an interrupt, capable to wakeup from Stop and Standby modes
- generate a hardware trigger for the low-power timers

**RTC backup registers**

The backup registers (RTC_BKPxR) are not reset by system reset or when the device wakes up from Standby mode.

The backup registers are reset when a tamper detection event occurs (see [Section 45.6.20: RTC backup registers (RTC_BKPxR)](https://example.com) and [Tamper detection initialization on page 1922](https://example.com)).
except if the TAMPxNOERASE bit is set, or if TAMPxFMF is set in the RTC_TAMPCR register.

Tamper detection initialization

Each input can be enabled by setting the corresponding TAMPxE bits to 1 in the RTC_TAMPCR register.

Each RTC_TAMPx tamper detection input is associated with a flag TAMPxF in the RTC_ISR register.

When TAMPxFMF is cleared:

The TAMPxF flag is asserted after the tamper event on the pin, with the latency provided below:

- 3 ck_apre cycles when TAMPFLT differs from 0x0 (Level detection with filtering)
- 3 ck_apre cycles when TAMPTS=1 (Timestamp on tamper event)
- No latency when TAMPFLT=0x0 (Edge detection) and TAMPTS=0

A new tamper occurring on the same pin during this period and as long as TAMPxF is set cannot be detected.

When TAMPxFMF is set:

A new tamper occurring on the same pin cannot be detected during the latency described above and 2.5 ck_rtc additional cycles.

By setting the TAMPIE bit in the RTC_TAMPCR register, an interrupt is generated when a tamper detection event occurs (when TAMPxF is set). Setting TAMPIE is not allowed when one or more TAMPxFMF is set.

When TAMPIE is cleared, each tamper pin event interrupt can be individually enabled by setting the corresponding TAMPxIE bit in the RTC_TAMPCR register. Setting TAMPxIE is not allowed when the corresponding TAMPxFMF is set.

Trigger output generation on tamper event

The tamper event detection can be used as trigger input by the low-power timers.

When TAMPxFMF bit in cleared in RTC_TAMPCR register, the TAMPxF flag must be cleared by software in order to allow a new tamper detection on the same pin.

When TAMPxFMF bit is set, the TAMPxF flag is masked, and kept cleared in RTC_ISR register. This configuration allows to trig automatically the low-power timers in Stop mode, without requiring the system wakeup to perform the TAMPxF clearing. In this case, the backup registers are not cleared.

Timestamp on tamper event

With TAMPTS set to ‘1’, any tamper event causes a timestamp to occur. In this case, either the TSF bit or the TSOVF bit are set in RTC_ISR, in the same manner as if a normal timestamp event occurs. The affected tamper flag register TAMPxF is set at the same time that TSF or TSOVF is set.

Edge detection on tamper inputs

If the TAMPFLT bits are “00”, the RTC_TAMPx pins generate tamper detection events when either a rising edge or a falling edge is observed depending on the corresponding
TAMPxTRG bit. The internal pull-up resistors on the RTC_TAMPx inputs are deactivated when edge detection is selected.

**Caution:** When using the edge detection, it is recommended to check by software the tamper pin level just after enabling the tamper detection (by reading the GPIO registers), and before writing sensitive values in the backup registers, to ensure that an active edge did not occur before enabling the tamper event detection. When TAMPFLT=“00” and TAMPxTRG = 0 (rising edge detection), a tamper event may be detected by hardware if the tamper input is already at high level before enabling the tamper detection.

After a tamper event has been detected and cleared, the RTC_TAMPx should be disabled and then re-enabled (TAMPxE set to 1) before re-programming the backup registers (RTC_BKPxR). This prevents the application from writing to the backup registers while the RTC_TAMPx input value still indicates a tamper detection. This is equivalent to a level detection on the RTC_TAMPx input.

**Note:** Tamper detection is still active when VDD power is switched off. To avoid unwanted resetting of the backup registers, the pin to which the RTC_TAMPx is mapped should be externally tied to the correct level.

**Level detection with filtering on RTC_TAMPx inputs**

Level detection with filtering is performed by setting TAMPFLT to a non-zero value. A tamper detection event is generated when either 2, 4, or 8 (depending on TAMPFLT) consecutive samples are observed at the level designated by the TAMPXTRG bits.

The RTC_TAMPx inputs are precharged through the I/O internal pull-up resistance before its state is sampled, unless disabled by setting TAMPPUDIS to 1, the duration of the precharge is determined by the TAMPPRCH bits, allowing for larger capacitances on the RTC_TAMPx inputs.

The trade-off between tamper detection latency and power consumption through the pull-up can be optimized by using TAMPFREQ to determine the frequency of the sampling for level detection.

**Note:** Refer to the datasheets for the electrical characteristics of the pull-up resistors.

**45.3.16 Calibration clock output**

When the COE bit is set to 1 in the RTC_CR register, a reference clock is provided on the RTC_CALIB device output.

If the COSEL bit in the RTC_CR register is reset and PREDIV_A = 0x7F, the RTC_CALIB frequency is \( \frac{f_{RTCCLK}}{64} \). This corresponds to a calibration output at 512 Hz for an RTCCLK frequency at 32.768 kHz. The RTC_CALIB duty cycle is irregular: there is a light jitter on falling edges. It is therefore recommended to use rising edges.

When COSEL is set and “PREDIV_S+1” is a non-zero multiple of 256 (i.e: PREDIV_S[7:0] = 0xFF), the RTC_CALIB frequency is \( \frac{f_{RTCCLK}}{(256 * (PREDIV_A+1))} \). This corresponds to a calibration output at 1 Hz for prescaler default values (PREDIV_A = Ox7F, PREDIV_S = 0xFF), with an RTCCLK frequency at 32.768 kHz. The 1 Hz output is affected when a shift operation is on going and may toggle during the shift operation (SHPF=1).
45.3.17 Alarm output

The OSEL[1:0] control bits in the RTC_CR register are used to activate the alarm output RTC_ALARM, and to select the function which is output. These functions reflect the contents of the corresponding flags in the RTC_ISR register.

The polarity of the output is determined by the POL control bit in RTC_CR so that the opposite of the selected flag bit is output when POL is set to 1.

**Alarm output**

The RTC_ALARM pin can be configured in output open drain or output push-pull using the control bit RTC_ALARM_TYPE in the RTC_OR register.

**Note:** Once the RTC_ALARM output is enabled, it has priority over RTC_CALIB (COE bit is don't care and must be kept cleared).

When the RTC_CALIB or RTC_ALARM output is selected, the RTC_OUT pin is automatically configured as output.

45.4 RTC low-power modes

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stop</td>
<td>Peripheral registers content is kept.</td>
</tr>
<tr>
<td>Standby</td>
<td>The RTC remains active when the RTC clock source is LSE or LSI. RTC alarm, RTC tamper event, RTC timestamp event, and RTC Wakeup cause the device to exit the Standby mode.</td>
</tr>
</tbody>
</table>

45.5 RTC interrupts

All RTC interrupts are connected to the EXTI controller. Refer to Section 19: Extended interrupt and event controller (EXTI).

To enable the RTC Alarm interrupt, the following sequence is required:
1. Configure and enable the EXTI line corresponding to the RTC Alarm event in interrupt mode and select the rising edge sensitivity.
2. Configure and enable the RTC_ALARM IRQ channel in the NVIC.
3. Configure the RTC to generate RTC alarms.

To enable the RTC Tamper interrupt, the following sequence is required:
1. Configure and enable the EXTI line corresponding to the RTC Tamper event in interrupt mode and select the rising edge sensitivity.
2. Configure and Enable the RTC_TAMP_STAMP IRQ channel in the NVIC.
3. Configure the RTC to detect the RTC tamper event.

To enable the RTC TimeStamp interrupt, the following sequence is required:
1. Configure and enable the EXTI line corresponding to the RTC TimeStamp event in interrupt mode and select the rising edge sensitivity.
2. Configure and Enable the RTC_TAMP_STAMP IRQ channel in the NVIC.
3. Configure the RTC to detect the RTC time-stamp event.

To enable the Wakeup timer interrupt, the following sequence is required:
1. Configure and enable the EXTI line corresponding to the Wakeup timer even in interrupt mode and select the rising edge sensitivity.
2. Configure and Enable the RTC_WKUP IRQ channel in the NVIC.
3. Configure the RTC to detect the RTC Wakeup timer event.

### 45.6 RTC registers

Refer to [Section 1.2 on page 98](#) of the reference manual for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by words (32-bit).

#### 45.6.1 RTC time register (RTC_TR)

The RTC_TR is the calendar time shadow register. This register must be written in initialization mode only. Refer to [Calendar initialization and configuration on page 1915](#) and [Reading the calendar on page 1916](#).

This register is write protected. The write access procedure is described in [RTC register write protection on page 1914](#).

Address offset: 0x00

Backup domain reset value: 0x0000 0000
System reset: 0x0000 0000 when BYPSHAD = 0. Not affected when BYPSHAD = 1.

Bits 31-23 Reserved, must be kept at reset value

Bit 22 **PM**: AM/PM notation
0: AM or 24-hour format
1: PM

Bits 21:20 **HT[1:0]**: Hour tens in BCD format

Bits 19:16 **HU[3:0]**: Hour units in BCD format

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **MNT[2:0]**: Minute tens in BCD format

Bits 11:8 **MNU[3:0]**: Minute units in BCD format

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **ST[2:0]**: Second tens in BCD format

Bits 3:0 **SU[3:0]**: Second units in BCD format

### 45.6.2 RTC date register (RTC_DR)

The RTC_DR is the calendar date shadow register. This register must be written in initialization mode only. Refer to *Calendar initialization and configuration on page 1915* and *Reading the calendar on page 1916*.

This register is write protected. The write access procedure is described in *RTC register write protection on page 1914*.

Address offset: 0x04

Backup domain reset value: 0x0000 2101

System reset: 0x0000 2101 when BYPSHAD = 0. Not affected when BYPSHAD = 1.

Bits 31:25  Reserved, must be kept at reset value.

Bit 24  **ITSE**: timestamp on internal event enable
0: internal event timestamp disabled
1: internal event timestamp enabled

Bit 23  **COE**: Calibration output enable
This bit enables the RTC_CALIB output
0: Calibration output disabled
1: Calibration output enabled

Bits 22:21  **OSEL[1:0]**: Output selection
These bits are used to select the flag to be routed to RTC_ALARM output
00: Output disabled
01: Alarm A output enabled
10: Alarm B output enabled
11: Wakeup output enabled

Bit 20  **POL**: Output polarity
This bit is used to configure the polarity of RTC_ALARM output
0: The pin is high when ALRAF/ALRBF/WUTF is asserted (depending on OSEL[1:0])
1: The pin is low when ALRAF/ALRBF/WUTF is asserted (depending on OSEL[1:0]).

Bit 19  **COSEL**: Calibration output selection
When COE=1, this bit selects which signal is output on RTC_CALIB.
0: Calibration output is 512 Hz (with default prescaler setting)
1: Calibration output is 1 Hz (with default prescaler setting)
These frequencies are valid for RTCCLK at 32.768 kHz and prescalers at their default values (PREDIV_A=127 and PREDIV_S=255). Refer to Section 45.3.16: Calibration clock output

Bit 18  **BKP**: Backup
This bit can be written by the user to memorize whether the daylight saving time change has been performed or not.
Bit 17  **SUB1H**: Subtract 1 hour (winter time change)
When this bit is set, 1 hour is subtracted to the calendar time if the current hour is not 0. This bit is always read as 0.
Setting this bit has no effect when current hour is 0.
0: No effect
1: Subtracts 1 hour to the current time. This can be used for winter time change outside initialization mode.

Bit 16  **ADD1H**: Add 1 hour (summer time change)
When this bit is set, 1 hour is added to the calendar time. This bit is always read as 0.
0: No effect
1: Adds 1 hour to the current time. This can be used for summer time change outside initialization mode.

Bit 15  **TSIE**: Time-stamp interrupt enable
0: Time-stamp Interrupt disable
1: Time-stamp Interrupt enable

Bit 14  **WUTIE**: Wakeup timer interrupt enable
0: Wakeup timer interrupt disabled
1: Wakeup timer interrupt enabled

Bit 13  **ALRBE**: Alarm B interrupt enable
0: Alarm B Interrupt disable
1: Alarm B Interrupt enable

Bit 12  **ALRAE**: Alarm A interrupt enable
0: Alarm A interrupt disabled
1: Alarm A interrupt enabled

Bit 11  **TSE**: timestamp enable
0: timestamp disable
1: timestamp enable

Bit 10  **WUTE**: Wakeup timer enable
0: Wakeup timer disabled
1: Wakeup timer enabled

*Note: When the wakeup timer is disabled, wait for WUTWF=1 before enabling it again.*

Bit 9  **ALRBE**: Alarm B enable
0: Alarm B disabled
1: Alarm B enabled

Bit 8  **ALRAE**: Alarm A enable
0: Alarm A disabled
1: Alarm A enabled

Bit 7  Reserved, must be kept at reset value.

Bit 6  **FMT**: Hour format
0: 24 hour/day format
1: AM/PM hour format
Bit 5 **BYPHAD:** Bypass the shadow registers
0: Calendar values (when reading from RTC_SSR, RTC_TR, and RTC_DR) are taken from the shadow registers, which are updated once every two RTCCLK cycles.
1: Calendar values (when reading from RTC_SSR, RTC_TR, and RTC_DR) are taken directly from the calendar counters.

*Note:* If the frequency of the APB clock is less than seven times the frequency of RTCCLK, **BYPHAD** must be set to ‘1’.

Bit 4 **REFCKON:** RTC_REFIN reference clock detection enable (50 or 60 Hz)
0: RTC_REFIN detection disabled
1: RTC_REFIN detection enabled

*Note:* **PREDIV_S** must be 0x00FF.

Bit 3 **TSEDGE:** Time-stamp event active edge
0: RTC_TS input rising edge generates a time-stamp event
1: RTC_TS input falling edge generates a time-stamp event

TSE must be reset when TSEDGE is changed to avoid unwanted TSF setting.

Bits 2:0 **WUCKSEL[2:0]:** Wakeup clock selection
000: RTC/16 clock is selected
001: RTC/8 clock is selected
010: RTC/4 clock is selected
011: RTC/2 clock is selected
10X: ck_spres (usually 1 Hz) clock is selected
11X: ck_spres (usually 1 Hz) clock is selected and \(2^{16}\) is added to the WUT counter value
(see note below)

*Note:* Bits 7, 6 and 4 of this register can be written in initialization mode only (RTC_ISR/INITF = 1).

\[ WUT = \text{Wakeup unit counter value. } WUT = (0x0000 \text{ to } 0xFFFF) + 0x10000 \text{ added when } WUCKSEL[2:1 = 11]. \]

Bits 2 to 0 of this register can be written only when RTC_CR WUTE bit = 0 and RTC_ISR WUTWF bit = 1.

It is recommended not to change the hour during the calendar hour increment as it could mask the incrementation of the calendar hour.

ADD1H and SUB1H changes are effective in the next second.

This register is write protected. The write access procedure is described in RTC register write protection on page 1914.

**Caution:** TSE must be reset when TSEDGE is changed to avoid spuriously setting of TSF.
45.6.4 RTC initialization and status register (RTC_ISR)

This register is write protected (except for RTC_ISR[13:8] bits). The write access procedure is described in RTC register write protection on page 1914.

Address offset: 0x0C

Backup domain reset value: 0x0000 0007

System reset: not affected except INIT, INITF, and RSF bits which are cleared to '0'

</tbody>
</table>

Bits 31:18 Reserved, must be kept at reset value

Bit 17 **ITSF**: Internal tTime-stamp flag

This flag is set by hardware when a time-stamp on the internal event occurs.
This flag is cleared by software by writing 0, and must be cleared together with TSF bit by writing 0 in both bits.

Bit 16 **RECALPF**: Recalibration pending Flag

The RECALPF status flag is automatically set to '1' when software writes to the RTC_CALR register, indicating that the RTC_CALR register is blocked. When the new calibration settings are taken into account, this bit returns to '0'. Refer to Re-calibration on-the-fly.

Bit 15 **TAMP3F**: RTC_TAMP3 detection flag

This flag is set by hardware when a tamper detection event is detected on the RTC_TAMP3 input.
It is cleared by software writing 0

Bit 14 **TAMP2F**: RTC_TAMP2 detection flag

This flag is set by hardware when a tamper detection event is detected on the RTC_TAMP2 input.
It is cleared by software writing 0

Bit 13 **TAMP1F**: RTC_TAMP1 detection flag

This flag is set by hardware when a tamper detection event is detected on the RTC_TAMP1 input.
It is cleared by software writing 0

Bit 12 **TSOVF**: Time-stamp overflow flag

This flag is set by hardware when a time-stamp event occurs while TSF is already set.
This flag is cleared by software by writing 0. It is recommended to check and then clear TSOVF only after clearing the TSF bit. Otherwise, an overflow might not be noticed if a time-stamp event occurs immediately before the TSF bit is cleared.

Bit 11 **TSF**: Time-stamp flag

This flag is set by hardware when a time-stamp event occurs.
This flag is cleared by software by writing 0. If ITSF flag is set, TSF must be cleared together with ITSF by writing 0 in both bits.
Bit 10 **WUTF**: Wakeup timer flag
- This flag is set by hardware when the wakeup auto-reload counter reaches 0.
- This flag is cleared by software by writing 0.
- This flag must be cleared by software at least 1.5 RTCCLK periods before WUTF is set to 1 again.

Bit 9 **ALRB**: Alarm B flag
- This flag is set by hardware when the time/date registers (RTC_TR and RTC_DR) match the Alarm B register (RTC_ALRMBR).
- This flag is cleared by software by writing 0.

Bit 8 **ALRA**: Alarm A flag
- This flag is set by hardware when the time/date registers (RTC_TR and RTC_DR) match the Alarm A register (RTC_ALRMAR).
- This flag is cleared by software by writing 0.

Bit 7 **INIT**: Initialization mode
- 0: Free running mode
- 1: Initialization mode used to program time and date register (RTC_TR and RTC_DR), and prescaler register (RTC_PRER). Counters are stopped and start counting from the new value when INIT is reset.

Bit 6 **INITF**: Initialization flag
- When this bit is set to 1, the RTC is in initialization state, and the time, date and prescaler registers can be updated.
- 0: Calendar registers update is not allowed
- 1: Calendar registers update is allowed

Bit 5 **RSF**: Registers synchronization flag
- This bit is set by hardware each time the calendar registers are copied into the shadow registers (RTC_SSRx, RTC_TRx and RTC_DRx). This bit is cleared by hardware in initialization mode, while a shift operation is pending (SHPF=1), or when in bypass shadow register mode (BYPSSHAD=1). This bit can also be cleared by software.
- It is cleared either by software or by hardware in initialization mode.
- 0: Calendar shadow registers not yet synchronized
- 1: Calendar shadow registers synchronized

Bit 4 **INITS**: Initialization status flag
- This bit is set by hardware when the calendar year field is different from 0 (Backup domain reset state).
- 0: Calendar has not been initialized
- 1: Calendar has been initialized

Bit 3 **SHPF**: Shift operation pending
- 0: No shift operation is pending
- 1: A shift operation is pending
- This flag is set by hardware as soon as a shift operation is initiated by a write to the RTC_SHIFTR register. It is cleared by hardware when the corresponding shift operation has been executed. Writing to the SHPF bit has no effect.
Bit 2  **WUTWF**: Wakeup timer write flag
This bit is set by hardware up to 2 RTCCLK cycles after the WUTE bit has been set to 0 in RTC_CR, and is cleared up to 2 RTCCLK cycles after the WUTE bit has been set to 1. The wakeup timer values can be changed when WUTE bit is cleared and WUTWF is set.
0: Wakeup timer configuration update not allowed
1: Wakeup timer configuration update allowed

Bit 1  **ALRBWF**: Alarm B write flag
This bit is set by hardware when Alarm B values can be changed, after the ALRBE bit has been set to 0 in RTC_CR.
It is cleared by hardware in initialization mode.
0: Alarm B update not allowed
1: Alarm B update allowed

Bit 0  **ALRAWF**: Alarm A write flag
This bit is set by hardware when Alarm A values can be changed, after the ALRAE bit has been set to 0 in RTC_CR.
It is cleared by hardware in initialization mode.
0: Alarm A update not allowed
1: Alarm A update allowed

**Note:** The bits ALRAF, ALRBF, WUTF and TSF are cleared 2 APB clock cycles after programming them to 0.
45.6.5 RTC prescaler register (RTC_PRER)

This register must be written in initialization mode only. The initialization must be performed in two separate write accesses. Refer to Calendar initialization and configuration on page 1915.

This register is write protected. The write access procedure is described in RTC register write protection on page 1914.

Address offset: 0x10
Backup domain reset value: 0x007F 00FF
System reset: not affected

Bits 31:16  Reserved, must be kept at reset value

Bits 15:0  **WUT[15:0]:** Wakeup auto-reload value bits

- When the wakeup timer is enabled (WUTE set to 1), the WUTF flag is set every (WUT[15:0] + 1) ck_wut cycles. The ck_wut period is selected through WUCKSEL[2:0] bits of the RTC_CR register.
- When WUCKSEL[2] = 1, the wakeup timer becomes 17-bits and WUCKSEL[1] effectively becomes WUT[16] the most-significant bit to be reloaded into the timer.
- The first assertion of WUTF occurs (WUT+1) ck_wut cycles after WUTE is set. Setting WUT[15:0] to 0x0000 with WUCKSEL[2:0] =011 (RTCCLK/2) is forbidden.
45.6.7 RTC alarm A register (RTC_ALRMAR)

This register can be written only when ALRAWF is set to 1 in RTC_ISR, or in initialization mode.

This register is write protected. The write access procedure is described in RTC register write protection on page 1914.

</thead>
<tbody>
<tr>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 31:16 Reserved, must be kept at reset value

Bit 15 CALP: Increase frequency of RTC by 488.5 ppm
0: No RTCCCLK pulses are added.
1: One RTCCCLK pulse is effectively inserted every \(2^{11}\) pulses (frequency increased by 488.5 ppm).

This feature is intended to be used in conjunction with CALM, which lowers the frequency of the calendar with a fine resolution. If the input frequency is 32768 Hz, the number of RTCCCLK pulses added during a 32-second window is calculated as follows: \((512 * \text{CALP}) - \text{CALM}\). Refer to Section 45.3.13: RTC smooth digital calibration.

Bit 14 CALW8: Use an 8-second calibration cycle period
When CALW8 is set to ‘1’, the 8-second calibration cycle period is selected.
Note: CALM[1:0] are stuck at “00” when CALW8=’1’. Refer to Section 45.3.13: RTC smooth digital calibration.

Bit 13 CALW16: Use a 16-second calibration cycle period
When CALW16 is set to ‘1’, the 16-second calibration cycle period is selected. This bit must not be set to ‘1’ if CALW8=1.
Note: CALM[0] is stuck at ‘0’ when CALW16=’1’. Refer to Section 45.3.13: RTC smooth digital calibration.

Bits 12:9 Reserved, must be kept at reset value

Bits 8:0 CALM[8:0]: Calibration minus
The frequency of the calendar is reduced by masking CALM out of \(2^{20}\) RTCCCLK pulses (32 seconds if the input frequency is 32768 Hz). This decreases the frequency of the calendar with a resolution of 0.9537 ppm.

To increase the frequency of the calendar, this feature should be used in conjunction with CALP. See Section 45.3.13: RTC smooth digital calibration on page 1919.
## 45.6.16 RTC tamper configuration register (RTC_TAMPCR)

Bits 31:25 Reserved, must be kept at reset value.

**Bit 24 TAMP3MF:** Tamper 3 mask flag

- 0: Tamper 3 event generates a trigger event and TAMPP3F must be cleared by software to allow next tamper event detection.
- 1: Tamper 3 event generates a trigger event. TAMPP3F is masked and internally cleared by hardware. The backup registers and the backup SRAM are not erased.

*Note: The Tamper 3 interrupt must not be enabled when TAMPP3MF is set.*

**Bit 23 TAMPP3NOERASE:** Tamper 3 no erase

- 0: Tamper 3 event erases the backup registers and the backup SRAM.
- 1: Tamper 3 event does not erase the backup registers and the backup SRAM.

**Bit 22 TAMPP3IE:** Tamper 3 interrupt enable

- 0: Tamper 3 interrupt is disabled if TAMPIE = 0.
- 1: Tamper 3 interrupt enabled.

**Bit 21 TAMPP2MF:** Tamper 2 mask flag

- 0: Tamper 2 event generates a trigger event and TAMPP2F must be cleared by software to allow next tamper event detection.
- 1: Tamper 2 event generates a trigger event. TAMPP2F is masked and internally cleared by hardware. The backup registers and the backup SRAM are not erased.

*Note: The Tamper 2 interrupt must not be enabled when TAMPP2MF is set.*

**Bit 20 TAMPP2NOERASE:** Tamper 2 no erase

- 0: Tamper 2 event erases the backup registers and the backup SRAM.
- 1: Tamper 2 event does not erase the backup registers and the backup SRAM.

**Bit 19 TAMPP2IE:** Tamper 2 interrupt enable

- 0: Tamper 2 interrupt is disabled if TAMPIE = 0.
- 1: Tamper 2 interrupt enabled.

**Bit 18 TAMPP1MF:** Tamper 1 mask flag

- 0: Tamper 1 event generates a trigger event and TAMPP1F must be cleared by software to allow next tamper event detection.
- 1: Tamper 1 event generates a trigger event. TAMPP1F is masked and internally cleared by hardware. The backup registers and the backup SRAM are not erased.

*Note: The Tamper 1 interrupt must not be enabled when TAMPP1MF is set.*

2: SS[14:2] are don’t care in Alarm A comparison. Only SS[1:0] are compared.
...
15: All 15 SS bits are compared and must match to activate alarm.
The overflow bits of the synchronous counter (bits 15) is never compared. This bit can be different from 0 only after a shift operation.

Bits 23:15 Reserved, must be kept at reset value.

Bits 14:0 SS[14:0]: Sub seconds value

This value is compared with the contents of the synchronous prescaler counter to determine if Alarm A is to be activated. Only bits 0 up MASKSS-1 are compared.
45.6.18 RTC alarm B sub second register (RTC_ALRMBSSR)

This register can be written only when ALRBE is reset in RTC_CR register, or in initialization mode.

This register is write protected. The write access procedure is described in Section: RTC register write protection.

Address offset: 0x48
Backup domain reset value: 0x0000 0000
System reset: not affected

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:24 **MASKSS[3:0]:** Mask the most-significant bits starting at this bit
- 0x0: No comparison on sub seconds for Alarm B. The alarm is set when the seconds unit is incremented (assuming that the rest of the fields match).
- 0x1: SS[14:1] are don't care in Alarm B comparison. Only SS[0] is compared.
- 0x2: SS[14:2] are don't care in Alarm B comparison. Only SS[1:0] are compared.
- 0x3: SS[14:3] are don't care in Alarm B comparison. Only SS[2:0] are compared.
- ...
- 0xC: SS[14:12] are don't care in Alarm B comparison. SS[11:0] are compared.
- 0xD: SS[14:13] are don't care in Alarm B comparison. SS[12:0] are compared.
- 0xE: SS[14] is don't care in Alarm B comparison. SS[13:0] are compared.
- 0xF: All 15 SS bits are compared and must match to activate alarm.

The overflow bits of the synchronous counter (bits 15) is never compared. This bit can be different from 0 only after a shift operation.

Bits 23:15 Reserved, must be kept at reset value.

Bits 14:0 **SS[14:0]:** Sub seconds value

This value is compared with the contents of the synchronous prescaler counter to determine if Alarm B is to be activated. Only bits 0 up to MASKSS-1 are compared.
45.6.19  **RTC option register (RTC_OR)**

Bits 31:2  Reserved, must be kept at reset value.

Bit 1  **RTC_OUT_RMP**: RTC_OUT remap
Setting this bit allows to remap the RTC outputs on PB2 as follows:

- **RTC_OUT_RMP = '0'**:  
  - If OSEL /= '00': RTC_ALARM is output on PC13  
  - If OSEL = '00' and COE = '1': RTC_CALIB is output on PC13

- **RTC_OUT_RMP = '1'**:  
  - If OSEL /= '00' and COE = '0': RTC_ALARM is output on PB2  
  - If OSEL = '00' and COE = '1': RTC_CALIB is output on PB2  
  - If OSEL /= '00' and COE = '1': RTC_CALIB is output on PB2 and RTC_ALARM is output on PC13.

Bit 0  **RTC_ALARM_TYPE**: RTC_ALARM output type on PC13
This bit is set and cleared by software
- 0: RTC_ALARM, when mapped on PC13, is open-drain output  
- 1: RTC_ALARM, when mapped on PC13, is push-pull output

Bits 31:0  BKP[31:0]
The application can write or read data to and from these registers.
They are powered-on by VBAT when VDD is switched off, so that they are not reset by System reset, and their contents remain valid when the device operates in low-power mode. This register is reset on a tamper detection event, as long as TAMPxF = 1.

Refer to Section 2.3 on page 126 for the register boundary addresses.
46 Inter-integrated circuit (I2C) interface

46.1 Introduction

The I2C (inter-integrated circuit) bus interface handles communications between the microcontroller and the serial I2C bus. It provides multimaster capability, and controls all I2C bus-specific sequencing, protocol, arbitration and timing. It supports Standard-mode (Sm), Fast-mode (Fm) and Fast-mode Plus (Fm+).

It is also SMBus (system management bus) and PMBus (power management bus) compatible.

DMA can be used to reduce CPU overload.

46.2 I2C main features

- I2C bus specification rev03 compatibility:
  - Slave and master modes
  - Multimaster capability
  - Standard-mode (up to 100 kHz)
  - Fast-mode (up to 400 kHz)
  - Fast-mode Plus (up to 1 MHz)
  - 7-bit and 10-bit addressing mode
  - Multiple 7-bit slave addresses (2 addresses, 1 with configurable mask)
  - All 7-bit addresses acknowledge mode
  - General call
  - Programmable setup and hold times
  - Easy to use event management
  - Optional clock stretching
  - Software reset
- 1-byte buffer with DMA capability
- Programmable analog and digital noise filters
The following additional features are also available depending on the product implementation (see Section 46.3: I2C implementation):

- SMBus specification rev 3.0 compatibility:
  - Hardware PEC (Packet Error Checking) generation and verification with ACK control
  - Command and data acknowledge control
  - Address resolution protocol (ARP) support
  - Host and Device support
  - SMBus alert
  - Timeouts and idle condition detection
- PMBus rev 1.3 standard compatibility
- Independent clock: a choice of independent clock sources allowing the I2C communication speed to be independent from the i2c_pclk reprogramming
- Wakeup from Stop mode on address match.

### 46.3 I2C implementation

This manual describes the full set of features implemented in I2C peripheral. In the STM32H7xxx devices I2C1, I2C2, I2C3 and I2C4 implement the full set of features as shown in the following table.

**Table 371. STM32H742, STM32H743/753 and STM32H750 I2C implementation**

### 46.4 I2C functional description

In addition to receiving and transmitting data, this interface converts it from serial to parallel format and vice versa. The interrupts are enabled or disabled by software. The interface is connected to the I2C bus by a data pin (SDA) and by a clock pin (SCL). It can be connected with a standard (up to 100 kHz), Fast-mode (up to 400 kHz) or Fast-mode Plus (up to 1 MHz) I2C bus.

This interface can also be connected to a SMBus with the data pin (SDA) and clock pin (SCL).
If SMBus feature is supported: the additional optional SMBus Alert pin (SMBA) is also available.

### 46.4.1 I2C block diagram

The block diagram of the I2C interface is shown in Figure 537.

![I2C block diagram](image)

The I2C is clocked by an independent clock source which allows to the I2C to operate independently from the i2c_pclk frequency.

For I2C I/Os supporting 20 mA output current drive for Fast-mode Plus operation, the driving capability is enabled through control bits in the system configuration controller (SYSCFG). Refer to Section 46.3: I2C implementation.

Table 373. I2C internal input/output signals

46.4.3 I2C clock requirements

The I2C kernel is clocked by i2c_ker_ck.

The i2c_ker_ck period \( t_{2CCLK} \) must respect the following conditions:

\[
t_{2CCLK} < \left( t_{LOW} - t_{filters} \right) / 4 \quad \text{and} \quad t_{2CCLK} < t_{HIGH}
\]

with:

- \( t_{LOW} \): SCL low time and \( t_{HIGH} \): SCL high time
- \( t_{filters} \): when enabled, sum of the delays brought by the analog filter and by the digital filter.

Analog filter delay is maximum 260 ns. Digital filter delay is \( DNF \times t_{2CCLK} \).

The i2c_pclk clock period \( t_{PCLK} \) must respect the following condition:

\[
t_{PCLK} < 4/3 \ t_{SCL}
\]

with \( t_{SCL} \): SCL period

**Caution:** When the I2C kernel is clocked by i2c_pclk, this clock must respect the conditions for \( t_{2CCLK} \).

46.4.4 Mode selection

The interface can operate in one of the four following modes:

- Slave transmitter
- Slave receiver
- Master transmitter
- Master receiver
By default, it operates in slave mode. The interface automatically switches from slave to master when it generates a START condition, and from master to slave if an arbitration loss or a STOP generation occurs, allowing multimaster capability.

**Communication flow**

In Master mode, the I2C interface initiates a data transfer and generates the clock signal. A serial data transfer always begins with a START condition and ends with a STOP condition. Both START and STOP conditions are generated in master mode by software.

In Slave mode, the interface is capable of recognizing its own addresses (7 or 10-bit), and the General Call address. The General Call address detection can be enabled or disabled by software. The reserved SMBus addresses can also be enabled by software.

Data and addresses are transferred as 8-bit bytes, MSB first. The first byte(s) following the START condition contain the address (one in 7-bit mode, two in 10-bit mode). The address is always transmitted in Master mode.

A 9th clock pulse follows the 8 clock cycles of a byte transfer, during which the receiver must send an acknowledge bit to the transmitter. Refer to the following figure.

---

**Figure 538. I2C bus protocol**

Acknowledge can be enabled or disabled by software. The I2C interface addresses can be selected by software.

---

**46.4.5 I2C initialization**

**Enabling and disabling the peripheral**

The I2C peripheral clock must be configured and enabled in the clock controller.

Then the I2C can be enabled by setting the PE bit in the I2C_CR1 register.

When the I2C is disabled (PE=0), the I2C performs a software reset. Refer to Section 46.4.6: Software reset for more details.

**Noise filters**

Before enabling the I2C peripheral by setting the PE bit in I2C_CR1 register, the user must configure the noise filters, if needed. By default, an analog noise filter is present on the SDA and SCL inputs. This analog filter is compliant with the I2C specification which requires the
suppression of spikes with a pulse width up to 50 ns in Fast-mode and Fast-mode Plus. The user can disable this analog filter by setting the ANFOFF bit, and/or select a digital filter by configuring the DNF[3:0] bit in the I2C_CR1 register.

When the digital filter is enabled, the level of the SCL or the SDA line is internally changed only if it remains stable for more than DNF x i2c_ker_ck periods. This allows to suppress spikes with a programmable length of 1 to 15 i2c_ker_ck periods.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

**Caution:** Changing the filter configuration is not allowed when the I2C is enabled.
I2C timings

The timings must be configured in order to guarantee a correct data hold and setup time, used in master and slave modes. This is done by programming the PRESC[3:0], SCLDEL[3:0] and SDADEL[3:0] bits in the I2C_TIMINGR register.

The STM32CubeMX tool calculates and provides the I2C_TIMINGR content in the I2C configuration window.

**Figure 539. Setup and hold timings**

- **DATA HOLD TIME**
  - SCL falling edge internal detection
  - $t_{SYNC}$: SCL stretched low by the I2C
  - SDA output delay
  - $t_{HOLD}^{1}$

  Data hold time: in case of transmission, the data is sent on SDA output after the SDADEL delay, if it is already available in I2C_TXDR.

- **DATA SETUP TIME**
  - SCLDEL
  - SCL stretched low by the I2C
  - $t_{SU}^{1}$

  Data setup time: in case of transmission, the SCLDEL counter starts when the data is sent on SDA output.
• When the SCL falling edge is internally detected, a delay is inserted before sending SDA output. This delay is \( t_{SDADEL} = SDADEL \times t_{PRESC} + t_{I2CCLK} \) where \( t_{PRESC} = (PRESC+1) \times t_{I2CCLK} \).

\( t_{SDADEL} \) impacts the hold time \( t_{HD;DAT} \).

The total SDA output delay is:

\[
t_{SYNC1} + \{(SDADEL \times (PRESC+1) + 1) \times t_{I2CCLK}\}
\]

\( t_{SYNC1} \) duration depends on these parameters:

- SCL falling slope
- When enabled, input delay brought by the analog filter: \( t_{AF(min)} < t_{AF} < t_{AF(max)} \)
- When enabled, input delay brought by the digital filter: \( t_{DNF} = DNF \times t_{I2CCLK} \)
- Delay due to SCL synchronization to \( i2c\_ker\_ck \) clock (2 to 3 \( i2c\_ker\_ck \) periods)

In order to bridge the undefined region of the SCL falling edge, the user must program SDADEL in such a way that:

\[
\begin{align*}
\{tf (max) + t_{HD;DAT} (min) - t_{AF(min)} - [(DNF+3) \times t_{I2CCLK}]\}/\{(PRESC+1) \times t_{I2CCLK}\} & \leq SDADEL \\
SDADEL & \leq \{t_{VD;DAT} (max) - t_{AF(max)} - [(DNF+4) \times t_{I2CCLK}]\}/\{(PRESC+1) \times t_{I2CCLK}\}
\end{align*}
\]

\( t_{AF(min)}/t_{AF(max)} \) are part of the equation only when the analog filter is enabled. Refer to device datasheet for \( t_{AF} \) values.

The maximum \( t_{HD;DAT} \) can be 3.45 µs, 0.9 µs and 0.45 µs for Standard-mode, Fast-mode and Fast-mode Plus, but must be less than the maximum of \( t_{VD;DAT} \) by a transition time. This maximum must only be met if the device does not stretch the LOW period (\( t_{LOW} \)) of the SCL signal. If the clock stretches the SCL, the data must be valid by the setup time before it releases the clock.

The SDA rising edge is usually the worst case, so in this case the previous equation becomes:

\[
SDADEL \leq \{t_{VD;DAT} (max) - t_{AF(max)} \times 260 \text{ ns} - [(DNF+4) \times t_{I2CCLK}]\}/\{(PRESC+1) \times t_{I2CCLK}\}.
\]

\( t_{AF(min)}/t_{AF(max)} \) are part of the equation only when the analog filter is enabled. Refer to device datasheet for \( t_{AF} \) values.

• After \( t_{SDADEL} \) delay, or after sending SDA output in case the slave had to stretch the clock because the data was not yet written in I2C_TXDR register, SCL line is kept at low level during the setup time. This setup time is \( t_{SCLDEL} = (SCLDEL+1) \times t_{I2CCLK} \) where \( t_{PRESC} = (PRESC+1) \times t_{I2CCLK} \).

\( t_{SCLDEL} \) impacts the setup time \( t_{SU;DAT} \).

In order to bridge the undefined region of the SDA transition (rising edge usually worst case), the user must program SCLDEL in such a way that:

\[
\{(t_{max}) + t_{SU;DAT} (min)\}/\{(PRESC+1) \times t_{I2CCLK}\} - 1 \leq SCLDEL
\]

Refer to Table 375: I2C-SMBUS specification data setup and hold times for \( t_r \), \( t_r \), \( t_{HD;DAT} \) and \( t_{VD;DAT} \) standard values.

• After \( t_{SDADEL} \) delay, or after sending SDA output in case the slave had to stretch the clock because the data was not yet written in I2C_TXDR register, SCL line is kept at low level during the setup time. This setup time is \( t_{SCLDEL} = (SCLDEL+1) \times t_{I2CCLK} \) where \( t_{PRESC} = (PRESC+1) \times t_{I2CCLK} \).

\( t_{SCLDEL} \) impacts the setup time \( t_{SU;DAT} \).

In order to bridge the undefined region of the SDA transition (rising edge usually worst case), the user must program SCLDEL in such a way that:

\[
\{(t_{max}) + t_{SU;DAT} (min)\}/\{(PRESC+1) \times t_{I2CCLK}\} - 1 \leq SCLDEL
\]

Refer to Table 375: I2C-SMBUS specification data setup and hold times for \( t_r \) and \( t_{SU;DAT} \) standard values.

The SDA and SCL transition time values to be used are the ones in the application. Using the maximum values from the standard increases the constraints for the SDADEL and SCLDEL calculation, but ensures the feature whatever the application.
Note: At every clock pulse, after SCL falling edge detection, the I2C master or slave stretches SCL low during at least \([(SDADEL+SCLDEL+1) \times (PRESC+1) + 1] \times t_{I2CCLK}\) in both transmission and reception modes. In transmission mode, in case the data is not yet written in I2C_TXDR when SDADEL counter is finished, the I2C keeps on stretching SCL low until the next data is written. Then new data MSB is sent on SDA output, and SCLDEL counter starts, continuing stretching SCL low to guarantee the data setup time.

If NOSTRETCH=1 in slave mode, the SCL is not stretched. Consequently the SDADEL must be programmed in such a way to guarantee also a sufficient setup time.

</tr>
</tbody>
</table>

Additionally, in master mode, the SCL clock high and low levels must be configured by programming the PRESC[3:0], SCLH[7:0] and SCLL[7:0] bits in the I2C_TIMINGR register.

- When the SCL falling edge is internally detected, a delay is inserted before releasing the SCL output. This delay is \(t_{SCLL} = (SCLL+1) \times t_{PRESC}\) where \(t_{PRESC} = (PRESC+1) \times t_{I2CCLK}\). 
  \(t_{SCLL}\) impacts the SCL low time \(t_{LOW}\).
- When the SCL rising edge is internally detected, a delay is inserted before forcing the SCL output to low level. This delay is \(t_{SCLH} = (SCLH+1) \times t_{PRESC}\) where \(t_{PRESC} = (PRESC+1) \times t_{I2CCLK}\). \(t_{SCLH}\) impacts the SCL high time \(t_{HIGH}\).

Refer to \(^{2}\text{C} \text{master initialization}\) for more details.

Caution: Changing the timing configuration is not allowed when the I2C is enabled.

The I2C slave NOSTRETCH mode must also be configured before enabling the peripheral. Refer to \(^{2}\text{C} \text{slave initialization}\) for more details.

Caution: Changing the NOSTRETCH configuration is not allowed when the I2C is enabled.
### 46.4.6 Software reset

A software reset can be performed by clearing the PE bit in the I2C_CR1 register. In that case I2C lines SCL and SDA are released. Internal states machines are reset and communication control bits, as well as status bits come back to their reset value. The configuration registers are not impacted.

Here is the list of impacted register bits:

1. I2C_CR2 register: START, STOP, NACK
2. I2C_ISR register: BUSY, TXE, TXIS, RXNE, ADDR, NACKF, TCR, TC, STOPF, BERR, ARLO, OVR

and in addition when the SMBus feature is supported:

1. I2C_CR2 register: PECBYTE
2. I2C_ISR register: PECERR, TIMEOUT, ALERT

PE must be kept low during at least 3 APB clock cycles in order to perform the software reset. This is ensured by writing the following software sequence: - Write PE=0 - Check PE=0 - Write PE=1.
46.4.7 Data transfer

The data transfer is managed through transmit and receive data registers and a shift register.

Reception

The SDA input fills the shift register. After the 8th SCL pulse (when the complete data byte is received), the shift register is copied into I2C_RXDR register if it is empty (RXNE=0). If RXNE=1, meaning that the previous received data byte has not yet been read, the SCL line is stretched low until I2C_RXDR is read. The stretch is inserted between the 8th and 9th SCL pulse (before the Acknowledge pulse).

Figure 541. Data reception
Transmission

If the I2C_TXDR register is not empty (TXE=0), its content is copied into the shift register after the 9th SCL pulse (the Acknowledge pulse). Then the shift register content is shifted out on SDA line. If TXE=1, meaning that no data is written yet in I2C_TXDR, SCL line is stretched low until I2C_TXDR is written. The stretch is done after the 9th SCL pulse.

Figure 542. Data transmission

Hardware transfer management

The I2C has a byte counter embedded in hardware in order to manage byte transfer and to close the communication in various modes such as:

- NACK, STOP and ReSTART generation in master mode
- ACK control in slave receiver mode
- PEC generation/checking when SMBus feature is supported

The byte counter is always used in master mode. By default it is disabled in slave mode, but it can be enabled by software by setting the SBC (Slave Byte Control) bit in the I2C_CR2 register.

The number of bytes to be transferred is programmed in the NBYTES[7:0] bit field in the I2C_CR2 register. If the number of bytes to be transferred (NBYTES) is greater than 255, or if a receiver wants to control the acknowledge value of a received data byte, the reload mode must be selected by setting the RELOAD bit in the I2C_CR2 register. In this mode, TCR flag is set when the number of bytes programmed in NBYTES has been transferred, and an interrupt is generated if TCIE is set. SCL is stretched as long as TCR flag is set. TCR is cleared by software when NBYTES is written to a non-zero value.

When the NBYTES counter is reloaded with the last number of bytes, RELOAD bit must be cleared.
When RELOAD=0 in master mode, the counter can be used in 2 modes:

- **Automatic end mode** (AUTOEND = ‘1’ in the I2C_CR2 register). In this mode, the master automatically sends a STOP condition once the number of bytes programmed in the NBYTES[7:0] bit field has been transferred.

- **Software end mode** (AUTOEND = ‘0’ in the I2C_CR2 register). In this mode, software action is expected once the number of bytes programmed in the NBYTES[7:0] bit field has been transferred; the TC flag is set and an interrupt is generated if the TCIE bit is set. The SCL signal is stretched as long as the TC flag is set. The TC flag is cleared by software when the START or STOP bit is set in the I2C_CR2 register. This mode must be used when the master wants to send a RESTART condition.

**Caution:** The AUTOEND bit has no effect when the RELOAD bit is set.

#### 46.4.8 I2C slave mode

**I2C slave initialization**

In order to work in slave mode, the user must enable at least one slave address. Two registers I2C_OAR1 and I2C_OAR2 are available in order to program the slave own addresses OA1 and OA2.

- OA1 can be configured either in 7-bit mode (by default) or in 10-bit addressing mode by setting the OA1MODE bit in the I2C_OAR1 register.
  
  OA1 is enabled by setting the OA1EN bit in the I2C_OAR1 register.

- If additional slave addresses are required, the 2nd slave address OA2 can be configured. Up to 7 OA2 LSB can be masked by configuring the OA2MSK[2:0] bits in the I2C_OAR2 register. Therefore for OA2MSK configured from 1 to 6, only OA2[7:2], OA2[7:3], OA2[7:4], OA2[7:5], OA2[7:6] or OA2[7] are compared with the received address. As soon as OA2MSK is not equal to 0, the address comparator for OA2 excludes the I2C reserved addresses (0000 XXX and 1111 XXX), which are not acknowledged. If OA2MSK=7, all received 7-bit addresses are acknowledged (except reserved addresses). OA2 is always a 7-bit address.

  These reserved addresses can be acknowledged if they are enabled by the specific enable bit, if they are programmed in the I2C_OAR1 or I2C_OAR2 register with OA2MSK=0.

  OA2 is enabled by setting the OA2EN bit in the I2C_OAR2 register.

- The General Call address is enabled by setting the GCEN bit in the I2C_CR1 register.

When the I2C is selected by one of its enabled addresses, the ADDR interrupt status flag is set, and an interrupt is generated if the ADDRIE bit is set.
By default, the slave uses its clock stretching capability, which means that it stretches the SCL signal at low level when needed, in order to perform software actions. If the master does not support clock stretching, the I2C must be configured with NOSTRETCH=1 in the I2C_CR1 register.

After receiving an ADDR interrupt, if several addresses are enabled the user must read the ADDCODE[6:0] bits in the I2C_ISR register in order to check which address matched. DIR flag must also be checked in order to know the transfer direction.

**Slave clock stretching (NOSTRETCH = 0)**

In default mode, the I2C slave stretches the SCL clock in the following situations:

- When the ADDR flag is set: the received address matches with one of the enabled slave addresses. This stretch is released when the ADDR flag is cleared by software setting the ADDRCF bit.
- In transmission, if the previous data transmission is completed and no new data is written in I2C_TXDR register, or if the first data byte is not written when the ADDR flag is cleared (TXE=1). This stretch is released when the data is written to the I2C_TXDR register.
- In reception when the I2C_RXDR register is not read yet and a new data reception is completed. This stretch is released when I2C_RXDR is read.
- When TCR = 1 in Slave Byte Control mode, reload mode (SBC=1 and RELOAD=1), meaning that the last data byte has been transferred. This stretch is released when then TCR is cleared by writing a non-zero value in the NBYTES[7:0] field.
- After SCL falling edge detection, the I2C stretches SCL low during $[(\text{SDADEL} + \text{SCLDEL} + 1) \times (\text{PRESC} + 1) + 1] \times t_{\text{I2CCLK}}$.

**Slave without clock stretching (NOSTRETCH = 1)**

When NOSTRETCH = 1 in the I2C_CR1 register, the I2C slave does not stretch the SCL signal.

- The SCL clock is not stretched while the ADDR flag is set.
- In transmission, the data must be written in the I2C_TXDR register before the first SCL pulse corresponding to its transfer occurs. If not, an underrun occurs, the OVR flag is set in the I2C_ISR register and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register. The OVR flag is also set when the first data transmission starts and the STOPF bit is still set (has not been cleared). Therefore, if the user clears the STOPF flag of the previous transfer only after writing the first data to be transmitted in the next transfer, he ensures that the OVR status is provided, even for the first data to be transmitted.
- In reception, the data must be read from the I2C_RXDR register before the 9th SCL pulse (ACK pulse) of the next data byte occurs. If not an overrun occurs, the OVR flag is set in the I2C_ISR register and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.
Slave Byte Control mode

In order to allow byte ACK control in slave reception mode, Slave Byte Control mode must be enabled by setting the SBC bit in the I2C_CR1 register. This is required to be compliant with SMBus standards.

Reload mode must be selected in order to allow byte ACK control in slave reception mode (RELOAD=1). To get control of each byte, NBYTES must be initialized to 0x1 in the ADDR interrupt subroutine, and reloaded to 0x1 after each received byte. When the byte is received, the TCR bit is set, stretching the SCL signal low between the 8th and 9th SCL pulses. The user can read the data from the I2C_RXDR register, and then decide to acknowledge it or not by configuring the ACK bit in the I2C_CR2 register. The SCL stretch is released by programming NBYTES to a non-zero value: the acknowledge or not-acknowledge is sent and next byte can be received.

NBYTES can be loaded with a value greater than 0x1, and in this case, the reception flow is continuous during NBYTES data reception.

Note: The SBC bit must be configured when the I2C is disabled, or when the slave is not addressed, or when ADDR=1.

The RELOAD bit value can be changed when ADDR=1, or when TCR=1.

Caution: Slave Byte Control mode is not compatible with NOSTRETCH mode. Setting SBC when NOSTRETCH=1 is not allowed.

Figure 543. Slave initialization flowchart

Slave initialization

Initial settings

Clear {OA1EN, OA2EN} in I2C_OAR1 and I2C_OAR2

Configure {OA1[9:0], OA1MODE, OA1EN, OA2[6:0], OA2MSK[2:0], OA2EN, GCEN}

Configure SBC in I2C_CR1*

Enable interrupts and/or DMA in I2C_CR1

End

*SBC must be set to support SMBus features
Slave transmitter

A transmit interrupt status (TXIS) is generated when the I2C_TXDR register becomes empty. An interrupt is generated if the TXIE bit is set in the I2C_CR1 register.

The TXIS bit is cleared when the I2C_TXDR register is written with the next data byte to be transmitted.

When a NACK is received, the NACKF bit is set in the I2C_ISR register and an interrupt is generated if the NACKIE bit is set in the I2C_CR1 register. The slave automatically releases the SCL and SDA lines in order to let the master perform a STOP or a RESTART condition. The TXIS bit is not set when a NACK is received.

When a STOP is received and the STOPIE bit is set in the I2C_CR1 register, the STOPF flag is set in the I2C_ISR register and an interrupt is generated. In most applications, the SBC bit is usually programmed to ‘0’. In this case, if TXE = 0 when the slave address is received (ADDR=1), the user can choose either to send the content of the I2C_TXDR register as the first data byte, or to flush the I2C_TXDR register by setting the TXE bit in order to program a new data byte.

In Slave Byte Control mode (SBC=1), the number of bytes to be transmitted must be programmed in NBYTES in the address match interrupt subroutine (ADDR=1). In this case, the number of TXIS events during the transfer corresponds to the value programmed in NBYTES.

Caution: When NOSTRETCH=1, the SCL clock is not stretched while the ADDR flag is set, so the user cannot flush the I2C_TXDR register content in the ADDR subroutine, in order to program the first data byte. The first data byte to be sent must be previously programmed in the I2C_TXDR register:

- This data can be the data written in the last TXIS event of the previous transmission message.
- If this data byte is not the one to be sent, the I2C_TXDR register can be flushed by setting the TXE bit in order to program a new data byte. The STOPF bit must be cleared only after these actions, in order to guarantee that they are executed before the first data transmission starts, following the address acknowledge.

If STOPF is still set when the first data transmission starts, an underrun error is generated (the OVR flag is set).

If a TXIS event is needed, (Transmit Interrupt or Transmit DMA request), the user must set the TXIS bit in addition to the TXE bit, in order to generate a TXIS event.

46.4.9  I2C master mode

I2C master initialization

Before enabling the peripheral, the I2C master clock must be configured by setting the SCLH and SCLL bits in the I2C_TIMINGR register.

The STM32CubeMX tool calculates and provides the I2C_TIMINGR content in the I2C Configuration window.

A clock synchronization mechanism is implemented in order to support multi-master environment and slave clock stretching.

In order to allow clock synchronization:
- The low level of the clock is counted using the SCLL counter, starting from the SCL low level internal detection.
- The high level of the clock is counted using the SCLH counter, starting from the SCL high level internal detection.

The I2C detects its own SCL low level after a \( t_{SYNC1} \) delay depending on the SCL falling edge, SCL input noise filters (analog + digital) and SCL synchronization to the I2CxCLK clock. The I2C releases SCL to high level once the SCLL counter reaches the value programmed in the SCLL[7:0] bits in the I2C_TIMINGR register.

The I2C detects its own SCL high level after a \( t_{SYNC2} \) delay depending on the SCL rising edge, SCL input noise filters (analog + digital) and SCL synchronization to I2CxCLK clock. The I2C ties SCL to low level once the SCLH counter is reached reaches the value programmed in the SCLH[7:0] bits in the I2C_TIMINGR register.

Consequently the master clock period is:

\[
 t_{SCL} = t_{SYNC1} + t_{SYNC2} + \left[ \left( SCLH + 1 \right) + \left( SCLL + 1 \right) \right] \times \left( PRES + 1 \right) \times t_{I2CCLK} 
\]

The duration of \( t_{SYNC1} \) depends on these parameters:
- SCL falling slope
- When enabled, input delay induced by the analog filter.
- When enabled, input delay induced by the digital filter: DNF \( \times t_{I2CCLK} \)
- Delay due to SCL synchronization with i2c_ker_ck clock (2 to 3 i2c_ker_ck periods)

The duration of \( t_{SYNC2} \) depends on these parameters:
- SCL rising slope
- When enabled, input delay induced by the analog filter.
- When enabled, input delay induced by the digital filter: DNF \( \times t_{I2CCLK} \)
- Delay due to SCL synchronization with i2c_ker_ck clock (2 to 3 i2c_ker_ck periods)
Caution: In order to be I²C or SMBus compliant, the master clock must respect the timings given below:
Master communication initialization (address phase)

In order to initiate the communication, the user must program the following parameters for the addressed slave in the I2C_CR2 register:

- Addressing mode (7-bit or 10-bit): ADD10
- Slave address to be sent: SADD[9:0]
- Transfer direction: RD_WRN
- In case of 10-bit address read: HEAD10R bit. HEAD10R must be configure to indicate if the complete address sequence must be sent, or only the header in case of a direction change.
- The number of bytes to be transferred: NBYTES[7:0]. If the number of bytes is equal to or greater than 255 bytes, NBYTES[7:0] must initially be filled with 0xFF.

The user must then set the START bit in I2C_CR2 register. Changing all the above bits is not allowed when START bit is set.

Then the master automatically sends the START condition followed by the slave address as soon as it detects that the bus is free (BUSY = 0) and after a delay of tBUF.

In case of an arbitration loss, the master automatically switches back to slave mode and can acknowledge its own address if it is addressed as a slave.

**Note:**
- The START bit is reset by hardware when the slave address has been sent on the bus, whatever the received acknowledge value. The START bit is also reset by hardware if an arbitration loss occurs.
- In 10-bit addressing mode, when the Slave Address first 7 bits is NACKed by the slave, the
master re-launches automatically the slave address transmission until ACK is received. In this case ADDRCF must be set if a NACK is received from the slave, in order to stop sending the slave address.

If the I2C is addressed as a slave (ADDR=1) while the START bit is set, the I2C switches to slave mode and the START bit is cleared, when the ADDRCF bit is set.

Note: The same procedure is applied for a Repeated Start condition. In this case BUSY=1.

**Initialization of a master receiver addressing a 10-bit address slave**

- If the slave address is in 10-bit format, the user can choose to send the complete read sequence by clearing the HEAD10R bit in the I2C_CR2 register. In this case the master automatically sends the following complete sequence after the START bit is set:
  (Re)Start + Slave address 10-bit header Write + Slave address 2nd byte + REStart + Slave address 10-bit header Read

**Figure 552. 10-bit address read access with HEAD10R=0**
• If the master addresses a 10-bit address slave, transmits data to this slave and then reads data from the same slave, a master transmission flow must be done first. Then a repeated start is set with the 10 bit slave address configured with HEAD10R=1. In this case the master sends this sequence: ReStart + Slave address 10-bit header Read.

![Figure 553. 10-bit address read access with HEAD10R=1](image)

Master transmitter

In the case of a write transfer, the TXIS flag is set after each byte transmission, after the 9th SCL pulse when an ACK is received.

A TXIS event generates an interrupt if the TXIE bit is set in the I2C_CR1 register. The flag is cleared when the I2C_TXDR register is written with the next data byte to be transmitted.

The number of TXIS events during the transfer corresponds to the value programmed in NBYTES[7:0]. If the total number of data bytes to be sent is greater than 255, reload mode must be selected by setting the RELOAD bit in the I2C_CR2 register. In this case, when NBYTES data have been transferred, the TCR flag is set and the SCL line is stretched low until NBYTES[7:0] is written to a non-zero value.

The TXIS flag is not set when a NACK is received.

• When RELOAD=0 and NBYTES data have been transferred:
  – In automatic end mode (AUTOEND=1), a STOP is automatically sent.
  – In software end mode (AUTOEND=0), the TC flag is set and the SCL line is stretched low in order to perform software actions:
    A RESTART condition can be requested by setting the START bit in the I2C_CR2 register with the proper slave address configuration, and number of bytes to be transferred. Setting the START bit clears the TC flag and the START condition is sent on the bus.
    A STOP condition can be requested by setting the STOP bit in the I2C_CR2 register. Setting the STOP bit clears the TC flag and the STOP condition is sent on the bus.

• If a NACK is received: the TXIS flag is not set, and a STOP condition is automatically sent after the NACK reception. the NACKF flag is set in the I2C_ISR register, and an interrupt is generated if the NACKIE bit is set.

Master receiver

In the case of a read transfer, the RXNE flag is set after each byte reception, after the 8th SCL pulse. An RXNE event generates an interrupt if the RXIE bit is set in the I2C_CR1 register. The flag is cleared when I2C_RXDR is read.

If the total number of data bytes to be received is greater than 255, reload mode must be selected by setting the RELOAD bit in the I2C_CR2 register. In this case, when NBYTES[7:0] data have been transferred, the TCR flag is set and the SCL line is stretched low until NBYTES[7:0] is written to a non-zero value.

- When RELOAD=0 and NBYTES[7:0] data have been transferred:
  - In automatic end mode (AUTOEND=1), a NACK and a STOP are automatically sent after the last received byte.
  - In software end mode (AUTOEND=0), a NACK is automatically sent after the last received byte, the TC flag is set and the SCL line is stretched low in order to allow software actions:
    - A RESTART condition can be requested by setting the START bit in the I2C_CR2 register with the proper slave address configuration, and number of bytes to be transferred. Setting the START bit clears the TC flag and the START condition, followed by slave address, are sent on the bus.
    - A STOP condition can be requested by setting the STOP bit in the I2C_CR2 register. Setting the STOP bit clears the TC flag and the STOP condition is sent on the bus.

1. SCL period t_SCL is greater than t_SCLL + t_SCLH due to SCL internal detection delay. Values provided for t_SCL are examples only.
This section is relevant only when SMBus feature is supported. Refer to Section 46.3: I2C implementation.

Introduction

The System Management Bus (SMBus) is a two-wire interface through which various devices can communicate with each other and with the rest of the system. It is based on I²C principles of operation. SMBus provides a control bus for system and power management related tasks.

This peripheral is compatible with the SMBUS specification (http://smbus.org).

The System Management Bus Specification refers to three types of devices.

- A slave is a device that receives or responds to a command.
- A master is a device that issues commands, generates the clocks and terminates the transfer.
- A host is a specialized master that provides the main interface to the system’s CPU. A host must be a master-slave and must support the SMBus host notify protocol. Only one host is allowed in a system.

This peripheral can be configured as master or slave device, and also as a host.

1. The SCL period tSCL is greater than tSCLL + tSCLH due to the SCL internal detection delay. Values provided for tSCL are only examples.
2. tSYNC1 + tSYNC2 minimum value is 4 x tI2CCLK = 83.3 ns. Example with tSYNC1 + tSYNC2 = 1000 ns.
3. tSYNC1 + tSYNC2 minimum value is 4 x tI2CCLK = 83.3 ns. Example with tSYNC1 + tSYNC2 = 750 ns.
4. tSYNC1 + tSYNC2 minimum value is 4 x tI2CCLK = 83.3 ns. Example with tSYNC1 + tSYNC2 = 250 ns.
Bus protocols

There are eleven possible command protocols for any given device. A device may use any or all of the eleven protocols to communicate. The protocols are Quick Command, Send Byte, Receive Byte, Write Byte, Write Word, Read Byte, Read Word, Process Call, Block Read, Block Write and Block Write-Block Read Process Call. These protocols should be implemented by the user software.

For more details of these protocols, refer to SMBus specification (http://smbus.org).

Address resolution protocol (ARP)

SMBus slave address conflicts can be resolved by dynamically assigning a new unique address to each slave device. In order to provide a mechanism to isolate each device for the purpose of address assignment each device must implement a unique device identifier (UDID). This 128-bit number is implemented by software.

This peripheral supports the Address Resolution Protocol (ARP). The SMBus Device Default Address (0b1100 001) is enabled by setting SMBDEN bit in I2C_CR1 register. The ARP commands should be implemented by the user software.

Arbitration is also performed in slave mode for ARP support.

For more details of the SMBus Address Resolution Protocol, refer to SMBus specification (http://smbus.org).

Received Command and Data acknowledge control

A SMBus receiver must be able to NACK each received command or data. In order to allow the ACK control in slave mode, the Slave Byte Control mode must be enabled by setting SBC bit in I2C_CR1 register. Refer to Slave Byte Control mode on page 1966 for more details.

Host Notify protocol

This peripheral supports the Host Notify protocol by setting the SMBHEN bit in the I2C_CR1 register. In this case the host acknowledges the SMBus Host address (0b0001 000).

When this protocol is used, the device acts as a master and the host as a slave.

SMBus alert

The SMBus ALERT optional signal is supported. A slave-only device can signal the host through the SMBALERT# pin that it wants to talk. The host processes the interrupt and simultaneously accesses all SMBALERT# devices through the Alert Response Address (0b0001 100). Only the device(s) which pulled SMBALERT# low acknowledges the Alert Response Address.

When configured as a slave device(SMBHEN=0), the SMBA pin is pulled low by setting the ALERTEN bit in the I2C_CR1 register. The Alert Response Address is enabled at the same time.

When configured as a host (SMBHEN=1), the ALERT flag is set in the I2C_ISR register when a falling edge is detected on the SMBA pin and ALERTEN=1. An interrupt is generated if the ERRIE bit is set in the I2C_CR1 register. When ALERTEN=0, the ALERT line is considered high even if the external SMBA pin is low.

*If the SMBus ALERT pin is not needed, the SMBA pin can be used as a standard GPIO if ALERTEN=0.*
Packet error checking

A packet error checking mechanism has been introduced in the SMBus specification to improve reliability and communication robustness. Packet Error Checking is implemented by appending a Packet Error Code (PEC) at the end of each message transfer. The PEC is calculated by using the \( C(x) = x_8 + x^2 + x + 1 \) CRC-8 polynomial on all the message bytes (including addresses and read/write bits).

The peripheral embeds a hardware PEC calculator and allows to send a Not Acknowledge automatically when the received byte does not match with the hardware calculated PEC.
Timeouts

This peripheral embeds hardware timers in order to be compliant with the 3 timeouts defined in SMBus specification.

Table 381. SMBus timeout specifications

<tr>
<td>t_LOW:SEXT(1)</td>
<td>Cumulative clock low extend time (slave device)</td>
<td>-</td>
<td>25</td>
</tr>
<tr>
<td>t_LOW:MEXT(2)</td>
<td>Cumulative clock low extend time (master device)</td>
<td>-</td>
<td>10</td>
</tr>
</tbody>
</table>

1. t_LOW:SEXT is the cumulative time a given slave device is allowed to extend the clock cycles in one message from the initial START to the STOP. It is possible that, another slave device or the master also extends the clock causing the combined clock low extend time to be greater than t_LOW:SEXT. Therefore, this parameter is measured with the slave device as the sole target of a full-speed master.

2. t_LOW:MEXT is the cumulative time a master device is allowed to extend its clock cycles within each byte of a message as defined from START-to-ACK, ACK-to-ACK, or ACK-to-STOP. It is possible that a slave device or another master also extends the clock causing the combined clock low time to be greater than t_LOW:MEXT on a given byte. Therefore, this parameter is measured with a full speed slave device as the sole target of the master.

Figure 560. Timeout intervals for t_LOW:SEXT, t_LOW:MEXT
Bus idle detection

A master can assume that the bus is free if it detects that the clock and data signals have been high for $t_{\text{IDLE}}$ greater than $t_{\text{HIGH,MAX}}$. (refer to Table 375: I2C-SMBUS specification data setup and hold times)

This timing parameter covers the condition where a master has been dynamically added to the bus and may not have detected a state transition on the SMBCLK or SMBDAT lines. In this case, the master must wait long enough to ensure that a transfer is not currently in progress. The peripheral supports a hardware bus idle detection.

46.4.12 SMBus initialization

This section is relevant only when SMBus feature is supported. Refer to Section 46.3: I2C implementation.

In addition to I2C initialization, some other specific initialization must be done in order to perform SMBus communication:

Received Command and Data Acknowledge control (Slave mode)

A SMBus receiver must be able to NACK each received command or data. In order to allow ACK control in slave mode, the Slave Byte Control mode must be enabled by setting the SBC bit in the I2C_CR1 register. Refer to Slave Byte Control mode on page 1966 for more details.

Specific address (Slave mode)

The specific SMBus addresses must be enabled if needed. Refer to Bus idle detection on page 1990 for more details.

- The SMBus Device Default address (0b1100 001) is enabled by setting the SMBDEN bit in the I2C_CR1 register.
- The SMBus Host address (0b0001 000) is enabled by setting the SMBHEN bit in the I2C_CR1 register.
- The Alert Response Address (0b0001100) is enabled by setting the ALERTEN bit in the I2C_CR1 register.

Packet error checking

PEC calculation is enabled by setting the PECEN bit in the I2C_CR1 register. Then the PEC transfer is managed with the help of a hardware byte counter: NBYTES[7:0] in the I2C_CR2 register. The PECEN bit must be configured before enabling the I2C.

The PEC transfer is managed with the hardware byte counter, so the SBC bit must be set when interfacing the SMBus in slave mode. The PEC is transferred after NBYTES-1 data have been transferred when the PECBYTE bit is set and the RELOAD bit is cleared. If RELOAD is set, PECBYTE has no effect.

Caution: Changing the PECEN configuration is not allowed when the I2C is enabled.
Timeout detection

The timeout detection is enabled by setting the TIMOUTEN and TEXTEN bits in the I2C_TIMEOUTR register. The timers must be programmed in such a way that they detect a timeout before the maximum time given in the SMBus specification.

- **T_TIMEOUT check**
  In order to enable the T_TIMEOUT check, the 12-bit TIMEOUTA[11:0] bits must be programmed with the timer reload value in order to check the T_TIMEOUT parameter. The TIDLE bit must be configured to '0' in order to detect the SCL low level timeout.

  Then the timer is enabled by setting the TIMOUTEN in the I2C_TIMEOUTR register.

  If SCL is tied low for a time greater than (TIMEOUTA+1) x 2048 x tI2CCLK, the TIMEOUT flag is set in the I2C_ISR register.

  Refer to Table 383: Examples of TIMEOUTA settings for various i2c_ker_ck frequencies (max T_TIMEOUT = 25 ms).
