Caution: Changing the TIMEOUTA[11:0] bits and TIDLE bit configuration is not allowed when the TIMOUTEN bit is set.

- **T_LOW:SEXT and T_LOW:MEXT check**
  Depending on if the peripheral is configured as a master or as a slave, The 12-bit TIMEOUTB timer must be configured in order to check T_LOW:SEXT for a slave and T_LOW:MEXT for a master. As the standard specifies only a maximum, the user can choose the same value for the both.

  Then the timer is enabled by setting the TEXTEN bit in the I2C_TIMEOUTR register.

  If the SMBus peripheral performs a cumulative SCL stretch for a time greater than (TIMEOUTB+1) x 2048 x tI2CCLK, and in the timeout interval described in Bus idle detection on page 1990 section, the TIMEOUT flag is set in the I2C_ISR register.

  Refer to Table 384: Examples of TIMEOUTB settings for various i2c_ker_ck frequencies

Caution: Changing the TIMEOUTB configuration is not allowed when the TEXTEN bit is set.

**Bus Idle detection**

In order to enable the T_IDLE check, the 12-bit TIMEOUTA[11:0] field must be programmed with the timer reload value in order to obtain the T_IDLE parameter. The TIDLE bit must be configured to '1' in order to detect both SCL and SDA high level timeout.

Then the timer is enabled by setting the TIMOUTEN bit in the I2C_TIMEOUTR register.

If both the SCL and SDA lines remain high for a time greater than (TIMEOUTA+1) x 4 x tI2CCLK, the TIMEOUT flag is set in the I2C_ISR register.

Refer to Table 385: Examples of TIMEOUTA settings for various i2c_ker_ck frequencies (max T_IDLE = 50 µs)
Caution: Changing the TIMEOUTA and TIDLE configuration is not allowed when the TIMEOUTEN is set.

46.4.13 SMBus: I2C_TIMEOUTR register configuration examples

This section is relevant only when SMBus feature is supported. Refer to Section 46.3: I2C implementation.

- Configuring the maximum duration of \( t_{\text{TIMEOUT}} \) to 25 ms:

46.4.14 SMBus slave mode

This section is relevant only when SMBus feature is supported. Refer to Section 46.3: I2C implementation.

In addition to I2C slave transfer management (refer to Section 46.4.8: I2C slave mode) some additional software flowcharts are provided to support SMBus.

**SMBus Slave transmitter**

When the IP is used in SMBus, SBC must be programmed to ‘1’ in order to allow the PEC transmission at the end of the programmed number of data bytes. When the PECBYTE bit is set, the number of bytes programmed in NBYTES[7:0] includes the PEC transmission. In
that case the total number of TXIS interrupts is NBYTES-1 and the content of the I2C_PECR register is automatically transmitted if the master requests an extra byte after the NBYTES-1 data transfer.

Caution: The PECBYTE bit has no effect when the RELOAD bit is set.

Figure 561. Transfer sequence flowchart for SMBus slave transmitter N bytes + PEC
Figure 562. Transfer bus diagrams for SMBus slave transmitter (SBC=1)

Example SMBus slave transmitter 2 bytes + PEC,

<table>
<thead>
<tr>
<th>NBYTES</th>
<th>3</th>
</tr>
</thead>
</table>

EV1: ADDR ISR: check ADDCODE, program NBYTES=3, set PECBYTE, set ADDRCF
EV2: TXIS ISR: wr data1
EV3: TXIS ISR: wr data2

SMBus Slave receiver

When the I2C is used in SMBus mode, SBC must be programmed to ‘1’ in order to allow the PEC checking at the end of the programmed number of data bytes. In order to allow the ACK control of each byte, the reload mode must be selected (RELOAD=1). Refer to Slave Byte Control mode on page 1966 for more details.

In order to check the PEC byte, the RELOAD bit must be cleared and the PECBYTE bit must be set. In this case, after NBYTES-1 data have been received, the next received byte is compared with the internal I2C_PECR register content. A NACK is automatically generated if the comparison does not match, and an ACK is automatically generated if the comparison matches, whatever the ACK bit value. Once the PEC byte is received, it is copied into the I2C_RXDR register like any other data, and the RXNE flag is set.

In the case of a PEC mismatch, the PECERR flag is set and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

If no ACK software control is needed, the user can program PECBYTE=1 and, in the same write operation, program NBYTES with the number of bytes to be received in a continuous flow. After NBYTES-1 are received, the next received byte is checked as being the PEC.

Caution: The PECBYTE bit has no effect when the RELOAD bit is set.

End

SCL stretched

No

Yes

Yes
This section is relevant only when SMBus feature is supported. Refer to Section 46.3: I2C implementation.

In addition to I2C master transfer management (refer to Section 46.4.9: I2C master mode) some additional software flowcharts are provided to support SMBus.

**SMBus Master transmitter**

When the SMBus master wants to transmit the PEC, the PECBYTE bit must be set and the number of bytes must be programmed in the NBYTES[7:0] field, before setting the START bit. In this case the total number of TXIS interrupts is NBYTES-1. So if the PECBYTE bit is set when NBYTES=0x1, the content of the I2C_PECR register is automatically transmitted.

If the SMBus master wants to send a STOP condition after the PEC, automatic end mode must be selected (AUTOEND=1). In this case, the STOP condition automatically follows the PEC transmission.
When the SMBus master wants to send a RESTART condition after the PEC, software mode must be selected (AUTOEND=0). In this case, once NBYTES-1 have been transmitted, the I2C_PECR register content is transmitted and the TC flag is set after the PEC transmission, stretching the SCL line low. The RESTART condition must be programmed in the TC interrupt subroutine.

**Caution:** The PECBYTE bit has no effect when the RELOAD bit is set.

**Figure 565. Bus transfer diagrams for SMBus master transmitter**

Example SMBus master transmitter 2 bytes + PEC, automatic end mode (STOP)

INIT: program Slave address, program NBYTES = 3, AUTOEND=1, set PECBYTE, set START
EV1: TXIS ISR: wr data1
EV2: TXIS ISR: wr data2

Example SMBus master transmitter 2 bytes + PEC, software end mode (RESTART)

INIT: program Slave address, program NBYTES = 3, AUTOEND=0, set PECBYTE, set START
EV1: TXIS ISR: wr data1
EV2: TXIS ISR: wr data2
EV3: TC ISR: program Slave address, program NBYTES = N, set START
SMBus Master receiver

When the SMBus master wants to receive the PEC followed by a STOP at the end of the transfer, automatic end mode can be selected (AUTOEND=1). The PECBYTE bit must be set and the slave address must be programmed, before setting the START bit. In this case, after NBYTES-1 data have been received, the next received byte is automatically checked versus the I2C_PECR register content. A NACK response is given to the PEC byte, followed by a STOP condition.

When the SMBus master receiver wants to receive the PEC byte followed by a RESTART condition at the end of the transfer, software mode must be selected (AUTOEND=0). The PECBYTE bit must be set and the slave address must be programmed, before setting the START bit. In this case, after NBYTES-1 data have been received, the next received byte is automatically checked versus the I2C_PECR register content. The TC flag is set after the PEC byte reception, stretching the SCL line low. The RESTART condition can be programmed in the TC interrupt subroutine.

Caution: The PECBYTE bit has no effect when the RELOAD bit is set.
Figure 566. Bus transfer diagrams for SMBus master receiver

Example SMBus master receiver 2 bytes + PEC, automatic end mode (STOP)

INIT: program Slave address, program NBYTES = 3, AUTOEND=1, set PECBYTE, set START
EV1: RXNE ISR: rd data1
EV2: RXNE ISR: rd data2
EV3: RXNE ISR: rd PEC

Example SMBus master receiver 2 bytes + PEC, software end mode (RESTART)

INIT: program Slave address, program NBYTES = 3, AUTOEND=0, set PECBYTE, set START
EV1: RXNE ISR: rd data1
EV2: RXNE ISR: rd data2
EV3: RXNE ISR: read PEC
EV4: TC ISR: program Slave address, program NBYTES = N, set START
46.4.15 Wakeup from Stop mode on address match

This section is relevant only when Wakeup from Stop mode feature is supported. Refer to Section 46.3: I2C implementation.

The I2C is able to wakeup the MCU from Stop mode (APB clock is off), when it is addressed. All addressing modes are supported.

Wakeup from Stop mode is enabled by setting the WUPEN bit in the I2C_CR1 register. The HSI or CSI oscillator must be selected as the clock source for I2CCLK in order to allow wakeup from Stop mode.

During Stop mode, the HSI or CSI is switched off. When a START is detected, the I2C interface switches the HSI or CSI on, and stretches SCL low until HSI or CSI is woken up.

HSI or CSI is then used for the address reception.

In case of an address match, the I2C stretches SCL low during MCU wakeup time. The stretch is released when ADDR flag is cleared by software, and the transfer goes on normally.

If the address does not match, the HSI or CSI is switched off again and the MCU is not woken up.

Note: If the I2C clock is the system clock, or if WUPEN = 0, the HSI or CSI is not switched on after a START is received.

Only an ADDR interrupt can wakeup the MCU. Therefore do not enter Stop mode when the I2C is performing a transfer as a master, or as an addressed slave after the ADDR flag is set. This can be managed by clearing SLEEPDEEP bit in the ADDR interrupt routine and setting it again only after the STOPF flag is set.

Caution: The digital filter is not compatible with the wakeup from Stop mode feature. If the DNF bit is not equal to 0, setting the WUPEN bit has no effect.

Caution: This feature is available only when the I2C clock source is the HSI or CSI oscillator.

Caution: Clock stretching must be enabled (NOSTRETCH=0) to ensure proper operation of the wakeup from Stop mode feature.

Caution: If wakeup from Stop mode is disabled (WUPEN=0), the I2C peripheral must be disabled before entering Stop mode (PE=0).

46.4.16 Error conditions

The following errors are the error conditions which may cause communication to fail.

Bus error (BERR)

A bus error is detected when a START or a STOP condition is detected and is not located after a multiple of 9 SCL clock pulses. A START or a STOP condition is detected when a SDA edge occurs while SCL is high.

The bus error flag is set only if the I2C is involved in the transfer as master or addressed slave (i.e not during the address phase in slave mode).

In case of a misplaced START or RESTART detection in slave mode, the I2C enters address recognition state like for a correct START condition.

When a bus error is detected, the BERR flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.
Arbitration lost (ARLO)

An arbitration loss is detected when a high level is sent on the SDA line, but a low level is sampled on the SCL rising edge.

- In master mode, arbitration loss is detected during the address phase, data phase and data acknowledge phase. In this case, the SDA and SCL lines are released, the START control bit is cleared by hardware and the master switches automatically to slave mode.
- In slave mode, arbitration loss is detected during data phase and data acknowledge phase. In this case, the transfer is stopped, and the SCL and SDA lines are released.

When an arbitration loss is detected, the ARLO flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

Overrun/underrun error (OVR)

An overrun or underrun error is detected in slave mode when NOSTRETCH=1 and:

- In reception when a new byte is received and the RXDR register has not been read yet. The new received byte is lost, and a NACK is automatically sent as a response to the new byte.
- In transmission:
  - When STOPF=1 and the first data byte should be sent. The content of the I2C_TXDR register is sent if TXE=0, 0xFF if not.
  - When a new byte must be sent and the I2C_TXDR register has not been written yet, 0xFF is sent.

When an overrun or underrun error is detected, the OVR flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

Packet Error Checking Error (PECERR)

This section is relevant only when the SMBus feature is supported. Refer to Section 46.3: I2C implementation.

A PEC error is detected when the received PEC byte does not match with the I2C_PECR register content. A NACK is automatically sent after the wrong PEC reception.

When a PEC error is detected, the PECERR flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

Timeout Error (TIMEOUT)

This section is relevant only when the SMBus feature is supported. Refer to Section 46.3: I2C implementation.

A timeout error occurs for any of these conditions:

- TIDLE=0 and SCL remained low for the time defined in the TIMEOUTA[11:0] bits: this is used to detect a SMBus timeout.
- TIDLE=1 and both SDA and SCL remained high for the time defined in the TIMEOUTA [11:0] bits: this is used to detect a bus idle condition.
- Master cumulative clock low extend time reached the time defined in the TIMEOUTB[11:0] bits (SMBus tLOW:MEXT parameter)
- Slave cumulative clock low extend time reached the time defined in TIMEOUTB[11:0] bits (SMBus tLOW:SEXT parameter)
When a timeout violation is detected in master mode, a STOP condition is automatically sent.

When a timeout violation is detected in slave mode, SDA and SCL lines are automatically released.

When a timeout error is detected, the TIMEOUT flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

**Alert (ALERT)**

This section is relevant only when the SMBus feature is supported. Refer to Section 46.3: I2C implementation.

The ALERT flag is set when the I2C interface is configured as a Host (SMBHEN=1), the alert pin detection is enabled (ALERTEN=1) and a falling edge is detected on the SMBA pin. An interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

### 46.4.17 DMA requests

**Transmission using DMA**

DMA (Direct Memory Access) can be enabled for transmission by setting the TXDMAEN bit in the I2C_CR1 register. Data is loaded from an SRAM area configured using the DMA peripheral (see Section 14: Direct memory access controller (DMA) on page 624) to the I2C_TXDR register whenever the TXIS bit is set.

Only the data are transferred with DMA.

- In master mode: the initialization, the slave address, direction, number of bytes and START bit are programmed by software (the transmitted slave address cannot be transferred with DMA). When all data are transferred using DMA, the DMA must be initialized before setting the START bit. The end of transfer is managed with the NBYTES counter. Refer to Master transmitter on page 1977.

- In slave mode:
  - With NOSTRETCH=0, when all data are transferred using DMA, the DMA must be initialized before the address match event, or in ADDR interrupt subroutine, before clearing ADDR.
  - With NOSTRETCH=1, the DMA must be initialized before the address match event.

- For instances supporting SMBus: the PEC transfer is managed with NBYTES counter. Refer to SMBus Slave transmitter on page 1992 and SMBus Master transmitter on page 1996.

**Note:** If DMA is used for transmission, the TXIE bit does not need to be enabled.

**Reception using DMA**

DMA (Direct Memory Access) can be enabled for reception by setting the RXDMAEN bit in the I2C_CR1 register. Data is loaded from the I2C_RXDR register to an SRAM area configured using the DMA peripheral (refer to Section 14: Direct memory access controller (DMA) on page 624) whenever the RXNE bit is set. Only the data (including PEC) are transferred with DMA.

- In master mode, the initialization, the slave address, direction, number of bytes and START bit are programmed by software. When all data are transferred using DMA, the
DMA must be initialized before setting the START bit. The end of transfer is managed with the NBYTES counter.

- In slave mode with NOSTRETCH=0, when all data are transferred using DMA, the DMA must be initialized before the address match event, or in the ADDR interrupt subroutine, before clearing the ADDR flag.
- If SMBus is supported (see Section 46.3: I2C implementation): the PEC transfer is managed with the NBYTES counter. Refer to SMBus Slave receiver on page 1994 and SMBus Master receiver on page 1998.

Note: If DMA is used for reception, the RXIE bit does not need to be enabled.

### 46.4.18 Debug mode

When the microcontroller enters debug mode (core halted), the SMBus timeout either continues to work normally or stops, depending on the DBG_I2Cx_ configuration bits in the DBG module.

### 46.5 I2C low-power modes

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>

46.7 I2C registers

Refer to Section 1.2 on page 98 for a list of abbreviations used in register descriptions.

The peripheral registers are accessed by words (32-bit).

46.7.1 I2C control register 1 (I2C_CR1)

Address offset: 0x00
Reset value: 0x0000 0000
Access: No wait states, except if a write access occurs while a write access to this register is ongoing. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to 2 x i2c_pclk + 6 x i2c_ker_ck.

```

Figure 567. I2C interrupt mapping diagram
Bit 22  **ALERTEN**: SMBus alert enable

**Device mode (SMBHEN=0):**
- 0: Releases SMBA pin high and Alert Response Address Header disabled: 0001100x followed by NACK.
- 1: Drives SMBA pin low and Alert Response Address Header enables: 0001100x followed by ACK.

**Host mode (SMBHEN=1):**
- 0: SMBus Alert pin (SMBA) not supported.
- 1: SMBus Alert pin (SMBA) supported.

*Note:* When ALERTEN=0, the SMBA pin can be used as a standard GPIO. If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'. Refer to Section 46.3: I2C implementation.

Bit 21  **SMBDEN**: SMBus Device Default address enable

- 0: Device default address disabled. Address 0b1100001x is NACKed.
- 1: Device default address enabled. Address 0b1100001x is ACKed.

*Note:* If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'. Refer to Section 46.3: I2C implementation.

Bit 20  **SMBHEN**: SMBus Host address enable

- 0: Host address disabled. Address 0b0001000x is NACKed.
- 1: Host address enabled. Address 0b0001000x is ACKed.

*Note:* If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'. Refer to Section 46.3: I2C implementation.

Bit 19  **GCEN**: General call enable

- 0: General call disabled. Address 0b00000000 is NACKed.
- 1: General call enabled. Address 0b00000000 is ACKed.

Bit 18  **WUPEN**: Wakeup from Stop mode enable

- 0: Wakeup from Stop mode disable.
- 1: Wakeup from Stop mode enable.

*Note:* If the Wakeup from Stop mode feature is not supported, this bit is reserved and forced by hardware to '0'. Refer to Section 46.3: I2C implementation.

*Note:* WUPEN can be set only when DNF = '0000'

Bit 17  **NOSTRETCH**: Clock stretching disable

This bit is used to disable clock stretching in slave mode. It must be kept cleared in master mode.

- 0: Clock stretching enabled
- 1: Clock stretching disabled

*Note:* This bit can only be programmed when the I2C is disabled (PE = 0).

Bit 16  **SBC**: Slave byte control

- 0: Slave byte control disabled
- 1: Slave byte control enabled

Bit 15  **RXDMAEN**: DMA reception requests enable

- 0: DMA mode disabled for reception
- 1: DMA mode enabled for reception

Bit 14  **TXDMAEN**: DMA transmission requests enable

- 0: DMA mode disabled for transmission
- 1: DMA mode enabled for transmission

Bit 13  Reserved, must be kept at reset value.
Bit 12 **ANFOFF**: Analog noise filter OFF
0: Analog noise filter enabled
1: Analog noise filter disabled

*Note: This bit can only be programmed when the I2C is disabled (PE = 0).*

Bits 11:8 **DNF[3:0]**: Digital noise filter
These bits are used to configure the digital noise filter on SDA and SCL input. The digital filter, filters spikes with a length of up to DNF[3:0] ⋅ tI2CCLK

<table>
<thead>
<tr>
<th>DNF[3:0]</th>
<th>Digital filter configuration</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

*Note: If the analog filter is also enabled, the digital filter is added to the analog filter. This filter can only be programmed when the I2C is disabled (PE = 0).*

Bit 7 **ERRIE**: Error interrupts enable
0: Error detection interrupts disabled
1: Error detection interrupts enabled

*Note: Any of these errors generate an interrupt:*
- Arbitration Loss (ARLO)
- Bus Error detection (BERR)
- Overrun/Underrun (OVR)
- Timeout detection (TIMEOUT)
- PEC error detection (PECERR)
- Alert pin event detection (ALERT)

Bit 6 **TCIE**: Transfer Complete interrupt enable
0: Transfer Complete interrupt disabled
1: Transfer Complete interrupt enabled

*Note: Any of these events generate an interrupt:*
- Transfer Complete (TC)
- Transfer Complete Reload (TCR)

Bit 5 **STOPIE**: Stop detection Interrupt enable
0: Stop detection (STOPF) interrupt disabled
1: Stop detection (STOPF) interrupt enabled

Bit 4 **NACKIE**: Not acknowledge received Interrupt enable
0: Not acknowledge (NACKF) received interrupts disabled
1: Not acknowledge (NACKF) received interrupts enabled

Bit 3 **ADDRIE**: Address match Interrupt enable (slave only)
0: Address match (ADDR) interrupts disabled
1: Address match (ADDR) interrupts enabled

Bit 2 **RXIE**: RX Interrupt enable
0: Receive (RXNE) interrupts disabled
1: Receive (RXNE) interrupts enabled

Bit 1 **TXIE**: TX Interrupt enable
0: Transmit (TXIS) interrupts disabled
1: Transmit (TXIS) interrupts enabled
46.7.2  
**I2C control register 2 (I2C_CR2)**

Address offset: 0x04

Reset value: 0x0000 0000

Access: No wait states, except if a write access occurs while a write access to this register is ongoing. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to 2 x i2c_pclk + 6 x i2c_ker_ck.

</table>

Bits 31:27  
Reserved, must be kept at reset value.

Bit 26  
**PECBYTE**: Packet error checking byte

This bit is set by software, and cleared by hardware when the PEC is transferred, or when a STOP condition or an Address matched is received, also when PE=0.

0: No PEC transfer.
1: PEC transmission/reception is requested

**Note:**  
Writing ‘0’ to this bit has no effect.

This bit has no effect when RELOAD is set.

This bit has no effect is slave mode when SBC=0.

If the SMBus feature is not supported, this bit is reserved and forced by hardware to ‘0’.

Refer to Section 46.3: I2C implementation.

Bit 25  
**AUTOEND**: Automatic end mode (master mode)

This bit is set and cleared by software.

0: software end mode: TC flag is set when NBYTES data are transferred, stretching SCL low.
1: Automatic end mode: a STOP condition is automatically sent when NBYTES data are transferred.

**Note:**  
This bit has no effect in slave mode or when the RELOAD bit is set.

Bit 24  
**RELOAD**: NBYTES reload mode

This bit is set and cleared by software.

0: The transfer is completed after the NBYTES data transfer (STOP or RESTART follows).
1: The transfer is not completed after the NBYTES data transfer (NBYTES is reloaded). TCR flag is set when NBYTES data are transferred, stretching SCL low.
Bits 23:16 **NBYES[7:0]**: Number of bytes
The number of bytes to be transmitted/received is programmed there. This field is don’t care in slave mode with SBC=0.

*Note: Changing these bits when the START bit is set is not allowed.*

Bit 15 **NACK**: NACK generation (slave mode)
The bit is set by software, cleared by hardware when the NACK is sent, or when a STOP condition or an Address matched is received, or when PE=0.
0: an ACK is sent after current received byte.
1: a NACK is sent after current received byte.

*Note: Writing ‘0’ to this bit has no effect.*

*This bit is used in slave mode only: in master receiver mode, NACK is automatically generated after last byte preceding STOP or RESTART condition, whatever the NACK bit value.*

*When an overrun occurs in slave receiver NOSTRETCH mode, a NACK is automatically generated whatever the NACK bit value.*

*When hardware PEC checking is enabled (PECBYTE=1), the PEC acknowledge value does not depend on the NACK value.*

Bit 14 **STOP**: Stop generation (master mode)
The bit is set by software, cleared by hardware when a STOP condition is detected, or when PE = 0.

**In Master Mode:**
0: No Stop generation.
1: Stop generation after current byte transfer.

*Note: Writing ‘0’ to this bit has no effect.*

Bit 13 **START**: Start generation
This bit is set by software, and cleared by hardware after the Start followed by the address sequence is sent, by an arbitration loss, by a timeout error detection, or when PE = 0. It can also be cleared by software by writing ‘1’ to the ADDRCF bit in the I2C_ICR register.

0: No Start generation.
1: Restart/Start generation:
If the I2C is already in master mode with AUTOEND = 0, setting this bit generates a Repeated Start condition when RELOAD=0, after the end of the NBYES transfer. Otherwise setting this bit generates a START condition once the bus is free.

*Note: Writing ‘0’ to this bit has no effect.*

*The START bit can be set even if the bus is BUSY or I2C is in slave mode.*

*This bit has no effect when RELOAD is set.*

Bit 12 **HEAD10R**: 10-bit address header only read direction (master receiver mode)

0: The master sends the complete 10 bit slave address read sequence: Start + 2 bytes 10bit address in write direction + Restart + 1st 7 bits of the 10 bit address in read direction.
1: The master only sends the 1st 7 bits of the 10 bit address, followed by Read direction.

*Note: Changing this bit when the START bit is set is not allowed.*
Bit 11 **ADD10**: 10-bit addressing mode (master mode)
- 0: The master operates in 7-bit addressing mode,
- 1: The master operates in 10-bit addressing mode

*Note: Changing this bit when the START bit is set is not allowed.*

Bit 10 **RD_WRN**: Transfer direction (master mode)
- 0: Master requests a write transfer.
- 1: Master requests a read transfer.

*Note: Changing this bit when the START bit is set is not allowed.*

Bits 9:0 **SADD[9:0]**: Slave address (master mode)

**In 7-bit addressing mode (ADD10 = 0):**
- SADD[7:1] should be written with the 7-bit slave address to be sent. The bits SADD[9], SADD[8] and SADD[0] are don’t care.

**In 10-bit addressing mode (ADD10 = 1):**
- SADD[9:0] should be written with the 10-bit slave address to be sent.

*Note: Changing these bits when the START bit is set is not allowed.*
46.7.3 I2C own address 1 register (I2C_OAR1)

Address offset: 0x08
Reset value: 0x0000 0000

Access: No wait states, except if a write access occurs while a write access to this register is ongoing. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to 2 x i2c_pclk + 6 x i2c_ker_ck.

OA1EN | OA1MODE | OA1[9:0]  
---|---------|---------
 rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **OA1EN**: Own Address 1 enable
0: Own address 1 disabled. The received slave address OA1 is NACKed.
1: Own address 1 enabled. The received slave address OA1 is ACKed.

Bits 14:11 Reserved, must be kept at reset value.

Bit 10 **OA1MODE**: Own Address 1 10-bit mode
0: Own address 1 is a 7-bit address.
1: Own address 1 is a 10-bit address.

*Note: This bit can be written only when OA1EN=0.*

Bits 9:0 **OA1[9:0]**: Interface own slave address
- 7-bit addressing mode: OA1[7:1] contains the 7-bit own slave address. The bits OA1[9], OA1[8] and OA1[0] are don’t care.
- 10-bit addressing mode: OA1[9:0] contains the 10-bit own slave address.

*Note: These bits can be written only when OA1EN=0.*
46.7.4  I2C own address 2 register (I2C_OAR2)

Address offset: 0x0C
Reset value: 0x0000 0000

Access: No wait states, except if a write access occurs while a write access to this register is ongoing. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to 2 x i2c_pclk + 6 x i2c_ker_ck.

</table>

| Note: These bits can be written only when OA2EN=0. |
| As soon as OA2MSK is not equal to 0, the reserved I2C addresses (0b0000xxx and 0b1111xxx) are not acknowledged even if the comparison matches. |

| Bits 7:1   | OA2[7:1]: Interface address         |
| 7-bit addressing mode: 7-bit address |

| Note: These bits can be written only when OA2EN=0. |

| Bit 0     | Reserved, must be kept at reset value. |

2012/3289  RM0433 Rev 6
46.7.5 I2C timing register (I2C_TIMINGR)

Address offset: 0x10
Reset value: 0x0000 0000
Access: No wait states

```
Bits 31:28  PRESC[3:0]: Timing prescaler
          This field is used to prescale i2c_ker_ck in order to generate the clock period tPRESC used for
          data setup and hold counters (refer to I2C timings on page 1958) and for SCL high and low
          level counters (refer to I2C master initialization on page 1973).
          tPRESC = (PRESC+1) x tI2CCLK

Bits 27:24 Reserved, must be kept at reset value.

Bits 23:20 SCLDEL[3:0]: Data setup time
          This field is used to generate a delay tSCLDEL between SDA edge and SCL rising edge. In
          master mode and in slave mode with NOSTRETCH = 0, the SCL line is stretched low during
          tSCLDEL:
          tSCLDEL = (SCLDEL+1) x tPRESC
          Note: tSCLDEL is used to generate tSU:DAT timing.

Bits 19:16 SDADEL[3:0]: Data hold time
          This field is used to generate the delay tSDADEL between SCL falling edge and SDA edge. In
          master mode and in slave mode with NOSTRETCH = 0, the SCL line is stretched low during
          tSDADEL:
          tSDADEL = SDADEL x tPRESC
          Note: SDADEL is used to generate tHD:DAT timing.

Bits 15:8 SCLH[7:0]: SCL high period (master mode)
          This field is used to generate the SCL high period in master mode.
          tSCLH = (SCLH+1) x tPRESC
          Note: SCLH is also used to generate tSU:STO and tHD:STA timing.

Bits 7:0 SCLL[7:0]: SCL low period (master mode)
          This field is used to generate the SCL low period in master mode.
          tSCLL = (SCLL+1) x tPRESC
          Note: SCLL is also used to generate tBUF and tSU:STA timings.

Note:  This register must be configured when the I2C is disabled (PE = 0).
Note:  The STM32CubeMX tool calculates and provides the I2C_TIMINGR content in the I2C
        Configuration window.
```
46.7.6 I2C timeout register (I2C_TIMEOUTR)

Address offset: 0x14
Reset value: 0x0000 0000

Access: No wait states, except if a write access occurs while a write access to this register is ongoing. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to 2 x i2c_pclk + 6 x i2c_ker_ck.

---

**TEXTEN**

0: Extended clock timeout detection is disabled
1: Extended clock timeout detection is enabled. When a cumulative SCL stretch for more than t\textsubscript{LOW:EXT} is done by the I2C interface, a timeout error is detected (TIMEOUT=1).

Bits 30:28 Reserved, must be kept at reset value.

**TIMEOUTB[11:0]**

This field is used to configure the cumulative clock extension timeout:
- In master mode, the master cumulative clock low extend time (t\textsubscript{LOW:MEXT}) is detected
- In slave mode, the slave cumulative clock low extend time (t\textsubscript{LOW:SEXT}) is detected

\[ t_{\text{LOW:EXT}} = (\text{TIMEOUTB} + 1) \times 2048 \times t_{\text{I2CCLK}} \]

Note: These bits can be written only when TEXTEN=0.

---

**TIDLE**

0: TIMEOUTA is used to detect SCL low timeout
1: TIMEOUTA is used to detect both SCL and SDA high timeout (bus idle condition)

Note: This bit can be written only when TIMOUTEN=0.

---

**TIMEOUTA[11:0]**

This field is used to configure:
- The SCL low timeout condition t\textsubscript{TIMEOUT} when TIDLE=0
- The bus idle condition (both SCL and SDA high) when TIDLE=1

\[ t_{\text{TIMEOUT}} = (\text{TIMEOUTA} + 1) \times 2048 \times t_{\text{I2CCLK}} \]
\[ t_{\text{IDLE}} = (\text{TIMEOUTA} + 1) \times 4 \times t_{\text{I2CCLK}} \]

Note: These bits can be written only when TIMOUTEN=0.

---

Note: If the SMBus feature is not supported, this register is reserved and forced by hardware to “0x00000000”. Refer to Section 46.3: I2C implementation.
### 46.7.7 I2C interrupt and status register (I2C_ISR)

Address offset: 0x18

Reset value: 0x0000 0001

Access: No wait states

| Bits 31:24 | Reserved, must be kept at reset value. |
| Bits 23:17 | ADDCODE[6:0]: Address match code (Slave mode) |
|           | These bits are updated with the received address when an address match event occurs (ADDR = 1). |
|           | In the case of a 10-bit address, ADDCODE provides the 10-bit header followed by the 2 MSBs of the address. |
| Bit 16    | **DIR**: Transfer direction (Slave mode) |
|           | This flag is updated when an address match event occurs (ADDR=1). |
|           | 0: Write transfer, slave enters receiver mode. |
|           | 1: Read transfer, slave enters transmitter mode. |
| Bit 15    | **BUSY**: Bus busy |
|           | This flag indicates that a communication is in progress on the bus. It is set by hardware when a START condition is detected. It is cleared by hardware when a STOP condition is detected, or when PE=0. |
| Bit 14    | Reserved, must be kept at reset value. |
| Bit 13    | **ALERT**: SMBus alert |
|           | This flag is set by hardware when SMBHEN=1 (SMBus host configuration), ALERTEN=1 and a SMBALERT event (falling edge) is detected on SMBA pin. It is cleared by software by setting the ALERTCF bit. |
|           | **Note**: This bit is cleared by hardware when PE=0. If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'. Refer to [Section 46.3: I2C implementation](#). |
| Bit 12    | **TIMEOUT**: Timeout or t\_LOW detection flag |
|           | This flag is set by hardware when a timeout or extended clock timeout occurred. It is cleared by software by setting the TIMEOUTCF bit. |
|           | **Note**: This bit is cleared by hardware when PE=0. If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'. Refer to [Section 46.3: I2C implementation](#). |
Bit 11 **PECERR**: PEC Error in reception

This flag is set by hardware when the received PEC does not match with the PEC register content. A NACK is automatically sent after the wrong PEC reception. It is cleared by software by setting the PECCF bit.

*Note: This bit is cleared by hardware when PE=0.*

*If the SMBus feature is not supported, this bit is reserved and forced by hardware to ‘0’. Refer to Section 46.3: I2C implementation.*

Bit 10 **OVR**: Overrun/Underrun (slave mode)

This flag is set by hardware in slave mode with NOSTRETCH=1, when an overrun/underrun error occurs. It is cleared by software by setting the OVRCF bit.

*Note: This bit is cleared by hardware when PE=0.*

Bit 9 **ARLO**: Arbitration lost

This flag is set by hardware in case of arbitration loss. It is cleared by software by setting the ARLOCF bit.

*Note: This bit is cleared by hardware when PE=0.*

Bit 8 **BERR**: Bus error

This flag is set by hardware when a misplaced Start or STOP condition is detected whereas the peripheral is involved in the transfer. The flag is not set during the address phase in slave mode. It is cleared by software by setting BERRCF bit.

*Note: This bit is cleared by hardware when PE=0.*

Bit 7 **TCR**: Transfer Complete Reload

This flag is set by hardware when RELOAD=1 and NBYTES data have been transferred. It is cleared by software when NBYTES is written to a non-zero value.

*Note: This bit is cleared by hardware when PE=0.*

This flag is only for master mode, or for slave mode when the SBC bit is set.

Bit 6 **TC**: Transfer Complete (master mode)

This flag is set by hardware when RELOAD=0, AUTOEND=0 and NBYTES data have been transferred. It is cleared by software when START bit or STOP bit is set.

*Note: This bit is cleared by hardware when PE=0.*

Bit 5 **STOPF**: Stop detection flag

This flag is set by hardware when a STOP condition is detected on the bus and the peripheral is involved in this transfer:

– either as a master, provided that the STOP condition is generated by the peripheral.
– or as a slave, provided that the peripheral has been addressed previously during this transfer.

It is cleared by software by setting the STOPCF bit.

*Note: This bit is cleared by hardware when PE=0.*

Bit 4 **NACKF**: Not Acknowledge received flag

This flag is set by hardware when a NACK is received after a byte transmission. It is cleared by software by setting the NACKCF bit.

*Note: This bit is cleared by hardware when PE=0.*

Bit 3 **ADDR**: Address matched (slave mode)

This bit is set by hardware as soon as the received slave address matched with one of the enabled slave addresses. It is cleared by software by setting ADDRCF bit.

*Note: This bit is cleared by hardware when PE=0.*
46.7.8 **I2C interrupt clear register (I2C_ICR)**

Bits 31:14 Reserved, must be kept at reset value.

**Bit 13** **ALERTCF**: Alert flag clear

Writing 1 to this bit clears the ALERT flag in the I2C_ISR register.

*Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to ‘0’. Refer to Section 46.3: I2C implementation.*

**Bit 12** **TIMOUTCF**: Timeout detection flag clear

Writing 1 to this bit clears the TIMEOUT flag in the I2C_ISR register.

*Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to ‘0’. Refer to Section 46.3: I2C implementation.*

**Bit 11** **PECCF**: PEC Error flag clear

Writing 1 to this bit clears the PECERR flag in the I2C_ISR register.

*Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to ‘0’. Refer to Section 46.3: I2C implementation.*
Bit 10 **OVRCF**: Overrun/Underrun flag clear
   Writing 1 to this bit clears the OVR flag in the I2C_ISR register.

Bit 9 **ARLOCF**: Arbitration lost flag clear
   Writing 1 to this bit clears the ARLO flag in the I2C_ISR register.

Bit 8 **BERRCF**: Bus error flag clear
   Writing 1 to this bit clears the BERRF flag in the I2C_ISR register.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **STOPCF**: STOP detection flag clear
   Writing 1 to this bit clears the STOPF flag in the I2C_ISR register.

Bit 4 **NACKCF**: Not Acknowledge flag clear
   Writing 1 to this bit clears the NACKF flag in I2C_ISR register.

Bit 3 **ADDRCF**: Address matched flag clear
   Writing 1 to this bit clears the ADDR flag in the I2C_ISR register. Writing 1 to this bit also clears the START bit in the I2C_CR2 register.

Bits 2:0 Reserved, must be kept at reset value.

### 46.7.9 I2C PEC register (I2C_PECR)

47 Universal synchronous/asynchronous receiver transmitter (USART/UART)

This section describes the universal synchronous asynchronous receiver transmitter (USART).

47.1 USART introduction

The USART offers a flexible means to perform Full-duplex data exchange with external equipments requiring an industry standard NRZ asynchronous serial data format. A very wide range of baud rates can be achieved through a fractional baud rate generator.

The USART supports both synchronous one-way and Half-duplex Single-wire communications, as well as LIN (local interconnection network), Smartcard protocol, IrDA (infrared data association) SIR ENDEC specifications, and Modem operations (CTS/RTS). Multiprocessor communications are also supported.

High-speed data communications are possible by using the DMA (direct memory access) for multibuffer configuration.
### 47.2 USART main features

- Full-duplex asynchronous communication
- NRZ standard format (mark/space)
- Configurable oversampling method by 16 or 8 to achieve the best compromise between speed and clock tolerance
- Baud rate generator systems
- Two internal FIFOs for transmit and receive data
  - Each FIFO can be enabled/disabled by software and come with a status flag.
- A common programmable transmit and receive baud rate
- Dual clock domain with dedicated kernel clock for peripherals independent from PCLK
- Auto baud rate detection
- Programmable data word length (7, 8 or 9 bits)
- Programmable data order with MSB-first or LSB-first shifting
- Configurable stop bits (1 or 2 stop bits)
- Synchronous master/slave mode and clock output/input for synchronous communications
- SPI slave transmission underrun error flag
- Single-wire Half-duplex communications
- Continuous communications using DMA
- Received/transmitted bytes are buffered in reserved SRAM using centralized DMA.
- Separate enable bits for transmitter and receiver
- Separate signal polarity control for transmission and reception
- Swappable Tx/Rx pin configuration
- Hardware flow control for modem and RS-485 transceiver
- Communication control/error detection flags
- Parity control:
  - Transmits parity bit
  - Checks parity of received data byte
- Interrupt sources with flags
- Multiprocessor communications: wakeup from Mute mode by idle line detection or address mark detection
47.3 **USART extended features**

- LIN master synchronous break send capability and LIN slave break detection capability
  - 13-bit break generation and 10/11 bit break detection when USART is hardware configured for LIN
- IrDA SIR encoder decoder supporting 3/16 bit duration for normal mode
- Smartcard mode
  - Supports the T=0 and T=1 asynchronous protocols for smartcards as defined in the ISO/IEC 7816-3 standard
  - 0.5 and 1.5 stop bits for Smartcard operation
- Support for Modbus communication
  - Timeout feature
  - CR/LF character recognition

47.4 **USART implementation**

*Table 389* describes USART implementation on STM32H742, STM32H743/753 and STM32H750 devices.

47.5 **USART functional description**

47.5.1 **USART block diagram**

The simplified block diagram given in Figure 568 shows two fully-independent clock domains:

- The **usart_pclk** clock domain
  
The **usart_pclk** clock signal feeds the peripheral bus interface. It must be active when accesses to the USART registers are required.

- The **usart_ker_ck** kernel clock domain.
  
The **usart_ker_ck** is the USART clock source. It is independent from **usart_pclk** and delivered by the RCC. The USART registers can consequently be written/read even when the **usart_ker_ck** clock is stopped.

  When the dual clock domain feature is disabled, the **usart_ker_ck** clock is the same as the **usart_pclk** clock.

There is no constraint between **usart_pclk** and **usart_ker_ck**: **usart_ker_ck** can be faster or slower than **usart_pclk**. The only limitation is the software ability to manage the communication fast enough.

When the USART operates in SPI slave mode, it handles data flow using the serial interface clock derived from the external SCLK signal provided by the external master SPI device. The **usart_ker_ck** clock must be at least 3 times faster than the clock on the CK input.
47.5.2 USART signals

USART bidirectional communications

USART bidirectional communications require a minimum of two pins: Receive Data In (RX) and Transmit Data Out (TX):

- **RX** (Receive Data Input)
  RX is the serial data input. Oversampling techniques are used for data recovery. They discriminate between valid incoming data and noise.

- **TX** (Transmit Data Output)
  When the transmitter is disabled, the output pin returns to its I/O port configuration. When the transmitter is enabled and no data needs to be transmitted, the TX pin is High. In Single-wire and Smartcard modes, this I/O is used to transmit and receive data.

RS232 Hardware flow control mode

The following pins are required in RS232 Hardware flow control mode:

- **CTS** (Clear To Send)
  When driven high, this signal blocks the data transmission at the end of the current transfer.

- **RTS** (Request To Send)
  When it is low, this signal indicates that the USART is ready to receive data.

RS485 Hardware control mode

The following pin is required in RS485 Hardware control mode:

- **DE** (Driver Enable)
  This signal activates the transmission mode of the external transceiver.

*Note:* **DE and RTS share the same pin.**

Synchronous master/slave mode and Smartcard mode

The following pin is required in synchronous master/slave mode and Smartcard mode:

- **CK**
  This pin acts as Clock output in Synchronous master and Smartcard modes. It acts as Clock input in Synchronous slave mode.

  In Synchronous Master mode, this pin outputs the transmitter data clock for synchronous transmission corresponding to SPI master mode (no clock pulses on start bit and stop bit, and a software option to send a clock pulse on the last data bit). In parallel, data can be received synchronously on RX pin. This mechanism can be used to control peripherals featuring shift registers (e.g. LCD drivers). The clock phase and polarity are software programmable.

  In Smartcard mode, CK output provides the clock to the smartcard.

- **NSS**
  This pin acts as Slave Select input in Synchronous slave mode.

*Note:* **NSS and CTS share the same pin.**
47.5.3 USART character description

The word length can be set to 7, 8 or 9 bits, by programming the M bits (M0: bit 12 and M1: bit 28) in the USART_CR1 register (see Figure 569):

- 7-bit character length: \text{M}[1:0] = '10'
- 8-bit character length: \text{M}[1:0] = '00'
- 9-bit character length: \text{M}[1:0] = '01'

\textit{Note: In 7-bit data length mode, the Smartcard mode, LIN master mode and Auto baud rate (0x7F and 0x55 frames detection) are not supported.}

By default, the signal (TX or RX) is in low state during the start bit. It is in high state during the stop bit.

These values can be inverted, separately for each signal, through polarity configuration control.

An \textit{Idle character} is interpreted as an entire frame of “1”s (the number of “1”s includes the number of stop bits).

A \textit{Break character} is interpreted on receiving “0”s for a frame period. At the end of the break frame, the transmitter inserts 2 stop bits.

Transmission and reception are driven by a common baud rate generator. The transmission and reception clock are generated when the enable bit is set for the transmitter and receiver, respectively.

A detailed description of each block is given below.
Figure 569. Word length programming

- **9-bit word length (M = 01), 1 Stop bit**
  - Data frame
  - Possible Parity bit
  - Next Start bit
  - **LBCL bit controls last data clock pulse**

- **8-bit word length (M = 00), 1 Stop bit**

- **7-bit word length (M = 10), 1 Stop bit**
  - Data frame
  - Possible Parity bit
  - Next Start bit

** Idle frame

** Break frame
47.5.4 USART FIFOs and thresholds

The USART can operate in FIFO mode.

The USART comes with a Transmit FIFO (TXFIFO) and a Receive FIFO (RXFIFO). The FIFO mode is enabled by setting FIFOEN in USART_CR1 register (bit 29). This mode is supported only in UART, SPI and Smartcard modes.

Since the maximum data word length is 9 bits, the TXFIFO is 9-bit wide. However the RXFIFO default width is 12 bits. This is due to the fact that the receiver does not only store the data in the FIFO, but also the error flags associated to each character (Parity error, Noise error and Framing error flags).

Note: The received data is stored in the RXFIFO together with the corresponding flags. However, only the data are read when reading the RDR.

The status flags are available in the USART_ISR register.

It is possible to configure the TXFIFO and RXFIFO levels at which the Tx and RX interrupts are triggered. These thresholds are programmed through RXFTCFG and TXFTCFG bitfields in USART_CR3 control register.

In this case:

- The RXFT flag is set in the USART_ISR register and the corresponding interrupt (if enabled) is generated, when the number of received data in the RXFIFO reaches the threshold programmed in the RXFTCFG bits fields.
  
This means that the RXFIFO is filled until the number of data in the RXFIFO is equal to the programmed threshold.

RXFTCFG data have been received: one data in USART_RDR and (RXFTCFG - 1) data in the RXFIFO. As an example, when the RXFTCFG is programmed to ‘101’, the RXFT flag will be set when a number of data corresponding to the FIFO size has been received (FIFO size -1 data in the RXFIFO and 1 data in the USART_RDR). As a result, the next received data will not set the overrun flag.

- The TXFT flag is set in the USART_ISR register and the corresponding interrupt (if enabled) is generated when the number of empty locations in the TXFIFO reaches the threshold programmed in the TXFTCFG bits fields.
  
This means that the TXFIFO is emptied until the number of empty locations in the TXFIFO is equal to the programmed threshold.

47.5.5 USART transmitter

The transmitter can send data words of either 7 or 8 or 9 bits, depending on the M bit status. The Transmit Enable bit (TE) must be set in order to activate the transmitter function. The data in the transmit shift register is output on the TX pin while the corresponding clock pulses are output on the SCLK pin.

Character transmission

During an USART transmission, data shifts out the least significant bit first (default configuration) on the TX pin. In this mode, the USART_TDR register consists of a buffer (TDR) between the internal bus and the transmit shift register.

When FIFO mode is enabled, the data written to the transmit data register (USART_TDR) are queued in the TXFIFO.
Every character is preceded by a start bit which corresponds to a low logic level for one bit period. The character is terminated by a configurable number of stop bits.

The number of stop bits can be configured to 0.5, 1, 1.5 or 2.

**Note:** The TE bit must be set before writing the data to be transmitted to the USART_TDR. The TE bit should not be reset during data transmission. Resetting the TE bit during the transmission corrupts the data on the TX pin as the baud rate counters get frozen. The current data being transmitted are then lost. An idle frame is sent when the TE bit is enabled.

**Configurable stop bits**

The number of stop bits to be transmitted with every character can be programmed in USART_CR2, bits 13,12.

- **1 stop bit:** This is the default value of number of stop bits.
- **2 stop bits:** This will be supported by normal USART, Single-wire and Modem modes.
- **1.5 stop bits:** To be used in Smartcard mode.

An idle frame transmission will include the stop bits.

A break transmission will be 10 low bits (when M[1:0] = '00') or 11 low bits (when M[1:0] = ‘01’) or 9 low bits (when M[1:0] = ‘10’) followed by 2 stop bits (see Figure 570). It is not possible to transmit long breaks (break of length greater than 9/10/11 low bits).

**Figure 570. Configurable stop bits**

![Configurable stop bits](MSv31887V1)
Character transmission procedure

To transmit a character, follow the sequence below:

1. Program the M bits in USART_CR1 to define the word length.
2. Select the desired baud rate using the USART_BRR register.
3. Program the number of stop bits in USART_CR2.
4. Enable the USART by writing the UE bit in USART_CR1 register to 1.
5. Select DMA enable (DMAT) in USART_CR3 if multibuffer communication must take place. Configure the DMA register as explained in Section 47.5.10: USART multiprocessor communication.
6. Set the TE bit in USART_CR1 to send an idle frame as first transmission.
7. Write the data to send in the USART_TDR register. Repeat this for each data to be transmitted in case of single buffer.
   - When FIFO mode is disabled, writing a data to the USART_TDR clears the TXE flag.
   - When FIFO mode is enabled, writing a data to the USART_TDR adds one data to the TXFIFO. Write operations to the USART_TDR are performed when TXFNF flag is set. This flag remains set until the TXFIFO is full.
8. When the last data is written to the USART_TDR register, wait until TC=1.
   - When FIFO mode is disabled, this indicates that the transmission of the last frame is complete.
   - When FIFO mode is enabled, this indicates that both TXFIFO and shift register are empty.

This check is required to avoid corrupting the last transmission when the USART is disabled or enters Halt mode.
Single byte communication

- When FIFO mode is disabled
  Writing to the transmit data register always clears the TXE bit. The TXE flag is set by hardware. It indicates that:
  - the data have been moved from the USART_TDR register to the shift register and the data transmission has started;
  - the USART_TDR register is empty;
  - the next data can be written to the USART_TDR register without overwriting the previous data.
  This flag generates an interrupt if the TXEIE bit is set.
  When a transmission is ongoing, a write instruction to the USART_TDR register stores the data in the TDR buffer. It is then copied in the shift register at the end of the current transmission.
  When no transmission is ongoing, a write instruction to the USART_TDR register places the data in the shift register, the data transmission starts, and the TXE bit is set.
- When FIFO mode is enabled, the TXFNF (TXFIFO not full) flag is set by hardware to indicate that:
  - the TXFIFO is not full;
  - the USART_TDR register is empty;
  - the next data can be written to the USART_TDR register without overwriting the previous data. When a transmission is ongoing, a write operation to the USART_TDR register stores the data in the TXFIFO. Data are copied from the TXFIFO to the shift register at the end of the current transmission.
  When the TXFIFO is not full, the TXFNF flag stays at ‘1’ even after a write operation to USART_TDR register. It is cleared when the TXFIFO is full. This flag generates an interrupt if the TXFNFIE bit is set.
  Alternatively, interrupts can be generated and data can be written to the FIFO when the TXFIFO threshold is reached. In this case, the CPU can write a block of data defined by the programmed trigger level.
  If a frame is transmitted (after the stop bit) and the TXE flag (TXFE in case of FIFO mode) is set, the TC flag goes high. An interrupt is generated if the TCIE bit is set in the USART_CR1 register.

After writing the last data to the USART_TDR register, it is mandatory to wait until TC is set before disabling the USART or causing the microcontroller to enter the low-power mode (see Figure 571: TC/TXE behavior when transmitting).
Break characters

Setting the SBKRQ bit transmits a break character. The break frame length depends on the M bit (see Figure 569).

If a ‘1’ is written to the SBKRQ bit, a break character is sent on the TX line after completing the current character transmission. The SBKF bit is set by the write operation and it is reset by hardware when the break character is completed (during the stop bits after the break character). The USART inserts a logic 1 signal (stop) for the duration of 2 bits at the end of the break frame to guarantee the recognition of the start bit of the next frame.

When the SBKRQ bit is set, the break character is sent at the end of the current transmission.

When FIFO mode is enabled, sending the break character has priority on sending data even if the TXFIFO is full.

Idle characters

Setting the TE bit drives the USART to send an idle frame before the first data frame.

47.5.6 USART receiver

The USART can receive data words of either 7 or 8 or 9 bits depending on the M bits in the USART_CR1 register.

Start bit detection

The start bit detection sequence is the same when oversampling by 16 or by 8.

In the USART, the start bit is detected when a specific sequence of samples is recognized. This sequence is: 1 1 1 0 X 0 X 0X 0 X 0X 0.
Figure 572. Start bit detection when oversampling by 16 or 8

<table>
<thead>
<tr>
<th>RX state</th>
<th>Idle</th>
<th>Start bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>RX line</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Ideal sample clock</td>
<td>1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16</td>
<td></td>
</tr>
<tr>
<td>Real sample clock</td>
<td>X X X X X X X 9 10 11 12 13 14 15 16</td>
<td></td>
</tr>
</tbody>
</table>

Note: If the sequence is not complete, the start bit detection aborts and the receiver returns to the idle state (no flag is set), where it waits for a falling edge.

The start bit is confirmed (RXNE flag set and interrupt generated if RXNEIE=1, or RXFNE flag set and interrupt generated if RXFNEIE=1 if FIFO mode enabled) if the 3 sampled bits are at '0' (first sampling on the 3rd, 5th and 7th bits finds the 3 bits at '0' and second sampling on the 8th, 9th and 10th bits also finds the 3 bits at '0').

The start bit is validated but the NE noise flag is set if,

a) for both samplings, 2 out of the 3 sampled bits are at '0' (sampling on the 3rd, 5th and 7th bits and sampling on the 8th, 9th and 10th bits)

or

b) for one of the samplings (sampling on the 3rd, 5th and 7th bits or sampling on the 8th, 9th and 10th bits), 2 out of the 3 bits are found at '0'.

If neither of the above conditions are met, the start detection aborts and the receiver returns to the idle state (no flag is set).
Character reception
During an USART reception, data are shifted out least significant bit first (default configuration) through the RX pin.

Character reception procedure
To receive a character, follow the sequence below:
1. Program the M bits in USART_CR1 to define the word length.
2. Select the desired baud rate using the baud rate register USART_BRR
3. Program the number of stop bits in USART_CR2.
4. Enable the USART by writing the UE bit in USART_CR1 register to ‘1’.
5. Select DMA enable (DMAR) in USART_CR3 if multibuffer communication is to take place. Configure the DMA register as explained in Section 47.5.10: USART multiprocessor communication.
6. Set the RE bit USART_CR1. This enables the receiver which begins searching for a start bit.

When a character is received:
• When FIFO mode is disabled, the RXNE bit is set to indicate that the content of the shift register is transferred to the RDR. In other words, data have been received and can be read (as well as their associated error flags).
• When FIFO mode is enabled, the RXFNE bit is set to indicate that the RXFIFO is not empty. Reading the USART_RDR returns the oldest data entered in the RXFIFO. When a data is received, it is stored in the RXFIFO together with the corresponding error bits.
• An interrupt is generated if the RXNEIE (RXFNEIE when FIFO mode is enabled) bit is set.
• The error flags can be set if a frame error, noise, parity or an overrun error was detected during reception.
• In multibuffer communication mode:
  – When FIFO mode is disabled, the RXNE flag is set after every byte reception. It is cleared when the DMA reads the Receive data Register.
  – When FIFO mode is enabled, the RXFNE flag is set when the RXFIFO is not empty. After every DMA request, a data is retrieved from the RXFIFO. A DMA request is triggered when the RXFIFO is not empty i.e. when there are data to be read from the RXFIFO.
• In single buffer mode:
  – When FIFO mode is disabled, clearing the RXNE flag is done by performing a software read from the USART_RDR register. The RXNE flag can also be cleared by programming RXFRQ bit to ‘1’ in the USART_RQR register. The RXNE flag must be cleared before the end of the reception of the next character to avoid an overrun error.
  – When FIFO mode is enabled, the RXFNE is set when the RXFIFO is not empty. After every read operation from USART_RDR, a data is retrieved from the RXFIFO. When the RXFIFO is empty, the RXFNE flag is cleared. The RXFNE flag can also be cleared by programming RXFRQ bit to ‘1’ in USART_RQR. When the RXFIFO is full, the first entry in the RXFIFO must be read before the end of the reception of the next character, to avoid an overrun error. The RXFNE flag generates an interrupt if the RXFNEIE bit is set. Alternatively, interrupts can be
generated and data can be read from RXFIFO when the RXFIFO threshold is reached. In this case, the CPU can read a block of data defined by the programmed threshold.

**Break character**

When a break character is received, the USART handles it as a framing error.

**Idle character**

When an idle frame is detected, it is handled in the same way as a data character reception except that an interrupt is generated if the IDLEIE bit is set.

**Overrun error**

- **FIFO mode disabled**
  
  An overrun error occurs if a character is received and RXNE has not been reset. Data can not be transferred from the shift register to the RDR register until the RXNE bit is cleared. The RXNE flag is set after every byte reception. An overrun error occurs if RXNE flag is set when the next data is received or the previous DMA request has not been serviced. When an overrun error occurs:
  
  - the ORE bit is set;
  
  - the RDR content will not be lost. The previous data is available by reading the USART_RDR register.
  
  - the shift register will be overwritten. After that, any data received during overrun is lost.
  
  - an interrupt is generated if either the RXNEIE or the EIE bit is set.

- **FIFO mode enabled**

  An overrun error occurs when the shift register is ready to be transferred and the receive FIFO is full. Data can not be transferred from the shift register to the USART_RDR register until there is one free location in the RXFIFO. The RXFNE flag is set when the RXFIFO is not empty.

  An overrun error occurs if the RXFIFO is full and the shift register is ready to be transferred. When an overrun error occurs:
  
  - The ORE bit is set.
  
  - The first entry in the RXFIFO will not be lost. It is available by reading the USART_RDR register.
  
  - The shift register will be overwritten. After that point, any data received during overrun is lost.
  
  - An interrupt is generated if either the RXFNEIE or EIE bit is set.

The ORE bit is reset by setting the ORECF bit in the USART_ICR register.
Note: The ORE bit, when set, indicates that at least 1 data has been lost.
When the FIFO mode is disabled, there are two possibilities

- if RXNE=1, then the last valid data is stored in the receive register (RDR) and can be read,
- if RXNE=0, the last valid data has already been read and there is nothing left to be read in the RDR register. This case can occur when the last valid data is read in the RDR register at the same time as the new (and lost) data is received.

Selecting the clock source and the appropriate oversampling method

The choice of the clock source is done through the Clock Control system (see Section 7: Reset and Clock Control (RCC)). The clock source must be selected through the UE bit before enabling the USART.

The clock source must be selected according to two criteria:

- Possible use of the USART in low-power mode
- Communication speed.

The clock source frequency is usart_ker_ck.

When the dual clock domain and the wakeup from low-power mode features are supported, the usart_ker_ck clock source can be configurable in the RCC (see Section 7: Reset and Clock Control (RCC)). Otherwise the usart_ker_ck clock is the same as usart_pclk.

The usart_ker_ck clock can be divided by a programmable factor, defined in the USART_PRESC register.

Figure 573. usart_ker_ck clock divider block diagram

Some usart_ker_ck sources allow the USART to receive data while the MCU is in low-power mode. Depending on the received data and wakeup mode selected, the USART wakes up the MCU, when needed, in order to transfer the received data, by performing a software read to the USART_RDR register or by DMA.

For the other clock sources, the system must be active to allow USART communications.

The communication speed range (specially the maximum communication speed) is also determined by the clock source.

The receiver implements different user-configurable oversampling techniques (except in synchronous mode) for data recovery by discriminating between valid incoming data and noise. This allows obtaining the best a trade-off between the maximum communication speed and noise-clock inaccuracy immunity.

The oversampling method can be selected by programming the OVER8 bit in the USART_CR1 register either to 16 or 8 times the baud rate clock (see Figure 574 and Figure 575).
Depending on your application:

- select oversampling by 8 (OVER8=1) to achieve higher speed (up to \(\text{usart	extunderscore ker	extunderscore ck	extunderscore pres}/8\)). In this case the maximum receiver tolerance to clock deviation is reduced (refer to Section 47.5.8: Tolerance of the USART receiver to clock deviation on page 2042).

- select oversampling by 16 (OVER8=0) to increase the tolerance of the receiver to clock deviations. In this case, the maximum speed is limited to maximum \(\text{usart	extunderscore ker	extunderscore ck	extunderscore pres}/16\) (where \(\text{usart	extunderscore ker	extunderscore ck	extunderscore pres}\) is the USART input clock divided by a prescaler).

Programming the ONEBIT bit in the USART\_CR3 register selects the method used to evaluate the logic level. Two options are available:

- The majority vote of the three samples in the center of the received bit. In this case, when the 3 samples used for the majority vote are not equal, the NE bit is set.

- A single sample in the center of the received bit.

Depending on your application:

- select the three sample majority vote method (ONEBIT=0) when operating in a noisy environment and reject the data when a noise is detected (refer to Figure 390) because this indicates that a glitch occurred during the sampling.

- select the single sample method (ONEBIT=1) when the line is noise-free to increase the receiver tolerance to clock deviations (see Section 47.5.8: Tolerance of the USART receiver to clock deviation on page 2042). In this case the NE bit will never be set.

When noise is detected in a frame:

- The NE bit is set at the rising edge of the RXNE bit (RXFNE in case of FIFO mode enabled).

- The invalid data is transferred from the Shift register to the USART\_RDR register.

- No interrupt is generated in case of single byte communication. However this bit rises at the same time as the RXNE bit (RXFNE in case of FIFO mode enabled) which itself generates an interrupt. In case of multibuffer communication an interrupt will be issued if the EIE bit is set in the USART\_CR3 register.

The NE bit is reset by setting NECF bit in USART\_ICR register.

*Note:* Noise error is not supported in SPI mode.

Oversampling by 8 is not available in the Smartcard, IrDA and LIN modes. In those modes, the OVER8 bit is forced to ‘0’ by hardware.

Framing error

A framing error is detected when the stop bit is not recognized on reception at the expected time, following either a de-synchronization or excessive noise.

When the framing error is detected:
- the FE bit is set by hardware;
- the invalid data is transferred from the Shift register to the USART_RDR register (RXFIFO in case FIFO mode is enabled).
- no interrupt is generated in case of single byte communication. However this bit rises at the same time as the RXNE bit (RXFNE in case FIFO mode is enabled) which itself generates an interrupt. In case of multibuffer communication an interrupt will be issued if the EIE bit is set in the USART_CR3 register.

The FE bit is reset by writing ‘1’ to the FECF in the USART_ICR register.

Note: Framing error is not supported in SPI mode.

Configurable stop bits during reception

The number of stop bits to be received can be configured through the control bits of USART_CR: it can be either 1 or 2 in normal mode and 0.5 or 1.5 in Smartcard mode.

- **0.5 stop bit (reception in Smartcard mode):** no sampling is done for 0.5 stop bit. As a consequence, no framing error and no break frame can be detected when 0.5 stop bit is selected.
- **1 stop bit:** sampling for 1 stop bit is done on the 8th, 9th and 10th samples.
- **1.5 stop bits (Smartcard mode)**
  When transmitting in Smartcard mode, the device must check that the data are correctly sent. The receiver block must consequently be enabled (RE =1 in USART_CR1) and the stop bit is checked to test if the Smartcard has detected a parity error.

  In the event of a parity error, the Smartcard forces the data signal low during the sampling (NACK signal), which is flagged as a framing error. The FE flag is then set through RXNE flag (RXFNE if the FIFO mode is enabled) at the end of the 1.5 stop bit. Sampling for 1.5 stop bits is done on the 16th, 17th and 18th samples (1 baud clock period after the beginning of the stop bit). The 1.5 stop bit can be broken into 2 parts: one 0.5 baud clock period during which nothing happens, followed by 1 normal stop bit period during which sampling occurs halfway through (refer to Section 47.5.16: USART receiver timeout on page 2055 for more details).

- **2 stop bits**
  Sampling for 2 stop bits is done on the 8th, 9th and 10th samples of the first stop bit. The framing error flag is set if a framing error is detected during the first stop bit. The second stop bit is not checked for framing error. The RXNE flag (RXFNE if the FIFO mode is enabled) is set at the end of the first stop bit.
47.5.7 USART baud rate generation

The baud rate for the receiver and transmitter (Rx and Tx) are both set to the value programmed in the USART_BRR register.

**Equation 1: baud rate for standard USART (SPI mode included) (OVER8 = ‘0’ or ‘1’)***

In case of oversampling by 16, the baud rate is given by the following formula:

\[ \text{Tx/Rx baud} = \frac{\text{uart\_ker\_ckpres}}{\text{USARTDIV}} \]

In case of oversampling by 8, the baud rate is given by the following formula:

\[ \text{Tx/Rx baud} = \frac{2 \times \text{uart\_ker\_ckpres}}{\text{USARTDIV}} \]

**Equation 2: baud rate in Smartcard, LIN and IrDA modes (OVER8 = 0)***

The baud rate is given by the following formula:

\[ \text{Tx/Rx baud} = \frac{\text{uart\_ker\_ckpres}}{\text{USARTDIV}} \]

USARTDIV is an unsigned fixed point number that is coded on the USART_BRR register.

- When OVER8 = 0, BRR = USARTDIV.
- When OVER8 = 1

**Note:** The baud counters are updated to the new value in the baud registers after a write operation to USART_BRR. Hence the baud rate register value should not be changed during communication.

*In case of oversampling by 16 and 8, USARTDIV must be greater than or equal to 16.*

**How to derive USARTDIV from USART_BRR register values**

**Example 1**

To obtain 9600 baud with uart_ker_ck_pres = 8 MHz:

- In case of oversampling by 16:
  - USARTDIV = 8 000 000/9600
  - BRR = USARTDIV = 833d = 0341h
- In case of oversampling by 8:
  - USARTDIV = 2 * 8 000 000/9600
  - USARTDIV = 1666.66 (1667d = 683h)
  - BRR[3:0] = 3h >>1 = 1h
  - BRR = 0x681
Example 2
To obtain 921.6 Kbaud with usart_ker_ck_pres = 48 MHz:

- In case of oversampling by 16:
  \[
  \text{USARTDIV} = \frac{48\,000\,000}{921\,600} \\
  \text{BRR} = \text{USARTDIV} = 52d = 34h
  \]

- In case of oversampling by 8:
  \[
  \text{USARTDIV} = 2 \times \frac{48\,000\,000}{921\,600} \\
  \text{USARTDIV} = 104 (104d = 68h) \\
  \text{BRR}[3:0] = \text{USARTDIV}[3:0] >> 1 = 8h >> 1 = 4h \\
  \text{BRR} = 0x64
  \]

47.5.8 Tolerance of the USART receiver to clock deviation

The USART asynchronous receiver operates correctly only if the total clock system deviation is less than the tolerance of the USART receiver.

The causes which contribute to the total deviation are:

- DTRA: deviation due to the transmitter error (which also includes the deviation of the transmitter’s local oscillator)
- DQUANT: error due to the baud rate quantization of the receiver
- DREC: deviation of the receiver local oscillator
- DTCL: deviation due to the transmission line (generally due to the transceivers which can introduce an asymmetry between the low-to-high transition timing and the high-to-low transition timing)

\[
\text{DTRA + DQUANT + DREC + DTCL + DWU < USART receiver tolerance}
\]

where

- DWU is the error due to sampling point deviation when the wakeup from low-power mode is used.
  - when M[1:0] = 01:
    \[
    \text{DWU} = \frac{t_{\text{WUSART}}}{11 \times T_{\text{bit}}}
    \]
  - when M[1:0] = 00:
    \[
    \text{DWU} = \frac{t_{\text{WUSART}}}{10 \times T_{\text{bit}}}
    \]
  - when M[1:0] = 10:
    \[
    \text{DWU} = \frac{t_{\text{WUSART}}}{9 \times T_{\text{bit}}}
    \]

\(t_{\text{WUSART}}\) is the time between the detection of the start bit falling edge and the instant when the clock (requested by the peripheral) is ready and reaching the peripheral, and the regulator is ready.
The USART receiver can receive data correctly at up to the maximum tolerated deviation specified in Table 391, Table 392, depending on the following settings:

- 9-, 10- or 11-bit character length defined by the M bits in the USART_CR1 register
- Oversampling by 8 or 16 defined by the OVER8 bit in the USART_CR1 register
- Bits BRR[3:0] of USART_BRR register are equal to or different from 0000.
- Use of 1 bit or 3 bits to sample the data, depending on the value of the ONEBIT bit in the USART_CR3 register.

### Table 391. Tolerance of the USART receiver when BRR [3:0] = 0000

*Note:* The data specified in Table 391 and Table 392 may slightly differ in the special case when the received frames contain some Idle frames of exactly 10-bit times when M bits = 00 (11-bit times when M = 01 or 9-bit times when M = 10).

### 47.5.9 USART Auto baud rate detection

The USART can detect and automatically set the USART_BRR register value based on the reception of one character. Automatic baud rate detection is useful under two circumstances:

- The communication speed of the system is not known in advance.
- The system is using a relatively low accuracy clock source and this mechanism allows the correct baud rate to be obtained without measuring the clock deviation.

The clock source frequency must be compatible with the expected communication speed.

- When oversampling by 16, the baud rate ranges from `usart_ker_ck_pres/65535` and `usart_ker_ck_pres/16`.
- When oversampling by 8, the baud rate ranges from `usart_ker_ck_pres/65535` and `usart_ker_ck_pres/8`.

Before activating the auto baud rate detection, the auto baud rate detection mode must be selected through the ABRMOD[1:0] field in the USART_CR2 register. There are four modes based on different character patterns. In these auto baud rate modes, the baud rate is...
measured several times during the synchronization data reception and each measurement is compared to the previous one.

These modes are the following:

- **Mode 0**: Any character starting with a bit at ‘1’.
  In this case the USART measures the duration of the start bit (falling edge to rising edge).

- **Mode 1**: Any character starting with a 10xx bit pattern.
  In this case, the USART measures the duration of the Start and of the 1st data bit. The measurement is done falling edge to falling edge, to ensure a better accuracy in the case of slow signal slopes.

- **Mode 2**: A 0x7F character frame (it may be a 0x7F character in LSB first mode or a 0xFE in MSB first mode).
  In this case, the baud rate is updated first at the end of the start bit (BRs), then at the end of bit 6 (based on the measurement done from falling edge to falling edge: BR6). Bit0 to bit6 are sampled at BRs while further bits of the character are sampled at BR6.

- **Mode 3**: A 0x55 character frame.
  In this case, the baud rate is updated first at the end of the start bit (BRs), then at the end of bit0 (based on the measurement done from falling edge to falling edge: BR0), and finally at the end of bit6 (BR6). Bit 0 is sampled at BRs, bit 1 to bit 6 are sampled at BR0, and further bits of the character are sampled at BR6. In parallel, another check is performed for each intermediate RX line transition. An error is generated if the transitions on RX are not sufficiently synchronized with the receiver (the receiver being based on the baud rate calculated on bit 0).

Prior to activating the auto baud rate detection, the USART_BRR register must be initialized by writing a non-zero baud rate value.

The automatic baud rate detection is activated by setting the ABREN bit in the USART_CR2 register. The USART will then wait for the first character on the RX line. The auto baud rate operation completion is indicated by the setting of the ABRF flag in the USART_ISR register. If the line is noisy, the correct baud rate detection cannot be guaranteed. In this case the BRR value may be corrupted and the ABRE error flag will be set. This also happens if the communication speed is not compatible with the automatic baud rate detection range (bit duration not between 16 and 65536 clock periods (oversampling by 16) and not between 8 and 65536 clock periods (oversampling by 8)).

The auto baud rate detection can be re-launched later by resetting the ABRF flag (by writing a ‘0’).

When FIFO management is disabled and an auto baud rate error occurs, the ABRE flag is set through RXNE and FE bits.

When FIFO management is enabled and an auto baud rate error occurs, the ABRE flag is set through RXFNE and FE bits.

If the FIFO mode is enabled, the auto baud rate detection should be made using the data on the first RXFIFO location. So, prior to launching the auto baud rate detection, make sure that the RXFIFO is empty by checking the RXFNE flag in USART_ISR register.

**Note:** The BRR value might be corrupted if the USART is disabled (UE=0) during an auto baud rate operation.
47.5.10 **USART multiprocessor communication**

It is possible to perform USART multiprocessor communications (with several USARTs connected in a network). For instance one of the USARTs can be the master with its TX output connected to the RX inputs of the other USARTs, while the others are slaves with their respective TX outputs logically ANDed together and connected to the RX input of the master.

In multiprocessor configurations, it is often desirable that only the intended message recipient actively receives the full message contents, thus reducing redundant USART service overhead for all non addressed receivers.

The non-addressed devices can be placed in Mute mode by means of the muting function. To use the Mute mode feature, the MME bit must be set in the USART\_CR1 register.

**Note:** When FIFO management is enabled and MME is already set, MME bit must not be cleared and then set again quickly (within two usart\_ker\_ck cycles), otherwise Mute mode might remain active.

When the Mute mode is enabled:

- none of the reception status bits can be set;
- all the receive interrupts are inhibited;
- the RWU bit in USART\_ISR register is set to ‘1’. RWU can be controlled automatically by hardware or by software, through the MMRQ bit in the USART\_RQR register, under certain conditions.

The USART can enter or exit from Mute mode using one of two methods, depending on the WAKE bit in the USART\_CR1 register:

- Idle Line detection if the WAKE bit is reset,
- Address Mark detection if the WAKE bit is set.

**Idle line detection (WAKE=0)**

The USART enters Mute mode when the MMRQ bit is written to ‘1’ and the RWU is automatically set.

The USART wakes up when an Idle frame is detected. The RWU bit is then cleared by hardware but the IDLE bit is not set in the USART\_ISR register. An example of Mute mode behavior using Idle line detection is given in Figure 576.
Figure 576. Mute mode using Idle line detection

<table>

RXNE

Note: If the MMRQ is set while the IDLE character has already elapsed, Mute mode will not be entered (RWU is not set).

If the USART is activated while the line is IDLE, the idle state is detected after the duration of one IDLE frame (not only after the reception of one character frame).

4-bit/7-bit address mark detection (WAKE=1)

In this mode, bytes are recognized as addresses if their MSB is a ‘1’, otherwise they are considered as data. In an address byte, the address of the targeted receiver is put in the 4 or 7 LSBs. The choice of 7 or 4 bit address detection is done using the ADDM7 bit. This 4-bit/7-bit word is compared by the receiver with its own address which is programmed in the ADD bits in the USART_CR2 register.

Note: In 7-bit and 9-bit data modes, address detection is done on 6-bit and 8-bit addresses (ADD[5:0] and ADD[7:0]) respectively.

The USART enters Mute mode when an address character is received which does not match its programmed address. In this case, the RWU bit is set by hardware. The RXNE flag is not set for this address byte and no interrupt or DMA request is issued when the USART enters Mute mode. When FIFO management is enabled, the software should ensure that there is at least one empty location in the RXFIFO before entering Mute mode.

The USART also enters Mute mode when the MMRQ bit is written to 1. The RWU bit is also automatically set in this case.

The USART exits from Mute mode when an address character is received which matches the programmed address. Then the RWU bit is cleared and subsequent bytes are received normally. The RXNE/RXFNE bit is set for the address character since the RWU bit has been cleared.

Note: When FIFO management is enabled, when MMRQ is set while the receiver is sampling last bit of a data, this data may be received before effectively entering in Mute mode.

An example of Mute mode behavior using address mark detection is given in Figure 577.
47.5.11 **USART Modbus communication**

The USART offers basic support for the implementation of Modbus/RTU and Modbus/ASCII protocols. Modbus/RTU is a Half-duplex, block-transfer protocol. The control part of the protocol (address recognition, block integrity control and command interpretation) must be implemented in software.

The USART offers basic support for the end of the block detection, without software overhead or other resources.

**Modbus/RTU**

In this mode, the end of one block is recognized by a “silence” (idle line) for more than 2 character times. This function is implemented through the programmable timeout function.

The timeout function and interrupt must be activated, through the RTOEN bit in the USART_CR2 register and the RTOIE in the USART_CR1 register. The value corresponding to a timeout of 2 character times (for example 22 x bit time) must be programmed in the RTO register. When the receive line is idle for this duration, after the last stop bit is received, an interrupt is generated, informing the software that the current block reception is completed.

**Modbus/ASCII**

In this mode, the end of a block is recognized by a specific (CR/LF) character sequence. The USART manages this mechanism using the character match function.

By programming the LF ASCII code in the ADD[7:0] field and by activating the character match interrupt (CMIE=1), the software is informed when a LF has been received and can check the CR/LF in the DMA buffer.
47.5.12 USART parity control

Parity control (generation of parity bit in transmission and parity checking in reception) can be enabled by setting the PCE bit in the USART_CR1 register. Depending on the frame length defined by the M bits, the possible USART frame formats are as listed in Table 393.

**Table 393. USART frame formats**

</tr>
</tbody>
</table>

1. Legends: SB: start bit, STB: stop bit, PB: parity bit. In the data register, the PB is always taking the MSB position (8th or 7th, depending on the M bit value).

**Even parity**

The parity bit is calculated to obtain an even number of “1s” inside the frame of the 6, 7 or 8 LSB bits (depending on M bit values) and the parity bit.

As an example, if data=00110101, and 4 bits are set, then the parity bit will be 0 if even parity is selected (PS bit in USART_CR1 = 0).

**Odd parity**

The parity bit is calculated to obtain an odd number of “1s” inside the frame made of the 6, 7 or 8 LSB bits (depending on M bit values) and the parity bit.

As an example, if data=00110101 and 4 bits set, then the parity bit will be 1 if odd parity is selected (PS bit in USART_CR1 = 1).

**Parity checking in reception**

If the parity check fails, the PE flag is set in the USART_ISR register and an interrupt is generated if PEIE is set in the USART_CR1 register. The PE flag is cleared by software writing 1 to the PECF in the USART_ICR register.

**Parity generation in transmission**

If the PCE bit is set in USART_CR1, then the MSB bit of the data written in the data register is transmitted but is changed by the parity bit (even number of “1s” if even parity is selected (PS=0) or an odd number of “1s” if odd parity is selected (PS=1)).
47.5.13 USART LIN (local interconnection network) mode

This section is relevant only when LIN mode is supported. Refer to Section 47.4: USART implementation on page 2024.

The LIN mode is selected by setting the LINEN bit in the USART_CR2 register. In LIN mode, the following bits must be kept cleared:
- CLKEN in the USART_CR2 register,
- STOP[1:0], SCEN, HDSEL and IREN in the USART_CR3 register.

**LIN transmission**

The procedure described in Section 47.5.4 has to be applied for LIN Master transmission. It must be the same as for normal USART transmission with the following differences:
- Clear the M bit to configure 8-bit word length.
- Set the LINEN bit to enter LIN mode. In this case, setting the SBKRQ bit sends 13 '0' bits as a break character. Then 2 bits of value '1' are sent to allow the next start detection.

**LIN reception**

When LIN mode is enabled, the break detection circuit is activated. The detection is totally independent from the normal USART receiver. A break can be detected whenever it occurs, during Idle state or during a frame.

When the receiver is enabled (RE=1 in USART_CR1), the circuit looks at the RX input for a start signal. The method for detecting start bits is the same when searching break characters or data. After a start bit has been detected, the circuit samples the next bits exactly like for the data (on the 8th, 9th and 10th samples). If 10 (when the LBDL = 0 in USART_CR2) or 11 (when LBDL=1 in USART_CR2) consecutive bits are detected as '0', and are followed by a delimiter character, the LBDF flag is set in USART_ISR. If the LBDIE bit=1, an interrupt is generated. Before validating the break, the delimiter is checked for as it signifies that the RX line has returned to a high level.

If a '1' is sampled before the 10 or 11 have occurred, the break detection circuit cancels the current detection and searches for a start bit again.

If the LIN mode is disabled (LINEN=0), the receiver continues working as normal USART, without taking into account the break detection.

If the LIN mode is enabled (LINEN=1), as soon as a framing error occurs (i.e. stop bit detected at '0', which will be the case for any break frame), the receiver stops until the break detection circuit receives either a '1', if the break word was not complete, or a delimiter character if a break has been detected.

The behavior of the break detector state machine and the break flag is shown on the Figure 578: Break detection in LIN mode (11-bit break length - LBDL bit is set) on page 2050.

Examples of break frames are given on Figure 579: Break detection in LIN mode vs. Framing error detection on page 2051.

### 47.5.14 USART synchronous mode

**Master mode**

The synchronous master mode is selected by programming the CLKEN bit in the USART_CR2 register to ‘1’. In synchronous mode, the following bits must be kept cleared:

- LINEN bit in the USART_CR2 register,
- SCEN, HDSEL and IREN bits in the USART_CR3 register.

In this mode, the USART can be used to control bidirectional synchronous serial communications in master mode. The SCLK pin is the output of the USART transmitter clock. No clock pulses are sent to the SCLK pin during start bit and stop bit. Depending on the state of the LBCL bit in the USART_CR2 register, clock pulses are, or are not, generated during the last valid data bit (address mark). The CPOL bit in the USART_CR2 register is used to select the clock polarity, and the CPHA bit in the USART_CR2 register is used to select the phase of the external clock (see Figure 580, Figure 581 and Figure 582).

During the Idle state, preamble and send break, the external SCLK clock is not activated.

In synchronous master mode, the USART transmitter operates exactly like in asynchronous mode. However, since SCLK is synchronized with TX (according to CPOL and CPHA), the data on TX is synchronous.

In synchronous master mode, the USART receiver operates in a different way compared to asynchronous mode. If RE is set to 1, the data are sampled on SCLK (rising or falling edge, depending on CPOL and CPHA), without any oversampling. A given setup and a hold time must be respected (which depends on the baud rate: 1/16 bit time).
Note: In master mode, the SCLK pin operates in conjunction with the TX pin. Thus, the clock is provided only if the transmitter is enabled (TE=1) and data are being transmitted (USART_TDR data register written). This means that it is not possible to receive synchronous data without transmitting data.

Figure 580. USART example of synchronous master transmission

Figure 581. USART data clock timing diagram in synchronous master mode
(M bits =00)
Figure 582. USART data clock timing diagram in synchronous master mode
(M bits = ‘01’)

Slave mode

The synchronous slave mode is selected by programming the SLVEN bit in the USART_CR2 register to ‘1’. In synchronous slave mode, the following bits must be kept cleared:
- LINEN and CLKEN bits in the USART_CR2 register,
- SCEN, HDSEL and IREN bits in the USART_CR3 register.

In this mode, the USART can be used to control bidirectional synchronous serial communications in slave mode. The SCLK pin is the input of the USART in slave mode.

Note: When the peripheral is used in SPI slave mode, the frequency of peripheral clock source (usart_ker_ck_pres) must be greater than 3 times the CK input frequency.

The CPOL bit and the CPHA bit in the USART_CR2 register are used to select the clock polarity and the phase of the external clock, respectively (see Figure 583).

An underrun error flag is available in slave transmission mode. This flag is set when the first clock pulse for data transmission appears while the software has not yet loaded any value to USART_TDR.

The slave supports the hardware and software NSS management.
Slave Select (NSS) pin management

The hardware or software slave select management can be set through the DIS_NSS bit in the USART_CR2 register:

- Software NSS management (DIS_NSS = 1)
  SPI slave will always be selected and NSS input pin will be ignored.
  The external NSS pin remains free for other application uses.

- Hardware NSS management (DIS_NSS = 0)
  The SPI slave selection depends on NSS input pin. The slave is selected when NSS is low and deselected when NSS is high.

Note: The LBCL (used only on SPI master mode), CPOL and CPHA bits have to be selected when the USART is disabled (UE=0) to ensure that the clock pulses function correctly.

In SPI slave mode, the USART must be enabled before starting the master communications (or between frames while the clock is stable). Otherwise, if the USART slave is enabled while the master is in the middle of a frame, it will become desynchronized with the master. The data register of the slave needs to be ready before the first edge of the communication clock or before the end of the ongoing communication, otherwise the SPI slave will transmit zeros.

SPI Slave underrun error

When an underrun error occurs, the UDR flag is set in the USART_ISR register, and the SPI slave goes on sending the last data until the underrun error flag is cleared by software.

The underrun flag is set at the beginning of the frame. An underrun error interrupt is triggered if EIE bit is set in the USART_CR3 register.

The underrun error flag is cleared by setting bit UDRCF in the USART_ICR register.
In case of underrun error, it is still possible to write to the TDR register. Clearing the underrun error will allow sending new data.

If an underrun error occurred and there is no new data written in TDR, then the TC flag is set at the end of the frame.

*Note:* An underrun error may occur if the moment the data is written to the USART_TDR is too close to the first SCLK transmission edge. To avoid this underrun error, the USART_TDR should be written 3 `usart_ker_ck` cycles before the first SCLK edge.

### 47.5.15 USART single-wire Half-duplex communication

Single-wire Half-duplex mode is selected by setting the HDSEL bit in the USART_CR3 register. In this mode, the following bits must be kept cleared:

- LINEN and CLKEN bits in the USART_CR2 register,
- SCEN and IREN bits in the USART_CR3 register.

The USART can be configured to follow a Single-wire Half-duplex protocol where the TX and RX lines are internally connected. The selection between half- and Full-duplex communication is made with a control bit HDSEL in USART_CR3.

As soon as HDSEL is written to ‘1’:

- The TX and RX lines are internally connected.
- The RX pin is no longer used.
- The TX pin is always released when no data is transmitted. Thus, it acts as a standard I/O in idle or in reception. It means that the I/O must be configured so that TX is configured as alternate function open-drain with an external pull-up.

Apart from this, the communication protocol is similar to normal USART mode. Any conflict on the line must be managed by software (for instance by using a centralized arbiter). In particular, the transmission is never blocked by hardware and continues as soon as data are written in the data register while the TE bit is set.

### 47.5.16 USART receiver timeout

The receiver timeout feature is enabled by setting the RTOEN bit in the USART_CR2 control register.

The timeout duration is programmed using the RTO bitfields in the USART_RTOR register.

The receiver timeout counter starts counting:

- from the end of the stop bit if STOP = ‘00’ or STOP = ‘11’
- from the end of the second stop bit if STOP = ‘10’.
- from the beginning of the stop bit if STOP = ‘01’.

When the timeout duration has elapsed, the RTOF flag in the USART_ISR register is set. A timeout will be generated if RTOIE bit in USART_CR1 register is set.
47.5.17 USART Smartcard mode

This section is relevant only when Smartcard mode is supported. Refer to Section 47.4: USART implementation on page 2024.

Smartcard mode is selected by setting the SCEN bit in the USART_CR3 register. In Smartcard mode, the following bits must be kept cleared:

- LINEN bit in the USART_CR2 register,
- HDSEL and IREN bits in the USART_CR3 register.

The CLKEN bit can also be set to provide a clock to the Smartcard.

The Smartcard interface is designed to support asynchronous Smartcard protocol as defined in the ISO 7816-3 standard. Both T=0 (character mode) and T=1 (block mode) are supported.

The USART should be configured as:

- 8 bits plus parity: M=1 and PCE=1 in the USART_CR1 register
- 1.5 stop bits when transmitting and receiving data: STOP=’11’ in the USART_CR2 register. It is also possible to choose 0.5 stop bit for reception.

In T=0 (character) mode, the parity error is indicated at the end of each character during the guard time period.

Figure 584 shows examples of what can be seen on the data line with and without parity error.

**Figure 584. ISO 7816-3 asynchronous protocol**

When connected to a Smartcard, the TX output of the USART drives a bidirectional line that is also driven by the Smartcard. The TX pin must be configured as open drain.

Smartcard mode implements a single wire half duplex communication protocol.

- Transmission of data from the transmit shift register is guaranteed to be delayed by a minimum of 1/2 baud clock. In normal operation a full transmit shift register starts shifting on the next baud clock edge. In Smartcard mode this transmission is further delayed by a guaranteed 1/2 baud clock.

- In transmission, if the Smartcard detects a parity error, it signals this condition to the USART by driving the line low (NACK). This NACK signal (pulling transmit line low for 1 baud clock) causes a framing error on the transmitter side (configured with 1.5 stop bits). The USART can handle automatic re-sending of data according to the protocol.
The number of retries is programmed in the SCARCNT bitfield. If the USART continues receiving the NACK after the programmed number of retries, it stops transmitting and signals the error as a framing error. The TXE bit (TXFNF bit in case FIFO mode is enabled) may be set using the TXFRQ bit in the USART_RQR register.

- Smartcard auto-retry in transmission: A delay of 2.5 baud periods is inserted between the NACK detection by the USART and the start bit of the repeated character. The TC bit is set immediately at the end of reception of the last repeated character (no guardtime). If the software wants to repeat it again, it must insure the minimum 2 baud periods required by the standard.

- If a parity error is detected during reception of a frame programmed with a 1.5 stop bit period, the transmit line is pulled low for a baud clock period after the completion of the receive frame. This is to indicate to the Smartcard that the data transmitted to the USART has not been correctly received. A parity error is NACKed by the receiver if the NACK control bit is set, otherwise a NACK is not transmitted (to be used in T=1 mode). If the received character is erroneous, the RXNE (RXFNE in case FIFO mode is enabled) receive DMA request is not activated. According to the protocol specification, the Smartcard must resend the same character. If the received character is still erroneous after the maximum number of retries specified in the SCARCNT bitfield, the USART stops transmitting the NACK and signals the error as a parity error.

- Smartcard auto-retry in reception: the BUSY flag remains set if the USART NACKs the card but the card doesn’t repeat the character.

- In transmission, the USART inserts the Guard Time (as programmed in the Guard Time register) between two successive characters. As the Guard Time is measured after the stop bit of the previous character, the GT[7:0] register must be programmed to the desired CGT (Character Guard Time, as defined by the 7816-3 specification) minus 12 (the duration of one character).

- The assertion of the TC flag can be delayed by programming the Guard Time register. In normal operation, TC is asserted when the transmit shift register is empty and no further transmit requests are outstanding. In Smartcard mode an empty transmit shift register triggers the Guard Time counter to count up to the programmed value in the Guard Time register. TC is forced low during this time. When the Guard Time counter reaches the programmed value TC is asserted high. The TCBGT flag can be used to detect the end of data transfer without waiting for guard time completion. This flag is set just after the end of frame transmission and if no NACK has been received from the card.

- The de-assertion of TC flag is unaffected by Smartcard mode.

- If a framing error is detected on the transmitter end (due to a NACK from the receiver), the NACK is not detected as a start bit by the receive block of the transmitter. According to the ISO protocol, the duration of the received NACK can be 1 or 2 baud clock periods.

- On the receiver side, if a parity error is detected and a NACK is transmitted the receiver does not detect the NACK as a start bit.

*Note:* Break characters are not significant in Smartcard mode. A 0x00 data with a framing error is treated as data and not as a break.

No Idle frame is transmitted when toggling the TE bit. The Idle frame (as defined for the other configurations) is not defined by the ISO protocol.

Figure 585 shows how the NACK signal is sampled by the USART. In this example the USART is transmitting data and is configured with 1.5 stop bits. The receiver part of the USART is enabled in order to check the integrity of the data and the NACK signal.
The USART can provide a clock to the Smartcard through the SCLK output. In Smartcard mode, SCLK is not associated to the communication but is simply derived from the internal peripheral input clock through a 5-bit prescaler. The division ratio is configured in the USART_GTPR register. SCLK frequency can be programmed from usart_ker_ck_pres/2 to usart_ker_ck_pres/62, where usart_ker_ck_pres is the peripheral input clock divided by a programmed prescaler.

**Block mode (T=1)**

In T=1 (block) mode, the parity error transmission can be deactivated by clearing the NACK bit in the USART_CR3 register.

When requesting a read from the Smartcard, in block mode, the software must program the RTOR register to the BWT (block wait time) - 11 value. If no answer is received from the card before the expiration of this period, a timeout interrupt will be generated. If the first character is received before the expiration of the period, it is signaled by the RXNE/RXFNE interrupt.

*Note:* The RXNE/RXFNE interrupt must be enabled even when using the USART in DMA mode to read from the Smartcard in block mode. In parallel, the DMA must be enabled only after the first received byte.

After the reception of the first character (RXNE/RXFNE interrupt), the RTO register must be programmed to the CWT (character wait time -11 value), in order to allow the automatic check of the maximum wait time between two consecutive characters. This time is expressed in baud time units. If the Smartcard does not send a new character in less than the CWT period after the end of the previous character, the USART will signal it to the software through the RTOF flag and interrupt (when RTOIE bit is set).

*Note:* As in the Smartcard protocol definition, the BWT/CWT values should be defined from the beginning (start bit) of the last character. The RTO register must be programmed to BWT - 11 or CWT - 11, respectively, taking into account the length of the last character itself.

A block length counter is used to count all the characters received by the USART. This counter is reset when the USART is transmitting. The length of the block is communicated by the Smartcard in the third byte of the block (prologue field). This value must be programmed to the BLEN field in the USART_RTOR register. When using DMA mode, before the start of the block, this register field must be programmed to the minimum value.
(0x0). With this value, an interrupt is generated after the 4th received character. The software must read the LEN field (third byte), its value must be read from the receive buffer.

In interrupt driven receive mode, the length of the block may be checked by software or by programming the BLEN value. However, before the start of the block, the maximum value of BLEN (0xFF) may be programmed. The real value will be programmed after the reception of the third character.

If the block is using the LRC longitudinal redundancy check (1 epilogue byte), the BLEN=LEN. If the block is using the CRC mechanism (2 epilog bytes), BLEN=LEN+1 must be programmed. The total block length (including prologue, epilogue and information fields) equals BLEN+4. The end of the block is signaled to the software through the EOBF flag and interrupt (when EOBIE bit is set).

In case of an error in the block length, the end of the block is signaled by the RTO interrupt (Character Wait Time overflow).

**Note:** The error checking code (LRC/CRC) must be computed/verified by software.

### Direct and inverse convention

The Smartcard protocol defines two conventions: direct and inverse.

The direct convention is defined as: LSB first, logical bit value of 1 corresponds to a H state of the line and parity is even. In order to use this convention, the following control bits must be programmed: MSBFIRST=0, DATAINV=0 (default values).

The inverse convention is defined as: MSB first, logical bit value 1 corresponds to an L state on the signal line and parity is even. In order to use this convention, the following control bits must be programmed: MSBFIRST=1, DATAINV=1.

**Note:** When logical data values are inverted (0=H, 1=L), the parity bit is also inverted in the same way.

In order to recognize the card convention, the card sends the initial character, TS, as the first character of the ATR (Answer To Reset) frame. The two possible patterns for the TS are: LHHL LLL LLH and LHHL HHH LLH.

- (H) LHHL LLL LLH sets up the inverse convention: state L encodes value 1 and moment 2 conveys the most significant bit (MSB first). When decoded by inverse convention, the conveyed byte is equal to '3F'.
- (H) LHHL HHH LLH sets up the direct convention: state H encodes value 1 and moment 2 conveys the least significant bit (LSB first). When decoded by direct convention, the conveyed byte is equal to '3B'.

Character parity is correct when there is an even number of bits set to 1 in the nine moments 2 to 10.

As the USART does not know which convention is used by the card, it needs to be able to recognize either pattern and act accordingly. The pattern recognition is not done in hardware, but through a software sequence. Moreover, supposing that the USART is configured in direct convention (default) and the card answers with the inverse convention, TS = LHHL LLL LLH => the USART received character will be '03' and the parity will be odd.
Therefore, two methods are available for TS pattern recognition:

**Method 1**

The USART is programmed in standard Smartcard mode/direct convention. In this case, the TS pattern reception generates a parity error interrupt and error signal to the card.

- The parity error interrupt informs the software that the card did not answer correctly in direct convention. Software then reprograms the USART for inverse convention
- In response to the error signal, the card retries the same TS character, and it will be correctly received this time, by the reprogrammed USART

Alternatively, in answer to the parity error interrupt, the software may decide to reprogram the USART and to also generate a new reset command to the card, then wait again for the TS.

**Method 2**

The USART is programmed in 9-bit/no-parity mode, no bit inversion. In this mode it receives any of the two TS patterns as:

- (H) LHHL LLL LLH = 0x103 -> inverse convention to be chosen
- (H) LHHL HHH LLH = 0x13B -> direct convention to be chosen

The software checks the received character against these two patterns and, if any of them match, then programs the USART accordingly for the next character reception.

If none of the two is recognized, a card reset may be generated in order to restart the negotiation.

### 47.5.18 USART IrDA SIR ENDEC block

This section is relevant only when IrDA mode is supported. Refer to [Section 47.4: USART implementation on page 2024.](#)

IrDA mode is selected by setting the IREN bit in the USART_CR3 register. In IrDA mode, the following bits must be kept cleared:

- LINEN, STOP and CLKEN bits in the USART_CR2 register,
- SCEN and HDSEL bits in the USART_CR3 register.

The IrDA SIR physical layer specifies use of a Return to Zero, Inverted (RZI) modulation scheme that represents logic 0 as an infrared light pulse (see [Figure 586](#)).

The SIR Transmit encoder modulates the Non Return to Zero (NRZ) transmit bit stream output from USART. The output pulse stream is transmitted to an external output driver and infrared LED. USART supports only bit rates up to 115.2 Kbps for the SIR ENDEC. In normal mode the transmitted pulse width is specified as 3/16 of a bit period.

The SIR receive decoder demodulates the return-to-zero bit stream from the infrared detector and outputs the received NRZ serial bit stream to the USART. The decoder input is normally high (marking state) in the Idle state. The transmit encoder output has the opposite polarity to the decoder input. A start bit is detected when the decoder input is low.

- IrDA is a half duplex communication protocol. If the Transmitter is busy (when the USART is sending data to the IrDA encoder), any data on the IrDA receive line is ignored by the IrDA decoder and if the Receiver is busy (when the USART is receiving decoded data from the USART), data on the TX from the USART to IrDA is not
encoded. While receiving data, transmission should be avoided as the data to be transmitted could be corrupted.

- A ‘0’ is transmitted as a high pulse and a ‘1’ is transmitted as a ‘0’. The width of the pulse is specified as 3/16th of the selected bit period in normal mode (see Figure 587).
- The SIR decoder converts the IrDA compliant receive signal into a bit stream for USART.
- The SIR receive logic interprets a high state as a logic one and low pulses as logic zeros.
- The transmit encoder output has the opposite polarity to the decoder input. The SIR output is in low state when Idle.
- The IrDA specification requires the acceptance of pulses greater than 1.41 µs. The acceptable pulse width is programmable. Glitch detection logic on the receiver end filters out pulses of width less than 2 PSC periods (PSC is the prescaler value programmed in the USART_GTPR). Pulses of width less than 1 PSC period are always rejected, but those of width greater than one and less than two periods may be accepted or rejected, those greater than 2 periods will be accepted as a pulse. The IrDA encoder/decoder doesn’t work when PSC=0.
- The receiver can communicate with a low-power transmitter.
- In IrDA mode, the stop bits in the USART_CR2 register must be configured to ‘1 stop bit’.

**IrDA low-power mode**

- Transmitter
  
  In low-power mode, the pulse width is not maintained at 3/16 of the bit period. Instead, the width of the pulse is 3 times the low-power baud rate which can be a minimum of 1.42 MHz. Generally, this value is 1.8432 MHz (1.42 MHz < PSC< 2.12 MHz). A low-power mode programmable divisor divides the system clock to achieve this value.

- Receiver
  
  Receiving in low-power mode is similar to receiving in normal mode. For glitch detection the USART should discard pulses of duration shorter than 1/PSC. A valid low is accepted only if its duration is greater than 2 periods of the IrDA low-power Baud clock (PSC value in the USART_GTPR).

**Note:** A pulse of width less than two and greater than one PSC period(s) may or may not be rejected.

The receiver set up time should be managed by software. The IrDA physical layer specification specifies a minimum of 10 ms delay between transmission and reception (IrDA is a half duplex protocol).
Figure 586. IrDA SIR ENDEC block diagram

Figure 587. IrDA data modulation (3/16) - Normal mode
47.5.19 Continuous communication using USART and DMA

The USART is capable of performing continuous communications using the DMA. The DMA requests for Rx buffer and Tx buffer are generated independently.

Note: Refer to Section 47.4: USART implementation on page 2024 to determine if the DMA mode is supported. If DMA is not supported, use the USART as explained in Section 47.5.6. To perform continuous communications when the FIFO is disabled, clear the TXE/ RXNE flags in the USART_ISR register.

Transmission using DMA

DMA mode can be enabled for transmission by setting DMAT bit in the USART_CR3 register. Data are loaded from an SRAM area configured using the DMA peripheral (refer to the corresponding Direct memory access controller section) to the USART_TDR register whenever the TXE flag (TXFNF flag if FIFO mode is enabled) is set. To map a DMA channel for USART transmission, use the following procedure (x denotes the channel number):

1. Write the USART_TDR register address in the DMA control register to configure it as the destination of the transfer. The data is moved to this address from memory after each TXE (or TXFNF if FIFO mode is enabled) event.
2. Write the memory address in the DMA control register to configure it as the source of the transfer. The data is loaded into the USART_TDR register from this memory area after each TXE (or TXFNF if FIFO mode is enabled) event.
3. Configure the total number of bytes to be transferred to the DMA control register.
4. Configure the channel priority in the DMA register
5. Configure DMA interrupt generation after half/ full transfer as required by the application.
6. Clear the TC flag in the USART_ISR register by setting the TCCF bit in the USART_ICR register.
7. Activate the channel in the DMA register.

When the number of data transfers programmed in the DMA Controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector.

In transmission mode, once the DMA has written all the data to be transmitted (the TCIF flag is set in the DMA_ISR register), the TC flag can be monitored to make sure that the USART communication is complete. This is required to avoid corrupting the last transmission before disabling the USART or before the system enters a low-power mode when the peripheral clock is disabled. Software must wait until TC=1. The TC flag remains cleared during all data transfers and it is set by hardware at the end of transmission of the last frame.
**Note:** When FIFO management is enabled, the DMA request is triggered by Transmit FIFO not full (i.e. TXFNF = 1).

### Reception using DMA

DMA mode can be enabled for reception by setting the DMAR bit in USART_CR3 register. Data are loaded from the USART_RDR register to an SRAM area configured using the DMA peripheral (refer to the corresponding Direct memory access controller section) whenever a data byte is received. To map a DMA channel for USART reception, use the following procedure:

1. Write the USART_RDR register address in the DMA control register to configure it as the source of the transfer. The data is moved from this address to the memory after each RXNE (RXFNE in case FIFO mode is enabled) event.
2. Write the memory address in the DMA control register to configure it as the destination of the transfer. The data is loaded from USART_RDR to this memory area after each RXNE (RXFNE in case FIFO mode is enabled) event.
3. Configure the total number of bytes to be transferred to the DMA control register.
4. Configure the channel priority in the DMA control register.
5. Configure interrupt generation after half/ full transfer as required by the application.
6. Activate the channel in the DMA control register.

When the number of data transfers programmed in the DMA Controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector.
Figure 589. Reception using DMA

<table>
<thead>
<tr>
<th>TX line</th>
<th>Frame 1</th>
<th>Frame 2</th>
<th>Frame 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>RXNE flag</td>

<td></td>
</tr>
<tr>
<td>DMA TCIF flag (transfer complete)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Software-configures the DMA to receive 3 data blocks and enables the USART. DMA reads F1 from USART_RDR, DMA reads F2 from USART_RDR, DMA reads F3 from USART_RDR. The DMA transfer is complete (TCIF=1 in DMA_ISR).

Note: When FIFO management is enabled, the DMA request is triggered by Receive FIFO not empty (i.e. RXFNE = 1).

Error flagging and interrupt generation in multibuffer communication

If any error occurs during a transaction in multibuffer communication mode, the error flag is asserted after the current byte. An interrupt is generated if the interrupt enable flag is set. For framing error, overrun error and noise flag which are asserted with RXNE (RXFNE in case FIFO mode is enabled) in single byte reception, there is a separate error flag interrupt enable bit (EIE bit in the USART_CR3 register), which, if set, enables an interrupt after the current byte if any of these errors occur.

47.5.20 RS232 Hardware flow control and RS485 Driver Enable

It is possible to control the serial data flow between 2 devices by using the nCTS input and the nRTS output. The Figure 590 shows how to connect 2 devices in this mode:

Figure 590. Hardware flow control between 2 USARTs
RS232 RTS and CTS flow control can be enabled independently by writing the RTSE and CTSE bits to ‘1’ in the USART_CR3 register.

**RS232 RTS flow control**

If the RTS flow control is enabled (RTSE=1), then nRTS is asserted (tied low) as long as the USART receiver is ready to receive a new data. When the receive register is full, nRTS is deasserted, indicating that the transmission is expected to stop at the end of the current frame. *Figure 591* shows an example of communication with RTS flow control enabled.

*Figure 591. RS232 RTS flow control*

![RS232 RTS flow control diagram](image)

**Note:** When FIFO mode is enabled, nRTS is de-asserted only when RXFIFO is full.

**RS232 CTS flow control**

If the CTS flow control is enabled (CTSE=1), then the transmitter checks the nCTS input before transmitting the next frame. If nCTS is asserted (tied low), then the next data is transmitted (assuming that data is to be transmitted, in other words, if TXE/TXFE=0), else the transmission does not occur. When nCTS is deasserted during a transmission, the current transmission is completed before the transmitter stops.

When CTSE=1, the CTSIF status bit is automatically set by hardware as soon as the nCTS input toggles. It indicates when the receiver becomes ready or not ready for communication. An interrupt is generated if the CTSIE bit in the USART_CR3 register is set. *Figure 592* shows an example of communication with CTS flow control enabled.
Note: For correct behavior, nCTS must be asserted at least 3 USART clock source periods before the end of the current character. In addition it should be noted that the CTSCF flag may not be set for pulses shorter than 2 x PCLK periods.

**RS485 driver enable**

The driver enable feature is enabled by setting bit DEM in the USART_CR3 control register. This allows the user to activate the external transceiver control, through the DE (Driver Enable) signal. The assertion time is the time between the activation of the DE signal and the beginning of the start bit. It is programmed using the DEAT [4:0] bitfields in the USART_CR1 control register. The de-assertion time is the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE signal. It is programmed using the DEDT [4:0] bitfields in the USART_CR1 control register. The polarity of the DE signal can be configured using the DEP bit in the USART_CR3 control register.

In USART, the DEAT and DEDT are expressed in sample time units (1/8 or 1/16 bit time, depending on the oversampling rate).
47.5.21 USART low-power management

The USART has advanced low-power mode functions, that allow transferring properly data even when the usart_pclk clock is disabled.

The USART is able to wake up the MCU from low-power mode when the UESM bit is set. When the usart_pclk is gated, the USART provides a wakeup interrupt (usart_wkup) if a specific action requiring the activation of the usart_pclk clock is needed:

- **If FIFO mode is disabled**
  - usart_pclk clock has to be activated to empty the USART data register.
  
  In this case, the usart_wkup interrupt source is RXNE set to ‘1’. The RXNEIE bit must be set before entering low-power mode.

- **If FIFO mode is enabled**
  - usart_pclk clock has to be activated to:
    - to fill the TXFIFO
    - or to empty the RXFIFO
  
  In this case, the usart_wkup interrupt source can be:
    - RXFIFO not empty. In this case, the RXFNEIE bit must be set before entering low-power mode.
    - RXFIFO full. In this case, the RXFFIE bit must be set before entering low-power mode, the number of received data corresponds to the RXFIFO size, and the RXFF flag is not set.
    - TXFIFO empty. In this case, the TXFIE bit must be set before entering low-power mode.

This allows sending/receiving the data in the TXFIFO/RXFIFO during low-power mode. To avoid overrun/underrun errors and transmit/receive data in low-power mode, the usart_wkup interrupt source can be one of the following events:

- TXFIFO threshold reached. In this case, the TXFTIE bit must be set before entering low-power mode.
- RXFIFO threshold reached. In this case, the RXFTIE bit must be set before entering low-power mode.

For example, the application can set the threshold to the maximum RXFIFO size if the wakeup time is less than the time required to receive a single byte across the line. Using the RXFIFO full, TXFIFO empty, RXFIFO not empty and RXFIFO/TXFIFO threshold interrupts to wakeup the MCU from low-power mode allows doing as many USART transfers as possible during low-power mode with the benefit of optimizing consumption.

Alternatively, a specific usart_wkup interrupt can be selected through the WUS bitfields.

When the wakeup event is detected, the WUF flag is set by hardware and a usart_wkup interrupt is generated if the WUFIIE bit is set. In this case the usart_wkup interrupt is not mandatory and setting the WUF being is sufficient to wake up the MCU from low-power mode.
Note: Before entering low-power mode, make sure that no USART transfers are ongoing.
Checking the BUSY flag cannot ensure that low-power mode is never entered when data reception is ongoing.

The WUF flag is set when a wakeup event is detected, independently of whether the MCU is in low-power or active mode.

When entering low-power mode just after having initialized and enabled the receiver, the REACK bit must be checked to make sure the USART is enabled.

When DMA is used for reception, it must be disabled before entering low-power mode and re-enabled when exiting from low-power mode.

When the FIFO is enabled, waking up from low-power mode on address match is only possible when Mute mode is enabled.

Using Mute mode with low-power mode

If the USART is put into Mute mode before entering low-power mode:
- Wakeup from Mute mode on idle detection must not be used, because idle detection cannot work in low-power mode.
- If the wakeup from Mute mode on address match is used, then the low-power mode wakeup source must also be the address match. If the RXNE flag was set when entering the low-power mode, the interface will remain in Mute mode upon address match and wake up from low-power mode.

Note: When FIFO management is enabled, Mute mode can be used with wakeup from low-power mode without any constraints (i.e. the two points mentioned above about Mute and low-power mode are valid only when FIFO management is disabled).

Wakeup from low-power mode when USART kernel clock (usart_ker_ck) is OFF in low-power mode

If during low-power mode, the usart_ker_ck clock is switched OFF when a falling edge on the USART receive line is detected, the USART interface requests the usart_ker_ck clock to be switched ON thanks to the usart_ker_ck_req signal. usart_ker_ck is then used for the frame reception.

If the wakeup event is verified, the MCU wakes up from low-power mode and data reception goes on normally.

If the wakeup event is not verified, usart_ker_ck is switched OFF again, the MCU is not woken up and remains in low-power mode, and the kernel clock request is released.

The example below shows the case of a wakeup event programmed to “address match detection” and FIFO management disabled.
Figure 593 shows the USART behavior when the wakeup event is verified.

Figure 593. Wakeup event verified (wakeup event = address match, FIFO disabled)

![Diagram showing USART behavior when the wakeup event is verified.]

Figure 594 shows the USART behavior when the wakeup event is not verified.

Figure 594. Wakeup event not verified (wakeup event = address match, FIFO disabled)

![Diagram showing USART behavior when the wakeup event is not verified.]

Note: The figures above are valid when address match or any received frame is used as wakeup event. If the wakeup event is the start bit detection, the USART sends the wakeup event to the MCU at the end of the start bit.
Determining the maximum USART baud rate that allows to correctly wake up the microcontroller from low-power mode

The maximum baud rate allowing to correctly wake up the microcontroller from low-power mode depends on the wakeup time parameter (refer to the device datasheet) and on the USART receiver tolerance (see Section 47.5.8: Tolerance of the USART receiver to clock deviation).

Let us take the example of OVER8 = 0, M bits = ‘01’, ONEBIT = 0 and BRR [3:0] = 0000.

In these conditions, according to Table 391: Tolerance of the USART receiver when BRR [3:0] = 0000, the USART receiver tolerance equals 3.41%.

\[
D_{WUmax} = \frac{t_{WUUSART}}{11 \times T_{bit Min}}
\]

where \( t_{WUUSART} \) is the wakeup time from low-power mode.

If we consider the ideal case where DTRA, DQUANT, DREC and DTCL parameters are at 0%, the maximum value of DWU is 3.41%. In reality, we need to consider at least the usart_ker_ck inaccuracy.

For example, if HSI is used as usart_ker_ck, and the HSI inaccuracy is of 1%, then we obtain:

\[
t_{WUUSART} = 3 \mu s \quad \text{(values provided only as examples; for correct values, refer to the device datasheet)}.
\]

\[
D_{WUmax} = 3.41\% - 1\% = 2.41\%
\]

\[
T_{bit min} = \frac{3 \mu s}{11 \times 2.41\%} = 11.32 \mu s.
\]

As a result, the maximum baud rate allowing to wake up correctly from low-power mode is: \( \frac{1}{11.32 \mu s} = 88.36 \text{ Kbaud} \).

### 47.6 USART interrupts

During USART communications, an interrupt (usart_it) can be generated by different events. The USART block can also generate a wakeup interrupt (usart_wkup).

Refer to Table 394 for a detailed description of all USART interrupt requests.

1. RXFF flag is asserted if the USART receives n+1 data (n being the RXFIFO size): n data in the RXFIFO and 1 data in USART_RDR. In Stop mode, USART_RDR is not clocked. As a result, this register will not be written and once n data are received and written in the RXFIFO, the RXFF interrupt will be asserted (RXFF flag is not set).

2. The WUF interrupt is active only in low-power mode.
47.7 USART registers

Refer to Section 1.2 on page 98 for a list of abbreviations used in register descriptions.

47.7.1 USART control register 1 [alternate] (USART_CR1)

Address offset: 0x00
Reset value: 0x0000 0000

The same register can be used in FIFO mode enabled (this section) and FIFO mode disabled (next section).

Note: In 7-bits data length mode, the Smartcard mode, LIN master mode and Auto baud rate (0x7F and 0x55 frames detection) are not supported.
Bit 27 **EOBIE**: End of Block interrupt enable  
This bit is set and cleared by software.  
0: Interrupt inhibited  
1: USART interrupt generated when the EOBF flag is set in the USART_ISR register  
*Note: If the USART does not support Smartcard mode, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.*

Bit 26 **RTOIE**: Receiver timeout interrupt enable  
This bit is set and cleared by software.  
0: Interrupt inhibited  
1: USART interrupt generated when the RTOF bit is set in the USART_ISR register.  
*Note: If the USART does not support the Receiver timeout feature, this bit is reserved and must be kept at reset value. Section 47.4: USART implementation on page 2024.*

Bits 25:21 **DEAT[4:0]**: Driver Enable assertion time  
This 5-bit value defines the time between the activation of the DE (Driver Enable) signal and the beginning of the start bit. It is expressed in sample time units (1/8 or 1/16 bit time, depending on the oversampling rate).  
This bitfield can only be written when the USART is disabled (UE=0).  
*Note: If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.*

Bits 20:16 **DEDT[4:0]**: Driver Enable deassertion time  
This 5-bit value defines the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE (Driver Enable) signal. It is expressed in sample time units (1/8 or 1/16 bit time, depending on the oversampling rate).  
If the USART_TDR register is written during the DEDT time, the new data is transmitted only when the DEDT and DEAT times have both elapsed.  
This bitfield can only be written when the USART is disabled (UE=0).  
*Note: If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.*

Bit 15 **OVER8**: Oversampling mode  
0: Oversampling by 16  
1: Oversampling by 8  
This bit can only be written when the USART is disabled (UE=0).  
*Note: In LIN, IrDA and Smartcard modes, this bit must be kept cleared.*

Bit 14 **CMIE**: Character match interrupt enable  
This bit is set and cleared by software.  
0: Interrupt inhibited  
1: USART interrupt generated when the CMF bit is set in the USART_ISR register.

Bit 13 **MME**: Mute mode enable  
This bit enables the USART Mute mode function. When set, the USART can switch between active and Mute mode, as defined by the WAKE bit. It is set and cleared by software.  
0: Receiver in active mode permanently  
1: Receiver can switch between Mute mode and active mode.

Bit 12 **M0**: Word length  
This bit is used in conjunction with bit 28 (M1) to determine the word length. It is set or cleared by software (refer to bit 28 (M1) description).  
This bit can only be written when the USART is disabled (UE=0).
Bit 11 **WAKE**: Receiver wakeup method

This bit determines the USART wakeup method from Mute mode. It is set or cleared by software.
0: Idle line
1: Address mark
This bitfield can only be written when the USART is disabled (UE=0).

Bit 10 **PCE**: Parity control enable

This bit selects the hardware parity control (generation and detection). When the parity control is enabled, the computed parity is inserted at the MSB position (9th bit if M=1, 8th bit if M=0) and the parity is checked on the received data. This bit is set and cleared by software. Once it is set, PCE is active after the current byte (in reception and in transmission).
0: Parity control disabled
1: Parity control enabled
This bitfield can only be written when the USART is disabled (UE=0).

Bit 9 **PS**: Parity selection

This bit selects the odd or even parity when the parity generation/detection is enabled (PCE bit set). It is set and cleared by software. The parity will be selected after the current byte.
0: Even parity
1: Odd parity
This bitfield can only be written when the USART is disabled (UE=0).

Bit 8 **PEIE**: PE interrupt enable

This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever PE=1 in the USART_ISR register

Bit 7 **TXFNFIE**: TXFIFO not full interrupt enable

This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever TXFNF =1 in the USART_ISR register

Bit 6 **TCIE**: Transmission complete interrupt enable

This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever TC=1 in the USART_ISR register

Bit 5 **RXFNEIE**: RXFIFO not empty interrupt enable

This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever ORE=1 or RXFNE=1 in the USART_ISR register

Bit 4 **IDLEIE**: IDLE interrupt enable

This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever IDLE=1 in the USART_ISR register
Bit 3 **TE**: Transmitter enable

This bit enables the transmitter. It is set and cleared by software.

0: Transmitter is disabled
1: Transmitter is enabled

*Note*: During transmission, a low pulse on the TE bit (‘0’ followed by ‘1’) sends a preamble (idle line) after the current word, except in Smartcard mode. In order to generate an idle character, the TE must not be immediately written to ‘1’. To ensure the required duration, the software can poll the TEACK bit in the USART_ISR register.

In Smartcard mode, when TE is set, there is a 1 bit-time delay before the transmission starts.

Bit 2 **RE**: Receiver enable

This bit enables the receiver. It is set and cleared by software.

0: Receiver is disabled
1: Receiver is enabled and begins searching for a start bit

Bit 1 **UESM**: USART enable in low-power mode

When this bit is cleared, the USART cannot wake up the MCU from low-power mode.
When this bit is set, the USART can wake up the MCU from low-power mode.

This bit is set and cleared by software.

0: USART not able to wake up the MCU from low-power mode.
1: USART able to wake up the MCU from low-power mode.

*Note*: It is recommended to set the UESM bit just before entering low-power mode and clear it when exit from low-power mode.

If the USART does not support the wakeup from Stop feature, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.

Bit 0 **UE**: USART enable

When this bit is cleared, the USART prescalers and outputs are stopped immediately, and all current operations are discarded. The USART configuration is kept, but all the USART_ISR status flags are reset. This bit is set and cleared by software.

0: USART prescaler and outputs disabled, low-power mode
1: USART enabled

*Note*: To enter low-power mode without generating errors on the line, the TE bit must be previously reset and the software must wait for the TC bit in the USART_ISR to be set before resetting the UE bit.

The DMA requests are also reset when UE = 0 so the DMA channel must be disabled before resetting the UE bit.

In Smartcard mode, (SCEN = 1), the SCLK is always available when CLKEN = 1, regardless of the UE bit value.
47.7.2 USART control register 1 [alternate] (USART_CR1)

Address offset: 0x00
Reset value: 0x0000 0000

The same register can be used in FIFO mode enabled (previous section) and FIFO mode disabled (this section).

</tbody>
</table>
Bits 25:21 **DEAT[4:0]**: Driver Enable assertion time

This 5-bit value defines the time between the activation of the DE (Driver Enable) signal and the beginning of the start bit. It is expressed in sample time units (1/8 or 1/16 bit time, depending on the oversampling rate).

This bitfield can only be written when the USART is disabled (UE=0).

*Note:* If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.

Bits 20:16 **DEDT[4:0]**: Driver Enable deassertion time

This 5-bit value defines the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE (Driver Enable) signal. It is expressed in sample time units (1/8 or 1/16 bit time, depending on the oversampling rate).

If the USART_TDR register is written during the DEDT time, the new data is transmitted only when the DEDT and DEAT times have both elapsed.

This bitfield can only be written when the USART is disabled (UE=0).

*Note:* If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.

Bit 15 **OVER8**: Oversampling mode

0: Oversampling by 16
1: Oversampling by 8

This bit can only be written when the USART is disabled (UE=0).

*Note:* In LIN, IrDA and Smartcard modes, this bit must be kept cleared.

Bit 14 **CMIE**: Character match interrupt enable

This bit is set and cleared by software.

0: Interrupt inhibited
1: USART interrupt generated when the CMF bit is set in the USART_ISR register.

Bit 13 **MME**: Mute mode enable

This bit enables the USART Mute mode function. When set, the USART can switch between active and Mute mode, as defined by the WAKE bit. It is set and cleared by software.

0: Receiver in active mode permanently
1: Receiver can switch between Mute mode and active mode.

Bit 12 **M0**: Word length

This bit is used in conjunction with bit 28 (M1) to determine the word length. It is set or cleared by software (refer to bit 28 (M1) description).

This bit can only be written when the USART is disabled (UE=0).

Bit 11 **WAKE**: Receiver wakeup method

This bit determines the USART wakeup method from Mute mode. It is set or cleared by software.

0: Idle line
1: Address mark

This bitfield can only be written when the USART is disabled (UE=0).

Bit 10 **PCE**: Parity control enable

This bit selects the hardware parity control (generation and detection). When the parity control is enabled, the computed parity is inserted at the MSB position (9th bit if M=1; 8th bit if M=0) and the parity is checked on the received data. This bit is set and cleared by software. Once it is set, PCE is active after the current byte (in reception and in transmission).

0: Parity control disabled
1: Parity control enabled

This bitfield can only be written when the USART is disabled (UE=0).
Bit 9  **PS**: Parity selection
This bit selects the odd or even parity when the parity generation/detection is enabled (PCE bit set). It is set and cleared by software. The parity will be selected after the current byte.
0: Even parity
1: Odd parity
This bitfield can only be written when the USART is disabled (UE=0).

Bit 8  **PEIE**: PE interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever PE=1 in the USART_ISR register

Bit 7  **TXEIE**: Transmit data register empty
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever TXE =1 in the USART_ISR register

Bit 6  **TCIE**: Transmission complete interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever TC=1 in the USART_ISR register

Bit 5  **RXNEIE**: Receive data register not empty
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever ORE=1 or RXNE=1 in the USART_ISR register

Bit 4  **IDLEIE**: IDLE interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever IDLE=1 in the USART_ISR register

Bit 3  **TE**: Transmitter enable
This bit enables the transmitter. It is set and cleared by software.
0: Transmitter is disabled
1: Transmitter is enabled

**Note**: During transmission, a low pulse on the TE bit ('0' followed by '1') sends a preamble (idle line) after the current word, except in Smartcard mode. In order to generate an idle character, the TE must not be immediately written to '1'. To ensure the required duration, the software can poll the TEACK bit in the USART_ISR register.

In Smartcard mode, when TE is set, there is a 1 bit-time delay before the transmission starts.
Bit 2 RE: Receiver enable
This bit enables the receiver. It is set and cleared by software.
0: Receiver is disabled
1: Receiver is enabled and begins searching for a start bit

Bit 1 UESM: USART enable in low-power mode
When this bit is cleared, the USART cannot wake up the MCU from low-power mode.
When this bit is set, the USART can wake up the MCU from low-power mode.
This bit is set and cleared by software.
0: USART not able to wake up the MCU from low-power mode.
1: USART able to wake up the MCU from low-power mode.

Note: It is recommended to set the UESM bit just before entering low-power mode and clear it when exit from low-power mode.
If the USART does not support the wakeup from Stop feature, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.

Bit 0 UE: USART enable
When this bit is cleared, the USART prescalers and outputs are stopped immediately, and all current operations are discarded. The USART configuration is kept, but all the USART_ISR status flags are reset. This bit is set and cleared by software.
0: USART prescaler and outputs disabled, low-power mode
1: USART enabled

Note: To enter low-power mode without generating errors on the line, the TE bit must be previously reset and the software must wait for the TC bit in the USART_ISR to be set before resetting the UE bit.
The DMA requests are also reset when UE = 0 so the DMA channel must be disabled before resetting the UE bit.
In Smartcard mode, (SCEN = 1), the SCLK is always available when CLKEN = 1, regardless of the UE bit value.

</table>
Bits 31:24  **ADD[7:0]**: Address of the USART node

**ADD[7:4]**:
These bits give the address of the USART node or a character code to be recognized.
They are used to wake up the MCU with 7-bit address mark detection in multiprocessor communication during Mute mode or low-power mode. The MSB of the character sent by the transmitter should be equal to 1. They can also be used for character detection during normal reception, Mute mode inactive (for example, end of block detection in ModBus protocol). In this case, the whole received character (8-bit) is compared to the ADD[7:0] value and CMF flag is set on match.
These bits can only be written when reception is disabled (RE = 0) or the USART is disabled (UE=0).

**ADD[3:0]**:
These bits give the address of the USART node or a character code to be recognized.
They are used for wakeup with address mark detection, in multiprocessor communication during Mute mode or low-power mode.
These bits can only be written when reception is disabled (RE = 0) or the USART is disabled (UE=0).

Bit 23  **RTOEN**: Receiver timeout enable
This bit is set and cleared by software.
0: Receiver timeout feature disabled.
1: Receiver timeout feature enabled.
When this feature is enabled, the RTOF flag in the USART_ISR register is set if the RX line is idle (no reception) for the duration programmed in the RTOR (receiver timeout register).

*Note*: If the USART does not support the Receiver timeout feature, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.

Bits 22:21  **ABRMOD[1:0]**: Auto baud rate mode
These bits are set and cleared by software.
00: Measurement of the start bit is used to detect the baud rate.
01: Falling edge to falling edge measurement (the received frame must start with a single bit = 1 -> Frame = Start10xxxxxx)
10: 0x7F frame detection.
11: 0x55 frame detection
This bitfield can only be written when ABREN = 0 or the USART is disabled (UE=0).

*Note*: If DATAINV=1 and/or MSBFIRST=1 the patterns must be the same on the line, for example 0xAA for MSBFIRST)
If the USART does not support the auto baud rate feature, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.

Bit 20  **ABREN**: Auto baud rate enable
This bit is set and cleared by software.
0: Auto baud rate detection is disabled.
1: Auto baud rate detection is enabled.

*Note*: If the USART does not support the auto baud rate feature, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.

Bit 19  **MSBFIRST**: Most significant bit first
This bit is set and cleared by software.
0: data is transmitted/received with data bit 0 first, following the start bit.
1: data is transmitted/received with the MSB (bit 7/8) first, following the start bit.
This bitfield can only be written when the USART is disabled (UE=0).
Bit 18 **DATAINV:** Binary data inversion
  This bit is set and cleared by software.
  0: Logical data from the data register are send/received in positive/direct logic. (1=H, 0=L)
  1: Logical data from the data register are send/received in negative/inverse logic. (1=L, 0=H). The parity bit is also inverted.
  This bitfield can only be written when the USART is disabled (UE=0).

Bit 17 **TXINV:** TX pin active level inversion
  This bit is set and cleared by software.
  0: TX pin signal works using the standard logic levels (VDD =1/idle, Gnd=0/mark)
  1: TX pin signal values are inverted. ((VDD =0/mark, Gnd=1/idle).
  This allows the use of an external inverter on the TX line.
  This bitfield can only be written when the USART is disabled (UE=0).

Bit 16 **RXINV:** RX pin active level inversion
  This bit is set and cleared by software.
  0: RX pin signal works using the standard logic levels (VDD =1/idle, Gnd=0/mark)
  1: RX pin signal values are inverted. ((VDD =0/mark, Gnd=1/idle).
  This allows the use of an external inverter on the RX line.
  This bitfield can only be written when the USART is disabled (UE=0).

Bit 15 **SWAP:** Swap TX/RX pins
  This bit is set and cleared by software.
  0: TX/RX pins are used as defined in standard pinout
  1: The TX and RX pins functions are swapped. This allows to work in the case of a cross-wired connection to another UART.
  This bitfield can only be written when the USART is disabled (UE=0).

Bit 14 **LINEN:** LIN mode enable
  This bit is set and cleared by software.
  0: LIN mode disabled
  1: LIN mode enabled
  The LIN mode enables the capability to send LIN synchronous breaks (13 low bits) using the SBKRQ bit in the USART_CR1 register, and to detect LIN Sync breaks.
  This bitfield can only be written when the USART is disabled (UE=0).

*Note: If the USART does not support LIN mode, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.*

Bits 13:12 **STOP[1:0]:** stop bits
  These bits are used for programming the stop bits.
  00: 1 stop bit
  01: 0.5 stop bit.
  10: 2 stop bits
  11: 1.5 stop bits
  This bitfield can only be written when the USART is disabled (UE=0).
Bit 11 **CLKEN**: Clock enable
This bit allows the user to enable the SCLK pin.
0: SCLK pin disabled
1: SCLK pin enabled
This bit can only be written when the USART is disabled (UE=0).

**Note**: *If neither synchronous mode nor Smartcard mode is supported, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.*

In Smartcard mode, in order to provide correctly the SCLK clock to the smartcard, the steps below must be respected:

- **UE** = 0
- **SCEN** = 1
- **GTPR** configuration
- **CLKEN** = 1
- **UE** = 1

Bit 10 **CPOL**: Clock polarity
This bit allows the user to select the polarity of the clock output on the SCLK pin in synchronous mode. It works in conjunction with the **CPHA** bit to produce the desired clock/data relationship

0: Steady low value on SCLK pin outside transmission window
1: Steady high value on SCLK pin outside transmission window

This bit can only be written when the USART is disabled (UE=0).

**Note**: *If synchronous mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.*

Bit 9 **CPHA**: Clock phase
This bit is used to select the phase of the clock output on the SCLK pin in synchronous mode. It works in conjunction with the **CPOL** bit to produce the desired clock/data relationship (see Figure 574 and Figure 575)

0: The first clock transition is the first data capture edge
1: The second clock transition is the first data capture edge

This bit can only be written when the USART is disabled (UE=0).

**Note**: *If synchronous mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.*

Bit 8 **LBCL**: Last bit clock pulse
This bit is used to select whether the clock pulse associated with the last data bit transmitted (MSB) has to be output on the SCLK pin in synchronous mode.

0: The clock pulse of the last data bit is not output to the SCLK pin
1: The clock pulse of the last data bit is output to the SCLK pin

**Caution**: The last bit is the 7th or 8th or 9th data bit transmitted depending on the 7 or 8 or 9 bit format selected by the **M** bit in the USART_CR1 register.

This bit can only be written when the USART is disabled (UE=0).

**Note**: *If synchronous mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.*

Bit 7 Reserved, must be kept at reset value.

Bit 6 **LBDIE**: LIN break detection interrupt enable
Break interrupt mask (break detection using break delimiter).

0: Interrupt is inhibited
1: An interrupt is generated whenever LBDF=1 in the USART_ISR register

**Note**: *If LIN mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.*
Bit 5 **LBLD**: LIN break detection length
This bit is for selection between 11 bit or 10 bit break detection.
0: 10-bit break detection
1: 11-bit break detection
This bit can only be written when the USART is disabled (UE=0).

*Note:* If LIN mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.

Bit 4 **ADDM7**: 7-bit Address Detection/4-bit Address Detection
This bit is for selection between 4-bit address detection or 7-bit address detection.
0: 4-bit address detection
1: 7-bit address detection (in 8-bit data mode)
This bit can only be written when the USART is disabled (UE=0)

*Note:* In 7-bit and 9-bit data modes, the address detection is done on 6-bit and 8-bit address (ADD[5:0] and ADD[7:0]) respectively.

Bit 3 **DIS_NSS**: When the DIS_NSS bit is set, the NSS pin input is ignored.
0: SPI slave selection depends on NSS input pin.
1: SPI slave is always selected and NSS input pin is ignored.

*Note:* When SPI slave mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.

Bits 2:1 Reserved, must be kept at reset value.

Bit 0 **SLVEN**: Synchronous Slave mode enable
When the SLVEN bit is set, the synchronous slave mode is enabled.
0: Slave mode disabled.
1: Slave mode enabled.

*Note:* When SPI slave mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.

*Note:* The CPOL, CPHA and LBCL bits should not be written while the transmitter is enabled.

Bits 31:29 **TXFTCFG[2:0]**: TXFIFO threshold configuration
- 000: TXFIFO reaches 1/8 of its depth
- 001: TXFIFO reaches 1/4 of its depth
- 010: TXFIFO reaches 1/2 of its depth
- 011: TXFIFO reaches 3/4 of its depth
- 100: TXFIFO reaches 7/8 of its depth
- 101: TXFIFO becomes empty
Remaining combinations: Reserved

Bit 28 **RXFTIE**: RXFIFO threshold interrupt enable
This bit is set and cleared by software.
- 0: Interrupt inhibited
- 1: USART interrupt generated when Receive FIFO reaches the threshold programmed in RXFTCFG.

Bits 27:25 **RXFTCFG[2:0]**: Receive FIFO threshold configuration
- 000: Receive FIFO reaches 1/8 of its depth
- 001: Receive FIFO reaches 1/4 of its depth
- 010: Receive FIFO reaches 1/2 of its depth
- 011: Receive FIFO reaches 3/4 of its depth
- 100: Receive FIFO reaches 7/8 of its depth
- 101: Receive FIFO becomes full
Remaining combinations: Reserved

Bit 24 **TCBGTE**: Transmission Complete before guard time, interrupt enable
This bit is set and cleared by software.
- 0: Interrupt inhibited
- 1: USART interrupt generated whenever TCBGT=1 in the USART_ISR register

**Note**: If the USART does not support the Smartcard mode, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.

Bit 23 **TXFTIE**: TXFIFO threshold interrupt enable
This bit is set and cleared by software.
- 0: Interrupt inhibited
- 1: USART interrupt generated when TXFIFO reaches the threshold programmed in TXFTCFG.

Bit 22 **WUFIE**: Wakeup from low-power mode interrupt enable
This bit is set and cleared by software.
- 0: Interrupt inhibited
- 1: USART interrupt generated whenever WUF=1 in the USART_ISR register

**Note**: **WUFIE must be set before entering in low-power mode.**

The WUF interrupt is active only in low-power mode.

If the USART does not support the wakeup from Stop feature, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.
Bits 21:20 **WUS[1:0]**: Wakeup from low-power mode interrupt flag selection
This bitfield specifies the event which activates the WUF (Wakeup from low-power mode flag).
- 00: WUF active on address match (as defined by ADD[7:0] and ADDM7)
- 01: Reserved.
- 10: WUF active on start bit detection
- 11: WUF active on RXNE/RXFNE.
This bitfield can only be written when the USART is disabled (UE=0).
*If the USART does not support the wakeup from Stop feature, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.*

Bits 19:17 **SCARCNT[2:0]**: Smartcard auto-retry count
This bitfield specifies the number of retries for transmission and reception in Smartcard mode.
In transmission mode, it specifies the number of automatic retransmission retries, before generating a transmission error (FE bit set).
In reception mode, it specifies the number of erroneous reception trials, before generating a reception error (RXNE/RXFNE and PE bits set).
This bitfield must be programmed only when the USART is disabled (UE=0). When the USART is enabled (UE=1), this bitfield may only be written to 0x0, in order to stop retransmission.
- 0x0: retransmission disabled - No automatic retransmission in transmit mode.
- 0x1 to 0x7: number of automatic retransmission attempts (before signaling error)
*Note: If Smartcard mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.*

Bit 16 Reserved, must be kept at reset value.

Bit 15 **DEP**: Driver enable polarity selection
- 0: DE signal is active high.
- 1: DE signal is active low.
This bit can only be written when the USART is disabled (UE=0).
*Note: If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.*

Bit 14 **DEM**: Driver enable mode
This bit allows the user to activate the external transceiver control, through the DE signal.
- 0: DE function is disabled.
- 1: DE function is enabled. The DE signal is output on the RTS pin.
This bit can only be written when the USART is disabled (UE=0).
*Note: If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Section 47.4: USART implementation on page 2024.*

Bit 13 **DDRE**: DMA Disable on Reception Error
- 0: DMA is not disabled in case of reception error. The corresponding error flag is set but RXNE is kept 0 preventing from overrun. As a consequence, the DMA request is not asserted, so the erroneous data is not transferred (no DMA request), but next correct received data will be transferred. (used for Smartcard mode)
- 1: DMA is disabled following a reception error. The corresponding error flag is set, as well as RXNE. The DMA request is masked until the error flag is cleared. This means that the software must first disable the DMA request (DMAR = 0) or clear RXNE/RXFNE is case FIFO mode is enabled) before clearing the error flag.
This bit can only be written when the USART is disabled (UE=0).
*Note: The reception errors are: parity error, framing error or noise error.*
Bit 12 **OVRDIS**: Overrun Disable
This bit is used to disable the receive overrun detection.
0: Overrun Error Flag, ORE, is set when received data is not read before receiving new data.
1: Overrun functionality is disabled. If new data is received while the RXNE flag is still set the ORE flag is not set and the new received data overwrites the previous content of the USART_RDR register. When FIFO mode is enabled, the RXFIFO will be bypassed and data will be written directly in USART_RDR register. Even when FIFO management is enabled, the RXNE flag is to be used.
This bit can only be written when the USART is disabled (UE=0).

*Note: This control bit allows checking the communication flow w/o reading the data*

Bit 11 **ONEBIT**: One sample bit method enable
This bit allows the user to select the sample method. When the one sample bit method is selected the noise detection flag (NE) is disabled.
0: Three sample bit method
1: One sample bit method
This bit can only be written when the USART is disabled (UE=0).

Bit 10 **CTSIE**: CTS interrupt enable
0: Interrupt is inhibited
1: An interrupt is generated whenever CTSIF=1 in the USART_ISR register

*Note: If the hardware flow control feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.*

Bit 9 **CTSE**: CTS enable
0: CTS hardware flow control disabled
1: CTS mode enabled, data is only transmitted when the nCTS input is asserted (tied to 0). If the nCTS input is deasserted while data is being transmitted, then the transmission is completed before stopping. If data is written into the data register while nCTS is asserted, the transmission is postponed until nCTS is asserted.
This bit can only be written when the USART is disabled (UE=0)

*Note: If the hardware flow control feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.*

Bit 8 **RTSE**: RTS enable
0: RTS hardware flow control disabled
1: RTS output enabled, data is only requested when there is space in the receive buffer. The transmission of data is expected to cease after the current character has been transmitted. The nRTS output is asserted (pulled to 0) when data can be received.
This bit can only be written when the USART is disabled (UE=0).

*Note: If the hardware flow control feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.*

Bit 7 **DMAT**: DMA enable transmitter
This bit is set/reset by software
1: DMA mode is enabled for transmission
0: DMA mode is disabled for transmission

Bit 6 **DMAR**: DMA enable receiver
This bit is set/reset by software
1: DMA mode is enabled for reception
0: DMA mode is disabled for reception
Bit 5 **SCEN**: Smartcard mode enable
- This bit is used for enabling Smartcard mode.
- 0: Smartcard Mode disabled
- 1: Smartcard Mode enabled
- This bitfield can only be written when the USART is disabled (UE=0).

*Note:* If the USART does not support Smartcard mode, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.

Bit 4 **NACK**: Smartcard NACK enable
- 0: NACK transmission in case of parity error is disabled
- 1: NACK transmission during parity error is enabled
- This bitfield can only be written when the USART is disabled (UE=0).

*Note:* If the USART does not support Smartcard mode, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.

Bit 3 **HDSEL**: Half-duplex selection
- Selection of Single-wire Half-duplex mode
- 0: Half duplex mode is not selected
- 1: Half duplex mode is selected
- This bit can only be written when the USART is disabled (UE=0).

Bit 2 **IRLP**: IrDA low-power
- This bit is used for selecting between normal and low-power IrDA modes
- 0: Normal mode
- 1: Low-power mode
- This bit can only be written when the USART is disabled (UE=0).

*Note:* If IrDA mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.

Bit 1 **IREN**: IrDA mode enable
- This bit is set and cleared by software.
- 0: IrDA disabled
- 1: IrDA enabled
- This bit can only be written when the USART is disabled (UE=0).

*Note:* If IrDA mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.

Bit 0 **EIE**: Error interrupt enable
- Error Interrupt Enable Bit is required to enable interrupt generation in case of a framing error, overrun error noise flag or SPI slave underrun error (FE=1 or ORE=1 or NE=1 or UDR = 1 in the USART_ISR register).
- 0: Interrupt inhibited
- 1: interrupt generated when FE=1 or ORE=1 or NE=1 or UDR = 1 (in SPI slave mode) in the USART_ISR register.
47.7.5 USART baud rate register (USART_BRR)

This register can only be written when the USART is disabled (UE=0). It may be automatically updated by hardware in auto baud rate detection mode.

Address offset: 0x0C
Reset value: 0x0000 0000

| Bit 31:16 | Reserved, must be kept at reset value. |
| Bit 15:0  | BRR[15:0]: USART baud rate |

BRR[3:0]

When OVER8 = 0, BRR[3:0] = USARTDIV[3:0].
When OVER8 = 1:
BRR[2:0] = USARTDIV[3:0] shifted 1 bit to the right.
BRR[3] must be kept cleared.

47.7.6 USART guard time and prescaler register (USART_GTPR)

Address offset: 0x10
Reset value: 0x0000 0000

| Bit 31:16 | Reserved, must be kept at reset value. |
| Bit 15:0  | GT[7:0]: Guard time, PSC[7:0]: Prescaler |

| Bit 31:16 | Reserved, must be kept at reset value. |
Bits 31:16  Reserved, must be kept at reset value.

Bits 15:8  **GT[7:0]: Guard time value**

This bitfield is used to program the Guard time value in terms of number of baud clock periods.
This is used in Smartcard mode. The Transmission Complete flag is set after this guard time value.
This bitfield can only be written when the USART is disabled (UE=0).

*Note: If Smartcard mode is not supported, this bit is reserved and must be kept at reset value.
Refer to Section 47.4: USART implementation on page 2024.*

Bits 7:0  **PSC[7:0]: Prescaler value**

**In IrDA low-power and normal IrDA mode:**
PSC[7:0] = IrDA Normal and Low-Power Baud Rate
Used for programming the prescaler for dividing the USART source clock to achieve the low-power frequency:
The source clock is divided by the value given in the register (8 significant bits):
00000000: Reserved - do not program this value
00000001: divides the source clock by 1
00000010: divides the source clock by 2
...

**In Smartcard mode:**
PSC[4:0]: Prescaler value
Used for programming the prescaler for dividing the USART source clock to provide the Smartcard clock.
The value given in the register (5 significant bits) is multiplied by 2 to give the division factor of the source clock frequency:
00000: Reserved - do not program this value
00001: divides the source clock by 2
00010: divides the source clock by 4
00011: divides the source clock by 6
...
This bitfield can only be written when the USART is disabled (UE=0).

*Note: Bits [7:5] must be kept cleared if Smartcard mode is used.*
This bitfield is reserved and forced by hardware to '0' when the Smartcard and IrDA modes are not supported. Refer to Section 47.4: USART implementation on page 2024.

### 47.7.7 USART receiver timeout register (USART_RTOR)

Address offset: 0x14
Reset value: 0x0000 0000

Bits 31:24 **BLEN[7:0]: Block Length**

This bitfield gives the Block length in Smartcard T=1 Reception. Its value equals the number of information characters + the length of the Epilogue Field (1-LEC/2-CRC) - 1.

Examples:
- BLEN = 0 -> 0 information characters + LEC
- BLEN = 1 -> 0 information characters + CRC
- BLEN = 255 -> 254 information characters + CRC (total 256 characters)

In Smartcard mode, the Block length counter is reset when TXE=0 (TXFE = 0 in case FIFO mode is enabled).

This bitfield can be used also in other modes. In this case, the Block length counter is reset when RE=0 (receiver disabled) and/or when the EOBCF bit is written to 1.

**Note:** This value can be programmed after the start of the block reception (using the data from the LEN character in the Prologue Field). It must be programmed only once per received block.

Bits 23:0 **RTO[23:0]: Receiver timeout value**

This bitfield gives the Receiver timeout value in terms of number of bits during which there is no activity on the RX line.

In standard mode, the RTOF flag is set if, after the last received character, no new start bit is detected for more than the RTO value.

In Smartcard mode, this value is used to implement the CWT and BWT. See Smartcard chapter for more details. In the standard, the CWT/BWT measurement is done starting from the start bit of the last received character.

**Note:** This value must only be programmed once per received character.

**Note:** RTOR can be written on-the-fly. If the new value is lower than or equal to the counter, the RTOF flag is set.

This register is reserved and forced by hardware to “0x00000000” when the Receiver timeout feature is not supported. Refer to Section 47.4: USART implementation on page 2024.

### 47.7.8 USART request register (USART_RQR)

Address offset: 0x18

Reset value: 0x0000 0000

</tr>
</tbody>
</table>
Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **TXFRQ**: Transmit data flush request

When FIFO mode is disabled, writing ‘1’ to this bit sets the TXE flag. This allows to discard the transmit data. This bit must be used only in Smartcard mode, when data have not been sent due to errors (NACK) and the FE flag is active in the USART_ISR register. If the USART does not support Smartcard mode, this bit is reserved and must be kept at reset value.

When FIFO is enabled, TXFRQ bit is set to flush the whole FIFO. This sets the TXFE flag (Transmit FIFO empty, bit 23 in the USART_ISR register). Flushing the Transmit FIFO is supported in both UART and Smartcard modes.

*Note*: In FIFO mode, the TXFNF flag is reset during the flush request until TxFIFO is empty in order to ensure that no data are written in the data register.

Bit 3 **RXFRQ**: Receive data flush request

Writing 1 to this bit empties the entire receive FIFO i.e. clears the bit RXFNE. This allows to discard the received data without reading them, and avoid an overrun condition.

Bit 2 **MMRQ**: Mute mode request

Writing 1 to this bit puts the USART in Mute mode and resets the RWU flag.

Bit 1 **SBKRQ**: Send break request

Writing 1 to this bit sets the SBKF flag and request to send a BREAK on the line, as soon as the transmit machine is available.

*Note*: When the application needs to send the break character following all previously inserted data, including the ones not yet transmitted, the software should wait for the TXE flag assertion before setting the SBKRQ bit.

Bit 0 **ABRRQ**: Auto baud rate request

Writing 1 to this bit resets the ABRF flag in the USART_ISR and requests an automatic baud rate measurement on the next received data frame.

*Note*: If the USART does not support the auto baud rate feature, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.

### 47.7.9 USART interrupt and status register [alternate] (USART_ISR)

Address offset: 0x1C

Reset value: 0x0C0

XX = 28 if FIFO/Smartcard mode is enabled

XX = 08 if FIFO is enabled and Smartcard mode is disabled

The same register can be used in FIFO mode enabled (this section) and FIFO mode disabled (next section).

**FIFO mode enabled**

**Notes**:

- **ABRF**: Auto baud rate feature
- **ABRE**: Auto baud rate enabled
- **UDR**: Undersized data received
- **EOBF**: End of break frame
- **RTOF**: Receiver timeout
- **CTS**: Clear to send
- **CTSIF**: CTS input facility
- **LBDF**: Line break detected
- **TXFNF**: Transmit FIFO not full
- **TC**: Transmitter complete
- **RXFNE**: Receiver complete
- **IDLE**: Idle bit
- **ORE**: Overrun error
- **NE**: Noise error
- **FE**: Framing error
- **PE**: Parity error

RM0433 Rev 6 2093/3289
Bits 31:28  Reserved, must be kept at reset value.

Bit 27  **TXFT**: TXFIFO threshold flag

This bit is set by hardware when the TXFIFO reaches the threshold programmed in TXFTCFG of USART_CR3 register i.e. the TXFIFO contains TXFTCFG empty locations. An interrupt is generated if the TXFTIE bit =1 (bit 31) in the USART_CR3 register.

0: TXFIFO does not reach the programmed threshold.
1: TXFIFO reached the programmed threshold.

Bit 26  **RXFT**: RXFIFO threshold flag

This bit is set by hardware when the threshold programmed in RXFTCFG in USART_CR3 register is reached. This means that there are (RXFTCFG - 1) data in the Receive FIFO and one data in the USART_RDR register. An interrupt is generated if the RXFTIE bit =1 (bit 27) in the USART_CR3 register.

0: Receive FIFO does not reach the programmed threshold.
1: Receive FIFO reached the programmed threshold.

**Note:** When the RXFTCFG threshold is configured to ‘101’, RXFT flag will be set if 16 data are available i.e. 15 data in the RXFIFO and 1 data in the USART_RDR. Consequently, the 17th received data will not cause an overrun error. The overrun error occurs after receiving the 18th data.

Bit 25  **TCBGT**: Transmission complete before guard time flag

This bit is set when the last data written in the USART_TDR has been transmitted correctly out of the shift register.

It is set by hardware in Smartcard mode, if the transmission of a frame containing data is complete and if the smartcard did not send back any NACK. An interrupt is generated if TCBGTE=1 in the USART_CR3 register.

This bit is cleared by software, by writing 1 to the TCBGTCF in the USART_ICR register or by a write to the USART_TDR register.

0: Transmission is not complete or transmission is complete unsuccessfully (i.e. a NACK is received from the card)
1: Transmission is complete successfully (before Guard time completion and there is no NACK from the smart card).

**Note:** If the USART does not support the Smartcard mode, this bit is reserved and kept at reset value. If the USART supports the Smartcard mode and the Smartcard mode is enabled, the TCBGT reset value is ‘1’. Refer to Section 47.4: USART implementation on page 2024.

Bit 24  **RXFF**: RXFIFO full

This bit is set by hardware when the number of received data corresponds to RXFIFO size + 1 (RXFIFO full + 1 data in the USART_RDR register.

An interrupt is generated if the RXFFIE bit =1 in the USART_CR1 register.

0: RXFIFO not full.
1: RXFIFO Full.

Bit 23  **TXFE**: TXFIFO empty

This bit is set by hardware when TXFIFO is empty. When the TXFIFO contains at least one data, this flag is cleared. The TXFE flag can also be set by writing 1 to the bit TXFRQ (bit 4) in the USART_RQR register.

An interrupt is generated if the TXFEIE bit =1 (bit 30) in the USART_CR1 register.

0: TXFIFO not empty.
1: TXFIFO empty.
Bit 22 **REACK**: Receive enable acknowledge flag
This bit is set/reset by hardware, when the Receive Enable value is taken into account by the USART.
It can be used to verify that the USART is ready for reception before entering low-power mode.

*Note: If the USART does not support the wakeup from Stop feature, this bit is reserved and kept at reset value. Refer to Section 47.4: USART implementation on page 2024.*

Bit 21 **TEACK**: Transmit enable acknowledge flag
This bit is set/reset by hardware, when the Transmit Enable value is taken into account by the USART.
It can be used when an idle frame request is generated by writing TE=0, followed by TE=1 in the USART_CR1 register, in order to respect the TE=0 minimum period.

Bit 20 **WUF**: Wakeup from low-power mode flag
This bit is set by hardware, when a wakeup event is detected. The event is defined by the WUS bitfield. It is cleared by software, writing a 1 to the WUCF in the USART_ICR register.
An interrupt is generated if WUFIE=1 in the USART_CR3 register.

*Note: When UESM is cleared, WUF flag is also cleared.*

The WUF interrupt is active only in low-power mode.

*If the USART does not support the wakeup from Stop feature, this bit is reserved and kept at reset value. Refer to Section 47.4: USART implementation on page 2024.*

Bit 19 **RWU**: Receiver wakeup from Mute mode
This bit indicates if the USART is in Mute mode. It is cleared/set by hardware when a wakeup/mute sequence is recognized. The Mute mode control sequence (address or IDLE) is selected by the WAKE bit in the USART_CR1 register.
When wakeup on IDLE mode is selected, this bit can only be set by software, writing 1 to the MMRQ bit in the USART_RQR register.

0: Receiver in active mode
1: Receiver in Mute mode

*Note: If the USART does not support the wakeup from Stop feature, this bit is reserved and kept at reset value. Refer to Section 47.4: USART implementation on page 2024.*

Bit 18 **SBKF**: Send break flag
This bit indicates that a send break character was requested. It is set by software, by writing 1 to the SBKRQ bit in the USART_CR3 register. It is automatically reset by hardware during the stop bit of break transmission.

0: No break character is transmitted
1: Break character will be transmitted

Bit 17 **CMF**: Character match flag
This bit is set by hardware, when a the character defined by ADD[7:0] is received. It is cleared by software, writing 1 to the CMCF in the USART_ICR register.
An interrupt is generated if CMIE=1 in the USART_CR1 register.

0: No Character match detected
1: Character Match detected

Bit 16 **BUSY**: Busy flag
This bit is set and reset by hardware. It is active when a communication is ongoing on the RX line (successful start bit detected). It is reset at the end of the reception (successful or not).

0: USART is idle (no reception)
1: Reception on going
Bit 15 **ABRF**: Auto baud rate flag

This bit is set by hardware when the automatic baud rate has been set (RXFNE will also be set, generating an interrupt if RXFNEIE = 1) or when the auto baud rate operation was completed without success (ABRE=1) (ABRE, RXFNE and FE are also set in this case).

It is cleared by software, in order to request a new auto baud rate detection, by writing 1 to the ABRRQ in the USART_RQR register.

*Note:* If the USART does not support the auto baud rate feature, this bit is reserved and kept at reset value.

Bit 14 **ABRE**: Auto baud rate error

This bit is set by hardware if the baud rate measurement failed (baud rate out of range or character comparison failed).

It is cleared by software, by writing 1 to the ABRRQ bit in the USART_CR3 register.

*Note:* If the USART does not support the auto baud rate feature, this bit is reserved and kept at reset value.

Bit 13 **UDR**: SPI slave underrun error flag

In slave transmission mode, this flag is set when the first clock pulse for data transmission appears while the software has not yet loaded any value into USART_TDR. This flag is reset by setting UDRCF bit in the USART_ICR register.

0: No underrun error
1: underrun error

*Note:* If the USART does not support the SPI slave mode, this bit is reserved and kept at reset value. Refer to Section 47.4: USART implementation on page 2024.

Bit 12 **EOBF**: End of block flag

This bit is set by hardware when a complete block has been received (for example T=1 Smartcard mode). The detection is done when the number of received bytes (from the start of the block, including the prologue) is equal or greater than BLEN + 4.

An interrupt is generated if the EOBIE=1 in the USART_CR2 register.

It is cleared by software, writing 1 to the EOBCF in the USART_ICR register.

0: End of Block not reached
1: End of Block (number of characters) reached

*Note:* If Smartcard mode is not supported, this bit is reserved and kept at reset value. Refer to Section 47.4: USART implementation on page 2024.

Bit 11 **RTOF**: Receiver timeout

This bit is set by hardware when the timeout value, programmed in the RTOR register has lapsed, without any communication. It is cleared by software, writing 1 to the RTOCF bit in the USART_ICR register.

An interrupt is generated if RTOIE=1 in the USART_CR2 register.

In Smartcard mode, the timeout corresponds to the CWT or BWT timings.

0: Timeout value not reached
1: Timeout value reached without any data reception

*Note:* If a time equal to the value programmed in RTOR register separates 2 characters, RTOF is not set. If this time exceeds this value + 2 sample times (2/16 or 2/8, depending on the oversampling method), RTOF flag is set.

The counter counts even if RE = 0 but RTOF is set only when RE = 1. If the timeout has already elapsed when RE is set, then RTOF will be set.

If the USART does not support the Receiver timeout feature, this bit is reserved and kept at reset value.
Bit 10  **CTS**: CTS flag
This bit is set/reset by hardware. It is an inverted copy of the status of the nCTS input pin.
0: nCTS line set
1: nCTS line reset
*Note: If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.*

Bit 9  **CTSIF**: CTS interrupt flag
This bit is set by hardware when the nCTS input toggles, if the CTSE bit is set. It is cleared by software, by writing 1 to the CTSCF bit in the USART_ICR register.
An interrupt is generated if CTSIE=1 in the USART_CR3 register.
0: No change occurred on the nCTS status line
1: A change occurred on the nCTS status line
*Note: If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.*

Bit 8  **LBDF**: LIN break detection flag
This bit is set by hardware when the LIN break is detected. It is cleared by software, by writing 1 to the LBDCF in the USART_ICR.
An interrupt is generated if LBDIE = 1 in the USART_CR2 register.
0: LIN Break not detected
1: LIN break detected
*Note: If the USART does not support LIN mode, this bit is reserved and kept at reset value. Refer to Section 47.4: USART implementation on page 2024.*

Bit 7  **TXFNF**: TXFIFO not full
TXFNF is set by hardware when TXFIFO is not full meaning that data can be written in the USART_TDR. Every write operation to the USART_TDR places the data in the TXFIFO. This flag remains set until the TXFIFO is full. When the TXFIFO is full, this flag is cleared indicating that data can not be written into the USART_TDR.
An interrupt is generated if the TXFNFIE bit =1 in the USART_CR1 register.
0: Transmit FIFO is full
1: Transmit FIFO is not full
*Note: The TXFNF is kept reset during the flush request until TXFIFO is empty. After sending the flush request (by setting TXFRQ bit), the flag TXFNF should be checked prior to writing in TXFIFO (TXFNF and TXFE will be set at the same time). This bit is used during single buffer transmission.*

Bit 6  **TC**: Transmission complete
This bit indicates that the last data written in the USART_TDR has been transmitted out of the shift register.
It is set by hardware when the transmission of a frame containing data is complete and when TXFE is set.
An interrupt is generated if TCIE=1 in the USART_CR1 register.
TC bit is is cleared by software, by writing 1 to the TCCF in the USART_ICR register or by a write to the USART_TDR register.
0: Transmission is not complete
1: Transmission is complete
*Note: If TE bit is reset and no transmission is on going, the TC bit will be set immediately.*
Bit 5  **RXFNE**: RXFIFO not empty

RXFNE bit is set by hardware when the RXFIFO is not empty, meaning that data can be read from the USART_RDR register. Every read operation from the USART_RDR frees a location in the RXFIFO.

RXFNE is cleared when the RXFIFO is empty. The RXFNE flag can also be cleared by writing 1 to the RXFRQ in the USART_RQR register.

An interrupt is generated if RXFNEIE=1 in the USART_CR1 register.

0: Data is not received
1: Received data is ready to be read.

Bit 4  **IDLE**: Idle line detected

This bit is set by hardware when an Idle Line is detected. An interrupt is generated if IDLEIE=1 in the USART_CR1 register. It is cleared by software, writing 1 to the IDLECF in the USART_IER register.

0: No Idle line is detected
1: Idle line is detected

*Note: The IDLE bit will not be set again until the RXFNE bit has been set (i.e. a new idle line occurs).*

If Mute mode is enabled (MME=1), IDLE is set if the USART is not mute (RWU=0), whatever the Mute mode selected by the WAKE bit. If RWU=1, IDLE is not set.

Bit 3  **ORE**: Overrun error

This bit is set by hardware when the data currently being received in the shift register is ready to be transferred into the USART_RDR register while RXFF = 1. It is cleared by a software, writing 1 to the ORECF, in the USART_ICR register.

An interrupt is generated if RXFNEIE=1 or EIE = 1 in the USART_CR1 register.

0: No overrun error
1: Overrun error is detected

*Note: When this bit is set, the USART_RDR register content is not lost but the shift register is overwritten. An interrupt is generated if the ORE flag is set during multi buffer communication if the EIE bit is set.*

This bit is permanently forced to 0 (no overrun detection) when the bit OVRDIS is set in the USART_CR3 register.
Bit 2 **NE**: Noise detection flag

This bit is set by hardware when noise is detected on a received frame. It is cleared by software, writing 1 to the NECF bit in the USART_ICR register.

0: No noise is detected
1: Noise is detected

*Note:* This bit does not generate an interrupt as it appears at the same time as the RXFNE bit which itself generates an interrupt. An interrupt is generated when the NE flag is set during multi buffer communication if the EIE bit is set.

When the line is noise-free, the NE flag can be disabled by programming the ONEBIT bit to 1 to increase the USART tolerance to deviations (Refer to **Section 47.5.8: Tolerance of the USART receiver to clock deviation on page 2042**).

This error is associated with the character in the USART_RDR.

Bit 1 **FE**: Framing error

This bit is set by hardware when a de-synchronization, excessive noise or a break character is detected. It is cleared by software, writing 1 to the FECF bit in the USART_ICR register. When transmitting data in Smartcard mode, this bit is set when the maximum number of transmit attempts is reached without success (the card NACKs the data frame). An interrupt is generated if EIE = 1 in the USART_CR1 register.

0: No Framing error is detected
1: Framing error or break character is detected

*Note:* This error is associated with the character in the USART_RDR.

Bit 0 **PE**: Parity error

This bit is set by hardware when a parity error occurs in receiver mode. It is cleared by software, writing 1 to the PECF in the USART_ICR register.

An interrupt is generated if PEIE = 1 in the USART_CR1 register.

0: No parity error
1: Parity error

*Note:* This error is associated with the character in the USART_RDR.

### 47.7.10 USART interrupt and status register [alternate] (USART_ISR)

Address offset: 0x1C

Reset value: 0x0000 00C0

The same register can be used in FIFO mode enabled (previous section) and FIFO mode disabled (this section).

#### FIFO mode disabled

*Notes:*
- *r* indicates a reserved bit.
Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **TCBGT**: Transmission complete before guard time flag
This bit is set when the last data written in the USART_TDR has been transmitted correctly out of the shift register.
It is set by hardware in Smartcard mode, if the transmission of a frame containing data is complete and if the smartcard did not send back any NACK. An interrupt is generated if TCBGTIE=1 in the USART_CR3 register.
This bit is cleared by software, by writing 1 to the TCBGTCF in the USART_ICR register or by a write to the USART_TDR register.
0: Transmission is not complete or transmission is complete unsuccessfully (i.e. a NACK is received from the card)
1: Transmission is complete successfully (before Guard time completion and there is no NACK from the smart card).

*Note: If the USART does not support the Smartcard mode, this bit is reserved and kept at reset value. If the USART supports the Smartcard mode and the Smartcard mode is enabled, the TCBGT reset value is ‘1’. Refer to Section 47.4: USART implementation on page 2024.*

Bits 24:23 Reserved, must be kept at reset value.

Bit 22 **REACK**: Receive enable acknowledge flag
This bit is set/reset by hardware, when the Receive Enable value is taken into account by the USART.
It can be used to verify that the USART is ready for reception before entering low-power mode.

*Note: If the USART does not support the wakeup from Stop feature, this bit is reserved and kept at reset value. Refer to Section 47.4: USART implementation on page 2024.*

Bit 21 **TEACK**: Transmit enable acknowledge flag
This bit is set/reset by hardware, when the Transmit Enable value is taken into account by the USART.
It can be used when an idle frame request is generated by writing TE=0, followed by TE=1 in the USART_CR1 register, in order to respect the TE=0 minimum period.

Bit 20 **WUF**: Wakeup from low-power mode flag
This bit is set by hardware, when a wakeup event is detected. The event is defined by the WUS bitfield. It is cleared by software, writing a 1 to the WUCF in the USART_ICR register.
An interrupt is generated if WUFIE=1 in the USART_CR3 register.

*Note: When UESM is cleared, WUF flag is also cleared.
The WUF interrupt is active only in low-power mode.
If the USART does not support the wakeup from Stop feature, this bit is reserved and kept at reset value. Refer to Section 47.4: USART implementation on page 2024.*

Bit 19 **RWU**: Receiver wakeup from Mute mode
This bit indicates if the USART is in Mute mode. It is cleared/set by hardware when a wakeup/mute sequence is recognized. The Mute mode control sequence (address or IDLE) is selected by the WAKE bit in the USART_CR1 register.
When wakeup on IDLE mode is selected, this bit can only be set by software, writing 1 to the MMRQ bit in the USART_RQR register.
0: Receiver in active mode
1: Receiver in Mute mode

*Note: If the USART does not support the wakeup from Stop feature, this bit is reserved and kept at reset value. Refer to Section 47.4: USART implementation on page 2024.*
Bit 18 **SBKF**: Send break flag
This bit indicates that a send break character was requested. It is set by software, by writing 1 to the SBKRQ bit in the USART_CR3 register. It is automatically reset by hardware during the stop bit of break transmission.
0: No break character is transmitted
1: Break character will be transmitted

Bit 17 **CMF**: Character match flag
This bit is set by hardware, when a the character defined by ADD[7:0] is received. It is cleared by software, writing 1 to the CMCF in the USART_ICR register.
An interrupt is generated if CMIE=1 in the USART_CR1 register.
0: No Character match detected
1: Character Match detected

Bit 16 **BUSY**: Busy flag
This bit is set and reset by hardware. It is active when a communication is ongoing on the RX line (successful start bit detected). It is reset at the end of the reception (successful or not).
0: USART is idle (no reception)
1: Reception on going

Bit 15 **ABRF**: Auto baud rate flag
This bit is set by hardware when the automatic baud rate has been set (RXNE will also be set, generating an interrupt if RXNEIE = 1) or when the auto baud rate operation was completed without success (ABRE=1) (ABRE, RXNE and FE are also set in this case)
It is cleared by software, in order to request a new auto baud rate detection, by writing 1 to the ABRQQ in the USART_RQR register.
*Note: If the USART does not support the auto baud rate feature, this bit is reserved and kept at reset value.*

Bit 14 **ABRE**: Auto baud rate error
This bit is set by hardware if the baud rate measurement failed (baud rate out of range or character comparison failed)
It is cleared by software, by writing 1 to the ABRQQ bit in the USART_CR3 register.
*Note: If the USART does not support the auto baud rate feature, this bit is reserved and kept at reset value.*

Bit 13 **UDR**: SPI slave underrun error flag
In slave transmission mode, this flag is set when the first clock pulse for data transmission appears while the software has not yet loaded any value into USART_TDR. This flag is reset by setting UDRCF bit in the USART_ICR register.
0: No underrun error
1: underrun error
*Note: If the USART does not support the SPI slave mode, this bit is reserved and kept at reset value. Refer to Section 47.4: USART implementation on page 2024.*

Bit 12 **EOBF**: End of block flag
This bit is set by hardware when a complete block has been received (for example T=1 Smartcard mode). The detection is done when the number of received bytes (from the start of the block, including the prologue) is equal or greater than BLEN + 4.
An interrupt is generated if the EOBIE=1 in the USART_CR2 register.
It is cleared by software, writing 1 to the EOBCF in the USART_ICR register.
0: End of Block not reached
1: End of Block (number of characters) reached
*Note: If Smartcard mode is not supported, this bit is reserved and kept at reset value. Refer to Section 47.4: USART implementation on page 2024.*
Bit 11 RTOF: Receiver timeout
This bit is set by hardware when the timeout value, programmed in the RTOR register has lapsed, without any communication. It is cleared by software, writing 1 to the RTOCF bit in the USART_ICR register.
An interrupt is generated if RTOIE=1 in the USART_CR2 register.
In Smartcard mode, the timeout corresponds to the CWT or BWT timings.
0: Timeout value not reached
1: Timeout value reached without any data reception
Note: If a time equal to the value programmed in RTOR register separates 2 characters, RTOF is not set. If this time exceeds this value + 2 sample times (2/16 or 2/8, depending on the oversampling method), RTOF flag is set.
The counter counts even if RE = 0 but RTOF is set only when RE = 1. If the timeout has already elapsed when RE is set, then RTOF will be set.
If the USART does not support the Receiver timeout feature, this bit is reserved and kept at reset value.

Bit 10 CTS: CTS flag
This bit is set/reset by hardware. It is an inverted copy of the status of the nCTS input pin.
0: nCTS line set
1: nCTS line reset
Note: If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.

Bit 9 CTSIF: CTS interrupt flag
This bit is set by hardware when the nCTS input toggles, if the CTSE bit is set. It is cleared by software, by writing 1 to the CTSCF bit in the USART_ICR register.
An interrupt is generated if CTSE=1 in the USART_CR3 register.
0: No change occurred on the nCTS status line
1: A change occurred on the nCTS status line
Note: If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.

Bit 8 LBDF: LIN break detection flag
This bit is set by hardware when the LIN break is detected. It is cleared by software, by writing 1 to the LBDCF in the USART_ICR.
An interrupt is generated if LBDFIE = 1 in the USART_CR2 register.
0: LIN Break not detected
1: LIN break detected
Note: If the USART does not support LIN mode, this bit is reserved and kept at reset value.
Refer to Section 47.4: USART implementation on page 2024.

Bit 7 TXE: Transmit data register empty
TXE is set by hardware when the content of the USART_TDR register has been transferred into the shift register. It is cleared by writing to the USART_TDR register. The TXE flag can also be set by writing 1 to the TXFRQ in the USART_RQR register, in order to discard the data (only in Smartcard T=0 mode, in case of transmission failure).
An interrupt is generated if the TXEIE bit =1 in the USART_CR1 register.
0: Data register full
1: Data register not full
Bit 6  **TC**: Transmission complete
This bit indicates that the last data written in the USART_TDR has been transmitted out of
the shift register.
It is set by hardware when the transmission of a frame containing data is complete and
when TXE is set.
An interrupt is generated if TCIE=1 in the USART_CR1 register.
TC bit is is cleared by software, by writing 1 to the TCCF in the USART_ICR register or by a
write to the USART_TDR register.
0: Transmission is not complete
1: Transmission is complete

*Note: If TE bit is reset and no transmission is on going, the TC bit will be set immediately.*

Bit 5  **RXNE**: Read data register not empty
RXNE bit is set by hardware when the content of the USART_RDR shift register has been
transferred to the USART_RDR register. It is cleared by reading from the USART_RDR
register. The RXNE flag can also be cleared by writing 1 to the RXFRQ in the USART_RQR
register.
An interrupt is generated if RXNEIE=1 in the USART_CR1 register.
0: Data is not received
1: Received data is ready to be read.

Bit 4  **IDLE**: Idle line detected
This bit is set by hardware when an Idle Line is detected. An interrupt is generated if
IDLEIE=1 in the USART_CR1 register. It is cleared by software, writing 1 to the IDLECF in
the USART_ICR register.
0: No Idle line is detected
1: Idle line is detected

*Note: The IDLE bit will not be set again until the RXNE bit has been set (i.e. a new idle line
occurs).*

If Mute mode is enabled (MME=1), IDLE is set if the USART is not mute (RWU=0),
whatever the Mute mode selected by the WAKE bit. If RWU=1, IDLE is not set.

Bit 3  **ORE**: Overrun error
This bit is set by hardware when the data currently being received in the shift register is
ready to be transferred into the USART_RDR register while RXNE=1. It is cleared by a
software, writing 1 to the ORECF, in the USART_ICR register.
An interrupt is generated if RXNEIE=1 or EIE = 1 in the USART_CR1 register.
0: No overrun error
1: Overrun error is detected

*Note: When this bit is set, the USART_RDR register content is not lost but the shift register is
overwritten. An interrupt is generated if the ORE flag is set during multi buffer
communication if the EIE bit is set.*

This bit is permanently forced to 0 (no overrun detection) when the bit OVRDIS is set in
the USART_CR3 register.
Bit 2 **NE**: Noise detection flag
This bit is set by hardware when noise is detected on a received frame. It is cleared by software, writing 1 to the NECF bit in the USART_ICR register.
0: No noise is detected
1: Noise is detected

*Note:* This bit does not generate an interrupt as it appears at the same time as the RXNE bit which itself generates an interrupt. An interrupt is generated when the NE flag is set during multi buffer communication if the EIE bit is set.

*When the line is noise-free, the NE flag can be disabled by programming the ONEBIT bit to 1 to increase the USART tolerance to deviations (Refer to Section 47.5.8: Tolerance of the USART receiver to clock deviation on page 2042).*

Bit 1 **FE**: Framing error
This bit is set by hardware when a de-synchronization, excessive noise or a break character is detected. It is cleared by software, writing 1 to the FECF bit in the USART_ICR register.

When transmitting data in Smartcard mode, this bit is set when the maximum number of transmit attempts is reached without success (the card NACKs the data frame).
An interrupt is generated if EIE = 1 in the USART_CR1 register.
0: No Framing error is detected
1: Framing error or break character is detected

Bit 0 **PE**: Parity error
This bit is set by hardware when a parity error occurs in receiver mode. It is cleared by software, writing 1 to the PECF in the USART_ICR register.
An interrupt is generated if PEIE = 1 in the USART_CR1 register.
0: No parity error
1: Parity error

**Bits 31:21** Reserved, must be kept at reset value.

**Bit 20** **WUCF**: Wakeup from low-power mode clear flag
Writing 1 to this bit clears the WUF flag in the USART_ISR register.

*Note:* If the USART does not support the wakeup from Stop feature, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.

**Bits 19:18** Reserved, must be kept at reset value.

**Bit 17** **CMCF**: Character match clear flag
Writing 1 to this bit clears the CMF flag in the USART_ISR register.
Bits 16:14 Reserved, must be kept at reset value.

Bit 13 **UDRCF**: SPI slave underrun clear flag
- Writing 1 to this bit clears the UDRF flag in the USART_ISR register.
- **Note**: If the USART does not support SPI slave mode, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.

Bit 12 **EOBCF**: End of block clear flag
- Writing 1 to this bit clears the EOBF flag in the USART_ISR register.
- **Note**: If the USART does not support Smartcard mode, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.

Bit 11 **RTOCF**: Receiver timeout clear flag
- Writing 1 to this bit clears the RTOF flag in the USART_ISR register.
- **Note**: If the USART does not support the Receiver timeout feature, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.

Bit 10 Reserved, must be kept at reset value.

Bit 9 **CTSCF**: CTS clear flag
- Writing 1 to this bit clears the CTSIF flag in the USART_ISR register.
- **Note**: If the hardware flow control feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.

Bit 8 **LBDCF**: LIN break detection clear flag
- Writing 1 to this bit clears the LBDF flag in the USART_ISR register.
- **Note**: If LIN mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation on page 2024.

Bit 7 **TCBGTCF**: Transmission complete before Guard time clear flag
- Writing 1 to this bit clears the TCBGT flag in the USART_ISR register.

Bit 6 **TCCF**: Transmission complete clear flag
- Writing 1 to this bit clears the TC flag in the USART_ISR register.

Bit 5 **TXFECF**: TXFIFO empty clear flag
- Writing 1 to this bit clears the TXFE flag in the USART_ISR register.

Bit 4 **IDLECF**: Idle line detected clear flag
- Writing 1 to this bit clears the IDLE flag in the USART_ISR register.

Bit 3 **ORECF**: Overrun error clear flag
- Writing 1 to this bit clears the ORE flag in the USART_ISR register.

Bit 2 **NECF**: Noise detected clear flag
- Writing 1 to this bit clears the NE flag in the USART_ISR register.

Bit 1 **FECF**: Framing error clear flag
- Writing 1 to this bit clears the FE flag in the USART_ISR register.

Bit 0 **PECF**: Parity error clear flag
- Writing 1 to this bit clears the PE flag in the USART_ISR register.

Bits 31:9 Reserved, must be kept at reset value.

Bits 8:0 **RDR[8:0]:** Receive data value
Contains the received data character.
The RDR register provides the parallel interface between the input shift register and the internal bus (see *Figure 568*).
When receiving with the parity enabled, the value read in the MSB bit is the received parity bit.

Bits 31:9 Reserved, must be kept at reset value.

Bits 8:0 **TDR[8:0]:** Transmit data value
Contains the data character to be transmitted.
The USART_TDR register provides the parallel interface between the internal bus and the output shift register (see *Figure 568*).
When transmitting with the parity enabled (PCE bit set to 1 in the USART_CR1 register), the value written in the MSB (bit 7 or bit 8 depending on the data length) has no effect because it is replaced by the parity.

*Note:* This register must be written only when TXE/TXFN=1.
47.7.14  USART prescaler register (USART_PRESC)

This register can only be written when the USART is disabled (UE=0).

Address offset: 0x2C

Reset value: 0x0000 0000

Bits 31:4  Reserved, must be kept at reset value.

Bits 3:0  **PRESCALER[3:0]:** Clock prescaler

The USART input clock can be divided by a prescaler factor:

- 0000: input clock not divided
- 0001: input clock divided by 2
- 0010: input clock divided by 4
- 0011: input clock divided by 6
- 0100: input clock divided by 8
- 0101: input clock divided by 10
- 0110: input clock divided by 12
- 0111: input clock divided by 16
- 1000: input clock divided by 32
- 1001: input clock divided by 64
- 1010: input clock divided by 128
- 1011: input clock divided by 256

Remaining combinations: Reserved

**Note:** When **PRESCALER** is programmed with a value different of the allowed ones, programmed prescaler value will be “1011” i.e. input clock divided by 256.

Refer to *Section 2.3: Memory organization* for the register boundary addresses.
48 Low-power universal asynchronous receiver transmitter (LPUART)

This section describes the low-power universal asynchronous receiver transmitted (LPUART).

48.1 LPUART introduction

The LPUART is an UART which allows bidirectional UART communications with a limited power consumption. Only 32.768 kHz LSE clock is required to allow UART communications up to 9600 baud/s. Higher baud rates can be reached when the LPUART is clocked by clock sources different from the LSE clock.

Even when the microcontroller is in low-power mode, the LPUART can wait for an incoming UART frame while having an extremely low energy consumption. The LPUART includes all necessary hardware support to make asynchronous serial communications possible with minimum power consumption.

It supports Half-duplex Single-wire communications and modem operations (CTS/RTS).

It also supports multiprocessor communications.

DMA (direct memory access) can be used for data transmission/reception.
48.2 LPUART main features

- Full-duplex asynchronous communications
- NRZ standard format (mark/space)
- Programmable baud rate
- From 300 baud/s to 9600 baud/s using a 32.768 kHz clock source.
- Higher baud rates can be achieved by using a higher frequency clock source
- Two internal FIFOs to transmit and receive data
  Each FIFO can be enabled/disabled by software and come with status flags for FIFO's states.
- Dual clock domain with dedicated kernel clock for peripherals independent from PCLK.
- Programmable data word length (7 or 8 or 9 bits)
- Programmable data order with MSB-first or LSB-first shifting
- Configurable stop bits (1 or 2 stop bits)
- Single-wire Half-duplex communications
- Continuous communications using DMA
- Received/transmitted bytes are buffered in reserved SRAM using centralized DMA.
- Separate enable bits for transmitter and receiver
- Separate signal polarity control for transmission and reception
- Swappable Tx/Rx pin configuration
- Hardware flow control for modem and RS-485 transceiver
- Transfer detection flags:
  - Receive buffer full
  - Transmit buffer empty
  - Busy and end of transmission flags
- Parity control:
  - Transmits parity bit
  - Checks parity of received data byte
- Four error detection flags:
  - Overrun error
  - Noise detection
  - Frame error
  - Parity error
- Interrupt sources with flags
- Multiprocessor communications: wakeup from Mute mode by idle line detection or address mark detection
48.3 LPUART functional description

48.3.1 LPUART block diagram

The simplified block diagram given in Figure 595 shows two fully independent clock domains:

- **The lpuart_pclk clock domain**
  The lpuart_pclk clock signal feeds the peripheral bus interface. It must be active when accesses to the LPUART registers are required.

- **The lpuart_ker_ck kernel clock domain**
  The lpuart_ker_ck is the LPUART clock source. It is independent of the lpuart_pclk and delivered by the RCC. So, the LPUART registers can be written/read even when the lpuart_ker_ck is stopped.
  When the dual clock domain feature is disabled, the lpuart_ker_ck is the same as the lpuart_pclk.

There is no constraint between lpuart_pclk and lpuart_ker_ck: lpuart_ker_ck can be faster or slower than lpuart_pclk, with no more limitation than the ability for the software to manage the communication fast enough.
48.3.2 LPUART signals

LPUART bidirectional communications requires a minimum of two pins: Receive Data In (RX) and Transmit Data Out (TX):

- **RX** (Receive Data Input)
  RX is the serial data input.

- **TX** (Transmit Data Output)
  When the transmitter is disabled, the output pin returns to its I/O port configuration. When the transmitter is enabled and nothing is to be transmitted, the TX pin is at high level. In Single-wire mode, this I/O is used to transmit and receive the data.

RS232 hardware flow control mode

The following pins are required in RS232 Hardware flow control mode:

- **CTS** (Clear To Send)
  When driven high, this signal blocks the data transmission at the end of the current transfer.

- **RTS** (Request to send)
  When it is low, this signal indicates that the USART is ready to receive data.

RS485 hardware flow control mode

The following pin is required in RS485 Hardware control mode:

- **DE** (Driver Enable)
  This signal activates the transmission mode of the external transceiver.

*Note:* *DE* and *RTS* share the same pin.

48.3.3 LPUART character description

The word length can be set to 7 or 8 or 9 bits, by programming the M bits (M0: bit 12 and M1: bit 28) in the LPUART_CR1 register (see Figure 569).

- 7-bit character length: M[1:0] = ‘10’
- 8-bit character length: M[1:0] = ‘00’
- 9-bit character length: M[1:0] = ‘01’

By default, the signal (TX or RX) is in low state during the start bit. It is in high state during the stop bit.

These values can be inverted, separately for each signal, through polarity configuration control.

An *Idle character* is interpreted as an entire frame of “1”s. (The number of “1” ‘s will include the number of stop bits).

A *Break character* is interpreted on receiving “0”s for a frame period. At the end of the break frame, the transmitter inserts 2 stop bits.

Transmission and reception are driven by a common baud rate generator. The transmission and reception clocks are generated when the enable bit is set for the transmitter and receiver, respectively.

The details of each block is given below.
48.3.4 LPUART FIFOs and thresholds

The LPUART can operate in FIFO mode.

The LPUART comes with a Transmit FIFO (TXFIFO) and a Receive FIFO (RXFIFO). The FIFO mode is enabled by setting FIFOEN bit (bit 29) in LPUART_CR1 register.

Since 9 bits the maximum data word length is 9 bits, the TXFIFO is 9-bits wide. However the RXFIFO default width is 12 bits. This is due to the fact that the receiver does not only store
the data in the FIFO, but also the error flags associated to each character (Parity error, Noise error and Framing error flags).

**Note:** The received data is stored in the RXFIFO together with the corresponding flags. However, only the data are read when reading the RDR.
The status flags are available in the LPUART_ISR register.

It is possible to define the TXFIFO and RXFIFO levels at which the Tx and RX interrupts are triggered. These thresholds are programmed through RXFTCFG and TXFTCFG bitfields in LPUART_CR3 control register.

In this case:

- The RXFT flag is set in the LPUART_ISR register and the corresponding interrupt (if enabled) is generated, when the number of received data in the RXFIFO reaches the threshold programmed in the RXFTCFG bits fields.
  This means that the RXFIFO is filled until the number of data in the RXFIFO is equal to the programmed threshold.
  RXFTCFG data have been received: one data in LPUART_RDR and (RXFTCFG - 1) data in the RXFIFO. As an example, when the RXFTCFG is programmed to ‘101’, the RXFT flag will be set when a number of data corresponding to the FIFO size has been received: FIFO size - 1 data in the RXFIFO and 1 data in the LPUART_RDR. As a result, the next received data will not set the overrun flag.

- The TXFT flag is set in the LPUART_ISR register and the corresponding interrupt (if enabled) is generated when the number of empty locations in the TXFIFO reaches the threshold programmed in the TXFTCFG bits fields.
  This means that the TXFIFO is emptied until the number of empty locations in the TXFIFO is equal to the programmed threshold.

### 48.3.5 LPUART transmitter

The transmitter can send data words of either 7 or 8 or 9 bits, depending on the M bit status.
The Transmit Enable bit (TE) must be set in order to activate the transmitter function. The data in the transmit shift register is output on the TX pin.

**Character transmission**

During an LPUART transmission, data shifts out least significant bit first (default configuration) on the TX pin. In this mode, the LPUART_TDR register consists of a buffer (TDR) between the internal bus and the transmit shift register (see Figure 595).

When FIFO mode is enabled, the data written to the LPUART_TDR register are queued in the TXFIFO.

Every character is preceded by a start bit which corresponds to a low logic level for one bit period. The character is terminated by a configurable number of stop bits.

The number of stop bits can be 1 or 2.

**Note:** The TE bit must be set before writing the data to be transmitted to the LPUART_TDR.
The TE bit should not be reset during data transmission. Resetting the TE bit during the transmission will corrupt the data on the TX pin as the baud rate counters is frozen. The current data being transmitted are lost.
An idle frame will be sent after the TE bit is enabled.
Configurable stop bits

The number of stop bits to be transmitted with every character can be programmed in LPUART_CR2 (bits 13,12).

- **1 stop bit**: This is the default value of number of stop bits.
- **2 Stop bits**: This will be supported by normal LPUART, Single-wire and Modem modes.

An idle frame transmission will include the stop bits.

A break transmission will be 10 low bits (when M[1:0] = ‘00’) or 11 low bits (when M[1:0] = ‘01’) or 9 low bits (when M[1:0] = ‘10’) followed by 2 stop bits. It is not possible to transmit long breaks (break of length greater than 9/10/11 low bits).

**Figure 597. Configurable stop bits**

Character transmission procedure

To transmit a character, follow the sequence below:

1. Program the M bits in LPUART_CR1 to define the word length.
2. Select the desired baud rate using the LPUART_BRR register.
3. Program the number of stop bits in LPUART_CR2.
4. Enable the LPUART by writing the UE bit in LPUART_CR1 register to ‘1’.
5. Select DMA enable (DMAT) in LPUART_CR3 if Multi buffer Communication is to take place. Configure the DMA register as explained in Section 47.5.10: USART multiprocessor communication.
6. Set the TE bit in LPUART_CR1 to send an idle frame as first transmission.
7. Write the data to send in the LPUART_TDR register. Repeat this operation for each data to be transmitted in case of single buffer.
   - When FIFO mode is disabled, writing a data in the LPUART_TDR clears the TXE flag.
   - When FIFO mode is enabled, writing a data in the LPUART_TDR adds one data to the TXFIFO. Write operations to the LPUART_TDR are performed when TXFNF flag is set. This flag remains set until the TXFIFO is full.
8. When the last data is written to the LPUART_TDR register, wait until TC=1. This indicates that the transmission of the last frame is complete.
   - When FIFO mode is disabled, this indicates that the transmission of the last frame is complete.
– When FIFO mode is enabled, this indicates that both TXFIFO and shift register are empty.
This check is required to avoid corrupting the last transmission when the LPUART is disabled or enters Halt mode.

**Single byte communication**

- **When FIFO mode disabled:**
  Writing to the transmit data register always clears the TXE bit. The TXE flag is set by hardware to indicate that:
  - the data have been moved from the LPUART_TDR register to the shift register and data transmission has started;
  - the LPUART_TDR register is empty;
  - the next data can be written to the LPUART_TDR register without overwriting the previous data.
  The TXE flag generates an interrupt if the TXEIE bit is set.
  When a transmission is ongoing, a write instruction to the LPUART_TDR register stores the data in the TDR register, which is copied to the shift register at the end of the current transmission.
  When no transmission is ongoing, a write instruction to the LPUART_TDR register places the data in the shift register, the data transmission starts, and the TXE bit is set.

- **When FIFO mode is enabled,** the TXFNF (TXFIFO Not Full) flag is set by hardware to indicate that:
  - the TXFIFO is not full;
  - the LPUART_TDR register is empty;
  - the next data can be written to the LPUART_TDR register without overwriting the previous data. When a transmission is ongoing, a write operation to the LPUART_TDR register stores the data in the TXFIFO. Data are copied from the TXFIFO to the shift register at the end of the current transmission.
  When the TXFIFO is not full, the TXFNF flag stays at ‘1’ even after a write in LPUART_TDR. It is cleared when the TXFIFO is full. This flag generates an interrupt if TXFNEIE bit is set.
  Alternatively, interrupts can be generated and data can be written to the TXFIFO when the TXFIFO threshold is reached. In this case, the CPU can write a block of data defined by the programmed threshold.
  If a frame is transmitted (after the stop bit) and the TXE flag (TXFE is case of FIFO mode) is set, the TC bit goes high. An interrupt is generated if the TCIE bit is set in the LPUART_CR1 register.
  After writing the last data in the LPUART_TDR register, it is mandatory to wait for TC=1 before disabling the LPUART or causing the microcontroller to enter the low-power mode (see *Figure 598: TC/TXE behavior when transmitting*).
Break characters

Setting the SBKRQ bit transmits a break character. The break frame length depends on the M bits (see Figure 596).

If a ‘1’ is written to the SBKRQ bit, a break character is sent on the TX line after completing the current character transmission. The SBKF bit is set by the write operation and it is reset by hardware when the break character is completed (during the stop bits after the break character). The LPUART inserts a logic 1 signal (STOP) for the duration of 2 bits at the end of the break frame to guarantee the recognition of the start bit of the next frame.

When the SBKRQ bit is set, the break character is sent at the end of the current transmission.

When FIFO mode is enabled, sending the break character has priority on sending data even if the TXFIFO is full.

Idle characters

Setting the TE bit drives the LPUART to send an idle frame before the first data frame.

48.3.6 LPUART receiver

The LPUART can receive data words of either 7 or 8 or 9 bits depending on the M bits in the LPUART_CR1 register.

Start bit detection

In the LPUART, the start bit is detected when a falling edge occurs on the Rx line, followed by a sample taken in the middle of the start bit to confirm that it is still ‘0’. If the start sample is at ‘1’, then the noise error flag (NE) is set, then the start bit is discarded and the receiver waits for a new start bit. Else, the receiver continues to sample all incoming bits normally.
Character reception

During an LPUART reception, data are shifted in least significant bit first (default configuration) through the RX pin. In this mode, the LPUART_RDR register consists of a buffer (RDR) between the internal bus and the received shift register.

Character reception procedure

To receive a character, follow the sequence below:

1. Program the M bits in LPUART_CR1 to define the word length.
2. Select the desired baud rate using the baud rate register LPUART_BRR.
3. Program the number of stop bits in LPUART_CR2.
4. Enable the LPUART by writing the UE bit in LPUART_CR1 register to ‘1’.
5. Select DMA enable (DMAR) in LPUART_CR3 if multibuffer communication is to take place. Configure the DMA register as explained in Section 47.5.10: USART multiprocessor communication.
6. Set the RE bit LPUART_CR1. This enables the receiver which begins searching for a start bit.

When a character is received

- When FIFO mode is disabled, the RXNE bit is set. It indicates that the content of the shift register is transferred to the RDR. In other words, data has been received and can be read (as well as its associated error flags).
- When FIFO mode is enabled, the RXFNE bit is set indicating that the RXFIFO is not empty. Reading the LPUART_RDR returns the oldest data entered in the RXFIFO. When a data is received, it is stored in the RXFIFO, together with the corresponding error bits.
- An interrupt is generated if the RXNEIE (RXFNEIE in case of FIFO mode) bit is set.
- The error flags can be set if a frame error, noise or an overrun error has been detected during reception.
- In multibuffer communication mode:
  - When FIFO mode is disabled, the RXNE flag is set after every byte received and is cleared by the DMA read of the Receive Data Register.
  - When FIFO mode is enabled, the RXFNE flag is set when the RXFIFO is not empty. After every DMA request, a data is retrieved from the RXFIFO. DMA request is triggered by RXFIFO is not empty i.e. there is a data in the RXFIFO to be read.
- In single buffer mode:
  - When FIFO mode is disabled, clearing the RXNE flag is done by performing a software read from the LPUART_RDR register. The RXNE flag can also be cleared by writing 1 to the RXFRQ in the LPUART_RQR register. The RXNE bit must be cleared before the end of the reception of the next character to avoid an overrun error.
  - When FIFO mode is enabled, the RXFNE flag is set when the RXFIFO is not empty. After every read operation from the LPUART_RDR register, a data is retrieved from the RXFIFO. When the RXFIFO is empty, the RXFNE flag is cleared. The RXFNE flag can also be cleared by writing 1 to the RXFRQ bit in the LPUART_RQR register. When the RXFIFO is full, the first entry in the RXFIFO must be read before the end of the reception of the next character to avoid an overrun error. The RXFNE flag generates an interrupt if the RXFNEIE bit is set.
Alternatively, interrupts can be generated and data can be read from RXFIFO when the RXFIFO threshold is reached. In this case, the CPU can read a block of data defined by the programmed threshold.

**Break character**

When a break character is received, the USART handles it as a framing error.

**Idle character**

When an idle frame is detected, it is handled in the same way as a data character reception except that an interrupt is generated if the IDLEIE bit is set.

**Overrun error**

- **FIFO mode disabled**
  
  An overrun error occurs when a character is received when RXNE has not been reset. Data can not be transferred from the shift register to the RDR register until the RXNE bit is cleared. The RXNE flag is set after every byte received.
  
  An overrun error occurs if RXNE flag is set when the next data is received or the previous DMA request has not been serviced. When an overrun error occurs:
  
  - the ORE bit is set;
  - the RDR content will not be lost. The previous data is available when a read to LPUART_RDR is performed;
  - the shift register will be overwritten. After that, any data received during overrun is lost.
  - an interrupt is generated if either the RXNEIE bit or EIE bit is set.

- **FIFO mode enabled**
  
  An overrun error occurs when the shift register is ready to be transferred when the receive FIFO is full.
  
  Data can not be transferred from the shift register to the LPUART_RDR register until there is one free location in the RXFIFO. The RXFNE flag is set when the RXFIFO is not empty.
  
  An overrun error occurs if the RXFIFO is full and the shift register is ready to be transferred. When an overrun error occurs:
  
  - the ORE bit is set;
  - the first entry in the RXFIFO will not be lost. It is available when a read to LPUART_RDR is performed.
  - the shift register will be overwritten. After that, any data received during overrun is lost.
  - an interrupt is generated if either the RXFNEIE bit or EIE bit is set.

The ORE bit is reset by setting the ORECF bit in the ICR register.
Note: The ORE bit, when set, indicates that at least 1 data has been lost. T
When the FIFO mode is disabled, there are two possibilities
• if RXNE=1, then the last valid data is stored in the receive register (RDR) and can be read,
• if RXNE=0, then the last valid data has already been read and there is nothing left to be read in the RDR. This case can occur when the last valid data is read in the RDR at the same time as the new (and lost) data is received.

Selecting the clock source

The choice of the clock source is done through the Clock Control system (see Section Reset and clock controller (RCC)). The clock source must be selected through the UE bit, before enabling the LPUART.

The clock source must be selected according to two criteria:
• Possible use of the LPUART in low-power mode
• Communication speed.

The clock source frequency is lpuart_ker_ck.

When the dual clock domain and the wakeup from low-power mode features are supported, the lpuart_ker_ck clock source can be configured in the RCC (see Section Reset and clock controller (RCC)). Otherwise, the lpuart_ker_ck is the same as lpuart_pclk.

The lpuart_ker_ck can be divided by a programmable factor in the LPUART_PRESC register.

Figure 599. lpuart_ker_ck clock divider block diagram

Some lpuart_ker_ck sources allow the LPUART to receive data while the MCU is in low-power mode. Depending on the received data and wakeup mode selection, the LPUART wakes up the MCU, when needed, in order to transfer the received data by software reading the LPUART_RDR register or by DMA.

For the other clock sources, the system must be active to allow LPUART communications.

The communication speed range (specially the maximum communication speed) is also determined by the clock source.

The receiver samples each incoming baud as close as possible to the middle of the baud-period. Only a single sample is taken of each of the incoming bauds.

Note: There is no noise detection for data.
Framing error

A framing error is detected when the stop bit is not recognized on reception at the expected time, following either a de-synchronization or excessive noise.

When the framing error is detected:
- the FE bit is set by hardware;
- the invalid data is transferred from the Shift register to the LPUART_RDR register.
- no interrupt is generated in case of single byte communication. However this bit rises at the same time as the RXNE bit which itself generates an interrupt. In case of multibuffer communication, an interrupt will be issued if the EIE bit is set in the LPUART_CR3 register.

The FE bit is reset by writing 1 to the FECF in the LPUART_ICR register.

Configurable stop bits during reception

The number of stop bits to be received can be configured through the control bits of LPUART_CR2: it can be either 1 or 2 in normal mode.
- 1 stop bit: sampling for 1 stop bit is done on the 8th, 9th and 10th samples.
- 2 stop bits: sampling for the 2 stop bits is done in the middle of the second stop bit. The RXNE and FE flags are set just after this sample i.e. during the second stop bit. The first stop bit is not checked for framing error.

48.3.7 LPUART baud rate generation

The baud rate for the receiver and transmitter (Rx and Tx) are both set to the value programmed in the LPUART_BRR register.

\[
\text{Tx/Rx baud} = \frac{256 \times \text{Lpuartckpres}}{\text{LPUARTDIV}}
\]

LPUARTDIV is defined in the LPUART_BRR register.

**Note:**

The baud counters are updated to the new value in the baud registers after a write operation to LPUART_BRR. Hence the baud rate register value should not be changed during communication.

It is forbidden to write values lower than 0x300 in the LPUART_BRR register.

\( f_{CK} \) must range from 3 x baud rate to 4096 x baud rate.

The maximum baud rate that can be reached when the LPUART clock source is the LSE, is 9600 baud. Higher baud rates can be reached when the LPUART is clocked by clock sources different from the LSE clock. For example, if the LPUART clock source frequency is 100 MHz, the maximum baud rate that can be reached is about 33 Mbaud.

48.3.8 Tolerance of the LPUART receiver to clock deviation

The asynchronous receiver of the LPUART works correctly only if the total clock system deviation is less than the tolerance of the LPUART receiver. The causes which contribute to the total deviation are:

- **DTRA**: deviation due to the transmitter error (which also includes the deviation of the transmitter’s local oscillator)
- **DQUANT**: error due to the baud rate quantization of the receiver
- **DREC**: deviation of the receiver local oscillator
- **DTCL**: deviation due to the transmission line (generally due to the transceivers which can introduce an asymmetry between the low-to-high transition timing and the high-to-low transition timing)

\[
DTRA + DQUANT + DREC + DTCL + DWU < \text{LPUART receiver tolerance}
\]

where

- **DWU** is the error due to sampling point deviation when the wakeup from low-power mode is used.

The LPUART receiver can receive data correctly at up to the maximum tolerated deviation specified in Table 398:

- Number of Stop bits defined through STOP[1:0] bits in the LPUART_CR2 register
- LPUART_BRR register value.

### Table 398. Tolerance of the LPUART receiver

</table>

**Note:** The data specified in Table 398 may slightly differ in the special case when the received frames contain some Idle frames of exactly 10-bit times when M bits = ’00’ (11-bit times when M=’01’ or 9- bit times when M = ’10’).

48.3.9 LPUART multiprocessor communication

It is possible to perform LPUART multiprocessor communications (with several LPUARTs connected in a network). For instance one of the LPUARTs can be the master, with its TX output connected to the RX inputs of the other LPUARTs. The others are slaves, with their respective TX outputs are logically ANDed together and connected to the RX input of the master.

In multiprocessor configurations it is often desirable that only the intended message recipient actively receives the full message contents, thus reducing redundant LPUART service overhead for all non addressed receivers.
The non addressed devices can be placed in Mute mode by means of the muting function. To use the Mute mode feature, the MME bit must be set in the LPUART_CR1 register.

**Note:** When FIFO management is enabled and MME is already set, MME bit must not be cleared and then set again quickly (within two lpuart_ker_ck cycles), otherwise Mute mode might remain active.

When the Mute mode is enabled:
- none of the reception status bits can be set;
- all the receive interrupts are inhibited;
- the RWU bit in LPUART_ISR register is set to ‘1’. RWU can be controlled automatically by hardware or by software, through the MMRQ bit in the LPUART_RQR register, under certain conditions.

The LPUART can enter or exit from Mute mode using one of two methods, depending on the WAKE bit in the LPUART_CR1 register:
- Idle Line detection if the WAKE bit is reset,
- Address Mark detection if the WAKE bit is set.

**Idle line detection (WAKE=0)**

The LPUART enters Mute mode when the MMRQ bit is written to 1 and the RWU is automatically set.

The LPUART wakes up when an Idle frame is detected. The RWU bit is then cleared by hardware but the IDLE bit is not set in the LPUART_ISR register. An example of Mute mode behavior using Idle line detection is given in Figure 600.

![Figure 600. Mute mode using Idle line detection](image)

**Note:** If the MMRQ is set while the IDLE character has already elapsed, Mute mode will not be entered (RWU is not set).

If the LPUART is activated while the line is IDLE, the idle state is detected after the duration of one IDLE frame (not only after the reception of one character frame).

**4-bit/7-bit address mark detection (WAKE=1)**

In this mode, bytes are recognized as addresses if their MSB is a ‘1’ otherwise they are considered as data. In an address byte, the address of the targeted receiver is put in the 4 or 7 LSBs. The choice of 7 or 4 bit address detection is done using the ADDM7 bit. This 4-
A bit/7-bit word is compared by the receiver with its own address which is programmed in the ADD bits in the LPUART_CR2 register.

**Note:** In 7-bit and 9-bit data modes, address detection is done on 6-bit and 8-bit addresses (ADD[5:0] and ADD[7:0]) respectively.

The LPUART enters Mute mode when an address character is received which does not match its programmed address. In this case, the RX bit is set by hardware. The RXNE flag is not set for this address byte and no interrupt or DMA request is issued when the LPUART enters Mute mode.

The LPUART also enters Mute mode when the MMRQ bit is written to ‘1’. The RWU bit is also automatically set in this case.

The LPUART exits from Mute mode when an address character is received which matches the programmed address. Then the RWU bit is cleared and subsequent bytes are received normally. The RXNE/RXFNE bit is set for the address character since the RWU bit has been cleared.

**Note:** When FIFO management is enabled, when MMRQ bit is set while the receiver is sampling the last bit of a data, this data may be received before effectively entering in Mute mode.

An example of Mute mode behavior using address mark detection is given in Figure 601.

![Figure 601. Mute mode using address mark detection](image)

**48.3.10 LPUART parity control**

Parity control (generation of parity bit in transmission and parity checking in reception) can be enabled by setting the PCE bit in the LPUART_CR1 register. Depending on the frame length defined by the M bits, the possible LPUART frame formats are as listed in Table 399.

<table>
<thead>
<tr>
<th>M bits</th>
<th>PCE bit</th>
<th>LPUART frame(1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>

<td>0</td>
<td></td>
</tr>
<tr>
<td>01</td>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>

*Note: Table 399: LPUART frame formats*
Even parity
The parity bit is calculated to obtain an even number of “1s” inside the frame which is made of the 6, 7 or 8 LSB bits (depending on M bit values) and the parity bit.

As an example, if data=00110101, and 4 bits are set, then the parity bit will be 0 if even parity is selected (PS bit in LPUART_CR1 = 0).

Odd parity
The parity bit is calculated to obtain an odd number of “1s” inside the frame made of the 6, 7 or 8 LSB bits (depending on M bit values) and the parity bit.

As an example, if data=00110101 and 4 bits set, then the parity bit will be 1 if odd parity is selected (PS bit in LPUART_CR1 = 1).

Parity checking in reception
If the parity check fails, the PE flag is set in the LPUART_ISR register and an interrupt is generated if PEIE is set in the LPUART_CR1 register. The PE flag is cleared by software writing 1 to the PECF in the LPUART_ICR register.

Parity generation in transmission
If the PCE bit is set in LPUART_CR1, then the MSB bit of the data written in the data register is transmitted but is changed by the parity bit (even number of “1s” if even parity is selected (PS=0) or an odd number of “1s” if odd parity is selected (PS=1)).

48.3.11 LPUART single-wire Half-duplex communication
Single-wire Half-duplex mode is selected by setting the HDSEL bit in the LPUART_CR3 register. In this mode, the following bits must be kept cleared:
- LINEN and CLKEN bits in the LPUART_CR2 register,
- SCEN and IREN bits in the LPUART_CR3 register.

The LPUART can be configured to follow a Single-wire Half-duplex protocol where the TX and RX lines are internally connected. The selection between half- and Full-duplex communication is made with a control bit HDSEL in LPUART_CR3.

As soon as HDSEL is written to ‘1’:
- The TX and RX lines are internally connected.
- The RX pin is no longer used
- The TX pin is always released when no data is transmitted. Thus, it acts as a standard I/O in idle or in reception. It means that the I/O must be configured so that TX is configured as alternate function open-drain with an external pull-up.
Apart from this, the communication protocol is similar to normal LPUART mode. Any conflict on the line must be managed by software (for instance by using a centralized arbiter). In particular, the transmission is never blocked by hardware and continues as soon as data is written in the data register while the TE bit is set.

*Note:* In LPUART communications, in the case of 1-stop bit configuration, the RXNE flag is set in the middle of the stop bit.

### 48.3.12 Continuous communication using DMA and LPUART

The LPUART is capable of performing continuous communication using the DMA. The DMA requests for Rx buffer and Tx buffer are generated independently.

*Note:* Refer to Section 47.4: USART implementation on page 2024 to determine if the DMA mode is supported. If DMA is not supported, use the LPUSRT as explained in Section 47.5.6. To perform continuous communication. When FIFO is disabled, you can clear the TXE/RXNE flags in the LPUART_ISR register.

#### Transmission using DMA

DMA mode can be enabled for transmission by setting DMAT bit in the LPUART_CR3 register. Data are loaded from an SRAM area configured using the DMA peripheral (refer to the corresponding Direct memory access controller section) to the LPUART_TDR register whenever the TXE flag (TXFNF flag if FIFO mode is enabled) is set. To map a DMA channel for LPUART transmission, use the following procedure (x denotes the channel number):

1. Write the LPUART_TDR register address in the DMA control register to configure it as the destination of the transfer. The data is moved to this address from memory after each TXE (or TXFNF if FIFO mode is enabled) event.
2. Write the memory address in the DMA control register to configure it as the source of the transfer. The data is loaded into the LPUART_TDR register from this memory area after each TXE (or TXFNF if FIFO mode is enabled) event.
3. Configure the total number of bytes to be transferred to the DMA control register.
4. Configure the channel priority in the DMA register.
5. Configure DMA interrupt generation after half/full transfer as required by the application.
6. Clear the TC flag in the LPUART_ISR register by setting the TCCF bit in the LPUART_ICR register.
7. Activate the channel in the DMA register.

When the number of data transfers programmed in the DMA Controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector.

In transmission mode, once the DMA has written all the data to be transmitted (the TCIF flag is set in the DMA_ISR register), the TC flag can be monitored to make sure that the LPUART communication is complete. This is required to avoid corrupting the last transmission before disabling the LPUART or entering low-power mode. Software must wait until TC=1. The TC flag remains cleared during all data transfers and it is set by hardware at the end of transmission of the last frame.
**Figure 602. Transmission using DMA**

<table>
<thead>
<tr>
<th>TX line</th>
<th>Idle preamble</th>
<th>Frame 1</th>
<th>Frame 2</th>
<th>Frame 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>TXE flag</td>
<td>Set by hardware cleared by DMA read</td>
<td>Set by hardware cleared by DMA read</td>
<td>Set by hardware</td>
<td></td>
</tr>
<tr>
<td>DMA request</td>
<td>Ignored by the DMA because the transfer is complete</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Note:** When FIFO management is enabled, the DMA request is triggered by Transmit FIFO not full (i.e. TXFNF = 1).

**Reception using DMA**

DMA mode can be enabled for reception by setting the DMAR bit in LPUART_CR3 register. Data are loaded from the LPUART_RDR register to a SRAM area configured using the DMA peripheral (refer to the corresponding Direct memory access controller (DMA) section) whenever a data byte is received. To map a DMA channel for LPUART reception, use the following procedure:

1. Write the LPUART_RDR register address in the DMA control register to configure it as the source of the transfer. The data is moved from this address to the memory after each RXNE (RXFNE in case FIFO mode is enabled) event.
2. Write the memory address in the DMA control register to configure it as the destination of the transfer. The data is loaded from LPUART_RDR to this memory area after each RXNE (RXFNE in case FIFO mode is enabled) event.
3. Configure the total number of bytes to be transferred to the DMA control register.
4. Configure the channel priority in the DMA control register
5. Configure interrupt generation after half/ full transfer as required by the application.
6. Activate the channel in the DMA control register.

When the number of data transfers programmed in the DMA Controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector.
Figure 603. Reception using DMA

Note: When FIFO management is enabled, the DMA request is triggered by Receive FIFO not empty (i.e. RXFNE = 1).

Error flagging and interrupt generation in multibuffer communication

If any error occurs during a transaction in multibuffer communication mode, the error flag is asserted after the current byte. An interrupt is generated if the interrupt enable flag is set. For framing error, overrun error and noise flag which are asserted with RXNE (RXFNE in case FIFO mode is enabled) in single byte reception, there is a separate error flag interrupt enable bit (EIE bit in the LPUART_CR3 register), which, if set, enables an interrupt after the current byte if any of these errors occur.

48.3.13 RS232 Hardware flow control and RS485 Driver Enable

It is possible to control the serial data flow between 2 devices by using the nCTS input and the nRTS output. The Figure 590 shows how to connect 2 devices in this mode:

Figure 604. Hardware flow control between 2 LPUARTs
RS232 RTS and CTS flow control can be enabled independently by writing the RTSE and CTSE bits respectively to 1 (in the LPUART_CR3 register).

**RS232 RTS flow control**

If the RTS flow control is enabled (RTSE=1), then nRTS is asserted (tied low) as long as the LPUART receiver is ready to receive a new data. When the receive register is full, nRTS is deasserted, indicating that the transmission is expected to stop at the end of the current frame. *Figure 605* shows an example of communication with RTS flow control enabled.

![Figure 605. RS232 RTS flow control](image)

*Note:* When FIFO mode is enabled, nRTS is de-asserted only when RXFIFO is full.

**RS232 CTS flow control**

If the CTS flow control is enabled (CTSE=1), then the transmitter checks the nCTS input before transmitting the next frame. If nCTS is asserted (tied low), then the next data is transmitted (assuming that data is to be transmitted, in other words, if TXE/TXFE=0), else the transmission does not occur. When nCTS is deasserted during a transmission, the current transmission is completed before the transmitter stops.

When CTSE=1, the CTSIF status bit is automatically set by hardware as soon as the nCTS input toggles. It indicates when the receiver becomes ready or not ready for communication. An interrupt is generated if the CTSIE bit in the LPUART_CR3 register is set. *Figure 606* shows an example of communication with CTS flow control enabled.
Figure 606. RS232 CTS flow control

Note: For correct behavior, nCTS must be asserted at least 3 LPUART clock source periods before the end of the current character. In addition it should be noted that the CTSCF flag may not be set for pulses shorter than 2 x PCLK periods.

RS485 driver enable

The driver enable feature is enabled by setting bit DEM in the LPUART_CR3 control register. This allows activating the external transceiver control, through the DE (Driver Enable) signal. The assertion time is the time between the activation of the DE signal and the beginning of the start bit. It is programmed using the DEAT [4:0] bitfields in the LPUART_CR1 control register. The de-assertion time is the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE signal. It is programmed using the DEDT [4:0] bitfields in the LPUART_CR1 control register. The polarity of the DE signal can be configured using the DEP bit in the LPUART_CR3 control register.

The LPUART DEAT and DEDT are expressed in LPUART clock source (fCK) cycles:

- The Driver enable assertion time equals
  - \((1 + \text{DEAT} \times \text{P})) \times f_{CK}\) if \(\text{P} \neq 0\)
  - \((1 + \text{DEAT}) \times f_{CK}\) if \(\text{P} = 0\)

- The Driver enable de-assertion time equals
  - \((1 + \text{DEDT} \times \text{P})) \times f_{CK}\) if \(\text{P} \neq 0\)
  - \((1 + \text{DEDT}) \times f_{CK}\) if \(\text{P} = 0\)

where \(\text{P} = \text{BRR}[20:11]\)
48.3.14 LPUART low-power management

The LPUART has advanced low-power mode functions allowing it to transfer properly data even when the luart_pclk clock is disabled. The LPUART is able to wake up the MCU from low-power mode when the UESM bit is set. When the usart_pclk is gated, the LPUART provides a wakeup interrupt (usart_wkup) if a specific action requiring the activation of the usart_pclk clock is needed:

- If FIFO mode is disabled
  luart_pclk clock has to be activated to empty the LPUART data register.
  In this case, the lpuart_wkup interrupt source is the RXNE set to ‘1’. The RXNEIE bit must be set before entering low-power mode.

- If FIFO mode is enabled
  luart_pclk clock has to be activated
  - to fill the TXFIFO
  - or to empty the RXFIFO
  In this case, the lpuart_wkup interrupt source can be:
    - RXFIFO not empty. In this case, the RXFNEIE bit must be set before entering low-power mode.
    - RXFIFO full. In this case, the RXFFIE bit must be set before entering low-power mode, the number of received data corresponds to the RXFIFO size, and the RXFF flag is not set.
    - TXFIFO empty. In this case, the TXFEIE bit must be set before entering low-power mode.
  This allows sending/receiving the data in the TXFIFO/RXFIFO during low-power mode.
  To avoid overrun/underrun errors and transmit/receive data in low-power mode, the lpuart_wkup interrupt source can be one of the following events:
    - TXFIFO threshold reached. In this case, the TXFTIE bit must be set before entering low-power mode.
    - RXFIFO threshold reached. In this case, the RXFTIE bit must be set before entering low-power mode.
  For example, the application can set the threshold to the maximum RXFIFO size if the wakeup time is less than the time to receive a single byte across the line.
  Using the RXFIFO full, TXFIFO empty, RXFIFO not empty and RXFIFO/TXFIFO threshold interrupts to wakeup the MCU from low-power mode allows doing as many LPUART transfers as possible during low-power mode with the benefit of optimizing consumption.

  Alternatively, a specific lpuart_wkup interrupt may be selected through the WUS bitfields.

  When the wakeup event is detected, the WUF flag is set by hardware and lpuart_wkup interrupt is generated if the WUFIE bit is set. In this case the lpuart_wkup interrupt is not mandatory for the wakeup. The WUF being set is sufficient to wakeup the MCU from low-power mode.
Note: Before entering low-power mode, make sure that no LPUART transfer is ongoing. Checking the BUSY flag cannot ensure that low-power mode is never entered when data reception is ongoing.

The WUF flag is set when a wakeup event is detected, independently of whether the MCU is in low-power or in an active mode.

When entering low-power mode just after having initialized and enabled the receiver, the REACK bit must be checked to ensure the LPUART is actually enabled.

When DMA is used for reception, it must be disabled before entering low-power mode and re-enabled upon exit from low-power mode.

When FIFO is enabled, the wakeup from low-power mode on address match is only possible when Mute mode is enabled.

**Using Mute mode with low-power mode**

If the LPUART is put into Mute mode before entering low-power mode:

- Wakeup from Mute mode on idle detection must not be used, because idle detection cannot work in low-power mode.
- If the wakeup from Mute mode on address match is used, then the low-power mode wakeup source from must also be the address match. If the RXNE flag was set when entering the low-power mode, the interface will remain in Mute mode upon address match and wake up from low-power mode.

Note: When FIFO management is enabled, Mute mode is used with wakeup from low-power mode without any constraints (i.e. the two points mentioned above about mute and low-power mode are valid only when FIFO management is disabled).

**Wakeup from low-power mode when LPUART kernel clock lpuart_ker_ck is OFF in low-power mode**

If during low-power mode, the lpuart_ker_ck clock is switched OFF, when a falling edge on the LPUART receive line is detected, the LPUART interface requests the lpuart_ker_ck clock to be switched ON thanks to the lpuart_ker_ck_req signal. The lpuart_ker_ck is then used for the frame reception.

If the wakeup event is verified, the MCU wakes up from low-power mode and data reception goes on normally.

If the wakeup event is not verified, the usart_ker_ck is switched OFF again, the MCU is not waken up and stays in low-power mode and the kernel clock request is released.

The example below shows the case of wakeup event programmed to “address match detection” and FIFO management disabled.

*Figure 607* shows the behavior when the wakeup event is verified.
Figure 607. Wakeup event verified (wakeup event = address match, FIFO disabled)

Figure 608. Wakeup event not verified (wakeup event = address match, FIFO disabled)

Note: The above figures are valid when address match or any received frame is used as wakeup event. In the case the wakeup event is the start bit detection, the LPUART sends the wakeup event to the MCU at the end of the start bit.
Determining the maximum LPUART baud rate that allows to correctly wake up the MCU from low-power mode

The maximum baud rate allowing to correctly wake up the MCU from low-power mode depends on the wakeup time parameter (refer to the device datasheet) and on the LPUART receiver tolerance (see Section 48.3.8: Tolerance of the LPUART receiver to clock deviation).

Let us take the example of OVER8 = 0, M bits = ‘01’, ONEBIT = 0 and BRR [3:0] = 0000.

In these conditions, according to Table 398: Tolerance of the LPUART receiver, the LPUART receiver tolerance equals 3.41%.

\[ D_{WU_{max}} = \frac{t_{WULPUART}}{(11 \times T_{bit\ Min})} \]
\[ T_{bit\ Min} = \frac{t_{WULPUART}}{(11 \times D_{WU_{max}})} \]

where \( t_{WULPUART} \) is the wakeup time from low-power mode.

If we consider the ideal case where DTRA, DQUANT, DREC and DTCL parameters are at 0%, the maximum value of DWU is 3.41%. In reality, we need to consider at least the lpuart_ker_ck inaccuracy.

For example, if HSI is used as lpuart_ker_ck, and the HSI inaccuracy is of 1%, then we obtain:

\[ t_{WULPUART} = 3 \mu s \] (values provided only as examples; for correct values, refer to the device datasheet).
\[ D_{WU_{max}} = 3.41\% - 1\% = 2.41\% \]
\[ T_{bit\ min} = \frac{3 \mu s}{(11 \times 2.41\%)} = 11.32 \mu s. \]

As a result, the maximum baud rate allowing to wakeup correctly from low-power mode is: 1/11.32 \mu s = 88.36 Kbaud.

48.4 LPUART interrupts

Refer to Table 394 for a detailed description of all LPUART interrupt requests.

</table>

1. RXFF flag is asserted if the LPUART receives n+1 data (n being the RXFIFO size): n data in the RXFIFO and 1 data in LPUART_RDR. In Stop mode, LPUART_RDR is not clocked. As a result, this register will not be written and once n data are received and written in the RXFIFO, the RXFF interrupt will be asserted (RXFF flag is not set).
2. The WUF interrupt is active only in low-power mode.

### 48.5 LPUART registers

Refer to *Section 1.2 on page 98* for a list of abbreviations used in register descriptions.

#### 48.5.1 Control register 1 [alternate] (LPUART_CR1)

Address offset: 0x00

Reset value: 0x0000 0000

The same register can be used in FIFO mode enabled (this section) and FIFO mode disabled (next section).

**FIFO mode enabled**

Bit 31 **RXFFIE**: RXFIFO Full interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited
1: An LPUART interrupt is generated when RXFF=1 in the LPUART_ISR register

Bit 30 **TXFEIE**: TXFIFO empty interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited
1: An LPUART interrupt is generated when TXFE=1 in the LPUART_ISR register

Bit 29 **FIFOEN**: FIFO mode enable

This bit is set and cleared by software.

0: FIFO mode is disabled
1: FIFO mode is enabled.

Bit 28 **M1**: Word length

This bit must be used in conjunction with bit 12 (M0) to determine the word length. It is set or cleared by software.

M[1:0] = '00': 1 Start bit, 8 Data bits, n Stop bit
M[1:0] = '01': 1 Start bit, 9 Data bits, n Stop bit
M[1:0] = '10': 1 Start bit, 7 Data bits, n Stop bit

This bit can only be written when the LPUART is disabled (UE=0).

**Note:** In 7-bit data length mode, the Smartcard mode, LIN master mode and Auto baud rate (0x7F and 0x55 frames detection) are not supported.

Bits 27:26 Reserved, must be kept at reset value.
Bits 25:21 **DEAT[4:0]:** Driver Enable assertion time

This 5-bit value defines the time between the activation of the DE (Driver Enable) signal and the beginning of the start bit. It is expressed in `lpuart_ker_ck` clock cycles. For more details, refer to Section 47.5.20: RS232 Hardware flow control and RS485 Driver Enable. This bitfield can only be written when the LPUART is disabled (UE=0).

Bits 20:16 **DEDT[4:0]:** Driver Enable deassertion time

This 5-bit value defines the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE (Driver Enable) signal. It is expressed in `lpuart_ker_ck` clock cycles. For more details, refer to Section 48.3.13: RS232 Hardware flow control and RS485 Driver Enable. If the LPUART_TDR register is written during the DEDT time, the new data is transmitted only when the DEDT and DEAT times have both elapsed. This bitfield can only be written when the LPUART is disabled (UE=0).

Bit 15 Reserved, must be kept at reset value.

Bit 14 **CMIE:** Character match interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited
1: A LPUART interrupt is generated when the CMF bit is set in the LPUART_ISR register.

Bit 13 **MME:** Mute mode enable

This bit activates the Mute mode function of the LPUART. When set, the LPUART can switch between the active and Mute modes, as defined by the WAKE bit. It is set and cleared by software.

0: Receiver in active mode permanently
1: Receiver can switch between Mute mode and active mode.

Bit 12 **M0:** Word length

This bit is used in conjunction with bit 28 (M1) to determine the word length. It is set or cleared by software (refer to bit 28 (M1) description). This bit can only be written when the LPUART is disabled (UE=0).

Bit 11 **WAKE:** Receiver wakeup method

This bit determines the LPUART wakeup method from Mute mode. It is set or cleared by software.

0: Idle line
1: Address mark

This bitfield can only be written when the LPUART is disabled (UE=0).

Bit 10 **PCE:** Parity control enable

This bit selects the hardware parity control (generation and detection). When the parity control is enabled, the computed parity is inserted at the MSB position (9th bit if \(M=1\); 8th bit if \(M=0\)) and parity is checked on the received data. This bit is set and cleared by software. Once it is set, PCE is active after the current byte (in reception and in transmission).

0: Parity control disabled
1: Parity control enabled

This bitfield can only be written when the LPUART is disabled (UE=0).

Bit 9 **PS:** Parity selection

This bit selects the odd or even parity when the parity generation/detection is enabled (PCE bit set). It is set and cleared by software. The parity will be selected after the current byte.

0: Even parity
1: Odd parity

This bitfield can only be written when the LPUART is disabled (UE=0).
Bit 8 **PEIE**: PE interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited
1: An LPUART interrupt is generated whenever PE=1 in the LPUART_ISR register

Bit 7 **TXFNFIE**: TX FIFO not full interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited
1: A LPUART interrupt is generated whenever TXE/TXFNF =1 in the LPUART_ISR register

Bit 6 **TCIE**: Transmission complete interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited
1: An LPUART interrupt is generated whenever TC=1 in the LPUART_ISR register

Bit 5 **RXFNEIE**: RX FIFO not empty interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited
1: A LPUART interrupt is generated whenever ORE=1 or RXNE/RXFNE=1 in the LPUART_ISR register

Bit 4 **IDLEIE**: IDLE interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited
1: An LPUART interrupt is generated whenever IDLE=1 in the LPUART_ISR register

Bit 3 **TE**: Transmitter enable
This bit enables the transmitter. It is set and cleared by software.
0: Transmitter is disabled
1: Transmitter is enabled

**Note**:  During transmission, a low pulse on the TE bit ("0" followed by "1") sends a preamble (idle line) after the current word. In order to generate an idle character, the TE must not be immediately written to 1. In order to ensure the required duration, the software can poll the TEACK bit in the LPUART_ISR register.

When TE is set there is a 1 bit-time delay before the transmission starts.
Bit 2 **RE**: Receiver enable
This bit enables the receiver. It is set and cleared by software.
- 0: Receiver is disabled
- 1: Receiver is enabled and begins searching for a start bit

Bit 1 **UESM**: LPUART enable in Stop mode
When this bit is cleared, the LPUART is not able to wake up the MCU from low-power mode. When this bit is set, the LPUART is able to wake up the MCU from low-power mode, provided that the LPUART clock selection is HSI or LSE in the RCC.
- 0: LPUART not able to wake up the MCU from low-power mode.
- 1: LPUART able to wake up the MCU from low-power mode. When this function is active, the clock source for the LPUART must be HSI or LSE (see RCC chapter)

*Note: It is recommended to set the UESM bit just before entering low-power mode and clear it on exit from low-power mode.*

Bit 0 **UE**: LPUART enable
When this bit is cleared, the LPUART prescalers and outputs are stopped immediately, and current operations are discarded. The configuration of the LPUART is kept, but all the status flags, in the LPUART_ISR are reset. This bit is set and cleared by software.
- 0: LPUART prescaler and outputs disabled, low-power mode
- 1: LPUART enabled

*Note: To enter low-power mode without generating errors on the line, the TE bit must be reset before and the software must wait for the TC bit in the LPUART_ISR to be set before resetting the UE bit.*

The DMA requests are also reset when UE = 0 so the DMA channel must be disabled before resetting the UE bit.

### 48.5.2 Control register 1 [alternate] (LPUART_CR1)

Address offset: 0x00
Reset value: 0x0000 0000

The same register can be used in FIFO mode enabled (previous section) and FIFO mode disabled (this section).

#### FIFO mode disabled

Bits 31:30  Reserved, must be kept at reset value.

Bit 29  **FIFOEN**: FIFO mode enable
This bit is set and cleared by software.
0: FIFO mode is disabled.
1: FIFO mode is enabled.

Bit 28  **M1**: Word length
This bit must be used in conjunction with bit 12 (M0) to determine the word length. It is set or cleared by software.
- M[1:0] = ‘00’: 1 Start bit, 8 Data bits, n Stop bit
- M[1:0] = ‘01’: 1 Start bit, 9 Data bits, n Stop bit
- M[1:0] = ‘10’: 1 Start bit, 7 Data bits, n Stop bit
This bit can only be written when the LPUART is disabled (UE=0).

*Note: In 7-bit data length mode, the Smartcard mode, LIN master mode and Auto baud rate (0x7F and 0x55 frames detection) are not supported.*

Bits 27:26  Reserved, must be kept at reset value.

Bits 25:21  **DEAT[4:0]**: Driver Enable assertion time
This 5-bit value defines the time between the activation of the DE (Driver Enable) signal and the beginning of the start bit. It is expressed in lpuart_ker_ck clock cycles. For more details, refer [Section 47.5.20: RS232 Hardware flow control and RS485 Driver Enable](#).
This bitfield can only be written when the LPUART is disabled (UE=0).

Bits 20:16  **DEDT[4:0]**: Driver Enable deassertion time
This 5-bit value defines the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE (Driver Enable) signal. It is expressed in lpuart_ker_ck clock cycles. For more details, refer [Section 48.3.13: RS232 Hardware flow control and RS485 Driver Enable](#).
If the LPUART_TDR register is written during the DEDT time, the new data is transmitted only when the DEDT and DEAT times have both elapsed.
This bitfield can only be written when the LPUART is disabled (UE=0).

Bit 15  Reserved, must be kept at reset value.

Bit 14  **CMIE**: Character match interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited
1: A LPUART interrupt is generated when the CMF bit is set in the LPUART_ISR register.

Bit 13  **MME**: Mute mode enable
This bit activates the Mute mode function of the LPUART. When set, the LPUART can switch between the active and Mute modes, as defined by the WAKE bit. It is set and cleared by software.
0: Receiver in active mode permanently
1: Receiver can switch between Mute mode and active mode.

Bit 12  **M0**: Word length
This bit is used in conjunction with bit 28 (M1) to determine the word length. It is set or cleared by software (refer to bit 28 (M1) description).
This bit can only be written when the LPUART is disabled (UE=0).
Bit 11 **WAKE**: Receiver wakeup method
This bit determines the LPUART wakeup method from Mute mode. It is set or cleared by software.
0: Idle line
1: Address mark
This bitfield can only be written when the LPUART is disabled (UE=0).

Bit 10 **PCE**: Parity control enable
This bit selects the hardware parity control (generation and detection). When the parity control is enabled, the computed parity is inserted at the MSB position (9th bit if M=1; 8th bit if M=0) and parity is checked on the received data. This bit is set and cleared by software. Once it is set, PCE is active after the current byte (in reception and in transmission).
0: Parity control disabled
1: Parity control enabled
This bitfield can only be written when the LPUART is disabled (UE=0).

Bit 9 **PS**: Parity selection
This bit selects the odd or even parity when the parity generation/detection is enabled (PCE bit set). It is set and cleared by software. The parity will be selected after the current byte.
0: Even parity
1: Odd parity
This bitfield can only be written when the LPUART is disabled (UE=0).

Bit 8 **PEIE**: PE interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited
1: An LPUART interrupt is generated whenever PE=1 in the LPUART_ISR register

Bit 7 **TXEIE**: Transmit data register empty
This bit is set and cleared by software.
0: Interrupt is inhibited
1: A LPUART interrupt is generated whenever TXE/TXFNF =1 in the LPUART_ISR register

Bit 6 **TCIE**: Transmission complete interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited
1: An LPUART interrupt is generated whenever TC=1 in the LPUART_ISR register

Bit 5 **RXNEIE**: Receive data register not empty
This bit is set and cleared by software.
0: Interrupt is inhibited
1: A LPUART interrupt is generated whenever ORE=1 or RXNE/RXFNE=1 in the LPUART_ISR register

Bit 4 **IDLEIE**: IDLE interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited
1: An LPUART interrupt is generated whenever IDLE=1 in the LPUART_ISR register
48.5.3 Control register 2 (LPUART_CR2)

Address offset: 0x04
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 3 TE</th>
<th>Transmitter enable</th>
</tr>
</thead>
<tbody>
<tr>
<td>This bit enables the transmitter. It is set and cleared by software.</td>
<td></td>
</tr>
<tr>
<td>0: Transmitter is disabled</td>
<td></td>
</tr>
<tr>
<td>1: Transmitter is enabled</td>
<td></td>
</tr>
</tbody>
</table>

**Note:** During transmission, a low pulse on the TE bit ("0" followed by "1") sends a preamble (idle line) after the current word. In order to generate an idle character, the TE must not be immediately written to 1. In order to ensure the required duration, the software can poll the TEACK bit in the LPUART_ISR register. When TE is set there is a 1 bit-time delay before the transmission starts.

<table>
<thead>
<tr>
<th>Bit 2 RE</th>
<th>Receiver enable</th>
</tr>
</thead>
<tbody>
<tr>
<td>This bit enables the receiver. It is set and cleared by software.</td>

<th>Bit 1 UESM</th>
<th>LPUART enable in Stop mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>When this bit is cleared, the LPUART is not able to wake up the MCU from low-power mode.</td>
<td></td>
</tr>
<tr>
<td>When this bit is set, the LPUART is able to wake up the MCU from low-power mode, provided that the LPUART clock selection is HSI or LSE in the RCC.</td>
<td></td>
</tr>
<tr>
<td>This bit is set and cleared by software.</td>
<td></td>
</tr>
<tr>
<td>0: LPUART not able to wake up the MCU from low-power mode.</td>
<td></td>
</tr>
<tr>
<td>1: LPUART able to wake up the MCU from low-power mode. When this function is active, the clock source for the LPUART must be HSI or LSE (see RCC chapter)</td>
<td></td>
</tr>
</tbody>
</table>

**Note:** It is recommended to set the UESM bit just before entering low-power mode and clear it on exit from low-power mode.

<table>
<thead>
<tr>
<th>Bit 0 UE</th>
<th>LPUART enable</th>
</tr>
</thead>
<tbody>
<tr>
<td>When this bit is cleared, the LPUART prescalers and outputs are stopped immediately, and current operations are discarded. The configuration of the LPUART is kept, but all the status flags, in the LPUART_ISR are reset. This bit is set and cleared by software.</td>
<td></td>
</tr>
<tr>
<td>0: LPUART prescaler and outputs disabled, low-power mode</td>
<td></td>
</tr>
<tr>
<td>1: LPUART enabled</td>
<td></td>
</tr>
</tbody>
</table>

**Note:** To enter low-power mode without generating errors on the line, the TE bit must be reset before and the software must wait for the TC bit in the LPUART_ISR to be set before resetting the UE bit. The DMA requests are also reset when UE = 0 so the DMA channel must be disabled before resetting the UE bit.
Bits 31:24  **ADD[7:0]**: Address of the LPUART node

**ADD[7:4]**: These bits give the address of the LPUART node or a character code to be recognized. They are used to wake up the MCU with 7-bit address mark detection in multiprocessor communication during Mute mode or Stop mode. The MSB of the character sent by the transmitter should be equal to 1. They can also be used for character detection during normal reception, Mute mode inactive (for example, end of block detection in ModBus protocol). In this case, the whole received character (8-bit) is compared to the ADD[7:0] value and CMF flag is set on match. These bits can only be written when reception is disabled (RE = 0) or the LPUART is disabled (UE=0)

**ADD[3:0]**: These bits give the address of the LPUART node or a character code to be recognized. They are used for wakeup with address mark detection in multiprocessor communication during Mute mode or low-power mode. These bits can only be written when reception is disabled (RE = 0) or the LPUART is disabled (UE=0)

Bits 23:20  Reserved, must be kept at reset value.

Bit 19  **MSBFIRST**: Most significant bit first
This bit is set and cleared by software.
0: data is transmitted/received with data bit 0 first, following the start bit.
1: data is transmitted/received with the MSB (bit 7/8) first, following the start bit.
This bitfield can only be written when the LPUART is disabled (UE=0).

Bit 18  **DATAINV**: Binary data inversion
This bit is set and cleared by software.
0: Logical data from the data register are send/received in positive/direct logic. (1=H, 0=L)
1: Logical data from the data register are send/received in negative/inverse logic. (1=L, 0=H). The parity bit is also inverted.
This bitfield can only be written when the LPUART is disabled (UE=0).

Bit 17  **TXINV**: TX pin active level inversion
This bit is set and cleared by software.
0: TX pin signal works using the standard logic levels (VDD =1/idle, Gnd=0/mark)
1: TX pin signal values are inverted. ((VDD =0/mark, Gnd=1/idle).
This allows the use of an external inverter on the TX line.
This bitfield can only be written when the LPUART is disabled (UE=0).

Bit 16  **RXINV**: RX pin active level inversion
This bit is set and cleared by software.
0: RX pin signal works using the standard logic levels (VDD =1/idle, Gnd=0/mark)
1: RX pin signal values are inverted. ((VDD =0/mark, Gnd=1/idle).
This allows the use of an external inverter on the RX line.
This bitfield can only be written when the LPUART is disabled (UE=0).

Bit 15  **SWAP**: Swap TX/RX pins
This bit is set and cleared by software.
0: TX/RX pins are used as defined in standard pinout
1: The TX and RX pins functions are swapped. This allows to work in the case of a cross-wired connection to another UART.
This bitfield can only be written when the LPUART is disabled (UE=0).

Bit 14  Reserved, must be kept at reset value.
Bits 13:12 **STOP[1:0]**: STOP bits
   These bits are used for programming the stop bits.
   00: 1 stop bit
   01: Reserved.
   10: 2 stop bits
   11: Reserved
   This bitfield can only be written when the LPUART is disabled (UE=0).

Bits 11:5 Reserved, must be kept at reset value.

Bit 4 **ADDM7**: 7-bit Address Detection/4-bit Address Detection
   This bit is for selection between 4-bit address detection or 7-bit address detection.
   0: 4-bit address detection
   1: 7-bit address detection (in 8-bit data mode)
   This bit can only be written when the LPUART is disabled (UE=0)
   **Note:** In 7-bit and 9-bit data modes, the address detection is done on 6-bit and 8-bit address
   (**ADD[5:0]** and **ADD[7:0])** respectively.

Bits 3:0 Reserved, must be kept at reset value.

Bits 31:29 **TXFTCFG[2:0]**: TXFIFO threshold configuration
   000: TXFIFO reaches 1/8 of its depth.
   001: TXFIFO reaches 1/4 of its depth.
   110: TXFIFO reaches 1/2 of its depth.
   100: TXFIFO reaches 7/8 of its depth.
   101: TXFIFO becomes empty.
   Remaining combinations: Reserved.

Bit 28 **RXFTIE**: RXFIFO threshold interrupt enable
   This bit is set and cleared by software.
   0: Interrupt is inhibited
   1: An LPUART interrupt is generated when Receive FIFO reaches the threshold programmed in RXFTCFG.

Bits 27:25 **RXFTCFG[2:0]**: Receive FIFO threshold configuration
   000: Receive FIFO reaches 1/8 of its depth.
   001: Receive FIFO reaches 1/4 of its depth.
   110: Receive FIFO reaches 1/2 of its depth.
   011: Receive FIFO reaches 3/4 of its depth.
   100: Receive FIFO reaches 7/8 of its depth.
   101: Receive FIFO becomes full.
   Remaining combinations: Reserved.

Bit 24 Reserved, must be kept at reset value.

Bit 23 **TXFTIE**: TXFIFO threshold interrupt enable
   This bit is set and cleared by software.
   0: Interrupt is inhibited
   1: A LPUART interrupt is generated when TXFIFO reaches the threshold programmed in TXFTCFG.

Bit 22 **WUFIE**: Wakeup from low-power mode interrupt enable
   This bit is set and cleared by software.
   0: Interrupt is inhibited
   1: An LPUART interrupt is generated whenever WUF=1 in the LPUART_ISR register
   
   **Note**: **WUFIE must be set before entering in low-power mode.**
   The WUF interrupt is active only in low-power mode.
   If the LPUART does not support the wakeup from Stop feature, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation.

Bits 21:20 **WUS[1:0]**: Wakeup from low-power mode interrupt flag selection
   This bitfield specifies the event which activates the WUF (Wakeup from low-power mode flag).
   00: WUF active on address match (as defined by ADD[7:0] and ADDM7)
   01: Reserved.
   10: WUF active on Start bit detection
   11: WUF active on RXNE.
   This bitfield can only be written when the LPUART is disabled (UE=0).
   
   **Note**: If the LPUART does not support the wakeup from Stop feature, this bit is reserved and must be kept at reset value. Refer to Section 47.4: USART implementation.

Bits 19:16 Reserved, must be kept at reset value.
Bit 15  **DEP**: Driver enable polarity selection
0: DE signal is active high.
1: DE signal is active low.
This bit can only be written when the LPUART is disabled (UE=0).

Bit 14  **DEM**: Driver enable mode
This bit allows the user to activate the external transceiver control, through the DE signal.
0: DE function is disabled.
1: DE function is enabled. The DE signal is output on the RTS pin.
This bit can only be written when the LPUART is disabled (UE=0).

Bit 13  **DDRE**: DMA Disable on Reception Error
0: DMA is not disabled in case of reception error. The corresponding error flag is set but RXNE is kept 0 preventing from overrun. As a consequence, the DMA request is not asserted, so the erroneous data is not transferred (no DMA request), but next correct received data will be transferred.
1: DMA is disabled following a reception error. The corresponding error flag is set, as well as RXNE. The DMA request is masked until the error flag is cleared. This means that the software must first disable the DMA request (DMAR = 0) or clear RXNE before clearing the error flag.
This bit can only be written when the LPUART is disabled (UE=0).
*Note: The reception errors are: parity error, framing error or noise error.*

Bit 12  **OVRDIS**: Overrun Disable
This bit is used to disable the receive overrun detection.
0: Overrun Error Flag, ORE is set when received data is not read before receiving new data.
1: Overrun functionality is disabled. If new data is received while the RXNE flag is still set the ORE flag is not set and the new received data overwrites the previous content of the LPUART_RDR register.
This bit can only be written when the LPUART is disabled (UE=0).
*Note: This control bit allows checking the communication flow w/o reading the data.*

Bit 11  Reserved, must be kept at reset value.

Bit 10  **CTSIE**: CTS interrupt enable
0: Interrupt is inhibited
1: An interrupt is generated whenever CTSIF=1 in the LPUART_ISR register

Bit 9  **CTSE**: CTS enable
0: CTS hardware flow control disabled
1: CTS mode enabled, data is only transmitted when the nCTS input is asserted (tied to 0). If the nCTS input is deasserted while data is being transmitted, then the transmission is completed before stopping. If data is written into the data register while nCTS is asserted, the transmission is postponed until nCTS is asserted.
This bit can only be written when the LPUART is disabled (UE=0)

Bit 8  **RTSE**: RTS enable
0: RTS hardware flow control disabled
1: RTS output enabled, data is only requested when there is space in the receive buffer. The transmission of data is expected to cease after the current character has been transmitted. The nRTS output is asserted (pulled to 0) when data can be received.
This bit can only be written when the LPUART is disabled (UE=0).

Bit 7  **DMAT**: DMA enable transmitter
This bit is set/reset by software
0: DMA mode is disabled for transmission
1: DMA mode is enabled for transmission
Bit 6 **DMAR**: DMA enable receiver
   This bit is set/reset by software
   1: DMA mode is enabled for reception
   0: DMA mode is disabled for reception

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **HDSEL**: Half-duplex selection
   Selection of Single-wire Half-duplex mode
   0: Half duplex mode is not selected
   1: Half duplex mode is selected
   This bit can only be written when the LPUART is disabled (UE=0).

Bits 2:1 Reserved, must be kept at reset value.

Bit 0 **EIE**: Error interrupt enable
   Error Interrupt Enable Bit is required to enable interrupt generation in case of a framing error, overrun error or noise flag (FE=1 or ORE=1 or NE=1 in the LPUART_ISR register).
   0: Interrupt is inhibited
   1: An interrupt is generated when FE=1 or ORE=1 or NE=1 in the LPUART_ISR register.

### 48.5.5 Baud rate register (LPUART_BRR)

This register can only be written when the LPUART is disabled (UE=0). It may be automatically updated by hardware in auto baud rate detection mode.

Address offset: 0x0C
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31:20</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit 19:0</td>
<td><strong>BRR[19:0]</strong>: LPUART baud rate</td>
</tr>
</tbody>
</table>

**Note:** It is forbidden to write values lower than 0x300 in the LPUART_BRR register.

Provided that LPUART_BRR must be ≥ 0x300 and LPUART_BRR is 20 bits, a care should be taken when generating high baud rates using high fck values. fck must be in the range [3 x baud rate..4096 x baud rate].
48.5.6 Request register (LPUART_RQR)

Address offset: 0x18
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>

</thead>
</table>

15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 TXFRQ: Transmit data flush request
This bit is used when FIFO mode is enabled. TXFRQ bit is set to flush the whole FIFO. This will set the flag TXFE (TXFIFO empty, bit 23 in the LPUART_ISR register).

Note: In FIFO mode, the TXFNF flag is reset during the flush request until TxFIFO is empty in order to ensure that no data are written in the data register.

Bit 3 RXFRQ: Receive data flush request
Writing 1 to this bit clears the RXNE flag. This allows discarding the received data without reading it, and avoid an overrun condition.

Bit 2 MMRQ: Mute mode request
Writing 1 to this bit puts the LPUART in Mute mode and resets the RWU flag.

Bit 1 SBKRQ: Send break request
Writing 1 to this bit sets the SBKF flag and request to send a BREAK on the line, as soon as the transmit machine is available.

Note: If the application needs to send the break character following all previously inserted data, including the ones not yet transmitted, the software should wait for the TXE flag assertion before setting the SBKRQ bit.

Bit 0 Reserved, must be kept at reset value.

48.5.7 Interrupt and status register [alternate] (LPUART_ISR)

Address offset: 0x1C
Reset value: 0x0080 00C0

The same register can be used in FIFO mode enabled (this section) and FIFO mode disabled (next section).

FIFO mode enabled

Bits 31:28  Reserved, must be kept at reset value.

Bit 27  **TXFT**: TXFIFO threshold flag

    This bit is set by hardware when the TXFIFO reaches the threshold programmed in TXFTCFG in LPUART_CR3 register i.e. the TXFIFO contains TXFTCFG empty locations. An interrupt is generated if the TXFTIE bit = 1 (bit 31) in the LPUART_CR3 register.
    0: TXFIFO does not reach the programmed threshold.
    1: TXFIFO reached the programmed threshold.

Bit 26  **RXFT**: RXFIFO threshold flag

    This bit is set by hardware when the RXFIFO reaches the threshold programmed in RXFTCFG in LPUART_CR3 register i.e. the Receive FIFO contains RXFTCFG data. An interrupt is generated if the RXFTIE bit = 1 (bit 27) in the LPUART_CR3 register.
    0: Receive FIFO does not reach the programmed threshold.
    1: Receive FIFO reached the programmed threshold.

Bit 25  Reserved, must be kept at reset value.

Bit 24  **RXFF**: RXFIFO full

    This bit is set by hardware when the number of received data corresponds to RXFIFO size + 1 (RXFIFO full + 1 data in the LPUART_RDR register. An interrupt is generated if the RXFFIE bit = 1 in the LPUART_CR1 register.
    0: RXFIFO is not full
    1: RXFIFO is full

Bit 23  **TXFE**: TXFIFO empty

    This bit is set by hardware when TXFIFO is empty. When the TXFIFO contains at least one data, this flag is cleared. The TXFE flag can also be set by writing 1 to the bit TXFRQ (bit 4) in the LPUART_RQR register. An interrupt is generated if the TXFEIE bit = 1 (bit 30) in the LPUART_CR1 register.
    0: TXFIFO is not empty
    1: TXFIFO is empty

Bit 22  **REACK**: Receive enable acknowledge flag

    This bit is set/reset by hardware, when the Receive Enable value is taken into account by the LPUART. It can be used to verify that the LPUART is ready for reception before entering low-power mode.

    *Note*: If the LPUART does not support the wakeup from Stop feature, this bit is reserved and kept at reset value.

Bit 21  **TEACK**: Transmit enable acknowledge flag

    This bit is set/reset by hardware, when the Transmit Enable value is taken into account by the LPUART. It can be used when an idle frame request is generated by writing TE=0, followed by TE=1 in the LPUART_CR1 register, in order to respect the TE=0 minimum period.

Bit 20  **WUF**: Wakeup from low-power mode flag

    This bit is set by hardware, when a wakeup event is detected. The event is defined by the WUS bitfield. It is cleared by software, writing a 1 to the WUCF in the LPUART_ICR register. An interrupt is generated if WUFIE=1 in the LPUART_CR3 register.

    *Note*: When UESM is cleared, WUF flag is also cleared.

    The WUF interrupt is active only in low-power mode.

    *Note*: If the LPUART does not support the wakeup from Stop feature, this bit is reserved and kept at reset value.
Bit 19 **RWU:** Receiver wakeup from Mute mode
This bit indicates if the LPUART is in Mute mode. It is cleared/set by hardware when a wakeup/mute sequence is recognized. The Mute mode control sequence (address or IDLE) is selected by the WAKE bit in the LPUART_CR1 register.
When wakeup on IDLE mode is selected, this bit can only be set by software, writing 1 to the MMRQ bit in the LPUART_RQR register.
0: Receiver in Active mode
1: Receiver in Mute mode
*Note:* If the LPUART does not support the wakeup from Stop feature, this bit is reserved and kept at reset value.

Bit 18 **SBKF:** Send break flag
This bit indicates that a send break character was requested. It is set by software, by writing 1 to the SBKRQ bit in the LPUART_CR3 register. It is automatically reset by hardware during the stop bit of break transmission.
0: No break character is transmitted
1: Break character will be transmitted

Bit 17 **CMF:** Character match flag
This bit is set by hardware, when a the character defined by ADD[7:0] is received. It is cleared by software, writing 1 to the CMCF in the LPUART_ICR register.
An interrupt is generated if CMIE=1 in the LPUART_CR1 register.
0: No Character match detected
1: Character Match detected

Bit 16 **BUSY:** Busy flag
This bit is set and reset by hardware. It is active when a communication is ongoing on the RX line (successful start bit detected). It is reset at the end of the reception (successful or not).
0: LPUART is idle (no reception)
1: Reception on going

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 **CTS:** CTS flag
This bit is set/reset by hardware. It is an inverted copy of the status of the nCTS input pin.
0: nCTS line set
1: nCTS line reset
*Note:* If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.

Bit 9 **CTSIF:** CTS interrupt flag
This bit is set by hardware when the nCTS input toggles, if the CTSE bit is set. It is cleared by software, by writing 1 to the CTSCF bit in the LPUART_ICR register.
An interrupt is generated if CTSIE=1 in the LPUART_CR3 register.
0: No change occurred on the nCTS status line
1: A change occurred on the nCTS status line
*Note:* If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.

Bit 8 Reserved, must be kept at reset value.
Bit 7 **TXFNF**: TXFIFO not full

TXFNF is set by hardware when TXFIFO is not full, and so data can be written in the LPUART_TDR. Every write in the LPUART_TDR places the data in the TXFIFO. This flag remains set until the TXFIFO is full. When the TXFIFO is full, this flag is cleared indicating that data can not be written into the LPUART_TDR.

The TXFNF is kept reset during the flush request until TXFIFO is empty. After sending the flush request (by setting TXFRQ bit), the flag TXFNF should be checked prior to writing in TXFIFO (TXFNF and TXFE will be set at the same time).

An interrupt is generated if the TXFNFIE bit = 1 in the LPUART_CR1 register.

0: Data register is full/Transmit FIFO is full.
1: Data register/Transmit FIFO is not full.

*Note: This bit is used during single buffer transmission.*

Bit 6 **TC**: Transmission complete

This bit is set by hardware if the transmission of a frame containing data is complete and if TXFF is set. An interrupt is generated if TCIE=1 in the LPUART_CR1 register. It is cleared by software, writing 1 to the TCCF in the LPUART_ICR register or by a write to the LPUART_TDR register.

An interrupt is generated if TCIE=1 in the LPUART_CR1 register.

0: Transmission is not complete
1: Transmission is complete

*Note: If TE bit is reset and no transmission is on going, the TC bit will be set immediately.*

Bit 5 **RXFNE**: RXFIFO not empty

RXFNE bit is set by hardware when the RXFIFO is not empty, and so data can be read from the LPUART_RDR register. Every read of the LPUART_RDR frees a location in the RXFIFO. It is cleared when the RXFIFO is empty.

The RXFNE flag can also be cleared by writing 1 to the RXFRQ in the LPUART_RQR register.

An interrupt is generated if RXFNEIE=1 in the LPUART_CR1 register.

0: Data is not received
1: Received data is ready to be read.

Bit 4 **IDLE**: Idle line detected

This bit is set by hardware when an Idle line is detected. An interrupt is generated if IDLEIE=1 in the LPUART_CR1 register. It is cleared by software, writing 1 to the IDLECF in the LPUART_ICR register.

0: No Idle line is detected
1: Idle line is detected

*Note: The IDLE bit will not be set again until the RXFNE bit has been set (i.e. a new idle line occurs).*

*If Mute mode is enabled (MME=1), IDLE is set if the LPUART is not mute (RWU=0), whatever the Mute mode selected by the WAKE bit. If RWU=1, IDLE is not set.*
Bit 3 **ORE**: Overrun error
This bit is set by hardware when the data currently being received in the shift register is ready to be transferred into the LPUART_RDR register while RXFF = 1. It is cleared by a software, writing 1 to the ORECF, in the LPUART_ICR register.
An interrupt is generated if RXFNEIE=1 or EIE = 1 in the LPUART_CR1 register.
0: No overrun error
1: Overrun error is detected

*Note:* When this bit is set, the LPUART_RDR register content is not lost but the shift register is overwritten. An interrupt is generated if the ORE flag is set during multi buffer communication if the EIE bit is set.
This bit is permanently forced to 0 (no overrun detection) when the bit OVRDIS is set in the LPUART_CR3 register.

Bit 2 **NE**: Start bit noise detection flag
This bit is set by hardware when noise is detected on the start bit of a received frame. It is cleared by software, writing 1 to the NECF bit in the LPUART_ICR register.
0: No noise is detected
1: Noise is detected

*Note:* This bit does not generate an interrupt as it appears at the same time as the RXFNE bit which itself generates an interrupt. An interrupt is generated when the NE flag is set during multi buffer communication if the EIE bit is set.
This error is associated with the character in the LPUART_RDR.

Bit 1 **FE**: Framing error
This bit is set by hardware when a de-synchronization, excessive noise or a break character is detected. It is cleared by software, writing 1 to the FECF bit in the LPUART_ICR register.
When transmitting data in Smartcard mode, this bit is set when the maximum number of transmit attempts is reached without success (the card NACKs the data frame).
An interrupt is generated if EIE = 1 in the LPUART_CR1 register.
0: No Framing error is detected
1: Framing error or break character is detected

*Note:* This error is associated with the character in the LPUART_RDR.

Bit 0 **PE**: Parity error
This bit is set by hardware when a parity error occurs in receiver mode. It is cleared by software, writing 1 to the PECF in the LPUART_ICR register.
An interrupt is generated if PEIE = 1 in the LPUART_CR1 register.
0: No parity error
1: Parity error

*Note:* This error is associated with the character in the LPUART_RDR.
48.5.8 Interrupt and status register [alternate] (LPUART_ISR)

Address offset: 0x1C
Reset value: 0x0000 00C0

The same register can be used in FIFO mode enabled (previous section) and FIFO mode disabled (this section).

FIFO mode disabled

<table>
<thead>
<tr>
<th>Bit 31:23 Reserved, must be kept at reset value.</th>
</tr>
</thead>
</table>

**Bit 22** REACK: Receive enable acknowledge flag

This bit is set/reset by hardware when the Receive Enable value is taken into account by the LPUART.

It can be used to verify that the LPUART is ready for reception before entering low-power mode.

*Note: If the LPUART does not support the wakeup from Stop feature, this bit is reserved and kept at reset value.*

**Bit 21** TEACK: Transmit enable acknowledge flag

This bit is set/reset by hardware, when the Transmit Enable value is taken into account by the LPUART.

It can be used when an idle frame request is generated by writing TE=0, followed by TE=1 in the LPUART_CR1 register, in order to respect the TE=0 minimum period.

**Bit 20** WUF: Wakeup from low-power mode flag

This bit is set by hardware, when a wakeup event is detected. The event is defined by the WUS bitfield. It is cleared by software, writing a 1 to the WUCF in the LPUART_ICR register. An interrupt is generated if WUFIE=1 in the LPUART_CR3 register.

*Note: When UESM is cleared, WUF flag is also cleared. The WUF interrupt is active only in low-power mode.*

*If the LPUART does not support the wakeup from Stop feature, this bit is reserved and kept at reset value*

**Bit 19** RWU: Receiver wakeup from Mute mode

This bit indicates if the LPUART is in Mute mode. It is cleared/set by hardware when a wakeup/mute sequence is recognized. The Mute mode control sequence (address or IDLE) is selected by the WAKE bit in the LPUART_CR1 register.

When wakeup on IDLE mode is selected, this bit can only be set by software, writing 1 to the MMRQ bit in the LPUART_RQR register.

0: Receiver in active mode
1: Receiver in Mute mode

*Note: If the LPUART does not support the wakeup from Stop feature, this bit is reserved and kept at reset value.*
Bit 18 **SBKF**: Send break flag

This bit indicates that a send break character was requested. It is set by software, by writing 1 to the SBKREQ bit in the LPUART_CR3 register. It is automatically reset by hardware during the stop bit of break transmission.

0: No break character is transmitted
1: Break character will be transmitted

Bit 17 **CMF**: Character match flag

This bit is set by hardware, when a the character defined by ADD[7:0] is received. It is cleared by software, writing 1 to the CMCF in the LPUART_ICR register.

An interrupt is generated if CMIE=1 in the LPUART_CR1 register.

0: No Character match detected
1: Character Match detected

Bit 16 **BUSY**: Busy flag

This bit is set and reset by hardware. It is active when a communication is ongoing on the RX line (successful start bit detected). It is reset at the end of the reception (successful or not).

0: LPUART is idle (no reception)
1: Reception ongoing

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 **CTS**: CTS flag

This bit is set/reset by hardware. It is an inverted copy of the status of the nCTS input pin.

0: nCTS line set
1: nCTS line reset

*Note: If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.*

Bit 9 **CTSF**: CTS interrupt flag

This bit is set by hardware when the nCTS input toggles, if the CTSE bit is set. It is cleared by software, by writing 1 to the CTSCF bit in the LPUART_ICR register.

An interrupt is generated if CTSIE=1 in the LPUART_CR3 register.

0: No change occurred on the nCTS status line
1: A change occurred on the nCTS status line

*Note: If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.*

Bit 8 Reserved, must be kept at reset value.

Bit 7 **TXE**: Transmit data register empty/TXFIFO not full

TXE is set by hardware when the content of the LPUART_TDR register has been transferred into the shift register. It is cleared by a write to the LPUART_TDR register.

An interrupt is generated if the TXEIE bit =1 in the LPUART_CR1 register.

0: Data register full
1: Data register not full

*Note: This bit is used during single buffer transmission.*
Bit 6 **TC**: Transmission complete

This bit is set by hardware if the transmission of a frame containing data is complete and if TXE is set. An interrupt is generated if TCIE=1 in the LPUART_CR1 register. It is cleared by software, writing 1 to the TCCF in the LPUART_ICR register or by a write to the LPUART_TDR register.

An interrupt is generated if TCIE=1 in the LPUART_CR1 register.

0: Transmission is not complete
1: Transmission is complete

Note: **If TE bit is reset and no transmission is on going, the TC bit will be set immediately.**

Bit 5 **RXNE**: Read data register not empty

RXNE bit is set by hardware when the content of the LPUART_RDR shift register has been transferred to the LPUART_RDR register. It is cleared by reading from the LPUART_RDR register. The RXNE flag can also be cleared by writing 1 to the RXFRQ in the LPUART_RQR register.

An interrupt is generated if RXNEIE=1 in the LPUART_CR1 register.

0: Data is not received
1: Received data is ready to be read

Bit 4 **IDLE**: Idle line detected

This bit is set by hardware when an Idle Line is detected. An interrupt is generated if IDLEIE=1 in the LPUART_CR1 register. It is cleared by software, writing 1 to the IDLECF in the LPUART_ICR register.

0: No Idle line is detected
1: Idle line is detected

Note: **The IDLE bit will not be set again until the RXNE bit has been set (i.e. a new idle line occurs).**

If Mute mode is enabled (MME=1), IDLE is set if the LPUART is not mute (RWU=0), whatever the Mute mode selected by the WAKE bit. If RWU=1, IDLE is not set.

Bit 3 **ORE**: Overrun error

This bit is set by hardware when the data currently being received in the shift register is ready to be transferred into the LPUART_RDR register while RXNE=1. It is cleared by a software, writing 1 to the ORECF, in the LPUART_ICR register.

An interrupt is generated if RXNEIE=1 or EIE = 1 in the LPUART_CR1 register.

0: No overrun error
1: Overrun error is detected

Note: **When this bit is set, the LPUART_RDR register content is not lost but the shift register is overwritten. An interrupt is generated if the ORE flag is set during multi buffer communication if the EIE bit is set.**

This bit is permanently forced to 0 (no overrun detection) when the bit OVRDIS is set in the LPUART_CR3 register.

Bit 6  **TCCF**: Transmission complete clear flag  
Writing 1 to this bit clears the TC flag in the LPUART_ISR register.

Bit 5  Reserved, must be kept at reset value.

Bit 4  **IDLECF**: Idle line detected clear flag  
Writing 1 to this bit clears the IDLE flag in the LPUART_ISR register.

Bit 3  **ORECF**: Overrun error clear flag  
Writing 1 to this bit clears the ORE flag in the LPUART_ISR register.

Bit 2  **NECF**: Noise detected clear flag  
Writing 1 to this bit clears the NE flag in the LPUART_ISR register.

Bit 1  **FECF**: Framing error clear flag  
Writing 1 to this bit clears the FE flag in the LPUART_ISR register.

Bit 0  **PECF**: Parity error clear flag  
Writing 1 to this bit clears the PE flag in the LPUART_ISR register.

</tbody>
</table>

Bits 31:9  Reserved, must be kept at reset value.

Bits 8:0  **RDR[8:0]**: Receive data value  
Contains the received data character.  
The RDR register provides the parallel interface between the input shift register and the  
internal bus (see Figure 595).  
When receiving with the parity enabled, the value read in the MSB bit is the received parity  
bit.

Bits 31:9  Reserved, must be kept at reset value.
Bits 31:9  Reserved, must be kept at reset value.

Bits 8:0  **TDR[8:0]: Transmit data value**

Contains the data character to be transmitted.

The TDR register provides the parallel interface between the internal bus and the output shift register (see Figure 595).

When transmitting with the parity enabled (PCE bit set to 1 in the LPUART_CR1 register), the value written in the MSB (bit 7 or bit 8 depending on the data length) has no effect because it is replaced by the parity.

*Note: This register must be written only when TXE/TXFNF=1.*

### 48.5.12 Prescaler register (LPUART_PRESC)

This register can only be written when the LPUART is disabled (UE=0).

Address offset: 0x2C

Reset value: 0x0000 0000

</tr>
</tbody>
</table>

Bits 31:4  Reserved, must be kept at reset value.

Bits 3:0  **PRESCALE[3:0]: Clock prescaler**

The LPUART input clock can be divided by a prescaler:

- 0000: input clock not divided
- 0001: input clock divided by 2
- 0010: input clock divided by 4
- 0011: input clock divided by 6
- 0100: input clock divided by 8
- 0101: input clock divided by 10
- 0110: input clock divided by 12
- 0111: input clock divided by 16
- 1000: input clock divided by 32
- 1001: input clock divided by 64
- 1010: input clock divided by 128
- 1011: input clock divided by 256

Remaining combinations: Reserved.

*Note: When PRESCALE is programmed with a value different of the allowed ones, programmed prescaler value will be «1011» i.e. input clock divided by 256.*
48.5.13 LPUART register map

The table below gives the LPUART register map and reset values.

Table 401. LPUART register map and reset values

| Offset | Register name | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|--------|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
|        | FIFO mode enabled |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |

Refer to *Section 2.3: Memory organization* for the register boundary addresses.
49  Serial peripheral interface (SPI)

49.1 Introduction

The serial peripheral interface (SPI) can be used to communicate with external devices while using the specific synchronous protocol. The (SPI) interface supports a half-duplex, full-duplex and simplex synchronous, serial communication with external devices. The interface can be configured as master or slave and is capable of operating in multi slave or multi master configurations. In case of master configuration it provides the communication clock (SCK) to the external slave device. The slave select signal can be provided by the master and accepted by the slave optionally, too. The Motorola data format is used by default, but some other specific modes are supported as well.
49.2 SPI main features

- Full-duplex synchronous transfers on three lines
- Half-duplex synchronous transfer on two lines (with bidirectional data line)
- Simplex synchronous transfers on two lines (with unidirectional data line)
- 4-bit to 32-bit data size selection
- Multi master or multi slave mode capability
- Dual clock domain, separated clock for the peripheral kernel which can be independent of PCLK
- 8 master mode baud rate prescalers up to kernel frequency/2
- Slave mode frequency up to kernel frequency/2
- Protection of configuration and setting
- Hardware or software management of SS for both master and slave
- Adjustable minimum delays between data and between SS and data flow
- Configurable SS signal polarity and timing, MISO x MOSI swap capability
- Programmable clock polarity and phase
- Programmable data order with MSB-first or LSB-first shifting
- Programmable number of data within a transaction to control SS and CRC
- Dedicated transmission and reception flags with interrupt capability
- Slave’s transmission and/or reception capability in Stop mode (no clock provided to the peripheral) with wake up
- SPI Motorola and TI formats support
- Hardware CRC feature can secure communication at the end of transaction by:
  - Adding CRC value at Tx mode
  - Automatic CRC error checking for Rx mode
- Error detection with interrupt capability in case of data overrun, CRC error, data underrun at slave, mode fault at master
- Two 16x or 8x 8-bit embedded Rx and TxFIFOs with DMA capability
- Programmable number of data in transaction
- Configurable FIFO thresholds (data packing)
- Configurable behavior at slave underrun condition (support of cascaded circular buffers)

49.4 SPI functional description

49.4.1 SPI block diagram

The SPI allows a synchronous, serial communication between the MCU and external devices. The application software can manage the communication by polling the status flag or using a dedicated SPI interrupt. The main elements of SPI and their interactions are shown in the following block diagram at Figure 609.

Figure 609. SPI2S block diagram

The simplified scheme of Figure 609 shows three fully independent clock domains:

- The spi_pclk clock domain,
- The spi_ker_ck kernel clock domain,
- The serial interface clock domain,

All the control and status signals between these domains are strictly synchronized. There is no specific constraint concerning the frequency ratio between these clock signals. The user has to consider a ratio compatible with the data flow speed in order to avoid any data underrun or overrun events only.
The **spi_pclk** clock signal feeds the peripheral bus interface. It has to be active when it accesses to the SPI registers are required.

The SPI working in slave mode handles data flow using the serial interface clock derived from the external SCK signal provided by external master SPI device. That is why the SPI slave is able to receive and send data even when the **spi_pclk** and **spi_ker_ck** clock signals are inactive.

This is not the case for the SPI master as it needs an active **spi_ker_ck** kernel clock coming from the RCC to feed the clock generator at least. On the other side, a specific slave logic working within the serial interface clock domain needs some additional traffic to be setup correctly (e.g. when underrun or overrun is evaluated). This cannot be done when the bus becomes into idle. At specific case the slave even requires the clock generator working (see Section 49.5.1: TI mode).

### 49.4.2 SPI signals

Four I/O pins are dedicated to SPI communication with external devices.

- **MISO**: Master In / Slave Out data. In the general case, this pin is used to transmit data in slave mode and receive data in master mode.
- **MOSI**: Master Out / Slave In data. In the general case, this pin is used to transmit data in master mode and receive data in slave mode.
- **SCK**: Serial Clock output pin for SPI masters and input pin for SPI slaves.
- **SS**: Slave select pin. Depending on the SPI and SS settings, this pin can be used to:
  - Select an individual slave device for communication
  - Synchronize the data frame or
  - Detect a conflict between multiple masters

  See Section 49.4.6: Multi-master communication for details.

The SPI bus allows the communication between one master device and one or more slave devices. The bus consists of at least two wires: one for the clock signal and the other for synchronous data transfer. Other signals can be added depending on the data exchange between SPI nodes and their slave select signal management. The functionality between MOSI and MISO pins can be inverted in any SPI mode (see the IOSWP bit at SPI_CFG2 register).

### 49.4.3 SPI communication general aspects

The SPI allows the MCU to communicate using different configurations, depending on the device targeted and the application requirements. These configurations use 2 or 3 wires (with software SS management) or 3/4 wires (with hardware SS management). The communication is always initiated and controlled by the master. The master provides a clock signal on the SCK line and selects or synchronizes slave(s) for communication by SS line when it is managed by HW. The data between the master and the slave, flow on the MOSI and/or MISO lines.

### 49.4.4 Communications between one master and one slave

The communication flow may use one of 3 possible modes: full-duplex (3 wires), half-duplex (2 wires) or simplex (2 wires). The SS signal is optional in single master-slave configuration and is often not connected between the two communication nodes. Nevertheless, the SS
signal can be helpful at this configuration to synchronize the data flow and it is used by default at some specific SPI modes (e.g. TI mode).

**Full-duplex communication**

By default, the SPI is configured for full-duplex communication (bits COMM[1:0]=00 in the SPI_CFG2 register). In this configuration, the shift registers of the master and slave are linked using two unidirectional lines between the MOSI and the MISO pins. During the SPI communication, the data are shifted synchronously on the SCK clock edges provided by the master. The master transmits the data to be sent to the slave via the MOSI line and receives data from the slave via the MISO line simultaneously. When the data frame transfer is complete (all the bits are shifted) the information between the master and slave is exchanged.

**Figure 610. Full-duplex single master/ single slave application**

1. The SS pin is configured at output mode at master. The pins can be left unconnected then SS is managed by software internally on both master and slave side.

**Half-duplex communication**

The SPI can communicate in half-duplex mode by setting COMM[1:0]=11 in the SPI_CFG2 register. In this configuration, one single cross connection line is used to link the shift registers of the master and slave together. During this communication, the data are synchronously shifted between the shift registers on the SCK clock edge in the transfer direction selected reciprocally by both master and slave with the HDDIR bit in their SPI_CR1 registers. Note that the SPI has to be disabled when changing direction of the communication. In this configuration, the MISO pin at master and the MOSI pin at slave are free for other application uses and act as GPIOs.

**Figure 611. Half-duplex single master/ single slave application**
1. The SS pin is configured at output mode at master. The pins can be left unconnected then SS is managed by software internally on both master and slave side.

2. In this configuration, the MISO pin at master and MOSI pin at slave can be used as GPIOs.

3. A critical situation can happen when communication direction is changed not synchronously between two nodes working at bidirectional mode and new transmitter accesses the common data line while former transmitter still keeps an opposite value on the line (the value depends on SPI configuration and communicated data). Both nodes can fight with opposite outputs levels on the line temporary till next node change its direction setting correspondingly, too. It is suggested to insert serial resistance between MISO and MOSI pins at this mode to protect the outputs and limit the current blowing between them at this situation.

### Simplex communications

The SPI can communicate in simplex mode by setting the SPI in transmit-only or in receive-only using the COMM[1:0] field in the SPI_CFG2 register. In this configuration, only one line is used for the transfer between the shift registers of the master and slave. The remaining MISO or MOSI pins pair is not used for communication and can be used as standard GPIOs.

- **Transmit-only mode: COMM[1:0]=01**

  The master in transmit-only mode generates the clock as long as there are data available in the TxFIFO and the master transfer is on-going.

  The slave in transmit only mode sends data as long as it receives a clock on the SCK pin and the SS pin (or SW managed internal signal) is active (see 49.4.6: Multi-master communication).

- **Receive-only mode: COMM[1:0]=10**

  In master mode, the MOSI output is disabled and may be used as GPIO. The clock signal is generated continuously as long as the SPI is enabled and the CSTART bit in the SPI_CR1 register is set. The clock is stopped either by SW explicitly requesting this by setting the CSUSP bit in the SPI_CR1 register or automatically when the RxxFIFO is full, when the MASRX bit in the SPI_CR1 is set.

  In slave configuration, the MISO output is disabled and the pin can be used as a GPIO. The slave continues to receive data from the MOSI pin while its slave select signal is active (see 49.4.6: Multi-master communication). Received data events appear depending on the data buffer configuration.

**Note:** At whatever master and slave modes, the data pin dedicated for transmission can be replaced by the data pin dedicated for reception and vice versa by changing the IOSWP bit value in the SPI_CFG2 register. (This bit may only be modified when the SPI is disabled). Any simplex communication can be replaced by a variant of the half duplex communication with a constant setting of the transaction direction (bidirectional mode is enabled, while the HDDIR bit is never changed).
Figure 612. Simplex single master/single slave application (master in transmit-only/ slave in receive-only mode)

1. The SS pin is configured at output mode at master. The pins can be left unconnected then SS is managed by software internally on both master and slave side.

2. The input information is captured in the shift register and must be ignored in standard transmit only mode (for example, OVF flag)

3. In this configuration, both the MISO pins can be used as GPIOs.

49.4.5 Standard multi-slave communication

In a configuration with two or more independent slaves, the master uses a star topology with dedicated GPIO pins to manage the chip select lines for each slave separately (see Figure 613). The master must select one of the slaves individually by pulling low the GPIO connected to the slave SS input (only one slave can control data on common MISO line at time). When this is done, a communication between the master and the selected slave is established. Except the simplicity, the advantage of this topology is that a specific SPI configuration can be applied for each slave as all the communication sessions are performed separately just within single master-slave pair. Optionally, when there is no need to read any information from slaves, the master can transmit the same information to the multiple slaves.
1. SS pin is not used on master side at this configuration. It has to be managed internally (SSM=1, SSI=1) to prevent any MODF error.

2. As MISO pins of the slaves are connected together, all slaves must have the GPIO configuration of their MISO pin set as alternate function open-drain (see Section 10.3.7: I/O alternate function input/output on page 521.)

The master can handle the SPI communication with all the slaves in time when a circular topology is applied (see Figure 614). All the slaves behave like simple shift registers applied at serial chain under common slave select and clock control. All the information is shifted simultaneously around the circle while returning back to the master. Sessions have fixed the length where the number of data frames transacted by the master is equal to the number of slaves. Then when a first data frame is transacted in the chain, the master just sends information dedicated for the last slave node in the chain via the first slave node input while the first information received by the master comes from the last node output at this time. Correspondingly, the lastly transacted data finishing the session is dedicated for the first slave node while its firstly outgoing data just reaches the master input after its circling around the chain passing through all the other slaves during the session. The data format configuration and clock setting has to be the same for all the nodes in the chain at this topology. As the receive and transmit shift registers are separated internally, a trick with
intentional underrun has to be applied at the TxFIFO slaves when information is transacted between the receiver and the transmitter by hardware. In this case, the transmission underrun feature is configured at a mode repeating lastly received data frame (UDRCFG[1:0]=01). A session can start optionally with a single data pattern written into the TxFIFO by each slave (usually slave status information is applied) before the session starts. In this case the underrun happens in fact after this first data frame is transacted (underrun detection has to be set at end of data transaction at slaves UDRDET[1:0]=01). To be able to clear the internal underrun condition immediately and restart the session by the TxFIFO content again, the user has to disable and enable the SPI between sessions and fill the TxFIFO by a new single data pattern (to overcome the propagating delay of the clearing raised in case the underrun is cleared in a standard way by the UDRC bit).

Figure 614. Master and three slaves at circular (daisy chain) topology

1. Underrun feature is used at slaves at this configuration when slaves are able to transmit data received previously into the Rx shift register once their TxFIFOs become empty.
49.4.6 Multi-master communication

Unless the SPI bus is not designed for a multi-master capability primarily, the user can use build in feature which detects a potential conflict between two nodes trying to master the bus at the same time. For this detection, the SS pin is used configured at hardware input mode. The connection of more than two SPI nodes working at this mode is impossible as only one node can apply its output on a common data line at time.

When nodes are non active, both stay at slave mode by default. Once one node wants to overtake control on the bus, it switches itself into master mode and applies active level on the slave select input of the other node via the dedicated GPIO pin. After the session is completed, the active slave select signal is released and the node mastering the bus temporary returns back to passive slave mode waiting for next session start.

If potentially both nodes raised their mastering request at the same time a bus conflict event appears (see mode fault MODF event). Then the user can apply some simple arbitration process (e.g. to postpone next attempt by predefined different time-outs applied at both nodes).

**Figure 615. Multi-master application**

1. The SS pin is configured at hardware input mode at both nodes. Its active level enable the MISO line output control as passive node is configured as a slave.

49.4.7 Slave select (SS) pin management

In slave mode, the SS works as a standard ‘chip select’ input and lets the slave communicate with the master. In master mode, the SS can be used either as an output or an input. As an input it can prevent a multi master bus collision, and as an output it can drive a slave select signal of a single slave. The SS signal can be managed internally (software management of the SS input) or externally when both the SS input and output are associated with the SS pin (hardware SS management). The user can configure which level of this input/output external signal (present on the SS pin) is considered as active one by the SSIOP bit setting. While low level is considered as active internally SSIOP=1 setting can invert this logic for external world.
The hardware or software slave select management can be set using the SSM bit in the SPI_CFG2 register:

- **Software SS management (SSM = 1):** in this configuration, slave select information is driven internally by the SSI bit value in the register SPI_CR1. The external SS pin is free for other application uses (as GPIO or other alternate function).

- **Hardware SS management (SSM = 0):** in this case, there are two possible configurations. The configuration used depends on the SS output configuration (SSOE bit in register SPI_CFG2).
  - **SS output enable (SSOE = 1):** this configuration is only used when the MCU is set as master. The SS pin is managed by the hardware.
    - a) When SSOM = 0 and SP = 000, the SS signal is driven to the active level as soon as the master transfer starts (CSTART=1) and it is kept active until its EOT flag is set or the transmission is suspended.
    - b) When SP = 001, a pulse is generated as defined by the TI mode.
    - c) When SSOM=1, SP=000 and MIDI>1 the SS is pulsed inactive between data frames, and kept inactive for a number of SPI clock periods defined by the MIDI value decremented by one (1 to 14).
  - **SS output disable (SSM=0, SSOE = 0):**
    - a) if the microcontroller is acting as the master on the bus, this configuration allows multi master capability. If the SS pin is pulled into an active level in this mode, the SPI enters master mode fault state and the SPI device is automatically reconfigured in slave mode (MASTER=0).
    - b) In slave mode, the SS pin works as a standard ‘chip select’ input and the slave is selected while the SS line is at its active level.

**Note:** The purpose of automatic switching into slave mode at mode fault condition is to avoid the possible conflicts on data and clock line. The SPE is not automatically reset, as this would automatically flush both RX and TxFIFOs and current data may be lost. Following the MODF event, the SW must correctly manage the FIFO read/flush and correctly re-program the SPI configuration for taking over the slave role in the system.

**Note:** When the SPI slave is enabled at the hardware SS management mode, all the traffics are ignored even in case of the SS is found at active level till the slave detects a start of the SS signal (its transaction from non-active to active level) just synchronizing the slave with the master. That is why the hardware management mode cannot be used when the external SS pin is fixed. There is no such protection at the SS software management. Then the SSI bit must be changed when there is no traffic on the bus and the SCK signal is at idle state level between transfers exclusively in this case.
When a hardware output SS control is applied (SSM=0, SSOE=1), by configuration of MIDI[3:0] and MSSI[3:0] bit fields the user can control timing of the SS signal between data frames and insert an extra delay at begin of every transaction (to separate the SS and clock starts). This can be useful when the slave needs to slow down the flow to obtain sufficient room for correct data handling (see Figure 617: Data flow timing control (SSOE=1, SSOM=0, SSM=0)).

### Figure 617. Data flow timing control (SSOE=1, SSOM=0, SSM=0)

2. CPHA=0, CPOL=0, SSOP=0, LSBFRST=0.

Additionally, bit SSOM=1 setting invokes specific mode which interleaves pulses between data frames if there is a sufficient space to provide them (MIDI[3:0] has to be set greater then one SPI period). Some configuration examples are shown at Figure 618: SS interleaving pulses between data (SSOE=1, SSOM=1, SSM=0).
Figure 618. SS interleaving pulses between data (SSOE=1, SSOM=1, SSM=0)

I. CPHA=0, CPOL=0, SSOP=0, LSBFRST=0

II. CPHA=1, CPOL=0, SSOP=0, LSBFRST=0

III. CPHA=0, CPOL=1, SSOP=1, LSBFRST=1

IV. CPHA=1, CPOL=1, SSOP=1, LSBFRST=1
2. SS interleaves between data when MIDI[3:0]>1.

49.4.8 Communication formats

During SPI communication, receive and transmit operations are performed simultaneously. The serial clock (SCK) synchronizes the shifting and sampling of the information on the data lines. The communication format depends on the clock phase, the clock polarity and the data frame format. To be able to communicate together, the master and slave devices must follow the same communication format and be synchronized correctly.

Clock phase and polarity controls

Four possible timing relationships may be chosen by software, using the CPOL and CPHA bits in the SPI_CFG2 register. The CPOL (clock polarity) bit controls the idle state value of the clock when no data are being transferred. This bit affects both master and slave modes. If CPOL is reset, the SCK pin has a low-level idle state. If CPOL is set, the SCK pin has a high-level idle state.

If the CPHA bit is set, the second edge on the SCK pin captures the first data bit transacted (falling edge if the CPOL bit is reset, rising edge if the CPOL bit is set). Data are latched on each occurrence of this clock transition type. If the CPHA bit is reset, the first edge on the SCK pin captures the first data bit transacted (falling edge if the CPOL bit is set, rising edge if the CPOL bit is reset). Data are latched on each occurrence of this clock transition type.

The combination of the CPOL (clock polarity) and CPHA (clock phase) bits selects the data capture clock edge.

Figure 619, shows an SPI full-duplex transfer with the four combinations of the CPHA and CPOL bits.

Note: Prior to changing the CPOL/CPHA bits the SPI must be disabled by resetting the SPE bit. The idle state of SCK must correspond to the polarity selected in the SPI_CFG2 register (by pulling up SCK if CPOL=1 or pulling down SCK if CPOL=0).
Figure 619. Data clock timing diagram

1. The order of data bits depends on LSFRST bit setting.

Data frame format

The SPI shift register can be set up to shift out MSB-first or LSB-first, depending on the value of the LSFRST bit in SPI_CFG2 register. The data frame size is chosen by using the DSIZE[4:0] bits. It can be set from 4-bit up to 32-bit length and the setting applies for both transmission and reception. When the SPI_TXDR/SPI_RXDR registers are accessed, data frames are always right-aligned into either a byte (if the data fit into a byte), a half-word or a word (see Figure 620).

If the access is a multiple of the minimum data size needed for a single data frame, 2 or 4 data frames are packed into the register. During communication, only bits within the data frame are clocked and transferred.
49.4.9 Configuration of SPI

The configuration procedure is almost the same for the master and the slave. For specific mode setups, follow the dedicated chapters. When a standard communication has to be initialized, perform these steps:

1. Write the proper GPIO registers: Configure GPIO for MOSI, MISO and SCK pins.
2. Write to the SPI_CFG1 and SPI_CFG2 registers to set up proper values of all not reserved bits and bit fields included there with next exceptions:
   a) SSOM, SSOE, MBR[2:0], MIDI[3:0] and MSSI[3:0] are required at master mode only, the MSSI bits take effect when SSOE is set, MBR setting is required for slave at TI mode, too
   b) UDRDET[1:0] and UDRCFG[1:0] are required at slave mode only,
   c) CRCSIZE[4:0] is required if CRCEN is set,
   d) CPOL, CPHA, LSBFRST, SSOM, SSOE, SSIOP and SSM are not required at TI mode.
   e) Once the AFCNTR bit is set at SPI_CFG2 register, all the SPI outputs start to be propagated onto the associated GPIO pins regardless the peripheral enable so any later configurations changes of the SPI_CFG1 and SPI_CFG2 registers can affect level of signals at these pins.
   f) The I2SMOD bit at SPI_I2SCFGR register has to be kept cleared to prevent any unexpected influence of occasional I2S configuration.
3. Write to the SPI_CR2 register to select length of the transfer, if it is not known TSIZE has to be programmed to zero.
4. Write to SPI_CRC POLY and into TC RCINI, RCRCINI and CRC33_17 bits at SPI2S_CR1 register to configure the CRC polynomial and CRC calculation if needed.
5. Configure DMA streams dedicated for the SPI Tx and Rx in DMA registers if the DMA streams are used (see chapter Communication using DMA).
6. Program the IOLOCK bit in the SPI_CFG1 register if the configuration protection is required (for safety).
49.4.10 Procedure for enabling SPI

It is recommended to configure and enable the SPI slave before the master sends the clock but there is no impact if the configuration and enabling procedure is done while a traffic is ongoing on the bus. The data register of the slave transmitter must contain data to be sent before the master starts its clocking. The SCK signal must be settled to idle state level corresponding to the selected polarity before the SPI slave is selected by SS else following transaction may be desynchronized.

When the SPI slave is enabled at the hardware SS management mode all the traffics are ignored even in case of the SS is found at active level till the slave detects a start of the SS signal (its transaction from non-active to active level) just synchronizing the slave with the master. That is why the hardware management mode cannot be used when external SS pin is fixed. There is no such protection at the SS software management. In this case the SSI bit must be changed when there is no traffic on the bus and the SCK signal is at idle state level between transfers exclusively in this case.

The master at full duplex (or in any transmit-only mode) starts to communicate when the SPI is enabled, the CSTART bit is set and the TxFIFO is not empty, or with the next write to TxFIFO.

In any master receive only mode, the master starts to communicate and the clock starts running after the SPI is enabled and the CSTART bit is set.

For handling DMA, see Section 49.4.14: Communication using DMA (direct memory addressing).

49.4.11 SPI data transmission and reception procedures

Rx FIFO and Tx FIFO

All SPI data transactions pass through the embedded FIFOs organized by bytes (N x 8-bit). The size of the FIFOs (N) is product and the peripheral instance dependent. This enables the SPI to work in a continuous flow, and prevents overruns when the data frame size is short or the interrupt/DMA latency is too long. Each direction has its own FIFO called TxFIFO and RxFIFO, respectively.

The handling of FIFOs depends on the data exchange mode (duplex, simplex), the data frame format (number of bits in the frame), the access size performed on the FIFO data registers (8-bit, 16-bit or 32-bit), and how data are organized at packets.

A read access to the SPI2S_RXDR register returns the oldest value stored in the RxFIFO that has not been read yet. A write access to the SPI2S_TXDR stores the written data in the TxFIFO at the end of a send queue.

A read access to the SPI2S_RXDR register must be managed by the RXP event. This flag is set by hardware when at least one complete data packet (defined as receiver threshold by FTHLV[3:0] bits at the SPI_CFG1 register) is available at the reception FIFO while reception is active. The RXP is cleared as soon as less data are available in the RxFIFO, when reading SPI2S_RXDR by software or by DMA.

The RXP triggers an interrupt if the RXPIE bit is set or a/o a DMA request if RXDMAEN is set.

Upon setting of the RXP flag, the application software performs the due number of SPI data register reads to download the content of one data packet. Once a complete data packet is downloaded, the application software checks the RXP value to see if other packets are
pending into the receive FIFO and, if so, downloads them packet by packet until the RXP reads 0. RxFIFO can store up to N data frames (for frame size <= 8-bit), N/2 data frames (for 8-bit < frame <= 16-bit), N/3 data frames (for 16-bit < frame <= 24-bit) or N/4 data frames (if data frame >24-bit) where N is the size of the FIFO in bytes.

At the end of a reception, it may happen that some data may still be available in the RxFIFO, without reaching the FTHLV level, thus the RXP is not set. In this case, the number of remaining RX data frames in the FIFO is indicated by RXWNE and RXPLVL fields in the SPI_SR register. It happens when number of the last data received in a transfer cannot fully accomplish the configured packet size in the case transfer size and packet size are not aligned. Nevertheless the application software can still perform the standard number of reads from the RxFIFO used for the previous complete data packets without drawbacks: only the consistent data (completed data frames) are popped from the RxFIFO while redundant reads (or any uncompleted data) are reading 0. Thanks to that, the application software can treat all the data in a transfer in the same way and is off-loaded to foresee the reception of the last data in a transfer and from calculating the due number of reads to be popped from RxFIFO.

In a similar way, write access of a data frame to be transmitted is managed by the TXP event. This flag is set by hardware when there is enough space for the application software to push at least one complete data packet (defined at FTHLV[3:0] bits at SPI_CFG1 register) into the transmission FIFO while transmission is active. The TXP is cleared as soon as the TxFIFO is filled by software a/o DMA and space currently available for any next complete data packet is lost. This can lead to oscillations of the TXP signal when data are released out from the TxFIFO while a new packet is stored frame by frame. Any write to the TxFIFO is ignored when there is no sufficient room to store at least a single data frame (TXP event is not respected), when TXTF is set or when the SPI is disabled.

The TXP triggers an interrupt if the TXPIE bit is set or a/o a DMA request if TXDMAEN is set. The TXPIE mask is cleared by hardware when the TXTF flag is set.

Upon setting of the TXP flag application software performs the due number of SPI data register writes to upload the content of one entire data packet. Once new complete data packet is uploaded, the application software checks the TXP value to see if other packets can be pushed into the TxFIFO and, if so, uploads them packet by packet until TXP reads 0 at the end of any packet load.

The number of last data in a transfer can be shorter than the configured packet size in the case when the transfer size and the packet size are not aligned. Nevertheless the application software can still perform the standard number of data register writes used for the previous packets without drawbacks: only the consistent data are pushed into the TxFIFO while redundant writes are discarded. Thanks to that, the application software can treat all the data in a transfer in the same way and is off-loaded to foresee the transmission of the last data in a transfer and from calculating the due number of writes to push the last data into TxFIFO. Just for the last data case, the TXP event is asserted by SPI once there is enough space into TxFIFO to store remaining data to complete current transfer.

Both TXP and RXP events can be polled or handled by interrupts. The DXP bit can be monitored as a common TXP and RXP event at full duplex mode.

Upon setting of the DXP flag the application software performs the due number of writes to the SPI data register to upload the content of one entire data packet for transmission, followed by the same number of reads from the SPI data register to download the content of one data packet. Once one data packet is uploaded and one is downloaded, the application software checks the DXP value to see if other packets can be pushed and popped in sequence and, if so, uploads/downloads them packet by packet until DXP reads 0.
The DXP triggers an interrupt if the DXPIE bit is set or a/o a DMA requests if TXDMAEN and RXDMAEN are set. The DXPIE mask is cleared by hardware when the TXTF flag is set.

The DXP is useful in Full-Duplex communication in order to optimize performance in data uploading/downloading, and reducing the number of interrupts required to support an SPI transfer thus minimizing the request for CPU bandwidth and system power especially when SPI is operated in Stop mode.

Another way to manage the data exchange is to use DMA (see Communication using DMA (direct memory addressing)).

If the next data is received when the RxFIFO is full, an overrun event occurs (see description of OVR flag at Section 49.5.2: SPI error flags). An overrun event can be polled or handled by an interrupt.

This may happen in slave mode or master mode (full duplex or receive only with MASRX = 0). In master receive only mode, with MASRX = 1, the generated clock stops automatically when the RxFIFO is full, therefore overrun is prevented.

Both RxFIFO and TxFIFO content is kept flushed when SPI is disabled (SPE=0).

Sequence handling

A few data frames can be passed at single sequence to complete a message. The user can handle number of data within a message thanks to values stored into TSIZE and TSER fields. In principle, the transaction of a message starts when the SPI is enabled by setting CSTART bit and finishes when number of required data is transacted. The end of transaction controls the CRC and the hardware SS management when applied. If TSIZE is kept at zero while CSTART is set, an endless transaction is initialized (no data size control is applied). The transaction can be suspended at any time thanks to CSUSP which clears the CSTART bit.

In master mode, the user can extend the number of data within the current session. When the number of data programmed into TSIZE is transacted and if TSER contains a non-zero value, the content of TSER is copied into TSIZE, and TSER value is cleared automatically. The transaction is then extended by a number of data corresponding to the value reloaded into TSIZE. The EOT event is not raised in this case as the transaction continues. After the reload operation, the TSERF flag is set and an interrupt is raised if TSERFIE is set. The user can write the next non-zero value into TSER before the next reload occurs, so an unlimited number of data can be transacted while repeating this process.

When any data extension is applied, it always starts by aligned data packet. That is why it is suggested to keep number of data to be extended always aligned with packet size else the last data packet just before the extension is applied has to be handled as an incomplete one (see data packing chapter). If overall number of data is not aligned, the user must implement the rest not aligned number of data into TSER just at the last extension cycle and then handle the last incomplete packet of data standardly within EOT event handler.

For example, if the user wants to transfer 23 bytes while applies data number extension at configuration of 8-bit data size, data packet set to 4 data and 32-bit access to FIFO is used then whatever next sequence is correct

- TSIZE=16 TSER=7;
- TSIZE=12 TSER=8; last extension TSER=3;

As the last not aligned MSB byte is ignored just within the last (6th) access of the FIFO.
When a not aligned sequence is applied for data to be extended like at the following cases
   - TSIZE=15 TSER=8 or
   - TSIZE=8 TSER=7; last extension TSER=8;

The MSB byte is ignored within the 4th access of the FIFO while the other accesses handle always 4 data at the FIFO.

When the transmission is enabled, a sequence begins and continues while any data is present in the TxFIFO of the master. The clock signal is provided permanently by the master until TxFIFO becomes empty, then it stops, waiting for additional data.

In receive-only modes, half duplex (COMM[1:0]=11, HDDIR=0) or simplex (COMM[1:0]=10) the master starts the sequence when SPI is enabled and transaction is released by setting the CSTART bit. The clock signal is provided by the master and it does not stop until either SPI or receive-only mode is disabled/suspended by the master. The master receives data frames permanently up to this moment. The reception can be suspended either by SW control, writing 1 to the CSUSP bit in the SPI_CR1 register, or automatically when MASRX=1 and RxFIFO becomes full. The reception is automatically stopped also when the number of frames programmed in TSIZE and TSER fields of the SPI_CR2 register has been completed.

In order to disable the master receive only mode, the SPI must be suspended at first. When the SPI is suspended, the current frame is completed, before changing the configuration.

Caution: If SPE is written to 0 at master, while reception is ongoing without any suspending, the clock is stopped without completing the current frame, and the RxFIFO is flushed.

While the master can provide all the transactions in continuous mode (SCK signal is continuous) it has to respect slave capability to handle data flow and its content at anytime. When necessary, the master must slow down the communication and provide either a slower clock or separate frames or data sessions with sufficient delays by MIDI[3:0] bits setting or provide an initial delay by setting MSS[1:0] which postpones any transaction start to give slave sufficient room for preparing data. Be aware data from the slave are always transacted and processed by the master even if the slave could not prepare it correctly in time. It is preferable for the slave to use DMA, especially when data frames are short, FIFO is accessed by bytes and the SPI bus rate is high.

In order to add some SW control on the SPI communication flow from a slave transmitter node, a specific value written in the SPI_UDRDR (SPI Underrun Data Register) may be used. On slave side, when TxFIFO becomes empty, this value is sent out automatically as next data and may be interpreted by SW on the master receiver side (either simply dropped or interpreted as a XOFF like command, in order to suspend the master receiver by SW).

At multi-slave star topology, a single slave can be only enabled for the output data at a time. The slave just selected for the communication with the master needs to detect a change of its SS input into active level before the communication with the master starts. In a single slave system it is not necessary to control the slave with SS, but it is often better to provide the pulse here too, to synchronize the slave with the beginning of each data sequence. The SS can be managed by both software and hardware (Section 49.4.7: Slave select (SS) pin management).
**49.4.12 Procedure for disabling the SPI**

When SPI is disabled, it is mandatory to follow the disable procedures described in this paragraph.

At the master mode, it is important to do this before the system enters a low-power mode when the peripheral clock is stopped. Otherwise, ongoing transactions may be corrupted in this case.

In slave mode, the SPI communication can continue when the `spi_pclk` and `spi_ker_ck` clocks are stopped, without interruption, until any end of communication or data service request condition is reached. The `spi_pclk` can generally be stopped by setting the system into STOP mode. Refer to the RCC section for further information.

The master in full duplex or transmit only mode can finish any transaction when it stops providing data for transmission. In this case, the clock stops after the last data transaction. TXC flag can be polled (or interrupt enabled with EOTIE=1) in order to wait for the last data frame to be sent.

When the master is in any receive only mode, in order to stop the peripheral, the SPI communication must be first suspended, by setting CSUSP to 1.

The data received but not read remain stored in RxFIFO when the SPI is suspended.

When SPI is disabled, RxFIFO is flushed. To prevent losing unread data, the user has to ensure that RxFIFO is empty when disabling the SPI, by reading all remaining data (as indicated by the RXP, RXWNE and RXPLVL fields in the SPI_SR register).

The standard disable procedure is based on polling EOT and/or TXC status to check if a transmission session is (fully) completed. This check can be done in specific cases, too, when it is necessary to identify the end of ongoing transactions, for example:

- When the SS signal is managed by software and the master has to provide proper end of SS pulse for slave, or
- When transaction streams from DMA or FIFO are completed while the last data frame or CRC frame transaction is still ongoing in the peripheral bus.

The correct disable procedure in master mode, except when receive only mode is used, is:

1. Wait until TXC=1 and/or EOT=1 (no more data to transmit and last data frame sent).
   - When CRC is used, it is sent automatically after the last data in the block is processed. TXC/EOT is set when CRC frame is completed in this case. When a transmission is suspended the software has to wait till CSTART bit is cleared.
2. Read all RxFIFO data (until RXWNE=0 and RXPLVL=00)
3. Disable the SPI (SPE=0).

The correct disable procedure for master receive only modes is:

1. Wait on EOT or break the receive flow by suspending SPI (CSUSP=1)
2. Wait until SUSP=1 (the last data frame is processed) if receive flow is suspended.
3. Read all RxFIFO data (until RXWNE=0 and RXPLVL=00)
4. Disable the SPI (SPE=0).

In slave mode, any ongoing data are lost when disabling the SPI.
49.4.13 Data packing

From user point of view there are two ways of data packing which can overlay each other:

- **Type of access when data are written to TxFIFO or read from RxFIFO**
  
  *Multiple data can be pushed or fetched effectively by single access if data size is considerably less than access performed upon SPI2S_TXDR or SPI2S_RXDR registers.*

- **Number of data to be handled during the single software service**
  
  *It is convenient to group data into packets and cumulate the FIFO services overall the data packet content exclusively instead of handling data frame by frame separately. The user can define packets by FIFO threshold settings. Then all the FIFO occupancy events are related to that threshold level while required services are signalized by proper flags with interrupt and/or wake up capabilities.*

When the data frame size fits into one byte (less than or equal to 8 bits), the data packing is used automatically when any read or write 16-bit or 32-bit access is performed on the SPI2S_RXDR/SPI2S_TXDR register. The multiple data frame pattern is handled in parallel in this case. At first, the SPI operates using the pattern stored in the LSB of the accessed word, then with the other data stored in the MSB. Figure 621 provides an example of data packing mode sequence handling. While DSIZE[3:0] is configured to 4-bit there, two or four data frames are written in the TxFIFO after the single 16-bit or 32-bit access the SPI2S_TXDR register of the transmitter.

When the data frame size fits into one byte (less than or equal to 8 bits), the data packing is used automatically when a 32-bit access is done. the least significant half-word is used first. (regardless of the LSBFRST value)

This sequence can generate two or four RXP events in the receiver if the RxFIFO threshold is set to 1 frame (and data is read on a frame basis, unpacked), or it can generate a single RXP event if the FTHLV[3:0] field in the SPI_CFG1 register is programmed to a multiple of the frames to be read in a packed mode (16-bit or 32-bit read access).

The data are aligned in accordance with Figure 620: *Data alignment when data size is not equal to 8-bit, 16-bit or 32-bit.* The valid bits are performed on the bus exclusively. Unused bits are not cared at transmitter while padded by zeros at receiver.

When short data frames (<8-bit or < 16-bit) are used together with a larger data access mode (16-bit or 32-bit), the FTHLV value must be programmed as a multiple of the number of frames/data access (i.e. multiple of 4 if 32-bit access is used to up to 8-bit frames or multiple of 2 if 16-bit access is used to up to 8-bit frames or 32-bit access to up to 16-bit frames.).

The RxFIFO threshold setting must always be higher than the following read access size, as spurious extra data would be read otherwise.

The FIFO data access less than the configured data size is forbidden. One complete data frame has to be always accessed at minimum.

A specific problem appears if an incomplete data packet is available at FIFO: less than 4x8-bit frames or one single 16-bit frame is available.

There are two ways of dealing with this problem:
A. without using TSIZE field
On transmitter side, writing the last data frame of any odd sequence with an 8-bit/16-bit access to SPI2S_TXDR is enough.
On receiver side, the remaining data may be read by any access. Any extra data read are padded with zeros. Polling the RXWNE and RXPLVL may be used to detect when the RX data are available in the RxFIFO. (a time out may be used at system level in order to detect the polling)

B. using the TSIZE field
On transmitter side, the transaction is stopped by the master when it faces EOT event. In reception, the RXP flag is not set when EOT is set. In the case when the number of data to be received (TSIZE) is not a multiple of packet size, the number of remaining data is indicated by the RXWNE and RXPLVL fields in the SPI_SR register. The remaining data can be read by any access. Any extra read is padded by zeros.

Figure 621. Packing data in FIFO for transmission and reception

1. DSIZE[3:0] is configured to 4-bit, data is right aligned, valid bits are performed only on the bus, their order depends on LSBFRST, content of LSB byte goes first on the bus.

49.4.14 Communication using DMA (direct memory addressing)
To operate at its maximum speed and to facilitate the data register read/write process required to avoid overrun, the SPI features a DMA capability, which implements a simple request/acknowledge protocol.

A DMA access is requested when the TXDMAEN or RXDMAEN enable bits in the SPI_CFG1 register are set. Separate requests must be issued to the Tx and Rx buffers.
- In transmission, a series of DMA requests is triggered each time TXP is set to 1. The DMA then performs series of writes to the SPI2S_TXDR register.
- In reception, a series of DMA requests is triggered each time RXP is set to 1. The DMA then performs series of reads from the SPI2S_RXDR register. When EOT is set at the end of transaction and last data packet is incomplete then DMA request is activated automatically in according with RXWNE and RXPLVL[1:0] setting to read rest of data.

When the SPI is used only to receive data, it is possible to enable only the SPI Rx DMA channel.
If the SPI is programmed in receive only mode, UDR is never set.

If the SPI is programmed in a transmit mode, TXP and UDR can be eventually set at slave side, because transmit data may not be available. In this case, some data are sent on the TX line according with the UDR management selection.

When the SPI is used only to transmit data, it is possible to enable only the SPI Tx DMA channel.

If the SPI is programmed in transmit only mode, RXP and OVR are never set.

If the SPI is programmed in full-duplex mode, RXP and OVR are eventually set, because received data are not read.

In transmission mode, when the DMA or the user has written all the data to be transmitted (the TXTF flag is set at SPI2C_SR register), the TXC flag can be monitored to ensure that the SPI communication is complete. This is required to avoid corrupting the last transmission before disabling the SPI or before disabling the spi_pclk in master mode. The software must first wait until EOT=1 and/or TXC=1.

When starting communication using DMA, to prevent DMA channel management raising error events, these steps must be followed in order:
1. Enable DMA Rx buffer in the RXDMAEN bit in the SPI_CFG1 register, if DMA Rx is used.
2. Enable DMA requests for Tx and Rx in DMA registers, if the DMA is used.
3. Enable DMA Tx buffer in the TXDMAEN bit in the SPI_CFG1 register, if DMA Tx is used.
4. Enable the SPI by setting the SPE bit.

To close communication it is mandatory to follow these steps in order:
1. Disable DMA request for Tx and Rx in the DMA registers, if the DMA issued.
2. Disable the SPI by following the SPI disable procedure.
3. Disable DMA Tx and Rx buffers by clearing the TXDMAEN and RXDMAEN bits in the SPI_CFG1 register, if DMA Tx and/or DMA Rx are used.

Data packing with DMA

If the transfers are managed by DMA (TXDMAEN and RXDMAEN set in the SPI_CFG1 register) the packing mode is enabled/disabled automatically depending on the PSIZE value configured for SPI TX and the SPI RX DMA channel.

If the DMA channel PSIZE value is equal to 16-bit or 32-bit and SPI data size is less than or equal to 8-bit, then packing mode is enabled. Similarly, If the DMA channel PSIZE value is equal to 32-bit and SPI data size is less than or equal to 16-bit, then packing mode is enabled. The DMA then automatically manages the write operations to the SPI2S_TXDR register.

Regardless data packing mode is used and the number of data to transfer is not a multiple of the DMA data size (16-bit or 32-bit) while the frame size is smaller, DMA completes the transfer automatically in according with the TSIZE field setting.

Alternatively, last data frames may be written by software, in the single/unpacked mode.

To configure any DMA data access less than the configured data size is forbidden. One complete data frame has to be always accessed at minimum.
49.5 SPI specific modes and control

49.5.1 TI mode

By specific setting of the SP[2:0] bit field at the SPI_CFG2 register the SPI can be configured to be compliant with TI protocol. The SCK and SS signals polarity, phase and flow as well as the bits order are fixed so the setting of CPOL, CPHA, LSBFRST, SSOM, SSOE, SSIOP and SSM is not required when the SPI is at TI mode configuration. The SS signal synchronizes the protocol by pulses over the LSB data bit as it is shown at the Figure 622: TI mode transfer.

In slave mode, the clock generator is used to define time when the slave output at MISO pin becomes to HiZ when the current transaction finishes. The master baud setting is applied and any baud rate can be used to determine this moment with optimal flexibility. The delay for the MISO signal to become HiZ (TRELEASE) depends on internal re-synchronization, too. It is given by formula:

\[
\frac{T_{\text{baud}}}{2} + 2 \times T_{\text{com}} < T_{\text{release}} < \frac{T_{\text{baud}}}{2} + 4 \times T_{\text{com}}
\]

If the slave detects misplaced SS pulse during data transaction the TIFRE flag is set.

49.5.2 SPI error flags

An SPI interrupt is generated if one of the following error flags is set and interrupt is enabled by setting the corresponding Interrupt Enable bit.

**Overrun flag (OVR)**

An overrun condition occurs when data are received by a master or slave and the RxFIFO has not enough space to store these received data. This can happen if the software or the DMA did not have enough time to read the previously received data (stored in the RxFIFO).

When an overrun condition occurs, the OVR flag is set and the newly received value does not overwrite the previous one in the RxFIFO. The newly received value is discarded and all data transmitted subsequently are lost. OVR flag triggers an interrupt if OVRIE bit is set. Clearing the OVR bit is done by a writing 1 to the OVRC bit in the SPI_IFCR. To prevent any
next overrun event the clearing must be done after RxFIFO is emptied by software reads. At master mode, the user can prevent the RxFIFO overrun by automatic communication suspend (MASRX bit).

**Underrun flag (UDR)**

At a slave-transmitting mode, the underrun condition is captured internally by hardware if no data is available for transmission in the slave Tx FIFO at the moment specified by UDRDET bits. The UDR flag setting is then propagated into the status register by hardware (see note below). UDR triggers an interrupt if the UDRIE bit is set.

Once the underrun is captured next provided data for transmission depends on the UDRCFG bits. The slave can provide out either data stored lastly to its Tx FIFO or the data received previously from the master or a constant pattern stored by the user at the UDRDR register. The second configuration can be used at circular topography structure (see Figure 614). Standard transmission is re-enabled once the software clears the UDR flag and this clearing is propagated into SPI logic by hardware. The user must write some data into Tx FIFO prior clearing UDR flag to prevent any next underrun condition occurrence capture.

The data transacted by slave is unpredictable especially when the transaction starts or continues while Tx FIFO is empty and underrun condition is either not yet captured or just cleared. Typically, this is the case when UDRDET[1:0]=00 or SPI is just enabled or when a transaction with a defined size just starts. First bits can be corrupted in this case, as well, when slave software writes first data into the empty Tx FIFO too close prior the data transaction starts (propagation of the data into Tx FIFO takes few APB clock cycles). If the user cannot ensure to write data into the empty Tx FIFO in time the UDRDET[1:0]=00 setting must be avoided.

To handle the underrun control feature correctly the user must avoid next critical encroachments especially

- Any fill of empty Tx FIFO when master starts clocking (at UDRDET[1:0]=00 especially)
- Any clear of UDR flag while Tx FIFO is empty
- Any setting of UDRDET[1:0]=00 together with UDRCFG[1:0]=10
- Any setting of UDRDET[1:0]=10 when underrun must be detected after each data frame while SS signal does not toggle between the frames
- Any setting of UDRDET[1:0]=10 while SS is managed by software

**Note:** The hardware propagation of an UDR flag change needs additional traffic on the bus. It always takes 3 SPI clock cycles after the event happen (underrun captured by hardware or the UDR flag cleared by software).

**Mode fault (MODF)**

Mode fault occurs when the master device has its internal SS signal (SS pin in SS hardware mode, or SSI bit in SS software mode) pulled low. This automatically affects the SPI interface in the following ways:

- The MODF bit is set and an SPI interrupt is generated if the MODFIE bit is set.
- The SPE bit is cleared. This blocks all output from the device and disables the SPI interface.
- The MASTER bit is cleared, thus forcing the device into slave mode.

MODF is cleared by writing 1 to the MODFC bit in the SPI_IFCR.

To avoid any multiple slave conflicts in a system comprising several MCUs, the SS pin must be pulled to its non-active level before re-enabling the SPI, by setting the SPE bit.
As a security, hardware does not allow the SPE bit to be set while the MODF bit is set. In a slave device the MODF bit cannot be set except as the result of a previous multi master conflict.

A correct SW procedure when master overtakes the bus at multi master system must be the following one:

- Switch into master mode while SSOE=0
  (potential conflict can appear when another master occupies the bus. MODF is raised in this case which prevents any next node switching into master mode)
- Put GPIO pin dedicated for another master SS control into active level
- Perform data transaction
- Put GPIO pin dedicated for another master SS control into non active level
- Switch back to slave mode

**CRC error (CRCE)**

This flag is used to verify the validity of the value received when the CRCEN bit in the SPI_CFG1 register is set. The CRCE flag in the SPI_SR register is set if the value received in the shift register does not match the receiver SPI_RXCRC value, after the last data is received (as defined by TSIZE). The CRCE flag triggers an interrupt if CRCIE bit is set. Clearing the bit CRCE is done by a writing 1 to the CRCEC bit in the SPI_IFCR.

**TI mode frame format error (TIFRE)**

A TI mode frame format error is detected when an SS pulse occurs during an ongoing communication when the SPI is operating in slave mode and configured to conform to the TI mode protocol. When this error occurs, the TIFRE flag is set in the SPI_SR register. The SPI is not disabled when an error occurs, the SS pulse is ignored, and the SPI waits for the next SS pulse before starting a new transfer. The data may be corrupted since the error detection may result in the loss of few data bytes.

The TIFRE flag is cleared by writing 1 to the TIFREC bit in the SPI_IFCR. If the TIFREIE bit is set, an interrupt is generated on the SS error detection. As data consistency is no longer guaranteed, communication must be re-initiated by software between master and slave.

### 49.5.3 CRC computation

Two separate 33-bit or two separate 17-bit CRC calculators are implemented in order to check the reliability of transmitted and received data. The SPI offers any CRC polynomial length from 5 to 33 bits when maximum data size is 32-bit and from 5 to 17 bits for the peripheral instances where maximum data size is limited to 16-bit. The length of the polynomial is defined by the most significant bit of the value stored at the CRCPOLY register. It has to be set greater than data frame length defined at DSIZE field. When maximum data size is applied, the CRC33_17 bit has to be set additionally to define the most significant bit of the polynomial string while keep its size always greater than data. The CRCFSIZE field in the SPI_CFG1 then defines how many the most significant bits from CRC calculation registers are transacted and compared as CRC frame. It is defined independently from the data frame length, but it must be either equal or an integer multiple of the data frame size.

**CRC principle**

The CRC calculation is enabled by setting the CRCEN bit in the SPI_CFG1 register before the SPI is enabled (SPE = 1). The CRC value is then calculated using the CRC polynomial
defined by the CRCPOLY register and CRC33_17 bit. When SPI is enabled, the CRC polynomial can be changed but only in case when there is no traffic on the bus.

The CRC computation is done, bit by bit, on the sampling clock edge defined by the CPHA and CPOL bits in the SPIx_CR1 register. The calculated CRC value is checked automatically at the end of the data block defined by the SPIx_CR2 register exclusively.

When a mismatch is detected between the CRC calculated internally on the received data and the CRC received from the transmitter, a CRCERR flag is set to indicate a data corruption error. The right procedure for handling the CRC depends on the SPI configuration and the chosen transfer management.

**CRC transfer management**

Communication starts and continues normally until the last data frame has to be sent or received in the SPIx_DR register.

The length of the transfer has to be defined by TSIZE and TSER. When the desired number of data is transacted, the TXCRC is transmitted and the data received on the line are compared to the RXCRC value.

TSIZE cannot be set to 0xFFFF value if CRC is enabled. A correct way of sending e.g. 65535 data with CRC is to set:

- TSIZE= 0xFFFF and TSER=1 when data packet is configured to keep one data respective
- TSIZE= 0xFFFC and TSER=3 when data packet keeps 4 data (to ensure the TSIZE value aligned with packet size when its extension is applied).

In transmission, the CRC computation is frozen during CRC transaction and the TXCRC is transmitted, in a frame of length equal to the CRCSIZE field value.

In reception, the RXCRC is also frozen when desired number of data is transacted. Information to be compared with the RXCRC register content is then received in a frame of length equal to the CRCSIZE value.

Once the CRC frame is completed, an automatic check is performed comparing the received CRC value and the value calculated in the SPIx_RXCRC register. Software has to check the CRCERR flag in the SPIx_SR register to determine if the data transfers were corrupted or not. Software clears the CRCERR flag by writing 1 to the CRCERRC.

The user takes no care about any flushing redundant CRC information, it is done automatically.

**Resetting the SPIx_TXCRC and SPIx_RXCRC values**

The SPIx_TXCRC and SPIx_RXCRC values are initialized automatically when new data is sampled after a CRC phase. This allows the use of DMA circular mode in order to transfer data without any interruption (several data blocks covered by intermediate CRC checking phases). Initialization patterns for receiver and transmitter can be configured either to zero or to all ones in dependency on setting bits TCRCINI and RCRCINI at SPI2S_CR1 register.

The CRC values are reset when the SPI is disabled.
49.6 **Low-power mode management**

The SPI has advanced low-power mode functions allowing it to transfer properly data between the FIFOs and the serial interface even when the `spi_pclk` clock is disabled.

In master mode the `spi_ker_ck` kernel clock is needed in order to provide the timings of the serial interface.

In slave mode, the `spi_ker_ck` clock can be removed as well during the transfer of data between the FIFOs and the serial interface. In this mode the clock is provided by the external SPI device.

When the `spi_pclk` clock is gated, (and the `spi_ker_ck` clock as well if the SPI is in slave), the SPI provides a wakeup event signal (`spi_wkup`) if a specific action requiring the activation of the `spi_pclk` clock is needed, such as:

- To fill-up the TxFIFO,
- To empty the RxFIFO,
- Other signaling: end of transfer, errors...

The generation of `spi_ker_ck` and `spi_pclk` clock are controlled by the RCC block according to register settings and the processors modes. Refer to the RCC section for details.

The application shall acknowledge all pending interrupts events before switching the SPI to low-power mode (i.e. removing `spi_pclk`).

The *Figure 623* shows an example of the clock handling when the SPI2S is working in low-power mode. The example is given for a transmit mode.

In master mode the `spi_ker_ck` clock is required for the timing generation.

The *Figure 623* shows two kinds of supported scenarios for the handling of the `spi_ker_ck` kernel clock in slave mode:

- In most of the slave modes, the `spi_ker_ck` kernel clock can be disabled,
- In some products, the `spi_ker_ck` kernel clock activation may follow the system state.
The figure clearly shows that the **spi_pclk** must be provided to the SPI2S, when data need to be transferred from the memory to the SPI2S TxFIFO. Here is the description of the most important steps:

- **Step 1**
  The TxFIFO level goes below the programmed threshold, this event (TXP) activates the **spi_wkup** signal. This signal is generally used to wake-up the system from low-power mode, and thus to activate the bus clock (**spi_pclk**).

- **Step 2**
  When **spi_pclk** is activated, the **spi_it** is also activated, and the product is ready to fill-up the TxFIFO either by DMA or by software. Note as well that for some product the system wake-up automatically enables the **spi_ker_ck** kernel clock as well.

- **Step 3**
  When the amount of empty locations in the TxFIFO is less than FTHVL, then the **spi_wkup** and **spi_it** signals are deactivated, but the fill-up of the TxFIFO may continue. Note that **spi_wkup** falling edge is aligned with the serial interface clock domain, and the falling edge of the **spi_it** is aligned with the **spi_pclk** clock domain.

- **Step 4**
  The fill-up of the TxFIFO is completed; the software can switch the system back to low-power mode until the next **spi_wkup** occurs.
49.7 SPI wakeup and interrupts

*Table 403* gives an overview of the SPI events capable to generate interrupt events (spi_it). Some of them feature wake-up from low-power mode capability additionally (spi_wkup).

Most of them can be enabled and disabled independently while using specific interrupt enable control bits.

**Table 403. SPI wakeup and interrupt requests**

1. Refer to SPI2S register description for more details about the event flags.
49.8  **I2S main features**

- Full duplex communication
- Half-duplex communication (only transmitter or receiver)
- Master or slave operations
- 8-bit programmable linear prescaler
- Data length may be 16, 24 or 32 bits
- Channel length can be 16 or 32 in master, any value in slave
- Programmable clock polarity
- Error flags signaling for improved reliability: Underrun, Overrun and Frame Error
- Embedded Rx and TxFIFOs
- Supported I2S protocols:
  - I2S Philips standard
  - MSB-Justified standard (Left-Justified)
  - LSB-Justified standard (Right-Justified)
  - PCM standard (with short and long frame synchronization)
- Data ordering programmable (LSb or MSb first)
- DMA capability for transmission and reception
- Master clock can be output to drive an external audio component. The ratio is fixed at 256 x F_{WS} (where F_{WS} is the audio sampling frequency)
49.9  I2S functional description

49.9.1  I2S general description

The block diagram shown on Figure 609 also applies for I2S mode.

The SPI/I2S block can work on I2S/PCM mode, when the bit I2SMOD is set to 1. A dedicated register (SPI_I2SCFGR) is available for configuring the dedicated I2S parameters, which include the clock generator, and the serial link interface.

The I2S/PCM function uses the clock generator to produce the communication clock when the SPI/I2S is set in master mode. This clock generator is also the source of the master clock output (MCK).

Resources such as RxFIFO, TxFIFO, DMA and parts of interrupt signaling are shared with SPI function. The low-power mode function is also available in I2S mode, refer to Section 49.6: Low-power mode management and Section 49.10: I2S wakeup and interrupts.

49.9.2  Pin sharing with SPI function

The I2S shares four common pins with the SPI:

- **SDO**: Serial Data Output (mapped on the MOSI pin) to transmit the audio samples in master, and to receive the audio sample in slave. Refer to Section : Serial Data Line swapping on page 2204.

- **SDI**: Serial Data Input (mapped on the MISO pin) to receive the audio samples in master, and to transmit the audio sample in slave. Refer to Section : Serial Data Line swapping on page 2204.

- **WS**: Word Select (mapped on the SS pin) is the frame synchronization. It is configured as output in master mode, and as input for slave mode.

- **CK**: Serial Clock (mapped on the SCK pin) is the serial bit clock. It is configured as output in master mode, and as input for slave mode.

An additional pin can be used when a master clock output is needed for some external audio devices:

- **MCK**: Master Clock (mapped separately) is used, when the I2S is configured in master mode. The master clock rate is fixed to 256 x F_WS, where F_WS is the audio sampling frequency.
49.9.3 Bits and fields usable in I2S/PCM mode

When the I2S/PCM mode is selected (I2SMOD = ‘1’), some bit fields are no longer relevant, and must be forced to a specific value in order to guarantee the behavior of the I2S/PCM function. Table 404 shows the list of bits and fields available in the I2S/PCM mode, and indicates which must be forced to a specific value.

</table>
49.9.4 Slave and master modes

The SPI/I2S block supports master and slave mode for both I2S and PCM protocols. In master mode, both CK, WS and MCK signals are set to output.

In slave mode, both CK and WS signals are set to input. The signal MCK is not used in slave mode.

In order to improve the robustness of the SPI/I2S block in slave mode, the peripheral re-synchronizes each reception and transmission on WS signal. This means that:

- In I2S Philips standard, the shift-in or shift-out of each data is triggered one bit clock after each transition of WS.
- In I2S MSB justified standard, the shift-in or shift-out of each data is triggered as soon as a transition of WS is detected.
- In PCM standard, the shift-in or shift-out of each data is triggered one bit clock after the rising edge WS.

Note: This re-synchronization mechanism is not available for the I2S LSB justified standard.

Note: Note as well that there is no need to provide a kernel clock when the SPI/I2S is configured in slave mode.

49.9.5 Supported audio protocols

The I2S/PCM interface supports four audio standards, configurable using the I2SSTD[1:0] and PCMSYNC bits in the SPIx_I2SCFGR register.

In the I2S protocol, the audio data are time-multiplexed on two channels: the left channel and the right channel. The WS signal is used to indicate which channel shall be considered as the left, and which one is the right.

In I2S master mode, four frames formats are supported:

- 16-bit data packed in a 16-bit channel
- 16-bit data packed in a 32-bit channel
- 24-bit data packed in a 32-bit channel
- 32-bit data packed in a 32-bit channel

In PCM master mode, three frames formats are supported:

- 16-bit data packed in a 16-bit channel
- 16-bit data packed in a 32-bit channel
- 24-bit data packed in a 32-bit channel
The figure hereafter shows the main definition used in this section: data length, channel length and frame length.

**Figure 624. Waveform examples**

- **I2S**
  - Sampling rate $F_{MCK} = 256 \times F_{WS}$
  - Data length
  - Channel length
  - Frame length

- **PCM**
  - Sampling rate $F_{MCK} = 256 \times F_{WS}$
  - Data length
  - Channel length = Frame length

**I2S Definition**
I²S Philips standard

The I²S Philips standard is selected by setting I²SSTD to 0b00. This standard is supported in master and slave mode.

In this standard, the WS signal toggles one CK clock cycle before the first bit (MSb in I²S Philips standard) is available. A falling edge transition of WS indicates that the next data transferred is the left channel, and a rising edge transition indicates that the next data transferred is the right channel.

**Figure 625. Master I²S Philips protocol waveforms (16/32-bit full accuracy)**

CKPOL is set to 0 in order to match the I²S Philips protocol. See *Selection of the CK sampling edge* for information concerning the handling of WS signal.

*Figure 625* shows an example of waveform generated by the SPI/I²S in the case where the channel length is equal to the data length. More precisely, this is true when CHLEN = 0 and DATLEN = 0b00 or when CHLEN = 1 and DATLEN = 0b10.

See *Control of the WS Inversion* for information concerning the handling of WS signal.

**Figure 626. I²S Philips standard waveforms**

In the case where the channel length is bigger than the data length, the remaining bits are forced to zero when the SPI/I²S is configured in transmit mode. This is applicable for both master and slave mode.
MSB justified standard

For this standard, the WS signal toggles when the first data bit is provided. The data transferred represents the left channel if WS is high, and the right channel if WS is low.

**Figure 627. Master MSB Justified 16-bit or 32-bit full-accuracy length**

CKPOL is set to 0 in order to match the I2S MSB justified protocol. See *Selection of the CK sampling edge* for information concerning the handling of WS signal.

See *Control of the WS Inversion* for information concerning the handling of WS signal.

**Figure 628. Master MSB justified 16 or 24-bit data length**

In the case where the channel length is bigger than the data length, the remaining bits are forced to zero when the SPI/I2S is configured in master transmit mode. In slave transmit the remaining bits are forced to the value of the first bit of the next data to be generated in order to avoid timing issues (see *Figure 629*).
LSB justified standard

This standard is similar to the MSB justified standard in master mode (no difference for the 16 and 32-bit full-accuracy frame formats). The LSB justified 16 or 32-bit full-accuracy format gives similar waveforms than MSB justified mode (see Figure 627) because the channel and data have the same length.

Note: In the LSB justified format, only 16 and 32-bit channel length are supported in master and slave mode. This is due to the fact that it is not possible to transfer properly the data if the channel length is not known by transmitter and receiver side.

Figure 630. LSB justified 16 or 24-bit data length

CKPOL is set to 0 in order to match the I2S LSB justified protocol. See Selection of the CK sampling edge for information concerning the handling of WS signal.

See Control of the WS Inversion for information concerning the handling of WS signal.
PCM standard

For the PCM standard, there is no need to use channel-side information. The two PCM modes (short and long frame) are available and configurable using the PCMSYNC bit in SPI_I2SCFGR register.

Note: The difference between the PCM long and short frame, is just the width of the frame synchronization: for both protocols, the active edge of the frame is generated (or is expected for the Slave mode) one CK clock cycle before the first bit.

Figure 631. Master PCM when the frame length is equal the data length

For long frame synchronization, the WS signal assertion time is fixed to 13 bits in master mode.

A data size of 16 or 24 bits can be used when the channel length is set to 32 bits.

For short frame synchronization, the WS synchronization signal is only one cycle long.

See Control of the WS Inversion for information concerning the handling of WS signal.

Figure 632. Master PCM standard waveforms (16 or 24-bit data length)

If the PCM protocol is used in slave mode, frame lengths can be different from 16 or 32 bits. As shown in Figure 633, in slave mode various pulse widths of WS can be accepted as the start of frame is detected by a rising edge of WS. The only constraint is that the WS must go back to its inactive state for at least one CK cycle.
CKPOL is set to 0 in order to match the PCM protocol. See Selection of the CK sampling edge for information concerning the handling of WS signal.

49.9.6 Additional Serial Interface Flexibility

Variable frame length in slave

In slave mode, channel lengths different from 16 or 32 bits can be accepted, as long as the channel length is bigger than the data length. This is true for all protocols except for I2S LSB justified protocol.

Data ordering

For all data formats and communication standards, it is possible to select the data ordering (MSb or LSb first) thanks to the bit LSBFRST located into SPI configuration register 2 (SPI_CFG2).

Selection of the CK sampling edge

The CKPOL bit located into SPI/I2S configuration register (SPI_I2SCFGR) allows the user to choose the sampling edge polarity of the CK for slave and master modes, for all protocols.

- When CKPOL = 0, serial data SDO and WS (when master) are changed on the falling edge of CK and the serial data SDI and WS (when slave) are read on the rising edge.
- When CKPOL = 1, serial data SDO and WS (when master) are changed on the rising edge of CK and the serial data SDI and WS (when slave) are read on the falling edge.

Control of the WS Inversion

It is possible to invert the default WS signal polarity for master and slave modes, for all protocols, by setting WSINV to 1. By default the WS polarity is the following:

- In I2S Philips Standard, WS is low for left channel, and high for right channel
- In MSB/LSB justified mode, WS is high for left channel, and low for right channel
- In PCM mode, the start of frame is indicated by a rising edge of WS.
When WSINV is set to 1, the WS polarity is inverted, then:
- In I2S Philips Standard, WS is high for left channel, and low for right channel
- In MSB/LSB justified mode, WS is low for left channel, and high for right channel
- In PCM mode, the start of frame is indicated by a falling edge of WS.

WSINV is located into SPI/I2S configuration register (SPI_I2SCFGR).

### Control of the IOs

The SPI/I2S block allows the settling of the WS and CK signals to their inactive state before enabling the SPI/I2S thanks to the AFCNTR bit of SPI configuration register 2 (SPI_CFG2).

This can be done by programming CKPOL and WSINV using the following sequence:

Assuming that AFCNTR is initially set to 0
- Set I2SMOD = 1. (In order to inform the hardware that the CK and WS polarity is controlled via CKPOL and WSINV).
- Set bits CKPOL and WSINV to the wanted value.
- Set AFCNTR = 1.
  Then the inactive level of CK and WS IOs is set according to CKPOL and WSINV values, even if the SPI/I2S is not yet enabled.
- Then performs the activation sequence of the I2S/PCM

Table 405 shows the level of WS and CK signals, when the AFCNTR bit is set to 1, and before the SPI/I2S block is enabled (i.e. inactive level). Note that the level of WS depends also on the protocol selected.

<table>

</table>

Note: **The bit AFCNTR shall not be set to 1, when the SPI/I2S is in slave mode.**

### Serial Data Line swapping

The SPI/I2S offers the possibility to swap the function of SDI and SDO lines thanks to IOSWP bit located into SPI configuration register 2 (SPI_CFG2). Table 406 gives details on this feature.

<table>

---

Table 405. WS and CK level before SPI/I2S is enabled when AFCNTR = 1

Table 406. Serial data line swapping
For simplification, the waveforms shown in the *I2S functional description* section have been done with IOSWP = 0.

### 49.9.7 Start-up sequence

When the bit SPE is set to 0, the user is not allowed to read and write into the SPI2S_RXDR and SPI2S_TXDR registers, but the access to other registers is allowed.

When the application wants to use the SPI/I2S block the user has to proceed as follow:

1. Insure that the SPE is set to 0, otherwise write SPE to 0.
2. Program all the configuration and control registers according to the wanted configuration. Refer to *Section 49.9.16* for detailed programming examples.
3. Set the SPE bit to 1, in order to activate the SPI/I2S block. When this bit is set, the serial interface is still disabled, but the DMA and interrupt services are working, allowing for example, the data transfer into the TxFIFO.
4. Set bit CSTART to 1, in order to activate the serial interface.

As shown in *Figure 634*, in I2S Philips standard master TX, the generation of the WS, MCK and CK signals is started as soon as the bit CSTART is set to 1 and the TxFIFO is not empty. Note that the bit clock CK is activated 4 rising edges before the falling edge of WS in order to insure that the external slave device can detect properly WS transition. Other standards behave similarly.

</tbody>
</table>

1. In this figure, the MCK is enabled before setting the bit SPE to 1. See *MCK Generation* for more information.
2. Note that the level of WS and CK signals are controlled by the SPI/I2S block during the configuration phase as soon as the AFCNTR bit is set to 1.
Note: Due to clock domain resynchronization, the CSTART bit is taken into account by the hardware after about 3 periods of CK clock (SYNC_DLY1).

In slave mode, once the bit CSTART is set to 1, the data transfer starts when the start-of-frame condition is met:

- For I2S Philips standard, the start-of-frame condition is a falling edge of WS signal. The transmission/reception starts one bit clock later.
  - If WSINV = 1, then the start-of-frame condition is a rising edge.
- For other protocols, the start-of-frame condition is a rising edge of WS signal. The transmission/reception starts at rising edge of WS for MSB aligned protocol. The transmission/reception starts one bit clock later for PCM protocol.
  - If WSINV = 1, then the start-of-frame condition is a falling edge.

Figure 635 shows an example of start-up sequence in I2S Philips standard, slave mode.

![Figure 635. Start-up sequence, I2S Philips standard, slave](MSv40487V1)

Note: Due to clock domain resynchronization, the CSTART bit is taken into account by the hardware after 2 periods of CK clock (SYNC_DLY).

49.9.8 Stop sequence

The application can stop the I2S/PCM transfers by setting the SPE bit to 0. In that case the communication is stopped immediately, without waiting for the end of the current frame.

In master mode it is also possible to stop the I2S/PCM transfers at the end of the current frame. For that purpose, the user has to set the bit CSUSP to 1, and polls the CSTART bit until it goes to 0. The CSTART bit goes to 0 when the current stereo (if an I2S mode was selected) or mono sample are completely shifted in or out. Then the SPE bit can be set to 0.

The Figure 636 shows an example of stop sequence in the case of master mode. The CSUSP bit is set to 1, during the transmission of left sample, the transfer continue until the last bit of the right sample is transferred. Then CSTART and CSUSP go back to 0, CK and WS signals go back to their inactive state, and the user can set SPE to 0.
Note: In slave mode, the stop sequence is only controlled by the SPE bit.

49.9.9 Clock generator

When the I2S or PCM is configured in master mode, the user needs to program the clock generator in order to produce the Frame Synchronization (WS), the bit clock (CK) and the master clock (MCK) at the desired frequency.

If the I2S or PCM is used in slave mode, there is no need to configure the clock generator.

Note: In master mode, there is no specific constraints on the ratio between the bus clock rate ($F_{pclk}$) and the bit clock ($F_{CK}$). The bus clock frequency must be high enough in order to support the data throughput.
When the master clock is generated (MCKOE = 1), the frequency of the frame synchronization is given by the following formula in I2S mode:

\[ F_{WS} = \frac{F_{i2s\_clk}}{256 \times \{2 \times I2SDIV\} + ODD} \]

and by this formula in PCM mode:

\[ F_{WS} = \frac{F_{i2s\_clk}}{128 \times \{2 \times I2SDIV\} + ODD} \]

In addition, the frequency of the MCK (F_{MCK}) is given by the formula:

\[ F_{MCK} = \frac{F_{i2s\_clk}}{(2 \times I2SDIV) + ODD} \]

When the master clock is disabled (MCKOE = 0), the frequency of the frame synchronization is given by the following formula in I2S mode:

\[ F_{WS} = \frac{F_{i2s\_clk}}{32 \times (\text{CHLEN} + 1) \times \{2 \times I2SDIV\} + ODD} \]

And by this formula in PCM mode:

\[ F_{WS} = \frac{F_{i2s\_clk}}{16 \times (\text{CHLEN} + 1) \times \{2 \times I2SDIV\} + ODD} \]

Where \( F_{WS} \) is the frequency of the frame synchronization, and \( F_{i2s\_clk} \) is the frequency of the kernel clock provided to the SPI/I2S block.

Note: \( \text{CHLEN} \) and \( \text{ODD} \) can be either 0 or 1.
\( I2SDIV \) can take any values from 0 to 255 when \( \text{ODD} = 0 \), but when \( \text{ODD} = 1 \), the value \( I2SDIV = 1 \) is not allowed.
When \( I2SDIV = 0 \), then \( \{2 \times I2SDIV\} + ODD \) is forced to 1.

Note: When \( \{2 \times I2SDIV\} + ODD \) is odd, the duty cycle of MCK or the CK signals is not 50%.
Care must be taken when odd ratio is used: it can impact margin on setup and hold time. For example if \( \{2 \times I2SDIV\} + ODD = 5 \), then the duty cycle can be 40%.

Table 407 provides examples of clock generator programming for I2S modes.

**MCK Generation**

The master clock MCK can be generated regardless to the SPE bit. The MCK generating is controlled by the following bits:
- \( I2SMOD \) must equal to 1,
- \( I2SCFG \) must select a master mode,
- MCKOE must be set to 1
49.9.10 Internal FIFOs

The I2S interface can use a dedicated FIFO for the RX and the TX path. The samples to transmit can be written into the TxFIFO via the SPI2S_TXDR register. The reading of RxFIFO is performed via the SPI2S_RXDR register.

Data alignment and ordering

It is possible to select the data alignment into the SPI2S_RXDR and SPI2S_TXDR registers thanks to the DATFMT bit.

Note as well that the format of the data located into the SPI2S_RXDR or SPI2S_TXDR depends as well on the way those registers are accessed via the APB bus.

Figure 638 shows the allowed settings between APB access sizes, DATFMT and DATLEN.

Note: Caution shall be taken when the APB access size is 32 bits, and DATLEN = 0. For read operation the RxFIFO must contain at least two data, otherwise the read data are invalid. In the same way, for write operation, the TxFIFO must have at least two empty locations, otherwise a data can be lost.
1. In I2S mode, the sample N represents the left sample, and the sample N+1 is the right sample.

It is possible to generate an interrupt or a DMA request according to a programmable FIFO threshold levels. The FIFO threshold is common to RX and TxFIFOs can be adjusted via FTHLV.

In I2S mode, the left and right audio samples are interleaved into the FIFOs. It means that for transmit operations, the user has to start to fill-up the TxFIFO with a left sample, followed by a right sample, and so on. For receive mode, the first data read from the RxFIFO is supposed to represent a left channel, the next one is a right channel, and so on.

Note that the read and write pointers of the FIFOs are reset when the bit SPE is set to 0.

Refer to Section 49.9.11 and Section 49.9.15 for additional information.

**FIFO size optimization**

The basic element of the FIFO is the byte. This allows an optimization of the FIFO locations. For example when the data size is fixed to 24 bits, each audio sample takes 3 basic FIFO elements.

For example, a FIFO with 16 basic elements can have a depth of:

- 8 samples, if the DATLEN = 0 (16 bits),
- 5 samples, if the DATLEN = 1 (24 bits),
- 4 samples, if the DATLEN = 2 (32 bits).

**49.9.11 FIFOs status flags**

Two status flags are provided for the application to fully monitor the state of the I2S interface. Both flags can generate an interrupt request. The receive interrupt is generated if RXPIE bit is enabled, the transmit interrupt is generated if TXPIE bit is enabled. Those bits are located into the SPI_IER register.

**TxFIFO threshold reached (TXP)**

When set, this flag indicates that the TxFIFO contains at least FTHLV empty locations. Thus FTHLV new data to be transmitted can be written into SPI2S_TXDR. The TXP flag is reset when the amount of empty locations is lower than FTHLV. Note that TXP = 1, when the I2S is disabled (SPE bit is reset).
**Rx FIFO threshold reached (RXP)**

When set, this flag indicates that there is at least FTHLV valid data into the Rx FIFO, thus the user can read those data via SPI2S_RXDR. It is reset when the Rx FIFO contains less than FTHLV data.

See Section 49.10 for additional information on interrupt function in I2S mode.

**49.9.12 Handling of underrun situation**

In transmit mode, the UDR flag is set when a new data needs to be loaded into the shift register while the Tx FIFO is already empty. In such a situation at least a data is lost.

In I2S mode, there is a hardware mechanism in order to prevent misalignment situation (left and right channel swapped). As shown in the following figure, when an underrun occurs, the peripheral re-plays the last valid data on left and right channels as long as conditions of restart are not met. The transmission restarts:

- When there is enough data into the Tx FIFO, and
- When the UDR flag is cleared by the software,

Then the next data transmitted is:

- A right channel if the underrun occurred when a right channel data needed to be transmitted, or
- A left channel if the underrun occurred when a left channel data needed to be transmitted.

The UDR flag can trigger an interrupt if the UDRIE bit in the SPI_IER register is set. The UDR bit is cleared by writing UDRC bit of SPI_IFCR register to 1.

When the block is configured in PCM mode, this re-alignment mechanism is not activated.

**Note:** An underrun situation can occur in master or slave mode. In master mode, when an underrun occurs, the WS, CK and MCK signal are not gated.

Due to resynchronization, any change on the UDR flag is taken into account by the hardware after at least 2 periods of CK clock.
49.9.13 Handling of overrun situation

The OVR flag is set when received data need to written into the RxFIFO, while the RxFIFO is already full. As a result, some incoming data are lost.

In I2S mode, there is a hardware mechanism in order to prevent misalignment situation (left and right channel swapped). As shown in the following figure, when an overrun occurs, the peripheral stops writing data into the RxFIFO as long as conditions of restart are not met. When there is enough room into the RxFIFO, and the OVR flag is cleared, the block starts by writing next the right channel into the RxFIFO if the overrun occurred when a right channel data was received or by writing the next left channel if the overrun occurred when a left channel data was received.

Figure 640. Handling of overrun situation

An interrupt may be generated if the OVRIE bit is set in the SPI_IER register. The OVR bit is cleared by writing OVRC bit of SPI_IFCR register to 1.

When the block is configured in PCM mode, this re-alignment mechanism is not activated.

Note: An overrun situation can occur in master or slave mode. In master mode, when an overrun occurs, the WS, CK and MCK signal are not gated.

49.9.14 Frame error detection

When configured in slave mode, the SPI/I2S block detects two kinds of frame errors:

- A frame synchronization received while the shift-in or shift-out of the previous data is not completed (early frame error). This mode is selected with FIXCH = 0.

- A frame synchronization occurring at an unexpected position. This mode is selected with FIXCH = 1.

In slave mode, if the frame length provided by the external master device is different from 32 or 64 bits, the user has to set FIXCH to 0. As the SPI/I2S synchronize each transfer with the WS there is no misalignment risk, but in a noisy environment, if a glitch occurs in the CK signal, a sample may be affected and the application is not aware of this.

If the frame length provided by the external master device is equal to 32 or 64 bits, then the user can set FIXCH to 1 and adjust accordingly CHLEN. As the SPI/I2S synchronize each transfer with the WS there is still no misalignment risk, and if the amount of bit clock
between each channel boundary is different from CHLEN, the frame error flag (TIFRE) is set to 1.

Figure 641 shows an example of frame error detection. The SPI/I2S block is in slave mode and the amount of bit clock periods for left channel are not enough to shift-in or shift-out the data. The figure shows that the on-going transfer is interrupted and the next one is started in order to remain aligned to the WS signal.

An interrupt can be generated if the TIFREIE bit is set. The frame error flag (TIFRE) is cleared by writing the TIFREC bit of the SPI_IFCR register to 1.

It is possible to extend the coverage of the frame error flag by setting the bit FIXCH to 1. When this bit is set to 1, then the SPI/I2S is expecting fixed channel lengths in slave mode. This means that the expected channel length can be 16 or 32 bits, according to CHLEN. As shown in Figure 642, in this mode the SPI/I2S block is able to detect if the WS signal is changing at the expected moment (too early or too late).

Note: Figure 641 and Figure 642 show the mechanism for the slave transmit mode, but this is also true for slave receive and slave full-duplex.

The frame error detection can be generally due to noisy environment disturbing the good reception of WS or CK signals.

Note: The SPI/I2S is not able to recover properly if an overrun and an early frame occur within the same frame. In this case the user has to disable and re-enable the SPI/I2S.
49.9.15 DMA Interface

The I2S/PCM mode shares the same DMA requests lines than the SPI function. There is a separated DMA channel for TX and RX paths. Each DMA channel can be enabled via RXDMAEN and TXDMAEN bits of SPI_CFG1 register.

In receive mode, the DMA interface is working as follow:
1. The hardware evaluates the RxFIFO level,
2. If the RxFIFO contains at least FTHLV samples, then FTHLV DMA requests are generated,
   – When the FTHLV DMA requests are completed, the hardware loops to step 1
3. If the RxFIFO contains less than FTHLV samples, no DMA request is generated, and the hardware loop to step 1

In transmit mode, the DMA interface is working as follow:
1. The hardware evaluates the TxFIFO level,
2. If the TxFIFO contains at least FTHLV empty locations, then FTHLV DMA requests are generated,
   – When the FTHLV DMA requests are completed, the hardware loops to step 1
3. If the TxFIFO contains less than FTHLV empty locations, no DMA request is generated, and the hardware loop to step 1
49.9.16 Programing examples

Master I2S Philips standard, transmit

This example shows how to program the interface for supporting the Philips I2S standard in master transmit mode, with a sampling rate of 48 kHz, using the master clock. The assumption taken is that SPI/I2S is receiving a kernel clock (i2s_clk) of 61.44 MHz from the clock controller of the circuit.

Start Procedure

1. Enable the bus interface clock (pclk or hclk), release the reset signal if needed in order to be able to program the SPI/I2S block.
2. Insure that the SPI/I2S block receives properly a kernel frequency (at 61.44 MHz in this example).
3. Insure that SPE is set to 0.
4. Program the clock generator in order to provide the MCK clock and to have a frame synchronization rate at exactly 48 kHz. So I2SDIV = 2, ODD = 1, and MCKOE = 1.
5. Program the serial interface protocol: CKPOL = 0, WSINV = 0, LSBFRST = 0, CHLEN = 1 (32 bits per channel) DATLEN = 1 (24 bits), I2SSTD = 0 (Philips Standard), I2SCFG = 2 (master transmit), I2SMOD = 1, for I2S/PCM mode. The register SPI_I2SCFGR must be updated before going to next steps.
6. Adjust the FIFO threshold, by setting the wanted value into FTHLV. For example if a threshold of 2 audio samples is required, FTHLV = 1.
7. Clear all status flag registers.
8. Enable the flags who shall generate an interrupt such as UDRIE. Note that TIFRE is not meaningful in master mode.
9. If the data transfer uses DMA:
   – Program the DMA peripheral,
   – Initialize the memory buffer with valid audio samples,
   – Enable the DMA channel,
10. If the data transfer is done via interrupt, then the user has to enable the interrupt by setting the TXPIE bit to 1.
11. Set SPE to 1, as soon as this bit is set to one the following actions may happen:
    – If the interrupt generation is enabled, the SPI/I2S generates an interrupt request allowing the interrupt handler to fill-up the TxFIFO.
    – If the DMA transfer are enabled (TXDMAEN = 1), the SPI/I2S generates DMA requests in order to fill-up the TxFIFO.
12. Finally, the user has to insure that the TxFIFO is not empty before enabling the serial interface. This is important in order to avoid an underrun condition when the interface is enabled. Then the SPI/I2S block can be enabled by setting the bit CSTART to 1. CSTART bit is located into SPI_CR1 register.

Stop Procedure in master mode

1. Set the bit CSUSP to 1, in order to stop on-going transfers
2. Check the value of CSTART bit until it goes to 0
3. Stop DMA peripheral, bus clock...
4. Set bit SPE to 0 in order to disable the SPI/I2S block
Master I2S MSB Aligned, full-duplex

This example shows how to program the interface for supporting the I2S MSB aligned protocol in master full-duplex mode, with a sampling rate of 48 kHz, without using the master clock. We took the assumption that the SPI/I2S is receiving a kernel clock (i2s_clk) of 12.288 MHz from the clock controller of the circuit.

Procedure

1. Enable the bus interface clock (pclk or hclk), release the reset signal if needed in order to be able to program the SPI/I2S block.
2. Insure that the SPI/I2S block receives properly a kernel frequency (at 12.288 MHz in this example).
3. Insure that SPE is set to 0.
4. Program the clock generator in order to provide the MCK clock, and to have a frame synchronization rate at exactly 48 kHz. So I2SDIV = 2, ODD = 0, and MCKOE = 0.
5. Program the serial interface protocol: CKPOL = 0, WSINV = 0, LSBFRST = 0, CHLEN = 1 (32 bits per channel) DATLEN = 1 (24 bits), I2SSSTD = 1 (MSB Justified), I2SCFG = 5 (master Full-duplex), I2SMOD = 1, for I2S/PCM mode. The register SPI_I2SCFGR must be updated before going to next steps.
6. Adjust the FIFO threshold, by setting the wanted value into FTHLV. For example if a threshold of 2 audio samples is required, FTHLV = 1.
7. Clear all status flag registers.
8. Enable the flags who shall generate an interrupt such as UDRIE. Note that TIFRE is not meaningful in master mode.
9. If the data transfer uses DMA:
   – Program the DMA peripheral: two channels, one for RX and one for TX
   – Initialize the memory buffer with valid audio samples for TX path
   – Enable the DMA channels,
   – In the SPI/I2S block, enable the DMA by setting the TXDMAEN and RXDMAEN bits to 1. As soon as these bits are set to 1, the SPI/I2S start to fill-up the TxFIFO by sending DMA requests
10. If the data transfer is done via interrupt, then the user has to enable the interrupt by setting the TXPIE and RXPIE bits to 1.
11. Set SPE to 1, as soon as this bit is set to one the following actions may happen:
   – If the interrupt generation is enabled, the SPI/I2S generates an interrupt request allowing the interrupt handler to fill-up the TxFIFO.
   – If the DMA transfer are enabled, the SPI/I2S generates DMA requests in order to fill-up the TxFIFO
12. Finally, the user has to insure that the TxFIFO is not empty before enabling the serial interface. This is important in order to avoid an underrun condition when the interface is enabled. Then the SPI/I2S block can be enabled by setting the bit CSTART to 1. CSTART bit is located into SPI_CR1 register.

Refer to Stop Procedure in master mode for details on the stop sequence.
49.9.17 Slave I2S Philips standard, receive

This example shows how to program the interface for supporting the I2S Philips standard protocol in slave receiver mode, with a sampling rate of 48 kHz. Note that in slave mode the SPI/I2S block cannot control the sample rate of the received samples. In this example we took the assumption that the external master device is delivering an I2S frame structure with a channel length of 24 bits. So we cannot use the capability offered for frame error detection when FIXCH is set to 1.

Procedure

1. Enable the bus interface clock (pclk or hclk), release the reset signal if needed in order to be able to program the SPI/I2S block.
2. Insure that SPE is set to 0.
3. Program the serial interface protocol: CKPOL = 0, WSINV = 0, LSBFRST = 0, FIXCH = 0 (because channel length is different from 16 and 32 bits), DATLEN = 0 (16 bits), I2SSTD = 0 (Philips protocol), I2SCFG = 1 (slave RX), I2SMOD = 1, for I2S mode. The register SPI_I2SCFGR must be properly programmed before going to next steps.
4. Adjust the FIFO threshold, by setting the wanted value into FTHLV. For example if a threshold of 2 audio samples is required, FTHLV = 1.
5. Clear all status flag registers.
6. Enable the flags who shall generate an interrupt such as UDRIE and TIFRE.
7. If the data transfer uses DMA:
   – Program the DMA peripheral: one RX channel
   – Enable the DMA channel,
   – In the SPI/I2S block, enable the DMA by setting the RXDMAEN bit to 1.
8. If the data transfer is done via interrupt, then the user has to enable the interrupt by setting the RXPIE bit to 1.
9. Set SPE to 1.
10. Finally the user can set the bit CSTART to 1 in order to enable the serial interface. The SPI/I2S starts to store data into the RxFIFO on the next occurrence of left data transmitted by the external master device.

Stop Procedure in slave mode

1. Set bit SPE to 0 in order to disable the SPI/I2S block
2. Stop DMA peripheral, bus clock...
49.10 I2S wakeup and interrupts

In PCM/I2S mode an interrupt (spi_it) or a wakeup event signal (spi_wkup) can be generated according to the events described in the Table 408.

Interrupt events can be enabled and disabled separately.

Table 408. I2S interrupt requests

Bits 31:17 Reserved, must be kept at reset value.

- **Bit 16 IOLOCK**: locking the AF configuration of associated IOs
  - This bit is set by software and cleared by hardware on next device reset
  - 0: AF configuration is not locked
  - 1: AF configuration is locked
  - When this bit is set, SPI_CFG2 register content cannot be modified any more.
  - This bit must be configured when the SPI is disabled. When SPE=1, it is write protected.

- **Bit 15 TCRCINI**: CRC calculation initialization pattern control for transmitter
  - 0: All zero pattern is applied
  - 1: All ones pattern is applied

- **Bit 14 RCRCINI**: CRC calculation initialization pattern control for receiver
  - 0: all zero pattern is applied
  - 1: all ones pattern is applied

- **Bit 13 CRC33_17**: 32-bit CRC polynomial configuration
  - 0: full size (33-bit or 17-bit) CRC polynomial is not used
  - 1: full size (33-bit or 17-bit) CRC polynomial is used

- **Bit 12 SSI**: internal SS signal input level
  - This bit has an effect only when the SSM bit is set. The value of this bit is forced onto the peripheral SS input and the I/O value of the SS pin is ignored.

- **Bit 11 HDDIR**: Rx/Tx direction at Half-duplex mode
  - In Half-Duplex configuration the HDDIR bit establishes the Rx/Tx direction of the data transfer. This bit is ignored in Full-Duplex or any Simplex configuration.
  - 0: SPI is Receiver
  - 1: SPI is transmitter

- **Bit 10 CSUSP**: master suspend request
  - This bit reads as zero.
  - In master mode, when this bit is set by software, CSTART bit is reset at the end of the current frame and SPI communication is suspended. The user has to check SUSP flag to check end of the frame transaction.
  - The master mode communication must be suspended (using this bit or keeping TXDR empty) before disabling the SPI or going to low-power mode.
**Serial peripheral interface (SPI)**

**Bit 9  CSTART:** master transfer start
This bit is set by software to start an SPI transfer in master mode. It is cleared by hardware when End Of Transfer (EOT) flag is set or when an CSUSPend request is accepted.
0: master transfer is at idle
1: master transfer is on-going or temporary suspended by automatic suspend
In SPI mode, CSTART can be set only when SPE=1 and MASTER=1.
In SPI mode, in case of master transmission is enabled, communication starts or continues only if any data is available in the transmission FIFO.
In I2S/PCM mode, CSTART can be set when SPE = 1.

**Bit 8  MASRX:** master automatic SUSP in Receive mode
This bit is set and cleared by software to control continuous SPI transfer in master receiver mode and automatic management in order to avoid overrun condition.
0: SPI flow/clock generation is continuous, regardless of overrun condition. (data are lost)
1: SPI flow is suspended temporary on RxFIFO full condition, before reaching overrun condition. The SUSP flag is set when SPI communication is suspended.
When SPI communication is suspended to prevent overrun condition it could happen that few bits of next frame are already clocked out due to internal synchronization delay. Once the RxFIFO is read the communication resumes and continues by subsequent bits transaction without any next constrain.
For the same reason, the automatic suspension is not quite reliable when size of data drops below 8 bits. In this case, a safe suspension can be achieved by combination with delay inserted between data frames applied when MIDI parameter keeps a non zero value; sum of data size and the interleaved SPI cycles must always produce interval at length of 8 SPI clock periods at minimum.

Bits 7:1  Reserved, must be kept at reset value.

**Bit 0  SPE:** serial peripheral enable
This bit is set by and cleared by software.
0: serial peripheral disabled.
1: serial peripheral enabled
When SPE=1, SPI data transfer is enabled. Configuration registers and IOLOCK bit in SPI_CR1 are write protected. They can be changed only when SPE=0.
When SPI=0 any SPI operation is stopped and disabled, internal state machine is reseted, all the FIFOs content is flushed, CRC calculation initialized, receive data register is read zero.
SPE cannot be set when MODF error flag is active.

Bit 31 Reserved, must be kept at reset value.

Bits 30:28 **MBR[2:0]**: master baud rate
- 000: SPI master clock/2
- 001: SPI master clock/4
- 010: SPI master clock/8
- 011: SPI master clock/16
- 100: SPI master clock/32
- 101: SPI master clock/64
- 110: SPI master clock/128
- 111: SPI master clock/256

Bits 27:23 Reserved, must be kept at reset value.

Bit 22 **CRCEN**: hardware CRC computation enable
- 0: CRC calculation disabled
- 1: CRC calculation Enabled

Bit 21 Reserved, must be kept at reset value.
Bits 20:16 **CRCSIZE[4:0]**: length of CRC frame to be transacted and compared

- Most significant bits are taken into account from polynomial calculation when CRC result is transacted or compared. The length of the polynomial is not affected by this setting.
- 00000: not used
- 00001: not used
- 00010: not used
- 00011: 4-bits
- 00100: 5-bits
- 00101: 6-bits
- 00110: 7-bits
- 00111: 8-bits
- ....
- 11101: 30-bits
- 11110: 31-bits
- 11111: 32-bits

The value must be equal or multiply of DSIZE length

*Note: The most significant bit at CRCSIZE bit field is reserved at the peripheral instances where data size is limited to 16-bit.*

Bit 15 **TXDMAEN**: Tx DMA stream enable
- 0: Tx DMA disabled
- 1: Tx DMA enabled

Bit 14 **RXDMAEN**: Rx DMA stream enable
- 0: Rx-DMA disabled
- 1: Rx-DMA enabled

Bit 13 Reserved, must be kept at reset value.

Bits 12:11 **UDRDET[1:0]**: detection of underrun condition at slave transmitter
- 00: underrun is detected at begin of data frame (no protection of 1-st bit)
- 01: underrun is detected at end of last data frame
- 10: underrun is detected by begin of active SS signal
- 11: reserved

The user can define here when and how the underrun condition is detected at slave receiver
Bits 10:9 **UDRCFG[1:0]**: behavior of slave transmitter at underrun condition

- 00: slave sends a constant pattern defined by the user at SPI_UDRDR register
- 01: slave repeats lastly received data frame from master
- 10: slave repeats its lastly transmitted data frame
- 11: reserved

While TxFIFO is empty shift register for transmission keeps value of SPI_UDRDR register. This register can be either locked to send value defined by the user or refreshed automatically by lastly transacted frame received from master or updated by data stored lastly at slave TxFIFO (by write to TXDR).

Bits 8:5 **FTHLV[3:0]**: FIFO threshold level

Defines number of data frames at single data packet. The size of the packet must not exceed 1/2 of FIFO space.

- 0000: 1-data
- 0001: 2-data
- 0010: 3-data
- 0011: 4-data
- 0100: 5-data
- 0101: 6-data
- 0110: 7-data
- 0111: 8-data
- 1000: 9-data
- 1001: 10-data
- 1010: 11-data
- 1011: 12-data
- 1100: 13-data
- 1101: 14-data
- 1110: 15-data
- 1111: 16-data

SPI interface is more efficient if configured packet sizes are aligned with data register access parallelism:

- If SPI data register is accessed as a 16-bit register and DSIZE<=8bit, better to select FTHLV=2, 4, 6 etc,
- If SPI data register is accessed as a 32-bit register and DSIZE>8bit, better to select FTHLV=2, 4, 6 etc, while if DSIZE<=8bit, better to select FTHLV=4, 8, 12 etc

Bits 4:0 **DSIZE[4:0]**: number of bits in at single SPI data frame

- 00000: not used
- 00001: not used
- 00010: not used
- 00011: 4-bits
- 00100: 5-bits
- 00101: 6-bits
- 00110: 7-bits
- 00111: 8-bits
- ...
- 11101: 30-bits
- 11110: 31-bits
- 11111: 32-bits

*Note:* The most significant bit at DSIZE bit field is reserved at the peripheral instances where data size is limited to 16-bit.

#### Bit 31 AFCNTR: alternate function GPIOs control
- This bit is taken into account when SPE=0 only
  - 0: the peripheral takes no control of GPIOs while it is disabled
  - 1: the peripheral keeps always control of all associated GPIOs
- When SPI master has to be disabled temporary for a specific configuration reason (e.g. CRC reset, CPHA or HDDIR change) setting this bit prevents any glitches on the associated outputs configured at alternate function mode by keeping them forced at state corresponding the current SPI configuration. This bit must be never used at slave mode as any slave transmitter must not force its MISO output once the SPI is disabled.

*Note: This bit can be also used in PCM and I2S modes.*

#### Bit 30 SSOM: SS output management in master mode
- This bit is used in master mode when SSOE is enabled. It allows to configure SS output between two consecutive data transfers.
  - 0: SS is kept at active level till data transfer is completed, it becomes inactive with EOT flag
  - 1: SPI data frames are interleaved with SS non active pulses when MIDI[3:0]>1

#### Bit 29 SSOE: SS output enable
- This bit is taken into account at master mode only
  - 0: SS output is disabled and the SPI can work in multi-master configuration
  - 1: SS output is enabled. The SPI cannot work in a multi-master environment. It forces the SS pin at inactive level after the transfer in according with SSOM, MIDI, MSSI, SSIOP bits setting

#### Bit 28 SSIOP: SS input/output polarity
- 0: low level is active for SS signal
- 1: high level is active for SS signal

#### Bit 27 Reserved, must be kept at reset value.

#### Bit 26 SSM: software management of SS signal input
- 0: SS input value is determined by the SS PAD
- 1: SS input value is determined by the SSI bit
- SS signal input has to be managed by software (SSM=1, SSI=1) when SS output mode is enabled (SSOE=1) at master mode.

#### Bit 25 CPOL: clock polarity
- 0: SCK signal is at 0 when idle
- 1: SCK signal is at 1 when idle
Bit 24 **CPHA:** clock phase
   0: the first clock transition is the first data capture edge
   1: the second clock transition is the first data capture edge

Bit 23 **LSBFRST:** data frame format
   0: MSB transmitted first
   1: LSB transmitted first
   *Note:* This bit can be also used in PCM and I2S modes.

Bit 22 **MASTER:** SPI master
   0: SPI Slave
   1: SPI Master

Bits 21:19 **SP[2:0]:** Serial protocol
   000: SPI Motorola
   001: SPI TI
   others: Reserved, must not be used

Bits 18:17 **COMM[1:0]:** SPI communication mode
   00: full-duplex
   01: simplex transmitter
   10: simplex receiver
   11: self-duplex

Bit 16 Reserved, must be kept at reset value.

Bit 15 **IOSWP:** swap functionality of MISO and MOSI pins
   0: no swap
   1: MOSI and MISO are swapped
   When this bit is set, the function of MISO and MOSI pins alternate functions are inverted.
   Original MISO pin becomes MOSI and original MOSI pin becomes MISO.
   *Note:* This bit can be also used in PCM and I2S modes.

Bits 14:8 Reserved, must be kept at reset value.

Bits 7:4 **MIDI[3:0]:** master Inter-Data Idleness
   Specifies minimum time delay (expressed in SPI clock cycles periods) inserted between two consecutive data frames in master mode.
   0000: no delay
   0001: 1 clock cycle period delay
   ... 1111: 15 clock cycle periods delay
   *Note:* This feature is not supported in TI mode.

Bits 3:0 **MSSI[3:0]:** master SS idleness
   Specifies an extra delay, expressed in number of SPI clock cycle periods, inserted additionally between active edge of SS and first data transaction start in master mode when SSOE is enabled.
   0000: no extra delay
   0001: 1 clock cycle period delay added
   ... 1111: 15 clock cycle periods delay added
   *Note:* This feature is not supported in TI mode.
49.11.5 SPI/I2S interrupt enable register (SPI2S_IER)

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 TSERFIE: additional number of transactions reload interrupt enable
0: TSERF interrupt disabled
1: TSERF interrupt enabled

Bit 9 MODFIE: mode fault interrupt enable
0: MODF interrupt disabled
1: MODF interrupt enabled

Bit 8 TIFREIE: TIFRE interrupt enable
0: TIFRE interrupt disabled
1: TIFRE interrupt enabled

Bit 7 CRCEIE: CRC error interrupt enable
0: CRC interrupt disabled
1: CRC interrupt enabled

Bit 6 OVRIE: OVR interrupt enable
0: OVR interrupt disabled
1: OVR interrupt enabled

Bit 5 UDRIE: UDR interrupt enable
0: UDR interrupt disabled
1: UDR interrupt enabled

Bit 4 TXTFIE: TXTFIE interrupt enable
0: TXTF interrupt disabled
1: TXTF interrupt enabled

Bit 3 EOTIE: EOT, SUSP and TXC interrupt enable
0: EOT/SUSP/TXC interrupt disabled
1: EOT/SUSP/TXC interrupt enabled
Bit 2 **DXPIE**: DXP interrupt enabled
DXPIE is set by software and cleared by TXTF flag set event.
0: DXP interrupt disabled
1: DXP interrupt enabled

Bit 1 **TXPIE**: TXP interrupt enable
TXPIE is set by software and cleared by TXTF flag set event.
0: TXP interrupt disabled
1: TXP interrupt enabled

Bit 0 **RXPIE**: RXP Interrupt Enable
0: RXP interrupt disabled
1: RXP interrupt enabled

### 49.11.6 SPI/I2S status register (SPI2S_SR)

**Address offset**: 0x14

**Reset value**: 0x0000 1002

<table>
<thead>
<tr>
<th>Bit 31:16</th>
<th>CTSIZE[15:0]</th>
<th>Bit 15</th>
<th>RXWNE</th>
<th>RXPLVL[1:0]</th>
<th>TXC</th>
<th>SUSP</th>
<th>TSERF</th>
<th>MODF</th>
<th>TIFRE</th>
<th>CRCE</th>
<th>OVR</th>
<th>UDR</th>
<th>TXTF</th>
<th>EOT</th>
<th>DXP</th>
<th>TXP</th>
<th>RXP</th>
</tr>
</thead>
</table>
| Bits 31:16 | CTSIZE[15:0]: number of data frames remaining in current TSIZE session
The value is not quite reliable when traffic is ongoing on bus
| Bit 15 | RXWNE: RxFIFO word not empty
RxFIFO contains more than one 32-bit data
0: less than 32-bit data frame available in RxFIFO
1: at least one 32-bit data is available in the RxFIFO
| Bits 14:13 | RXPLVL[1:0]: RxFIFO packing level
Number of packed frames available in the last 32-bit word of the RxFIFO. This number of frames is read from the RxFIFO when RXWNE=0.
When frame size is smaller than or equal to 8-bit
00: the number of frames in RxFIFO is 0 or a multiple of 4.
01: 1 frame available when RXWNE=0
10: 2 frames available when RXWNE=0
11: 3 frames available when RXWNE=0
When the frame size is smaller than or equal to 16-bit, but larger than 8-bit, RXPLVL[1:0] can take the values 0 or 1.
00: the number of frames in RxFIFO is 0 or a multiple of 2.
01: the number of frame in RxFIFO is odd. One 16-bit data is available when RXWNE=0
Other values forbidden.
When the frame size is greater than 16-bit, these bits read as 00.
00: -
Other values forbidden. |
### Bit 12  **TXC**: TxFIFO transmission complete  
This flag is changed by hardware.
When TSIZE=0 the TXC raises each time the TxFIFO becomes empty and there is no activity on the bus.
If TSIZE <>0 the TXC raises at the end of transfer no matter on TxFIFO occupancy.
When this flag is set, master transmission is completed. The flag is not reliable to consider end of master reception.
When CRC mode is enabled, TXC is set only after the CRC transmission. TXC generates an interrupt when EOTIE is set.
0: Current data transaction is still ongoing, data is available in TxFIFO or last frame transmission is on going (including CRC).
1: Last TxFIFO or CRC frame transmission completed

### Bit 11  **SUSP**: suspend  
In Master mode, SUSP is set by hardware when a CSUSP request is done, as soon as the current frame is completed or at master automatic suspend receive mode (MASRX bit is set at SPI2S_CR1 register) on RxFIFO full condition.
SUSP generates an interrupt when EOTIE is set.
This bit is cleared by write 1 to SUSPC bit at SPI2S_IFCR
0: SPI not suspended (master mode active or other mode).
1: Master mode SUSPended (Current Frame completed)

### Bit 10  **TSERF**: additional number of SPI data to be transacted was reload  
This bit is cleared by write 1 to TSERFC bit at SPI2S_IFCR or by writing the TSER[15:0] (SPI_CR2) register
0: no acceptation
1: additional number of data accepted, current transaction continues

### Bit 9  **MODF**: mode fault  
0: no mode fault
1: mode fault detected
This bit is cleared by write 1 to MODFC bit at SPI2S_IFCR

### Bit 8  **TIFRE**: TI frame format error  
0: no TI Frame Error
1: TI Frame Error detected
This bit is cleared by write 1 to TIFREC bit at SPI2S_IFCR

### Bit 7  **CRCE**: CRC error  
0: no CRC error
1: CRC error detected
This bit is cleared by write 1 to CRCEC bit at SPI2S_IFCR

### Bit 6  **OVR**: overrun  
0: no overrun
1: overrun detected
This bit is cleared by write 1 to OVRC bit at SPI2S_IFCR

### Bit 5  **UDR**: underrun at slave transmission mode  
0: no underrun
1: underrun detected
This bit is cleared by write 1 to UDRC bit at SPI2S_IFCR

*Note: UDR flag applies to Slave mode only*
Bit 4  **TXTF**: transmission transfer filled  
0: upload of TxFIFO is on-going or not started  
1: TxFIFO upload is finished  
TXTF is set by hardware as soon as all of the data packets in a transfer have been submitted for transmission by application software or DMA, that is when TSIZE number of data have been pushed into the TxFIFO.  
This bit is cleared by software write 1 to TXTFC bit at SPI2S_IFCR  
TXTF flag triggers an interrupt if TXTFIE bit is set.  
TXTF setting clears the TXIE and DXPIE masks so to off-load application software from calculating when to disable TXP and DXP interrupts.

Bit 3  **EOT**: end of transfer  
EOT is set by hardware as soon as a full transfer is complete, that is when TSIZE number of data have been transmitted and/or received on the SPI. EOT is cleared by software write 1 to EOTC bit at SPI2S_IFCR.  
EOT flag triggers an interrupt if EOTIE bit is set.  
If DXP flag is used until TXTF flag is set and DXPIE is cleared, EOT can be used to download the last packets contained into RxFIFO in one-shot.  
0: transfer is on-going or not started  
1: transfer complete  
In master, EOT event terminates the data transaction and handles SS output optionally. In both master and slave, the event handles CRC transaction.

Bit 2  **DXP**: duplex packet  
0: TxFIFO is Full and/or RxFIFO is Empty  
1: Both TxFIFO has space for write and RxFIFO contains for read a single packet at least  
**DXP flag is set when both TXP and RXP flags are set.**

Bit 1  **TXP**: Tx-packet space available  
0: there is not enough space to locate next data packet at TxFIFO  
1: TxFIFO has enough free location to host 1 data packet  
TXP flag is changed by hardware. It monitors overall space currently available at TxFIFO if SPI is enabled. It has to be checked once a complete data packet is stored at TxFIFO.

Bit 0  **RXP**: Rx-packet available  
0: RxFIFO is empty or a not complete data packet is received  
1: RxFIFO contains at least 1 data packet  
RXP flag is changed by hardware. It monitors number of overall data currently available at RxFIFO if SPI is enabled. It has to be checked once a data packet is completely read out from RxFIFO.

49.11.7  **SPI/I2S interrupt/status flags clear register (SPI2S_IFCR)**

49.11.8 SPI/I2S transmit data register (SPI2S_TXDR)

Address offset: 0x20

Reset value: 0x0000 0000

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **SUSPC:** SUSPend flag clear
Writing a 1 into this bit clears SUSP flag in the SPI2S_SR register

Bit 10 **TSERFC:** TSERF flag clear
Writing a 1 into this bit clears TSERF flag in the SPI2S_SR register
Note: TSERF is also reset by writing the TSER[15:0] (SPI_CR2) register

Bit 9 **MODFC:** mode fault flag clear
Writing a 1 into this bit clears MODF flag in the SPI2S_SR register

Bit 8 **TIFREC:** TI frame format error flag clear
Writing a 1 into this bit clears TIFRE flag in the SPI2S_SR register

Bit 7 **CRCEC:** CRC error flag clear
Writing a 1 into this bit clears CRCE flag in the SPI2S_SR register

Bit 6 **OVRC:** overrun flag clear
Writing a 1 into this bit clears OVR flag in the SPI2S_SR register

Bit 5 **UDRC:** underrun flag clear
Writing a 1 into this bit clears UDR flag in the SPI2S_SR register

Bit 4 **TXTFC:** transmission Transfer Filled flag clear
Writing a 1 into this bit clears TXTF flag in the SPI2S_SR register

Bit 3 **EOTC:** end of transfer flag clear
Writing a 1 into this bit clears EOT flag in the SPI2S_SR register

Bits 2:0 Reserved, must be kept at reset value.

The register serves as an interface with TxFIFO. A write to it accesses TxFIFO.

Note: data is always right-aligned. Unused bits are ignored when writing to the register, and read as zero when the register is read.

Note: DR can be accessed byte-wise (8-bit access): in this case only one data-byte is written by single access.
halfword-wise (16 bit access) in this case 2 data-bytes or 1 halfword-data can be written by single access.
word-wise (32 bit access). In this case 4 data-bytes or 2 halfword-data or word-data can be written by single access.
49.11.9 SPI/I2S receive data register (SPI2S_RXDR)

TXCRC[31:16]

Bits 31:0 TXCRC[31:0]: CRC register for transmitter
When CRC calculation is enabled, the TXCRC[31:0] bits contain the computed CRC value of the subsequently transmitted bytes. CRC calculation is initialized when the CRCEN bit of SPI_CR1 is written to 1 or when a data block is transacted completely. The CRC is calculated serially using the polynomial programmed in the SPI_CRCPOLY register. The number of bits considered at calculation depends on SPI_CRCPOLY register and CRCSIZE bits settings at SPI_CFG1 register.

Note: A read to this register when the communication is ongoing could return an incorrect value.
Not used for the I²S mode.
Bits 31-16 are reserved at the peripheral instances with data size limited to 16-bit. There is no constrain when 32-bit access is applied at these addresses. Reserved bits 31-16 are always read zero while any write to them is ignored.

RXCRC[31:16]

RXCRC[15:0]
49.11.13 SPI underrun data register (SPI_UDRDR)

Address offset: 0x4C
Reset value: 0x0000 0000

Note: A read to this register when the communication is ongoing could return an incorrect value.

Not used for the I2S mode.

Bits 31-16 are reserved at the peripheral instances with data size limited to 16-bit.
There is no constrain when 32-bit access is applied at these addresses. Reserved bits 31-16 are always read zero while any write to them is ignored.

49.11.14 SPI/I2S configuration register (SPI_I2SCFGR)

Address offset: 0x50
Reset value: 0x0000 0000

Note: All documented bits in this register must be configured when the I2S is disabled (SPE = 0). These bits are not used in SPI mode except for I2SMOD which needs to be set to 0 in SPI mode.
Bits 31:26  Reserved, must be kept at reset value.

Bit 25  MCKOE: master clock output enable
0: Master clock output is disabled
1: Master clock output is enabled

Bit 24  ODD: odd factor for the prescaler
0: Real divider value is = I2SDIV * 2
1: Real divider value is = (I2SDIV * 2) + 1
Refer to Section 49.9.9: Clock generator for details

Bits 23:16  I2SDIV[7:0]: I2S linear prescaler
I2SDIV can take any values except the value 1, when ODD is also equal to 1.
Refer to Section 49.9.9: Clock generator for details

Bit 15  Reserved, must be kept at reset value.

Bit 14  DATFMT: data format
0: the data inside the SPI2S_RXDR or SPI2S_TXDR are right aligned
1: the data inside the SPI2S_RXDR or SPI2S_TXDR are left aligned.

Bit 13  WSINV: Word select inversion
This bit is used to invert the default polarity of WS signal.
0: in I2S Philips standard, Left channel is transfered when WS is low, and right channel when WS is high.
In MSB or LSB justified mode, Left channel is transfered when WS is high, and right channel when WS is low.
In PCM mode the start of frame is indicated by a rising edge.
1: in I2S Philips standard, Left channel is transfered when WS is high, and right channel when WS is low.
In MSB or LSB justified mode, Left channel is transfered when WS is low, and right channel when WS is high.
In PCM mode the start of frame is indicated by a falling edge.

Bit 12  FIXCH: fixed channel length in slave
0: the channel length in slave mode is different from 16 or 32 bits (CHLEN not taken into account)
1: the channel length in slave mode is supposed to be 16 or 32 bits (according to CHLEN)

Bit 11  CKPOL: serial audio clock polarity
0: the signals generated by the SPI/I2S (i.e. SDO and WS) are changed on the falling edge of CK
and the signals received by the SPI/I2S (i.e. SDI and WS) are read of the rising edge of CK.
1: the signals generated by the SPI/I2S (i.e. SDO and WS) are changed on the rising edge of CK
and the signals received by the SPI/I2S (i.e. SDI and WS) are read of the falling edge of CK.

Bit 10  CHLEN: channel length (number of bits per audio channel)
0: 16-bit wide
1: 32-bit wide
The bit write operation has a meaning only if DATLEN = 00 otherwise the channel length is fixed to
32-bit by hardware whatever the value filled in.

Bits 9:8  DATLEN[1:0]: data length to be transferred
00: 16-bit data length
01: 24-bit data length
10: 32-bit data length
11: not allowed
Bit 7 **PCMSYNC**: PCM frame synchronization
   0: short frame synchronization
   1: long frame synchronization

Bit 6 Reserved, must be kept at reset value.

Bits 5:4 **I2STD[1:0]**: I²S standard selection
   00: I²S Philips standard.
   01: MSB justified standard (left justified)
   10: LSB justified standard (right justified)
   11: PCM standard

For more details on I²S standards, refer to *Section 49.9.5: Supported audio protocols*

Bits 3:1 **I2SCFG[2:0]**: I²S configuration mode
   000: slave - transmit
   001: slave - receive
   010: master - transmit
   011: master - receive
   100: slave - full duplex
   101: master - full duplex
   others, not used

Bit 0 **I2SMOD**: I²S mode selection
   0: SPI mode is selected
   1: I²S/PCM mode is selected
# SPI register map and reset values

## Table 409. SPI register map and reset values

| Offset | Register name | Name | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|--------|---------------|------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|

Note: (1) Some registers are only present in the SPI2S configuration and are not available in the SPI configuration.
Refer to Section 2.3 on page 126 for the register boundary addresses.
50 **Serial audio interface (SAI)**

50.1 **Introduction**

The SAI interface (Serial Audio Interface) offers a wide set of audio protocols due to its flexibility and wide range of configurations. Many stereo or mono audio applications may be targeted. I2S standards, LSB or MSB-justified, PCM/DSP, TDM, and AC’97 protocols may be addressed for example. SPDIF output is offered when the audio block is configured as a transmitter.

To bring this level of flexibility and reconfigurability, the SAI contains two independent audio subblocks. Each block has its own clock generator and I/O line controller.

The SAI works in master or slave configuration. The audio subblocks are either receiver or transmitter and work synchronously or not (with respect to the other one).

The SAI can be connected with other SAIs to work synchronously.
50.2 **SAI main features**

- Two independent audio subblocks which can be transmitters or receivers with their respective FIFO.
- 8-word integrated FIFOs for each audio subblock.
- Synchronous or asynchronous mode between the audio subblocks.
- Possible synchronization between multiple SAIs.
- Master or slave configuration independent for both audio subblocks.
- Clock generator for each audio block to target independent audio frequency sampling when both audio subblocks are configured in master mode.
- Data size configurable: 8-, 10-, 16-, 20-, 24-, 32-bit.
- Audio protocol: I2S, LSB or MSB-justified, PCM/DSP, TDM, AC’97
- PDM interface, supporting up to 4 microphone pairs
- SPDIF output available if required.
- Up to 16 slots available with configurable size.
- Number of bits by frame can be configurable.
- Frame synchronization active level configurable (offset, bit length, level).
- First active bit position in the slot is configurable.
- LSB first or MSB first for data transfer.
- Mute mode.
- Stereo/Mono audio frame capability.
- Communication clock strobing edge configurable (SCK).
- Error flags with associated interrupts if enabled respectively.
  - Overrun and underrun detection,
  - Anticipated frame synchronization signal detection in slave mode,
  - Late frame synchronization signal detection in slave mode,
  - Codec not ready for the AC’97 mode in reception.
- Interruption sources when enabled:
  - Errors,
  - FIFO requests.
- 2-channel DMA interface.
50.3 SAI functional description

50.3.1 SAI block diagram

*Figure 643* shows the SAI block diagram while *Table 410* and *Table 411* list SAI internal and external signals.

The SAI is mainly composed of two audio subblocks with their own clock generator. Each audio block integrates a 32-bit shift register controlled by their own functional state machine. Data are stored or read from the dedicated FIFO. FIFO may be accessed by the CPU, or by DMA in order to leave the CPU free during the communication. Each audio block is independent. They can be synchronous with each other.

An I/O line controller manages a set of 4 dedicated pins (SD, SCK, FS, MCLK) for a given audio block in the SAI. Some of these pins can be shared if the two subblocks are declared as synchronous to leave some free to be used as general purpose I/Os. The MCLK pin can be output, or not, depending on the application, the decoder requirement and whether the audio block is configured as the master.

If one SAI is configured to operate synchronously with another one, even more I/Os can be freed (except for pins SD_ x).

The functional state machine can be configured to address a wide range of audio protocols. Some registers are present to set-up the desired protocols (audio frame waveform generator).
The audio subblock can be a transmitter or receiver, in master or slave mode. The master mode means the SCK\_x bit clock and the frame synchronization signal are generated from the SAI, whereas in slave mode, they come from another external or internal master. There is a particular case for which the FS signal direction is not directly linked to the master or slave mode definition. In AC’97 protocol, it will be an SAI output even if the SAI (link controller) is set-up to consume the SCK clock (and so to be in Slave mode).

Note: For ease of reading of this section, the notation SAI\_x refers to SAI\_A or SAI\_B, where ‘x’ represents the SAI A or B subblock.

50.3.3 Main SAI modes

Each audio subblock of the SAI can be configured to be master or slave via MODE bits in the SAI\_xCR1 register of the selected audio block.

Master mode

In master mode, the SAI delivers the timing signals to the external connected device:

- The bit clock and the frame synchronization are output on pin SCK\_x and FS\_x, respectively.
- If needed, the SAI can also generate a master clock on MCLK\_x pin.
Both SCK\_x, FS\_x and MCLK\_x are configured as outputs.

**Slave mode**

The SAI expects to receive timing signals from an external device.
- If the SAI subblock is configured in asynchronous mode, then SCK\_x and FS\_x pins are configured as inputs.
- If the SAI subblock is configured to operate synchronously with another SAI interface or with the second audio subblock, the corresponding SCK\_x and FS\_x pins are left free to be used as general purpose I/Os.

In slave mode, MCLK\_x pin is not used and can be assigned to another function.

It is recommended to enable the slave device before enabling the master.

**Configuring and enabling SAI modes**

Each audio subblock can be independently defined as a transmitter or receiver through the MODE bit in the SAI\_xCR1 register of the corresponding audio block. As a result, SAI\_SD\_x pin will be respectively configured as an output or an input.

Two master audio blocks in the same SAI can be configured with two different MCLK and SCK clock frequencies. In this case they have to be configured in asynchronous mode.

Each of the audio blocks in the SAI are enabled by SAIEN bit in the SAI\_xCR1 register. As soon as this bit is active, the transmitter or the receiver is sensitive to the activity on the clock line, data line and synchronization line in slave mode.

In master TX mode, enabling the audio block immediately generates the bit clock for the external slaves even if there is no data in the FIFO. However FS signal generation is conditioned by the presence of data in the FIFO. After the FIFO receives the first data to transmit, this data is output to external slaves. If there is no data to transmit in the FIFO, 0 values are then sent in the audio frame with an underrun flag generation.

In slave mode, the audio frame starts when the audio block is enabled and when a start of frame is detected.

In Slave TX mode, no underrun event is possible on the first frame after the audio block is enabled, because the mandatory operating sequence in this case is:
1. Write into the SAI\_xDR (by software or by DMA).
2. Wait until the FIFO threshold (FLH) flag is different from 0b000 (FIFO empty).
3. Enable the audio block in slave transmitter mode.

**50.3.4 SAI synchronization mode**

There are two levels of synchronization, either at audio subblock level or at SAI level.

**Internal synchronization**

An audio subblock can be configured to operate synchronously with the second audio subblock in the same SAI. In this case, the bit clock and the frame synchronization signals are shared to reduce the number of external pins used for the communication. The audio block configured in synchronous mode sees its own SCK\_x, FS\_x, and MCLK\_x pins released back as GPIOs while the audio block configured in asynchronous mode is the one for which FS\_x and SCK\_x ad MCLK\_x I/O pins are relevant (if the audio block is considered as master).
Typically, the audio block in synchronous mode can be used to configure the SAI in full
duplex mode. One of the two audio blocks can be configured as a master and the other as
slave, or both as slaves with one asynchronous block (corresponding SYNCEN[1:0] bits set
to 00 in SAI_xCR1) and one synchronous block (corresponding SYNCEN[1:0] bits set to 01
in the SAI_xCR1).

Note: Due to internal resynchronization stages, PCLK APB frequency must be higher than twice
the bit rate clock frequency.

External synchronization

The audio subblocks can also be configured to operate synchronously with another SAI.
This can be done as follow:

1. The SAI, which is configured as the source from which the other SAI is synchronized,
   has to define which of its audio subblock is supposed to provide the FS and SCK
   signals to other SAI. This is done by programming SYNCOUT[1:0] bits.

2. The SAI which shall receive the synchronization signals has to select which SAI will
   provide the synchronization by setting the proper value on SYNCIN[1:0] bits. For each
   of the two SAI audio subblocks, the user must then specify if it operates synchronously
   with the other SAI via the SYNCEN bit.

Note: SYNCIN[1:0] and SYNCOUT[1:0] bits are located into the SAI_GCR register, and SYNCEN
bits into SAI_xCR1 register.

If both audio subblocks in a given SAI need to be synchronized with another SAI, it is
possible to choose one of the following configurations:

- Configure each audio block to be synchronous with another SAI block through the
  SYNCEN[1:0] bits.
- Configure one audio block to be synchronous with another SAI through the
  SYNCEN[1:0] bits. The other audio block is then configured as synchronous with the
  second SAI audio block through SYNCEN[1:0] bits.

The following table shows how to select the proper synchronization signal depending on the
SAI block used. For example SAI2 can select the synchronization from SAI1 by setting SAI2
SYNCIN to 0. If SAI1 wants to select the synchronization coming from SAI2, SAI1 SYNCIN
must be set to 1. Positions noted as ‘Res.’ shall not be used.

50.3.5 Audio data size

The audio frame can target different data sizes by configuring bit DS[2:0] in the SAI_xCR1
register. The data sizes may be 8, 10, 16, 20, 24 or 32 bits. During the transfer, either the
MSB or the LSB of the data are sent first, depending on the configuration of bit LSBFIRST in
the SAI_xCR1 register.
50.3.6 Frame synchronization

The FS signal acts as the Frame synchronization signal in the audio frame (start of frame). The shape of this signal is completely configurable in order to target the different audio protocols with their own specificities concerning this Frame synchronization behavior. This reconfigurability is done using register SAI_xFRCR. Figure 644 illustrates this flexibility.

**Figure 644. Audio frame**

In AC’97 mode or in SPDIF mode (bit PRTCFG[1:0] = 10 or PRTCFG[1:0] = 01 in the SAI_xCR1 register), the frame synchronization shape is forced to match the AC’97 protocol. The SAI_xFRCR register value is ignored.

Each audio block is independent and consequently each one requires a specific configuration.

**Frame length**

- **Master mode**
  
The audio frame length can be configured to up to 256 bit clock cycles, by setting FRL[7:0] field in the SAI_xFRCR register.

  If the frame length is greater than the number of declared slots for the frame, the remaining bits to transmit will be extended to 0 or the SD line will be released to HI-z depending the state of bit TRIS in the SAI_xCR2 register (refer to FS signal role). In reception mode, the remaining bit is ignored.

  If bit NOMCK is cleared, (FRL+1) must be equal to a power of 2, from 8 to 256, to ensure that an audio frame contains an integer number of MCLK pulses per bit clock cycle.

  If bit NOMCK is set, the (FRL+1) field can take any value from 8 to 256. Refer to Section 50.3.8: SAI clock generator.

- **Slave mode**
  
The audio frame length is mainly used to specify to the slave the number of bit clock cycles per audio frame sent by the external master. It is used mainly to detect from the master any anticipated or late occurrence of the Frame synchronization signal during an on-going audio frame. In this case an error will be generated. For more details refer to Section 50.3.14: Error flags.

  In slave mode, there are no constraints on the FRL[7:0] configuration in the SAI_xFRCR register.

  The number of bits in the frame is equal to FRL[7:0] + 1.
The minimum number of bits to transfer in an audio frame is 8.

**Frame synchronization polarity**

FSPOL bit in the SAI_xFRCR register sets the active polarity of the FS pin from which a frame is started. The start of frame is edge sensitive.

In slave mode, the audio block waits for a valid frame to start transmitting or receiving. Start of frame is synchronized to this signal. It is effective only if the start of frame is not detected during an ongoing communication and assimilated to an anticipated start of frame (refer to Section 50.3.14: Error flags).

In master mode, the frame synchronization is sent continuously each time an audio frame is complete until the SAIEN bit in the SAI_xCR1 register is cleared. If no data are present in the FIFO at the end of the previous audio frame, an underrun condition will be managed as described in Section 50.3.14: Error flags, but the audio communication flow will not be interrupted.

**Frame synchronization active level length**

The FSALL[6:0] bits of the SAI_xFRCR register allow configuring the length of the active level of the Frame synchronization signal. The length can be set from 1 to 128 bit clock cycles.

As an example, the active length can be half of the frame length in I2S, LSB or MSB-justified modes, or one-bit wide for PCM/DSP or TDM.

**Frame synchronization offset**

Depending on the audio protocol targeted in the application, the Frame synchronization signal can be asserted when transmitting the last bit or the first bit of the audio frame (this is the case in I2S standard protocol and in MSB-justified protocol, respectively). FSOFF bit in the SAI_xFRCR register allows to choose one of the two configurations.

**FS signal role**

The FS signal can have a different meaning depending on the FS function. FSDEF bit in the SAI_xFRCR register selects which meaning it will have:

- 0: start of frame, like for instance the PCM/DSP, TDM, AC’97, audio protocols,
- 1: start of frame and channel side identification within the audio frame like for the I2S, the MSB or LSB-justified protocols.

When the FS signal is considered as a start of frame and channel side identification within the frame, the number of declared slots must be considered to be half the number for the left channel and half the number for the right channel. If the number of bit clock cycles on half audio frame is greater than the number of slots dedicated to a channel side, and TRIS = 0, 0 is sent for transmission for the remaining bit clock cycles in the SAI_xCR2 register. Otherwise if TRIS = 1, the SD line is released to HI-Z. In reception mode, the remaining bit clock cycles are not considered until the channel side changes.
Figure 645. FS role is start of frame + channel side identification (FSDEF = TRIS = 1)

1. The frame length should be even.

If FSDEF bit in SAI_xFRCR is kept clear, so FS signal is equivalent to a start of frame, and if the number of slots defined in NBSLOT[3:0] in SAI_xSLOTR multiplied by the number of bits by slot configured in SLOTSZ[1:0] in SAI_xSLOTR is less than the frame size (bit FRL[7:0] in the SAI_xFRCR register), then:

- if TRIS = 0 in the SAI_xCR2 register, the remaining bit after the last slot will be forced to 0 until the end of frame in case of transmitter,
- if TRIS = 1, the line will be released to HI-Z during the transfer of these remaining bits. In reception mode, these bits are discarded.
The FS signal is not used when the audio block in transmitter mode is configured to get the SPDIF output on the SD line. The corresponding FS I/O will be released and left free for other purposes.

50.3.7 Slot configuration

The slot is the basic element in the audio frame. The number of slots in the audio frame is equal to NBSLOT[3:0] + 1.

The maximum number of slots per audio frame is fixed at 16.

For AC'97 protocol or SPDIF (when bit PRTCFG[1:0] = 10 or PRTCFG[1:0] = 01), the number of slots is automatically set to target the protocol specification, and the value of NBSLOT[3:0] is ignored.

Each slot can be defined as a valid slot, or not, by setting SLOTEN[15:0] bits of the SAI_xSLOTR register.

When an invalid slot is transferred, the SD data line is either forced to 0 or released to HI-z depending on TRIS bit configuration (refer to Output data line management on an inactive slot) in transmitter mode. In receiver mode, the received value from the end of this slot is ignored. Consequently, there will be no FIFO access and so no request to read or write the FIFO linked to this inactive slot status.

The slot size is also configurable as shown in Figure 647. The size of the slots is selected by setting SLOTSZ[1:0] bits in the SAI_xSLOTR register. The size is applied identically for each slot in an audio frame.
It is possible to choose the position of the first data bit to transfer within the slots. This offset is configured by FBOFF[4:0] bits in the SAI_xSLOTR register. 0 values will be injected in transmitter mode from the beginning of the slot until this offset position is reached. In reception, the bit in the offset phase is ignored. This feature targets the LSB justified protocol (if the offset is equal to the slot size minus the data size).

It is mandatory to respect the following conditions to avoid bad SAI behavior:

1. \( \text{FBOFF} \leq (\text{SLOTSZ} - \text{DS}) \),
2. \( \text{DS} \leq \text{SLOTSZ} \),
3. \( \text{NBSLOT} \times \text{SLOTSZ} \leq \text{FRL} \) (frame length).

The number of slots must be even when bit FSDEF in the SAI_xFRCR register is set.

In AC’97 and SPDIF protocol (bit PRTCFG[1:0] = 10 or PRTCFG[1:0] = 01), the slot size is automatically set as defined in Section 50.3.11: AC’97 link controller.
50.3.8 SAI clock generator

Each audio subblock has its own clock generator that makes these two blocks completely independent. There is no difference in terms of functionality between these two clock generators.

When the audio block is configured as master, the clock generator provides the bit clock (SCK_x) and the master clock (MCLK_x) for external decoders. The frame synchronization (FS_x) is also derived from the signals provided by the clock generator. The clock source for the SAI clock generator (sai_x_ker_ck) is delivered by the product clock controller (RCC).

When the audio block is defined as slave, the clock generator is OFF. The value of NOMCK, MCKDIV and OSR bits are ignored. In addition, MCLK_x I/O pin is released and can be used as a general purpose I/O.

The bit clock strobing edge of (SCK_x) can be configured through CKSTR bit in the SAI_xCR1 register. This bit is functional in master and slave mode.

*Figure 649* illustrates the architecture of the audio block clock generator.

The NOMCK bit of the SAI_xCR1 register is used to define whether the master clock is generated or not.

When the SAI is used in master mode, the clock generator configuration differs depending on whether a master clock (MCLK_x) needs to be provided or not.

If NOMCK is set to 1, the master clock is not generated, and the user has more flexibility to select the frame length and frame synchronization frequency. In addition, MCLK_x signal is driven Low if this pin is configured as the SAI pin in GPIO peripherals. MCKDIV can still be used to adjust the SCK_x clock to the required frequency.

If NOMCK is set to 0, the master clock is generated, and can be used as reference clock for external decoders. In this case, the frequency ratio between the frame synchronization and the master clock is fixed to 512 or 256, and the frame length must be a power of 2. More details are given hereafter.
Clock generator programming with MCLK (NOMCK = 0)
In that case, MCLK\_x frequency will be:

\[ F_{MCLK\_x} = 256 \times F_{FS\_x} \text{ if } OSR=0 \]

\[ F_{MCLK\_x} = 512 \times F_{FS\_x} \text{ if } OSR=1 \]

When MCKDIV is different from 0, MCLK\_x frequency is given by the equation below:

\[ F_{MCLK\_x} = \frac{F_{sai\_x\_ker\_ck}}{MCKDIV} \]

The frame synchronization frequency is given by:

\[ F_{FS\_x} = \frac{F_{sai\_x\_ker\_ck}}{MCKDIV \times (OSR + 1) \times 256} \]

The frequency of the bit clock (SCK\_x) is given by the following expression:

\[ F_{SCK\_x} = \frac{F_{MCLK\_x \times (FRL + 1)}}{(OSR + 1) \times 256} \]

**Note:**

If NOMCK = 0, (FRL+1) must be a power of two. In addition (FRL+1) must be between 8 and 256 (see Section : FS signal role).

When MCKDIV division ratio is odd, the duty cycle of MCLK will not be 50%. The bit clock signal (SCK\_x) can also have a duty cycle different from 50% if MCKDIV is odd, and if OSR is equal to 0, and if \((FRL+1) = 2^8\).

It is recommended to configure MCKDIV to an even or big values (higher than 10).

Note that MCKDIV = 0 gives the same result as MCKDIV = 1.

Clock generator programming without MCLK (NOMCK = 1)
When MCKDIV is different from 0, SCK\_x frequency is given in the equation below:

\[ F_{SCK\_x} = \frac{F_{sai\_x\_ker\_ck}}{MCKDIV} \]

The frequency of the frame synchronization (FS\_x) is given by the following equation:

\[ F_{FS\_x} = \frac{F_{sai\_x\_ker\_ck}}{(FRL + 1) \times MCKDIV} \]

**Note:**

When NOMCK = 0, (FRL+1) can take any values from 8 to 256.

Note that MCKDIV = 0 gives the same result as MCKDIV = 1.

1. N is an integer value between 3 and 8.

### 50.3.9 Internal FIFOs

Each audio block in the SAI has its own FIFO. Depending if the block is defined to be a transmitter or a receiver, the FIFO can be written or read, respectively. There is therefore only one FIFO request linked to FREQ bit in the SAI_xSR register.

An interrupt is generated if FREQIE bit is enabled in the SAI_xIM register. This depends on:

- FIFO threshold setting (FLVL bits in SAI_xCR2)
- Communication direction (transmitter or receiver). Refer to *Interrupt generation in transmitter mode* and *Interrupt generation in reception mode*.

#### Interrupt generation in transmitter mode

The interrupt generation depends on the FIFO configuration in transmitter mode:

- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO empty (FTH[2:0] set to 0b000), an interrupt is generated (FREQ bit set by hardware to 1 in SAI_xSR register) if no data are available in SAI_xDR register (FLVL[2:0] bits in SAI_xSR is less than 001b). This Interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when the FIFO is no more empty (FLVL[2:0] bits in SAI_xSR are different from 0b000) i.e one or more data are stored in the FIFO.

- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO quarter full (FTH[2:0] set to 001b), an interrupt is generated (FREQ bit set by hardware to 1 in SAI_xSR register) if less than a quarter of the FIFO contains data (FLVL[2:0] bits in SAI_xSR are less than 0b010). This Interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when at least a quarter of the FIFO contains data (FLVL[2:0] bits in SAI_xSR are higher or equal to 0b010).

- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO half full (FTH[2:0] set to 0b010), an interrupt is generated (FREQ bit set by hardware to 1 in
Serial audio interface (SAI) RM0433

SAI_xSR register) if less than half of the FIFO contains data (FLVL[2:0] bits in SAI_xSR are less than 011b). This Interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when at least half of the FIFO contains data (FLVL[2:0] bits in SAI_xSR are higher or equal to 011b).

- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO three quarter (FTH[2:0] set to 011b), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI_xSR register) if less than three quarters of the FIFO contain data (FLVL[2:0] bits in SAI_xSR are less than 0b100). This Interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when at least three quarters of the FIFO contain data (FLVL[2:0] bits in SAI_xSR are higher or equal to 0b100).

- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO full (FTH[2:0] set to 0b100), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI_xSR register) if the FIFO is not full (FLVL[2:0] bits in SAI_xSR is less than 101b). This Interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when the FIFO is full (FLVL[2:0] bits in SAI_xSR is equal to 101b value).

Interrupt generation in reception mode

The interrupt generation depends on the FIFO configuration in reception mode:

- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO empty (FTH[2:0] set to 0b000), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI_xSR register) if at least one data is available in SAI_xDR register (FLVL[2:0] bits in SAI_xSR is higher or equal to 001b). This Interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when the FIFO becomes empty (FLVL[2:0] bits in SAI_xSR is equal to 0b000) i.e no data are stored in FIFO.

- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO quarter fully (FTH[2:0] set to 001b), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI_xSR register) if at least one quarter of the FIFO data locations are available (FLVL[2:0] bits in SAI_xSR is higher or equal to 0b010). This Interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when less than a quarter of the FIFO data locations become available (FLVL[2:0] bits in SAI_xSR is less than 0b010).

- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO half fully (FTH[2:0] set to 0010 value), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI_xSR register) if at least half of the FIFO data locations are available (FLVL[2:0] bits in SAI_xSR is higher or equal to 011b). This Interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when less than half of the FIFO data locations become available (FLVL[2:0] bits in SAI_xSR is less than 011b).

- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO three quarter full (FTH[2:0] set to 011b value), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI_xSR register) if at least three quarters of the FIFO data locations are available (FLVL[2:0] bits in SAI_xSR is higher or equal to 0b100). This Interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when the FIFO has less than three quarters of the FIFO data locations available (FLVL[2:0] bits in SAI_xSR is less than 0b100).

- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO full (FTH[2:0] set to 0b100), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI_xSR register) if the FIFO is full (FLVL[2:0] bits in SAI_xSR is equal to 101b). This Interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when the FIFO is not full (FLVL[2:0] bits in SAI_xSR is less than 101b).
Like interrupt generation, the SAI can use the DMA if DMAEN bit in the SAI_xCR1 register is set. The FREQ bit assertion mechanism is the same as the interruption generation mechanism described above for FREQIE.

Each FIFO is an 8-word FIFO. Each read or write operation from/to the FIFO targets one word FIFO location whatever the access size. Each FIFO word contains one audio slot. FIFO pointers are incremented by one word after each access to the SAI_xDR register.

Data should be right aligned when it is written in the SAI_xDR.

Data received will be right aligned in the SAI_xDR.

The FIFO pointers can be reinitialized when the SAI is disabled by setting bit FFLUSH in the SAI_xCR2 register. If FFLUSH is set when the SAI is enabled the data present in the FIFO will be lost automatically.

### 50.3.10 PDM Interface

The PDM (Pulse Density Modulation) interface is provided in order to support digital microphones. Up to 4 digital microphone pairs can be connected in parallel. Figure 650 shows a typical connection of a digital microphone pair via a PDM interface. Both microphones share the same bitstream clock and data line. Thanks to a configuration pin (LR), a microphone can provide valid data on SAI_CK[m] rising edge while the other provides valid data on SAI_CK[m] falling edge (m being the number of clock lines).

The PDM function is intended to be used in conjunction with SAI_A subblock configured in TDM master mode. It cannot be used with SAI_B subblock. The PDM interface uses the timing signals provided by the TDM interface of SAI_A and adapts them to generate a bitstream clock (SAI_CK[m]).

1. $n$ refers to the number of data lines and $p$ to the number of microphone pairs.
The data processing sequence into the PDM is the following:

1. The PDM interface builds the bitstream clock from the bit clock received from the TDM interface of SAI_A.
2. The bitstream data received from the microphones (SAI_D[n]) are de-interleaved and go through a 7-bit delay line in order to fine-tune the delay of each microphone with the accuracy of the bitstream clock.
3. The shift registers translate each serial bitstream into bytes.
4. The last operation consists in shifting-out the resulting bytes to SAI_A via the serial data line of the TDM interface.

Figure 651 hereafter shows the block diagram of PDM interface, with a detailed view of a de-interleaver.

Note: The PDM interface does not embed the decimation filter required to build-up the PCM audio samples from the bitstream. It is up to the application software to perform this operation.

1. \( n \) refers to the number of data lines and \( p \) to the number of microphone pairs.

The PDM interface can be enabled through the PDMEN bit in SAI_PDMCR register. However the PDM interface must be enabled prior to enabling SAI_A block.

To reduce the memory footprint, the user can select the amount of microphones the application needs. This can be done through MICNBR[1:0] bits. It is possible to select between 2, 4, 6 or 8 microphones. For example, if the application is using 3 microphones, the user has to select 4.
Enabling the PDM interface

To enable the PDM interface, follow the sequence below:

1. Configure SAI_A in TDM master mode (see Table 414).
2. Configure the PDM interface as follows:
   a) Define the number of digital microphones via MICNBR.
   b) Enable the bitstream clock needed in the application by setting the corresponding bits on CKEN to 1.
3. Enable the PDM interface, via PDMEN bit.
4. Enable the SAI_A.

Note: Once the PDM interface and SAI_A are enabled, the first 2 TDMA frames received on SAI_ADR are invalid and shall be dropped.

Start-up sequence

Figure 652 shows the start-up sequence: Once the PDM interface is enabled, it waits for the frame synchronization event prior to starting the acquisition of the microphone samples. After 8 SAI_CK clock periods, a data byte coming from each microphone is available, and transferred to the SAI, via the TDM interface.

Figure 652. Start-up sequence

SAI_ADR data format

The arrangement of the data coming from the microphone into the SAI_ADR register depends on the following parameters:

- The amount of microphones
- The slot width selected
- LSBFIRST bit.

The slot width defines the amount of significant bits into each word available into the SAI_ADR.

When a slot width of 32 bits is selected, each data available into the SAI_ADR will contain 32 useful bits. This reduces the amount of words stored into the memory. However the
counterpart is that the software has to perform some operations to de-interleave the data of each microphone.

In the other hand, when the slot width is set to 8 bits, each data available into the SAI_ADR will contain 8 useful bits. This increases the amount of words stored into the memory. However, it offers the advantage to avoid extra processing since each word contains information from one microphone.

**SAI_ADR data format example**

- **32-bit slot width** (DS = 0b111 and SLOTSZ = 0). Refer to *Figure 653*.
  
  For an 8 microphone configuration, two consecutive words read from the SAI_ADR register contain a data byte from each microphone.

  For a 4 microphones configuration, each word read from the SAI_ADR register contains a data byte from each microphone.

  *Figure 653. SAI_ADR format in TDM, 32-bit slot width*

- **16-bit slot width** (DS = 0b100 and SLOTSZ = 0). Refer to *Figure 654*.
  
  For an 8 microphone configuration, four consecutive words read from the SAI_ADR register contain a data byte from each microphone. Note that the 16-bit data of SAI_ADR are right aligned.

  For 4 or 2 microphone configuration, the SAI behavior is similar to 8-microphone configurations. Up to 2 words of 16 bits are required to acquire a byte from 4 microphones and a single word for 2 microphones.
**Figure 654. SAI_ADR format in TDM, 16-bit slot width**

- **Using a 8-bit slot width** (DS = 0b010 and SLOTSZ = 0). Refer to *Figure 655.*
  For an 8 microphone configuration, 8 consecutive words read from the SAI_ADR register contain a byte of data from each microphone. Note that the 8-bit data of SAI_ADR are right aligned.

For 4 or 2 microphone configuration, the SAI behavior is similar to 8 microphone configurations. Up to 4 words of 8 bits are required to acquire a byte from 4 microphones and 2 words from 2 microphones.
TDM configuration for PDM interface

SAI_A TDM interface is internally connected to the PDM interface to get the microphone samples. The user application must configure the PDM interface as shown in Table 414 to ensure a good connection with the PDM interface.

Adjusting the bitstream clock rate

To properly program the SAI TDM interface, the user application must take into account the settings given in Table 414, and follow the below rules:

1. Adjust the bit clock frequency (F_{SCK_A}) according to the required frequency for the PDM bitstream clock, using the following formula:

\[ F_{SCK_A} = F_{PDM_{CK}} \times (MICNBR + 1) \times 2 \]

MICNBR can be 0, 1, 2 or 3 (0 = 2 microphones, see Section 50.5.18)

2. Set the frame length (FRL) using the following formula

\[ FRL = (16 \times (MICNBR + 1)) - 1 \]

3. Configure the slot size (DS) to a multiple of (FRL+1).

Adjusting the delay lines

When the PDM interface is enabled, the application can adjust on-the-fly the delay cells of each microphone input via SAI_PDMDLY register.

The new delays values will become effective after two TDM frames.

---

1. Refer to Table 414: TDM settings for additional information on TDM configuration. The sai_a_ker_ck clock frequency provided to the SAI should be a multiple of the SCK_A frequency, and MCKDIV should be programmed accordingly.

2. The table above gives allowed settings for a decimation ratio of 64.
50.3.11 AC’97 link controller

The SAI is able to work as an AC’97 link controller. In this protocol:

- The slot number and the slot size are fixed.
- The frame synchronization signal is perfectly defined and has a fixed shape.

To select this protocol, set PRTCFG[1:0] bits in the SAI_xCR1 register to 10. When AC’97 mode is selected, only data sizes of 16 or 20 bits can be used, otherwise the SAI behavior is not guaranteed.

- NBSLOT[3:0] and SLOTSZ[1:0] bits are consequently ignored.
- The number of slots is fixed to 13 slots. The first one is 16-bit wide and all the others are 20-bit wide (data slots).
- FBOFF[4:0] bits in the SAI_xSLOTR register are ignored.
- The SAI_xFRCR register is ignored.
- The MCLK is not used.

The FS signal from the block defined as asynchronous is configured automatically as an output, since the AC’97 controller link drives the FS signal whatever the master or slave configuration.

*Figure 656* shows an AC’97 audio frame structure.

*Figure 656. AC’97 audio frame*

Note: In AC’97 protocol, bit 2 of the tag is reserved (always 0), so bit 2 of the TAG is forced to 0 level whatever the value written in the SAI FIFO.

For more details about tag representation, refer to the AC’97 protocol standard.

One SAI can be used to target an AC’97 point-to-point communication.

Using two SAIs (for devices featuring two embedded SAIs) allows controlling three external AC’97 decoders as illustrated in *Figure 657*.

In SAI1, the audio block A must be declared as asynchronous master transmitter whereas the audio block B is defined to be slave receiver and internally synchronous to the audio block A.

The SAI2 is configured for audio block A and B both synchronous with the external SAI1 in slave receiver mode.
In receiver mode, the SAI acting as an AC’97 link controller requires no FIFO request and so no data storage in the FIFO when the Codec ready bit in the slot 0 is decoded low. If bit CNRDYIE is enabled in the SAI_xIM register, flag CNRDY will be set in the SAI_xSR register and an interrupt is generated. This flag is dedicated to the AC’97 protocol.

Clock generator programming in AC’97 mode

In AC’97 mode, the frame length is fixed at 256 bits, and its frequency shall be set to 48 kHz. The formulas given in Section 50.3.8: SAI clock generator shall be used with FRL = 255, in order to generate the proper frame rate ($F_{FS\_x}$).
50.3.12 **SPDIF output**

The SPDIF interface is available in transmitter mode only. It supports the audio IEC60958. To select SPDIF mode, set PRTCFG[1:0] bit to 01 in the SAI_xCR1 register.

For SPDIF protocol:

- Only SD data line is enabled.
- FS, SCK, MCLK I/Os pins are left free.
- MODE[1] bit is forced to 0 to select the master mode in order to enable the clock generator of the SAI and manage the data rate on the SD line.
- The data size is forced to 24 bits. The value set in DS[2:0] bits in the SAI_xCR1 register is ignored.
- The clock generator must be configured to define the symbol-rate, knowing that the bit clock should be twice the symbol-rate. The data is coded in Manchester protocol.
- The SAI_xFRCR and SAI_xSLOTR registers are ignored. The SAI is configured internally to match the SPDIF protocol requirements as shown in **Figure 658**.

**Figure 658. SPDIF format**

A SPDIF block contains 192 frames. Each frame is composed of two 32-bit sub-frames, generally one for the left channel and one for the right channel. Each sub-frame is composed of a SOPD pattern (4-bit) to specify if the sub-frame is the start of a block (and so is identifying a channel A) or if it is identifying a channel A somewhere in the block, or if it is referring to channel B (see **Table 416**). The next 28 bits of channel information are composed of 24 bits data + 4 status bits.
The data stored in SAI_xDR has to be filled as follows:

- SAI_xDR[26:24] contain the Channel status, User and Validity bits.
- SAI_xDR[23:0] contain the 24-bit data for the considered channel.

If the data size is 20 bits, then data shall be mapped on SAI_xDR[23:4].
If the data size is 16 bits, then data shall be mapped on SAI_xDR[23:8].
SAI_xDR[23] always represents the MSB.

**Table 416. SOPD pattern**

<table>
<thead>
<tr>

<td>11100100</td>
<td>00011011</td>
</tr>
<tr>
<td>M</td>
<td>11100010</td>
<td>00011101</td>
</tr>
</tbody>
</table>

**Figure 659. SAI_xDR register ordering**

Note: The transfer is performed always with LSB first.

The SAI first sends the adequate preamble for each sub-frame in a block. The SAI_xDR is then sent on the SD line (manchester coded). The SAI ends the sub-frame by transferring the Parity bit calculated as described in **Table 417**.

**Table 417. Parity bit calculation**

<table>
<thead>
<tr>

</thead>
<tbody>
<tr>
<td>odd number of 0</td>
<td>0</td>
</tr>
<tr>
<td>odd number of 1</td>
<td>1</td>
</tr>
</tbody>
</table>

The underrun is the only error flag available in the SAI_xSR register for SPDIF mode since the SAI can only operate in transmitter mode. As a result, the following sequence should be
executed to recover from an underrun error detected via the underrun interrupt or the underrun status bit:
1. Disable the DMA stream (via the DMA peripheral) if the DMA is used.
2. Disable the SAI and check that the peripheral is physically disabled by polling the SAIEN bit in SAI_xCR1 register.
3. Clear the COVRUNDR flag in the SAI_xCLRFR register.
4. Flush the FIFO by setting the FFLUSH bit in SAI_xCR2.
   The software needs to point to the address of the future data corresponding to a start of new block (data for preamble B). If the DMA is used, the DMA source base address pointer should be updated accordingly.
5. Enable again the DMA stream (DMA peripheral) if the DMA used to manage data transfers according to the new source base address.
6. Enable again the SAI by setting SAIEN bit in SAI_xCR1 register.

Clock generator programming in SPDIF generator mode

For the SPDIF generator, the SAI shall provide a bit clock twice faster as the symbol-rate. The table hereafter shows usual examples of symbol rates with respect to the audio sampling rate.

<table>
<thead>
<tr>
<th>Audio Sampling Frequencies ((F_S))</th>
<th>Symbol-rate</th>
</tr>
</thead>
<tbody>
<tr>
<td>44.1 kHz</td>
<td>2.8224 MHz</td>
</tr>
<tr>
<td>48 kHz</td>
<td>3.072 MHz</td>
</tr>
<tr>
<td>96 kHz</td>
<td>6.144 MHz</td>
</tr>
<tr>
<td>192 kHz</td>
<td>12.288 MHz</td>
</tr>
</tbody>
</table>

More generally, the relationship between the audio sampling frequency (\(F_S\)) and the bit clock rate (\(F_{SCK,x}\)) is given by the formula:

\[
F_S = \frac{F_{SCK,x}}{128}
\]

The bit clock rate is obtained as follows:

\[
F_{SCK,x} = \frac{F_{SAI\_CK\_x}}{MCKDIV}
\]

Note: The above formulas are valid only if NOMCK is set to 1 in SAI_ACR1 register.
50.3.13 Specific features

The SAI interface embeds specific features which can be useful depending on the audio protocol selected. These functions are accessible through specific bits of the SAI_xCR2 register.

Mute mode

The mute mode can be used when the audio subblock is a transmitter or a receiver.

Audio subblock in transmission mode

In transmitter mode, the mute mode can be selected at anytime. The mute mode is active for entire audio frames. The MUTE bit in the SAI_xCR2 register enables the mute mode when it is set during an ongoing frame.

The mute mode bit is strobed only at the end of the frame. If it is set at this time, the mute mode is active at the beginning of the new audio frame and for a complete frame, until the next end of frame. The bit is then strobed to determine if the next frame will still be a mute frame.

If the number of slots set through NBSLOT[3:0] bits in the SAI_xSLOTR register is lower than or equal to 2, it is possible to specify if the value sent in mute mode is 0 or if it is the last value of each slot. The selection is done via MUTEVAL bit in the SAI_xCR2 register.

If the number of slots set in NBSLOT[3:0] bits in the SAI_xSLOTR register is greater than 2, MUTEVAL bit in the SAI_xCR2 is meaningless as 0 values are sent on each bit on each slot.

The FIFO pointers are still incremented in mute mode. This means that data present in the FIFO and for which the mute mode is requested are discarded.

Audio subblock in reception mode

In reception mode, it is possible to detect a mute mode sent from the external transmitter when all the declared and valid slots of the audio frame receive 0 for a given consecutive number of audio frames (MUTECNT[5:0] bits in the SAI_xCR2 register).

When the number of MUTE frames is detected, the MUTEDET flag in the SAI_xSR register is set and an interrupt can be generated if MUTEDETIE bit is set in SAI_xCR2.

The mute frame counter is cleared when the audio subblock is disabled or when a valid slot receives at least one data in an audio frame. The interrupt is generated just once, when the counter reaches the value specified in MUTECNT[5:0] bits. The interrupt event is then reinitialized when the counter is cleared.

*Note:* The mute mode is not available for SPDIF audio blocks.

Mono/stereo mode

In transmitter mode, the mono mode can be addressed, without any data preprocessing in memory, assuming the number of slots is equal to 2 (NBSLOT[3:0] = 0001 in SAI_xSLOTR). In this case, the access time to and from the FIFO will be reduced by 2 since the data for slot 0 is duplicated into data slot 1.

To enable the mono mode,
1. Set MONO bit to 1 in the SAI_xCR1 register.
2. Set NBSLOT to 1 and SLOTEN to 3 in SAI_xSLOTR.
In reception mode, the MONO bit can be set and is meaningful only if the number of slots is equal to 2 as in transmitter mode. When it is set, only slot 0 data will be stored in the FIFO. The data belonging to slot 1 will be discarded since, in this case, it is supposed to be the same as the previous slot. If the data flow in reception mode is a real stereo audio flow with a distinct and different left and right data, the MONO bit is meaningless. The conversion from the output stereo file to the equivalent mono file is done by software.

Companding mode

Telecommunication applications can require to process the data to be transmitted or received using a data companding algorithm.

Depending on the COMP[1:0] bits in the SAI_xCR2 register (used only when Free protocol mode is selected), the application software can choose to process or not the data before sending it on SD serial output line (compression) or to expand the data after the reception on SD serial input line (expansion) as illustrated in Figure 660. The two companding modes supported are the µ-Law and the A-Law log which are a part of the CCITT G.711 recommendation.

The companding standard used in the United States and Japan is the µ-Law. It supports 14 bits of dynamic range (COMP[1:0] = 10 in the SAI_xCR2 register).

The European companding standard is A-Law and supports 13 bits of dynamic range (COMP[1:0] = 11 in the SAI_xCR2 register).

Both µ-Law or A-Law companding standard can be computed based on 1’s complement or 2’s complement representation depending on the CPL bit setting in the SAI_xCR2 register.

In µ-Law and A-Law standards, data are coded as 8 bits with MSB alignment. Companded data are always 8-bit wide. For this reason, DS[2:0] bits in the SAI_xCR1 register will be forced to 010 when the SAI audio block is enabled (SAIEN bit = 1 in the SAI_xCR1 register) and when one of these two companding modes selected through the COMP[1:0] bits.

If no companding processing is required, COMP[1:0] bits should be kept clear.
Expansion and compression mode are automatically selected through the SAI_xCR2:

- If the SAI audio block is configured to be a transmitter, and if the COMP[1] bit is set in the SAI_xCR2 register, the compression mode will be applied.
- If the SAI audio block is declared as a receiver, the expansion algorithm will be applied.

**Output data line management on an inactive slot**

In transmitter mode, it is possible to choose the behavior of the SD line output when an inactive slot is sent on the data line (via TRIS bit).

- Either the SAI forces 0 on the SD output line when an inactive slot is transmitted, or
- The line is released in HI-z state at the end of the last bit of data transferred, to release the line for other transmitters connected to this node.

It is important to note that the two transmitters cannot attempt to drive the same SD output pin simultaneously, which could result in a short circuit. To ensure a gap between transmissions, if the data is lower than 32-bit, the data can be extended to 32-bit by setting bit SLOTSZ[1:0] = 10 in the SAI_xSLOTR register. The SD output pin will then be tri-stated at the end of the LSB of the active slot (during the padding to 0 phase to extend the data to 32-bit) if the following slot is declared inactive.

In addition, if the number of slots multiplied by the slot size is lower than the frame length, the SD output line will be tri-stated when the padding to 0 is done to complete the audio frame.

*Figure 661* illustrates these behaviors.
When the selected audio protocol uses the FS signal as a start of frame and a channel side identification (bit FSDEF = 1 in the SAI_xFRCR register), the tristate mode is managed according to Figure 662 (where bit TRIS in the SAI_xCR1 register = 1, and FSDEF=1, and half frame length is higher than number of slots/2, and NBSLOT=6).
If the TRIS bit in the SAI_xCR2 register is cleared, all the High impedance states on the SD output line on Figure 661 and Figure 662 are replaced by a drive with a value of 0.

50.3.14 Error flags

The SAI implements the following error flags:
- FIFO overrun/underrun
- Anticipated frame synchronization detection
- Late frame synchronization detection
- Codec not ready (AC'97 exclusively)
- Wrong clock configuration in master mode.

**FIFO overrun/underrun (OVRUDR)**

The FIFO overrun/underrun bit is called OVRUDR in the SAI_xSR register.

The overrun or underrun errors share the same bit since an audio block can be either receiver or transmitter and each audio block in a given SAI has its own SAI_xSR register.

**Overrun**

When the audio block is configured as receiver, an overrun condition may appear if data are received in an audio frame when the FIFO is full and not able to store the received data. In this case, the received data are lost, the flag OVRUDR in the SAI_xSR register is set and an interrupt is generated if OVRUDRIE bit is set in the SAI_xIM register. The slot number, from which the overrun occurs, is stored internally. No more data will be stored into the FIFO until it becomes free to store new data. When the FIFO has at least one data free, the SAI audio block receiver will store new data (from new audio frame) from the slot number which was stored internally when the overrun condition was detected. This avoids data slot de-alignment in the destination memory (refer to Figure 663).
The OVRUDR flag is cleared when COVRUDR bit is set in the SAI_xCLRFR register.

**Figure 663. Overrun detection error**

---

**Underrun**

An underrun may occur when the audio block in the SAI is a transmitter and the FIFO is empty when data need to be transmitted. If an underrun is detected, the slot number for which the event occurs is stored and MUTE value (00) is sent until the FIFO is ready to transmit the data corresponding to the slot for which the underrun was detected (refer to **Figure 664**). This avoids desynchronization between the memory pointer and the slot in the audio frame.

The underrun event sets the OVRUDR flag in the SAI_xSR register and an interrupt is generated if the OVRUDRIE bit is set in the SAI_xIM register. To clear this flag, set COVRUDR bit in the SAI_xCLRFR register.

The underrun event can occur when the audio subblock is configured as master or slave.

**Figure 664. FIFO underrun event**
Anticipated frame synchronization detection (AFSDET)

The AFSDET flag is used only in slave mode. It is never asserted in master mode. It indicates that a frame synchronization (FS) has been detected earlier than expected since the frame length, the frame polarity, the frame offset are defined and known.

Anticipated frame detection sets the AFSDET flag in the SAI_xSR register.

This detection has no effect on the current audio frame which is not sensitive to the anticipated FS. This means that “parasitic” events on signal FS are flagged without any perturbation of the current audio frame.

An interrupt is generated if the AFSDETIE bit is set in the SAI_xIM register. To clear the AFSDET flag, CAFSDET bit must be set in the SAI_xCLRFR register.

To resynchronize with the master after an anticipated frame detection error, four steps are required:

1. Disable the SAI block by resetting SAIEN bit in SAI_xCR1 register. To make sure the SAI is disabled, read back the SAIEN bit and check it is set to 0.
2. Flush the FIFO via FFLUS bit in SAI_xCR2 register.
3. Enable again the SAI peripheral (SAIEN bit set to 1).
4. The SAI block will wait for the assertion on FS to restart the synchronization with master.

Note: The AFSDET flag is not asserted in AC’97 mode since the SAI audio block acts as a link controller and generates the FS signal even when declared as slave. It has no meaning in SPDIF mode since the FS signal is not used.

Late frame synchronization detection

The LFSDET flag in the SAI_xSR register can be set only when the SAI audio block operates as a slave. The frame length, the frame polarity and the frame offset configuration are known in register SAI_xFRCR.

If the external master does not send the FS signal at the expecting time thus generating the signal too late, the LFSDET flag is set and an interrupt is generated if LFSDETIE bit is set in the SAI_xIM register.

The LFSDET flag is cleared when CLFSDET bit is set in the SAI_xCLRFR register.

The late frame synchronization detection flag is set when the corresponding error is detected. The SAI needs to be resynchronized with the master (see sequence described in Anticipated frame synchronization detection (AFSDET)).

In a noisy environment, glitches on the SCK clock may be wrongly detected by the audio block state machine and shift the SAI data at a wrong frame position. This event can be detected by the SAI and reported as a late frame synchronization detection error.

There is no corruption if the external master is not managing the audio data frame transfer in continuous mode, which should not be the case in most applications. In this case, the LFSDET flag will be set.

Note: The LFSDET flag is not asserted in AC’97 mode since the SAI audio block acts as a link controller and generates the FS signal even when declared as slave. It has no meaning in SPDIF mode since the signal FS is not used by the protocol.
Codec not ready (CNRDY AC'97)

The CNRDY flag in the SAI_xSR register is relevant only if the SAI audio block is configured to operate in AC'97 mode (PRTCFG[1:0] = 10 in the SAI_xCR1 register). If CNRDYIE bit is set in the SAI_xIM register, an interrupt is generated when the CNRDY flag is set.

CNRDY is asserted when the Codec is not ready to communicate during the reception of the TAG 0 (slot0) of the AC'97 audio frame. In this case, no data will be automatically stored into the FIFO since the Codec is not ready, until the TAG 0 indicates that the Codec is ready. All the active slots defined in the SAI_xSLOTTR register will be captured when the Codec is ready.

To clear CNRDY flag, CCNRDY bit must be set in the SAI_xCLRFR register.

Wrong clock configuration in master mode (with NOMCK = 0)

When the audio block operates as a master (MODE[1] = 0) and NOMCK bit is equal to 0, the WCKCFG flag is set as soon as the SAI is enabled if the following conditions are met:

- (FRL+1) is not a power of 2, and
- (FRL+1) is not between 8 and 256.

MODE, NOMCK, and SAIEN bits belong to SAI_xCR1 register and FRL to SAI_xFRCR register.

If WCKCFGIE bit is set, an interrupt is generated when WCKCFG flag is set in the SAI_xSR register. To clear this flag, set CWCKCFG bit in the SAI_xCLRFR register.

When WCKCFG bit is set, the audio block is automatically disabled, thus performing a hardware clear of SAIEN bit.

50.3.15 Disabling the SAI

The SAI audio block can be disabled at any moment by clearing SAIEN bit in the SAI_xCR1 register. All the already started frames are automatically completed before the SAI is stops working. SAIEN bit remains High until the SAI is completely switched-off at the end of the current audio frame transfer.

If an audio block in the SAI operates synchronously with the other one, the one which is the master must be disabled first.

50.3.16 SAI DMA interface

To free the CPU and to optimize bus bandwidth, each SAI audio block has an independent DMA interface to read/write from/to the SAI_xDR register (to access the internal FIFO). There is one DMA channel per audio subblock supporting basic DMA request/acknowledge protocol.

To configure the audio subblock for DMA transfer, set DMAEN bit in the SAI_xCR1 register. The DMA request is managed directly by the FIFO controller depending on the FIFO threshold level (for more details refer to Section 50.3.9: Internal FIFOs). DMA transfer direction is linked to the SAI audio subblock configuration:

- If the audio block operates as a transmitter, the audio block FIFO controller outputs a DMA request to load the FIFO with data written in the SAI_xDR register.
- If the audio block is operates as a receiver, the DMA request is related to read operations from the SAI_xDR register.
Follow the sequence below to configure the SAI interface in DMA mode:
1. Configure SAI and FIFO threshold levels to specify when the DMA request will be launched.
2. Configure SAI DMA channel.
3. Enable the DMA.
4. Enable the SAI interface.

Note: Before configuring the SAI block, the SAI DMA channel must be disabled.

### 50.4 SAI interrupts

The SAI supports 7 interrupt sources as shown in Table 419.

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:4 SYNOUT[1:0]: Synchronization outputs
These bits are set and cleared by software.
- 00: No synchronization output signals. SYNOUT[1:0] should be configured as “No synchronization output signals” when audio block is configured as SPDIF
- 01: Block A used for further synchronization for others SAI
- 10: Block B used for further synchronization for others SAI
- 11: Reserved. These bits must be set when both audio block (A and B) are disabled.

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 SYNCCIN[1:0]: Synchronization inputs
These bits are set and cleared by software.
Refer to for information on how to program this field.
These bits must be set when both audio blocks (A and B) are disabled.
They are meaningful if one of the two audio blocks is defined to operate in synchronous mode with an external SAI (SYNCCIN[1:0] = 10 in SAI_ACR1 or in SAI_BCR1 registers).

</table>
Bits 31:27  Reserved, must be kept at reset value.

Bit 26  **OSR**: Oversampling ratio for master clock
  0: Master clock frequency = \(F_{FS} \times 256\)
  1: Master clock frequency = \(F_{FS} \times 512\)

Bits 25:20  **MCKDIV[5:0]**: Master clock divider
  These bits are set and cleared by software.
  000000: Divides by 1 the kernel clock input (sai_x_ker_ck).
  Otherwise, The master clock frequency is calculated according to the formula given in
  Section 50.3.8: SAI clock generator.
  These bits have no meaning when the audio block is slave.
  They have to be configured when the audio block is disabled.

Bit 19  **NOMCK**: No divider
  This bit is set and cleared by software.
  0: Master clock generator is enabled
  1: Master clock generator is disabled. The clock divider controlled by MCKDIV can still be used to
generate the bit clock.

Bit 18  Reserved, must be kept at reset value.

Bit 17  **DMAEN**: DMA enable
  This bit is set and cleared by software.
  0: DMA disabled
  1: DMA enabled
  Note: Since the audio block defaults to operate as a transmitter after reset, the MODE[1:0] bits must
  be configured before setting DMAEN to avoid a DMA request in receiver mode.

Bit 16  **SAIEN**: Audio block enable
  This bit is set by software.
  To switch off the audio block, the application software must program this bit to 0 and poll the bit till it
  reads back 0, meaning that the block is completely disabled. Before setting this bit to 1, check that it
  is set to 0, otherwise the enable command will not be taken into account.
  This bit allows controlling the state of the SAI audio block. If it is disabled when an audio frame
  transfer is ongoing, the ongoing transfer completes and the cell is fully disabled at the end of this
  audio frame transfer.
  0: SAI audio block disabled
  1: SAI audio block enabled.
  Note: When the SAI block (A or B) is configured in master mode, the clock must be present on the
  SAI block input before setting SAIEN bit.

Bits 15:14  Reserved, must be kept at reset value.

Bit 13  **OUTDRIV**: Output drive
  This bit is set and cleared by software.
  0: Audio block output driven when SAIEN is set
  1: Audio block output driven immediately after the setting of this bit.
  Note: This bit has to be set before enabling the audio block and after the audio block configuration.

Bit 12  **MONO**: Mono mode
  This bit is set and cleared by software. It is meaningful only when the number of slots is equal to 2.
  When the mono mode is selected, slot 0 data are duplicated on slot 1 when the audio block operates
  as a transmitter. In reception mode, the slot1 is discarded and only the data received from slot 0 are
  stored. Refer to Section : Mono/stereo mode for more details.
  0: Stereo mode
  1: Mono mode.
Bits 11:10 **SYNCEN[1:0]:** Synchronization enable

These bits are set and cleared by software. They must be configured when the audio subblock is disabled.

00: audio subblock in asynchronous mode.
01: audio subblock is synchronous with the other internal audio subblock. In this case, the audio subblock must be configured in slave mode.
10: audio subblock is synchronous with an external SAI embedded peripheral. In this case the audio subblock should be configured in Slave mode.
11: Reserved

*Note: The audio subblock should be configured as asynchronous when SPDIF mode is enabled.*

Bit 9 **CKSTR:** Clock strobing edge

This bit is set and cleared by software. It must be configured when the audio block is disabled. This bit has no meaning in SPDIF audio protocol.

0: Signals generated by the SAI change on SCK rising edge, while signals received by the SAI are sampled on the SCK falling edge.
1: Signals generated by the SAI change on SCK falling edge, while signals received by the SAI are sampled on the SCK rising edge.

Bit 8 **LSBFIRST:** Least significant bit first

This bit is set and cleared by software. It must be configured when the audio block is disabled. This bit has no meaning in AC’97 audio protocol since AC’97 data are always transferred with the MSB first. This bit has no meaning in SPDIF audio protocol since in SPDIF data are always transferred with LSB first.

0: Data are transferred with MSB first
1: Data are transferred with LSB first

Bits 7:5 **DS[2:0]:** Data size

These bits are set and cleared by software. These bits are ignored when the SPDIF protocols are selected (bit PRTCFG[1:0]), because the frame and the data size are fixed in such case. When the companding mode is selected through COMP[1:0] bits, DS[1:0] are ignored since the data size is fixed to 8 bits by the algorithm.

These bits must be configured when the audio block is disabled.

000: Reserved
001: Reserved
010: 8 bits
011: 10 bits
100: 16 bits
101: 20 bits
110: 24 bits
111: 32 bits
Bit 4: Reserved, must be kept at reset value.

Bits 3:2 \textbf{PRTCFG[1:0]: Protocol configuration}

These bits are set and cleared by software. These bits have to be configured when the audio block is disabled.

00: Free protocol. Free protocol allows to use the powerful configuration of the audio block to address a specific audio protocol (such as I2S, LSB/MSB justified, TDM, PCM/DSP...) by setting most of the configuration register bits as well as frame configuration register.

01: SPDIF protocol

10: AC’97 protocol

11: Reserved

Bits 1:0 \textbf{MODE[1:0]: SAIx audio block mode}

These bits are set and cleared by software. They must be configured when SAIx audio block is disabled.

00: Master transmitter

01: Master receiver

10: Slave transmitter

11: Slave receiver

\textit{Note: When the audio block is configured in SPDIF mode, the master transmitter mode is forced (MODE[1:0] = 00).}

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:14 **COMP[1:0]:** Companding mode.

These bits are set and cleared by software. The μ-Law and the A-Law log are a part of the CCITT G.711 recommendation, the type of complement that will be used depends on CPL bit.

The data expansion or data compression are determined by the state of bit MODE[0].

The data compression is applied if the audio block is configured as a transmitter.

The data expansion is automatically applied when the audio block is configured as a receiver.

Refer to Section: Companding mode for more details.

00: No companding algorithm  
01: Reserved.  
10: μ-Law algorithm  
11: A-Law algorithm

**Note:** **Companding mode is applicable only when Free protocol mode is selected.**

Bit 13 **CPL:** Complement bit.

This bit is set and cleared by software.  
It defines the type of complement to be used for companding mode  
0: 1’s complement representation.  
1: 2’s complement representation.

**Note:** **This bit has effect only when the companding mode is μ-Law algorithm or A-Law algorithm.**

Bits 12:7 **MUTECNT[5:0]:** Mute counter.

These bits are set and cleared by software. They are used only in reception mode.  
The value set in these bits is compared to the number of consecutive mute frames detected in reception. When the number of mute frames is equal to this value, the flag MUTEDET will be set and an interrupt will be generated if bit MUTEDETIE is set.

Refer to Section: Mute mode for more details.
Bit 6 **MUTEVAL**: Mute value.
This bit is set and cleared by software. It must be written before enabling the audio block: SAIEN.
This bit is meaningful only when the audio block operates as a transmitter, the number of slots is lower or equal to 2 and the MUTE bit is set.
If more slots are declared, the bit value sent during the transmission in mute mode is equal to 0, whatever the value of MUTEVAL.
If the number of slots is lower or equal to 2 and MUTEVAL = 1, the MUTE value transmitted for each slot is the one sent during the previous frame.
Refer to Section: Mute mode for more details.
0: Bit value 0 is sent during the mute mode.
1: Last values are sent during the mute mode.

*Note: This bit is meaningless and should not be used for SPDIF audio blocks.*

Bit 5 **MUTE**: Mute.
This bit is set and cleared by software. It is meaningful only when the audio block operates as a transmitter. The MUTE value is linked to value of MUTEVAL if the number of slots is lower or equal to 2, or equal to 0 if it is greater than 2.
Refer to Section: Mute mode for more details.
0: No mute mode.
1: Mute mode enabled.

*Note: This bit is meaningless and should not be used for SPDIF audio blocks.*

Bit 4 **TRIS**: Tristate management on data line.
This bit is set and cleared by software. It is meaningful only if the audio block is configured as a transmitter. This bit is not used when the audio block is configured in SPDIF mode. It should be configured when SAI is disabled.
Refer to Section: Output data line management on an inactive slot for more details.
0: SD output line is still driven by the SAI when a slot is inactive.
1: SD output line is released (HI-Z) at the end of the last data bit of the last active slot if the next one is inactive.

Bit 3 **FFLUSH**: FIFO flush.
This bit is set by software. It is always read as 0. This bit should be configured when the SAI is disabled.
0: No FIFO flush.
1: FIFO flush. Programming this bit to 1 triggers the FIFO Flush. All the internal FIFO pointers (read and write) are cleared. In this case data still present in the FIFO are lost (no more transmission or received data lost). Before flushing, SAI DMA stream/interruption must be disabled.

Bits 2:0 **FTH[2:0]**: FIFO threshold.
This bit is set and cleared by software.
000: FIFO empty
001: ¼ FIFO
010: ½ FIFO
011: ¾ FIFO
100: FIFO full
101: Reserved
110: Reserved
111: Reserved

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:14 **COMP[1:0]:** Compinging mode.

These bits are set and cleared by software. The μ-Law and the A-Law log are a part of the CCITT G.711 recommendation, the type of complement that will be used depends on **CPL bit.**

The data expansion or data compression are determined by the state of bit **MODE[0].**

The data compression is applied if the audio block is configured as a transmitter.

The data expansion is automatically applied when the audio block is configured as a receiver.

Refer to Section : Companding mode for more details.

00: No companding algorithm  
01: Reserved.  
10: μ-Law algorithm  
11: A-Law algorithm

**Note:** *Companding mode is applicable only when Free protocol mode is selected.*

Bit 13 **CPL:** Complement bit.

This bit is set and cleared by software.

It defines the type of complement to be used for companding mode

0: 1’s complement representation.  
1: 2’s complement representation.

**Note:** *This bit has effect only when the companding mode is μ-Law algorithm or A-Law algorithm.*

Bits 12:7 **MUTECNT[5:0]:** Mute counter.

These bits are set and cleared by software. They are used only in reception mode.

The value set in these bits is compared to the number of consecutive mute frames detected in reception. When the number of mute frames is equal to this value, the flag MUTEDET will be set and an interrupt will be generated if bit MUTEDETIE is set.

Refer to Section : Mute mode for more details.
Bit 6  **MUTEVAL**: Mute value.

This bit is set and cleared by software. It must be written before enabling the audio block: SAIEN.
This bit is meaningful only when the audio block operates as a transmitter, the number of slots is lower or equal to 2 and the MUTE bit is set.
If more slots are declared, the bit value sent during the transmission in mute mode is equal to 0, whatever the value of MUTEVAL.
If the number of slot is lower or equal to 2 and MUTEVAL = 1, the MUTE value transmitted for each slot is the one sent during the previous frame.
Refer to  Section: Mute mode  for more details.
0: Bit value 0 is sent during the mute mode.
1: Last values are sent during the mute mode.

*Note: This bit is meaningless and should not be used for SPDIF audio blocks.*

Bit 5  **MUTE**: Mute.

This bit is set and cleared by software. It is meaningful only when the audio block operates as a transmitter. The MUTE value is linked to value of MUTEVAL if the number of slots is lower or equal to 2, or equal to 0 if it is greater than 2.
Refer to  Section: Mute mode  for more details.
0: No mute mode.
1: Mute mode enabled.

*Note: This bit is meaningless and should not be used for SPDIF audio blocks.*

Bit 4  **TRIS**: Tristate management on data line.

This bit is set and cleared by software. It is meaningful only if the audio block is configured as a transmitter. This bit is not used when the audio block is configured in SPDIF mode. It should be configured when SAI is disabled.
Refer to  Section: Output data line management on an inactive slot  for more details.
0: SD output line is still driven by the SAI when a slot is inactive.
1: SD output line is released (HI-Z) at the end of the last data bit of the last active slot if the next one is inactive.

Bit 3  **FFLUSH**: FIFO flush.

This bit is set by software. It is always read as 0. This bit should be configured when the SAI is disabled.
0: No FIFO flush.
1: FIFO flush. Programming this bit to 1 triggers the FIFO Flush. All the internal FIFO pointers (read and write) are cleared. In this case data still present in the FIFO are lost (no more transmission or received data lost). Before flushing, SAI DMA stream/interruption must be disabled.

Bits 2:0  **FTH[2:0]**: FIFO threshold.

This bit is set and cleared by software.
000: FIFO empty
001: ¼ FIFO
010: ½ FIFO
011: ¾ FIFO
100: FIFO full
101: Reserved
110: Reserved
111: Reserved

*Note: This bit is meaningless and should not be used for SPDIF audio blocks.*
50.5.6 Frame configuration register (SAI_AFRCR)

Bits 31:19 Reserved, must be kept at reset value.

Bit 18 **FSOFF**: Frame synchronization offset.

This bit is set and cleared by software. It is meaningless and is not used in AC’97 or SPDIF audio block configuration. This bit must be configured when the audio block is disabled.

0: FS is asserted on the first bit of the slot 0.
1: FS is asserted one bit before the first bit of the slot 0.

Bit 17 **FSPOL**: Frame synchronization polarity.

This bit is set and cleared by software. It is used to configure the level of the start of frame on the FS signal. It is meaningless and is not used in AC’97 or SPDIF audio block configuration.

This bit must be configured when the audio block is disabled.

0: FS is active low (falling edge)
1: FS is active high (rising edge)

Bit 16 **FSDEF**: Frame synchronization definition.

This bit is set and cleared by software.

0: FS signal is a start frame signal
1: FS signal is a start of frame signal + channel side identification

When the bit is set, the number of slots defined in the SAI_xSLOTR register has to be even. It means that half of this number of slots will be dedicated to the left channel and the other slots for the right channel (e.g: this bit has to be set for I2S or MSB/LSB-justified protocols...).

This bit is meaningless and is not used in AC’97 or SPDIF audio block configuration. It must be configured when the audio block is disabled.
50.5.7 Frame configuration register (SAI_BFRCR)

Bits 31:19 Reserved, must be kept at reset value.

Bit 18 FSOFF: Frame synchronization offset.
This bit is set and cleared by software. It is meaningless and is not used in AC’97 or SPDIF audio block configuration. This bit must be configured when the audio block is disabled.
0: FS is asserted on the first bit of the slot 0.
1: FS is asserted one bit before the first bit of the slot 0.

Bit 17 FSPOL: Frame synchronization polarity.
This bit is set and cleared by software. It is used to configure the level of the start of frame on the FS signal. It is meaningless and is not used in AC’97 or SPDIF audio block configuration.
This bit must be configured when the audio block is disabled.
0: FS is active low (falling edge)
1: FS is active high (rising edge)
Bit 16 **FSDEF**: Frame synchronization definition.
This bit is set and cleared by software.
- 0: FS signal is a start frame signal
- 1: FS signal is a start of frame signal + channel side identification
When the bit is set, the number of slots defined in the SAI_xSLOTR register has to be even. It means that half of this number of slots will be dedicated to the left channel and the other slots for the right channel (e.g. this bit has to be set for I2S or MSB/LSB-justified protocols...).
This bit is meaningless and is not used in AC’97 or SPDIF audio block configuration. It must be configured when the audio block is disabled.

Bit 15 **Reserved**, must be kept at reset value.

Bits 14:8 **FSALL[6:0]**: Frame synchronization active level length.
These bits are set and cleared by software. They specify the length in number of bit clock (SCK) + 1 (FSALL[6:0] + 1) of the active level of the FS signal in the audio frame
These bits are meaningless and are not used in AC’97 or SPDIF audio block configuration.
They must be configured when the audio block is disabled.

Bits 7:0 **FRL[7:0]**: Frame length.
These bits are set and cleared by software. They define the audio frame length expressed in number of SCK clock cycles: the number of bits in the frame is equal to FRL[7:0] + 1.
The minimum number of bits to transfer in an audio frame must be equal to 8, otherwise the audio block will behave in an unexpected way. This is the case when the data size is 8 bits and only one slot 0 is defined in NBSLOT[4:0] of SAI_xSLOTR register (NBSLOT[3:0] = 0000).
In master mode, if the master clock (available on MCLK_x pin) is used, the frame length should be aligned with a number equal to a power of 2, ranging from 8 to 256. When the master clock is not used (NOMCK = 1), it is recommended to program the frame length to an value ranging from 8 to 256.
These bits are meaningless and are not used in AC’97 or SPDIF audio block configuration.

Bits 31:16 **SLOT[15:0]**: Slot enable.
These bits are set and cleared by software.
Each SLOTEN bit corresponds to a slot position from 0 to 15 (maximum 16 slots).
0: Inactive slot.
1: Active slot.
The slot must be enabled when the audio block is disabled.
They are ignored in AC’97 or SPDIF mode.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **NBSLOT[3:0]**: Number of slots in an audio frame.
These bits are set and cleared by software.
The value set in this bitfield represents the number of slots + 1 in the audio frame (including the number of inactive slots). The maximum number of slots is 16.
The number of slots should be even if FSDEF bit in the SAI_xFRCR register is set.
The number of slots must be configured when the audio block is disabled.
They are ignored in AC’97 or SPDIF mode.

Bits 7:6 **SLOTSZ[1:0]**: Slot size
This bits is set and cleared by software.
The slot size must be higher or equal to the data size. If this condition is not respected, the behavior of the SAI will be undetermined.
Refer to Section: Output data line management on an inactive slot for information on how to drive SD line.
These bits must be set when the audio block is disabled.
They are ignored in AC’97 or SPDIF mode.
00: The slot size is equivalent to the data size (specified in DS[3:0] in the SAI_xCR1 register).
01: 16-bit
10: 32-bit
11: Reserved

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **FBOFF[4:0]**: First bit offset
These bits are set and cleared by software.
The value set in this bitfield defines the position of the first data transfer bit in the slot. It represents an offset value. In transmission mode, the bits outside the data field are forced to 0. In reception mode, the extra received bits are discarded.
These bits must be set when the audio block is disabled.
They are ignored in AC’97 or SPDIF mode.

ST
Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **LFSDETIE**: Late frame synchronization detection interrupt enable.
This bit is set and cleared by software.
0: Interrupt is disabled
1: Interrupt is enabled
When this bit is set, an interrupt will be generated if the LFSDET bit is set in the SAI_xSR register.
This bit is meaningless in AC’97, SPDIF mode or when the audio block operates as a master.

Bit 5 **AFSDETIE**: Anticipated frame synchronization detection interrupt enable.
This bit is set and cleared by software.
0: Interrupt is disabled
1: Interrupt is enabled
When this bit is set, an interrupt will be generated if the AFSDET bit in the SAI_xSR register is set.
This bit is meaningless in AC’97, SPDIF mode or when the audio block operates as a master.

Bit 4 **CNRDYIE**: Codec not ready interrupt enable (AC’97).
This bit is set and cleared by software.
0: Interrupt is disabled
1: Interrupt is enabled
When the interrupt is enabled, the audio block detects in the slot 0 (tag0) of the AC’97 frame if the Codec connected to this line is ready or not. If it is not ready, the CNRDY flag in the SAI_xSR register is set and an interruption is generated.
This bit has a meaning only if the AC’97 mode is selected through PRTCFG[1:0] bits and the audio block is operates as a receiver.

Bit 3 **FREQIE**: FIFO request interrupt enable.
This bit is set and cleared by software.
0: Interrupt is disabled
1: Interrupt is enabled
When this bit is set, an interrupt is generated if the FREQ bit in the SAI_xSR register is set.
Since the audio block defaults to operate as a transmitter after reset, the MODE bit must be configured before setting FREQIE to avoid a parasitic interruption in receiver mode,

Bit 2 **WCKCFGIE**: Wrong clock configuration interrupt enable.
This bit is set and cleared by software.
0: Interrupt is disabled
1: Interrupt is enabled
This bit is taken into account only if the audio block is configured as a master (MODE[1] = 0) and NOMCK = 0.
It generates an interrupt if the WCKCFG flag in the SAI_xSR register is set.
*Note: This bit is used only in Free protocol mode and is meaningless in other modes.*

Bit 1 **MUTEDETIE**: Mute detection interrupt enable.
This bit is set and cleared by software.
0: Interrupt is disabled
1: Interrupt is enabled
When this bit is set, an interrupt is generated if the MUTEDET bit in the SAI_xSR register is set.
This bit has a meaning only if the audio block is configured in receiver mode.

Bit 0 **OVRUDRIE**: Overrun/underrun interrupt enable.
This bit is set and cleared by software.
0: Interrupt is disabled
1: Interrupt is enabled
When this bit is set, an interrupt is generated if the OVRUDR bit in the SAI_xSR register is set.
50.5.11 **Interrupt mask register (SAI_BIM)**

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **LFSDETIE**: Late frame synchronization detection interrupt enable.
- This bit is set and cleared by software.
- 0: Interrupt is disabled
- 1: Interrupt is enabled

When this bit is set, an interrupt will be generated if the LFSDET bit is set in the SAI_xSR register.
This bit is meaningless in AC’97, SPDIF mode or when the audio block operates as a master.

Bit 5 **AFSDETIE**: Anticipated frame synchronization detection interrupt enable.
- This bit is set and cleared by software.
- 0: Interrupt is disabled
- 1: Interrupt is enabled

When this bit is set, an interrupt will be generated if the AFSDET bit in the SAI_xSR register is set.
This bit is meaningless in AC’97, SPDIF mode or when the audio block operates as a master.

Bit 4 **CNRDYIE**: Codec not ready interrupt enable (AC’97).
- This bit is set and cleared by software.
- 0: Interrupt is disabled
- 1: Interrupt is enabled

When the interrupt is enabled, the audio block detects in the slot 0 (tag0) of the AC’97 frame if the Codec connected to this line is ready or not. If it is not ready, the CNRDY flag in the SAI_xSR register is set and an interruption i generated.
This bit has a meaning only if the AC’97 mode is selected through PRTCFG[1:0] bits and the audio block is operates as a receiver.

Bit 3 **FREQIE**: FIFO request interrupt enable.
- This bit is set and cleared by software.
- 0: Interrupt is disabled
- 1: Interrupt is enabled

When this bit is set, an interrupt is generated if the FREQ bit in the SAI_xSR register is set.
Since the audio block defaults to operate as a transmitter after reset, the MODE bit must be configured before setting FREQIE to avoid a parasitic interruption in receiver mode,
Bit 2 **WCKCFGIE**: Wrong clock configuration interrupt enable.
This bit is set and cleared by software.
0: Interrupt is disabled
1: Interrupt is enabled
This bit is taken into account only if the audio block is configured as a master (MODE[1] = 0) and NOMCK = 0.
It generates an interrupt if the WCKCFG flag in the SAI_xSR register is set.
*Note: This bit is used only in Free protocol mode and is meaningless in other modes.*

Bit 1 **MUTEDETIE**: Mute detection interrupt enable.
This bit is set and cleared by software.
0: Interrupt is disabled
1: Interrupt is enabled
When this bit is set, an interrupt is generated if the MUTEDET bit in the SAI_xSR register is set.
This bit has a meaning only if the audio block is configured in receiver mode.

Bit 0 **OVRUDRIE**: Overrun/underrun interrupt enable.
This bit is set and cleared by software.
0: Interrupt is disabled
1: Interrupt is enabled
When this bit is set, an interrupt is generated if the OVRUDR bit in the SAI_xSR register is set.

</table>
Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **FLVL[2:0]**: FIFO level threshold.

This bit is read only. The FIFO level threshold flag is managed only by hardware and its setting depends on SAI block configuration (transmitter or receiver mode).

If the SAI block is configured as transmitter:
- 000: FIFO empty
- 001: FIFO <= ¼ but not empty
- 010: ¼ < FIFO <= ½
- 011: ½ < FIFO <= ¾
- 100: ¾ < FIFO but not full
- 101: FIFO full

If SAI block is configured as receiver:
- 000: FIFO empty
- 001: FIFO < ¼ but not empty
- 010: ¼ <= FIFO < ½
- 011: ½ <= FIFO < ¾
- 100: ¾ <= FIFO but not full
- 101: FIFO full

Bits 15:7 Reserved, must be kept at reset value.

Bit 6 **LFSDET**: Late frame synchronization detection.

This bit is read only.
- 0: No error.
- 1: Frame synchronization signal is not present at the right time.

This flag can be set only if the audio block is configured in slave mode.

It is not used in AC’97 or SPDIF mode.

It can generate an interrupt if LFSDETIE bit is set in the SAI_xIM register.

This flag is cleared when the software sets bit CLFSDET in SAI_xCLRFR register.

Bit 5 **AFSDET**: Anticipated frame synchronization detection.

This bit is read only.
- 0: No error.
- 1: Frame synchronization signal is detected earlier than expected.

This flag can be set only if the audio block is configured in slave mode.

It is not used in AC’97 or SPDIF mode.

It can generate an interrupt if AFSDETIE bit is set in SAI_xIM register.

This flag is cleared when the software sets CAFSDET bit in SAI_xCLRFR register.

Bit 4 **CNRDY**: Codec not ready.

This bit is read only.
- 0: External AC’97 Codec is ready
- 1: External AC’97 Codec is not ready

This bit is used only when the AC’97 audio protocol is selected in the SAI_xCR1 register and configured in receiver mode.

It can generate an interrupt if CNRDYIE bit is set in SAI_xIM register.

This flag is cleared when the software sets CCNRDY bit in SAI_xCLRFR register.
Bit 3 **FREQ**: FIFO request.  
This bit is read only.  
0: No FIFO request.  
1: FIFO request to read or to write the SAI_xDR.  
The request depends on the audio block configuration:  
– If the block is configured in transmission mode, the FIFO request is related to a write request operation in the SAI_xDR.  
– If the block configured in reception, the FIFO request related to a read request operation from the SAI_xDR.  
This flag can generate an interrupt if FREQIE bit is set in SAI_xIM register.

Bit 2 **WCKCFG**: Wrong clock configuration flag.  
This bit is read only.  
0: Clock configuration is correct  
1: Clock configuration does not respect the rule concerning the frame length specification defined in Section 50.3.6: Frame synchronization (configuration of FRL[7:0] bit in the SAI_xFRCR register)  
This bit is used only when the audio block operates in master mode (MODE[1] = 0) and NOMCK = 0.  
It can generate an interrupt if WCKCFGIE bit is set in SAI_xIM register.  
This flag is cleared when the software sets CWCKCFG bit in SAI_xCLRFR register.

Bit 1 **MUTEDET**: Mute detection.  
This bit is read only.  
0: No MUTE detection on the SD input line  
1: MUTE value detected on the SD input line (0 value) for a specified number of consecutive audio frames  
This flag is set if consecutive 0 values are received in each slot of a given audio frame and for a consecutive number of audio frames (set in the MUTECNT bit in the SAI_xCR2 register).  
It can generate an interrupt if MUTEDETIE bit is set in SAI_xIM register.  
This flag is cleared when the software sets CMUTEDET in the SAI_xCLRFR register.

Bit 0 **OVRUDR**: Overrun / underrun.  
This bit is read only.  
0: No overrun/underrun error.  
1: Overrun/underrun error detection.  
The overrun and underrun conditions can occur only when the audio block is configured as a receiver and a transmitter, respectively.  
It can generate an interrupt if OVRUDRIE bit is set in SAI_xIM register.  
This flag is cleared when the software sets COVRUDR bit in SAI_xCLRFR register.

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **FLVL[2:0]**: FIFO level threshold.
This bit is read only. The FIFO level threshold flag is managed only by hardware and its setting depends on SAI block configuration (transmitter or receiver mode).
If the SAI block is configured as transmitter:
000: FIFO empty
001: FIFO <= ¼ but not empty
010: ¼ < FIFO <= ½
011: ½ < FIFO <= ¾
100: ¾ < FIFO but not full
101: FIFO full
If SAI block is configured as receiver:
000: FIFO empty
001: FIFO < ¼ but not empty
010: ¼ <= FIFO < ½
011: ½ <= FIFO < ¾
100: ¾ <= FIFO but not full
101: FIFO full

Bits 15:7 Reserved, must be kept at reset value.

Bit 6 **LFSDET**: Late frame synchronization detection.
This bit is read only.
0: No error.
1: Frame synchronization signal is not present at the right time.
This flag can be set only if the audio block is configured in slave mode.
It is not used in AC’97 or SPDIF mode.
It can generate an interrupt if LFSDETIE bit is set in the SAI_xIM register.
This flag is cleared when the software sets bit CLFSDET in SAI_xCLRFR register.

Bit 5 **AFSDET**: Anticipated frame synchronization detection.
This bit is read only.
0: No error.
1: Frame synchronization signal is detected earlier than expected.
This flag can be set only if the audio block is configured in slave mode.
It is not used in AC’97 or SPDIF mode.
It can generate an interrupt if AFSDETIE bit is set in SAI_xIM register.
This flag is cleared when the software sets CAFSDET bit in SAI_xCLRFR register.

Bit 4 **CNRDY**: Codec not ready.
This bit is read only.
0: External AC’97 Codec is ready
1: External AC’97 Codec is not ready
This bit is used only when the AC’97 audio protocol is selected in the SAI_xCR1 register and configured in receiver mode.
It can generate an interrupt if CNRDYIE bit is set in SAI_xIM register.
This flag is cleared when the software sets CCNRDY bit in SAI_xCLRFR register.
Bit 3  **FREQ**: FIFO request.
   This bit is read only.
   0: No FIFO request.
   1: FIFO request to read or to write the SAI_xDR.
   The request depends on the audio block configuration:
   – If the block is configured in transmission mode, the FIFO request is related to a write request operation in the SAI_xDR.
   – If the block configured in reception, the FIFO request related to a read request operation from the SAI_xDR.
   This flag can generate an interrupt if FREQIE bit is set in SAI_xIM register.

Bit 2  **WCKCFG**: Wrong clock configuration flag.
   This bit is read only.
   0: Clock configuration is correct
   1: Clock configuration does not respect the rule concerning the frame length specification defined in Section 50.3.6: Frame synchronization (configuration of FRL[7:0] bit in the SAI_xFRCR register)
   This bit is used only when the audio block operates in master mode (MODE[1] = 0) and NOMCK = 0.
   It can generate an interrupt if WCKCFGIE bit is set in SAI_xIM register.
   This flag is cleared when the software sets CWCKCFG bit in SAI_xCLRFR register.

Bit 1  **MUTEDET**: Mute detection.
   This bit is read only.
   0: No MUTE detection on the SD input line
   1: MUTE value detected on the SD input line (0 value) for a specified number of consecutive audio frame
   This flag is set if consecutive 0 values are received in each slot of a given audio frame and for a consecutive number of audio frames (set in the MUTECNT bit in the SAI_xCR2 register).
   It can generate an interrupt if MUTEDETIE bit is set in SAI_xIM register.
   This flag is cleared when the software sets CMUTEDET in the SAI_xCLRFR register.

Bit 0  **OVRUDR**: Overrun / underrun.
   This bit is read only.
   0: No overrun/underrun error.
   1: Overrun/underrun error detection.
   The overrun and underrun conditions can occur only when the audio block is configured as a receiver and a transmitter, respectively.
   It can generate an interrupt if OVRUDRIBE bit is set in SAI_xIM register.
   This flag is cleared when the software sets COVRUDR bit in SAI_xCLRFR register.

2296/3289
Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **CLFSDET**: Clear late frame synchronization detection flag.
   This bit is write only.
   Programming this bit to 1 clears the LFSDET flag in the SAI_xSR register.
   This bit is not used in AC’97 or SPDIF mode.
   Reading this bit always returns the value 0.

Bit 5 **CAFSDET**: Clear anticipated frame synchronization detection flag.
   This bit is write only.
   Programming this bit to 1 clears the AFSDET flag in the SAI_xSR register.
   It is not used in AC’97 or SPDIF mode.
   Reading this bit always returns the value 0.

Bit 4 **CCNRDY**: Clear Codec not ready flag.
   This bit is write only.
   Programming this bit to 1 clears the CNRDY flag in the SAI_xSR register.
   This bit is used only when the AC’97 audio protocol is selected in the SAI_xCR1 register.
   Reading this bit always returns the value 0.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **CWCKCFG**: Clear wrong clock configuration flag.
   This bit is write only.
   Programming this bit to 1 clears the WCKCFG flag in the SAI_xSR register.
   This bit is used only when the audio block is set as master (MODE[1] = 0) and NOMCK = 0 in the SAI_xCR1 register.
   Reading this bit always returns the value 0.

Bit 1 **CMUTEDET**: Mute detection flag.
   This bit is write only.
   Programming this bit to 1 clears the MUTEDET flag in the SAI_xSR register.
   Reading this bit always returns the value 0.

Bit 0 **COVRUDR**: Clear overrun / underrun.
   This bit is write only.
   Programming this bit to 1 clears the OVRUDR flag in the SAI_xSR register.
   Reading this bit always returns the value 0.

       This bit is write only.
       Programming this bit to 1 clears the AFSDET flag in the SAI_xSR register.
       It is not used in AC’97 or SPDIF mode.
       Reading this bit always returns the value 0.

Bit 4  **CCNRDY**: Clear Codec not ready flag.
       This bit is write only.
       Programming this bit to 1 clears the CNRDY flag in the SAI_xSR register.
       This bit is used only when the AC’97 audio protocol is selected in the SAI_xCR1 register.
       Reading this bit always returns the value 0.

Bit 3  Reserved, must be kept at reset value.

Bit 2  **CWCKCFG**: Clear wrong clock configuration flag.
       This bit is write only.
       Programming this bit to 1 clears the WCKCFG flag in the SAI_xSR register.
       This bit is used only when the audio block is set as master (MODE[1] = 0) and NOMCK = 0 in the
       SAI_xCR1 register.
       Reading this bit always returns the value 0.

Bit 1  **CMUTEDET**: Mute detection flag.
       This bit is write only.
       Programming this bit to 1 clears the MUTEDET flag in the SAI_xSR register.
       Reading this bit always returns the value 0.

Bit 0  **COVRUDR**: Clear overrun / underrun.
       This bit is write only.
       Programming this bit to 1 clears the OVRUDR flag in the SAI_xSR register.
       Reading this bit always returns the value 0.

Bit 9 **CKE2**: Clock enable of bitstream clock number 2
This bit is set and cleared by software.
0: SAI_CK2 clock disabled
1: SAI_CK2 clock enabled

*Note: It is not recommended to configure this bit when PDMEN = 1.*

Bit 8 **CKE1**: Clock enable of bitstream clock number 1
This bit is set and cleared by software.
0: SAI_CK1 clock disabled
1: SAI_CK1 clock enabled

*Note: It is not recommended to configure this bit when PDMEN = 1.*

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **MICNBR[1:0]**: Number of microphones
This bit is set and cleared by software.
00: Configuration with 2 microphones
01: Configuration with 4 microphones
10: Configuration with 6 microphones
11: Configuration with 8 microphones

*Note: It is not recommended to configure this field when PDMEN = 1.*

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **PDMEN**: PDM enable
This bit is set and cleared by software. This bit allows to control the state of the PDM interface block.
Make sure that the SAI is already operating in TDM master mode before enabling the PDM interface.
0: PDM interface disabled
1: PDM interface enabled
Bit 31  Reserved, must be kept at reset value.

Bits 30:28  DLYM4R[2:0]: Delay line for second microphone of pair 4
This bit is set and cleared by software.
000: No delay
001: Delay of 1 T_{SAI_CK} period
010: Delay of 2 T_{SAI_CK} periods
... 111: Delay of 7 T_{SAI_CK} periods

This field can be changed on-the-fly.

Bit 27  Reserved, must be kept at reset value.

Bits 26:24  DLYM4L[2:0]: Delay line for first microphone of pair 4
This bit is set and cleared by software.
000: No delay
001: Delay of 1 T_{SAI_CK} period
010: Delay of 2 T_{SAI_CK} periods
... 111: Delay of 7 T_{SAI_CK} periods

This field can be changed on-the-fly.

Bit 23  Reserved, must be kept at reset value.

Bits 22:20  DLYM3R[2:0]: Delay line for second microphone of pair 3
This bit is set and cleared by software.
000: No delay
001: Delay of 1 T_{SAI_CK} period
010: Delay of 2 T_{SAI_CK} periods
... 111: Delay of 7 T_{SAI_CK} periods

This field can be changed on-the-fly.

Bit 19  Reserved, must be kept at reset value.

Bits 18:16  DLYM3L[2:0]: Delay line for first microphone of pair 3
This bit is set and cleared by software.
000: No delay
001: Delay of 1 T_{SAI_CK} period
010: Delay of 2 T_{SAI_CK} periods
... 111: Delay of 7 T_{SAI_CK} periods

This field can be changed on-the-fly.

Bit 15  Reserved, must be kept at reset value.
Bits 14:12 **DLYM2R[2:0]**: Delay line for second microphone of pair 2
This bit is set and cleared by software.
000: No delay
001: Delay of 1 $T_{SAI\_CK}$ period
010: Delay of 2 $T_{SAI\_CK}$ periods
... 
111: Delay of 7 $T_{SAI\_CK}$ periods
This field can be changed on-the-fly.

Bit 11 Reserved, must be kept at reset value.

Bits 10:8 **DLYM2L[2:0]**: Delay line for first microphone of pair 2
This bit is set and cleared by software.
000: No delay
001: Delay of 1 $T_{SAI\_CK}$ period
010: Delay of 2 $T_{SAI\_CK}$ periods
... 
111: Delay of 7 $T_{SAI\_CK}$ periods
This field can be changed on-the-fly.

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **DLYM1R[2:0]**: Delay line adjust for second microphone of pair 1
This bit is set and cleared by software.
000: No delay
001: Delay of 1 $T_{SAI\_CK}$ period
010: Delay of 2 $T_{SAI\_CK}$ periods
... 
111: Delay of 7 $T_{SAI\_CK}$ periods
This field can be changed on-the-fly.

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **DLYM1L[2:0]**: Delay line adjust for first microphone of pair 1
This bit is set and cleared by software.
000: No delay
001: Delay of 1 $T_{SAI\_CK}$ period
010: Delay of 2 $T_{SAI\_CK}$ periods
... 
111: Delay of 7 $T_{SAI\_CK}$ periods
This field can be changed on-the-fly.
## 50.5.20 SAI register map

The following table summarizes the SAI registers.

| Offset | Register name | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

Table 420. SAI register map and reset values (continued)
51  **SPDIF receiver interface (SPDIFRX)**

51.1  **SPDIFRX interface introduction**

The SPDIFRX interface handles S/PDIF audio protocol.

51.2  **SPDIFRX main features**

- Up to 4 inputs available
- Automatic symbol rate detection
- Maximum symbol rate: 12.288 MHz
- Stereo stream from 8 to 192 kHz supported
- Supports Audio IEC-60958 and IEC-61937, consumer applications
- SOPDs B, M and W insertion inside S/PDIF flow
- Parity bit management
- Communication using DMA for audio samples
- Communication using DMA for control and user channel information
- Interrupt capabilities

51.3  **SPDIFRX functional description**

The SPDIFRX peripheral, is designed to receive an S/PDIF flow compliant with IEC-60958 and IEC-61937. These standards support simple stereo streams up to high sample rate, and compressed multi-channel surround sound, such as those defined by Dolby or DTS.

The receiver provides all the necessary features to detect the symbol rate, and decode the incoming data. It is possible to use a dedicated path for the user and channel information in order to ease the interface handling. *Figure 665* shows a simplified block diagram.

The SPDIFRX_DC block is responsible of the decoding of the S/PDIF stream received from SPDIFRX_IN[4:1] inputs. This block re-sample the incoming signal, decode the manchester stream, recognize frames, sub-frames and blocks elements. It delivers to the REG_IF part, decoded data, and associated status flags.

This peripheral can be fully controlled via the APB1 bus, and can handle two DMA channels:

- A DMA channel dedicated to the transfer of audio samples
- A DMA channel dedicated to the transfer of IEC60958 channel status and user information

Interrupt services are also available either as an alternative function to the DMA, or for signaling error or key status of the peripheral.

The SPDIFRX also offers a signal named `spdifrx_frame_sync`, which toggles every time that a sub-frame’s preamble is detected. So the duty cycle will be 50%, and the frequency equal to the frame rate.

This signal can be connected to timer events, in order to compute frequency drift.
1. ‘n’ is fixed to 4.

51.3.1 SPDIFRX pins and internal signals

Table 421 lists the SPDIFRX internal input/output signals, Table 422 the SPDIFRX pins (alternate functions).

51.3.2  S/PDIF protocol (IEC-60958)

S/PDIF block

A S/PDIF frame is composed of two sub-frames (see Figure 667). Each sub-frame contains 32 bits (or time slots):

- Bits 0 to 3 carry one of the synchronization preambles
- Bits 4 to 27 carry the audio sample word in linear 2’s complement representation. The most significant bit (MSB) is carried by bit 27. When a 20-bit coding range is used, bits 8 to 27 carry the audio sample word with the LSB in bit 8.
- Bit 28 (validity bit “V”) indicates if the data is valid (for converting it to analog for example)
- Bit 29 (user data bit “U”) carries the user data information like the number of tracks of a Compact Disk.
- Bit 30 (channel status bit “C”) carries the channel status information like sample rate and protection against copy.
- Bit 31 (parity bit “P”) carries a parity bit such that bits 4 to 31 inclusive carry an even number of ones and an even number of zeroes (even parity).

Figure 666. S/PDIF Sub-Frame Format

For linear coded audio applications, the first sub-frame (left or “A” channel in stereophonic operation and primary channel in monophonic operation) normally starts with preamble “M”. However, the preamble changes to preamble “B” once every 192 frames to identify the start of the block structure used to organize the channel status and user information. The second sub-frame (right or “B” channel in stereophonic operation and secondary channel in monophonic operation) always starts with preamble “W”.

A S/PDIF block contains 192 pairs of sub-frames of 32 bits.

Figure 667. S/PDIF block format

NOTE
For historical reasons preambles “B”, “M” and “W” are, for use in professional applications, referred to as “Z”, “X” and “Y”, respectively.
**Synchronization preambles**

The preambles patterns are inverted or not according to the previous half-bit value. This previous half-bit value is the level of the line before enabling a transfer for the first “B” preamble of the first frame. For the others preambles, this previous half-bit value is the second half-bit of the parity bit of the previous sub-frame. The preambles patterns B, M and W are described in the Figure 668.

![Figure 668. S/PDIF Preambles](image)

**Coding of information bits**

In order to minimize the DC component value on the transmission line, and to facilitate clock recovery from the data stream, bits 4 to 31 are encoded in biphase-mark.

Each bit to be transmitted is represented by a symbol comprising two consecutive binary states. The first state of a symbol is always different from the second state of the previous symbol. The second state of the symbol is identical to the first if the bit to be transmitted is logical 0. However, it is different if the bit is logical 1. These states are named “UI” (Unit Interval) in the IEC-60958 specification.

The 24 data bits are transferred LSB first.
51.3.3 SPDIFRX decoder (SPDIFRX_DC)

Main principle

The technique used by the SPDIFRX in order to decode the S/PDIF stream is based on the measurement of the time interval between two consecutive edges. Three kinds of time intervals may be found into an S/PDIF stream:

- The long time interval, having a duration of 3 x UI, noted TL. It appears only during preambles.
- The medium time interval, having a duration of 2 x UI, noted TM. It appears both in some preambles or into the information field.
- The short time interval, having a duration of 1 x UI, noted TS. It appears both in some preambles or into the information field.

The SPDIFRX_DC block is responsible of the decoding of the received S/PDIF stream. It takes care of the following functions:

- Resampling and filtering of the incoming signal
- Estimation of the time-intervals
- Estimation of the symbol rate and synchronization
- Decoding of the serial data, and check of integrity
- Detection of the block, and sub-frame preambles
- Continuous tracking of the symbol rate
Figure 670 gives a detailed view of the SPDIFRX decoder.

**Noise filtering & rising/falling edge detection**

The S/PDIF signal received on the selected SPDIFRX_IN is re-sampled using the `spdifrx_ker_ck` clock (acquisition clock). A simple filtering is applied in order to cancel spurs. This is performed by the stage detecting the edge transitions. The edge transitions are detected as follow:

- A rising edge is detected when the sequence 0 followed by two 1 is sampled.
- A falling edge is detected when the sequence 1 followed by two 0 is sampled.
- After a rising edge, a falling edge sequence is expected.
- After a falling edge, a rising edge sequence is expected.

**Longest and shortest transition detector**

The longest and shortest transition detector block detects the maximum (MAX_CNT) and minimum (MIN_CNT) duration between two transitions. The TRCNT counter is used to measure the time interval duration. It is clocked by the `spdifrx_ker_ck` signal. On every transition pulse, the counter value is stored and the counter is reset to start counting again.

The maximum duration is normally found during the preamble period. This maximum duration is sent out as MAX_CNT. The minimum duration is sent out as MIN_CNT.
The search of the longest and shortest transition is stopped when the transition timer expires. The transition timer is like a watchdog timer that generates a trigger after 70 transitions of the incoming signal. Note that counting 70 transitions insures a delay a bit longer than a sub-frame.

Note that when the TRCNT overflows due to a too long time interval between two pulses, the SPDIFRX is stopped and the flag TERR of SPDIFRX_SR register is set to 1.

### Transition coder and preamble detector

The **transition coder and preamble detector** block receives the MAX_CNT and MIN_CNT. It also receives the current transition width from the TRCNT counter (see Figure 670). This block encodes the current transition width by comparing the current transition width with two different thresholds, names $TH_{HI}$ and $TH_{LO}$.

- If the current transition width is less than ($TH_{LO} - 1$), then the data received is half part of data bit ‘1’, and is coded as TS.
- If the current transition width is greater than ($TH_{LO} - 1$), and less than $TH_{HI}$, then the data received is data bit ‘0’, and is coded as TM.
- If the current transition width is greater than $TH_{HI}$, then the data received is the long pulse of preambles, and is coded as TL.
- Else an error code is generated (FERR flag is set).

The thresholds $TH_{HI}$ and $TH_{LO}$ are elaborated using two different methods.

If the peripheral is doing its initial synchronization (‘coarse synchronization’), then the thresholds are computed as follow:

- $TH_{LO} = MAX\_CNT / 2$.
- $TH_{HI} = MIN\_CNT + MAX\_CNT / 2$.

Once the ‘coarse synchronization’ is completed, then the SPDIFRX uses a more accurate reference in order to elaborate the thresholds. The SPDIFRX measures the length of 24 symbols (WIDTH24) for defining $TH_{LO}$ and the length of 40 symbols (WIDTH40) for $TH_{HI}$. $TH_{HI}$ and $TH_{LO}$ are computed as follow:

- $TH_{LO} = (WIDTH24) / 32$
- $TH_{HI} = (WIDTH40) / 32$

This second synchronization phase is called the ‘fine synchronization’. Refer to Figure 674 for additional information.

As shown in the figure hereafter, $TH_{LO}$ is ideally equal to 1.5 UI, and to $TH_{HI}$ 2.5 UI.
The preamble detector checks four consecutive transitions of a specific sequence to determine if they form the part of preamble. Let us say TRANS0, TRANS1, TRANS2 and TRANS3 represent four consecutive transitions encoded as mentioned above. Table 423 shows the values of these four transitions to form a preamble. Absence of this pattern indicates that these transitions form part of the data in the sub frame and bi-phase decoder will decode them.

Bi-phase decoder

The bi-phase decoder decodes the input bi-phase marked data stream using the transition information provided by the transition coder and preamble detector block. It first waits for the preamble detection information. After the preamble detection, it decodes the following transition information:

- If the incoming transition information is TM then it is decoded as a ‘0’.
- Two consecutive TS are decoded as a ‘1’.
- Any other transition sequence generates an error signal (FERR set to 1).

After decoding 28 data bits this way, this module looks for the following preamble data. If the new preamble is not what is expected, then this block generates an error signal (FERR set to 1). Refer to Section 51.3.9: Reception errors, for additional information on error flags.

Data packing

This block is responsible of the decoding of the IEC-60958 frames and blocks. It also handles the writing into the RX_BUF or into SPDIFRX_CSR register.
51.3.4 SPDIFRX tolerance to clock deviation

The SPDIFRX tolerance to clock deviation depends on the number of sample clock cycles in one bit slot. The fastest spdifrx_ker_ck is, the more robust the reception will be. The ratio between spdifrx_ker_ck frequency and the symbol rate must be at least 11.

Two kinds of phenomenon (at least!) can degrade the reception quality:

- The cycle-to-cycle jitter which reflects the difference of transition length between two consecutive transitions.
- The long term jitter which reflects a cumulative effect of the cycle-to-cycle jitter. It can be seen as a low-frequency symbol modulation.

51.3.5 SPDIFRX synchronization

The synchronization phase starts when setting SPDIFRXEN to 01 or 11. Figure 673 shows the synchronization process.

If the bit WFA of SPDIFRX_CR register is set to 1, then the peripheral must first detect activity on the selected SPDIFRX_IN line before starting the synchronization process. The activity detection is performed by detecting four transitions on the selected SPDIFRX_IN. The peripheral remains in this state until transitions are not detected. This function can be particularly helpful because the IP switches in COARSE SYNC mode only if activity is present on the selected SPDIFRX_IN input, avoiding synchronization errors. See Section 51.4: Programming procedures for additional information.

The user can still set the SPDIFRX into STATE_IDLE by setting SPDIFRXEN to 0. If the WFA is set to 0, the peripheral starts the coarse synchronization without checking activity.

The next step consists on doing a first estimate of the thresholds (COARSE SYNC), in order to perform the fine synchronization (FINE SYNC). Due to disturbances of the SPDIFRX line, it could happen that the process is not executed first time right. For this purpose, the user can program the number of allowed re-tries (NBTR) before setting SERR error flag. When the SPDIFRX has been able to measure properly the duration of 24 and 40 consecutive symbols then the FINE SYNC is completed, the threshold values are updated, and the flag SYNCD is set to 1. Refer to Section : Transition coder and preamble detector for additional information.

Two kinds of errors are detected:

- An overflow of the TRCNT, which generally means that there is no valid S/PDIF stream in the input line. This overflow is indicated by TERR flag.
- The number of retries reached the programmed value. This means that strong jitter is present on the S/PDIF signal. This error is indicated by SERR flag.

When the first FINE SYNC is completed, the reception of channel status (C) and user data (U) will start when the next “B” preamble is detected (see Figure 677). Then the user can read IEC-60958 C and U bits through SPDIFRX_CSR register. According to this information the user can then select the proper settings for DRFMT and RXSTEO. For example if the user detects that the current audio stream transports encoded data, then he can put RXSTEO to 0, and DRFMT to 10 prior to start data reception. Note that DRFMT and RXSTEO cannot be modified when SPDIFRXEN = 11. Writes to these fields are ignored if SPDIFRXEN is already 11, though these field can be changed with the same write instruction that causes SPDIFRXEN to become 11.

Then the SPDIFRX waits for SPDIFRXEN = 11 and the “B” preamble before starting saving audio samples.
Refer to *Frame structure and synchronization error* for additional information concerning TRCNT overflow.

The FINE SYNC process is re-triggered every frame in order to update thresholds as shown in *Figure 674* in order to continuously track S/PDIF synchronization.
51.3.6 SPDIFRX handling

The software can control the state of the SPDIFRX through SPDIFRXEN field. The SPDIFRX can be into one of the following states:

- **STATE_IDLE**: The peripheral is disabled, the spdifrx_ker_ck domain is reset. The spdifrx_pclk domain is functional.
- **STATE_SYNC**: The peripheral is synchronized to the stream, thresholds are updated regularly, user and channel status can be read via interrupt of DMA. The audio samples are not provided to receive buffer.
- **STATE_RCV**: The peripheral is synchronized to the stream, thresholds are updated regularly, user, channel status and audio samples can be read via interrupt or DMA channels. When SPDIFRXEN goes to 11, the SPDIFRX waits for “B” preamble before starting saving audio samples.
- **STOP_STATE**: The peripheral is no longer synchronized, the reception of the user, channel status and audio samples are stopped. It is expected that the software re-starts the SPDIFRX.

The Figure 675 shows the possible states of the SPDIFRX, and how to transition from one state to the other. The bits under software control are followed by the mention “(SW)”, the bits under IP control are followed by the mention “(HW)”. 

![Figure 674. Synchronization process scheduling](image)

<td></td>
</tr>
</tbody>
</table>

**Legend**
- **COARSE**: Coarse Synchronization process
- **FINE**: Fine Synchronization process
- **Transition Search (optional phase)**
When SPDIFRX is in STATE_IDLE:
- The software can transition to STATE_SYNC by setting SPDIFRXEN to 01 or 11

When SPDIFRX is in STATE_SYNC:
- If the synchronization fails or if the received data are not properly decoded with no chance of recovery without a re-synchronization (FERR or SERR or TERR = 1), the SPDIFRX goes to STATE_STOP, and waits for software acknowledge.
- When the synchronization phase is completed, if SPDIFRXEN = 01 the peripheral remains in this state.
- At any time the software can set SPDIFRXEN to 0, then SPDIFRX returns immediately to STATE_IDLE. If a DMA transfer is on-going, it will be properly completed.
- The SPDIFRX goes to STATE_RCV if SPDIFRXEN = 11 and if the SYNCD = 1

When SPDIFRX is in STATE_RCV:
- If the received data are not properly decoded with no chance of recovery without a re-synchronization (FERR or SERR or TERR = 1), the SPDIFRX goes to STATE_STOP, and waits for software acknowledge.
- At any time the software can set SPDIFRXEN to 0, then SPDIFRX returns immediately to STATE_IDLE. If a DMA transfer is on-going, it will properly be completed.

When SPDIFRX is in STATE_STOP:
- The SPDIFRX stops reception and synchronization, and waits for the software to set the bit SPDIFRXEN to 0, in order to clear the error flags.
When SPDIFRXEN is set to 0, the IP is disabled, meaning that all the state machines are reset, and RX_BUF is flushed. Note as well that flags FERR, SERR and TERR are reset.

51.3.7 Data reception management

The SPDIFRX offers a double buffer for the audio sample reception. A 32-bit buffer located into the spdifrx_ker_ck clock domain (RX_BUF), and the SPDIFRX_FMTx_DR register. The valid data contained into the RX_BUF will be immediately transferred into SPDIFRX_FMTx_DR if SPDIFRX_FMTx_DR is empty.

The valid data contained into the RX_BUF will be transferred into SPDIFRX_FMTx_DR when the two following conditions are reached:

- The transition between the parity bit (P) and the next preamble is detected (this indicated that the word has been completely received).
- The SPDIFRX_FMTx_DR is empty.

Having a 2-word buffer gives more flexibility for the latency constraint.

The maximum latency allowed is $T_{SAMPLE} - 2T_{PCLK} - 2T_{spdifrx_ker_ck}$

Where $T_{SAMPLE}$ is the audio sampling rate of the received stereo audio samples, $T_{PCLK}$ is the period of spdifrx_pclk clock, and $T_{spdifrx_ker_ck}$ is the period of spdifrx_ker_ck clock.

The SPDIFRX offers the possibility to use either DMA (spdifrx_dat_dma and spdifrx_ctrl_dma) or interrupts for transferring the audio samples into the memory. The recommended option is DMA, refer to Section 51.3.11: DMA Interface for additional information.

The SPDIFRX offers several way on handling the received data. The user can either have a separate flow for control information and audio samples, or get them all together.

For each sub-frame, the data reception register SPDIFRX_FMTx_DR contains the 24 data bits, and optionally the V, U, C, PE status bits, and the PT (see Mixing data and control flow).

Note that PE bit stands for Parity Error bit, and will be set to 1 when a parity error is detected in the decoded sub-frame.

The PT field carries the preamble type (B, M or W).

V, U and C are a direct copy of the value received from the S/PDIF interface.

The bit DRFMT allows the selection between 3 audio formats as shown in Figure 676.

This document describes 3 data registers: SPDIFRX_FMTx[2:0] (x = 2 to 0), but in reality there is only one physical data register, having 3 possible formats:

- When DRFMT = 0, the format of the data register is the one described by SPDIFRX_FMT0_DR
- When DRFMT = 1, the format of the data register is the one described by SPDIFRX_FMT1_DR
- When DRFMT = 2, the format of the data register is the one described by SPDIFRX_FMT2_DR"
Setting DRFMT to 00 or 01, offers the possibility to have the data either right or left aligned into the SPDIFRX_FMTx_DR register. The status information can be enabled or forced to zero according to the way the software wants to handle them.

The format given by DRFMT= 10 is interesting in non-linear mode, as only 16 bits per sub-frame are used. By using this format, the data of two consecutive sub-frames are stored into SPDIFRX_FMTx_DR, dividing by two the amount of memory footprint. Note that when RXSTEO = 1, there is no misalignment risks (i.e. data from ChA will be always stored into SPDIFRX_FMTx_DR[31:16]). If RXSTEO = 0, then there is a misalignment risk is case of overrun situation. In that case SPDIFRX_FMTx_DR[31:16] will always contain the oldest value and SPDIFRX_FMTx_DR[15:0] the more recent value (see Figure 678).

In this format the status information cannot be mixed with data, but the user can still get them through SPDIFRX_CSR register, and use a dedicated DMA channel or interrupt to transfer them to memory (see Section 51.3.8: Dedicated control flow).
Mixing data and control flow

The user can choose to use this mode in order to get the full flexibility of the handling of the control flow. The user can select which field shall be kept into the data register (SPDIFRX_FMTx_DR).

- When bit PMSK = 1, the Parity Error information is masked (set to 0), otherwise it is copied into SPDIFRX_FMTx_DR.
- When bit VMSK = 1, the Validity information is masked (set to 0), otherwise it is copied into SPDIFRX_FMTx_DR.
- When bit CUMSK = 1, the Channel Status, and Used data information are masked (set to 0), otherwise they are copied into SPDIFRX_FMTx_DR.
- When bit PTMSK = 1, the Preamble Type is masked (set to 0), otherwise it is copied into SPDIFRX_FMTx_DR.

51.3.8 Dedicated control flow

The SPDIFRX offers the possibility to catch both user data and channel status information via a dedicated DMA channel. This feature allows the SPDIFRX to acquire continuously the channel status and user information. The acquisition will start at the beginning of a IEC 60958 block. Two fields are available to control this path: CBDMAEN and SPDIFRXEN. When SPDIFRXEN is set to 01 or 0x11, the acquisition is started, after completion of the synchronization phase. When 8 channel status and 16 user data bits have been received, they are packed and stored into SPDIFRX_CSR register. A DMA request is triggered if the bit CBDMAEN is set to 1 (see Figure 677).

If CS[0] corresponds to the first bit of a new block, the bit SOB will be set to 1. Refer to Section 51.5.8: Channel status register (SPDIFRX_CSR). A bit is available (CHSEL) in order to select if the user wants to select channel status information (C) from the channel A or B.

![Figure 677. Channel/user data format](image)

Note: Once the first start of block is detected (B preamble), the SPDIFRX is checking the preamble type every 8 frames.

Note: Overrun error on SPDIFRX_FMTx_DR register does not affect this path.
51.3.9  Reception errors

Frame structure and synchronization error

The SPDIFRX, detects errors, when one of the following condition occurs:

- The FERR bit is set to 1 on the following conditions:
  - For each of the 28 information bits, if one symbol transition sequence is not correct: for example if short pulses are not grouped by pairs.
  - If preambles occur to an unexpected place, or an expected preamble is not received.
- The SERR bit is set when the synchronization fails, because the number of re-tries exceeded the programmed value.
- The TERR bit is set when the counter used to estimate the width between two transitions overflows (TRCNT).
  The overflow occurs when no transition is detected during 8192 periods of spdfrx_ker_ck clock. It represents at most a time interval of 11.6 frames.

When one of those flags goes to 1, the traffic on selected SPDIFRX_IN is then ignored, an interrupt is generated if the IFEIE bit of the SPDIFRX_CR register is set.

The normal procedure when one of those errors occur is:

- Set SPDIFRXEN to 0 in order to clear the error flags
- Set SPDIFRXEN to 01 or 11 in order to restart the IP

Refer to Figure 675 for additional information.

Parity error

For each sub-frame, an even number of zeros and ones is expected inside the 28 information bits. If not, the parity error bit PERR is set in the SPDIFRX_SR register and an interrupt is generated if the parity interrupt enable PERRIE bit is set in the SPDIFRX_CR register. The reception of the incoming data is not paused, and the SPDIFRX continue to deliver data to SPDIFRX_FMTx_DR even if the interrupt is still pending.

The interrupt is acknowledged by clearing the PERR flag through PERRCF bit.

If the software wants to guarantee the coherency between the data read in the SPDIFRX_FMTx_DR register and the value of the bit PERR, the bit PMSK must be set to 0.

Overrun error

If both SPDIFRX_FMTx_DR and RX_BUF are full, while the SPDIFRX_DC needs to write a new sample in RX_BUF, this new sample is dropped, and an overrun condition is triggered. The overrun error flag OVR is set in the SPDIFRX_SR register and an interrupt is generated if the OVRIE bit of the SPDIFRX_CR register is set.

If the RXSTEO bit is set to 0, then as soon as the RX_BUF is empty, the IP will store the next incoming data, even if the OVR flag is still pending. The main purpose is to reduce as much as possible the amount of lost samples. Note that the behavior is similar independently of DRFMT value. See Figure 678.
If the RXSTEO bit is set to 1, it means that stereo data are transported, then the SPDIFRX has to avoid misalignment between left and right channels. So the peripheral has to drop a second sample even if there is room inside the RX_BUF in order to avoid misalignment. Then the incoming samples can be written normally into the RX_BUF even if the OVR flag is still pending. Refer to Figure 679.

The OVR flag is cleared by software, by setting the OVRCF bit to 1.
51.3.10 Clocking strategy

The SPDIFRX block needs two different clocks:

- The APB clock (spdifrx_pclk), which is used for the register interface,
- The spdifrx_ker_ck which is mainly used by the SPDIFRX_DC part. Those clocks are not supposed to be phase locked, so all signals crossing those clock domains are re-synchronized (SYNC block on Figure 665).

In order to decode properly the incoming S/PDIF stream the SPDIFRX_DC shall re-sample the received data with a clock at least 11 times higher than the maximum symbol rate, or 704 times higher than the audio sample rate. For example if the user expects to receive a symbol rate to up to 12.288 MHz, the sample rate shall be at least 135.2 MHz. The clock used by the SPDIFRX_DC is the spdifrx_ker_ck.

The frequency of the spdifrx_pclk must be at least equal to the symbol rate.

</tbody>
</table>

51.3.11 DMA Interface

The SPDIFRX interface is able to perform communication using the DMA.

*Note: The user should refer to product specifications for availability of the DMA controller.*

The SPDIFRX offers two independent DMA channels:

- A DMA channel dedicated to the data transfer
- A DMA channel dedicated to the channel status and user data transfer
The DMA mode for the data can be enabled for reception by setting the RXDMAEN bit in the SPDIFRX_CR register. In this case, as soon as the SPDIFRX_FMTx_DR is not empty, the SPDIFRX interface sends a transfer request to the DMA. The DMA reads the data received through the SPDIFRX_FMTx_DR register without CPU intervention.

For the use of DMA for the control data refer to Section 51.3.8: Dedicated control flow.

51.3.12 Interrupt Generation

An interrupt line is shared between:
- Reception events for data flow (RXNE)
- Reception event for control flow (CSRNE)
- Data corruption detection (PERR)
- Transfer flow interruption (OVR)
- Frame structure and synchronization errors (SERR, TERR and FERR)
- Start of new block interrupt (SBD)
- Synchronization done (SYNCD)

Figure 680. SPDIFRX interface interrupt mapping diagram
Clearing interrupt source

- RXNE is cleared when SPDIFRX_FMTx_DR register is read
- CSRNE is cleared when SPDIFRX_CSR register is read
- FERR is cleared when SPDIFRXEN is set to 0
- SERR is cleared when SPDIFRXEN is set to 0
- TERR is cleared when SPDIFRXEN is set to 0
- Others are cleared through SPDIFRX_IFCR register

Note: The SBD event can only occur when the SPDIFRX is synchronized to the input stream (SYNCD = 1).
The SBD flag behavior is not guaranteed when the sub-frame which contains the B preamble is lost due to an overrun.

51.3.13 Register protection

The SPDIFRX block embeds some hardware protection to avoid erroneous use of control registers. The table hereafter shows the bit field properties according to the SPDIFRX state.

<table>
<thead>
<tr>

</table>

The table clearly shows that fields such as INSEL must be programmed when the IP is in STATE_IDLE. In the others IP states, the hardware prevents writing to this field.

Note: Even if the hardware allows the writing of CBDMAEN and RXDMAEN “on-the-fly”, it is not recommended to enable the DMA when the IP is already receiving data.

Note: Note that each of the mask bits (PMSK, VMSK, ...) can be changed “on-the-fly” at any IP state, but any change does not affect data which is already being held in SPDIFRX_FMTx_DR.
51.4 Programming procedures

The following example illustrates a complete activation sequence of the SPDIFRX block. The data path and channel status & user information will both use a dedicated DMA channel. The activation sequence is then split into the following steps:

- Wait for valid data on the selected SPDIFRX_IN input
- Synchronize to the S/PDIF stream
- Read the channel status and user information in order to setup the complete audio path
- Start data acquisition

A simple way to check if valid data are available into the SPDIFRX_IN line is to switch the SPDIFRX into the STATE_SYNC, with bit WFA set to 1. The description hereafter will focus on detection. It is also possible to implement this function as follow:

- The software has to check from time to time (i.e. every 100 ms for example) if the SPDIFRX can find synchronization. This can be done by checking if the bit TERR is set. When it is set it indicates that no activity as been found.
- Connect the SPDIFRX_IN input to an external interrupt event block in order to detect transitions of SPDIFRX_IN line. When activity is detected, then SPDIFRXEN can be set to 01 or 11.

For those two implementations, the bit WFA is set to 0.

51.4.1 Initialization phase

- The initialization function will look like this:
- Configure the DMA transfer for both audio samples and IEC60958 channel status and user information (DMA channel selection and activation, priority, number of data to transfer, circular/no circular mode, DMA interrupts)
- Configure the destination address:
  - Configure the address of the SPDIFRX_CSR register as source address for IEC60958 channel status and user information
  - Configure the address of the SPDIFRX_FMTx_DR register as source address for audio samples
  - Enable the generation of the spdifrx_ker_ck. Refer to Table 424 in order to define the minimum clock frequency versus supported audio sampling rate. Note that the audio sampling rate of the received stream is not known in advance. This means that the user has to select a spdifrx_ker_ck frequency at least 704 times higher than the maximum audio sampling rate the application is supposed to
handle: for example if the application is able to handle streams to up to 96 kHz, then $F_{\text{spdifrx, ker, ck}}$ shall be at least $704 \times 96 \text{ kHz} = 67.6 \text{ MHz}$

- Enable interrupt for errors and event signaling ($\text{IFEIE} = \text{SYNCDIE} = \text{OVRIE}, \text{PERRIE} = 1$, others set to 0). Note that SYNCDIE can be set to 0.

- Configure the SPDIFRX_CR register:
  - $\text{INSEL}$ shall select the wanted input
  - $\text{NBTR} = 2$, $\text{WFA} = 1$ (16 re-tries allowed, wait for activity before going to synchronization phase),
  - $\text{PTMSK} = \text{CUMSK} = 1$ (Preamble, C and U bits are not mixed with data)
  - $\text{VMSK} = \text{PMSK} = 0$ (Parity error and validity bit mixed with data)
  - $\text{CHSEL} = 0$ (channels status will be read from sub-frame A)
  - $\text{DRFMT} = 01$ (data aligned to the left)
  - $\text{RXSTEO} = 1$ (expected stereo mode linear)
  - $\text{CBDMAEN} = \text{RXDMAEN} = 1$ (enable DMA channels)
  - $\text{SPDIFRXEN} = 01$ (switch SPDIFRX to STATE_SYNC)

- The CPU can enter in WFI mode

Then the CPU will receive interrupts coming either from DMA or SPDIFRX.

### 51.4.2 Handling of interrupts coming from SPDIFRX

When an interrupt from the SPDIFRX is received, then the software has to check what is the source of the interrupt by reading the SPDIFRX_SR register.

- If $\text{SYNCD}$ is set to 1, then it means that the synchronization has been properly completed. No action has to be performed in our case as the DMA is already programmed. The software just needs to wait for DMA interrupt in order to read channel status information.
  The $\text{SYNCD}$ flag must be cleared by setting $\text{SYNCDCF}$ bit of SPDIFRX_IFCR register to 1.

- If $\text{TERR}$ or $\text{SERR}$ or $\text{FERR}$ are set to 1, the software has to set SPDIFRXEN to 0, and re-start from the initialization phase.
  - $\text{TERR}$ indicates that a time-out occurs either during synchronization phase or after.
  - $\text{SERR}$ indicates that the synchronization fails because the maximum allowed re-tries have been reached.
  - $\text{FERR}$ indicates that the reading of information after synchronization fails (unexpected preamble, bad data decoding...).

- If $\text{PERR}$ is set to 1, it means that a parity error has been detected, so one of the received audio sample or the channel status or user data bits are corrupted. The action taken here depends on the application: one action could be to drop the current channel status block as it is not reliable. There is no need to re-start from the initialization phase, as the synchronization is not lost.
  The $\text{PERR}$ flag must be cleared by setting $\text{PERRCF}$ bit of SPDIFRX_IFCR register to 1.
51.4.3 Handling of interrupts coming from DMA

If an interrupt is coming from the DMA channel used of the channel status (SPDIFRX_CSR):
If no error occurred (i.e. PERR), the CPU can start the decoding of channel information. For example bit 1 of the channel status informs the user if the current stream is linear or not. This information is very important in order to set-up the proper processing chain. In the same way, bits 24 to 27 of the channel status give the sampling frequency of the stream incoming stream.
Thanks to that information, the user can then configure the RXSTEO bit and DRFMT field prior to start the data reception. For example if the current stream is non linear PCM then RXSTEO is set to 0, and DRFMT is set to 10. Then the user can enable the data reception by setting SPDIFRXEN to 11.
The bit SOB, when set to 1 indicates the start of a new block. This information will help the software to identify the bit 0 of the channel status. Note that if the DMA generates an interrupt every time 24 values are transferred into the memory, then the first word will always correspond to the start of a new block.

If an interrupt is coming from the DMA channel used of the audio samples (SPDIFRX_FMTx_DR):
The process performed here depends of the data type (linear or non-linear), and on the data format selected.
For example in linear mode, if PE or V bit is set a special processing can be performed locally in order to avoid spurs on output. In non-linear mode those bits are not important as data frame have their own checksum.

Bits 31:19  Reserved, must be kept at reset value.

Bits 18:16 **INSEL[2:0]**: SPDIFRX input selection
- 000: SPDIFRX_IN1 selected
- 001: SPDIFRX_IN2 selected
- 010: SPDIFRX_IN3 selected
- 011: SPDIFRX_IN4 selected
- others reserved

Bit 15  Reserved, must be kept at reset value.

Bit 14 **WFA**: Wait for activity
- This bit is set/reset by software
- 1: The SPDIFRX waits for activity on SPDIFRX_IN line (4 transitions) before performing the synchronization
- 0: The SPDIFRX does not wait for activity on SPDIFRX_IN line before performing the synchronization

Bits 13:12 **NBTR[1:0]**: Maximum allowed re-tries during synchronization phase
- 00: No re-try is allowed (only one attempt)
- 01: 3 re-tries allowed
- 10: 15 re-tries allowed
- 11: 63 re-tries allowed

Bit 11 **CHSEL**: Channel selection
- This bit is set/reset by software
- 1: The control flow will take the channel status from channel B
- 0: The control flow will take the channel status from channel A

Bit 10 **CBDMAEN**: Control buffer DMA enable for control flow
- This bit is set/reset by software
- 1: DMA mode is enabled for reception of channel status and used data information.
- 0: DMA mode is disabled for reception of channel status and used data information.

When this bit is set, the DMA request is made whenever the CSRNE flag is set.

Bit 9 **PTMSK**: Mask of preamble type bits
- This bit is set/reset by software
- 1: The preamble type bits are not copied into the SPDIFRX_FMTx_DR, zeros are written instead
- 0: The preamble type bits are copied into the SPDIFRX_FMTx_DR

Bit 8 **CUMSK**: Mask of channel status and user bits
- This bit is set/reset by software
- 1: The channel status and user bits are not copied into the SPDIFRX_FMTx_DR, zeros are written instead
- 0: The channel status and user bits are copied into the SPDIFRX_FMTx_DR

Bit 7 **VMSK**: Mask of validity bit
- This bit is set/reset by software
- 1: The validity bit is not copied into the SPDIFRX_FMTx_DR, a zero is written instead
- 0: The validity bit is copied into the SPDIFRX_FMTx_DR

Bit 6 **PMSK**: Mask parity error bit
- This bit is set/reset by software
- 1: The parity error bit is not copied into the SPDIFRX_FMTx_DR, a zero is written instead
- 0: The parity error bit is copied into the SPDIFRX_FMTx_DR
Bits 5:4  **DRFMT[1:0]: RX data format**

  - This bit is set/reset by software
  - 11: reserved
  - 10: Data sample are packed by setting two 16-bit sample into a 32-bit word
  - 01: Data samples are aligned in the left (MSB)
  - 00: Data samples are aligned in the right (LSB)

Bit 3  **RXSTEO**: Stereo mode

  - This bit is set/reset by software
  - 1: The peripheral is in STEREO mode
  - 0: The peripheral is in MONO mode
  - This bit is used in case of overrun situation in order to handle misalignment

Bit 2  **RXDMAEN**: Receiver DMA enable for data flow

  - This bit is set/reset by software
  - 1: DMA mode is enabled for reception.
  - 0: DMA mode is disabled for reception.
  - When this bit is set, the DMA request is made whenever the RXNE flag is set.

Bits 1:0  **SPDIFRXEN[1:0]: Peripheral block enable**

  - This field is modified by software.
  - It shall be used to change the peripheral phase among the three possible states: STATE_IDLE, STATE_SYNC and STATE_RCV.
  - 00: Disable SPDIFRX (STATE_IDLE).
  - 01: Enable SPDIFRX Synchronization only
  - 10: Reserved
  - 11: Enable SPDIF Receiver

*Note:* it is not possible to transition from STATE_RCV to STATE_SYNC, the user shall first go the STATE_IDLE.

  - it is possible to transition from STATE_IDLE to STATE_RCV: in that case the peripheral transitions from STATE_IDLE to STATE_SYNC and as soon as the synchronization is performed goes to STATE_RCV.

---

1. Refer to *Section 51.3.13: Register protection* for additional information on fields properties.

Bit 31: Reserved, must be kept at reset value.

Bits 30:16 **WIDTH5[14:0]:** Duration of 5 symbols counted with spdifrx_ker_ck

This value represents the amount of spdifrx_ker_ck clock periods contained on a length of 5 consecutive symbols. This value can be used to estimate the S/PDIF symbol rate. Its accuracy is limited by the frequency of spdifrx_ker_ck.

For example, if the spdifrx_ker_ck is fixed to 84 MHz, and WIDTH5 = 147d. The estimated sampling rate of the S/PDIF stream is:

\[
Fs = \frac{5 \times F_{\text{spdifrx_ker_ck}}}{\text{WIDTH5} \times 64} \approx 44.6 \text{ kHz},
\]

so the closest standard sampling rate is 44.1 kHz.

Note that WIDTH5 is updated by the hardware when SYNCD goes high, and then every frame.

Bits 15:9: Reserved, must be kept at reset value.

Bit 8 **TERR:** Time-out error

This bit is set by hardware when the counter TRCNT reaches its max value. It indicates that the time interval between two transitions is too long. It generally indicates that there is no valid signal on SPDIFRX_IN input.

This flag is cleared by writing SPDIFRXEN to 0

An interrupt is generated if IFEIE=1 in the SPDIFRX_IMR register

0: No sequence error is detected
1: Sequence error is detected

Bit 7 **SERR:** Synchronization error

This bit is set by hardware when the synchronization fails due to amount of re-tries for NBTR.

This flag is cleared by writing SPDIFRXEN to 0

An interrupt is generated if IFEIE=1 in the SPDIFRX_IMR register.

0: No synchronization error is detected
1: Synchronization error is detected

Bit 6 **FERR:** Framing error

This bit is set by hardware when an error occurs during data reception: preamble not at the expected place, short transition not grouped by pairs...

This bit is set by the hardware only if the synchronization has been completed (SYNCD = 1).

This flag is cleared by writing SPDIFRXEN to 0

An interrupt is generated if IFEIE=1 in the SPDIFRX_IMR register.

0: no Manchester Violation detected
1: Manchester Violation detected
Bit 5  **SYNCD**: Synchronization Done  
This bit is set by hardware when the initial synchronization phase is properly completed.  
This flag is cleared by writing a 1 to its corresponding bit on SPDIFRX_IFCR register.  
An interrupt is generated if SYNCDIE = 1 in the SPDIFRX_IMR register  
0: Synchronization is pending  
1: Synchronization is completed

Bit 4  **SBD**: Synchronization Block Detected  
This bit is set by hardware when a “B” preamble is detected  
This flag is cleared by writing a 1 to its corresponding bit on SPDIFRX_IFCR register.  
An interrupt is generated if SBLKIE = 1 in the SPDIFRX_IMR register  
0: No “B” preamble detected  
1: “B” preamble has been detected

Bit 3  **OVR**: Overrun error  
This bit is set by hardware when a received data is ready to be transferred in the SPDIFRX_FMTx_DR register while RXNE = 1 and both SPDIFRX_FMTx_DR and RX_BUF are full.  
This flag is cleared by writing a 1 to its corresponding bit on SPDIFRX_IFCR register.  
An interrupt is generated if OVRIE=1 in the SPDIFRX_IMR register.  
0: No Overrun error  
1: Overrun error is detected  
*Note: When this bit is set, the SPDIFRX_FMTx_DR register content will not be lost but the last data received will.*

Bit 2  **PERR**: Parity error  
This bit is set by hardware when the data and status bits of the sub-frame received contain an odd number of 0 and 1.  
This flag is cleared by writing a 1 to its corresponding bit on SPDIFRX_IFCR register.  
An interrupt is generated if PIE = 1 in the SPDIFRX_IMR register.  
0: No parity error  
1: Parity error

Bit 1  **CSRNE**: The Control Buffer register is not empty  
This bit is set by hardware when a valid control information is ready.  
This flag is cleared when reading SPDIFRX_CSR register.  
An interrupt is generated if CBRDYIE = 1 in the SPDIFRX_IMR register  
0: No control word available on SPDIFRX_CSR register  
1: A control word is available on SPDIFRX_CSR register

Bit 0  **RXNE**: Read data register not empty  
This bit is set by hardware when a valid data is available into SPDIFRX_FMTx_DR register.  
This flag is cleared by reading the SPDIFRX_FMTx_DR register.  
An interrupt is generated if RXNEIE=1 in the SPDIFRX_IMR register.  
0: Data is not received  
1: Received data is ready to be read.

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **SYNCDCF**: Clears the Synchronization Done flag
- Writing 1 in this bit clears the flag SYNCD in the SPDIFRX_SR register.
- Reading this bit always returns the value 0.

Bit 4 **SBDCF**: Clears the Synchronization Block Detected flag
- Writing 1 in this bit clears the flag SBD in the SPDIFRX_SR register.
- Reading this bit always returns the value 0.

Bit 3 **OVRCF**: Clears the Overrun error flag
- Writing 1 in this bit clears the flag OVR in the SPDIFRX_SR register.
- Reading this bit always returns the value 0.

Bit 2 **PERRCF**: Clears the Parity error flag
- Writing 1 in this bit clears the flag PERR in the SPDIFRX_SR register.
- Reading this bit always returns the value 0.

Bits 1:0 Reserved, must be kept at reset value.
51.5.5 Data input register (SPDIFRX_FMT0_DR)

Address offset: 0x10
Reset value: 0x0000 0000

This register can take 3 different formats according to DRFMT. Here is the format when DRFMT = 00:

Bits 31:29 Reserved, must be kept at reset value.
Bits 28:16  **TLO[12:0]**: Threshold LOW (TLO = 1.5 x UI / T_{spdifrx_ker_ck})

This field contains the current threshold LOW estimation. This value can be used to estimate the sampling rate of the received stream. The accuracy of TLO is limited to a period of the spdifrx_ker_ck. The sampling rate can be estimated as follow:
Sampling Rate = \[2 x TLO x T_{spdifrx_ker_ck} \pm T_{spdifrx_ker_ck}\] x 2/3

Note that TLO is updated by the hardware when SYNCD goes high, and then every frame.

Bits 15:13  Reserved, must be kept at reset value.

Bits 12:0  **THI[12:0]**: Threshold HIGH (THI = 2.5 x UI / T_{spdifrx_ker_ck})

This field contains the current threshold HIGH estimation. This value can be used to estimate the sampling rate of the received stream. The accuracy of THI is limited to a period of the spdifrx_ker_ck. The sampling rate can be estimated as follow:
Sampling Rate = \[2 x THI x T_{spdifrx_ker_ck} \pm T_{spdifrx_ker_ck}\] x 2/5

Note that THI is updated by the hardware when SYNCD goes high, and then every frame.
51.5.10  SPDIFRX interface register map

Table 426 gives the SPDIFRX interface register map and reset values.

Refer to Section 2.3 on page 126 for the register boundary addresses.
52 Single Wire Protocol Master Interface (SWPMI)

52.1 Introduction

The Single Wire Protocol Master Interface (SWPMI) is the master interface corresponding to the Contactless front-end (CLF) defined in the ETSI TS 102 613 technical specification.

The principle of the Single wire protocol (SWP) is based on the transmission of digital information in full duplex mode:

- S1 signal (from Master to Slave) is transmitted by a digital modulation (L or H) in the voltage domain (refer to Figure 681: S1 signal coding).
- S2 signal (from Slave to Master) is transmitted by a digital modulation (L or H) in the current domain (refer to Figure 682: S2 signal coding).

![Figure 681. S1 signal coding](MS33342V1)

![Figure 682. S2 signal coding](MS33343V1)
52.2 SWPMI main features

The SWPMI module main features are the following (see Figure 52.3.4: SWP bus states):

- Full-duplex communication mode
- Automatic SWP bus state management
- Automatic handling of Start of frame (SOF)
- Automatic handling of End of frame (EOF)
- Automatic handling of stuffing bits
- Automatic CRC-16 calculation and generation in transmission
- Automatic CRC-16 calculation and checking in reception
- 32-bit Transmit data register
- 32-bit Receive data register
- Multi software buffer mode for efficient DMA implementation and multi frame buffering
- Configurable bit-rate up to 2 Mbit/s
- Configurable interrupts
- CRC error, underrun, overrun flags
- Frame reception and transmission complete flags
- Slave resume detection flag
- Loopback mode for test purpose
- Embedded SWPMI_IO transceiver compliant with ETSI TS 102 613 technical specification
- Dedicated mode to output SWPMI_RX, SWPMI_TX and SWPMI_SUSPEND signals on GPIOs, in case of external transceiver connection
52.3 SWPMI functional description

52.3.1 SWPMI block diagram

Refer to the bit SWPSRC in Section 7.7.20: RCC Domain 2 Kernel Clock Configuration Register (RCC_D2CCIP1R) to select the swpmi_ker_ck (SWPMI core clock source).

Note: In order to support the exit from Stop mode by a RESUME by slave, it is mandatory to select HSI for swpmi_ker_ck. If this feature is not required, swpmi_pclk can be selected, and SWPMI must be disabled before entering the Stop mode.

52.3.2 SWPMI pins and internal signals

Table 427 lists the SWPMI slave inputs and output signals connected to package pins or balls, while Table 428 shows the internal SWPMI signals.

<table>
<thead>

<td>Digital input</td>
<td>SWPMI receive signal</td>
</tr>
</tbody>
</table>
52.3.3 SWP initialization and activation

The initialization and activation will set the SWPMI_IO state from low to high.

When using the internal transceiver, the procedure is the following:
1. Configure the SWP_CLASS bit in SWPMI_OR register according to the VDD voltage (3 V or 1.8 V),
2. Set SWPTEN in SWPMI_CR register to enable the SWPMI_IO transceiver and set the SWPMI_IO to low level (SWP bus DEACTIVATED)
3. Wait for the RDYF flag in SWPMI_SR register to be set (polling the flag or enabling the interrupt with RDYIE bit in SWPMI_IER register),
4. Set SWPACT bit in SWPMI_CR register to ACTIVATE the SWP i.e. to move from DEACTIVATED to SUSPENDED.

52.3.4 SWP bus states

The SWP bus can have the following states: DEACTIVATED, SUSPENDED, ACTIVATED.
Several transitions are possible:
- ACTIVATE: transition from DEACTIVATED to SUSPENDED state,
- SUSPEND: transition from ACTIVATED to SUSPENDED state,
- RESUME by master: transition from SUSPENDED to ACTIVATED state initiated by the master,
- RESUME by slave: transition from SUSPENDED to ACTIVATED state initiated by the slave,
- DEACTIVATE: transition from SUSPENDED to DEACTIVATED state.

ACTIVATE

During and just after reset, the SWPMI_IO is configured in analog mode. Refer to Section 52.3.3: SWP initialization and activation to activate the SWP bus.
SUSPEND

The SWP bus stays in the ACTIVATED state as long as there is a communication with the slave, either in transmission or in reception. The SWP bus switches back to the SUSPENDED state as soon as there is no more transmission or reception activity, after 7 idle bits.

RESUME by master

Once the SWPMI is enabled, the user can request a SWPMI frame transmission. The SWPMI first sends a transition sequence and 8 idle bits (RESUME by master) before starting the frame transmission. The SWP moves from the SUSPENDED to ACTIVATED state after the RESUME by master (refer to Figure 684: SWP bus states).

RESUME by slave

Once the SWPMI is enabled, the SWP can also move from the SUSPENDED to ACTIVATED state if the SWPMI receives a RESUME from the slave. The RESUME by slave sets the SRF flag in the SWPMI_ISR register.

DEACTIVATE

Deactivate request

If no more communication is required, and if SWP is in the SUSPENDED mode, the user can request to switch the SWP to the DEACTIVATED mode by disabling the SWPMI peripheral. The software must set DEACT bit in the SWPMI_CR register in order to request the DEACTIVATED mode. If no RESUME by slave is detected by SWPMI, the DEACTF flag is set in the SWPMI_ISR register and the SWPACT bit is cleared in the SWPMI_ICR register. In case a RESUME by slave is detected by the SWPMI while the software is setting DEACT bit, the SRF flag is set in the SWPMI_ISR register, DEACTF is kept cleared, SWPACT is kept set and DEACT bit is cleared.

In order to activate SWP again, the software must clear DEACT bit in the SWPMI_CR register before setting SWPACT bit.

Deactivate mode

In order to switch the SWP to the DEACTIVATED mode immediately, ignoring any possible incoming RESUME by slave, the user must clear SWPACT bit in the SWPMI_CR register.

Note: In order to further reduce current consumption, configure the SWPMI_IO port as output push pull low in GPIO controller and then clear the SWPTEN bit in SWPMI_CR register (refer to Section 10: General-purpose I/Os (GPIO)).
52.3.5 SWPMI_IO (internal transceiver) bypass

A SWPMI_IO (transceiver), compliant with ETSI TS 102 613 technical specification, is embedded in the microcontroller. Nevertheless, this is possible to bypass it by setting SWP_TBYP bit in SWPMI_OR register. In this case, the SWPMI_IO is disabled and the SWPMI_RX, SWPMI_TX and SWPMI_SUSPEND signals are available as alternate functions on three GPIOs (refer to “Pinouts and pin description” in product datasheet). This configuration is selected to connect an external transceiver.

*Note:* In SWPMI_IO bypass mode, SWPTEN bit in SWPMI_CR register must be kept cleared.

52.3.6 SWPMI Bit rate

The bit rate must be set in the SWPMI_BRR register, according to the following formula:

\[ F_{SWP} = \frac{F_{swpmi_ker_ck}}{(BR[7:0]+1) \times 4} \]

*Note:* The maximum bitrate is 2 Mbit/s.
52.3.7 SWPMI frame handling

The SWP frame is composed of a Start of frame (SOF), a Payload from 1 to 30 bytes, a 16-bit CRC and an End of frame (EOF) (Refer to Figure 685: SWP frame structure).

![Figure 685. SWP frame structure](image)

The SWPMI embeds one 32-bit data register for transmission (SWPMI_TDR), and one 32-bit data register for reception (SWPMI_RDR).

In transmission, the SOF insertion, the CRC calculation and insertion, and the EOF insertion are managed automatically by the SWPMI. The user only has to provide the Payload content and size. A frame transmission starts as soon as data is written into the SWPMI_TDR register. Dedicated flags indicate an empty transmit data register and a complete frame transmission event.

In reception, the SOF deletion, the CRC calculation and checking, and the EOF deletion are managed automatically by the SWPMI. The user only has to read the Payload content and size. Dedicated flags indicate a full receive data register, a complete frame reception and possibly CRC error events.

The stuffing bits insertion (in transmission) and stuffing bits deletion (in reception) are managed automatically by the SWPMI core. These operations are transparent for the user.

52.3.8 Transmission procedure

Before starting any frame transmission, the user must activate the SWP. Refer to Section 52.3.3: SWP initialization and activation.

There are several possible software implementations for a frame transmission: No software buffer mode, Single software buffer mode, and Multi software buffer mode.

The software buffer usage requires the use of a DMA channel to transfer data from the software buffer in the RAM memory to the transmit data register in the SWPMI peripheral.

**No software buffer mode**

This mode does not require the use of DMA. The SWP frame transmission handling is done by polling status flags in the main loop or inside the SWPMI interrupt routine. There is a 32-bit transmit data register (SWPMI_TDR) in the SWPMI, thus writing to this register will trigger the transmission of up to 4 bytes.

The No software buffer mode is selected by clearing TXDMA bit in the SWPMI_CR register.

The frame transmission is started by the first write to the SWPMI_TDR register. The low significant byte of the first 32-bit word (bits [7:0]) written into the SWPMI_TDR register indicates the number of data bytes in the payload, and the 3 other bytes of this word must...
contain the first 3 bytes of the payload (bits [15:8] contain the first byte of the payload, bits [23:16] the second byte and bits [31:24] the third byte). Then, the following writes to the SWPMI_TDR register will only contain the following payload data bytes, up to 4 for each write.

**Note:** The low significant byte of the first 32-bit word written into the SWPMI_TDR register is coding the number of data bytes in the payload. This number could be from 1 to 30. Any other value in the low significant byte will be ignored and the transmission will not start.

Writing to the SWPMI_TDR register will induce the following actions:
- Send the transition sequence and 8 idle bits (RESUME by master) if the SWP bus state is SUPENDED (this will not happen if the SWP bus state is already ACTIVATED),
- Send a Start of frame (SOF),
- Send the payload according to the SWPMI_TRD register content. If the number of bytes in the payload is greater than 3, the SWPMI_TDR needs to be refilled by software, each time the TXE flag in the SWPMI_ISR register is set, and as long as the TXBEF flag is not set in the SWPMI_ISR register,
- Send the 16-bit CRC, automatically calculated by the SWPMI core,
- Send an End of frame (EOF).

The TXE flag is cleared automatically when the software is writing to the SWPMI_TDR register.

Once the complete frame is sent, provided that no other frame transmission has been requested (i.e. SWPMI_TDR has not been written again after the TXBEF flag setting), TCF and SUSP flags are set in the SWPMI_ISR register 7 idle bits after the EOF transmission, and an interrupt is generated if TCIE bit is set in the SWPMI_IER register (refer to **Figure 686: SWPMI No software buffer mode transmission**).

![Figure 686. SWPMI No software buffer mode transmission](image_url)

If another frame transmission is requested before the end of the EOF transmission, the TCF flag is not set and the frame will be consecutive to the previous one, with only one idle bit in between (refer to **Figure 687: SWPMI No software buffer mode transmission, consecutive frames**).
Single software buffer mode

This mode allows to transmit a complete SWP frame without a CPU intervention, using the DMA. The DMA will refill the 32-bit SWPMI_TDR register, and the software can poll the end of the frame transmission using the SWPMI_TXBEF flag.

The Single software buffer mode is selected by setting TXDMA bit and clearing TXMODE bit in the SWPMI_CR register.

The DMA channel or stream must be configured in following mode (refer to DMA section):

- memory to memory mode disabled,
- memory increment mode enabled,
- memory size set to 32-bit,
- peripheral size set to 32-bit,
- peripheral increment mode disabled,
- circular mode disabled,
- data transfer direction set to read from memory.
- the number of words to be transfered must be set according to the SWP frame length,
- the source address is the SWP frame buffer in RAM,
- the destination address is the SWPMI_TDR register.

Then the user must:

1. Set TXDMA bit in the SWPMI_CR register,
2. Set TXBEIE bit in the SWPMI_IER register,
3. Fill the buffer in the RAM memory (with the number of data bytes in the payload on the least significant byte of the first word),
4. Enable stream or channel in DMA module to start DMA transfer and frame transmission.

A DMA request is issued by SWPMI when TXE flag in SWPMI_ISR is set. The TXE flag is cleared automatically when the DMA is writing to the SWPMI_TDR register.
In the SWPMI interrupt routine, the user must check TXBEF bit in the SWPMI_ISR register. If it is set, and if another frame needs to be transmitted, the user must:
1. Disable stream or channel in DMA module
2. Update the buffer in the RAM memory with the content of the next frame to be sent
3. Configure the total number of words to be transferred in DMA module
4. Enable stream or channel in DMA module to start next frame transmission
5. Set CTXBEF bit in the SWPMI_ICR register to clear the TXBEF flag

Multi software buffer mode
This mode allows to work with several frame buffers in the RAM memory, in order to ensure a continuous transmission, keeping a very low CPU load, and allowing more latency for buffer update by software thanks to the DMA. The software can check the DMA counters at any time and update SWP frames accordingly in the RAM memory.

The Multi software buffer mode must be used in combination with DMA in circular mode. Each transmission buffer in the RAM memory must have a fixed length of eight 32-bit words, whatever the number of bytes in the SWP frame payload. The transmission buffers in the RAM memory must be filled by the software, keeping an offset of 8 between two consecutive ones. The first data byte of the buffer is the number of bytes of the frame payload. See the buffer example in Figure 688: SWPMI Multi software buffer mode

transmission

The Multi software buffer mode is selected by setting both TXDMA and TXMODE bits in SWPMI_CR register.

For example, in order to work with 4 transmission buffers, the user must configure the DMA as follows:

The DMA channel or stream must be configured in following mode (refer to DMA section):
- memory to memory mode disabled,
- memory increment mode enabled,
- memory size set to 32-bit,
- peripheral size set to 32-bit,
- peripheral increment mode disabled,
- circular mode enabled,
- data transfer direction set to read from memory,
- the number of words to be transferred must be set to 32 (8 words per buffer),
- the source address is the buffer1 in RAM,
- the destination address is the SWPMI_TDR register.

Then, the user must:
1. Set TXDMA in the SWPMI_CR register
2. Set TXBEIE in the SWPMI_IER register
3. Fill buffer1, buffer2, buffer3 and buffer4 in the RAM memory (with the number of data bytes in the payload on the least significant byte of the first word)
4. Enable stream or channel in DMA module to start DMA.
In the SWPMI interrupt routine, the user must check TXBEF bit in the SWPMI_ISR register. If it is set, the user must set CTXBEF bit in SWPMI_ICR register to clear TXBEF flag and the user can update buffer1 in the RAM memory.

In the next SWPMI interrupt routine occurrence, the user will update buffer2, and so on.

The Software can also read the DMA counter (number of data to transfer) in the DMA registers in order to retrieve the frame which has already been transferred from the RAM memory and transmitted. For example, if the software works with 4 transmission buffers, and if the DMA counter equals 17, it means that two buffers are ready for updating in the RAM area. This is useful in case several frames are sent before the software can handle the SWPMI interrupt. If this happens, the software will have to update several buffers.

When there are no more frames to transmit, the user must disable the circular mode in the DMA module. The transmission will stop at the end of the buffer4 transmission.

If the transmission needs to stop before (for example at the end of buffer2), the user must set the low significant byte of the first word to 0 in buffer3 and buffer4.

TXDMA bit in the SWPMI_CR register will be cleared by hardware as soon as the number of data bytes in the payload is read as 0 in the least significant byte of the first word.

**Figure 688. SWPMI Multi software buffer mode transmission**

![Diagram of SWPMI Multi software buffer mode transmission](image)
52.3.9 Reception procedure

Before starting any frame reception, the user must activate the SWP (refer to Section 52.3.3: SWP initialization and activation).

Once SWPACT bit is set in the SWPMI_CR register, a RESUME from slave state sets the SRF flag in the SWPMI_ISR register and automatically enables the SWPMI for the frame reception.

If the SWP bus is already in the ACTIVATED state (for example because a frame transmission is ongoing), the SWPMI core does not need any RESUME by slave state, and the reception can take place immediately.

There are several possible software implementations for a frame reception:
- No software buffer mode,
- Single software buffer mode,
- Multi software buffer mode.

The software buffer usage requires the use of a DMA channel to transfer data from the receive data register in the SWPMI peripheral to the software buffer in the RAM memory.

No software buffer mode

This mode does not require the use of DMA. The SWP frame reception handling is done by polling status flags in the main loop or inside the SWPMI interrupt routine. There is a 32-bit receive data register (SWPMI_RDR) in the SWPMI, allowing to receive up to 4 bytes before reading this register.

The No software buffer mode is selected by resetting RXDMA bit in the SWPMI_CR register.

Once a Start of frame (SOF) is received, the following bytes (payload) are stored in the SWPMI_RDR register. Once the SWPMI_RDR is full, the RXNE flag is set in SWPMI_ISR and an interrupt is generated if RIE bit is set in SWPMI_IER register. The user can read the SWPMI_RDR register and the RXNE flag is cleared automatically when the software is reading the SWPMI_RDR register.

Once the complete frame has been received, including the CRC and the End of frame (EOF), both RXNE and RXBFF flags are set in the SWPMI_ISR register. The user must read the last byte(s) of the payload in the SWPMI_RDR register and set CRXBFF flag in SWPMI_ICR in order to clear the RXBFF flag. The number of data bytes in the payload is available in the SWPMI_RFL register. Again, the RXNE flag is reset automatically when the software is reading the SWPMI_RDR register (refer to Figure 689: SWPMI No software buffer mode reception).

Reading the SWPMI_RDR register while RXNE is cleared will return 0.
Single software buffer mode

This mode allows to receive a complete SWP frame without any CPU intervention using the DMA. The DMA transfers received data from the 32-bit SWPMI_RDR register to the RAM memory, and the software can poll the end of the frame reception using the SWPMI_RBFF flag.

The Single software buffer mode is selected by setting RXDMA bit and clearing RXMODE bit in the SWPMI_CR register.

The DMA must be configured as follows:

The DMA channel or stream must be configured in following mode (refer to DMA section):
- memory to memory mode disabled,
- memory increment mode enabled,
- memory size set to 32-bit,
- peripheral size set to 32-bit,
- peripheral increment mode disabled,
- circular mode disabled,
- data transfer direction set to read from peripheral,
- the number of words to be transfered must be set to 8,
- the source address is the SWPMI_RDR register,
- the destination address is the SWP frame buffer in RAM.

Then the user must:
1. Set RXDMA bit in the SWPMI_CR register
2. Set RXBFIE bit in the SWPMI_IER register
3. Enable stream or channel in DMA module.

A DMA request is issued by SWPMI when RXNE flag is set in SWPMI_ISR. The RXNE flag is cleared automatically when the DMA is reading the SWPMI_RDR register.

In the SWPMI interrupt routine, the user must check RXBFF bit in the SWPMI_ISR register. If it is set, the user must:
1. Disable stream or channel in DMA module
2. Read the number of bytes in the received frame payload in the SWPMI_RFL register
3. Read the frame payload in the RAM buffer
4. Enable stream or channel in DMA module
5. Set CRXBFF bit in the SWPMI_ICR register to clear RXBFF flag (refer to Figure 690: SWPMI single software buffer mode reception).

### Figure 690. SWPMI single software buffer mode reception

#### Multi software buffer mode

This mode allows to work with several frame buffers in the RAM memory, in order to ensure a continuous reception, keeping a very low CPU load, using the DMA. The frame payloads are stored in the RAM memory, together with the frame status flags. The software can check the DMA counters and status flags at any time to handle the received SWP frames in the RAM memory.

The Multi software buffer mode must be used in combination with the DMA in circular mode. The Multi software buffer mode is selected by setting both RXDMA and RXMODE bits in SWPMI_CR register.
In order to work with n reception buffers in RAM, the DMA channel or stream must be configured in following mode (refer to DMA section):

- memory to memory mode disabled,
- memory increment mode enabled,
- memory size set to 32-bit,
- peripheral size set to 32-bit,
- peripheral increment mode disabled,
- circular mode enabled,
- data transfer direction set to read from peripheral,
- the number of words to be transferred must be set to 8 x n (8 words per buffer),
- the source address is the SWPMI_TDR register,
- the destination address is the buffer1 address in RAM

Then the user must:
1. Set RXDMA in the SWPMI_CR register
2. Set RXBFIE in the SWPMI_IER register
3. Enable stream or channel in the DMA module.

In the SWPMI interrupt routine, the user must check RXBFF in the SWPMI_ISR register. If it is set, the user must set CRXBFF bit in the SWPMI_ICR register to clear RXBFF flag and the user can read the first frame payload received in the first buffer (at the RAM address set in DMA2_CMAR1).

The number of data bytes in the payload is available in bits [23:16] of the last 8th word.

In the next SWPMI interrupt routine occurrence, the user will read the second frame received in the second buffer (address set in DMA2_CMAR1 + 8), and so on (refer to Figure 691: SWPMI Multi software buffer mode reception).

In case the application software cannot ensure to handle the SMPMI interrupt before the next frame reception, each buffer status is available in the most significant byte of the 8th buffer word:

- The CRC error flag (equivalent to RXBERF flag in the SWPMI_ISR register) is available in bit 24 of the 8th word. Refer to Section 52.3.10: Error management for an CRC error description.
- The receive overrun flag (equivalent to RXOVRF flag in the SWPMI_ISR register) is available in bit 25 of the 8th word. Refer to Section 52.3.10: Error management for an overrun error description.
- The receive buffer full flag (equivalent to RXBFF flag in the SWPMI_ISR register) is available in bit 26 of the 8th word.

In case of a CRC error, both RXBFF and RXBERF flags are set, thus bit 24 and bit 26 are set.

In case of an overrun, an overrun flag is set, thus bit 25 is set. The receive buffer full flag is set only in case of an overrun during the last word reception; then, both bit 25 and bit 26 are set for the current and the next frame reception.

The software can also read the DMA counter (number of data to transfer) in the DMA registers in order to retrieve the frame which has already been received and transferred into the RAM memory through DMA. For example, if the software works with 4 reception buffers,
and if the DMA counter equals 17, it means that two buffers are ready for reading in the RAM area.

In Multi software buffer reception mode, if the software is reading bits 24, 25 and 26 of the 8th word, it does not need to clear RXBERF, RXOVRF and RXBFF flags after each frame reception.

**Figure 691. SWPMI Multi software buffer mode reception**

### 52.3.10 Error management

#### Underrun during payload transmission

During the transmission of the frame payload, a transmit underrun is indicated by the TXUNRF flag in the SWPMI_ISR register. An interrupt is generated if TXBUNREIE bit is set in the SWPMI_IER register.

If a transmit underrun occurs, the SWPMI stops the payload transmission and sends a corrupted CRC (the first bit of the first CRC byte sent is inverted), followed by an EOF. If DMA is used, TXDMA bit in the SWPMI_CR register is automatically cleared.
Any further write to the SWPMI_TDR register while TXUNRF is set will be ignored. The user must set CTXUNRF bit in the SWPMI_ICR register to clear TXUNRF flag.

**Overrun during payload reception**

During the reception of the frame payload, a receive overrun is indicated by RXOVRF flag in the SWPMI_ISR register. If a receive overrun occurs, the SWPMI does not update SWPMI_RDR with the incoming data. The incoming data will be lost.

The reception carries on up to the EOF and, if the overrun condition disappears, the RXBFF flag is set. When RXBFF flag is set, the user can check the RXOVRF flag. The user must set CRXOVRF bit in the SWPMI_ICR register to clear RXBOVRF flag.

If the user wants to detect the overrun immediately, RXBOVREIE bit in the SWPMI_IER register can be set in order to generate an interrupt as soon as the overrun occurs.

The RXOVRF flag is set at the same time as the RXNE flag, two SWPMI_RDR reads after the overrun event occurred. It indicates that at least one received byte was lost, and the loaded word in SWPMI_RDR contains the bytes received just before the overrun.

In Multi software buffer mode, if RXOVRF flag is set for the last word of the received frame, then the overrun bit (bit 25 of the 8th word) is set for both the current and the next frame.

**CRC error during payload reception**

Once the two CRC bytes have been received, if the CRC is wrong, the RXBERF flag in the SWPMI_ISR register is set after the EOF reception. An interrupt is generated if RXBEIE bit in the SWPMI_IER register is set (refer to *Figure 692: SWPMI single buffer mode reception with CRC error*). The user must set CRXBERF bit in SWPMI_ICR to clear RXBERF flag.

**Figure 692. SWPMI single buffer mode reception with CRC error**

**Missing or corrupted stuffing bit during payload reception**

When a stuffing bit is missing or is corrupted in the payload, RXBERF and RXBFF flags are set in SWPMI_ISR after the EOF reception.
Corrupted EOF reception

Once an SOF has been received, the SWPMI accumulates the received bytes until the reception of an EOF (ignoring any possible SOF). Once an EOF has been received, the SWPMI is ready to start a new frame reception and waits for an SOF.

In case of a corrupted EOF, RXBERF and RXBFF flags will be set in the SWPMI_ISR register after the next EOF reception.

Note: In case of a corrupted EOF reception, the payload reception carries on, thus the number of bytes in the payload might get the value 31 if the number of received bytes is greater than 30. The number of bytes in the payload is read in the SWPMI_RFL register or in bits [23:16] of the 8th word of the buffer in the RAM memory, depending on the operating mode.

52.3.11 Loopback mode

The loopback mode can be used for test purposes. The user must set the LPBK bit in the SWPMI_CR register in order to enable the loopback mode.

When the loopback mode is enabled, SWPMI_TX and SWPMI_RX signals are connected together. As a consequence, all frames sent by the SWPMI will be received back.

52.4 SWPMI low-power modes

<table>

Bits 31:12  Reserved, must be kept at reset value.

Bit 11  **RDYF**: transceiver ready flag

This bit is set by hardware as soon as transceiver is ready. After setting the SWPTEN bit in SWPMI_CR register to enable the SWPMI_IO transceiver, software must wait for this flag to be set before setting the SWPACT bit to activate the SWP bus.

0: transceiver not ready
1: transceiver ready

Bit 10  **DEACTF**: DEACTIVATED flag

This bit is a status flag, acknowledging the request to enter the DEACTIVATED mode.

0: SWP bus is in ACTIVATED or SUSPENDED state
1: SWP bus is in DEACTIVATED state

If a RESUME by slave state is detected by the SWPMI while DEACT bit is set by software, the SRF flag will be set, DEACTF will not be set and SWP will move in ACTIVATED state.

Bit 9  **SUSP**: SUSPEND flag

This bit is a status flag, reporting the SWP bus state

0: SWP bus is in ACTIVATED state
1: SWP bus is in SUSPENDED or DEACTIVATED state

Bit 8  **SRF**: Slave resume flag

This bit is set by hardware to indicate a RESUME by slave detection. It is cleared by software, writing 1 to CSRF bit in the SWPMI_ICR register.

0: No Resume by slave state detected
1: A Resume by slave state has been detected during the SWP bus SUSPENDED state

Bit 7  **TCF**: Transfer complete flag

This flag is set by hardware as soon as both transmission and reception are completed and SWP is switched to the SUSPENDED state. It is cleared by software, writing 1 to CTCF bit in the SWPMI_ICR register.

0: Transmission or reception is not completed
1: Both transmission and reception are completed and SWP is switched to the SUSPENDED state

Bit 6  **TXE**: Transmit data register empty

This flag indicates the transmit data register status

0: Data written in transmit data register SWPMI_TDR is not transmitted yet
1: Data written in transmit data register SWPMI_TDR has been transmitted and SWPMI_TDR can be written to again
Bit 5 **RXNE**: Receive data register not empty
This flag indicates the receive data register status
0: Data is not received in the SWPMI_RDR register
1: Received data is ready to be read in the SWPMI_RDR register

Bit 4 **TXUNRF**: Transmit underrun error flag
This flag is set by hardware to indicate an underrun during the payload transmission i.e.
SWPMI_TDR has not been written in time by the software or the DMA. It is cleared by
software, writing 1 to the CTXUNRF bit in the SWPMI_ICR register.
0: No underrun error in transmission
1: Underrun error in transmission detected

Bit 3 **RXOVRF**: Receive overrun error flag
This flag is set by hardware to indicate an overrun during the payload reception, i.e.
SWPMI_RDR has not be read in time by the software or the DMA. It is cleared by software,
writing 1 to CRXOVRF bit in the SWPMI_ICR register.
0: No overrun in reception
1: Overrun in reception detected

Bit 2 **RXBERF**: Receive CRC error flag
This flag is set by hardware to indicate a CRC error in the received frame. It is set
synchronously with RXBFF flag. It is cleared by software, writing 1 to CRXBERF bit in the
SWPMI_ICR register.
0: No CRC error in reception
1: CRC error in reception detected

Bit 1 **TXBEF**: Transmit buffer empty flag
This flag is set by hardware to indicate that no more SWPMI_TDR update is required to
complete the current frame transmission. It is cleared by software, writing 1 to CTXBEF bit in
the SWPMI_ICR register.
0: Frame transmission buffer no yet emptied
1: Frame transmission buffer has been emptied

Bit 0 **RXBFF**: Receive buffer full flag
This flag is set by hardware when the final word for the frame under reception is available in
SWPMI_RDR. It is cleared by software, writing 1 to CRXBFF bit in the SWPMI_ICR register.
0: The last word of the frame under reception has not yet arrived in SWPMI_RDR
1: The last word of the frame under reception has arrived in SWPMI_RDR

Bits 31:12  Reserved, must be kept at reset value.

Bit 11  **CRDYF**: Clear transceiver ready flag
        Writing 1 to this bit clears the RDYF flag in the SWPMI_ISR register
        Writing 0 to this bit does not have any effect

Bits 10:9  Reserved, must be kept at reset value.

Bit 8  **CSRF**: Clear slave resume flag
        Writing 1 to this bit clears the SRF flag in the SWPMI_ISR register
        Writing 0 to this bit does not have any effect

Bit 7  **CTCF**: Clear transfer complete flag
        Writing 1 to this bit clears the TCF flag in the SWPMI_ISR register
        Writing 0 to this bit does not have any effect

Bits 6:5  Reserved, must be kept at reset value.

Bit 4  **CTXUNRF**: Clear transmit underrun error flag
        Writing 1 to this bit clears the TXUNRF flag in the SWPMI_ISR register
        Writing 0 to this bit does not have any effect

Bit 3  **CRXOVRF**: Clear receive overrun error flag
        Writing 1 to this bit clears the RXBOCREF flag in the SWPMI_ISR register
        Writing 0 to this bit does not have any effect

Bit 2  **CRXBERF**: Clear receive CRC error flag
        Writing 1 to this bit clears the RXBERF flag in the SWPMI_ISR register
        Writing 0 to this bit does not have any effect

Bit 1  **CTXBEF**: Clear transmit buffer empty flag
        Writing 1 to this bit clears the TXBEF flag in the SWPMI_ISR register
        Writing 0 to this bit does not have any effect

Bit 0  **CRXBFF**: Clear receive buffer full flag
        Writing 1 to this bit clears the RXBFF flag in the SWPMI_ISR register
        Writing 0 to this bit does not have any effect

### 52.6.5 SWPMI Interrupt Enable register (SMPMI_IER)

Address offset: 0x14

Reset value: 0x0000 0000

Bits 31:2  Reserved, must be kept at reset value

Bit 1 **SWP_CLASS**: SWP class selection  
This bit is used to select the SWP class (refer to Section 52.3.3: SWP initialization and activation).

- 0: Class C: SWPMI_IO uses directly VDD voltage to operate in class C.  
  This configuration must be selected when VDD is in the range [1.62 V to 1.98 V]
- 1: Class B: SWPMI_IO uses an internal voltage regulator to operate in class B.  
  This configuration must be selected when VDD is in the range [2.70 V to 3.30 V]

Bit 0 **SWP_TBYP**: SWP transceiver bypass  
This bit is used to bypass the internal transceiver (SWPMI_IO), and connect an external transceiver.

- 0: Internal transceiver is enabled. The external interface for SWPMI is SWPMI_IO  
  (SWPMI_RX, SWPMI_TX and SWPMI_SUSPEND signals are not available on GPIOs)
- 1: Internal transceiver is disabled. SWPMI_RX, SWPMI_TX and SWPMI_SUSPEND signals are available as alternate function on GPIOs. This configuration is selected to connect an external transceiver

Refer to Section 2.3 on page 126 for the register boundary addresses.
53 Management data input/output (MDIOS)

53.1 MDIOS introduction

An MDIO bus can be useful in systems where a master chip needs to manage (configure and get status data from) one or multiple slave chips. The bus protocol uses only two signals:

- MDC: the Management Data Clock
- MDIO: the data line carrying the opcode (write or read), the slave (port) address, the MDIOS register address, and the data

In each transaction, the master either reads the contents of an MDIOS register in one of its slaves, or it writes data to an MDIOS register in one of its slaves.

The MDIOS peripheral serves as a slave interface to an MDIO bus. An MDIO master can use the MDC/MDIO lines to write and read 32 16-bit MDIOS registers which are held in the MDIOS. These MDIOS registers are managed by the firmware, thus allowing the MDIO master to configure the application running on the STM32 and get status information from it.

The MDIOS can operate in Stop mode, optionally waking up the STM32 if the MDIO master performs a read or a write to one of its MDIOS registers.

53.2 MDIOS main features

The MDIOS includes the following features:

- 32 MDIOS registers addresses, each of which is managed using separate input and output data registers:
  - 32 x 16-bit firmware read/write, MDIOS read-only output data registers
  - 32 x 16-bit firmware read-only, MDIOS write-only input data registers
- Configurable slave (port) address
- Independently maskable interrupts/events:
  - MDIOS register write
  - MDIOS register read
  - MDIOS protocol error
- Able to operate in and wake up from Stop mode
53.3 MDIOS functional description

53.3.1 MDIOS block diagram

Figure 693. MDIOS block diagram

53.3.2 MDIOS pins and internal signals

Table 433 lists the MDIOS inputs and output signals connected to package pins or balls, while Table 434 shows the internal PWR signals.

</tbody>
</table>
53.3.3 MDIOS protocol

The MDIOS protocol uses two signals:
1. MDIOS_MDC: the clock, always driven by the master
2. MDIOS_MDIO: signal carrying the opcode, address, and bidirectional data

Each transaction is performed using a “frame”. Each frame contains 32 bits: 14 control bits, 2 turn-around bits, and then 16 data bits, each passed serially.

- 14 control bits, driven by the master
  - 2 start bits: always “01”
  - 2 opcode bits: read=”10”, write=”01”
  - 5 port address bits, indicating which slave device is being addressed
  - 5 MDIOS register address bits, up to 32 MDIOS registers can be addressed in each slave
- 2 turn-around state bits
  - On write operations, the master drives “10”
  - On read operations, the first bit is high-impedance, and the second bit is driven by the slave to ‘0’
- 16 data bits
  - On write operations, data written to slave’s MDIOS register is driven by the master
  - On read operations, data read from slave’s MDIOS register is driven by the slave

Each frame is usually preceded by a preamble, where the MDIOS stays at ‘1’ for 32 MDC clocks. The master can continue to keep MDIO at ‘1’, indicating the “idle” condition, when it has no frame to send.

When MDIO signal is driven by the master, MDIOS samples it using the rising edge of MDC. When MDIOS drives MDIO, the output changes on the rising edge of MDC.

**Figure 694. MDIO protocol write frame waveform**

**Figure 695. MDIO protocol read frame waveform**
53.3.4 MDIOS enabling and disabling

The MDIOS is enabled by setting the EN bit in the MDIOS_CR register. When EN=1, the MDIOS monitors the MDIO bus and service frames addressed to one of its MDIOS registers.

When the MDIOS is enabled (setting EN to ‘1’), the same write operation to the MDIOS_CR register must properly set the PORT_ADDRESS[4:0] field to indicate the slave port address. A frame is ignored by the MDIOS if its port address is not the same as PORT_ADDRESS[4:0] (presumably intended for another slave).

When EN=0, the MDIOS ignores the frames being transmitted on the MDC/MDIO lines, and the IP is in a reduced consumption mode. Clearing EN also clears all of the DIN registers. If EN is cleared while the MDIOS is receiving a frame, the frame is aborted and the data is lost.

When the MDIOS is enabled, then disabled and subsequently re-enabled, the status flags are not cleared. For a correct operation the firmware shall clear the status flag before re-enabling the MDIOS.

53.3.5 MDIOS data

From the point of view of the MDIO master, there are 32 16-bit MDIOS registers in the MDIOS which can be written and read. In reality, for each MDIOS register ‘n’ there are two sets of registers: DIN[n][15:0] and DOUT[n][15:0].

Input data

When the MDIO master transmits a frame which writes to MDIOS register ‘n’ in the MDIOS, it is the DIN[n][15:0] register which is updated with the incoming data. The DIN registers (DIN0 - DIN31) can be read by the firmware, but they can be written only by the MDIO master via the MDIO bus.

The contents of DINn change immediately after the MDC rising edge when the last data bit is sampled.

If the firmware happens to read the contents of DINn at the moment that it is being updated, there is a possibility that the value read is corrupted (a bit-by-bit cross between the old value and the new value). For this reason, the firmware should assure that two subsequent reads from the same DINn register give the same value and assure that the data was stable when it was read. In the very worst case, the firmware would need to read DINn four times: first to get the old value, second to get an incoherent value (when reading at the moment the register changes), third to get the new value, and forth to confirm the new value.

If the firmware uses the WRF interrupt and can guarantee that it reads the DINn register before any new MDIOS write frame completes, the firmware can perform a single read.

If the MDIO master performs a write operation with a register address that is greater than 31, the MDIOS ignores the frame (the data is not saved and no flag is set).

Output data

When the MDIOS receives a frame which requests to read register ‘n’, it returns the value found in the DOUT[n][15:0] register. Thus, if the MDIO master expects to read the same value which it previously wrote to MDIOS register ‘n’, the firmware must copy the data from
DINn to DOUTn each time new data is written to DINn. For correct operation, the firmware must copy the data to the DOUTn register within a preamble (if the master sends preambles before each frame) plus 15 cycles time.

When an MDIOS register is read via the MDIO bus, the MDIOS passes the 16-bit value (from the corresponding DOUTn register) to the MDIOS clock domain during the 15th cycle of the read frame. If the firmware attempts to write the DOUTn register while the MDIO Master is currently reading MDIOS register ‘n’, then the firmware write operation will be ignored if it occurs during the 15th cycle of the frame (during a one-MDC-cycle window).

Therefore, after writing a DOUTn register, the firmware should read back the same DOUTn register and confirm that the value was actually written. If the DOUTn register does not contain the value which was written, then the firmware can simply try writing and re-reading again.

If the MDIOS frequency is very slow compared to the mdios_pclk frequency, then it might be best not to tie up the CPU by continuously writing and re-reading a DOUT register. Please note that the read flag (RDFn) is set as soon as the DOUTn value is passed to the MDIOS clock domain. Thus, when a write to DOUTn is ignored (when the value read back is not the value which was just written), then the firmware can use a read interrupt to know when it is able to write DOUTn.
Here is a procedure which can be used if the MDC clock is very slow:

1. Write DOUTn.
2. Assure that all of the read flags are zero (MDIOS_RDFR = 0x0000). Clear the flags if necessary using MDIOS_CRDFR.
3. Read back the same DOUTn register and compare the value with the value which was written in step 1.
4. If the values are the same, then the procedure is done. Otherwise, continue to step 5.
5. Enable read interrupts by setting the RDIE bit in MDIOS_CR1.
6. In the interrupt routine, assure that RDFn is set. (no other read flags will be set before bit n).
7. There is a 31 cycle + preamble time window (if the master sends a preamble before each frame) to write DOUTn safely without needing to do a read-back and compare. If this maximum delay cannot be guaranteed, go back to step #1.

If the MDIO master performs a read operation with a register address which is greater than 31, the MDIOS returns a data value of all zeros.

53.3.6 MDIOS APB frequency

Whenever the firmware reads from an MDIOS_DINRn register or writes to an MDIOS_DOUTRn register, the frequency of the APB bus must be at least 1.5 times the MDC frequency. For example, if MDC is at 20MHz, the APB must be at 30MHz or faster.

53.3.7 Write/read flags and interrupts

When MDIOS register ‘n’ is written via the MDIO bus, the WRFn bit in the MDIOS_WRFR register is set. WRFn becomes ‘1’ a the moment that DINn is updated, which is when the last data bit is sampled on a write frame. An interrupt is generated if WRIEN=1 (in the MDIOS_CR register). WRFn is cleared by software by writing ‘1’ to CWRFn (in the MDIOS_CWRFR register).

When MDIOS register ‘n’ is read via the MDIO bus, the RDFn bit in the MDIOS_RDFR register is set. RDFn becomes ‘1’ at the moment that DOUTn is copied to the MDC clock domain, which is on the 15th cycle of a read frame. An interrupt is generated if RDIEN=1 (in the MDIOS_CR register). RDFn is cleared by software by writing ‘1’ to CRDFn (in the MDIOS_CRDFR register).

53.3.8 MDIOS error management

There are three types of errors with their corresponding error flags:

- Preamble error: PERF (bit 0 of MDIOS_SR register)
- Start error: SERF (bit 1 of MDIOS_SR register)
- Turnaround error: TERF (bit 2 of MDIOS_SR register)

Each error flag is set by hardware when the corresponding error condition occurs. Each flag can be cleared by writing ‘1’ to the corresponding bit in the clear flag register (MDIOS_CLRFR).

An interrupt occurs if any of the three error flags is set while EIE=1 (MDIOS_CR).
Besides setting an error flag, the MDIOS performs no action for a frame in which an error is detected: the DIN\textsubscript{n} registers are not updated and the MDIO line is not forced during the data phase.

For a given frame, errors do not accumulate. For example, if a preamble error is detected, no check is done for a start error or a turnaround error for the rest of the current frame.

When DPC=0, following an detected error, all new frames and errors will be ignored until a complete full preamble has been detected.

When DPC=1 (Disable Preamble Check, MDIOS\_CR[7]), all frames and new errors are ignored as long as one of the error flags is set. As soon as the error bit is cleared, the MDIOS starts looking for a start sequence. Thus, the application must clear the error flag only when it is sure that no frame is currently in progress. Otherwise, the MDIOS will likely misinterpret the bits being sent and become desynchronized with the master.

### Preamble errors

A preamble error occurs when a start sequence begins (with MDIO sampled at '0') without being immediately preceded by a preamble (MDIO sampled at '1' for at least 32 consecutive clocks).

Preamble errors are not reported after the MDIOS is first enabled (EN=1 in MDIOS\_CR) until after a full preamble is received. This is to avoid an error condition when the peripheral frame detection is enabled while a preamble or frame is already in progress. In this case, the MDIOS ignores the first frame (since it did not first detect a full preamble), but does not set PERF.

If the DPC bit (Disable Preamble Check, MDIOS\_CR[7]) is set, then the MDIO Master can send frames without preceding preambles and no preamble error will be signaled. When DPC=1, the application must assure that the master is not in the process of sending a frame at the moment that the MDIOS is enabled (EN is set). Otherwise, the slave might become desynchronized with the master.

### Start errors

A start error occurs when an illegal start sequence occurs or if an illegal command is given. The start sequence must always be "01", and the command must be either "01" (write) or "10" (read).

As with preamble errors, start errors are not reported until after a full preamble is received.

### Turnaround errors

A turnaround error occurs when an error is detected in the turnaround bits of write frames. The 15th bit of the write frame must be '1' and the 16th bit must be '0'.

Turnaround errors are only reported after a full preamble is received, there is no start error, the port address in the current frame matches and the register address is in the supported range 0 to 31.

### 53.3.9 MDIOS in Stop mode

The MDIOS can operate in Stop mode, responding to all reads, performing all writes, and causing the STM32 to wakeup from Stop mode on MDIOS interrupts.
53.3.10 MDIOS interrupts

There is a single interrupt vector for the three types of interrupts (write, read, and error). Any of these interrupt sources can wake the STM32 up from Stop mode. All interrupt flags need to be cleared in order to clear the interrupt line.

Bits 31:13  Reserved, must be kept at reset value.

Bits 12:8  PORT_ADDRESS[4:0]: Slave’s address.
Can be written only when the peripheral is disabled (EN=0).
If the address given by the MDIO master matches PORT_ADDRESS[4:0], then the MDIOS services the frame. Otherwise the frame is ignored.

Bit 7  DPC: Disable Preamble Check.
0: MDIO Master must give preamble before each frame.
1: MDIO Master can send each frame without a preceding preamble, and the MDIOS will not signal a preamble error.
When this bit is set, the application must be sure that no frame is currently in progress when the MDIOS is enabled. Otherwise, the MDIOS can become desynchronized with the master.
This bit cannot be changed unless EN=0 (though it can be changed at the same time that EN is being set).

Bits 6:4  Reserved, must be kept at reset value.

Bit 3  EIE: Error interrupt enable.
0: Interrupt is disabled
1: Interrupt is enabled
When this bit is set, an interrupt is generated if any of the error flags (PERF, SERF, or TERF in the MDIOS_SR register) is set.

Bit 2  RDIE: Register Read Interrupt Enable.
0: Interrupt is disabled
1: Interrupt is enabled
When this bit is set, an interrupt is generated if any of the read flags (RDF[31:0] in the MDIOS_RDFR register) is set.

Bit 1  WRIE: Register write interrupt enable.
0: Interrupt is disabled
1: Interrupt is enabled
When this bit is set, an interrupt is generated if any of the read flags (WRF[31:0] in the MDIOS_WRFR register) is set.

Bit 0  EN: Peripheral enable.
0: MDIOS is disabled
1: MDIOS is enabled and monitoring the MDIO bus (MDC/MDIO)
53.4.2 MDIOS write flag register (MDIOS_WRFR)

Bits 31:0 **WRF[31:0]**: Write flags for MDIOS registers 0 to 31.
Each bit is set by hardware when the MDIO master performs a write to the corresponding MDIOS register. An interrupt is generated if WRIE (in MDIOS_CR) is set.
Each bit is cleared by software by writing ‘1’ to the corresponding CWRF bit in the MDIOS_CWFR register.
For WRFn:
0: MDIOS register ‘n’ has not been written by the MDIO master
1: MDIOS register ‘n’ has been written by the MDIO master and the data is available in DIN[n][15:0] in the MDIOS_DINRn register

**DOUTn[15:0]**

- Bits 31:16: Reserved, must be kept at reset value.
- Bits 15:0: DOUTn[15:0]: Output data sent to MDIO Master during read frames
  - This field is written by SW. These 16 bits are serially output on the MDIO bus during read frames which address the MDIOS register ‘n’.
53.4.10 MDIOS register map

Refer to Section 2.3 on page 126 for the register boundary addresses.
Secure digital input/output MultiMediaCard interface (SDMMC)

54.1 SDMMC main features

The SD/SDIO, embedded MultiMediaCard (eMMC) host interface (SDMMC) provides an interface between the AHB bus and SD memory cards, SDIO cards and eMMC devices.

The MultiMediaCard system specifications are available through the MultiMediaCard Association website at www.mmca.org, published by the MMCA technical committee.

SD memory card and SD I/O card system specifications are available through the SD card Association website at www.sdcard.org.

The SDMMC features include the following:

- Compliance with Embedded MultiMediaCard System Specification Version 4.51. Card support for three different databus modes: 1-bit (default), 4-bit and 8-bit. (HS200 SDMMC_CK speed limited to maximum allowed I/O speed)
- Full compatibility with previous versions of MultiMediaCards (backward compatibility).
- Full compliance with SD memory card specifications version 4.1. (SDR104 SDMMC_CK speed limited to maximum allowed I/O speed, SPI mode and UHS-II mode not supported).
- Full compliance with SDIO card specification version 4.0. Card support for two different databus modes: 1-bit (default) and 4-bit. (SDR104 SDMMC_CK speed limited to maximum allowed I/O speed, SPI mode and UHS-II mode not supported).
- Data transfer up to 208 Mbyte/s for the 8-bit mode. (depending maximum allowed I/O speed).
- Data and command output enable signals to control external bidirectional drivers.

The MultiMediaCard/SD bus connects cards to the host.

The current version of the SDMMC supports only one SD/SDIO/eMMC card at any one time and a stack of eMMC.

54.2 SDMMC bus topology

Communication over the bus is based on command/response and data transfers.

The basic transaction on the SD/SDIO/eMMC bus is the command/response transaction. These types of bus transaction transfer their information directly within the command or response structure. In addition, some operations have a data token.

Data transfers are done in the following ways:

- Block mode: data block(s) with block size $2^N$ bytes with N in the range 0-14.
- SDIO multibyte mode: single data block with block size range 1-512 bytes
- eMMC Stream mode: continuous data stream

Data transfers to/from eMMC cards are done in data blocks or streams.
Figure 696. SDMMC “no response” and “no data” operations

![Diagram showing SDMMC CMD and SDMMC D signals with response and no data operations.]

Note: The Stop Transmission command is not required at the end of an eMMC multiple block read with predefined block count.

Figure 697. SDMMC (multiple) block read operation

![Diagram showing SDMMC CMD and SDMMC D signals with block read and multiple block read operations.]

Note: The Stop Transmission command is not required at the end of an eMMC multiple block read with predefined block count.

Note: The SDMMC will not send any data as long as the Busy signal is asserted (SDMMC_D0 pulled low).

Figure 698. SDMMC (multiple) block write operation

![Diagram showing SDMMC CMD and SDMMC D signals with block write and multiple block write operations.]

Note: The Stop Transmission command is not required at the end of an eMMC multiple block write with predefined block count.
Stream data transfer operates only in a 1-bit wide bit configuration on SDMMC_D0 in single data rate modes (DS, HS, and SDR).

### 54.3 SDMMC operation modes

<table>
<thead>
<tr>

1. SDR single data rate signaling.
2. DDR double data rate signaling. (data is sampled on both SDMMC_CK clock edges).
3. eMMC bus speed with 8bit bus width.
4. Maximum frequency depending on maximum allowed IO speed.

HS200 mode requires variable delay support using sampling point tuning.

54.4 SDMMC functional description

The SDMMC consists of four parts:
- The AHB slave interface accesses the SDMMC adapter registers, and generates interrupt signals and IDMA control signals.
- The SDMMC adapter block provides all functions specific to the eMMC/SD/SD I/O card such as the clock generation unit, command and data transfer.
- The internal DMA (IDMA) block with its AHB master interface.
- A delay block (DLYB) taking care of the receive data sample clock alignment. The delay block is NOT part of the SDMMC. A delay block is mandatory when supporting SDR104 or HS200.
54.4.1 SDMMC block diagram

*Figure 701* shows the SDMMC block diagram.

![SDMMC block diagram](image.png)

54.4.2 SDMMC pins and internal signals

*Table 439* lists the SDMMC internal input/output signals, *Table 440* the SDMMC pins (alternate functions).

</tr>
</tbody>
</table>
The SDMMC_D[7:0] lines have different operating modes:

- By default, SDMMC_D0 line is used for data transfer. After initialization, the host can change the databus width.
- For an eMMC, 1-bit (SDMMC_D0), 4-bit (SDMMC_D[3:0]) or 8-bit (SDMMC_D[7:0]) data bus widths can be used.
- For an SD or an SDIO card, 1-bit (SDMMC_D0) or 4-bit (SDMMC_D[3:0]) can be used.

All data lines operate in push-pull mode.

To allow the connection of an external driver (a voltage switch transceiver), the direction of data flow on the data lines is indicated with I/O direction signals. The SDMMC_D0DIR signal indicates the I/O direction for the SDMMC_D0 data line, the SDMMC_D123DIR for the SDMMC_D[3:1] data lines.

SDMMC_CMD only operates in push-pull mode:

To allow the connection of an external driver (a voltage switch transceiver), the direction of data flow on the SDMMC_CMD line is indicated with the I/O direction signal SDMMC_CDIR.

SDMMC_CK clock to the card originates from sdmmc_ker_ck:

- When the sdmmc_ker_ck clock has 50% duty cycle, it can be used even in bypass mode (CLKDIV = 0).
- When the sdmmc_ker_ck duty cycle is not 50%, the CLKDIV must be used to divide it by 2 or more (CLKDIV > 0).
- The phase relation between the SDMMC_CMD / SDMMC_D[7:0] outputs and the SDMMC_CK can be selected through the NEGEDGE bit. The phase relation depends on the CLKDIV, NEGEDGE, and DDR settings. See Figure 702.
By default, the \texttt{sdmmc_io_in_ck} feedback clock input is selected for sampling incoming data in the SDMMC receive path. It is derived from the SDMMC\_CK pin.

For tuning the phase of the sampling clock to accommodate the receive data timing, the DLYB delay block available on the device can be connected between \texttt{sdmmc_io_in_ck} signal (DLYB input \texttt{dlyb\_in\_ck}) and \texttt{sdmmc\_fb\_ck} clock input of SDMMC (DLYB output \texttt{dlyb\_out\_ck}). Selecting the \texttt{sdmmc\_fb\_ck} clock input in the receive path then allows using the phase-tuned sampling clock for the incoming data. This is required for SDMMC to support the SDR104 and HS200 operating mode and optional for SDR50 and DDR50 modes.

When using an external driver (a voltage switch transceiver), the SDMMC\_CKIN feedback clock input can be selected to sample the receive data.

For an SD/SDIO/e\textsuperscript{MMC} card, the clock frequency can vary between 0 and 208 MHz (limited by maximum I/O speed).
Depending on the selected bus mode (SDR or DDR), one bit or two bits are transferred on SDMMC_D[7:0] lines with each clock cycle. The SDMMC_CMD line transfers only one bit per clock cycle.

54.4.4 SDMMC adapter

The SDMMC adapter (see Figure 701: SDMMC block diagram) is a multimedia/secure digital memory card bus master that provides an interface to a MultiMediaCard stack or to a secure digital memory card. It consists of the following subunits:

- Control unit
- Data transmit path
- Command path
- Data receive path
- Response path
- Receive data path clock multiplexer
- Delay block (DLYB), external to the SDMMC
- Adapter register block
- Data FIFO
- Internal DMA (IDMA)

Note: The adapter registers and FIFO use the AHB clock domain (sdmmc_hclk). The control unit, command path and data transmit path use the SDMMC adapter clock domain (sdmmc_ker_ck). The response path and data receive path use the SDMMC adapter feedback clock domain from the sdmmc_io_in_ck, or SDMMC_CKIN, or from the sdmmc_fb_ck generated by DLYB.

The DLYB delay block on the device can be used in conjunction with the SDMMC adapter, to tune the phase of the sampling clock for incoming data in SDMMC receive mode. It is required for the SDMMC to support the SDR104 and HS200 operating mode and optional for SDR50 and DDR50 modes.

Adapter register block

The adapter register block contains all system control registers, the SDMMC command and response registers and the data FIFO.

This block also generates the signals from the corresponding bit location in the SDMMC Clear register that clear the static flags in the SDMMC adapter.

Control unit

The control unit illustrated in Figure 703, contains the power management functions, the SDMMC_CK clock management with divider, and the I/O direction management.
The power management subunit disables the card bus output signals during the power-off and power-up phases.

There are three power phases:
- power-off
- power-up
- power-on

The clock management subunit uses the sdmmc_ker_ck to generate the SDMMC_CK and provides the division control. It also takes care of stopping the SDMMC_CK for i.e. flow control.

The clock outputs are inactive:
- after reset
- during the power-off or power-up phases
- if the power saving mode (register bit PWRSAV) is enabled and the card bus is in the Idle state for eight clock periods. The clock will be stopped eight cycles after both the command/response CPSM and data path DPSM subunits have enter the Idle phase. The clock will be restarted when the command/response CPSM or data path DPSM is activated (enabled).

The I/O management subunit takes care of the SDMMC_Dn and SDMMC_CMD I/O direction signals, which controls the external voltage transceiver.

**Command/Response path**

The Command/Response path subunit transfers commands and responses on the SDMMC_CMD line. The Command path is clocked on the SDMMC_CK and sends commands to the card. The Response path is clocked on the sdmmc_rx_ck and receives responses from the card.
Command/Response path state machine (CPSM)

- When the command register is written to and the enable bit is set, command transfer starts. When the command has been sent the CRC is appended and the command path state machine (CPSM) sets the status flags and:
  - if a response is not required enters the Idle state.
  - If a response is required, it waits for the response.
- When the response is received,
  - for a response with CRC, the received CRC code and the internally generated code are compared, and the appropriate status flag is set according the result.
  - for a response without CRC, no CRC is checked, and the appropriate status flag is not set.

When ever the CPSM is active, i.e. not in the Idle state, the CPSMACT bit is set.
Figure 705. Command path state machine (CPSM)

- **Idle**: The command path is inactive. When the command control register is written and the enable bit (CPSMEN) is set, the CPSM will activate the SDMMC_CK clock (when stopped due to power save PWRSAV bit) and moves
  - to the Send state when WAITPEND = 0 & BOOTEN = 0.
  - to the Pending state when WAITPEND = 1.
  - to the boot state when BOOTEN = 1.

- **Send**: The command is sent and the CRC is appended.
  - When CMDTRANS bit is set or when BOOTEN bit is set and BOOTMODE is alternative boot, and the DTDIR = receive, the CPSM DataEnable signal will be issued to the DPSM at the end of the command.
  - When the CMDTRANS bit is set and the CMDSUSPEND bit is 0 the interrupt period will be terminated at the end of the command.
  - When CMDSTOP bit is set the CPSM Abort signal will be issue to the DPSM at the end of the command.
  - If no response is expected (WAITRESP = 00) the CPSM will move to the Idle state and the CMDSENT flag is set. When BOOTMODE = 1 & BOOTEN = 0 the CMDSENT flag is delayed 56 cycles after the command End bit, otherwise the
CMDSENT flag is generated immediately after the command End bit. The RESPCMDR and RESPxR registers are not modified.

- If a command response is expected (WAITRESP = not 00) the CPSM will move to the Wait state and start the response timeout.

• **Wait:** The Command path waits for a response.
  - When WAITINT bit is 0 the command timer starts running and the CPSM waits for a Start bit.
    a) If a Start bit is detected before the timeout the CPSM moves to the Receive state.
    b) If the timeout is reached before the CPSM detect a response start bit, the timeout flag (CTIMEOUT) is set and the CPSM moves to the Idle state. The RESPCMDR and RESPxR registers are not modified.
  - When WAITINT bit is 1, the timer is disabled and the CPSM waits for an interrupt request (Response Start bit) from one of the cards.
    a) When a Start bit is detected the CPSM moves to the Receive state.
    b) When writing WAITINT to 0 (interrupt mode abort), the host will send a response by its self and on detecting the Start bit the CPSM move to the Receive state.

• **Receive:** The command response will be received. Depending the response mode bits WAITRESP in the command control register, the response can be either short or long, with CRC or without CRC. The received CRC code when present will be verified against the internally generated CRC code.
  - When the CMD SUSPEND bit is set and the SDIO Response bit BS = 0 (response bit [39]), the interrupt period will be started after the response.
    When the CMD SUSPEND bit is cleared, or the CMD SUSPEND bit is 1 and the SDIO Response bit BS = 1 (response bit [39]), there will be no interrupt period started.
  - When the CMDTRANS bit is set and the CMD SUSPEND bit is set and the SDIO Response bit DF= 1 (response bit [32]) the interrupt period will be terminated after the response.
  - When the CRC status passes or no CRC is present the CMDREND flag is set, the CPSM moves to the Idle state. The RESPCMDR and RESPxR registers are updated with received response.
    - When BOOTMODE = 1 & BOOTEN = 0 the CMDREND flag is delayed 56 cycles after the response End bit, otherwise the CMDREND flag is generated immediately after the response End bit.
    - When CMDTRANS bit is set and the DTDIR = transmit, the CPSM DataEnable signal will be issued to the DPSM at the end of the command response.
  - When the CRC status fails the CCRCFAIL flag is set and the CPSM moves to the Idle state. The RESPCMDR and RESPxR registers are updated with received response.

• **Pending:** According the pending WAITPEND bit in the command register, the CPSM enters the pending state.
  - When DATALENGTH <= 5 bytes the CPSM moves to the Sent state and generates the DataEnable signal to start the data transfer aligned with the CMD12 Stop Transmission command.
  - When DATALENGTH > 5 bytes, the CPSM DataEnable signal will be issued to the DPSM to start the data transfer. The CPSM waits for a sendCMD signal from the...
DPSM before moving to the Sent state. This enables i.e. the CMD12 Stop Transmission command to be sent aligned with the data.

- When writing WAITPEND to 0, the CPSM will move to the Sent state.

- **Boot**: If the BOOTEN bit is set in the command register, the CPSM enters the boot state, and when:
  - BOOTMODE = 0 the SDMMC_CMD line is driven low and when CMDTRANS bit is set and the DTDIR = receive, the CPSM DataEnable signal will be issued to the DPSM. This enables normal boot operation. This state is left at the end of the boot procedure by clearing the register bit BOOTEN, which cause the SDMMC_CMD line to be driven high and the CPSM Abort signal will be issued to the DPSM, before moving to the Idle state. The CMDSENT flag is generated 56 cycles after SDMMC_CMD line is high.
  - BOOTMODE = 1, move to the Send state. This enables sending of the CMD0 (boot). Clearing BOOTEN has no effect.

*Note:* The CPSM remains in the Idle state for at least eight SDMMC_CK periods to meet the $N_{CC}$ and $N_{RC}$ timing constraints. $N_{CC}$ is the minimum delay between two host commands, and $N_{RC}$ is the minimum delay between the host command and the card response.

*Note:* The response timeout has a fixed value of 64 SDMMC_CK clock periods.

A Command is a token that starts an operation. Commands are sent from the host to either a single card (addressed command) or all connected cards (broadcast command are available for eMMC V3.31 or previous). Commands are transferred serially on the SDMMC_CMD line. All commands have a fixed length of 48 bits. The general format for a command token for SD-Memory cards, SDIO cards, and eMMC cards is shown in Table 442.

The Command token data is taken from 2 registers, one containing a 32-bits argument and the other containing the 6-bits command index (six bits sent to a card).

<table>
<thead>
<tr>
<th>Bit position</th>
<th>Width</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>

</tr>
</tbody>
</table>

Next to the Command data there are command type (WAITRESP) bits controlling the command path state machine (CPSM). These bits also determine whether the command requires a response, and whether the response is short (48 bit) or long (136 bits) long, and if a CRC is present or not.

A Response is a token that is sent from an addressed card or synchronously from all connected cards to the host as an answer to a previous received Command. All responses are sent via the command line SDMMC_CMD. The response transmission always starts with the left bit of the bit string corresponding to the response code word. The code length depends on the response type. Response tokens R1, R2, R3, R4, R5, and R6 have various
coding schemes, depending on their content. The general formats for the response tokens for SD-Memory cards, SDIO cards, and eMMC cards are shown in Table 443, Table 444, and Table 445.

A response always starts with a start bit (always 0), followed by the bit indicating the direction of transmission (card = 0). A value denoted by x in the tables below indicates a variable entry. Most responses, except some, are protected by a CRC. Every command code word is terminated by the End bit (always 1).

The Response token data is stored in 5 registers, four containing the 32-bits card status, OCR register, argument or 127-bits CID or CSD register including internal CRC, and one register containing the 6-bits command index.

Table 445. Long response with CRC token format

The Command/Response path operates in a half-duplex mode, so that either commands can be sent or responses can be received. If the CPSM is not in the Send state, the
SDMMC_CMD output is in the Hi-Z state. Data sent on SDMMC_CMD are synchronous with the SDMMC_CK according the NEGEDGE register bit see Figure 702.

The Command and Short Response with CRC, the CRC generator calculates the CRC checksum for all 40 bits before the CRC code. This includes the start bit, transmitter bit, command index, and command argument (or card status).

For the Long Response the CRC checksum is calculated only over the 120 bits of R2 CID or CSD. Note that the start bit, transmitter bit and the six reserved bits are not used in the CRC calculation.

The CRC checksum is a 7-bit value:
\[ \text{CRC}[6:0] = \text{Remainder} \left[ (M(x) \times x^7) / G(x) \right] \]
\[ G(x) = x^7 + x^3 + 1 \]
\[ M(x) = (\text{first bit}) \times x^n + (\text{second bit}) \times x^{n-1} + \ldots + (\text{last bit before CRC}) \times x^0 \]
Where \( n = 39 \) or 119.

The CPSM allows to send a number of specific commands to handle various operating modes when CPSMEN is set, see Table 446.

1. When CMDTRANS is set, also a stop_transmission command shall be send to move the DPSM to Idle.

Data path

The data path subunit transfers data on the SDMMC_D[7:0] lines to and from cards. The data transmit path is clocked on the SDMMC_CK and sends data to the card. The data receive path is clocked on the sdmmc_rx_ck and receives data from the card. Figure 706 shows the data path block diagram.
The card data bus width can be programmed in the clock control register bits WIDBUS. The supported data bus width modes are:

- If the wide bus mode is not enabled, only one bit is transferred over SDMMC_D0.
- If the 4-bit wide bus mode is enabled, data is transferred at four bits over SDMMC_D[3:0].
- If the 8-bit wide bus mode is enabled, data is transferred at eight bits over SDMMC_D[7:0].

Next to the data bus width the data sampling mode can be programmed in the clock control register bit DDR. The supported data sampling modes are:

- Single data rate signaling (SDR), data is clocked on the rising edge of the clock.
- Double data rate signaling (DDR), data is clocked on the both edges of the clock. DDR mode is only supported in wide bus mode (4-bit wide and 8-bit wide).

*Note:* The data sampling mode only applies to the SDMMC_D[7:0] lines. (not applicable to the SDMMC_CMD line.)
In DDR mode, data is sampled on both edges of the SDMMC_CK according to the following rules, see also Figure 707 and Figure 708:

- On the rising edge of the clock Odd bytes are sampled.
- On the falling edge of the clock Even bytes are sampled.
- Data payload size is always a multiple of 2 Bytes.
- Two CRC16 are computed per data line
  - Odd bits CRC16 clocked on the falling edge of the clock.
  - Even bits CRC16 clocked on the rising edge of the clock.
- Start, End bits and idle conditions are full cycle.
- CRC status / boot acknowledgment and Busy signaling are full cycle and are only sampled on the rising edge of the clock.

In DDR mode the SDMMC_CK clock division shall be >= 2.

**Figure 707. DDR mode data packet clocking**

**Figure 708. DDR mode CRC status / boot acknowledgment clocking**

Data path state machine (DPSM)

Depending on the transfer direction (send or receive), the data path state machine (DPSM) moves to the Wait_S or Wait_R state when it is enabled:

- **Send:** the DPSM moves to the Wait_S state. If there is data in the transmit FIFO, the DPSM moves to the Send state, and the data path subunit starts sending data to a card.
- **Receive:** the DPSM moves to the Wait_R state and waits for a start bit. When it receives a start bit, the DPSM moves to the Receive state, and the data path subunit starts receiving data from a card.
For boot operation with acknowledgment the DPSM moves to the Wait_Ack state and waits for the boot acknowledgment before moving to the Wait_R state.

The DPSM operates at SDMMC_CK. The DPSM has the following states, as shown in Figure 709. When ever the DPSM is active, i.e. not in the Idle state, the DPSM_ACT bit is set.

**Figure 709. Data path state machine (DPSM)**

- **Idle state**: the data path is inactive, and the SDMMC_D[7:0] outputs are according the PWRCTRL setting. The DPSM will be activated either by sending a command with CMDTRANS bit set or by setting the DTEN bit, or by detecting Busy on SDMMC_D0 (that is, after a command with R1b response).

  When not busy, the DPSM will activate the SDMMC_CK clock (when stopped due to power save PWRSAV bit), loads the data counter with a new (DATALENGTH) value and:
  - When the data direction bit (DTDIR) indicates send, moves to the Wait_S.
  - When the data direction bit (DTDIR) indicates receive, moves to the
    - Wait_R when BOOTACKEN register bit is clear.
    - Wait_Ack when BOOTACKEN register bit is set and start the acknowledgment timeout.

  When busy the DPSM will keep the SDMMC_CK clock active and move to the Busy state.
Note: *DTEN shall not be used to start data transfer with SD, SDIO and eMMC cards.*

- **Wait_Ack** state: the data path waits for the boot acknowledgment token.
  - The DPSM moves to the Wait_R state if it receives an error free acknowledgment before a timeout.
  - When a pattern different from the acknowledgment is received an acknowledgment status error is generated, and the Ack fail status flag (ACKFAIL) is set. The DPSM stays in Wait_Ack.
  - If it reaches a timeout (ACKTIME) before it detects a start bit, it sets the timeout status flag (ACKTIMEOUT). The DPSM stays in Wait_Ack.
  - When the CPSM Abort signal is set it moves to the Idle state and sets the DABORT flag.

- **Wait_R** state: the data path, if the data counter is not zero and data is not hold, waits for a start bit on SDMMC_D[n:0]. If the data counter is zero or data is hold, wait for the FIFO to be empty.
  - In block mode, if a start bit is received before a timeout the DPSM moves to the Receive state and loads the data block counter with DBLOCKSIZE.
  - In SDIO multibyte mode, if a start bit is received before a timeout the DPSM moves to the Receive state and loads the data block counter with DATALENGTH.
  - In stream mode, if a start bit is received before a timeout the DPSM moves to the Receive state and loads the data counter with DATALENGTH.
  - If the data counter (DATACOUNT) equals zero (end of data) the DPSM moves to the Idle state when the receive FIFO is empty and the DATAEND flag is set.
  - If it reaches a timeout (DATATIME) before it detects a start bit, it sets the timeout status flag (DTIMEOUT) and the DPSM stays in the WAIT_R state.
  - If the CPSM Abort signal is set:
    - If DATACOUNT > 0, the DPSM moves to the Idle state when the FIFO is empty and when IDMAEN = 0 reset with FIFORST, and sets the DABORT flag.
    - If DATACOUNT is zero normal operation is continued, there will be no DABORT flag since the transfer has completed normally.
  - if the DTHOLD bit is set:
    - When DATACOUNT > 0, the DPSM moves to the Idle state when the receive FIFO is empty and when IDMAEN = 0 reset with FIFORST, and issues the DHOLD flag. When Holding the timeout is disabled. When an CPSM Abort signal is received during Holding, the transfer is Aborted.
- When DATACOUNT = 0, the transfer is completed normally and there will be no DHOLD flag.
  – When DPSM has been started with DTEN, after an error (DTIMEOUT) the DPSM moves to the Idle state when the FIFO is empty and when IDMAEN = 0 reset with FIFORST.

- **ReadWrite** state: the data path ReadWait the bus.
  – The DPSM moves to the Wait_R state when the ReadWait stop bit (RWSTOP) is set, and start the receive timeout.
  – If the CPSM Abort signal is set, wait for the FIFO to be empty and when IDMAEN = 0 reset with FIFORST, then moves to the Idle state and sets the DABORT flag.

- **Receive** state: the data path receives serial data from a card. Pack the data in bytes and write it to the data FIFO. Depending on the transfer mode selected in the data control register (DTMODE), the data transfer mode can be either block or stream:
  – In block mode, when the data block size (DBLOCKSIZE) number of data bytes are received, the DPSM waits until it receives the CRC code.
  – In SDIO multibyte mode, when the data block size (DATALENGTH) number of data bytes are received, the DPSM waits until it receives the CRC code.

  a) If the received CRC code matches the internally generated CRC code, the DPSM moves to the
     - Wait_R state when RWSTART= 0 and start the receive timeout.
     - ReadWait state when RWSTART = 1 and DATACOUNT > zero, and the DBCKEND flag is set.

  b) If the received CRC code fails the internally generated CRC code any further data reception is prevented.
     - When not all data has been received (DATACOUNT > 0), the CRC fail status flag (DCRCFAIL) is set and the DPSM stays in the Receive state.
     - When all data has been received (DATACOUNT = 0), wait for the FIFO to be empty after which the CRC fail status flag (DCRCFAIL) is set and the DPSM moves to the Idle state.

  – In stream mode, the DPSM receives data while the data counter DATACOUNT > 0. When the counter is zero, the remaining data in the shift register is written to the data FIFO, and the DPSM moves to the Wait_R state.

  – When a FIFO overrun error occurs, the DPSM sets the FIFO overrun error flag (RXOVERR) and any further data reception is prevented. The DPSM stays in the Receive state.

  – When an CPSM_Abort signal is received:
    - If the CPSM_Abort signal is received before the 2 last bits of the data with DATACOUNT = 0, the transfer is aborted. The remaining data in the shift register is written to the data FIFO, wait for the FIFO to be empty and when IDMAEN = 0 reset with FIFORST, then the DPSM moves to the Idle state and the DABORT flag is set.
    - If the CPSM_Abort signal is received during or after the 2 last bits of the transfer with DATACOUNT=0, the transfer is completed normally. The DPSM stays in the Receive state no DABORT flag is generated.

  – When DPSM has been started with DTEN, after an error (DCRCFAIL when DATACOUNT > 0, or RXOVERR) the DPSM moves to the Idle state when the FIFO is empty and when IDMAEN = 0 reset with FIFORST.
- **Wait_S state:** the data path waits for data to be available from the FIFO.
  - If the data counter \( \text{DATACOUNT} > 0 \), waits until the data FIFO empty flag (TXFIFOE) is de-asserted and DTHOLD is not set, and moves to the Send state.
  - If the data counter (DATACOUNT) = 0 the DPSM moves to the Idle state.
    - When DTHOLD is disabled, the DATAEND flag is set.
    - When DTHOLD is enabled, the DHOLD flag is set.
  - When DTHOLD is set and the DATACOUNT > 0
    - When IDMA is enabled, the DBCKEND flag is set and subsequently the FIFO is flushed, furthermore the DPSM will move to the Idle state and the DHOLD flag is set.
    - When IDMA is disabled the DBCKEND flag is set. Wait for the FIFO to be reset by software with FIFORST, then DPSM will move to the Idle state and issues the DHOLD flag.
  - When DTHOLD is set and DATACOUNT = 0 the transfer is completed normally.
  - When receiving the CPSM Abort signal
    - If the CPSM_Abort signal is received before the 2 last bits of the data with \( \text{DATACOUNT} = 0 \), the transfer is aborted, wait for the FIFO to be empty and when IDMAEN = 0 reset with FIFORST, then the DPSM moves to the Idle state and sets the DABORT flag.
    - If the CPSM_Abort signal is received during or after the 2 last bits of the transfer with \( \text{DATACOUNT}=0 \), normal operation is continued, there will be no DABORT flag since the transfer has completed normally.

**Note:** The DPSM remains in the Wait_S state for at least two clock periods to meet the \( N_{WR} \) timing requirements, where \( N_{WR} \) is the number of clock cycles between the reception of the card response and the start of the data transfer from the host.

- **Send state:** the DPSM starts sending data to a card. Depending on the transfer mode bit in the data control register, the data transfer mode can be either block, SDIO multibyte or stream:
  - In block mode, when the data block size (DBLOCKSIZE) number of data bytes are send, the DPSM sends an internally generated CRC code and End bit, and moves to the Busy state and start the transmit timeout.
  - In SDIO multibyte mode, when the data block size (DATALENGTH) number of data bytes are send, the DPSM sends an internally generated CRC code and End bit, and moves to the Busy state and start the transmit timeout.
  - In stream mode, the DPSM sends data to a card while the data counter DATACOUNT > 0. When the data counter reaches zero moves to the Busy state and start the transmit timeout. Before sending the last stream Byte according to DATACOUNT, the DPSM issues a trigger on the sendCMD signal. This signal is used by the CPSM to sent any pending command. (i.e. CMD12 Stop Transmission command)
  - If a FIFO underrun error occurs, the DPSM sets the FIFO underrun error flag (TXUNDERR). The DPSM stays in the Send state.
  - When receiving the CPSM Abort signal
    - If the CPSM_Abort signal is received before the 2 last bits of the transfer with \( \text{DATACOUNT}=0 \), the transfer is aborted. The DPSM will send a last data bit followed by an End bit. The FIFO will be disabled/flushed, and the DPSM moves to the Busy state to wait for not busy before setting the DABORT flag.
    - If the CPSM_Abort signal is received during or after the 2 last bits of the transfer
• **Busy** state: the DPSM waits for the CRC status token when expected, and wait for a not busy signal:
  - If a CRC status token is expected and indicate “non-erroneous transmission” or when there is no CRC expected:
    - it moves to the Wait_S state when SDMMC_D0 is not low (the card is not busy).
    - When the card is busy SDMMC_D0 is low it will remain in the Busy state.
  - If a CRC status token is expected and indicates “erroneous transmission”.
    - When not all data has been send (DATACOUNT > 0). The DPSM waits for not busy after which the CRC fail status flag (DCRCFAIL) is set. The FIFO will be disabled/flushed and the DPSM stays in the Busy state.
    - When all data has been send (DATACOUNT = 0). The DPSM waits for not busy after which the CRC fail status flag (DCRCFAIL) is set and the DPSM moves to the Idle state.
  - If a CRC status (Ncrc) timeout occurs while the DPSM is in the Busy state, it sets the data timeout flag (DTIMEOUT) and stays in the Busy state.
  - If a busy timeout occurs while the DPSM is in the Busy state, it sets the data timeout flag (DTIMEOUT) and stays in the Busy state.
  - When receiving the CPSM Abort signal in the Busy state:
    - If the CPSM_Abort signal is received before the 2 last bits of the CRC response with DATACOUNT > 0, the data transfer is aborted. The DPSM waits for not busy and the FIFO to be disabled/flushed before moving to the Idle state and the DABORT flag is set.
    - If the CPSM_Abort signal is received during or after the 2 last bits of the CRC response when DATACOUNT=0 or when no CRC is expected and DATACOUNT = 0 and there has been no DTIMEOUT error, the DPSM stays in the Busy state no DABORT flag is generated, since the transfer may completed normally.
    - If the CPSM_Abort signal is received when a DTIMEOUT error has occurred the DPSM waits for not busy and the FIFO to be disabled/flushed before moving to the Idle state and the DABORT flag is set.
  - When entering the Busy state due to an Abort in the Send state, the DPSM waits for not busy before moving to the Idle state and the DABORT flag is set.
  - When DPSM has been started with DTEN, after an error (DCRCFAIL when DATACOUNT > 0, or DTIMEOUT) the DPSM moves to the Idle state when the FIFO is reset.
  - When the DPSM has been started due to Busy on SDMMC_D0, waits for not busy after which the Busy end status flag (BUSYD0END) is set and the DPSM moves to the Idle state.

with DATACOUNT=0, the transfer is completed normally, there will be no DABORT flag.
The data timer (DATATIME) is enabled when the DPSM is in the Wait_R or Busy state 2 cycles after the data block end bit, or data read command end bit, or R1b response, and generates the data timeout error (DTIMEOUT):

- When transmitting data, the timeout occurs
  - when a CRC status is expected and no start bit is received within 8 SDMMC_CK cycles, the DTIMEOUT flag is set.
  - when the Busy state takes longer than the programmed timeout period, the DTIMEOUT flag is set.

- When receiving data, the timeout occurs
  - when there is still data to be received $DATACOUNT > 0$ and no start bit is received before the programmed timeout period, the DTIMEOUT flag is set.

- After a R1b response, the timeout occurs
  - when the Busy state takes longer than the programmed timeout period, the DTIMEOUT flag is set.

When $DATATIME = 0$,
- In receive the start bit shall be present 2 cycles after the data block end bit or data read command end bit.
- In transmit busy is timed out 2 cycles after the CRC token end bit or stream data end bit.
- After a R1b response busy is timed out 2 cycles after the response end bit.

Data can be transferred from the card to the host (transmit, send) or vice versa (receive). Data are transferred via the SDMMC_Dn data lines, they are stored in a FIFO.

### Table 449. Data token format

<table>
<thead>
<tr>

**Data FIFO**

The data FIFO (first-in-first-out) subunit contains the transmit and receive data buffer. A single FIFO is used for either transmit or receive as selected by the DTDIR bit. The FIFO contain a 32-bit wide, 16-word deep data buffer and control logic. Because the data FIFO operates in the AHB clock domain (sdmmc_hclk), all signals from the subunits in the SDMMC clock domain (SDMMC_CK/sdmmc_rx_ck) are resynchronized.

The FIFO can be in one of the following states:

- The transmit FIFO refers to the transmit logic and data buffer when sending data out to the card. (DTDIR = 0)
- The receive FIFO refers to the receive logic and data buffer when receiving data in from the card. (DTDIR = 1)
The end of a correctly completed SDMMC data transfer from the FIFO is indicated by the DATAEND flags driven by the data path subunit. Any incorrect (aborted) SDMMC data transfer from the FIFO is indicated by one of the error flags (DCRCFAIL, DTIMEOUT, DABORT) driven by the data path subunit, or one of the FIFO error flags (TXUNDERR, RXOVERR) driven by the FIFO control.

The data FIFO can be accessed in the following ways, see Table 452.

**Table 452. Data FIFO access**

<table>
<thead>
<tr>
<th>Data FIFO access IDMAEN</th>
</tr>
</thead>
<tbody>
<tr>
<td>From FW via AHB slave interface</td>
</tr>
<tr>
<td>From IDMA via AHB master interface</td>
</tr>
</tbody>
</table>

Transmit FIFO:

Data can be written to the transmit FIFO when the DPSM has been activated (DPSMACT = 1).

When IDMAEN = 1 the FIFO is fully handled by the IDMA.

When IDMAEN = 0 the FIFO is controlled by FW via the AHB slave interface. The transmit FIFO is accessible via sequential addresses. The transmit FIFO contains a data output register that holds the data word pointed to by the read pointer. When the data path subunit has loaded its shift register, it increments the read pointer and drives new data out. The transmit FIFO is handled in the following way:

1. Write the data length into DATALENGTH and the block length in DBLOCKSIZE.
   - For block data transfer (DTMODE = 0), DATALENGTH shall be an integer multiple of DBLOCKSIZE.
2. Set the SDMMC in transmit mode (DTDIR = 0).
   - Configures the FIFO in transmit mode.
3. Enabled the data transfer
   - either by sending a Command from the CPSM with the CMDTRANS bit set
   - or by setting DTEN bit
4. When (DPSMACT = 1) write data to the FIFO.
   - The DPSM will stay in the Wait_S state until FIFO is full (TXFIFOF = 1), or the number indicated by DATALENGTH.
   - The SDMMC start sending data as long as FIFO is not empty.
5. When the FIFO is half empty (TXFIFOHE flag), write data to the FIFO until FIFO is full (TXFIFOF = 1), or last data has been written.
6. When last data has been written wait for end of data (DATAEND flag)
   - SDMMC has completely sent all data and the DPSM is disabled (DPSMACT = 0).

In case of a data transfer error or transfer hold when IDMAEN = 0, FW shall stop writing to the FIFO and flush and reset the FIFO with the FIFORST register bit.

The transmit FIFO status flags are listed in Table 453.
Receive FIFO:

Data can be read from the receive FIFO when the DPSM is activated (DPSMACT = 1).

When IDMAEN = 0 the FIFO is fully handled by the IDMA.

When IDMAEN = 0 the FIFO is controlled by FW via the AHB slave interface. When the data path subunit receives a word of data, it drives the data on the write databus. The write pointer is incremented after the write operation completes. On the read side, the contents of the FIFO word pointed to by the current value of the read pointer is driven onto the read databus. The receive FIFO is accessible via sequential addresses. The receive FIFO is handled in the following way:

1. Write the data length into DATALENGTH and the block length in DBLOCKSIZE.
   – For block data transfer (DTMODE = 0), DATALENGTH shall be an integer multiple of DBLOCKSIZE.
2. Set the SDMMC in receive mode (DTDIR = 1).
   – Configures the FIFO in receive mode.
3. Enable the DPSM transfer
   – either by sending a command from the CPSM with the CMDTRANS bit set
   – or by setting DTEN bit.
4. When (DPSMACT = 1) the FIFO is ready to receive data.
   – The DPSM will write the received data to the FIFO.
5. When the FIFO is half full (RXFIFOHF flag), read data from the FIFO until FIFO is empty (RXFIFOE = 1).
6. When last data has been received end of data (DATAEND flag), read data from the FIFO until FIFO is empty (RXFIFOE = 1).
   – SDMMC has completely received all data and the DPSM is disabled (DPSMACT = 0).

In case of a data transfer hold when IDMAEN = 0, FW shall read the remaining data until the FIFO is empty and reset the FIFO with the FIFORST register bit. This will cause the DPSM to go to the Idle state (DPSMACT = 0).

In case of a data transfer error when IDMAEN = 0, FW shall stop reading the FIFO and flush and reset the FIFO with the FIFORST register bit. This will cause the DPSM to go to the Idle state (DPSMACT = 0).

The receive FIFO status flags are listed in Table 454.

<table>

</tbody>
</table>
The CLKMUX selects the source for clock sdmmc rx_ck to be used with the received data and command response. The receive data clock source can be selected by the clock control register bit SELCLKRX, between:

- sdmmc_io_in_ck bus master main feedback clock.
- SDMMC_CKIN external bus feedback clock.
- sdmmc_fb_ck bus tuned feedback clock.

The sdmmc_io_in_ck is selected when there is no external driver, with DS and HS.

The SDMMC_CKIN is selected when there is an external driver with SDR12, SDR25, SDR50 and DDR50.

The sdmmc_fb ck clock input must be selected when the DLYB block on the device is used with SDR104, HS200 and optionally with SDR50 and DDR50 modes.

The sdmmc_rx_ck source shall be changed when the CPSM and DPSM are in the Idle state.

### 54.4.5 SDMMC AHB slave interface

The AHB slave interface generates the interrupt requests, and accesses the SDMMC adapter registers and the data FIFO. It consists of a data path, register decoder, and interrupt logic.

#### SDMMC FIFO

The FIFO access is restricted to word access:

- In transmit FIFO mode
  - Data are written to the FIFO in words (32-bits) until all data according DATALENGTH has been transferred. When the DATALENGTH is not an integer...
multiple of 4, the last remaining data (1, 2 or 3 bytes) are written with a word transfer.

- In receive FIFO mode
  - Data are read from the FIFO in words (32-bits) until all data according DATALENGTH has been transferred. When the DATALENGTH is not an integer multiple of 4, the last remaining data (1, 2 or 3 bytes) are read with a word transfer padded with 0 value bytes.

When accessing the FIFO with half word or byte accesses an AHB bus fault is generated.

**SDMMC interrupts**

The interrupt logic generates an interrupt request signal that is asserted when at least one of the unmasked status flags is active. A mask register is provided to allow selection of the conditions that will generate an interrupt. A status flag generates the interrupt request if a corresponding mask flag is set. Some status flags require an implicit clear in the clear register.

### 54.4.6 SDMMC AHB master interface

The AHB master interface is used to transfer the data between a memory and the FIFO using the SDMMC IDMA.

**SDMMC IDMA**

Direct memory access (DMA) is used to provide high-speed transfer between the SDMMC FIFO and the memory. The AHB master optimizes the bandwidth of the system bus. The SDMMC internal DMA (IDMA) provides one channel to be used either for transmit or receive.

The IDMA is enabled by the IDMAEN bit and supports burst transfers of 8 beats.

- In transmit burst transfer mode:
  - Data are fetched in burst from memory whenever the FIFO is empty for the number of burst transfers, until all data according DATALENGTH has been transfered. When the DATALENGTH is not an integer multiple of the burst size the remaining, smaller than burst size data is transfered using single transfer mode. When the DATALENGTH is not an integer multiple of 4, the last remaining data (1, 2 or 3 bytes) are fetched with a word transfer.

- In receive burst transfer mode:
  - Data are stored in burst in to memory whenever the FIFO contains the number of burst transfers, until all data according DATALENGTH has been transfered. When the DATALENGTH is not an integer multiple of the burst transfer the remaining, smaller than burst size data, is transfered using single transfer mode. When the DATALENGTH is not an integer multiple of 4, the last remaining data (1, 2 or 3 bytes) are stored with halfword and or byte transfers.

In addition the IDMA provides the following channel configurations selected by bit IDMABMODE:

- single buffered channel
- double buffered channel
Single buffered channel

In single buffer configuration the data at the memory side is accessed in a linear matter starting from the base address IDMABASE0. When the IDMA has finished transferring all data the and the DPSM has completed the transfer the DATAEND flag is set.

Double buffered channel

In double buffer configuration the data at the memory side is subsequently accessed from 2 buffers, one located from base address IDMABASE0 and a second located from base address IDMABASE1. This allows firmware to process one memory buffer while the IDMA is accessing the other memory buffer. The size of the memory buffers is defined by IDMABSIZE. The buffer size shall be an integer multiple of the burst size. It is possible to update the base address of the buffers on-the-fly when the channel is enabled, the following rule apply:

- When IDMABACT bit is ‘0’ the IDMA hardware uses the IDMABASE0 to access memory. When attempting to write to this register by Firmware the write is discarded, IDMABASE0 data will not be changed. Firmware is allowed to write IDMABASE1.
- When IDMABACT bit is ‘1’ the IDMA hardware uses the IDMABASE1 to access memory. When attempting to write to this register by Firmware the write is discarded, IDMABASE1 data will not be changed. Firmware is allowed to write IDMABASE0.

When the IDMA has finished transferring the data of one buffer the buffer transfer complete flag (IDMABTC) is set and the IDMABACT bit toggles where after the IDMA continues transferring data from the other buffer. When the IDMA has finished transferring all data and the DPSM has completed the transfer the DATAEND flag is set.

The IDMABASEn address shall be word aligned.

IDMA transfer error management

An IDMA transfer error can occur:

- When reading or writing a reserved address space.

On a IDMA transfer error subsequent IDMA transfers are disabled and an IDMATE flag is set. Depending when the IDMA transfer error occurs, it will normally cause the generation of a TXUNDERR or RXOVERR error.

The behavior of the IDMATE flag depend on when the IDMA transfer error occurs during the SDMMC transfer:

- An IDMA transfer error is detected before any SDMMC transfer error (TXUNDERR, RXOVERR, DCRCFAIL, or DTIMEOUT):
  - The IDMATE flag is set at the same time as the SDMMC transfer error flag.
  - The TXUNDERR, RXOVERR, DCRCFAIL, or DTIMEOUT interrupt is generated.
- An IDMA transfer error is detected during a STOP_TRANSNSSION command:
  - The IDMATE flag is set at the same time as the DABORT flag.
  - The DABORT interrupt is generated.
- An IDMA transfer error is detected at the end of the SDMMC transfer (DHALD, or DATAEND):
  - The IDMATE flag is set at the end of the SDMMC transfer.
  - A SDMMC transfer end interrupt is generated and a DHALD or DATAEND flag is set.
The IDMate will be generated on an other SDMMC transfer interrupt (TXUNDERR, RXOVERR, DCRCFAIL, DTIMEOUT, DABORT, DHOLD, or DATAEND).

54.4.7 MDMA request generation

The internal trigger line from the SDMMC allows passing direct request to MDMA controller to enable successive transfers from/to different internal RAM addresses without CPU use.

When a data transfer from/to the card completes successfully, the DATAEND flag of the status register is set. The event is signaled to an MDMA request input through the sdmmc_dataend_trg output. It can trigger the clearance of the DATAEND and CMDREND flags and, eventually, a new transfer start, through MDMA direct access to the SDMMC control and configuration registers, thus without CPU intervention.

The action to program in the MDMA according to the SDMMC requests is provided in the following table:

<table>
<thead>
<tr>
<th>Trigger signal</th>
<th>Event signaled</th>
<th>Event occurrence condition</th>
<th>MDMA transfer configuration</th>
<th>MDMA action</th>
</tr>
</thead>
<tbody>
<tr>
<td>sdmmc_dataend_trg</td>
<td>End of successful data transfer</td>
<td>DATAEND = 1 single</td>
<td></td>
<td>Set DATAENDC</td>
</tr>
</tbody>
</table>

54.4.8 AHB and SDMMC_CK clock relation

The AHB shall at least have 3x more bandwidth than the SDMMC bus bandwidth i.e. for SDR50 4-bit mode (50Mbyte/s) the minimum sdmmc_hclk frequency is 37.5MHz (150Mbyte/s).

54.4.9 Hardware flow control

The hardware flow control functionality is used to avoid FIFO underrun (TX mode) and overrun (RX mode) errors.
The behavior is to stop SDMMC_CK during data transfer and freeze the SDMMC state machines. The data transfer is stalled when the FIFO is unable to transmit or receive data. The data transfer remains stalled until the transmit FIFO is half full or all data according DATALENIGHT has been stored, or until the receive FIFO is half empty. Only state machines clocked by SDMMC_CK are frozen, the AHB interfaces are still alive. The FIFO can thus be filled or emptied even if flow control is activated.

To enable hardware flow control, the HWFC_EN register bit must be set to 1. After reset hardware flow control is disabled.

Hardware flow control shall only be used when the SDMMC_Dn data is cycle-aligned with the SDMMC_CK. Whenever the sdmmc_fb_ck from the DLYB delay block is used, i.e in the case of SDR104 mode with a tOP and DtOP delay > 1 cycle, hardware flow control can NOT be used.

**Figure 711. Hardware flow timing**

![Hardware flow timing diagram]

### 54.5 Card functional description

#### 54.5.1 SD I/O mode

The following features are SDMMC specific operations:

- SDIO interrupts
- SDIO suspend/resume operation (write and read suspend)
- SDIO read wait operation by stopping the clock
- SDIO read wait operation by SDMMC_D2 signaling

**Table 457. SDIO special operation control**

SD I/O interrupts

To allow the SD I/O card to interrupt the host, an interrupt function is available on pin 8 (shared with SDMMC_D1 in 4-bit mode) on the SD interface. The use of the interrupt is optional for each card or function within a card. The SD I/O interrupt is level-sensitive, which means that the interrupt line must be held active (low) until it is either recognized and acted upon by the host or de-asserted due to the end of the interrupt period. After the host has serviced the interrupt, the interrupt status bit is cleared via an I/O write to the appropriate bit in the SD I/O card internal registers. The interrupt output of all SD I/O cards is active low and the application must provide external pull-up resistors on all data lines (SDMMC_D[3:0]).

In SD 1-bit mode pin 8 is dedicated to the interrupt function (IRQ), and there are no timing constraints on interrupts.

In SD 4-bit mode the host samples the level of pin 8 (SDMMC_D1/IRQ) into the interrupt detector only during the interrupt period. At all other times, the host interrupt ignores this value. The interrupt period begins when interrupts are enabled at the card and SDIOEN bit is set see register settings in Table 457.

In 4-bit mode the card can generate a synchronous or asynchronous interrupt as indicated by the card CCCR register SAI and EAI bits.

- Synchronous interrupt, require the SDMMC_CK to be active.
- Asynchronous interrupt, can be generated when the SDMMC_CK is stopped, 4 cycles after the start of the card interrupt period following the last data block.

**Figure 712. Asynchronous interrupt generation**
The timing of the interrupt period is depended on the bus speed mode:

In DS, HS, SDR12, and SDR25 mode, selected by register bit BUSSPEED, the interrupt period is synchronous to the SD clock.

- The interrupt period ends at the next clock from the End bit of a command that transfers data block(s) (Command sent with the CMDTRANS bit is set), or when the DTEN bit is set.
- The interrupt period resumes 2 SDMMC_CK after the completion of the data block.
- At the data block gap the interrupt period is limited to 2 SDMMC_CK cycles.

**Note:** *DTEN shall not be used to start data transfer with SD and eMMC cards.*

**Figure 713. Synchronous interrupt period data read**
In SDR50, SDR104, and DDR50, selected by register bit BUSSPEED, due to propagation delay from the card to host, the interrupt period is asynchronous.

- The card interrupt period ends after 0 to 2 SDMMC_CK cycles after the End bit of a command that transfers data block(s) (Command sent with the CMDTRANS bit is set), or when the DTEN bit is set. At the host the interrupt period ends after the End bit of a command that transfers data block(s). A card interrupt issued in the 1 to 2 cycles after the command End bit are not detected by the host during this interrupt period.
- The card interrupt period resumes 2 to 4 SDMMC_CK after the completion of the last data block. The host will resume the interrupt period always 2 cycles after the last data block.
- There is NO interrupt period at the data block gap.

*Note:* *DTEN shall not be used to start data transfer with SD and eMMC cards.*
When transferring Open-ended multiple block data and using DTMODE “block data transfer ending with STOP_TRANSMISSION command”, the SDMMC will mask the interrupt period after the last data block until the end of the CMD12 STOP_TRANSMISSION command.

The interrupt period is applicable for both memory and I/O operations.

In 4-bit mode interrupts can be differentiated from other signaling according Table 458.
SD I/O suspend and resume

This function is NOT supported in SDIO version 4.00 or later.

Within a multifunction SD I/O or a card with both I/O and memory functions, there are multiple devices (I/O and memory) that share access to the eMMC/SD bus. To share access to the host among multiple devices, SD I/O and combo cards optionally implement the concept of suspend/resume. When a card supports suspend/resume, the host can temporarily halt (suspend) a data transfer operation to one function or memory to free the bus for a higher-priority transfer to a different function or memory. After this higher-priority transfer is complete, the original transfer is restarted (resume) where it left off.

To perform the suspend/resume operation on the bus, the host performs the following steps:
1. Determines the function currently using the SDMMC_D[3:0] line(s)
2. Requests the lower-priority or slower transaction to suspend
3. Waits for the transaction suspension to complete
4. Begins the higher-priority transaction
5. Waits for the completion of the higher priority transaction
6. Restores the suspended transaction

The card receiving a suspend command will respond with its current bus status. Only when the bus has been suspended by the card the bus status will indicated suspension completed.

There are different suspend cases conditions:
- Suspend request accepted prior to the start of data transfer.
- Suspend request not accepted, (due to data being transferred at the same time), the host keeps checking the request until it is accepted. (data transfer has suspended)
- Suspend request during write busy.
- Suspend request with write multiple.
- Suspend request during ReadWait.

For the host to know if the bus has been released it shall check the status of the suspend request, suspension completed.

When the bus status of the suspend request response indicates suspension completed, the card has released the bus. At this time the state of the suspended operation shall be saved where after an other operation can start.

The suspend command shall be sent with the CMDSUSPEND bit set. This allows to start the interrupt period after the suspend command response when the bus is suspended (response bit BS = 0).

Table 458. 4-bit mode Start, interrupt, and CRC-status Signaling detection

<table>
<thead>

<td>1</td>
<td>X</td>
</tr>
</tbody>
</table>
The hardware does not save the number of remaining data to be transferred when resuming the suspended operation. It is up to firmware to determine the data that has been transferred and resume with the correct remaining number of data bytes.

While receiving data from the card, the SDMMC can suspend the read operation after the read data block end (DPSM in Wait_R). After receiving the suspend acknowledgment response from the card the following steps shall be taken by firmware:

1. The normal receive process shall be stopped by setting DTHOLD bit.
   a) The remaining number of data bytes in the FIFO shall be read until the receive FIFO is empty (RXFIFOE flag is set), and when IDMAEN = 0 the FIFO shall be reset with FIFORST.
2. The confirmation that all data has been read from the FIFO, and that the suspend is completed is indicated by the DHOLD flag.
   a) The remaining number of data bytes (multiple of data blocks) still to be read when resuming the operation shall be determined from the remaining number of bytes indicated by the DATACOUNT.

**Note:** When a DTIMEOUT flag occurs during the suspend procedure, this shall be ignored.

To resume receiving data from the card, the following steps shall be taken by firmware:

1. The remaining number of data bytes (multiple of data blocks) shall be programmed in DATALENGTH.
2. The DPSM shall be configured to receive data in the DTDIR bit.
3. The resume command shall be sent from the CPSM, with the CMDTRANS bit set and the CMDSUSPEND bit set, which will end the interrupt period when data transfer is resumed (response bit DF = 1) and enabled the DPSM, after which the card will resume sending data.

While sending data to the card, the SDMMC can suspend the write operation after the write data block CRC status end (DPSM in Busy). Before sending the suspend command to the card the following steps shall be taken by firmware:

1. Enable DHOLD flag (and DBCKEND flag when IDMAEN = 0)
2. The DPSM shall be prevented from start sending a new data block by setting DTHOLD.
3. When IDMAEN = 0: When receiving the DBCKEND flag the data transfer is stopped. Firmware can stop filling the FIFO, after which the FIFO shall be reset with FIFORST. Any bytes still in the FIFO need to be rewritten when resuming the operation.
4. When receiving the DHOLD flag the data transfer is stopped. The remaining number of data bytes still to be written when resuming shall be determined from the remaining number of bytes indicated by the DATACOUNT.
5. To suspend the card the suspend command shall be sent by the CPSM with the CMDSUSPEND bit set. This allows to start the interrupt period after the suspend command response when the bus is suspended (response bit BS = 0).

To resume sending data to the card, the following steps shall be taken by firmware:

1. The remaining number of data bytes shall be programmed in DATALENGTH.
2. The DPSM shall be configured for transmission with DTDIR set and enabled by having the CPSM send the resume command with the CMDTRANS bit set and the CMDSUSPEND bit set. This will end the interrupt period and start the data transfer.
The DPSM will either go to the Wait_S state when SDMMC_D0 does not signal busy, or will go to the Busy state when busy is signaled.

3. When IDMAEN = 1: The IDMA needs to be reprogrammed for the remaining bytes to be transferred.
4. When IDMAEN = 0: Firmware shall start filling the FIFO with the remaining data.

SD I/O ReadWait

There are 2 methods to pause the data transfer during the Block gap:
1. Stopping the SDMMC_CK.
2. Using ReadWait signaling on SDMMC_D2.

The SDMMC can perform a ReadWait with register settings according Table 457.

Depending the SDMMC operation mode (DS, HS, SDR12, SDR25) or (SDR50, SDR104, DDR) each method has a different characteristic.

The timing for pause read operation by stopping the SDMMC_CK for DS, HS, SDR12, and SDR25, the SDMMC_CK may be stopped 2 SDMMC_CK cycles after the End bit. When ready the host resumes by restarting clock, see Figure 717.

**Figure 717. Clock stop with SDMMC_CK for DS, HS, SDR12, SDR25**

The timing for pause read operation by stopping the SDMMC_CK for SDR50, SDR104, and DDR50, the SDMMC_CK may be stopped minimum 2 SDMMC_CK cycles and maximum 5 SDMMC_CK cycles, after the End bit. When ready the host resumes by restarting clock, see Figure 718. (In DDR50 mode the SDMMC_CK shall only be stopped after the falling edge, when the clock line is low.)

**Figure 718. Clock stop with SDMMC_CK for DDR50, SDR50, SDR104**
In ReadWait SDMMC_CK clock stopping, when RWSTART is set, the DSPM stops the clock after the End bit of the current received data block CRC. The clock start again after writing 1 to the RWSTOP bit, where after the DPSM waits for a Start bit from the card.

As SDMMC_CK is stopped, no command can be issued to the card. During a ReadWait interval, the SDMMC can still detect SDIO interrupts on SDMMC_D1.

The optional ReadWait signaling on SDMMC_D2 (RW) operation is defined only for the SD 1-bit and 4-bit modes. The ReadWait operation allows the host to signal a card that is reading multiple registers (IO_RW_EXTENDED, CMD53) to temporarily stall the data transfer while allowing the host to send commands to any function within the SD I/O device. To determine when a card supports the ReadWait protocol, the host must test capability bits in the internal card registers.

The timing for ReadWait with a SDMMC_CK less then 50MHz (DS, HS, SDR12, SDR25) is based on the interrupt period generated by the card on SDMMC_D1. The host by asserting SDMMC_D2 low during the interrupt period requests the card to enter ReadWait. To exit ReadWait the host shall raise SDMMC_D2 high during one SDMMC_CK cycles before making it Hi-Z, see Figure 719.

For SDR50, SDR104 with a SDMMC_CK more than 50MHz, and DDR50, the card will treat the ReadWait request on SDMMC_D2 as an asynchronous event. The host by asserting SDMMC_D2 low after minimum 2 SDMMC_CK cycles and maximum 5 SDMMC_CK cycles, request the card to enter ReadWait. To exit ReadWait the host shall raise SDMMC_D2 high during one SDMMC_CK cycles before making it Hi-Z. The host shall raise SDMMC_D2 on the SDMMC_CK clock (see Figure 720).
In ReadWait SDMMC_D2 signaling, when RWSTART is set, the DPSM drives SDMMC_D2 after the End bit of the current received data block CRC. The ReadWait signaling on SDMMC_D2 will be removed when writing 1 to the RWSTOP bit. The DPSM remains in ReadWait state for two more SDMMC_CK clock cycles to drive SDMMC_D2 to 1 for one clock cycle (in accordance with SDIO specification), where after the DPSM waits for a Start bit from the card.

During the ReadWait signaling on SDMMC_D2 commands can be issued to the card. During the ReadWait interval, the SDMMC can detect SDIO interrupts on SDMMC_D1.

54.5.2 CMD12 send timing

CMD12 is used to stop/abort the data transfer, the card data transmission is terminated two clock cycles after the End bit of the Stop Transmission command.

<table>
<thead>
<tr>
<th>Data operation</th>
<th>Stop Transmission command CMD12 Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SDMMC stream write</td>

</tr>
<tr>
<td>SDMMC open ended multiple block write</td>
<td>The data transfer is stopped/aborted by sending the Stop Transmission command. If the card detects an</td>
</tr>
<tr>
<td></td>
<td>error, the host must abort the operation by sending the Stop Transmission command.</td>
</tr>
<tr>
<td>SDMMC block write with predefined block count</td>
<td>The Stop Transmission command is not required at the end of this type of multiple block write. (sending the Stop Transmission command after the card has received the last block is regarded as an illegal command.) If the card detects an error, the host must abort the operation by sending the Stop Transmission command.</td>
</tr>
<tr>
<td>SDMMC stream read</td>
<td>The data transfer is stopped/aborted by sending the Stop Transmission command.</td>
</tr>
</tbody>
</table>
All data write and read commands can be aborted any time by a Stop Transmission command CMD12. The following data abort procedure applies during an ongoing data transfer:

1. Load CMD12 Stop Transmission command in registers and set the CMDSTOP bit.
   a) This causes the CPSM to generate the Abort signal when the command is sent to the DPSM.
2. Configure the CPSM to send a command immediately (clear WAITPEND bit).
   a) The card, when sending data, will stop data transfer 2 cycles after the Stop Transmission command End bit.
   The card when no data is being sent, will not start sending any new data.
   b) The host, when sending data, will send one last data bit followed by an End bit after the Stop Transmission command End bit.
   The host when not sending data, will not start sending any new data.
3. When IDMAEN = 0, the FIFO need to be reset with FIFORST.
   a) When writing data to the card. On the CMDREND flag FW shall stop writing data to the FIFO. Subsequently the FIFO shall be reset with FIFORST, this will flush the FIFO.
   b) When reading data from the card. On the CMDREND flag FW shall read the remaining data from the FIFO. Subsequently the FIFO shall be reset with FIFORST.
4. When IDMAEN = 1, hardware will take care of the FIFO.
   a) When writing data to the card. On the Abort signal hardware will stop the IDMA and subsequently the FIFO will be flushed.
   b) When reading data from the card. On the Abort signal hardware will instruct the IDMA to transfer the remaining data from the FIFO to RAM.
5. When the FIFO is empty/reset the DABORT flag will be generated.

**Stream operation and CMD12**

To stop the stream transfer after the last byte to be transfered, the CMD12 End bit timing shall be sent aligned with the data stream end of last byte. The following write stream data procedure applies:
1. Initialize the stream data in the DPSM, DTMODE = MCC stream data transfer.
2. Send the WRITE_DATA_STREAM command from the CPSM with CMDTRANS = 1.
3. Preload CMD12 in command registers, with the CMDSTOP bit set.
4. Configure the CPSM to send a command only after a wait pending (WAITPEND = 1) end of last data (according DATALENGTH).
5. Enabling the CPSM to send the STOP_TRANSMISSION command, the stream data End bit and command End bit will be aligned.
   a) When DATALENGTH > 5 bytes, Command CMD12 will be waited in the CPSM to be aligned with the data transfer End bit.
   b) When DATALENGTH < 5 bytes, Command CMD12 will be started before and the DPSM will remain in the Wait_S state to align the data transfer end with the CMD12 End bit.
6. The write stream data can be aborted any time by clearing the WAITPEND bit. This will cause the Preloaded CMD12 to be sent immediately and stop the write data stream.

Figure 721. CMD12 stream timing

To stop the read stream transfer after the last byte, the CMD12 End bit timing shall occur after the last data stream byte. The following read stream data procedure applies:
1. Wait for all data to be received by the DPSM (DATAEND flag).
   a) The DPSM will not receive more data than indicated by DATALENGTH, even if the card is sending more data.
2. Send CMD12 by the CPSM.
   a) CMD12 will stop the card sending data.

Note: The SDMMC will not receive any more data from the card when DATACOUNT = 0, even when the card continues sending data.

Block operation and CMD12

To stop block transfer at the end of the data, the CMD12 End bit shall be sent after the last block End bit.

When writing data to the card the CMD12 End bit shall be sent after the write data block CRC token End bit. This requires the CMD12 sending to be tied to the data block transmission timing. To stop an Open-ended Multiple block write, the following procedure applies:
1. Before starting the data transfer, set DTMODE to "block data transfer ending with STOP_TRANSMISSION command".
2. Wait for all data to be sent by the DPSM and the CRC token to be received, (DATAEND flag).
   a) The DPSM will not send more data than indicated by DATALENGTH.
3. Send CMD12 by the CPSM.
   a) CMD12 will set the card to Idle mode.

When reading data from the card the CMD12 End bit shall be sent earliest at the same time as the card read data block last data bit. This requires the CMD12 sending to be tied to the data block reception timing. The following stop Open-ended Multiple block read data block procedure applies:
1. Before starting the data transfer, set DTMODE to "block data transfer ending with STOP_TRANSMISSION command".
2. Wait for all data to be received by the DPSM (DATAEND flag).
   a) The DPSM will not receive more data than indicated by DATALENGTH, even if the card is sending more data.
3. Send CMD12 with CMDSTOP bit set by the CPSM.
   a) CMD12 will stop the Card sending more data and set the card to Idle mode. Any ongoing block transfer will be aborted by the Card.

Note: The SDMMC will not receive any more data from the card when DATACOUNT = 0, even when the card continues sending data.

54.5.3 Sleep (CMD5)

The e•MMC card may be switched between a Sleep state and a Standby state by CMD5. In the Sleep state the power consumption of the card is minimized and the Vcc power supply may be switched off.

The CMD5 (SLEEP) is used to initiate the state transition from Standby state to Sleep state. The card indicates Busy, pulling down SDMMC_D0, during the transition phase. The Sleep state is reached when the card stops pulling down the SDMMC_D0 line.

To set the card into Sleep state the following procedure applies:
1. Enable interrupt on BUSYD0END.
2. Send CMD5 (SLEEP).
3. On BUSYD0END interrupt, card is in Sleep state
4. Vcc power supply is allowed to be switched off

The CMD5 (AWAKE) is used to initiate the state transition from Sleep state to Standby state. The card indicates Busy, pulling down SDMMC_D0, during the transition phase. The Standby state is reached when the card stops pulling down the SDMMC_D0 line.

To set the card into Standby state the following procedure applies:
1. Switch on Vcc power supply and wait unit minimum operating level is reached.
2. Enable interrupt on BUSYD0END.
3. Send CMD5 (AWAKE).
4. On BUSYD0END interrupt card is in Standby state.

The Vcc power supply is allowed to be switched off only after the Sleep state has been reached. The Vcc supply shall be reinstalled before CMD5 (AWAKE) is sent.
54.5.4 Interrupt mode (Wait-IRQ)

The host and card enter and exit interrupt mode (Wait-IRQ) simultaneously. In interrupt mode there is no data transfer. The only message allowed is an interrupt service request response from the card or the host. For the interrupt mode to work correctly the SDMMC_CK frequency shall be set in accordance with the achievable SDMMC_CMD data rate in Open Drain mode, which depend on the capacitive load and pull-up resistor. The CLKDIV shall be set >1, and the SETCLKRX shall select either the sdmmc_io_in_ck or SDMMC_CLKin source.

The host must ensure that the card is in Standby state before issuing the CMD40 (GO_IRQ_STATE). While waiting for an interrupt response the SDMMC_CK clock signal must be kept active.

A card in interrupt mode (IRQ state):
- is waiting for an internal card interrupt event. Once the event occurs, the card starts to send the interrupt service request response. The response is sent in open-drain mode.
- while waiting for the internal card interrupt event, the card also monitors the SDMMC_CMD line for a Start bit. Upon detection of a Start bit the card will abort the interrupt mode and switch to Standby state.

The host in interrupt mode (CPSM Wait state waiting for interrupt):
- is waiting for a card interrupt service request response (Start bit).
- while waiting for a card interrupt service request response the host may abort the interrupt mode (by clearing the WAITINT register bit), which causes the host to send a interrupt service request response R5 with RCA = 0x0000 in open-drain mode.

When sending the interrupt service request response, the sender bit-wise monitors the SDMMC_CMD bit stream. The sender whose interrupt service request response bit does not correspond to the bit on the SDMMC_CMD line stops sending. In the case of multiple senders only one will successfully send its full interrupt service request response. i.e. If the host sends simultaneously, it will lose sending after the transmission bit.

To handle the interrupt mode, the following procedure applies:
1. Set the SDMMC_CK frequency in accordance with the achievable SDMMC_CMD data rate in Open-drain mode, CLKDIV shall be set >1, and SETCLKRX shall select the sdmmc_io_in_ck.
2. Load CMD40 (GO_IRQ_STATE) in the command registers.
3. Enable wait for interrupt by setting WAITINT register bit.
4. Configure the CPSM to send a command immediately.
   a) This will cause the CMD40 to be sent and the CPSM to be halted in the Wait state, waiting for an interrupt service request response.
5. To exit the wait for interrupt state (CPSM Wait state):
   a) Upon the detection of an interrupt service request response Start bit the CPSM moves to the Receive state where the response is received. The complete reception of the response is indicated by the CMDREND or the command CRC error flags.
   b) To abort the interrupt mode the host clears the WAITINT register bit, which will cause the host to send an interrupt service request response by itself. Which will move the CPSM to the Receive state. The complete reception of the response is indicated by the CMDREND or the command CRC error flags.

Note: On a simultaneous send interrupt service request response Start bit collision the host will lose the bus access after the Transmission bit.

54.5.5 Boot operation

In boot operation mode the host can read boot data from the card by either one of the 2 boot operation functions:
1. Normal boot. (keeping CMD line low)
2. Alternative boot (sending CMD0 with argument 0xFFFFFFFA)

The boot data can be read according the following configuration options, depending on card register settings:
- The partition from which boot data is read (EXT_CSD Byte[179])
- The boot data size (EXT_CSD Byte[226])
- The bus configuration during boot (EXT_CSD Byte[177])
- Receiving boot acknowledgment from the card. (EXT_CSD Byte[179])

If boot acknowledgment is enabled the card send pattern 010 on SDMMC_D0 within 50ms after boot mode has been requested by either CMD line going low or after CMD0 with argument 0xFFFFFFFA. A boot acknowledgment timeout (ACKTIMEOUT) and acknowledgment status (ACKFAIL) is provided.

Normal boot operation

If the SDMMC_CMD line is held low for at least 74 clock cycles after card power-up or reset, before the first command is issued, the card recognizes that boot mode is being initiated. Within 1 second after the CMD line goes low, the card starts to sent the first boot code data on the SDMMC_Dn line(s). The host must keep the SDMMC_CMD line low until after all boot data has been read. The host can terminate boot mode by pulling the SDMMC_CMD line high.
To perform the normal boot procedure the following steps needed:

1. Reset the card.
2. if a boot acknowledgment is requested enable the BOOTACKEN and set the ACKTIME and enable the ACKFAIL and ACKTIMEOUT interrupt.
3. enable the data reception by setting the DPSM in receive mode (DTDIR) and the number of data bytes to be received in DATALENGTH.
4. Enable the DTIMEOUT, DATAEND, and CMDSENT interrupts for end of boot command confirmation.
5. Select the normal boot operation mode in BOOTMODE, and enable boot in BOOTEN. The boot procedure is started by enabling the CPSM with CPSMEN. This will cause:
   - the SDMMC_CMD to be driven low. (BOOTMODE = normal boot).
   - the ACK timeout to start.
   - DPSM to be enabled.
6. The incorrect reception of the boot acknowledgment can be detected with ACKFAIL flag or ACKTIMEOUT flag when enabled.
   - when an incorrect boot acknowledgment is received the ACKFAIL flag occurs.
   - when the boot acknowledgment is not received in time the ACKTIMEOUT flag occurs.
7. when all boot data has been received the DATAEND flag will occur.
   - when data CRC fails the DCRCFAIL flag is also generated.
   - when the data timeout occurs the DTIMEOUT flag is also generated.
8. When last data has been received, read data from the FIFO until FIFO is empty (RXFIFOE = 1) after which end of data DATAEND flag is generated.
   - SDMMC has completely received all data and the DPSM is disabled.
9. The boot procedure will be terminated by FW clearing BOOTEN, which will cause the SDMMC_CMD line to go high. The CMDSENT flag is generated 56 cycles later to indicate that a new command can be sent.
   a) If the boot procedure is aborted by FW before all data has been received the CPSM Abort signal will stop data reception and disable the DPSM which will trigger an DABORT flag when enabled.
10. The CMDSENT flag signals the end of the boot procedure and the card is ready to receive a new command.
Alternative boot operation

After card power-up or reset, if the host send CMD0 with the argument 0xFFFFFFFFA after 74 clock cycles before CMD0 is issued, the card recognizes that boot mode is being initiated. Within 1 second after the CMD0 with argument 0xFFFFFFFFA has been sent, the card starts to send the first boot code data on the SDMMC_Dn line(s). The master terminates boot operation by sending CMD0 (Reset).

Figure 724. Alternative boot mode operation

To perform the alternative boot procedure the following steps needed:

1. Move the SDMMC to power-off state, and reset the card
2. Move the SDMMC to power-on state. This will guarantee the 74 SCDMMC_CK cycles to be clocked before any command.
3. If a boot acknowledgment is requested enable the BOOTACKEN and set the ACKTIME and enable the ACKTIMEOUT flag.
4. Enable the data reception by setting the DPSM in receive mode (DTDIR) and the number of data to be received in DATALENGTH. Enable the DTIMEOUT and DATAEND flags.
5. Select the alternative boot operation mode in BOOTMODE, load the CMD0 with the 0xFFFFFFFFA argument in the command registers. Enable CMDSENT flag for end of
boot command confirmation, and enable boot in BOOTEN. The boot procedure is started by enabling the CPSM with CPSMEN. This will cause:
– the loaded command and argument to be sent out. (BOOTMODE = alternative boot).
– the ACK timeout to start.
– DPSM to be enabled.
6. When the command has been sent the CMDSENT flag is generated, at which time the BOOTEN bit shall be cleared.
7. The reception of the boot acknowledgment can be detected with ACKFAIL flag when enabled.
– when the boot acknowledgment is not received in time the ACKTIMEOUT flag will occur.
8. When all boot data has been received the DATAEND flag will occur.
– when data CRC fails the DCRCFAIL flag is also generated.
– when the data timeout occurs the DTIMEOUT flag is also generated.
9. When last data has been received, read data from the FIFO until FIFO is empty (RXFIFOE = 1) after which end of data DATAEND flag is generated.
– SDMMC has completely received all data and the DPSM is disabled.
10. The BOOTEN bit shall be cleared, before terminating the boot procedure by sending CMD0 (Reset) with BOOTMODE = alternative boot. This will cause the CMDSENT flag to occur 56 cycles after the Command.
– if the boot procedure is aborted by FW before all data has been received the CPSM Abort signal will stop the data transfer and disable the DPSM which will trigger an DABORT flag when enabled.
11. The CMDSENT flag signals the end of the boot procedure and the card is ready to receive a new command. When the RESET command has been sent successfully, the BOOTMODE control bit has to be cleared to terminate the boot operation.

54.5.6 Response R1b handling
When sending commands which have a R1b response the busy signaling is reflected in the BUSYD0 register bit and the release of busy with the BUSYD0END flag. The SDMMC_D0 line is sampled at the end of the R1b response and signaled in the BUSYD0 register bit. The BUSYD0 register bit is reset to not busy when the SDMMC_D0 line release busy, at the same time the BUSYD0END flag is generated.
The expected maximum busy time shall be set in the DATATIME register before sending the command. When enabled, the DTIMEOUT flag will be set when after the R1b response busy stays active longer then the programmed time.

To detect the SDMMC_D0 busy signaling when sending a Command with R1b response the following procedure applies:
- Enable CMDREND flag
- Send Command through CPSM.
- On the CMDREND flag check the BUSYD0 register bit.
  - If BUSYD0 signals not busy, signal busy release to the Firmware
  - If BUSYD0 signals busy, wait for BUSYD0END flag
- On BUSYD0END flag signal busy released to the firmware.
- On DTIMEOUT flag busy is active longer then programmed time.

54.5.7 Reset and card cycle power

Reset

Following reset the SDMMC will be in the reset state. In this state the SDMMC is disabled and no command nor data can be transferred. The SDMMC_D[7:0], and SDMMC_CMD are in HiZ and the SDMMC_CK is driven low.

Before moving to the power-on state the SDMMC shall be configured.

In the power-on state the SDMMC_CK clock is running. First 74 SDMMC_CK cycles will be clocked after which the SDMMC is enabled and command and data can be transferred.

The SDMMC states are controlled by Firmware with the PWRCTRL register bits according Figure 726.

Card cycle power

To perform a card cycle power the following procedure applies:
1. Reset the SDMMC with the RCC.SDMMCxRST register bit. This will reset the SDMMC to the reset state and the CPSM and DPSM to the Idle state.
2. Disable the Vcc power to the card.
3. Set the SDMMC in power-cycle state. This will make that the SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are driven low, to prevent the card from being supplied through the signal lines.
4. After minimum 1ms enable the Vcc power to the card.
5. After the power ramp period set the SDMMC to the power-off state for minimum 1ms. The SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are set to drive “1”.
6. After the 1ms delay set the SDMMC to power-on state in which the SDMMC_CK clock will be enabled.
7. After 74 SDMMC_CK cycles the first command can be sent to the card.

Figure 727. Card cycle power / power up diagram

54.6 **Ultra-high-speed phase I (UHS-I) voltage switch**

UHS-I mode (SDR12, SDR25, SDR50, SDR104, and DDR50) requires the support for 1.8V signaling. After power up the card starts in 3.3V mode. CMD11 invokes the voltage switch sequence to the 1.8V mode. When the voltage sequence is completed successfully the card enters UHS-I mode with default SDR12 and card input and output timings are changed.
To perform the signal voltage switch sequence the following steps are needed:

1. Before starting the Voltage Switch procedure, the SDMMC_CK frequency shall be set in the range 100 kHz - 400 kHz.
2. The host starts the Voltage Switch procedure by setting the VSWITCHEN bit before sending the CMD11.
3. The card returns an R1 response.
   - if the response CRC is pass, the Voltage Switch procedure continues the host will no longer drive the CMD and SDMMC_D[3:0] signals until completion of the voltage switch sequence. Some cycles after the response the SDMMC_CK will be stopped and the CKSTOP flag will be set.
   - if the response CRC is fail (CCRCFAIL flag) or no response is received before the timeout (CTIMEOUT flag), the Voltage Switch procedure is stopped.
4. The card drives CMD and SDMMC_D[3:0] to low at the next clock after the R1 response.
5. The host, after having received the R1 response, may monitor the SDMMC_D0 line using the BUSYD0 register bit. The Firmware may read the BUSYD0 register bit following the CKSTOP flag.
   - When the BUSYD0 is detected low the host FW will switch the Voltage regulator to 1.8V, after which it instructs the SDMMC to start the timing critical section of the
Voltage Switch sequence by setting register bit VSWITCH. The hardware will continue to stop the SDMMC_CK by holding it low for at least 5ms.

- When the BUSYD0 is detected high the host will abort the Voltage Switch sequence and cycle power the card.

6. The card after detecting SDMMC_CK low will begin switching signaling voltage to 1.8V.

7. The host SDMMC hardware after at least 5ms will restart the SDMMC_CK.

8. The card within 1ms from detecting SDMMC_CK transition will drive CMD and DAT[3:0] high for at least 1 SDMMC_CK cycle and then stop driving CMD and DAT[3:0].

9. The host SDMMC hardware, 1ms after the SDMMC_CK has been restarted, the SDMMC_D0 is sampled into BUSYD0 and the VSWEND flag is set.

10. The host, on the VSWEND flag, will check SDMMC_D0 line using the BUSYD0 register bit, to confirm completion of voltage switch sequence:

- When BUSYD0 is detected high, Voltage Switch has been completed successfully.
- When BUSYD0 is detected low, Voltage Switch has failed, the host will cycle power the card power.

The minimum 5ms time to stop the SDMMC_CK is derived from the internal ungated SDMMC_CK clock, which will have a maximum frequency of 25MHz (SD mode), as set by the clock divider CLKDIV. The >5ms time will be counted by $2^{12}$ cycles (10.24ms @ 400 kHz). If a lower SDMMC_CK frequency is selected by the clock divider CLKDIV the time for the SDMMC_CK clock to be stopped will be longer.

The maximum 1 ms time for the card to drive the SDMMC_Dn and SDMMC_CMD lines high is derived from the internal ungated SDMMC_CK which will have a maximum frequency of 25MHz (SD mode), as set by the clock divider CLKDIV. The SDMMC will check the lines after >1ms time which will be counted by $2^9$ cycles (1.28ms @25MHz). If a lower SDMMC_CK frequency is selected by the clock divider CLKDIV the time to check the lines will be longer.

The signal voltage level is supported through an external voltage translation transceiver i.e. ST6G3244ME.
To interface with an external driver (a voltage switch transceiver), next to the standard signals the SDMMC uses the following signals:

- **SDMMC_CKin** feedback input clock
- **SDMMC_CDir** I/O direction control for the CMD signal.
- **SDMMC_D0Dir** I/O direction control for the SDMMC_D0 signal.
- **SDMMC_D123Dir** I/O direction control for the SDMMC_D1, SDMMC_D2 and SDMMC_D3 signals.

The voltage transceiver signals **EN** and **SEL** are to be handled through general-purpose I/O.

The polarity of the SDMMC_CDir, SDMMC_D0Dir and SDMMC_D123Dir signals can be selected through SDMMC_POWER.DIRPOL control bit.

54.8 SDMMC registers

The device communicates to the system via 32-bit control registers accessible via AHB slave interface.

The peripheral registers have to be accessed by words (32-bit). Byte (8-bit) and halfword (16-bit) accesses trigger an AHB bus error.

54.8.1 SDMMC power control register (SDMMC_POWER)

Address offset: 0x000
Reset value: 0x0000 0000

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **DIRPOL**: Data and command direction signals polarity selection
This bit can only be written when the SDMMC is in the power-off state (PWRCTRL = 00).
0: Voltage transceiver IOs driven as output when direction signal is low.
1: Voltage transceiver IOs driven as output when direction signal is high.

Bit 3 **VSWITCHEN**: Voltage switch procedure enable
This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).
This bit is used to stop the SDMMC_CK after the voltage switch command response:
0: SDMMC_CK clock kept unchanged after successfully received command response.
1: SDMMC_CK clock stopped after successfully received command response.

Bit 2 **VSWITCH**: Voltage switch sequence start
This bit is used to start the timing critical section of the voltage switch sequence:
0: Voltage switch sequence not started and not active.
1: Voltage switch sequence started or active.

Bits 1:0 **PWRCTRL[1:0]**: SDMMC state control bits
These bits can only be written when the SDMMC is not in the power-on state (PWRCTRL ≠ 11).
These bits are used to define the functional state of the SDMMC signals:
00: After reset, Reset: the SDMMC is disabled and the clock to the Card is stopped, SDMMC_D[7:0], and SDMMC_CMD are HiZ and SDMMC_CK is driven low. When written 00, power-off: the SDMMC is disabled and the clock to the card is stopped, SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are driven high.
01: Reserved. (When written 01, PWRCTRL value will not change)
10: Power-cycle, the SDMMC is disabled and the clock to the card is stopped, SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are driven low.
11: Power-on: the card is clocked, The first 74 SDMMC_CK cycles the SDMMC is still disabled. After the 74 cycles the SDMMC is enabled and the SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are controlled according the SDMMC operation. Any further write will be ignored, PWRCTRL value will keep 11.
54.8.2 SDMMC clock control register (SDMMC_CLKCR)

Address offset: 0x004
Reset value: 0x0000 0000

The SDMMC_CLKCR register controls the SDMMC_CK output clock, the sdmmc_rx_ck receive clock, and the bus width.

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:20 **SELCLKRX[1:0]:** Receive clock selection

These bits can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)
00: sdmmc_io_in_ck selected as receive clock
01: SDMMC_CKIN feedback clock selected as receive clock
10: sdmmc_fb_ck tuned feedback clock selected as receive clock.
11: Reserved (select sdmmc_io_in_ck)

Bit 19 **BUSSPEED:** Bus speed mode selection between DS, HS, SDR12, SDR25 and SDR50, DDR50, SDR104

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)
0: DS, HS, SDR12, SDR25 bus speed mode selected
1: SDR50, DDR50, SDR104 bus speed mode selected.

Bit 18 **DDR:** Data rate signaling selection

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)

DDR rate shall only be selected with 4-bit or 8-bit wide bus mode. (WIDBUS > 00). DDR = 1 has no effect when WIDBUS = 00 (1-bit wide bus).

DDR rate shall only be selected with clock division >1. (CLKDIV > 0)
0: SDR Single data rate signaling
1: DDR double data rate signaling

Bit 17 **HWFC_EN:** Hardware flow control enable

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)
0: Hardware flow control is disabled
1: Hardware flow control is enabled

When Hardware flow control is enabled, the meaning of the TXFIFOE and RXFIFOF flags change, please see SDMMC status register definition in Section 54.8.11.
Bit 16 **NEGEDGE**: SDMMC_CK dephasing selection bit for data and command

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0).

- When clock division = 1 (CLKDIV = 0), this bit has no effect. Data and Command change on SDMMC_CK falling edge.
- When clock division >1 (CLKDIV > 0) & DDR = 0:
  0: Command and data changed on the sdmmc_ker_ck falling edge succeeding the rising edge of SDMMC_CK.
  - SDMMC_CK edge occurs on sdmmc_ker_ck rising edge.
  1: Command and data changed on the same sdmmc_ker_ck rising edge generating the SDMMC_CK falling edge.
- When clock division >1 (CLKDIV > 0) & DDR = 1:
  0: Command changed on the sdmmc_ker_ck falling edge succeeding the rising edge of SDMMC_CK.
  - Data changed on the sdmmc_ker_ck falling edge succeeding a SDMMC_CK edge.
  - SDMMC_CK edge occurs on sdmmc_ker_ck rising edge.
  1: Command changed on the same sdmmc_ker_ck rising edge generating the SDMMC_CK falling edge.
  - Data changed on the SDMMC_CK falling edge succeeding a SDMMC_CK edge.
  - SDMMC_CK edge occurs on sdmmc_ker_ck rising edge.

Bits 15:14 **WIDBUS[1:0]**: Wide bus mode enable bit

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)

- 00: Default 1-bit wide bus mode: SDMMC_D0 used (Does not support DDR)
- 01: 4-bit wide bus mode: SDMMC_D[3:0] used
- 10: 8-bit wide bus mode: SDMMC_D[7:0] used

Bit 13 Reserved, must be kept at reset value.

Bit 12 **PWRSAV**: Power saving configuration bit

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)

- For power saving, the SDMMC_CK clock output can be disabled when the bus is idle by setting PWRSAV:
  0: SDMMC_CK clock is always enabled
  1: SDMMC_CK is only enabled when the bus is active

Bits 11:10 Reserved, must be kept at reset value.

Bits 9:0 **CLKDIV[9:0]**: Clock divide factor

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0).

This field defines the divide factor between the input clock (sdmmc_ker_ck) and the output clock (SDMMC_CK): SDMMC_CK frequency = sdmmc_ker_ck / [2 * CLKDIV].

- 0x000: SDMMC_CK frequency = sdmmc_ker_ck / 1 (Does not support DDR)
- 0x001: SDMMC_CK frequency = sdmmc_ker_ck / 2
- 0x002: SDMMC_CK frequency = sdmmc_ker_ck / 4
- 0x0XX: etc..
- 0x080: SDMMC_CK frequency = sdmmc_ker_ck / 256
- 0xXXX: etc..
- 0x3FF: SDMMC_CK frequency = sdmmc_ker_ck / 2046
Note: 1 While the SD/SDIO card or eMMC is in identification mode, the SDMMC_CK frequency must be less than 400 kHz.
2 The clock frequency can be changed to the maximum card bus frequency when relative card addresses are assigned to all cards.
3 At least seven sdmmc_hclk clock periods are needed between two write accesses to this register. SDMMC_CK can also be stopped during the ReadWait interval for SD I/O cards: in this case the SDMMC_CLKCR register does not control SDMMC_CK.

54.8.3 SDMMC argument register (SDMMC_ARGR)

Address offset: 0x008
Reset value: 0x0000 0000

The SDMMC_ARGR register contains a 32-bit command argument, which is sent to a card as part of a command message.

Bits 31:0 CMDARG[31:0]: Command argument
These bits can only be written by firmware when CPSM is disabled (CPSMEN = 0). Command argument sent to a card as part of a command message. If a command contains an argument, it must be loaded into this register before writing a command to the command register.

54.8.4 SDMMC command register (SDMMC_CMDR)

Address offset: 0x00C
Reset value: 0x0000 0000

The SDMMC_CMDR register contains the command index and command type bits. The command index is sent to a card as part of a command message. The command type bits control the command path state machine (CPSM).

</table>
Bits 31:17  Reserved, must be kept at reset value.

Bit 16  **CMDSUSPEND**: The CPSM treats the command as a Suspend or Resume command and signals interrupt period start/end

   This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).
   CMDSUSPEND = 1 and CMDTRANS = 0 Suspend command, start interrupt period when response bit BS=0.
   CMDSUSPEND = 1 and CMDTRANS = 1 Resume command with data, end interrupt period when response bit DF=1.

Bit 15  **BOOTEN**: Enable boot mode procedure

   0: Boot mode procedure disabled
   1: Boot mode procedure enabled

Bit 14  **BOOTMODE**: Select the boot mode procedure to be used

   This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0)
   0: Normal boot mode procedure selected
   1: Alternative boot mode procedure selected.

Bit 13  **DTHOLD**: Hold new data block transmission and reception in the DPSM

   If this bit is set, the DPSM will not move from the Wait_S state to the Send state or from the Wait_R state to the Receive state.

Bit 12  **CPSMEN**: Command path state machine (CPSM) enable bit

   This bit is written 1 by firmware, and cleared by hardware when the CPSM enters the Idle state.
   If this bit is set, the CPSM is enabled.
   When DTEN = 1, no command will be transfered nor boot procedure will be started.
   CPSMEN is cleared to 0.
   During ReadWait with SDMMC_CK stopped no command will be sent and CPSMEN is kept 0.

Bit 11  **WAITPEND**: CPSM waits for end of data transfer (CmdPend internal signal) from DPSM

   This bit when set, the CPSM waits for the end of data transfer trigger before it starts sending a command.
   WAITPEND is only taken into account when DTMODE = eMMC stream data transfer,
   WIDBUS = 1-bit wide bus mode, DPSMACT = 1 and DTDIR = from host to card.

Bit 10  **WAITINT**: CPSM waits for interrupt request

   If this bit is set, the CPSM disables command timeout and waits for an card interrupt request (Response).
   If this bit is cleared in the CPSM Wait state, will cause the abort of the interrupt mode.

Bits 9:8  **WAITRESP[1:0]**: Wait for response bits

   This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).
   They are used to configure whether the CPSM is to wait for a response, and if yes, which kind of response.
   00: No response, expect CMDSENT flag
   01: Short response, expect CMDREND or CCRCFAIL flag
   10: Short response, expect CMDREND flag (No CRC)
   11: Long response, expect CMDREND or CCRCFAIL flag
Bit 7 CMDSTOP: The CPSM treats the command as a Stop Transmission command and signals Abort to the DPSM

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).

If this bit is set, the CPSM issues the Abort signal to the DPSM when the command is sent.

Bit 6 CMDTRANS: The CPSM treats the command as a data transfer command, stops the interrupt period, and signals DataEnable to the DPSM

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).

If this bit is set, the CPSM issues an end of interrupt period and issues DataEnable signal to the DPSM when the command is sent.

Bits 5:0 CMDINDEX[5:0]: Command index

This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).

The command index is sent to the card as part of a command message.

Note:
1. At least seven sdmmc_hclk clock periods are needed between two write accesses to this register.

2. MultiMediaCard can send two kinds of response: short responses, 48 bits, or long responses, 136 bits. SD card and SD I/O card can send only short responses, the argument can vary according to the type of response: the software will distinguish the type of response according to the send command.

54.8.5 SDMMC command response register (SDMMC_RESPCMDR)

Address offset: 0x010

Reset value: 0x0000 0000

The SDMMC_RESPCMDR register contains the command index field of the last command response received. If the command response transmission does not contain the command index field (long or OCR response), the RESPCMD field is unknown, although it must contain 111111b (the value of the reserved field from the response).

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 RESPCMD[5:0]: Response command index

Read-only bit field. Contains the command index of the last command response received.
54.8.6 SDMMC response x register (SDMMC_RESPxR)

Address offset: 0x010 + 0x004 * x, (x = 1 to 4)
Reset value: 0x0000 0000

The SDMMC_RESP1/2/3/4R registers contain the status of a card, which is part of the received response.

```
<table>
<thead>
<tr>
<th>Bits 31:0</th>
<th>CARDSTATUSx[31:16]</th>
<th>Bits 15:0</th>
<th>CARDSTATUSx[15:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>r r r r</td>
<td>r r r r r r r r r r</td>
<td>r r r r r r r r r r</td>

<tr>
<td>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

The card status size is 32 or 128 bits, depending on the response type.

### Table 461. Response type and SDMMC_RESPxR registers

<table>
<thead>
<tr>
<th>Register(1)</th>
<th>Short response</th>
<th>Long response</th>
</tr>
</thead>
<tbody>
<tr>
<td>SDMMC_RESP1R</td>
<td>Card status[31:0]</td>

<td>Card status [63:32]</td>
</tr>
<tr>
<td>SDMMC_RESP4R</td>
<td>all 0</td>
<td>Card status <a href="2">31:0</a></td>
</tr>
</tbody>
</table>

1. The most significant bit of the card status is received first.
2. The SDMMC_RESP4R register LSB is always 0.

54.8.7 SDMMC data timer register (SDMMC_DTIMER)

Address offset: 0x024
Reset value: 0x0000 0000

The SDMMC_DTIMER register contains the data timeout period, in card bus clock periods.

A counter loads the value from the SDMMC_DTIMER register, and starts decrementing when the data path state machine (DPSM) enters the Wait_R or Busy state. If the timer reaches 0 while the DPSM is in either of these states, the timeout status flag is set.

```

</tbody>
</table>
```

2446/3289 RM0433 Rev 6
Bits 31:0 **DATATIME[31:0]**: Data and R1b busy timeout period

This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0).

Data and R1b busy timeout period expressed in card bus clock periods.

**Note:** A data transfer must be written to the data timer register and the data length register before being written to the data control register.

### 54.8.8 SDMMC data length register (SDMMC_DLENR)

Address offset: 0x028

Reset value: 0x0000 0000

The SDMMC_DLENR register contains the number of data bytes to be transferred. The value is loaded into the data counter when data transfer starts.

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Access</th>
<th>Mask</th>
<th>Value</th>

<td>DATALENGTH[15:0]</td>
</tr>
</tbody>
</table>

**Note:** For a block data transfer, the value in the data length register must be a multiple of the block size (see SDMMC_DCTRL). A data transfer must be written to the data timer register and the data length register before being written to the data control register.

For an SDMMC multibyte transfer the value in the data length register must be between 1 and 512.
54.8.9 SDMMC data control register (SDMMC_DCTRL)

Address offset: 0x02C
Reset value: 0x0000 0000

The SDMMC_DCTRL register control the data path state machine (DPSM).

<table>

</tbody>
</table>

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **FIFORST**: FIFO reset, will flush any remaining data

This bit can only be written by firmware when IDMAEN= 0 and DPSM is active (DPSMACT = 1). This bit will only take effect when a transfer error or transfer hold occurs.

0: FIFO not affected.
1: Flush any remaining data and reset the FIFO pointers. This bit automatically will be cleared to 0 by hardware when DPSM gets inactive (DPSMACT = 0).

Bit 12 **BOOTACKEN**: Enable the reception of the boot acknowledgment

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

0: Boot acknowledgment disabled, not expected to be received
1: Boot acknowledgment enabled, expected to be received

Bit 11 **SDIOEN**: SD I/O interrupt enable functions

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

If this bit is set, the DPSM enables the SD I/O card specific interrupt operation.

Bit 10 **RWMOD**: Read wait mode

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

0: Read Wait control using SDMMC_D2
1: Read Wait control stopping SDMMC_CK

Bit 9 **RWSTOP**: Read wait stop

This bit is written by firmware and auto cleared by hardware when the DPSM moves from the READ_WAIT state to the WAIT_R or IDLE state.

0: No read wait stop.
1: Enable for read wait stop when DPSM is in the READ_WAIT state.

Bit 8 **RWSTART**: Read wait start

If this bit is set, read wait operation starts.
RM0433 Secure digital input/output MultiMediaCard interface (SDMMC)

Bits 7:4 **DBLOCKSIZE[3:0]**: Data block size

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

- 0000: (0 decimal) lock length = $2^0 = 1$ byte
- 0001: (1 decimal) lock length = $2^1 = 2$ bytes
- 0010: (2 decimal) lock length = $2^2 = 4$ bytes
- 0011: (3 decimal) lock length = $2^3 = 8$ bytes
- 0100: (4 decimal) lock length = $2^4 = 16$ bytes
- 0101: (5 decimal) lock length = $2^5 = 32$ bytes
- 0110: (6 decimal) lock length = $2^6 = 64$ bytes
- 0111: (7 decimal) lock length = $2^7 = 128$ bytes
- 1000: (8 decimal) lock length = $2^8 = 256$ bytes
- 1001: (9 decimal) lock length = $2^9 = 512$ bytes
- 1010: (10 decimal) lock length = $2^{10} = 1024$ bytes
- 1011: (11 decimal) lock length = $2^{11} = 2048$ bytes
- 1100: (12 decimal) lock length = $2^{12} = 4096$ bytes
- 1101: (13 decimal) lock length = $2^{13} = 8192$ bytes
- 1110: (14 decimal) lock length = $2^{14} = 16384$ bytes
- 1111: (15 decimal) reserved

When DATALENGTH is not a multiple of DBLOCKSIZE, the transferred data is truncated at a multiple of DBLOCKSIZE. (Any remain data will not be transferred.)

When DDR = 1, DBLOCKSIZE = 0000 shall not be used. (No data will be transferred)

Bits 3:2 **DTMODE[1:0]**: Data transfer mode selection

- 00: Block data transfer ending on block count.
- 01: SDIO multibyte data transfer.
- 10: e-MMC Stream data transfer. (WIDBUS shall select 1-bit wide bus mode)
- 11: Block data transfer ending with STOP_TRANSMISSION command (not to be used with DTEN initiated data transfers).

Bit 1 **DTDIR**: Data transfer direction selection

- 0: From host to card.
- 1: From card to host.

Bit 0 **DTEN**: Data transfer enable bit

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0). This bit is cleared by Hardware when data transfer completes.

This bit shall only be used to transfer data when no associated data transfer command is used, i.e. shall not be used with SD or e-MMC cards.

- 0: Do not start data transfer without CPSM data transfer command.
- 1: Start data transfer without CPSM data transfer command.

### 54.8.10 SDMMC data counter register (SDMMC_DCNTR)

Address offset: 0x030

Reset value: 0x0000 0000

The SDMMC_DCNTR register loads the value from the data length register (see SDMMC_DLENR) when the DPSM moves from the Idle state to the Wait_R or Wait_S state. As data is transferred, the counter decrements the value until it reaches 0. The DPSM then
moves to the Idle state and when there has been no error, and no transmit data transfer hold, the data status end flag (DATAEND) is set.

**Note:** This register should be read only after the data transfer is complete, or hold. When reading after an error event the read data count value may be different from the real number of data bytes transferred.

### 54.8.11 SDMMC status register (SDMMC_STAR)

**Address offset:** 0x034

**Reset value:** 0x0000 0000

The SDMMC_STAR register is a read-only register. It contains two types of flag:

- **Static flags** (bits [28, 21, 11:0]): these bits remain asserted until they are cleared by writing to the SDMMC interrupt Clear register (see SDMMC_ICR)
- **Dynamic flags** (bits [20:12]): these bits change state depending on the state of the underlying logic (for example, FIFO full and empty flags are asserted and de-asserted as data while written to the FIFO)

**Bits 31:29** Reserved, must be kept at reset value.

**Bit 28** **IDMABTC:** IDMA buffer transfer complete

The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

**Bit 27** **IDMATE:** IDMA transfer error

The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

**Bit 26** **CKSTOP:** SDMMC_CK stopped in Voltage switch procedure

The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.
Bit 25 **VSWEND**: Voltage switch critical timing section completion
   The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 24 **ACKTIMEOUT**: Boot acknowledgment timeout
   The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 23 **ACKFAIL**: Boot acknowledgment received (boot acknowledgment check fail)
   The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 22 **SDIOT**: SDIO interrupt received
   The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 21 **BUSYD0END**: end of SDMMC_D0 Busy following a CMD response detected
   This indicates only end of busy following a CMD response. This bit does not signal busy due
to data transfer. Interrupt flag is cleared by writing corresponding interrupt clear bit in
SDMMC_ICR.
   0: card SDMMC_D0 signal does NOT signal change from busy to not busy.
   1: card SDMMC_D0 signal changed from busy to NOT busy.

Bit 20 **BUSYD0**: Inverted value of SDMMC_D0 line (Busy), sampled at the end of a CMD response
   and a second time 2 SDMMC_CK cycles after the CMD response
   This bit is reset to not busy when the SDMMCD0 line changes from busy to not busy. This bit
does not signal busy due to data transfer. This is a hardware status flag only, it does not
generate an interrupt.
   0: card signals not busy on SDMMC_D0.
   1: card signals busy on SDMMC_D0.

Bit 19 **RXFIFOE**: Receive FIFO empty
   This is a hardware status flag only, does not generate an interrupt. This bit is cleared when
one FIFO location becomes full.

Bit 18 **TXFIFOE**: Transmit FIFO empty
   This bit is cleared when one FIFO location becomes full.

Bit 17 **RXFIFOF**: Receive FIFO full
   This bit is cleared when one FIFO location becomes empty.

Bit 16 **TXFIFOF**: Transmit FIFO full
   This is a hardware status flag only, does not generate an interrupt. This bit is cleared when
one FIFO location becomes empty.

Bit 15 **RXFIFOHF**: Receive FIFO half full
   There are at least half the number of words in the FIFO. This bit is cleared when the FIFO
becomes half+1 empty.

Bit 14 **TXFIFOHE**: Transmit FIFO half empty
   At least half the number of words can be written into the FIFO. This bit is cleared when the
FIFO becomes half+1 full.

Bit 13 **CPSMACT**: Command path state machine active, i.e. not in Idle state
   This is a hardware status flag only, does not generate an interrupt.

Bit 12 **DPSMACT**: Data path state machine active, i.e. not in Idle state
   This is a hardware status flag only, does not generate an interrupt.

Bit 11 **DABORT**: Data transfer aborted by CMD12
   Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.
Bit 10 **DBCKEND**: Data block sent/received
DBCKEND is set when:
- CRC check passed and DPSM moves to the READWAIT state
  or
- IDMAEN = 0 and transmit data transfer hold and DATACOUNT >0 and DPSM moves to WAIT_S.
  Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 9 **DHOLOD**: Data transfer Hold
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 8 **DATAEND**: Data transfer ended correctly
DATAEND is set if data counter DATACOUNT is zero and no errors occur, and no transmit data transfer hold.
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 7 **CMDSENT**: Command sent (no response required)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 6 **CMDREND**: Command response received (CRC check passed, or no CRC)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 5 **RXOVERR**: Received FIFO overrun error
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 4 **TXUNDERR**: Transmit FIFO underrun error
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 3 **DTIMEOUT**: Data timeout
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 2 **CTIMEOUT**: Command response timeout
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.
The Command Timeout period has a fixed value of 64 SDMMC_CK clock periods.

Bit 1 **DCRCFAIL**: Data block sent/received (CRC check failed)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 0 **CCRCFAIL**: Command response received (CRC check failed)
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

*Note:* FIFO interrupt flags shall be masked in SDMMC_MASKR when using IDMA mode.
54.8.12  SDMMC interrupt clear register (SDMMC_ICR)

Address offset: 0x038

Reset value: 0x0000 0000

The SDMMC_ICR register is a write-only register. Writing a bit with 1 clears the corresponding bit in the SDMMC_STAR status register.

| Bit 31:29 Reserved, must be kept at reset value. |
| Bit 28 IDMABTCC: IDMA buffer transfer complete clear bit |
| Set by software to clear the IDMABTC flag. |
| 0: IDMABTC not cleared |
| 1: IDMABTC cleared |
| Bit 27 IDMATEC: IDMA transfer error clear bit |
| Set by software to clear the IDMATE flag. |
| 0: IDMATE not cleared |
| 1: IDMATE cleared |
| Bit 26 CKSTOPC: CKSTOP flag clear bit |
| Set by software to clear the CKSTOP flag. |
| 0: CKSTOP not cleared |
| 1: CKSTOP cleared |
| Bit 25 VSWENDC: VSWEND flag clear bit |
| Set by software to clear the VSWEND flag. |
| 0: VSWEND not cleared |
| 1: VSWEND cleared |
| Bit 24 ACKTIMEOUTC: ACKTIMEOUT flag clear bit |
| Set by software to clear the ACKTIMEOUT flag. |
| 0: ACKTIMEOUT not cleared |
| 1: ACKTIMEOUT cleared |
| Bit 23 ACKFAILC: ACKFAIL flag clear bit |
| Set by software to clear the ACKFAIL flag. |
| 0: ACKFAIL not cleared |
| 1: ACKFAIL cleared |
| Bit 22 SDIOITC: SDIOIT flag clear bit |
| Set by software to clear the SDIOIT flag. |
| 0: SDIOIT not cleared |
| 1: SDIOIT cleared |
Bit 21 **BUSYD0ENDC**: BUSYD0END flag clear bit
Set by software to clear the BUSYD0END flag.
0: BUSYD0END not cleared
1: BUSYD0END cleared

Bits 20:12 Reserved, must be kept at reset value.

Bit 11 **DABORTC**: DABORT flag clear bit
Set by software to clear the DABORT flag.
0: DABORT not cleared
1: DABORT cleared

Bit 10 **DBCKENDC**: DBCKEND flag clear bit
Set by software to clear the DBCKEND flag.
0: DBCKEND not cleared
1: DBCKEND cleared

Bit 9 **DHOLDC**: DHOLD flag clear bit
Set by software to clear the DHOLD flag.
0: DHOLD not cleared
1: DHOLD cleared

Bit 8 **DATAENDC**: DATAEND flag clear bit
Set by software to clear the DATAEND flag.
0: DATAEND not cleared
1: DATAEND cleared

Bit 7 **CMDSENTC**: CMDSENT flag clear bit
Set by software to clear the CMDSENT flag.
0: CMDSENT not cleared
1: CMDSENT cleared

Bit 6 **CMDRENDC**: CMDRENDC flag clear bit
Set by software to clear the CMDRENDC flag.
0: CMDRENDC not cleared
1: CMDRENDC cleared

Bit 5 **RXOVERRC**: RXOVERR flag clear bit
Set by software to clear the RXOVERR flag.
0: RXOVERR not cleared
1: RXOVERR cleared

Bit 4 **TXUNDERRC**: TXUNDERR flag clear bit
Set by software to clear TXUNDERR flag.
0: TXUNDERR not cleared
1: TXUNDERR cleared

Bit 3 **DTIMEOUTC**: DTIMEOUT flag clear bit
Set by software to clear the DTIMEOUT flag.
0: DTIMEOUT not cleared
1: DTIMEOUT cleared
Bit 2  **CTIMEOUT**: CTIMEOUT flag clear bit
   Set by software to clear the CTIMEOUT flag.
   0: CTIMEOUT not cleared
   1: CTIMEOUT cleared

Bit 1  **DCRCFAIL**: DCRCFAIL flag clear bit
   Set by software to clear the DCRCFAIL flag.
   0: DCRCFAIL not cleared
   1: DCRCFAIL cleared

Bit 0  **CCRCFAIL**: CCRCFAIL flag clear bit
   Set by software to clear the CCRCFAIL flag.
   0: CCRCFAIL not cleared
   1: CCRCFAIL cleared

### 54.8.13 SDMMC mask register (SDMMC_MASKR)

Address offset: 0x03C
Reset value: 0x0000 0000
The interrupt mask register determines which status flags generate an interrupt request by setting the corresponding bit to 1.

| Bit 31:29 | Reserved, must be kept at reset value. |
|----------------|
| Bit 28 | **IDMABTCIE**: IDMA buffer transfer complete interrupt enable
   Set and cleared by software to enable/disable the interrupt generated when the IDMA has transferred all data belonging to a memory buffer.
   0: IDMA buffer transfer complete interrupt disabled
   1: IDMA buffer transfer complete interrupt enabled |
| Bit 27 | Reserved, must be kept at reset value. |
| Bit 26 | **CKSTOPIE**: Voltage Switch clock stopped interrupt enable
   Set and cleared by software to enable/disable interrupt caused by Voltage Switch clock stopped.
   0: Voltage Switch clock stopped interrupt disabled
   1: Voltage Switch clock stopped interrupt enabled |
| Bit 25 | **VSWENDIE**: Voltage switch critical timing section completion interrupt enable
   Set and cleared by software to enable/disable the interrupt generated when voltage switch critical timing section completion.
   0: Voltage switch critical timing section completion interrupt disabled
   1: Voltage switch critical timing section completion interrupt enabled |
Bit 24 **ACKTIMEOUTIE**: Acknowledgment timeout interrupt enable
Set and cleared by software to enable/disable interrupt caused by acknowledgment timeout.
0: Acknowledgment timeout interrupt disabled
1: Acknowledgment timeout interrupt enabled

Bit 23 **ACKFAILIE**: Acknowledgment Fail interrupt enable
Set and cleared by software to enable/disable interrupt caused by acknowledgment Fail.
0: Acknowledgment Fail interrupt disabled
1: Acknowledgment Fail interrupt enabled

Bit 22 **SDIOITIE**: SDIO mode interrupt received interrupt enable
Set and cleared by software to enable/disable the interrupt generated when receiving the SDIO mode interrupt.
0: SDIO Mode interrupt received interrupt disabled
1: SDIO Mode interrupt received interrupt enabled

Bit 21 **BUSYD0ENDIE**: BUSYD0END interrupt enable
Set and cleared by software to enable/disable the interrupt generated when SDMMC_D0 signal changes from busy to NOT busy following a CMD response.
0: BUSYD0END interrupt disabled
1: BUSYD0END interrupt enabled

Bits 20:19 Reserved, must be kept at reset value.

Bit 18 **TXFIFOEIE**: Tx FIFO empty interrupt enable
Set and cleared by software to enable/disable interrupt caused by Tx FIFO empty.
0: Tx FIFO empty interrupt disabled
1: Tx FIFO empty interrupt enabled

Bit 17 **RXFIFOFIE**: Rx FIFO full interrupt enable
Set and cleared by software to enable/disable interrupt caused by Rx FIFO full.
0: Rx FIFO full interrupt disabled
1: Rx FIFO full interrupt enabled

Bit 16 Reserved, must be kept at reset value.

Bit 15 **RXFIFOHFIE**: Rx FIFO half full interrupt enable
Set and cleared by software to enable/disable interrupt caused by Rx FIFO half full.
0: Rx FIFO half full interrupt disabled
1: Rx FIFO half full interrupt enabled

Bit 14 **TXFIFOHEIE**: Tx FIFO half empty interrupt enable
Set and cleared by software to enable/disable interrupt caused by Tx FIFO half empty.
0: Tx FIFO half empty interrupt disabled
1: Tx FIFO half empty interrupt enabled

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **DABORTIE**: Data transfer aborted interrupt enable
Set and cleared by software to enable/disable interrupt caused by a data transfer being aborted.
0: Data transfer abort interrupt disabled
1: Data transfer abort interrupt enabled

Bit 10 **DBCKENDIE**: Data block end interrupt enable
Set and cleared by software to enable/disable interrupt caused by data block end.
0: Data block end interrupt disabled
1: Data block end interrupt enabled
Bit 9  **DHOLDIE**: Data hold interrupt enable  
Set and cleared by software to enable/disable the interrupt generated when sending new data is held in the DPSM Wait_S state.  
0: Data hold interrupt disabled  
1: Data hold interrupt enabled  

Bit 8  **DATAENDIE**: Data end interrupt enable  
Set and cleared by software to enable/disable interrupt caused by data end.  
0: Data end interrupt disabled  
1: Data end interrupt enabled  

Bit 7  **CMDSENTIE**: Command sent interrupt enable  
Set and cleared by software to enable/disable interrupt caused by sending command.  
0: Command sent interrupt disabled  
1: Command sent interrupt enabled  

Bit 6  **CMDRENDIE**: Command response received interrupt enable  
Set and cleared by software to enable/disable interrupt caused by receiving command response.  
0: Command response received interrupt disabled  
1: Command response received interrupt enabled  

Bit 5  **RXOVERRIE**: Rx FIFO overrun error interrupt enable  
Set and cleared by software to enable/disable interrupt caused by Rx FIFO overrun error.  
0: Rx FIFO overrun error interrupt disabled  
1: Rx FIFO overrun error interrupt enabled  

Bit 4  **TXUNDERIE**: Tx FIFO underrun error interrupt enable  
Set and cleared by software to enable/disable interrupt caused by Tx FIFO underrun error.  
0: Tx FIFO underrun error interrupt disabled  
1: Tx FIFO underrun error interrupt enabled  

Bit 3  **DTIMEOUTIE**: Data timeout interrupt enable  
Set and cleared by software to enable/disable interrupt caused by data timeout.  
0: Data timeout interrupt disabled  
1: Data timeout interrupt enabled  

Bit 2  **CTIMEOUTIE**: Command timeout interrupt enable  
Set and cleared by software to enable/disable interrupt caused by command timeout.  
0: Command timeout interrupt disabled  
1: Command timeout interrupt enabled  

Bit 1  **DCRCFAILIE**: Data CRC fail interrupt enable  
Set and cleared by software to enable/disable interrupt caused by data CRC failure.  
0: Data CRC fail interrupt disabled  
1: Data CRC fail interrupt enabled  

Bit 0  **CCRCFAILIE**: Command CRC fail interrupt enable  
Set and cleared by software to enable/disable interrupt caused by command CRC failure.  
0: Command CRC fail interrupt disabled  
1: Command CRC fail interrupt enabled
54.8.14 SDMMC acknowledgment timer register (SDMMC_ACKTIMER)

Address offset: 0x040
Reset value: 0x0000 0000

The SDMMC_ACKTIMER register contains the acknowledgment timeout period, in SDMMC_CK bus clock periods.

A counter loads the value from the SDMMC_ACKTIMER register, and starts decrementing when the data path state machine (DPSM) enters the Wait_Ack state. If the timer reaches 0 while the DPSM is in this state, the acknowledgment timeout status flag is set.

Note: The data transfer must be written to the acknowledgment timer register before being written to the data control register.

54.8.15 SDMMC data FIFO registers x (SDMMC_FIFORx)

Address offset: 0x080 + 0x004 * x, (x =0 to 15)
Reset value: 0x0000 0000

The receive and transmit FIFOs can be only read or written as word (32-bit) wide registers. The FIFOs contain 16 entries on sequential addresses. This allows the CPU to use its load and store multiple operands to read from/write to the FIFO. The FIFO register interface takes care of correct data alignment inside the FIFO, the FIFO register address used by the CPU does matter.

When accessing SDMMC_FIFOR with half word or byte access an AHB bus fault is generated.
Bits 31:0 **FIFODATA[31:0]**: Receive and transmit FIFO data

This register can only be read or written by firmware when the DPSM is active (DPSMACT = 1).
The FIFO data occupies 16 entries of 32-bit words.

### 54.8.16 SDMMC DMA control register (SDMMC_IDMACTRLR)

**Address offset: 0x050**

**Reset value: 0x0000 0000**

The receive and transmit FIFOs can be read or written as 32-bit wide registers. The FIFOs contain 32 entries on 32 sequential addresses. This allows the CPU to use its load and store multiple operands to read from/write to the FIFO.

Bits 31:3 Reserved, must be kept at reset value.

**Bit 2 IDMABACT**: Double buffer mode active buffer indication

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0). When IDMA is enabled this bit is toggled by hardware.

0: When IDMA is enabled, uses buffer0 and firmware write access to IDMABASE0 is prohibited.

1: When IDMA is enabled, uses buffer1 and firmware write access to IDMABASE1 is prohibited.

**Bit 1 IDMABMODE**: Buffer mode selection

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

0: Single buffer mode.

1: Double buffer mode.

**Bit 0 IDMAEN**: IDMA enable

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

0: IDMA disabled

1: IDMA enabled
54.8.17  SDMMC IDMA buffer size register (SDMMC_IDMABSIZER)

Address offset: 0x054

Reset value: 0x0000 0000

The SDMMC_IDMABSIZER register contains the buffers size when in double buffer configuration.

- Bits 31:13: Reserved, must be kept at reset value.
- Bits 12:5 **IDMABNDT[7:0]**: Number of bytes per buffer
  - This 8-bit value shall be multiplied by 8 to get the size of the buffer in 32-bit words and by 32 to get the size of the buffer in bytes.
  - Example: IDMABNDT = 0x01: buffer size = 8 words = 32 bytes.
  - Example: IDMABNDT = 0x80: buffer size = 1024 words = 4 Kbyte
  - These bits can only be written by firmware when DPSM is inactive (DPSMACT = 0).
- Bits 4:0: Reserved, must be kept at reset value.

54.8.18  SDMMC IDMA buffer 0 base address register (SDMMC_IDMABASE0R)

Address offset: 0x058

Reset value: 0x0000 0000

The SDMMC_IDMABASE0R register contains the memory buffer base address in single buffer configuration and the buffer 0 base address in double buffer configuration.

- Bits 31:0 **IDMABASE0[31:0]**: Buffer 0 memory base address bits [31:2], shall be word aligned (bit [1:0] are always 0 and read only)
  - This register can be written by firmware when DPSM is inactive (DPSMACT = 0), and can dynamically be written by firmware when DPSM active (DPSMACT = 1) and memory buffer 0 is inactive (IDMABACT = '1').
54.8.19  SDMMC IDMA buffer 1 base address register  
(SDMMC_IDMABASE1R)

Address offset: 0x05C
Reset value: 0x0000 0000

The SDMMC_IDMABASE1R register contains the double buffer configuration second buffer memory base address.

55 Controller area network with flexible data rate (FDCAN)

55.1 Introduction

The controller area network (CAN) subsystem (see Figure 730) consists of two CAN modules, a shared message RAM and a clock calibration unit. Refer to the product memory organization for the base address of each of these four parts.

Both modules (FDCAN1 and FDCAN2) are compliant with ISO 11898-1: 2015 (CAN protocol specification version 2.0 part A, B) and CAN FD protocol specification version 1.0.

In addition, the first CAN module FDCAN1 supports time triggered CAN (TTCAN), specified in ISO 11898-4, including event synchronized time-triggered communication, global system time, and clock drift compensation. The FDCAN1 contains additional registers, specific to the time triggered feature. The CAN FD option can be used together with event-triggered and time-triggered CAN communication.

A 10 Kbyte message RAM implements filters, receive FIFOs, receive buffers, transmit event FIFOs, transmit buffers (and triggers for TTCAN). This message RAM is shared between the FDCAN1 and FDCAN2 modules.

The common clock calibration unit is optional. It can be used to generate a calibrated clock for both FDCAN1 and FDCAN2 from the HSI internal RC oscillator and the PLL, by evaluating CAN messages received by the FDCAN1.

The CAN subsystem I/O signals and pins are detailed, respectively, in Table 463 and Table 464.

Figure 730. CAN subsystem
55.2 FDCAN main features

- Conform with CAN protocol version 2.0 part A, B and ISO 11898-1: 2015, -4
- CAN FD with max. 64 data bytes supported
- TTCAN protocol level 1 and level 2 completely in hardware (FDCAN1 only)
- Event synchronized time-triggered communication supported (FDCAN1 only)
- CAN error logging
- AUTOSAR and J1939 support
- Improved acceptance filtering
- Two configurable receive FIFOs
- Separate signaling on reception of high priority messages
- Up to 64 dedicated receive buffers
- Up to 32 dedicated transmit buffers
- Configurable transmit FIFO /queue
- Configurable transmit event FIFO
- Both FDCAN1 and FDCAN2 modules share the same message RAM
- Programmable loop-back test mode
- Maskable module interrupts
- Two clock domains: APB bus interface and CAN core kernel clock
- Power-down support
55.3 FDCAN functional description

Figure 731. FDCAN block diagram

Dual interrupt lines

The FDCAN peripheral provides two interrupt lines fdcan_intr0_it and fdcan_intr1_it. By programming EINT0 and EINT1 bits in FDCAN_IIE register, the interrupt lines can be enabled or disabled separately.

CAN core

The CAN core contains the protocol controller and receive/transmit shift registers. It handles all ISO 11898-1: 2015 protocol functions and supports both 11-bit and 29-bit identifiers.

Sync

The sync block synchronizes signals from the APB clock domain to the CAN kernel clock domain and vice versa.
**Tx handler**

Controls the message transfer from the message RAM to the CAN core. A maximum of 32 Tx buffers can be configured for transmission. Tx buffers can be used as dedicated Tx buffers, as Tx FIFO, part of a Tx queue, or as a combination of them. A Tx event FIFO stores Tx timestamps together with the corresponding message ID. Transmit cancellation is also supported.

On FDCAN1, the Tx handler also implements the frame synchronization entity (FSE) which controls time-triggered communication according to ISO11898-4. It synchronizes itself with the reference messages on the CAN bus, controls cycle time and global time, and handles transmissions according to the predefined message schedule, the system matrix. It also handles the time marks of the system matrix that are linked to the messages in the message RAM. Stop watch trigger, event trigger, and time mark interrupt are synchronization interfaces.

**Rx handler**

Controls the transfer of received messages from the CAN core to the external message RAM. The Rx handler supports two receive FIFOs, each of configurable size, and up to 64 dedicated Rx buffers for storage of all messages that have passed acceptance filtering. A dedicated Rx buffer, in contrast to a receive FIFO, is used to store only messages with a specific identifier. An Rx timestamp is stored together with each message. Up to 128 filters can be defined for 11-bit IDs and up to 64 filters for 29-bit IDs.

**APB Interface**

Connects the FDCAN to the APB bus.

**Message RAM Interface**

Connects the FDCAN access to an external 10 Kbytes message RAM through a RAM controller/arbiter.

### 55.3.1 Operating modes

**Software initialization**

Software initialization is started by setting INIT bit in FDCAN_CCCR register, either by software or by a hardware reset, or by going Bus_Off. While INIT bit in FDCAN_CCCR register is set, message transfer from and to the CAN bus is stopped, the status of the CAN bus output FDCAN_TX is recessive (high). The counters of the error management logic (EML) are unchanged. Setting INIT bit in FDCAN_CCCR does not change any configuration register. Clearing INIT bit in FDCAN_CCCR finishes the software initialization. Afterwards the bit stream processor (BSP) synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (Bus_Idle) before it can take part in bus activities and start the message transfer.

Access to the FDCAN configuration registers is only enabled when both INIT bit in FDCAN_CCCR register and CCE bit in FDCAN_CCCR register are set.

CCE bit in FDCAN_CCCR register can only be set/cleared while INIT bit in FDCAN_CCCR is set. CCE bit in FDCAN_CCCR register is automatically cleared when INIT bit in FDCAN_CCCR is cleared.
The following registers are reset when CCE bit in FDCAN_CCCR register is set:

- FDCAN_HPMS - high priority message status
- FDCAN_RXF0S - Rx FIFO 0 status
- FDCAN_RXF1S - Rx FIFO 1 status
- FDCAN_TXFQS - Tx FIFO/queue status
- FDCAN_TXBRP - Tx buffer request pending
- FDCAN_TXBTO - Tx buffer transmission occurred
- FDCAN_TXBCF - Tx buffer cancellation finished
- FDCAN_TXEFS - Tx event FIFO status
- FDCAN_TTOST - TT (time trigger) operation status (FDCAN1 only)
- FDCAN_TTLGT - TT local and global time, only global time FDCAN_TTLGT.GT is reset (FDCAN1 only)
- FDCAN_TTCTC - TT cycle time and count (FDCAN1 only)
- FDCAN_TTCSM - TT cycle sync mark (FDCAN1 only)

The timeout counter value TOC bit in FDCAN_TOCV register is preset to the value configured by TOP bit in FDCAN_TOCC register when CCE bit in FDCAN_CCCR is set.

In addition the state machines of the Tx handler and Rx handler are held in idle state while CCE bit in FDCAN_CCCR is set.

The following registers can be written only when CCE bit in FDCAN_CCCR register is cleared:

- FDCAN_TXBAR - Tx buffer add request
- FDCAN_TXBCR - Tx buffer cancellation request

TEST bit in FDCAN_CCCR and MON bit in FDCAN_CCCR can only be set by software while both INIT bit and CCE bit in FDCAN_CCCR register are set. Both bits may be reset at any time. DAR bit in FDCAN_CCCR can only be set/cleared while both INIT bit in FDCAN_CCCR and CCE bit in FDCAN_CCCR are set.

**Normal operation**

The FDCAN1 default operating mode after hardware reset is event-driven CAN communication without time triggers (FDCAN_TTOCF.OM = 00). It is required that both INIT bit and CCE bit in FDCAN_CCCR register are set before the TT operation mode can be changed.

Once the FDCAN is initialized and INIT bit in FDCAN_CCCR register is cleared, the FDCAN synchronizes itself to the CAN bus and is ready for communication.

After passing the acceptance filtering, received messages including message ID and DLC are stored into a dedicated Rx buffer or into the Rx FIFO 0 or Rx FIFO 1.

For messages to be transmitted dedicated Tx buffers and/or a Tx FIFO or a Tx queue can be initialized or updated. Automated transmission on reception of remote frames is not supported.

**CAN FD operation**

There are two variants in the FDCAN protocol, first the long frame mode (LFM) where the data field of a CAN frame may be longer that eight bytes. The second variant is the fast frame mode (FFM) where control field, data field, and CRC field of a CAN frame are
transmitted with a higher bitrate than the beginning and the end of the frame. Fast frame mode can be used in combination with long frame mode.

The previously reserved bit in CAN frames with 11-bit identifiers and the first previously reserved bit in CAN frames with 29-bit identifiers will now be decoded as FDF bit. FDF recessive signifies a CAN FD frame, while FDF dominant signifies a classic CAN frame. In a CAN FD frame, the two bits following FDF, res and BRS, decide whether the bitrate inside this CAN FD frame is switched. A CAN FD bitrate switch is signified by res dominant and BRS recessive. The coding of res recessive is reserved for future expansion of the protocol. If the FDCAN receives a frame with FDF recessive and res recessive, it will signal a protocol exception event by setting bit FDCAN_PSR.PXE. When protocol exception handling is enabled (FDCAN_CCCR.PXHD = 0), this causes the operation state to change from receiver (FDCAN_PSR.ACT = 10) to Integrating (FDCAN_PSR.ACT = 00) at the next sample point. In case protocol exception handling is disabled (FDCAN_CCCR.PXHD = 1), the FDCAN will treat a recessive res bit as a form error and will respond with an error frame.

CAN FD operation is enabled by programming FDCAN_CCCR.FDOE. If FDCAN_CCCR.FDOE = 1, transmission and reception of CAN FD frames is enabled. Transmission and reception of classic CAN frames is always possible. Whether a CAN FD frame or a classic CAN frame is transmitted can be configured via bit FDF in the respective Tx buffer element. With FDCAN_CCCR.FDOE = 0, received frames are interpreted as classic CAN frames, which leads to the transmission of an error frame when receiving a CAN FD frame. When CAN FD operation is disabled, no CAN FD frames are transmitted, even if bit FDF of a Tx buffer element is set. FDCAN_CCCR.FDOE and FDCAN_CCCR.BRSE can only be changed while FDCAN_CCCR.INIT and FDCAN_CCCR.CCE are both set.

With FDCAN_CCCR.FDOE = 0, the setting of bits FDF and BRS is ignored and frames are transmitted in classic CAN format. With FDCAN_CCCR.FDOE = 1 and FDCAN_CCCR.BRSE = 0, only bit FDF of a Tx buffer element is evaluated. With FDCAN_CCCR.FDOE = 1 and FDCAN_CCCR.BRSE = 1, transmission of CAN FD frames with bitrate switching is enabled. All Tx buffer elements with bits FDF and BRS set are transmitted in CAN FD format with bitrate switching.

A mode change during CAN operation is only recommended under the following conditions:

- The failure rate in the CAN FD data phase is significant higher than in the CAN FD arbitration phase. In this case disable the CAN FD bitrate switching option for transmissions.
- During system startup all nodes are transmitting classic CAN messages until it is verified that they are able to communicate in CAN FD format. If this is true, all nodes switch to CAN FD operation.
- Wake-up messages in CAN partial networking have to be transmitted in classic CAN format.
- End-of-line programming in case not all nodes are CAN FD capable. Non CAN FD nodes are held in Silent mode until programming has completed. Then all nodes switch back to classic CAN communication.

In the FDCAN format, the coding of the DLC differs from the standard CAN format. The DLC codes 0 to 8 have the same coding as in standard CAN, the codes 9 to 15 (that in standard CAN all code a data field of 8 bytes) are coded according to Table 465.
In CAN FD fast frames, the bit timing will be switched inside the frame, after the BRS (bitrate Switch) bit, if this bit is recessive. Before the BRS bit, in the FDCAN arbitration phase, the nominal CAN bit timing is used as defined by the bit timing and prescaler register FDCAN_NBTP. In the following FDCAN data phase, the fast CAN bit timing is used as defined by the fast bit timing and prescaler register FDCAN_DBTP. The bit timing is switched back from the fast timing at the CRC delimiter or when an error is detected, whichever occurs first.

The maximum configurable bitrate in the CAN FD data phase depends on the FDCAN kernel clock frequency. For example, with a FDCAN kernel clock frequency of 20 MHz and the shortest configurable bit time of four time quanta (tq), the bitrate in the data phase is 5 Mbit/s.

In both data frame formats, CAN FD long frames and CAN FD fast frames, the value of the bit ESI (error status Indicator) is determined by the transmitter error state at the start of the transmission. If the transmitter is error passive, ESI is transmitted recessive, else it is transmitted dominant. In CAN FD remote frames the ESI bit is always transmitted dominant, independent of the transmitter error state. The data length code of CAN FD remote frames is transmitted as 0.

In case a FDCAN Tx buffer is configured for FDCAN transmission with DLC > 8, the first eight bytes are transmitted as configured in the Tx buffer while the remaining part of the data field is padded with 0xCC. When the FDCAN receives a FDCAN frame with DLC > 8, the first eight bytes of that frame are stored into the matching Rx buffer or Rx FIFO. The remaining bytes are discarded.

Transceiver delay compensation

During the data phase of a FDCAN transmission only one node is transmitting, all others are receivers. The length of the bus line has no impact. When transmitting via pin FDCAN_TX the protocol controller receives the transmitted data from its local CAN transceiver via pin FDCAN_RX. The received data is delayed by the CAN transceiver loop delay. In case this delay is greater than TSEG1 (time segment before sample point), a bit error is detected. Without transceiver delay compensation, the bitrate in the data phase of a FDCAN frame is limited by the transceivers loop delay.

The FDCAN implements a delay compensation mechanism to compensate the CAN transceiver loop delay, thereby enabling transmission with higher bitrates during the FDCAN data phase independent of the delay of a specific CAN transceiver.

To check for bit errors during the data phase of transmitting nodes, the delayed transmit data is compared against the received data at the Secondary Sample Point SSP. If a bit error is detected, the transmitter will react on this bit error at the next following regular sample point. During arbitration phase the delay compensation is always disabled.

The transmitter delay compensation enables configurations where the data bit time is shorter than the transmitter delay, it is described in detail in the new ISO11898-1. It is enabled by setting bit FDCAN_DBTP.TDC.
The received bit is compared against the transmitted bit at the SSP. The SSP position is defined as the sum of the measured delay from the FDCAN transmit output pin FDCAN_TX through the transceiver to the receive input pin FDCAN_RX plus the transmitter delay compensation offset as configured by FDCAN_TDCR.TDCO. The transmitter delay compensation offset is used to adjust the position of the SSP inside the received bit (e.g. half of the bit time in the data phase). The position of the secondary sample point is rounded down to the next integer number of mtq (minimum time quantum, that is one period of fdcan_to_ck clock).

FDCAN_PSR.TDCV shows the actual transmitter delay compensation value, it is cleared when FDCAN_CCCR.INIT is set and is updated at each transmission of an FD frame while FDCAN_DBTP.TDC is set.

The following boundary conditions have to be considered for the transmitter delay compensation implemented in the FDCAN:

- The sum of the measured delay from FDCANx_TX to FDCANx_RX and the configured transmitter delay compensation offset FDCAN_TDCR.TDCO has to be less than six bit times in the data phase.
- The sum of the measured delay from FDCANx_TX to FDCANx_RX and the configured transmitter delay compensation offset FDCAN_TDCR.TDCO has to be less or equal 127 mtq. In case this sum exceeds 127 mtq, the maximum value (127 mtq) is used for transmitter delay compensation.
- The data phase ends at the sample point of the CRC delimiter, that stops checking received bits at the SSPs

If transmitter delay compensation is enabled by programming FDCAN_DBTP.TDC = 1, the measurement is started within each transmitted CAN FD frame at the falling edge of bit FDF to bit res. The measurement is stopped when this edge is seen at the receive input pin FDCAN_TX of the transmitter. The resolution of this measurement is one mtq.

**Figure 732. Transceiver delay measurement**

To avoid that a dominant glitch inside the received FDF bit ends the delay compensation measurement before the falling edge of the received res bit (resulting in a to early SSP position) the use of a transmitter delay compensation filter window can be enabled by
programming FDCAN_TDCR.TDCF. This defines a minimum value for the SSP position. Dominant edges on FDCANx_RX, that would result in an earlier SSP position are ignored for transmitter delay measurement. The measurement is stopped when the SSP position is at least FDCAN_TDCR.TDCF and FDCAN_RX is low.

**Restricted operation mode**

In restricted operation mode the node is able to receive data and remote frames and to give acknowledge to valid frames, but it does not send data frames, remote frames, active error frames, or overload frames. In case of an error condition or overload condition, it does not send dominant bits, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication. The error counters (FDCAN_ECR.REC, FDCAN_ECR.TEC) are frozen while error logging (FDCAN_ECR.CEL) is active. The software can set the FDCAN into restricted operation mode by setting bit FDCAN_CCCR.ASM. The bit can only be set by software when both FDCAN_CCCR.CCE and FDCAN_CCCR.INIT are set to 1. The bit can be cleared by software at any time.

Restricted operation mode is automatically entered when the Tx handler was not able to read data from the message RAM in time. To leave restricted operation mode, the software has to reset FDCAN_CCCR.ASM.

The restricted operation mode can be used in applications that adapt themselves to different CAN bitrates. In this case the application tests different bitrates and leaves the restricted operation mode after it has received a valid frame.

FDCAN_CCCR.ASM is also controlled by the clock calibration unit. When the clock calibration process is enabled, the restricted operation mode is entered and the FDCAN_CCR.ASM bit is set. Once the calibration is completed, FDCAN_CCCR.ASM bit is cleared.

*Note:* The restricted operation mode must not be combined with the loop back mode (internal or external).

**Bus monitoring mode**

The FDCAN is set in bus monitoring mode by setting FDCAN_CCCR.MON bit or when error level S3 (FDCAN_TTOST.EL = 11) is entered. In bus monitoring mode (For more details please refer to ISO11898-1, 10.12 bus monitoring), the FDCAN is able to receive valid data frames and valid remote frames, but cannot start a transmission. In this mode, it sends only recessive bits on the CAN bus, if the FDCAN is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the FDCAN monitors this dominant bit, although the CAN bus may remain in recessive state. In bus monitoring mode register FDCAN_TXBRP is held in reset state.

The bus monitoring mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits. *Figure 733* shows the connection of FDCAN_TX and FDCAN_RX signals to the FDCAN in bus monitoring mode.
Disabled automatic retransmission (DAR) mode

According to the CAN Specification (see ISO11898-1, 6.3.3 recovery management), the FDCAN provides means for automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission. By default automatic retransmission is enabled.

To support time-triggered communication as described in ISO 11898-1: 2015, chapter 9.2, the automatic retransmission may be disabled via FDCAN_CCCR.DAR.

Frame transmission in disabled automatic retransmission (DAR) mode

In DAR mode all transmissions are automatically canceled after they started on the CAN bus. A Tx buffer Tx request pending bit FDCAN_TXBRP.TRPx is reset after successful transmission, when a transmission has not yet been started at the point of cancellation, has been aborted due to lost arbitration, or when an error occurred during frame transmission.

- **Successful transmission:**
  - Corresponding Tx buffer transmission occurred bit FDCAN_TXBTO.TOx set
  - Corresponding Tx buffer cancellation finished bit FDCAN_TXBCF.CFx not set

- **Successful transmission in spite of cancellation:**
  - Corresponding Tx buffer transmission occurred bit FDCAN_TXBTO.TOx set
  - Corresponding Tx buffer cancellation finished bit FDCAN_TXBCF.CFx set

- **Arbitration loss or frame transmission disturbed:**
  - Corresponding Tx buffer transmission occurred bit FDCAN_TXBTO.TOx not set
  - Corresponding Tx buffer cancellation finished bit FDCAN_TXBCF.CFx set

In case of a successful frame transmission, and if storage of Tx events is enabled, a Tx event FIFO element is written with event type ET = 10 (transmission in spite of cancellation).

Power down (Sleep mode)

The FDCAN can be set into power down mode controlled by clock stop request input via register FDCAN_CCCR.CSR. As long as the clock stop request is active, bit FDCAN_CCCR.CSR is read as 1.
When all pending transmission requests have completed, the FDCAN waits until bus idle state is detected. Then the FDCAN sets FDCAN_CCCR.INIT to 1 to prevent any further CAN transfers. Now the FDCAN acknowledges that it is ready for power down by setting FDCAN_CCCR.CSA to 1. In this state, before the clocks are switched off, further register accesses can be made. A write access to FDCAN_CCCR.INIT will have no effect. Now the module clock inputs may be switched off.

To leave power down mode, the application has to turn on the module clocks before resetting CC control register flag FDCAN_CCCR.CSR. The FDCAN will acknowledge this by resetting FDCAN_CCCR.CSA. Afterwards, the application can restart CAN communication by resetting bit FDCAN_CCCR.INIT.

Test modes

To enable write access to FDCAN Test register (see Section 55.4.4 on page 2530), bit FDCAN_CCCR.TEST has to be set to 1, thus enabling the configuration of test modes and functions.

Four output functions are available for the CAN transmit pin FDCAN_TX by programming FDCAN_TEST.TX. Additionally to its default function – the serial data output – it can drive the CAN Sample Point signal to monitor the FDCAN bit timing and it can drive constant dominant or recessive values. The actual value at pin FDCAN_RX can be read from FDCAN_TEST.RX. Both functions can be used to check the CAN bus physical layer.

Due to the synchronization mechanism between CAN kernel clock and APB clock domain, there may be a delay of several APB clock periods between writing to FDCAN_TEST.TX until the new configuration is visible at FDCAN_TX output pin. This applies also when reading FDCAN_RX input pin via FDCAN_TEST.RX.

*Note:* Test modes should be used for production tests or self test only. The software control for FDCAN_TX pin interferes with all CAN protocol functions. It is not recommended to use test modes for application.

External loop back mode

The FDCAN can be set in external loop back mode by programming FDCAN_TEST.LBCK to 1. In loop back mode, the FDCAN treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) into Rx FIFOs. Figure 734 (left side) shows the connection of transmit and receive signals FDCAN_TX and FDCAN_RX to the FDCAN in external loop back mode.

This mode is provided for hardware self-test. To be independent from external stimulation, the FDCAN ignores acknowledge errors (recessive bit sampled in the acknowledge slot of a data/remote frame) in loop back mode. In this mode the FDCAN performs an internal feedback from its transmit output to its receive input. The actual value of the FDCAN_RX input pin is disregarded by the FDCAN. The transmitted messages can be monitored at the FDCAN_TX transmit pin.

Internal loop back mode

Internal loop back mode is entered by programming bits FDCAN_TEST.LBCK and FDCAN_CCCR.MON to 1. This mode can be used for a “Hot Selftest”, meaning the FDCAN can be tested without affecting a running CAN system connected to the FDCAN_TX and FDCAN_RX pins. In this mode, FDCAN_RX pin is disconnected from the FDCAN and FDCAN_TX pin is held recessive. Figure 734 (right side) shows the connection of FDCAN_TX and FDCAN_RX pins to the FDCAN in case of internal loop back mode.
Application watchdog (FDCAN1 only)

The application watchdog is served by reading register FDCAN_TTOST. When the application watchdog is not served in time, bit FDCAN_TTOST.AWE is set, all TTCAN communication is stopped, and the FDCAN1 is set into bus monitoring mode.

The TT application watchdog can be disabled by programming the application watchdog limit FDCAN_TTOCF.AWL to 0x00. The TT application watchdog should not be disabled in a TTCAN application program.

Timestamp generation

For timestamp generation the FDCAN supplies a 16-bit wraparound counter. A prescaler FDCAN_TSCC.TCP can be configured to clock the counter in multiples of CAN bit times (1 … 16). The counter is readable via FDCAN_TSCV.TCV. A write access to register FDCAN_TSCV resets the counter to 0. When the timestamp counter wraps around interrupt flag FDCAN_IR.TSW is set.

On start of frame reception/transmission the counter value is captured and stored into the timestamp section of a Rx buffer/Rx FIFO (RXTS[15:0]) or Tx event FIFO (TXTS[15:0]) element.

By programming bit FDCAN_TSCC.TSS, a 16-bit timestamp can be used.

Timeout counter

To signal timeout conditions for Rx FIFO 0, Rx FIFO 1, and the Tx event FIFO the FDCAN supplies a 16-bit timeout counter. It operates as down-counter and uses the same prescaler controlled by FDCAN_TSCC.TCP as the timestamp counter. The timeout counter is configured via register FDCAN_TOCC. The actual counter value can be read from FDCAN_TOCV.TOC. The timeout counter can only be started while FDCAN_CCCR.INIT = 0. It is stopped when FDCAN_CCCR.INIT = 1, e.g. when the FDCAN enters Bus_Off state.

The operation mode is selected by FDCAN_TOCC.TOS. When operating in Continuous mode, the counter starts when FDCAN_CCCR.INIT is reset. A write to FDCAN_TOCV
presets the counter to the value configured by FDCAN_TOCC.TOP and continues
down-counting.

When the timeout counter is controlled by one of the FIFOs, an empty FIFO presets the
counter to the value configured by FDCAN_TOCC.TOP. Down-counting is started when the
first FIFO element is stored. Writing to FDCAN_TOCV has no effect.

When the counter reaches 0, interrupt flag FDCAN_IR.TOO is set. In Continuous mode, the
counter is immediately restarted at FDCAN_TOCC.TOP.

Note: The clock signal for the timeout counter is derived from the CAN core sample point signal.
Therefore the point in time where the timeout counter is decremented may vary due to the
synchronization/re-synchronization mechanism of the CAN core. If the baudrate switch
feature in FDCAN is used, the timeout counter is clocked differently in arbitration and data
fields.

55.3.2 Message RAM

The message RAM has a width of 32 bits. The FDCAN module can be configured to allocate
up to 2560 words in the message RAM. It is not necessary to configure each of the sections
listed in Figure 735, nor is there any restriction with respect to the sequence of the sections.

Figure 735. Message RAM configuration

When the FDCAN addresses the message RAM it addresses 32-bit words, not single bytes.
The configured start addresses are 32-bit word addresses, i.e. only bits 15 to 2 are
evaluated, the two least significant bits are ignored.

Note: The FDCAN does not check for erroneous configuration of the message RAM. Especially
the configuration of the start addresses of the different sections and the number of elements
of each section has to be done carefully to avoid falsification or loss of data.
Rx handling

The Rx handler controls the acceptance filtering, the transfer of received messages to Rx buffers or to 1 of the two Rx FIFOs, as well as the Rx FIFO put and get Indices.

Acceptance filter

The FDCAN offers the possibility to configure two sets of acceptance filters, one for standard identifiers and one for extended identifiers. These filters can be assigned to Rx buffer, Rx FIFO 0 or Rx FIFO 1. For acceptance filtering each list of filters is executed from element #0 until the first matching element. Acceptance filtering stops at the first matching element. The following filter elements are not evaluated for this message.

The main features are:

- Each filter element can be configured as
  - range filter (from 0 to 128 elements for the 11-bit filter and from 0 to -1 for the 29-bit filter)
  - filter for one or two dedicated IDs
  - classic bit mask filter
- Each filter element is configurable for acceptance or rejection filtering
- Each filter element can be enabled/disabled individually
- Filters are checked sequentially, execution stops with the first matching filter element

Related configuration registers are:

- Global filter configuration (FDCAN_GFC)
- Standard ID filter configuration (FDCAN_SIDFC)
- Extended ID filter configuration (FDCAN_XIDFC)
- Extended ID AND Mask (FDCAN_XIDAM)

Depending on the configuration of the filter element (SFEC / EFEC) a match triggers one of the following actions:

- Store received frame in FIFO 0 or FIFO 1
- Store received frame in Rx buffer
- Store received frame in Rx buffer and generate pulse at filter event pin
- Reject received frame
- Set high priority message interrupt flag FDCAN_IR.HPM
- Set high priority message interrupt flag FDCAN_IR.HPM and store received frame in FIFO 0 or FIFO 1
- Set high priority message interrupt flag FDCAN_IR.HPM and store received frame in FIFO 0 or FIFO 1

Acceptance filtering is started after the complete identifier has been received. After acceptance filtering has completed, and if a matching Rx buffer or Rx FIFO has been found, the message handler starts writing the received message data in portions of 32 bit to the
matching Rx buffer or Rx FIFO. If the CAN protocol controller has detected an error condition (e.g. CRC error), this message is discarded with the following impact:

- **Rx buffer**
  New data flag of matching Rx buffer is not set, but Rx buffer (partly) overwritten with received data. For error type see FDCAN_PSR.LEC and FDCAN_PSR.DLEC.

- **Rx FIFO**
  Put index of matching Rx FIFO is not updated, but related Rx FIFO element (partly) overwritten with received data. For error type see FDCAN_PSR.LEC and FDCAN_PSR.DLEC. In case the matching Rx FIFO is operated in overwrite mode, the boundary conditions described in *Rx FIFO overwrite mode* have to be considered.

**Note:** When an accepted message is written to one of the two Rx FIFOs, or into an Rx buffer, the unmodified received identifier is stored independent of the filter(s) used. The result of the acceptance filter process is strongly depending on the sequence of configured filter elements.

**Range filter**

The filter matches for all received frames with message IDs in the range defined by SF1ID / SF2ID and EF1ID / EF2ID.

There are two possibilities when range filtering is used together with extended frames:

- **EFT = 00:** The message ID of received frames is AND-ed with the extended ID AND Mask (FDCAN_XIDAM) before the range filter is applied
- **EFT = 11:** The extended ID AND Mask (FDCAN_XIDAM) is not used for range filtering

**Filter for dedicated IDs**

A filter element can be configured to filter for one or two specific message IDs. To filter for one specific message ID, the filter element has to be configured with SF1ID = SF2ID and EF1ID = EF2ID.

**Classic bit mask filter**

Classic bit mask filtering is intended to filter groups of message IDs by masking single bits of a received message ID. With classic bit mask filtering SF1ID / EF1ID is used as message ID filter, while SF2ID / EF2ID is used as filter mask.

A 0 bit at the filter mask will mask out the corresponding bit position of the configured ID filter, e.g. the value of the received message ID at that bit position is not relevant for acceptance filtering. Only those bits of the received message ID where the corresponding mask bits are one are relevant for acceptance filtering.

In case all mask bits are one, a match occurs only when the received message ID and the message ID filter are identical. If all mask bits are 0, all message IDs match.
Standard message ID filtering

*Figure 736* shows the flow for standard message ID (11-bit Identifier) filtering. The standard message ID filter element is described in *Section 55.3.21.*

**Figure 736. Standard message ID filter path**

Controlled by the global filter configuration (FDCAN_GFC) and the standard ID filter configuration (FDCAN_SIDFC) message ID, remote transmission request bit (RTR), and the Identifier Extension bit (IDE) of received frames are compared against the list of configured filter elements.

Extended message ID filtering

*Figure 737* shows the flow for extended message ID (29-bit Identifier) filtering. The extended message ID filter element is described in *Section 55.3.22.*
Controller area network with flexible data rate (FDCAN)

Controlled by the global filter configuration FDCAN_GFC and the extended ID filter configuration FDCAN_XIDFC message ID, remote transmission request bit (RTR), and the Identifier Extension bit (IDE) of received frames are compared against the list of configured filter elements.

The extended ID AND Mask (FDCAN_XIDAM) is AND-ed with the received identifier before the filter list is executed.

Rx FIFOs

Rx FIFO 0 and Rx FIFO 1 can be configured to hold up to 64 elements each. Configuration of the two Rx FIFOs is done via registers FDCAN_RXF0C and FDCAN_RXF1C.
Received messages that passed acceptance filtering are transferred to the Rx FIFO as configured by the matching filter element. For a description of the filter mechanisms available for Rx FIFO 0 and Rx FIFO 1, see Acceptance filter. The Rx buffer and FIFO element is described in Section 55.3.18.

When an Rx FIFO full condition is signaled by FDCAN_IR.RFnF, no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO get index has been incremented. In case a message is received while the corresponding Rx FIFO is full, this message is discarded and interrupt flag FDCAN_IR.RFnL is set.

To avoid an Rx FIFO overflow, the Rx FIFO watermark can be used. When the Rx FIFO fill level reaches the Rx FIFO watermark configured by FDCAN_RXFnC.FnWM, interrupt flag FDCAN_IR.RFnW is set.

When reading from an Rx FIFO, Rx FIFO get index RXFnS[FnGI] + FIFO element size has to be added to the corresponding Rx FIFO start address RXFnC[FnSA].

**Rx FIFO blocking mode**

The Rx FIFO blocking mode is configured by RXFnC.FnOM = 0. This is the default operation mode for the Rx FIFOs.

When an Rx FIFO full condition is reached (RXFnS.FnPI = RXFnS.FnGI), no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO get index has been incremented. An Rx FIFO full condition is signaled by RXFnS.FnF = 1. In addition interrupt flag FDCAN_IR.RFnF is set.

In case a message is received while the corresponding Rx FIFO is full, this message is discarded and the message lost condition is signaled by RXFnS.RFnL = 1. In addition interrupt flag FDCAN_IR.RFnL is set.

**Rx FIFO overwrite mode**

The Rx FIFO overwrite mode is configured by RXFnC.FnOM = 1.

When an Rx FIFO full condition (RXFnS.FnPI = RXFnS.FnGI) is signaled by RXFnS.FnF = 1, the next message accepted for the FIFO will overwrite the oldest FIFO message. Put and get index are both incremented by one.

When an Rx FIFO is operated in overwrite mode and an Rx FIFO full condition is signaled, reading of the Rx FIFO elements should start at least at get index + 1. The reason for that is that it can happen that a received message is written to the message RAM (put index) while the CPU is reading from the message RAM (get index). In this case inconsistent data may be read from the respective Rx FIFO element. Adding an offset to the get index when reading from the Rx FIFO avoids this problem. The offset depends on how fast the CPU accesses the Rx FIFO. Figure 739 shows an offset of two with respect to the get index when reading the Rx FIFO. In this case the two messages stored in elements 1 and 2 are lost.

After reading from the Rx FIFO, the number of the last element read has to be written to the Rx FIFO acknowledge index RXFnA.FnA. This increments the get index to that element number. In case the put index has not been incremented to this Rx FIFO element, the Rx FIFO full condition is reset (RXFnS.FnF = 0).

**Dedicated Rx buffers**

The FDCAN supports up to 64 dedicated Rx buffers. The start address of the dedicated Rx buffer section is configured via FDCAN_RXBC.RBSA.
For each Rx buffer a standard or extended message ID filter element with SFEC / EFEC=111 and SFID2 / EFID2[10:9] = 00 has to be configured (see Section 55.3.21 and Section 55.3.22).

After a received message has been accepted by a filter element, the message is stored into the Rx buffer in the message RAM referenced by the filter element. The format is the same as for an Rx FIFO element. In addition the flag FDCAN_IR.DRX (message stored in dedicated Rx buffer) in the interrupt register is set.

After the last word of a matching received message has been written to the message RAM, the respective New data flag in register NDAT1,2 is set. As long as the New data flag is set, the respective Rx buffer is locked against updates from received matching frames. The New data flags have to be reset by the Host by writing a 1 to the respective bit position.

While an Rx buffer New data flag is set, a message ID filter element referencing this specific Rx buffer will not match, causing the acceptance filtering to continue. The following message ID filter elements may cause the received message to be stored into another Rx buffer, or into an Rx FIFO, or the message may be rejected, depending on filter configuration.

**Rx buffer handling**

- Reset interrupt flag FDCAN_IR.DRX
- Read New data registers
- Read messages from message RAM
- Reset New data flags of processed messages

**Filtering for Debug messages**

Filtering for debug messages is done by configuring one standard/extended message ID filter element for each of the three debug messages. To enable a filter element to filter for debug messages SFEC/EFEC has to be programmed to 111. In this case fields SFID1 / SFID2 and EFID1 / EFID2 have a different meaning. While SFID2 / EFID2[10:9] controls the debug message handling state machine, SFID2 / EFID2[5:0] controls the location for storage of a received debug message.

When a debug message is stored, neither the respective New data flag nor FDCAN_IR.DRX are set. The reception of debug messages can be monitored via FDCAN_RXF1S.DMS.
### Tx handling

The Tx handler handles transmission requests for the dedicated Tx buffers, the Tx FIFO, and the Tx queue. It controls the transfer of transmit messages to the CAN core, the put and get Indices, and the Tx event FIFO. Up to 32 Tx buffers can be set up for message transmission (see Dedicated Tx buffers). Depending on the configuration of the element size (FDCAN_RXESC), between two and sixteen 32-bit words \((Rn = 3 \ldots 17)\) are used for storage of a CAN message data field.

Note: AUTOSAR requires at least three Tx queue buffers and support of transmit cancellation.

The Tx handler starts a Tx scan to check for the highest priority pending Tx request (Tx buffer with lowest message ID) when the Tx buffer request pending register FDCAN_TXBRP is updated, or when a transmission has been started.

### Transmit pause

This feature is intended for use in CAN systems where the CAN message identifiers are (permanently) specified to specific values and cannot easily be changed. These message identifiers may have a higher CAN arbitration priority than other defined messages, while in a specific application their relative arbitration priority should be inverse. This may lead to a case where one ECU sends a burst of CAN messages that cause another ECU CAN messages to be delayed because that other messages have a lower CAN arbitration priority.

If, as an example, CAN ECU-1 has the feature enabled and is requested by its application software to transmit four messages, it will, after the first successful message transmission, wait for two CAN bit times of bus idle before it is allowed to start the next requested message. If there are other ECUs with pending messages, those messages are started in the idle time, they would not need to arbitrate with the next message of ECU-1. After having

Note: AUTOSAR requires at least three Tx queue buffers and support of transmit cancellation.
received a message, ECU-1 is allowed to start its next transmission as soon as the received message releases the CAN bus.

The feature is controlled by TXP bit in FDCAN_CCCR register. If the bit is set, the FDCAN will, each time it has successfully transmitted a message, pause for two CAN bit times before starting the next transmission. This enables other CAN nodes in the network to transmit messages even if their messages have lower prior identifiers. Default is disabled (FDCAN_CCCR.TXP = 0).

This feature looses up burst transmissions coming from a single node and it protects against "babbling idiot" scenarios where the application program erroneously requests too many transmissions.

**Dedicated Tx buffers**

Dedicated Tx buffers are intended for message transmission under complete control of the CPU. Each dedicated Tx buffer is configured with a specific message ID. In case that multiple Tx buffers are configured with the same message ID, the Tx buffer with the lowest buffer number is transmitted first.

If the data section has been updated, a transmission is requested by an add request via FDCAN_TXBAR.ARn. The requested messages arbitrate internally with messages from an optional Tx FIFO or Tx queue and externally with messages on the CAN bus, and are sent out according to their message ID.

A dedicated Tx buffer allocates four 32-bit words in the message RAM. Therefore the start address of a dedicated Tx buffer in the message RAM is calculated by adding four times the transmit buffer index (0 … 31) to the Tx buffer start address FDCAN_TXBC.TBSA.

**Tx FIFO**

Tx FIFO operation is configured by programming FDCAN_TXBC.TFQM to 0. Messages stored in the Tx FIFO are transmitted starting with the message referenced by the get index FDCAN_TXFQS.TFGI. After each transmission the get index is incremented cyclically until the Tx FIFO is empty. The Tx FIFO enables transmission of messages with the same message ID from different Tx buffers in the order these messages have been written to the Tx FIFO. The FDCAN calculates the Tx FIFO free level FDCAN_TXFQS.TFFL as difference between get and put index. It indicates the number of available (free) Tx FIFO elements.
New transmit messages have to be written to the Tx FIFO starting with the Tx buffer referenced by the put index FDCAN_TXFQS.TFQPI. An add request increments the put index to the next free Tx FIFO element. When the put index reaches the get index, Tx FIFO Full (FDCAN_TXFQS.TFQF = 1) is signaled. In this case no further messages should be written to the Tx FIFO until the next message has been transmitted and the get index has been incremented.

When a single message is added to the Tx FIFO, the transmission is requested by writing a 1 to the FDCAN_TXBAR bit related to the Tx buffer referenced by the Tx FIFO put index.

When multiple (n) messages are added to the Tx FIFO, they are written to n consecutive Tx buffers starting with the put index. The transmissions are then requested via FDCAN_TXBAR. The put index is then cyclically incremented by n. The number of requested Tx buffers should not exceed the number of free Tx buffers as indicated by the Tx FIFO free level.

When a transmission request for the Tx buffer referenced by the get index is canceled, the get index is incremented to the next Tx buffer with pending transmission request and the Tx FIFO free level is recalculated. When transmission cancellation is applied to any other Tx buffer, the get index and the FIFO free level remain unchanged.

A Tx FIFO element allocates four 32-bit words in the message RAM. Therefore the start address of the next available (free) Tx FIFO buffer is calculated by adding four times the put index FDCAN_TXFQS.TFQPI (0 … 31) to the Tx buffer start address FDCAN_TXBC.TBSA.

**Tx queue**

Tx queue operation is configured by programming FDCAN_TXBC.TFQM to 1. Messages stored in the Tx queue are transmitted starting with the message with the lowest message ID (highest priority). In case that multiple queue buffers are configured with the same message ID, the queue buffer with the lowest buffer number is transmitted first.

New messages have to be written to the Tx buffer referenced by the put index FDCAN_TXFQS.TFQPI. An add request cyclically increments the put index to the next free Tx buffer. In case that the Tx queue is full (FDCAN_TXFQS.TFQF = 1), the put index is not valid and no further message should be written to the Tx queue until at least one of the requested messages has been sent out or a pending transmission request has been canceled.

The application may use register FDCAN_TXBRP instead of the put index and may place messages to any Tx buffer without pending transmission request.

A Tx queue buffer allocates four 32-bit words in the message RAM. Therefore the start address of the next available (free) Tx queue buffer is calculated by adding four times the Tx queue put index FDCAN_TXFQS.TFQPI (0 … 31) to the Tx buffer start address FDCAN_TXBC.TBSA.

**Mixed dedicated Tx buffers / Tx FIFO**

In this case the Tx buffers section in the message RAM is subdivided into a set of dedicated Tx buffers and a Tx FIFO. The number of dedicated Tx buffers is configured by FDCAN_TXBC.NDTB. The number of Tx buffers assigned to the Tx FIFO is configured by FDCAN_TXBC.TFQS. In case, FDCAN_TXBC.TFQS is programmed to 0, only dedicated Tx buffers are used.

Tx priority setting:
- Scan all Tx buffers with activated transmission request
- Tx buffer with lowest message ID gets highest priority and is transmitted next
Transmit cancellation

The FDCAN supports transmit cancellation. To cancel a requested transmission from a
dedicated Tx buffer or a Tx queue buffer the Host has to write a 1 to the corresponding bit
position (= number of Tx buffer) of register FDCAN_TXBCR. Transmit cancellation is not
intended for Tx FIFO operation.

Successful cancellation is signaled by setting the corresponding bit of register
FDCAN_TXBCF to 1.

In case a transmit cancellation is requested while a transmission from a Tx buffer is already
ongoing, the corresponding FDCAN_TXBRP bit remains set as long as the transmission is
in progress. If the transmission was successful, the corresponding FDCAN_TXBTO and
FDCAN_TXBCF bits are set. If the transmission was not successful, it is not repeated and
only the corresponding FDCAN_TXBCF bit is set.

Note: In case a pending transmission is canceled immediately before this transmission could have
been started, there follows a short time window where no transmission is started even if
another message is pending in this node. This may enable another node to transmit a
message that may have a priority lower than that of the second message in this node.

Tx event handling

To support Tx event handling the FDCAN has implemented a Tx event FIFO. After the
FDCAN has transmitted a message on the CAN bus, message ID and timestamp are stored
in a Tx event FIFO element. To link a Tx event to a Tx event FIFO element, the message
marker from the transmitted Tx buffer is copied into the Tx event FIFO element.

The Tx event FIFO can be configured to a maximum of 32 elements. The Tx event FIFO
element is described in \textit{Tx FIFO}. Depending on the configuration of the element size
(FDCAN_TXESC), between two and sixteen 32-bit words (Tn = 3 ..17) are used for storage
of a CAN message data field.

The purpose of the Tx event FIFO is to decouple handling transmit status information from
transmit message handling i.e. a Tx buffer holds only the message to be transmitted, while
the transmit status is stored separately in the Tx event FIFO. This has the advantage,
especially when operating a dynamically managed transmit queue, that a Tx buffer can be
used for a new message immediately after successful transmission. There is no need to
save transmit status information from a Tx buffer before overwriting that Tx buffer.

When a Tx event FIFO full condition is signaled by FDCAN\_IR.TEFF, no further elements
are written to the Tx event FIFO until at least one element has been read out and the Tx
event FIFO get index has been incremented. In case a Tx event occurs while the Tx event
FIFO is full, this event is discarded and interrupt flag FDCAN\_IR.TEFL is set.

To avoid a Tx event FIFO overflow, the Tx event FIFO watermark can be used. When the Tx
event FIFO fill level reaches the Tx event FIFO watermark configured by
FDCAN\_TXEFC.EFWM, interrupt flag FDCAN\_IR.TEFW is set.

When reading from the Tx event FIFO, two times the Tx event FIFO get index
FDCAN\_TXEFS.EFGI has to be added to the Tx event FIFO start address
FDCAN\_TXEFC.EFSA.

55.3.3 FIFO acknowledge handling

The get indices of Rx FIFO 0, Rx FIFO 1, and the Tx event FIFO are controlled by writing to
the corresponding FIFO acknowledge index, see \textit{FDCAN Rx FIFO 0 acknowledge register}
Writing to the FIFO acknowledge index will set the FIFO get index to the FIFO acknowledge index plus one and thereby updates the FIFO fill level. There are two use cases:

1. When only a single element has been read from the FIFO (the one being pointed to by the get index), this get index value is written to the FIFO acknowledge index.
2. When a sequence of elements has been read from the FIFO, it is sufficient to write the FIFO acknowledge index only once at the end of that read sequence (value: index of the last element read), to update the FIFO get index.

Due to the fact that the CPU has free access to the FDCAN message RAM, special care has to be taken when reading FIFO elements in an arbitrary order (get index not considered). This might be useful when reading a high priority message from one of the two Rx FIFOs. In this case the FIFO acknowledge index should not be written because this would set the get index to a wrong position and also alters the FIFO fill level. In this case some of the older FIFO elements would be lost.

Note: The application has to ensure that a valid value is written to the FIFO acknowledge index. The FDCAN does not check for erroneous values.

### 55.3.4 Bit timing

The bit timing logic monitors the serial bus-line and performs sampling and adjustment of the sample point by synchronizing on the start-bit edge and resynchronizing on the following edges.

As shown in Figure 740, its operation may be explained simply by splitting the bit time in three segments, as follows:

- **Synchronization segment (SYNC_SEG):** a bit change is expected to occur within this time segment, that has a fixed length of one time quantum (1 x tq).
- **Bit segment 1 (BS1):** defines the location of the sample point. It includes the PROP_SEG and PHASE_SEG1 of the CAN standard, its duration is programmable between 1 and 16 time quanta, but may be automatically lengthened to compensate for positive phase drifts due to differences in the frequency of the various nodes of the network.
- **Bit segment 2 (BS2):** defines the location of the transmit point. It represents the PHASE_SEG2 of the CAN standard, its duration is programmable between one and eight time quanta, but may also be automatically shortened to compensate for negative phase drifts.

**Figure 740. Bit timing**
The baudrate is the inverse of bit time (baudrate = 1 / bit time), which, in turn, is the sum of three components. Figure 740 indicates that bit time = t_{SyncSeg} + t_{BS1} + t_{BS2}, where:

- for the nominal bit time
  - \( t_q = (FDCAN\_NBTP.NBRP[8:0] + 1) * t_{fdcan\_tq\_ck} \)
  - \( t_{SyncSeg} = 1 * t_q \)
  - \( t_{BS1} = t_q * (FDCAN\_NBTP.\_NTSEG1[7:0] + 1) \)
  - \( t_{BS2} = t_q * (FDCAN\_NBTP.\_NTSEG2[6:0] + 1) \)

- for the data bit time
  - \( t_q = (FDCAN\_DBTP.DBRP[4:0] + 1) * t_{fdcan\_tq\_ck} \)
  - \( t_{SyncSeg} = 1 * t_q \)
  - \( t_{BS1} = t_q * (FDCAN\_DBTP.\_DTSEG1[4:0] + 1) \)
  - \( t_{BS2} = t_q * (FDCAN\_DBTP.\_DTSEG2[3:0] + 1) \)

The (re)synchronization jump width (SJW) defines an upper bound for the amount of lengthening or shortening of the bit segments. It is programmable between one and four time quanta.

A valid edge is defined as the first transition in a bit time from dominant to recessive bus level, provided the controller itself does not send a recessive bit.

If a valid edge is detected in BS1 instead of SYNC_SEG, BS1 is extended by up to SJW so that the sample point is delayed.

Conversely, if a valid edge is detected in BS2 instead of SYNC_SEG, BS2 is shortened by up to SJW so that the transmit point is moved earlier.

As a safeguard against programming errors, the configuration of the bit timing register is only possible while the device is in Standby mode. Registers FDCAN\_DBTP and FDCAN\_NBTP (dedicated, respectively, to data and nominal bit timing) are only accessible when FDCAN\_CCCR.CCE and FDCAN\_CCCR.INIT are set.

*Note:* For a detailed description of the CAN bit timing and resynchronization mechanism, refer to the ISO 11898-1 standard.

### 55.3.5 Clock calibration on CAN

After device reset the clock calibration unit (CCU) does not provide a valid clock signal to the FDCAN1 and FDCAN2. The CCU has to be initialized via FDCAN\_CCFG register. The FDCAN\_CCFG register can be written only when FDCAN1 has both FDCAN\_CCCR.CCE and FDCAN\_CCCR.INIT bits set. In consequence the CCU and the FDCAN1 initialization needs to be completed before any FDCAN1 and/or FDCAN2 module can operate.

Clock calibration is bypassed when FDCAN\_CCFG.BCC = 1 (see Figure 741).
Operating conditions

The clock calibration on CAN unit is designed to operate under the following conditions:

- a CAN kernel clock frequency \( \text{fdcan\_ker\_ck} \) up to 80 MHz
- FDCAN bitrates:
  - Nominal bitrate: up to 1 Mbit/s
  - Data bitrate: between nominal bitrate and 8 Mbit/s

The clock calibration on FDCAN unit generates a calibrated time quanta clock \( \text{fdcan\_tq\_ck} \) in the range from 0.5 to 25 MHz.

Note: The FDCAN requires that the CAN time quanta clock is always below or equal to the APB clock (\( \text{fdcan\_tq\_ck} < \text{fdcan\_pclk} \)). This has to be considered when the clock calibration on CAN unit is bypassed (\( \text{FDCAN\_CCFG.BCC} = 1 \)).

Calibration accuracy

The calibration accuracy in state Precision_Calibrated depends upon the factors listed below.

- Dynamic clock tolerance at the CAN kernel clock input \( \text{fdcan\_ker\_ck} \)
- Measurement error. For each bit sequence used for calibration measurement, there is a maximum error of one \( \text{fdcan\_pclk} \) period. The number of bits used for measurement of the bit time is 32 or 64-bit, depending on configuration of \( \text{FDCAN\_CCFG.CFL} \).
- Tolerable error in calibration mechanism

The distance between two calibration messages has to be chosen to fit the clock tolerance requirements of the FDCAN1 module.

Note: Dynamic clock tolerance is the clock frequency variation between two calibration messages e.g. caused by change of temperature or operating voltage.

Functional description

Calibration of the time quanta clock \( \text{fdcan\_tq\_ck} \) via CAN messages is performed by adapting a clock divider that generates the CAN protocol time quantum \( tq \) from the clock \( \text{fdcan\_ker\_ck} \).

1. First step: basic calibration
   The minimum distance between two consecutive falling edges from recessive to dominant is measured, this time to be assumed two CAN bit times, counted in PLL clock periods. The clock divider (\( \text{FDCAN\_CCFG.CDIV} \)) is updated each time a new
measurement finds a smaller distance between edges. Basic calibration is achieved when the CAN protocol controller detects a valid CAN message.

2. Second step: Precision calibration

The calibration state machine measures the length of a longer bit sequence inside a CAN frame by counting the number of fdcan_ker_clk periods. The length of this bit sequence can be configured to 32 or 64 bits via FDCAN_CCFG.CLF. For a calibration field length of 32/64 bit a calibration message with at least 2/6 byte data field is required. Precision calibration is based on the new clock divider value calculated from the measurement of the longer bit sequence.

![Figure 742. FSM calibration](image)

A change in the calibration state sets interrupt flag FDCAN_CCU_IR.CSC, if enabled by the interrupt enable FDCAN_CCU_IE.CSCE. It remains set until cleared by writing 1 in FDCAN_CCU_IR.CSC.

Until precision calibration is achieved, FDCAN1 and FDCAN2 operate in a restricted mode (no frame transmission, no error or overload flag transmission, no error counting). In case calibration of the fdcan_ker_clk is done by software by evaluating the calibration status from register CCU_CSTAT, FDCAN1 and FDCAN2 have to be set to restricted operation mode (FDCAN_CCCR.ASM = 1) until the calibration on CAN unit is in state Precision_Calibrated (see Application).

Precision calibration may be performed only on valid CAN frames transmitted by a node with a stable, quartz-controlled clock. Calibration frames are detected by the FDCAN1 acceptance filtering A filter element and a Rx buffer have to be configured in the FDCAN1 to identify and store calibration messages. After reception of a calibration message the Rx buffer new data flag has to be reset to enable signaling of the next calibration message.
In case there is only one CAN transmitter with a quartz clock in the network, this node has to transmit its first message after startup with at least one 1010 binary sequence in the data field or in the identifier. This assures that the non-quartz nodes can enter state Basic_Calibrated and then acknowledge the quartz node messages.

Precision calibration must be repeated in predefined maximum intervals supervised by the calibration watchdog.

**Note:** When the clock calibration on CAN unit transits from state Precision_Calibrated back to Basic_Calibrated, the calibration OK signal is deasserted, the FDCAN1 complete ongoing transmissions, and then enter restricted operation (no frame transmission, no error or overload flag transmission, no error counting).

**Configuration**

The clock calibration on CAN unit is configured via register FDCAN_CCFG, i.e. when FDCAN1 has FDCAN_CCCR.CCE and FDCAN_CCCR.INIT bits set.

For basic calibration the minimum number of oscillator periods between two consecutive falling edges at pin FDCAN1_RX is measured. The number of clock periods depends on the clock frequency applied at input fdcan_ker_ck. In case the measured number of clock periods is below the minimum configured by FDCAN_CCFG.OCPM (as an example, because of a glitch on FDCAN1_RX) the value is discarded and measurement continues.

It is recommended to configure FDCAN_CCFG.OCPM slightly below two CAN bit times:

\[
\text{FDCAN_CCFG.OCPM} < \left( \frac{(2 \times \text{CAN bit time})}{\text{fdcan_ker_ck period}} \right) / 32
\]

The length of the bit field used for precision calibration can be configured to 32 or 64 bits via FDCAN_CCFG.CFL. The number of bits used for precision calibration has an impact on calibration accuracy and the maximum distance between two calibration messages.

The number of time quanta per bit time configured by FDCAN_CCFG.TQBT is used together with the measured number of oscillator clock periods FDCAN_CCU_CSTAT.OCPC to define the number of oscillator clocks per bit time.

When the clock calibration is bypassed by configuring FDCAN_CCFG.BCC = 1, the internal clock divider has to be configured via FDCAN_CCFG.CDIV to fulfill the condition fdcan_tq_ck < fdcan_pclk.

**Note:** When clock calibration on CAN is active (FDCAN_CCFG.BCC = 0), the baudrate prescalers of FDCAN1 and FDCAN2 have to be configured to inactive.

**Status signaling**

The status of the clock calibration on CAN unit can be monitored by reading register FDCAN_CCU_CSTAT. When in state Precision_Calibrated the oscillator clock period counter FDCAN_CCU_CSTAT.OCPC signals the number of oscillator clock periods in the calibration field while FDCAN_CCU_CSTAT.TQC signals the number of time quanta in the calibration field.

The calibration state is monitored by FDCAN_CCU_CSTAT.CALS. A change in the calibration state sets interrupt flag FDCAN_CCU_IR.CSC, if enabled by the interrupt enable FDCAN_CCU_IE.CSCE. It remains set until cleared by writing 1 in CCU_IR.CSC.

A calibration watchdog event also sets interrupt flag FDCAN_CCU_IR.CWE. If enabled by FDCAN_CCU_IE.CWEE, interrupt line cu_int is activated (set to high). Interrupt line cu_int remains active until interrupt flag FDCAN_CCU_IR.CWE is reset.
55.3.6 Application

Clock calibration bypassed

The CCU internal clock divider is configured for division by one (FDCAN_CCFG.CDIV = 0x0000). In this operation mode the input clock fdcan_ker_ck is directly routed to the clock output fdcan_tq_ck. In this case fdcan_tq_ck is independent from the configuration and status of FDCAN1 and FDCAN2 connected to the CCU. With a fdcan_ker_ck of 20 / 40 / 80 MHz CAN FD operation is possible.

Software calibration

The clock calibration on CAN unit also supports software calibration of fdcan_ker_ck by trimming of an on-chip oscillator. For calculation of the trimming values the Host has to read the CCU state from CCU_CSTAT. In this operation mode the CCU output signal cu_cok is fixed to 1, the clock from fdcan_ker_ck is routed to output fdcan_tq_ck (FDCAN_CCFG.BCC = 1).

The input clock fdcan_ker_ck must be in the range between 80MHz and 100 MHz. The clock divider of CCU has to be configured via FDCAN_CCFG.CDIV to bring fdcan_tq_ck to a valid range. All other configuration parameters have to be set via FDCAN_CCFG. For correct operation of FDCAN1 and FDCAN2, the APB clock fdcan_pclk needs to be equal or higher than the time quanta clock (fdcan_tq_ck). CAN FD operation is not possible.

For startup FDCAN1 and FDCAN2 have to be both configured for restricted operation (FDCAN_CCCR.ASM = 1) before FDCAN_CCCR.INIT is reset. The input clock fdcan_ker_ck has to be adjusted until the clock calibration on CAN unit has reached state Precision_Calibrated. Now the software can reset FDCAN_CCCR.ASM and the CANFD1 and CANFD2 can start normal operation.

During operation the software has to check regularly whether the clock calibration on CAN unit is still in state Precision_Calibrated. In case the clock calibration on CAN unit has left state Precision_Calibrated due to drift of fdcan_ker_ck, FDCAN1 and FDCAN2 have to be set into restricted operation mode by programming FDCAN_CCCR.INIT, FDCAN_CCCR.CCE, and FDCAN_CCCR.ASM to 1. After fdcan_ker_ck has been adjusted successfully (clock calibration on CAN unit is in state Precision_Calibrated), FDCAN1 and FDCAN2 can resume normal operation.

Note: Trimming accuracy must be to sufficient to meet the CAN clock tolerance requirements for the configured bitrate.

Clock calibration active

This operation mode is entered by resetting FDCAN_CCFG.BCC to 0. In this operation mode the CCU output signals cu_cok and fdcan_ker_ck are controlled by the CCU. When the CCU is not in state Precision_Calibrated cu_cok is 0.

Generation of CCU output signals fdcan_tq_ck and cu_cok depends on the state of the FDCAN1. Input clock fdcan_ker_ck must be in the range between 80 and 100 MHz. Configuration of the CCU and FDCAN1 is required. CAN FD operation is not possible.

In case FDCAN1 turns to Bus_Off or when its INIT bit is set by Host command (FDCAN_CCCR.INIT = 1), the CCU enters state Not_Calibrated and output cu_cok is reset to 0. CANFD1 and CANFD2 enter restricted operation mode.

Note: This is the default operation mode after reset in case the reset value of FDCAN_CCFG.BCC is configured to 0.
55.3.7 TTCAN operations (FDCAN1 only)

Reference message

A reference message is a data frame characterized by a specific CAN identifier. It is received and accepted by all nodes except the time master (sender of the reference message).

For level 1 the data length must be at least one; for level 0, 2 the data length must be at least four; otherwise, the message is not accepted as reference message. The reference message may be extended by other data up to the sum of eight CAN data bytes. All bits of the identifier except the three LSBs characterize the message as a reference message. The last three bits specify the priorities of up to eight potential time masters. Reserved bits are transmitted as logical 0 and are ignored by the receivers. The reference message is configured via register FDCAN_TTRMC.

The time master transmits the reference message. If the reference message is disturbed by an error, it is retransmitted immediately. In case of a retransmission, the transmitted Master_Ref_Mark is updated. The reference message is sent periodically, but is allowed to stop the periodic transmission (Next_is_Gap bit) and to initiate transmission event-synchronized at the start of the next basic cycle by the current time master or by one of the other potential time masters.

The node transmitting the reference message is the current time master. The time master is allowed to transmit other messages. If the current time master fails, its function is replicated by the potential time master with the highest priority. Nodes that are neither time master nor potential time master are time-receiving nodes.

Level 1

Level 1 operation is configured via FDCAN_TTOCF.OM = 01 and FDCAN_TTOCF.GEN. External clock synchronization is not available in level 1. The information related to the reference message is stored in the first data byte as shown in Table 470. Cycle_Count is optional.

Level 2

Level 2 operation is configured via FDCAN_TTOCF.OM = 10 and FDCAN_TTOCF.GEN. The information related to the reference message is stored in the first four data bytes as shown in Table 471. Cycle_Count and the lower four bits of FDCAN_NTU_Res are optional. The TTCAN does not evaluate NTU_Res[3:0] from received reference messages, it always transmits these bits as 0.
Level 0

Level 0 operation is configured via FDCAN_TTOCF.OM = 11. External event-synchronized time-triggered operation is not available in level 0. The information related to the reference message is stored in the first four data bytes as shown in the table below. In level 0 Next_is_Gap is always 0. Cycle_Count and the lower four bits of NTU_Res are optional. The TTCAN does not evaluate NTU_Res[3:0] from received reference messages, it always transmits these bits as 0.

55.3.8 TTCAN configuration

TTCAN timing

The network time unit (NTU) is the unit in which all times are measured. The NTU is a constant of the whole network and is defined as a priority by the network system designer. In TTCAN level 1 the NTU is the nominal CAN bit time. In TTCAN level 0 and level 2 the NTU is a fraction of the physical second.

The NTU is the time base for the local time. The integer part of the local time (16-bit value) is incremented once each NTU. Cycle time and global time are both derived from local time. The fractional part (3-bit value) of local time, cycle time, and global time is not readable.

In TTCAN level 0 and level 2 the length of the NTU is defined by the time unit Ratio TUR. The TUR is in general a non-integer number, given by 

\[
TUR = \frac{FDCAN\_TURN.ANV}{FDCAN\_TURCF.DC}
\]

The NTU length is given by

\[
NTU = CAN\_clock\_period \times TUR
\]
The TUR numerator configuration NC is an 18-bit number, FDCAN_TURCF[NCL[15:0]] can be programmed in the range 0x0000–0xFFFF. FDCAN_TURCF[NCL[15:0]] is hard wired to 0b01. When 0xnnnn is written to FDCAN_TURCF[NCL[15:0]], FDCAN_TURNA.NAV starts with the value 0x10000 + 0x0nnnn = 0x1nnnn. The TUR denominator configuration FDCAN_TURCF.DC is a 14-bit number. FDCAN_TURCF.DC may be programmed in the range 0x0001 - 0x3FFF (0x0000 is an illegal value).

In level 1, NC must be equal or higher than 4 x FDCAN_TURCF.DC. In level 0 and level 2 NC must be equal or higher than 8 x FDCAN_TURCF.DC to get the 3-bit resolution for the internal fractional part of the NTU.

A hardware reset presets FDCAN_TURCF.DC to 0x1000 and FDCAN_TURCF.NCL to 0x10000, resulting in an NTU consisting of sixteen CAN clock periods. Local time and application watchdog are not started before either the FDCAN_CCCR.INIT is reset, or FDCAN_TURCF.ELT is set. FDCAN_TURCF.ELT may not be set before the NTU is configured. Setting FDCAN_TURCF.ELT to 1 also locks the write access to register FDCAN_TURCF.

At startup FDCAN_TURNA.NAV is updated from NC (= FDCAN_TURCF.NCL + 0x10000) when FDCAN_TURCF.ELT is set. In TTCAN level 1 there is no drift compensation. FDCAN_TURNA.NAV does not change during operation, it is always equal to NC.

In TTCAN level 0 and level 2 there are two possibilities for FDCAN_TURNA.NAV to change. When operating as time slave or backup time master, and when FDCAN_TTOCF.ECC is set, FDCAN_TURNA.NAV is updated automatically to the value calculated from the monitored global time speed, as long as the TTCAN is in synchronization state In_Schedule or In_Gap. When it loses synchronization, it returns to NC. When operating as the actual time master, and when FDCAN_TTOCF.EECS is set, the Host may update FDCAN_TURCF.NCL. When the Host sets FDCAN_TTOCN.ECS, FDCAN_TURNA.NAV will be updated from the new value of NC at the next reference message. The status flag FDCAN_TTOST.WECS as is set when FDCAN_TTOCN.ECS is set and is cleared when FDCAN_TURNA.NAV is updated. FDCAN_TURCF.NCL is write locked while FDCAN_TTOST.WECS is set.

In TTCAN level 0 and level 2 the clock calibration process adapts FDCAN_TURNA.NAV in the range of the synchronization deviation limit SDL of NC ± 2(FDCAN_TTOCF.LDSDL + 5). FDCAN_TURCF.NCL should be programmed to the largest applicable numerical value in order to achieve the best accuracy in the calculation of FDCAN_TURNA.NAV.

The synchronization deviation SD is the difference between NC and FDCAN_TURNA.NAV (SD = | NC - FDCAN_TURNA.NAV |). It is limited by the synchronization deviation limit SDL, which is configured by its dual logarithm FDCAN_TTOCF.LDSDL (SDL = 2 (FDCAN_TTOCF.LDSDL + 5)) and should not exceed the clock tolerance given by the CAN bit timing configuration. SD is calculated at each new basic cycle. When the calculated TURNA[NAV deviates by more than SDL from NC, or if the Disc_Bit in the reference message is set, the drift compensation is suspended and FDCAN_TTIR.GTE is set and FDCAN_TTOSC.QCS is reset, or in case of the Disc_Bit = 1, FDCAN_TTIR.GTD is set.

Table 473. TUR configuration example

RM0433 Rev 6 2499/3289
FDCAN_TTOCN.ECS schedules NC for activation by the next reference message. FDCAN_TTOCN.SGT schedules FDCAN_TTGTP.TP for activation by the next reference message. Setting FDCAN_TTOCN.ECS and FDCAN_TTOCN.SGT requires FDCAN_TTOCF.EECS to be set (external clock synchronization enabled) while the FDCAN is actual time master.

The TTCAN module provides an application watchdog to verify the function of the application program. The Host has to serve this watchdog regularly, else all CAN bus activity is stopped. The application watchdog limit FDCAN_TTOCF.AWL specifies the number of NTUs between two times the watchdog has to be served. The maximum number of NTUs is 256. The application watchdog is served by reading register FDCAN_TTOST. FDCAN_TTOST.AWE indicates whether the watchdog has been served in time. In case the application failed to serve the application watchdog, interrupt flag FDCAN_TTIR.AW is set. For software development, the application watchdog may be disabled by programming FDCAN_TTOCF.AWL to 0x00, see Section 55.4.49.

**Timing of interface signals**

The timing events that cause a pulse at output FDCAN trigger time mark interrupt pulse fdcan1_tmp for more than one instance and fdcan_tmp if only one instance; FDCAN register time mark interrupt pulse fdcan1_rtp for more than one instance and fdcan_rtp if only one instance are generated in the CAN clock domain.

There is a clock domain crossing delay to be considered before the same event is visible in the APB clock domain (when FDCAN_TTIR.TTMI is set or FDCAN_TTIR.RTMI is set). As an example, the signals can be connected to the timing input(s) of another FDCAN node (fdcan_swt/fdcan_evt), in order to automatically synchronize two TTCAN networks.

Output FDCAN start of cycle_fdcan1_soc for more than one instance and cycle_fdcan_soc if only one instance gets active whenever a reference message is completed (either transmitted or received). The output is controlled in the APB clock domain.

55.3.9 **Message scheduling**

FDCAN_TTOCF.TM controls whether the TTCAN operates as potential time master or as a time slave. If it is a potential time master, the three LSBs of the reference message identifier FDCAN_TTRMC.RID define the master priority, 0 giving the highest and 7 giving the lowest. There cannot be two nodes in the network using the same master priority. FDCAN_TTRMC.RID is used for recognition of reference messages. FDCAN_TTRMC.RMPS is not relevant for time slaves.

The initial reference trigger offset FDCAN_TTOCF.IRTO is a 7-bit-value that defines (in NTUs) how long a backup time master waits before it starts the transmission of a reference message when a reference message is expected but the bus remains idle. The recommended value for FDCAN_TTOCF.IRTO is the master priority multiplied with a factor depending on the expected clock drift between the potential time masters in the network. The sequential order of the backup time masters, when one of them starts the reference message in case the current time master fails, should correspond to their master priority, even with maximum clock drift.

FDCAN_TTOCF.OM decides whether the node operates in TTCAN level 0, level 1, or level 2. In one network, all potential time masters have to operate on the same level. Time slaves may operate on level 1 in a level 2 network, but not vice versa. The configuration of the TTCAN operation mode via FDCAN_TTOCF.OM is the last step in the setup. With FDCAN_TTOCF.OM = 00 (event-driven CAN communication), the FDCAN operates.
according to ISO 11898-1: 2015, without time triggers. With FDCAN_TTOCF.OM = 01 (level 1), the FDCAN operates according to ISO 11898-4, but without the possibility to synchronize the basic cycles to external events, the Next_is_Gap bit in the reference message is ignored. With FDCAN_TTOCF.OM = 10 (level 2), the TTCAN operates according to ISO 11898-4, including the event-synchronized start of a basic cycle. With FDCAN_TTOCF.OM = 11 (level 0), the FDCAN operates as event-driven CAN but maintains a calibrated global time base as in level 2.

FDCAN_TTOCF.EECS enables the external clock synchronization, allowing the application program of the current time master to update the TUR configuration during time-triggered operation, to adapt the clock speed and (in levels 0 and level 2 only) the global clock phase to an external reference.

FDCAN_TTMLM.ENTT in the TT matrix limits register specifies the number of expected Tx_Triggers in the system matrix. This is the sum of Tx_Triggers for exclusive, single arbitrating and merged arbitrating windows, excluding the Tx_Ref_Triggers. Note that this is usually not the number of Tx_Trigger memory elements; the number of basic cycles in the system matrix and the trigger repeat factors have to be taken into account.

An inaccurate configuration of FDCAN_TTMLM.ENTT will result either in a TxCount Underflow (FDCAN_TTIR.TXU = 1 and FDCAN_TTOST.EL = 01, severity 1), or in a Tx count Overflow (FDCAN_TTIR.TXO = 1 and FDCAN_TTOST.EL = 10, severity 2).

Note: In case the first reference message seen by a node does not have Cycle_Count 0, this node may finish its first matrix cycle with its Tx count resulting in a Tx count underflow condition. As long as a node is in state Synchronizing its Tx_Triggers will not lead to transmissions.

FDCAN_TTMLM.CCM specifies the number of the last basic cycle in the system matrix. The counting of basic cycles starts at 0. In a system matrix consisting of eight basic cycles FDCAN_TTMLM.CCM would be 7. FDCAN_TTMLM.CCM is ignored by time slaves, a receiver of a reference message considers the received cycle count as the valid cycle count for the actual basic cycle.

FDCAN_TTMLM.TXEW specifies the length of the Tx enable window in NTUs. The Tx enable window is that period of time at the beginning of a time window where a transmission may be started. If a transmission of a message cannot be started inside the Tx enable window because of for example, a slight overlap from the previous time window message, the transmission cannot be started in that time window at all. FDCAN_TTMLM.TXEW has to be chosen with respect to the network synchronization quality and with respect to the relation between the length of the time windows and the length of the messages.

**Trigger memory**

The trigger memory is part of the external message RAM to which the TTCAN is connected to (see Section 55.4.26). It stores up to 64 trigger elements. A trigger memory element consists of time mark TM, cycle code CC, trigger type TYPE, filter type FTYPE, message Number MNR, message status count MSC, time mark event internal TMIN, time mark event external TMEX (see Section 55.3.23).

The time mark defines at which cycle time a trigger becomes active. The triggers in the trigger memory have to be sorted by their time marks. The trigger element with the lowest time mark is written to the first trigger memory word. Message number and cycle code are ignored for triggers of type Tx_Ref_Trigger, Tx_Ref_Trigger_Gap, Watch_Trigger, Watch_Trigger_Gap, and End_of_List.

When the cycle time reaches the time mark of the actual trigger, the FSE switches to the next trigger and starts to read the following trigger from the trigger memory. In case of a
transmit trigger, the Tx handler starts to read the message from the message RAM as soon as the FSE switches to its trigger. The RAM access speed defines the minimum time step between a transmit trigger and its preceding trigger, the Tx handler has to be able to prepare the transmission before the transmit trigger time mark is reached. The RAM access speed also limits the number of non-matching (with regard to their cycle code) triggers between two matching triggers, the next matching trigger must be read before its time mark is reached. If the reference message is n NTU long, a trigger with a time mark lower than n will never become active and will be treated as a configuration error.

Starting point of the cycle time is the sample point of the reference message start of frame bit. The next reference message is requested when cycle time reaches the Tx_Ref_Trigger time mark. The FDCAN reacts on the transmission request at the next sample point. A new Sync_Mark is captured at the start of frame bit, but the cycle time is incremented until the reference message is successfully transmitted (or received) and the Sync_Mark is taken as the new Ref_Mark. At that point in time, cycle time is restarted. As a consequence, cycle time can never (with the exception of initialization) be seen at a value lower than n, with n being the length of the reference message measured in NTU.

Length of a basic cycle: Tx_Ref_Trigger time mark + 1 NTU + 1 CAN bit time.

The trigger list will be different for all nodes in the FDCAN network. Each node knows only the Tx_Triggers for its own transmit messages, the Rx_Triggers for those receive messages that are processed by this node, and the triggers concerning the reference messages.

**Trigger types**

Tx_Ref_Trigger (TYPE = 0000) and Tx_Ref_Trigger_Gap (TYPE = 0001) cause the transmission of a reference message by a time master. A configuration error (FDCAN_TTOST.EL = 11, severity 3) is detected when a time slave encounters a Tx_Ref_Trigger(_Gap) in its trigger memory. Tx_Ref_Trigger_Gap is only used in external event-synchronized time-triggered operation mode. In that mode, Tx_Ref_Trigger is ignored when the FDCAN synchronization state is In_Gap (FDCAN_TTOST.SYS = 10).

Tx_Trigger_Single (TYPE = 0010), Tx_Trigger_Continuous (TYPE = 0011), Tx_Trigger_Arbitration (TYPE = 0100), and Tx_Trigger_Merged (TYPE = 0101) cause the start of a transmission. They define the start of a time window.

Tx_Trigger_Single starts a single transmission in an exclusive time window when the message buffer transmission request pending bit is set. After successful transmission the transmission request pending bit is reset.

Tx_Trigger_Continuous starts a transmission in an exclusive time window when the message buffer transmission request pending bit is set. After successful transmission the transmission request pending bit remains set, and the message buffer is transmitted again in the next matching time window.

Tx_Trigger_Arbitration starts an arbitrating time window, Tx_Trigger_Merged a merged arbitrating time window. The last Tx_Trigger of a merged arbitrating time window must be of type Tx_Trigger_Arbitration. A configuration error (FDCAN_TTOST.EL = 11, severity 3) is detected when a trigger of type Tx_Trigger_Merged is followed by any other Tx_Trigger than one of type Tx_Trigger_Merged or Tx_Trigger_Arbitration. Several Tx_Triggers may be defined for the same Tx message buffer. Depending on their cycle code, they may be ignored in some basic cycles. The cycle code has to be considered when the expected number of Tx_Triggers (FDCAN_TTMLM.ENTT) is calculated.
Watch_Trigger (TYPE = 0110) and Watch_Trigger_Gap (TYPE = 0111) check for missing reference messages. They are used by both time masters and time slaves. Watch_Trigger_Gap is only used in external event-synchronized time-triggered operation mode. In that mode, a Watch_Trigger is ignored when the FDCAN synchronization state is In_Gap (FDCAN_TTOST.SYS = 10).

Rx_Trigger (TYPE = 1000) is used to check for the reception of periodic messages in exclusive time windows. Rx_Triggers are not active until state In_Schedule or In_Gap is reached. The time mark of an Rx_Trigger shall be placed after the end of that message transmission, independent of time window boundaries. Depending on their cycle code, Rx_Triggers may be ignored in some basic cycles. At the time mark of the Rx_Trigger, it is checked whether the last received message before this time mark and after start of cycle or previous Rx_Trigger had matched the acceptance filter element referenced by MNR. Accepted messages are stored in one of the two receive FIFOs, according to the acceptance filtering, independent of the Rx_Trigger. Acceptance filter elements referenced by Rx_Triggers should be placed at the beginning of the filter list to ensure that the filtering is finished before the Rx_Trigger time mark is reached.

Time_Base_Trigger (TYPE = 1001) are used to generate internal/external events depending on the configuration of TMIN and TMEX.

End_of_List (TYPE = 1010 … 1111) is an illegal trigger type, a configuration error (FDCAN_TTOST.EL = 11, severity 3) is detected when an End_of_List trigger is encountered in the trigger memory before the Watch_Trigger and Watch_Trigger_Gap.

Restrictions for the node trigger list

There may not be two triggers that are active at the same cycle time and cycle count, but triggers that are active in different basic cycles (different cycle code) may share the same time mark.

Rx_Triggers and Time_Base_Triggers may not be placed inside the Tx enable windows of Tx_Trigger_Single/Continuous/Arbitration, but they may be placed after Tx_Trigger_Merged.

Triggers that are placed after the Watch_Trigger (or the Watch_Trigger_Gap when FDCAN_TTOST.SYS = 10) will never become active. The watch triggers themselves will not become active when the reference messages are transmitted on time.

All unused trigger memory words (after the Watch_Trigger or after the Watch_Trigger_Gap when FDCAN_TTOST.SYS = 10) must be set to trigger type End_of_List.

A typical trigger list for a potential time master will begin with a number of Tx_Triggers and Rx_Triggers followed by the Tx_Ref_Trigger and the Watch_Trigger. For networks with external event-synchronized time-triggered communication, this is followed by the Tx_Ref_Trigger_Gap and the Watch_Trigger_Gap. The trigger list for a time slave will be the same but without the Tx_Ref_Trigger and the Tx_Ref_Trigger_Gap.

At the beginning of each basic cycle, that is at each reception or transmission of a reference message, the trigger list is processed starting with the first trigger memory element. The FSE looks for the first trigger with a cycle code that matches the current cycle count. The FSE waits until cycle time reaches the trigger time mark and activates the trigger. Afterwards the FSE looks for the next trigger in the list with a cycle code that matches the current cycle count.

Special consideration is needed for the time around Tx_Ref_Trigger and Tx_Ref_Trigger_Gap. In a time master competing for master ship, the effective time mark of
a Tx_Ref_Trigger may be decremented in order to be the first node to start a reference message. In backup time masters the effective time mark of a Tx_Ref_Trigger or Tx_Ref_Trigger_Gap is the sum of its configured time mark and the reference trigger offset FDCAN_TTOCF.IRTO. In case error level 2 is reached (FDCAN_TTOST.EL = 10), the effective time mark is the sum of its time mark and 0x127. No other trigger elements should be placed in this range otherwise it may happen that the time marks appear out of order and are flagged as a configuration error. Trigger elements which are coming after Tx_Ref_Trigger may never become active as long as the reference messages come in time.

There are interdependencies between the following parameters:
- APB clock frequency
- Speed and waiting time for trigger RAM accesses
- Length of the acceptance filter list
- Number of trigger elements
- Complexity of cycle code filtering in the trigger elements
- Offset between time marks of the trigger elements

**Example for trigger handling**

The example shows how the trigger list is derived from a node system matrix. Assumption is that node A is first time master and has knowledge of the section of the system matrix shown in Table 474.

**Table 474. System matrix, Node A**

</tbody>
</table>

The cycle count starts with 0 and runs until 0, 1, 3, 7, 15, 31, 63 (the corresponding number of basic cycles in the system matrix is, respectively, 1, 2, 4, 8, 16, 32, 64). The maximum cycle count is configured by FDCAN_TTMLM.CCM. The cycle code CC is composed of repeat factor (= value of most significant 1) and the number of the first basic cycle in the system matrix (= bit field after most significant 1).

As an example, with a cycle code of 0b0010011 (repeat factor = 16, first basic cycle = 3) and a maximum cycle count of FDCAN_TTMLM.CCM = 0x3F matches occur at cycle counts 3, 19, 35 and 51.

A trigger element consists of time mark TM, cycle code CC, trigger type TYPE, and message Number MNR. For transmission MNR references the Tx buffer number (0 ... 31). For reception MNR references the number of the filter element (0 ... 127) that matched during acceptance filtering. Depending on the configuration of the filter type FTYPE, the 11-bit or 29-bit message ID filter list is referenced.
In addition a trigger element can be configured for generation of time mark event internal TMIN, and time mark event external TMEX. The message status count MSC holds the counter value (0 ... 7) for scheduling errors for periodic messages in exclusive time windows at the point in time when the time mark of the trigger element became active.

Tx_Trigger_Single, Tx_Trigger_Continuous, Tx_Trigger_Merged, Tx_Trigger_Arbitration, Rx_Trigger, and Time_Base_Trigger are only valid for the specified cycle code. For all other trigger types the cycle code is ignored.

The FSE starts the basic cycle with scanning the trigger list starting from 0 until a trigger with time mark higher than cycle time and with its cycle code CC matching the actual cycle count is reached, or a trigger of type Tx_Ref_Trigger, Tx_Ref_Trigger_Gap, Watch_Trigger, or Watch_Trigger_Gap is encountered.

When the cycle time reached the time mark TM, the action defined by trigger type TYPE and message Number MNR is started. There is an error in the configuration when End_of_List is reached.

At mark 6 the reference message (always TxRef) is transmitted. After transmission of the reference message the FSE returns to the beginning of the trigger list. When the watch trigger at mark 7 is reached, the node was not able to transmit the reference message; error treatment is started.

Detection of configuration errors

A configuration error is signaled via FDCAN TTOST.EL = 11 (severity 3) when:

- The FSE comes to a trigger in the list with a cycle code that matches the current cycle count but with a time mark that is less than the cycle time.
- The previous active trigger was a Tx_Trigger_Merged and the FSE comes to a trigger in the list with a cycle code that matches the current cycle count but that is neither a
The FSE of a node with FDCAN_TTOCF.TM=0 (time slave) encounters a Tx_Ref_Trigger or a Tx_Ref_Trigger_Gap.

Any time mark placed inside the Tx enable window (defined by FDCAN_TTMLM.TXEW) of a Tx_Trigger with a matching cycle code.

A time mark is placed near the time mark of a Tx_Ref_Trigger and the reference trigger offset FDCAN_TTOST.RTO causes a reversal of their sequential order measured in cycle time.

TTCAN schedule initialization

The synchronization to the TTCAN message schedule starts when FDCAN_CCCR.INIT is reset. The TTCAN can operate strictly time-triggered (FDCAN_TTOCF.GEN = 0) or external event-synchronized time-triggered (FDCAN_TTOCF.GEN = 1). All nodes start with cycle time 0 at the beginning of their trigger list with FDCAN_TTOST.SYS = 00 (out of synchronization), no transmission is enabled with the exception of the reference message. Nodes in external event-synchronized time-triggered operation mode will ignore Tx_Ref_Trigger and Watch_Trigger and will use instead Tx_Ref_Trigger_Gap and Watch_Trigger_Gap until the first reference message decides whether a Gap is active.

Time slaves

After configuration, a time slave will ignore its Watch_Trigger and Watch_Trigger_Gap when it did not receive any message before reaching the Watch_Triggers. When it reaches Init_Watch_Trigger, interrupt flag FDCAN_TTIR.IWT is set, the FSE is frozen, and the cycle time will become invalid, but the node will still be able to take part in CAN bus communication (to acknowledge or to send error flags). The first received reference message will restart the FSE and the cycle time.

Note: Init_Watch_Trigger is not part of the trigger list. It is implemented as an internal counter that counts up to 0xFFFF = maximum cycle time.

When a time slave has received any message but the reference message before reaching the Watch_Triggers, it will assume a fatal error (FDCAN_TTOST.EL = 11, severity 3), set interrupt flag FDCAN_TTIR.WT, switch off its CAN bus output, and enter the bus monitoring mode (FDCAN_CCCR.MON set to 1). In the bus monitoring mode it is still able to receive messages, but it cannot send any dominant bits and therefore cannot give acknowledge.

Note: To leave the fatal error state, the Host has to set FDCAN_CCCR.INIT = 1. After reset of FDCAN_CCCR.INIT, the node restarts TTCAN communication.

Potential time masters

After configuration, a potential time master will start the transmission of a reference message when it reaches its Tx_Ref_Trigger (or its Tx_Ref_Trigger_Gap when in external event-synchronized time-triggered operation). It will ignore its Watch_Trigger and Watch_Trigger_Gap when it did not receive any message or transmit the reference message successfully before reaching the Watch_Triggers (assumed reason: all other nodes still in reset or configuration, giving no acknowledge). When it reaches
Init_Watch_Trigger, the attempted transmission is aborted, interrupt flag FDCAN_TTIR.IWT is set, the FSE is frozen, and the cycle time will become invalid, but the node will still be able to take part in CAN bus communication (to give acknowledge or to send error flags). Resetting FDCAN_TTIR.IWT will re-enable the transmission of reference messages until next time the Init_Watch_Trigger condition is met, or another CAN message is received. The FSE will not be restarted by the reception of a reference message.

When a potential time master reaches the Watch_Triggers after it has received any message but the reference message, it will assume a fatal error (FDCAN_TTOST.EL = 11, severity 3), set interrupt flag FDCAN_TTIR.WT, switch off its CAN bus output, and enter the bus monitoring mode (FDCAN_CCRC.MON set to 1). In bus monitoring mode, it is still able to receive messages, but cannot send any dominant bits and therefore cannot give acknowledge.

When no error is detected during initialization, the first reference message sets FDCAN_TTOST.SYS = 01 (synchronizing), the second sets the FDCAN synchronization state (depending on its Next_is_Gap bit) to FDCAN_TTOST.SYS = 11 (In_Schedule) or FDCAN_TTOST.SYS = 10 (In_Gap), enabling all Tx_Triggers and Rx_Triggers.

A potential time master is current time master (FDCAN_TTOST.MS = 11) when it was the transmitter of the last reference message, else it is backup time master (FDCAN_TTOST.MS = 10).

When all potential time masters have finished configuration, the node with the highest time master priority in the network will become the current time master.

### 55.3.10 TTCAN gap control

All functions related to Gap control apply only when the FDCAN is operated in external event synchronized time-triggered mode (FDCAN_TTOCF.GEN = 1). In this operation mode the FDCAN message schedule may be interrupted by inserting Gaps between the basic cycles of the system matrix. All nodes connected to the CAN network have to be configured for external event- synchronized time-triggered operation.

During a Gap, all transmissions are stopped and the CAN bus remains idle. A Gap is finished when the next reference message starts a new basic cycle. A Gap starts at the end of a basic cycle that itself was started by a reference message with bit Next_is_Gap = 1 e.g. Gaps are initiated by the current time master.

The current time master has two options to initiate a Gap. A Gap can be initiated under software control when the application program writes FDCAN_TTOCN.NIG = 1. The Next_is_Gap bit will be transmitted as 1 with the next reference message. A Gap can also be initiated under hardware control when the application program enables the event trigger input pin fdcan_evt by writing FDCAN_TTOCN.GCS = 1. When a reference message is started and FDCAN_TTOCN.GCS is set, a HIGH level at event trigger pin fdcan_evt will set Next_is_Gap = 1.

As soon as that reference message is completed, the FDCAN_TTOST.WFE bit will announce the Gap to the time master as well as to the time slaves. The current basic cycle will continue until its last time window. The time after the last time window is the Gap time.

For the actual time master and the potential time masters, FDCAN_TTOST.GSI will be set when the last basic cycle has finished and the Gap time starts. In nodes that are time slaves, bit FDCAN_TTOST.GSI will remain at 0.

When a potential time master is in synchronization state In_Gap (FDCAN_TTOST.SYS = 10), it has four options to intentionally finish a Gap:
1. Under software control by writing FDCAN_TTOCN.FGP = 1.
2. Under hardware control (FDCAN_TTOCN.GCS = 1) an edge from HIGH to LOW at the event-trigger input pin fdcan_evt sets FDCAN_TTOCN.FGP and restarts the schedule.
3. The third option is a time-triggered restart. When FDCAN_TTOCN.TMG = 1, the next register time mark interrupt (FDCAN_TTIR.RTMI = 1) will set FDCAN_TTOCN.FGP and start the reference message.
4. Finally any potential time master will finish a Gap when it reaches its Tx_Ref_Trigger_Gap, assuming that the event to synchronize on did not occur in time. None of these options can cause a basic cycle to be interrupted with a reference message. Setting of FDCAN_TTOCN.FGP after the Gap time has started will start the transmission of a reference message immediately and will thereby synchronize the message schedule. When FDCAN_TTOCN.FGP is set before the Gap time has started (while the basic cycle is still in progress), the next reference message is started at the end of the basic cycle, at the Tx_Ref_Trigger – there will be no Gap time in the message schedule.

In strictly time-triggered operation, bit Next_is_Gap = 1 in the reference message will be ignored, as well as the event-trigger input pin fdcan_evt and the bits FDCAN_TTOCN.NIG, FDCAN_TTOCN.FGP, and FDCAN_TTOCN.TMG.

55.3.11 Stop watch
The stop watch function enables capturing of FDCAN internal time values (local time, cycle time, or global time) triggered by an external event.

To enable the stop watch function, the application program first has to define local time, cycle time, or global time as stop watch source via FDCAN_TTOCN.SWS. When FDCAN_TTOCN.SWS is different from 00 and TT interrupt register flag FDCAN_TTIR.SWE is 0, the actual value of the time selected by FDCAN_TTOCN.SWS will be copied into FDCAN_TTCPT.SWV on the next rising / falling edge (as configured via FDCAN_TTOCN.SWP) on stop watch trigger pin fdcan_swt. This will set interrupt flag FDCAN_TTIR.SWE. After the application program has read FDCAN_TTCPT.SWV, it may enable the next stop watch event by resetting FDCAN_TTIR.SWE to 0.

55.3.12 Local time, cycle time, global time, and external clock synchronization
There are two possible levels in time-triggered CAN:
1. Level 1 only provides time-triggered operation using cycle time.
2. Level 2 additionally provides increased synchronization quality, global time and external clock synchronization. In both levels, all timing features are based on a local time base - the local time.

The local time is a 16-bit cyclic counter, it is incremented once each NTU. Internally the NTU is represented by a 3-bit counter which can be regarded as a fractional part (three binary digits) of the local time. Generally, the 3-bit NTU counter is incremented eight times each NTU. If the length of the NTU is shorter than eight CAN clock periods (as may be configured in level 1, or as a result of clock calibration in level 2), the length of the NTU fraction is adapted, and the NTU counter is incremented only four times each NTU.

_Figure 743_ describes the synchronization of the cycle time and global time, performed in the same manner by all FDCAN nodes, including the time master. Any message received or transmitted invokes a capture of the local time taken at the message is frame.
synchronization event. This frame synchronization event occurs at the sample point of each start of frame (SoF) bit and causes the local time to be stored as Sync_Mark. Sync_Marks and Ref_Marks are captured including the 3-bit fractional part.

Whenever a valid reference message is transmitted or received, the internal Ref_Mark is updated from the Sync_Mark. The difference between Ref_Mark and Sync_Mark is the cycle sync mark (cycle sync mark = Sync_Mark - Ref_Mark) stored in register FDCAN_TTCSM. The most significant 16 bits of the difference between Ref_Mark and the actual value of the local time is the cycle time (cycle time = local time - Ref_Mark).

**Figure 743. Cycle time and global time synchronization**

The cycle time that can be read from FDCAN_TTCTC.CT is the difference of the node local time and Ref_Mark, both synchronized into the APB clock domain and truncated to 16 bit.

The global time exists for TTCAN level 0 and level 2 only, in level 1 it is invalid. The node view of the global time is the local image of the global time in (local) NTUs. After configuration, a potential time master will use its own local time as global time. The time master establishes its own local time as global time by transmitting its own Ref_Marks as Master_Ref_Marks in the reference message (bytes 3 and 4). The global time that can be read from FDCAN_TTTLGT.GT is the sum of the node local time and its local offset, both synchronized into the APB clock domain and truncated to 16 bit. The fractional part is used for clock synchronization only.

A node that receives a reference message calculates its local offset to the global time by comparing its local Ref_Mark with the received Master_Ref_Mark (see Figure 744). The node view of the global time is local time plus local offset. In a potential time master that has never received another time master reference message, Local_Offset will be 0. When a node becomes the current time master after first having received other reference messages,
Local_Offset will be frozen at its last value. In the time receiving nodes, Local_Offset may be subject to small adjustments, due to clock drift, when another node becomes time master, or when there is a global time discontinuity, signaled by Disc_Bit in the reference message. With the exception of global time discontinuity, the global time provided to the application program by register FDCAN_TTLGT is smoothed by a low-pass filtering to have a continuous monotonic value.

**Figure 744. TTCAN level 0 and level 2 drift compensation**

Figure 744 describes how in TTCAN levels 0 and 2 each time receiving node compensates the drift between its own local clock and the time master clock by comparing the length of a basic cycle in local time and in global time. If there is a difference between the two values and the Disc_Bit in the reference message is not set, a new value for FDCAN_TURNA.NAV is calculated. If the synchronization deviation $SD = | NC - FDCAN\_TURNA\_NAV | \leq SDL$ (synchronization deviation limit), the new value for FDCAN_TURNA.NAV takes effect. Else the automatic drift compensation is suspended.

In TTCAN level 0 and level 2, FDCAN_TTOST.QCS indicates whether the automatic drift compensation is active or suspended. In TTCAN level 1, FDCAN_TOST.QCS is always 1.

The current time master may synchronize its local clock speed and the global time phase to an external clock source. This is enabled by bit FDCAN_TTOCF.EECS.

The stop watch function (see Section 55.3.11: Stop watch) may be used to measure the difference in clock speed between the local clock and the external clock. The local clock speed is adjusted by first writing the newly calculated numerator configuration low to
FDCAN_TURCF.NCL (FDCAN_TURCF.DC cannot be updated during operation). The new value takes effect by writing FDCAN_TTOCN.ECS to 1.

The global time phase is adjusted by first writing the phase offset into the TT global time Preset register FDCAN_TTGTP. The new value takes effect by writing FDCAN_TTOCN.SGT to 1. The first reference message transmitted after the global time phase adjustment will have the Disc_Bit set to 1.

FDCAN_TTOST.QGTP shows whether the node global time is in phase with the time master global time. FDCAN_TTOST.QGTP is permanently 0 in TTCAN level 1 and when the synchronization deviation limit is exceeded in TTCAN level 0, 2 (FDCAN_TTOST.QCS = 0). It is temporarily 0 while the global time is low-pass filtered to supply the application with a continuous monotonic value. There is no low-pass filtering when the last reference message contained a Disc_Bit = 1 or when FDCAN_TTOST.QCS = 0.

55.3.13 TTCAN error level

The ISO 11898-4 specifies four levels of error severity:

1. S0 - No error
2. S1 - Warning - Only notification of application, reaction application-specific.
3. S2 error - Notification of application. All transmissions in exclusive or arbitrating time windows are disabled (i.e. no data or remote frames may be started). Potential time masters still transmit reference messages with the reference trigger offset FDCAN_TTOST.RTO set to the maximum value of 127.
4. S3 - Severe error - Notification of application. All CAN bus operations are stopped, i.e. transmission of dominant bits is not allowed, and FDCAN_CCCR.MON is set. The S3 error condition remains active until the application updates the configuration (set FDCAN_CCCR.CCE).

If several errors are detected at the same time, the highest severity prevails. When an error is detected, the application is notified by FDCAN_TTIR.ELC. The error level is monitored by FDCAN_TTOST.EL.

The TTCAN signals the following error conditions as required by ISO 11898-4:

- **Config_error (S3)**
  - Sets error level FDCAN_TTOST.EL to 11 when a merged arbitrating time window is not properly closed or when there is a Tx_Trigger with a time mark beyond the Tx_Ref_Trigger.
- **Watch_Trigger_Reached (S3)**
  - Sets error level FDCAN_TTOST.EL to 11 when a watch trigger was reached because the reference message is missing.
- **Application_Watchdog (S3)**
  - Sets error level FDCAN_TTOST.EL to 11 when the application failed to serve the application watchdog. The application watchdog is configured via FDCAN_TTOCF.AWL. It is served by reading register FDCAN_TTOST. When the watchdog is not served in time, bit FDCAN_TTOST.AWE and interrupt flag
Controller area network with flexible data rate (FDCAN) RM0433

FDCAN_TTIR.AW are set, all FDCAN communication is stopped, and the FDCAN is set into bus monitoring mode (FDCAN_CCCR.MON set to 1).

- **CAN_Bus_Off** (S3)
  - Entering CAN_Bus_Off state sets error level FDCAN_TTOST.EL to 11. CAN_Bus_Off state is signaled by FDCAN_PSR.BO = 1 and FDCAN_CCCR.INIT = 1.

- **Scheduling_Error_2** (S2)
  - Sets error level FDCAN_TTOST.EL to 10 if the MSC of one Tx_Trigger has reached 7. In addition interrupt flag FDCAN_TTIR.SE2 is set. The error level FDCAN_TTOST.EL is reset to 00 at the beginning of a matrix cycle when no Tx_Trigger has an MSC of 7 in the preceding matrix cycle.

- **Scheduling_Error_1** (S1)
  - Sets error level FDCAN_TTOST.EL to 01 if within one matrix cycle the difference between the maximum MSC and the minimum MSC for all trigger memory elements (of exclusive time windows) is larger than two, or if one of the MSCs of an exclusive Rx_Trigger has reached seven. In addition interrupt flag FDCAN_TTIR.SE1 is set. If within one matrix cycle none of these conditions is valid, the error level FDCAN_TTOST.EL is reset to 00.

- **Tx_Underflow** (S1)
  - Sets error level FDCAN_TTOST.EL to 01 when the Tx count is less than the expected number of Tx_Triggers FDCAN_TTMLM.ENTT at the start of a new matrix cycle. In addition interrupt flag FDCAN_TTIR.TXU is set. The error level FDCAN_TTOST.EL is reset to 00 when the Tx count is at least FDCAN_TTMLM.ENTT at the start of a new matrix cycle.

### 55.3.14 TTCAN message handling

**Reference message**

For potential time masters the identifier of the reference message is configured via FDCAN_TTRMC.RID. No dedicated Tx buffer is required for transmission of the reference message. When a reference message is transmitted, the first data byte for TTCAN level 1 (that is, the first four data bytes for TTCAN level 0 and the first four data bytes for TTCAN level 2) will be provided by the FSE.

In case the reference message Payload select FDCAN_TTRMC.RMPS is set, the rest of the reference message payload (level 1: bytes 2-8, level 0, 2: bytes 5-6) is taken from Tx buffer 0. In this case the data length DLC code from message buffer 0 is used.

<table>
<thead>
<tr>
<th>FDCAN_TTRMC.RMPS</th>
<th>FDCAN_TXBRP.TR0</th>
<th>Level 0</th>
<th>Level 1</th>
<th>Level 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>4</td>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>4</td>
<td>1</td>
<td>4</td>
</tr>
</tbody>
</table>
To send additional payload with the reference message in level 1 a DLC > 1 has to be configured, for level 0 and level 2 a DLC > 4 is required. In addition the transmission request pending bit FDCAN_TXBRP.TRP0 of message buffer 0 must be set (see Table 476). In case bit FDCAN_TXBRP.TRP0 is not set when a reference message is started, the reference message is transmitted with the data bytes supplied by the FSE only.

For acceptance filtering of reference messages the reference identifier FDCAN_TTRMC.RID is used.

**Message reception**

Message reception is done via the two Rx FIFOs in the same way as for event-driven CAN communication (see *Rx handler*).

The message status count MSC is part of the corresponding trigger memory element and has to be initialized to 0 during configuration. It is updated while the TTCAN is in synchronization states In_Gap or In_Schedule. The update happens at the message Rx_Trigger. At this point in time it is checked at which acceptance filter element the latest message received in this basic cycle had matched. The matching filter number is stored as the acceptance filter result. If this is the same the filter number as defined in this trigger memory element, the MSC is decremented by one. If the acceptance filter result is not the same filter number as defined for this filter element, or if the acceptance filter result is cleared, the MSC is incremented by one. At each Rx_Trigger and at each start of cycle, the last acceptance filter result is cleared.

The time mark of an Rx_Trigger should be set to a value where it is ensured that reception and acceptance filtering for the targeted message has completed. This has to take into consideration the RAM access time and the order of the filter list. It is recommended, that filters which are used for Rx_Triggers are placed at the beginning of the filter list. It is not recommended to use an Rx_Trigger for the reference message.

**Message transmission**

For time-triggered message transmission the TTCAN supplies 32 dedicated Tx buffers (see *Transmit pause*). A Tx FIFO or Tx queue is not available when the FDCAN is configured for time-triggered operation (FDCAN_TTOCF.OM = 01 or 10).

Each Tx_Trigger in the trigger memory points to a particular Tx buffer containing a specific message. There may be more than one Tx_Trigger for a given Tx buffer if that Tx buffer contains a message that is to be transmitted more than once in a basic cycle or matrix cycle.

The application program has to update the data regularly and on time, synchronized to the cycle time. The Host CPU is responsible that no partially updated messages are transmitted. To assure this the Host has to proceed in the following way:

---

**Table 476. Number of data bytes transmitted with a reference message (continued)**

</tr>
</tbody>
</table>
Controller area network with flexible data rate (FDCAN) RM0433

Tx_Trigger_Single / Tx_Trigger_Merged / Tx_Trigger_Arbitration
• Check whether the previous transmission has completed by reading FDCAN_TXBTO
• Update the Tx buffer configuration and/or payload
• Issue an add request to set the Tx buffer request pending bit

Tx_Trigger_Continuous
• Issue a cancellation request to reset the Tx buffer request pending bit
• Check whether the cancellation has finished by reading FDCAN_TXBCF
• Update Tx buffer configuration and/or payload
• Issue an add request to set the Tx buffer request pending bit

The message MSC stored with the corresponding Tx_Trigger provides information on the success of the transmission.

The MSC is incremented by one when the transmission could not be started because the CAN bus was not idle within the corresponding transmit enable window or when the message was started and could not be completed successfully. The MSC is decremented by one when the message was transmitted successfully or when the message could have been started within its transmit enable window but was not started because transmission was disabled (TTCAN in error level S2 or Host has disabled this particular message).

The Tx buffers may be managed dynamically, i.e. several messages with different identifiers may share the same Tx buffer element. In this case the Host has to assure that no transmission request is pending for the Tx buffer element to be reconfigured by checking FDCAN_TXBRP.

If a Tx buffer with pending transmission request should be updated, the Host first has to issue a cancellation request and check whether the cancellation has completed by reading FDCAN_TXBCF before it starts updating.

The Tx handler will transfer a message from the message RAM to its intermediate output buffer at the trigger element which becomes active immediately before the Tx_Trigger element which defines the beginning of the transmit window. During and after the transfer time the transmit message may not be updated and its FDCAN_TXBRP bit may not be changed. To control this transfer time, an additional trigger element may be placed before the Tx_Trigger. This may be example of a Time_Base_Trigger which need not cause any other action. The difference in time marks between the Tx_Trigger and the preceding trigger has to be large enough to guarantee that the Tx handler can read four words from the message RAM even at high RAM access load from other modules.

Transmission in exclusive time windows

A transmission is started time-triggered when the cycle time reaches the time mark of a Tx_Trigger_Single or Tx_Trigger_Continuous. There is no arbitration on the bus with messages from other nodes. The MSC is updated according the result of the transmission attempt. After successful transmission started by a Tx_Trigger_Single the respective Tx buffer request pending bit is reset. After successful transmission started by a Tx_Trigger_Continuous the respective Tx buffer request pending remains set. When the transmission was not successful due to disturbances, it will be repeated next time (one of) its Tx_Trigger(s) become(s) active.
Transmission in arbitrating time windows

A transmission is started time-triggered when the cycle time reaches the time mark of a Tx_Trigger_Arbitration. Several nodes may start to transmit at the same time. In this case the message has to arbitrate with the messages from other nodes. The MSC is not updated. When the transmission was not successful (lost arbitration or disturbance), it will be repeated next time (one of) its Tx_Trigger(s) become(s) active.

Transmission in merged arbitrating time windows

The purpose of a merged arbitrating time window is, to enable multiple nodes to send a limited number of frames which are transmitted in immediate sequence, the order given by CAN arbitration. It is not intended for burst transmission by a node. Since the node does not have exclusive access within this time window, it may happen that not all requested transmissions are successful.

Messages which have lost arbitration or were disturbed by an error, may be re-transmitted inside the same merged arbitrating time window. The re-transmission will not be started if the corresponding transmission request pending flag was reset by a successful Tx cancellation.

In single transmit windows, the Tx handler transmits the message indicated by the message number of the trigger element. In merged arbitrating time windows, it can handle up to three message numbers from the trigger list. Their transmissions will be attempted in the sequence defined by the trigger list. If the time mark of a fourth message is reached before the first is transmitted (or canceled by the Host), the fourth the request will be ignored.

The transmission inside a merged arbitrating time window is not time-triggered. The transmission of a message may start before its time mark, or after the time mark if the bus was not idle.

The messages transmitted by a specific node inside a merged arbitrating time window will be started in the order of their Tx_Triggers, so a message with low CAN priority may prevent the successful transmission of a following message with higher priority, if their is compelling bus traffic. This has to be considered for the configuration of the trigger list.

Time_Base_Triggers may be placed between consecutive Tx_Triggers to define the time until the data of the corresponding Tx buffer needs to be updated.

55.3.15 TTCAN interrupt and error handling

The TT interrupt register FDCAN_TTIR consists of our segments. Each interrupt can be enabled separately by the corresponding bit in the TT interrupt enable register FDCAN_TTIE. The flags remain set until the Host clears them. A flag is cleared by writing a 1 to the corresponding bit position.

The first segment consists of flags CER, AW, WT, and IWT. Each flag indicates a fatal error condition where the CAN communication is stopped. With the exception of IWT, these error conditions require a re-configuration of the FDCAN module before the communication can be restarted.

The second segment consists of flags ELC, SE1, SE2, TXO, TXU, and GTE. Each flag indicates an error condition where the CAN communication is disturbed. If they are caused by a transient failure, e.g. by disturbances on the CAN bus, they will be handled by the FDCAN protocol failure handling and do not require intervention by the application program.

The third segment consists of flags GTD, GTW, SWE, TTMI, and RTMI. The first two flags are controlled by global time events (level 0, 2 only) that require a reaction by the application
program. With a stop watch event triggered by a rising edge on pin fdcan_swt internal time values are captured. The trigger time mark interrupt notifies the application that a specific Time_Base_Trigger is reached. The register time mark interrupt signals that the time referenced by FDCAN_TTOCN.TMC (cycle, local, or global) equals time mark FDCAN_TTTMK.TM. It can also be used to finish a Gap.

The fourth segment consists of flags SOG, CSM, SMC, and SBC. These flags provide a means to synchronize the application program to the communication schedule.

55.3.16 Level 0

TTCAN level 0 is not part of ISO11898-4. This operation mode makes the hardware, that in TTCAN level 2 maintains the calibrated global time base, also available for event-driven CAN according to ISO11898-1.

Level 0 operation is configured via FDCAN_TTOCF.OM = 11. In this mode the FDCAN operates in event driven CAN communication, there is no fixed schedule, the configuration of FDCAN_TTOCF.GEN is ignored. External event-synchronized operation is not available in level 0. A synchronized time base is maintained by transmission of reference messages.

In level 0 the trigger memory is not active and therefore needs not to be configured. The time mark interrupt flag (FDCAN_TTIR.TTMI) is set when the cycle time has reached FDCAN_TTOCF.IRTO ` 0x200, it reminds the Host to set a transmission request for message buffer 0. The Watch_Trigger interrupt flag (FDCAN_TTIR.WT) is set when the cycle time has reached 0xFF00. These values were chosen to have enough margin for a stable clock calibration. There are no further TT-error-checks.

Register time mark interrupts (FDCAN_TTIR.RTMI) are also possible.

The reference message is configured as for level 2 operation. Received reference messages are recognized by the identifier configured in register FDCAN_TTRMC. For the transmission of reference messages only message buffer 0 may be used. The node transmits reference messages any time the Host sets a transmission request for message buffer 0, there is no reference trigger offset.

Level 0 operation is configured via:
- FDCAN_TTRMC
- FDCAN_TTOCF except EVTP, AWL, GEN
- FDCAN_TTMLM except ENTT, TXEW
- FDCAN_TURCF

Level 0 operation is controlled via:
- FDCAN_TTOCN except NiG, TMG, FGP, GCS, TTMIE
- FDCAN_TTGTP
- FDCAN_TTTMK
- FDCAN_TTIR excluding bits CER, AW, IWT SE2, SE1, TXO, TXU, SOG (no function)
- FDCAN_TTIR the following bits have changed function
  - TTMI not defined by trigger memory - activated at cycle time FDCAN_TTOCF.IRTO 0x200
  - WT not defined by trigger memory - activated at cycle time 0xFF00

Level 0 operation is signaled via:
- TTOST excluding bits AWE, WFE, GSI, GFI, RTO (no function)
Synchronizing

Figure 745 describes the states and the state transitions in TTCAN level 0 operation. level 0 has no In_Gap state.

Figure 745. Level 0 schedule synchronization state machine

Handling of error levels

During level 0 operation only the following error conditions may occur:
- Watch_Trigger_Reached (S3), reached cycle time 0xFF00
- CAN_Bus_Off (S3)

Since no S1 and S2 errors are possible, the error level can only switch between S0 (No error) and S3 (Severe error). In TTCAN level 0 an S3 error is handled differently. When error level S3 is reached, both FDCAN_TTOST.SYS and FDCAN_TTOST.MS are reset, and interrupt flags FDCAN_TTIR.GTE and FDCAN_TTIR.GTD are set.

When error level S3 (FDCAN_TTOST.EL = 11) is entered, bus monitoring mode is (contrary to TTCAN level 1 and level 2) not entered. S3 error level is left automatically after transmission (time master) or reception (time slave) of the next reference message.
Master slave relation

*Figure 746* describes the master slave relation in TTCAN level 0. In case of an S3 error the FDCAN returns to state Master_Off.

*Figure 746. Level 0 master to slave relation*

T0: Transition condition, always taking prevalence

T1: Reference message observed when not potential time master

T2: Reference message observed with master priority different from own master priority, Error state ≠ S3

T3: Reference message observed with master priority equal to own master priority, Error state ≠ S3

T4: Reference message observed with own master priority

T5: Reference message observed with master priority higher than own master priority

T6: Error state S3

T7: Error state S3

T8: Error state S3

55.3.17 Synchronization to external time schedule

This feature can be used to synchronize the phase of the FDCAN schedule to an external schedule (e.g. that of a second TTCAN network or FlexRay network). It is applicable only when the FDCAN is current time master (FDCAN_TTOST.MS = 11).

External synchronization is controlled by event trigger input pin fdcan_evt. If bit FDCAN_TTOCN.ESCN is set, a rising edge at event trigger pin fdcan_evt the FDCAN compares its actual cycle time with the target phase value configured by FDCAN_TTGTP.CTP.

Before setting FDCAN_TTOCN.ESCN the Host has to adapt the phases of the two time schedules e.g. by using the FDCAN gap control (see Section 55.3.10: TTCAN gap control). When the Host sets FDCAN_TTOCN.ESCN, FDCAN_TTOSTSPL is set.

If the difference between the cycle time and the target phase value FDCAN_TTGTP.CTP at the rising edge at event trigger pin fdcan_evt is greater than 9 NTU, the phase lock bit FDCAN_TTOST.SPL is reset, and interrupt flag FDCAN_TTIR.CSM is set.
FDCAN_TTOST.SPL is also reset (and FDCAN_TTIR.CSM is set), when another node becomes time master.

If both FDCAN_TTOST.SPL and FDCAN_TTOCN.ESCN are set, and if the difference between the cycle time and the target phase value FDCAN_TTGTP.CTP at the rising edge at event trigger pin fdcan_evt is lower or equal to nine NTU, the phase lock bit FDCAN_TTOST.SPL remains set, and the measured difference is used as reference trigger offset value to adjust the phase at the next transmitted reference message.

**Note:** The rising edge detection at event trigger pin fdcan_evt is enabled with the start of each basic cycle. The first rising edge triggers the compare of the actual cycle time with FDCAN_TTGTP.CTP. All further edges until the beginning of the next basic cycle are ignored.

### 55.3.18 FDCAN Rx buffer and FIFO element

Up to 64 Rx buffers and two Rx FIFOs can be configured in the message RAM. Each Rx FIFO section can be configured to store up to 64 received messages. The structure of a Rx buffer / FIFO element is shown in Table 477, the description is provided in Table 478.

55.3.19 FDCAN Tx buffer element

The Tx buffers section can be configured to hold dedicated Tx buffers as well as a Tx FIFO / Tx queue. In case that the Tx buffers section is shared by dedicated Tx buffers and a Tx FIFO / Tx queue, the dedicated Tx buffers start at the beginning of the Tx buffers section followed by the buffers assigned to the Tx FIFO or Tx queue. The Tx handler distinguishes between dedicated Tx buffers and Tx FIFO / Tx queue by evaluating the Tx buffer configuration FDCAN_TXBC.TFQS and FDCAN_TXBC.NDTB. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via register FDCAN_TXESC.

</tbody>
</table>
55.3.20 **FDCAN Tx event FIFO element**

Each element stores information about transmitted messages. By reading the Tx event FIFO the Host CPU gets this information in the order the messages were transmitted. Status information about the Tx event FIFO can be obtained from register FDCAN_TXEFS.

### Table 480. Tx buffer element description (continued)

<table>
<thead>
<tr>

<tr>
<td>Tn bits 7:0 DBm-3[7:0]</td>
<td>Data Byte m-3</td>
</tr>
</tbody>
</table>

1. The ESI bit of the transmit buffer is OR-ed with the error passive flag to decide the value of the ESI bit in the transmitted FD frame. As required by the CAN FD protocol specification, an error active node may optionally transmit the ESI bit recessive, but an error passive node will always transmit the ESI bit recessive.

2. When RTR = 1, the FDCAN transmits a remote frame according to ISO11898-1, even if FDCAN_CCCR.FDOE enables the transmission in CAN FD format.

3. Bits ESI, FDF, and BRS are only evaluated when CAN FD operation is enabled FDCAN_CCCR.FDOE = 1. Bit BRS is only evaluated when in addition FDCAN_CCCR.BRSE = 1.

<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| E0 bit 31 ESI | Error state indicator  
| – 0: Transmitting node is error active  
| – 1: Transmitting node is error passive |
| E0 bit 30 XTD | Extended Identifier  
| – 0: 11-bit standard identifier  
| – 1: 29-bit extended identifier |
| E0 bit 29 RTR | Remote transmission request  
| – 0: Transmit data frame  
| – 1: Transmit remote frame |
| E0 bits 28:0 ID[28:0] | Identifier  
| Standard or extended identifier depending on bit XTD. A standard identifier has to be written to ID[28:18]. |
| E1 bits 31:24 MM[7:0] | Message marker  
| Copied from Tx buffer into Tx event FIFO element for identification of Tx message status. |
55.3.21 FDCAN standard message ID filter element

Up to 128 filter elements can be configured for 11-bit standard IDs. When accessing a standard message ID filter element, its address is the filter list standard start address FDCAN_SIDFC.FLSSA plus the index of the filter element (0 … 127).

– 10: Transmission in spite of cancellation (always set for transmissions in DAR mode)  
– 11: Reserved |
| E1 bit 21 EDL | Extended data length  
– 0: Standard frame format  
– 1: FDCAN frame format (new DLC-coding and CRC) |
| E1 bit 20 BRS | Bitrate switching  
– 0: Frame transmitted without bitrate switching  
– 1: Frame transmitted with bitrate switching |
| T1 bits 19:16 DLC[3:0] | Data length code  
– 0 - 8: Frame with 0-8 data bytes transmitted  
– 9 - 15: Frame with eight data bytes transmitted |
| E1 bits 15:0 TXTS[15:0] | Tx timestamp  
Timestamp counter value captured on start of frame transmission. Resolution depending on configuration of the timestamp counter prescaler FDCAN_TSCC.TCP. |

Table 482. Tx Event FIFO element description (continued)
### Table 484. Standard message ID filter element field description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| Bit 31:30 SFT[1:0](1) | Standard filter type  
- 00: Range filter from SFID1 to SFID2  
- 01: Dual ID filter for SFID1 or SFID2  
- 10: Classic filter: SFID1 = filter, SFID2 = mask  
- 11: Filter element disabled |
| Bit 29:27 SFEC[2:0] | Standard filter element configuration  
All enabled filter elements are used for acceptance filtering of standard frames.  
Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If SFEC = “100”, “101”, or “110” a match sets interrupt flag FDCAN_IR.HPM and, if enabled, an interrupt is generated. In this case register FDCAN_HPMS is updated with the status of the priority match.  
- 000: Disable filter element  
- 001: Store in Rx FIFO 0 if filter matches  
- 010: Store in Rx FIFO 1 if filter matches  
- 011: Reject ID if filter matches  
- 100: Set priority if filter matches  
- 101: Set priority and store in FIFO 0 if filter matches  
- 110: Set priority and store in FIFO 1 if filter matches  
- 111: Store into Rx buffer or as debug message, configuration of FDCAN_SFT[1:0] ignored |
| Bits 26:16 SFID1[10:0] | Standard filter ID 1  
First ID of standard ID filter element.  
When filtering for Rx buffers or for debug messages this field defines the ID of a standard message to be stored. The received identifiers must match exactly, no masking mechanism is used. |
| SFID2[15:10] | Standard filter ID 2  
This bit field has a different meaning depending on the configuration of SFEC:  
- SFEC = 001 ... 110 Second ID of standard ID filter element  
- SFEC = 111 Filter for Rx buffers or for debug messages |
| SFID2[10:9] | Decides whether the received message is stored into an Rx buffer or treated as message A, B, or C of the debug message sequence.  
- 00: Store message into an Rx buffer  
- 01: Debug message A  
- 10: Debug message B  
- 11: Debug message C |
| SFID2[8:6] | Is used to control the filter event pins at the Extension Interface. A 1 at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one fdcan_pclk period in case the filter matches. SFID2[8] is used by the calibration unit. |
| SFID2[5:0] | Defines the offset to the Rx buffer start address FDCAN_RXBC.RBSA for storage of a matching message. |

1. With SFT = “11” the filter element is disabled and the acceptance filtering continues (same behavior as with SFEC = “000”).

**Note:** In case a reserved value is configured, the filter element is considered disabled.
55.3.22 **FDCAN extended message ID filter element**

Up to 64 filter elements can be configured for 29-bit extended IDs. When accessing an Extended message ID filter element, its address is the filter list extended start address FDCAN_XIDFC.FLESA plus two times the index of the filter element (0 … 63).

<td>– 0-7= Actual status</td>
</tr>
</tbody>
</table>

1. The trigger memory elements have to be written when the FDCAN is in INIT state. Write access to the trigger memory elements outside INIT state is not allowed. There is an exception for TMIN and TMEX when they are defined as part of a trigger memory element of TYPE Tx_Ref_Trigger. In this case they become active at the time mark modified by the actual reference trigger offset (TTOST[RTO]).

</tbody>
</table>

Bits 31:0 ETV[31:0]: Endianness Test value
The endianness test value is 0x8765 4321.

55.4.3 FDCAN data bit timing and prescaler register (FDCAN_DBTP)
Address offset: 0x000C
Reset value: 0x0000 0A33

This register is dedicated to data bit timing phase and only writable if bits
FDCAN_CCCR.CCE and FDCAN_CCCR.INIT are set. The CAN time quantum may be
programmed in the range from 1 to 32 FDCAN clock periods. tq = (DBRP + 1) FDCAN clock
periods.
DTSEG1 is the sum of Prop_Seg and Phase_Seg1. DTSEG2 is Phase_Seg2. Therefore the length of the bit time is \((DTSEG1 + DTSEG2 + 3)\) \(tq\) for programmed values, or \((Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2)\) \(tq\) for functional values.

The information processing time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.

Note: With a FDCAN clock of 8 MHz, the reset value 0x00000A33 configures the FDCAN for a fast bitrate of 500 kbit/s.

### 55.4.4 FDCAN test register (FDCAN_TEST)

Write access to this register has to be enabled by setting bit FDCAN_CCCR.TEST to 1. All register functions are set to their reset values when bit FDCAN_CCCR.TEST is reset.

Loop back mode and software control of Tx pin FDCANx_TX are hardware test modes. Programming TX differently from 00 may disturb the message transfer on the CAN bus.

Address offset: 0x0010

Reset value: 0x0000 0000
The RAM watchdog monitors the READY output of the message RAM. A message RAM access starts the message RAM watchdog counter with the value configured by the FDCAN_RWD.WDC bits.

The counter is reloaded with FDCAN_RWD.WDC bits when the message RAM signals successful completion by activating its READY output. In case there is no response from the message RAM until the counter has counted down to 0, the counter stops and interrupt flag FDCAN_IR.WDI bit is set. The RAM watchdog counter is clocked by the fdcan_pclk clock.

Address offset: 0x0014

Reset value: 0x0000 0000

55.4.5 FDCAN RAM watchdog register (FDCAN_RWD)

The RAM watchdog monitors the READY output of the message RAM. A message RAM access starts the message RAM watchdog counter with the value configured by the FDCAN_RWD.WDC bits.

The counter is reloaded with FDCAN_RWD.WDC bits when the message RAM signals successful completion by activating its READY output. In case there is no response from the message RAM until the counter has counted down to 0, the counter stops and interrupt flag FDCAN_IR.WDI bit is set. The RAM watchdog counter is clocked by the fdcan_pclk clock.

Address offset: 0x0014

Reset value: 0x0000 0000

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 RX: Receive pin
Monitors the actual value of transmit pin FDCANx_RX
0: The CAN bus is dominant (FDCANx_RX = 0)
1: The CAN bus is recessive (FDCANx_RX = 1)

Bits 6:5 TX[1:0]: Control of transmit pin
00: Reset value, FDCANx_TX TX is controlled by the CAN core, updated at the end of the CAN bit time
01: Sample point can be monitored at pin FDCANx_TX
10: Dominant (0) level at pin FDCANx_TX
11: Recessive (1) at pin FDCANx_TX

Bit 4 LBCK: Loop back mode
0: Reset value, loop back mode is disabled
1: Loop back mode is enabled (see Test modes)

Bits 3:0 Reserved, must be kept at reset value.
55.4.6 **FDCAN CC control register (FDCAN_CCCR)**

Address offset: 0x0018

Reset value: 0x0000 0001

For details about setting and resetting of single bits see *Software initialization*.

Bits 31:16  Reserved, must be kept at reset value.

Bit 15 **NISO**: Non ISO operation
- If this bit is set, the FDCAN uses the CAN FD frame format as specified by the Bosch CAN FD Specification V1.0.
  - 0: CAN FD frame format according to ISO11898-1
  - 1: CAN FD frame format according to Bosch CAN FD Specification V1.0

Bit 14 **TXP**: If this bit is set, the FDCAN pauses for two CAN bit times before starting the next transmission after successfully transmitting a frame.
- 0: disabled
- 1: enabled

Bit 13 **EFBI**: Edge Filtering during bus Integration
- 0: Edge filtering disabled
- 1: Two consecutive dominant tq required to detect an edge for hard synchronization

Bit 12 **PXHD**: Protocol exception handling disable
- 0: Protocol exception handling enabled
- 1: Protocol exception handling disabled

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **BRSE**: FDCAN bitrate Switching
- 0: Bitrate switching for transmissions disabled
- 1: Bitrate switching for transmissions enabled
Bit 8 **FDOE**: FD operation enable
- 0: FD operation disabled
- 1: FD operation enabled

Bit 7 **TEST**: Test mode enable
- 0: Normal operation, register TEST holds reset values
- 1: Test mode, write access to register TEST enabled

Bit 6 **DAR**: Disable automatic retransmission
- 0: Automatic retransmission of messages not transmitted successfully enabled
- 1: Automatic retransmission disabled

Bit 5 **MON**: Bus monitoring mode
Bit MON can only be set by software when both CCE and INIT are set to 1. The bit can be reset by the Host at any time.
- 0: Bus monitoring mode is disabled
- 1: Bus monitoring mode is enabled

Bit 4 **CSR**: Clock stop request
- 0: No clock stop is requested
- 1: Clock stop requested. When clock stop is requested, first INIT and then CSA will be set after all pending transfer requests have been completed and the CAN bus reached idle.

Bit 3 **CSA**: Clock stop acknowledge
- 0: No clock stop acknowledged
- 1: FDCAN may be set in power down by stopping APB clock and kernel clock

Bit 2 **ASM**: ASM restricted operation mode
The restricted operation mode is intended for applications that adapt themselves to different CAN bitrates. The application tests different bitrates and leaves the restricted operation mode after it has received a valid frame. In the optional restricted operation mode the node is able to transmit and receive data and remote frames and it gives acknowledge to valid frames, but it does not send active error frames or overload frames. In case of an error condition or overload condition, it does not send dominant bits, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication. The error counters are not incremented. Bit ASM can only be set by software when both CCE and INIT are set to 1. The bit can be reset by the software at any time. This bit will be set automatically set to 1 when the Tx handler was not able to read data from the message RAM in time.
If the FDCAN is connected to a clock calibration on CAN unit, ASM bit is set by hardware as long as the calibration is not completed.
- 0: Normal CAN operation
- 1: Restricted operation mode active

Bit 1 **CCE**: Configuration change enable
- 0: The CPU has no write access to the protected configuration registers
- 1: The CPU has write access to the protected configuration registers (while FDCAN_CCCR.INIT = 1 CCE bit is automatically cleared when INIT bit is cleared)

Bit 0 **INIT**: Initialization
- 0: Normal operation
- 1: Initialization is started (while FDCAN_CCCR.INIT = 1 CCE bit is automatically cleared when INIT bit is cleared)

**Note:** Due to the synchronization mechanism between the two clock domains, there may be a delay until the value written to INIT can be read back. Therefore the programmer has to
assure that the previous value written to INIT has been accepted by reading INIT before setting INIT to a new value.

55.4.7 FDCAN nominal bit timing and prescaler register (FDCAN_NBTP)

Address offset: 0x001C
Reset value: 0x06000A03

This register is dedicated to the nominal bit timing used during the arbitration phase, and is only writable if bits FDCAN_CCCR.CCE and FDCAN_CCCR.INIT are set. The CAN bit time may be programmed in the range of 4 to 81 tq. The CAN time quantum may be programmed in the range of [1 … 1024] FDCAN kernel clock periods.

\[ \text{tq} = (\text{BRP} + 1) \times \text{FDCAN clock period fdcan_tq_ck} \]

NTSEG1 is the sum of Prop_Seg and Phase_Seg1. NTSEG2 is Phase_Seg2. Therefore the length of the bit time is (programmed values) \([\text{NTSEG1} + \text{NTSEG2} + 3]\) tq or (functional values) \([\text{Sync_Seg} + \text{Prop_Seg} + \text{Phase_Seg1} + \text{Phase_Seg2}]\) tq.

The information processing time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.

Bits 31:25 **NSJW[6:0]:** Nominal (re)synchronization jump width
Should be smaller than NTSEG2, valid values are 0 to 127. The value used by the hardware is the one programmed, incremented by 1, i.e. \( t_{SJW} = (\text{NSJW} + 1) \times \text{tq} \).
These are protected write bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bits 24:16 **NBRP[8:0]:** Bitrate prescaler
Value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid values are 0 to 511. The value used by the hardware is the one programmed, incremented by 1.
These are protected write bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bits 15:8 **NTSEG1[7:0]:** Nominal time segment before sample point
Valid values are 0 to 255. The value used by the hardware is the one programmed, incremented by 1, i.e. \( t_{BS1} = (\text{NTSEG1} + 1) \times \text{tq} \).
These are protected write bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bit 7 Reserved, must be kept at reset value.

Bits 6:0 **NTSEG2[6:0]:** Nominal time segment after sample point
Valid values are 0 to 127. The value used by the hardware is the one programmed, incremented by 1, i.e. \( t_{BS2} = (\text{NTSEG2} + 1) \times \text{tq} \).
Controller area network with flexible data rate (FDCAN)

Note: With a CAN kernel clock of 8 MHz, the reset value of 0x00000A33 configures the FDCAN for a bitrate of 125 kbit/s.

55.4.8 FDCAN timestamp counter configuration register (FDCAN_TSCC)

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:16 **TCP[3:0]**: Timestamp counter prescaler
Configures the timestamp and timeout counters time unit in multiples of CAN bit times [1 … 16].
The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.
In CAN FD mode the internal timestamp counter TCP does not provide a constant time base due to the different CAN bit times between arbitration phase and data phase. Thus CAN FD requires an external counter for timestamp generation (TSS = 10).
These are protected write bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bits 15:2 Reserved, must be kept at reset value.

Bits 1:0 **TSS[1:0]**: Timestamp select
00: Timestamp counter value always 0x0000
01: Timestamp counter value incremented according to TCP
10: External timestamp counter from TIM3 value used (tim3_cnt[0:15])
11: Same as 00.
These are protected write bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

55.4.9 FDCAN timestamp counter value register (FDCAN_TSCV)

Address offset: 0x0024
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>

<th>22</th>
<th>21</th>
<th>20</th>
<th>19</th>
<th>18</th>
<th>17</th>
<th>16</th>
</tr>
</thead>
</table>
Note: A "wrap around" is a change of the timestamp counter value from non-0 to 0 not caused by write access to FDCAN_TSCV.

55.4.10 FDCAN timeout counter configuration register (FDCAN_TOCC)

Address offset: 0x0028
Reset value: 0xFFFF 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **TSC[15:0]:** Timestamp counter

The internal/external timestamp counter value is captured on start of frame (both Rx and Tx). When FDCAN_TSCC.TSS = 01, the timestamp counter is incremented in multiples of CAN bit times [1 … 16] depending on the configuration of FDCAN_TSCC.TCP. A wrap around sets interrupt flag FDCAN_IR.TSW. Write access resets the counter to 0. When FDCAN_TSCC.TSS = 10, TSC reflects the external timestamp counter value. A write access has no impact.

Bits 31:16 **TOP[15:0]:** Timeout period

Start value of the timeout counter (down-counter). Configures the timeout period. These are protected write bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.
Bits 15:3  Reserved, must be kept at reset value.

Bits 2:1  **TOS[1:0]: Timeout select**
When operating in Continuous mode, a write to FDCAN_TOCV presets the counter to the value configured by FDCAN_TOCC.TOP and continues down-counting. When the timeout counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by FDCAN_TOCC.TOP. Down-counting is started when the first FIFO element is stored.
00: Continuous operation
01: Timeout controlled by Tx event FIFO
10: Timeout controlled by Rx FIFO 0
11: Timeout controlled by Rx FIFO 1

These are protected write bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bit 0  **ETOC: Enable timeout counter**
0: Timeout counter disabled
1: Timeout counter enabled

This is a protected write bit, write access is possible only when the bit 1 (CCE) and bit 0 (INIT) of FDCAN_CCCR register are set to 1.

For more details see **Timeout counter**.

**TOC[15:0]**

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:0  **TOC[15:0]: Timeout counter**
The timeout counter is decremented in multiples of CAN bit times [1 … 16] depending on the configuration of FDCAN_TSCC.TCP. When decremented to 0, interrupt flag FDCAN_IR.TOO is set and the timeout counter is stopped. Start and reset/restart conditions are configured via FDCAN_TOCC.TOS.

**TCR[15:0]**

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:0  **TCR[15:0]: Error counter**
The error counter is incremented in multiples of CAN bit times [1 … 16] depending on the configuration of FDCAN_TSCC.TCP. When incremented to 0, interrupt flag FDCAN_IR.TOO is set and the error counter is stopped. Start and reset/restart conditions are configured via FDCAN_TOCC.TOS.
55.4.13 FDCAN protocol status register (FDCAN_PSR)

Address offset: 0x0044
Reset value: 0x0000 0707

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **CEL[7:0]:** CAN error logging

The counter is incremented each time when a CAN protocol error causes the transmit error counter or the receive error counter to be incremented. It is reset by read access to CEL. The counter stops at 0xFF; the next increment of TEC or REC sets interrupt flag FDCAN_IR.ELO.

Bit 15 **RP:** Receive error passive
0: The receive error counter is below the error passive level of 128
1: The receive error counter has reached the error passive level of 128

Bits 14:8 **REC[6:0]:** Receive error counter
Actual state of the receive error counter, values between 0 and 127.

Bits 7:0 **TEC[7:0]:** Transmit error counter
Actual state of the transmit error counter, values between 0 and 255.

When FDCAN_CCCR.ASM is set, the CAN protocol controller does not increment TEC and REC when a CAN protocol error is detected, but CEL is still incremented.
Bit 14 PXE: Protocol exception event
   0: No protocol exception event occurred since last read access
   1: Protocol exception event occurred

Bit 13 REDL: Received FDCAN message
   This bit is set independent of acceptance filtering.
   0: Since this bit was reset by the CPU, no FDCAN message has been received
   1: Message in FDCAN format with EDL flag set has been received
   Access type is RX: reset on read.

Bit 12 RBRS: BRS flag of last received FDCAN message
   This bit is set together with REDL, independent of acceptance filtering.
   0: Last received FDCAN message did not have its BRS flag set
   1: Last received FDCAN message had its BRS flag set
   Access type is RX: reset on read.

Bit 11 RESI: ESI flag of last received FDCAN message
   This bit is set together with REDL, independent of acceptance filtering.
   0: Last received FDCAN message did not have its ESI flag set
   1: Last received FDCAN message had its ESI flag set
   Access type is RX: reset on read.

Bits 10:8 DLEC[2:0]: Data Last error code
   Type of last error that occurred in the data phase of a FDCAN format frame with its BRS
   flag set. Coding is the same as for LEC. This field will be cleared to 0 when a FDCAN
   format frame with its BRS flag set has been transferred (reception or transmission)
   without error.
   Access type is RS: set on read.

Bit 7 BO: Bus_Off status
   0: The FDCAN is not Bus_Off
   1: The FDCAN is in Bus_Off state

Bit 6 EW: Warning status
   0: Both error counters are below the Error_Warning limit of 96
   1: At least one of error counter has reached the Error_Warning limit of 96

Bit 5 EP: Error Passive
   0: The FDCAN is in the Error_Active state. It normally takes part in bus communication
   and sends an active error flag when an error has been detected
   1: The FDCAN is in the Error_Passive state

Bits 4:3 ACT[1:0]: Activity
   Monitors the module CAN communication state.
   00: Synchronizing: node is synchronizing on CAN communication
   01: Idle: node is neither receiver nor transmitter
   10: Receiver: node is operating as receiver
   11: Transmitter: node is operating as transmitter
Note: When a frame in FDCAN format has reached the data phase with BRS flag set, the next CAN event (error or valid frame) will be shown in FLEC instead of LEC. An error in a fixed stuff bit of a FDCAN CRC sequence will be shown as a Form error, not Stuff error.

Note: The Bus_Off recovery sequence (see CAN Specification Rev. 2.0 or ISO11898-1) cannot be shortened by setting or resetting FDCAN_CCCR.INIT. If the device goes Bus_Off, it will set FDCAN_CCCR.INIT of its own, stopping all bus activities. Once FDCAN_CCCR.INIT has been cleared by the CPU, the device will then wait for 129 occurrences of bus Idle (129 × 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus_Off recovery sequence, the error management counters will be reset. During the waiting time after the reset of FDCAN_CCCR.INIT, each time a sequence of 11 recessive bits has been monitored, a Bit0 error code is written to FDCAN_PSR.LEC, enabling the CPU to readily check whether the CAN bus is stuck at dominant or continuously disturbed and to monitor the Bus_Off recovery sequence. FDCAN_ECR.REC is used to count these sequences.

55.4.14 FDCAN transmitter delay compensation register (FDCAN_TDCR)

Address offset: 0x0048

Reset value: 0x0000 0000
55.4.15 FDCAN interrupt register (FDCAN_IR)

The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the Host clears them. A flag is cleared by writing a 1 to the corresponding bit position.

Writing a 0 has no effect. A hard reset will clear the register. The configuration of IE controls whether an interrupt is generated. The configuration of ILS controls on which interrupt line an interrupt is signaled.

Address offset: 0x0050
Reset value: 0x0000 0000

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 ARA: Access to Reserved address
0: No access to reserved address occurred
1: Access to reserved address occurred

Bit 28 PED: Protocol error in data phase (data Bit time is used)
0: No protocol error in data phase
1: Protocol error in data phase detected (PSR.DLEC different from 0,7)
Bit 27 **PEA**: Protocol error in Arbitration phase (Nominal bit time is used)
   0: No protocol error in arbitration phase
   1: Protocol error in arbitration phase detected (PSR.LEC different from 0,7)

Bit 26 **WDI**: Watchdog interrupt
   0: No message RAM watchdog event occurred
   1: Message RAM watchdog event due to missing READY

Bit 25 **BO**: Bus_Off status
   0: Bus_Off status unchanged
   1: Bus_Off status changed

Bit 24 **EW**: Warning status
   0: Error_Warning status unchanged
   1: Error_Warning status changed

Bit 23 **EP**: Error Passive
   0: Error_Passive status unchanged
   1: Error_Passive status changed

Bit 22 **ELO**: Error logging Overflow
   0: CAN error logging counter did not overflow
   1: Overflow of CAN error logging counter occurred

Bits 21:20 Reserved, must be kept at reset value.

Bit 19 **DRX**: Message stored to dedicated Rx buffer
   The flag is set whenever a received message has been stored into a dedicated Rx buffer.
   0: No Rx buffer updated
   1: At least one received message stored into a Rx buffer

Bit 18 **TOO**: Timeout occurred
   0: No timeout
   1: Timeout reached

Bit 17 **MRAF**: Message RAM Access Failure
   The flag is set when the Rx handler
   1 Has not completed acceptance filtering or storage of an accepted message until the
     arbitration field of the following message has been received. In this case acceptance
     filtering or message storage is aborted and the Rx handler starts processing of the
     following message.
   1 Was unable to write a message to the message RAM. In this case message storage
     is aborted.

In both cases the FIFO put index is not updated or the New data flag for a dedicated Rx
buffer is not set. The partly stored message is overwritten when the next message is
stored to this location.

The flag is also set when the Tx handler was not able to read a message from the
message RAM in time. In this case message transmission is aborted. In case of a Tx
handler access failure the FDCAN is switched into restricted operation mode (see
Restricted operation mode). To leave restricted operation mode, the Host CPU has to
reset FDCAN_CCCR.ASM.

0: No message RAM access failure occurred
1: Message RAM access failure occurred
Bit 16  **TSW**: Timestamp wraparound  
0: No timestamp counter wraparound  
1: Timestamp counter wraparound  

Bit 15  **TEFL**: Tx event FIFO element Lost  
0: No Tx event FIFO element lost  
1: Tx event FIFO element lost, also set after write attempt to Tx event FIFO of size zero  

Bit 14  **TEFF**: Tx event FIFO Full  
0: Tx event FIFO not full  
1: Tx event FIFO full  

Bit 13  **TEFW**: Tx event FIFO Watermark Reached  
0: Tx event FIFO fill level below watermark  
1: Tx event FIFO fill level reached watermark  

Bit 12  **TEFN**: Tx event FIFO New Entry  
0: Tx event FIFO unchanged  
1: Tx handler wrote Tx event FIFO element  

Bit 11  **TFE**: Tx FIFO Empty  
0: Tx FIFO non-empty  
1: Tx FIFO empty  

Bit 10  **TCF**: Transmission cancellation finished  
0: No transmission cancellation finished  
1: Transmission cancellation finished  

Bit 9  **TC**: Transmission Completed  
0: No transmission completed  
1: Transmission completed  

Bit 8  **HPM**: High priority message  
0: No high priority message received  
1: High priority message received  

Bit 7  **RF1L**: Rx FIFO 1 message Lost  
0: No Rx FIFO 1 message lost  
1: Rx FIFO 1 message lost, also set after write attempt to Rx FIFO 1 of size zero  

Bit 6  **RF1F**: Rx FIFO 1 Full  
0: Rx FIFO 1 not full  
1: Rx FIFO 1 full  

Bit 5  **RF1W**: Rx FIFO 1 Watermark Reached  
0: Rx FIFO 1 fill level below watermark  
1: Rx FIFO 1 fill level reached watermark  

Bit 4  **RF1N**: Rx FIFO 1 new message  
0: No new message written to Rx FIFO 1  
1: New message written to Rx FIFO 1  

Bit 3  **RF0L**: Rx FIFO 0 message Lost  
0: No Rx FIFO 0 message lost  
1: Rx FIFO 0 message lost, also set after write attempt to Rx FIFO 0 of size zero  

Bit 2  **RF0F**: Rx FIFO 0 Full  
0: Rx FIFO 0 not full  
1: Rx FIFO 0 full  

Bit 1  **RF0W**: Rx FIFO 0 Watermark Reached  
0: Rx FIFO 0 fill level below watermark  
1: Rx FIFO 0 fill level reached watermark  

Bit 0  **RF0N**: Rx FIFO 0 new message  
0: No new message written to Rx FIFO 0  
1: New message written to Rx FIFO 0
55.4.16 FDCAN interrupt enable register (FDCAN_IE)

The settings in the interrupt enable register determine which status changes in the interrupt register will be signaled on an interrupt line.

Address offset: 0x0054

Reset value: 0x0000 0000

- 1: Interrupt enabled

Bit 9   **TCE**: Transmission completed interrupt enable
- 0: Interrupt disabled
- 1: Interrupt enabled

Bit 8   **HPME**: High priority message interrupt enable
- 0: Interrupt disabled
- 1: Interrupt enabled

Bit 7   **RF1LE**: Rx FIFO 1 message lost interrupt enable
- 0: Interrupt disabled
- 1: Interrupt enabled

Bit 6   **RF1FE**: Rx FIFO 1 full interrupt enable
- 0: Interrupt disabled
- 1: Interrupt enabled
55.4.17 FDCAN interrupt line select register (FDCAN_ILS)

This register assigns an interrupt generated by a specific interrupt flag from the interrupt register to one of the two module interrupt lines. For interrupt generation the respective interrupt line has to be enabled via FDCAN_IIE.EINT0 and FDCAN_IIE.EINT1.

**Bits 31:6** Reserved, must be kept at reset value.

**Bits 5:4** **ANFS[1:0]**: Accept non-matching frames standard

Defines how received messages with 11-bit ID that do not match any element of the filter list are treated.

- 00: Accept in Rx FIFO 0
- 01: Accept in Rx FIFO 1
- 10: Reject
- 11: Reject

These are protected write bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

**Bits 3:2** **ANFE[1:0]**: Accept non-matching frames extended

Defines how received messages with 29-bit ID that do not match any element of the filter list are treated.

- 00: Accept in Rx FIFO 0
- 01: Accept in Rx FIFO 1
- 10: Reject
- 11: Reject

These are protected write bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.
Bit 1 **RRFS**: Reject remote frames standard
- 0: Filter remote frames with 11-bit standard ID
- 1: Reject all remote frames with 11-bit standard ID
These are protected write bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bit 0 **RRFE**: Reject remote frames extended
- 0: Filter remote frames with 29-bit standard ID
- 1: Reject all remote frames with 29-bit standard ID
These are protected write bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

### 55.4.20 FDCAN standard ID filter configuration register (FDCAN_SIDFC)
Settings for 11-bit standard message ID filtering. The standard ID filter configuration register controls the filter path for standard messages as described in Figure 736.
Address offset: 0x0084
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit</th>

<td>Filter list standard start address</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **LSS[7:0]**: List size standard
- 0: No standard message ID filter
- 1-128: Number of standard message ID filter elements
>128: Values greater than 128 are interpreted as 128.
These are protected write bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bits 15:2 **FLSSA[13:0]**: Filter list standard start address
Start address of standard message ID filter list (32-bit word address, see Table 483: Standard message ID filter element). These are protected write bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bits 1:0 Reserved, must be kept at reset value.

### 55.4.21 FDCAN extended ID filter configuration register (FDCAN_XIDFC)
Settings for 29-bit extended filter configuration register controls the filter path for standard messages as described in Figure 737: Extended message ID filter path.
Address offset: 0x0088
Reset value: 0x0000 0000
**Controller area network with flexible data rate (FDCAN)**

**FDCAN extended ID and mask register (FDCAN_XIDAM)**

Address offset: 0x0090

Reset value: 0x1FFF FFFF

| bits: 31-24 | reserved, must be kept at reset value. |
| bits: 23-16 | **LSE[7:0]**: List size extended |
| 0: no standard message ID filter |
| 1-128: number of standard message ID filter elements |
| >128: values greater than 128 are interpreted as 128. |
| these are protected write bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1. |

| bits: 15-2 | FLESA[13:0]: Filter list standard start address |
| start address of standard message ID filter list (32-bit word address, see Table 485: Extended message ID filter element). |
| these are protected write bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1. |

| bits: 1-0 | reserved, must be kept at reset value. |

**55.4.22 FDCAN extended ID and mask register (FDCAN_XIDAM)**

Address offset: 0x0090

Reset value: 0x1FFF FFFF

| bits: 31-29 | reserved, must be kept at reset value. |
| bits: 28-0 | **EIDM[28:0]**: Extended ID Mask |
| for acceptance filtering of extended frames the extended ID AND Mask is AND-ed with the message ID of a received frame. Intended for masking of 29-bit IDs in SAE J1939. |
| with the reset value of all bits set to 1 the mask is not active. |
| these are protected write bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1. |
55.4.23  FDCAN high priority message status register (FDCAN_HPMS)

This register is updated every time a message ID filter element configured to generate a priority event match. This can be used to monitor the status of incoming high priority messages and to enable fast access to these messages.

Address offset: 0x0094
Reset value: 0x0000 0000

FLST  FIDX[6:0]  MSI[1:0]  BIDX[5:0]

Bits 31:16  Reserved, must be kept at reset value.

Bit 15  FLST: Filter list
Indicates the filter list of the matching filter element.
0: Standard filter list
1: Extended filter list

Bits 14:8  FIDX[6:0]: Filter index
Index of matching filter element. Range is 0 to FDCAN_SIDFC[LSS] - 1 or FDCAN_XIDFC[LSE] - 1.

Bits 7:6  MSI[1:0]: Message Storage Indicator
00: No FIFO selected
01: FIFO overrun
10: Message stored in FIFO 0
11: Message stored in FIFO 1

Bits 5:0  BIDX[5:0]: Buffer index
Index of Rx FIFO element to which the message was stored. Only valid when MSI[1] = 1.

Bits 31:0  **ND[31:0]: New data[31:0]**  
The register holds the New data flags of Rx buffers 0 to 31. The flags are set when the respective Rx buffer has been updated from a received frame. The flags remain set until the Host clears them. A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect. A hard reset will clear the register.  
0: Rx buffer not updated  
1: Rx buffer updated from new message

| rw  | rw  | rw  | rw  | rw  | rw  | rw  | rw  | rw  | rw  | rw  | rw  | rw  | rw  | rw  |
Bit 31  **F0OM**: FIFO 0 operation mode
   FIFO 0 can be operated in blocking or in overwrite mode.
   0: FIFO 0 blocking mode
   1: FIFO 0 overwrite mode

Bits 30:24 **F0WM[6:0]**: FIFO 0 Watermark
   0: Watermark interrupt disabled
   1-64: Level for Rx FIFO 0 watermark interrupt (FDCAN_IR.RF0W)
   >64: Watermark interrupt disabled
   These are protected write bits, write access is possible only when bit CCE and bit INIT of
   FDCAN_CCCR register are set to 1.

Bit 23 Reserved, must be kept at reset value.

Bits 22:16 **F0S[6:0]**: Rx FIFO 0 size
   0: No Rx FIFO 0
   1-64: Number of Rx FIFO 0 elements
   >64: Values greater than 64 are interpreted as 64
   The Rx FIFO 0 elements are indexed from 0 to F0S-1.

Bits 15:2 **F0SA[13:0]**: Rx FIFO 0 start address
   Start address of Rx FIFO 0 in message RAM (32-bit word address, see Figure 735).

   Bits 1:0 Reserved, must be kept at reset value.

   Bits 31:26 Reserved, must be kept at reset value.

   Bit 25 **RF0L**: Rx FIFO 0 message Lost
   This bit is a copy of interrupt flag FDCAN_IR.RF0L. When FDCAN_IR.RF0L is reset, this
   bit is also reset.
   0: No Rx FIFO 0 message lost
   1: Rx FIFO 0 message lost, also set after write attempt to Rx FIFO 0 of size zero

   Bit 24 **F0F**: Rx FIFO 0 Full
   0: Rx FIFO 0 not full
   1: Rx FIFO 0 full

   Bits 23:22 Reserved, must be kept at reset value.

   Bits 21:16 **F0PI[5:0]**: Rx FIFO 0 put index
   Rx FIFO 0 write index pointer, range 0 to 63.
55.4.28 FDCAN Rx FIFO 0 acknowledge register (FDCAN_RXF0A)

Address offset: 0x00A8
Reset value: 0x0000 0000

Bits 15:14 Reserved, must be kept at reset value.
Bits 13:8 F0GI[5:0]: Rx FIFO 0 get index
Rx FIFO 0 read index pointer, range 0 to 63.
Bit 7 Reserved, must be kept at reset value.
Bits 6:0 F0FL[6:0]: Rx FIFO 0 fill level
Number of elements stored in Rx FIFO 0, range 0 to 64.

55.4.29 FDCAN Rx buffer configuration register (FDCAN_RXBC)

Address offset: 0x00AC
Reset value: 0x0000 0000

Bits 31:6 Reserved, must be kept at reset value.
Bits 5:0 F0AI[5:0]: Rx FIFO 0 acknowledge index
After the Host has read a message or a sequence of messages from Rx FIFO 0 it has to write the buffer index of the last element read from Rx FIFO 0 to F0AI. This will set the Rx FIFO 0 get index FDCAN_RXF0S.F0GI to F0AI + 1 and update the FIFO 0 fill level FDCAN_RXF0S.F0FL.
### 55.4.30 FDCAN Rx FIFO 1 configuration register (FDCAN_RXF1C)

Address offset: 0x00B0  
Reset value: 0x0000 0000

<td>2</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bit 31  Reserved, must be kept at reset value.

Bit 30  **TFQM**: Tx FIFO/queue mode.

0: Tx FIFO operation
1: Tx queue operation.

These are protected write bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bits 29:24  **TFQS[5:0]**: Transmit FIFO/queue size.

0: No Tx FIFO/queue
1-32: Number of Tx buffers used for Tx FIFO/queue
>32: Values greater than 32 are interpreted as 32.

These are protected write bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.
55.4.35 FDCAN Tx FIFO/queue status register (FDCAN_TXFQS)

The Tx FIFO/queue status is related to the pending Tx requests listed in register FDCAN_TXBRP. Therefore the effect of add/cancellation requests may be delayed due to a running Tx scan (FDCAN_TXBRP not yet updated).

Address offset: 0x00C4
Reset value: 0x0000 0000

| Bits 31:22 | Reserved, must be kept at reset value. |
| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 | | | | | | | | | | | | | | | | TFQF | TFQPI[4:0] |

| 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0 | | | | | | | | | | | | | | | | TFGI[4:0] | TFFL[5:0] |
| - | - | - | - | - | - | - | - | - | - | - | - | - | - | - | r | r | r | r | r | r |

Bits 31:22  Reserved, must be kept at reset value.

Bit 21  **TFQF**: Tx FIFO/queue Full
0  Tx FIFO/queue not full
1  Tx FIFO/queue full

Bits 20:16  **TFQPI[4:0]**: Tx FIFO/queue put index
Tx FIFO/queue write index pointer, range 0 to 31

Bits 15:13  Reserved, must be kept at reset value.

Bits 12:8  **TFGI[4:0]**:
Tx FIFO get index.
Tx FIFO read index pointer, range 0 to 31. Read as zero when Tx queue operation is configured (FDCAN_TXBC.TFQM = 1)
Bits 7:6 Reserved, must be kept at reset value.

Bits 5:0 **TFFL[5:0]**: Tx FIFO free level
   Number of consecutive free Tx FIFO elements starting from TFGI, range 0 to 32. Read as zero when Tx queue operation is configured (FDCAN_TXBC.TFQM = 1).

**Note:** In case of mixed configurations where dedicated Tx buffers are combined with a Tx FIFO or a Tx queue, the put and get index indicate the number of the Tx buffer starting with the first dedicated Tx buffers. For example: For a configuration of 12 dedicated Tx buffers and a Tx FIFO of 20 buffers a put index of 15 points to the fourth buffer of the Tx FIFO.

### 55.4.36 FDCAN Tx buffer element size configuration register (FDCAN_TXESC)

Configures the number of data bytes belonging to a Tx buffer element. Data field sizes >8 bytes are intended for CAN FD operation only.

Address offset: 0x00C8

Reset value: 0x0000 0000

Bits 31:3 Reserved, must be kept at reset value.

Bits 2:0 **TBDS[2:0]**: Tx buffer data Field size:
  000: 8 byte data field
  001: 12 byte data field
  010: 16 byte data field
  011: 20 byte data field
  100: 24 byte data field
  101: 32 byte data field
  110: 48 byte data field
  111: 64 byte data field
55.4.37  FDCAN Tx buffer request pending register (FDCAN_TXBRP)

Address offset: 0x00CC
Reset value: 0x0000 0000

Bits 31:0  **TRP[31:0]**: Transmission request pending.
Each Tx buffer has its own transmission request pending bit. The bits are set via register FDCAN_TXBAR. The bits are reset after a requested transmission has completed or has been canceled via register FDCAN_TXBCR.
FDCAN_TXBRP bits are set only for those Tx buffers configured via FDCAN_TXBC. After a FDCAN_TXBRP bit has been set, a Tx scan (see Filtering for Debug messages) is started to check for the pending Tx request with the highest priority (Tx buffer with lowest message ID).
A cancellation request resets the corresponding transmission request pending bit of register FDCAN_TXBRP. In case a transmission has already been started when a cancellation is requested, this is done at the end of the transmission, regardless whether the transmission was successful or not. The cancellation request bits are reset directly after the corresponding FDCAN_TXBRP bit has been reset.
After a cancellation has been requested, a finished cancellation is signaled via FDCAN_TXBCF
– after successful transmission together with the corresponding FDCAN_TXBTO bit
– when the transmission has not yet been started at the point of cancellation
– when the transmission has been aborted due to lost arbitration
– when an error occurred during frame transmission
In DAR mode all transmissions are automatically canceled if they are not successful. The corresponding FDCAN_TXBCF bit is set for all unsuccessful transmissions.
0: No transmission request pending
1: Transmission request pending

**Note:**  FDCAN_TXBRP bits set while a Tx scan is in progress are not considered during this particular Tx scan. In case a cancellation is requested for such a Tx buffer, this add request is canceled immediately, the corresponding FDCAN_TXBRP bit is reset.
55.4.38  FDCAN Tx buffer add request register (FDCAN_TXBAR)

Address offset: 0x00D0
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>

<td>0</td>
</tr>
</tbody>
</table>

Bits 31:0  AR[31:0]: Add request
Each Tx buffer has its own add request bit. Writing a 1 will set the corresponding add request bit; writing a 0 has no impact. This enables the Host to set transmission requests for multiple Tx buffers with one write to FDCAN_TXBAR. FDCAN_TXBAR bits are set only for those Tx buffers configured via FDCAN_TXBC. When no Tx scan is running, the bits are reset immediately, else the bits remain set until the Tx scan process has completed.
0: No transmission request added
1: Transmission requested added.

Note:  If an add request is applied for a Tx buffer with pending transmission request (corresponding FDCAN_TXBRP bit already set), the request is ignored.

55.4.39  FDCAN Tx buffer cancellation request register (FDCAN_TXBCR)

**Bit 31  **RMPS**: Reference message Payload select
- Ignored in case of time slaves.
- 0: Reference message has no additional payload
- 1: The following elements are taken from Tx buffer 0:
  - Message marker MM,
  - Event FIFO control EFC,
  - Data length code DLC,
  - Data Bytes DB (level 1: bytes 2-8, level 0, 2: bytes 5-8)
  These are protected write bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

**Bit 30  **XTD**: Extended identifier
- 0: 11-bit standard identifier
- 1: 29-bit extended identifier
  These are protected write bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.
Bit 29  Reserved, must be kept at reset value.

Bits 28:0  **RID[28:0]**: Reference identifier.
Identifier transmitted with reference message and used for reference message filtering.
Standard or extended reference identifier depending on bit XTD. A standard identifier has to be written to ID[28:18].
These are protected write bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bits 31:27  Reserved, must be kept at reset value.

Bit 26  **EVTP**: Event trigger polarity.
0: Rising edge trigger
1: Falling edge trigger
These are protected write bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bit 25  **ECC**: Enable clock calibration.
0: Automatic clock calibration in FDCAN level 0, 2 is disabled
1: Automatic clock calibration in FDCAN level 0, 2 is enabled
These are protected write bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bit 24  **EGTF**: Enable global time Filtering.
0: Global time filtering in FDCAN level 0, 2 is disabled
1: Global time filtering in FDCAN level 0, 2 is enabled
These are protected write bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bits 23:16  **AWL[7:0]**: Application watchdog limit.
The application watchdog can be disabled by programming AWL to 0x00.
0x00–FF: Maximum time after which the application has to serve the application watchdog. The application watchdog is incremented once each 256 NTUs.
These are protected write bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.
Bit 15  **EECS**: Enable external clock synchronization
If enabled, TUR configuration (FDCAN_TURCF.NCL only) may be updated during FDCAN operation.
0: External clock synchronization in FDCAN level 0, 2 disabled
1: External clock synchronization in FDCAN level 0, 2 enabled
These are protected write bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bits 14:8  **IRTO[6:0]**: Initial reference trigger offset.
0x00–7F Positive offset, range from 0 to 127
These are protected write bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bits 7:5  **LDSDL[2:0]**: LD of synchronization deviation limit.
The synchronization deviation limit SDL is configured by its dual logarithm LDSDL with SDL = 2 * (LDSDL + 5). SDL is comprised between 32 and 4096. It should not exceed the clock tolerance given by the CAN bit timing configuration.
These are protected write bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bit 4  **TM**: Time master.
0: Time master function disabled
1: Potential time master
These are protected write bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bit 3  **GEN**: Gap enable.
0: Strictly time-triggered operation
1: External event-synchronized time-triggered operation
These are protected write bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bit 2  Reserved, must be kept at reset value.

Bits 1:0  **OM[1:0]**: Operation mode.
00: Event-driven CAN communication, default
01: TTCAN level 1
10: TTCAN level 2
11: TTCAN level 0
These are protected write bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

55.4.50  **FDCAN TT matrix limits register (FDCAN_TTMLM)**
Address offset: 0x010C
Reset value: 0x0000 0000
Note: ISO 11898-4, Section 5.2.1 requires that only the listed cycle count values are configured. Other values are possible, but may lead to inconsistent matrix cycles.

55.4.51 FDCAN TUR configuration register (FDCAN_TURCF)

The length of the NTU is given by: \( NTU = \text{CAN clock period} \times \text{NC/DC} \).

NC is an 18-bit value. Its high part, \( \text{NCH}[17:16] \) is hard wired to 0b01. Therefore the range of NC extends from 0x10000 to 0x1FFFF. The value configured by NCL is the initial value for NC.
FDCAN_TURNNAV[15:0]. DC is set to 0x1000 by hardware reset and it may not be written to 0x0000.

- Level 1: NC 4 × DC and NTU = CAN bit time
- Levels 0 and 2: NC 8 × DC

The actual value of FDCAN_TUR may be changed by the clock drift compensation function of TTCAN level 0 and level 2 in order to adjust the node local view of the NTU to the time master view of the NTU. DC will not be changed by the automatic drift compensation, FDCAN_TURNNAV may be adjusted around NC in the range of the synchronization deviation limit given by FDCAN_TTOCF.LDSDL. NC and DC should be programmed to the largest suitable values in achieve the best computational accuracy for the drift compensation process.

Address offset: 0x0110
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>

<td>DC[13:0]: Denominator configuration.</td>
</tr>
<tr>
<td>15:0</td>
<td>NCL[15:0]: Numerator configuration low.</td>
</tr>
</tbody>
</table>

Bit 31 ELT: Enable local time.
0: Local time is stopped, default
1: Local time is enabled

These are protected write bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Note: The local time is started by setting ELT. It remains active until ELT is reset or until the next hardware reset. FDCAN_TURCF.DC is locked when FDCAN_TURCF.ELT = 1. If ELT is written to 0, the readable value will stay at 1 until the new value has been synchronized into the CAN clock domain. During this time write access to the other bits of the register remains locked.

Bits 29:16 DC[13:0]: Denominator configuration.
0x0000: Illegal value
0x0001 to 0x3FFF: Denominator configuration

These are protected write bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bits 15:0 NCL[15:0]: Numerator configuration low.
Write access to the TUR numerator configuration low is only possible during configuration with FDCAN_TURCF.ELT = 0 or if FDCAN_TTOCF.EECS (external clock synchronization enabled) is set. When a new value for NCL is written outside TT configuration mode, the new value takes effect when FDCAN_TTOST.WECS is cleared to 0. NCL is locked FDCAN_TTOST.WECS is 1.
0x0000–FFFF Numerator configuration low

These are protected write bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.
Note: If NC < 7 × DC in TTCAN level 1, it is required that subsequent time marks in the trigger memory must differ by at least two NTUs.

55.4.52 FDCAN TT operation control register (FDCAN_TTOCN)

Address offset: 0x0114

</tbody>
</table>
Bit 9  **GCS**: Gap control select  
0: Gap control independent from event trigger  
1: Gap control by input event trigger pin  

Bit 8  **TTIE**: Trigger time mark interrupt pulse enable  
External time mark events are configured by trigger memory element TMEX. A trigger time mark interrupt pulse is generated when the trigger memory element becomes active, and the FDCAN is in synchronization state In_Schedule or In_Gap.  
0: Trigger time mark interrupt output fdcan1_tmp for more than one instance and fdcan_tmp if only one instance disabled  
1: Trigger time mark interrupt output fdcan1_tmp for more than one instance and fdcan_tmp if only one instance enabled  

Bits 7:6  **TMC[1:0]**: Register time mark Compare.  
00: No Register time mark interrupt generated  
01: Register time mark interrupt if time mark = cycle time  
10: Register time mark interrupt if time mark = local time  
11: Register time mark interrupt if time mark = global time  

*Note: When changing the time mark reference (cycle, local, global time), it is recommended to first write TMC = 00, then reconfigure FDCAN_TTTMK, and finally set FDCAN_TMC to the intended time reference.*  

Bit 5  **RTIE**: Register time mark interrupt pulse enable.  
Register time mark interrupts are configured by register FDCAN_TTTMK. A register time mark interrupt pulse with the length of one fdcan_tq_ck period is generated when time referenced by FDCAN_TTOCN.TMC (cycle, local, or global) equals FDCAN_TTTMK.TM, independent of the synchronization state.  
0: Register time mark interrupt output disabled  
1: Register time mark interrupt output enabled  

Bits 4:3  **SWS[1:0]**: Stop watch source.  
00: Stop watch disabled  
01: Actual value of cycle time is copied to FDCAN_TTCPT.SWV  
10: Actual value of local time is copied to FDCAN_TTCPT.SWV  
11: Actual value of global time is copied to FDCAN_TTCPT.SWV  

Bit 2  **SWP**: Stop watch polarity.  
0: Rising edge trigger  
1: Falling edge trigger  

Bit 1  **ECS**: External clock synchronization.  
Writing a 1 to ECS sets FDCAN_TTOST.WECS if the node is the actual time master. ECS is reset after one APB clock period. The external clock synchronization takes effect at the start of the next basic cycle.  

Bit 0  **SGT**: Set global time.  
Writing a 1 to SGT sets FDCAN_TTOST.WGDT if the node is the actual time master. SGT is reset after one APB clock period. The global time preset takes effect when the node transmits the next reference message with the Master_Ref_Mark modified by the preset value written to FDCAN_TTGTP.
55.4.53  FDCAN TT global time preset register (FDCAN_TTGTP)

If TTOST.WGDT is set, the next reference message will be transmitted with the Master_Ref_Mark modified by the preset value and with Disc_Bit = 1, presetting the global time in all nodes simultaneously.

TP is reset to 0x0000 each time a reference message with Disc_Bit = 1 becomes valid or if the node is not the current time master. TP is locked while FDCAN_TTOST.WGTD = 1 after setting FDCAN_TTOCN.SGT until the reference message with Disc_Bit = 1 becomes valid or until the node is no longer the current time master.

Address offset: 0x0118
Reset value: 0x0000 0000

<td></td>
</tr>
</tbody>
</table>

Bits 31:16  CTP[15:0]: Cycle time target phase
CTP is write-protected while FDCAN_TTOCN.ESCN or FDCAN_TTOST.SPL are set (see Section 55.3.17: Synchronization to external time schedule).
0x0000–FFFF Defines the target value of cycle time when a rising edge of event trigger is expected.

Bits 15:0  TP[15:0]: Time Preset.
TP is write-protected while FDCAN_TTOST.WGTD is set.
0x0000–7FFF next master reference mark = master reference mark + TP
0x8000 reserved
0x8001–FFFF Next master reference mark = master reference mark - (0x10000 - TP).

55.4.54  FDCAN TT time mark register (FDCAN_TTTMK)

A time mark interrupt (FDCAN_TTIR.TMI = 1) is generated when the time base indicated by FDCAN_TTOCN.TMC (cycle time, local time, or global time) has the same value as TM.

Address offset: 0x011C
Reset value: 0x0000 0000

Bit 31  **LCKM**: TT time mark register Locked.
Always set by a write access to registers FDCAN_TTOCN. Set by write access to register FDCAN_TTTMK when FDCAN_TTOCN.TMC 00. Reset when the registers have been synchronized into the CAN clock domain.
0: Write access to FDCAN_TTTMK enabled
1: Write access to FDCAN_TTTMK locked

Bits 30:23 Reserved, must be kept at reset value.

Bits 22:16  **TICC[6:0]**: Time mark cycle code.
Cycle count for which the time mark is valid.
0b000000x valid for all cycles
0b000001c valid every second cycle at cycle count mod2 = c
0b00001cc valid every fourth cycle at cycle count mod4 = cc
0b0001ccc valid every eighth cycle at cycle count mod8 = ccc
0b001cccc valid every sixteenth cycle at cycle count mod16 = ccccc
0b01ccccc valid every thirty-second cycle at cycle count mod32 = ccccc
0b1cccccc valid every sixty-fourth cycle at cycle count mod64 = cccccc

Bits 15:0  **TM[15:0]**: Time mark.
0x0000–FFFF time mark

**Note**: When using byte access to register FDCAN_TTTMK it is recommended to first disable the time mark compare function (FDCAN_TTOCN.TMC = 00) to avoid comparisons on inconsistent register values.

### 55.4.55 FDCAN TT interrupt register (FDCAN_TTIR)

The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the Host clears them. A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect. A hard reset will clear the register.

Bits 31:19 Reserved, must be kept at reset value.

Bit 18  **CER**: Configuration error.
Trigger out of order.
0: No error found in trigger list
1: Error found in trigger list
Bit 17  **AW**: Application watchdog.
0: Application watchdog served in time
1: Application watchdog not served in time

Bit 16  **WT**: Watch trigger.
0: No missing reference message
1: Missing reference message (level 0: cycle time 0xFF00)

Bit 15  **IWTG**: Initialization watch trigger.
The initialization is restarted by resetting IWT.
0: No missing reference message during system startup
1: No system startup due to missing reference message

Bit 14  **ELC**: Error level Changed.
Not set when error level changed during initialization.
0: No change in error level
1: Error level changed

Bit 13  **SE2**: Scheduling error 2.
0: No scheduling error 2
1: Scheduling error 2 occurred

Bit 12  **SE1**: Scheduling error 1.
0: No scheduling error 1
1: Scheduling error 1 occurred

Bit 11  **TXO**: Tx count overflow.
0: Number of Tx trigger as expected
1: More Tx trigger than expected in one cycle

Bit 10  **TXU**: Tx count underflow.
0: Number of Tx trigger as expected
1: Less Tx trigger than expected in one cycle

Bit 9  **GTE**: Global time error.
Synchronization deviation SD exceeds limit specified by FDCAN_TTOCF.LDSDL, TTCAN level 0, 2 only.
0: Synchronization deviation within limit
1: Synchronization deviation exceeded limit

Bit 8  **GTD**: Global time discontinuity.
0: No discontinuity of global time
1: Discontinuity of global time

Bit 7  **GTW**: Global time wrap
0: No global time wrap occurred
1: Global time wrap from 0xFFFF to 0x0000 occurred

Bit 6  **SWE**: Stop watch event
0: No rising/falling edge at stop watch trigger pin detected
1: Rising/falling edge at stop watch trigger pin detected
Bit 5  **TTMI**: Trigger time mark event internal
Internal time mark events are configured by trigger memory element TMIN (see Section 55.3.23: FDCAN trigger memory element). Set when the trigger memory element becomes active, and the FDCAN is in synchronization state In_Gap or In_Schedule.
0: Time mark not reached
1: Time mark reached (level 0: cycle time FDCAN_TTOCF.RTO x 0x200)

Bit 4  **RTMI**: Register time mark interrupt.
Set when time referenced by TTOCN.TMC (cycle, local, or global) equals FDCAN_TTTMK.TM, independently from the synchronization state.
0: Time mark not reached
1: Time mark reached

Bit 3  **SOG**: Start of Gap
0: No reference message seen with Next_is_Gap bit set
1: Reference message with Next_is_Gap bit set becomes valid

Bit 2  **CSM**: Change of synchronization mode.
0: No change in master to slave relation or schedule synchronization
1: Master to slave relation or schedule synchronization changed, also set when FDCAN_TTOST.SPL is reset

Bit 1  **SMC**: Start of matrix cycle.
0: No matrix cycle started since bit has been reset
1: Matrix cycle started

Bit 0  **SBC**: Start of basic cycle.
0: No basic cycle started since bit has been reset
1: Basic cycle started

### 55.4.56 FDCAN TT interrupt enable register (FDCAN_TTIE)

The settings in the TT interrupt enable register determine which status changes in the TT interrupt register will result in an interrupt.

- 1: TT interrupt enabled

### 55.4.57 FDCAN TT interrupt line select register (FDCAN_TTILS)

The TT interrupt Line select register assigns an interrupt generated by a specific interrupt flag from the TT interrupt register to one of the two module interrupt lines. For interrupt generation the respective interrupt line has to be enabled via FDCAN_ILE.EINT0 and FDCAN_ILE.EINT1.

Address offset: 0x0128

### 55.4.58 FDCAN TT operation status register (FDCAN_TTOST)

Address offset: 0x012C

Reset value: 0x0000 0080

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td><strong>SPL</strong> Schedule phase lock.</td>
<td>0: Phase outside range 1: Phase inside range</td>
</tr>
<tr>
<td></td>
<td>The bit is valid only when external synchronization is enabled (FDCAN_TTOCN.ESCN = 1). In this case it signals that the difference between cycle time configured by FDCAN_TTGTP.CTP and the cycle time at the rising edge at event trigger pin is less or equal 9 NTU (see Section 55.3.17: Synchronization to external time schedule).</td>
<td></td>
</tr>
<tr>
<td>30</td>
<td><strong>WECS</strong> Wait for external clock synchronization.</td>
<td>0: No external clock synchronization pending 1: Node waits for external clock synchronization to take effect. The bit is reset at the start of the next basic cycle.</td>
</tr>
<tr>
<td>29</td>
<td><strong>AWE</strong> Application watchdog event.</td>
<td>The application watchdog is served by reading FDCAN_TTOST. When the watchdog is not served in time, bit AWE is set, all FDCAN communication is stopped, and the FDCAN is set into bus monitoring mode. 0: Application watchdog served in time 1: Failed to serve application watchdog in time</td>
</tr>
<tr>
<td>28</td>
<td><strong>WFE</strong> Wait for event.</td>
<td>0: No Gap announced, reset by a reference message with Next_is_Gap = 0 1: Reference message with Next_is_Gap = 1 received</td>
</tr>
<tr>
<td>27</td>
<td><strong>GSI</strong> Gap started Indicator.</td>
<td>0: No Gap in schedule, reset by each reference message and for all time slaves 1: Gap time after basic cycle has started</td>
</tr>
<tr>
<td>26-24</td>
<td><strong>TMP[2:0]</strong> Time master priority.</td>
<td>0x0-7 Priority of actual time master</td>
</tr>
</tbody>
</table>

Bits 25:24 **WGT[2:0]**: GFI (GFI), Res_5, Res_4, Res_3, Res_2, Res_1, Res_0, Res_31-26:** This register contains various flags and status information related to the FDCAN TT operation status. The flags and their descriptions are as follows:

- **SPL** (Schedule phase lock): Indicates whether the current phase is inside or outside the schedule range. This bit is valid only when external synchronization is enabled.
- **WECS** (Wait for external clock synchronization): Indicates if the node is waiting for an external clock synchronization to take effect.
- **AWE** (Application watchdog event): Indicates if the application watchdog event has been served.
- **WFE** (Wait for event): Indicates if a Gap event has been announced or not.
- **GSI** (Gap started Indicator): Indicates if a Gap has started.
- **TMP[2:0]** (Time master priority): Specifies the priority of the time master.
Bit 23  **GFI**: Gap finished Indicator.
Set when the CPU writes FDCAN_TTOCN.FGP, or by a time mark interrupt if TMG = 1, or via input pin (event trigger) if FDCAN_TTOCN.GCS = 1. Not set by Ref_Trigger_Gap or when Gap is finished by another node sending a reference message.
0: Reset at the end of each reference message
1: Gap finished by FDCAN

Bit 22  **WGTD**: Wait for global time discontinuity.
0: No global time preset pending
1: Node waits for the global time preset to take effect. The bit is reset when the node has transmitted a reference message with Disc_Bit = 1 or after it received a reference message.

Bits 21:16  Reserved, must be kept at reset value.

Bits 15:8  **RTO[7:0]**: Reference trigger offset.
The reference trigger offset value is a signed integer with a range from -127 (0x81) to 127 (0x7F). There is no notification when the lower limit of -127 is reached. In case the FDCAN becomes time master (MS[1:0] = 11), the reset of RTO is delayed due to synchronization between Host and CAN clock domain. For time slaves the value configured by FDCAN_TTOCF.IRTO is read.
0x00-FF Actual reference trigger offset value

Bit 7  **QCS**: Quality of clock Speed.
Only relevant in TTCAN level 0 and level 2, otherwise fixed to 1.
0: Local clock speed not synchronized to time master clock speed
1: Synchronization deviation ≤ SDL

Bit 6  **QGTP**: Quality of global time phase.
Only relevant in TTCAN level 0 and level 2, otherwise fixed to 0.
0: Global time not valid
1: Global time in phase with time master

Bits 5:4  **SYS[1:0]**: Synchronization state
00: Out of Synchronization
01: Synchronizing to FDCAN communication
10: Schedule suspended by Gap (In_Gap)
11: Synchronized to schedule (In_Schedule)

Bits 3:2  **MS[1:0]**: Master state.
00: Master_Off, no master properties relevant
01: Operating as time Slave
10: Operating as backup time master
11: Operating as current time master

Bits 1:0  **EL[1:0]**: Error level.
00: Severity 0 - No error
01: Severity 1 - Warning
10: Severity 2 - error
11: Severity 3 - Severe error

55.4.59  **FDCAN TUR numerator actual register (FDCAN_TURNA)**
There is no drift compensation in TTCAN level 1 (NAV = NC). In TTCAN level 0 and level 2, the drift between the node local clock and the time master local clock is calculated. The drift
is compensated when the synchronization deviation (difference between NC and the calculated NAV) is lower than 2 * (FDCAN_TTOCF.LDSDL + 5). With FDCAN_TTOCF.LDSDL < 7, this results in a maximum range for NAV of (NC - 0x1000) ≤ NAV ≤ (NC + 0x1000).

Address offset: 0x0130
Reset value: 0x0000 0000

55.4.60 FDCAN TT local and global time register (FDCAN_TTLGT)

Address offset: 0x0134
Reset value: 0x0000 0000

Bits 31:18 Reserved, must be kept at reset value.

Bits 17:0 NAV[17:0]: Numerator actual value.
0x0EFFF Illegal value
0x0F000–20FFF Actual numerator value
0x21000 Illegal value

55.4.61 FDCAN TT cycle time and count register (FDCAN_TTCTC)

Address offset: 0x0138
55.4.62 FDCAN TT capture time register (FDCAN_TTCPT)

Address offset: 0x013C

Reset value: 0x0000 0000

Bits 31:16 **SWV[15:0]**: Stop watch value.

On a rising / falling edge (as configured via FDCAN_TTOCN.SWP) at the stop watch trigger pin, when FDCAN_TTOCN.SWS is different from 00 and FDCAN_TTIR.SWE is 0, the actual time value as selected by FDCAN_TTOCN.SWS (cycle, local, global) is copied to SWV and TFDCAN_TIR.SWE will be set to 1. Capturing of the next stop watch value is enabled by resetting FDCAN_TTIR.SWE.

0x0000–FFFF Captured stop watch value

Bits 15:6 Reserved, must be kept at reset value.

Bits 5:0 **CCV[5:0]**: Cycle count value

Cycle count value captured together with SWV.

0x00–3F Captured cycle count value

55.4.63 FDCAN TT cycle sync mark register (FDCAN_TTCSM)

Address offset: 0x0140
Reset value: 0x0000 0000

</table>

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **CSM[15:0]**: Cycle sync mark.

The cycle sync mark is measured in cycle time. It is updated when the reference message becomes valid and retains its value until the next reference message becomes valid.

0x0000–FFFF Captured cycle time

### 55.4.64 FDCAN TT trigger select register (FDCAN_TTTS)

The settings in the FDCAN_TTTS register select the input to be used as event trigger and stop watch trigger.

</tbody>
</table>

Bit 31  **SWR**: Software Reset

Writing a 1 to this bit will reset the calibration FSM to state Not_Calibrated
(CCUCSTAT.CALS = 00). The calibration watchdog value CWD.WDV is also reset.
Registers FDCAN_CCFG, CCUCSTAT and the calibration watchdog configuration
CWD.WDC are unchanged. The bit remains set until reset is completed.

Write access by the Host CPU to registers/bits marked with "P=Protected Write" is possible only when the FDCAN control bits FDCAN_CCCR.CCE = 1 AND
FDCAN_CCCR.INIT = 1.

Bits 30:20  Reserved, must be kept at reset value.
Bits 19:16 **CDIV[3:0]:** Clock Divider

The clock divider has to be configured when the clock calibration is bypassed (BCC = 1) to ensure that the FDCAN requirement is fulfilled.

- **0000:** Divide by 1
- **0001:** Divide by 2
- **0010:** Divide by 4
- **0011:** Divide by 6
- **0100:** Divide by 8
- **0101:** Divide by 10
- **0110:** Divide by 12
- **0111:** Divide by 14
- **1000:** Divide by 16
- **1001:** Divide by 18
- **1010:** Divide by 20
- **1011:** Divide by 22
- **1100:** Divide by 24
- **1101:** Divide by 26
- **1110:** Divide by 28
- **1111:** Divide by 30

Write access by the Host CPU to registers/bits marked with “P=Protected Write” is possible only when the FDCAN control bits FDCAN_CCCR.CCE = 1 AND FDCAN_CCCR.INIT = 1.

Bits 15:8 **OCPM[7:0]:** Oscillator clock periods minimum

Configures the minimum number of periods in two CAN bit times. OCPM is used in basic calibration to avoid false measurements in case of glitches on the bus line. The configured number of periods is OCPM × 32. The configuration depends on the frequency (from 80 to 100 MHz) and the bitrate configured in FDCAN1 and FDCAN2 (from 125 kbit/s up to 1 Mbit/s). It is recommended to configure a value slightly below two CAN bit times. The reset value is 1.6 bit times at 80 MHz fdcan_ker_ck and 1 Mbit/s CAN bitrate.

Write access by the Host CPU to registers/bits marked with “P=Protected Write” is possible only when the FDCAN control bits FDCAN_CCCR.CCE = 1 AND FDCAN_CCCR.INIT = 1.

Bit 7 **CFL:** Calibration Field length

- **0:** Calibration field length is 32 bits
- **1:** Calibration field length is 64 bits

Write access by the Host CPU to registers/bits marked with “P=Protected Write” is possible only when the FDCAN control bits FDCAN_CCCR.CCE = 1 AND FDCAN_CCCR.INIT = 1.

Bit 6 **BCC:** Bypass clock calibration

If this bit is set, the clock input fdcan_ker_ck is routed to the time quanta clock through a clock divider configurable via CDIV, cu_cok is always 1. In this case the baudrate prescaler of the connected FDCANs has to be configured to generate the FDCAN internal time quanta clock.

- **0:** Clock calibration unit generates time quanta clock
- **1:** Clock calibration unit bypassed (default configuration)

*Note:* As long as fdcan_ker_ck is equal or above 80 MHz the clock calibration on CAN unit is functional, even when BCC = 1. The calibration state can be read from register CCU_CSTAT.
55.5.3 Calibration status register (FDCAN_CCU_CSTAT)

Address offset: 0x0008
Reset value: 0x0203 FFFF

- **Bit 29:** Reserved, must be kept at reset value.

- **Bits 28:18 TQC[10:0]:** Time quanta counter
  Captured number of time quanta in calibration field (32 or 64 bits). Only valid when the clock calibration unit is in state Precision_Calibrated.

- **Bits 17:0 OCPC[17:0]:** Oscillator clock period counter
  Captured number of oscillator clock periods in calibration field (32 or 64 bits). Only valid when the clock calibration unit is in state Precision_Calibrated.

55.5.4 Calibration watchdog register (FDCAN_CCU_CWD)

Address offset: 0x000C
Reset value: 0x0000 0000

The calibration watchdog is started after the first falling edge when the calibration FSM is in state Not_Calibrated (CCU_CSTAT.CALS = 00). In this state the calibration watchdog monitors the message received. In case no message was received until the calibration watchdog has counted down to 0, the calibration FSM stays in state Not_Calibrated (CCU_CSTAT.CALS = 00), the counter is reloaded with FDCAN_RWD.WDC and basic calibration is restarted after the next falling edge.
When in state Basic_Calibrated (CCU_CSTAT.CALS = 01), the calibration watchdog is restarted with each received message. In case no message was received until the calibration watchdog has counted down to 0, the calibration FSM returns to state Not_Calibrated (CCU_CSTAT.CALS = 00), the counter is reloaded with FDCAN_RWD.WDC and basic calibration is restarted after the next falling edge.

When a quartz message is received, state Precision_Calibrated (CCU_CSTAT.CALS = 10) is entered and the calibration watchdog is restarted. In this state the calibration watchdog monitors the quartz message received input. In case no message from a quartz controlled node is received by the attached TTCAN until the calibration watchdog has counted down to 0, the calibration FSM transits back to state Basic_Calibrated (CCU_CSTAT.CALS = 01). The signal is active when the CAN protocol engine on the attached TTCAN is started i.e. when the INIT bit is reset.

A calibration watchdog event also sets interrupt flag CCU_IR.CWE. If enabled by CCU_IE.CWEE, interrupt line is activated (set to high). Interrupt line remains active until interrupt flag CCU_IR.CWE is reset.

### 55.5.5 Clock calibration unit interrupt register (FDCAN_CCU_IR)

The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the Host clears them. A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect. A hard reset will clear the register. The configuration of CCU_IE controls whether an interrupt is generated or not.

**Address offset:** 0x0010

**Reset value:** 0x0000 0000
55.5.6 Clock calibration unit interrupt enable register (FDCAN_CCU_IE)

Address offset: 0x0014  
Reset value: 0x0000 0000

The settings in the CU interrupt enable register determine whether a status change in the CU interrupt register will be signaled on an interrupt line.

56 USB on-the-go high-speed (OTG_HS)

56.1 Introduction

Portions Copyright (c) Synopsys, Inc. All rights reserved. Used with permission.

This section presents the architecture and the programming model of the OTG_HS controller.

The following acronyms are used throughout the section:

- FS Full-speed
- LS Low-speed
- HS High-speed
- MAC Media access controller
- OTG On-the-go
- PFC Packet FIFO controller
- PHY Physical layer
- USB Universal serial bus
- UTMI USB 2.0 Transceiver Macrocell interface (UTMI)
- ULPI UTMI+ Low Pin Interface
- LPM Link power management
- BCD Battery charging detector
- HNP Host negotiation protocol
- SRP Session request protocol

References are made to the following documents:

- USB On-The-Go Supplement, Revision 2.0
- Universal Serial Bus Revision 2.0 Specification
- USB 2.0 Link Power Management Addendum Engineering Change Notice to the USB 2.0 specification, July 16, 2007
- Errata for USB 2.0 ECN: Link Power Management (LPM) - 7/2007
- Battery Charging Specification, Revision 1.2

The USB OTG is a dual-role device (DRD) controller that supports both device and host functions and is fully compliant with the On-The-Go Supplement to the USB 2.0 Specification. It can also be configured as a host-only or device-only controller, fully compliant with the USB 2.0 Specification. OTG_HS supports the speeds defined in the Table 491: OTG_HS speeds supported below. The USB OTG supports both HNP and SRP. The only external device required is a charge pump for VBUS in OTG mode.
56.2 **OTG main features**

The main features can be divided into three categories: general, host-mode and device-mode features.

<table>

Table 491. OTG_HS speeds supported
56.2.1 General features

The OTG_HS interface general features are the following:

- It is USB-IF certified to the Universal Serial Bus Specification Rev 2.0
- OTG_HS supports the following PHY interfaces:
  - An on-chip full-speed PHY
  - An ULPI interface for external high-speed PHY
- It includes full support (PHY) for the optional On-The-Go (OTG) protocol detailed in the On-The-Go Supplement Rev 2.0 specification
  - Integrated support for A-B device identification (ID line)
  - Integrated support for host Negotiation protocol (HNP) and session request protocol (SRP)
  - It allows host to turn VBUS off to conserve battery power in OTG applications
  - It supports OTG monitoring of VBUS levels with internal comparators
  - It supports dynamic host-peripheral switch of role
- It is software-configurable to operate as:
  - SRP capable USB HS Peripheral (B-device)
  - SRP capable USB HS/LS host (A-device)
  - USB On-The-Go Full-Speed Dual Role device
- It supports HS SOF and LS Keep-alives with
  - SOF pulse PAD connectivity
  - SOF pulse internal connection to timer (TIMx)
  - Configurable framing period
  - Configurable end of frame interrupt
- OTG_HS embeds an internal DMA with shareholding support and software selectable AHB burst type in DMA mode.
- It includes power saving features such as system stop during USB suspend, switch-off of clock domains internal to the digital core, PHY and DFIFO power management.
- It features a dedicated RAM of 4 Kbytes with advanced FIFO control:
  - Configurable partitioning of RAM space into different FIFOs for flexible and efficient use of RAM
  - Each FIFO can hold multiple packets
  - Dynamic memory allocation
  - Configurable FIFO sizes that are not powers of 2 to allow the use of contiguous memory locations
- It guarantees max USB bandwidth for up to one frame (1 ms) without system intervention.
- It supports charging port detection as described in Battery Charging Specification Revision 1.2 on the FS PHY transceiver only.
56.2.2 Host-mode features

The OTG_HS interface main features and requirements in host-mode are the following:

- External charge pump for \( V_{BUS} \) voltage generation.
- Up to 16 host channels (pipes): each channel is dynamically reconfigurable to allocate any type of USB transfer.
- Built-in hardware scheduler holding:
  - Up to 16 interrupt plus isochronous transfer requests in the periodic hardware queue
  - Up to 16 control plus bulk transfer requests in the non-periodic hardware queue
- Management of a shared Rx FIFO, a periodic Tx FIFO and a nonperiodic Tx FIFO for efficient usage of the USB data RAM.

56.2.3 Peripheral-mode features

The OTG_HS interface main features in peripheral-mode are the following:

- 1 bidirectional control endpoint0
- 8 IN endpoints (EPs) configurable to support bulk, interrupt or isochronous transfers
- 8 OUT endpoints configurable to support bulk, interrupt or isochronous transfers
- Management of a shared Rx FIFO and a Tx-OUT FIFO for efficient usage of the USB data RAM
- Management of up to 9 dedicated Tx-IN FIFOs (one for each active IN EP) to put less load on the application
- Support for the soft disconnect feature.
56.3 OTG implementation

56.4.3 OTG core

The USB OTG receives the 48 MHz clock from the reset and clock controller (RCC). The USB clock is used for driving the 48 MHz domain at full-speed (12 Mbit/s) and must be enabled prior to configuring the OTG core.

The CPU reads and writes from/to the OTG core registers through the AHB peripheral bus. It is informed of USB events through the single USB OTG interrupt line described in Section 56.12: OTG_HS interrupts.
The CPU submits data over the USB by writing 32-bit words to dedicated OTG locations (push registers). The data are then automatically stored into Tx-data FIFOs configured within the USB data RAM. There is one Tx FIFO push register for each in-endpoint (peripheral mode) or out-channel (host mode).

The CPU receives the data from the USB by reading 32-bit words from dedicated OTG addresses (pop registers). The data are then automatically retrieved from a shared Rx FIFO configured within the 4-Kbyte USB data RAM. There is one Rx FIFO pop register for each out-endpoint or in-channel.

The USB protocol layer is driven by the serial interface engine (SIE) and serialized over the USB by the transceiver module within the on-chip physical layer (PHY) or external HS PHY.

### 56.4.4 Embedded full speed OTG PHY

The full-speed OTG PHY includes the following components:

- **FS/LS transceiver module used by both host and device.** It directly drives transmission and reception on the single-ended USB lines.
- **Integrated ID pull-up resistor used to sample the ID line for A/B device identification.**
- **DP/DM integrated pull-up and pull-down resistors controlled by the OTG_HS core depending on the current role of the device.** As a peripheral, it enables the DP pull-up resistor to signal full-speed peripheral connections as soon as \( V_{BUS} \) is sensed to be at a valid level (B-session valid). In host mode, pull-down resistors are enabled on both DP/DM. Pull-up and pull-down resistors are dynamically switched when the peripheral role is changed via the host negotiation protocol (HNP).
- **Pull-up/pull-down resistor ECN circuit.** The DP pull-up consists of 2 resistors controlled separately from the OTG_HS as per the resistor Engineering Change Notice applied to USB Rev2.0. The dynamic trimming of the DP pull-up strength allows to achieve a better noise rejection and Tx/Rx signal quality.
- **\( V_{BUS} \) sensing comparators with hysteresis used to detect \( V_{BUS} \) valid, A-B session valid and session-end voltage thresholds.** They are used to drive the session request protocol (SRP), detect valid startup and end-of-session conditions, and constantly monitor the \( V_{BUS} \) supply during USB operations.

To guarantee a correct operation for the USB OTG_HS peripheral, the AHB frequency should be higher than 30 MHz.

### 56.4.5 High-speed OTG PHY

The USB OTG_HS core includes an ULPI interface to connect an external HS PHY.

ULPI interface is only available on OTG HS1 (see Section 56.4.1: OTG block diagram).

### 56.5 OTG dual role device (DRD)

#### 56.5.1 ID line detection

The host or peripheral (the default) role is assumed depending on the ID input pin. The ID line status is determined on plugging in the USB cable, depending on whether a MicroA or MicroB plug is connected to the micro-AB receptacle.

- **If the B-side of the USB cable is connected with a floating ID wire, the integrated pull-up resistor detects a high ID level and the default peripheral role is confirmed.** In this
configuration the OTG_HS complies with the standard FSM described in section 4.2.4: ID pin of the On-the-Go specification Rev2.0, supplement to the USB2.0.

- If the A-side of the USB cable is connected with a grounded ID, the OTG_HS issues an ID line status change interrupt (CIDSCHG bit in OTG_GINTSTS) for host software initialization, and automatically switches to the host role. In this configuration the OTG_HS complies with the standard FSM described by section 4.2.4: ID pin of the On-the-Go specification Rev2.0, supplement to the USB2.0.

56.5.2 HNP dual role device

The HNP capable bit in the Global USB configuration register (HNPCAP bit in OTG_GUSBCFG) enables the OTG_HS core to dynamically change its role from A-host to A-peripheral and vice-versa, or from B-Peripheral to B-host and vice-versa according to the host negotiation protocol (HNP). The current device status can be read by the combined values of the connector ID status bit in the Global OTG control and status register (CIDSTS bit in OTG_GOTGCTL) and the current mode of operation bit in the global interrupt and status register (CMOD bit in OTG_GINTSTS).

The HNP program model is described in detail in Section 56.15: OTG_HS programming model.

56.5.3 SRP dual role device

The SRP capable bit in the global USB configuration register (SRPCAP bit in OTG_GUSBCFG) enables the OTG_HS core to switch off the generation of VBUS for the A-device to save power. Note that the A-device is always in charge of driving VBUS regardless of the host or peripheral role of the OTG_HS.

The SRP A/B-device program model is described in detail in Section 56.15: OTG_HS programming model.

56.6 USB peripheral

This section gives the functional description of the OTG_HS in the USB peripheral mode. The OTG_HS works as an USB peripheral in the following circumstances:

- OTG B-Peripheral
  - OTG B-device default state if B-side of USB cable is plugged in
- OTG A-Peripheral
  - OTG A-device state after the HNP switches the OTG_HS to its peripheral role
- B-device
  - If the ID line is present, functional and connected to the B-side of the USB cable, and the HNP-capable bit in the Global USB Configuration register (HNPCAP bit in OTG_GUSBCFG) is cleared.
- Peripheral only
  - The force device mode bit (FDMOD) in the Section 56.14.4: OTG USB configuration register (OTG_GUSBCFG) is set to 1, forcing the OTG_HS core to work as an USB peripheral-only. In this case, the ID line is ignored even if it is present on the USB connector.
Note: To build a bus-powered device implementation in case of the B-device or peripheral-only configuration, an external regulator has to be added, that generates the necessary power-supply from \( V_{BUS} \).

### 56.6.1 SRP-capable peripheral

The SRP capable bit in the Global USB configuration register (SRPCAP bit in OTG_GUSBCFG) enables the OTG_HS to support the session request protocol (SRP). In this way, it allows the remote A-device to save power by switching off \( V_{BUS} \) while the USB session is suspended.

The SRP peripheral mode program model is described in detail in the B-device session request protocol section.

### 56.6.2 Peripheral states

#### Powered state

The \( V_{BUS} \) input detects the B-session valid voltage by which the USB peripheral is allowed to enter the powered state (see USB2.0 section 9.1). The OTG_HS then automatically connects the DP pull-up resistor to signal full-speed device connection to the host and generates the session request interrupt (SRQINT bit in OTG_GINTSTS) to notify the powered state.

The \( V_{BUS} \) input also ensures that valid \( V_{BUS} \) levels are supplied by the host during USB operations. If a drop in \( V_{BUS} \) below B-session valid happens to be detected (for instance because of a power disturbance or if the host port has been switched off), the OTG_HS automatically disconnects and the session end detected (SEDET bit in OTG_GOTGINT) interrupt is generated to notify that the OTG_HS has exited the powered state.

In the powered state, the OTG_HS expects to receive some reset signaling from the host. No other USB operation is possible. When a reset signaling is received the reset detected interrupt (USBRST in OTG_GINTSTS) is generated. When the reset signaling is complete, the enumeration done interrupt (ENUMDNE bit in OTG_GINTSTS) is generated and the OTG_HS enters the Default state.

#### Soft disconnect

The powered state can be exited by software with the soft disconnect feature. The DP pull-up resistor is removed by setting the soft disconnect bit in the device control register (SDIS bit in OTG_DCTL), causing a device disconnect detection interrupt on the host side even though the USB cable was not really removed from the host port.

#### Default state

In the Default state the OTG_HS expects to receive a SET_ADDRESS command from the host. No other USB operation is possible. When a valid SET_ADDRESS command is decoded on the USB, the application writes the corresponding number into the device address field in the device configuration register (DAD bit in OTG_DCFG). The OTG_HS then enters the address state and is ready to answer host transactions at the configured USB address.
Suspended state

The OTG_HS peripheral constantly monitors the USB activity. After counting 3 ms of USB idleness, the early suspend interrupt (ESUSP bit in OTG_GINTSTS) is issued, and confirmed 3 ms later, if appropriate, by the suspend interrupt (USBSUSP bit in OTG_GINTSTS). The device suspend bit is then automatically set in the device status register (SUSPSTS bit in OTG_DSTS) and the OTG_HS enters the suspended state.

The suspended state may optionally be exited by the device itself. In this case the application sets the remote wakeup signaling bit in the device control register (RWUSIG bit in OTG_DCTL) and clears it after 1 to 15 ms.

When a resume signaling is detected from the host, the resume interrupt (WKUPINT bit in OTG_GINTSTS) is generated and the device suspend bit is automatically cleared.

56.6.3 Peripheral endpoints

The OTG_HS core instantiates the following USB endpoints:

- **Control endpoint 0:**
  - Bidirectional and handles control messages only
  - Separate set of registers to handle in and out transactions
  - Proper control (OTG_DIEPCTL0/OTG_DOEPCON0), transfer configuration (OTG_DIEPTSIZ0/OTG_DOEPFTSZ0), and status-interrupt (OTG_DIEPINT0/OTG_DOEPIN0) registers. The available set of bits inside the control and transfer size registers slightly differs from that of other endpoints

- **8 IN endpoints**
  - Each of them can be configured to support the isochronous, bulk or interrupt transfer type
  - Each of them has proper control (OTG_DIEPCTLx), transfer configuration (OTG_DIEPTSIZx), and status-interrupt (OTG_DIEPINTx) registers
  - The device IN endpoints common interrupt mask register (OTG_DIEPMASK) is available to enable/disable a single kind of endpoint interrupt source on all of the IN endpoints (EP0 included)
  - Support for incomplete isochronous IN transfer interrupt (IISOIXFR bit in OTG_GINTSTS), asserted when there is at least one isochronous IN endpoint on which the transfer is not completed in the current frame. This interrupt is asserted along with the end of periodic frame interrupt (OTG_GINTSTS/EOPF).

- **8 OUT endpoints**
  - Each of them can be configured to support the isochronous, bulk or interrupt transfer type
  - Each of them has a proper control (OTG_DOEPCTLx), transfer configuration (OTG_DOEPTSIZx) and status-interrupt (OTG_DOEPINTx) register
  - Device OUT endpoints common interrupt mask register (OTG_DOEPMSK) is available to enable/disable a single kind of endpoint interrupt source on all of the OUT endpoints (EP0 included)
  - Support for incomplete isochronous OUT transfer interrupt (INCOMPISOOUT bit in OTG_GINTSTS), asserted when there is at least one isochronous OUT endpoint on which the transfer is not completed in the current frame. This interrupt is asserted along with the end of periodic frame interrupt (OTG_GINTSTS/EOPF).
Endpoint control

- The following endpoint controls are available to the application through the device endpoint-x IN/OUT control register (OTG_DIEPCTLx/OTG_DOEPCTLx):
  - Endpoint enable/disable
  - Endpoint activate in current configuration
  - Program USB transfer type (isochronous, bulk, interrupt)
  - Program supported packet size
  - Program Tx FIFO number associated with the IN endpoint
  - Program the expected or transmitted data0/data1 PID (bulk/interrupt only)
  - Program the even/odd frame during which the transaction is received or transmitted (isochronous only)
  - Optionally program the NAK bit to always negative-acknowledge the host regardless of the FIFO status
  - Optionally program the STALL bit to always stall host tokens to that endpoint
  - Optionally program the SNOOP mode for OUT endpoint not to check the CRC field of received data

Endpoint transfer

The device endpoint-x transfer size registers (OTG_DIEPTSIZx/OTG_DOEPPTSIZx) allow the application to program the transfer size parameters and read the transfer status. Programming must be done before setting the endpoint enable bit in the endpoint control register. Once the endpoint is enabled, these fields are read-only as the OTG_HS core updates them with the current transfer status.

The following transfer parameters can be programmed:

- Transfer size in bytes
- Number of packets that constitute the overall transfer size

Endpoint status/interrupt

The device endpoint-x interrupt registers (OTG_DIEPINTx/OTG_DOPEPINTx) indicate the status of an endpoint with respect to USB- and AHB-related events. The application must read these registers when the OUT endpoint interrupt bit or the IN endpoint interrupt bit in the core interrupt register (OEPINT bit in OTG_GINTSTS or IEPINT bit in OTG_GINTSTS, respectively) is set. Before the application can read these registers, it must first read the device all endpoints interrupt (OTG_DAINT) register to get the exact endpoint number for the device endpoint-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG_DAINT and OTG_GINTSTS registers.
The peripheral core provides the following status checks and interrupt generation:

- Transfer completed interrupt, indicating that data transfer was completed on both the application (AHB) and USB sides
- Setup stage has been done (control-out only)
- Associated transmit FIFO is half or completely empty (in endpoints)
- NAK acknowledge has been transmitted to the host (isochronous-in only)
- IN token received when Tx FIFO was empty (bulk-in/interrupt-in only)
- Out token received when endpoint was not yet enabled
- Babble error condition has been detected
- Endpoint disable by application is effective
- Endpoint NAK by application is effective (isochronous-in only)
- More than 3 back-to-back setup packets were received (control-out only)
- Timeout condition detected (control-in only)
- Isochronous out packet has been dropped, without generating an interrupt

56.7 USB host

This section gives the functional description of the OTG_HS in the USB host mode. The OTG_HS works as a USB host in the following circumstances:

- OTG A-host
  - OTG A-device default state when the A-side of the USB cable is plugged in
- OTG B-host
  - OTG B-device after HNP switching to the host role
- A-device
  - If the ID line is present, functional and connected to the A-side of the USB cable, and the HNP-capable bit is cleared in the Global USB Configuration register (HNPCAP bit in OTG_GUSBCFG). Integrated pull-down resistors are automatically set on the DP/DM lines.
- Host only
  - The force host mode bit (FHMOD) in the OTG USB configuration register (OTG_GUSBCFG) forces the OTG_HS core to work as a USB host-only. In this case, the ID line is ignored even if present on the USB connector. Integrated pull-down resistors are automatically set on the DP/DM lines.

Note: On-chip 5 V VBUS generation is not supported. For this reason, a charge pump or, if 5 V are available on the application board, a basic power switch must be added externally to drive the 5 V VBUS line. The external charge pump can be driven by any GPIO output. This is required for the OTG A-host, A-device and host-only configurations.

56.7.1 SRP-capable host

SRP support is available through the SRP capable bit in the global USB configuration register (SRPCAP bit in OTG_GUSBCFG). With the SRP feature enabled, the host can save power by switching off the VBUS power while the USB session is suspended.

The SRP host mode program model is described in detail in the A-device session request protocol section.
56.7.2 USB host states

Host port power

On-chip 5 V $V_{BUS}$ generation is not supported. For this reason, a charge pump or, if 5 V are available on the application board, a basic power switch, must be added externally to drive the 5 V $V_{BUS}$ line. The external charge pump can be driven by any GPIO output or via an I²C interface connected to an external PMIC (power management IC). When the application decides to power on $V_{BUS}$, it must also set the port power bit in the host port control and status register (PPWR bit in OTG_HPRT).

$V_{BUS}$ valid

When HNP or SRP is enabled the VBUS sensing pin should be connected to $V_{BUS}$. The $V_{BUS}$ input ensures that valid $V_{BUS}$ levels are supplied by the charge pump during USB operations. Any unforeseen $V_{BUS}$ voltage drop below the $V_{BUS}$ valid threshold (4.4 V) leads to an OTG interrupt triggered by the session end detected bit (SEDET bit in OTG_GINTINT). The application is then required to remove the $V_{BUS}$ power and clear the port power bit.

When HNP and SRP are both disabled, the VBUS sensing pin does not need to be connected to $V_{BUS}$.

The charge pump overcurrent flag can also be used to prevent electrical damage. Connect the overcurrent flag output from the charge pump to any GPIO input and configure it to generate a port interrupt on the active level. The overcurrent ISR must promptly disable the $V_{BUS}$ generation and clear the port power bit.

Host detection of a peripheral connection

If SRP or HNP are enabled, even if USB peripherals or B-devices can be attached at any time, the OTG_HS will not detect any bus connection until $V_{BUS}$ is no longer sensed at a valid level (5 V). When $V_{BUS}$ is at a valid level and a remote B-device is attached, the OTG_HS core issues a host port interrupt triggered by the device connected bit in the host port control and status register (PCDET bit in OTG_HPRT).

When HNP and SRP are both disabled, USB peripherals or B-device are detected as soon as they are connected. The OTG_HS core issues a host port interrupt triggered by the device connected bit in the host port control and status (PCDET bit in OTG_HPRT).

Host detection of peripheral a disconnection

The peripheral disconnection event triggers the disconnect detected interrupt (DISCINT bit in OTG_GINTSTS).

Host enumeration

After detecting a peripheral connection the host must start the enumeration process by sending USB reset and configuration commands to the new peripheral.

Before starting to drive a USB reset, the application waits for the OTG interrupt triggered by the debounce done bit (DBCDNE bit in OTG_GINTINT), which indicates that the bus is stable again after the electrical debounce caused by the attachment of a pull-up resistor on DP (FS) or DM (LS).

The application drives a USB reset signaling (single-ended zero) over the USB by keeping the port reset bit set in the host port control and status register (PRST bit in OTG_HPRT) for
a minimum of 10 ms and a maximum of 20 ms. The application takes care of the timing count and then of clearing the port reset bit.

Once the USB reset sequence has completed, the host port interrupt is triggered by the port enable/disable change bit (PENCHNG bit in OTG_HPRT). This informs the application that the speed of the enumerated peripheral can be read from the port speed field in the host port control and status register (PSPD bit in OTG_HPRT) and that the host is starting to drive SOFs (FS) or Keep alives (LS). The host is now ready to complete the peripheral enumeration by sending peripheral configuration commands.

**Host suspend**

The application decides to suspend the USB activity by setting the port suspend bit in the host port control and status register (PSUSP bit in OTG_HPRT). The OTG_HS core stops sending SOFs and enters the suspended state.

The suspended state can be optionally exited on the remote device’s initiative (remote wakeup). In this case the remote wakeup interrupt (WKUPINT bit in OTG_GINTSTTS) is generated upon detection of a remote wakeup signaling, the port resume bit in the host port control and status register (PRES bit in OTG_HPRT) self-sets, and resume signaling is automatically driven over the USB. The application must time the resume window and then clear the port resume bit to exit the suspended state and restart the SOF.

If the suspended state is exited on the host initiative, the application must set the port resume bit to start resume signaling on the host port, time the resume window and finally clear the port resume bit.

### 56.7.3 Host channels

The OTG_HS core instantiates 16 host channels. Each host channel supports an USB host transfer (USB pipe). The host is not able to support more than 16 transfer requests at the same time. If more than 16 transfer requests are pending from the application, the host controller driver (HCD) must re-allocate channels when they become available from previous duty, that is, after receiving the transfer completed and channel halted interrupts.

Each host channel can be configured to support in/out and any type of periodic/nonperiodic transaction. Each host channel makes use of proper control (OTG_HCCHARx), transfer configuration (OTG_HCTSIZX) and status/interrupt (OTG_HCINTx) registers with associated mask (OTG_HCINTMSKx) registers.

**Host channel control**

- The following host channel controls are available to the application through the host channel-x characteristics register (OTG_HCCHARx):
  - Channel enable/disable
  - Program the HS/FS/LS speed of target USB peripheral
  - Program the address of target USB peripheral
  - Program the endpoint number of target USB peripheral
  - Program the transfer IN/OUT direction
  - Program the USB transfer type (control, bulk, interrupt, isochronous)
  - Program the maximum packet size (MPS)
  - Program the periodic transfer to be executed during odd/even frames
Host channel transfer

The host channel transfer size registers (OTG_HCTSIZx) allow the application to program the transfer size parameters, and read the transfer status. Programming must be done before setting the channel enable bit in the host channel characteristics register. Once the endpoint is enabled the packet count field is read-only as the OTG_HS core updates it according to the current transfer status.

- The following transfer parameters can be programmed:
  - transfer size in bytes
  - number of packets making up the overall transfer size
  - initial data PID

Host channel status/interrupt

The host channel-x interrupt register (OTG_HCINTx) indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read these register when the host channels interrupt bit in the core interrupt register (HCINT bit in OTG_GINTSTS) is set. Before the application can read these registers, it must first read the host all channels interrupt (OTG_HAINT) register to get the exact channel number for the host channel-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG_HAINT and OTG_GINTSTS registers. The mask bits for each interrupt source of each channel are also available in the OTG_HCINTMSKx register.

- The host core provides the following status checks and interrupt generation:
  - Transfer completed interrupt, indicating that the data transfer is complete on both the application (AHB) and USB sides
  - Channel has stopped due to transfer completed, USB transaction error or disable command from the application
  - Associated transmit FIFO is half or completely empty (IN endpoints)
  - ACK response received
  - NAK response received
  - STALL response received
  - USB transaction error due to CRC failure, timeout, bit stuff error, false EOP
  - Babble error
  - frame overrun
  - data toggle error

56.7.4 Host scheduler

The host core features a built-in hardware scheduler which is able to autonomously re-order and manage the USB transaction requests posted by the application. At the beginning of each frame the host executes the periodic (isochronous and interrupt) transactions first, followed by the nonperiodic (control and bulk) transactions to achieve the higher level of priority granted to the isochronous and interrupt transfer types by the USB specification.

The host processes the USB transactions through request queues (one for periodic and one for nonperiodic). Each request queue can hold up to 8 entries. Each entry represents a pending transaction request from the application, and holds the IN or OUT channel number along with other information to perform a transaction on the USB. The order in which the
requests are written to the queue determines the sequence of the transactions on the USB interface.

At the beginning of each frame, the host processes the periodic request queue first, followed by the nonperiodic request queue. The host issues an incomplete periodic transfer interrupt (IPXFR bit in OTG_GINTSTS) if an isochronous or interrupt transaction scheduled for the current frame is still pending at the end of the current frame. The OTG_HS core is fully responsible for the management of the periodic and nonperiodic request queues. The periodic transmit FIFO and queue status register (OTG_HPTXSTS) and nonperiodic transmit FIFO and queue status register (OTG_HNPTXSTS) are read-only registers which can be used by the application to read the status of each request queue. They contain:

- The number of free entries currently available in the periodic (nonperiodic) request queue (8 max)
- Free space currently available in the periodic (nonperiodic) Tx FIFO (out-transactions)
- IN/OUT token, host channel number and other status information.

As request queues can hold a maximum of 8 entries each, the application can push to schedule host transactions in advance with respect to the moment they physically reach the SB for a maximum of 8 pending periodic transactions plus 8 pending non-periodic transactions.

To post a transaction request to the host scheduler (queue) the application must check that there is at least 1 entry available in the periodic (nonperiodic) request queue by reading the PTXQSAV bits in the OTG_HNPTXSTS register or NPTQXSAV bits in the OTG_HNPTXSTS register.

56.8 SOF trigger

Figure 749. SOF connectivity (SOF trigger output to TIM and ITR1 connection)

The OTG_HS core provides means to monitor, track and configure SOF framing in the host and peripheral, as well as an SOF pulse output connectivity feature.

Such utilities are especially useful for adaptive audio clock generation techniques, where the audio peripheral needs to synchronize to the isochronous stream provided by the PC, or the host needs to trim its framing rate according to the requirements of the audio peripheral.
56.8.1 Host SOFs

In host mode the number of PHY clocks occurring between the generation of two consecutive SOF (HS/FS) or Keep-alive (LS) tokens is programmable in the host frame interval register (HFIR), thus providing application control over the SOF framing period. An interrupt is generated at any start of frame (SOF bit in OTG_GINTSTS). The current frame number and the time remaining until the next SOF are tracked in the host frame number register (HFNUM).

A SOF pulse signal, is generated at any SOF starting token and with a width of 20 HCLK cycles. The SOF pulse is also internally connected to the input trigger of the timer, so that the input capture feature, the output compare feature and the timer can be triggered by the SOF pulse.

56.8.2 Peripheral SOFs

In device mode, the start of frame interrupt is generated each time an SOF token is received on the USB (SOF bit in OTG_GINTSTS). The corresponding frame number can be read from the device status register (FNSOF bit in OTG_DSTS). A SOF pulse signal with a width of 20 HCLK cycles is also generated. The SOF pulse signal is also internally connected to the TIM input trigger, so that the input capture feature, the output compare feature and the timer can be triggered by the SOF pulse.

The end of periodic frame interrupt (OTG_GINTSTS/EOPF) is used to notify the application when 80%, 85%, 90% or 95% of the time frame interval elapsed depending on the periodic frame interval field in the device configuration register (PFIVL bit in OTG_DCFG). This feature can be used to determine if all of the isochronous traffic for that frame is complete.

56.9 OTG low-power modes

Table 496 below defines the STM32 low power modes and their compatibility with the OTG.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
<th>USB compatibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>Run</td>
<td>MCU fully active</td>
<td>Required when USB not in suspend state.</td>
</tr>
<tr>
<td>Sleep</td>
<td>USB suspend exit causes the device to exit Sleep mode. Peripheral registers content is kept.</td>
<td>Available while USB is in suspend state.</td>
</tr>
<tr>
<td>Stop</td>
<td>USB suspend exit causes the device to exit Stop mode. Peripheral registers content is kept(1).</td>
<td>Available while USB is in suspend state.</td>
</tr>
<tr>
<td>Standby</td>
<td>Powered-down. The peripheral must be reinitialized after exiting Standby mode.</td>
<td>Not compatible with USB applications.</td>
</tr>
</tbody>
</table>

1. Within Stop mode there are different possible settings. Some restrictions may also exist, please refer to Section 5: Power control (PWR) to understand which (if any) restrictions apply when using OTG.

The following bits and procedures reduce power consumption.
The power consumption of the OTG PHY is controlled by two or three bits in the general core configuration register, depending on OTG revision supported.

- **PHY power down (OTG_GCCFG/PWRDWN)**
  It switches on/off the full-speed transceiver module of the PHY. It must be preliminarily set to allow any USB operation.

- **V_{BUS} detection enable (OTG_GCCFG/VBDEN)**
  It switches on/off the V_{BUS} sensing comparators associated with OTG operations.

Power reduction techniques are available while in the USB suspended state, when the USB session is not yet valid or the device is disconnected.

- **Stop PHY clock (STPPCLK bit in OTG_PCGCCTL)**
  When setting the stop PHY clock bit in the clock gating control register, most of the 48 MHz clock domain internal to the OTG full-speed core is switched off by clock gating. The dynamic power consumption due to the USB clock switching activity is cut even if the 48 MHz clock input is kept running by the application.
  Most of the transceiver is also disabled, and only the part in charge of detecting the asynchronous resume or remote wakeup event is kept alive.

- **Gate HCLK (GATEHCLK bit in OTG_PCGCCTL)**
  When setting the Gate HCLK bit in the clock gating control register, most of the system clock domain internal to the OTG_HS core is switched off by clock gating. Only the register read and write interface is kept alive. The dynamic power consumption due to the USB clock switching activity is cut even if the system clock is kept running by the application for other purposes.

- **USB system stop**
  When the OTG_HS is in the USB suspended state, the application may decide to drastically reduce the overall power consumption by a complete shut down of all the clock sources in the system. USB System Stop is activated by first setting the Stop PHY clock bit and then configuring the system deep sleep mode in the power control system module (PWR).
  The OTG_HS core automatically reactivates both system and USB clocks by asynchronous detection of remote wakeup (as an host) or resume (as a device) signaling on the USB.

To save dynamic power, the USB data FIFO is clocked only when accessed by the OTG_HS core.

### 56.10 Dynamic update of the OTG_HFIR register

The USB core embeds a dynamic trimming capability of micro-SOF framing period in host mode allowing to synchronize an external device with the micro-SOF frames.

When the OTG_HFIR register is changed within a current micro-SOF frame, the SOF period correction is applied in the next frame as described in *Figure 750*.

For a dynamic update, it is required to set RLDCTRL=0.
The USB system features 4 Kbytes of dedicated RAM with a sophisticated FIFO control mechanism. The packet FIFO controller module in the OTG_HS core organizes RAM space into Tx FIFOs into which the application pushes the data to be temporarily stored before the USB transmission, and into a single Rx FIFO where the data received from the USB are temporarily stored before retrieval (popped) by the application. The number of instructed FIFOs and how these are organized inside the RAM depends on the device's role. In peripheral mode an additional Tx FIFO is instructed for each active IN endpoint. Any FIFO size is software configured to better meet the application requirements.
56.11.1 Peripheral FIFO architecture

The OTG peripheral uses a single receive FIFO that receives the data directed to all OUT endpoints. Received packets are stacked back-to-back until free space is available in the Rx FIFO. The status of the received packet (which contains the OUT endpoint destination number, the byte count, the data PID and the validity of the received data) is also stored by the core on top of the data payload. When no more space is available, host transactions are NACKed and an interrupt is received on the addressed endpoint. The size of the receive FIFO is configured in the receive FIFO size register (OTG_GRXFSIZ).

The single receive FIFO architecture makes it more efficient for the USB peripheral to fill in the receive RAM buffer:
- All OUT endpoints share the same RAM buffer (shared FIFO)
- The OTG_HS core can fill in the receive FIFO up to the limit for any host sequence of OUT tokens

The application keeps receiving the Rx FIFO non-empty interrupt (RXFLVL bit in OTG_GINTSTS) as long as there is at least one packet available for download. It reads the packet information from the receive status read and pop register (OTG_GRXSTSP) and finally pops data off the receive FIFO by reading from the endpoint-related pop address.
Peripheral Tx FIFOs

The core has a dedicated FIFO for each IN endpoint. The application configures FIFO sizes by writing the endpoint 0 transmit FIFO size register (OTG_DIEPTXF0) for IN endpoint 0 and the device IN endpoint transmit FIFOx registers (OTG_DIEPTXFx) for IN endpoint-x.

56.11.2 Host FIFO architecture

The application configures FIFO sizes by writing the appropriate registers. The FIFOs are used to hold the received data (payload of the received packet) until it is transferred to the system memory. Packets received from any remote IN endpoint are stacked back-to-back until free space is available. The status of each received packet with the host channel destination, byte count, data PID and validity of the received data are also stored into the FIFO. The size of the receive FIFO is configured in the receive FIFO size register (OTG_GRXFSIZ).

The single receive FIFO architecture makes it highly efficient for the USB host to fill in the receive data buffer:

- All IN configured host channels share the same RAM buffer (shared FIFO)
- The OTG_HS core can fill in the receive FIFO up to the limit for any sequence of IN tokens driven by the host software

The application receives the Rx FIFO not-empty interrupt as long as there is at least one packet available for download. It reads the packet information from the receive status read and pop register and finally pops the data off the receive FIFO.
Host Tx FIFOs

The host uses one transmit FIFO for all non-periodic (control and bulk) OUT transactions and one transmit FIFO for all periodic (isochronous and interrupt) OUT transactions. FIFOs are used as transmit buffers to hold the data (payload of the transmit packet) to be transmitted over the USB. The size of the periodic (nonperiodic) Tx FIFO is configured in the host periodic (nonperiodic) transmit FIFO size OTG_HPTXFSIZ / OTG_HNPTXFSIZ) register.

The two Tx FIFO implementation derives from the higher priority granted to the periodic type of traffic over the USB frame. At the beginning of each frame, the built-in host scheduler processes the periodic request queue first, followed by the nonperiodic request queue.

The two transmit FIFO architecture provides the USB host with separate optimization for periodic and nonperiodic transmit data buffer management:

- All host channels configured to support periodic (nonperiodic) transactions in the OUT direction share the same RAM buffer (shared FIFOs)
- The OTG_HS core can fill in the periodic (nonperiodic) transmit FIFO up to the limit for any sequence of OUT tokens driven by the host software.

The OTG_HS core issues the periodic Tx FIFO empty interrupt (PTXFE bit in OTG_GINTSTS) as long as the periodic Tx FIFO is half or completely empty, depending on the value of the periodic Tx FIFO empty level bit in the AHB configuration register (PTXFELVL bit in OTG_GAHBCFG). The application can push the transmission data in advance as long as free space is available in both the periodic Tx FIFO and the periodic request queue. The host periodic transmit FIFO and queue status register (OTG_HPTXSTS) can be read to know how much space is available in both.

The OTG_HS core issues the non-periodic Tx FIFO empty interrupt (NPTXFE bit in OTG_GINTSTS) as long as the nonperiodic Tx FIFO is half or completely empty depending on the non-periodic Tx FIFO empty level bit in the AHB configuration register (TXFELVL bit in OTG_GAHBCFG). The application can push the transmission data as long as free space is available in both the nonperiodic Tx FIFO and nonperiodic request queue. The host nonperiodic transmit FIFO and queue status register (OTG_HNPTXSTS) can be read to know how much space is available in both.

56.11.3 FIFO RAM allocation

Device mode

Receive FIFO RAM allocation: the application should allocate RAM for SETUP packets:

- 10 locations must be reserved in the receive FIFO to receive SETUP packets on control endpoint. The core does not use these locations, which are reserved for SETUP packets, to write any other data.
- One location is to be allocated for Global OUT NAK.
- Status information is written to the FIFO along with each received packet. Therefore, a minimum space of (largest packet size / 4) + 1 must be allocated to receive packets. If multiple isochronous endpoints are enabled, then at least two (largest packet size / 4) + 1 spaces must be allocated to receive back-to-back packets. Typically, two (largest packet size / 4) + 1 spaces are recommended so that when the previous packet is being transferred to the CPU, the USB can receive the subsequent packet.
- Along with the last packet for each endpoint, transfer complete status information is also pushed to the FIFO. One location for each OUT endpoint is recommended.
Device RxFIFO =

\[(5 \times \text{number of control endpoints} + 8) + ((\text{largest USB packet used} / 4) + 1 \text{ for status information}) + (2 \times \text{number of OUT endpoints}) + 1 \text{ for Global NAK}\]

Example: The MPS is 1,024 bytes for a periodic USB packet and 512 bytes for a non-periodic USB packet. There are three OUT endpoints, three IN endpoints, one control endpoint, and three host channels.

Device RxFIFO = \[(5 \times 1 + 8) + ((1,024 / 4) + 1) + (2 \times 4) + 1 = 279\]

Transmit FIFO RAM allocation: the minimum RAM space required for each IN endpoint

Transmit FIFO is the maximum packet size for that particular IN endpoint.

Note: More space allocated in the transmit IN endpoint FIFO results in better performance on the USB.

Host mode

Receive FIFO RAM allocation:

Status information is written to the FIFO along with each received packet. Therefore, a minimum space of \((\text{largest packet size} / 4) + 1\) must be allocated to receive packets. If multiple isochronous channels are enabled, then at least two \((\text{largest packet size} / 4) + 1\) spaces must be allocated to receive back-to-back packets. Typically, two \((\text{largest packet size} / 4) + 1\) spaces are recommended so that when the previous packet is being transferred to the CPU, the USB can receive the subsequent packet.

Along with the last packet in the host channel, transfer complete status information is also pushed to the FIFO. So one location must be allocated for this.

Host RxFIFO = \((\text{largest USB packet used} / 4) + 1 \text{ for status information} + 1 \text{ transfer complete}\)

Example: Host RxFIFO = \((1,024 / 4) + 1 + 1 = 258\)

Transmit FIFO RAM allocation:

The minimum amount of RAM required for the host Non-periodic Transmit FIFO is the largest maximum packet size among all supported non-periodic OUT channels.

Typically, two largest packet sizes worth of space is recommended, so that when the current packet is under transfer to the USB, the CPU can get the next packet.

Non-Periodic TxFIFO = \(\text{largest non-periodic USB packet used} / 4\)

Example: Non-Periodic TxFIFO = \(512 / 4 = 128\)

The minimum amount of RAM required for host periodic Transmit FIFO is the largest maximum packet size out of all the supported periodic OUT channels. If there is at least one isochronous OUT endpoint, then the space must be at least two times the maximum packet size of that channel.

Host Periodic TxFIFO = \(\text{largest periodic USB packet used} / 4\)

Example: Host Periodic TxFIFO = \(1,024 / 4 = 256\)

Note: More space allocated in the Transmit Non-periodic FIFO results in better performance on the USB.
56.12 OTG_HS interrupts

When the OTG_HS controller is operating in one mode, either device or host, the application must not access registers from the other mode. If an illegal access occurs, a mode mismatch interrupt is generated and reflected in the core interrupt register (MMIS bit in the OTG_GINTSTS register). When the core switches from one mode to the other, the registers in the new mode of operation must be reprogrammed as they would be after a power-on reset.

*Figure 753* shows the interrupt hierarchy.
1. OTG_HS_WKUP becomes active (high state) when resume condition occurs during L1 SLEEP or L2 SUSPEND states.
56.13 OTG_HS control and status registers

By reading from and writing to the control and status registers (CSRs) through the AHB slave interface, the application controls the OTG_HS controller. These registers are 32 bits wide, and the addresses are 32-bit block aligned. The OTG_HS registers must be accessed by words (32 bits).

CSRs are classified as follows:
- Core global registers
- Host-mode registers
- Host global registers
- Host port CSRs
- Host channel-specific registers
- Device-mode registers
- Device global registers
- Device endpoint-specific registers
- Power and clock-gating registers
- Data FIFO (DFIFO) access registers

Only the core global, power and clock-gating, data FIFO access, and host port control and status registers can be accessed in both host and device modes. When the OTG_HS controller is operating in one mode, either device or host, the application must not access registers from the other mode. If an illegal access occurs, a mode mismatch interrupt is generated and reflected in the core interrupt register (MMIS bit in the OTG_GINTSTS register). When the core switches from one mode to the other, the registers in the new mode of operation must be reprogrammed as they would be after a power-on reset.

56.13.1 CSR memory map

The host and device mode registers occupy different addresses. All registers are implemented in the AHB clock domain.

Global CSR map

These registers are available in both host and device modes.

</table>

56.14 OTG_HS registers

These registers are available in both host and device modes, and do not need to be reprogrammed when switching between these modes.

Bit values in the register descriptions are expressed in binary unless otherwise specified.

56.14.1 OTG control and status register (OTG_GOTGCTL)

Address offset: 0x000

Reset value: 0x0001 0000

The OTG_GOTGCTL register controls the behavior and reflects the status of the OTG function of the core.
Bits 31:22  Reserved, must be kept at reset value.

Bit 21  **CURMOD:** Current mode of operation
Indicates the current mode (host or device).
0: Device mode
1: Host mode

Bit 20  **OTGVER:** OTG version
Selects the OTG revision.
0: OTG Version 1.3. OTG1.3 is obsolete for new product development.
1: OTG Version 2.0. In this version the core supports only data line pulsing for SRP.

Bit 19  **BSVLD:** B-session valid
Indicates the device mode transceiver status.
0: B-session is not valid.
1: B-session is valid.
In OTG mode, the user can use this bit to determine if the device is connected or disconnected.
*Note:* Only accessible in device mode.

Bit 18  **ASVLD:** A-session valid
Indicates the host mode transceiver status.
0: A-session is not valid
1: A-session is valid
*Note:* Only accessible in host mode.

Bit 17  **DBCT:** Long/short debounce time
Indicates the debounce time of a detected connection.
0: Long debounce time, used for physical connections (100 ms + 2.5 µs)
1: Short debounce time, used for soft connections (2.5 µs)
*Note:* Only accessible in host mode.

Bit 16  **CIDSTS:** Connector ID status
Indicates the connector ID status on a connect event.
0: The OTG_HS controller is in A-device mode
1: The OTG_HS controller is in B-device mode
*Note:* Accessible in both device and host modes.

Bits 15:13  Reserved, must be kept at reset value.

Bit 12  **EHEN:** Embedded host enable
It is used to select between OTG A device state machine and embedded host state machine.
0: OTG A device state machine is selected
1: Embedded host state machine is selected

Bit 11  **DHNPEN:** Device HNP enabled
The application sets this bit when it successfully receives a SetFeature.SetHNPEnable command from the connected USB host.
0: HNP is not enabled in the application
1: HNP is enabled in the application
*Note:* Only accessible in device mode.
**Bit 10  ** **HSHNPEN:** host set HNP enable
The application sets this bit when it has successfully enabled HNP (using the SetFeature.SetHNPEnable command) on the connected device.
0: Host Set HNP is not enabled
1: Host Set HNP is enabled
*Note: Only accessible in host mode.*

**Bit 9  ** **HNPRQ:** HNP request
The application sets this bit to initiate an HNP request to the connected USB host. The application can clear this bit by writing a 0 when the host negotiation success status change bit in the OTG_GOTGINT register (HNSSCHG bit in OTG_GOTGINT) is set. The core clears this bit when the HNSSCHG bit is cleared.
0: No HNP request
1: HNP request
*Note: Only accessible in device mode.*

**Bit 8  ** **HNGSCS:** Host negotiation success
The core sets this bit when host negotiation is successful. The core clears this bit when the HNP request (HNPRQ) bit in this register is set.
0: Host negotiation failure
1: Host negotiation success
*Note: Only accessible in device mode.*

**Bit 7  ** **BVALOVAL:** B-peripheral session valid override value.
This bit is used to set override value for Bvalid signal when BVALOEN bit is set.
0: Bvalid value is '0' when BVALOEN = 1
1: Bvalid value is '1' when BVALOEN = 1
*Note: Only accessible in device mode.*

**Bit 6  ** **BVALOEN:** B-peripheral session valid override enable.
This bit is used to enable/disable the software to override the Bvalid signal using the BVALOVAL bit.
0: Override is disabled and Bvalid signal from the respective PHY selected is used internally by the core
1: Internally Bvalid received from the PHY is overridden with BVALOVAL bit value
*Note: Only accessible in device mode.*

**Bit 5  ** **AVALOVAL:** A-peripheral session valid override value.
This bit is used to set override value for Avalid signal when AVALOEN bit is set.
0: Avalid value is '0' when AVALOEN = 1
1: Avalid value is '1' when AVALOEN = 1
*Note: Only accessible in device mode.*

**Bit 4  ** **AVALOEN:** A-peripheral session valid override enable.
This bit is used to enable/disable the software to override the Avalid signal using the AVALOVAL bit.
0: Override is disabled and Avalid signal from the respective PHY selected is used internally by the core
1: Internally Avalid received from the PHY is overridden with AVALOVAL bit value
*Note: Only accessible in host mode.*
Bit 3 **VBVALOVAL**: \( V_{BUS} \) valid override value.

This bit is used to set override value for \( vbusvalid \) signal when VBVALOEN bit is set.

- 0: \( vbusvalid \) value is '0' when VBVALOEN = 1
- 1: \( vbusvalid \) value is '1' when VBVALOEN = 1

*Note: Only accessible in host mode.*

Bit 2 **VBVALOEN**: \( V_{BUS} \) valid override enable.

This bit is used to enable/disable the software to override the \( vbusvalid \) signal using the VBVALOVAL bit.

- 0: Override is disabled and \( vbusvalid \) signal from the respective PHY selected is used internally by the core
- 1: Internally \( vbusvalid \) received from the PHY is overridden with VBVALOVAL bit value

*Note: Only accessible in host mode.*

Bit 1 **SRQ**: Session request

The application sets this bit to initiate a session request on the USB. The application can clear this bit by writing a 0 when the host negotiation success status change bit in the OTG_GOTGINT register (HNSSCHG bit in OTG_GOTGINT) is set. The core clears this bit when the HNSSCHG bit is cleared.

If the user uses the USB 1.1 full-speed serial transceiver interface to initiate the session request, the application must wait until \( V_{BUS} \) discharges to 0.2 V, after the B-session valid bit in this register (BSVLD bit in OTG_GOTGCTL) is cleared.

- 0: No session request
- 1: Session request

*Note: Only accessible in device mode.*

Bit 0 **SRQSCS**: Session request success

The core sets this bit when a session request initiation is successful.

- 0: Session request failure
- 1: Session request success

*Note: Only accessible in device mode.*

### 56.14.2 OTG interrupt register (OTG_GOTGINT)

**Address offset**: 0x04

**Reset value**: 0x0000 0000

The application reads this register whenever there is an OTG interrupt and clears the bits in this register to clear the OTG interrupt.
Bits 31:21 Reserved, must be kept at reset value.

Bit 20 IDCHNG:
This bit when set indicates that there is a change in the value of the ID input pin.

Bit 19 DBCDNE: Debounce done
The core sets this bit when the debounce is completed after the device connect. The application can start driving USB reset after seeing this interrupt. This bit is only valid when the HNP Capable or SRP Capable bit is set in the OTG_GUSBCFG register (HNPCAP bit or SRPCAP bit in OTG_GUSBCFG, respectively).

*Note: Only accessible in host mode.*

Bit 18 ADTOCHG: A-device timeout change
The core sets this bit to indicate that the A-device has timed out while waiting for the B-device to connect.

*Note: Accessible in both device and host modes.*

Bit 17 HNGDET: Host negotiation detected
The core sets this bit when it detects a host negotiation request on the USB.

*Note: Accessible in both device and host modes.*

Bits 16:10 Reserved, must be kept at reset value.

Bit 9 HNSSCHG: Host negotiation success status change
The core sets this bit on the success or failure of a USB host negotiation request. The application must read the host negotiation success bit of the OTG_GOTGCTL register (HNGSCS bit in OTG_GOTGCTL) to check for success or failure.

*Note: Accessible in both device and host modes.*

Bits 7:3 Reserved, must be kept at reset value.

Bit 8 SRSSCHG: Session request success status change
The core sets this bit on the success or failure of a session request. The application must read the session request success bit in the OTG_GOTGCTL register (SRQSCS bit in OTG_GOTGCTL) to check for success or failure.

*Note: Accessible in both device and host modes.*

Bit 2 SEDET: Session end detected
The core sets this bit to indicate that the level of the voltage on VBUS is no longer valid for a B-Peripheral session when VBUS < 0.8 V.

*Note: Accessible in both device and host modes.*

Bits 1:0 Reserved, must be kept at reset value.
56.14.3 OTG AHB configuration register (OTG_GAHBCFG)

Address offset: 0x008
Reset value: 0x0000 0000

This register can be used to configure the core after power-on or a change in mode. This register mainly contains AHB system-related configuration parameters. Do not change this register after the initial programming. The application must program this register before starting any transactions on either the AHB or the USB.

| Bit 31-9 Reserved, must be kept at reset value. |
| Bit 8 | PTXFELVL: Periodic Tx FIFO empty level |
| Indicates when the periodic Tx FIFO empty interrupt bit in the OTG_GINTSTS register (PTXFE bit in OTG_GINTSTS) is triggered. |
| 0: PTXFE (in OTG_GINTSTS) interrupt indicates that the Periodic Tx FIFO is half empty |
| 1: PTXFE (in OTG_GINTSTS) interrupt indicates that the Periodic Tx FIFO is completely empty |
| Note: Only accessible in host mode. |
| Bit 7 | TXFELVL: Tx FIFO empty level |
| In device mode, this bit indicates when IN endpoint Transmit FIFO empty interrupt (TXFE in OTG_DIEPINTx) is triggered: |
| 0: The TXFE (in OTG_DIEPINTx) interrupt indicates that the IN endpoint Tx FIFO is half empty |
| 1: The TXFE (in OTG_DIEPINTx) interrupt indicates that the IN endpoint Tx FIFO is completely empty |
| In host mode, this bit indicates when the nonperiodic Tx FIFO empty interrupt (NPTXFE bit in OTG_GINTSTS) is triggered: |
| 0: The NPTXFE (in OTG_GINTSTS) interrupt indicates that the nonperiodic Tx FIFO is half empty |
| 1: The NPTXFE (in OTG_GINTSTS) interrupt indicates that the nonperiodic Tx FIFO is completely empty |
| Bit 6 Reserved, must be kept at reset value. |
Bit 5 **DMAEN**: DMA enabled

- 0: The core operates in slave mode
- 1: The core operates in DMA mode

Bits 4:1 **HBSTLEN[3:0]**: Burst length/type

- 0000 Single: Bus transactions use single 32 bit accesses (not recommended)
- 0001 INCR: Bus transactions use unspecified length accesses (not recommended, uses the INCR AHB bus command)
- 0011 INCR4: Bus transactions target 4x 32 bit accesses
- 0101 INCR8: Bus transactions target 8x 32 bit accesses
- 0111 INCR16: Bus transactions based on 16x 32 bit accesses

Others: Reserved

Bit 0 **GINTMSK**: Global interrupt mask

The application uses this bit to mask or unmask the interrupt line assertion to itself. Irrespective of this bit’s setting, the interrupt status registers are updated by the core.

- 0: Mask the interrupt assertion to the application.
- 1: Unmask the interrupt assertion to the application.

*Note*: Accessible in both device and host modes.

### 56.14.4 OTG USB configuration register (OTG_GUSBCFG)

**Address offset**: 0x00C

**Reset value**: 0x0000 1400

This register can be used to configure the core after power-on or a changing to host mode or device mode. It contains USB and USB-PHY related configuration parameters. The application must program this register before starting any transactions on either the AHB or the USB. Do not make changes to this register after the initial programming.

![Register Configuration Table](image-url)
Bit 31  Reserved, must be kept at reset value.

Bit 30  **FDMOD:** Force device mode
   Writing a 1 to this bit, forces the core to device mode irrespective of the OTG_ID input pin.
   0: Normal mode
   1: Force device mode
   After setting the force bit, the application must wait at least 25 ms before the change takes effect.
   
   *Note:* Accessible in both device and host modes.

Bit 29  **FHMOD:** Force host mode
   Writing a 1 to this bit, forces the core to host mode irrespective of the OTG_ID input pin.
   0: Normal mode
   1: Force host mode
   After setting the force bit, the application must wait at least 25 ms before the change takes effect.
   
   *Note:* Accessible in both device and host modes.

Bits 28:26  Reserved, must be kept at reset value.

Bit 25  **ULPIIPD:** ULPI interface protect disable
   This bit controls the circuitry built in the PHY to protect the ULPI interface when the link tri-states stp and data. Any pull-up or pull-down resistors employed by this feature can be disabled. Refer to the ULPI specification for more details.
   0: Enables the interface protection circuit
   1: Disables the interface protection circuit

Bit 24  **PTCI:** Indicator pass through
   This bit controls whether the complement output is qualified with the internal \( V_{BUS} \) valid comparator before being used in the \( V_{BUS} \) state in the RX CMD. Refer to the ULPI specification for more details.
   0: Complement Output signal is qualified with the Internal \( V_{BUS} \) valid comparator
   1: Complement Output signal is not qualified with the Internal \( V_{BUS} \) valid comparator

Bit 23  **PCCI:** Indicator complement
   This bit controls the PHY to invert the External\( V_{bus} \)Indicator input signal, and generate the complement output. Refer to the ULPI specification for more details.
   0: PHY does not invert the External\( V_{bus} \)Indicator signal
   1: PHY inverts External\( V_{bus} \)Indicator signal

Bit 22  **TSDPS:** TermSel DLine pulsing selection
   This bit selects utmi_termselect to drive the data line pulse during SRP (session request protocol).
   0: Data line pulsing using utmi_tvalid (default)
   1: Data line pulsing using utmi_termsel

Bit 21  **ULPIEVBUSI:** ULPI external \( V_{BUS} \) indicator
   This bit indicates to the ULPI PHY to use an external \( V_{BUS} \) overcurrent indicator.
   0: PHY uses an internal \( V_{BUS} \) valid comparator
   1: PHY uses an external \( V_{BUS} \) valid comparator

Bit 20  **ULPIEVBUSD:** ULPI External \( V_{BUS} \) Drive
   This bit selects between internal or external supply to drive 5 V on \( V_{BUS} \), in the ULPI PHY.
   0: PHY drives \( V_{BUS} \) using internal charge pump (default)
   1: PHY drives \( V_{BUS} \) using external supply.
Bit 19 **ULPICSM**: ULPI clock SuspendM  
This bit sets the ClockSuspendM bit in the interface control register on the ULPI PHY. This bit applies only in the serial and carkit modes.  
0: PHY powers down the internal clock during suspend  
1: PHY does not power down the internal clock  

Bit 18 **ULPIAR**: ULPI Auto-resume  
This bit sets the AutoResume bit in the interface control register on the ULPI PHY.  
0: PHY does not use AutoResume feature  
1: PHY uses AutoResume feature  

Bit 17 **ULPIFSLS**: ULPI FS/LS select  
The application uses this bit to select the FS/LS serial interface for the ULPI PHY. This bit is valid only when the FS serial transceiver is selected on the ULPI PHY.  
0: ULPI interface  
1: ULPI FS/LS serial interface  

Bit 16 Reserved, must be kept at reset value.  

Bit 15 **PHYLPC**: PHY Low-power clock select  
This bit selects either 480 MHz or 48 MHz (low-power) PHY mode. In FS and LS modes, the PHY can usually operate on a 48 MHz clock to save power.  
0: 480 MHz internal PLL clock  
1: 48 MHz external clock  
In 480 MHz mode, the UTMI interface operates at either 60 or 30 MHz, depending on whether the 8- or 16-bit data width is selected. In 48 MHz mode, the UTMI interface operates at 48 MHz in FS and LS modes.  

Bit 14 Reserved, must be kept at reset value.  

Bits 13:10 **TRDT[3:0]**: USB turnaround time  
These bits allow to set the turnaround time in PHY clocks. They must be configured according to or Table 503: TRDT values (HS), depending on the application AHB frequency. Higher TRDT values allow stretching the USB response time to IN tokens in order to compensate for longer AHB read access latency to the data FIFO.  
*Note: Only accessible in device mode.*  

Bit 9 **HNPCAP**: HNP-capable  
The application uses this bit to control the OTG_HS controller’s HNP capabilities.  
0: HNP capability is not enabled.  
1: HNP capability is enabled.  
*Note: Accessible in both device and host modes.*  

Bit 8 **SRPCAP**: SRP-capable  
The application uses this bit to control the OTG_HS controller’s SRP capabilities. If the core operates as a non-SRP-capable B-device, it cannot request the connected A-device (host) to activate VBUS and start a session.  
0: SRP capability is not enabled.  
1: SRP capability is enabled.  
*Note: Accessible in both device and host modes.*  

Bit 7 Reserved, must be kept at reset value.  

Bit 6 **PHYSEL**: Full speed serial transceiver select  
0: USB 2.0 external ULPI high-speed PHY.  
1: USB 1.1 full-speed serial transceiver.
Bit 5  Reserved, must be kept at reset value.
Bit 4  Reserved, must be kept at reset value.
Bit 3  Reserved, must be kept at reset value.

Bits 2:0  **TOCAL[2:0]: FS timeout calibration**

The number of PHY clocks that the application programs in this field is added to the full-speed interpacket timeout duration in the core to account for any additional delays introduced by the PHY. This can be required, because the delay introduced by the PHY in generating the line state condition can vary from one PHY to another.

The USB standard timeout value for full-speed operation is 16 to 18 (inclusive) bit times. The application must program this field based on the speed of enumeration. The number of bit times added per PHY clock is 0.25 bit times.

</tr>
</tbody>
</table>
```
Bit 4 **RXFFLSH:** Rx FIFO flush

The application can flush the entire Rx FIFO using this bit, but must first ensure that the core is not in the middle of a transaction.

The application must only write to this bit after checking that the core is neither reading from the Rx FIFO nor writing to the Rx FIFO.

The application must wait until the bit is cleared before performing any other operations. This bit requires 8 clocks (slowest of PHY or AHB clock) to clear.

*Note:* Accessible in both device and host modes.

Bit 3 Reserved, must be kept at reset value.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **PSRST:** Partial soft reset

Resets the internal state machines but keeps the enumeration info. Could be used to recover some specific PHY errors.

*Note:* Accessible in both device and host modes.

Bit 0 **CSRST:** Core soft reset

Resets the HCLK and PHY clock domains as follows:

- Clears the interrupts and all the CSR register bits except for the following bits:
  - GATEHCLK bit in OTG_PCGCCTL
  - STPPCLK bit in OTG_PCGCCTL
  - FSLSPCS bits in OTG_HCFG
  - DSPD bit in OTG_DCFG
  - SDIS bit in OTG_DCTL
  - OTG_GCCFG register

All module state machines (except for the AHB slave unit) are reset to the Idle state, and all the transmit FIFOs and the receive FIFO are flushed.

Any transactions on the AHB Master are terminated as soon as possible, after completing the last data phase of an AHB transfer. Any transactions on the USB are terminated immediately.

The application can write to this bit any time it wants to reset the core. This is a self-clearing bit and the core clears this bit after all the necessary logic is reset in the core, which can take several clocks, depending on the current state of the core. Once this bit has been cleared, the software must wait at least 3 PHY clocks before accessing the PHY domain (synchronization delay). The software must also check that bit 31 in this register is set to 1 (AHB Master is Idle) before starting any operation.

Typically, the software reset is used during software development and also when the user dynamically changes the PHY selection bits in the above listed USB configuration registers. When you change the PHY, the corresponding clock for the PHY is selected and used in the PHY domain. Once a new clock is selected, the PHY domain has to be reset for proper operation.

*Note:* Accessible in both device and host modes.
56.14.6 OTG core interrupt register (OTG_GINTSTS)

Address offset: 0x014
Reset value: 0x1400 0020

This register interrupts the application for system-level events in the current mode (device mode or host mode).

Some of the bits in this register are valid only in host mode, while others are valid in device mode only. This register also indicates the current mode. To clear the interrupt status bits of the rc_w1 type, the application must write 1 into the bit.

The FIFO status interrupts are read-only; once software reads from or writes to the FIFO while servicing these interrupts, FIFO interrupt conditions are cleared automatically.

The application must clear the OTG_GINTSTS register at initialization before unmasking the interrupt bit to avoid any interrupts generated prior to initialization.

</table>

Bit 31 **WKUPINT**: Resume/remote wakeup detected interrupt
Wakeup interrupt during suspend(L2) or LPM(L1) state.
- During suspend(L2):
  - In device mode, this interrupt is asserted when a resume is detected on the USB. In host mode, this interrupt is asserted when a remote wakeup is detected on the USB.
  - During LPM(L1):
    - This interrupt is asserted for either host initiated resume or device initiated remote wakeup on USB.

*Note: Accessible in both device and host modes.*

Bit 30 **SRQINT**: Session request/new session detected interrupt
In host mode, this interrupt is asserted when a session request is detected from the device. In device mode, this interrupt is asserted when VBUS is in the valid range for a B-peripheral device. Accessible in both device and host modes.

Bit 29 **DISCINT**: Disconnect detected interrupt
Asserted when a device disconnect is detected.
*Note: Only accessible in host mode.*

Bit 28 **CIDSCHG**: Connector ID status change
The core sets this bit when there is a change in connector ID status.
*Note: Accessible in both device and host modes.*

Bit 27 Reserved, must be kept at reset value.
Bit 26  **PTXFE**: Periodic Tx FIFO empty
Asserted when the periodic transmit FIFO is either half or completely empty and there is space for at least one entry to be written in the periodic request queue. The half or completely empty status is determined by the periodic Tx FIFO empty level bit in the OTG_GAHBCFG register (PTXFELVL bit in OTG_GAHBCFG).

*Note: Only accessible in host mode.*

Bit 25  **HCINT**: Host channels interrupt
The core sets this bit to indicate that an interrupt is pending on one of the channels of the core (in host mode). The application must read the OTG_HAINT register to determine the exact number of the channel on which the interrupt occurred, and then read the corresponding OTG_HCINTx register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the OTG_HCINTx register to clear this bit.

*Note: Only accessible in host mode.*

Bit 24  **HPRTINT**: Host port interrupt
The core sets this bit to indicate a change in port status of one of the OTG_HS controller ports in host mode. The application must read the OTG_HPRT register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the OTG_HPRT register to clear this bit.

*Note: Reserved, must be kept at reset value.*

Bit 22  **DATAFSUSP**: Data fetch suspended
This interrupt is valid only in DMA mode. This interrupt indicates that the core has stopped fetching data for IN endpoints due to the unavailability of TxFIFO space or request queue space. This interrupt is used by the application for an endpoint mismatch algorithm. For example, after detecting an endpoint mismatch, the application:
- Sets a global nonperiodic IN NAK handshake
- Disables IN endpoints
- Flushes the FIFO
- Determines the token sequence from the IN token sequence learning queue
- Re-enables the endpoints

Clears the global nonperiodic IN NAK handshake if the global nonperiodic IN NAK is cleared, the core has not yet fetched data for the IN endpoint, and the IN token is received: the core generates an "IN token received when FIFO empty" interrupt. The OTG then sends a NAK response to the host. To avoid this scenario, the application can check the FetSusp interrupt in OTG_GINTSTS, which ensures that the FIFO is full before clearing a global NAK handshake. Alternatively, the application can mask the "IN token received when FIFO empty" interrupt when clearing a global IN NAK handshake.

Bit 21  **IPXFR**: Incomplete periodic transfer
In host mode, the core sets this interrupt bit when there are incomplete periodic transactions still pending, which are scheduled for the current frame.

**INCOMPISOOUT**: Incomplete isochronous OUT transfer
In device mode, the core sets this interrupt to indicate that there is at least one isochronous OUT endpoint on which the transfer is not completed in the current frame. This interrupt is asserted along with the End of periodic frame interrupt (EOPF) bit in this register.

Bit 20  **ISOIXFR**: Incomplete isochronous IN transfer
The core sets this interrupt to indicate that there is at least one isochronous IN endpoint on which the transfer is not completed in the current frame. This interrupt is asserted along with the End of periodic frame interrupt (EOPF) bit in this register.

*Note: Only accessible in device mode.*
Bit 19 **OEPINT**: OUT endpoint interrupt
The core sets this bit to indicate that an interrupt is pending on one of the OUT endpoints of the core (in device mode). The application must read the OTG_DAINT register to determine the exact number of the OUT endpoint on which the interrupt occurred, and then read the corresponding OTG_DOEPINTx register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the corresponding OTG_DOEPINTx register to clear this bit.

*Note: Only accessible in device mode.*

Bit 18 **IEPINT**: IN endpoint interrupt
The core sets this bit to indicate that an interrupt is pending on one of the IN endpoints of the core (in device mode). The application must read the OTG_DAINT register to determine the exact number of the IN endpoint on which the interrupt occurred, and then read the corresponding OTG_DIEPINTx register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the corresponding OTG_DIEPINTx register to clear this bit.

*Note: Only accessible in device mode.*

Bits 17:16 Reserved, must be kept at reset value.

Bit 15 **EOPF**: End of periodic frame interrupt
Indicates that the period specified in the periodic frame interval field of the OTG_DCFG register (PFIVL bit in OTG_DCFG) has been reached in the current frame.

*Note: Only accessible in device mode.*

Bit 14 **ISOODRP**: Isochronous OUT packet dropped interrupt
The core sets this bit when it fails to write an isochronous OUT packet into the Rx FIFO because the Rx FIFO does not have enough space to accommodate a maximum size packet for the isochronous OUT endpoint.

*Note: Only accessible in device mode.*

Bit 13 **ENUMDNE**: Enumeration done
The core sets this bit to indicate that speed enumeration is complete. The application must read the OTG_DSTS register to obtain the enumerated speed.

*Note: Only accessible in device mode.*

Bit 12 **USBRST**: USB reset
The core sets this bit to indicate that a reset is detected on the USB.

*Note: Only accessible in device mode.*

Bit 11 **USBSUSP**: USB suspend
The core sets this bit to indicate that a suspend was detected on the USB. The core enters the suspended state when there is no activity on the data lines for an extended period of time.

*Note: Only accessible in device mode.*

Bit 10 **ESUSP**: Early suspend
The core sets this bit to indicate that an Idle state has been detected on the USB for 3 ms.

*Note: Only accessible in device mode.*

Bits 9:8 Reserved, must be kept at reset value.

Bit 7 **GONAKEFF**: Global OUT NAK effective
Indicates that the Set global OUT NAK bit in the OTG_DCTL register (SGONAK bit in OTG_DCTL), set by the application, has taken effect in the core. This bit can be cleared by writing the Clear global OUT NAK bit in the OTG_DCTL register (CGONAK bit in OTG_DCTL).

*Note: Only accessible in device mode.*
Bit 6 **GINAKEFF**: Global IN non-periodic NAK effective
 Indicates that the Set global non-periodic IN NAK bit in the OTG_DCTL register (SGINAK bit in OTG_DCTL), set by the application, has taken effect in the core. That is, the core has sampled the Global IN NAK bit set by the application. This bit can be cleared by clearing the Clear global non-periodic IN NAK bit in the OTG_DCTL register (CGINAK bit in OTG_DCTL).
 This interrupt does not necessarily mean that a NAK handshake is sent out on the USB. TheSTALL bit takes precedence over the NAK bit.
*Note:* Only accessible in device mode.

Bit 5 **NPTXFE**: Non-periodic Tx FIFO empty
 This interrupt is asserted when the non-periodic Tx FIFO is either half or completely empty, and there is space for at least one entry to be written to the non-periodic transmit request queue. The half or completely empty status is determined by the non-periodic Tx FIFO empty level bit in the OTG_GAHBCFG register (TXFELVL bit in OTG_GAHBCFG).
*Note:* Accessible in host mode only.

Bit 4 **RXFLVL**: Rx FIFO non-empty
 Indicates that there is at least one packet pending to be read from the Rx FIFO.
*Note:* Accessible in both host and device modes.

Bit 3 **SOF**: Start of frame
 In host mode, the core sets this bit to indicate that an SOF (FS), or Keep-Alive (LS) is transmitted on the USB. The application must write a 1 to this bit to clear the interrupt.
 In device mode, in the core sets this bit to indicate that an SOF token has been received on the USB. The application can read the OTG_DSTS register to get the current frame number. This interrupt is seen only when the core is operating in FS.
*Note:* This register may return ‘1’ if read immediately after power on reset. If the register bit reads ‘1’ immediately after power on reset it does not indicate that an SOF has been sent (in case of host mode) or SOF has been received (in case of device mode). The read value of this interrupt is valid only after a valid connection between host and device is established. If the bit is set after power on reset the application can clear the bit.
*Note:* Accessible in both host and device modes.

Bit 2 **OTGINT**: OTG interrupt
 The core sets this bit to indicate an OTG protocol event. The application must read the OTG interrupt status (OTG_GOTGINT) register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the OTG_GOTGINT register to clear this bit.
*Note:* Accessible in both host and device modes.

Bit 1 **MMIS**: Mode mismatch interrupt
 The core sets this bit when the application is trying to access:
 – A host mode register, when the core is operating in device mode
 – A device mode register, when the core is operating in host mode
 The register access is completed on the AHB with an OKAY response, but is ignored by the core internally and does not affect the operation of the core.
*Note:* Accessible in both host and device modes.

Bit 0 **CMOD**: Current mode of operation
 Indicates the current mode.
0: Device mode
1: Host mode
*Note:* Accessible in both host and device modes.
OTG interrupt mask register (OTG_GINTMSK)

Address offset: 0x018
Reset value: 0x0000 0000

This register works with the core interrupt register to interrupt the application. When an interrupt bit is masked, the interrupt associated with that bit is not generated. However, the core interrupt (OTG_GINTSTS) register bit corresponding to that interrupt is still set.

56.14.8 OTG receive status debug read register (OTG_GRXSTSR)

Address offset for read: 0x01C
Reset value: 0x0000 0000

This description is for register OTG_GRXSTSR in Device mode.

A read to the receive status debug read register returns the contents of the top of the receive FIFO.

The core ignores the receive status read when the receive FIFO is empty and returns a value of 0x0000 0000.

56.14.10 OTG status read and pop registers (OTG_GRXSTSP)

Address offset for pop: 0x020
Reset value: 0x0000 0000

This description is for register OTG_GRXSTSP in Device mode.

Similarly to OTG_GRXSTSR (receive status debug read register) where a read returns the contents of the top of the receive FIFO, a read to OTG_GRXSTSP (receive status read and pop register) additionally pops the top data entry out of the Rx FIFO.

The core ignores the receive status pop/read when the receive FIFO is empty and returns a value of 0x0000 0000. The application must only pop the receive status FIFO when the receive FIFO non-empty bit of the core interrupt register (RXFLVL bit in OTG_GINTSTS) is asserted.

Host mode

Bits 31:16 **NPTXFD[15:0]:** Non-periodic Tx FIFO depth
This value is in terms of 32-bit words.
Minimum value is 16
Programmed values must respect the available FIFO memory allocation and must not exceed the power-on value.

Bits 15:0 **NPTXFSA[15:0]:** Non-periodic transmit RAM start address
This field configures the memory start address for non-periodic transmit FIFO RAM.

Device mode

Bits 31:16 **TX0FD:** Endpoint 0 Tx FIFO depth
This value is in terms of 32-bit words.
Minimum value is 16
Programmed values must respect the available FIFO memory allocation and must not exceed the power-on value.

Bits 15:0 **TX0FSA:** Endpoint 0 transmit RAM start address
This field configures the memory start address for the endpoint 0 transmit FIFO RAM.

56.14.14 OTG non-periodic transmit FIFO/queue status register (OTG_HNPTXSTS)

Address offset: 0x02C
Reset value: 0x0008 0400

**Note:** *In device mode, this register is not valid.*

This read-only register contains the free space information for the non-periodic Tx FIFO and the non-periodic transmit request queue.

ST
Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **VBDEN**: USB $V_{BUS}$ detection enable

This bit is set by the software to put the BCD into SD mode. Only one detection mode (DCD, PD, SD or OFF) should be selected to work correctly.

Bit 20 **SDEN**: Secondary detection (SD) mode enable

This bit is set by the software to put the BCD into SD mode. Only one detection mode (DCD, PD, SD or OFF) should be selected to work correctly.

Bit 19 **PDEN**: Primary detection (PD) mode enable

This bit is set by the software to put the BCD into PD mode. Only one detection mode (DCD, PD, SD or OFF) should be selected to work correctly.

Bit 18 **DCDEN**: Data contact detection (DCD) mode enable

This bit is set by the software to put the BCD into DCD mode. Only one detection mode (DCD, PD, SD or OFF) should be selected to work correctly.

Bit 17 **BCDEN**: Battery charging detector (BCD) enable

This bit is set by the software to enable the BCD support within the USB device. When enabled, the USB PHY is fully controlled by BCD and cannot be used for normal communication. Once the BCD discovery is finished, the BCD should be placed in OFF mode by clearing this bit to '0' in order to allow the normal USB operation.

Bit 16 **PWRDWN**: Power down control

Used to activate the transceiver in transmission/reception. When reset, the transceiver is kept in power-down. When set, the BCD function must be off (BCDEN=0).

Bits 15:4 Reserved, must be kept at reset value.

Bit 3 **PS2DET**: DM pull-up detection status

This bit is active only during PD and gives the result of comparison between DM voltage level and VLGC threshold. In normal situation, the DM level should be below this threshold. If it is above, it means that the DM is externally pulled high. This can be caused by connection to a PS2 port (which pulls-up both DP and DM lines) or to some proprietary charger not following the BCD specification.

0: Normal port detected (connected to SDP, CDP or DCP)
1: PS2 port or proprietary charger detected

Bit 2 **SDET**: Secondary detection (SD) status

This bit gives the result of SD.
0: CDP detected
1: DCP detected

Bit 1 **PDET**: Primary detection (PD) status

This bit gives the result of PD.
0: no BCD support detected (connected to SDP or proprietary device).
1: BCD support detected (connected to CDP or DCP).

Bit 0 **DCDET**: Data contact detection (DCD) status

This bit gives the result of DCD.
0: data lines contact not detected
1: data lines contact detected
56.14.16  OTG core ID register (OTG_CID)

Address offset: 0x03C
Reset value: 0x0000 2300

This is a register containing the Product ID as reset value.

</tbody>
</table>
```

Bits 31:29  Reserved, must be kept at reset value.

Bit 28 **ENBESL**: Enable best effort service latency

This bit enables the BESL feature as defined in the LPM errata:

0: The core works as described in the following document:
   *USB 2.0 Link Power Management Addendum Engineering Change Notice to the USB 2.0 specification, July 16, 2007*

1: The core works as described in the LPM Errata:
   *Errata for USB 2.0 ECN: Link Power Management (LPM) - 7/2007*

Note: Only the updated behavior (described in LPM Errata) is considered in this document and so the ENBESL bit should be set to ‘1’ by application SW.

Bits 27:25 **LPMRCNTSTS[2:0]**: LPM retry count status

Number of LPM host retries still remaining to be transmitted for the current LPM sequence.

Note: Accessible only in host mode.
Bit 24 **SNDLPM**: Send LPM transaction
When the application software sets this bit, an LPM transaction containing two tokens, EXT and LPM is sent. The hardware clears this bit once a valid response (STALL, NYET, or ACK) is received from the device or the core has finished transmitting the programmed number of LPM retries.

*Note: This bit must be set only when the host is connected to a local port.*

*Note: Accessible only in host mode.*

Bits 23:21 **LPMRCNT[2:0]**: LPM retry count
When the device gives an ERROR response, this is the number of additional LPM retries that the host performs until a valid device response (STALL, NYET, or ACK) is received.

*Note: Accessible only in host mode.*

Bits 20:17 **LPMCHIDX[3:0]**: LPM Channel Index
The channel number on which the LPM transaction has to be applied while sending an LPM transaction to the local device. Based on the LPM channel index, the core automatically inserts the device address and endpoint number programmed in the corresponding channel into the LPM transaction.

*Note: Accessible only in host mode.*

Bit 16 **L1RSMOK**: Sleep state resume OK
Indicates that the device or host can start resume from Sleep state. This bit is valid in LPM sleep (L1) state. It is set in sleep mode after a delay of 50 μs (\(T_{L1Residency}\)). This bit is reset when SLPSTS is 0.

- 1: The application or host can start resume from Sleep state
- 0: The application or host cannot start resume from Sleep state

Bit 15 **SLPSTS**: Port sleep status

**Device mode:**
This bit is set as long as a Sleep condition is present on the USB bus. The core enters the Sleep state when an ACK response is sent to an LPM transaction and the \(T_{L1TokenRetry}\) timer has expired. To stop the PHY clock, the application must set the STPPCLK bit in OTG_PCGCCTL, which asserts the PHY suspend input signal.

The application must rely on SLPSTS and not ACK in LPMRSP to confirm transition into sleep.

The core comes out of sleep:
- When there is any activity on the USB linestate
- When the application writes to the RWUSIG bit in OTG_DCTL or when the application resets or soft-disconnects the device.

**Host mode:**
The host transitions to Sleep (L1) state as a side-effect of a successful LPM transaction by the core to the local port with ACK response from the device. The read value of this bit reflects the current Sleep status of the port.

The core clears this bit after:
- The core detects a remote L1 wakeup signal,
- The application sets the PRST bit or the PRES bit in the OTG_HPRT register, or
- The application sets the L1Resume/ remote wakeup detected interrupt bit or disconnect detected interrupt bit in the core interrupt register (WKUPINT or DISCINT bit in OTG_GINTSTS, respectively).

- 0: Core not in L1
- 1: Core in L1
Bits 14:13 **LPMRSP[1:0]**: LPM response

**Device mode**: The response of the core to LPM transaction received is reflected in these two bits.

**Host mode**: Handshake response received from local device for LPM transaction
- 11: ACK
- 10: NYET
- 01: STALL
- 00: ERROR (No handshake response)

Bit 12 **L1DSEN**: L1 deep sleep enable
Enables suspending the PHY in L1 Sleep mode. For maximum power saving during L1 Sleep mode, this bit should be set to ‘1’ by application SW in all the cases.

Bits 11:8 **BESLTHRS[3:0]**: BESL threshold

**Device mode**: The core puts the PHY into deep low power mode in L1 when BESL value is greater than or equal to the value defined in this field BESL_Thres[3:0].

**Host mode**: The core puts the PHY into deep low power mode in L1. BESLTHRS[3:0] specifies the time for which resume signaling is to be reflected by host ($T_{L1HubDrvResume2}$) on the USB bus when it detects device initiated resume. BESLTHRS must not be programmed with a value greater than 1100b in host mode, because this exceeds maximum $T_{L1HubDrvResume2}$:

<table>
<thead>
<tr>
<th>BESLTHRS[3:0]</th>
<th>Resume signaling time (μs)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000</td>

<td>450</td>
</tr>
<tr>
<td>0110</td>
<td>950</td>
</tr>
<tr>
<td>All other</td>
<td>reserved</td>
</tr>
</tbody>
</table>

Bit 7 **L1SSEN**: L1 Shallow Sleep enable
Enables suspending the PHY in L1 Sleep mode. For maximum power saving during L1 Sleep mode, this bit should be set to ‘1’ by application SW in all the cases.

Bit 6 **REMWAKE**: bRemoteWake value

**Host mode**: The value of remote wake up to be sent in the wIndex field of LPM transaction.

**Device mode (read-only)**: This field is updated with the received LPM token bRemoteWake bmAttribute when an ACK, NYET, or STALL response is sent to an LPM transaction.
Bits 5:2  **BESL[3:0]:** Best effort service latency

**Host mode:**
The value of BESL to be sent in an LPM transaction. This value is also used to initiate resume for a duration $T_{L_HubDrvResume}$ for host initiated resume.

**Device mode (read-only):**
This field is updated with the received LPM token BESL bmAttribute when an ACK, NYET, or STALL response is sent to an LPM transaction.

<table>
<thead>
<tr>
<th>BESL[3:0] $\mu$s</th>
</tr>
</thead>
<tbody>
<tr>
<td>0000: 125</td>

</tr>
<tr>
<td>1111: 10000</td>
</tr>
</tbody>
</table>

Bit 1  **LPMACK:** LPM token acknowledge enable
Handshake response to LPM token preprogrammed by device application software.

- **1:** ACK
- **0:** NYET

Even though ACK is preprogrammed, the core device responds with ACK only on successful LPM transaction. The LPM transaction is successful if:
- No PID/CRC5 errors in either EXT token or LPM token (else ERROR)
- Valid bLinkState = 0001B (L1) received in LPM transaction (else STALL)
- No data pending in transmit queue (else NYET).

0: NYET
The preprogrammed software bit is over-ridden for response to LPM token when:
- The received bLinkState is not L1 (STALL response), or
- An error is detected in either of the LPM token packets because of corruption (ERROR response).

*Note:* Accessible only in device mode.

Bit 0  **LPMEN:** LPM support enable
The application uses this bit to control the OTG_HS core LPM capabilities.
- If the core operates as a non-LPM-capable host, it cannot request the connected device or hub to activate LPM mode.
- If the core operates as a non-LPM-capable device, it cannot respond to any LPM transactions.

- **0:** LPM capability is not enabled
- **1:** LPM capability is enabled
### 56.14.18 OTG host periodic transmit FIFO size register (OTG_HPTXFSIZ)

56.14.20 Host-mode registers

Bit values in the register descriptions are expressed in binary unless otherwise specified. Host-mode registers affect the operation of the core in the host mode. Host mode registers must not be accessed in device mode, as the results are undefined. Host mode registers can be categorized as follows:

56.14.21 OTG host configuration register (OTG_HCFG)

Address offset: 0x400

Reset value: 0x0000 0000

This register configures the core after power-on. Do not make changes to this register after initializing the host.

Bits 31:16 **INEPTXFD[15:0]**: IN endpoint Tx FIFO depth
This value is in terms of 32-bit words.
Minimum value is 16

Bits 15:0 **INEPTXSA[15:0]**: IN endpoint FIFOx transmit RAM start address
This field contains the memory start address for IN endpoint transmit FIFOx. The address must be aligned with a 32-bit memory location.

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **FSLSS**: FS- and LS-only support
The application uses this bit to control the core’s enumeration speed. Using this bit, the application can make the core enumerate as an FS host, even if the connected device supports HS traffic. Do not make changes to this field after initial programming.

Bits 1:0 **FSLSPCS[1:0]**: FS/LS PHY clock select
When the core is in FS host mode
01: PHY clock is running at 48 MHz
Others: Reserved
When the core is in LS host mode
00: Reserved
01: Select 48 MHz PHY clock frequency
10: Select 6 MHz PHY clock frequency
11: Reserved

*Note: The FSLSPCS must be set on a connection event according to the speed of the connected device (after changing this bit, a software reset must be performed).*
56.14.22 OTG host frame interval register (OTG_HFIR)

Address offset: 0x404

Reset value: 0x0000 EA60

This register stores the frame interval information for the current speed to which the OTG_HS controller has enumerated.

```
| 31| 30| 29| 28| 27| 26| 25| 24| 23| 22| 21| 20| 19| 18| 17| 16| 15| 14| 13| 12| 11| 10|  9|  8|  7|  6|  5|  4|  3|  2|  1|  0 |
| 15| 14| 13| 12| 11| 10|  9|  8|  7|  6|  5|  4|  3|  2|  1|  0 |  |
```

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **RLDCTRL**: Reload control

This bit allows dynamic reloading of the HFIR register during run time.

0: The HFIR can be dynamically reloaded during run time.

1: The HFIR cannot be reloaded dynamically

This bit needs to be programmed during initial configuration and its value must not be changed during run time.

**Caution**: RLDCTRL = 1 is not recommended.

Bits 15:0 **FRIVL[15:0]**: Frame interval

The value that the application programs to this field, specifies the interval between two consecutive micro-SOFs (HS) or Keep-Alive tokens (LS). This field contains the number of PHY clocks that constitute the required frame interval. The application can write to this register only after the port enable bit of the host port control and status register (PENA bit in OTG_HPRT) has been set. If no value is programmed, the core calculates the value based on the PHY clock specified in the FS/LS PHY clock select field of the host configuration register (FSLSPCS in OTG_HCFG). Do not change the value of this field after the initial configuration, unless the RLDCTRL bit is set. In such case, the FRIVL is reloaded with each SOF event.

- Frame interval = 125 μs × (FRIVL - 1) in high speed operation (PHYSEL = 0)
- Frame interval = 1 ms × (FRIVL - 1) in low/full speed operation (PHYSEL = 1)
56.14.23  OTG host frame number/frame time remaining register (OTG_HFNUM)

Address offset: 0x408
Reset value: 0x0000 3FFF

This register indicates the current frame number. It also indicates the time remaining (in terms of the number of PHY clocks) in the current frame.

Bits 31:16  FTREM[15:0]: Frame time remaining
Indicates the amount of time remaining in the current frame, in terms of PHY clocks. This field decrements on each PHY clock. When it reaches zero, this field is reloaded with the value in the Frame interval register and a new SOF is transmitted on the USB.

Bits 15:0  FRNUM[15:0]: Frame number
This field increments when a new SOF is transmitted on the USB, and is cleared to 0 when it reaches 0x3FFF.

56.14.24  OTG_Host periodic transmit FIFO/queue status register (OTG_HPTXSTS)

Address offset: 0x410
Reset value: 0x0008 0100

This read-only register contains the free space information for the periodic Tx FIFO and the periodic transmit request queue.

Bits 31:24  **PTXQTOP[7:0]**: Top of the periodic transmit request queue

This indicates the entry in the periodic Tx request queue that is currently being processed by the MAC.

This register is used for debugging.

Bit 31: Odd/Even frame
0: send in even frame
1: send in odd frame

Bits 30:27: Channel/endpoint number

Bits 26:25: Type
00: IN/OUT
01: Zero-length packet
11: Disable channel command

Bit 24: Terminate (last entry for the selected channel/endpoint)

Bits 23:16  **PTXQSAV[7:0]**: Periodic transmit request queue space available

Indicates the number of free locations available to be written in the periodic transmit request queue. This queue holds both IN and OUT requests.

00: Periodic transmit request queue is full
01: 1 location available
10: 2 locations available
bn: n locations available (0 ≤ n ≤ 8)
Others: Reserved

Bits 15:0  **PTXFSAVL[15:0]**: Periodic transmit data FIFO space available

 Indicates the number of free locations available to be written to in the periodic Tx FIFO.

Values are in terms of 32-bit words
0000: Periodic Tx FIFO is full
0001: 1 word available
0010: 2 words available
bn: n words available (where 0 ≤ n ≤ PTXFD)
Others: Reserved

56.14.25  **OTG host all channels interrupt register (OTG_HAINT)**

Address offset: 0x414

Reset value: 0x0000 0000

When a significant event occurs on a channel, the host all channels interrupt register interrupts the application using the host channels interrupt bit of the core interrupt register (HCINT bit in OTG_GINTSTS). This is shown in Figure 753. There is one interrupt bit per channel, up to a maximum of 16 bits. Bits in this register are set and cleared when the application sets and clears bits in the corresponding host channel-x interrupt register.
56.14.26 OTG host all channels interrupt mask register (OTG_HAINTMSK)

Address offset: 0x418
Reset value: 0x0000 0000

The host all channel interrupt mask register works with the host all channel interrupt register to interrupt the application when an event occurs on a channel. There is one interrupt mask bit per channel, up to a maximum of 16 bits.

HAINTM[15:0]

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 HAINTM[15:0]: Channel interrupt mask
- 0: Masked interrupt
- 1: Unmasked interrupt

One bit per channel: Bit 0 for channel 0, bit 15 for channel 15
56.14.27  OTG host port control and status register (OTG_HPRT)

Address offset: 0x440
Reset value: 0x0000 0000

This register is available only in host mode. Currently, the OTG host supports only one port. A single register holds USB port-related information such as USB reset, enable, suspend, resume, connect status, and test mode for each port. It is shown in Figure 753. The rc_w1 bits in this register can trigger an interrupt to the application through the host port interrupt bit of the core interrupt register (HPRTINT bit in OTG_GINTSTS). On a port interrupt, the application must read this register and clear the bit that caused the interrupt. For the rc_w1 bits, the application must write a 1 to the bit to clear the interrupt.

PTCTL[2:0]  PPWR  PLSTS[1:0]  Res.  PRST  PSUSP  PRES  POC  CHNG  POCA  PEN  PCDET  PCSTS
rw  rw  rw  rw  r  r  rw  rs  rw  rc_w1  r  rc_w1  rc_w1  rc_w1  r

Bits 31:19  Reserved, must be kept at reset value.

Bits 18:17  **PSPD[1:0]:** Port speed
Indicates the speed of the device attached to this port.
01: Full speed
10: Low speed
11: Reserved
00: High speed

Bits 16:13  **PTCTL[3:0]:** Port test control
The application writes a nonzero value to this field to put the port into a Test mode, and the corresponding pattern is signaled on the port.
0000: Test mode disabled
0001: Test_J mode
0010: Test_K mode
0011: Test_SE0_NAK mode
0100: Test_Packet mode
0101: Test_Force_Enable
Others: Reserved

Bit 12  **PPWR:** Port power
The application uses this field to control power to this port, and the core clears this bit on an overcurrent condition.
0: Power off
1: Power on

Bits 11:10  **PLSTS[1:0]:** Port line status
Indicates the current logic level USB data lines
Bit 10: Logic level of OTG_DP
Bit 11: Logic level of OTG_DM

Bit 9  Reserved, must be kept at reset value.
Bit 8 **PRST**: Port reset

When the application sets this bit, a reset sequence is started on this port. The application must time the reset period and clear this bit after the reset sequence is complete.

0: Port not in reset
1: Port in reset

The application must leave this bit set for a minimum duration of at least 10 ms to start a reset on the port. The application can leave it set for another 10 ms in addition to the required minimum duration, before clearing the bit, even though there is no maximum limit set by the USB standard.

High speed: 50 ms
Full speed/Low speed: 10 ms

Bit 7 **PSUSP**: Port suspend

The application sets this bit to put this port in suspend mode. The core only stops sending SOFs when this is set. To stop the PHY clock, the application must set the port clock stop bit, which asserts the suspend input pin of the PHY.

The read value of this bit reflects the current suspend status of the port. This bit is cleared by the core after a remote wakeup signal is detected or the application sets the port reset bit or port resume bit in this register or the resume/remote wakeup detected interrupt bit or disconnect detected interrupt bit in the core interrupt register (WKUPINT or DISCINT in OTG_GINTSTS, respectively).

0: Port not in suspend mode
1: Port in suspend mode

Bit 6 **PRES**: Port resume

The application sets this bit to drive resume signaling on the port. The core continues to drive the resume signal until the application clears this bit.

If the core detects a USB remote wakeup sequence, as indicated by the port resume/remote wakeup detected interrupt bit of the core interrupt register (WKUPINT bit in OTG_GINTSTS), the core starts driving resume signaling without application intervention and clears this bit when it detects a disconnect condition. The read value of this bit indicates whether the core is currently driving resume signaling.

0: No resume driven
1: Resume driven

When LPM is enabled and the core is in L1 state, the behavior of this bit is as follow:

1. The application sets this bit to drive resume signaling on the port.
2. The core continues to drive the resume signal until a predetermined time specified in BESLTHRS[3:0] field of OTG_GLPMCFG register.
3. If the core detects a USB remote wakeup sequence, as indicated by the port L1Resume/Remote L1Wakeup detected interrupt bit of the core interrupt register (WKUPINT in OTG_GINTSTS), the core starts driving resume signaling without application intervention and clears this bit at the end of resume. This bit can be set or cleared by both the core and the application. This bit is cleared by the core even if there is no device connected to the host.

Bit 5 **POCCHNG**: Port overcurrent change

The core sets this bit when the status of the port overcurrent active bit (bit 4) in this register changes.

Bit 4 **POCA**: Port overcurrent active

Indicates the overcurrent condition of the port.

0: No overcurrent condition
1: Overcurrent condition

Bit 3 **PENCHNG**: Port enable/disable change

The core sets this bit when the status of the port enable bit 2 in this register changes.
Bit 2  **PENA**: Port enable
A port is enabled only by the core after a reset sequence, and is disabled by an overcurrent condition, a disconnect condition, or by the application clearing this bit. The application cannot set this bit by a register write. It can only clear it to disable the port. This bit does not trigger any interrupt to the application.
0: Port disabled
1: Port enabled

Bit 1  **PCDET**: Port connect detected
The core sets this bit when a device connection is detected to trigger an interrupt to the application using the host port interrupt bit in the core interrupt register (HPRTINT bit in OTG_GINTSTS). The application must write a 1 to this bit to clear the interrupt.

Bit 0  **PCSTS**: Port connect status
0: No device is attached to the port
1: A device is attached to the port

### 56.14.28 OTG host channel x characteristics register (OTG_HCCHARx)

Address offset: 0x500 + 0x20 * x, (x = 0 to 15)
Reset value: 0x0000 0000

Bit 31  **CHENA**: Channel enable
This field is set by the application and cleared by the OTG host.
0: Channel disabled
1: Channel enabled

Bit 30  **CHDIS**: Channel disable
The application sets this bit to stop transmitting/receiving data on a channel, even before the transfer for that channel is complete. The application must wait for the Channel disabled interrupt before treating the channel as disabled.

Bit 29  **ODDFRM**: Odd frame
This field is set (reset) by the application to indicate that the OTG host must perform a transfer in an odd frame. This field is applicable for only periodic (isochronous and interrupt) transactions.
0: Even frame
1: Odd frame

Bits 28:22  **DAD[6:0]**: Device address
This field selects the specific device serving as the data source or sink.
Bits 21:20 **MCNT[1:0]: Multicount**
This field indicates to the host the number of transactions that must be executed per frame for this periodic endpoint. For non-periodic transfers, this field is not used.
- 00: Reserved. This field yields undefined results
- 01: 1 transaction
- 10: 2 transactions per frame to be issued for this endpoint
- 11: 3 transactions per frame to be issued for this endpoint

*Note: This field must be set to at least 01.*

Bits 19:18 **EPTYP[1:0]: Endpoint type**
Indicates the transfer type selected.
- 00: Control
- 01: Isochronous
- 10: Bulk
- 11: Interrupt

Bit 17 **LSDEV: Low-speed device**
This field is set by the application to indicate that this channel is communicating to a low-speed device.

Bit 16 Reserved, must be kept at reset value.

Bit 15 **EPDIR: Endpoint direction**
Indicates whether the transaction is IN or OUT.
- 0: OUT
- 1: IN

Bits 14:11 **EPNUM[3:0]: Endpoint number**
Indicates the endpoint number on the device serving as the data source or sink.

Bits 10:0 **MPSIZ[10:0]: Maximum packet size**
Indicates the maximum packet size of the associated endpoint.

### 56.14.29 OTG host channel x split control register (OTG_HCSPLTx)

Bit 31 **SPLITEN: Split enable**
The application sets this bit to indicate that this channel is enabled to perform split transactions.

Bits 30:17 Reserved, must be kept at reset value.

Bit 16 **COMPLSPLT: Do complete split**
The application sets this bit to request the OTG host to perform a complete split transaction.
56.14.30 OTG host channel x interrupt register (OTG_HCINTx)

Address offset: 0x508 + 0x20 * x, (x = 0 to 15)
Reset value: 0x0000 0000

This register indicates the status of a channel with respect to USB- and AHB-related events. It is shown in Figure 753. The application must read this register when the host channels interrupt bit in the core interrupt register (HCINT bit in OTG_GINTSTS) is set. Before the application can read this register, it must first read the host all channels interrupt (OTG_HAINT) register to get the exact channel number for the host channel-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG_HAINT and OTG_GINTSTS registers.

</table>
Bit 3 \textbf{STALL}: STALL response received interrupt.

Bit 2 \textbf{AHBERR}: AHB error

This error is generated only in Internal DMA mode when an AHB error occurs during an AHB read/write operation. The application can read the corresponding DMA channel address register to get the error address.

Bit 1 \textbf{CHH}: Channel halted.

Indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application.

Bit 0 \textbf{XFRC}: Transfer completed.

Transfer completed normally without any errors.

\section*{56.14.31 OTG host channel x interrupt mask register (OTG_HCINTMSKx)}

Address offset: 0x50C + 0x20 * x, (x = 0 to 15)

Reset value: 0x0000 0000

This register reflects the mask for each channel status described in the previous section.

Bit 31: Reserved, must be kept at reset value.
Bits 30:29 **DPID[1:0]**: Data PID
The application programs this field with the type of PID to use for the initial transaction. The host maintains this field for the rest of the transfer.
00: DATA0
01: DATA2
10: DATA1
11: SETUP (control) / MDATA (non-control)

Bits 28:19 **PKTCNT[9:0]**: Packet count
This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN).
The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion.

Bits 18:0 **XFRSIZ[18:0]**: Transfer size
For an OUT, this field is the number of data bytes the host sends during the transfer.
For an IN, this field is the buffer size that the application has reserved for the transfer. The application is expected to program this field as an integer multiple of the maximum packet size for IN transactions (periodic and non-periodic).

### 56.14.33 OTG host channel x DMA address register (OTG_HCDMAx)

Address offset: 0x514 + 0x20 * x, (x = 0 to 15)
Reset value: 0x0000 0000

</tbody>
</table>

Bits 31:0 **DMAADDR[31:0]**: DMA address
This field holds the start address in the external memory from which the data for the endpoint must be fetched or to which it must be stored. This register is incremented on every AHB transaction.

### 56.14.34 Device-mode registers
These registers must be programmed every time the core changes to device mode
### 56.14.35 OTG device configuration register (OTG_DCFG)

Address offset: 0x800

Reset value: 0x0220 0000

This register configures the core in device mode after power-on or after certain control commands or enumeration. Do not make changes to this register after initial programming.

<table>

</tr>
</tbody>
</table>

```
- Bits 31:26 Reserved, must be kept at reset value.
- Bits 25:24 **PERSCHIVL[1:0]**: Periodic schedule interval
  - This field specifies the amount of time the Internal DMA engine must allocate for fetching periodic IN endpoint data. Based on the number of periodic endpoints, this value must be specified as 25, 50 or 75% of the (micro)frame.
  - When any periodic endpoints are active, the internal DMA engine allocates the specified amount of time in fetching periodic IN endpoint data
  - When no periodic endpoint is active, then the internal DMA engine services nonperiodic endpoints, ignoring this field
  - After the specified time within a (micro)frame, the DMA switches to fetching nonperiodic endpoints
  - 00: 25% of (micro)frame
  - 01: 50% of (micro)frame
  - 10: 75% of (micro)frame
  - 11: Reserved

- Bits 23:16 Reserved, must be kept at reset value.
- Bit 15 **ERRATIM**: Erratic error interrupt mask
  - 1: Mask early suspend interrupt on erratic error
  - 0: Early suspend interrupt is generated on erratic error

- Bit 14 **XCVRDLY**: Transceiver delay
  - Enables or disables delay in ULPI timing during device chirp.
  - 0: Disable delay (use default timing)
  - 1: Enable delay to default timing, necessary for some ULPI PHYs

- Bit 13 Reserved, must be kept at reset value.

- Bits 12:11 **PFIVL[1:0]**: Periodic frame interval
  - Indicates the time within a frame at which the application must be notified using the end of periodic frame interrupt. This can be used to determine if all the isochronous traffic for that frame is complete.
  - 00: 80% of the frame interval
  - 01: 85% of the frame interval
  - 10: 90% of the frame interval
  - 11: 95% of the frame interval
```
Bits 10:4 **DAD[6:0]: Device address**

The application must program this field after every SetAddress control command.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **NZLSOHSH: Non-zero-length status OUT handshake**

The application can use this field to select the handshake the core sends on receiving a non-zero-length data packet during the OUT transaction of a control transfer’s status stage.

1: Send a STALL handshake on a non-zero-length status OUT transaction and do not send the received OUT packet to the application.

0: Send the received OUT packet to the application (zero-length or non-zero-length) and send a handshake based on the NAK and STALL bits for the endpoint in the device endpoint control register.

Bits 1:0 **DSPD[1:0]: Device speed**

Indicates the speed at which the application requires the core to enumerate, or the maximum speed the application can support. However, the actual bus speed is determined only after the chirp sequence is completed, and is based on the speed of the USB host to which the core is connected.

00: High speed

01: Full speed using HS

10: Reserved

11: Full speed using internal FS PHY

</tbody>
</table>

Bits 31:19 Reserved, must be kept at reset value.

Bit 18 **DBESLRJCT: Deep sleep BESL reject**

Core rejects LPM request with BESL value greater than BESL threshold programmed. NYET response is sent for LPM tokens with BESL value greater than BESL threshold. By default, the deep sleep BESL reject feature is disabled.

Bits 17:12 Reserved, must be kept at reset value.

Bit 11 **POPRGDNE: Power-on programming done**

The application uses this bit to indicate that register programming is completed after a wakeup from power down mode.

Bit 10 **CGONAK: Clear global OUT NAK**

Writing 1 to this field clears the Global OUT NAK.
Bit 9 **SGONAK**: Set global OUT NAK
Writing 1 to this field sets the Global OUT NAK.
The application uses this bit to send a NAK handshake on all OUT endpoints.
The application must set the this bit only after making sure that the Global OUT NAK effective bit in the core interrupt register (GONAKEFF bit in OTG_GINTSTS) is cleared.

Bit 8 **CGINAK**: Clear global IN NAK
Writing 1 to this field clears the Global IN NAK.

Bit 7 **SGINAK**: Set global IN NAK
Writing 1 to this field sets the Global non-periodic IN NAK. The application uses this bit to send a NAK handshake on all non-periodic IN endpoints.
The application must set this bit only after making sure that the Global IN NAK effective bit in the core interrupt register (GINAKEFF bit in OTG_GINTSTS) is cleared.

Bits 6:4 **TCTL[2:0]**: Test control
000: Test mode disabled
001: Test_J mode
010: Test_K mode
011: Test_SE0_NAK mode
100: Test_Packet mode
101: Test_Force_Enable
Others: Reserved

Bit 3 **GONSTS**: Global OUT NAK status
0: A handshake is sent based on the FIFO status and the NAK and STALL bit settings.
1: No data is written to the Rx FIFO, irrespective of space availability. Sends a NAK handshake on all packets, except on SETUP transactions. All isochronous OUT packets are dropped.

Bit 2 **GINSTS**: Global IN NAK status
0: A handshake is sent out based on the data availability in the transmit FIFO.
1: A NAK handshake is sent out on all non-periodic IN endpoints, irrespective of the data availability in the transmit FIFO.

Bit 1 **SDIS**: Soft disconnect
The application uses this bit to signal the USB OTG core to perform a soft disconnect. As long as this bit is set, the host does not see that the device is connected, and the device does not receive signals on the USB. The core stays in the disconnected state until the application clears this bit.

0: Normal operation. When this bit is cleared after a soft disconnect, the core generates a device connect event to the USB host. When the device is reconnected, the USB host restarts device enumeration.
1: The core generates a device disconnect event to the USB host.

Bit 0 **RWUSIG**: Remote wakeup signaling
When the application sets this bit, the core initiates remote signaling to wake up the USB host. The application must set this bit to instruct the core to exit the suspend state. As specified in the USB 2.0 specification, the application must clear this bit 1 ms to 15 ms after setting it.

If LPM is enabled and the core is in the L1 (sleep) state, when the application sets this bit, the core initiates L1 remote signaling to wake up the USB host. The application must set this bit to instruct the core to exit the sleep state. As specified in the LPM specification, the hardware automatically clears this bit 50 µs (TL1DevDrvResume) after being set by the application. The application must not set this bit when bRemoteWake from the previous LPM transaction is zero (refer to REMWAKE bit in GLPMCFG register).
Table 504 contains the minimum duration (according to device state) for which the Soft disconnect (SDIS) bit must be set for the USB host to detect a device disconnect. To accommodate clock jitter, it is recommended that the application add some extra delay to the specified minimum duration.

### Table 504. Minimum duration for soft disconnect

#### 56.14.37 OTG device status register (OTG_DSTS)

Address offset: 0x808

Reset value: 0x0000 0010

This register indicates the status of the core with respect to USB-related events. It must be read on interrupts from the device all interrupts (OTG_DAINT) register.

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>

</tr>
</tbody>
</table>

Bits 31:24: Reserved, must be kept at reset value.

Bits 23:22 **DEVLNSTS[1:0]:** Device line status

- Indicates the current logic level USB data lines.
- Bit [23]: Logic level of D+
- Bit [22]: Logic level of D-

Bits 21:8 **FNSOF[13:0]:** Frame number of the received SOF

Bits 7:4: Reserved, must be kept at reset value.
Bit 3 **ERR**: Erratic error

The core sets this bit to report any erratic errors. Due to erratic errors, the OTG_HS controller goes into suspended state and an interrupt is generated to the application with Early suspend bit of the OTG_GINTSTS register (ESUSP bit in OTG_GINTSTS). If the early suspend is asserted due to an erratic error, the application can only perform a soft disconnect recover.

Bits 2:1 **ENUMSPD[1:0]**: Enumerated speed

Indicates the speed at which the OTG_HS controller has come up after speed detection through a chirp sequence.

- 01: Reserved
- 10: Reserved
- 11: Full speed (PHY clock is running at 48 MHz)
- Others: reserved

Bit 0 **SUSPSTS**: Suspend status

In device mode, this bit is set as long as a suspend condition is detected on the USB. The core enters the suspended state when there is no activity on the USB data lines for a period of 3 ms. The core comes out of the suspend:

- When there is an activity on the USB data lines
- When the application writes to the remote wakeup signaling bit in the OTG_DCTL register (RWUSIG bit in OTG_DCTL).

### 56.14.38 OTG device IN endpoint common interrupt mask register (OTG_DIEPMSK)

Address offset: 0x810

Reset value: 0x0000 0000

This register works with each of the OTG_DIEPINTx registers for all endpoints to generate an interrupt per IN endpoint. The IN endpoint interrupt for a specific status in the OTG_DIEPINTx register can be masked by writing to the corresponding bit in this register. Status bits are masked by default.

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **NAKM**: NAK interrupt mask

- 0: Masked interrupt
- 1: Unmasked interrupt

Bits 12:10 Reserved, must be kept at reset value.

Bit 9 Reserved, must be kept at reset value.
**OTG device OUT endpoint common interrupt mask register (OTG_DOEPMSK)**

Address offset: 0x814

Reset value: 0x0000 0000

This register works with each of the OTG_DOEPINTx registers for all endpoints to generate an interrupt per OUT endpoint. The OUT endpoint interrupt for a specific status in the OTG_DOEPINTx register can be masked by writing into the corresponding bit in this register. Status bits are masked by default.

| Bit 8 TXFURM: FIFO underrun mask | 0: Masked interrupt | 1: Unmasked interrupt |
| Bit 7 Reserved, must be kept at reset value. |
| Bit 6 INEPNEM: IN endpoint NAK effective mask | 0: Masked interrupt | 1: Unmasked interrupt |
| Bit 5 INEPNMM: IN token received with EP mismatch mask | 0: Masked interrupt | 1: Unmasked interrupt |
| Bit 4 ITTXFEMSK: IN token received when Tx FIFO empty mask | 0: Masked interrupt | 1: Unmasked interrupt |
| Bit 3 TOM: Timeout condition mask (Non-isochronous endpoints) | 0: Masked interrupt | 1: Unmasked interrupt |
| Bit 2 AHBERRM: AHB error mask | 0: Masked interrupt | 1: Unmasked interrupt |
| Bit 1 EPDM: Endpoint disabled interrupt mask | 0: Masked interrupt | 1: Unmasked interrupt |
| Bit 0 XFRCM: Transfer completed interrupt mask | 0: Masked interrupt | 1: Unmasked interrupt |

Bits 11:10  Reserved, must be kept at reset value.

Bit 9  Reserved, must be kept at reset value.

Bit 8  OUTPKTERRM: Out packet error mask
   0: Masked interrupt
   1: Unmasked interrupt

Bit 7  Reserved, must be kept at reset value.

Bit 6  B2BSTUPM: Back-to-back SETUP packets received mask
   Applies to control OUT endpoints only.
   0: Masked interrupt
   1: Unmasked interrupt

Bit 5  STSPHSRXM: Status phase received for control write mask
   0: Masked interrupt
   1: Unmasked interrupt

Bit 4  OTEPDM: OUT token received when endpoint disabled mask. Applies to control OUT endpoints only.
   0: Masked interrupt
   1: Unmasked interrupt

Bit 3  STUPM: STUPM: SETUP phase done mask. Applies to control endpoints only.
   0: Masked interrupt
   1: Unmasked interrupt

Bit 2  AHBERRM: AHB error mask
   0: Masked interrupt
   1: Unmasked interrupt

Bit 1  EPDM: Endpoint disabled interrupt mask
   0: Masked interrupt
   1: Unmasked interrupt

Bit 0  XFRCM: Transfer completed interrupt mask
   0: Masked interrupt
   1: Unmasked interrupt
56.14.40 OTG device all endpoints interrupt register (OTG_DAINT)

Address offset: 0x818
Reset value: 0x0000 0000

When a significant event occurs on an endpoint, a OTG_DAINT register interrupts the application using the device OUT endpoints interrupt bit or device IN endpoints interrupt bit of the OTG_GINTSTS register (OEPINT or IEPINT in OTG_GINTSTS, respectively). There is one interrupt bit per endpoint, up to a maximum of 16 bits for OUT endpoints and 16 bits for IN endpoints. For a bidirectional endpoint, the corresponding IN and OUT interrupt bits are used. Bits in this register are set and cleared when the application sets and clears bits in the corresponding device endpoint-x interrupt register (OTG_DIEPINTx/OTG_DOEPINTx).

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
</tr>
</thead>
</table>
| OEPINT[15:0] | OUT endpoint interrupt bits
| OEPINT[15:0] | One bit per OUT endpoint: Bit 16 for OUT endpoint 0, bit 19 for OUT endpoint 3. |
| IEPINT[15:0] | IN endpoint interrupt bits
| IEPINT[15:0] | One bit per IN endpoint: Bit 0 for IN endpoint 0, bit 3 for endpoint 3. |

56.14.41 OTG all endpoints interrupt mask register (OTG_DAINTMSK)

Address offset: 0x81C
Reset value: 0x0000 0000

The OTG_DAINTMSK register works with the device endpoint interrupt register to interrupt the application when an event occurs on a device endpoint. However, the OTG_DAINT register bit corresponding to that interrupt is still set.

</tbody>
</table>

Bit 31  **EPENA**: Endpoint enable
The application sets this bit to start transmitting data on an endpoint.
The core clears this bit before setting any of the following interrupts on this endpoint:
- SETUP phase done
- Endpoint disabled
- Transfer completed

Bit 30  **EPDIS**: Endpoint disable
The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the endpoint disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the endpoint disabled interrupt. The application must set this bit only if endpoint enable is already set for this endpoint.

Bit 29  **SODDFRM**: Set odd frame
Applies to isochronous IN and OUT endpoints only.
Writing to this field sets the Even/Odd frame (EONUM) field to odd frame.

Bit 28  **SDD0PID**: Set DATA0 PID
Applies to interrupt/bulk IN endpoints only.
Writing to this field sets the endpoint data PID (DPID) field in this register to DATA0.

Bit 27  **SEVNFRM**: Set even frame
Applies to isochronous IN endpoints only.
Writing to this field sets the Even/Odd frame (EONUM) field to even frame.

Bit 26  **SNAK**: Set NAK
A write to this bit sets the NAK bit for the endpoint.
Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit for OUT endpoints on a transfer completed interrupt, or after a SETUP is received on the endpoint.

Bit 25  **CNAK**: Clear NAK
A write to this bit clears the NAK bit for the endpoint.
Bits 25:22 **TXFNUM[3:0]:** Tx FIFO number
These bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number.
This field is valid only for IN endpoints.

Bit 21 **STALL:** STALL handshake
Applies to non-control, non-isochronous IN endpoints only (access type is rw).
The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority.
Only the application can clear this bit, never the core.
Applies to control endpoints only (access type is rs).
The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 20 Reserved, must be kept at reset value.

Bits 19:18 **EPTYP[1:0]:** Endpoint type
This is the transfer type supported by this logical endpoint.
00: Control
01: Isochronous
10: Bulk
11: Interrupt

Bit 17 **NAKSTS:** NAK status
It indicates the following:
0: The core is transmitting non-NAK handshakes based on the FIFO status.
1: The core is transmitting NAK handshakes on this endpoint.
When either the application or the core sets this bit:
For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there are data available in the Tx FIFO.
For isochronous IN endpoints: The core sends out a zero-length data packet, even if there are data available in the Tx FIFO.
Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 16 **EONUM:** Even/odd frame
Applies to isochronous IN endpoints only.
Indicates the frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd frame number in which it intends to transmit/receive isochronous data for this endpoint using the SEVNFRM and SODDFRM fields in this register.
0: Even frame
1: Odd frame

**DPID:** Endpoint data PID
Applies to interrupt/bulk IN endpoints only.
Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The application uses the SD0PID register field to program either DATA0 or DATA1 PID.
0: DATA0
1: DATA1
Bit 15 **USBAEP:** USB active endpoint  
Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.

Bits 14:11 Reserved, must be kept at reset value.

Bits 10:0 **MPSIZ[10:0]: Maximum packet size**  
The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.

### 56.14.51 OTG device IN endpoint x interrupt register (OTG_DIEPINTx)

**Address offset:** 0x908 + 0x20 * x, (x = 0 to 8)  
**Reset value:** 0x0000 0080

This register indicates the status of an endpoint with respect to USB- and AHB-related events. It is shown in Figure 753. The application must read this register when the IN endpoints interrupt bit of the core interrupt register (IEPINT in OTG_GINTSTS) is set. Before the application can read this register, it must first read the device all endpoints interrupt (OTG_DAINT) register to get the exact endpoint number for the device endpoint-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG_DAINT and OTG_GINTSTS registers.

**Bits 31:14** Reserved, must be kept at reset value.

**Bit 13 **NAK:** NAK input  
The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to unavailability of data in the Tx FIFO.

**Bit 12** Reserved, must be kept at reset value.

**Bit 11 **PKTDRPSTS:** Packet dropped status  
This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt.

**Bit 10** Reserved, must be kept at reset value.

**Bit 9** Reserved, must be kept at reset value.

**Bit 8 **TXFIFOUDRN:** Transmit FIFO Underrun (TxfifoUndrn)  
The core generates this interrupt when it detects a transmit FIFO underrun condition for this endpoint. Dependency: This interrupt is valid only when Thresholding is enabled.
Bit 7  **TXFE**: Transmit FIFO empty
This interrupt is asserted when the Tx FIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the Tx FIFO Empty Level bit in the OTG_GAHBCFG register (TXFELVL bit in OTG_GAHBCFG).

Bit 6  **INEPNE**: IN endpoint NAK effective
This bit can be cleared when the application clears the IN endpoint NAK by writing to the CNAK bit in OTG_DIEPCTLx.
This interrupt indicates that the core has sampled the NAK bit set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit set by the application has taken effect in the core.
This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit.

Bit 5  **INEPNM**: IN token received with EP mismatch
Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received.

Bit 4  **ITTXFE**: IN token received when Tx FIFO is empty
Indicates that an IN token was received when the associated Tx FIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received.

Bit 3  **TOC**: Timeout condition
Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint.

Bit 2  **AHBERR**: AHB error
This is generated only in internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address.

Bit 1  **EPDISD**: Endpoint disabled interrupt
This bit indicates that the endpoint is disabled per the application's request.

Bit 0  **XFRC**: Transfer completed interrupt
This field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint.
56.14.52 OTG device IN endpoint 0 transfer size register
(OTG_DIEPTSIZ0)

Address offset: 0x910
Reset value: 0x0000 0000

The application must modify this register before enabling endpoint 0. Once endpoint 0 is enabled using the endpoint enable bit in the device control endpoint 0 control registers (EPENA in OTG_DIEPCTL0), the core modifies this register. The application can only read this register once the core has cleared the endpoint enable bit.

Nonzero endpoints use the registers for endpoints 1–3.

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:19 PKTCNT[1:0]: Packet count
Indicates the total number of USB packets that constitute the transfer size amount of data for endpoint 0.
This field is decremented every time a packet (maximum size or short packet) is read from the Tx FIFO.

Bits 18:7 Reserved, must be kept at reset value.

Bits 6:0 XFRSIZ[6:0]: Transfer size
Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet.
The core decrements this field every time a packet from the external memory is written to the Tx FIFO.

56.14.53 OTG device IN endpoint x DMA address register
(OTG_DIEPDMAx)

Address offset: 0x914 + 0x20 * x, (x = 0 to 8)
Reset value: 0x0000 0000
56.14.54 OTG device IN endpoint transmit FIFO status register (OTG_DTXFSTSx)

Address offset: 0x918 + 0x20 * x, (x = 0 to 8)
Reset value: 0x0000 0200

This read-only register contains the free space information for the device IN endpoint Tx FIFO.

<table>
<thead>
<tr>
<th>Bit 31:0</th>

</tr>
</thead>
<tbody>
<tr>
<td>DMAADDR[31:0]</td>
<td>DMA Address</td>
</tr>
<tr>
<td>This field holds the start address in the external memory from which the data for the endpoint must be fetched. This register is incremented on every AHB transaction.</td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 INEPTFSAV[15:0]: IN endpoint Tx FIFO space available
- Indicates the amount of free space available in the endpoint Tx FIFO.
- Values are in terms of 32-bit words:
  - 0x0: Endpoint Tx FIFO is full
  - 0x1: 1 word available
  - 0x2: 2 words available
  - 0xn: n words available
  - Others: Reserved

56.14.55 OTG device IN endpoint x transfer size register (OTG_DIEPTSIZx)

Address offset: 0x910 + 0x20 * x, (x = 1 to 8)
Reset value: 0x0000 0000

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using the endpoint enable bit in the OTG_DIEPCTLx registers (EPENA bit in OTG_DIEPCTLx), the core modifies this register. The application can only read this register once the core has cleared the endpoint enable bit.

<table>

</tr>
</tbody>
</table>

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 XFRSIZ[15:0]: IN endpoint Tx FIFO space available
- Indicates the amount of free space available in the endpoint Tx FIFO.
- Values are in terms of 32-bit words:
  - 0x0: Endpoint Tx FIFO is full
  - 0x1: 1 word available
  - 0x2: 2 words available
  - 0xn: n words available
  - Others: Reserved
Bit 31 Reserved, must be kept at reset value.

Bits 30:29 **MCNT[1:0]: Multi count**
For periodic IN endpoints, this field indicates the number of packets that must be transmitted per frame on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints.
01: 1 packet
10: 2 packets
11: 3 packets

Bits 28:19 **PKTCNT[9:0]: Packet count**
Indicates the total number of USB packets that constitute the transfer size amount of data for this endpoint.
This field is decremented every time a packet (maximum size or short packet) is read from the Tx FIFO.

Bits 18:0 **XFRSIZ[18:0]: Transfer size**
This field contains the transfer size in bytes for the current endpoint. The core only interrupts the application after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet.
The core decrements this field every time a packet from the external memory is written to the Tx FIFO.

### 56.14.56 OTG device control OUT endpoint 0 control register (OTG_DOEPCTL0)

Address offset: 0xB00
Reset value: 0x0000 8000

This section describes the OTG_DOEPCTL0 register. Nonzero control endpoints use registers for endpoints 1–3.

</tbody>
</table>

Bit 31 **EPENA**: Endpoint enable
The application sets this bit to start transmitting data on endpoint 0.
The core clears this bit before setting any of the following interrupts on this endpoint:
– SETUP phase done
– Endpoint disabled
– Transfer completed

Bit 30 **EPDIS**: Endpoint disable
The application cannot disable control OUT endpoint 0.

Bits 29:28 Reserved, must be kept at reset value.
Bit 27 **SNAK**: Set NAK
A write to this bit sets the NAK bit for the endpoint.
Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit on a transfer completed interrupt, or after a SETUP is received on the endpoint.

Bit 26 **CNAK**: Clear NAK
A write to this bit clears the NAK bit for the endpoint.

Bits 25:22 Reserved, must be kept at reset value.

Bit 21 **STALL**: STALL handshake
The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit’s setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 20 **SNPM**: Snoop mode
This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory.

Bits 19:18 **EPTYP[1:0]**: Endpoint type
Hardcoded to 2'b00 for control.

Bit 17 **NAKSTS**: NAK status
Indicates the following:
0: The core is transmitting non-NAK handshakes based on the FIFO status.
1: The core is transmitting NAK handshakes on this endpoint.
When either the application or the core sets this bit, the core stops receiving data, even if there is space in the Rx FIFO to accommodate the incoming packet. Irrespective of this bit’s setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 16 Reserved, must be kept at reset value.

Bit 15 **USBAEP**: USB active endpoint
This bit is always set to 1, indicating that a control endpoint 0 is always active in all configurations and interfaces.

Bits 14:2 Reserved, must be kept at reset value.

Bits 1:0 **MPSIZ[1:0]**: Maximum packet size
The maximum packet size for control OUT endpoint 0 is the same as what is programmed in control IN endpoint 0.
00: 64 bytes
01: 32 bytes
10: 16 bytes
11: 8 bytes
56.14.57  OTG device OUT endpoint x interrupt register (OTG_DOEPINTx)

Address offset: 0xB08 + 0x20 * x, (x = 0 to 8)

Reset value: 0x0000 0080

This register indicates the status of an endpoint with respect to USB- and AHB-related events. It is shown in Figure 753. The application must read this register when the OUT endpoints interrupt bit of the OTG_GINTSTS register (OEPINT bit in OTG_GINTSTS) is set. Before the application can read this register, it must first read the OTG_DAINT register to get the exact endpoint number for the OTG_DOEPINTx register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG_DAINT and OTG_GINTSTS registers.

rc_w1 rc_w1 rc_w1 rc_w1 rc_w1 rc_w1 rc_w1 rc_w1 rc_w1 rc_w1 rc_w1 rc_w1 rc_w1 rc_w1

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **STPKTRX**: Setup packet received.

Applicable for control OUT endpoints in only in the Buffer DMA Mode. Set by the OTG_HS, this bit indicates that this buffer holds 8 bytes of setup data. There is only one setup packet per buffer. On receiving a setup packet, the OTG_HS closes the buffer and disables the corresponding endpoint after SETUP_COMPLETE status is seen in the Rx FIFO. OTG_HS puts a SETUP_COMPLETE status into the Rx FIFO when it sees the first IN or OUT token after the SETUP packet for that particular endpoint. The application must then re-enable the endpoint to receive any OUT data for the control transfer and reprogram the buffer start address. Because of the above behavior, OTG_HS can receive any number of back to back setup packets and one buffer for every setup packet is used.

Bit 14 **NYET**: NYET interrupt

This interrupt is generated when a NYET response is transmitted for a non isochronous OUT endpoint.

Bit 13 **NAK**: NAK input

The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to unavailability of data in the Tx FIFO.

Bit 12 **BERR**: Babble error interrupt

The core generates this interrupt when babble is received for the endpoint.

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 Reserved, must be kept at reset value.

Bit 8 **OUTPKTERR**: OUT packet error

This interrupt is asserted when the core detects an overflow or a CRC error for an OUT packet. This interrupt is valid only when thresholding is enabled.

Bit 7 Reserved, must be kept at reset value.
Bit 6 **B2BSTUP**: Back-to-back SETUP packets received
   Applies to control OUT endpoint only.
   This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint.

Bit 5 **STSPHSRX**: Status phase received for control write
   This interrupt is valid only for control OUT endpoints. This interrupt is generated only after OTG_HS has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a control write transfer. The application can use this interrupt to ACK or STALL the status phase, after it has decoded the data phase.

Bit 4 **OTEPDIS**: OUT token received when endpoint disabled
   Applies only to control OUT endpoints.
   Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received.

Bit 3 **STUP**: SETUP phase done
   Applies to control OUT endpoint only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet.

Bit 2 **AHBERR**: AHB error
   This is generated only in internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address.

Bit 1 **EPDISD**: Endpoint disabled interrupt
   This bit indicates that the endpoint is disabled per the application’s request.

Bit 0 **XFRC**: Transfer completed interrupt
   This field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint.
### 56.14.58 OTG device OUT endpoint 0 transfer size register (OTG_DOEPTSIZ0)

Address offset: 0xB10

Reset value: 0x0000 0000

The application must modify this register before enabling endpoint 0. Once endpoint 0 is enabled using the endpoint enable bit in the OTG_DOEPCTL0 registers (EPENA bit in OTG_DOEPCTL0), the core modifies this register. The application can only read this register once the core has cleared the endpoint enable bit.

Nonzero endpoints use the registers for endpoints 1–8.

Bit 31 Reserved, must be kept at reset value.

Bits 30:29 **STUPCNT[1:0]:** SETUP packet count

This field specifies the number of back-to-back SETUP data packets the endpoint can receive.

- 01: 1 packet
- 10: 2 packets
- 11: 3 packets

Bits 28:20 Reserved, must be kept at reset value.

Bit 19 **PKTCNT:** Packet count

This field is decremented to zero after a packet is written into the Rx FIFO.

Bits 18:7 Reserved, must be kept at reset value.

Bits 6:0 **XFRSIZ[6:0]:** Transfer size

Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet.

The core decrements this field every time a packet is read from the Rx FIFO and written to the external memory.
### 56.14.59 OTG device OUT endpoint x DMA address register (OTG_DOEPDMAx)

**USBA**
Bit 31 **EPENA**: Endpoint enable
Applies to IN and OUT endpoints.
The application sets this bit to start transmitting data on an endpoint.
The core clears this bit before setting any of the following interrupts on this endpoint:
- SETUP phase done
- Endpoint disabled
- Transfer completed

Bit 30 **EPDIS**: Endpoint disable
The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the endpoint disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the endpoint disabled interrupt. The application must set this bit only if endpoint enable is already set for this endpoint.

Bit 29 **SD1PID**: Set DATA1 PID
Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the endpoint data PID (DPID) field in this register to DATA1.
**SODDFRM**: Set odd frame
Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd frame (EONUM) field to odd frame.

Bit 28 **SD0PID**: Set DATA0 PID
Applies to interrupt/bulk OUT endpoints only.
Writing to this field sets the endpoint data PID (DPID) field in this register to DATA0.
**SEVNFRM**: Set even frame
Applies to isochronous OUT endpoints only.
Writing to this field sets the Even/Odd frame (EONUM) field to even frame.

Bit 27 **SNAK**: Set NAK
A write to this bit sets the NAK bit for the endpoint.
Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit for OUT endpoints on a transfer completed interrupt, or after a SETUP is received on the endpoint.

Bit 26 **CNAK**: Clear NAK
A write to this bit clears the NAK bit for the endpoint.

Bits 25:22 Reserved, must be kept at reset value.

Bit 21 **STALL**: STALL handshake
Applies to non-control, non-isochronous OUT endpoints only (access type is rw).
The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core.
Applies to control endpoints only (access type is rs).
The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit’s setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 20 **SNPM**: Snoop mode
This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory.
Bits 19:18 **EPTYP[1:0]:** Endpoint type  
This is the transfer type supported by this logical endpoint.  
00: Control  
01: Isochronous  
10: Bulk  
11: Interrupt  

Bit 17 **NAKSTS:** NAK status  
Indicates the following:  
0: The core is transmitting non-NAK handshakes based on the FIFO status.  
1: The core is transmitting NAK handshakes on this endpoint.  
When either the application or the core sets this bit:  
The core stops receiving any data on an OUT endpoint, even if there is space in the Rx FIFO to accommodate the incoming packet.  
Irrespective of this bit’s setting, the core always responds to SETUP data packets with an ACK handshake.  

Bit 16 **EONUM:** Even/odd frame  
Applies to isochronous IN and OUT endpoints only.  
Indicates the frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd frame number in which it intends to transmit/receive isochronous data for this endpoint using the SEVNFRM and SODDFRM fields in this register.  
0: Even frame  
1: Odd frame  

**DPID:** Endpoint data PID  
Applies to interrupt/bulk OUT endpoints only.  
Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The application uses the SD0PID register field to program either DATA0 or DATA1 PID.  
0: DATA0  
1: DATA1  

Bit 15 **USBAEP:** USB active endpoint  
Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.  

Bits 14:11 Reserved, must be kept at reset value.  

Bits 10:0 **MPSIZ[10:0]:** Maximum packet size  
The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.
56.14.61 OTG device OUT endpoint x transfer size register (OTG_DOEPTSIZx)

Address offset: 0xB10 + 0x20 * x, (x = 1 to 8)
Reset value: 0x0000 0000

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using endpoint enable bit of the OTG_DOEPCTLx registers (EPENA bit in OTG_DOEPCTLx), the core modifies this register. The application can only read this register once the core has cleared the endpoint enable bit.

Bit 31 Reserved, must be kept at reset value.

Bits 30:29 RXDPID[1:0]: Received data PID
Applies to isochronous OUT endpoints only.
This is the data PID received in the last packet for this endpoint.
00: DATA0
01: DATA2
10: DATA1
11: MDATA

STUPCNT[1:0]: SETUP packet count
Applies to control OUT endpoints only.
This field specifies the number of back-to-back SETUP data packets the endpoint can receive.
01: 1 packet
10: 2 packets
11: 3 packets

Bits 28:19 PKTCNT[9:0]: Packet count
Indicates the total number of USB packets that constitute the transfer size amount of data for this endpoint.
This field is decremented every time a packet (maximum size or short packet) is written to the Rx FIFO.

Bits 18:0 XFRSIZ[18:0]: Transfer size
This field contains the transfer size in bytes for the current endpoint. The core only interrupts the application after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet.
The core decrements this field every time a packet is read from the Rx FIFO and written to the external memory.
56.14.62 OTG power and clock gating control register (OTG_PCGCCTL)

Address offset: 0xE00
Reset value: 0x200B 8000

This register is available in host and device modes.

Table 505. OTG_HS register map and reset values (continued)
Refer to Section 2.3 on page 126 for the register boundary addresses.
56.15 OTG_HS programming model

56.15.1 Core initialization

The application must perform the core initialization sequence. If the cable is connected during power-up, the current mode of operation bit in the OTG_GINTSTS (CMOD bit in OTG_GINTSTS) reflects the mode. The OTG_HS controller enters host mode when an “A” plug is connected or device mode when a “B” plug is connected.

This section explains the initialization of the OTG_HS controller after power-on. The application must follow the initialization sequence irrespective of host or device mode operation. All core global registers are initialized according to the core’s configuration:

1. Program the following fields in the OTG_GAHBCFG register:
   - Global interrupt mask bit GINTMSK = 1
   - Rx FIFO non-empty (RXFLVL bit in OTG_GINTSTS)
   - Periodic Tx FIFO empty level

2. Program the following fields in the OTG_GUSBCFG register:
   - HNP capable bit
   - SRP capable bit
   - OTG_HS timeout calibration field
   - USB turnaround time field

3. The software must unmask the following bits in the OTG_GINTMSK register:
   - OTG interrupt mask
   - Mode mismatch interrupt mask

4. The software can read the CMOD bit in OTG_GINTSTS to determine whether the OTG_HS controller is operating in host or device mode.

56.15.2 Host initialization

To initialize the core as host, the application must perform the following steps:

...
1. Program the HPRTINT in the OTG_GINTMSK register to unmask
2. Program the OTG_HCFG register to select full-speed host
3. Program the PPWR bit in OTG_HPRT to 1. This drives VBUS on the USB.
4. Wait for the PCDET interrupt in OTG_HPRT0. This indicates that a device is connecting to the port.
5. Program the PRST bit in OTG_HPRT to 1. This starts the reset process.
6. Wait at least 10 ms for the reset process to complete.
7. Program the PRST bit in OTG_HPRT to 0.
8. Wait for the PENCHNG interrupt in OTG_HPRT.
9. Read the PSPD bit in OTG_HPRT to get the enumerated speed.
10. Program the HFIR register with a value corresponding to the selected PHY clock
11. Program the FSLSPCS field in the OTG_HCFG register following the speed of the device detected in step 9. If FSLSPCS has been changed a port reset must be performed.
12. Program the OTG_GRXFSIZ register to select the size of the receive FIFO.
13. Program the OTG_HNPTXFSIZ register to select the size and the start address of the Non-periodic transmit FIFO for non-periodic transactions.
14. Program the OTG_HPTXFSIZ register to select the size and start address of the periodic transmit FIFO for periodic transactions.

To communicate with devices, the system software must initialize and enable at least one channel.

56.15.3 Device initialization

The application must perform the following steps to initialize the core as a device on power-up or after a mode change from host to device.

1. Program the following fields in the OTG_DCFG register:
   - Device speed
   - Non-zero-length status OUT handshake
2. Program the OTG_GINTMSK register to unmask the following interrupts:
   - USB reset
   - Enumeration done
   - Early suspend
   - USB suspend
   - SOF
3. Wait for the USBRST interrupt in OTG_GINTSTS. It indicates that a reset has been detected on the USB that lasts for about 10 ms on receiving this interrupt.

Wait for the ENUMDNE interrupt in OTG_GINTSTS. This interrupt indicates the end of reset on the USB. On receiving this interrupt, the application must read the OTG_DSTS register to determine the enumeration speed and perform the steps listed in Endpoint initialization on enumeration completion on page 2747.

At this point, the device is ready to accept SOF packets and perform control transfers on control endpoint 0.
56.15.4 DMA mode

The OTG host uses the AHB master interface to fetch the transmit packet data (AHB to USB) and receive the data update (USB to AHB). The AHB master uses the programmed DMA address (OTG_HCDMAx register in host mode and OTG_DIEPDMAx/OTG_DOEPDMAx register in peripheral mode) to access the data buffers.

56.15.5 Host programming model

Channel initialization

The application must initialize one or more channels before it can communicate with connected devices. To initialize and enable a channel, the application must perform the following steps:

1. Program the OTG_GINTMSK register to unmask the following:
2. Channel interrupt
   - Non-periodic transmit FIFO empty for OUT transactions (applicable when operating in pipelined transaction-level with the packet count field programmed with more than one).
   - Non-periodic transmit FIFO half-empty for OUT transactions (applicable when operating in pipelined transaction-level with the packet count field programmed with more than one).
3. Program the OTG_HAINTMSK register to unmask the selected channels' interrupts.
4. Program the OTG_HCINTMSK register to unmask the transaction-related interrupts of interest given in the host channel interrupt register.
5. Program the selected channel's OTG_HCTSIZx register with the total transfer size, in bytes, and the expected number of packets, including short packets. The application must program the PID field with the initial data PID (to be used on the first OUT transaction or to be expected from the first IN transaction).
6. Program the OTG_HCCHARx register of the selected channel with the device’s endpoint characteristics, such as type, speed, direction, and so forth. (The channel can be enabled by setting the channel enable bit to 1 only when the application is ready to transmit or receive any packet).
7. Program the selected channels in the OTG_HCSPLTx register(s) with the hub and port addresses (split transactions only).
8. Program the selected channels in the OTG_HCDMAx register(s) with the buffer start address (DMA transactions only).

Halting a channel

The application can disable any channel by programming the OTG_HCCHARx register with the CHDIS and CHENA bits set to 1. This enables the OTG_HS host to flush the posted requests (if any) and generates a channel halted interrupt. The application must wait for the CHH interrupt in OTG_HCINTx before reallocating the channel for other transactions. The OTG_HS host does not interrupt the transaction that has already been started on the USB.

To disable a channel in DMA mode operation, the application does not need to check for space in the request queue. The OTG_HS host checks for space to write the disable request on the disabled channel’s turn during arbitration. Meanwhile, all posted requests are dropped from the request queue when the CHDIS bit in OTG_HCCHARx is set to 1.
Before disabling a channel, the application must ensure that there is at least one free space available in the non-periodic request queue (when disabling a non-periodic channel) or the periodic request queue (when disabling a periodic channel). The application can simply flush the posted requests when the request queue is full (before disabling the channel), by programming the OTG_HCCHARx register with the CHDIS bit set to 1, and the CHENA bit cleared to 0.

The application is expected to disable a channel on any of the following conditions:

1. When an STALL, TXERR, BBERR or DTERR interrupt in OTG_HCINTx is received for an IN or OUT channel. The application must be able to receive other interrupts (DTERR, Nak, data, TXERR) for the same channel before receiving the halt.
2. When an XFRC interrupt in OTG_HCINTx is received during a non periodic IN transfer or high-bandwidth interrupt IN transfer.
3. When a DISCINT (disconnect device) interrupt in OTG_GINTSTS is received. (The application is expected to disable all enabled channels).
4. When the application aborts a transfer before normal completion.

Ping protocol

When the OTG_HS host operates in high speed, the application must initiate the ping protocol when communicating with high-speed bulk or control (data and status stage) OUT endpoints. The application must initiate the ping protocol when it receives a NAK/NYET/TXERR interrupt. When the OTG_HS host receives one of the above responses, it does not continue any transaction for a specific endpoint, drops all posted or fetched OUT requests (from the request queue), and flushes the corresponding data (from the transmit FIFO). This is valid in slave mode only. In Slave mode, the application can send a ping token either by setting the DOPING bit in OTG_HCTSIZx before enabling the channel or by just writing the OTG_HCTSIZx register with the DOPING bit set when the channel is already enabled. This enables the OTG_HS host to write a ping request entry to the request queue. The application must wait for the response to the ping token (a NAK, ACK, or TXERR interrupt) before continuing the transaction or sending another ping token. The application can continue the data transaction only after receiving an ACK from the OUT endpoint for the requested ping. In DMA mode operation, the application does not need to set the DOPING bit in OTG_HCTSIZx for a NAK/NYET response in case of bulk/control OUT. The OTG_HS host automatically sets the DOPING bit in OTG_HCTSIZx, and issues the ping tokens for bulk/control OUT. The OTG_HS host continues sending ping tokens until it receives an ACK, and then switches automatically to the data transaction.

Operational model

The application must initialize a channel before communicating to the connected device. This section explains the sequence of operation to be performed for different types of USB transactions.

- **Writing the transmit FIFO**
  The OTG_HS host automatically writes an entry (OUT request) to the periodic/non-periodic request queue, along with the last 32-bit word write of a packet. The application must ensure that at least one free space is available in the periodic/non-periodic request queue before starting to write to the transmit FIFO. The application must always write to the transmit FIFO in 32-bit words. If the packet size is non-32-bit word aligned, the application must use padding. The OTG_HS host determines the actual packet size based on the programmed maximum packet size and transfer size.
• **Reading the receive FIFO**

The application must ignore all packet statuses other than IN data packet (bx0010).
- **Bulk and control OUT/SETUP transactions**

  A typical bulk or control OUT/SETUP pipelined transaction-level operation is shown in Figure 756. See channel 1 (ch_1). Two bulk OUT packets are transmitted. A control SETUP transaction operates in the same way but has only one packet. The assumptions are:
  - The application is attempting to send two maximum-packet-size packets (transfer size = 1, 024 bytes).
  - The non-periodic transmit FIFO can hold two packets (1 KB for HS).
  - The non-periodic request queue depth = 4.

- **Normal bulk and control OUT/SETUP operations**

  The sequence of operations in (channel 1) is as follows:
  1. Initialize channel 1
  2. Write the first packet for channel 1
  3. Along with the last word write, the core writes an entry to the non-periodic request queue
  4. As soon as the non-periodic queue becomes non-empty, the core attempts to send an OUT token in the current frame
  5. Write the second (last) packet for channel 1
  6. The core generates the XFRC interrupt as soon as the last transaction is completed successfully
  7. In response to the XFRC interrupt, de-allocate the channel for other transfers
  8. Handling non-ACK responses
Figure 756. Normal bulk/control OUT/SETUP

1. The grayed elements are not relevant in the context of this figure.
The channel-specific interrupt service routine for bulk and control OUT/SETUP transactions is shown in the following code samples.

- **Interrupt service routine for bulk/control OUT/SETUP and bulk/control IN transactions**
  - **a) Bulk/control OUT/SETUP**
    Unmask (NAK/TXERR/STALL/XFRC)
    if (XFRC)
    {
      Reset Error Count
      Mask ACK
      De-allocate Channel
    }
    else if (STALL)
    {
      Transfer Done = 1
      Unmask CHH
      Disable Channel
    }
    else if (NAK or TXERR)
    {
      Rewind Buffer Pointers
      Unmask CHH
      Disable Channel
      if (TXERR)
      {
        Increment Error Count
        Unmask ACK
      }
      else
      {
        Reset Error Count
      }
    }
    else if (CHH)
    {
      Mask CHH
      if (Transfer Done or (Error_count == 3))
      {
        De-allocate Channel
      }
      else
      {
        Re-initialize Channel
      }
    }
else if (ACK)
    {
        Reset Error Count
        Mask ACK
    }

The application is expected to write the data packets into the transmit FIFO when the space is available in the transmit FIFO and the request queue. The application can make use of the NPTXFE interrupt in OTG_GINTSTS to find the transmit FIFO space.

b) Bulk/control IN

Unmask (TXERR/XFRC/BBERR/STALL/DTErr)
if (XFRC)
    {
        Reset Error Count
        Unmask CHH
        Disable Channel
        Reset Error Count
        Mask ACK
    }
else if (TXERR or BBERR or STALL)
    {
        Unmask CHH
        Disable Channel
        if (TXERR)
            {
                Increment Error Count
                Unmask ACK
            }
    }
else if (CHH)
    {
        Mask CHH
        if (Transfer Done or (Error_count == 3))
            {
                De-allocate Channel
            }
        else
            {
                Re-initialize Channel
            }
    }
else if (ACK)
    {
        Reset Error Count
        Mask ACK
    }
else if (DTERR)
{
    Reset Error Count
}

The application is expected to write the requests as and when the request queue space is available and until the XFRC interrupt is received.

- **Bulk and control IN transactions**
  
  A typical bulk or control IN pipelined transaction-level operation is shown in Figure 757. See channel 2 (ch_2). The assumptions are:
  
  - The application is attempting to receive two maximum-packet-size packets (transfer size = 1 024 bytes).
  - The receive FIFO can contain at least one maximum-packet-size packet and two status words per packet (520 bytes for HS).
  - The non-periodic request queue depth = 4.
Figure 757. Bulk/control IN transactions

1. The grayed elements are not relevant in the context of this figure.
The sequence of operations is as follows:
1. Initialize channel 2.
2. Set the CHENA bit in OTG_HCCHAR2 to write an IN request to the non-periodic request queue.
3. The core attempts to send an IN token after completing the current OUT transaction.
4. The core generates an RXFLVL interrupt as soon as the received packet is written to the receive FIFO.
5. In response to the RXFLVL interrupt, mask the RXFLVL interrupt and read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. Following this, unmask the RXFLVL interrupt.
6. The core generates the RXFLVL interrupt for the transfer completion status entry in the receive FIFO.
7. The application must read and ignore the receive packet status when the receive packet status is not an IN data packet (PKTSTS in OTG_GRXSTSR ≠ 0b0010).
8. The core generates the XFRC interrupt as soon as the receive packet status is read.
9. In response to the XFRC interrupt, disable the channel and stop writing the OTG_HCCHAR2 register for further requests. The core writes a channel disable request to the non-periodic request queue as soon as the OTG_HCCHAR2 register is written.
10. The core generates the RXFLVL interrupt as soon as the halt status is written to the receive FIFO.
11. Read and ignore the receive packet status.
12. The core generates a CHH interrupt as soon as the halt status is popped from the receive FIFO.
13. In response to the CHH interrupt, de-allocate the channel for other transfers.
14. Handling non-ACK responses

- **Control transactions**
  Setup, data, and status stages of a control transfer must be performed as three separate transfers. setup-, data- or status-stage OUT transactions are performed similarly to the bulk OUT transactions explained previously. Data- or status-stage IN transactions are performed similarly to the bulk IN transactions explained previously. For all three stages, the application is expected to set the EPTYP field in OTG_HCCHAR1 to control. During the setup stage, the application is expected to set the PID field in OTG_HCTSIZ1 to SETUP.

- **Interrupt OUT transactions**
  A typical interrupt OUT operation is shown in Figure 758. The assumptions are:
  - The application is attempting to send one packet in every frame (up to 1 maximum packet size), starting with the odd frame (transfer size = 1 024 bytes)
  - The periodic transmit FIFO can hold one packet (1 KB)
  - Periodic request queue depth = 4

The sequence of operations is as follows:
1. Initialize and enable channel 1. The application must set the ODDFRM bit in OTG_HCCHAR1.
2. Write the first packet for channel 1.
3. Along with the last word write of each packet, the OTG_HS host writes an entry to the periodic request queue.
4. The OTG_HS host attempts to send an OUT token in the next (odd) frame.
5. The OTG_HS host generates an XFRC interrupt as soon as the last packet is transmitted successfully.
6. In response to the XFRC interrupt, reinitialize the channel for the next transfer.
1. The grayed elements are not relevant in the context of this figure.

   - Interrupt service routine for interrupt OUT/IN transactions
     a) Interrupt OUT
        Unmask (NAK/TXERR/STALL/XFRC/FRMOR)
if (XFRC)
  {
    Reset Error Count
    Mask ACK
    De-allocate Channel
  }
else
  if (STALL or FRMOR)
    {
      Mask ACK
      Unmask CHH
      Disable Channel
      if (STALL)
        {
          Transfer Done = 1
        }
    }
  else
    if (NAK or TXERR)
      {
        Rewind Buffer Pointers
        Reset Error Count
        Mask ACK
        Unmask CHH
        Disable Channel
      }
  else
    if (CHH)
      {
        Mask CHH
        if (Transfer Done or (Error_count == 3))
          {
            De-allocate Channel
          }
        else
          {
            Re-initialize Channel (in next b_interval - 1 Frame)
          }
      }
  else
    if (ACK)
      {
        Reset Error Count
        Mask ACK
      }
The application uses the NPTXFE interrupt in OTG_GINTSTS to find the transmit FIFO space.

Interrupt IN

Unmask (NAK/TXERR/XFRC/BBERR/STALL/FRMOR/DTERR)

if (XFRC)
{
    Reset Error Count
    Mask ACK
    if (OTG_HCTSIZx.PKTCNT == 0)
    {
        De-allocate Channel
    }
    else
    {
        Transfer Done = 1
        Unmask CHH
        Disable Channel
    }
}
else

if (STALL or FRMOR or NAK or DTERR or BBERR)
{
    Mask ACK
    Unmask CHH
    Disable Channel
    if (STALL or BBERR)
    {
        Reset Error Count
        Transfer Done = 1
    }
    else
    if (!FRMOR)
    {
        Reset Error Count
    }
}
else

if (TXERR)
{
    Increment Error Count
    Unmask ACK
    Unmask CHH
    Disable Channel
}
else
if (CHH) {
    Mask CHH
    if (Transfer Done or (Error_count == 3)) {
        De-allocate Channel
    } else {
        Re-initialize Channel (in next b_interval - 1 /Frame)
    }
} else{
    if (ACK) {
        Reset Error Count
        Mask ACK
    }
}

• Interrupt IN transactions
The assumptions are:
  – The application is attempting to receive one packet (up to 1 maximum packet size) in every frame, starting with odd (transfer size = 1 024 bytes).
  – The receive FIFO can hold at least one maximum-packet-size packet and two status words per packet (1 031 bytes).
  – Periodic request queue depth = 4.

• Normal interrupt IN operation
The sequence of operations is as follows:
1. Initialize channel 2. The application must set the ODDFRM bit in OTG_HCCHAR2.
2. Set the CHENA bit in OTG_HCCHAR2 to write an IN request to the periodic request queue.
3. The OTG_HS host writes an IN request to the periodic request queue for each OTG_HCCHAR2 register write with the CHENA bit set.
4. The OTG_HS host attempts to send an IN token in the next (odd) frame.
5. As soon as the IN packet is received and written to the receive FIFO, the OTG_HS host generates an RXFLVL interrupt.
6. In response to the RXFLVL interrupt, read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. The application must mask the RXFLVL interrupt before reading the receive FIFO, and unmask after reading the entire packet.
7. The core generates the RXFLVL interrupt for the transfer completion status entry in the receive FIFO. The application must read and ignore the receive packet status when the receive packet status is not an IN data packet (PKTSTS in GRXSTSR ≠ 0b0010).
8. The core generates an XFRC interrupt as soon as the receive packet status is read.
9. In response to the XFRC interrupt, read the PKTCNT field in OTG_HCTSIZ2. If the PKTCNT bit in OTG_HCTSIZ2 is not equal to 0, disable the channel before re-
initializing the channel for the next transfer, if any). If PKTCNT bit in OTG_HCTSZ2 = 0, reinitialize the channel for the next transfer. This time, the application must reset the ODDFRM bit in OTG_HCCHAR2.
1. The grayed elements are not relevant in the context of this figure.

- **Isochronous OUT transactions**

  A typical isochronous OUT operation is shown in Figure 759. The assumptions are:
  - The application is attempting to send one packet every frame (up to 1 maximum
packet size), starting with an odd frame. (transfer size = 1 024 bytes).

- The periodic transmit FIFO can hold one packet (1 KB).
- Periodic request queue depth = 4.

The sequence of operations is as follows:

1. Initialize and enable channel 1. The application must set the ODDFRM bit in OTG_HCCHAR1.
2. Write the first packet for channel 1.
3. Along with the last word write of each packet, the OTG_HS host writes an entry to the periodic request queue.
4. The OTG_HS host attempts to send the OUT token in the next frame (odd).
5. The OTG_HS host generates the XFRC interrupt as soon as the last packet is transmitted successfully.
6. In response to the XFRC interrupt, reinitialize the channel for the next transfer.
7. Handling non-ACK responses
1. The grayed elements are not relevant in the context of this figure.

            else
                {
                    Unmask CHH
                    Disable Channel
                }
        }
    else
        if (TXERR or BBERR)
            {
                Increment Error Count
                Unmask CHH
                Disable Channel
            }
        else
            if (CHH)
                {
                    Mask CHH
                    if (Transfer Done or (Error_count == 3))
                        {
                            De-allocate Channel
                        }
else
{
  Re-initialize Channel
}

- **Isochronous IN transactions**

  The assumptions are:
  - The application is attempting to receive one packet (up to 1 maximum packet size) in every frame starting with the next odd frame (transfer size = 1 024 bytes).
  - The receive FIFO can hold at least one maximum-packet-size packet and two status word per packet (1 031 bytes).
  - Periodic request queue depth = 4.

  The sequence of operations is as follows:

  1. Initialize channel 2. The application must set the ODDFRM bit in OTG_HCCHAR2.
  2. Set the CHENA bit in OTG_HCCHAR2 to write an IN request to the periodic request queue.
  3. The OTG_HS host writes an IN request to the periodic request queue for each OTG_HCCHAR2 register write with the CHENA bit set.
  4. The OTG_HS host attempts to send an IN token in the next odd frame.
  5. As soon as the IN packet is received and written to the receive FIFO, the OTG_HS host generates an RXFLVL interrupt.
  6. In response to the RXFLVL interrupt, read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. The application must mask the RXFLVL interrupt before reading the receive FIFO, and unmask it after reading the entire packet.
  7. The core generates an RXFLVL interrupt for the transfer completion status entry in the receive FIFO. This time, the application must read and ignore the receive packet status when the receive packet status is not an IN data packet (PKTSTS bit in OTG_GRXSTSR ≠ 0b0010).
  8. The core generates an XFRC interrupt as soon as the receive packet status is read.
  9. In response to the XFRC interrupt, read the PKTCNT field in OTG_HCTSIZ2. If PKTCNT ≠ 0 in OTG_HCTSIZ2, disable the channel before re-initializing the channel for the next transfer, if any. If PKTCNT = 0 in OTG_HCTSIZ2, reinitialize the channel for the next transfer. This time, the application must reset the ODDFRM bit in OTG_HCCHAR2.
Figure 761. Isochronous IN transactions

1. The grayed elements are not relevant in the context of this figure.

- **Selecting the queue depth**
  
  Choose the periodic and non-periodic request queue depths carefully to match the number of periodic/non-periodic endpoints accessed.

  The non-periodic request queue depth affects the performance of non-periodic
transfers. The deeper the queue (along with sufficient FIFO size), the more often the core is able to pipeline non-periodic transfers. If the queue size is small, the core is able to put in new requests only when the queue space is freed up.

The core’s periodic request queue depth is critical to perform periodic transfers as scheduled. Select the periodic queue depth, based on the number of periodic transfers scheduled in a microframe. If the periodic request queue depth is smaller than the periodic transfers scheduled in a microframe, a frame overrun condition occurs.

- **Handling babble conditions**
  OTG_HS controller handles two cases of babble: packet babble and port babble. Packet babble occurs if the device sends more data than the maximum packet size for the channel. Port babble occurs if the core continues to receive data from the device at EOF2 (the end of frame 2, which is very close to SOF).

  When OTG_HS controller detects a packet babble, it stops writing data into the Rx buffer and waits for the end of packet (EOP). When it detects an EOP, it flushes already written data in the Rx buffer and generates a Babble interrupt to the application.

  When OTG_HS controller detects a port babble, it flushes the Rx FIFO and disables the port. The core then generates a port disabled interrupt (HPRTINT in OTG_GINTSTS, PENCHNG in OTG_HPRT). On receiving this interrupt, the application must determine that this is not due to an overcurrent condition (another cause of the port disabled interrupt) by checking POCA in OTG_HPRT, then perform a soft reset. The core does not send any more tokens after it has detected a port babble condition.

- **Bulk and control OUT/SETUP transactions in DMA mode**
  The sequence of operations is as follows:

  1. Initialize and enable channel 1 as explained in *Section: Channel initialization*.
  2. The OTG_HS host starts fetching the first packet as soon as the channel is enabled. For internal DMA mode, the OTG_HS host uses the programmed DMA address to fetch the packet.
  3. After fetching the last 32-bit word of the second (last) packet, the OTG_HS host masks channel 1 internally for further arbitration.
  4. The OTG_HS host generates a CHH interrupt as soon as the last packet is sent.
  5. In response to the CHH interrupt, de-allocate the channel for other transfers.
**NAK and NYET handling with internal DMA:**

1. The OTG_HS host sends a bulk OUT transaction.
2. The device responds with NAK or NYET.
3. If the application has unmasked NAK or NYET, the core generates the corresponding interrupt(s) to the application. The application is not required to service these interrupts, since the core takes care of rewinding the buffer pointers and re-initializing the Channel without application intervention.
4. The core automatically issues a ping token.
5. When the device returns an ACK, the core continues with the transfer. Optionally, the application can utilize these interrupts, in which case the NAK or NYET interrupt is masked by the application.
The core does not generate a separate interrupt when NAK or NYET is received by the host functionality.

- **Bulk and control IN transactions in DMA mode**
  The sequence of operations is as follows:
  1. Initialize and enable the used channel (channel x) as explained in *Section: Channel initialization*.
  2. The OTG_HS host writes an IN request to the request queue as soon as the channel receives the grant from the arbiter (arbitration is performed in a round-robin fashion).
  3. The OTG_HS host starts writing the received data to the system memory as soon as the last byte is received with no errors.
  4. When the last packet is received, the OTG_HS host sets an internal flag to remove any extra IN requests from the request queue.
  5. The OTG_HS host flushes the extra requests.
  6. The final request to disable channel x is written to the request queue. At this point, channel 2 is internally masked for further arbitration.
  7. The OTG_HS host generates the CHH interrupt as soon as the disable request comes to the top of the queue.
  8. In response to the CHH interrupt, de-allocate the channel for other transfers.
Interrupt OUT transactions in DMA mode
1. Initialize and enable channel x as explained in Section: Channel initialization.
2. The OTG_HS host starts fetching the first packet as soon the channel is enabled and writes the OUT request along with the last 32-bit word fetch. In high-bandwidth transfers, the OTG_HS host continues fetching the next packet (up to the value specified in the MC field) before switching to the next channel.
3. The OTG_HS host attempts to send the OUT token at the beginning of the next odd frame/micro-frame.
4. After successfully transmitting the packet, the OTG_HS host generates a CHH interrupt.

5. In response to the CHH interrupt, reinitialize the channel for the next transfer.

Figure 764. Normal interrupt OUT transactions - DMA mode

- **Interrupt IN transactions in DMA mode**
  - The sequence of operations (channelx) is as follows:
    1. Initialize and enable channel x as explained in Section: Channel initialization.
    2. The OTG_HS host writes an IN request to the request queue as soon as the channel x gets the grant from the arbiter (round-robin with fairness). In high-bandwidth transfers, the OTG_HS host writes consecutive writes up to MC times.
3. The OTG_HS host attempts to send an IN token at the beginning of the next (odd) frame/micro-frame.
4. As soon the packet is received and written to the receive FIFO, the OTG_HS host generates a CHH interrupt.
5. In response to the CHH interrupt, reinitialize the channel for the next transfer.

**Figure 765. Normal interrupt IN transactions - DMA mode**

- Isochronous OUT transactions in DMA mode
  1. Initialize and enable channel x as explained in Section: Channel initialization.
  2. The OTG_HS host starts fetching the first packet as soon as the channel is enabled, and writes the OUT request along with the last 32-bit word fetch. In high-bandwidth
transfers, the OTG_HS host continues fetching the next packet (up to the value specified in the MC field) before switching to the next channel.

3. The OTG_HS host attempts to send an OUT token at the beginning of the next (odd) frame/micro-frame.

4. After successfully transmitting the packet, the OTG_HS host generates a CHH interrupt.

5. In response to the CHH interrupt, reinitialize the channel for the next transfer.

**Figure 766. Normal isochronous OUT transaction - DMA mode**

- **Isochronous IN transactions in DMA mode**
  
The sequence of operations ((channel x) is as follows:

1. Initialize and enable channel x as explained in Section : Channel initialization.

2. The OTG_HS host writes an IN request to the request queue as soon as the channel x gets the grant from the arbiter (round-robin with fairness). In high-bandwidth transfers, the OTG_HS host performs consecutive write operations up to MC times.
3. The OTG_HS host attempts to send an IN token at the beginning of the next (odd) frame/micro-frame.
4. As soon the packet is received and written to the receive FIFO, the OTG_HS host generates a CHH interrupt.
5. In response to the CHH interrupt, reinitialize the channel for the next transfer.

**Figure 767. Normal isochronous IN transactions - DMA mode**

- **Bulk and control OUT/SETUP split transactions in DMA mode**

  The sequence of operations in (channel x) is as follows:

  1. Initialize and enable channel x for start split as explained in *Section: Channel initialization*.

  2. The OTG_HS host starts fetching the first packet as soon the channel is enabled and writes the OUT request along with the last 32-bit word fetch.

  3. After successfully transmitting start split, the OTG_HS host generates the CHH interrupt.

  4. In response to the CHH interrupt, set the COMPLSPLT bit in OTG_HCSPLT1 to send the complete split.
5. After successfully transmitting complete split, the OTG_HS host generates the CHH interrupt.
6. In response to the CHH interrupt, de-allocate the channel.

• **Bulk/control IN split transactions in DMA mode**
  The sequence of operations (channel x) is as follows:
  1. Initialize and enable channel x as explained in *Section : Channel initialization*.
  2. The OTG_HS host writes the start split request to the nonperiodic request after getting the grant from the arbiter. The OTG_HS host masks the channel x internally for the arbitration after writing the request.
  3. As soon as the IN token is transmitted, the OTG_HS host generates the CHH interrupt.
  4. In response to the CHH interrupt, set the COMPLSPLT bit in OTG_HCSPLT2 and re-enable the channel to send the complete split token. This unmasks channel x for arbitration.
  5. The OTG_HS host writes the complete split request to the nonperiodic request after receiving the grant from the arbiter.
  6. The OTG_HS host starts writing the packet to the system memory after receiving the packet successfully.
  7. As soon as the received packet is written to the system memory, the OTG_HS host generates a CHH interrupt.
  8. In response to the CHH interrupt, de-allocate the channel.

• **Interrupt OUT split transactions in DMA mode**
  The sequence of operations in (channel x) is as follows:
  1. Initialize and enable channel 1 for start split as explained in *Section : Channel initialization*. The application must set the ODDFRM bit in OTG_HCCHAR1.
  2. The OTG_HS host starts reading the packet.
  3. The OTG_HS host attempts to send the start split transaction.
  4. After successfully transmitting the start split, the OTG_HS host generates the CHH interrupt.
  5. In response to the CHH interrupt, set the COMPLSPLT bit in OTG_HCSPLT1 to send the complete split.
  6. After successfully completing the complete split transaction, the OTG_HS host generates the CHH interrupt.
  7. In response to CHH interrupt, de-allocate the channel.

• **Interrupt IN split transactions in DMA mode**
  The sequence of operations in (channel x) is as follows:
  1. Initialize and enable channel x for start split as explained in *Section : Channel initialization*.
  2. The OTG_HS host writes an IN request to the request queue as soon as channel x receives the grant from the arbiter.
  3. The OTG_HS host attempts to send the start split IN token at the beginning of the next odd micro-frame.
  4. The OTG_HS host generates the CHH interrupt after successfully transmitting the start split IN token.
  5. In response to the CHH interrupt, set the COMPLSPLT bit in OTG_HCSPLT2 to send the complete split.
6. As soon as the packet is received successfully, the OTG_HS host starts writing the data to the system memory.

7. The OTG_HS host generates the CHH interrupt after transferring the received data to the system memory.

8. In response to the CHH interrupt, de-allocate or reinitialize the channel for the next start split.

- **Isochronous OUT split transactions in DMA mode**
  The sequence of operations (channel x) is as follows:
  1. Initialize and enable channel x for start split (begin) as explained in Section : Channel initialization. The application must set the ODDFRM bit in OTG_HCCHAR1. Program the MPS field.
  2. The OTG_HS host starts reading the packet.
  3. After successfully transmitting the start split (begin), the OTG_HS host generates the CHH interrupt.
  4. In response to the CHH interrupt, reinitialize the registers to send the start split (end).
  5. After successfully transmitting the start split (end), the OTG_HS host generates a CHH interrupt.
  6. In response to the CHH interrupt, de-allocate the channel.

- **Isochronous IN split transactions in DMA mode**
  The sequence of operations (channel x) is as follows:
  1. Initialize and enable channel x for start split as explained in Section : Channel initialization.
  2. The OTG_HS host writes an IN request to the request queue as soon as channel x receives the grant from the arbiter.
  3. The OTG_HS host attempts to send the start split IN token at the beginning of the next odd micro-frame.
  4. The OTG_HS host generates the CHH interrupt after successfully transmitting the start split IN token.
  5. In response to the CHH interrupt, set the COMPLSPLT bit in OTG_HCSPLT2 to send the complete split.
  6. As soon as the packet is received successfully, the OTG_HS host starts writing the data to the system memory.
   The OTG_HS host generates the CHH interrupt after transferring the received data to the system memory. In response to the CHH interrupt, de-allocate the channel or reinitialize the channel for the next start split.
56.15.6 Device programming model

Endpoint initialization on USB reset

1. Set the NAK bit for all OUT endpoints
   - SNAK = 1 in OTG_DOEPCTLx (for all OUT endpoints)

2. Unmask the following interrupt bits
   - INEP0 = 1 in OTG_DAINTMSK (control 0 IN endpoint)
   - OUTEP0 = 1 in OTG_DAINTMSK (control 0 OUT endpoint)
   - STUPM = 1 in OTG_DOEPMSK
   - XFRCM = 1 in OTG_DOEPMSK
   - XFRCM = 1 in OTG_DIEPMSK
   - TOM = 1 in OTG_DIEPMSK

3. Set up the data FIFO RAM for each of the FIFOs
   - Program the OTG_GRXFSIZ register, to be able to receive control OUT data and setup data. If thresholding is not enabled, at a minimum, this must be equal to 1 max packet size of control endpoint 0 + 2 words (for the status of the control OUT data packet) + 10 words (for setup packets).
   - Program the OTG_DIEPTXF0 register (depending on the FIFO number chosen) to be able to transmit control IN data. At a minimum, this must be equal to 1 max packet size of control endpoint 0.

4. Program the following fields in the endpoint-specific registers for control OUT endpoint 0 to receive a SETUP packet
   - STUPCNT = 3 in OTG_DOEPTSIZ0 (to receive up to 3 back-to-back SETUP packets)

5. For USB OTG_HS in DMA mode, the OTG_DOEPDMA0 register should have a valid memory address to store any SETUP packets received.

At this point, all initialization required to receive SETUP packets is done.

Endpoint initialization on enumeration completion

1. On the Enumeration Done interrupt (ENUMDNE in OTG_GINTSTS), read the OTG_DSTS register to determine the enumeration speed.

2. Program the MPSIZ field in OTG_DIEPCTL0 to set the maximum packet size. This step configures control endpoint 0. The maximum packet size for a control endpoint depends on the enumeration speed.

3. For USB OTG_HS in DMA mode, program the OTG_DOEPCTL0 register to enable control OUT endpoint 0, to receive a SETUP packet.

At this point, the device is ready to receive SOF packets and is configured to perform control transfers on control endpoint 0.

Endpoint initialization on SetAddress command

This section describes what the application must do when it receives a SetAddress command in a SETUP packet.

1. Program the OTG_DCFG register with the device address received in the SetAddress command

2. Program the core to send out a status IN packet
Endpoint initialization on SetConfiguration/SetInterface command

This section describes what the application must do when it receives a SetConfiguration or SetInterface command in a SETUP packet.

1. When a SetConfiguration command is received, the application must program the endpoint registers to configure them with the characteristics of the valid endpoints in the new configuration.

2. When a SetInterface command is received, the application must program the endpoint registers of the endpoints affected by this command.

3. Some endpoints that were active in the prior configuration or alternate setting are not valid in the new configuration or alternate setting. These invalid endpoints must be deactivated.

4. Unmask the interrupt for each active endpoint and mask the interrupts for all inactive endpoints in the OTG_DAINTMSK register.

5. Set up the data FIFO RAM for each FIFO.

6. After all required endpoints are configured, the application must program the core to send a status IN packet.

At this point, the device core is configured to receive and transmit any type of data packet.

Endpoint activation

This section describes the steps required to activate a device endpoint or to configure an existing device endpoint to a new type.

1. Program the characteristics of the required endpoint into the following fields of the OTG_DIEPCTLx register (for IN or bidirectional endpoints) or the OTG_DOEPCTLx register (for OUT or bidirectional endpoints).
   - Maximum packet size
   - USB active endpoint = 1
   - Endpoint start data toggle (for interrupt and bulk endpoints)
   - Endpoint type
   - Tx FIFO number

2. Once the endpoint is activated, the core starts decoding the tokens addressed to that endpoint and sends out a valid handshake for each valid token received for the endpoint.

Endpoint deactivation

This section describes the steps required to deactivate an existing endpoint.

1. In the endpoint to be deactivated, clear the USB active endpoint bit in the OTG_DIEPCTLx register (for IN or bidirectional endpoints) or the OTG_DOEPCTLx register (for OUT or bidirectional endpoints).

2. Once the endpoint is deactivated, the core ignores tokens addressed to that endpoint, which results in a timeout on the USB.

Note: The application must meet the following conditions to set up the device core to handle traffic:
NPTXFEM and RXFLVLM in the OTG_GINTMSK register must be cleared.
Operational model

SETUP and OUT data transfers:

This section describes the internal data flow and application-level operations during data OUT transfers and SETUP transactions.

1. **Packet read**

   This section describes how to read packets (OUT data and SETUP packets) from the receive FIFO.

   1. On catching an RXFLVL interrupt (OTG_GINTSTS register), the application must read the receive status pop register (OTG_GRXSTSP).
   2. The application can mask the RXFLVL interrupt (in OTG_GINTSTS) by writing to RXFLVLM = 0 (in OTG_GINTMSK), until it has read the packet from the receive FIFO.
   3. If the received packet's byte count is not 0, the byte count amount of data is popped from the receive data FIFO and stored in memory. If the received packet byte count is 0, no data is popped from the receive data FIFO.
   4. The receive status readout of the packet of FIFO indicates one of the following:
      a) Global OUT NAK pattern:
         
         PKTSTS = Global OUT NAK, BCNT = 0x000, EPNUM = (0x0),
         DPID = (0b00).
         These data indicate that the global OUT NAK bit has taken effect.
      b) SETUP packet pattern:
         
         PKTSTS = SETUP, BCNT = 0x008, EPNUM = Control EP Num,
         DPID = DATA0. These data indicate that a SETUP packet for the specified endpoint is now available for reading from the receive FIFO.
      c) Setup stage done pattern:
         
         PKTSTS = Setup Stage Done, BCNT = 0x0, EPNUM = Control EP Num,
         DPID = (0b00).
         These data indicate that the setup stage for the specified endpoint has completed and the data stage has started. After this entry is popped from the receive FIFO, the core asserts a setup interrupt on the specified control OUT endpoint.
      d) Data OUT packet pattern:
         
         PKTSTS = DataOUT, BCNT = size of the received data OUT packet (0 ≤ BCNT ≤ 1 024), EPNUM = EPNUM on which the packet was received, DPID = Actual Data PID.
      e) Data transfer completed pattern:
         
         PKTSTS = Data OUT transfer done, BCNT = 0x0, EPNUM = OUT EP Num on which the data transfer is complete, DPID = (0b00).
         These data indicate that an OUT data transfer for the specified OUT endpoint has completed. After this entry is popped from the receive FIFO, the core asserts a transfer completed interrupt on the specified OUT endpoint.
   5. After the data payload is popped from the receive FIFO, the RXFLVL interrupt (OTG_GINTSTS) must be unmasked.
   6. Steps 1–5 are repeated every time the application detects assertion of the interrupt line due to RXFLVL in OTG_GINTSTS. Reading an empty receive FIFO can result in undefined core behavior.

   *Figure 768* provides a flowchart of the above procedure.
Figure 768. Receive FIFO packet read

 SETUP transactions

This section describes how the core handles SETUP packets and the application’s sequence for handling SETUP transactions.

• Application requirements

1. To receive a SETUP packet, the STUPCNT field (OTG_DOEPTSIZx) in a control OUT endpoint must be programmed to a non-zero value. When the application programs the STUPCNT field to a non-zero value, the core receives SETUP packets and writes them to the receive FIFO, irrespective of the NAK status and EPENA bit setting in OTG_DOEPCTLx. The STUPCNT field is decremented every time the control endpoint receives a SETUP packet. If the STUPCNT field is not programmed to a proper value before receiving a SETUP packet, the core still receives the SETUP packet and decrements the STUPCNT field, but the application may not be able to determine the correct number of SETUP packets received in the setup stage of a control transfer.
   – STUPCNT = 3 in OTG_DOEPTSIZx

2. The application must always allocate some extra space in the receive data FIFO, to be able to receive up to three SETUP packets on a control endpoint.
   – The space to be reserved is 10 words. Three words are required for the first SETUP packet, 1 word is required for the setup stage done word and 6 words are required to store two extra SETUP packets among all control endpoints.
   – 3 words per SETUP packet are required to store 8 bytes of SETUP data and 4 bytes of SETUP status (setup packet pattern). The core reserves this space in the
receive data FIFO to write SETUP data only, and never uses this space for data packets.
3. The application must read the 2 words of the SETUP packet from the receive FIFO.
4. The application must read and discard the setup stage done word from the receive FIFO.

- **Internal data flow**
  1. When a SETUP packet is received, the core writes the received data to the receive FIFO, without checking for available space in the receive FIFO and irrespective of the endpoint's NAK and STALL bit settings.
     - The core internally sets the IN NAK and OUT NAK bits for the control IN/OUT endpoints on which the SETUP packet was received.
  2. For every SETUP packet received on the USB, 3 words of data are written to the receive FIFO, and the STUPCNT field is decremented by 1.
     - The first word contains control information used internally by the core
     - The second word contains the first 4 bytes of the SETUP command
     - The third word contains the last 4 bytes of the SETUP command
  3. When the setup stage changes to a data IN/OUT stage, the core writes an entry (setup stage done word) to the receive FIFO, indicating the completion of the setup stage.
  4. On the AHB side, SETUP packets are emptied by the application.
  5. When the application pops the setup stage done word from the receive FIFO, the core interrupts the application with an STUP interrupt (OTG_DOEPINTx), indicating it can process the received SETUP packet.
  6. The core clears the endpoint enable bit for control OUT endpoints.

- **Application programming sequence**
  1. Program the OTG_DOEPTSIZx register.
     - STUPCNT = 3
  2. Wait for the RXFLVL interrupt (OTG_GINTSTS) and empty the data packets from the receive FIFO.
  3. Assertion of the STUP interrupt (OTG_DOEPINTx) marks a successful completion of the SETUP data transfer.
     - On this interrupt, the application must read the OTG_DOEPTSIZx register to determine the number of SETUP packets received and process the last received SETUP packet.
Handling more than three back-to-back SETUP packets
Per the USB 2.0 specification, normally, during a SETUP packet error, a host does not send more than three back-to-back SETUP packets to the same endpoint. However, the USB 2.0 specification does not limit the number of back-to-back SETUP packets a host can send to the same endpoint. When this condition occurs, the OTG_HS controller generates an interrupt (B2BSTUP in OTG_DOEPINTx).

Setting the global OUT NAK
Internal data flow:
1. When the application sets the Global OUT NAK (SGONAK bit in OTG_DCTL), the core stops writing data, except SETUP packets, to the receive FIFO. Irrespective of the space availability in the receive FIFO, non-isochronous OUT tokens receive a NAK handshake response, and the core ignores isochronous OUT data packets.
2. The core writes the Global OUT NAK pattern to the receive FIFO. The application must reserve enough receive FIFO space to write this data pattern.
3. When the application pops the Global OUT NAK pattern word from the receive FIFO, the core sets the GONAKEFF interrupt (OTG_GINTSTS).
4. Once the application detects this interrupt, it can assume that the core is in Global OUT NAK mode. The application can clear this interrupt by clearing the SGONAK bit in OTG_DCTL.

Application programming sequence:
1. To stop receiving any kind of data in the receive FIFO, the application must set the Global OUT NAK bit by programming the following field:
   - SGONAK = 1 in OTG_DCTL
2. Wait for the assertion of the GONAKEFF interrupt in OTG_GINTSTS. When asserted, this interrupt indicates that the core has stopped receiving any type of data except SETUP packets.
3. The application can receive valid OUT packets after it has set SGONAK in OTG_DCTL and before the core asserts the GONAKEFF interrupt (OTG_GINTSTS).
4. The application can temporarily mask this interrupt by writing to the GONAKEFFM bit in the OTG_GINTMSK register.
   - GONAKEFFM = 0 in the OTG_GINTMSK register
5. Whenever the application is ready to exit the Global OUT NAK mode, it must clear the SGONAK bit in OTG_DCTL. This also clears the GONAKEFF interrupt (OTG_GINTSTS).
   - CGONAK = 1 in OTG_DCTL
6. If the application has masked this interrupt earlier, it must be unmasked as follows:
   - GONAKEFFM = 1 in OTG_GINTMSK

• **Disabling an OUT endpoint**

The application must use this sequence to disable an OUT endpoint that it has enabled.

Application programming sequence:
1. Before disabling any OUT endpoint, the application must enable Global OUT NAK mode in the core.
   - SGONAK = 1 in OTG_DCTL
2. Wait for the GONAKEFF interrupt (OTG_GINTSTS)
3. Disable the required OUT endpoint by programming the following fields:
   - EPDIS = 1 in OTG_DOEPCTLx
   - SNAK = 1 in OTG_DOEPCTLx
4. Wait for the EPDISD interrupt (OTG_DOEPINTx), which indicates that the OUT endpoint is completely disabled. When the EPDISD interrupt is asserted, the core also clears the following bits:
   - EPDIS = 0 in OTG_DOEPCTLx
   - EPENA = 0 in OTG_DOEPCTLx
5. The application must clear the Global OUT NAK bit to start receiving data from other non-disabled OUT endpoints.
   - SGONAK = 0 in OTG_DCTL

• **Generic non-isochronous OUT data transfers**

This section describes a regular non-isochronous OUT data transfer (control, bulk, or interrupt).

Application requirements:
1. Before setting up an OUT transfer, the application must allocate a buffer in the memory to accommodate all data to be received as part of the OUT transfer.

2. For OUT transfers, the transfer size field in the endpoint’s transfer size register must be a multiple of the maximum packet size of the endpoint, adjusted to the word boundary.
   - transfer size[EPNUM] = n × (MPSIZ[EPNUM] + 4 – (MPSIZ[EPNUM] mod 4))
   - packet count[EPNUM] = n
   - n > 0

3. On any OUT endpoint interrupt, the application must read the endpoint’s transfer size register to calculate the size of the payload in the memory. The received payload size can be less than the programmed transfer size.
   - Payload size in memory = application programmed initial transfer size – core updated final transfer size
   - Number of USB packets in which this payload was received = application programmed initial packet count – core updated final packet count

Internal data flow:

1. The application must set the transfer size and packet count fields in the endpoint-specific registers, clear the NAK bit, and enable the endpoint to receive the data.

2. Once the NAK bit is cleared, the core starts receiving data and writes it to the receive FIFO, as long as there is space in the receive FIFO. For every data packet received on the USB, the data packet and its status are written to the receive FIFO. Every packet (maximum packet size or short packet) written to the receive FIFO decrements the packet count field for that endpoint by 1.
   - OUT data packets received with bad data CRC are flushed from the receive FIFO automatically.
   - After sending an ACK for the packet on the USB, the core discards non-isochronous OUT data packets that the host, which cannot detect the ACK, resends. The application does not detect multiple back-to-back data OUT packets on the same endpoint with the same data PID. In this case the packet count is not decremented.
   - If there is no space in the receive FIFO, isochronous or non-isochronous data packets are ignored and not written to the receive FIFO. Additionally, non-isochronous OUT tokens receive a NAK handshake reply.
   - In all the above three cases, the packet count is not decremented because no data are written to the receive FIFO.

3. When the packet count becomes 0 or when a short packet is received on the endpoint, the NAK bit for that endpoint is set. Once the NAK bit is set, the isochronous or non-isochronous data packets are ignored and not written to the receive FIFO, and non-isochronous OUT tokens receive a NAK handshake reply.

4. After the data are written to the receive FIFO, the application reads the data from the receive FIFO and writes it to external memory, one packet at a time per endpoint.

5. At the end of every packet write on the AHB to external memory, the transfer size for the endpoint is decremented by the size of the written packet.

6. The OUT data transfer completed pattern for an OUT endpoint is written to the receive FIFO on one of the following conditions:
   - The transfer size is 0 and the packet count is 0
   - The last OUT data packet written to the receive FIFO is a short packet (0 ≤ packet size < maximum packet size)
7. When either the application pops this entry (OUT data transfer completed), a transfer completed interrupt is generated for the endpoint and the endpoint enable is cleared.

Application programming sequence:
1. Program the OTG_DOEPTSIZx register for the transfer size and the corresponding packet count.
2. Program the OTG_DOEPCTLx register with the endpoint characteristics, and set the EPENA and CNAK bits.
   - EPENA = 1 in OTG_DOEPCTLx
   - CNAK = 1 in OTG_DOEPCTLx
3. Wait for the RXFLVL interrupt (in OTG_GINTSTS) and empty the data packets from the receive FIFO.
   - This step can be repeated many times, depending on the transfer size.
4. Asserting the XFRC interrupt (OTG_DOEPINTx) marks a successful completion of the non-isochronous OUT data transfer.
5. Read the OTG_DOEPTSIZx register to determine the size of the received data payload.

- **Generic isochronous OUT data transfer**
  This section describes a regular isochronous OUT data transfer.

Application requirements:
1. All the application requirements for non-isochronous OUT data transfers also apply to isochronous OUT data transfers.
2. For isochronous OUT data transfers, the transfer size and packet count fields must always be set to the number of maximum-packet-size packets that can be received in a single frame and no more. Isochronous OUT data transfers cannot span more than 1 frame.
3. The application must read all isochronous OUT data packets from the receive FIFO (data and status) before the end of the periodic frame (EOPF interrupt in OTG_GINTSTS).
4. To receive data in the following frame, an isochronous OUT endpoint must be enabled after the EOPF (OTG_GINTSTS) and before the SOF (OTG_GINTSTS).

Internal data flow:
1. The internal data flow for isochronous OUT endpoints is the same as that for non-isochronous OUT endpoints, but for a few differences.
2. When an isochronous OUT endpoint is enabled by setting the endpoint enable and clearing the NAK bits, the Even/Odd frame bit must also be set appropriately. The core receives data on an isochronous OUT endpoint in a particular frame only if the following condition is met:
   - EONUM (in OTG_DOEPCTLx) = FNSOF[0] (in OTG_DSTS)
3. When the application completely reads an isochronous OUT data packet (data and status) from the receive FIFO, the core updates the RXDPID field in OTG_DOEPTSIZx with the data PID of the last isochronous OUT data packet read from the receive FIFO.

Application programming sequence:
1. Program the OTG_DOEPTSIZx register for the transfer size and the corresponding packet count
2. Program the OTG_DOEPCTLx register with the endpoint characteristics and set the endpoint enable, ClearNAK, and Even/Odd frame bits.
   - EPENA = 1
   - CNAK = 1
   - EONUM = (0: Even/1: Odd)
3. Wait for the RXFLVL interrupt (in OTG_GINTSTS) and empty the data packets from the receive FIFO
   - This step can be repeated many times, depending on the transfer size.
4. The assertion of the XFRC interrupt (in OTG_DOEPINTx) marks the completion of the isochronous OUT data transfer. This interrupt does not necessarily mean that the data in memory are good.
5. This interrupt cannot always be detected for isochronous OUT transfers. Instead, the application can detect the INCOMPISOOUT interrupt in OTG_GINTSTS.
6. Read the OTG_DOEPTSIZx register to determine the size of the received transfer and to determine the validity of the data received in the frame. The application must treat the data received in memory as valid only if one of the following conditions is met:
   - RXDPID = DATA0 (in OTG_DOEPTSIZx) and the number of USB packets in which this payload was received = 1
   - RXDPID = DATA1 (in OTG_DOEPTSIZx) and the number of USB packets in which this payload was received = 2
   - RXDPID = D2 (in OTG_DOEPTSIZx) and the number of USB packets in which this payload was received = 3
   - The number of USB packets in which this payload was received = Application programmed initial packet count – core updated final packet count
   - The application can discard invalid data packets.

**Incomplete isochronous OUT data transfers**

This section describes the application programming sequence when isochronous OUT data packets are dropped inside the core.

**Internal data flow:**

1. For isochronous OUT endpoints, the XFRC interrupt (in OTG_DOEPINTx) may not always be asserted. If the core drops isochronous OUT data packets, the application could fail to detect the XFRC interrupt (OTG_DOEPINTx) under the following circumstances:
   - When the receive FIFO cannot accommodate the complete ISO OUT data packet, the core drops the received ISO OUT data
   - When the isochronous OUT data packet is received with CRC errors
   - When the isochronous OUT token received by the core is corrupted
   - When the application is very slow in reading the data from the receive FIFO
2. When the core detects an end of periodic frame before transfer completion to all isochronous OUT endpoints, it asserts the incomplete isochronous OUT data interrupt (INCOMPISOOUT in OTG_GINTSTS), indicating that an XFRC interrupt (in OTG_DOEPINTx) is not asserted on at least one of the isochronous OUT endpoints. At
this point, the endpoint with the incomplete transfer remains enabled, but no active transfers remain in progress on this endpoint on the USB.

Application programming sequence:
1. Asserting the INCOMPISOOUT interrupt (OTG_GINTSTS) indicates that in the current frame, at least one isochronous OUT endpoint has an incomplete transfer.
2. If this occurs because isochronous OUT data is not completely emptied from the endpoint, the application must ensure that the application empties all isochronous OUT data (data and status) from the receive FIFO before proceeding.
   - When all data are emptied from the receive FIFO, the application can detect the XFRC interrupt (OTG_DOEPINTx). In this case, the application must re-enable the endpoint to receive isochronous OUT data in the next frame.
3. When it receives an INCOMPISOOUT interrupt (in OTG_GINTSTS), the application must read the control registers of all isochronous OUT endpoints (OTG_DOEPCTLx) to determine which endpoints had an incomplete transfer in the current microframe. An endpoint transfer is incomplete if both the following conditions are met:
   - EONUM bit (in OTG_DOEPCTLx) = FNSOF[0] (in OTG_DSTS)
   - EPENA = 1 (in OTG_DOEPCTLx)
4. The previous step must be performed before the SOF interrupt (in OTG_GINTSTS) is detected, to ensure that the current frame number is not changed.
5. For isochronous OUT endpoints with incomplete transfers, the application must discard the data in the memory and disable the endpoint by setting the EPDIS bit in OTG_DOEPCTLx.
6. Wait for the EPDISD interrupt (in OTG_DOEPINTx) and enable the endpoint to receive new data in the next frame.
   - Because the core can take some time to disable the endpoint, the application may not be able to receive the data in the next frame after receiving bad isochronous data.

- **Stalling a non-isochronous OUT endpoint**

This section describes how the application can stall a non-isochronous endpoint.
1. Put the core in the Global OUT NAK mode.
2. Disable the required endpoint
   - When disabling the endpoint, instead of setting the SNAK bit in OTG_DOEPCTL, set STALL = 1 (in OTG_DOEPCTL).
   - The STALL bit always takes precedence over the NAK bit.
3. When the application is ready to end the STALL handshake for the endpoint, the STALL bit (in OTG_DOEPCTLx) must be cleared.
4. If the application is setting or clearing a STALL for an endpoint due to a SetFeature.Endpoint Halt or ClearFeature.Endpoint Halt command, the STALL bit must be set or cleared before the application sets up the status stage transfer on the control endpoint.

**Examples**

This section describes and depicts some fundamental transfer types and scenarios.
- **Bulk OUT transaction**
Figure 770 depicts the reception of a single Bulk OUT data packet from the USB to the AHB and describes the events involved in the process.

**Figure 770. Bulk OUT transaction**

After a SetConfiguration/SetInterface command, the application initializes all OUT endpoints by setting CNAK = 1 and EPENA = 1 (in OTG_DOEPCTLx), and setting a suitable XFRSIZ and PKTCNT in the OTG_DOEPTSIZx register.

1. Host attempts to send data (OUT token) to an endpoint.
2. When the core receives the OUT token on the USB, it stores the packet in the Rx FIFO because space is available there.
3. After writing the complete packet in the Rx FIFO, the core then asserts the RXFLVL interrupt (in OTG_GINTSTS).
4. On receiving the PKTCNT number of USB packets, the core internally sets the NAK bit for this endpoint to prevent it from receiving any more packets.
5. The application processes the interrupt and reads the data from the Rx FIFO.
6. When the application has read all the data (equivalent to XFRSIZ), the core generates an XFRC interrupt (in OTG_DOEPIINTx).
7. The application processes the interrupt and uses the setting of the XFRC interrupt bit (in OTG_DOEPIINTx) to determine that the intended transfer is complete.

**IN data transfers**

- **Packet write**

  This section describes how the application writes data packets to the endpoint FIFO when dedicated transmit FIFOs are enabled.
1. The application can either choose the polling or the interrupt mode.
   – In polling mode, the application monitors the status of the endpoint transmit data FIFO by reading the OTG_DTXFSTSx register, to determine if there is enough space in the data FIFO.
   – In interrupt mode, the application waits for the TXFE interrupt (in OTG_DIEPINTx) and then reads the OTG_DTXFSTSx register, to determine if there is enough space in the data FIFO.
   – To write a single non-zero length data packet, there must be space to write the entire packet in the data FIFO.
   – To write zero length packet, the application must not look at the FIFO space.

2. Using one of the above mentioned methods, when the application determines that there is enough space to write a transmit packet, the application must first write into the endpoint control register, before writing the data into the data FIFO. Typically, the application, must do a read modify write on the OTG_DIEPCTLx register to avoid modifying the contents of the register, except for setting the endpoint enable bit.

The application can write multiple packets for the same endpoint into the transmit FIFO, if space is available. For periodic IN endpoints, the application must write packets only for one microframe. It can write packets for the next periodic transaction only after getting transfer complete for the previous transaction.

- **Setting IN endpoint NAK**

  **Internal data flow:**
  1. When the application sets the IN NAK for a particular endpoint, the core stops transmitting data on the endpoint, irrespective of data availability in the endpoint’s transmit FIFO.
  2. Non-isochronous IN tokens receive a NAK handshake reply
     – Isochronous IN tokens receive a zero-data-length packet reply
  3. The core asserts the INEPNE (IN endpoint NAK effective) interrupt in OTG_DIEPINTx in response to the SNAK bit in OTG_DIEPCTLx.
  4. Once this interrupt is seen by the application, the application can assume that the endpoint is in IN NAK mode. This interrupt can be cleared by the application by setting the CNAK bit in OTG_DIEPCTLx.

  **Application programming sequence:**
  1. To stop transmitting any data on a particular IN endpoint, the application must set the IN NAK bit. To set this bit, the following field must be programmed.
     – SNAK = 1 in OTG_DIEPCTLx
  2. Wait for assertion of the INEPNE interrupt in OTG_DIEPINTx. This interrupt indicates that the core has stopped transmitting data on the endpoint.
  3. The core can transmit valid IN data on the endpoint after the application has set the NAK bit, but before the assertion of the NAK Effective interrupt.
  4. The application can mask this interrupt temporarily by writing to the INEPNEM bit in OTG_DIEPMSK.
     – INEPNEM = 0 in OTG_DIEPMSK
  5. To exit endpoint NAK mode, the application must clear the NAK status bit (NAKSTS) in OTG_DIEPCTLx. This also clears the INEPNE interrupt (in OTG_DIEPINTx).
IN endpoint disable

Use the following sequence to disable a specific IN endpoint that has been previously enabled.

Application programming sequence:
1. The application must stop writing data on the AHB for the IN endpoint to be disabled.
2. The application must set the endpoint in NAK mode.
   - SNAK = 1 in OTG_DIEPCTLx
3. Wait for the INEPNE interrupt in OTG_DIEPINTx.
4. Set the following bits in the OTG_DIEPCTLx register for the endpoint that must be disabled.
   - EPDIS = 1 in OTG_DIEPCTLx
   - SNAK = 1 in OTG_DIEPCTLx
5. Assertion of the EPDISD interrupt in OTG_DIEPINTx indicates that the core has completely disabled the specified endpoint. Along with the assertion of the interrupt, the core also clears the following bits:
   - EPENA = 0 in OTG_DIEPCTLx
   - EPDIS = 0 in OTG_DIEPCTLx
6. The application must read the OTG_DIEPTSIZx register for the periodic IN EP, to calculate how much data on the endpoint were transmitted on the USB.
7. The application must flush the data in the endpoint transmit FIFO, by setting the following fields in the OTG_GRSTCTL register:
   - TXFNUM (in OTG_GRSTCTL) = Endpoint transmit FIFO number
   - TXFFLSH in (OTG_GRSTCTL) = 1

The application must poll the OTG_GRSTCTL register, until the TXFFLSH bit is cleared by the core, which indicates the end of flush operation. To transmit new data on this endpoint, the application can re-enable the endpoint at a later point.

Generic non-periodic IN data transfers

Application requirements:
1. Before setting up an IN transfer, the application must ensure that all data to be transmitted as part of the IN transfer are part of a single buffer.
2. For IN transfers, the transfer size field in the endpoint transfer size register denotes a payload that constitutes multiple maximum-packet-size packets and a single short packet. This short packet is transmitted at the end of the transfer.
   - To transmit a few maximum-packet-size packets and a short packet at the end of the transfer:
     Transfer size[EPNUM] = x × MPSIZ[EPNUM] + sp
     If (sp > 0), then packet count[EPNUM] = x + 1.
     Otherwise, packet count[EPNUM] = x
   - To transmit a single zero-length data packet:
Transfer size[EPNUM] = 0
Packet count[EPNUM] = 1
– To transmit a few maximum-packet-size packets and a zero-length data packet at the end of the transfer, the application must split the transfer into two parts. The first sends maximum-packet-size data packets and the second sends the zero-length data packet alone.
  
First transfer: transfer size[EPNUM] = x × MPSIZ[epnum]; packet count = n;
Second transfer: transfer size[EPNUM] = 0; packet count = 1;

3. Once an endpoint is enabled for data transfers, the core updates the transfer size register. At the end of the IN transfer, the application must read the transfer size register to determine how much data posted in the transmit FIFO have already been sent on the USB.

4. Data fetched into transmit FIFO = Application-programmed initial transfer size – core-updated final transfer size
– Data transmitted on USB = (application-programmed initial packet count – core updated final packet count) × MPSIZ[EPNUM]
– Data yet to be transmitted on USB = (Application-programmed initial transfer size – data transmitted on USB)

Internal data flow:
1. The application must set the transfer size and packet count fields in the endpoint-specific registers and enable the endpoint to transmit the data.
2. The application must also write the required data to the transmit FIFO for the endpoint.
3. Every time a packet is written into the transmit FIFO by the application, the transfer size for that endpoint is decremented by the packet size. The data is fetched from the memory by the application, until the transfer size for the endpoint becomes 0. After writing the data into the FIFO, the “number of packets in FIFO” count is incremented (this is a 3-bit count, internally maintained by the core for each IN endpoint transmit FIFO. The maximum number of packets maintained by the core at any time in an IN endpoint FIFO is eight). For zero-length packets, a separate flag is set for each FIFO, without any data in the FIFO.
4. Once the data are written to the transmit FIFO, the core reads them out upon receiving an IN token. For every non-isochronous IN data packet transmitted with an ACK handshake, the packet count for the endpoint is decremented by one, until the packet count is zero. The packet count is not decremented on a timeout.
5. For zero length packets (indicated by an internal zero length flag), the core sends out a zero-length packet for the IN token and decrements the packet count field.
6. If there are no data in the FIFO for a received IN token and the packet count field for that endpoint is zero, the core generates an “IN token received when Tx FIFO is empty” (ITTXFE) interrupt for the endpoint, provided that the endpoint NAK bit is not set. The core responds with a NAK handshake for non-isochronous endpoints on the USB.
7. The core internally rewinds the FIFO pointers and no timeout interrupt is generated.
8. When the transfer size is 0 and the packet count is 0, the transfer complete (XFRC) interrupt for the endpoint is generated and the endpoint enable is cleared.

Application programming sequence:
1. Program the OTG_DIEPTSiZx register with the transfer size and corresponding packet count.
2. Program the OTG_DIEPCTLx register with the endpoint characteristics and set the CNAK and EPENA (endpoint enable) bits.
3. When transmitting non-zero length data packet, the application must poll the OTG_DTXFSTSx register (where x is the FIFO number associated with that endpoint) to determine whether there is enough space in the data FIFO. The application can optionally use TXFE (in OTG_DIEPINTx) before writing the data.

- **Generic periodic IN data transfers**

This section describes a typical periodic IN data transfer.

**Application requirements:**

1. Application requirements 1, 2, 3, and 4 of *Generic non-periodic IN data transfers on page 2760* also apply to periodic IN data transfers, except for a slight modification of requirement 2.
   - The application can only transmit multiples of maximum-packet-size data packets or multiples of maximum-packet-size packets, plus a short packet at the end. To transmit a few maximum-packet-size packets and a short packet at the end of the transfer, the following conditions must be met:
     
     \[
     \text{transfer size}[\text{EPNUM}] = x \times \text{MPSIZ}[\text{EPNUM}] + \text{sp}
     \]
     
     (where \(x\) is an integer \(\geq 0\), and \(0 \leq \text{sp} < \text{MPSIZ}[\text{EPNUM}]\))
     
     If \(\text{sp} > 0\), \(\text{packet count}[\text{EPNUM}] = x + 1\)
     
     Otherwise, \(\text{packet count}[\text{EPNUM}] = x\);
     
     \(\text{MCNT}[\text{EPNUM}] = \text{packet count}[\text{EPNUM}]\)
   - The application cannot transmit a zero-length data packet at the end of a transfer. It can transmit a single zero-length data packet by itself. To transmit a single zero-length data packet:
     
     \(\text{transfer size}[\text{EPNUM}] = 0\)
     
     \(\text{packet count}[\text{EPNUM}] = 1\)
     
     \(\text{MCNT}[\text{EPNUM}] = \text{packet count}[\text{EPNUM}]\)

2. The application can only schedule data transfers one frame at a time.
   - \(\text{(MCNT} - 1) \times \text{MPSIZ} \leq \text{XFERSIZ} \leq \text{MCNT} \times \text{MPSIZ}\)
   - \(\text{PKTCNT} = \text{MCNT} \) (in OTG_DIEPTSiZx)
   - If XFERSIZ < MCNT × MPSIZ, the last data packet of the transfer is a short packet.
   - Note that: MCNT is in OTG_DIEPTSiZx, MPSIZ is in OTG_DIEPCTLx, PKTCNT is in OTG_DIEPTSiZx and XFERSIZ is in OTG_DIEPTSiZx

3. The complete data to be transmitted in the frame must be written into the transmit FIFO by the application, before the IN token is received. Even when 1 word of the data to be transmitted per frame is missing in the transmit FIFO when the IN token is received, the core behaves as when the FIFO is empty. When the transmit FIFO is empty:
   - A zero data length packet would be transmitted on the USB for isochronous IN endpoints
   - A NAK handshake would be transmitted on the USB for interrupt IN endpoints

**Internal data flow:**
1. The application must set the transfer size and packet count fields in the endpoint-specific registers and enable the endpoint to transmit the data.

2. The application must also write the required data to the associated transmit FIFO for the endpoint.

3. Every time the application writes a packet to the transmit FIFO, the transfer size for that endpoint is decremented by the packet size. The data are fetched from application memory until the transfer size for the endpoint becomes 0.

4. When an IN token is received for a periodic endpoint, the core transmits the data in the FIFO, if available. If the complete data payload (complete packet, in dedicated FIFO mode) for the frame is not present in the FIFO, then the core generates an IN token received when Tx FIFO empty interrupt for the endpoint.
   - A zero-length data packet is transmitted on the USB for isochronous IN endpoints
   - A NAK handshake is transmitted on the USB for interrupt IN endpoints

5. The packet count for the endpoint is decremented by 1 under the following conditions:
   - For isochronous endpoints, when a zero- or non-zero-length data packet is transmitted
   - For interrupt endpoints, when an ACK handshake is transmitted
   - When the transfer size and packet count are both 0, the transfer completed interrupt for the endpoint is generated and the endpoint enable is cleared.

6. At the “Periodic frame Interval” (controlled by PFIVL in OTG_DCFG), when the core finds non-empty any of the isochronous IN endpoint FIFOs scheduled for the current frame non-empty, the core generates an IISOIXFR interrupt in OTG_GINTSTS.

Application programming sequence:
1. Program the OTG_DIEPCTLx register with the endpoint characteristics and set the CNAK and EPENA bits.
2. Write the data to be transmitted in the next frame to the transmit FIFO.
3. Asserting the ITTXFE interrupt (in OTG_DIEPINTx) indicates that the application has not yet written all data to be transmitted to the transmit FIFO.
4. If the interrupt endpoint is already enabled when this interrupt is detected, ignore the interrupt. If it is not enabled, enable the endpoint so that the data can be transmitted on the next IN token attempt.
5. Asserting the XFRC interrupt (in OTG_DIEPINTx) with no ITTXFE interrupt in OTG_DIEPINTx indicates the successful completion of an isochronous IN transfer. A read to the OTG_DIEPTSIZx register must give transfer size = 0 and packet count = 0, indicating all data were transmitted on the USB.
6. Asserting the XFRC interrupt (in OTG_DIEPINTx), with or without the ITTXFE interrupt (in OTG_DIEPINTx), indicates the successful completion of an interrupt IN transfer. A read to the OTG_DIEPTSIZx register must give transfer size = 0 and packet count = 0, indicating all data were transmitted on the USB.
7. Asserting the incomplete isochronous IN transfer (IISOIXFR) interrupt in OTG_GINTSTS with none of the aforementioned interrupts indicates the core did not receive at least 1 periodic IN token in the current frame.

- **Incomplete isochronous IN data transfers**

This section describes what the application must do on an incomplete isochronous IN data transfer.
Internal data flow:

1. An isochronous IN transfer is treated as incomplete in one of the following conditions:
   a) The core receives a corrupted isochronous IN token on at least one isochronous IN endpoint. In this case, the application detects an incomplete isochronous IN transfer interrupt (IISOIXFR in OTG_GINTSTS).
   b) The application is slow to write the complete data payload to the transmit FIFO and an IN token is received before the complete data payload is written to the FIFO. In this case, the application detects an IN token received when Tx FIFO empty interrupt in OTG_DIEPINTx. The application can ignore this interrupt, as it eventually results in an incomplete isochronous IN transfer interrupt (IISOIXFR in OTG_GINTSTS) at the end of periodic frame.

   The core transmits a zero-length data packet on the USB in response to the received IN token.

2. The application must stop writing the data payload to the transmit FIFO as soon as possible.

3. The application must set the NAK bit and the disable bit for the endpoint.

4. The core disables the endpoint, clears the disable bit, and asserts the endpoint disable interrupt for the endpoint.

Application programming sequence:

1. The application can ignore the IN token received when Tx FIFO empty interrupt in OTG_DIEPINTx on any isochronous IN endpoint, as it eventually results in an incomplete isochronous IN transfer interrupt (in OTG_GINTSTS).

2. Assertion of the incomplete isochronous IN transfer interrupt (in OTG_GINTSTS) indicates an incomplete isochronous IN transfer on at least one of the isochronous IN endpoints.

3. The application must read the endpoint control register for all isochronous IN endpoints to detect endpoints with incomplete IN data transfers.

4. The application must stop writing data to the Periodic Transmit FIFOs associated with these endpoints on the AHB.

5. Program the following fields in the OTG_DIEPCTLx register to disable the endpoint:
   - SNAK = 1 in OTG_DIEPCTLx
   - EPDIS = 1 in OTG_DIEPCTLx

6. The assertion of the endpoint disabled interrupt in OTG_DIEPINTx indicates that the core has disabled the endpoint.
   - At this point, the application must flush the data in the associated transmit FIFO or overwrite the existing data in the FIFO by enabling the endpoint for a new transfer in the next microframe. To flush the data, the application must use the OTG_GRSTCTL register.

- Stalling non-isochronous IN endpoints

   This section describes how the application can stall a non-isochronous endpoint.

   Application programming sequence:
1. Disable the IN endpoint to be stalled. Set the STALL bit as well.
2. EPDIS = 1 in OTG_DIEPCTLx, when the endpoint is already enabled
   – STALL = 1 in OTG_DIEPCTLx
   – The STALL bit always takes precedence over the NAK bit
3. Assertion of the endpoint disabled interrupt (in OTG_DIEPINTx) indicates to the
   application that the core has disabled the specified endpoint.
4. The application must flush the non-periodic or periodic transmit FIFO, depending on
   the endpoint type. In case of a non-periodic endpoint, the application must re-enable
   the other non-periodic endpoints that do not need to be stalled, to transmit data.
5. Whenever the application is ready to end the STALL handshake for the endpoint, the
   STALL bit must be cleared in OTG_DIEPCTLx.
6. If the application sets or clears a STALL bit for an endpoint due to a
   SetFeature.Endpoint Halt command or ClearFeature.Endpoint Halt command, the
   STALL bit must be set or cleared before the application sets up the status stage
   transfer on the control endpoint.

**Special case: stalling the control OUT endpoint**

The core must stall IN/OUT tokens if, during the data stage of a control transfer, the host
sends more IN/OUT tokens than are specified in the SETUP packet. In this case, the
application must enable the ITTXFE interrupt in OTG_DIEPINTx and the OTEPDIS interrupt
in OTG_DOEPINTx during the data stage of the control transfer, after the core has
transferred the amount of data specified in the SETUP packet. Then, when the application
receives this interrupt, it must set the STALL bit in the corresponding endpoint control
register, and clear this interrupt.

56.15.7 **Worst case response time**

When the OTG_HS controller acts as a device, there is a worst case response time for any
tokens that follow an isochronous OUT. This worst case response time depends on the AHB
clock frequency.

The core registers are in the AHB domain, and the core does not accept another token
before updating these register values. The worst case is for any token following an
isochronous OUT, because for an isochronous transaction, there is no handshake and the
next token could come sooner. This worst case value is 7 PHY clocks when the AHB clock
is the same as the PHY clock. When the AHB clock is faster, this value is smaller.

If this worst case condition occurs, the core responds to bulk/interrupt tokens with a NAK
and drops isochronous and SETUP tokens. The host interprets this as a timeout condition
for SETUP and retries the SETUP packet. For isochronous transfers, the Incomplete
isochronous IN transfer interrupt (IISOIXFR) and Incomplete isochronous OUT transfer
interrupt (IISOOXFR) inform the application that isochronous IN/OUT packets were
dropped.

**Choosing the value of TRDT in OTG_GUSBCFG**

The value in TRDT (OTG_GUSBCFG) is the time it takes for the MAC, in terms of PHY
clocks after it has received an IN token, to get the FIFO status, and thus the first data from
the PFC block. This time involves the synchronization delay between the PHY and AHB
clocks. The worst case delay for this is when the AHB clock is the same as the PHY clock.
In this case, the delay is 5 clocks.
Once the MAC receives an IN token, this information (token received) is synchronized to the AHB clock by the PFC (the PFC runs on the AHB clock). The PFC then reads the data from the SPRAM and writes them into the dual clock source buffer. The MAC then reads the data out of the source buffer (4 deep).

If the AHB is running at a higher frequency than the PHY, the application can use a smaller value for TRDT (in OTG_GUSBCFG).

*Figure 771* has the following signals:
- tkn_rcvd: Token received information from MAC to PFC
- dynced_tkn_rcvd: Doubled sync tkn_rcvd, from PCLK to HCLK domain
- spr_read: Read to SPRAM
- spr_addr: Address to SPRAM
- spr_rdata: Read data from SPRAM
- srcbuf_push: Push to the source buffer
- srcbuf_rdata: Read data from the source buffer. Data seen by MAC

To calculate the value of TRDT, refer to *Table 503: TRDT values (HS).*

---

![Figure 771. TRDT max timing case](image)
56.15.8 OTG programming model

The OTG_HS controller is an OTG device supporting HNP and SRP. When the core is connected to an “A” plug, it is referred to as an A-device. When the core is connected to a “B” plug it is referred to as a B-device. In host mode, the OTG_HS controller turns off $V_{BUS}$ to conserve power. SRP is a method by which the B-device signals the A-device to turn on $V_{BUS}$ power. A device must perform both data-line pulsing and $V_{BUS}$ pulsing, but a host can detect either data-line pulsing or $V_{BUS}$ pulsing for SRP. HNP is a method by which the B-device negotiates and switches to host role. In Negotiated mode after HNP, the B-device suspends the bus and reverts to the device role.

A-device session request protocol

The application must set the SRP-capable bit in the core USB configuration register. This enables the OTG_HS controller to detect SRP as an A-device.

![Figure 772. A-device SRP](image)

1. DRV_VBUS = $V_{BUS}$ drive signal to the PHY
2. VBUS_VALID = $V_{BUS}$ valid signal from PHY
3. A_VALID = A peripheral $V_{BUS}$ level signal to PHY
4. $D^+$ = Data plus line
5. $D^-$ = Data minus line

The following points refer and describe the signal numeration shown in the Figure 772:

1. To save power, the application suspends and turns off port power when the bus is idle by writing the port suspend and port power bits in the host port control and status register.
2. PHY indicates port power off by deasserting the VBUS_VALID signal.
3. The device must detect SE0 for at least 2 ms to start SRP when $V_{BUS}$ power is off.
4. To initiate SRP, the device turns on its data line pull-up resistor for 5 to 10 ms. The OTG_HS controller detects data-line pulsing.
5. The device drives $V_{BUS}$ above the A-device session valid (2.0 V minimum) for $V_{BUS}$ pulsing.

The OTG_HS controller interrupts the application on detecting SRP. The session
request detected bit is set in Global interrupt status register (SRQINT set in OTG_GINTSTS).

6. The application must service the session request detected interrupt and turn on the port power bit by writing the port power bit in the host port control and status register. The PHY indicates port power-on by asserting the VBUS_VALID signal.

7. When the USB is powered, the device connects, completing the SRP process.

**B-device session request protocol**

The application must set the SRP-capable bit in the core USB configuration register. This enables the OTG_HS controller to initiate SRP as a B-device. SRP is a means by which the OTG_HS controller can request a new session from the host.

**Figure 773. B-device SRP**

1. VBUS_VALID = VBUS valid signal from PHY
   B_VALID = B-peripheral valid session to PHY
   DISCHRG_VBUS = discharge signal to PHY
   SESS_END = session end signal to PHY
   CHRG_VBUS = charge VBUS signal to PHY
   DP = Data plus line
   DM = Data minus line

The following points refer and describe the signal numeration shown in the **Figure 773**:

1. To save power, the host suspends and turns off port power when the bus is idle. The OTG_HS controller sets the early suspend bit in the core interrupt register after 3 ms of bus idleness. Following this, the OTG_HS controller sets the USB suspend bit in the core interrupt register. The OTG_HS controller informs the PHY to discharge VBUS.

2. The PHY indicates the session’s end to the device. This is the initial condition for SRP. The OTG_HS controller requires 2 ms of SE0 before initiating SRP. For a USB 1.1 full-speed serial transceiver, the application must wait until VBUS discharges to 0.2 V after BSVLD (in OTG_GOTGCTL) is deasserted. This discharge
time can be obtained from the transceiver vendor and varies from one transceiver to another.

3. The OTG_HS core informs the PHY to speed up $V_{BUS}$ discharge.

4. The application initiates SRP by writing the session request bit in the OTG control and status register. The OTG_HS controller perform data-line pulsing followed by $V_{BUS}$ pulsing.

5. The host detects SRP from either the data-line or $V_{BUS}$ pulsing, and turns on $V_{BUS}$. The PHY indicates $V_{BUS}$ power-on to the device.

6. The OTG_HS controller performs $V_{BUS}$ pulsing. The host starts a new session by turning on $V_{BUS}$, indicating SRP success. The OTG_HS controller interrupts the application by setting the session request success status change bit in the OTG interrupt status register. The application reads the session request success bit in the OTG control and status register.

7. When the USB is powered, the OTG_HS controller connects, completing the SRP process.

A-device host negotiation protocol

HNP switches the USB host role from the A-device to the B-device. The application must set the HNP-capable bit in the core USB configuration register to enable the OTG_HS controller to perform HNP as an A-device.

Figure 774. A-device HNP

1. DPPULLDOWN = signal from core to PHY to enable/disable the pull-down on the DP line inside the PHY.
2. DMPULLDOWN = signal from core to PHY to enable/disable the pull-down on the DM line inside the PHY.

The following points refer and describe the signal numeration shown in the Figure 774:

1. The OTG_HS controller sends the B-device a SetFeature b_hnp_enable descriptor to enable HNP support. The B-device's ACK response indicates that the B-device supports HNP. The application must set host Set HNP enable bit in the OTG control
and status register to indicate to the OTG_HS controller that the B-device supports HNP.

2. When it has finished using the bus, the application suspends by writing the port suspend bit in the host port control and status register.

3. When the B-device observes a USB suspend, it disconnects, indicating the initial condition for HNP. The B-device initiates HNP only when it must switch to the host role; otherwise, the bus continues to be suspended.
   The OTG_HS controller sets the host negotiation detected interrupt in the OTG interrupt status register, indicating the start of HNP.
   The OTG_HS controller deasserts the DM pull down and DM pull down in the PHY to indicate a device role. The PHY enables the OTG_DP pull-up resistor to indicate a connect for B-device.
   The application must read the current mode bit in the OTG control and status register to determine device mode operation.

4. The B-device detects the connection, issues a USB reset, and enumerates the OTG_HS controller for data traffic.

5. The B-device continues the host role, initiating traffic, and suspends the bus when done.
   The OTG_HS controller sets the early suspend bit in the core interrupt register after 3 ms of bus idleness. Following this, the OTG_HS controller sets the USB suspend bit in the core interrupt register.

6. In Negotiated mode, the OTG_HS controller detects the suspend, disconnects, and switches back to the host role. The OTG_HS controller asserts the DM pull down and DM pull down in the PHY to indicate its assumption of the host role.

7. The OTG_HS controller sets the connector ID status change interrupt in the OTG interrupt status register. The application must read the connector ID status in the OTG control and status register to determine the OTG_HS controller operation as an A-device. This indicates the completion of HNP to the application. The application must read the Current mode bit in the OTG control and status register to determine host mode operation.

8. The B-device connects, completing the HNP process.

**B-device host negotiation protocol**

HNP switches the USB host role from B-device to A-device. The application must set the HNP-capable bit in the core USB configuration register to enable the OTG_HS controller to perform HNP as a B-device.
1. **DPPULLDOWN** = signal from core to PHY to enable/disable the pull-down on the DP line inside the PHY.  
**DMPULLDOWN** = signal from core to PHY to enable/disable the pull-down on the DM line inside the PHY.

The following points refer and describe the signal numeration shown in the Figure 775:

1. The A-device sends the SetFeature b_hnp_enable descriptor to enable HNP support.  
The OTG_HS controller’s ACK response indicates that it supports HNP. The application must set the device HNP enable bit in the OTG control and status register to indicate HNP support.  
The application sets the HNP request bit in the OTG control and status register to indicate to the OTG_HS controller to initiate HNP.

2. When it has finished using the bus, the A-device suspends by writing the port suspend bit in the host port control and status register.  
The OTG_HS controller sets the Early suspend bit in the core interrupt register after 3 ms of bus idleness. Following this, the OTG_HS controller sets the USB suspend bit in the core interrupt register.  
The OTG_HS controller disconnects and the A-device detects SE0 on the bus, indicating HNP. The OTG_HS controller asserts the DP pull down and DM pull down in the PHY to indicate its assumption of the host role.  
The A-device responds by activating its OTG_DP pull-up resistor within 3 ms of detecting SE0. The OTG_HS controller detects this as a connect.  
The OTG_HS controller sets the host negotiation success status change interrupt in the OTG interrupt status register, indicating the HNP status. The application must read the host negotiation success bit in the OTG control and status register to determine
host negotiation success. The application must read the current Mode bit in the core interrupt register (OTG_GINTSTS) to determine host mode operation.

3. The application sets the reset bit (PRST in OTG_HPRT) and the OTG_HS controller issues a USB reset and enumerates the A-device for data traffic.

4. The OTG_HS controller continues the host role of initiating traffic, and when done, suspends the bus by writing the port suspend bit in the host port control and status register.

5. In Negotiated mode, when the A-device detects a suspend, it disconnects and switches back to the host role. The OTG_HS controller deasserts the DP pull down and DM pull down in the PHY to indicate the assumption of the device role.

6. The application must read the current mode bit in the core interrupt (OTG_GINTSTS) register to determine the host mode operation.

7. The OTG_HS controller connects, completing the HNP process.
Ethernet (ETH): media access control (MAC) with DMA controller

57.1 Ethernet introduction

The Ethernet peripheral enables the devices to transmit and receive data over Ethernet in compliance with the IEEE 802.3-2002 standard.

The Ethernet provides a configurable, flexible peripheral to meet the needs of various applications and customers. It supports two industry standard interfaces to the external physical layer (PHY): the default media independent interface (MII) defined in the IEEE 802.3 specifications and the reduced media independent interface (RMII). It can be used in number of applications such as switches and network interface cards.

In addition to the default interfaces defined in the IEEE 802.3 specifications, the Ethernet peripheral supports several industry standard interfaces to the PHY. It is compliant with the following standards:

- IEEE 802.3-2008 for Ethernet MAC, Media Independent Interface (MII)
- IEEE 1588-2008 for precision networked clock synchronization (PTP)
- IEEE 802.3az-2010 for Energy Efficient Ethernet (EEE)
- AMBA 2.0 for AHB master and AHB slave ports
- RMII specification version 1.2 from RMII consortium

57.2 Ethernet main features

Ethernet peripheral embeds a dedicated DMA for direct memory interface, a media access controller (MAC) and a PHY interface block supporting several formats.

57.2.1 MAC core features

Interfaces

- Separate transmission, reception, and control interfaces to the application
- 32-bit data transfer interface on the application side
- 10, 100 Mbps data transfer rates with the following PHY interfaces:
  - IEEE 802.3-compliant MII (default) interface to communicate with an external Fast Ethernet PHY
  - RMII interface to communicate with an external Fast Ethernet PHY
- MDIO (Clause 22 and Clause 45) master interface for PHY device configuration and management
- Supports mandatory network statistics with RMON counters (RFC2819/RFC2665)
Main operations

- Support of both full-duplex and half-duplex operations:
  - CSMA/CD protocol for half-duplex operation
  - IEEE 802.3x flow control for full-duplex operation
  - Optional forwarding of received pause control frames to the user application in full-duplex operation
  - Back-pressure in half-duplex operation
  - Automatic transmission of zero-quanta pause frame on deassertion of flow control input in full-duplex operation
- Full-duplex flow control operations (IEEE 802.3x Pause packets and Priority flow control)
- Preamble and start-of-frame data (SFD) insertion in Transmit mode, and deletion in Receive paths
- Automatic CRC and pad generation controllable on a per-frame basis
- Programmable packet length to support Standard or up to 16 Kbyte Jumbo Ethernet packets
- Programmable Inter Packet Gap
- Layer 3/Layer 4 checksum offload for received packets
- Calculation and insertion of IPv4 header checksum and TCP, UDP, or ICMP checksum in frames transmitted in Store-and-Forward mode
- Two sets of FIFOs: a 2048-byte Transmit FIFO with programmable threshold capability, and a 2048-byte Receive FIFO with a configurable threshold
- Store-and-Forward mechanism or threshold mode (cut-through) for transmission to the MAC
- Programmable Rx queue threshold (or cut-through) mode
- Internal loopback from Tx to Rx on MII for debugging.

VLAN management

- Source Address field insertion or replacement, as well as VLAN insertion, replacement, and deletion in transmitted packets with per-packet or static-global control
- Insertion, replacement or deletion of up to two VLAN tags
- IEEE 802.1Q VLAN tag detection and possibility to delete the VLAN tags in received packets
- Stripping of up to two VLAN tags and providing the tags in the status.
Packet filtering

- Flexible address filtering modes:
  - 3 additional 48-bit perfect destination address (DA) filters with masks for each byte
  - 3 additional 48-bit source address (SA) comparison check with masks for each byte
  - 64 bit Hash filter for multicast and unicast (DA) addresses
  - Option to pass all multicast addressed packets
  - Promiscuous mode to pass all packets without any filtering for network monitoring
  - Pass all incoming packets (as per filter) with a status report

- Additional packet filtering:
  - VLAN tag-based: perfect match and Hash-based filtering with filtering based either on the outer or inner VLAN tag
  - Layer 3 and Layer 4-based: TCP or UDP over IPv4 or IPv6

IEEE 1588-2008/PTPv2

- Ethernet packet time-stamping as described in IEEE 1588-2002 and IEEE 1588-2008 specifications (64-bit timestamps given in the Tx or Rx status of PTP packet). Both one-step and two-step timestamping is supported in Tx direction.
- Flexibility to control the Pulse-Per-Second (PPS) output signal (ptp_pps_o)

Low-power modes

- Standard IEEE 802.3az-2010 for Energy Efficient Ethernet in MII PHYs.
- Module to detect remote wakeup packets and AMD Magic packets
57.2.2  DMA features

The DMA block exchanges data between the peripheral and the system memory. DMA transfers are driven by software descriptors structure. The application can use a set of registers (see Section 57.11.2: Ethernet DMA registers) to control the DMA operations. The DMA block supports the following features:

- 32-bit data transfers
- Separate DMA in Transmit path and receive paths
- Optimization for packet-oriented DMA transfers with packet delimiters
- Byte-aligned addressing for data buffer support
- Dual-buffer (ring) descriptor support
- Descriptor architecture allowing large blocks of data transfer with minimum CPU intervention (each descriptor can transfer up to 32 Kbytes of data)
- Comprehensive status reporting normal operation and transfer errors
- Individual programmable burst length for Tx DMA and Rx DMA engines for optimal host bus utilization
- Programmable interrupt options for different operational conditions
- Per-packet Transmit or Receive Complete Interrupt control
- Round-robin or fixed-priority arbitration between the Receive and Transmit engines
- Start and Stop modes
- Separate ports for host control (AHB) access and host data interface
- Tx DMA channel with TCP Segmentation Offload (TSO) feature enabled

57.2.3  Bus interface features

AHB master interface

The AHB master interface features as the following:

- Interfaces with the application through AHB
- Little-endian mode
- 32-bit data on the AHB master port
- Split, Retry, and Error AHB responses
- AHB 1K boundary burst splitting
- Software-selected type of AHB burst (fixed burst, indefinite burst, or mix of both)

The AHB master interface does not generate the following:

- Wrap burst
- Locked or protected transfers

AHB slave interface

The AHB slave interface supports the following features:

- Interfaces with the application through AHB
- Little-endian mode
- AHB slave interface (32-bit) for CSR access
- All AHB burst types
The AHB slave interface does not generate the following responses:
- Split
- Retry
- Error

57.3 **Ethernet pins and internal signals**

*Table 506* lists the Ethernet inputs and output signals connected to package pins or balls, while *Table 507* shows the internal Ethernet signals.

57.4 Ethernet architecture

The Ethernet peripheral is composed of 4 main functional modules:

- **The control and status register module (CSR)** that controls the registers access through AHB 32-bit slave interface
- The direct memory access interface (DMA)
  This is the logical DMA module with one physical channel for reception and 1 for transmission. It controls the data transfers between MAC and system memory through the AMBA AHB 32-bit master interface.
- **The media access control module (MAC)** in charge of implementing the Ethernet protocol
- **The mac transaction layer (MTL)** in charge of controlling the data flow between application and MAC.

A protocol adaption module is added to support the RMII PHY Media Independent Interfaces.

---

1. For a definition of the internal signals, refer to Table 507.
2. Refer to RCC chapter “Clock distribution for Ethernet” for a detailed description of the Ethernet clock architecture.
57.4.1 DMA controller

The DMA has independent Transmit (Tx) and Receive (Rx) engines. The Tx engine transfers data from the system memory to the MAC Transaction Layer (MTL), whereas the Rx engine transfers data from the device port (PHY) to the system memory.

The controller uses descriptors to efficiently move data from source to destination with minimal application CPU intervention. The DMA is designed for packet-oriented data transfers such as packets in Ethernet. The controller can be programmed to interrupt the application CPU for situations such as Packet Transmit and Receive Transfer completion, and other normal or error conditions.

DMA data structures

The DMA and the application communicate through the following two data structures:

- Control and Status registers (CSR)
- Descriptor lists and data buffers

The DMA transfers the data packets received by the MAC to the Rx buffer in system memory and Tx data packets from the Tx buffer in the system memory. The descriptors that reside in the system memory contain the pointers to these buffers.

The base address of each list is written to the respective Tx and Rx registers: Channel Tx descriptor list address register (ETH_DMACTXDLAR) and Channel Rx descriptor list address register (ETH_DMACRXDLAR).

The descriptor list is forward linked and the next descriptor is always considered at a fixed offset to the current one. The number of descriptors in the list is programmed in the respective Tx/Rx, Channel Tx descriptor ring length register (ETH_DMACTXRLR) and Channel Rx descriptor ring length register (ETH_DMACRXRLR).

Once the DMA processes the last descriptor in the list, it automatically jumps back to the descriptor in the List address register to create a descriptor ring. The descriptor lists reside in the physical memory address space of the application. Each descriptor can point to a maximum of two buffers. This enables two buffers to be used and physically addressed, rather than contiguous buffers in memory.

A data buffer resides in the application physical memory space and consists of an entire packet or part of a packet, but cannot exceed a single packet. Buffers contain only data. The buffer status is saved in the descriptor. Data chaining refers to packets that span multiple data buffers. However, a single descriptor cannot span multiple packets. The DMA skips to the data buffer of next packet when EOP is detected.

Descriptors are specified in Section 57.10: Descriptors.

DMA arbitration

The DMA module incorporates an arbiter that performs the arbitration between the Tx and Rx channels accesses from the AHB master interface. The following two types of arbitrations are supported and can be selected through DMA mode register (ETH_DMAMR):

- Round-robin arbitration: the arbiter allocates the data bus between Rx and Tx in ratio set by Bits [14:12] of ETH_DMAMR.
- Fixed-priority arbitration: by default Rx DMA always gets priority over Tx DMA for data access. Setting bit 11 of ETH_DMAMR register gives priority to the Tx DMA.
DMA transmission in default mode

The Tx DMA engine in default mode proceeds as follows:

1. The application sets up the Transmit descriptor (TDES0–TDES3) and sets the Own bit (TDES0[31]) after setting up the corresponding data buffer(s) with Ethernet Packet data.
2. The application shifts the Descriptor tail pointer offset value of the Transmit channel.
3. The DMA fetches the descriptor from the application memory.
4. If the DMA detects one of the following conditions, the transmission from that channel is suspended, bit 2 and 16 of the corresponding DMA channel Status register are set, and the Tx engine proceeds to step 11:
   - The descriptor is flagged as owned by the application (TDES3[31] = 0).
   - The descriptor tail pointer is equal to the current descriptor pointer in Ring Descriptor list mode.
   - An error condition occurs.
5. If the acquired descriptor is flagged as owned by the DMA (TDES3[31] = 1), the DMA decodes the Transmit Data Buffer address from the acquired descriptor.
6. The DMA fetches the Transmit data from the system memory and transfers the data to the MTL for transmission.
7. If an Ethernet packet is stored over data buffers in multiple descriptors, the DMA closes the intermediate descriptor and fetches the next descriptor. Steps 3 through 7 are repeated until the end-of-Ethernet-packet data is transferred to the MTL.
8. When packet transmission is complete, if IEEE 1588 timestamp feature was enabled for the packet (as indicated in the Tx status), the timestamp value obtained from MTL is written to the Tx descriptor (TDES0 and TDES1) that contains the EOP buffer. The status information is written to this Tx descriptor (TDES3). The application now owns this descriptor because the Own bit is cleared during this step. If the timestamp feature is disabled for this packet, the DMA does not alter TDES0 and TDES1 contents.
9. Bit 0 of Channel status register (ETH_DMACSR) is set after completing transmission of a packet that has Interrupt on Completion (TDES2[31]) set in its Last Descriptor. The DMA engine returns to step 3.
10. In the Suspend state, the DMA tries to acquire the descriptor again (and thereby return to step 3). A poll demand command is triggered by writing any value to the Channel Tx descriptor tail pointer register (ETH_DMACTXDTPR) when it receives a Transmit Poll demand and the Underflow Interrupt Status bit is cleared. If the application stopped the DMA by clearing Bit 0 of Transmit control register of corresponding DMA channel, the DMA enters the Stop state.
DMA transmission in OSP (Operate on Second Packet) mode

In Run state, if bit 4 is set in the Channel transmit control register (ETH_DMACTXCR), the Transmit process can simultaneously acquire two packets without closing the Status descriptor of the first packet. While the Transmit process completes the first packet transfer, it immediately polls the Transmit descriptor list for the second packet. If the second packet is valid, the Transmit process transfers this packet before writing the status information of the first packet.
In OSP mode, DMA transmission in the Run state operates as described in the following sequence:

1. The DMA executes steps 1 to 7 of the DMA transmission sequence in default mode (see Section: DMA transmission in default mode).
2. The DMA fetches the next descriptor without closing previous packet last descriptor.
3. If the DMA owns the acquired descriptor, the DMA decodes the transmit buffer address in this descriptor. If the DMA does not own the descriptor, the DMA goes into Suspend mode and jumps to step 7.
4. The DMA fetches the Transmit packet from the system memory and transfers the packet to the MTL until the EOP data is transferred, closing the intermediate descriptors if this packet is split across multiple descriptors.
5. The DMA waits for the packet transmission status and timestamp of previous packet. When the status is available, the DMA writes the timestamp to TDES0 and TDES1 if such timestamp was captured (as indicated by a status bit). The DMA writes the status, with a cleared Own bit, to the corresponding TDES3, thus closing the descriptor. If Timestamp feature is not enabled for the previous packet, the DMA does not alter the contents of TDES2 and TDES3.
6. The Transmit interrupt is set (if enabled). The DMA fetches the next descriptor and proceeds to step 3 (when Status is normal). If the previous transmission status shows an underflow error, the DMA goes into Suspend mode (step 7).
7. In Suspend mode, if a pending status and timestamp are received from the MTL, the DMA performs the following operations:
   a) The DMA writes the timestamp (if enabled for the current packet) to TDES2 and TDES3.
   a) The DMA writes the status to the corresponding TDES3.
   a) The DMA sets the relevant interrupts and returns to Suspend mode.
   If no status is pending and the application stopped the DMA by clearing bit 0 of Transmit Control Register of corresponding DMA channel, the DMA enters the Stop state.
8. The DMA can exit Suspend mode and enter the Run state (it goes either to step 1 or to step 2 depending on pending status) only after receiving a Transmit Poll demand in Transmit Descriptor Tail Pointer register of corresponding channel.

A description of the basic DMA transmission flow in OSP mode in given in Figure 779: Receive DMA flow.
Figure 778. DMA transmission flow (OSP mode)

1. Start Tx DMA
2. (Re-)fetch next descriptor from Tx Queue
3. Own bit set?
   - Yes: Transfer data from Buffer(s)
   - No: Close intermediate descriptor
4. Packet read completely?
   - Yes: Second packet?
     - Yes: Wait for previous packet status
     - No: Timestamp present?
       - Yes: Write timestamp to TDES0 and TDES1
       - No: Wait status word to TDES3
5. End of descriptor ring?
   - Yes: Tx DMA queue suspended
   - No: Prev. packet status available?
     - Yes: Tx Poll demand?
       - Yes: DMA Tx stopped?
         - Yes: Stop DMA
         - No: No
       - No: <Branch to previous step>
     - No: No
6. No
**DMA reception**

In the Receive path, the DMA reads a packet from the MTL receive queue and writes it to the packet data buffers of the corresponding DMA channel.

The reception sequence for Rx DMA engine is as follows (see also Figure 779: Receive DMA flow):

1. The application sets up the Rx descriptors (RDES0-RDES3) and the Own bit (RDES3[31]). The application must set the correct value in the Receive descriptor tail pointer register of corresponding DMA channel.
2. When bit 0 of Channel receive control register (ETH_DMACRXCR) is set, the DMA enters the Run state. The DMA looks for free descriptors based on the Rx Current Descriptor and Descriptor tail pointer register values. If there are no free descriptors, the DMA channel enters the Suspend state and goes to step 11.
3. The DMA fetches the next available descriptor in the ring and decodes the receive data buffer address from acquired descriptors.
4. If IEEE 1588 timestamping is enabled and the timestamp is available for the previous packet, the DMA writes the timestamp (if available) to the RDES0 and RDES1 of current descriptor and sets the CTXT field (RDES3[30]).
5. The DMA processes the incoming packets and stores them in the data buffers of acquired descriptor.
6. If the current packet transfer is not complete, the DMA closes the current descriptor as intermediate and goes to step 10.
7. The DMA retrieves the status of the Receive frame from the MTL and writes the status word to current descriptor with the Own bit cleared and the Last descriptor bit set.
8. The DMA writes the Frame Length to RDES3 and the VLAN tag to RDES0. The DMA also writes the MAC control frame opcode, OAM control frame code, and extended status information (if available) to RDES1 of the last descriptor.
9. If IEEE 1588 timestamp feature is enabled, the DMA stores the timestamp (if available). The DMA writes the context descriptor after the last descriptor for the current packet (in the next available descriptor).
10. If more descriptors are available in the Rx DMA descriptor ring, go to step 3, otherwise go to the Suspend state (step 11).
11. The Receive DMA exits the Suspend state when a Receive Poll demand is given and the application increments the channel Receive tail pointer register. The engine proceeds to step 2 and fetches again the next descriptor.
57.4.2 MTL

The MAC Transaction Layer (MTL) provides the FIFO memory interface to buffer and regulate the packets between the application system memory and the MAC. It also enables the data to be transferred between the application clock and MAC clock domains. The MTL layer features two 32-bit wide data paths: the Transmit path and the Receive Path.

- Transmit path
The application or internal DMA pushes the Ethernet packets read from the application or system memory into the Tx FIFO. The packet is then popped out and transferred to the MAC when the queue threshold is reached (threshold mode) or complete packet is in the queue (store-and-forward mode). When EOP is transferred, the status of the transmission is taken from the MAC and transferred back to the application or internal DMA. The Tx queue size is 2048 bytes.

- **Receive path**
  The MTL Rx module receives the packets from the MAC and pushes them into the Rx queue. The status (fill level) of the queue is indicated to the application or to DMA when it crosses the configured Receive threshold (RTC bits[1:0] defined in Rx queue operating mode register (ETH_MTLRXQOMR)), or when the complete packet was received. The MTL also indicates the queue fill level so that the DMA can initiate preconfigured burst transfers towards the master interface. The Rx queue size is 2048 bytes.

### 57.4.3 MAC

The MAC is responsible of the Ethernet protocol processing. In Transmission mode, it receives data from MTL before transferring it to the PHY interface. In Reception mode, the MAC receives data from the PHY interface before transferring them to the Rx FIFO of the MTL module.

This section briefly describes transmission and reception sequences.

#### MAC transmission

The transmission sequence is as follows:

1. Transmission is initiated when the MTL application pushes in data with the SOP (Start of packet) signal asserted.
2. When the SOP signal is detected, the MAC accepts the data and begins the transmission to the MII.
3. When the EOP (End of packet) is transferred to the MAC, the MAC does one of the following:
   - The MAC completes the normal transmission and provides the transmission status to the MTL.
   - If a normal collision (in half-duplex mode) occurs during transmission, the MAC provides the Transmit status to the MTL, with the Retry bit set. The MAC provides the Retry request till one of the following is true:
     The packet was successfully transmitted
     The maximum number of Retry requests expires. In this case, the MAC aborts the packet transmission with Excessive Collision Transmit status. The MAC accepts and drops all further data until the next SOP is received. The MTL block should retransmit the same packet from SOP when a Retry request (in the Status) is observed from the MAC.
   - If any one of the following happens, the MAC aborts the packet transmission:
     - No carrier (half-duplex mode)
     - Loss of carrier (half-duplex mode)
     - Excessive deferral (half-duplex mode)
     - Late collisions (half-duplex mode)
     - Jabber
The MAC accepts and drops all further data until the next SOP is received.

4. The MAC issues an underflow status if the MTL is not able to provide the data continuously during the transmission. The MAC accepts and drops all further data until the next SOP is received.

5. During the normal transfer of a packet from MTL, if the MAC receives a SOP without getting an EOP for the previous packet, it ignores the SOP and considers the new packet as continuation of the previous packet.

*Figure 780: Overview of MAC transmission flow* illustrates the MAC transmission process flow.
Figure 780. Overview of MAC transmission flow

1. **Start**

2. **Wait for data & SOP From MTL**

3. **SOP asserted by MTL?**
   - **YES**
     - Wait for IPG/any back-off delay (half-duplex)
   - **NO**
     - **Collision**
       - **YES**
         - **Condition B**
           - A. EOP asserted by MTL?
             - B. Underflow asserted by MAC?
               - **YES**
                 - Normal transmission completed and Transmission status conveyed to MTL
               - **NO**
                 - Drop all the data received from MTL and abort transmission
       - **NO**
         - Drop all the data received from MTL and abort transmission

4. **Transmit preamble+SFD+Data received from the MTL to the PHY**

5. **No carrier/Carrier loss/Excessive deferral/Late collisions/Jabber?**
   - **YES**
     - Drop all the data received from MTL and abort transmission
   - **NO**
     - **Condition A**
       - **Condition D:** Retry_count ≤ retry_limit
         - **YES**
           - Send status to MTL with Retry bit set
         - **NO**
           - Drop all the data received from MTL and abort transmission

6. **Send status to MTL with Retry bit set**
MAC reception

A receive operation is initiated when the MAC detects an SFD on MII. The MAC strips the preamble and SFD before proceeding to process the packet. The header fields are checked for filtering and the FCS field used to verify the CRC for the packet. The received packet is stored in a shallow buffer until the address filtering is performed. The packet is dropped in the MAC if it fails the address filter.

The reception sequence is as follows:

1. When the receive data valid signal (RxDV) of MII becomes active, the Receive State Machine (RSM) starts looking for the SFD field (0xD nibble in MII mode). The state machine drops received packets until it detects SFD.

2. When SFD is detected, the state machine starts sending the data of Ethernet packet to the RPC module, beginning with the first byte following the SFD (destination address).

3. If IEEE 1588 timestamp feature is enabled, the MAC takes a snapshot of the system time at which SFD of any packet is detected on MII. If this packet is not dropped during MAC filtering, the timestamp is passed to the application. The MAC converts the received nibble data into bytes and forwards the valid packet data to the RFC module.

4. The Receive State Machine decodes the Length/Type field of the Ethernet packet being received.

   If the Length/Type field is less than 1,536 and if the MAC is programmed for the Auto CRC/Pad Stripping (bit 20 of the `Operating mode configuration register (ETH_MACCR)`), the state machine sends the packet data up to the count specified in the Length/Type field and starts dropping bytes (including the FCS field). The state machine decodes the Length/Type field and checks for the Length interpretation.

5. If the Length/Type field is greater than or equal to 1,536, the RPE module sends all received Ethernet packet data to the RFC module if you have not enabled the CRC stripping for Type packets in Bit 21 of the `Operating mode configuration register (ETH_MACCR)`. However, if the CRC stripping has been enabled for Type packets and not enabled the Receive Checksum Offload Engine, the MAC strips and drops the last 4 bytes of all packets of ether type before forwarding the packets to the application.

6. By default, the MAC is programmed for watchdog timer to be enabled, that is, packets above 2,048 (10,240 if Jumbo Packet is enabled) bytes (DA + SA + LT + DATA + PAD + FCS) are cut off at the RPE module. In addition, you can use a programmable watchdog timer (bit 16 of `Watchdog timeout register (ETH_MACWTR)`) to override the fixed timeout of 2,048 or 10,240 bytes. You can disable the watchdog timer by programming bit 19 of `Operating mode configuration register (ETH_MACCR)`. However, even if the watchdog timer is disabled, a packet greater than 32 Kbytes is cut off and a watchdog timeout status is given.
Figure 781. MAC reception flow

1. **Start**
2. Wait for phy_rxdv_i from GMII/MII
3. Wait until SFD is detected
4. Start sending the received Ethernet packet to the application layer, starting from DA field
5. **IEEE 1588 timestamp feature enabled?**
   - YES: Store the snapshot of the system time when SFD detected
   - NO: Length/Type field ≤1536 & Auto CRC/Pad stripping enabled?
     - YES: Send only the number of bytes (specified in the Length field) of the received Ethernet packet to RFC. Drop extra padding and FCS field
     - NO: Length/Type field ≥1536
       - CRC stripping for Type packets enabled?
         - YES: Receive checksum Offload engine enabled?
           - YES: Send all received Ethernet packet data to RFC
           - NO: Drop the last 4 bytes of all Ether type packets and send the remaining bytes to RFC
         - NO: CRC error? OR Packet to be filtered?
           - NO: Send the packet, timestamp and Status to the Application layer
           - YES: Drop the packet and send the Status to the Application layer

MSv40391V1
57.5 Ethernet functional description: MAC

57.5.1 Double VLAN processing

The Ethernet peripheral supports the double VLAN (Virtual LAN) tagging feature in which the MAC can process up to two VLAN tags (inner and outer).

The MAC supports the following:

- Insertion, replacement, or deletion of up to two VLAN tags in the Transmit path
- Packet filtering and stripping based on any one of the two VLAN Tags in the Receive path. Stripping and providing up to two VLAN Tags in the Receive path as a part of the Receive status

**Transmit path**

*Table 508: Double VLAN processing features in Tx path* describes the features supported by the MAC on the Transmit side.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
</table>
| Support for C-VLAN and S-VLAN Tag types      | The inner or outer VLAN tag can be of C-VLAN and S-VLAN type. The VLAN type is specified through the CSVL bit of *VLAN inclusion register (ETH_MACVIR)* and *Inner VLAN inclusion register (ETH_MACIVIR)*, respectively. The Ethernet peripheral supports processing of any sequence of outer and inner VLAN tags. However, it does not support the C-VLAN S-VLAN sequence. The MAC does not check whether the packet provided by the application has a valid sequence of the VLAN Tag types or the insertion or replacement operation results in invalid sequence of VLAN Tag type. Therefore, the application must provide correct sequence of VLAN Tag types and program the MAC in such a way that it results in correct sequence of VLAN Tag types in the transmitted packet. The application must ensure the following:  
  - The inner tag should not be S-VLAN when outer C-VLAN Tag insertion is enabled.
  - The outer tag should not be C-VLAN when inner S-VLAN Tag insertion is enabled.
  - The inner tag should not be S-VLAN when outer tag should be replaced with C-VLAN.
  - The outer tag should not be C-VLAN when inner tag should be replaced with S-VLAN. |
Table 509. Double VLAN processing in Rx path describes the features supported by the MAC on the Receive side and the corresponding bits in the VLAN tag register (ETH_MACVTR).

57.5.2 Source Address and VLAN insertion, replacement, or deletion

Source address insertion or replacement

The software can use the SA (source address) insertion or replacement feature to instruct the MAC to do the following for Tx packets:
- Insert the content of the MAC Address registers in the SA field
- Replace the content of the SA field with the content of the MAC Address registers

When SA insertion is enabled, the application must ensure that the packets sent to the MAC do not have the SA field. The MAC does not check whether the SA field is present in the Transmit packet and it inserts the content of MAC Address Registers in the SA field.
Similarly, when SA replacement is enabled, the application must ensure that the SA field is present in the packets sent to the MAC. The MAC replaces the six bytes following the Destination Address field in the Transmit packet with the content of the MAC Address Registers.

SA insert or replacement feature can be enabled for all Transmit packets or selective packets:

- **Enabling SA insertion or replacement for all packets**
  
  To enable this feature for all packets, program the SARC field of the Operating mode configuration register (ETH_MACCR).

- **Enabling SA insertion or replacement for selective packets**
  
  To enable this feature for selective packets, use the following program the SA Insertion Control field (bits[25:23] of Transmit Descriptor Word 3/TDES3, refer to Section 57.10.3: Transmit descriptor) in the first Transmit descriptor of the packet. When Bit 25 of TDES3 is set, the SA Insertion Control field indicates insertion or replacement by MAC Address1 registers. When bit 25 of TDES3 is reset, it indicates insertion or replacement by MAC Address 0 registers.

If MAC Address1 registers are not enabled, the MAC Address0 registers are used for insertion or replacement whatever of the value of the most-significant bit of the SA Insertion Control field.

**VLAN insertion, replacement, or deletion**

The software can use the VLAN insertion, replacement, or deletion feature to instruct the MAC to do the following for Tx packets:

- Delete the VLAN Type and VLAN Tag fields
- Insert or replace the VLAN Type and VLAN Tag fields

Insertion or replacement is performed based on the setting of VLTI bit in the VLAN inclusion register (ETH_MACVIR) as described in Table 510: VLAN insertion or replacement based on VLTI bit.

<table>
<thead>
<tr>
<th>Condition</th>
<th>Description</th>
</tr>
</thead>
</table>
| VLTI bit is set | The MAC inserts or replaces the following:  
VLAN Type field (C-VLAN or S-VLAN as indicated by the CSVL bit of VLAN inclusion register (ETH_MACVIR))  
VLAN Tag field with VT field of Transmit context descriptor of the packet |
| VLTI bit is reset | The MAC inserts or replaces the following:  
VLAN Type field (C-VLAN or S-VLAN as indicated by the CSVL bit of VLAN inclusion register (ETH_MACVIR))  
VLAN Tag field with the VLT field of VLAN inclusion register (ETH_MACVIR) |

When VLAN replacement or deletion is enabled, the MAC checks if the VLAN Type field (0x8100 or 0x88A8) is present after the DA and SA fields in the Transmit packet. The replace or delete operation does not occur if the VLAN Type field is not detected in two bytes following the DA and SA fields. However, when VLAN insertion is enabled, the MAC does not check the presence of VLAN Type field in the Transmit packet and just inserts the VLAN Type and VLAN Tag fields.
You can enable the VLAN insertion, replacement, or deletion feature for all Tx packets or selective packets:

- To enable this feature for all packets, program the VLC and VLP fields of *VLAN inclusion register (ETH_MACVIR)*.
- To enable this feature for selective packets, program the VTIR field of TDES2 Normal Descriptor (see *Table 530: TDES2 normal descriptor (read format)*).

In addition, the VLP (VLAN Priority control) bit must be reset in *VLAN inclusion register (ETH_MACVIR)* (for outer VLAN) and *Inner VLAN inclusion register (ETH_MACIVIR)* (in inner VLAN) for the MAC to take the control inputs from the host, depending on the configuration.

### 57.5.3 Packet filtering

The MAC supports the following types of filtering for Rx packets:

- **MAC source or destination address filtering**: the Address Filtering Module (AFM) checks the source address and destination address fields of each incoming packet.
- **VLAN filtering**: the MAC supports the VLAN tag-based and VLAN Hash filtering.
- **Layer 3 and Layer 4 filtering**: Layer 3 filtering refers to IP source address and destination address filtering. Layer 4 filtering refers to source port and destination port filtering.

The three filter types can be cascaded. *Figure 782* shows the filtering sequence for Rx packets.
MAC source or destination address filtering

The MAC address filtering module checks the source address (SA) and destination address (DA) fields of each incoming packet.

Unicast destination address filtering

The MAC supports 4 MAC addresses for unicast perfect filtering. If perfect filtering is selected (HUC bit of Packet filtering control register (ETH_MACPFR) is reset), the MAC compares all 48 bits of received unicast address with the programmed MAC address for any match. The default MacAddr0 is always enabled.

The MacAddr1 to MacAddr3 addresses are selected with an individual enable bit. You can mask each byte during comparison with corresponding received DA byte by setting the corresponding Mask Byte Control bit in the register. This enables group address filtering for the DA.

In Hash filtering mode (when HUC bit is set), the MAC performs imperfect filtering for unicast addresses using a 64-bit Hash table. For Hash filtering, the MAC uses the upper 6 bits CRC of the received destination address to index the content of the Hash table. A value of 00000 selects bit 0 of selected register, and a value of 11111 selects bit 63 of Hash Table register. If the corresponding bit (indicated by the 6-bit CRC) is set to 1, the unicast packet is considered to have passed the Hash filter; otherwise, the packet is considered to have failed the Hash filter.
Multicast destination address filtering

To program the MAC to pass all multicast packets, set the PM bit in Packet filtering control register (ETH_MACPFR). If the PM bit is reset, the MAC performs the filtering for multicast addresses based on the HMC bit of the Packet filtering control register (ETH_MACPFR).

In Perfect filtering mode, the multicast address is compared with the programmed MAC Destination Address registers (1–31). Group address filtering is also supported.

In Hash filtering mode, the MAC performs imperfect filtering using a 64-bit Hash table. The MAC uses the upper 6-bits CRC of received multicast address to index the content of the Hash table. A value of 000000 selects bit 0 of selected register and a value of 111111 selects bit 63 of the Hash Table register. If the corresponding bit is set to 1, the multicast packet is considered to have passed the Hash filter. Otherwise, the packet is considered to have failed the Hash filter.

Hash or Perfect address filtering

To configure the DA filter to pass a packet when its DA matches either the Hash filter or the Perfect filter, set the HPF bit and the corresponding HUC or HMC bits in Packet filtering control register (ETH_MACPFR). This is applicable to both unicast and multicast packets. If the HPF bit is reset, only one of the filters (Hash or Perfect) is applied to receive packet.

Broadcast address filtering

The MAC does not filter any broadcast packets by default. To program the MAC to reject all broadcast packets, set the DBF bit in Packet filtering control register (ETH_MACPFR).

Unicast source address filtering

The MAC can perform perfect filtering based on the source address field of received packets. By default, the MAC compares the SA field with the values programmed in the SA registers. You can configure the MAC Address registers to use SA instead of DA for comparison by setting bit 30 of corresponding register.

The MAC also supports group filtering with SA. You can filter a group of addresses by masking one or more bytes of the address. The MAC drops the packets that fail the SA filter if the SAF bit is set in Packet filtering control register (ETH_MACPFR). Otherwise, the result of the SA filter is given as a status bit in the Receive Status word (see Table 512). When the SAF bit is set, the SA filter and DA filter result is ANDed to decide whether the packet needs to be forwarded. This means that the packet is dropped if either filter fails. The packet is forwarded to the application only if the packet passes both filters in-order.

Inverse filtering

For DA and SA filtering, you can invert the filter-match result at the final output by setting the DAIF and SAIF bits of Packet filtering control register (ETH_MACPFR). The DAIF bit is applicable for both Unicast and Multicast DA packets. The result of the unicast or multicast destination address filter is inverted in this mode. Similarly, when the SAIF bit is set, the result of unicast SA filter is reversed.

Table 511 and Table 512 summarize the DA and SA filtering based on the type of packets received.

</tbody>
</table>
The MAC supports Perfect and Hash VLAN filtering. Refer to Section 57.9.11: Programming guidelines to perform VLAN filtering on the receive for detailed programming steps.

**VLAN tag Perfect filtering**

In VLAN tag Perfect filtering, the MAC compares the VLAN tag of received packet and provides the VLAN packet status to the application. Based on the programmed mode, the MAC compares the lower 12 bits or all 16 bits of received VLAN tag to determine the perfect match.

If VLAN tag Perfect filtering is enabled, the MAC forwards the VLAN-tagged packets along with VLAN tag match status and drops the VLAN packets that do not match. You can also enable the inverse matching for VLAN packets by setting the VTIM bit of VLAN tag register (ETH_MACVTR). In addition, you can enable matching of S-VLAN tagged packets along with the default C-VLAN tagged packets by setting the ESVL bit of ETH_MACVTR register. The VLAN packet status bit (bit 10 of RDES0) indicates the VLAN tag match status for the matched packets.

*Note:* The source or destination address (if enabled) has precedence over the VLAN tag filters. This means that a packet that fails the source or destination address filter is dropped irrespective of the VLAN tag filter results. By default, the VLAN tag-based Perfect filter is available in all configurations.

**VLAN tag Hash filtering**

The MAC provides VLAN tag Hash filtering with a 16-bit Hash table. The MAC performs the VLAN Hash matching based on the VTHM of the VLAN tag register (ETH_MACVTR). If the VTHM bit is set, the most significant four bits of CRC-32 of VLAN tag are used to index the content of the VLAN Hash Table register. A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the VLAN tag of the packet matched and the packet should be forwarded. A value of 0 indicates that VLAN-tagged packet should be dropped.

*Note:* The 16 or 12 bits of VLAN Tag are considered for CRC-32 computation based on ETV bit in ETH_MACVTR register.

*When ETV bit is reset, most significant four bits of CRC-32 of VLAN Tag are inverted and used to index the content of VLAN Hash table register (ETH_MACVHTR).*

*When ETV bit is set, most significant four bits of CRC-32 of VLAN Tag are directly used to index the content of VLAN tag register (ETH_MACVTR).*

Table 512. Source address filtering

---

VLAN filtering

The MAC supports Perfect and Hash VLAN filtering. Refer to Section 57.9.11: Programming guidelines to perform VLAN filtering on the receive for detailed programming steps.

**VLAN tag Perfect filtering**

In VLAN tag Perfect filtering, the MAC compares the VLAN tag of received packet and provides the VLAN packet status to the application. Based on the programmed mode, the MAC compares the lower 12 bits or all 16 bits of received VLAN tag to determine the perfect match.

If VLAN tag Perfect filtering is enabled, the MAC forwards the VLAN-tagged packets along with VLAN tag match status and drops the VLAN packets that do not match. You can also enable the inverse matching for VLAN packets by setting the VTIM bit of VLAN tag register (ETH_MACVTR). In addition, you can enable matching of S-VLAN tagged packets along with the default C-VLAN tagged packets by setting the ESVL bit of ETH_MACVTR register. The VLAN packet status bit (bit 10 of RDES0) indicates the VLAN tag match status for the matched packets.

*Note:* The source or destination address (if enabled) has precedence over the VLAN tag filters. This means that a packet that fails the source or destination address filter is dropped irrespective of the VLAN tag filter results. By default, the VLAN tag-based Perfect filter is available in all configurations.

**VLAN tag Hash filtering**

The MAC provides VLAN tag Hash filtering with a 16-bit Hash table. The MAC performs the VLAN Hash matching based on the VTHM of the VLAN tag register (ETH_MACVTR). If the VTHM bit is set, the most significant four bits of CRC-32 of VLAN tag are used to index the content of the VLAN Hash Table register. A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the VLAN tag of the packet matched and the packet should be forwarded. A value of 0 indicates that VLAN-tagged packet should be dropped.

*Note:* The 16 or 12 bits of VLAN Tag are considered for CRC-32 computation based on ETV bit in ETH_MACVTR register.

*When ETV bit is reset, most significant four bits of CRC-32 of VLAN Tag are inverted and used to index the content of VLAN Hash table register (ETH_MACVHTR).*

*When ETV bit is set, most significant four bits of CRC-32 of VLAN Tag are directly used to index the content of VLAN tag register (ETH_MACVTR).*
The MAC also supports the inverse matching for VLAN packets. In the inverse matching mode, when the VLAN tag of a packet matches the Perfect or Hash filter, the packet should be dropped. If the VLAN perfect and VLAN Hash match are enabled, a packet is considered as matched if either the VLAN Hash or the VLAN perfect filter matches. When inverse match is set, a packet is forwarded only when both perfect and Hash filters indicate mismatch.

*Table 513* shows the different possibilities for VLAN matching and the final VLAN match status. When the RA bit of *Packet filtering control register (ETH_MACPFR)* is set, all packets are received and the VLAN match status is indicated in the VF bit of *RDES2 normal descriptor (write-back format)*. When the RA bit is not set and the VTFE bit is set in *Packet filtering control register (ETH_MACPFR)*, the packet is dropped if the final VLAN match status is Fail. In *Table 513*, value X means that this column can have any value.

When VLAN VID is programmed to 0 in the VL field of *VLAN tag register (ETH_MACVTR)*, all VLAN-tagged packets are considered as perfect matched but the status of the VLAN Hash match depends on the VTHM and VTIM bits in ETH_MACVTR register.

</table>

1. In this table, X represents any value.
Layer 3 and Layer 4 filtering

The MAC supports Layer 3 and Layer 4 based packet filtering. The Layer 3 filtering refers to the IP Source or Destination Address filtering in the IPv4 or IPv6 packets whereas Layer 4 filtering refers to the Source or Destination Port number filtering in TCP or UDP.

The Layer 3 and Layer 4 packet filtering feature automatically enables the IPC Full Checksum Offload Engine on the Receive side. For Layer 3 or Layer 4 filtering operation, you must set the IPC bit of the Operating mode configuration register (ETH_MACCR) to enable the Rx Checksum Offload engine.

When Layer 3 and Layer 4 filtering is enabled, the packets are filtered in the following way:

- Matched packets
  The MAC forwards the packets that match all enabled fields to the application along with the status. The MAC gives the matched field status only if the IPC bit of Operating mode configuration register (ETH_MACCR) is set and one of the following conditions is true:
    - All enabled Layer 3 and Layer 4 fields match.
    - At least one of the enabled field matches and other fields are bypassed or disabled
  When multiple Layer 3 and Layer 4 filters are enabled, any filter match is considered as a match. If more than one filter matches, the MAC provides the status of the lowest filter where Filter 0 is the lowest filter and Filter 3 is the highest filter. For example, if Filter 0 and Filter 1 match, the MAC gives the status corresponding to filter 0.
  The source or destination address and VLAN tag filters (if enabled) have precedence over Layer 3 and Layer 4 filter. This means that a packet which fails the source or destination address or VLAN tag filter is dropped irrespective of the Layer 3 and Layer 4 filter results.

- Unmatched packets
  The MAC drops the packets that do not match any of the enabled fields. You can use the inverse match feature to block or drop a packet with specific TCP or UDP over IP fields and forward all other packets.

- Non-TCP or UDP IP Packets
  By default, all non-TCP or UDP IP packets are bypassed from the Layer 3 and Layer 4 filters. You can optionally program the MAC to drop all non-TCP or UDP over IP packets.

Layer 3 and Layer 4 filters register set

The MAC implements two sets of registers for Layer 3 and Layer 4 based packet filtering. In a register set, there is a control register, such as ETH_MACL3L4C0R, to control the packet filtering. In addition, there are five address registers to program the Layer 3 and Layer 4 fields to be matched, such as:

- Layer 4 address filter 0 register (ETH_MACL4A0R)
- Layer 3 Address 0 filter 0 register (ETH_MACL3A00R)
- Layer 3 address 1 filter 0 register (ETH_MACL3A10R)
- Layer 3 Address 2 filter 0 register (ETH_MACL3A20)
- Layer 3 Address 3 filter 0 register (ETH_MACL3A30)
The second, and independent set of registers are: ETH_MACL3L4C1R, ETH_MACL4A01R, ETH_MACL4A11R, ETH_MACL4A21R and ETH_MACL4A31R

Layer 3 filtering
The MAC supports perfect matching or inverse matching for IP Source Address and Destination Address. In addition, you can match the complete IP address or mask the lower bits matching, that is, compare all bits of the address except the specified lower mask bits.

For IPv6 packets filtering, you can enable the last four data registers of a register set to contain the 128-bit IP Source Address or IP Destination Address. The IP Source Address or Destination Address should be programmed in the order defined in the IPv6 specification, that is, the first byte of the IP Source Address or Destination Address in the received packet is in the higher byte of the register and the subsequent registers follow the same order.

For IPv4 packet filtering, you can enable the second and third data registers of a register set to contain the 32-bit IP Source Address and IP Destination Address. The remaining two data registers are reserved. The IP Source Address or Destination Address should be programmed in the order defined in the IPv4 specification, that is, the first byte of IP Source Address and Destination Address in the received packet in the higher byte of the respective register.

Layer 4 filtering
The MAC supports perfect matching or inverse matching for TCP or UDP Source and Destination Port numbers. However, you can program only one type (TCP or UDP) at a time. The first data register contains the 16-bit Source and Destination Port numbers of TCP or UDP, that is, the lower 16 bits for Source Port number and higher 16 bits for Destination Port number.

The TCP or UDP Source and Destination Port numbers should be programmed in the order defined in the TCP or UDP specification, that is, the first byte of TCP or UDP Source and Destination Port number in the received packet is in the higher byte of the register.

57.5.4 IEEE 1588 timestamps
The IEEE 1588 standard defines a Precision Time Protocol (PTP) which allows precise synchronization of clocks in measurement and control systems implemented with technologies such as network communication, local computing, and distributed objects. The PTP applies to systems communicating by local area networks supporting multicast messaging, including (but not limited to) Ethernet. This protocol enables heterogeneous systems that include clocks of varying inherent precision, resolution, and stability to synchronize. The protocol supports system-wide synchronization accuracy in the sub-microsecond range with minimal network and local clock computing resources.

The Ethernet peripheral supports the IEEE 1588-2002 (version 1) and IEEE 1588-2008 (version 2). The IEEE 1588-2002 supports PTP transported over UDP/IP. The IEEE 1588
2008 supports PTP transported over Ethernet. The peripheral provides programmable support for both standards. It supports the following features:

- Support of both timestamp formats
- Optional snapshot of all packets or only PTP type packets
- Optional snapshot of only event messages
- Optional snapshot based on the clock type: ordinary, boundary, end-to-end transparent, and peer-to-peer transparent
- Optional selection of the node to act as master or slave for ordinary and boundary clock
- Identification of the PTP message type, version, and PTP payload in packets sent directly over Ethernet and sends the status
- Optional measurement sub-second time in digital or binary format

**Delay request-response mechanism**

The system or network is classified into the master and slave nodes for distributing the timing and clock information. *Figure 783* shows the process that PTP uses for synchronizing a slave node to a master node by exchanging PTP messages.

*Figure 783. Networked time synchronization*
As shown in Figure 783, the PTP uses the following process:

1. The master broadcasts the PTP Sync messages to all its nodes. The Sync message contains the reference time information of the master. This message leaves the system of the master at t1. This time must be captured for Ethernet ports at MII.
2. The slave receives the Sync message and also captures the exact time, t2, using its timing reference.
3. The master sends a Follow_up message to the slave, which contains t1 information for later use.
4. The slave sends a Delay_Req message to the master and notes the exact time, t3, at which this packet leaves the MII interface.
5. The master receives the message, capturing the exact time t4, at which the message enters its system.
6. The master sends the t4 information to the slave in the Delay_Resp message.
7. The slave uses the four values of t1, t2, t3, and t4 to synchronize its local timing reference to the timing reference of the master.

Most of the PTP implementation is done in the software above the UDP layer. However, the hardware support is required to capture the exact time when specific PTP packets enter or leave the Ethernet port at the MII interface. This timing information must be captured and returned to the software for proper implementation of PTP with high accuracy.

**Peer-to-peer PTP transparent clock (P2P TC) message support**

The IEEE 1588-2008 standard supports peer-to-peer PTP (Pdelay) message in addition to the Sync, Delay Request, Follow-up, and Delay Response messages. Figure 784 shows the method to calculate the propagation delay in clocks supporting peer-to-peer path correction.

**Figure 784. Propagation delay calculation in clocks supporting peer-to-peer path correction**
As shown in Figure 784, the propagation delay is calculated as follows:

1. Port 1 issues a Pdelay_Req message and generates a timestamp (t1) for the Pdelay_Req message.
2. Port 2 receives the Pdelay_Req message and generates a timestamp (t2) for this message.
3. Port 2 returns a Pdelay_Resp message and generates a timestamp (t3) for this message.

To minimize errors caused by frequency offset between the two ports, Port 2 returns the Pdelay_Resp message as quickly as possible after the receipt of the Pdelay_Req message. Port 2 returns any one of the following:

- Difference between the timestamps t2 and t3 in the Pdelay_Resp message
- Difference between the timestamps t2 and t3 in the Pdelay_Resp_Follow_Up message
- Timestamps t2 and t3 in the Pdelay_Resp and Pdelay_Resp_Follow_Up messages, respectively

Port 1 generates a timestamp (t4) on receiving the Pdelay_Resp message.
Port 1 uses all four timestamps to compute the mean link delay.

**Clock types**

The MAC supports the following clock types defined in the IEEE 1588-2008 specifications:

- **Ordinary clock**

  The ordinary clock of a domain supports a single copy of the protocol. It has a single PTP state and a single physical port. In typical industrial automation applications, an ordinary clock is associated with an application device such as a sensor or an actuator. In telecom applications, the ordinary clock can be associated with a timing demarcation device.

  The ordinary clock can be a grandmaster or a slave clock. It supports the following features:
  
  - Transmission and reception of PTP messages. The timestamp snapshot can be controlled as described in Timestamp control Register (ETH_MACTSCR).
  - Maintenance of the data sets such as timestamp values.

  The table below shows the messages for which you can take the timestamp snapshot on the receive side for master and slave nodes.

  **Table 514. Ordinary clock: PTP messages for snapshot**

<table>
<thead>
<tr>
<th></th>
<th>Master</th>
<th>Slave</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delay_Req</td>
<td></td>
<td>SYNC</td>
</tr>
</tbody>
</table>

For an ordinary clock, you can take the snapshot of either of the following PTP message types: version 1 or version 2. You cannot take the snapshots for both PTP message types. You can take the snapshot by setting the TSVER2ENA bit and selecting the snapshot mode in Timestamp control Register (ETH_MACTSCR).

- **Boundary clock**

  The boundary clock typically has several physical ports which communicate with the network. The messages related to synchronization, master-slave hierarchy, and signaling end in the protocol engine of the boundary clock. Such messages are not
forwarded. The PTP message type status given by the MAC helps you to identify the type of message and take appropriate action.

The boundary clock is similar to the ordinary clock except for the following features:
- The clock data sets are common to all ports of the boundary clock.
- The local clock is common to all ports of the boundary clock.

**End-to-end transparent clock**

The end-to-end transparent clock supports the end-to-end delay measurement mechanism between the slave clocks and the master clock. The end-to-end transparent clock forwards all messages like normal bridge, router, or repeater. The residence time of a PTP packet is the time taken by the PTP packet from the Ingress port to the Egress port.

The residence time of a SYNC packet inside the end-to-end transparent clock is updated in the correction field of the associated Follow_Up PTP packet before it is transmitted. Similarly, the residence time of a Delay_Req packet, inside the end-to-end transparent clock, is updated in the correction field of the associated Delay_Resp PTP packet before it is transmitted. Therefore, the snapshot needs to be taken at both Ingress and Egress ports only for the messages mentioned in the residence time of a SYNC packet inside the end-to-end transparent clock is updated in the correction field of the associated Follow_Up PTP packet before it is transmitted. Similarly, the residence time of a Delay_Req packet, inside the end-to-end transparent clock, is updated in the correction field of the associated Delay_Resp PTP packet before it is transmitted. Therefore, the snapshot needs to be taken at both Ingress and Egress ports only for the messages mentioned in The residence time of a SYNC packet inside the end-to-end transparent clock is updated in the correction field of the associated Follow_Up PTP packet before it is transmitted. Similarly, the residence time of a Delay_Req packet, inside the end-to-end transparent clock, is updated in the correction field of the associated Delay_Resp PTP packet before it is transmitted. Therefore, the snapshot needs to be taken at both Ingress and Egress ports only for the messages mentioned in

The snapshot can be taken by setting the SNAPTYPSEL bits to 10 in the Timestamp control Register (ETH_MACTSCR). You can take the snapshot by setting the SNAPTYPSEL bits to 10 in the Timestamp control Register (ETH_MACTSCR).

<table>
<thead>
<tr>
<th>PTP Messages</th>
</tr>
</thead>
<tbody>
<tr>
<td>SYNC</td>
</tr>
<tr>
<td>Delay_Req</td>
</tr>
</tbody>
</table>

**Peer-to-peer transparent clock**

The peer-to-peer transparent clock differs from the end-to-end transparent clock in the way it corrects and handles the PTP timing messages. In all other aspects, it is identical to the end-to-end transparent clock.

In the peer-to-peer transparent clock, the computation of the link delay is based on an exchange of Pdelay_Req, Pdelay_Resp, and Pdelay_Resp_Follow_Up messages with the link peer. The residence time of the Pdelay_Req and the associated Pdelay_Resp packets is added and inserted into the correction field of the associated Pdelay_Resp_Followup packet. Therefore, support for taking snapshot for the event messages related to Pdelay is added as shown in the Timestamp control Register (ETH_MACTSCR).
You can take the snapshot by setting the SNAPTYPESEL bit to 11 in Timestamp control Register (ETH_MACTSCR).

Reference timing source

To get a snapshot of the time, the MAC provides an internal reference time in 80-bit format as defined in the IEEE 1588-2008 specifications.

The MAC clock input is used to generate the reference time (also called the system time) and capture timestamps. The timestamp has the following fields:

- **UInteger48 secondsField**
  - The secondsField is the integer portion of the timestamp in units of seconds. It is 48-bits wide. For example, 2.000000001 seconds are represented as secondsField = 0x0000_0000_0002.

- **UInteger32 nanosecondsField**
  - The nanosecondsField is the fractional portion of the timestamp in units of nanoseconds. For example, 2.000000001 nanoseconds are represented as nanoSeconds = 0x0000_0001.

The nanosecondsField supports the following two modes:

- **Digital rollover mode**: In this mode, the maximum value in the nanoseconds field is 0x3B9A_C9FF, that is, \(10^{9}-1\) nanoseconds.

- **Binary rollover mode**: In this mode, the nanoseconds field rolls over and increments the seconds field after value 0x7FFF_FFFF. Accuracy is \(~0.466\) ns per bit.

You can set these modes through TSCTRLSSR bit in Timestamp control Register (ETH_MACTSCR).

The reference timing is accessible by an output pulse-per-second signal (see Pulse-per-second output) or by storing up to 4 snapshots in dedicated FIFO register (Auxiliary snapshots with external events).

**Pulse-per-second output**

<table>
<thead>
<tr>
<th>PTP Messages</th>
</tr>
</thead>
<tbody>
<tr>
<td>SYNC</td>
</tr>
<tr>
<td>Pdelay_Req</td>
</tr>
<tr>
<td>Pdelay RESP</td>
</tr>
</tbody>
</table>

Table 516. Peer-to-peer transparent clock: PTP messages for snapshot
The MAC supports either a fixed or a flexible pulse-per-second signal (ptp_pps_o).

- Fixed pulse-per-second output
  - In this mode, only frequency of the PPS output can be changed by setting the PPSCTRL0 field in the PPS control register [alternate] (ETH_MACPPSCR).

- Fixed pulse-per-second output
  - In this mode, you have the flexibility to program the start or stop time, width, and interval of the pulse generated on the ptp_pps_o output.
    - The start and stop time are programmed through PPS target time seconds register (ETH_MACPPSTTSR) and PPS target time nanoseconds register (ETH_MACPPSTTNR) registers.
    - The PPS width and interval are programmed in terms of granularity of system time (number of the units of sub-second increment value) through respective registers PPS width register (ETH_MACPPSWR) and PPS interval register (ETH_MACPPSIR).

Refer to Section 57.9.9: Programming guidelines for flexible pulse-per-second (PPS) output for further details on how configuring flexible pulse output.

**Note:** To ensure proper PPS signal output, it is recommended to program advanced system time for the start or stop time. If the application programs a start or stop time that has already elapsed, the MAC sets an error status bit indicating the programming error. If enabled, the MAC also sets the Target Time Reached interrupt event. The application can cancel the start or stop request only if the corresponding start or stop time has not elapsed. If the time has elapsed, the cancel command has no effect.

**Auxiliary snapshots with external events**

The auxiliary snapshot feature allows you to store a snapshot of the system time based on an external event. The event is considered to be the rising edge of the ptp_aux_ts_trig_i sideband signal.

You can configure up to four auxiliary snapshot inputs and store up to 4 snapshots. A FIFO is accessible through registers: Auxiliary timestamp seconds register (ETH_MACATSSR) and Auxiliary timestamp nanoseconds register (ETH_MACATSNR).

The snapshots taken for any input are stored in a common FIFO; only 64 bits are kept. The application can read the Timestamp status register (ETH_MACTSSR) to know the timestamp of which input is available for reading at the top of this FIFO.

When a snapshot is stored, the MAC indicates this to the application with an interrupt. The value of the snapshot is read through a FIFO register access. If the FIFO becomes full and an external trigger to take the snapshot is asserted, a snapshot trigger-missed status (ATSSTM) is set in the Timestamp status register (ETH_MACTSSR). This indicates that the latest auxiliary snapshot of the timestamp is not stored in the FIFO. The latest snapshot is not written to the FIFO when it is full.

When a application reads the 64-bit timestamp from the FIFO, the space becomes available to store the next snapshot. You can clear a FIFO by setting the ATSFC bit in Auxiliary control register (ETH_MACACR). When multiple snapshots are present in the FIFO, the count is indicated in Bits[27:25] of ETH_MACTSSR register.

**System time register module**

The 64-bit PTP time is updated using the PTP input reference clock, HCLK. This PTP time is used as a source to take snapshots (timestamps) of the Ethernet frames being
transmitted or received at the MII. The System Time counter can be initialized or corrected using either the Coarse or the Fine correction method.

In the Coarse correction method, the initial value or the offset value is written to the Time stamp update register. For initialization, the System Time counter is written with the value in the Time stamp update registers, whereas for system time correction, the offset value (Time stamp update register) is added to or subtracted from the system time.

In the Fine correction method, the slave clock (reference clock) frequency drift with respect to the master clock (as defined in IEEE 1588 specifications) is corrected over a period of time, unlike in the Coarse correction method where it is corrected in a single clock cycle. The longer correction time helps maintain linear time and does not introduce drastic changes (or a large jitter) in the reference time between PTP Sync message intervals. In this method, an accumulator sums up the contents of the Addend register as shown in Figure 785. The arithmetic carry that the accumulator generates is used as a pulse to increment the system time counter. The accumulator and the addend are 32-bit registers. The accumulator acts as a high-precision frequency multiplier or divider.

This system time update algorithm is shown in Figure 785.

![Figure 785. System time update using Fine method](image)

The System Time Update logic requires a 50 MHz clock frequency to achieve 20 ns accuracy. The frequency division is the ratio of the reference clock frequency to the required clock frequency. For example, if the reference clock (HCLK) is 66 MHz, this ratio is calculated as 66 MHz/50 MHz = 1.32. Therefore, the default addend value to be set in the register is $2^{32} / 1.32$, 0xC1F07C1F.

If the reference clock drifts lower, for example, to 65 MHz, the ratio is 65 / 50, that is 1.3 and the value to set in the addend register is $2^{32} / 1.30$, or 0xC4EC4EC4.
If the clock drifts higher, for example to 67 MHz, the addend register must be set to 0xBF0B7672. When there is not clock drift, the default addend value of 0xC1F07C1F \((2^{32} / 1.32)\) must be programmed.

In Figure 785, the constant value used to accumulate the sub-second register is decimal 43, which achieves a system time accuracy of 20 ns (in other words, it is incremented in 20 ns steps). When External Time Update is enabled, the optional System Time module is not available. Two different methods are used to update the System Time register depending on the configuration.

The software must calculate the drift in frequency based on the SYNC messages and accordingly update the Addend register.

Initially, the slave clock is set with \(F_{comp0}\) in the Addend register. This value is as follows:

\[
F_{comp0} = 2^{32} / F_{freq\_division\_ratio}
\]

If \(MasterToSlave\_Delay\) is initially assumed to be the same for consecutive Sync messages, the algorithm given in this section must be applied. After a few Sync cycles, frequency lock occurs. The slave clock can then determine a precise \(MasterToSlave\_Delay\) value and re-synchronize with the master using the new value.

The algorithm is as follows:

1. At time Master\_Sync\_Time\_n the master sends the slave clock a SYNC message. The slave receives this message when its local clock is Slave\_Clock\_Time\_n and computes Master\_Clock\_Time\_n as follows:

\[
Master\_Clock\_Time\_n = Master\_Sync\_Time\_n + MasterToSlave\_Delay\_n
\]

2. The master clock counts for current Sync cycle, Master\_Count\_n is

\[
Master\_Count\_n = Master\_Clock\_Time\_n - Master\_Clock\_Time\_n-1
\]

(assuming that MasterToSlave\_Delay is the same for Sync cycles \(n\) and \(n - 1\))

3. The slave clock count for current Sync cycle, Slave\_Count\_n is

\[
Slave\_Clock\_Count\_n = Slave\_Clock\_Time\_n - Slave\_Clock\_Time\_n-1
\]

4. The difference between master and slave clock counts for current Sync cycle, Clock\_Diff\_Count\_n is

\[
Clock\_Diff\_Count\_n = Master\_Clock\_Time\_n - Slave\_Clock\_Time\_n
\]

5. The frequency-scaling factor for slave clock, Freq\_Scale\_Factor\_n is

\[
Freq\_Scale\_Factor\_n = (Master\_Count\_n + Clock\_Diff\_Count\_n) / Slave\_Count\_n
\]

6. The frequency compensation value for Addend register, Freq\_Comp\_Value\_n is

\[
Freq\_Comp\_Value\_n = Freq\_Scale\_Factor\_n \times Freq\_Comp\_Value\_n-1
\]

In theory, this algorithm achieves lock in one Sync cycle. However, it may take several cycles, because of changing network propagation delays and operating conditions. This
algorithm is self-correcting. If the slave clock is initially set to an incorrect value from the master, the algorithm corrects it at the cost of more Sync cycles.

Refer to Section 57.9.7: Programming guidelines for IEEE 1588 timestamping for detailed programming steps.

Transmit path functions

The MAC captures a timestamp when the Start Packet Delimiter (SFD) of a packet is sent on the MII interface. The packets, for which you want to capture timestamps, can be controlled on per-packet basis. Each Transmit packet can be marked to indicate whether a timestamp should be captured for it.

The MAC does not process the transmitted packets to identify the PTP packets. You need to specify the packets for which you want to capture timestamps. You can specify the packets by using the control bits in Transmit Descriptor (see Section 57.10.3: Transmit descriptor). The MAC returns the timestamp to the software inside the corresponding Transmit descriptor, thus connecting the timestamp automatically to the specific PTP packet.

The 64-bit timestamp information is written to the TDES0 and TDES1 fields. The TDES0 field holds the 32 least significant bits of the timestamp.

Receive path functions

The MAC can be programmed to capture the timestamp of all packets received on the MII interface or to process packets to identify the valid PTP messages. You can control the snapshot of the time to be sent to the application by using the following options of the Timestamp control Register (ETH_MACTSCR):

- Enable snapshot for all packets
- Enable snapshot for IEEE 1588 version 1 or version 2 timestamp
- Enable snapshot for PTP packets transmitted directly over Ethernet or UDP-IP-Ethernet
- Enable timestamp snapshot for the received packet for IPv4 or IPv6
- Enable timestamp snapshot only for EVENT messages (SYNC, DELAY_REQ, PDELAY_REQ, or PDELAY_RESP)
- Enable the node to be a master or slave and select the snapshot type

This feature controls the type of messages for which snapshots are taken.

The DMA returns the timestamp to the software application inside the corresponding Receive descriptor. The extended status, containing the timestamp message status and the IPC status, is written in the RDES1 normal descriptor and the snapshot of the timestamp is written in RDES0 and RDES1 fields of the context descriptor. The RDES0 field holds the 32 least significant bits of the timestamp.

Timestamp correction

According to the IEEE 1588 specification, a timestamp must be captured when the message timestamp point (leading edge of the first bit of the octet immediately following the Start Frame Delimiter octet) crosses the boundary between the node and the network. Because the reference timing source (the PTP clock HCLK) is different from the MAC Tx or Rx clock, the captured timestamp must be corrected for latency issues because of synchronization. In addition, latency issues between the internal snapshot point and the recommended capture point (the boundary between the node and the network), must also be corrected.
Ingress correction

In the Receive side the timestamp captured at the internal snapshot point is corrected for latency and synchronization by adding the correction value (Ingress Correction Value) programmed in the Ingress Correction register. The value that needs to be programmed in the ingress correction register is calculated as follows:

1. The timestamp correction because of synchronization is compensated by adding \( \text{INGRESS\_SYNC\_CORR} \) to the synchronized timestamp value as follows:
   \[
   \text{INGRESS\_SYNC\_CORR} = -(2\times PT\_CLK\_PER)
   \]
2. The latency correction between the message timestamp point and the internal timestamp snapshot point is done by subtracting the latency value \( \text{INGRESS\_LATENCY} \) with the captured timestamp as follows:
   \[
   \text{Ingress Correction} = \text{INGRESS\_SYNC\_CORR} - \text{INGRESS\_LATENCY}
   \]
3. Ingress correction is performed by programming the TSIC field in the MAC Timestamp Ingress correction register. The ingress correction is always negative and is expressed in nanoseconds. The value is represented in complement form as follows:
   - When TSCTRLSSR bit in Timestamp control Register (ETH_MACTSCR) is set, the accuracy is of 1 ns: it is represented by setting bit 31 to 1 and bits 30:0 containing \( 10^9 - \text{<ingress\_correction\_value>} \) represented in binary. For example, if the required correction value is -5 ns, then the programmed value must be 0xBB9A_C9FB.
   - When TSCTRLSSR bit in ETH_MACTSCR register is reset, the accuracy is of ~0.466 ns: it is represented by setting bit 31 to 1 and bits 30:0 containing \( 2^31 - \text{<ingress\_correction\_value>} \) represented in binary.

Egress correction

In the Transmit side the timestamp captured at the internal snapshot point is corrected for latency and synchronization by adding the correction value (Egress correction value) programmed in the Egress Correction register. The value that needs to be programmed in the egress correction register is calculated as follows:

1. The timestamp correction because of synchronization is compensated by adding \( \text{EGRESS\_SYNC\_CORR} \) to the synchronized timestamp value as follows:
   - When Enable one step timestamp feature is selected,
     \[
     \text{EGRESS\_SYNC\_CORR} = (1\times PT\_CLK\_PER + 4\times TX\_CLK\_PER)
     \]
   - Otherwise,
     \[
     \text{EGRESS\_SYNC\_CORR} = -(2\times PT\_CLK\_PER)
     \]
2. The egress latency correction between the recommended capture point and the internal timestamp snapshot point is obtained by adding the latency value \( \text{EGRESS\_LATENCY} \) to the captured timestamp as follows:
   \[
   \text{Egress Correction} = \text{EGRESS\_SYNC\_CORR} + \text{EGRESS\_LATENCY}
   \]
3. Egress correction is performed by programming the TSEC field in the MAC Timestamp Egress correction register. The egress correction can be positive or negative. It is
expressed in nanoseconds. Negative values are represented in complement form as follows:

- When TSCTRLSSR bit in Timestamp control Register (ETH_MACTSCR) is set, the accuracy is of 1 ns.
  
  If the correction is positive, it is represented by setting bit 31 to 0 and bits 30:0 containing \(<\text{egress}\_\text{correction}\_\text{value}>\) represented in binary. The value must not exceed \(0x\ 3B9A\_C9FF\).
  
  If the correction is negative, it is represented by setting bit 31 to 1 and bits 30:0 containing \(10^9 - <\text{egress}\_\text{correction}\_\text{value}>\) represented in binary.
  
  For example, if the required correction value is -5 ns, then the programmed value should be \(0xBB9A\_C9FB\).

- When TSCTRLSSR bit in Timestamp control Register (ETH_MACTSCR) is reset, the accuracy is of \(~0.466\) ns.
  
  If the correction is positive, it is represented by setting bit 31 to 0 and bits 30:0 containing \(<\text{egress}\_\text{correction}\_\text{value}>\) represented in binary. The maximum value is \(0x7FFF\_FFFF\).
  
  If the correction is negative, it is represented by setting bit 31 to 1 and bits 30:0 containing \(2^31 - <\text{egress}\_\text{correction}\_\text{value}>\) represented in binary.

One-step timestamp

The MAC supports the one-step timestamp feature: It identifies the offset in the packet and inserts the timestamp received from the application at that offset.

You can enable the one-step timestamp feature for a packet by setting bit 20 (OSTC) in ATI Control Word. The inserted timestamp consists of the 64-bit TSSL and TSSH received from the application.

The one-step timestamp feature is supported only for the PTP over Ethernet packets. It is not supported for PTP over IPv4/IPv6 packets.

PTP offload function

This feature enables the automatic generation of specific PTP packets to be performed, when the MAC operates as a specific node in the PTP network. These packets can be generated periodically or triggered by the host software. In other modes, this feature can parse the incoming PTP packets on the receiver, and automatically generate and respond to the required PTP packets. It helps to offload certain PTP node functions with better accuracy and lower response latency.

Depending on the programmed mode, the MAC generates PTP Ethernet messages periodically or from the application, or based on reception of a particular PTP message. Table 517 indicates the PTP message generation criteria.
The PTP offload feature is configured through *PTP Offload control register (ETH_MACPOCR)* register. 80 bits-PTP node identity is given in the three following registers: *PTP Source Port Identity 0 Register (ETH_MACSPI0R)*, *PTP Source port identity 1 register (ETH_MACSPI1R)* and *PTP Source port identity 2 register (ETH_MACSPI2R)*.

All other programming combinations are invalid for PTP Offload feature.
57.5.5 IPv4 ARP offload

The MAC supports the Address Recognition Protocol (ARP) Offload for IPv4 packets. This feature allows to process the IPv4 ARP request packet in the receive path and to generate the corresponding ARP response packet in the transmit path.

The MAC generates the ARP reply packets for appropriate ARP request packets. ARP packets for IPv4 are L2 layer packets with Length/Type of 0x0806.

The ARP offloading sequence is as follows:
1. The MAC receiver gets an ARP request if the request Target Protocol Address matches the IPv4 address programmed in the MAC L3 register.
2. The MAC generates an ARP reply packet.
3. The MAC copies the Sender Hardware Address field in the ARP request to the following fields:
   - DA field of the Ethernet packet header
   - Target Hardware Address field of the ARP reply packet
4. The MAC copies the Sender Protocol Address field in the ARP request to the Target Protocol Address field in the ARP reply packet.
5. The MAC places its MAC address in the following fields:
   - SA field of the Ethernet packet header
   - Sender Hardware Address field of the ARP reply packet
6. The MAC copies the Target Protocol Address field in the ARP request to the Sender Protocol Address field in the ARP reply packet.
7. The MAC sets the opcode field in ARP reply packet to 2 indicating ARP reply.
8. The MAC recalculates the CRC and performs padding for the generated ARP reply packet.
9. The MAC transmitter sends the ARP reply

57.5.6 TCP segmentation offload

The MAC supports the TCP segmentation offload (TSO) feature in which the DMA splits a large TCP packet into multiple small packets and passes these packets to the MTL as shown in Figure 786.

This feature is enabled by programming the TSE bit of corresponding ETH_DMACCR register (see Channel control register (ETH_DMACCR)). It is only supported when the MAC operates in full-duplex mode.

For detailed programming steps, refer to Section 57.9.10: Programming guidelines for TSO.
Enabling the TSO feature

To enable segmentation for a packet, the application must set the TSE bit of TDES3 of first normal descriptor (see Section 57.10.3: Transmit descriptor).

The application must program the length of the TCP packet payload in TDES3[17:0] and the TCP header in TDES3[22:19]. The maximum length of TCP packet payload that can be segmented is 256 Kbytes.

The header of the packet including Ethernet header, L3 header and L4 header should be provided in Buffer1 of the first normal descriptor of the TSO packet. Only buffer 1 of the first normal descriptor of a packet enabled for TSO is taken as the buffer containing the header.

The TCP payload can begin from buffer 2 of the first normal descriptor and continue to buffer 1 and buffer 2 of second normal descriptor and subsequent descriptors.

The TCP payload may span across multiple buffers and multiple descriptors. The size of buffers containing the TCP payload should add up to be equal to the TCP payload length provided in TDES3[17:0] of the first normal descriptor.

The MAC always calculates and appends CRC and inserts Padding (if required) for all packets segmented by the DMA. If the TSE bit of TDES3 is enabled, the CRC PAD Control (CPC) field of TDES3 is reserved. To determine the size of a TCP packet after segmentation, the DMA uses the Maximum Segment Size (MSS) provided by the application through context descriptor. The DMA segments only those packets which have payload size greater than MSS. The application must provide the MSS by either programming the MSS value in ETH_DMACCR (see Channel control register (ETH_DMACCR)) or by providing a context descriptor. The DMA uses the last programmed value of MSS or the last MSS value provided through context (whichever is provided later).

The header length plus the MSS size (which is equal to the size of each TCP segment) should not exceed 16383 bytes otherwise the MAC transmitter truncates the packet after 16383 bytes causing a CRC error.

The header length plus MSS size plus programmed PBL value in ETH_DMACTXCR register (see Channel transmit control register (ETH_DMACTXCR)) should be lesser than the Tx queue size programmed in TQS field of ETH_MTLTXQOMR register (see Tx queue operat-
ing mode Register (ETH_MTLTXQOMR)). A MSS plus header equal to half the programmed Tx queue size is recommended.

If the TCP packet has a VLAN tag, then the same tag is used for all the segments irrespective of the VLAN tag type provided (C-VLAN or S-VLAN). The VLAN tag insert/replace control bits are used for all segments.

If the Double VLAN feature is selected, then the DMA passes both tags for all segments irrespective of the VLAN tag types provided (C-VLAN or S-VLAN). The VLAN tag Insert/Replace control bits for both tags is applicable to all segments. If the Double VLAN feature is not selected, then the application must not set the TSE bit in TDES3 for a TCP/IP packet with two tags. The DMA behavior in this scenario is unpredictable.

**TCP/IP header fields**

While segmenting a TCP packet, the DMA automatically updates the TCP/IP header fields. *Table 518* describes how the TCP and IP headers are updated.

<table>
<thead>
<tr>
<th>Packet sequence</th>
<th>TCP header</th>
<th>IP header</th>
</tr>
</thead>
</table>
| **First packet** | 1. The sequence number is not updated. The value provided in the header is used. 2. If set, the FIN and PSH flags are cleared. 3. The TCP checksum is calculated again. | IPv4 Header  
– Total Length = MSS + TCP Header Length + IP Header Length  
– Identification field is not modified. It is sent as per the header provided by the software.  
– IPv4 Header Checksum is recalculated. IPv6 Header  
– Payload Length = MSS + TCP Header Length + IP Extension Header Length | |
| **Subsequent packets** | 1. The sequence number is updated. The MSS value is added to the sequence number value of previous segment. 2. If set, the FIN and PSH flags are cleared. 3. The TCP checksum is calculated again. | IPv4 Header

– Identification field = Previous Identification Field + 1  
– IPv4 Header Checksum is recalculated. IPv6 Header  
– Payload Length = MSS + TCP Header Length + IP Extension Header Length | |
| **Last packet** | 1. The sequence number is updated. The MSS value is added to the sequence number value of previous segment. 2. If FIN and PSH flags were set in original header, these flags are set. 3. The TCP checksum is calculated again. | IPv4 Header  
– Total Length = Remaining Payload + TCP Header Length + IP Header Length  
– Identification Field = Previous Identification Field + 1  
– IPv4 header Checksum is recalculated. IPv6 Header  
– Payload Length = Remaining Payload Length + TCP Header Length + IP Extension Header Length | |
Header and payload fields of segmented packets

After segmentation, the split packets use the same header as the parent TCP packet for header fields other than the ones described in Table 518: TSO: TCP and IP header fields. Figure 787: Header and payload fields of segmented packets shows how same header is used for the header fields of segmented packets.

The application must create the header in Buffer 1 of the first descriptor of the packet to be segmented and provide the header length in TDES2 of the first descriptor (FD = 1). When the FD bit is set, the DMA reads the header from the header buffer to which the TDES0 is pointing. Buffer 2 of the first descriptor can be used for payload and TDES0 and TDES1 of subsequent descriptors. For subsequent descriptors (FD = 0), the address to which the TDES0 and TDES1 are pointing is treated as payload buffer address of the same packet.

Figure 787. Header and payload fields of segmented packets

Context descriptor sequence

The context descriptor can provide the maximum segment size (MSS) value for segmentation. The application must provide the context descriptor before the normal descriptor to be used for the corresponding TCP packet. If the application needs to provide a new MSS, it must create the context descriptor in the descriptor list before the first normal descriptor of the packet to be segmented with the new MSS value. The MSS value in the context descriptor is valid only if the TCMSSV bit of TDES3 in context descriptor is set and the OSTC bit is reset (refer to Section 57.10.3: Transmit descriptor).

When the application provides a context descriptor with a valid MSS value, the DMA internally stores the MSS value and uses this value for all subsequent packets for which the TSO is enabled through the TSE bit of TDES3 normal descriptor.
If the application places a context descriptor in the middle of a packet (between the first and last descriptors of a packet), the DMA does the following:

1. The DMA ignores the context and closes the descriptor.
2. The DMA indicates the error in descriptor status.
3. The DMA generates an interrupt if the CDEE bit is set in the Interrupt enable register corresponding to a DMA channel (see Channel interrupt enable register (ETH_DMACIER)).

The application can read the interrupt status through CDE bit of Status register corresponding to a DMA channel (see Channel status register (ETH_DMACSR)).

57.5.7 Loopback

The MAC supports the Loopback of transmitted packets to its receiver. By default, the MAC Loopback function is disabled, but it can be enabled by programming the LM bit of the Operating mode configuration register (ETH_MACCR) register.

The Loopback function is available for all PHY interfaces. The data is always looped back on the MII interface irrespective of which PHY interface is selected.

57.5.8 Flow control

This section describes the flow control for Transmit and Receive paths.

Transmit flow control

The Transmit Flow Control is enabled when TFE bit is set in Tx Queue flow control register (ETH_MACQTXFCR).

Flow control trigger

The Transmit Flow Control involves transmitting Pause packets in full-duplex mode and backpressure in half-duplex mode to control the flow of packets from the remote end. The application can request the MAC to send a Pause packet or initiate backpressure by using setting the FCB bit in the corresponding Tx Queue flow control register (ETH_MACQTXFCR).

Flow control in full-duplex mode: pause packets control

In full-duplex mode, the MAC uses IEEE 802.3x Pause packets for flow control. Table 519 describes the fields of a Pause packet.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DA</td>
<td>Contains the special multicast address</td>
</tr>
<tr>
<td>SA</td>
<td>Contains the MAC address 0</td>
</tr>
<tr>
<td>Type</td>
<td>Contains 8808</td>
</tr>
<tr>
<td>MAC Control opcode</td>
<td>Contains 0001 for IEEE 802.3x Pause Control packets; 0101 for PFC packets</td>
</tr>
<tr>
<td>PT</td>
<td>Contains Pause time specified in the PT field of the Tx Queue flow control register (ETH_MACQTXFCR)</td>
</tr>
</tbody>
</table>
When the FCB bit is set, the MAC generates and transmits a single Pause packet. If the FCB bit is set again after the Pause packet transmission is complete, the MAC sends another Pause packet irrespective of whether the pause time is complete or not. To extend the pause or terminate the pause prior to the time specified in the previously-transmitted Pause packet, the application should program the Pause Time register with appropriate value and then again set the FCB bit.

**Flow control in half-duplex mode**

In half-duplex mode, the MAC uses the deferral mechanism for the flow control (backpressure). When the application requests to stop receiving packets, the MAC sends a JAM pattern of 32 bytes when it senses a packet reception, provided the transmit flow control is enabled. This results in a collision and the remote station backs off. If the application requests a packet to be transmitted, it is scheduled and transmitted even when the backpressure is activated. If the backpressure is kept activated for a long time (and more than 16 consecutive collision events occur), the remote stations abort the transmission because of excessive collisions.

*Table 520* describes the flow control in the Tx path based on the setting of the following bits:
- EHFC bit of *Rx queue operating mode register (ETH_MTLRXQOMR)*
- TFE bit of *Tx Queue flow control register (ETH_MACQTXFCR)*
- DM bit of *Operating mode configuration register (ETH_MACCR)*

Flow control is similar for all queues.

**Table 520. Tx MAC flow control**

<table>
<thead>

</tr>
<tr>
<td>1</td>
<td>1</td>
<td>0</td>
<td>The MAC transmitter performs backpressure when Bit 0 of <em>Tx Queue flow control register (ETH_MACQTXFCR)</em> is set. In addition, the MAC Tx performs backpressure when Rx queue level crosses the threshold set by Bits[10:8] of <em>Rx queue operating mode register (ETH_MTLRXQOMR)</em>.</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>1</td>
<td>The MAC transmitter sends the Pause packet when Bit 0 of <em>Tx Queue flow control register (ETH_MACQTXFCR)</em> is set.</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
<td>The MAC transmitter sends the Pause packet when Bit 0 of <em>Tx Queue flow control register (ETH_MACQTXFCR)</em> is set. In addition, the MAC Tx sends a Pause packet when Rx queue level crosses the threshold set by Bits[10:8] of <em>Rx queue operating mode register (ETH_MTLRXQOMR)</em>.</td>
</tr>
</tbody>
</table>

**Receive flow control**

In the Receive path, the flow control is functional only in full-duplex mode. If any Pause packet is received in half-duplex mode, the packet is considered as a normal control packet.
You can enable the Pause flow control by setting the RFE bit in the Rx flow control register (ETH_MACRXFCR). Table 521 describes the flow control in the Rx path based on the setting of the following bits:

- RFE bit of Rx flow control register (ETH_MACRXFCR)
- DM bit of Operating mode configuration register (ETH_MACCR)

### Table 521. Rx MAC Flow Control

<table>
<thead>
<tr>
<th>RFE</th>
<th>DM</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>x</td>
<td>The MAC receiver does not detect the received Pause packets.</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>The MAC receiver does not detect the received Pause packets but recognizes such packets as Control packets.</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>The MAC receiver detects or processes the Pause packets and responds to such packets by stopping the MAC transmitter.</td>
</tr>
</tbody>
</table>

The following sequence describes the Rx flow control:

1. The MAC checks the destination address of the received Pause packet for either multicast or unicast destination address.
2. The MAC decodes the Type (0x8808) and Opcode (0x0001: Pause packet) fields of the received packet. The Pause time (for Pause packet) is captured to determine the time for which transmitter needs to be blocked.
3. If the byte count of the status indicates 64 bytes and there is no CRC error, the MAC pauses the transmission of any data packet for the duration of the decoded Pause Time value multiplied by the slot time (64 byte times).

#### 57.5.9 Checksum offload engine

Communication protocols such as TCP and UDP implement checksum fields, which help determine the integrity of data transmitted over a network. The most widespread use of Ethernet is to encapsulate TCP and UDP over IP datagrams. The MAC has a Checksum Offload Engine (COE) to support checksum calculation and insertion in the Transmit path, as well as error detection in the Receive path.

**Transmit checksum offload engine**

The COE module supports two types of checksum calculation and insertion. The checksum engine can be controlled for each packet by setting the CIC bits (TDES3 bits[17:16]).

*Note:* The checksum for TCP, UDP, or ICMP is calculated over a complete packet, and then inserted into its corresponding header field. Because of this requirement the Tx FIFO automatically operates in the store-and-forward mode even if the MAC is configured for Threshold (cut-through) mode.

**IP header checksum engine**

In IPv4 datagrams, the integrity of the header fields is indicated by the 16-bit Header Checksum field (the eleventh and twelfth bytes of the IPv4 datagram). The COE detects an IPv4 datagram when the Type field of Ethernet packet has the value 0x800 and the Version field of IP datagram has the value 0x4. The checksum field of the input packet is ignored during calculation and replaced with the calculated value.
IPv6 headers do not have a checksum field. Therefore, the COE does not modify the IPv6 header fields.

The result of this IP header checksum calculation is indicated by the IP Header Error status it in the Transmit status (bit 0 in Table 535: TDES3 normal descriptor (write-back format)).

TCP/UDP/ICMP checksum engine

The TCP/UDP/ICMP Checksum Engine processes the IPv4 or IPv6 header (including extension headers) and determines whether the encapsulated payload is TCP, UDP, or ICMP. The checksum is calculated for the TCP, UDP, or ICMP payload and inserted into its corresponding field in the header. The Tx COE can work in the following two modes:

- The TCP, UDP, or ICMPv6 pseudo-header is not included in the checksum calculation and is assumed to be present in the Checksum field of the input packet. This engine includes the Checksum field in the checksum calculation, and then replaces the Checksum field with the final calculated checksum.
- The engine ignores the Checksum field, includes the TCP, UDP, or ICMPv6 pseudo-header data into the checksum calculation, and overwrites the checksum field with the final calculated value.

Note: For ICMP-over-IPv4 packets, the Checksum field in the ICMP packet must always be 0x0000 in both modes, because pseudo-headers are not defined for such packets. If it does not equal 0x0000, an incorrect checksum may be inserted into the packet.

The result of this operation is indicated by the Payload Checksum Error status bit in the Transmit Status vector (bit 12 in Table 535: TDES3 normal descriptor (write-back format)). This engine sets the Payload Checksum Error status bit when it detects that the packet has been forwarded to the MAC Transmitter engine in the store-and-forward mode without the end of packet (EOP) being written to the FIFO, or when the packet ends before the number of bytes indicated by the Payload Length field in the IP Header is received. When the packet is longer than the indicated payload length, the COE ignores them as stuff bytes, and no error is reported. When this engine detects the first type of error, it does not modify the TCP, UDP, or ICMP header. For the second error type, it still inserts the calculated checksum into the corresponding header field.

Table 522 describes the functions supported by Transmit Checksum Offload engine based on the packet type. When the MAC does not insert the checksum, it is indicated as “No” in the table.

Receive checksum offload engine

You can enable the Receive Checksum Offload Engine (Rx COE) by selecting the Enable Receive TCP/IP Checksum Check option and setting the IPC bit of Operating mode configuration register (ETH_MACCR). When this option is selected, both IPv4 and IPv6 packet in the received Ethernet packets are detected and processed for data integrity. The MAC receiver identifies IPv4 or IPv6 packets by checking for value 0x0800 or 0x86DD, respectively, in the Type field of the received Ethernet packet. This identification is applicable to single VLAN-tagged packets. It is also applicable to double VLAN-tagged packets when the Enable Double VLAN Processing option is selected and the EDVLP bit of the VLAN tag register (ETH_MACVTR) is set.

The Rx COE calculates the IPv4 header checksums and checks that they match the received IPv4 header checksums. The result of this operation (pass or fail) is given to the RFC module for insertion into the receive status word. The IP Header Error bit is set for any mismatch between the indicated payload type (Ethernet Type field) and the IP header version, or when the received packet does not have enough bytes, as indicated by the Length field of the IPv4 header (or when fewer than 20 bytes are available in an IPv4 or IPv6 header).

This engine also identifies a TCP, UDP, or ICMP payload in the received IP datagrams (IPv4 or IPv6) and calculates the checksum of such payloads properly, as defined in the TCP, UDP, or ICMP specifications. This engine includes the TCP, UDP, or ICMPv6 pseudo-header bytes for checksum calculation and checks whether the received checksum field matches the calculated value. The result of this operation is given as a Payload Checksum Error bit in the receive status word. This status bit is also set if the length of the TCP, UDP, or ICMP payload does not match the expected payload length given in the IP header.

Table 523: Receive checksum offload engine functions for different packet types describes the functions supported by the Rx COE based on the packet type. When the payload of an IP packet is not processed (indicated as "No" in the table), the information (whether the checksum engine is bypassed or not) is given in the receive status.

Note: The MAC does not append any payload checksum bytes to the received Ethernet packets.

57.5.10 **MAC management counters**

The counters in the MAC Management Counters (MMC) module can be viewed as an extension of the register address space of the CSR module. The MMC module maintains a set of registers for gathering statistics on the received and transmitted packets. The register set includes a control register for controlling the behavior of the registers, two 32-bit registers containing interrupts generated (receive and transmit), and two 32-bit registers containing masks for the Interrupt register (receive and transmit). These registers are accessible from the Application through the AHB slave interface in the same way the CSR registers are accessed. The organization of these registers is shown in *Section 57.11.4: Ethernet MAC and MMC registers*.

The MMC counters are free running. There is no separate enable for the counters to start. A particular MMC counter starts counting when corresponding packet is received or transmitted.

In addition to control registers, two sets of registers are implemented:

- 6 registers used for collision, error and good packets counters
- 4 registers to record LPI mode transition

57.5.11 **Interrupts generated by the MAC**

Interrupts can be generated from the MAC as a result of various events. These interrupt events are combined with the events in the DMA on the eth_sbd_intr_it signal. The MAC interrupts are of level type, that is, the interrupt remains asserted (high) until it is cleared by the application or software.

The *Interrupt status register (ETH_MACISR)* describes the events that can cause an interrupt from the MAC. The MAC interrupts are enabled by default. Each event can be prevented from asserting the interrupt on the eth_sbd_intr_it signals by setting the corresponding mask bits in the *Interrupt enable register (ETH_MACIER)*.

The interrupt register bits only indicate the block from which the event is reported. You must read the corresponding status registers and other registers to clear the interrupt.

57.5.12 **MAC and MMC register descriptions**

Refer to *Section 57.11.4: Ethernet MAC and MMC registers*. 
57.6 Ethernet functional description: PHY interfaces

The Ethernet peripheral support several PHY interfaces. The root interface is the MII one. All other interfaces are derived from it as shown in Figure 788.

Figure 788. Supported PHY interfaces

This section describes the SMA module used for PHY control and different PHY interfaces. It contains the following sections:

- Station management agent (SMA)
- Media Independent Interface (MII)
- Reduced media independent interface (RMII)

57.6.1 Station management agent (SMA)

The application can access the PHY registers through the station management agent (SMA) module. The SMA includes a two-wire station management interface (MIM).

The SMA module supports accessing up to 32 PHYs. The application can address one of the 32 registers from any 32 PHYs. Only one register in one PHY can be addressed at a time. The application sends the control data to the PHY and receives status information from the PHY through the SMA module, as shown in Figure 789.

Figure 789. SMA Interface block
SMA functional overview

The MAC initiates the management write or read operation with respect to the MDC clock. The MDC clock is derived from the CSR clock. The division factor depends on the clock range setting in the MDIO address register (ETH_MACMDIOAR) register. The MDC clock is selected as follows:

<table>
<thead>
<tr>
<th>Selection</th>

The data exchange between the MAC and the PHY is performed through mdi_i, mdo_o and mdo_oe signals. This signal group is passed through a three-state buffer and brought out as MDIO line connected to the PHY.

The following figure shows the structure of a packet on the MDIO packet while **Table 525** provides a detailed description of the packet fields.

MII management write operations

When bit[3:2] are set to 01 and bit 0 to 1 in the MDIO address register (ETH_MACMDIOAR), the MAC CSR module transfers the PHY address, the register address in PHY, and the write data (MDIO data register (ETH_MACMDIODR)) to the SMA to initiate a Write operation into the PHY registers. At this point, the SMA module starts a Write operation on the MII Management Interface using the Management Packet Format specified in the MII specifications (as per IEEE 802.3-2002 specifications, Section 22.2.4.5).

When the SMA module starts a Write operation, the write data packet is transmitted on the MDIO line. The MAC drives the MDIO line for complete duration of the packet. The Busy bit is set high until the write operation is complete. The CSR ignores the Write operations performed to the MDIO address register (ETH_MACMDIOAR) or the MDIO data register (ETH_MACMDIODR) during this period (the Busy bit is high). When the Write operation is complete, the SMA module indicates this to the CSR, and the CSR resets the Busy bit. The packet format for the Write operation is as follows:

![Figure 791. Write data packet](image)

MII management read operation

When bit[3:2] are set to 11 and bit 0 to 1 in the MDIO address register (ETH_MACMDIOAR), the MAC CSR module transfers the PHY address and the register address in PHY to the SMA to initiate a Read operation in the PHY registers. At this point, the SMA module starts a Read operation on the MII Management Interface using the Management Packet Format specified in the MII specifications (as per IEEE 802.3-2002 specifications, Section 22.2.4.5).

When the SMA module starts a Read operation on the MDIO, the CSR ignores the Write operations to the MDIO address register (ETH_MACMDIOAR) or MDIO data register (ETH_MACMDIODR) register during this period (the Busy bit is high) and the transaction is completed without any error on the MCI interface. When the Read operation is complete, the SMA indicates this to the CSR. The CSR resets the Busy bit and updates the MDIO data register (ETH_MACMDIODR) with the data read from the PHY. The MAC drives the MDIO line for the complete duration of the frame except during the Data fields when the PHY is driving the MDIO line. For more information about the communication from the application to the PHYs, see the Reconciliation Sublayer and Media Independent Interface Specifications sections of the IEEE 802.3z, 1000BASE Ethernet.
The packet format for the Read operation is as follows:

57.6.2 **Media Independent Interface (MII)**

The media-independent interface (MII) defines the interconnection between the MAC sub-layer and the PHY for data transfer at 10 Mbit/s and 100 Mbit/s.

MII signals are given in *Figure 793: Media independent interface (MII) signals*.

**Figure 793. Media independent interface (MII) signals**

- **TX_CLK**: continuous clock that provides the timing reference for Tx data transfers. The nominal frequency is 2.5 MHz at 10 Mbit/s and 25 MHz at 100 Mbit/s.
- **RX_CLK**: continuous clock that provides the timing reference for Rx data transfers. The nominal frequency is 2.5 MHz at 10 Mbit/s, 25 MHz at 100 Mbit/s.
- **TX_EN**: transmission enable signal indicating that the MAC is presenting nibbles on the MII for transmission. It must be asserted synchronously (TX_CLK) with the first nibble of the preamble and must remain asserted while all nibbles to be transmitted are presented to the MII.
- **TXD[3:0]**: transmit data. TXD is a bundle of 4 data signals driven synchronously by the MAC sub-layer and qualified (valid data) on the assertion of the TX_EN signal. TXD[0] is the least significant.
significant bit, TXD[3] is the most significant bit. While TX_EN is deasserted the transmit data must have no effect upon the PHY.

- **CRS:** carrier sense.
  This signal is asserted by the PHY when either transmit or receive medium is non idle. It shall be deasserted by the PHY when both transmit and receive media are idle. The PHY must ensure that the CS signal remains asserted throughout the duration of a collision condition. This signal is not required to transition synchronously with respect to the Tx and Rx clocks. In full duplex mode the state of this signal is don’t care for the MAC sub-layer.

- **COL:** collision detection signal
  This signal must be asserted by the PHY upon detection of a collision on the medium and must remain asserted while the collision condition persists. This signal is not required to transition synchronously with respect to the Tx and Rx clocks. In full-duplex mode the state of this signal is don’t care for the MAC sub-layer.

- **RXD[3:0]:** reception data
  RXD is a bundle of 4 data signals driven synchronously by the PHY and qualified (valid data) on the assertion of the RX_DV signal. RXD[0] is the least significant bit, RXD[3] is the most significant bit. While RX_EN is deasserted and RX_ER is asserted, a specific RXD[3:0] value is used to transfer specific information from the PHY (see Table 526).

- **RX_DV:** receive data valid
  This signal indicates that the PHY is presenting recovered and decoded nibbles on the MII for reception. It must be asserted synchronously (RX_CLK) with the first recovered nibble of the frame and must remain asserted through the final recovered nibble. It must be deasserted prior to the first clock cycle that follows the final nibble. In order to receive the frame correctly, the RX_DV signal must encompass the frame, starting no later than the SFD field.

- **RX_ER:** receive error
  This signal must be asserted for one or more clock periods (RX_CLK) to indicate to the MAC sub-layer that an error was detected somewhere in the frame. This error condition must be qualified by RX_DV assertion as described in Table 526.

57.6.3 Reduced media independent interface (RMII)

The Reduced media independent interface (RMII) specification reduces the pin count between Ethernet PHYs and STM32 MCU. According to the IEEE 802.3u, an MII contains 16 pins for data and control. RMII specification reduces the pin count to 7.

Part of the Ethernet peripheral, the RMII module is instantiated at the MAC output. This helps in translating the MII of the MAC into the RMII. The RMII block has the following characteristics:

- Supports 10 Mbps and 100 Mbps operating rates. It does not support the 1000 Mbps operation.
- Provides independent 2-bits wide Transmit and Receive paths by sourcing two clock references externally.

RMII block diagram

Figure 794: RMII block diagram shows the position of the RMII block relative to the MAC and RMII PHY. The RMII block is placed in front of the MAC to translate the MII signals to RMII signals.

Figure 794. RMII block diagram
Transmit bit order

Each nibble from the MII interface must be transmitted on the RMII interface di-bit at a time with the order of di-bit transmission shown in Figure 795: Transmission bit order. The lower order bits (D1 and D0) are transmitted first followed by higher order bits (D2 and D3).

**Figure 795. Transmission bit order**
Receive bit order

Each nibble is transmitted to the MII interface from the di-bit received from the RMII interface in the nibble transmission order shown in Figure 796: Receive bit order. The lower order bits (D0 and D1) are received first, followed by the higher order bits (D2 and D3).

Figure 796. Receive bit order
57.7 Ethernet low-power modes

57.7.1 Energy Efficient Ethernet

Energy Efficient Ethernet (EEE) is an operating mode that enables the MAC sub-layer along with a family of Physical layers to operate in Low-power Idle (LPI) mode. The EEE mode supports operations at 100 Mbps.

The LPI mode allows power saving to be achieved by switching off some of the communication device functions when there is no data to be transmitted and received. The MAC controls whether the system should enter or exit the LPI mode and communicates this to the PHY interface.

The EEE specifies the negotiation methods that the link partners can use to determine whether EEE is supported, and then select the set of parameters that are common to both devices.

Note: The EEE feature is not supported when the MAC is configured to use the RMII single PHY interface. Even if the MAC supports multiple PHY interfaces, the EEE mode should be activate only when the MAC operates with the MII interface. The LPI mode is supported only in full-duplex mode.

Transmit path functions

In the Transmit path, the software must set the LPIEN bit of the LPI control status register (ETH_MACLCSR) to request the MAC to stop transmission and initiate the LPI protocol.

To exit the PHY from the LPI state, the MAC performs the following tasks:
1. Stops transmitting the LPI pattern and starts transmitting the IDLE pattern.
2. Starts the LPI TW TIMER:
   The MAC cannot start the transmission until the wakeup time specified for the PHY expires. The auto-negotiated wakeup interval is programmed in the TWT field of the LPI control status register (ETH_MACLCSR).
3. Updates the LPI exit status (TLPIEX bit of the LPI control status register (ETH_MACLCSR)) and generates an interrupt.

Refer to Section: Entering and exiting Tx LPI mode for programming guideline of LPI mode.

Automatically entering/exiting LPI mode in Tx path

The MAC transmitter can be programmed to enter/exit LPI mode automatically based on whether it is IDLE for a specific period of time or has a packet to transfer. These modes are enabled and controlled by LPI control status register (ETH_MACLCSR).

When LPITXA (bit19) and LPITXEN (bit16) of LPI control status register (ETH_MACLCSR) are set, the MAC transmitter enters LPI IDLE state when the MAC transmit path (including the MTL layers and DMA layers) are idle. The MAC transmitter will exit the LPI IDLE state and clear the LPITXEN bit as soon as any of functions in the Tx path (DMA, MTL or MAC) becomes non-idle due to initiation of a packet transfer.

In addition to the above, when Bit[20] (LPIATE) is also set, the MAC transmitter will enter LPI IDLE state only if the Transmit path remains in idle state (no activity) for the time period indicated by the value in LPI entry timer register (ETH_MACLETR). In this mode also, the MAC transmitter will exit the LPI IDLE state as soon as any of the functions becomes non-idle. However, the LPITXEN bit is not cleared but remains active so that re-entry to LPI IDLE state is possible without any software intervention when the MAC becomes idle again.
When both LPIATE and LPITXA bits are cleared, you can directly control the entry and exit of LPI IDLE state by programming the LPITXEN bit.

**Receive path functions**

In the receive path, when the PHY receives the signals from the link partner to enter into the LPI state, the PHY goes in LPI mode and MAC updates the RLPIEN bit of the LPI control status register (ETH_MACLCSR) and immediately generates an interrupt.

When the PHY receives signals from the link partner to exit the LPI state, the PHY goes out of the LPI mode and MAC updates the RLPIEX bit of the LPI control status register (ETH_MACLCSR). An interrupt is generated immediately.

**LPI Interrupt**

The MAC generates the LPI interrupt when the Tx or Rx side enters or exits the LPI state. The LPI interrupt can be cleared by reading the LPI control status register (ETH_MACLCSR).

A sideband signal, lpi_intr_o, is generated together with the interrupt. This signal is used by the wakeup mechanism. It is ORed with pmt_intr_o signal (see Section: PMT interrupts) and tied to the EXTI peripheral (line 86).

### 57.7.2 Power management

The power management (PMT) block supports the reception of network (remote) wakeup packets and magic packets. The PMT block generates interrupts for remote wakeup packets and magic packets that the MAC receives.

When the power-down mode is enabled in the PMT block, the MAC drops all received packets and does not forward any packet to the RxFIFO or the application. The MAC comes out of the power-down mode only when a magic packet or a remote wakeup packet is received and the corresponding detection is enabled.

The PMT block is available in the receive path of MAC. Both types of power management packet (remote wakeup packet and magic packet) can be selected. RWKPKTEN and MGKPKTEN bits of the PMT control status register (ETH_MACPCSR) can be set to generate power management events.

The following are the PMT block registers:

- PMT control status register (ETH_MACPCSR)
- Remote wakeup packet filter register (ETH_MACRWKPFR)

**Remote wakeup packet detection**

When the MAC is in sleep mode and the remote wakeup bit is enabled in the PMT control status register (ETH_MACPCSR), the normal operation is resumed after a remote wakeup packet is received.

**Remote wakeup frame filter register**

The PMT block supports 16 programmable filters that allow support of different receive packet patterns. If the incoming packet passes the address filtering of Filter Command, and if Filter CRC-16 matches the CRC of the incoming pattern, the MAC identifies the packet as a wakeup packet.
Remote wakeup packet filter register (ETH_MACRWKPFR) define the filtering management:

- Filter Byte Mask: determines which bytes of the packet must be examined
- Filter Offset: determines the offset from which the packet is to be examined
- Filter CRC-16

The remote wakeup CRC block determines the CRC value that is compared with Filter CRC-16. The remote wakeup packet is checked only for length error, FCS error, dribble bit error, receive error and collision. In addition, the remote wakeup packet is checked to ensure that it is not a runt packet. Even if the remote wakeup packet is more than 512 bytes long, if the packet has a valid CRC value, it is considered valid. The remote wakeup packet detection is updated in the PMT Control and Status register for every remote wakeup packet received. A PMT interrupt to the application triggers a Read to the PMT Control and Status register to determine reception of a remote wakeup packet.

Magic packet detection

The magic packet is based on a method that uses the magic packet technology from Advanced Micro Device to power up the sleeping device on the network. The MAC receives a specific packet of information, called a magic packet, addressed to the node on the network.

The MAC checks only those magic packets that are addressed to the MAC or a multicast address (including broadcast address) to determine whether these packets meet the wakeup requirements. The magic packets that pass the address filtering (unicast or multicast (including broadcast) address) are checked to determine whether they meet the remote wakeup packet data format of 6 bytes of all ones followed by a Unicast MAC Address (that matches the value in MAC Address 0) appearing 16 times.

The application enables the magic packet wakeup by writing 1 to the MGKPKTEN bit of the PMT control status register (ETH_MACPCSR). The PMT block constantly monitors each packet addressed to the node for a specific magic packet pattern. Each packet received is checked for a 48'hFF_FF_FF_FF_FF_FF pattern following the destination and source address field. The PMT block then checks the packet for 16 repetitions of the MAC address without any breaks or interruptions. In case of a break in the 16 repetitions of the address, the PMT block again scans the 48'hFF_FF_FF_FF_FF_FF pattern in the incoming packet. The 16 repetitions can be anywhere in the packet, but must be preceded by the synchronization stream (48'hFF_FF_FF_FF_FF_FF). The device can also accept a multicast packet, as long as the 16 duplications of the MAC address are detected. If the number of repetitions of 8'hFF are more than 6, the PMT block checks for 16 repetitions of the MAC address without any breaks or interruptions, after the last 6 repetitions of 8'hFF.

If the MAC address of a node is 48'h00_11_22_33_44_55, the MAC scans for the following data sequence:

```
Destination Address Source Address ................. FF FF FF FF FF FF
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
...CRC
```

The MAC checks the remote wakeup packet only for length error, FCS error, dribble bit error, receive or collision error. In addition, the remote wakeup packet is checked to ensure
that it is not a runt packet. Even if the remote wakeup packet is more than 512 bytes long, if the packet has a valid CRC value, MAC considers it a valid packet.

The magic packet detection is updated in the \textit{PMT control status register (ETH_MACPCSR)} for the received magic packet. A PMT interrupt to the Application triggers a read to the \textit{PMT control status register (ETH_MACPCSR)} to determine whether a magic packet has been received.

**PMT interrupts**

The PMT interrupt signal is asserted when a valid remote wakeup packet is received.

When software resets the PWRDWN bit in \textit{Remote wakeup packet filter register (ETH_MACRWKPFR)}, the MAC comes out of the power-down mode. This event does not generate the PMT interrupt.

As for EEE mode, a sideband signal, pmt\_intr\_o, is generated together with the wakeup interrupt. It is ORed with lpi\_intr\_o signal (see \textit{Section : LPI Interrupt}) and tied to the EXTI peripheral (line 86).

### 57.7.3 Power-down and wakeup sequence

The recommended Power-down and wakeup sequence is as follows.

1. Disable the Transmit DMA and wait for any previous packet transmissions to complete. These transmissions can be detected when Transmit Interrupt (bit 0 of the ETH\_DMACSR register) is received.

2. Disable the MAC transmitter and MAC receiver by clearing the corresponding bits (0 and 1) in the MAC Configuration register (ETH\_MACCR).

3. Wait until the Receive DMA empties all the packets from the Rx FIFO to system memory. This can be done by reading the corresponding Debug register bits in the DMA (ETH\_DMADSR) and MTL (ETH\_MTLTXQDR and ETH\_MTLRXQDR).

4. Enable Power-down mode by appropriately configuring the PMT registers ETH\_MACPCSR and ETH\_MACRWKPFR.

5. Enable the MAC Receiver and enter Power-down mode.

6. When receiving a valid remote wakeup packet, the Ethernet peripheral asserts the pmt\_intr\_o signal and exits Power-down mode.

7. Read the PMT Status register to clear the interrupt, then enable the other modules in the system and resume normal operation.
57.8 Ethernet interrupts

The Ethernet peripheral generates a single interrupt signal (eth_sbd_intr_it). This signal can be raised as a result of various events. These events are captured in status registers and interrupt enables are provided for each source of interrupt such that the interrupt signal is asserted for an event only when the corresponding interrupt enable is set.

The interrupt status and corresponding enable registers are organized in a hierarchical manner so that it is easier for software to traverse and identify the source of interrupt event quickly. When interrupt is asserted, the Interrupt status register (ETH_DMAISR) register is first level that indicates the major blocks for the interrupt event source. This register is read-only, and it contains bits corresponding to each DMA channel (TX & RX pair), the MTL, and the MAC. The software application must then read one (or more) of the following registers corresponding to the bits that are set:

- ETH_DMACSR: Channel Status (see Channel status register (ETH_DMACSR))
- ETH_MTLISR: Interrupt Status (see Interrupt status Register (ETH_MTLISR))
- ETH_MACISR: Interrupt Status (see Interrupt status register (ETH_MACISR))

57.8.1 DMA interrupts

Interrupt registers description

The ETH_DMACSR: Channel Status register (see Channel status register (ETH_DMACSR)) captures all the interrupt events of that TxDMA and RxDMA channel. The ETH_DMACIER: Channel Interrupt Enable register (see Channel interrupt enable register (ETH_DMACIER)) contains the corresponding enable bits for each of the interrupt event.

There are two groups of interrupts in the DMA channel namely Normal and Abnormal interrupts. They are indicated by Bits[15:14] of ETH_DMACSR register respectively. The normal group is for events that happen during the normal transfer of packets (TI: transmit interrupt, RI: receive interrupt, TBU: Transmit buffer unavailable) while the abnormal interrupt events are for error events.

Interrupts are not queued. If the same interrupt event occurs again before the driver responds to the previous one, no additional interrupts are generated. An interrupt is generated only once for multiple events. The driver must scan the Interrupt status register (ETH_DMAISR) for the cause of the interrupt and clear the source in the respective Status register. The interrupt is cleared only when all the bits of Interrupt status register (ETH_DMAISR) are cleared.

Periodic scheduling of Transmit and Receive Interrupt

It is not preferable to generate interrupts for every packet transferred by DMA (RI and TI) for system throughput performance reasons. The Ethernet peripheral gives the flexibility to schedule the interrupt at regular intervals using two methods:

1. Set Interrupt on Completion bit in Transmit descriptor (TDES2[31] in Table 530: TDES2 normal descriptor (read format)) once for every “required” number of packets to be transmitted.

2. Similarly, set the IOC (RDES3[30] in Table 543: RDES3 normal descriptor (read format)) bit only at some specific intervals of Receive descriptors. This way, whenever a received packet transfer to system memory is complete and any of the descriptors used for that packet transfer has the IOC bit set, only then the RI event is generated.
In addition to above, an interrupt timer (ETH_DMACRXIWTR: Channel Rx Interrupt Watchdog Timer) is given for flexible control and periodic scheduling of Receive Interrupt. When this interrupt timer is programmed with a nonzero value, it gets activated as soon as the Rx DMA completes a transfer of a received packet to system memory without asserting the Receive Interrupt because the corresponding interrupt of completion IOC bit (RDES3[30] in Table 543: RDES3 normal descriptor (read format)) is not set. When this timer runs out as per the programmed value, RI bit is set and the interrupt is asserted if the corresponding RIE is enabled in ETH_DMACIER register (see Channel interrupt enable register (ETH_DMACIER)). The timer is stopped and cleared before it expires, if the RI is set for a packet transfer whose descriptor’s IOC was set. The timer is reactivated automatically after the next packet transfer is complete without the RI event being generated.

**Channel Transfer Complete Interrupt**

The Transmit Transfer complete interrupt (TI) and Receive Transfer complete interrupt (RI) is reflected in the Channel Status register (Channel status register (ETH_DMACSR)). The TI bit is set whenever the Tx DMA channel closes the descriptor in which the IOC bit is set (Interrupt On Completion - TDES2[31]). Similarly, the RI bit is set whenever the Rx DMA channel closes the descriptor with the LD bit set and, in any of the descriptors used for transferring that packet, IOC bit is set (Interrupt Enable on completion - RDES3[30]).

The interrupt signal is asserted for the Transfer complete interrupts only when the corresponding interrupts are enabled in the channel interrupt enable register (Channel interrupt enable register (ETH_DMACIER)).

The behavior of the RI/TI interrupts changes depending on the settings of INTM field (bit[17:16]) in the ETH_DMAMR register (DMA mode register (ETH_DMAMR)). Table 527 explains the behavior of the Transfer Complete interrupt.

<table>
<thead>
<tr>
<th>Interrupt Mode</th>
<th>Behavior of TI/RI and interrupt signal</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTM=0</td>
<td>The TI/RI status signals are set whenever the Transfer complete event is detected. These bits are cleared whenever the software driver writes 1 to these bits. The interrupt signal is asserted whenever the corresponding interrupts are also enabled in ETH_DMACIER register.</td>
</tr>
<tr>
<td>INTM=1</td>
<td>The TI/RI is set as explained above. However, the interrupt is not asserted for any RI/TI event.</td>
</tr>
<tr>
<td>INTM=2</td>
<td>The RI/TI status bits are set whenever the Transfer Complete event is detected and are reset whenever software driver clears them by writing 1. However, if another Transfer complete event is detected before it is cleared (serviced) by the software, then these status bits are automatically set again. However, the interrupt is not generated based on TI/RI.</td>
</tr>
</tbody>
</table>

**57.8.2 MTL interrupts**

MTL interrupt events are combined with the events in the DMA to generate the interrupt signal.
The register **Interrupt status Register (ETH_MTLISR)** report the queue number responsible for the event. ETH_MTLQICSR: Queue Interrupt Control Status shall be read for event description.

The MTL interrupts are enabled by default. Each event can be prevented from asserting the interrupt by setting the corresponding mask bits in the **Interrupt status Register (ETH_MTLISR)** register.

MTL interrupt signal is driven by one of these events:
- Receive Queue Overflow Interrupt
- Transmit Queue Underflow

### 57.8.3 MAC Interrupts

MAC interrupt events are combined with the events in the DMA to generate the interrupt signal.

The MAC interrupts are of level type, that is, the interrupt remains asserted (high) until it is cleared by the application or software.

The **Interrupt status register (ETH_MACISR)** describes the events that can cause an interrupt from the MAC. The MAC interrupts are enabled by default. Each event can be prevented from asserting the interrupt by setting the corresponding mask bits in the **Interrupt status register (ETH_MACISR)**.

The interrupt register bits only indicate the block from which the event is reported. You must read the corresponding status registers and other registers to clear the interrupt.

MAC interrupt signal is driven by one of these events:
- Receive Status Interrupt
- Transmit Status Interrupt
- Timestamp Interrupt Status
- MMC Interrupt Status
  - MMC Receive Checksum Offload Interrupt Status
  - MMC Transmit Interrupt Status
  - MMC Receive Interrupt Status
- LPI Interrupt Status
- PMT Interrupt Status
- PHY Interrupt

**Note:** Two sidebands signals are generated together with LPI and PMT interrupts: lpi_intr_o and pmt_intr_o. They are used for wakeup event detection at EXTI level.
57.9 Ethernet programming model

This chapter provides the instructions for initializing the DMA or MAC registers in the proper sequence. It contains the following sections:

- DMA initialization (see Section 57.9.1)
- MTL initialization (see Section 57.9.2)
- MAC initialization (see Section 57.9.3)
- Performing Normal Receive and Transmit Operation (see Section 57.9.4)
- Stopping and Starting Transmission (see Section 57.9.5)
- Programming Guidelines for MII Link State Transitions (see Section 57.9.6)
- Programming Guidelines for Energy Efficient Ethernet (see Section 57.9.7)
- Programming Guidelines for flexible pulse-per-second (PPS) output (see Section 57.9.8)
- Programming Guidelines for VLAN filtering on Receive (see Section 57.9.9)
- Programming Guidelines for TSO (see Section 57.9.10)
- Programming Guidelines for IEEE 1588 Timestamping (see Section 57.9.11)

57.9.1 DMA initialization

Complete the following steps to initialize the DMA:

1. Provide a software reset to reset all MAC internal registers and logic (bit 0 of DMA mode register (ETH_DMAMR)).
2. Wait for the completion of the reset process (poll bit 0 of the DMA mode register (ETH_DMAMR), which is cleared when the reset operation is completed).
3. Program the following fields to initialize the System bus mode register (ETH_DMASBMR):
   a) AAL
   b) Fixed burst or undefined burst
   c) Burst mode values in case of AHB bus interface.
   d) If fixed length value is enabled, select the maximum burst length possible on the AXI Bus (bits [7:1])
4. Create a transmit and a receive descriptor list. In addition, ensure that the receive descriptors are owned by the DMA (set bit 31 of TDES3/RDES3 descriptor). For more information on descriptors, refer to Section 57.10: Descriptors.
   Note: Descriptor address from start to end of the ring should not cross the 4GB boundary.
5. Program ETH_DMACRXLRLR and ETH_DMCTRXLRLR registers (see Channel Tx descriptor ring length register (ETH_DMACRXLRLR) and Channel Rx descriptor ring length register (ETH_DMCTRXLRLR)). The programmed ring length must be at least 4.
6. Initialize receive and transmit descriptor list address with the base address of transmit and receive descriptor (Channel Tx descriptor list address register (ETH_DMACRXLRLAR), Channel Rx descriptor list address register (ETH_DMCTRXLRLAR)). In addition, program the transmit and receive tail pointer registers that inform the DMA about the available descriptors (see Channel Tx
7. Program ETH_DMACCR, ETH_DMACTXCR and ETH_DMACRXCR registers (see Channel control register (ETH_DMACCR) and Channel transmit control register (ETH_DMACTXCR)) to configure the parameters such as the maximum burst-length (PBL) initiated by the DMA, descriptor skip lengths, OSP for TxDMA, RBSZ for RxDMA.

8. Enable the interrupts by programming the ETH_DMACIER register (see Channel interrupt enable register (ETH_DMACIER)).

9. Start the Receive and Transmit DMAs by setting SR (bit 0) of Channel receive control register (ETH_DMACRXCR) and ST (bit 0) of the ETH_DMACTXCR (see Channel transmit control register (ETH_DMACTXCR)).

57.9.2 MTL initialization

Complete the following steps to initialize the MTL registers:

1. Program the following fields to initialize the operating mode in the ETH_MTLTXQOMR (see Tx queue operating mode Register (ETH_MTLTXQOMR)).
   a) Transmit Store And Forward (TSF) or Transmit Threshold Control (TTC) if the Threshold mode is used.
   b) Transmit Queue Enable (TXQEN) to value 2'b10 to enable Transmit Queue 0.
   c) Transmit Queue Size (TQS).

2. Program the following fields to initialize the operating mode in the ETH_MTLRXQOMR register (see Rx queue operating mode register (ETH_MTLRXQOMR)):
   a) Receive Store and Forward (RSF) or RTC if Threshold mode is used.
   b) Flow Control Activation and De-activation thresholds for MTL Receive FIFO (RFA and RFD).
   c) Error Packet and undersized good Packet forwarding enable (FEP and FUP).
   d) Receive Queue Size (RQS).

57.9.3 MAC initialization

The following MAC Initialization operations can be performed after DMA initialization. If the MAC initialization is complete before the DMA is configured, enable the MAC receiver (last step in the following sequence) only after the DMA is active. Otherwise, received frames fill the Rx FIFO and overflow.

1. Provide the MAC address registers: Address x low register (ETH_MACAxLR) and Address 0 high register (ETH_MACA0HR). If more than one MAC address is enabled in your configuration (up to 3 additional addresses), program the MAC addresses appropriately.

2. Program the following fields to set the appropriate filters for the incoming frames in the Packet filtering control register (ETH_MACPFR):
   a) Receive All.
   b) Promiscuous mode.
   c) Hash or Perfect Filter.
   d) Unicast, multicast, broadcast, and control frames filter settings.

3. Program the following fields for proper flow control in the Tx Queue flow control register (ETH_MACQTXFCR):
a) Pause time and other Pause frame control bits.
b) Transmit Flow control bits.
c) Flow Control Busy.
4. Program the Interrupt enable register (ETH_MACIER) as required, if it is applicable for your configuration.
5. Program the appropriate fields in the Operating mode configuration register (ETH_MACCR) register.
   For example: Inter-packet gap while transmission and jabber disable.
6. Set bit 0 and 1 in Operating mode configuration register (ETH_MACCR) register to start the MAC transmitter and receiver.

57.9.4 Performing normal receive and transmit operation

For normal operation, complete the following steps:
1. For normal transmit and receive interrupts, read the interrupt status. Then, poll the descriptor by reading the status of the descriptor owned by the Host (either transmit or receive).
2. Set the descriptors to appropriate values. Make sure that transmit and receive descriptors are owned by the DMA to resume the transmission and reception of data.
3. If the descriptors are not owned by the DMA (or no descriptor is available), the DMA goes into Suspend state. The transmission or reception can be resumed by freeing the descriptors and writing the ETH_DMACTXDTPR (see Channel Tx descriptor tail pointer register (ETH_DMACTXDTPR) and ETH_DMACRXDTPR (see Channel Rx descriptor tail pointer register (ETH_DMACRXDTPR)).
4. In debug mode, the values of the current host transmitter or receiver descriptor address pointer can be read in ETH_DMACCATXDR and ETH_DMACCARXDR registers (see Channel current application transmit descriptor register (ETH_DMACCATXDR) and Channel current application receive descriptor register (ETH_DMACCARXDR)).
5. In debug mode, the values of the current host transmit buffer address pointer and receive buffer address pointer can be read in ETH_DMACCATXDR and ETH_DMACCARXDR registers (see Channel current application transmit descriptor register (ETH_DMACCATXDR) and Channel current application receive descriptor register (ETH_DMACCARXDR)).
57.9.5 Stopping and starting transmission

Complete the following steps to pause the transmission for some time:

1. Disable the Transmit DMA (if applicable) by clearing Bit 0 (ST) of ETH_DMACTXCR register (see Channel transmit control register (ETH_DMACTXCR)).
2. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of ETH_MTLTXQDR register (TRCSTS is not 01 and TXQSTS=0).
3. Disable the MAC transmitter and MAC receiver by clearing Bit (RE) and Bit 1(TE) of the Operating mode configuration register (ETH_MACCR) Register.
4. Disable the Receive DMA (if applicable), after making sure that the data in the Rx FIFO is transferred to the system memory (by reading the appropriate bits of Tx queue debug Register (ETH_MTLTXQDR), PRXQ=0 and RXQSTS=0).
5. Make sure that both Tx queue and Rx queue are empty (TXQSTS is 0 in Tx queue debug Register (ETH_MTLTXQDR) and RXQSTS is set to 0.
6. To restart the operation, first start the DMAs, and then enable the MAC Transmitter and Receiver.

57.9.6 Programming guidelines for MII link state transitions

Transmit and Receive clocks are running when the link is down

Complete the following steps when the link is down while the Transmit and Receive clocks are running:

1. Disable the Transmit DMA (if applicable) by clearing bit 0 (ST) of Channel control register (ETH_DMACC)R.
2. Disable the MAC receiver by clearing bit 2 (RE) of Operating mode configuration register (ETH_MACCR).
3. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of Tx queue debug Register (ETH_MTLTXQDR) (TRCSTS is not 01).
   or
   Flush the Tx FIFO for faster empty operation.
4. Disable the MAC transmitter by clearing Bit 1(TE) of the Operating mode configuration register (ETH_MACCR) Register.
5. Make sure that both Tx and Rx queues are empty (TXQSTS is set to 0 in Tx queue debug Register (ETH_MTLTXQDR) and RXQSTS to 0 in Rx queue debug register (ETH_MTLRXQDR)).
6. After the link is up, read the PHY registers to identify the latest configuration and program the MAC registers accordingly.
7. Restart the operation by starting the Tx DMA. Then enable the MAC Transmitter and Receiver.
   The Rx DMA does not need to be enabled: since the Receiver is disabled, there are no data in the Rx FIFO.
Transmit and Receive clocks are stopped when the link is down

Complete the following steps when the link is down and the Transmit and Receive clocks are stopped:

1. Disable the MAC Transmitter and Receiver by clearing RE and TE bits in the Operating mode configuration register (ETH_MACCR). This will not take immediate effect as the clocks are absent.
2. Wait till the link is up and the clocks are restored.
3. Wait until the transfer of any partial frame is complete if any was ongoing when the Transmit/Receive clock is stopped. This can be checked by reading the Debug register (ETH_MACDR) (all bits should be set to 0). Some old packets may still remain in the TXFIFO as the MAC Transmitter is stopped.
4. Read the PHY registers to identify the latest operating mode and program the MAC registers accordingly.
5. Restart the MAC Transmitter and Receiver by setting RE and TE bits.

57.9.7 Programming guidelines for IEEE 1588 timestamping

Initializing the System time generation

The timestamp feature can be enabled by setting bit 0 of the Timestamp control Register (ETH_MACTSCR). However, it is essential that the timestamp counter is initialized after this bit is set. Complete the following steps to perform the peripheral initialization:

1. Mask the Timestamp Trigger interrupt by clearing bit 16 of Interrupt enable register (ETH_MACIER).
2. Set bit 0 of Timestamp control Register (ETH_MACTSCR) to enable timestamping.
3. Program Sub-second increment register (ETH_MACSSIR) based on the PTP clock frequency.
4. If you use the Fine Correction method, program Timestamp addend register (ETH_MACTSAR) and set bit 5 of Timestamp control Register (ETH_MACTSCR).
5. Poll the Timestamp control Register (ETH_MACTSCR) until bit 5 is cleared.
6. Program bit 1 of Timestamp control Register (ETH_MACTSCR) to select the Fine Update method (if required).
7. Program System time seconds update register (ETH_MACSTSUR) and System time nanoseconds update register (ETH_MACSTNUR) with the appropriate time value.
8. Set bit 2 in Timestamp control Register (ETH_MACTSCR).

The timestamp counter starts as soon as it is initialized with the value written in the Timestamp Update registers. If one-step timestamping is required:

a) Enable one-step timestamping by programming bit 27 of the TDES3 Context Descriptor.

b) Program Timestamp Ingress asymmetric correction register (ETH_MACTSIACR) to update the correction field in PDelay_Req PTP messages.

9. Enable the MAC receiver and transmitter for proper timestamping.

Note: If timestamp operation is disabled by clearing bit 0 of Timestamp control Register (ETH_MACTSCR), repeat all these steps to restart the timestamp operation.
System time correction

To synchronize or update the system time in one shot (coarse correction method), complete the following steps:

1. Set the offset (positive or negative) in the Timestamp Update registers (System time seconds update register (ETH_MACSTSUR) and System time nanoseconds update register (ETH_MACSTNUR)).
2. Set bit 3 (TSUPDT) of the Timestamp control Register (ETH_MACTSCR).

The value in the Timestamp Update registers is added to or subtracted from the system time when the TSUPDT bit is cleared.

To synchronize or update the system time to reduce system-time jitter (fine correction method), complete the following steps:

1. With the help of the algorithm described in Section : System time register module, calculate at which rate you intend increment or decrement the system time.
2. Update the Timestamp addend register (ETH_MACTSAR) with the new value and set bit 5 of the Timestamp control Register (ETH_MACTSCR) Register.
3. Wait for the time during which you want the new value of the Addend register to be active. This can be done by enabling the Timestamp Trigger interrupt after the system time reaches the target value.
4. Program the required target time in PPS target time seconds register (ETH_MACPPSTTSR) and PPS target time nanoseconds register (ETH_MACPPSTTNR).
5. Enable the Timestamp interrupt in bit 12 of Interrupt enable register (ETH_MACIER).
6. Set bit 4 in Register Timestamp control Register (ETH_MACTSCR).
7. When this trigger generates an interrupt, read Interrupt status register (ETH_MACISR).
8. Reprogram Timestamp addend register (ETH_MACTSAR) with the old value and set bit 5 again.

57.9.8 Programming guidelines for Energy Efficient Ethernet (EEE)

Entering and exiting Tx LPI mode

Complete the following steps during MAC initialization:

1. Read the PHY register through the MDIO interface and check if the remote end has the EEE capability. Then negotiate the timer values.
2. Program the PHY registers through the MDIO interface (including the RX_CLK_stoppable bit that indicates to the PHY whether to stop Rx clock in LPI mode or not).
3. Program bits 25 to 16 and bits 1 to 0 in LPI timers control register (ETH_MACLTCTR).
4. Read the PHY link status by using the MDIO interface and update bit 17 of LPI control status register (ETH_MACLCSR).
5. Update LPI control status register (ETH_MACLCSR) accordingly. This update should be done whenever the link status in the PHY chip changes.
6. Program 1-microsecond-tick counter register (ETH_MAC1USTCR) as per the frequency of the clock used for accessing the CSR slave port.
7. Program the LPIET bit in the LPI entry timer register (ETH_MACLETR) with the IDLE time for which the MAC should wait before entering the LPI state on its own.
8. Set LPITE and LPITXA (bits 20 to 19) of LPI control status register (ETH_MACLCSR).
9. Update LPI control status register (ETH_MACLCSR) to enable LPI auto-entry and MAC auto-exit from LPI state.
10. Program the 1-microsecond-tick counter register (ETH_MAC1USTCR) according to the frequency of the clock used to access the CSR slave port.
11. Program the LPIET bit in LPI entry timer register (ETH_MACLETR) register with the IDLE time for which the MAC should wait before entering the LPI state on its own.
12. Set LPITE and LPITXA (bits 20 and 19) of LPI control status register (ETH_MACLCSR) to enable LPI auto-entry and MAC auto-exit from LPI state.
13. Set bit 16 of LPI control status register (ETH_MACLCSR) to put the MAC transmitter in LPI state.
   The MAC enters the LPI state when all scheduled packets are completed. It remains IDLE for the time indicated by LPIET bits. It sets the TLPIEN (bit 0) after entering LPI state.
14. When a packet transmission is scheduled (when the TxDMA exits IDLE state or when a packet is presented at ATi or MTi interface), the MAC Transmitter automatically exits the LPI state. It waits for TWT time before setting the TLPIEX interrupt status bit and then resume the packet transmission.
15. The MAC Transmitter enters again LPI state if it remains IDLE for LPIET time. It then sets the TLPIEN bit and the entry-exit cycle continues.
16. Reset LPITXEN bit if the application needs to override the auto-entry/exit modes and directly exit the MAC Transmitter from LPI state.

57.9.9 Programming guidelines for flexible pulse-per-second (PPS) output

Generating a single pulse on PPS

To generate a single pulse on PPS:
1. Program TRGTMODSEL bit to 11 or 10 (for interrupt) in PPS control register [alternate] (ETH_MACPPSCR). This instructs the MAC to use the Target Time registers (register 736 and 737) as start time of PPS signal output.
2. Program the start time value in the Target Time registers (register 736 and 737).
3. Program the width of the PPS signal output in PPS width register (ETH_MACPPSWR) Register.
4. Program PPSCMD of PPS control register [alternate] (ETH_MACPPSCR) to 0001. This instructs the MAC to generate a single pulse on the PPS signal output at the time programmed in the Target Time registers.

When the PPSCMD is executed (PPSCMD bits = 0), you can cancel the pulse generation by giving the Cancel Start Command (PPSCMD=0011) before the programmed start time has elapsed. You can also program the behavior of the next pulse in advance. To program the next pulse:
1. Program the start time for the next pulse in the Target Time registers. This time should be higher than the time at which the falling edge occurs for the previous pulse.
2. Program the width of the next PPS signal output in PPS width register (ETH_MACPPSWR).
3. Program PPSCMD bits of PPS control register [alternate] (ETH_MACPPSCR) to generate a single pulse after the previous pulse is de-asserted. This instructs the MAC
to generate a single pulse on the PPS signal output at the time programmed in Target Time registers.

If this command is given before the previous pulse becomes low, then the new command overwrites the previous command and the QOS may generate only 1 extended pulse.

**Generating a pulse train on PPS**

To generate a pulse train on PPS:

1. Program TRGTMODSEL bits to 11 or 10 (for interrupt) in **PPS control register [alternate] (ETH_MACPPSCR)**. This instructs the MAC to use the Target Time registers (register 736 and 737) for start time of the PPS signal output.

2. Program the start time value in the Target Time registers (register 736 and 737).

3. Program the interval value between the train of pulses on the PPS signal output in **PPS interval register (ETH_MACPPSIR)**.

4. Program the width of the PPS signal output in **PPS width register (ETH_MACPPSWR)**.

5. Program PPSCMD bits in **PPS control register [alternate] (ETH_MACPPSCR)** to 0010. This instructs the MAC to generate a train of pulses on the PPS signal output at the start time programmed in Target Time registers.

   By default, the PPS pulse train is free-running unless it is stopped by issuing a ‘STOP Pulse train at time’ or ‘STOP Pulse Train immediately’ commands.

6. Program the stop value in the Target Time registers. Ensure that TSTRBUSY bit in **PPS target time nanoseconds register (ETH_MACPPSTTNR)** is reset before programming the Target Time registers again.

7. Program the PPSCMD bits in **PPS control register [alternate] (ETH_MACPPSCR)** to 0100 to stop the train of pulses on PPS signal output after the programmed stop time specified at step 6 has elapsed.

The pulse train can be stopped at any time by programming 0101 in the PPSCMD field.

Similarly, the Stop Pulse train command (given in Step 5) can be canceled by programming PPSCMD bits to 0110 before the time (programmed at step 6) has elapsed.

The pulse train generation can be stopped by programming PPSCMD to 0011 before the start time programmed at step 2) has elapsed.

**Generating an interrupt without affecting the PPS**

TRGTMODSEL bits in **PPS control register [alternate] (ETH_MACPPSCR)** enable you to program the Target Time registers (register 736 and 737) to do any one of the following:

- Generate only interrupts.
- Generate interrupts and the PPS start and stop time.
- Generate only PPS start and stop time.
To program the Target Time registers to generate only interrupt event:

1. Program TRGTMODSEL bits of **PPS control register [alternate] (ETH_MACPPSCR)** to 00 (for interrupt). This instructs the MAC to use the Target Time registers for target time interrupt.

2. Program a target time value in the Target Time registers. This instructs the MAC to generate an interrupt when the target time elapses.

   If TRGTMODSEL bits are changed (for example, to control the PPS), then the interrupt generation is overwritten with the new mode and new programmed Target Time register value.

### 57.9.10 Programming guidelines for TSO

Follow the steps below to program TSO:

1. Program TSE bit of the corresponding ETH_DMACTXCR register to enable TCP packet segmentation in that DMA.

2. In addition to the normal transfer descriptor setting, the following descriptor fields must be programmed to enable TSO for the current packet:
   a) Enable TSE of TDES3 (bit 18).
   b) Program the length of the unsegmented TCP/IP packet payload in bits 17 to 0 of TDES3, and the TCP header in bits 22 to 19 of TDES3.
   c) Program the maximum size of the segment in:
      - MSS of ETH_DMACCR
      - or MSS in the context descriptor
      
      If MSS field is programmed in both ETH_DMACCR and in the context descriptor, the latest software programmed sequence is considered.

3. The unsegmented TCP/IP packet header should be stored in Buffer 1 of the first descriptor. This buffer must not hold any payload bytes. The payload is allocated to Buffer 2 and the buffers of the subsequent descriptors.

**Caution:** If TSE is enabled in TDES3 for a non-TCP-IP packet, the result is unpredictable.

### 57.9.11 Programming guidelines to perform VLAN filtering on the receive

Follow the sequence below to perform VLAN filtering on the receiver:

1. Program **VLAN tag register (ETH_MACVTR)** for the following bit to select the filtering method:
   - ETV: Enable 12-bit VLAN Tag Comparison or 16-bit VLAN Tag comparison.
   - VTHM: VLAN Tag Hash Table Match Enable.
   - ERIVLT: Enable inner VLAN Tag or outer VLAN Tag (to enable the inner or outer VLAN Tag filtering, Double VLAN Processing should enabled by setting EDVLP)
   - ERSVLM: Enable Receive S-VLAN Match or C-VLAN match (for S-VLAN processing to be enabled, set ESVL)
   - DOVLTC: Ignores VLAN Type for Tag Match
   - VTIM: to enable VLAN Tag Inverse Match instead of the normal VLAN Tag matching

2. Program VL bit in **VLAN tag register (ETH_MACVTR)** for the 12-bit or 16-bit VLAN tag.

3. If VLAN tag Hash filtering is enabled, program **VLAN Hash table register (ETH_MACVHTR)**. The upper four bits of the calculated CRC are used to index the
contents of the VLAN Hash table. For example, a Hash value of ‘1000 selects bit 8 of
the VLAN Hash table.

57.10 Descriptors

57.10.1 Descriptor overview
In the Ethernet peripheral, the DMA transfers data based on a linked list of descriptors. The
application creates the descriptors in the system memory (SRAM). The following two types
of descriptors are supported:

- Normal descriptors
  The normal descriptors are used for packet data and to provide control information
  applicable to the packets to be transmitted.

- Context descriptors
  The context descriptors are used to provide control information applicable to the packet
to be transmitted.

Each normal descriptor contains two buffers and two address pointers. These buffers
enable the adapter port to be compatible with various types of memory management
schemes.

There is no limit to the number of descriptors that can be used for a single packet.

57.10.2 Descriptor structure

The Ethernet peripheral supports the ring structure for DMA descriptors.

![Descriptor ring structure](MSv40392V1)
In a ring structure, descriptors are separated by the 32-bit word number programmed in the DSL field of the Channel control register (ETH_DMACCR). The application needs to program the total ring length, that is the total number of descriptors in ring span, in the following registers of a DMA channel:

- Channel Tx descriptor ring length register (ETH_DMACTXRLR)
- Channel Rx descriptor ring length register (ETH_DMACRXRLR)

The Channel Tx descriptor tail pointer register (ETH_DMACTXDTPR) or Channel Rx descriptor tail pointer register (ETH_DMACRXDTPR) contains the pointer to the descriptor address (N). The base address and the current descriptor pointer decide the address of the current descriptor that the DMA can process. The descriptors up to one location less than the one indicated by the descriptor tail pointer (N – 1) are owned by the DMA. The DMA continues to process the descriptors until the following condition occurs:

```
Current Descriptor Pointer == Descriptor Tail Pointer;
```

The DMA enters the Suspend state when this condition occurs. The application must perform a write operation to the Descriptor tail pointer register and update the tail pointer so that the following condition is met:

```
Current Descriptor Pointer < Descriptor Tail Pointer;
```

The DMA automatically wraps around the base address when the end of ring is reached, as shown in Figure 798: DMA descriptor ring.

**Figure 798. DMA descriptor ring**

For descriptors owned by the application, the OWN bit of DES3 is reset to 0.

For descriptors owned by the DMA, the OWN bit is set to 1.

At the beginning, if the application has only one descriptor, it sets the last descriptor address (tail pointer) to Descriptor Base Address + 1. The DMA then processes the first descriptor and waits for the application to increment the tail pointer.
57.10.3 Transmit descriptor

The Ethernet peripheral DMA requires at least one descriptor for a transmit packet. In addition to two buffers, two byte-count buffers, and two address pointers, the transmit descriptor features control fields which can be used to manage the MAC operation on per-transmit packet basis. The Transmit normal descriptor has the following two formats: Read format and Write-back format.

Transmit normal descriptor (read format)

*Figure 799* shows the Read format for Transmit normal descriptor. *Table 528* to *Table 531* provide a detailed description of all Transmit normal descriptors (read format).

*Figure 799. Transmit descriptor (read format)*

![Transmit descriptor (read format)](image)

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| 29   | FD   | First Descriptor  
This bit indicates that the buffer contains the first segment of a packet. |
| 28   | LD   | Last Descriptor  
This bit is set 1 for last descriptor of a packet. The DMA writes the status fields only in the last descriptor of the packet. |
| 27:18 | Reserved | |
| 17   | TTSS | Tx Timestamp Status  
This status bit indicates that a timestamp has been captured for the corresponding transmit packet. When this bit is set, TDES2 and TDES3 have timestamp values that were captured for the Transmit packet. This field is valid only when the Last Segment control bit (TDES3 [28]) in a descriptor is set. |
| 16   | Reserved | |
| 15   | ES   | Error Summary:  
This bit indicates the logical OR of the following bits:  
– TDES3[0]: IP Header Error  
– TDES3[14]: Jabber Timeout  
– TDES3[13]: Packet Flush  
– TDES3[12]: Payload Checksum Error  
– TDES3[11]: Loss of Carrier  
– TDES3[10]: No Carrier  
– TDES3[9]: Late Collision  
– TDES3[8]: Excessive Collision  
– TDES3[3]: Excessive Deferral  
– TDES3[2]: Underflow Error |
| 14   | JT   | Jabber Timeout  
This bit indicates that the MAC transmitter has experienced a jabber timeout. This bit is set only when the JD bit of the Operating mode configuration register (ETH_MACCR) is not set. |
| 13   | FF   | Packet Flushed  
This bit indicates that the DMA or MTL flushed the packet because of a software flush command given by the CPU. |
| 12   | PCE  | Payload Checksum Error  
This bit indicates that the Checksum Offload engine had a failure and did not insert any checksum into the encapsulated TCP, UDP, or ICMP payload. This failure can be either caused by insufficient bytes, as indicated by the Payload Length field of the IP Header, or by the MTL starting to forward the packet to the MAC transmitter in Store-and-Forward mode without the checksum having been calculated yet. This second error condition only occurs when the Transmit FIFO depth is less than the length of the Ethernet packet being transmitted to avoid deadlock, the MTL starts forwarding the packet when the FIFO is full, even in the store-and-forward mode. |
Loss of Carrier
This bit indicates that Loss of Carrier occurred during packet transmission (that is, the ETH_CRS signal was inactive for one or more transmit clock periods during packet transmission). This is valid only for the packets transmitted without collision and when the MAC operates in the half-duplex mode.

No Carrier
This bit indicates that the carrier sense signal from the PHY was not asserted during transmission.

Late Collision
This bit indicates that packet transmission was aborted because a collision occurred after the collision window (64 byte times including Preamble. This bit is not valid if Underflow Error is set.

Excessive Collision
This bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the Operating mode configuration register (ETH_MACCR), this bit is set after first collision and the transmission of the packet is aborted.

Collision Count
This 4-bit counter value indicates the number of collisions occurred before the packet was transmitted. The count is not valid when the EC bit is set.

Excessive Deferral
This bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times if DC bit is set in the Operating mode configuration register (ETH_MACCR).

Underflow Error
This bit indicates that the MAC aborted the packet because the data arrived late from the system memory. The underflow error can occur because of either of the following conditions:

- The DMA encountered an empty Transmit Buffer while transmitting the packet
- The application filled the MTL Tx FIFO slower than the MAC transmit rate

The transmission process enters the Suspend state and sets the underflow bit corresponding to a queue in the ETH_MTLISR register.

Deferred Bit
This bit indicates that the MAC deferred before transmitting because of presence of carrier. This bit is valid only in the half-duplex mode.

IP Header Error
When IP Header Error is set, this bit indicates that the Checksum Offload engine detected an IP header error. This bit is valid only when Tx Checksum Offload is enabled. Otherwise, it is reserved. If COE detects an IP header error, it still inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload.
1. This format is only applicable to the last descriptor of a packet.

**Transmit context descriptor**

The Transmit context descriptor can be provided any time before a packet descriptor. The context is valid for the current packet and subsequent packets. The context descriptor is used to provide the timestamps for one-step timestamp correction, VLAN Tag ID for VLAN insertion feature, and SA insertion bit for SA insertion. Write-back is only done on a context descriptor to reset the OWN bit.

*Note:* The VLAN tag IDs and MSS values, which are provided by the application in a context descriptor with their corresponding Valid bits set, are stored internally by the DMA.

When the outer or inner VLAN tag is provided with the Valid bit set, the DMA always passes the last valid VLAN tag to the MTL. The application cannot invalidate the valid VLAN tag stored by the DMA. The VLAN tag is inserted or replaced based on the control inputs provided for the packet.

The Inner VLAN Tag Control input is used only for the packet that immediately follows the context descriptor. The application must provide a context descriptor before the normal descriptor of each packet for which the DMA should use the inner VLAN Tag control input.

*Figure 801* shows the format for Transmit context descriptors. *Table 536* to *Table 539* provide a detailed description of all Transmit context descriptors.

57.10.4 Receive descriptor

The DMA in the Ethernet peripheral attempts to read a descriptor only if the Tail pointer is different from the Base pointer or current pointer. It is recommended to have a descriptor ring with a length that can accommodate at least two complete packets received by the MAC; otherwise, the performance of the DMA is greatly impacted because of the unavailability of the descriptors. In such a situation, the MTL RxFIFO becomes full and starts dropping packets.

The following Receive descriptors are present:
- Normal descriptors with read and write-back formats
- Context descriptors

All received descriptors are prepared by the software and given to the DMA as “normal” descriptors (see Figure 802: Receive normal descriptor (read format) for a description of their content). The DMA reads this descriptor and, after transferring a received packet (or part of it) to the buffers indicated by the descriptor, the Rx DMA closes the descriptor with the corresponding packet status. The status format is given in Figure 803: Receive normal descriptor (write-back format).

For some packets, the normal descriptor bits are not sufficient to write the complete status. For such packets, the Rx DMA will write the extended status to the next descriptor (without processing or using the Buffers pointers embedded in that descriptor). The format and content of this write-back descriptor is described in Figure 804: Receive context descriptor.

Receive normal descriptor (read format)

Figure 802 shows the read format for Receive normal descriptors. Table 540 to Table 543 provide a detailed description of all Receive normal descriptors (read format).

![Figure 802. Receive normal descriptor (read format)](image)

Note: In the Receive descriptor (read format), if the Buffer Address field contains only 0s, the MAC does not transfer data to this buffer and skips to the next buffer or next descriptor.
- RDES0 normal descriptor (read format)

<tbody>
<tr>
<td>31:0</td>
<td>BUF1AP</td>
<td><strong>Header or Buffer 1 Address Pointer</strong>&lt;br&gt;The application can program a byte-aligned address for this buffer, which means that the LS bits of this field can be non-zero. However, while transferring the start of packet, the DMA performs a write operation with RDES0[1:0] (or RDES0[2:0][3:0] in case of 64-/128-bit configuration) as zero. However, the packet data is shifted by the actual offset as given in the buffer address pointer. If the address pointer points to a buffer where the middle or last part of the packet is stored, the DMA ignores the offset address and writes to the full location as indicated by the data-width.</td>

RM0433 Ethernet (ETH): media access control (MAC) with DMA controller

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| 31:16 | OPC | OAM Sub-Type Code, or MAC Control Packet opcode  
OAM Sub-Type Code  
If bits[18:16] of RDES3 are set to 111, this field contains the OAM sub-type and code fields.  
MAC Control Packet opcode  
If bits[18:16] of RDES3 are set to 110, this field contains the MAC Control packet opcode field. |
| 15 | TD | Timestamp Dropped  
This bit indicates that the timestamp was captured for this packet but got dropped in the MTL Rx FIFO because of overflow. |
| 14 | TSA | Timestamp Available  
When Timestamp is present, this bit indicates that the timestamp value is available in a context descriptor word 2 (RDES2) and word 1(RDES1).  
This is valid only when the Last Descriptor bit (RDES3 [28]) is set. The context descriptor is written in the next descriptor just after the last normal descriptor for a packet. |
| 13 | PV | PTP Version  
1: Received PTP message in IEEE 1588 version 2 format  
0: Received PTP message in IEEE 1588 version 1 format |
| 12 | PFT | PTP Packet Type  
This bit indicates that the PTP message is sent directly over Ethernet. |
| 11:8 | PMT | PTP Message Type  
These bits are encoded to give the type of the message received:  
– 0000: No PTP message received  
– 0001: SYNC (all clock types)  
– 0010: Follow_Up (all clock types)  
– 0011: Delay_Req (all clock types)  
– 0100: Delay_Resp (all clock types)  
– 0101: Pdelay_Req (in peer-to-peer transparent clock)  
– 0110: Pdelay_Resp (in peer-to-peer transparent clock)  
– 0111: Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock)  
– 1000: Announce  
– 1001: Management  
– 1010: Signaling  
– 1011–1110: Reserved  
– 1111: PTP packet with Reserved message type  
These bits are available only when you select the timestamp feature. |

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| 31:29 | L3L4FM   | **Layer 3 and Layer 4 Filter Number Match**  
These bits indicate the number of the Layer 3 and Layer 4 Filter that matched the received packet:  
– 000: Filter 0  
– 001: Filter 1  
– 010: Filter 2  
– 011: Filter 3  
– 100: Filter 4  
– 101: Filter 5  
– 110: Filter 6  
– 111: Filter 7  
This field is valid only when bit 28 or bit 27 is set high. When more than one filter matches, these bits give the number of lowest filter. |
| 28    | L4FM     | **Layer 4 Filter Match**  
When this bit is set, it indicates that the received packet matches one of the enabled Layer 4 Port Number fields. This status is given only when one of the following conditions is true:  
– Layer 3 fields are not enabled and all enabled Layer 4 fields match  
– All enabled Layer 3 and Layer 4 filter fields match  
When more than one filter matches, this bit gives the layer 4 filter status of filter indicated by bits[31:29]. |
| 27    | L3FM     | **Layer 3 Filter Match**  
When this bit is set, it indicates that the received packet matches one of the enabled Layer 3 IP Address fields. This status is given only when one of the following conditions is true:  
– All enabled Layer 3 fields match and all enabled Layer 4 fields are bypassed  
– All enabled filter fields match  
When more than one filter matches, this bit gives the layer 3 filter status of filter indicated by bits[31:29]. |
| 26:19 | MADRM    | **MAC Address Match or Hash Value**  
When the HF bit is reset, this field contains the MAC address register number that matched the Destination address of the received packet. This field is valid only if the DAF bit is reset.  
When the HF bit is set, this field contains the Hash value computed by the MAC. A packet passes the Hash filter when the bit corresponding to the Hash value is set in the Hash filter register. |
| 18    | HF       | **Hash Filter Status**  
When this bit is set, it indicates that the packet passed the MAC address Hash filter. Its[26:19] indicate the Hash value. |
| 17    | DAF      | **Destination Address Filter Fail**  
When this bit is set, it indicates that the packet failed the DA Filter in the MAC. |

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| 31  | OWN  | Own bit  
1: The DMA owns the descriptor.  
0: The application owns the descriptor.  
The DMA clears this bit when either of the following conditions is true:  
– The DMA completes the packet reception  
– The buffers associated with the descriptor are full |
| 30  | CTXT | Receive Context Descriptor  
When this bit is set, it indicates that the current descriptor is a context type descriptor. The DMA writes 0 to this bit for normal receive descriptor. |
| 29  | FD   | First Descriptor  
When this bit is set, it indicates that this descriptor contains the first buffer of the packet. If the size of the first buffer is 0, the second buffer contains the beginning of the packet. If the size of the second buffer is also 0, the next descriptor contains the beginning of the packet. |
| 28  | LD   | Last Descriptor  
When this bit is set, it indicates that the buffers to which this descriptor is pointing are the last buffers of the packet. |
<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| 27  | RS2V | Receive Status RDES2 Valid  
When this bit is set, it indicates that the status in RDES2 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set. |
| 26  | RS1V | Receive Status RDES1 Valid  
When this bit is set, it indicates that the status in RDES1 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set. |
| 25  | RS0V | Receive Status RDES0 Valid  
When this bit is set, it indicates that the status in RDES0 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set. |
| 24  | CE   | CRC Error  
When this bit is set, it indicates that a Cyclic Redundancy Check (CRC) Error occurred on the received packet. This field is valid only when the LD bit of RDES3 is set. |
| 23  | GP   | Giant Packet  
When this bit is set, it indicates that the packet length exceeds the specified maximum Ethernet size of 1518, 1522, or 2000 bytes (9018 or 9022 bytes if jumbo packet enable is set).  
*Note:* Giant packet indicates only the packet length. It does not cause any packet truncation. |
| 22  | RWT  | Receive Watchdog Timeout  
When this bit is set, it indicates that the Receive Watchdog Timer has expired while receiving the current packet. The current packet is truncated after watchdog timeout. |
| 21  | OE   | Overflow Error  
When this bit is set, it indicates that the received packet is damaged because of buffer overflow in Rx FIFO.  
*Note:* This bit is set only when the DMA transfers a partial packet to the application. This happens only when the Rx FIFO is operating in the threshold mode. In the store-and-forward mode, all partial packets are dropped completely in Rx FIFO. |
| 20  | RE   | Receive Error  
When this bit is set, it indicates that the ETH_RX_ER signal is asserted while the ETH_RX_DV signal is asserted during packet reception. |
| 19  | DE   | Dribble Bit Error  
When this bit is set, it indicates that the received packet has a non-integer multiple of bytes (odd nibbles). This bit is valid only in the MII Mode. |

</table>
| 18:16| LT   | Length/Type Field  
This field indicates if the packet received is a length packet or a type packet. The encoding of the 3 bits is as follows:  
– 000: The packet is a length packet  
– 001: The packet is a type packet.  
– 011: The packet is a ARP Request packet type  
– 100: The packet is a type packet with VLAN Tag  
– 101: The packet is a type packet with Double VLAN Tag  
– 110: The packet is a MAC Control packet type  
– 111: The packet is a OAM packet type  
– 010: Reserved |
**Receive context descriptor**

This descriptor is read-only for the application. This descriptor can be written only by the DMA.

The context descriptor provides information about the extended status related to the last received packet. Bit 30 of RDES3 indicates the context type descriptor. 

*Figure 804* shows the format for Receive context descriptors. *Table 548* to *Table 551* provide a detailed description of all Receive context descriptors.

57.11 Ethernet registers

57.11.1 Ethernet registers maps

This section provides the following register maps:
- DMA registers (see Section 57.11.2: Ethernet DMA registers)
- MTL registers (see Section 57.11.3: Ethernet MTL registers)
- MAC registers including MMC register (see Section 57.11.4: Ethernet MAC and MMC registers)

57.11.2 Ethernet DMA registers

DMA mode register (ETH_DMAMR)

Address offset: 0x1000
Reset value: 0x0000 0000

The DMA mode register establishes the bus operating modes for the DMA.

</table>

Bits 31:18 Reserved, must be kept at reset value.

Bits 17:16 **INTM[1:0]:** Interrupt Mode

This field defines the interrupt mode of the Ethernet peripheral.

The behavior of the interrupt signal and of the RI/TI bits in the ETH_DMACSR register changes depending on the INTM value (refer to Table 527: Transfer complete interrupt behavior).

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **PR[2:0]:** Priority ratio

These bits control the priority ratio in weighted round-robin arbitration between the Rx DMA and Tx DMA. These bits are valid only when the DA bit is reset. The priority ratio is Rx:Tx or Tx:Rx depending on whether the TXPR bit is reset or set.

000: The priority ratio is 1:1
001: The priority ratio is 2:1
010: The priority ratio is 3:1
011: The priority ratio is 4:1
100: The priority ratio is 5:1
101: The priority ratio is 6:1
110: The priority ratio is 7:1
111: The priority ratio is 8:1
Bit 11  **TXPR**: Transmit priority
When set, this bit indicates that the Tx DMA has higher priority than the Rx DMA during arbitration for the system-side bus.

Bits 10:2  Reserved, must be kept at reset value.

Bit 1  **DA**: DMA Tx or Rx Arbitration Scheme
This bit specifies the arbitration scheme between the Transmit and Receive paths of all channels:
0: Weighted Round-Robin with Rx:Tx or Tx:Rx
The priority between the paths is according to the priority specified in Bits[14:12] and the priority weight is specified in the TXPR bit.
1: Fixed priority
The Tx path has priority over the Rx path when the TXPR bit is set. Otherwise, the Rx path has priority over the Tx path.

Bit 0  **SWR**: Software Reset
When this bit is set, the MAC and the DMA controller reset the logic and all internal registers of the DMA, MTL, and MAC. This bit is automatically cleared after the reset operation is complete in all clock domains. Before reprogramming any register, a value of zero should be read in this bit.

*Note:* The reset operation is complete only when all resets in all active clock domains are de-asserted. Therefore, it is essential that all PHY inputs clocks (applicable for the selected PHY interface) are present for software reset completion. The time to complete the software reset operation depends on the frequency of the slowest active clock.
System bus mode register (ETH_DMASBMR)

Address offset: 0x1004
Reset value: 0x0101 0000

The System bus mode register controls the behavior of the AHB master. It mainly controls burst splitting and number of outstanding requests.

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>

<th>23</th>
<th>22</th>
<th>21</th>
<th>20</th>
<th>19</th>
<th>18</th>
<th>17</th>
<th>16</th>
</tr>
</thead>
</table>

Bits 31:16 Reserved, must be kept at reset value.

**Bit 15 RB**: Rebuild INCRx Burst

When this bit is set high and the AHB master gets SPLIT, RETRY, or Early Burst Termination (EBT) response, the AHB master interface rebuilds the pending beats of any initiated burst transfer with INCRx and SINGLE transfers. By default, the AHB master interface rebuilds pending beats of an EBT with an unspecified (INCR) burst.

**Bit 14 MB**: Mixed Burst

When this bit is set high and the MB bit is low, the AHB master performs undefined bursts transfers (INCR) for burst length of 16 or more. For burst length of 16 or less, the AHB master performs fixed burst transfers (INCRx and SINGLE).

**Bit 13** Reserved, must be kept at reset value.

**Bit 12 AAL**: Address-Aligned Beats

When this bit is set to 1, the master performs address-aligned burst transfers on Read and Write channels.

Bits 11:1 Reserved, must be kept at reset value.

**Bit 0 FB**: Fixed Burst Length

When this bit is set to 1, the AHB master will initiate burst transfers of specified length (INCRx or SINGLE).

When this bit is set to 0, the AHB master will initiate transfers of unspecified length (INCR) or SINGLE transfers.
**Interrupt status register (ETH_DMAISR)**

Address offset: 0x1008  
Reset value: 0x0000 0000

The application reads this Interrupt Status register during interrupt service routine or polling to determine the interrupt status of DMA channels, MTL queues, and the MAC.

<table>
<thead>
<tr>
<th>Bits 31:18</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
</table>
| Bit 17 **MACIS**: MAC Interrupt Status  
This bit indicates an interrupt event in the MAC. To reset this bit to 1'b0, the software must read the corresponding register in the MAC to get the exact cause of the interrupt and clear its source. |
| Bit 16 **MTLIS**: MTL Interrupt Status  
This bit indicates an interrupt event in the MTL. To reset this bit to 1'b0, the software must read the corresponding register in the MTL to get the exact cause of the interrupt and clear its source. |
| Bits 15:1 | Reserved, must be kept at reset value.  
Bit 0 **DC0IS**: DMA Channel Interrupt Status  
This bit indicates an interrupt event in DMA Channel. To reset this bit to 0, the software must read the corresponding register in DMA Channel to get the exact cause of the interrupt and clear its source. |

**Debug status register (ETH_DMADSR)**

Address offset: 0x100C  
Reset value: 0x0000 0000

The Debug status register gives the Receive and Transmit process status for DMA Channel for debugging purpose.

<table>
<thead>

| Bit 17 **MACIS**: MAC Interrupt Status  
This bit indicates an interrupt event in the MAC. To reset this bit to 1'b0, the software must read the corresponding register in the MAC to get the exact cause of the interrupt and clear its source. |
| Bit 16 **MTLIS**: MTL Interrupt Status  
This bit indicates an interrupt event in the MTL. To reset this bit to 1'b0, the software must read the corresponding register in the MTL to get the exact cause of the interrupt and clear its source. |
| Bits 15:1 | Reserved |
| Bit 0 **DC0IS**: DMA Channel Interrupt Status  
This bit indicates an interrupt event in DMA Channel. To reset this bit to 0, the software must read the corresponding register in DMA Channel to get the exact cause of the interrupt and clear its source. |
Channel control register (ETH_DMACCR)

Address offset: 0x1100

Reset value: 0x0000 0000

The DMA Channel Control register specifies the MSS value for segmentation, length to skip between two descriptors, and also the features such as header splitting and 8xPBL mode.
Channel transmit control register (ETH_DMACTXCR)

Address offset: 0x1104
Reset value: 0x0000 0000

The DMA Channel Transmit Control register controls the Tx features such as PBL, TCP segmentation, and Tx Channel weights.
RM0433  Ethernet (ETH): media access control (MAC) with DMA controller

Bits 31:22  Reserved, must be kept at reset value.

Bits 21:16  **TXPBL[5:0]**: Transmit Programmable Burst Length
These bits indicate the maximum number of beats to be transferred in one DMA data transfer. This is the maximum value that is used in a single block Read or Write. The DMA always attempts to burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior.
To transfer more than 32 beats, perform the following steps:
1. Set the PBLx8 mode in ETH_DMACCR.
2. Set the PBL.

Bits 15:13  Reserved, must be kept at reset value.

Bit 12  **TSE**: TCP Segmentation Enabled
When this bit is set, the DMA performs the TCP segmentation for packets in Channel i. The TCP segmentation is done only for those packets for which the TSE bit (TDES0[19]) is set in the Tx Normal descriptor. When this bit is set, the TxPBL value must be greater than or equal to 4.
This field is reserved if Enable TCP Segmentation Offloading for TCP/IP Packets option is not selected.

Bits 11:5  Reserved, must be kept at reset value.

Bit 4  **OSF**: Operate on Second Packet
When this bit is set, it instructs the DMA to process the second packet of the Transmit data even before the status for the first packet is obtained.

Bits 3:1  Reserved, must be kept at reset value.

Bit 0  **ST**: Start or Stop Transmission Command
When this bit is set, transmission is placed in the Running state. The DMA checks the Transmit list at the current position for a packet to be transmitted.
The DMA tries to acquire descriptor from either of the following positions:

- The current position in the list: this is the base address of the Transmit list set by the ETH_DMACTXDLAR register.

- The position at which the transmission was previously stopped
If the DMA does not own the current descriptor, the transmission enters the Suspended state and the TBU bit of the ETH_DMACSR is set. The Start Transmission command is effective only when the transmission is stopped. If the command is issued before setting the ETH_DMACTXDLAR register, the DMA behavior is unpredictable.
When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current packet. The Next Descriptor position in the Transmit list is saved, and it becomes the current position when the transmission is restarted.
To change the list address, you need to program ETH_DMACTXDLAR register with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current packet is complete or the transmission is in the Suspended state.
Channel receive control register (ETH_DMACRXCR)

Address offset: 0x1108
Reset value: 0x0000 0000

The DMA Channel Receive Control register controls the Rx features such as PBL, buffer size, and extended status.

### Bit 31  **RPF**: DMA Rx Channel Packet Flush
When this bit is set to 1, the DMA will automatically flush the packet from the Rx queues destined to DMA Rx Channel when the DMA Rx Channel is stopped after a system bus error has occurred. The flushing happens on the Read side of the Rx queue. When this bit is set to 0 the EQOS will not flush the packet in the Rx queue destined to DMA Rx Channel after the DMA is stopped due to a system bus error.

### Bits 30:22  Reserved, must be kept at reset value.

### Bits 21:16  **RXPBL[5:0]**: Receive Programmable Burst Length
These bits indicate the maximum number of beats to be transferred in one DMA data transfer. This is the maximum value that is used in a single block Read or Write. The DMA always attempts to burst as specified in PBL each time it starts a burst transfer on the application bus. You can program PBL with any of the following values: 1, 2, 4, 8, 16, or 32. Any other value results in undefined behavior.

To transfer more than 32 beats, perform the following steps:
1. Set the PBLX8 mode in the ETH_DMACCR.
2. Set the PBL.
Bit 15  Reserved, must be kept at reset value.

Bits 14:1  **RBSZ[13:0]: Receive Buffer size**

This field indicates the size of the Rx buffers specified in bytes. The maximum buffer size is limited to 16 Kbytes. The buffer size is applicable to payload buffers when split headers are enabled.

**Note:** The buffer size must be a multiple of 4, 8, or 16 depending on the bus widths (32, 64, or 128 respectively). This is required even if the value of buffer address pointer is not aligned to bus width. If the buffer size is not a multiple of 4, 8, or 16, it may result into undefined behavior.

The LSB bits (1:0, 2:0, or 3:0) for 32-bit, 64-bit, or 128-bit bus width are ignored and the DMA internally takes the LSB bits as all-zero. Therefore, these LSB bits are read-only (RO).

Bit 0  **SR: Start or Stop Receive**

When this bit is set, the DMA tries to acquire the descriptor from the Receive list and processes the incoming packets.

The DMA tries to acquire descriptor from either of the following positions:

- The current position in the list: this is the address set by the ETH_DMACRXDLAR register.
- The position at which the Rx process was previously stopped

If the DMA does not own the current descriptor, the reception is suspended and the RBU bit of the ETH_DMACSR is set. The Start Receive command is effective only when the reception is stopped. If the command is issued before setting the ETH_DMACRXDLAR register, the DMA behavior is unpredictable.

When this bit is reset, the Rx DMA operation is stopped after the transfer of the current packet. The next descriptor position in the Receive list is saved, and it becomes the current position after the Rx process is restarted. The Stop Receive command is effective only when the Rx process is in the Running (waiting for Rx packet) or Suspended state.
Channel Tx descriptor list address register (ETH_DMACTXDLAR)

Address offset: 0x1114
Reset value: 0x0000 0000

Channel Tx Descriptor List Address register points the DMA to the start of Transmit descriptor list. The descriptor lists reside in the physical memory space of the application and must be word-aligned. The DMA internally converts it to bus width aligned address by making the corresponding LSB to low.

You can write to this register only when the Tx DMA has stopped, that is, the ST bit is set to zero in ETH_DMACiTXCR register. When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly-programmed descriptor base address. If this register is not changed when the ST bit is set to 0, the DMA takes the descriptor address where it was stopped earlier.

<table>
<thead>

</tr>
</tbody>
</table>

Bits 1:0  Reserved, must be kept at reset value.
Channel Rx descriptor list address register (ETH_DMACRXDLAR)

Address offset: 0x111C
Reset value: 0x0000 0000

The Channel Rx Descriptor List Address register points the DMA to the start of Receive descriptor list.

This register points to the start of the Receive Descriptor List. The descriptor lists reside in the physical memory space of the application and must be word-aligned. The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, SR bit is set to zero in ETH_DMACRXCR register. When stopped, this register can be written with a new descriptor list address.

When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address.

Bits 31:2 **RDESLA[29:0]**: Start of Receive List

This field contains the base address of the first descriptor in the Rx Descriptor list. The DMA ignores the LSB bits (1:0, 2:0, or 3:0) for 32-bit bus width and internally takes these bits as all-zero. Therefore, these LSB bits are read-only (RO).

The width of this field depends on the configuration:

31:2 for 32-bit configuration

Bits 1:0  Reserved, must be kept at reset value.
Channel Tx descriptor tail pointer register (ETH_DMACTXDTPR)

Address offset: 0x1120
Reset value: 0x0000 0000

The ChannelTx Descriptor Tail Pointer register points to an offset from the base and indicates the location of the last valid descriptor.

<table>

Bits 31:2 **TDT[31:2]**: Transmit Descriptor Tail Pointer
This field contains the tail pointer for the Tx descriptor ring. The software writes the tail pointer to add more descriptors to the Tx channel. The hardware tries to transmit all packets referenced by the descriptors between the head and the tail pointer registers.
The width of this field depends on the configuration:
31:2 for 32-bit configuration

Bits 1:0 Reserved, must be kept at reset value.
Channel Rx descriptor tail pointer register (ETH_DMACRXDTPR)

Address offset: 0x1128
Reset value: 0x0000 0000

The Channel Rx Descriptor Tail Pointer Points to an offset from the base and indicates the location of the last valid descriptor.

Bits 31:2  **RDT[31:2]: Receive Descriptor Tail Pointer**

This field contains the tail pointer for the Rx descriptor ring. The software writes the tail pointer to add more descriptors to the Rx channel. The hardware tries to write all received packets to the descriptors referenced between the head and the tail pointer registers.

The width of this field depends on the configuration:

- 31:2 for 32-bit configuration

Bits 1:0  Reserved, must be kept at reset value.

Channel Tx descriptor ring length register (ETH_DMACTXRLR)

Address offset: 0x112C
Reset value: 0x0000 0000

The Tx Descriptor Ring Length register contains the length of the Transmit descriptor ring.

Bits 31:10  Reserved, must be kept at reset value.

Bits 9:0  **TDRL[9:0]: Transmit Descriptor Ring Length**

This field sets the maximum number of Tx descriptors in the circular descriptor ring. The maximum number of descriptors is limited to 1K descriptors. It is recommended to put a minimum ring descriptor length of 4.
Channel Rx descriptor ring length register (ETH_DMACRXRLR)

Address offset: 0x1130

Reset value: 0x0000 0000

The Channel Rx Descriptor Ring Length register contains the length of the Receive descriptor circular ring.

Bits 31:10  Reserved, must be kept at reset value.

Bits 9:0  RDRL[9:0]: Receive Descriptor Ring Length

This register sets the maximum number of Rx descriptors in the circular descriptor ring. The maximum number of descriptors is limited to 1K descriptors.

Channel interrupt enable register (ETH_DMACIER)

Address offset: 0x1134

Reset value: 0x0000 0000

The Channel Interrupt Enable register enables the interrupts reported by the Status register.
Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **NIE**: Normal Interrupt Summary Enable
When this bit is set, the normal interrupt summary is enabled. This bit enables the following interrupts in the ETH_DMACSR:
- Bit 0: Transmit Interrupt
- Bit 2: Transmit Buffer Unavailable
- Bit 6: Receive Interrupt
- Bit 11: Early Receive Interrupt
When this bit is reset, the normal interrupt summary is disabled.

Bit 14 **AIE**: Abnormal Interrupt Summary Enable
When this bit is set, the abnormal interrupt summary is enabled. This bit enables the following interrupts in the ETH_DMACSR:
- Bit 1: Transmit Process Stopped
- Bit 7: Rx Buffer Unavailable
- Bit 8: Receive Process Stopped
- Bit 9: Receive Watchdog Timeout
- Bit 10: Early Transmit Interrupt
- Bit 12: Fatal Bus Error
When this bit is reset, the abnormal interrupt summary is disabled.

Bit 13 **CDEE**: Context Descriptor Error Enable
When this bit is set along with the AIE bit, the Context Descriptor error interrupt is enabled. When this bit is reset, the Context Descriptor error interrupt is disabled.

Bit 12 **FBEE**: Fatal Bus Error Enable
When this bit is set along with the AIE bit, the Fatal Bus error interrupt is enabled. When this bit is reset, the Fatal Bus Error error interrupt is disabled.

Bit 11 **ERIE**: Early Receive Interrupt Enable
When this bit is set along with the NIE bit, the Early Receive interrupt is enabled. When this bit is reset, the Early Receive interrupt is disabled.

Bit 10 **ETIE**: Early Transmit Interrupt Enable
When this bit is set along with the AIE bit, the Early Transmit interrupt is enabled. When this bit is reset, the Early Transmit interrupt is disabled.

Bit 9 **RWTE**: Receive Watchdog Timeout Enable
When this bit is set along with the AIE bit, the Receive Watchdog Timeout interrupt is enabled. When this bit is reset, the Receive Watchdog Timeout interrupt is disabled.

Bit 8 **RSE**: Receive Stopped Enable
When this bit is set along with the AIE bit, the Receive Stopped Interrupt is enabled. When this bit is reset, the Receive Stopped interrupt is disabled.

Bit 7 **RBUE**: Receive Buffer Unavailable Enable
When this bit is set along with the AIE bit, the Receive Buffer Unavailable interrupt is enabled. When this bit is reset, the Receive Buffer Unavailable interrupt is disabled.

Bit 6 **RIE**: Receive Interrupt Enable
When this bit is set along with the NIE bit, the Receive Interrupt is enabled. When this bit is reset, the Receive Interrupt is disabled.

Bits 5:3 Reserved, must be kept at reset value.
Bit 2  **TBUE**: Transmit Buffer Unavailable Enable
   When this bit is set along with the NIE bit, the Transmit Buffer Unavailable interrupt is enabled. When this bit is reset, the Transmit Buffer Unavailable interrupt is disabled.

Bit 1  **TXSE**: Transmit Stopped Enable
   When this bit is set along with the AIE bit, the Transmission Stopped interrupt is enabled. When this bit is reset, the Transmission Stopped interrupt is disabled.

Bit 0  **TIE**: Transmit Interrupt Enable
   When this bit is set along with the NIE bit, the Transmit Interrupt is enabled. When this bit is reset, the Transmit Interrupt is disabled.
Figure 805. Generation of ETH_DMAISR flags
Channel Rx interrupt watchdog timer register (ETH_DMACRXIWTR)

Address offset: 0x1138
Reset value: 0x0000 0000

The Receive Interrupt Watchdog Timer register indicates the watchdog timeout for Receive Interrupt (RI) from the DMA. When this register is written with a non-zero value, it enables the watchdog timer for the RI bit of the ETH_DMACSR register.

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 \textbf{RWT}[7:0]: Receive Interrupt Watchdog Timer Count
This field indicates the number of system clock cycles, multiplied by factor indicated in RWTU field, for which the watchdog timer is set.
The watchdog timer is triggered with the programmed value after the Rx DMA completes the transfer of a packet for which the RI bit is not set in the ETH_DMACSR, because of the setting of Interrupt Enable bit in the corresponding descriptor RDES3[30].
When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per the Interrupt Enable bit RDES3[30] of any received packet.

Channel current application transmit descriptor register (ETH_DMACCATXDR)

Address offset: 0x1144
Reset value: 0x0000 0000

The Channel Current Application Transmit Descriptor register points to the current Transmit descriptor read by the DMA.
Bits 31:0  **CURRDESAPTR[31:0]**: Application Transmit Descriptor Address Pointer  
The DMA updates this pointer during Tx operation. This pointer is cleared on reset.

Channel current application receive descriptor register (ETH_DMACCARXDR)  
Address offset: 0x114C  
Reset value: 0x0000 0000  
The Channel Current Application Receive Descriptor register points to the current Receive descriptor read by the DMA.

Bits 31:0  **CURTBUFAPTR[31:0]**: Application Transmiit Buffer Address Pointer  
The DMA updates this pointer during Tx operation. This pointer is cleared on reset.

Channel current application receive buffer register (ETH_DMACCARXBR)  
Address offset: 0x115C
Reset value: 0x0000 0000

The Channel Current Application Receive Buffer Address register points to the current Rx buffer address read by the DMA.

Bits 31:0 **CURRBUFFAPTR[31:0]**: Application Receive Buffer Address Pointer

The DMA updates this pointer during Rx operation. This pointer is cleared on reset.

**Channel status register (ETH_DMACSR)**

Address offset: 0x1160

Reset value: 0x0000 0000

The software driver (application) reads the Status register during interrupt service routine or polling to determine the status of the DMA.
Bits 31:22  Reserved, must be kept at reset value.

Bits 21:19  **REB[2:0]: Rx DMA Error Bits**
This field indicates the type of error that caused a Bus Error. For example, error response on the AHB interface.
Bit 21
1: Error during data transfer by Rx DMA
0: No Error during data transfer by Rx DMA
Bit 20
1: Error during descriptor access
0: Error during data buffer access
Bit 19
1: Error during read transfer
0: Error during write transfer
This field is valid only when the FBE bit is set. This field does not generate an interrupt.

Bits 18:16  **TEB[2:0]: Tx DMA Error Bits**
This field indicates the type of error that caused a Bus Error. For example, error response on the AHB interface.
Bit 18
1: Error during data transfer by Tx DMA
0: No Error during data transfer by Tx DMA
Bit 17
1: Error during descriptor access
0: Error during data buffer access
Bit 16
1: Error during read transfer
0: Error during write transfer
This field is valid only when the FBE bit is set. This field does not generate an interrupt.

Bit 15  **NIS: Normal Interrupt Summary**
Normal Interrupt Summary bit value is the logical OR of the following bits when the corresponding interrupt bits are enabled in the ETH_DMACIER register:
Bit 0: Transmit Interrupt
Bit 2: Transmit Buffer Unavailable
Bit 6: Receive Interrupt
Bit 11: Early Receive Interrupt
Only unmasked bits (interrupts for which interrupt enable is set in ETH_DMACIER register) affect the Normal Interrupt Summary bit.
This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit which causes NIS to be set is cleared.

Bit 14  **AIS: Abnormal Interrupt Summary**
Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the ETH_DMACIER register:
Bit 1: Transmit Process Stopped
Bit 7: Receive Buffer Unavailable
Bit 8: Receive Process Stopped
Bit 10: Early Transmit Interrupt
Bit 12: Fatal Bus Error
Bit 13: Context Descriptor Error
Only unmasked bits affect the Abnormal Interrupt Summary bit.
This is a sticky bit. You must clear this bit (by writing 1 to this bit) each time a corresponding bit, which causes AIS to be set, is cleared.
Bit 13  **CDE**: Context Descriptor Error  
This bit indicates that the DMA Tx engine received a context descriptor in the middle of a packet (in an intermediate descriptor), and the DMA Tx engine ignored it.

Bit 12  **FBE**: Fatal Bus Error  
This bit indicates that a bus error occurred (as described in the EB field). When this bit is set, the corresponding DMA channel engine disables all bus accesses.

Bit 11  **ERI**: Early Receive Interrupt  
This bit indicates that the DMA filled the first data buffer of the packet. The RI bit of this register automatically clears this bit.

Bit 10  **ETI**: Early Transmit Interrupt  
This bit indicates that the packet to be transmitted is fully transferred to the MTL Tx FIFO.

Bit 9  **RWT**: Receive Watchdog Timeout  
This bit is asserted when a packet with length greater than 2,048 bytes (10,240 bytes when Jumbo Packet mode is enabled) is received.

Bit 8  **RPS**: Receive Process Stopped  
This bit is asserted when the Rx process enters the Stopped state.

Bit 7  **RBU**: Receive Buffer Unavailable  
This bit indicates that the application owns the next descriptor in the Receive list, and the DMA cannot acquire it. The Rx process is suspended. To resume processing Rx descriptors, the application should change the ownership of the descriptor and issue a Receive Poll Demand command. If this command is not issued, the Rx process resumes when the next recognized incoming packet is received. In ring mode, the application should advance the Receive Descriptor Tail Pointer register of a channel. This bit is set only when the DMA owns the previous Rx descriptor.

Bit 6  **RI**: Receive Interrupt  
This bit indicates that the packet reception is complete. When packet reception is complete, Bit 31 of RDES1 is reset in the last descriptor, and the specific packet status information is updated in the descriptor.  
The reception remains in the Running state.

Bits 5:3  Reserved, must be kept at reset value.

Bit 2  **TBU**: Transmit Buffer Unavailable  
This bit indicates that the application owns the next descriptor in the Transmit list, and the DMA cannot acquire it. Transmission is suspended. The TPS0 field of the DMA_Debug_Status0 register explains the Transmit Process state transitions. To resume processing the Transmit descriptors, the application should do the following:  
1. Change the ownership of the descriptor by setting Bit 31 of TDES3.  
2. Issue a Transmit Poll Demand command.  
For ring mode, the application should advance the Transmit Descriptor Tail Pointer register of a channel.

Bit 1  **TPS**: Transmit Process Stopped  
This bit is set when the transmission is stopped.

Bit 0  **TI**: Transmit Interrupt  
This bit indicates that the packet transmission is complete. When transmission is complete, Bit 31 of TDES3 is reset in the last descriptor, and the specific packet status information is updated in the descriptor.
Channel missed frame count register (ETH_DMACMFCR)

Address offset: 0x116C
Reset value: 0x0000 0000

This register has the number of packet counter that got dropped by the DMA either due to Bus Error or due to programing RPF field in ETH_DMACRXCR register.

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **MFCO**: Overflow status of the MFC Counter
When this bit is set then the MFC counter does not get incremented further. The bit gets cleared when this register is read.

Bits 14:11 Reserved, must be kept at reset value.

Bits 10:0 **MFC[10:0]**: Dropped Packet Counters
This counter indicates the number of packet counters that are dropped by the DMA either because of bus error or because of programing RPF field in ETH_DMACRXCR register. The counter gets cleared when this register is read.

Refer to [Section 2.3 on page 126](#) for the register boundary addresses.
57.11.3 Ethernet MTL registers

Operating mode Register (ETH_MTLOMR)

Address offset: 0x0C00
Reset value: 0x0000 0000

The Operating Mode register establishes the Transmit and Receive operating modes and commands.

| Bit 31:10 | Reserved, must be kept at reset value. |

Bit 9 CNTCLR: Counters Reset
When this bit is set, all counters are reset. This bit is cleared automatically after 1 clock cycle. If this bit is set along with CNT_PRESET bit, CNT_PRESET has precedence.

Bit 8 CNTPRST: Counters Preset
When this bit is set:
- ETH_MTLTXQUR register is initialized/preset to 0x7F0.
- Missed Packet and Overflow Packet counters in ETH_MTLRXQMPOCR register is initialized/preset to 0x7F0

Bit 7 Reserved, must be kept at reset value.

Bits 6:2 Reserved, must be kept at reset value.

Bit 1 DTXSTS: Drop Transmit Status
When this bit is set, the Tx packet status received from the MAC is dropped in the MTL. When this bit is reset, the Tx packet status received from the MAC is forwarded to the application.
This bit is reserved and read-only when the Disable Transmit Status in MTL feature is selected while configuring the core.

Bit 0 Reserved, must be kept at reset value.
## Interrupt status Register (ETH_MTLISR)

Address offset: 0x0C20  
Reset value: 0x0000 0000

The software driver (application) reads this register during interrupt service routine or polling to determine the interrupt status of MTL queues and the MAC.

![Interrupt status Register](image)

Bit 0 **Q0IS**: Queue interrupt status  
This bit indicates that an interrupt has been generated by Queue. To reset this bit, read ETH_MTLQICSR register to identify the interrupt cause and clear the source.

## Tx queue operating mode Register (ETH_MTLTXQOMR)

Address offset: 0x0D00  
Reset value: 0x0007 0008  

The Queue Transmit Operating Mode register establishes the Transmit queue operating modes and commands.

![Tx queue operating mode Register](image)
Bits 31:25  Reserved, must be kept at reset value.

Bits 24:16  **TQS[8:0]:** Transmit Queue Size

This field indicates the size of the allocated Transmit queues in blocks of 256 bytes. The sixteenth bit is the starting bit of this field. The width of this field depends on the Tx memory size selected in your configuration. For example, if the memory size is 2048, the width of this field is 3 bits:

\[
\log_2(2048/256) = \log_2(8) = 3 \text{ bits}
\]

\[TQS = 0 \text{ corresponds to 256 bytes.}\]

Bits 15:7  Reserved, must be kept at reset value.

Bits 6:4  **TTC[2:0]:** Transmit Threshold Control

These bits control the threshold level of the MTL Tx queue. The transmission starts when the packet size within the MTL Tx queue is larger than the threshold. In addition, full packets with length less than the threshold are also transmitted. These bits are used only when the TSF bit is reset.

- 000: 32
- 001: 64
- 010: 96
- 011: 128
- 100: 192
- 101: 256
- 110: 384
- 111: 512

Bits 3:2  **TXQEN[1:0]:** Transmit Queue Enable

This field is used to enable/disable the transmit queue.

- 00: Not enabled
- 01: Reserved
- 10: Enabled
- 11: Reserved

*Note: In multiple Tx queues configuration, all the queues are disabled by default. Enable the Tx queue by programming this field.*

Bit 1  **TSF:** Transmit Store and Forward

When this bit is set, the transmission starts when a full packet resides in the MTL Tx queue. When this bit is set, the TTC values specified in Bits[6:4] of this register are ignored. This bit should be changed only when the transmission is stopped.

Bit 0  **FTQ:** Flush Transmit Queue

When this bit is set, the Tx queue controller logic is reset to its default values. Therefore, all the data in the Tx queue is lost or flushed. This bit is internally reset when the flushing operation is complete. Until this bit is reset, you should not write to the ETH_MTLTXQOMR register. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt packet transmission.

*Note: The flush operation is complete only when the Tx queue is empty and the application has accepted the pending Tx Status of all transmitted packets. To complete this flush operation, the PHY Tx clock (eth_mii_tx_clk) should be active.*
Tx queue underflow register (ETH_MTLTXQUR)

Address offset: 0x0D04
Reset value: 0x0000 0000

The Queue Underflow Counter register contains the counter for packets aborted because of Transmit queue underflow and packets missed because of Receive queue packet flush.

| Bits 31:12 | Reserved, must be kept at reset value. |
| Bit 11 | UFCNTOFV: Overflow Bit for Underflow Packet Counter |
| This bit is set every time the Tx queue Underflow Packet Counter field overflows, that is, it has crossed the maximum count. In such a scenario, the overflow packet counter is reset to all-zeros and this bit indicates that the rollover happened. |
| Bits 10:0 | UFFRMCNT[10:0]: Underflow Packet Counter |
| This field indicates the number of packets aborted by the controller because of Tx queue Underflow. This counter is incremented each time the MAC aborts outgoing packet because of underflow. The counter is cleared when this register is read. |

Tx queue debug Register (ETH_MTLTXQDR)

Address offset: 0x0D08
Reset value: 0x0000 0000

The Queue Transmit Debug register gives the debug status of various blocks related to the Transmit queue.
Bits 31:23  Reserved, must be kept at reset value.

Bits 22:20  **STXSTS[2:0]: Number of Status Words in Tx Status FIFO of Queue**
This field indicates the current number of status in the Tx Status FIFO of this queue. This field is reserved when the Disable Transmit Status in MTL feature is selected while configuring the core.
When the DTXSTS bit of ETH_MTLOMR register is set to 1, this field does not reflect the number of status words in Tx Status FIFO.

Bit 19  Reserved, must be kept at reset value.

Bits 18:16  **PTXQ[2:0]: Number of Packets in the Transmit Queue**
This field indicates the current number of packets in the Tx queue. This field is reserved when the Disable Transmit Status in MTL feature is selected while configuring the core.
When the DTXSTS bit of ETH_MTLOMR register is set to 1, this field does not reflect the number of packets in the Transmit queue.

Bits 15:6  Reserved, must be kept at reset value.

Bit 5  **TXSTSFSST**: MTL Tx Status FIFO Full Status
When high, this bit indicates that the MTL Tx Status FIFO is full. Therefore, the MTL cannot accept any more packets for transmission.
This field is reserved when the Disable Transmit Status in MTL feature is selected while configuring the core.

Bit 4  **TXQSTS**: MTL Tx Queue Not Empty Status
When this bit is high, it indicates that the MTL Tx queue is not empty and some data is left for transmission.

Bit 3  **TWCSST**: MTL Tx Queue Write Controller Status
When high, this bit indicates that the MTL Tx queue Write Controller is active, and it is transferring the data to the Tx queue.

Bits 2:1  **TRCSTS[1:0]: MTL Tx Queue Read Controller Status**
This field indicates the state of the Tx Queue Read Controller:
00: Idle state
01: Read state (transferring data to the MAC transmitter)
10: Waiting for pending Tx Status from the MAC transmitter
11: Flushing the Tx queue because of the Packet Abort request from the MAC

Bit 0  **TXQPAUSED**: Transmit Queue in Pause
When this bit is high and the Rx flow control is enabled, it indicates that the Tx queue is in the Pause condition (in the full-duplex only mode) because of the following:
- Reception of the PFC packet for the priorities assigned to the Tx queue when PFC is enabled
- Reception of 802.3x Pause packet when PFC is disabled
Queue interrupt control status Register (ETH_MTLQICSR)

Address offset: 0x0D2C
Reset value: 0x0000 0000

This register contains the interrupt enable and status bits for the queue interrupts.

Bits 31:25  Reserved, must be kept at reset value.

Bit 24  **RXOIE**: Receive Queue Overflow Interrupt Enable
When this bit is set, the Receive Queue Overflow interrupt is enabled. When this bit is reset, the Receive Queue Overflow interrupt is disabled.

Bits 23:17  Reserved, must be kept at reset value.

Bit 16  **RXOVFIS**: Receive Queue Overflow Interrupt Status
This bit indicates that the Receive Queue had an overflow while receiving the packet. If a partial packet is transferred to the application, the overflow status is set in RDES3[21]. This bit is cleared when the application writes 1 to this bit.

Bits 15:9  Reserved, must be kept at reset value.

Bit 8  **TXUIE**: Transmit Queue Underflow Interrupt Enable
When this bit is set, the Transmit Queue Underflow interrupt is enabled. When this bit is reset, the Transmit Queue Underflow interrupt is disabled.

Bits 7:1  Reserved, must be kept at reset value.

Bit 0  **TXUNFIS**: Transmit Queue Underflow Interrupt Status
This bit indicates that the Transmit Queue had an underflow while transmitting the packet. Transmission is suspended and an Underflow Error TDES3[2] is set. This bit is cleared when the application writes 1 to this bit.
Rx queue operating mode register (ETH_MTLRXQOMR)

Address offset: 0x0D30
Reset value: 0x0070 0000

The Queue Receive operating Mode register establishes the Receive queue operating modes and command.

Bits 31:23: Reserved, must be kept at reset value.

Bits 22:20 **RQS[2:0]:** Receive Queue Size
This field indicates the size of the allocated Receive queues in blocks of 256 bytes. The RQS field is read-write only if the number of Rx queues more than one and the reset value is 0x0.

Bits 19:17: Reserved, must be kept at reset value.

Bits 16:14 **RFD[2:0]:** Threshold for Deactivating Flow Control (in half-duplex and full-duplex modes)
These bits control the threshold (fill-level of Rx queue) at which the flow control is de-asserted after activation:

- 0: Full minus 1 Kbyte, that is, FULL 1 Kbyte
- 1: Full minus 1.5 Kbyte, that is, FULL 1.5 Kbyte
- 2: Full minus 2 Kbytes, that is, FULL 2 Kbytes
- 3: Full minus 2.5 Kbytes, that is, FULL 2.5 Kbytes
- 4: Full minus 2.5 Kbytes, that is, FULL 3 Kbytes
- 5: Full minus 2.5 Kbytes, that is, FULL 3.5 Kbytes

The de-assertion is effective only after flow control is asserted.

**Note:** The value must be programmed in such a way to make sure that the threshold is a positive number.

When the EHFC is set high, these values are applicable only when the Rx queue size determined by the RQS field of this register, is equal to or greater than 4 Kbytes.

For a given queue size, the values ranges between 0 and the encoding for FULL minus (QSIZE - 0.5 Kbyte) and all other values are illegal. Here the term FULL and QSIZE refers to the queue size determined by the RQS field of this register.

Bits 13:11: Reserved, must be kept at reset value.

Bits 10:8 **RFA[2:0]:** Threshold for Activating Flow Control (in half-duplex and full-duplex)
These bits control the threshold (fill-level of Rx queue) at which the flow control is activated:

For more information on encoding for this field, see RFD.
<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>EHFC: Enable Hardware Flow Control</td>
<td>When this bit is set, the flow control signal operation, based on the fill-level of Rx queue, is enabled. When reset, the flow control operation is disabled. This bit is not used (reserved and always reset) when the Rx queue is less than 4 Kbytes.</td>
</tr>
<tr>
<td>6</td>
<td>DIS_TCP_EF: Disable Dropping of TCP/IP Checksum Error Packets</td>
<td>When this bit is set, the MAC does not drop the packets which only have the errors detected by the Receive Checksum Offload engine. Such packets have errors only in the encapsulated payload. There are no errors (including FCS error) in the Ethernet packet received by the MAC. When this bit is reset, all error packets are dropped if the FEP bit is reset.</td>
</tr>
<tr>
<td>5</td>
<td>RSF: Receive Queue Store and Forward</td>
<td>When this bit is set, the Ethernet peripheral reads a packet from the Rx queue only after the complete packet has been written to it, ignoring the RTC field of this register. When this bit is reset, the Rx queue operates in the Threshold (cut-through) mode, subject to the threshold specified by the RTC field of this register.</td>
</tr>
<tr>
<td>4</td>
<td>FEP: Forward Error Packets</td>
<td>When this bit is reset, the Rx queue drops packets with error status (CRC error, receive error, watchdog timeout, or overflow). However, if the start byte (write) pointer of a packet is already transferred to the read controller side (in Threshold mode), the packet is not dropped. When this bit is set, all packets except the runt error packets are forwarded to the application or DMA. If the RSF bit is set and the Rx queue overflows when a partial packet is written, the packet is dropped irrespective of the setting of this bit. However, if the RSF bit is reset and the Rx queue overflows when a partial packet is written, a partial packet may be forwarded to the application or DMA.</td>
</tr>
<tr>
<td>3</td>
<td>FUP: Forward Undersized Good Packets</td>
<td>When this bit is set, the Rx queue forwards the undersized good packets (packets with no error and length less than 64 bytes), including pad-bytes and CRC. When this bit is reset, the Rx queue drops all packets of less than 64 bytes, unless a packet is already transferred because of the lower value of Rx Threshold, for example, RTC = 01.</td>
</tr>
<tr>
<td>2</td>
<td>Reserved, must be kept at reset value.</td>

</tr>
<tr>
<td>1:0</td>
<td>RTC[1:0]: Receive Queue Threshold Control</td>
<td>These bits control the threshold level of the MTL Rx queue (in bytes): 00: 64 01: 32 10: 96 11: 128 The received packet is transferred to the application or DMA when the packet size within the MTL Rx queue is larger than the threshold. In addition, full packets with length less than the threshold are automatically transferred. This field is valid only when the RSF bit is zero. This field is ignored when the RSF bit is set to 1.</td>
</tr>
</tbody>
</table>
**Rx queue missed packet and overflow counter register (ETH_MTLRXQMPOCR)**

Address offset: 0x0D34

Reset value: 0x0000 0000

The Queue missed packet and overflow counter register contains the counter for packets missed because of Receive queue packet flush and packets discarded because of Receive queue overflow.

Bits 31:28  Reserved, must be kept at reset value.

Bit 27 **MISCNTOVF**: Missed Packet Counter Overflow Bit
When set, this bit indicates that the Rx Queue Missed Packet Counter crossed the maximum limit.

Bits 26:16 **MISPKTCNT[10:0]**: Missed Packet Counter
This field indicates the number of packets missed by the Ethernet peripheral because the application asserted ar_i_pkt_flush_i for this queue. This counter is reset when this register is read.
This counter is incremented by 1 when the DMA discards the packet because of buffer unavailability.

Bits 15:12  Reserved, must be kept at reset value.

Bit 11 **OVFCNTOVF**: Overflow Counter Overflow Bit
When set, this bit indicates that the Rx Queue Overflow Packet Counter field crossed the maximum limit.

Bits 10:0 **OVFPKTCNT[10:0]**: Overflow Packet Counter
This field indicates the number of packets discarded by the Ethernet peripheral because of Receive queue overflow. This counter is incremented each time the Ethernet peripheral discards an incoming packet because of overflow. This counter is reset when this register is read.

**Rx queue debug register (ETH_MTLRXQDR)**

Address offset: 0x0D38

Reset value: 0x0000 0000

The Queue Receive Debug register gives the debug status of various blocks related to the Receive queue.
Ethernet (ETH): media access control (MAC) with DMA controller

| Bits 31:30 | Reserved, must be kept at reset value. |
| Bits 29:16 | **PRXQ[13:0]**: Number of Packets in Receive Queue |
| This field indicates the current number of packets in the Rx queue. The theoretical maximum value for this field is 256Kbyte/16bytes = 16K Packets, that is, \(\text{Max Queue Size}/\text{Min Packet Size}\). |
| Bits 15:6 | Reserved, must be kept at reset value. |
| Bits 5:4 | **RXQSTS[1:0]**: MTL Rx Queue Fill-Level Status |
| This field gives the status of the fill-level of the Rx queue: |
| 00: Rx queue empty |
| 01: Rx queue fill-level below flow-control deactivate threshold |
| 10: Rx queue fill-level above flow-control activate threshold |
| 11: Rx queue full |
| Bit 3 | Reserved, must be kept at reset value. |
| Bits 2:1 | **RRCSTS[1:0]**: MTL Rx Queue Read Controller State |
| This field gives the state of the Rx queue Read controller: |
| 00: Idle state |
| 01: Reading packet data |
| 10: Reading packet status (or timestamp) |
| 11: Flushing the packet data and status |
| Bit 0 | **RWCSTS**: MTL Rx Queue Write Controller Active Status |
| When high, this bit indicates that the MTL Rx queue Write controller is active, and it is transferring a received packet to the Rx queue. |
### Ethernet MTL register map and reset values

| Offset  | Register name               | 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |

## 57.11.4 Ethernet MAC and MMC registers

### Operating mode configuration register (ETH_MACCR)

Address offset: 0x0000

Reset value: 0x0000 0000

The MAC Configuration Register establishes the operating mode of the MAC.

</table>
Bit 31 **ARPEN**: ARP Offload Enable

When this bit is set, the MAC can recognize an incoming ARP request packet and schedules the ARP packet for transmission. It will forward the ARP packet to the application and also indicate the events in the RxStatus.

When this bit is reset, the MAC receiver does not recognize any ARP packet and indicates them as Type frame in the RxStatus.

This bit is available only when the Enable IPv4 ARP Offload is selected.

Bits 30:28 **SARC[2:0]**: Source Address Insertion or Replacement Control

This field controls the source address insertion or replacement for all transmitted packets. Bit 30 specifies which MAC Address register (0 or 1) is used for source address insertion or replacement based on the values of Bits[29:28]:

0x: Reserved.

10:

– If Bit 30 is set to 0, the MAC inserts the content of the MAC Address 0 registers (MAC registers 192 and 193) in the SA field of all transmitted packets.

– If Bit 30 is set to 1 and the Enable MAC Address Register 1 option is selected while configuring the core, the MAC inserts the content of the MAC Address 1 registers (MAC registers 194 and 195) in the SA field of all transmitted packets.

11:

– If Bit 30 is set to 0, the MAC replaces the content of the MAC Address 0 registers (MAC registers 192 and 193) in the SA field of all transmitted packets.

– If Bit 30 is set to 1 and the MAC Address Register 1 is enabled, the MAC replaces the content of the MAC Address 1 registers (MAC registers 194 and 195) in the SA field of all transmitted packets.

*Note: Changes to this field take effect only on the start of a packet. If you write to this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value.*

These bits are reserved and RO when the Enable SA and VLAN Insertion on Tx feature is not selected while configuring the core.

Bit 27 **IPC**: Checksum Offload

When set, this bit enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When this bit is reset, the COE function in the receiver is disabled.

If the IP Checksum Offload feature is not enabled while configuring the core, this bit is reserved and RO (with default value).

The Layer 3 and Layer 4 Packet Filter and Enable Split Header features automatically selects the IPC Full Checksum Offload Engine on the Receive side. When any of these features are enabled, you must set the IPC bit.
Bits 26:24  **IPG[2:0]:** Inter-Packet Gap

These bits control the minimum IPG between packets during transmission.
- 000: 96 bit times
- 001: 88 bit times
- 010: 80 bit times
...
- 111: 40 bit times

This range of minimum IPG is valid in full-duplex mode.
In the half-duplex mode, the minimum IPG can be configured only for 64-bit times (IPG = 100). Lower values are not considered.

When a JAM pattern is being transmitted because of backpressure activation, the MAC does not consider the minimum IPG.

The above function (IPG less than 96 bit times) is valid only when EIPGEN bit in ETH_MACECR register is reset. When EIPGEN is set, then the minimum IPG (greater than 96 bit times) is controlled as per the description given in EIPG field in ETH_MACECR register.

Bit 23  **GPSLCE:** Giant Packet Size Limit Control Enable

When this bit is set, the MAC considers the value in GPSL field in ETH_MACECR register to declare a received packet as Giant packet. This field must be programmed to more than 1,518 bytes. Otherwise, the MAC considers 1,518 bytes as giant packet limit.

When this bit is reset, the MAC considers a received packet as Giant packet when its size is greater than 1,518 bytes (1522 bytes for tagged packet).

The watchdog timeout limit, Jumbo Packet Enable and 2K Packet Enable have higher precedence over this bit, that is the MAC considers a received packet as Giant packet when its size is greater than 9,018 bytes (9,022 bytes for tagged packet) with Jumbo Packet Enabled and greater than 2,000 bytes with 2K Packet Enabled. The watchdog timeout, if enabled, terminates the received packet when watchdog limit is reached. Therefore, the programmed giant packet limit should be less than the watchdog limit to get the giant packet status.

Bit 22  **S2KP:** IEEE 802.3as Support for 2K Packets

When this bit is set, the MAC considers all packets with up to 2,000 bytes length as normal packets. When the JE bit is not set, the MAC considers all received packets of size more than 2K bytes as Giant packets.

When this bit is reset and the JE bit is not set, the MAC considers all received packets of size more than 1,518 bytes (1,522 bytes for tagged) as giant packets. For more information about how the setting of this bit and the JE bit impact the Giant packet status, see Giant Packet Status based on S2KP and JE Bits.

**Note:** When the JE bit is set, setting this bit has no effect on the giant packet status.

Bit 21  **CST:** CRC stripping for Type packets

When this bit is set, the last four bytes (FCS) of all packets of Ether type (type field greater than 1,536) are stripped and dropped before forwarding the packet to the application. This function is not valid when the IP Checksum Engine (Type 1) is enabled in the MAC receiver.

This function is valid when Type 2 Checksum Offload Engine is enabled.

**Note:** For information about how the settings of the ACS bit and this bit impact the packet length, see Packet Length based on the CST and ACS Bits.
Bit 20  **ACS**: Automatic Pad or CRC Stripping
When this bit is set, the MAC strips the Pad or FCS field on the incoming packets only if the value of the length field is less than 1,536 bytes. All received packets with length field greater than or equal to 1,536 bytes are passed to the application without stripping the Pad or FCS field.
When this bit is reset, the MAC passes all incoming packets to the application, without any modification.

*Note:* For information about how the settings of CST bit and this bit impact the packet length, see the Table, Packet Length based on the CST and ACS Bit.

Bit 19  **WD**: Watchdog Disable
When this bit is set, the MAC disables the watchdog timer on the receiver. The MAC can receive packets of up to 16,383 bytes.
When this bit is reset, the MAC does not allow more than 2,048 bytes (10,240 if JE is set high) of the packet being received. The MAC cuts off any bytes received after 2,048 bytes.

Bit 18  Reserved, must be kept at reset value.

Bit 17  **JD**: Jabber Disable
When this bit is set, the MAC disables the jabber timer on the transmitter. The MAC can transfer packets of up to 16,383 bytes.
When this bit is reset, if the application sends more than 2,048 bytes of data (10,240 if JE is set high) during transmission, the MAC does not send rest of the bytes in that packet.

Bit 16  **JE**: Jumbo Packet Enable
When this bit is set, the MAC allows jumbo packets of 9,018 bytes (9,022 bytes for VLAN tagged packets) without reporting a giant packet error in the Rx packet status.

Bit 15  Reserved, must be kept at reset value.

Bit 14  **FES**: MAC Speed
This bit selects the speed in the 10/100 Mbps mode:
0: 10 Mbps
1: 100 Mbps
In the 1000 Mbps-only configurations, this bit is read-only with the reset value. In the 10 or 100 Mbps-only or default 10/100 Mbps configurations, this bit is read-write. The mac_speed_o[0] signal reflects the value of this bit.

Bit 13  **DM**: Duplex Mode
When this bit is set, the MAC operates in the full-duplex mode in which it can transmit and receive simultaneously. This bit is RO with default value of 1'b1 in the full-duplex-only configurations.

Bit 12  **LM**: Loopback Mode
When this bit is set, the MAC operates in the loopback mode at MII. The MII Rx clock input (eth_mii_rx_clk) is required for the loopback to work properly. This is because the Tx clock is not internally looped back.

Bit 11  **ECRSFD**: Enable Carrier Sense Before Transmission in Full-Duplex Mode
When this bit is set, the MAC transmitter checks the CRS signal before packet transmission in the full-duplex mode. The MAC starts the transmission only when the CRS signal is low. When this bit is reset, the MAC transmitter ignores the status of the CRS signal.
Bit 10 **DO**: Disable Receive Own
When this bit is set, the MAC disables the reception of packets when the ETH_TX_EN is asserted in the half-duplex mode. When this bit is reset, the MAC receives all packets given by the PHY.
This bit is not applicable in the full-duplex mode. This bit is reserved and read-only (RO) with default value in the full-duplex-only configurations.

Bit 9 **DCRS**: Disable Carrier Sense During Transmission
When this bit is set, the MAC transmitter ignores the (G)MII CRS signal during packet transmission in the half-duplex mode. As a result, no errors are generated because of Loss of Carrier or No Carrier during transmission.
When this bit is reset, the MAC transmitter generates errors because of Carrier Sense. The MAC can even abort the transmission.
This bit is reserved and read-only (RO) in the full-duplex-only configurations.

Bit 8 **DR**: Disable Retry
When this bit is set, the MAC attempts only one transmission. When a collision occurs on the MII interface, the MAC ignores the current packet transmission and reports a Packet Abort with excessive collision error in the Tx packet status.
When this bit is reset, the MAC retries based on the settings of the BL field. This bit is applicable only in the half-duplex mode. This bit is reserved and read-only (RO) in the full-duplex-only configurations.

Bit 7 Reserved, must be kept at reset value.

Bits 6:5 **BL[1:0]**: Back-Off Limit
The back-off limit determines the random integer number \( r \) of slot time delays (4,096 bit times for 1000 Mbps; 512 bit times for 10/100 Mbps) for which the MAC waits before rescheduling a transmission attempt during retries after a collision.
00: \( k = \min(n, 10) \)
01: \( k = \min(n, 8) \)
10: \( k = \min(n, 4) \)
11: \( k = \min(n, 1) \)
where \( n \) = retransmission attempt
The random integer \( r \) takes the value in the range \( 0 \leq r < 2^k \)
This bit is applicable only in the half-duplex mode. This bit is reserved and read-only (RO) in the full-duplex-only configurations.

Bit 4 **DC**: Deferral Check
When this bit is set, the deferral check function is enabled in the MAC. The MAC issues a Packet Abort status, along with the excessive deferral error bit set in the Tx packet status, when the Tx state machine is deferred for more than 24,288 bit times in 10 or 100 Mbps mode.
If the MAC is configured for 1000 Mbps operation, the threshold for deferral is 155,680 bit times. Deferral begins when the transmitter is ready to transmit, but it is prevented because of an active carrier sense signal (CRS) on MII.
The defer time is not cumulative. For example, if the transmitter defers for 10,000 bit times because the CRS signal is active and the CRS signal becomes inactive, the transmitter transmits and collision happens. Because of collision, the transmitter needs to back off and then defer again after back off completion. In such a scenario, the deferral timer is reset to 0, and it is restarted.
When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive.
This bit is applicable only in the half-duplex mode. This bit is reserved and read-only (RO) in the full-duplex-only configurations.
Bits 3:2 **PRELEN[1:0]:** Preamble Length for Transmit packets

These bits control the number of preamble bytes that are added to the beginning of every Tx packet. The preamble reduction occurs only when the MAC is operating in the full-duplex mode.

- **00:** 7 bytes of preamble
- **01:** 5 bytes of preamble
- **10:** 3 bytes of preamble
- **11:** Reserved

Bit 1 **TE:** Transmitter Enable

When this bit is set, the Tx state machine of the MAC is enabled for transmission on the MII interface. When this bit is reset, the MAC Tx state machine is disabled after it completes the transmission of the current packet. The Tx state machine does not transmit any more packets.

Bit 0 **RE:** Receiver Enable

When this bit is set, the Rx state machine of the MAC is enabled for receiving packets from the MII interface. When this bit is reset, the MAC Rx state machine is disabled after it completes the reception of the current packet. The Rx state machine does not receive any more packets from the MII interface.

**Table 555** shows how the settings of S2KP and JE bits of the ETH_MACCR register impact the giant packet status.

2920/3289 RM0433 Rev 6
Bits 31:30  Reserved, must be kept at reset value.

Bits 29:25  **EIPG[4:0]:** Extended Inter-Packet Gap

The value in this field is applicable when the EIPGEN bit is set. This field (as Most Significant bits), along with IPG field in ETH_MACCR, gives the minimum IPG greater than 96 bit times in steps of 8 bit times:

(EIPG, IPG)

0x00: 104 bit times
0x01: 112 bit times
0x02: 120 bit times
...
0xFF: 2144 bit times

Bit 24  **EIPGEN:** Extended Inter-Packet Gap Enable

When this bit is set, the MAC interprets EIPG field and IPG field in ETH_MACCR together as minimum IPG greater than 96 bit times in steps of 8 bit times. When this bit is reset, the MAC ignores EIPG field and interprets IPG field in ETH_MACCR as minimum IPG less than or equal to 96 bit times in steps of 8 bit times.

*Note:* The extended Inter-Packet Gap feature must be enabled when operating in Full-Duplex mode only. There may be undesirable effects on back-pressure function and frame transmission if it is enabled in Half-Duplex mode.

Bits 23:19 Reserved, must be kept at reset value.

Bit 18  **USP:** Unicast Slow Protocol Packet Detect

When this bit is set, the MAC detects the Slow Protocol packets with unicast address of the station specified in the ETH_MACA0HR and ETH_MACA0LR registers. The MAC also detects the Slow Protocol packets with the Slow Protocols multicast address (01-80-C2-00-00-02).

When this bit is reset, the MAC detects only Slow Protocol packets with the Slow Protocol multicast address specified in the IEEE 802.3-2008, Section 5.

Bit 17  **SPEN:** Slow Protocol Detection Enable

When this bit is set, MAC processes the Slow Protocol packets (Ether Type 0x8809) and provides the Rx status. The MAC discards the Slow Protocol packets with invalid sub-types. When this bit is reset, the MAC forwards all error-free Slow Protocol packets to the application. The MAC considers such packets as normal Type packets.

Bit 16  **DCRCC:** Disable CRC Checking for Received Packets

When this bit is set, the MAC receiver does not check the CRC field in the received packets. When this bit is reset, the MAC receiver always checks the CRC field in the received packets.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:0  **GPSL[13:0]:** Giant Packet Size Limit

If the received packet size is greater than the value programmed in this field in units of bytes, the MAC declares the received packet as Giant packet. The value programmed in this field must be greater than or equal to 1,518 bytes. Any other programmed value is considered as 1,518 bytes.

For VLAN tagged packets, the MAC adds 4 bytes to the programmed value. When the Enable Double VLAN Processing option is selected, the MAC adds 8 bytes to the programmed value for double VLAN tagged packets. The value in this field is applicable when the GPSLCE bit is set in ETH_MACCR register.
Packet filtering control register (ETH_MACPFR)

Address offset: 0x0008
Reset value: 0x0000 0000

The MAC Packet Filter register contains the filter controls for receiving packets. Some of the controls from this register go to the address check block of the MAC which performs the first level of address filtering. The second level of filtering is performed on the incoming packet based on other controls such as Pass Bad Packets and Pass Control Packets.

</tr>
</tbody>
</table>
Bit 10  **HPF**: Hash or Perfect Filter
When this bit is set, the address filter passes a packet if it matches either the perfect filtering or Hash filtering as set by the HMC or HUC bit.
When this bit is reset and the HUC or HMC bit is set, the packet is passed only if it matches the Hash filter. This bit is reserved (and RO) if the Enable Address Filter Hash Table option is not selected.

Bit 9  **SAF**: Source Address Filter Enable
When this bit is set, the MAC compares the SA field of the received packets with the values programmed in the enabled SA registers. If the comparison fails, the MAC drops the packet.
When this bit is reset, the MAC forwards the received packet to the application with updated SAF bit of the Rx Status depending on the SA address comparison.

*Note:* According to the IEEE specification, Bit 47 of the SA is reserved. However, the MAC compares all 48 bits. The software driver should take this into consideration while programming the MAC address registers for SA.

Bit 8  **SAIF**: SA Inverse Filtering
When this bit is set, the Address Check block operates in the inverse filtering mode for SA address comparison. If the SA of a packet matches the values programmed in the SA registers, it is marked as failing the SA Address filter.
When this bit is reset, if the SA of a packet does not match the values programmed in the SA registers, it is marked as failing the SA Address filter.

Bits 7:6  **PCF[1:0]**: Pass Control Packets
These bits control the forwarding of all control packets (including unicast and multicast Pause packets).
00: The MAC filters all control packets from reaching the application.
01: The MAC forwards all control packets except Pause packets to the application even if they fail the Address filter.
10: The MAC forwards all control packets to the application even if they fail the Address filter.
11: The MAC forwards the control packets that pass the Address filter.

Bit 5  **DBF**: Disable Broadcast Packets
When this bit is set, the AFM module blocks all incoming broadcast packets. In addition, it overrides all other filter settings.
When this bit is reset, the AFM module passes all received broadcast packets.

Bit 4  **PM**: Pass All Multicast
When this bit is set, it indicates that all received packets with a multicast destination address (first bit in the destination address field is ‘1’) are passed. When this bit is reset, filtering of multicast packet depends on HMC bit.

Bit 3  **DAIF**: DA Inverse Filtering
When this bit is set, the Address Check block operates in inverse filtering mode for the DA address comparison for both unicast and multicast packets. When this bit is reset, normal filtering of packets is performed.
Bit 2  **HMC**: Hash Multicast
When this bit is set, the MAC performs the destination address filtering of received multicast packets according to the Hash table.
When this bit is reset, the MAC performs the perfect destination address filtering for multicast packets, that is, it compares the DA field with the values programmed in DA registers.
If the Enable Address Filter Hash Table option is not selected, this bit is reserved (and RO).

Bit 1  **HUC**: Hash Unicast
When this bit is set, the MAC performs the destination address filtering of unicast packets according to the Hash table.
When this bit is reset, the MAC performs a perfect destination address filtering for unicast packets, that is, it compares the DA field with the values programmed in DA registers.
If the Enable Address Filter Hash Table option is not selected, this bit is reserved (and RO).

Bit 0  **PR**: Promiscuous Mode
When this bit is set, the Address Filtering module passes all incoming packets irrespective of the destination or source address. The SA or DA Filter Fails status bits of the Rx Status Word are always cleared when PR is set.
**Watchdog timeout register (ETH_MACWTR)**

Address offset: 0x000C
Reset value: 0x0000 0000

The Watchdog Timeout register controls the watchdog timeout for received packets.

Bits 31:9  Reserved, must be kept at reset value.

**Bit 8**  **PWE**: Programmable Watchdog Enable

When this bit is set and the WD bit of the ETH_MACCR register is reset, the WTO field is used as watchdog timeout for a received packet. When this bit is cleared, the watchdog timeout for a received packet is controlled by setting of WD and JE bits in ETH_MACCR register.

Bits 7:4  Reserved, must be kept at reset value.

**Bits 3:0**  **WTO[3:0]**: Watchdog Timeout

When the PWE bit is set and the WD bit of the ETH_MACCR register is reset, this field is used as watchdog timeout for a received packet. If the length of a received packet exceeds the value of this field, such packet is terminated and declared as an error packet.

Encoding is as follows:

- 0x0: 2 Kbytes
- 0x1: 3 Kbytes
- 0x2: 4 Kbytes
- 0x3: 5 Kbytes
- ...
- 0xC: 14 Kbytes
- 0xD: 15 Kbytes
- 0xE: 16383 Bytes
- 0xF: Reserved

**Note:**  *When the PWE bit is set, the value in this field should be more than 1,522 (0x05F2). Otherwise, the IEEE 802.3-specified valid tagged packets are declared as error packets and then dropped.*
Hash Table 0 register (ETH_MACHT0R)

Address offset: 0x0010
Reset value: 0x0000 0000

The Hash Table Register 0 contains the first 32 bits of the Hash table (64 bits).

For Hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register 0 or 1).

The Hash value of the destination address is calculated in the following way:

1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
2. Perform bitwise reversal for the value obtained in Step 1.
3. Take the upper 7 or 8 bits from the value obtained in Step 2.

If the corresponding bit value of the register is 1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in ETH_MACPFR, all multicast packets are accepted regardless of the multicast Hash values.

If the Hash Table register is configured to be double-synchronized to the MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written.

Bits 31:0 **HT31T0[31:0]**: MAC Hash Table First 32 Bits
This field contains the first 32 Bits [31:0] of the Hash table.
Hash Table 1 register (ETH_MACHT1R)

Address offset: 0x0014
Reset value: 0x0000 0000

The Hash Table Register 1 contains the last 32 bits of the Hash table (64 bits).

For Hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register 0 or 1).

The Hash value of the destination address is calculated in the following way:
1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
2. Perform bitwise reversal for the value obtained in Step 1.
3. Take the upper 7 or 8 bits from the value obtained in Step 2.

If the corresponding bit value of the register is 1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in ETH_MACPFR, all multicast packets are accepted regardless of the multicast Hash values.

If the Hash Table register is configured to be double-synchronized to the MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written.

</tbody>
</table>

Bit 31 **EIVLRXS**: Enable Inner VLAN Tag in Rx Status
When this bit is set, the MAC provides the inner VLAN Tag in the Rx status. When this bit is reset, the MAC does not provide the inner VLAN Tag in Rx status.

Bit 30 Reserved, must be kept at reset value.

Bits 29:28 **EVLS[1:0]**: Enable Inner VLAN Tag Stripping on Receive
This field indicates the stripping operation on inner VLAN Tag in received packet:
00: Do not strip
01: Strip if VLAN filter passes
10: Strip if VLAN filter fails
11: Always strip

Bit 27 **ERIVLT**: Enable Inner VLAN Tag
When this bit and the EDVLP field are set, the MAC receiver enables operation on the inner VLAN Tag (if present). When this bit is reset, the MAC receiver enables operation on the outer VLAN Tag (if present). The ERSVLM bit determines which VLAN type is enabled for filtering or matching.

Bit 26 **EDVLP**: Enable Double VLAN Processing
When this bit is set, the MAC enables processing of up to two VLAN Tags on Tx and Rx (if present). When this bit is reset, the MAC enables processing of up to one VLAN Tag on Tx and Rx (if present).

Bit 25 **VTHM**: VLAN Tag Hash Table Match Enable
When this bit is set, the most significant four bits of CRC of VLAN Tag are used to index the content of the ETH_MACVLANHTR register. A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the packet matched the VLAN Hash table.
When the ETV bit is set, the CRC of the 12-bit VLAN Identifier (VID) is used for comparison. When the ETV bit is reset, the CRC of the 16-bit VLAN tag is used for comparison.
When this bit is reset, the VLAN Hash Match operation is not performed. If the VLAN Hash feature is not enabled, this bit is reserved (RO with default value).

Bit 24 **EVLRXS**: Enable VLAN Tag in Rx status
When this bit is set, MAC provides the outer VLAN Tag in the Rx status. When this bit is reset, the MAC does not provide the outer VLAN Tag in Rx status.

Bit 23 Reserved, must be kept at reset value.
Bits 22:21  **EVLS[1:0]**: Enable VLAN Tag Stripping on Receive

This field indicates the stripping operation on the outer VLAN Tag in received packet:

00: Do not strip
01: Strip if VLAN filter passes
10: Strip if VLAN filter fails
11: Always strip

Bit 20  **DOVLTC**: Disable VLAN Type Check

When this bit is set, the MAC does not check whether the VLAN Tag specified by the ERIVLT bit is of type S-VLAN or C-VLAN.

When this bit is reset, the MAC filters or matches the VLAN Tag specified by the ERIVLT bit only when VLAN Tag type is similar to the one specified by the ERSVLM bit.

Bit 19  **ERSVLM**: Enable Receive S-VLAN Match

When this bit is set, the MAC receiver enables filtering or matching for S-VLAN (Type = 0x88A8) packets. When this bit is reset, the MAC receiver enables filtering or matching for C-VLAN (Type = 0x8100) packets.

The ERIVLT bit determines the VLAN tag position considered for filtering or matching.

Bit 18  **ESVL**: Enable S-VLAN

When this bit is set, the MAC transmitter and receiver consider the S-VLAN packets (Type = 0x88A8) as valid VLAN tagged packets.

Bit 17  **VTIM**: VLAN Tag Inverse Match Enable

When this bit is set, this bit enables the VLAN Tag inverse matching. The packets without matching VLAN Tag are marked as matched. When reset, this bit enables the VLAN Tag perfect matching. The packets with matched VLAN Tag are marked as matched.

Bit 16  **ETV**: Enable 12-Bit VLAN Tag Comparison

When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits[11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged packet. Similarly, when enabled, only 12 bits of the VLAN tag in the received packet are used for Hash-based VLAN filtering.

When this bit is reset, all 16 bits of the 15th and 16th bytes of the received VLAN packet are used for comparison and VLAN Hash filtering.

Bits 15:0  **VL[15:0]**: VLAN Tag Identifier for Receive Packets

This field contains the 802.1Q VLAN tag to identify the VLAN packets. This VLAN tag identifier is compared to the 15th and 16th bytes of the packets being received for VLAN packets. The following list describes the bits of this field:

- Bits[15:13]: User Priority
- Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI)
- Bits[11:0]: VLAN Identifier (VID) field of VLAN tag

When the ETV bit is set, only the VID is used for comparison. If this field ([11:0] if ETV is set) is all zeros, the MAC does not check the 15th and 16th bytes for VLAN tag comparison and declares all packets with Type field value of 0x8100 or 0x88a8 as VLAN packets.
VLAN Hash table register (ETH_MACVHTR)

Address offset: 0x0058
Reset value: 0x0000 0000

When the ERSVLM bit of ETH_MACT1R register is set, the 16-bit VLAN Hash Table register is used for group address filtering based on the VLAN tag. For Hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on the ETV bit of ETH_MACVTR register) in the incoming packet is passed through the CRC logic. The upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. For example, a Hash value of 1000 selects Bit 8 of the VLAN Hash table.

The Hash value of the destination address is calculated in the following way:
1. Calculate the 32-bit CRC for the VLAN tag or ID (For steps to calculate CRC32, see Section 3.2.8 of IEEE 802.3).
2. Perform bitwise reversal for the value obtained in step 1.
3. Take the upper four bits from the value obtained in step 2.

If the VLAN Hash Table register is configured to be double-synchronized to the MII clock domain, the synchronization is triggered only when Bits[15:8] (in little-endian mode) or Bits[7:0] (in big-endian mode) of this register are written.

VLHT[15:0]: VLAN Hash Table
This field contains the 16-bit VLAN Hash Table.

Bits 31:16 Reserved, must be kept at reset value.
Bits 15:0 **VLHT[15:0]**: VLAN Hash Table
VLAN inclusion register (ETH_MACVIR)

Address offset: 0x0060
Reset value: 0x0000 0000

The VLAN Tag Inclusion or Replacement register contains the VLAN tag for insertion or replacement in the Transmit packets. It also contains the VLAN tag insertion controls.

</table>

Bits 31:21  Reserved, must be kept at reset value.

Bit 20  **VLTI**: VLAN Tag Input
When this bit is set, it indicates that the VLAN tag to be inserted or replaced in Tx packet should be taken from the Tx descriptor.

Bit 19  **CSVL**: C-VLAN or S-VLAN
When this bit is set, S-VLAN type (0x88A8) is inserted or replaced in the 13th and 14th bytes of transmitted packets. When this bit is reset, C-VLAN type (0x8100) is inserted or replaced in the 13th and 14th bytes of transmitted packets.

Bit 18  **VLP**: VLAN Priority Control
When this bit is set, the control bits[17:16] are used for VLAN deletion, insertion, or replacement. When this bit is reset, bits[17:16] are ignored.

Bits 17:16  **VLC[1:0]**: VLAN Tag Control in Transmit Packets
00: No VLAN tag deletion, insertion, or replacement
01: VLAN tag deletion. The MAC removes the VLAN type (bytes 13 and 14) and VLAN tag (bytes 15 and 16) of all transmitted packets with VLAN tags.
10: VLAN tag insertion. The MAC inserts VLT in bytes 15 and 16 of the packet after inserting the Type value (0x8100 or 0x88a8) in bytes 13 and 14. This operation is performed on all transmitted packets, irrespective of whether they already have a VLAN tag.
11: VLAN tag replacement. The MAC replaces VLT in bytes 15 and 16 of all VLAN-type transmitted packets (Bytes 13 and 14 are 0x8100 or 0x88a8).

**Note**: Changes to this field take effect only on the start of a packet. If you write this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value.

Bits 15:0  **VLT[15:0]**: VLAN Tag for Transmit Packets
This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase.
Bits[15:13] are the User Priority field, Bit 12 is the CFI/DEI field, and Bits[11:0] are the VID field in the VLAN tag.
The following list describes the bits of this field:
Bits[15:13]: User Priority
Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI)
Bits[11:0]: VLAN Identifier (VID) field of VLAN tag
**Inner VLAN inclusion register (ETH_MACIVIR)**

Address offset: 0x0064  
Reset value: 0x0000 0000

The Inner VLAN Tag Inclusion or Replacement register contains the inner VLAN tag to be inserted or replaced in the Transmit packet. It also contains the inner VLAN tag insertion controls.

| Bit 31 | Bit 30 | Bit 29 | Bit 28 | Bit 27 | Bit 26 | Bit 25 | Bit 24 | Bit 23 | Bit 22 | Bit 21 | Bit 20 | Bit 19 | Bit 18 | Bit 17 | Bit 16 | Bit 15 | Bit 14 | Bit 13 | Bit 12 | Bit 11 | Bit 10 | Bit 9  | Bit 8  | Bit 7  | Bit 6  | Bit 5  | Bit 4  | Bit 3  | Bit 2  | Bit 1  | Bit 0  |
|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|
| 15     | 14     | 13     | 12     | 11     | 10     | 9      | 8      | 7      | 6      | 5      | 4      | 3      | 2      | 1      | 0      |

Bits 31:21 Reserved, must be kept at reset value.

**Bit 20 VLTI: VLAN Tag Input**  
When this bit is set, it indicates that the VLAN tag to be inserted or replaced in Tx packet should be taken from the Tx descriptor.

**Bit 19 CSVL: C-VLAN or S-VLAN**  
When this bit is set, S-VLAN type (0x88A8) is inserted or replaced in the 13th and 14th bytes of transmitted packets. When this bit is reset, C-VLAN type (0x8100) is inserted or replaced in the 13th and 14th bytes of transmitted packets.
Bit 18 **VLP**: VLAN Priority Control

When this bit is set, the VLC field is used for VLAN deletion, insertion, or replacement. When this bit is reset, the VLC field is ignored.

Bits 17:16 **VLC[1:0]**: VLAN Tag Control in Transmit Packets

- 00: No VLAN tag deletion, insertion, or replacement
- 01: VLAN tag deletion
- 10: VLAN tag insertion
- 11: VLAN tag replacement

The MAC removes the VLAN type (bytes 17 and 18) and VLAN tag (bytes 19 and 20) of all transmitted packets with VLAN tags.

The MAC inserts VLT in bytes 19 and 20 of the packet after inserting the Type value (0x8100 or 0x88a8) in bytes 17 and 18. This operation is performed on all transmitted packets, irrespective of whether they already have a VLAN tag.

**Note:** Changes to this field take effect only on the start of a packet. If you write this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value.

Bits 15:0 **VLT[15:0]**: VLAN Tag for Transmit Packets

This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase.

Bits[15:13] are the User Priority field, Bit 12 is the CFI/DEI field, and Bits[11:0] are the VID field in the VLAN tag.

The following list describes the bits of this field:

- Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI)
- Bits[11:0]: VLAN Identifier (VID) field of VLAN tag

**Tx Queue flow control register (ETH_MACQTXFCR)**

Address offset: 0x0070

Reset value: 0x0000 0000

The Flow Control register controls the generation and reception of the Control (Pause Command) packets by the Flow control module of the MAC. A Write to a register with the Busy bit set to 1 triggers the Flow Control block to generate a Pause packet. The fields of the control packet are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control packet. The Busy bit remains set until the control packet is transferred onto the cable. The application must make sure that the Busy bit is cleared before writing to the register.
Bits 31:16  **PT[15:0]: Pause Time**

This field holds the value to be used in the Pause Time field in the Tx control packet. If the Pause Time bits are configured to be double-synchronized to the (G)MII clock domain, consecutive writes to this register should be performed only after at least four clock cycles in the destination clock domain.

Bits 15:8  Reserved, must be kept at reset value.

Bit 7  **DZPQ: Disable Zero-Quanta Pause**

When this bit is set, it disables the automatic generation of the zero-quanta Pause packets. When this bit is reset, normal operation with automatic zero-quanta Pause packet generation is enabled.

Bits 6:4  **PLT[2:0]: Pause Low Threshold**

This field configures the threshold of the Pause timer at which the input flow is checked for automatic retransmission of the Pause packet.

The threshold values should be always less than the Pause Time configured in Bits[31:16]. For example, if PT = 100H (256 slot times), and PLT = 001, a second Pause packet is automatically transmitted at 228 (256-28) slot times after the first Pause packet is transmitted.

The following list provides the threshold values for different values:

- **000**: Pause Time minus 4 Slot Times (PT -4 slot times)
- **001**: Pause Time minus 28 Slot Times (PT -28 slot times)
- **010**: Pause Time minus 36 Slot Times (PT -36 slot times)
- **011**: Pause Time minus 144 Slot Times (PT -144 slot times)
- **100**: Pause Time minus 256 Slot Times (PT -256 slot times)
- **101**: Pause Time minus 512 Slot Times (PT -512 slot times)
- **110-111**: Reserved

The slot time is defined as the time taken to transmit 512 bits (64 bytes) on the MII interface. This (approximate) computation is based on the packet size (64, 1518, 2000, 9018, 16384, or 32768) + 2 Pause Packet Size + IPG in Slot Times.

Bits 3:2  Reserved, must be kept at reset value.

Bit 1  **TFE: Transmit Flow Control Enable**

**Full-Duplex Mode**: when this bit is set, the MAC enables the flow control operation to Tx Pause packets. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause packets.

**Half-Duplex Mode**: when this bit is set, the MAC enables the backpressure operation. When this bit is reset, the backpressure feature is disabled.

Bit 0  **FCB_BPA: Flow Control Busy or Backpressure Activate**

This bit initiates a Pause packet in the full-duplex mode and activates the backpressure function in the half-duplex mode if the TFE bit is set.

**Full-Duplex Mode**: this bit should be read as 0 before writing to this register. To initiate a Pause packet, the application must set this bit to 1. During Control packet transfer, this bit continues to be set to indicate that a packet transmission is in progress. When Pause packet transmission is complete, the MAC resets this bit to 0. You should not write to this register until this bit is cleared.

**Half-Duplex Mode**: When this bit is set (and TFE bit is set) in the half-duplex mode, the MAC asserts the backpressure. During backpressure, when the MAC receives a new packet, the transmitter starts sending a JAM pattern resulting in a collision. When the MAC is configured for the full-duplex mode, the BPA is automatically disabled.
Rx flow control register (ETH_MACRXFCR)

Address offset: 0x0090
Reset value: 0x0000 0000

The Receive Flow Control register controls the pausing of MAC Transmit based on the received Pause packet.

Bits 31:2  Reserved, must be kept at reset value.

Bit 1  **UP**: Unicast Pause Packet Detect

A pause packet is processed when it has the unique multicast address specified in the IEEE 802.3. When this bit is set, the MAC can also detect Pause packets with unicast address of the station. This unicast address should be as specified in ETH_MACA0HR and ETH_MACA0LR.

When this bit is reset, the MAC only detects Pause packets with unique multicast address.

**Note**: The MAC does not process a Pause packet if the multicast address is different from the unique multicast address. This is also applicable to the received PFC packet when the Priority Flow Control (PFC) is enabled. The unique multicast address (0x01_80_C2_00_00_01) is as specified in IEEE 802.1 Qbb-2011.

Bit 0  **RFE**: Receive Flow Control Enable

When this bit is set and the MAC is operating in full-duplex mode, the MAC decodes the received Pause packet and disables its transmitter for a specified (Pause) time. When this bit is reset or the MAC is operating in half-duplex mode, the decode function of the Pause packet is disabled.

When PFC is enabled, flow control is enabled for PFC packets. The MAC decodes the received PFC packet and disables the Transmit queue, with matching priorities, for a duration of received Pause time.
Interrupt status register (ETH_MACISR)

Address offset: 0x00B0
Reset value: 0x0000 0000

The Interrupt Status register contains the status of interrupts.

Bits 31:15  Reserved, must be kept at reset value.

Bit 14 RXSTSIS: Receive Status Interrupt
This bit indicates the status of received packets. This bit is set when the RWT bit is set in the ETH_MACISR register. This bit is cleared when the corresponding interrupt source bit is read in the ETH_MACISR register.

Bit 13 TXSTSIS: Transmit Status Interrupt
This bit indicates the status of transmitted packets. This bit is set when any of the following bits is set in the ETH_MACISR register:
- Excessive Collision (EXCOL)
- Late Collision (LCOL)
- Excessive Deferral (EXDEF)
- Loss of Carrier (LCARR)
- No Carrier (NCARR)
- Jabber Timeout (TJT)
This bit is cleared when the corresponding interrupt source bit is read in the ETH_MACISR register.

Bit 12 TSIS: Timestamp Interrupt Status
If the Timestamp feature is enabled, this bit is set when any of the following conditions is true:
- The system time value is equal to or exceeds the value specified in the Target Time High and Low registers.
- There is an overflow in the Seconds register.
- The Target Time Error occurred, that is, programmed target time already elapsed.
If the Auxiliary Snapshot feature is enabled, this bit is set when the auxiliary snapshot trigger is asserted.
When drop transmit status is enabled in MTL, this bit is set when the captured transmit timestamp is updated in the ETH_MACTXTSSNR and ETH_MACTXTSSSR registers. When PTP offload feature is enabled, this bit is set when the captured transmit timestamp is updated in the ETH_MACTXTSSNR and ETH_MACTXTSSSR registers, for PTO generated Delay Request and Pdelay request packets.
This bit is cleared when the corresponding interrupt source bit is read in the ETH_MACTSSR register.

Bit 11 Reserved, must be kept at reset value.
Bit 10 **MMCTXIS**: MMC Transmit Interrupt Status
This bit is set high when an interrupt is generated in the MMC Transmit Interrupt Register.
This bit is cleared when all bits in this interrupt register are cleared.
This bit is valid only when you select the Enable MAC Management Counters (MMC) option.

Bit 9 **MMCRXIS**: MMC Receive Interrupt Status
This bit is set high when an interrupt is generated in the MMC Receive Interrupt Register.
This bit is cleared when all bits in this interrupt register are cleared.
This bit is valid only when you select the Enable MAC Management Counters (MMC) option.

Bit 8 **MMCIS**: MMC Interrupt Status
This bit is set high when Bit 11, Bit 10, or Bit 9 is set high. This bit is cleared only when all these bits are low. This bit is valid only when you select the Enable MAC Management Counters (MMC) option.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **LPIIS**: LPI Interrupt Status
When the Energy Efficient Ethernet feature is enabled, this bit is set for any LPI state entry or exit in the MAC Transmitter or Receiver. This bit is cleared when the TLPIEN bit of ETH_MACLCSR register is read. In all other modes, this bit is reserved.

Bit 4 **PMTIS**: PMT Interrupt Status
This bit is set when a Magic packet or Wake-on-LAN packet is received in the power-down mode (RWKPRCVD and MGKPRCVD bits in ETH_MACPCSR register). This bit is cleared when Bits[6:5] are cleared because of a Read operation to the ETH_MACPCSR register.
This bit is valid only when you select the Enable Power Management option.

Bit 3 **PHYIS**: PHY Interrupt
This bit is set when rising edge is detected on the phy_intr_i input. This bit is cleared when this register is read.

Bits 2:0 Reserved, must be kept at reset value.
Interrupt enable register (ETH_MACIER)

Address offset: 0x00B4
Reset value: 0x0000 0000

The Interrupt Enable register contains the masks for generating the interrupts.

</table>

Bits 31:15  Reserved, must be kept at reset value.

Bit 14  **RXSTSIE**: Receive Status Interrupt Enable
When this bit is set, it enables the assertion of the interrupt signal because of the setting of RXSTSIS bit in the ETH_MACISR register.

Bit 13  **TXSTSIE**: Transmit Status Interrupt Enable
When this bit is set, it enables the assertion of the interrupt signal because of the setting of TXSTSIS bit in the ETH_MACISR register.

Bit 12  **TSIE**: Timestamp Interrupt Enable
When this bit is set, it enables the assertion of the interrupt signal because of the setting of TSIS bit in ETH_MACISR register.
This bit is valid only when the Enable IEEE 1588 Timestamp Support option is selected. Otherwise, this bit is reserved.

Bits 11:6  Reserved, must be kept at reset value.

Bit 5  **LPIIE**: LPI Interrupt Enable
When this bit is set, it enables the assertion of the interrupt signal because of the setting of LPIIS bit in ETH_MACISR register.
This bit is valid only when the Enable Energy Efficient Ethernet (EEE) option is selected. Otherwise, this bit is reserved.

Bit 4  **PMTIE**: PMT Interrupt Enable
When this bit is set, it enables the assertion of the interrupt signal because of the setting of PMTIS bit in ETH_MACISR register.

Bit 3  **PHYIE**: PHY Interrupt Enable
When this bit is set, it enables the assertion of the interrupt signal because of the setting of PHYIS bit in ETH_MACISR register.

Bits 2:0  Reserved, must be kept at reset value.

Rx Tx status register (ETH_MACRXTXSR)

Address offset: 0x00B8
Reset value: 0x0000 0000

The Receive Transmit Status register contains the Receive and Transmit Error status.
Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **RWT**: Receive Watchdog Timeout

This bit is set when a packet with length greater than 2,048 bytes is received (10,240 bytes when Jumbo Packet mode is enabled) and the WD bit is reset in the ETH_MACCR register. This bit is set when a packet with length greater than 16,383 bytes is received and the WD bit is set in the ETH_MACCR register.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **EXCOL**: Excessive Collisions

When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the transmission aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the ETH_MACCR register, this bit is set after the first collision and the packet transmission is aborted.

Bit 4 **LCOL**: Late Collision

When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the packet transmission aborted because a collision occurred after the collision window (64 bytes including preamble in MII mode).

This bit is not valid if the Underflow error occurs.

Bit 3 **EXDEF**: Excessive Deferral

When the DTXSTS bit is set in the MTL_Operation_Mode register and the DC bit is set in the ETH_MACCR register, this bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 in 1000 Mbps mode or when Jumbo packet is enabled).

Bit 2 **LCARR**: Loss of Carrier

When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the loss of carrier occurred during packet transmission, that is, the phy_crs_i signal was inactive for one or more transmission clock periods during packet transmission. This bit is valid only for packets transmitted without collision.

Bit 1 **NCARR**: No Carrier

When the DTXSTS bit is set in the MTL_Operation_Mode register, this bit indicates that the carrier signal from the PHY is not present at the end of preamble transmission.

Bit 0 **TJT**: Transmit Jabber Timeout

This bit indicates that the Transmit Jabber Timer expired which happens when the packet size exceeds 2,048 bytes (10,240 bytes when the Jumbo packet is enabled) and JD bit is reset in the ETH_MACCR register. This bit is set when the packet size exceeds 16,383 bytes and the JD bit is set in the ETH_MACCR register.
PMT control status register (ETH_MACPCSR)

Address offset: 0x00C0

Reset value: 0x0000 0000

The PMT Control and Status Register is present only when you select the PMT module in coreConsultant.

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>RWKFILTRST: Remote wakeup Packet Filter Register Pointer Reset</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>When this bit is set, the remote wakeup packet filter register pointer is reset to 3'b000. It is automatically cleared after 1 clock cycle.</td>
</tr>
</tbody>
</table>

Bits 30:29 Reserved, must be kept at reset value.

Bits 28:24 RWKPTR[4:0]: Remote wakeup FIFO Pointer

This field gives the current value (0 to 7) of the Remote wakeup Packet Filter register pointer. When the value of this pointer is equal to 7, the contents of the Remote wakeup Packet Filter Register are transferred to the eth_mii_rx_clk domain when a Write occurs to that register.

Bits 23:11 Reserved, must be kept at reset value.

Bit 10 RWKPFE: Remote wakeup Packet Forwarding Enable

When this bit is set along with RWPKTEN, the MAC receiver drops all received frames until it receives the expected wakeup frame. All frames after that event including the received wakeup frame are forwarded to application. This bit is then self-cleared on receiving the wakeup packet. The application can also clear this bit before the expected wakeup frame is received. In such cases, the MAC reverts to the default behavior where packets received are forwarded to the application. This bit must only be set when RWPKTEN is set high and PWRDWN is set low. The setting of this bit has no effect when PWRDWN is set high.

Note: If Magic Packet Enable and wakeup Frame Enable are both set along with setting of this bit and Magic Packet is received prior to wake up frame, this bit is self-cleared on receiving Magic Packet, the received Magic packet is dropped, and all frames after received Magic Packet are forwarded to application.

Bit 9 GLBLUCAST: Global Unicast

When this bit set, any unicast packet filtered by the MAC (DAF) address recognition is detected as a remote wakeup packet.

Bits 8:7 Reserved, must be kept at reset value.
Bit 6  **RWKPRCVD**: Remote wakeup Packet Received
   When this bit is set, it indicates that the power management event is generated because of the reception of a remote wakeup packet. This bit is cleared when this register is read.

Bit 5  **MGKPRCVD**: Magic Packet Received
   When this bit is set, it indicates that the power management event is generated because of the reception of a magic packet. This bit is cleared when this register is read.

Bits 4:3  Reserved, must be kept at reset value.

Bit 2  **RWKPKTEN**: Remote wakeup Packet Enable
   When this bit is set, a power management event is generated when the MAC receives a remote wakeup packet.

Bit 1  **MGKPKTEN**: Magic Packet Enable
   When this bit is set, a power management event is generated when the MAC receives a magic packet.

Bit 0  **PWRDWN**: Power Down
   When this bit is set, the MAC receiver drops all received packets until it receives the expected magic packet or remote wakeup packet. This bit is then self-cleared and the power-down mode is disabled. The software can clear this bit before the expected magic packet or remote wakeup packet is received. The packets received by the MAC after this bit is cleared are forwarded to the application. This bit must only be set when the Magic Packet Enable, Global Unicast, or Remote wakeup Packet Enable bit is set high.

*Note:* You can gate-off the CSR clock during the power-down mode. However, when the CSR clock is gated-off, you cannot perform any read or write operations on this register. Therefore, the Software cannot clear this bit.
Remote wakeup packet filter register (ETH_MACRWKPFR)

Address offset: 0x00C4
Reset value: 0x0000 0000

</tbody>
</table>

Bits 31:0 **MACRWKPFR[31:0]**: Remote wakeup packet filter

Refer to Table 557 and Table 558 for details on register content and programming sequence.

The ETH_MACRWKPFR register at address 0x00C4 loads the wakeup Packet Filter register.

To load values in a wakeup Packet Filter register, the entire register (ETH_MACRWKPFR) must be written. The ETH_MACRWKPFR register is loaded by sequentially loading the eight, sixteen or thirty two register values in address (0x00C4) for ETH_MACRWKPFR value 0 to 7, respectively. The ETH_MACRWKPFR register is read in a similar way. The Ethernet peripheral updates the ETH_MACRWKPFR register current pointer value in Bits[26:24] of ETH_MACPCSR register.

The below table lists the remote wakeup scenarios in which PMT interrupt is generated.

### Table 558. ETH_MACRWKPFR

<table>
<thead>
<tr>
<th>Register</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Filter i Byte mask</td>
<td>The filter i byte mask register defines the bytes of the packet that are examined by filter i (0, 1, 2 or 3) to determine whether or not a packet is a wakeup packet.</td>
</tr>
<tr>
<td></td>
<td>- The MSB (31st bit) must be zero.</td>
</tr>
<tr>
<td></td>
<td>- Bit j[30:0] is the byte mask.</td>
</tr>
<tr>
<td></td>
<td>- If Bit j (byte number) of the byte mask is set, the CRC block processes the Filter i Offset + j of the incoming packet; otherwise Filter i Offset + j is ignored.</td>
</tr>
<tr>
<td>Filter i Command</td>
<td>The 4-bit filter i command controls the filter i operation.</td>
</tr>
<tr>
<td></td>
<td>- Bit 3 specifies the address type, defining the destination address type of the pattern.</td>
</tr>
<tr>
<td></td>
<td>When the bit is set, the pattern applies to only multicast packets; when the bit is reset, the pattern applies only to unicast packet.</td>
</tr>
<tr>
<td></td>
<td>- Bit 2 (Inverse mode), when set, reverses the logic of the CRC16 Hash function signal, to reject a packet with matching CRC_16 value.</td>
</tr>
<tr>
<td></td>
<td>Bit 2, along with Bit 1, allows a MAC to reject a subset of remote wakeup packets by creating filter logic such as &quot;Pattern 1 AND NOT Pattern 2&quot;.</td>
</tr>
<tr>
<td></td>
<td>- Bit 1 (And_Previous) implements the Boolean logic.</td>
</tr>
<tr>
<td></td>
<td>When set, the result of the current entry is logically ANDed with the result of the previous filter. This AND logic allows a filter pattern longer than 32 bytes by splitting the mask among two, three, or four filters. This depends on the number of filters that have the And_Previous bit set.</td>
</tr>
<tr>
<td></td>
<td>- Bit 0 is the enable for filter i. If Bit 0 is not set, filter i is disabled.</td>
</tr>
<tr>
<td>Filter i Offset</td>
<td>This filter i offset register defines the offset (within the packet) from which the filter i examines the packets.</td>
</tr>
<tr>
<td></td>
<td>- This 8-bit pattern-offset is the offset for the filter i first byte to be examined.</td>
</tr>
<tr>
<td></td>
<td>- The minimum allowed offset is 12, which refers to the 13th byte of the packet.</td>
</tr>
<tr>
<td></td>
<td>- The offset value 0 refers to the first byte of the packet.</td>
</tr>
<tr>
<td>Filter i CRC-16</td>
<td>This filter i CRC-16 register contains the CRC_16 value calculated from the pattern and also the byte mask programmed to the wakeup filter register block.</td>
</tr>
<tr>
<td></td>
<td>- The 16-bit CRC calculation uses the following polynomial: ( G(x) = x^{16} + x^{15} + x^2 + 1 )</td>
</tr>
<tr>
<td></td>
<td>Each mask, used in the Hash function calculation, is compared with a 16-bit value associated with that mask. Each filter has the following:</td>
</tr>
<tr>
<td></td>
<td>- 32-bit Mask: Each bit in this mask corresponds to one byte in the detected packet. If the bit is 1, the corresponding byte is taken into the CRC16 calculation.</td>
</tr>
<tr>
<td></td>
<td>- 8-bit Offset Pointer: Specifies the byte to start the CRC16 computation. The pointer and the mask are used together to locate the bytes to be used in the CRC16 calculations.</td>
</tr>
</tbody>
</table>

1. In all other combinations, the Remote Wakeup packet is not detected and PMT interrupt is not generated.

### LPI control status register (ETH_MACLCSR)

Address offset: 0x00D0  
Reset value: 0x0000 0000  

The LPI Control and Status Register controls the LPI functions and provides the LPI interrupt status. The status bits are cleared when this register is read.
Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **LPITE**: LPI Timer Enable
This bit controls the automatic entry of the MAC Transmitter into and exit out of the LPI state.
When LPITE, LPITXA and LPITXEN bits are set, the MAC Transmitter enters LPI state only when the complete MAC TX data path is IDLE for a period indicated by the ETH_MACLETR register.
After entering LPI state, if the data path becomes non-IDLE (due to a new packet being accepted for transmission), the Transmitter exits LPI state but does not clear LPITXEN bit.
This enables the re-entry into LPI state when it is IDLE again.
When LPITE is 0, the LPI Auto timer is disabled and MAC Transmitter enters LPI state based on the settings of LPITXA and LPITXEN bit descriptions.

Bit 19 **LPITXA**: LPI Tx Automate
This bit controls the behavior of the MAC when it is entering or coming out of the LPI mode on the Transmit side.
If the LPITXA and LPIEN bits are set to 1, the MAC enters the LPI mode only after all outstanding packets (in the core) and pending packets (in the application interface) have been transmitted. The MAC comes out of the LPI mode when the application sends any packet for transmission or the application issues a Tx FIFO Flush command. In addition, the MAC automatically clears the LPIEN bit when it exits the LPI state. If Tx FIFO Flush is set in the FTQ bit of ETH_MTLTxQOMR, when the MAC is in the LPI mode, it exits the LPI mode.
When this bit is 0, the LPIEN bit directly controls behavior of the MAC when it is entering or coming out of the LPI mode.

Bit 18 **PLSEN**: PHY Link Status Enable
This bit enables the link status received on the Receive paths to be used for activating the LPI LS TIMER.
When this bit is set, the MAC uses the PLS bit for the LPI LS Timer trigger. When this bit is reset, the MAC ignores the link-status bits of the ETH_MACPHYCSR register and takes only the PLS bit.
This bit is RO and reserved if you have not selected the PHY interface.

Bit 17 **PLS**: PHY Link Status
This bit indicates the link status of the PHY. The MAC Transmitter asserts the LPI pattern only when the link status is up (OKAY) at least for the time indicated by the LPI LS TIMER.
When this bit is set, the link is considered to be okay (UP) and when this bit is reset, the link is considered to be down.

Bit 16 **LPIEN**: LPI Enable
When this bit is set, it instructs the MAC Transmitter to enter the LPI state. When this bit is reset, it instructs the MAC to exit the LPI state and resume normal transmission.
This bit is cleared when the LPITXA bit is set and the MAC exits the LPI state because of the arrival of a new packet for transmission.

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **RLPIST**: Receive LPI State
When this bit is set, it indicates that the MAC is receiving the LPI pattern on the MII interface.

Bit 8 **TLPIST**: Transmit LPI State
When this bit is set, it indicates that the MAC is transmitting the LPI pattern on the MII interface.

Bits 7:4 Reserved, must be kept at reset value.
Bit 3 **RLPIEX:** Receive LPI Exit

When this bit is set, it indicates that the MAC Receiver has stopped receiving the LPI pattern on the MII interface, exited the LPI state, and resumed the normal reception. This bit is cleared by a read into this register.

*Note:* This bit may not be set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than three clock cycles of CSR clock.

Bit 2 **RLPIEN:** Receive LPI Entry

When this bit is set, it indicates that the MAC Receiver has received an LPI pattern and entered the LPI state. This bit is cleared by a read into this register.

*Note:* This bit may not be set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than three clock cycles of CSR clock.

Bit 1 **TLPIEX:** Transmit LPI Exit

When this bit is set, it indicates that the MAC transmitter exited the LPI state after the application cleared the LPIEN bit and the LPI TW Timer has expired. This bit is cleared by a read into this register.

Bit 0 **TLPIEN:** Transmit LPI Entry

When this bit is set, it indicates that the MAC Transmitter has entered the LPI state because of the setting of the LPIEN bit. This bit is cleared by a read into this register.

### LPI timers control register (ETH_MACLTCR)

Address offset: 0x00D4

Reset value: 0x03E8 0000

The LPI Timers Control register controls the timeout values in the LPI states. It specifies the time for which the MAC transmits the LPI pattern and also the time for which the MAC waits before resuming the normal transmission.

</tbody>
</table>

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:16 **LST[9:0]:** LPI LS Timer

This field specifies the minimum time (in milliseconds) for which the link status from the PHY should be up (OKAY) before the LPI pattern can be transmitted to the PHY. The MAC does not transmit the LPI pattern even when the LPIEN bit is set unless the LPI LS Timer reaches the programmed terminal count. The default value of the LPI LS Timer is 1000 (1 sec) as defined in the IEEE standard.

Bits 15:0 **TWT[15:0]:** LPI TW Timer

This field specifies the minimum time (in microseconds) for which the MAC waits after it stops transmitting the LPI pattern to the PHY and before it resumes the normal transmission. The TLPIEX status bit is set after the expiry of this timer.
### LPI entry timer register (ETH_MACLETR)

**Address offset:** 0x00D8  
**Reset value:** 0x0000 0000  

The LPI Entry Timer Register is used to store the LPI Idle Timer Value in Micro-Seconds.

<table>
<thead>
<tr>

</thead>
<tbody>
<tr>
<td>31-16</td>
<td>LPIET[16:13]</td>
</tr>
<tr>
<td>15-0</td>
<td>LPIET[12:0]</td>
</tr>
</tbody>
</table>

**Bits 31:20**  
Reserved, must be kept at reset value.

**Bits 19:3**  
**LPIET[16:0]:** LPI Entry Timer  
This field specifies the time in micro-seconds the MAC will wait to enter LPI mode, after it has transmitted all the frames. This field is valid and used only when LPITE and LPITXA are set to 1.  
Bits [2:0] are read-only so that the granularity of this timer is in steps of 8 micro-seconds.

**Bits 2:0**  
Reserved, must be kept at reset value.

### 1-microsecond-tick counter register (ETH_MAC1USTCR)

**Address offset:** 0x00DC  
**Reset value:** 0x0000 0000  

This register controls the generation of the Reference time (1-microsecond tick) for all the LPI timers. This timer has to be programmed by the software initially.

<table>

</table>

**Bits 31:12**  
Reserved, must be kept at reset value.

**Bits 11:0**  
**TIC_1US_CNTR[11:0]:** 1 µs tick Counter  
The application must program this counter so that the number of clock cycles of CSR clock is 1 µs.  
(Subtract 1 from the value before programming).  
For example if the CSR clock is 100 MHz then this field needs to be programmed to 100 - 1 = 99 (which is 0x63).  
This is required to generate the 1 µs events that are used to update some of the EEE related counters.
Version register (ETH_MACVR)

Address offset: 0x0110
Reset value: 0x0000 3041

The version register identifies the version of the Ethernet peripheral.

</table>
Bits 31:19  Reserved, must be kept at reset value.

Bits 18:17  **TFCSTS[1:0]:** MAC Transmit Packet Controller Status
            This field indicates the state of the MAC Transmit Packet Controller module:
            00: Idle state
            01: Waiting for one of the following:
                – Status of the previous packet OR
                – IPG or backoff period to be over
            10: Generating and transmitting a Pause control packet (in full-duplex mode)
            11: Transferring input packet for transmission

Bit 16  **TPESTS:** MAC MII Transmit Protocol Engine Status
        When this bit is set, it indicates that the MAC MII transmit protocol engine is actively
        transmitting data, and it is not in the Idle state.

Bits 15:3  Reserved, must be kept at reset value.

Bits 2:1  **RFCFCSTS[1:0]:** MAC Receive Packet Controller FIFO Status
         When this bit is set, this field indicates the active state of the small FIFO Read and Write
         controllers of the MAC Receive Packet Controller module.

Bit 0  **RPESTS:** MAC MII Receive Protocol Engine Status
       When this bit is set, it indicates that the MAC MII receive protocol engine is actively receiving
       data, and it is not in the Idle state.

**HW feature 1 register (ETH_MACHWF1R)**

Address offset: 0x0120

Reset value: 0x1184 1904

This register indicates the presence of second set of the optional features or functions of the
Ethernet peripheral. The software driver can use this register to dynamically enable or
disable the programs related to the optional blocks.
Bit 31  Reserved, must be kept at reset value.

Bits 30:27  **L3L4FNUM[3:0]**: Total number of L3 or L4 Filters
   This field indicates the total number of L3 or L4 filters:
   0000: No L3 or L4 Filter
   0001: 1 L3 or L4 Filter
   0010: 2 L3 or L4 Filters
   ...
   1000: 8 L3 or L4

Bit 26  Reserved, must be kept at reset value.

Bits 25:24  **HASHTBLSZ[1:0]**: Hash Table Size
   This field indicates the size of the Hash table:
   00: No Hash table
   01: 64
   10: 128
   11: 256

Bits 23:21  Reserved, must be kept at reset value.

Bit 20  **AVSEL**: AV Feature Enable
   This bit is set to 1 when the Enable Audio Video Bridging option is selected.

Bit 19  **DBGMEM**: DMA Debug Registers Enable
   This bit is set to 1 when the Debug Mode Enable option is selected

Bit 18  **TSOEN**: TCP Segmentation Offload Enable
   This bit is set to 1 when the Enable TCP Segmentation Offloading for TCP/IP Packets option is selected

Bit 17  **SPHEN**: Split Header Feature Enable
   This bit is set to 1 when the Enable Split Header Structure option is selected

Bit 16  **DCBEN**: DCB Feature Enable
   This bit is set to 1 when the Enable Data Center Bridging option is selected

Bits 15:14  **ADDR64[1:0]**: Address width
   This field indicates the configured address width.
   00: 32 bits
   Others: Reserved

Bit 13  **ADVTWORD**: IEEE 1588 High Word Register Enable
   This bit is set to 1 when the Add IEEE 1588 Higher Word Register option is selected

Bit 12  **PTOEN**: PTP Offload Enable
   This bit is set to 1 when the Enable PTP Timestamp Offload Feature is selected.

Bit 11  **OSTEN**: One-Step Timestamping Enable
   This bit is set to 1 when the Enable One-Step Timestamp Feature is selected.
Bits 10:6  **TXFIFOSIZE[4:0]**: MTL Transmit FIFO Size

This field contains the configured value of MTL Tx FIFO in bytes expressed as Log to base 2 minus 7, that is, \( \text{Log}_2(\text{TXFIFO\_SIZE}) -7 \):

- 00000: 128 bytes
- 00001: 256 bytes
- 00010: 512 bytes
- 00011: 1,024 bytes
- 00100: 2,048 bytes
- 00101: 4,096 bytes
- 00110: 8,192 bytes
- 00111: 16,384 bytes
- 01000: 32 Kbytes
- 01001: 64 Kbytes
- 01010: 128 Kbytes
- 01011-11111: Reserved

Bit 5  Reserved, must be kept at reset value.

Bits 4:0  **RXFIFOSIZE[4:0]**: MTL Receive FIFO Size

This field contains the configured value of MTL Rx FIFO in bytes expressed as Log to base 2 minus 7, that is, \( \text{Log}_2(\text{RXFIFO\_SIZE}) -7 \):

- 00000: 128 bytes
- 00001: 256 bytes
- 00010: 512 bytes
- 00011: 1,024 bytes
- 00100: 2,048 bytes
- 00101: 4,096 bytes
- 00110: 8,192 bytes
- 00111: 16,384 bytes
- 01000: 32,767 bytes
- 01001: 64 Kbytes
- 01010: 128 Kbytes
- 01011: 256 Kbytes
- 01100-11111: Reserved
HW feature 2 register (ETH_MACHWF2R)

Address offset: 0x0124

Reset value: 0x4100 0000

This register indicates the presence of third set of the optional features or functions of the Ethernet peripheral. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.

Bit 31  Reserved, must be kept at reset value.

Bits 30:28  **AUXSNAPNUM[2:0]: Number of Auxiliary Snapshot Inputs**

This field indicates the number of auxiliary snapshot inputs:

- 000: No auxiliary input
- 001: 1 auxiliary input
- 010: 2 auxiliary inputs
- 011: 3 auxiliary inputs
- 100: 4 auxiliary inputs
- 101-111: Reserved

Bit 27  Reserved, must be kept at reset value.

Bits 26:24  **PPSOUTNUM[2:0]: Number of PPS Outputs**

This field indicates the number of PPS outputs:

- 000: No PPS output
- 001: 1 PPS output
- 010: 2 PPS outputs
- 011: 3 PPS outputs
- 100: 4 PPS outputs
- 101-111: Reserved

Bits 23:22  Reserved, must be kept at reset value.

Bits 21:18  **TXCHCNT[3:0]: Number of DMA Transmit Channels**

This field indicates the number of DMA Transmit channels:

- 0000: 1 DMA Tx Channel
- 0001: 2 DMA Tx Channels
- ...  
- 0111: 8 DMA Tx

Bits 17:16  Reserved, must be kept at reset value.
Bits 15:12 **RXCHCNT[3:0]**: Number of DMA Receive Channels

This field indicates the number of DMA Receive channels:
- 0000: 1 DMA Rx Channel
- 0001: 2 DMA Rx Channels
- ..
- 0111: 8 DMA Rx

Bits 11:10 Reserved, must be kept at reset value.

Bits 9:6 **TXQNT[3:0]**: Number of MTL Transmit Queues

This field indicates the number of MTL Transmit queues:
- 0000: 1 MTL Tx queue
- 0001: 2 MTL Tx queues
- ..
- 0111: 8 MTL Tx

Bits 5:4 Reserved, must be kept at reset value.

Bits 3:0 **RXQNT[3:0]**: Number of MTL Receive Queues

This field indicates the number of MTL Receive queues:
- 0000: 1 MTL Rx queue
- 0001: 2 MTL Rx queues
- ..
- 0111: 8 MTL Rx

**MDIO address register (ETH_MACMDIOAR)**

Address offset: 0x0200

Reset value: 0x0000 0000

The MDIO Address register controls the management cycles to external PHY through a management interface.
Bits 31:28  Reserved, must be kept at reset value.

Bit 27  **PSE**: Preamble Suppression Enable
When this bit is set, the SMA will suppress the 32-bit preamble and transmit MDIO frames with only 1 preamble bit.
When this bit is 0, the MDIO frame always has 32 bits of preamble as defined in the IEEE specifications.

Bit 26  **BTB**: Back to Back transactions
When this bit is set and the NTC has value greater than 0, then the MAC will inform the completion of a read or write command at the end of frame transfer (before the trailing clocks are transmitted). The software can thus initiate the next command which will be executed immediately irrespective of the number trailing clocks generated for the previous frame.
When this bit is reset, then the read/write command completion (MII busy is cleared) only after the trailing clocks are generated. In this mode, it is ensured that the NTC is always generated after each frame.
This bit must not be set when NTC=0.

Bits 25:21  **PA[4:0]**: Physical Layer Address
This field indicates which Clause 22 PHY devices (out of 32 devices) the MAC is accessing.
This field indicates which Clause 45 capable PHYs (out of 32 PHYs) the MAC is accessing.

Bits 20:16  **RDA[4:0]**: Register/Device Address
These bits select the PHY register in selected Clause 22 PHY device. These bits select the Device (MMD) in selected Clause 45 capable PHY.

Bit 15  Reserved, must be kept at reset value.

Bits 14:12  **NTC[2:0]**: Number of Training Clocks
This field controls the number of trailing clock cycles generated on ETH_MDC after the end of transmission of MDIO frame. The valid values can be from 0 to 7. Programming the value to 3'h3 indicates that there are additional three clock cycles on the MDC line after the end of MDIO frame transfer.
Bits 11:8  **CR[3:0]: CSR Clock Range**

The CSR Clock Range selection determines the frequency of the MDC clock according to the CSR clock frequency used in your design:

- **0000:** CSR clock = 60-100 MHz; MDC clock = CSR clock/42
- **0001:** CSR clock = 100-150 MHz; MDC clock = CSR clock/62
- **0010:** CSR clock = 20-35 MHz; MDC clock = CSR clock/16
- **0011:** CSR clock = 35-60 MHz; MDC clock = CSR clock/26
- **0100:** CSR clock = 150-250 MHz; MDC clock = CSR clock/102
- **0101:** CSR clock = 250-300 MHz; MDC clock = CSR clock/124
- **0110, 0111:** Reserved

The suggested range of CSR clock frequency applicable for each value (when Bit 11 = 0) ensures that the MDC clock is approximately between 1.0 MHz to 2.5 MHz frequency range. When Bit 11 is set, you can achieve a higher frequency of the MDC clock than the frequency limit of 2.5 MHz (specified in the IEEE 802.3) and program a clock divider of lower value. For example, when CSR clock is of 100 MHz frequency and you program these bits as 1010, the resultant MDC clock is of 12.5 MHz which is above the range specified in IEEE 802.3.

Program the following values only if the interfacing chips support faster MDC clocks:

- **1000:** CSR clock/4
- **1001:** CSR clock/6
- **1010:** CSR clock/8
- **1011:** CSR clock/10
- **1100:** CSR clock/12
- **1101:** CSR clock/14
- **1110:** CSR clock/16
- **1111:** CSR clock/18

Bits 7:5  **Reserved, must be kept at reset value.**

Bit 4  **SKAP: Skip Address Packet**

When this bit is set, the SMA does not send the address packets before read, write, or post-read increment address packets. This bit is valid only when C45E is set.
MDIO data register (ETH_MACMDIODR)

Address offset: 0x0204
Reset value: 0x0000 0000

The MDIO Data register stores the Write data to be written to the PHY register located at the address specified in ETH_MACMDIOAR. This register also stores the Read data from the PHY register located at the address specified by MDIO Address register.

### Bits 31:16 RA[15:0]: Register Address

This field is valid only when C45E is set. It contains the Register Address in the PHY to which the MDIO frame is intended for.

### Bits 15:0 MD[15:0]: MII Data

This field contains the 16-bit data value read from the PHY after a Management Read operation or the 16-bit data value to be written to the PHY before a Management Write operation.
ARP address register (ETH_MACARPAR)

Address offset: 0x0AE0
Reset value: 0x0000 0000

The ARP Address register contains the IPv4 Destination Address of the MAC.

ARPPA[15:0]

Bits 31:0 ARPPA[31:0]: ARP Protocol Address
This field contains the IPv4 Destination Address of the MAC. This address is used for perfect match with the Protocol Address of Target field in the received ARP packet.
This field is available only when the Enable IPv4 ARP Offload option is selected.

Address 0 high register (ETH_MACA0HR)

Address offset: 0x0300
Reset value: 0x8000 FFFF

The MAC Address0 High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the MII interface corresponds to the LS byte (Bits [7:0]) of the MAC Address Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the MII as the destination address, then the MacAddress0 Register [47:0] is compared with 0x665544332211.

If the MAC address registers are configured to be double-synchronized to the MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address0 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

ADDRHI[15:0]

Bit 31 AE: Address Enable
This bit is always set to 1.

Bits 30:16 Reserved, must be kept at reset value.

Bits 15:0 ADDRHI[15:0]: MAC Address0[47:32]
This field contains the upper 16 bits [47:32] of the first 6-byte MAC address. The MAC uses this field for filtering the received packets and inserting the MAC address in the Transmit Flow Control (Pause) Packets.
Address x low register (ETH_MACAxLR)

Address offset: 0x0304 + 0x8 * x, (x = 0 to 3)
Reset value: 0xFFFF FFFF

The MAC Address x Low register holds the lower 32 bits of the 6-byte first MAC address of the station.

ADDRHI[15:0]
Bit 31  **AE**: Address Enable
       When this bit is set, the address filter module uses the second MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering.

Bit 30  **SA**: Source Address
       When this bit is set, the MAC Address1[47:0] is used to compare with the SA fields of the received packet. When this bit is reset, the MAC Address x[47:0] is used to compare with the DA fields of the received packet.

Bits 29:24  **MBC[5:0]**: Mask Byte Control
       These bits are mask control bits for comparing each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address1 registers. Each bit controls the masking of the bytes as follows:
       Bit 29: Register 194[15:8]
       Bit 28: Register 194[7:0]
       Bit 27: Register 195[31:24]
       ..
       Bit 24: Register 195[7:0]
       You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address.

Bits 23:16  Reserved, must be kept at reset value.

Bits 15:0  **ADDRH[15:0]**: MAC Address1 [47:32]
       This field contains the upper 16 bits[47:32] of the second 6-byte MAC address.
**MMC control register (ETH\_MMC\_CONTROL)**

Address offset: 0x0700

Reset value: 0x0000 0000

This register configures the MMC operating mode.

<table>

<td></td>
</tr>
</tbody>
</table>
Bit 2 **RSTONRD**: Reset on Read
When this bit is set, the MMC counters are reset to zero after Read (self-clearing after reset).
The counters are cleared when the least significant byte lane (Bits[7:0]) is read.

Bit 1 **CNTSTOPRO**: Counter Stop Rollover
When this bit is set, the counter does not roll over to zero after reaching the maximum value.

Bit 0 **CNTRST**: Counters Reset
When this bit is set, all counters are reset. This bit is cleared automatically after 1 clock cycle.

**MMC Rx interrupt register (ETH_MMC_RX_INTERRUPT)**
Address offset: 0x0704
Reset value: 0x0000 0000

This register maintains the interrupts generated from all Receive statistics counters.
The MMC Receive Interrupt register maintains the interrupts that are generated when the following occur:
- Receive statistic counters reach half of their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter).
- Receive statistic counters cross their maximum values (0xFFFF_FFFF for 32 bit counter and 0xFFFF for 16 bit counter).

When the Counter Stop Rollover is set, interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit.

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **RXLPITRCIS**: MMC Receive LPI transition counter interrupt status
This bit is set when the Rx_LPI_Tran_Cntr counter reaches half of the maximum value or the maximum value.

Bit 26 **RXLPIUSCIS**: MMC Receive LPI microsecond counter interrupt status
This bit is set when the Rx_LPI_USEC_Cntr counter reaches half of the maximum value or the maximum value.

Bits 25:18 Reserved, must be kept at reset value.
Bit 17  **RXUCGPI**S: MMC Receive Unicast Good Packet Counter Interrupt Status

   This bit is set when the rxunicastpackets_g counter reaches half of the maximum value or the maximum value.

Bits 16-7  Reserved, must be kept at reset value.

Bit 6  **RXALGNERPIS**: MMC Receive Alignment Error Packet Counter Interrupt Status

   This bit is set when the rxalignmenterror counter reaches half of the maximum value or the maximum value.

Bit 5  **RXCRCPi**RIS: MMC Receive CRC Error Packet Counter Interrupt Status

   This bit is set when the rxcrcerror counter reaches half of the maximum value or the maximum value.

Bits 4:0  Reserved, must be kept at reset value.

**MMC Tx interrupt register (ETH_MMC_TX_INTERRUPT)**

Address offset: 0x0708

Reset value: 0x0000_0000

This register maintains the interrupts generated from all Transmit statistics counters.

The MMC Transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half their maximum values (0x8000_0000 for 32 bit counter and 0x8000 for 16 bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter).

When Counter Stop Rollover is set, the interrupts are set but the counter remains at all-ones.

The MMC Transmit Interrupt register is a 32 bit register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read.

The least significant byte lane (Bits[7:0]) of the respective counter must be read to clear the interrupt bit.
Bits 31:28  Reserved, must be kept at reset value.

Bit 27  **TXLPITRCIS**: MMC Transmit LPI transition counter interrupt status
        This bit is set when the Tx_LPI_Tran_Cntr counter reaches half of the maximum value or the maximum value.

Bit 26  **TXLPIUSCIS**: MMC Transmit LPI microsecond counter interrupt status
        This bit is set when the Tx_LPI_USEC_Cntr counter reaches half of the maximum value or the maximum value.

Bits 25:22  Reserved, must be kept at reset value.

Bit 21  **TXGPKTIS**: MMC Transmit Good Packet Counter Interrupt Status
        This bit is set when the txpacketcount_g counter reaches half of the maximum value or the maximum value.

Bits 20:16  Reserved, must be kept at reset value.

Bit 15  **TXMCOLGPIS**: MMC Transmit Multiple Collision Good Packet Counter Interrupt Status
        This bit is set when the txmulticol_g counter reaches half of the maximum value or the maximum value.

Bit 14  **TXSCOLGPIS**: MMC Transmit Single Collision Good Packet Counter Interrupt Status
        This bit is set when the txsinglecol_g counter reaches half of the maximum value or the maximum value.

Bits 13:0  Reserved, must be kept at reset value.
MMC Rx interrupt mask register (ETH_MMC_RX_INTERRUPT_MASK)

Address offset: 0x070C
Reset value: 0x0000 0000

The MMC Receive Interrupt Mask register maintains the masks for the interrupts generated when receive statistic counters reach half of their maximum value or the maximum values.

Bits 31:28  Reserved, must be kept at reset value.

Bit 27  RXLPITRCIM: MMC Receive LPI transition counter interrupt Mask
Setting this bit masks the interrupt when the Rx_LPI_Tran_Cntr counter reaches half of the maximum value or the maximum value.

Bit 26  RXLPIUSCIM: MMC Receive LPI microsecond counter interrupt Mask
Setting this bit masks the interrupt when the Rx_LPI_USEC_Cntr counter reaches half of the maximum value or the maximum value.

Bits 25:18  Reserved, must be kept at reset value.

Bit 17  RXUCGPIM: MMC Receive Unicast Good Packet Counter Interrupt Mask
Setting this bit masks the interrupt when the rxunicastpackets_g counter reaches half of the maximum value or the maximum value.

Bits 16:7  Reserved, must be kept at reset value.

Bit 6  RXALGNERPIM: MMC Receive Alignment Error Packet Counter Interrupt Mask
Setting this bit masks the interrupt when the rxalignmenterror counter reaches half of the maximum value or the maximum value.

Bit 5  RXCRCERPIM: MMC Receive CRC Error Packet Counter Interrupt Mask
Setting this bit masks the interrupt when the rxcrcerror counter reaches half of the maximum value or the maximum value.

Bits 4:0  Reserved, must be kept at reset value.
MMC Tx interrupt mask register (ETH_MMC_TX_INTERRUPT_MASK)

Address offset: 0x0710
Reset value: 0x0000 0000

This register maintains the masks for interrupts generated from all Transmit statistics counters.

The MMC Transmit Interrupt Mask register maintains the masks for the interrupts generated when the transmit statistic counters reach half of their maximum value or the maximum values. This register is 32 bit wide. This register is present only when any one of the MMC Transmit Counters is selected during core configuration.

Bits 31:28  Reserved, must be kept at reset value.

Bit 27  **TXLPITRCIM**: MMC Transmit LPI transition counter interrupt Mask
Setting this bit masks the interrupt when the Tx_LPI_Tran_Cntr counter reaches half of the maximum value or the maximum value.

Bit 26  **TXLPUSCIM**: MMC Transmit LPI microsecond counter interrupt Mask
Setting this bit masks the interrupt when the Tx_LPI_USEC_Cntr counter reaches half of the maximum value or the maximum value.

Bits 25:21  Reserved, must be kept at reset value.

Bit 21  **TXGPKTIM**: MMC Transmit Good Packet Counter Interrupt Mask
Setting this bit masks the interrupt when the txpacketcount_g counter reaches half of the maximum value or the maximum value.

Bits 20:16  Reserved, must be kept at reset value.

Bit 15  **TXMCOLGPIM**: MMC Transmit Multiple Collision Good Packet Counter Interrupt Mask
Setting this bit masks the interrupt when the txmulticol_g counter reaches half of the maximum value or the maximum value.

Bit 14  **TXSCOLGPIM**: MMC Transmit Single Collision Good Packet Counter Interrupt Mask
Setting this bit masks the interrupt when the txsinglecol_g counter reaches half of the maximum value or the maximum value.

Bits 13:0  Reserved, must be kept at reset value.
Tx single collision good packets register  
(ETH_TX_SINGLE_COLLISION_GOOD_PACKETS)

Address offset: 0x074C
Reset value: 0x0000 0000

This register provides the number of successfully transmitted packets by Ethernet peripheral after a single collision in the half-duplex mode.

Bits 31:0 TXMULTCOLG[31:0]: Tx Multiple Collision Good Packets
This field indicates the number of successfully transmitted packets after multiple collisions in the half-duplex mode.

Tx packet count good register (ETH_TX_PACKET_COUNT_GOOD)

Address offset: 0x0768
Reset value: 0x0000 0000

This register provides the number of good packets transmitted by Ethernet peripheral.
RM0433 Ethernet (ETH): media access control (MAC) with DMA controller

---

Rx CRC error packets register (ETH_RX_CRC_ERROR_PACKETS)

Address offset: 0x0794
Reset value: 0x0000 0000

This register provides the number of packets received by Ethernet peripheral with CRC error.

- **TXPKTG[31:16]**
  - Bits 31:0: Tx Packet Count Good
    - This field indicates the number of good packets transmitted.

- **RXCRCERR[31:16]**
  - Bits 31:0: Rx CRC Error Packets
    - This field indicates the number of packets received with CRC error.

- **RXALGNERR[31:16]**
  - Bits 31:0: Rx Alignment Error Packets
    - This field indicates the number of packets received with alignment (dribble) error. It is valid only in 10/100 mode.

15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 L4DPIM0: Layer 4 Destination Port Inverse Match Enable
When this bit is set, the Layer 4 Destination Port number field is enabled for inverse matching. When this bit is reset, the Layer 4 Destination Port number field is enabled for perfect matching.
This bit is valid and applicable only when the L4DPM0 bit is set high.

Bit 20 L4DPM0: Layer 4 Destination Port Match Enable
When this bit is set, the Layer 4 Destination Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Destination Port number field for matching.

Bit 19 L4SPIM0: Layer 4 Source Port Inverse Match Enable
When this bit is set, the Layer 4 Source Port number field is enabled for inverse matching. When this bit is reset, the Layer 4 Source Port number field is enabled for perfect matching.
This bit is valid and applicable only when the L4SPM0 bit is set high.

Bit 18 L4SPM0: Layer 4 Source Port Match Enable
When this bit is set, the Layer 4 Source Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Source Port number field for matching.

Bit 17 Reserved, must be kept at reset value.

Bit 16 L4PEN0: Layer 4 Protocol Enable
When this bit is set, the Source and Destination Port number fields of UDP packets are used for matching. When this bit is reset, the Source and Destination Port number fields of TCP packets are used for matching.
The Layer 4 matching is done only when the L4SPM0 or L4DPM0 bit is set.
Bits 15:11 **L3HDBM0[4:0]**: Layer 3 IP DA Higher Bits Match

IPv4 Packets:
This field contains the number of higher bits of IP Destination Address that are matched in the IPv4 packets. The following list describes the values of this field:
0: No bits are masked.
1: LSB[0] is masked
2: Two LSBs [1:0] are masked
.. 31: All bits except MSB are masked.

IPv6 Packets:
Bits[12:11] of this field correspond to Bits[6:5] of L3HSBM0 which indicate the number of lower bits of IP Source or Destination Address that are masked in the IPv6 packets. The following list describes the concatenated values of the L3HDBM0[1:0] and L3HSBM0 bits:
0: No bits are masked.
1: LSB[0] is masked.
2: Two LSBs [1:0] are masked
.. 127: All bits except MSB are masked.

This field is valid and applicable only when the L3DAM0 or L3SAM0 bit is set.

Bits 10:6 **L3HSBM0[4:0]**: Layer 3 IP SA Higher Bits Match

IPv4 Packets:
This field contains the number of lower bits of IP Source Address that are masked for matching in the IPv4 packets. The following list describes the values of this field:
0: No bits are masked.
1: LSB[0] is masked
2: Two LSBs [1:0] are masked
.. 31: All bits except MSB are masked.

IPv6 Packets:
This field contains Bits[4:0] of L3HSBM0. These bits indicate the number of higher bits of IP Source or Destination Address matched in the IPv6 packets. This field is valid and applicable only when the L3DAM0 or L3SAM0 bit is set.

Bit 5 **L3DAIM0**: Layer 3 IP DA Inverse Match Enable
When this bit is set, the Layer 3 IP Destination Address field is enabled for inverse matching. When this bit is reset, the Layer 3 IP Destination Address field is enabled for perfect matching.

This bit is valid and applicable only when the L3DAM0 bit is set high.

Bit 4 **L3DAM0**: Layer 3 IP DA Match Enable
When this bit is set, the Layer 3 IP Destination Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Destination Address field for matching.

*Note:* When the L3PEN0 bit is set, you should set either this bit or the L3SAM0 bit because either IPv6 DA or SA can be checked for filtering.

Bit 3 **L3SAIM0**: Layer 3 IP SA Inverse Match Enable
When this bit is set, the Layer 3 IP Source Address field is enabled for inverse matching. When this bit is reset, the Layer 3 IP Source Address field is enabled for perfect matching.

This bit is valid and applicable only when the L3SAM0 bit is set.
Bit 2  **L3SAM0**: Layer 3 IP SA Match Enable  
When this bit is set, the Layer 3 IP Source Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Source Address field for matching.  
*Note:* When the L3PEN0 bit is set, you should set either this bit or the L3DAM0 bit because either IPv6 SA or DA can be checked for filtering.

Bit 1  Reserved, must be kept at reset value.

Bit 0  **L3PEN0**: Layer 3 Protocol Enable  
When this bit is set, the Layer 3 IP Source or Destination Address matching is enabled for IPv6 packets. When this bit is reset, the Layer 3 IP Source or Destination Address matching is enabled for IPv4 packets.  
The Layer 3 matching is done only when the L3SAM0 or L3DAM0 bit is set.

**Layer4 address filter 0 register (ETH_MACL4A0R)**

Address offset: 0x0904  
Reset value: 0x0000 0000

   Bit 21 **L4DPM1**: Layer 4 Destination Port Match Enable
      When this bit is set, the Layer 4 Destination Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Destination Port number field for matching.

   Bit 19 **L4SPIM1**: Layer 4 Source Port Inverse Match Enable
      When this bit is set, the Layer 4 Source Port number field is enabled for inverse matching. When this bit is reset, the MAC ignores the Layer 4 Source Port number field for inverse matching.

   Bit 18 **L4SPM1**: Layer 4 Source Port Match Enable
      When this bit is set, the Layer 4 Source Port number field is enabled for matching. When this bit is reset, the MAC ignores the Layer 4 Source Port number field for matching.
Bit 16 **L4PEN1**: Layer 4 Protocol Enable
When this bit is set, the Source and Destination Port number fields of UDP packets are used for matching. When this bit is reset, the Source and Destination Port number fields of TCP packets are used for matching.
The Layer 4 matching is done only when the L4SPM0 or L4DPM0 bit is set.

Bits 15:11 **L3HDBM1[4:0]**: Layer 3 IP DA Higher Bits Match
IPv4 Packets:
This field contains the number of higher bits of IP Destination Address that are matched in the IPv4 packets. The following list describes the values of this field:
0: No bits are masked.
1: LSb[0] is masked
2: Two LSbs [1:0] are masked
.. 31: All bits except MSb are masked.
IPv6 Packets:
Bits[12:11] of this field correspond to Bits[6:5] of L3HSBM0 which indicate the number of lower bits of IP Source or Destination Address that are masked in the IPv6 packets. The following list describes the concatenated values of the L3HDBM0[1:0] and L3HSBM0 bits:
0: No bits are masked.
1: LSb[0] is masked.
2: Two LSbs [1:0] are masked
.. 127: All bits except MSb are masked.
This field is valid and applicable only when the L3DAM0 or L3SAM0 bit is set.

Bits 10:6 **L3HSBM1[4:0]**: Layer 3 IP SA Higher Bits Match
IPv4 Packets:
This field contains the number of lower bits of IP Source Address that are masked for matching in the IPv4 packets. The following list describes the values of this field:
0: No bits are masked.
1: LSb[0] is masked
2: Two LSbs [1:0] are masked
.. 31: All bits except MSb are masked.
IPv6 Packets:
This field contains Bits[4:0] of L3HSBM0. These bits indicate the number of higher bits of IP Source or Destination Address matched in the IPv6 packets. This field is valid and applicable only when the L3DAM0 or L3SAM0 bit is set high.

Bit 5 **L3DAIM1**: Layer 3 IP DA Inverse Match Enable
When this bit is set, the Layer 3 IP Destination Address field is enabled for inverse matching. When this bit is reset, the Layer 3 IP Destination Address field is enabled for perfect matching.
This bit is valid and applicable only when the L3DAM0 bit is set high.

Bit 4 **L3DAM1**: Layer 3 IP DA Match Enable
When this bit is set, the Layer 3 IP Destination Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Destination Address field for matching.
**Note:** When the L3PEN0 bit is set, you should set either this bit or the L3SAM0 bit because either IPv6 DA or SA can be checked for filtering.
Bit 3  **L3SAIM1**: Layer 3 IP SA Inverse Match Enable
   When this bit is set, the Layer 3 IP Source Address field is enabled for inverse matching.
   When this bit reset, the Layer 3 IP Source Address field is enabled for perfect matching.
   This bit is valid and applicable only when the L3SAM0 bit is set.

Bit 2  **L3SAM1**: Layer 3 IP SA Match Enable
   When this bit is set, the Layer 3 IP Source Address field is enabled for matching. When this bit is reset, the MAC ignores the Layer 3 IP Source Address field for matching.
   
   Note: When the L3PEN0 bit is set, you should set either this bit or the L3DAM0 bit because either IPv6 SA or DA can be checked for filtering.

Bit 1  Reserved, must be kept at reset value.

Bit 0  **L3PEN1**: Layer 3 Protocol Enable
   When this bit is set, the Layer 3 IP Source or Destination Address matching is enabled for IPv6 packets. When this bit is reset, the Layer 3 IP Source or Destination Address matching is enabled for IPv4 packets.
   The Layer 3 matching is done only when the L3SAM0 or L3DAM0 bit is set.

**Layer 4 address filter 1 register (ETH_MACL4A1R)**

Address offset: 0x0934
Reset value: 0x0000 0000

The Layer 4 Address 0 register and registers 580 through 667 are reserved (RO with default value) if Enable Layer 3 and Layer 4 Packet Filter option is not selected while configuring the core.

You can configure the Layer 3 and Layer 4 Address Registers to be double-synchronized by selecting the Synchronize Layer 3 and Layer 4 Address Registers to Rx Clock Domain option while configuring the core. When you select this option, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform consecutive writes to same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

Bits 31:0 L3A21[31:0]: Layer 3 Address 2 Field

When the L3PEN0 and L3SAM0 bits are set in the ETH_MACL3L4C0R register, this field contains the value to be matched with Bits[95:64] of the IP Source Address field in the IPv6 packets.

When the L3PEN0 and L3DAM0 bits are set in the ETH_MACL3L4C0R register, this field contains the value to be matched with Bits[95:64] of the IP Destination Address field in the IPv6 packets.

When the L3PEN0 bit is reset in the ETH_MACL3L4C0R register, this field is not used.
Layer 3 address 3 filter 1 register (ETH_MACL3A31R)

Address offset: 0x94C
Reset value: 0x0000 0000

The Layer 3 Address 3 Register 0 register is reserved for IPv4 packets. For IPv6 packets, it contains Bits[127:96] of 128-bit IP Source Address or Destination Address field.

Bits 31:0 L3A31[31:0]: Layer 3 Address 3 Field
- When the L3PEN0 and L3SAM0 bits are set in the ETH_MACL3L4C0R register, this field contains the value to be matched with Bits[127:96] of the IP Source Address field in the IPv6 packets.
- When the L3PEN0 and L3DAM0 bits are set in the ETH_MACL3L4C0R register, this field contains the value to be matched with Bits[127:96] of the IP Destination Address field in the IPv6 packets.
- When the L3PEN0 bit is reset in the ETH_MACL3L4C0R register, this field is not used.

Timestamp control Register (ETH_MACTSCR)

Address offset: 0x0B00
Reset value: 0x0000 2000

This register controls the operation of the System Time generator and processing of PTP packets for timestamping in the Receiver.
Bits 31:25  Reserved, must be kept at reset value.

Bit 24  **TXTSSTSM**: Transmit Timestamp Status Mode
- When this bit is set, the MAC overwrites the earlier transmit timestamp status even if it is not read by the software. The MAC indicates this by setting the TXTSSTSMIS bit of the ETH_MACTXTSSNR register.
- When this bit is reset, the MAC ignores the timestamp status of current packet if the timestamp status of previous packet is not read by the software. The MAC indicates this by setting the TXTSSTSHI bit of the ETH_MACTXTSSSR register.

Bits 23:20  Reserved, must be kept at reset value.

Bit 19  **CSC**: Enable checksum correction during OST for PTP over UDP/IPv4 packets
- When this bit is set, the last two bytes of PTP message sent over UDP/IPv4 is updated to keep the UDP checksum correct, for changes made to origin timestamp and/or correction field as part of one step timestamp operation. The application shall form the packet with these two dummy bytes.
- When reset, no updates are done to keep the UDP checksum correct. The application shall form the packet with UDP checksum set to 0.

Bit 18  **TSENMACADDR**: Enable MAC Address for PTP Packet Filtering
- When this bit is set, the DA MAC address (that matches any MAC Address register) is used to filter the PTP packets when PTP is directly sent over Ethernet.
- When this bit is set, received PTP packets with DA containing a special multicast or unicast address that matches the one programmed in MAC address registers are considered for processing as indicated below, when PTP is directly sent over Ethernet.
- For normal time stamping operation, MAC address registers 0 to 31 is considered for unicast destination address matching.
- For PTP offload, only MAC address register 0 is considered for unicast destination address matching.

Bits 17:16  **SNAPTYPESEL[1:0]**: Select PTP packets for Taking Snapshots
- These bits, along with Bits 15 and 14, decide the set of PTP packet types for which snapshot needs to be taken. The encoding is given in Timestamp Snapshot Dependency on Register Bits Table.

Bit 15  **TSMSTRENA**: Enable Snapshot for Messages Relevant to Master
- When this bit is set, the snapshot is taken only for the messages that are relevant to the master node. Otherwise, the snapshot is taken for the messages relevant to the slave node.

Bit 14  **TSEVNTENA**: Enable Timestamp Snapshot for Event Messages
- When this bit is set, the timestamp snapshot is taken only for event messages (SYNC, Delay_Req, Pdelay_Req, or Pdelay_Resp). When this bit is reset, the snapshot is taken for all messages except Announce, Management, and Signaling. For more information about the timestamp snapshots, see Timestamp Snapshot Dependency on Register Bits Table.

Bit 13  **TSIPV4ENA**: Enable Processing of PTP Packets Sent over IPv4-UDP
- When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv4-UDP packets. When this bit is reset, the MAC ignores the PTP transported over IPv4-UDP packets. This bit is set by default.

Bit 12  **TSIPV6ENA**: Enable Processing of PTP Packets Sent over IPv6-UDP
- When this bit is set, the MAC receiver processes the PTP packets encapsulated in IPv6-UDP packets. When this bit is clear, the MAC ignores the PTP transported over IPv6-UDP packets.

Bit 11  **TSIPENA**: Enable Processing of PTP over Ethernet Packets
- When this bit is set, the MAC receiver processes the PTP packets encapsulated directly in the Ethernet packets. When this bit is reset, the MAC ignores the PTP over Ethernet packets.
Bit 10 **TSVER2ENA**: Enable PTP Packet Processing for Version 2 Format
   When this bit is set, the IEEE 1588 version 2 format is used to process the PTP packets.
   When this bit is reset, the IEEE 1588 version 1 format is used to process the PTP packets.
   The IEEE 1588 formats are described in 'PTP Processing and Control'.

Bit 9 **TSCTRLSSR**: Timestamp Digital or Binary Rollover Control
   When this bit is set, the Timestamp Low register rolls over after 0x3B9A_C9FF value (that is, 1 nanosecond accuracy) and increments the timestamp (High) seconds. When this bit is reset, the rollover value of sub-second register is 0x7FFF_FFFF. The sub-second increment must be programmed correctly depending on the PTP reference clock frequency and the value of this bit.

Bit 8 **TSENALL**: Enable Timestamp for All Packets
   When this bit is set, the timestamp snapshot is enabled for all packets received by the MAC.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **TSADDREG**: Update Addend Register
   When this bit is set, the content of the Timestamp Addend register is updated in the PTP block for fine correction. This bit is cleared when the update is complete. This bit should be zero before it is set.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **TSUPDT**: Update Timestamp
   When this bit is set, the system time is updated (added or subtracted) with the value specified in ETH_MACSTSUR and ETH_MACSTNUR.
   This bit should be zero before updating it. This bit is reset when the update is complete in hardware. The Timestamp Higher Word register (if enabled during core configuration) is not updated.

Bit 2 **TSINIT**: Initialize Timestamp
   When this bit is set, the system time is initialized (overwritten) with the value specified in the MAC Register 80 (System Time Seconds Update Register) and MAC Register 81 (System Time Nanoseconds Update Register).
   This bit should be zero before it is updated. This bit is reset when the initialization is complete. The Timestamp Higher Word register (if enabled during core configuration) can only be initialized.

Bit 1 **TSCFUPDT**: Fine or Coarse Timestamp Update
   When this bit is set, the Fine method is used to update system timestamp. When this bit is reset, Coarse method is used to update the system timestamp.

Bit 0 **TSENA**: Enable Timestamp
   When this bit is set, the timestamp is added for Transmit and Receive packets. When disabled, timestamp is not added for transmit and receive packets and the Timestamp Generator is also suspended. You need to initialize the Timestamp (system time) after enabling this mode.
   On the Receive side, the MAC processes the 1588 packets only if this bit is set.

*Table 560* indicates the PTP messages for which a snapshot is taken depending on the SNAPTYPSEL field in ETH_MACTSCR register.

Sub-second increment register (ETH_MACSSIR)

Address offset: 0x0B04

Reset value: 0x0000 0000

The Sub-second Increment register is present only when the IEEE 1588 timestamp feature is selected without an external timestamp input. In Coarse Update mode [Bit 1 in ETH_MACTSCR register, the value in this register is added to the system time every clock cycle of HCLK. In Fine Update mode, the value in this register is added to the system time whenever the Accumulator gets an overflow.
Bits 31:24  Reserved, must be kept at reset value.

Bits 23:16  **SSINC[7:0]: Sub-second Increment Value**

The value programmed in this field is accumulated every clock cycle (of clk_ptp_i) with the contents of the sub-second register. For example, when the PTP clock is 50 MHz (period is 20 ns), you should program 20 (0x14) when the System Time Nanoseconds register has an accuracy of 1 ns [Bit 9 (TSCTRLSSR) is set in ETH_MACTSCR]. When TSCTRLSSR is clear, the Nanoseconds register has a resolution of ~0.465 ns. In this case, you should program a value of 43 (0x2B) which is derived by 20 ns/0.465.

Bits 15:8  **SNSINC[7:0]: Sub-nanosecond Increment Value**

This field contains the sub-nanosecond increment value, represented in nanoseconds multiplied by $2^8$. This value is accumulated with the sub-nanoseconds field of the sub-second register. For example, when TSCTRLSSR field in the ETH_MACTSCR register is set, and if the required increment is 5.3 ns, then SSINC should be 0x05 and SNSINC should be 0x4C.

Bits 7:0  Reserved, must be kept at reset value.
System time seconds register (ETH_MACSTSR)

Address offset: 0x0B08
Reset value: 0x0000 0000

The System Time Seconds register, along with System Time Nanoseconds register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from HCLK to CSR clock).

This register is present only when the IEEE 1588 Timestamp feature is selected without external timestamp input.

Bits 31:0   TSS[31:16]: Timestamp Second
The value in this field indicates the current value in seconds of the System Time maintained by the MAC.

System time nanoseconds register (ETH_MACSTNR)

Address offset: 0x0B0C
Reset value: 0x0000 0000

The System Time Nanoseconds register, along with System Time Seconds register, indicates the current value of the system time maintained by the MAC.

This register is present only when the IEEE 1588 Timestamp feature is selected without external timestamp input.

Bit 31 Reserved, must be kept at reset value.

Bits 30:0   TSSS[30:0]: Timestamp Sub-seconds
The value in this field has the sub-second representation of time, with an accuracy of 0.46 ns. When Bit 9 is set in ETH_MACTSCR, each bit represents 1 ns. The maximum value is 0x3B9A_C9FF after which it rolls-over to zero.
System time seconds update register (ETH_MACSTSUR)

Address offset: 0x0B10
Reset value: 0x0000 0000

The System Time Seconds Update register, along with the System Time Nanoseconds Update register, initializes or updates the system time maintained by the MAC. You must write both registers before setting the TSINIT or TSUPDT bits in ETH_MACTSCR register.

This register is present only when the IEEE 1588 Timestamp feature is selected without external timestamp input.

</tbody>
</table>

Bits 31:0 **TSS[31:0]: Timestamp Seconds**

The value in this field is the sub-second part of the update. When ADDSUB is reset, this field must be programmed with the sub-second part of the update value, with an accuracy based on the TSCTRLSSR bit of the ETH_MACTSCR register. When ADDSUB is set, then this field must be programmed with the complement of the sub-second part of the update value as described below.

When TSCTRLSSR is set, then the programmed value must be $10^9 \times <\text{sub-second value}>$. When TSCTRLSSR is reset, then the programmed value must be $2^31 \times <\text{sub-second value}>$.

For example, when TSCTRLSSR bit is set and if 2.000000001 seconds need to be subtracted from the system time, then the TSS field in the MAC_TimeStamp Seconds update register must be 0xFFFF_FFFE (that is, $2^32 - 2$), ADDSUB bit in this register should be set, and the TSSS field must be 0x3B9A_C9FF (that is, $10^9 - 1$).

System time nanoseconds update register (ETH_MACSTNUR)

Address offset: 0x0B14
Reset value: 0x0000 0000

This register is present only when the IEEE 1588 timestamp feature is selected without external timestamp input.

2986/3289
Bit 31 **ADDSUB**: Add or Subtract Time
When this bit is set, the time value is subtracted with the contents of the update register.
When this bit is reset, the time value is added with the contents of the update register.

Bits 30:0 **TSSS[30:0]**: Timestamp Sub-seconds
The value in this field has the sub-second representation of time, with an accuracy of 0.46 ns.
When the TSCTRLSSR bit is set in the ETH_MACTSCR register, each bit represents 1 ns and the programmed value should not exceed 0x3B9A_C9FF.

**Timestamp addend register (ETH_MACTSAR)**

Address offset: 0x0B18
Reset value: 0x0000 0000

The Timestamp Addend register is present only when the IEEE 1588 Timestamp feature is selected without external timestamp input. This register value is used only when the system time is configured for Fine Update mode (TSCFUPDT bit in the ETH_MACTSCR register). The content of this register is added to a 32-bit accumulator in every clock cycle (of HCLK) and the system time is updated whenever the accumulator overflows.

Bits 31:0 **TSAR[31:0]**: Timestamp Addend Register
This field indicates the 32-bit time value to be added to the Accumulator register to achieve time synchronization.

**Timestamp status register (ETH_MACTSSR)**

Address offset: 0x0B20
Reset value: 0x0000 0000

The Timestamp Status register is present only when the IEEE 1588 Timestamp feature is selected. All bits except Bits[27:25] gets cleared when the application reads this register.

**TSTAGTF0** |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
**AUXTSTAG** |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
**TSTARGT0** |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
**TSSOVF** |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
Bits 31:30  Reserved, must be kept at reset value.

Bits 29:25  **ATSNS[4:0]: Number of Auxiliary Timestamp Snapshots**
This field indicates the number of Snapshots available in the FIFO. A value equal to the selected depth of FIFO (4, 8, or 16) indicates that the Auxiliary Snapshot FIFO is full. These bits are cleared (to 00000) when the Auxiliary snapshot FIFO clear bit is set. This bit is valid only if the Add IEEE 1588 Auxiliary Snapshot option is selected.

Bit 24  **ATSSTM: Auxiliary Timestamp Snapshot Trigger Missed**
This bit is set when the Auxiliary timestamp snapshot FIFO is full and external trigger was set. This indicates that the latest snapshot is not stored in the FIFO. This bit is valid only if the Add IEEE 1588 Auxiliary Snapshot option is selected.

Bits 23:20  Reserved, must be kept at reset value.

Bits 19:16  **ATSSTN[3:0]: Auxiliary Timestamp Snapshot Trigger Identifier**
These bits identify the Auxiliary trigger inputs for which the timestamp available in the Auxiliary Snapshot Register is applicable. When more than one bit is set at the same time, it means that corresponding auxiliary triggers were sampled at the same clock. These bits are applicable only if the number of Auxiliary snapshots is more than one. One bit is assigned for each trigger as shown in the following list:
- Bit 16: Auxiliary trigger 0
- Bit 17: Auxiliary trigger 1
- Bit 18: Auxiliary trigger 2
- Bit 19: Auxiliary trigger 3
The software can read this register to find the triggers that are set when the timestamp is taken.

Bit 15  **TXTSSIS: Tx Timestamp Status Interrupt Status**
When drop transmit status is enabled in MTL, this bit is set when the captured transmit timestamp is updated in the ETH_MACTXTSSNR and ETH_MACTXTSSSR registers. When PTP offload feature is enabled, this bit is set when the captured transmit timestamp is updated in the ETH_MACTXTSSNR and ETH_MACTXTSSSR registers, for PTO generated Delay Request and Pdelay request packets.
This bit is cleared when the ETH_MACTXTSSSR register is read.
This bit is reserved in all other configurations.

Bits 14:4  Reserved, must be kept at reset value.

Bit 3  **TSTRGTER0: Timestamp Target Time Error**
This bit is set when the latest target time programmed in the ETH_MACPPS_Target_Time_seconds and ETH_MACPPS_Target_Time_Nanoseconds registers elapses. This bit is cleared when the application reads this bit.

Bit 2  **AUXTSTRIG: Auxiliary Timestamp Trigger Snapshot**
This bit is set high when the auxiliary snapshot is written to the FIFO. This bit is valid only if the Add IEEE 1588 Auxiliary Snapshot option is selected.

Bit 1  **TSTARGT0: Timestamp Target Time Reached**
When set, this bit indicates that the value of system time is greater than or equal to the value specified in the ETH_MACPPS_Target_Time_seconds and ETH_MACPPS_Target_Time_Nanoseconds registers.

Bit 0  **TSSOVF: Timestamp Seconds Overflow**
When this bit is set, it indicates that the seconds value of the timestamp (when supporting version 2 format) has overflowed beyond 32'hFFFF_FFFF.
**Tx timestamp status nanoseconds register (ETH_MACTXTSSNR)**

Address offset: 0x0B30  
Reset value: 0x0000 0000  
This register contains the nanosecond part of timestamp captured for Transmit packets when Tx status is disabled.

Bit 31 **TXTSSMIS**: Transmit Timestamp Status Missed  
When this bit is set, it indicates one of the following:  
- The timestamp of the current packet is ignored if TXTSSTSM bit of the ETH_MACTSCR register is reset  
- The timestamp of the previous packet is overwritten with timestamp of the current packet if TXTSSTSM bit of the ETH_MACTSCR register is set.

Bits 30:0 **TXTSSLO[30:0]**: Transmit Timestamp Status Low  
This field contains the 31 bits of the Nanoseconds field of the Transmit packet's captured timestamp.

**Tx timestamp status seconds register (ETH_MACTXTSSSR)**

Address offset: 0x0B34  
Reset value: 0x0000 0000  
The register contains the higher 32 bits of the timestamp (in seconds) captured when a PTP packet is transmitted.

Bit 4  **ATSEN0**: Auxiliary Snapshot 0 Enable
This bit controls the capturing of Auxiliary Snapshot Trigger 0. When this bit is set, the auxiliary snapshot of the event on ptp_aux_trig_i[0] input is enabled. When this bit is reset, the events on this input are ignored.
This bit is reserved when the Add IEEE 1588 Auxiliary Snapshot option is not selected while configuring the core.

Bits 3:1  Reserved, must be kept at reset value.

Bit 0  **ATSFC**: Auxiliary Snapshot FIFO Clear
When set, this bit resets the pointers of the Auxiliary Snapshot FIFO. This bit is cleared when the pointers are reset and the FIFO is empty. When this bit is high, the auxiliary snapshots are stored in the FIFO.
This bit is reserved when the Add IEEE 1588 Auxiliary Snapshot option is not selected while configuring the core.

**Auxiliary timestamp nanoseconds register (ETH_MACATSNR)**

Address offset: 0x0B48
Reset value: 0x0000 0000

The Auxiliary Timestamp Nanoseconds register, along with ETH_MACATSSR, gives the 64-bit timestamp stored as auxiliary snapshot. These two registers form the read port of a 64-bit wide FIFO with a depth of 4 words.

You can store multiple snapshots in this FIFO. Bits[29:25] in ETH_MACTSSR indicate the fill-level of the FIFO. The top of the FIFO is removed only when the last byte of MAC Register 91 (Auxiliary Timestamp - Seconds Register) is read. In the little-endian mode, this means when Bits[31:24] are read and in big-endian mode, Bits[7:0] are read.

   OSTIAC[15:0]
   rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw
```

Bits 31:0 **OSTIAC[31:0]**: One-Step Timestamp Ingress Asymmetry Correction
This field contains the ingress path asymmetry value to be added to correctionField of Pdelay_Resp PTP packet. The programmed value should be in units of nanoseconds and multiplied by 2^16. For example, 2.5 ns is represented as 0x00028000.
The value can also be negative, which is represented in 2's complement form with bit 31 representing the sign bit.
Timestamp Egress asymmetric correction register (ETH_MACTSEACR)

Address offset: 0x0B54
Reset value: 0x0000 0000

The MAC Timestamp Egress Asymmetry Correction register contains the Egress Asymmetry Correction value to be used while updating the correction field in PDelay_Req PTP messages.

<table>

</table>

Bits 31:7  Reserved, must be kept at reset value.
Bits 6:5 **TRGTMODSEL0[1:0]**: Target Time Register Mode for PPS Output
This field indicates the Target Time registers (MAC registers 96 and 97) mode for PPS output signal:
00: Target Time registers are programmed only for generating the interrupt event.
01: Reserved
10: Target Time registers are programmed for generating the interrupt event and starting or stopping the PPS output signal generation.
11: Target Time registers are programmed only for starting or stopping the PPS output signal generation. No interrupt is asserted.

Bit 4 **PPSEN0**: Flexible PPS Output Mode Enable
When this bit is set, Bits[3:0] function as PPSCMD. When this bit is reset, Bits[3:0] function as PPSCTRL (Fixed PPS mode).

Bits 3:0 **PPSCTRL[3:0]**: PPS Output Frequency Control
This field controls the frequency of the PPS output (ptp_pps_o) signal. The default value of PPSCTRL is 0000, and the PPS output is 1 pulse (of width clk_ptp_i) every second. For other values of PPSCTRL, the PPS output becomes a generated clock of following frequencies:
0001: The binary rollover is 2 Hz, and the digital rollover is 1 Hz.
0010: The binary rollover is 4 Hz, and the digital rollover is 2 Hz.
0011: The binary rollover is 8 Hz, and the digital rollover is 4 Hz.
0100: The binary rollover is 16 Hz, and the digital rollover is 8 Hz.
1111: The binary rollover is 32.768 KHz and the digital rollover is 16.384 KHz.

Note: In the binary rollover mode, the PPS output (ptp_pps_o) has a duty cycle of 50 percent with these frequencies. In the digital rollover mode, the PPS output frequency is an average number. The actual clock is of different frequency that gets synchronized every second. For example:
- When PPSCTRL = 0001, the PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms
- When PPSCTRL = 0010, the PPS (2 Hz) is a sequence of One clock of 50 percent duty cycle and 537 ms period Second clock of 463 ms period (268 ms low and 195 ms high)
- When PPSCTRL = 0011, the PPS (4 Hz) is a sequence of Three clocks of 50 percent duty cycle and 268 ms period Fourth clock of 195 ms period (134 ms low and 61 ms high)

This behavior is because of the non-linear toggling of bits in the digital rollover mode in the ETH_MACSTNR register.
PPS control register [alternate] (ETH_MACPPSCR)

Address offset: 0x0B70
Reset value: 0x0000 0000

The PPS Control register is present only when the Timestamp feature is selected and External Timestamp is not enabled.

Bits[30:24] of this register are valid only when four Flexible PPS outputs are selected. Bits[22:16] are valid only when three or more Flexible PPS outputs are selected. Bits[14:8] are valid only when two or more Flexible PPS outputs are selected. Bits[6:4] are valid only when Flexible PPS feature is selected.

</tbody>
</table>

Bits 31:7  Reserved, must be kept at reset value.
Bits 6:5 **TRGTMODSEL[1:0]:** Target Time Register Mode for PPS Output

This field indicates the Target Time registers (MAC registers 96 and 97) mode for PPS output signal:
- 00: Target Time registers are programmed only for generating the interrupt event.
- 01: Reserved
- 10: Target Time registers are programmed for generating the interrupt event and starting or stopping the PPS output signal generation.
- 11: Target Time registers are programmed only for starting or stopping the PPS output signal generation. No interrupt is asserted.

Bit 4 **PPSEN0:** Flexible PPS Output Mode Enable

When this bit is set, Bits[3:0] function as PPSCMD. When this bit is reset, Bits[3:0] function as PPSCTRL (Fixed PPS mode).

Bits 3:0 **PPSCMD[3:0]:** Flexible PPS Output (ptp_pps_o[0]) Control

Programming these bits with a non-zero value instructs the MAC to initiate an event. When the command is transferred or synchronized to the PTP clock domain, these bits get cleared automatically. The software should ensure that these bits are programmed only when they are ‘all-zero’. The following list describes the values of PPSCMD0:
- 0000: No Command
- 0001: START Single Pulse
- 0010: START Pulse Train
- 0011: Cancel START
- 0100: STOP Pulse train at time
- 0101: STOP Pulse Train immediately
- 0110: Cancel STOP Pulse train
- 0111-1111: Reserved

**PPS target time seconds register (ETH_MACPPSTTSR)**

Address offset: 0x0B80

Reset value: 0x0000 0000

The PPS Target Time Seconds register, along with PPS Target Time Nanoseconds register, is used to schedule an interrupt event [Bit 1 of ETH_MACTSSR] when the system time exceeds the value programmed in these registers.
RM0433 Ethernet (ETH): media access control (MAC) with DMA controller

PPS target time nanoseconds register (ETH_MACPPSTTNR)

Address offset: 0x0B84
Reset value: 0x0000 0000

The PPS Target Time Nanoseconds register is present only when more than one Flexible PPS output is selected.

PPS interval register (ETH_MACPPSIR)

Address offset: 0x0B88
Reset value: 0x0000 0000

Bits 31:0

TSTRH0[31:16]: PPS Target Time Seconds Register
This field stores the time in seconds. When the timestamp value matches or exceeds both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on Target Time mode selected for the corresponding PPS output in the ETH_MACPPSCR register.

TTSL0[31:16]: Target Time High for PPS Register
This register stores the time in (signed) nanoseconds. When the value of the timestamp matches the value in both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on the TRGTMODSEL0 field (Bits [6:5]) in ETH_MACPPSCR.

When the TSCTRLSSR bit is set in the ETH_MACTSCR register, this value should not exceed 0x3B9A_C9FF. The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value.

Bit 31

TRGTBUSY0: PPS Target Time Register Busy
The MAC sets this bit when the PPSCMD0 field in the ETH_MACPPSCR register is programmed to 010 or 011. Programming the PPSCMD0 field to 010 or 011 instructs the MAC to synchronize the Target Time Registers to the PTP clock domain.
The MAC clears this bit after synchronizing the Target Time Registers to the PTP clock domain. The application must not update the Target Time Registers when this bit is read as 1. Otherwise, the synchronization of the previous programmed time gets corrupted.

Bits 30:0

TTSL0[30:0]: Target Time Low for PPS Register
This register stores the time in (signed) nanoseconds. When the value of the timestamp matches the value in both Target Timestamp registers, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled) based on the TRGTMODSEL0 field (Bits [6:5]) in ETH_MACPPSCR.
When the TSCTRLSSR bit is set in the ETH_MACTSCR register, this value should not exceed 0x3B9A_C9FF. The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value.
The PPS Interval register contains the number of units of sub-second increment value between the rising edges of PPS signal output (ptp_pps_o[0]).

</tbody>
</table>

Bits 31:0 **PPSINT0[31:0]**: PPS Output Signal Interval

These bits store the interval between the rising edges of PPS signal output. The interval is stored in terms of number of units of sub-second increment value.

You need to program one value less than the required interval. For example, if the PTP reference clock is 50 MHz (period of 20 ns), and desired interval between the rising edges of PPS signal output is 100 ns (that is, 5 units of sub-second increment value), you should program value 4 (5-1) in this register.

**PPS width register (ETH_MACPPSWR)**

Address offset: 0x0B8C

Reset value: 0x0000 0000

The PPS Width register contains the number of units of sub-second increment value between the rising and corresponding falling edges of PPS signal output (ptp_pps_o).

</table>

Bits 31:0 **PPSWIDTH0[31:0]**: PPS Output Signal Width

These bits store the width between the rising edge and corresponding falling edge of PPS signal output. The width is stored in terms of number of units of sub-second increment value.

You need to program one value less than the required interval. For example, if PTP reference clock is 50 MHz (period of 20 ns), and width between the rising and corresponding falling edges of PPS signal output is 80 ns (that is, four units of sub-second increment value), you should program value 3 (4-1) in this register.

*Note:* The value programmed in this register must be lesser than the value programmed in **ETH_MACPPOIR register**.
PTP Offload control register (ETH_MACPOCR)

Address offset: 0x0BC0
Reset value: 0x0000 0000

This register controls the PTP Offload Engine operation. This register is available only when the Enable PTP Timestamp Offload feature is selected.

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 DN[7:0]: Domain Number
This field indicates the domain Number in which the PTP node is operating.

Bit 7 Reserved, must be kept at reset value.

Bit 6 DRRDIS: Disable PTO Delay Request/Response response generation
When this bit is set, the Delay Request and Delay response will not be generated for received SYNC and Delay request packet respectively, as required by the programmed mode.

Bit 5 APDREQTRIG: Automatic PTP Pdelay_Req message Trigger
When this bit is set, one PTP Pdelay_Req message is transmitted. This bit is automatically cleared after the PTP Pdelay_Req message is transmitted. The application should set the APDREQEN bit for this operation.

Bit 4 ASYNCTRIG: Automatic PTP SYNC message Trigger
When this bit is set, one PTP SYNC message is transmitted. This bit is automatically cleared after the PTP SYNC message is transmitted. The application should set the ASYNCEN bit for this operation.

Bit 3 Reserved, must be kept at reset value.

Bit 2 APDREQEN: Automatic PTP Pdelay_Req message Enable
When this bit is set, PTP Pdelay_Req message is generated periodically based on interval programmed or trigger from application, when the MAC is programmed to be in Peer-to-Peer Transparent mode.

Bit 1 ASYNCEN: Automatic PTP SYNC message Enable
When this bit is set, PTP SYNC message is generated periodically based on interval programmed or trigger from application, when the MAC is programmed to be in Clock Master mode.

Bit 0 PTOEN: PTP Offload Enable
When this bit is set, the PTP Offload feature is enabled.

PTP Source Port Identity 0 Register (ETH_MACSPI0R)

Address offset: 0x0BC4
Reset value: 0x0000 0000

This register contains Bits[31:0] of the 80-bit Source Port Identity of the PTP node. This register is available only when the Enable PTP Timestamp Offload feature is selected.

### PTP Source port identity 1 register (ETH_MACSPI1R)

Address offset: 0x0BC8

Reset value: 0x0000 0000

This register contains Bits[63:32] of the 80-bit Source Port Identity of the PTP node. This register is available only when the Enable PTP Timestamp Offload feature is selected.

### PTP Source port identity 2 register (ETH_MACSPI2R)

Address offset: 0x0BCC

Reset value: 0x0000 0000

This register contains Bits[79:64] of the 80-bit Source Port Identity of the PTP node.
Log message interval register (ETH_MACLMIR)

Address offset: 0x0BD0
Reset value: 0x0000 0000

This register contains the periodic intervals for automatic PTP packet generation.

<table>

Refer to Section 2.3 on page 126 for the register boundary addresses.
58 HDMI-CEC controller (CEC)

58.1 Introduction

Consumer electronics control (CEC) is part of HDMI (high-definition multimedia interface) standard as appendix supplement 1. It contains a protocol that provides high-level control functions between various audiovisual products. CEC operates at low speeds, with minimum processing and memory overhead.

The HDMI-CEC controller provides hardware support for this protocol.

58.2 HDMI-CEC controller main features

- Complies with HDMI-CEC v1.4 specification
- Independent 32 kHz CEC kernel (refer to Section RCC kernel clock distribution)
- Works in Stop mode for ultra-low-power applications
- Configurable signal-free time before start of transmission
  - Automatic by hardware, according to CEC state and transmission history
  - Fixed by software (7 timing options)
- Configurable peripheral address (OAR)
- Supports Listen mode
  - Enables reception of CEC messages sent to destination address different from OAR without interfering with the CEC line
- Configurable Rx-tolerance margin
  - Standard tolerance
  - Extended tolerance
- Receive-error detection
  - Bit rising error (BRE), with optional stop of reception (BRESTP)
  - Short bit period error (SBPE)
  - Long bit period error (LBPE)
- Configurable error-bit generation
  - on BRE detection (BREGEN)
  - on LBPE detection (LBPEGEN)
  - always generated on SBPE detection
- Transmission error detection (TXERR)
- Arbitration lost detection (ARBLST)
  - With automatic transmission retry
- Transmission underrun detection (TXUDR)
- Reception overrun detection (RXOVR)
58.3 HDMI-CEC functional description

58.3.1 HDMI-CEC pin and internal signals

The CEC bus consists of a single bidirectional line that is used to transfer data in and out of the device. It is connected to a +3.3 V supply voltage via a 27 kΩ pull-up resistor. The output stage of the device must have an open-drain or open-collector to allow a wired-AND connection.

The HDMI-CEC controller manages the CEC bidirectional line as an alternate function of a standard GPIO, assuming that it is configured as alternate function open drain. The 27 kΩ pull-up must be added externally to the microcontroller.

To not interfere with the CEC bus when the application power is removed, it is mandatory to isolate the CEC pin from the bus in such conditions. This can be done by using a MOS transistor, as shown on Figure 806.

Table 563 lists the internal signals that are exchanged between the HDMI-CEC and other functional blocks (such as RCC and EXTI).

58.3.2 HDMI-CEC block diagram

Figure 806. HDMI-CEC block diagram

58.3.3 Message description

All transactions on the CEC line consist of an initiator and one or more followers. The initiator is responsible for sending the message structure and the data. The follower is the recipient of any data and is responsible for setting any acknowledgment bits.

A message is conveyed in a single frame that consists of a start bit followed by a header block and optionally an opcode and a variable number of operand blocks.

All these blocks are made of a 8-bit payload - most significant bit is transmitted first - followed by an end of message (EOM) bit and an acknowledge (ACK) bit.

The EOM bit is set in the last block of a message and kept reset in all others. In case a message contains additional blocks after an EOM is indicated, those additional blocks must be ignored. The EOM bit may be set in the header block to ‘ping’ other devices, to make sure they are active.

The acknowledge bit is always set to high impedance by the initiator so that it can be driven low either by the follower that has read its own address in the header, or by the follower that needs to reject a broadcast message.

The header consists of the source logical address field, and the destination logical address field. Note that the special address 0xF is used for broadcast messages.

Figure 807. Message structure
58.3.4 Bit timing

The format of the start bit is unique and identifies the start of a message. It must be validated by its low duration and its total duration.

All remaining data bits in the message, after the start bit, have consistent timing. The high-to-low transition at the end of the data bit is the start of the next data bit except for the final bit where the CEC line remains high.

58.4 Arbitration

All devices transmitting - or retransmitting - a message onto the CEC line must ensure that it has been inactive for a number of bit periods. This signal-free time is defined as the time starting from the final bit of the previous frame and depends on the initiating device and the current status as shown in the table below.
Since only one initiator is allowed at any one time, an arbitration mechanism is provided to avoid conflict when more than one initiator begins transmitting at the same time.

CEC line arbitration starts with the leading edge of the start bit and continues until the end of the initiator address bits within the header block. During this period, the initiator must monitor the CEC line, if whilst driving the line to high impedance it reads it back to 0. Assuming then it has lost arbitration, it stops transmitting and becomes a follower.

A configurable time window is counted before starting the transmission.
In the SFT = 0 configuration, HDMI-CEC performs automatic SFT calculation ensuring compliance with the HDMI-CEC standard:

- 2.5 data bit periods if the CEC is the last bus initiator with unsuccessful transmission
- 4 data bit periods if the CEC is the new bus initiator
- 6 data bit periods if the CEC is the last bus initiator with successful transmission

This is done to guarantee the maximum priority to a failed transmission and the lowest one to the last initiator that completed successfully its transmission.

Otherwise there is the possibility to configure the SFT bits to count a fixed timing value. Possible values are 0.5, 1.5, 2.5, 3.5, 4.5, 5.5, 6.5 data bit periods.

58.4.1 SFT option bit

In case of SFTOPT = 0 configuration, SFT starts being counted when the start-of-transmission command is set by software (TXSOM=1).

In case of SFTOPT=1, SFT starts automatically being counted by the HDMI-CEC device when a bus-idle or line error condition is detected. If the SFT timer is completed at the time TXSOM command is set then transmission starts immediately without latency. If the SFT timer is still running instead, the system waits until the timer elapses before transmission can start.

In case of SFTOPT = 1 a bus-event condition starting the SFT timer is detected in the following cases:

- In case of a regular end of transmission/reception, when TXEND/RXEND bits are set at the minimum nominal data bit duration of the last bit in the message (ACK bit).
- In case of a transmission error detection, SFT timer starts when the TXERR transmission error is detected (TXERR=1).
- In case of a missing acknowledge from the CEC follower, the SFT timer starts when the TXACKE bit is set, that is at the nominal sampling time of the ACK bit.
- In case of a transmission underrun error, the SFT timer starts when the TXUDR bit is set at the end of the ACK bit.
- In case of a receive error detection implying reception abort, the SFT timer starts at the same time the error is detected. If an error bit is generated, then SFT starts being counted at the end of the error bit.
- In case of a wrong start bit or of any uncodified low impedance bus state from idle, the SFT timer is restarted as soon as the bus comes back to hi-impedance idleness.

58.5 Error handling

58.5.1 Bit error

If a data bit - excluding the start bit - is considered invalid, the follower is expected to notify such error by generating a low bit period on the CEC line of 1.4 to 1.6 times the nominal data bit period, i.e. 3.6 ms nominally.
58.5.2 Message error

A message is considered lost and therefore may be retransmitted under the following conditions:
- a message is not acknowledged in a directly addressed message
- a message is negatively acknowledged in a broadcast message
- a low impedance is detected on the CEC line while it is not expected (line error)

Three kinds of error flag can be detected when the CEC interface is receiving a data bit:

58.5.3 Bit Rising Error (BRE)

BRE (bit rising error): is set when a bit rising edge is detected outside the windows where it is expected (see Figure 814). BRE flag also generates a CEC interrupt if the BREIE=1.

In the case of a BRE detection, the message reception can be stopped according to the BRESTP bit value and an error bit can be generated if BREGEN bit is set.

When BRE is detected in a broadcast message with BRESTP=1 an error bit is generated even if BREGEN=0 to enforce initiator’s retry of the failed transmission. Error bit generation can be disabled by configuring BREGEN=0, BRDNOGEN=1.

58.5.4 Short Bit Period Error (SBPE)

SBPE is set when a bit falling edge is detected earlier than expected (see Figure 814). SBPE flag also generates a CEC interrupt if the SBPEIE=1.

An error bit is always generated on the line in case of a SBPE error detection. An Error Bit is not generated upon SBPE detection only when Listen mode is set (LSTN=1) and the following conditions are met:
- A directly addressed message is received containing SBPE
- A broadcast message is received containing SBPE AND BRDNOGEN=1

58.5.5 Long Bit Period Error (LBPE)

LBPE is set when a bit falling edge is not detected in a valid window (see Figure 814). LBPE flag also generates a CEC interrupt if the LBPEIE=1.

LBPE always stops the reception, an error bit is generated on the line when LBPEGEN bit is set.

When LBPE is detected in a broadcast message an error bit is generated even if LBPEGEN=0 to enforce initiator’s retry of the failed transmission. Error bit generation can be disabled by configuring LBPEGEN=0, BRDNOGEN=1.
Note: The BREGEN=1, BRESTP=0 configuration must be avoided

58.5.6 Transmission Error Detection (TXERR)

The CEC initiator sets the TXERR flag if detecting low impedance on the CEC line when it is transmitting high impedance and is not expecting a follower asserted bit. TXERR flag also generates a CEC interrupt if the TXERRIE=1.

TXERR assertion stops the message transmission. Application is in charge to retry the failed transmission up to 5 times.

TXERR checks are performed differently depending on the different states of the CEC line and on the RX tolerance configuration.

58.6 HDMI-CEC interrupts

An interrupt can be produced:

- during reception if a Receive Block Transfer is finished or if a Receive Error occurs.
- during transmission if a Transmit Block Transfer is finished or if a Transmit Error occurs.

Bits 31:3 Reserved, must be kept at reset value.
Bit 2 TXEOM: Tx End Of Message
The TXEOM bit is set by software to command transmission of the last byte of a CEC message. TXEOM is cleared by hardware at the same time and under the same conditions as for TXSOM.
0: TXDR data byte is transmitted with EOM=0
1: TXDR data byte is transmitted with EOM=1

Note: TXEOM must be set when CECEN=1.
TXEOM must be set before writing transmission data to TXDR.
If TXEOM is set when TXSOM=0, transmitted message will consist of 1 byte (HEADER) only (PING message)

Bit 1 TXSOM: Tx Start Of Message
TXSOM is set by software to command transmission of the first byte of a CEC message. If the CEC message consists of only one byte, TXEOM must be set before of TXSOM.

Start-Bit is effectively started on the CEC line after SFT is counted. If TXSOM is set while a message reception is ongoing, transmission will start after the end of reception.

TXSOM is cleared by hardware after the last byte of the message is sent with a positive acknowledge (TXEND=1), in case of transmission underrun (TXUDR=1), negative acknowledge (TXACKE=1), and transmission error (TXERR=1). It is also cleared by CECEN=0. It is not cleared and transmission is automatically retried in case of arbitration lost (ARBLST=1).

TXSOM can be also used as a status bit informing application whether any transmission request is pending or under execution. The application can abort a transmission request at any time by clearing the CECEN bit.
0: No CEC transmission is on-going
1: CEC transmission command

Note: TXSOM must be set when CECEN=1.
TXSOM must be set when transmission data is available into TXDR.
HEADER first four bits containing own peripheral address are taken from TXDR[7:4], not from CEC_CFGR.OAR which is used only for reception.

Bit 0 CECEN: CEC enable
The CECEN bit is set and cleared by software. CECEN=1 starts message reception and enables the TXSOM control. CECEN=0 disables the CEC peripheral, clears all bits of CEC_CR register and aborts any on-going reception or transmission.
0: CEC peripheral is off
1: CEC peripheral is on

58.7.2 CEC configuration register (CEC_CFGR)
This register is used to configure the HDMI-CEC controller.

Address offset: 0x04
Reset value: 0x0000 0000

Caution: It is mandatory to write CEC_CFGR only when CECEN=0.

</table>
Bit 31  **LSTN**: Listen mode
LSTN bit is set and cleared by software.
0: CEC peripheral receives only message addressed to its own address (OAR). Messages addressed to different destination are ignored. Broadcast messages are always received.
1: CEC peripheral receives messages addressed to its own address (OAR) with positive acknowledge. Messages addressed to different destination are received, but without interfering with the CEC bus: no acknowledge sent.

Bits 30:16  **OAR[14:0]**: Own addresses configuration
The OAR bits are set by software to select which destination logical addresses has to be considered in receive mode. Each bit, when set, enables the CEC logical address identified by the given bit position.
At the end of HEADER reception, the received destination address is compared with the enabled addresses. In case of matching address, the incoming message is acknowledged and received. In case of non-matching address, the incoming message is received only in listen mode (LSTN=1), but without acknowledge sent. Broadcast messages are always received.
Example:
OAR = 0b000 0000 0010 0001 means that CEC acknowledges addresses 0x0 and 0x5. Consequently, each message directed to one of these addresses is received.

Bits 15:9  Reserved, must be kept at reset value.

Bit 8  **SFTOP**: SFT Option Bit
The SFTOPT bit is set and cleared by software.
0: SFT timer starts when TXSOM is set by software
1: SFT timer starts automatically at the end of message transmission/reception.

Bit 7  **BRDNOGEN**: Avoid Error-Bit Generation in Broadcast
The BRDNOGEN bit is set and cleared by software.
0: BRE detection with BRESTP=1 and BREGEN=0 on a broadcast message generates an Error-Bit on the CEC line. LBPE detection with LBPEGEN=0 on a broadcast message generates an Error-Bit on the CEC line
1: Error-Bit is not generated in the same condition as above. An Error-Bit is not generated even in case of an SBPE detection in a broadcast message if listen mode is set.

Bit 6  **LBPEGEN**: Generate Error-Bit on Long Bit Period Error
The LBPEGEN bit is set and cleared by software.
0: LBPE detection does not generate an Error-Bit on the CEC line
1: LBPE detection generates an Error-Bit on the CEC line
*Note*: If BRDNOGEN=0, an Error-bit is generated upon LBPE detection in broadcast even if LBPEGEN=0

Bit 5  **BREGEN**: Generate Error-Bit on Bit Rising Error
The BREGEN bit is set and cleared by software.
0: BRE detection does not generate an Error-Bit on the CEC line
1: BRE detection generates an Error-Bit on the CEC line (if BRESTP is set)
*Note*: If BRDNOGEN=0, an Error-bit is generated upon BRE detection with BRESTP=1 in broadcast even if BREGEN=0
Bit 4 **BRESTP**: Rx-Stop on Bit Rising Error  
The BRESTP bit is set and cleared by software.  
0: BRE detection does not stop reception of the CEC message. Data bit is sampled at 1.05 ms.  
1: BRE detection stops message reception  

Bit 3 **RXTOL**: Rx-Tolerance  
The RXTOL bit is set and cleared by software.  
0: Standard tolerance margin:  
   – Start-Bit: +/- 200 µs rise, +/- 200 µs fall.  
   – Data-Bit: +/- 200 µs rise, +/- 350 µs fall.  
1: Extended Tolerance  
   – Start-Bit: +/- 400 µs rise, +/- 400 µs fall  
   – Data-Bit: +/- 300 µs rise, +/- 500 µs fall  

Bits 2:0 **SFT[2:0]**: Signal Free Time  
The SFT bits are set by software. In the SFT=0x0 configuration the number of nominal data bit periods waited before transmission is ruled by hardware according to the transmission history. In all the other configurations the SFT number is determined by software.  
0x0  
   – 2.5 Data-Bit periods if CEC is the last bus initiator with unsuccessful transmission (ARBLST=1, TXERR=1, TXUDR=1 or TXACKE= 1)  
   – 4 Data-Bit periods if CEC is the new bus initiator  
   – 6 Data-Bit periods if CEC is the last bus initiator with successful transmission (TXEOM=1)  
0x1: 0.5 nominal data bit periods  
0x2: 1.5 nominal data bit periods  
0x3: 2.5 nominal data bit periods  
0x4: 3.5 nominal data bit periods  
0x5: 4.5 nominal data bit periods  
0x6: 5.5 nominal data bit periods  
0x7: 6.5 nominal data bit periods
### 58.7.3 CEC Tx data register (CEC_TXDR)

Address offset: 0x8  
Reset value: 0x0000 0000

Bits 31:8 Reserved, must be kept at reset value.  
Bits 7:0 **TXD[7:0]**: Tx data  
TXD is a write-only register containing the data byte to be transmitted.

### 58.7.4 CEC Rx data register (CEC_RXDR)

</tbody>
</table>

Bits 31:8 Reserved, must be kept at reset value.  
Bits 7:0 **RXD[7:0]**: Rx data  
RXD is read-only and contains the last data byte which has been received from the CEC line.

### 58.7.5 CEC Interrupt and Status Register (CEC_ISR)

Address offset: 0x10  
Reset value: 0x0000 0000

</tbody>
</table>
Bits 31:13 Reserved, must be kept at reset value.

Bit 12 TXACKE: Tx-Missing Acknowledge Error
In transmission mode, TXACKE is set by hardware to inform application that no acknowledge was received. In case of broadcast transmission, TXACKE informs application that a negative acknowledge was received. TXACKE aborts message transmission and clears TXSOM and TXEOM controls.
TXACKE is cleared by software write at 1.

Bit 11 TXERR: Tx-Error
In transmission mode, TXERR is set by hardware if the CEC initiator detects low impedance on the CEC line while it is released. TXERR aborts message transmission and clears TXSOM and TXEOM controls.
TXERR is cleared by software write at 1.

Bit 10 TXUDR: Tx-Buffer Underrun
In transmission mode, TXUDR is set by hardware if application was not in time to load TXDR before of next byte transmission. TXUDR aborts message transmission and clears TXSOM and TXEOM control bits.
TXUDR is cleared by software write at 1.

Bit 9 TXEND: End of Transmission
TXEND is set by hardware to inform application that the last byte of the CEC message has been successfully transmitted. TXEND clears the TXSOM and TXEOM control bits.
TXEND is cleared by software write at 1.

Bit 8 TXBR: Tx-Byte Request
TXBR is set by hardware to inform application that the next transmission data has to be written to TXDR. TXBR is set when the 4th bit of currently transmitted byte is sent. Application must write the next byte to TXDR within 6 nominal data-bit periods before transmission underrun error occurs (TXUDR).
TXBR is cleared by software write at 1.

Bit 7 ARBLST: Arbitration Lost
ARBLST is set by hardware to inform application that CEC device is switching to reception due to arbitration lost event following the TXSOM command. ARBLST can be due either to a contending CEC device starting earlier or starting at the same time but with higher HEADER priority. After ARBLST assertion TXSOM bit keeps pending for next transmission attempt.
ARBLST is cleared by software write at 1.

Bit 6 RXACKE: Rx-Missing Acknowledge
In receive mode, RXACKE is set by hardware to inform application that no acknowledge was seen on the CEC line. RXACKE applies only for broadcast messages and in listen mode also for not directly addressed messages (destination address not enabled in OAR). RXACKE aborts message reception.
RXACKE is cleared by software write at 1.

Bit 5 LBPE: Rx-Long Bit Period Error
LBPE is set by hardware in case a Data-Bit waveform is detected with Long Bit Period Error. LBPE is set at the end of the maximum bit-extension tolerance allowed by RXTOL, in case falling edge is still longing. LBPE always stops reception of the CEC message. LBPE generates an Error-Bit on the CEC line if LBPEGEN=1. In case of broadcast, Error-Bit is generated even in case of LBPEGEN=0. LBPE is cleared by software write at 1.

Bit 4 SBPE: Rx-Short Bit Period Error
SBPE is set by hardware in case a Data-Bit waveform is detected with Short Bit Period Error. SBPE is set at the time the anticipated falling edge occurs. SBPE generates an Error-Bit on the CEC line. SBPE is cleared by software write at 1.
Bit 3 **BRE**: Rx-Bit Rising Error
- BRE is set by hardware in case a Data-Bit waveform is detected with Bit Rising Error. BRE is set either at the time the misplaced rising edge occurs, or at the end of the maximum BRE tolerance allowed by RXTOL, in case rising edge is still longing. BRE stops message reception if BRESTP=1.
- BRE generates an Error-Bit on the CEC line if BREGEN=1.
- BRE is cleared by software write at 1.

Bit 2 **RXOVR**: Rx-Overrun
- RXOVR is set by hardware if RXBR is not yet cleared at the time a new byte is received on the CEC line and stored into RXD. RXOVR assertion stops message reception so that no acknowledge is sent. In case of broadcast, a negative acknowledge is sent.
- RXOVR is cleared by software write at 1.

Bit 1 **RXEND**: End Of Reception
- RXEND is set by hardware to inform application that the last byte of a CEC message is received from the CEC line and stored into the RXD buffer. RXEND is set at the same time of RXBR.
- RXEND is cleared by software write at 1.

Bit 0 **RXBR**: Rx-Byte Received
- The RXBR bit is set by hardware to inform application that a new byte has been received from the CEC line and stored into the RXD buffer.
- RXBR is cleared by software write at 1.

### 58.7.6 **CEC interrupt enable register (CEC_IER)**

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **TXACKIE**: Tx-Missing Acknowledge Error Interrupt Enable
- The TXACKIE bit is set and cleared by software.
  - 0: TXACKE interrupt disabled
  - 1: TXACKE interrupt enabled

Bit 11 **TXERRIE**: Tx-Error Interrupt Enable
- The TXERRIE bit is set and cleared by software.
  - 0: TXERR interrupt disabled
  - 1: TXERR interrupt enabled

Bit 10 **TXUDRIE**: Tx-Underrun Interrupt Enable
- The TXUDRIE bit is set and cleared by software.
  - 0: TXUDR interrupt disabled
  - 1: TXUDR interrupt enabled
Bit 9  **TXENDIE**: Tx-End Of Message Interrupt Enable
The TXENDIE bit is set and cleared by software.
0: TXEND interrupt disabled
1: TXEND interrupt enabled

Bit 8  **TXBRIE**: Tx-Byte Request Interrupt Enable
The TXBRIE bit is set and cleared by software.
0: TXBR interrupt disabled
1: TXBR interrupt enabled

Bit 7  **ARBLSTIE**: Arbitration Lost Interrupt Enable
The ARBLSTIE bit is set and cleared by software.
0: ARBLST interrupt disabled
1: ARBLST interrupt enabled

Bit 6  **RXACKIE**: Rx-Missing Acknowledge Error Interrupt Enable
The RXACKIE bit is set and cleared by software.
0: RXACKE interrupt disabled
1: RXACKE interrupt enabled

Bit 5  **LBPEIE**: Long Bit Period Error Interrupt Enable
The LBPEIE bit is set and cleared by software.
0: LBPE interrupt disabled
1: LBPE interrupt enabled

Bit 4  **SBPEIE**: Short Bit Period Error Interrupt Enable
The SBPEIE bit is set and cleared by software.
0: SBPE interrupt disabled
1: SBPE interrupt enabled

Bit 3  **BREIE**: Bit Rising Error Interrupt Enable
The BREIE bit is set and cleared by software.
0: BRE interrupt disabled
1: BRE interrupt enabled

Bit 2  **RXOVRIE**: Rx-Buffer Overrun Interrupt Enable
The RXOVRIE bit is set and cleared by software.
0: RXOVR interrupt disabled
1: RXOVR interrupt enabled

Bit 1  **RXENDIE**: End Of Reception Interrupt Enable
The RXENDIE bit is set and cleared by software.
0: RXEND interrupt disabled
1: RXEND interrupt enabled

Bit 0  **RXBRIE**: Rx-Byte Received Interrupt Enable
The RXBRIE bit is set and cleared by software.
0: RXBR interrupt disabled
1: RXBR interrupt enabled

**Caution:** (*) It is mandatory to write CEC_IER only when CECEN=0
58.7.7 HDMI-CEC register map

The following table summarizes the HDMI-CEC registers.

Table 567. HDMI-CEC register map and reset values

| Offset | Register name | 31 | 30 | 29 | 28 | 27 | 26 | 24 | 23 | 22 | 19 | 18 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|--------|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 0x00   | CEC_CR        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

Refer to Section 2.3 on page 126 for the register boundary addresses.
59 Debug infrastructure

59.1 Introduction

The debug infrastructure allows software designers to debug and trace their embedded software.

The debug features can be controlled via a JTAG/Serial-wire debug access port, using industry standard debugging tools. A trace port allows data to be captured for logging and analysis.

The trace and debug system has been designed to support a variety of typical use cases:

- **Low cost trace**
  Limited trace capability is available over the single-wire debug output. This supports code instrumentation using “printf”, tracing of data and address watchpoints, interrupt detection and program counter sampling. Single-wire trace can be maintained even when the processor is switched off or clock-stopped.

- **Breakpoint debugging**
  The processor can be debugged using equipment connected to the JTAG/SWD debug port. This allows breakpoint and watchpoint setting, code stepping, memory access etc.

- **Tracing code execution via the trace port**
  Trace information is combined into a single trace stream and output to a trace port analyzer in real time. An ID embedded in the trace allows the analyzer to identify the source of each information packet.

- **Capturing trace continuously in a circular buffer**
  Instead of streaming it off-chip, the combined trace information can be stored on-chip in a circular buffer. The trace storage can be started and stopped by a debugger command, a software command, an external trigger signal, an internal event, etc.

- **Draining the buffer to the trace port**
  The stored trace can be dumped off-chip to the trace port analyzer. The buffer draining can be initiated by the debugger, software, external trigger, internal event etc.

- **Reading the buffer with the debugger**
  The debugger can read the contents of the trace buffer via the debug port. This is slower than the trace port, but allows basic trace functionality on the debugger without the cost of a trace port analyzer.

- **Analyzing stored trace in software**
  The trace buffer can be read by the processor core, or transferred into system memory by DMA. This powerful feature allows built-in test software to monitor code execution in real time, analyze and identify faults, autonomously handle exceptions, etc.

- **Uploading stored trace**
  The stored trace can also be uploaded to a host machine using one of the MCU’s many communications interfaces (USB, USART, SPI, I2C, Ethernet, CAN etc). This is especially useful if the trace port is not accessible, for example remote monitoring and failure analysis of a deployed product.
59.2 Debug infrastructure features

A comprehensive set of trace and debug features is provided to support software development and system integration:

- Breakpoint debugging
- Code execution tracing
- Software instrumentation
- Cross-triggering
- JTAG debug port
- Serial-wire debug port
- Trigger input and output
- Serial-wire trace port
- Trace port
- Arm® CoreSight™ debug and trace components

The CoreSight components are described at high level in this document. Detailed information is available in the Arm® documents referenced in Section 59.7.

59.3 Debug infrastructure functional description

59.3.1 Debug infrastructure block diagram

The block diagram shows the logical partitioning of the debug infrastructure.

Figure 816. Block diagram of debug infrastructure

</table>

1. TRGIO can be configured as an input or an output by the TRGOEN bit in the DBGMCU. If configured as an input, it is connected to TRGIN. If an output, it is connected to TRGOUT. This is because TRGIN and TRGOUT are not available on certain packages.
59.3.3  Debug infrastructure powering, clocking and reset

Power domains

Figure 817. Power domains of debug infrastructure

The debug components are distributed across the power domains D1 and D3. The D3 power domain is considered to be always on when the debugger is connected. It therefore contains the SWJ-DP, so that the debugger does not lose the connection with the SoC when the other power domain is switched off. In addition, it contains the timestamp generator, the DBGMCU and the serial wire trace features.

The D1 power domain contains the Cortex-M7 core and the associated debug and trace components. It also contains the system trace components located on the APB-D. This power domain therefore needs to be on whenever a debug access to the Cortex-M7 is required, or whenever a trace functionality is active on the processor.
Clock domains

The debugger supplies the clock for the debug port, SWTCLK, via the debug interface pin, JTCK/SWCLK. This clock is used to register the serial input data in both serial wire and JTAG mode, as well as to operate the state machines and internal logic of the debug port. It must therefore continue to toggle for several cycles after the end of an access, to ensure that the debug port returns to the idle state.

The SWJ-DP contains an asynchronous interface to the DAPCLK domain, which covers the rest of the SWJ-DP and the access ports. The DBGMCU, timestamp generator and System ROM table 1 are also in the DAPCLK domain.

CK_DBG_D3 clocks the SWO and serial wire trace funnel.

Both DAPCLK and CK_DBG_D3 are gated versions of the D3 domain system clock (CK_HCLK_D3).

CK_DBG_D1 clocks the trace components in the D1 power domain: System ROM table 2, CoreSight trace funnel, ETF, system CTI and TPIU. It is a gated version of the D1 domain system clock (CK_HCLK_D1).

TRACECLK is the trace port output clock. It is a gated version of the system clock (CK_SYS), except when the PLL1 is the source for the system clock. In this case, TRACECLK is derived directly from the PLL1 VCO output, divided by three. This is required in order to support the high data throughput on the trace port when the processor operates at its maximum frequency.

All the debug clocks (except DAPCLK) can be enabled and disabled by register bits in the DBGMCU. The DAPCLK domain is enabled by the debugger using the CDBGPWRUPREQ.
bit in the debug port CTRL/STAT register. The clock must be enabled before the debugger can access any of the debug features on the device. It should be disabled at power up and when the debugger is disconnected, to avoid wasting energy.

The debug and trace components included in the processor (ETM ITM, DWG, FPB etc) are clocked with the corresponding core clock (CK_CORE_D1).

### Debug with low-power modes

The device includes power-saving features allowing individual power domains to be switched off or stopped when not required. If a power domain is switched off or not clocked, all debug components in that domain are inaccessible to the debugger. To avoid this, power saving mode emulation is implemented. If the emulation is enabled for a domain, the domain still enters power saving mode, but its clock and power are maintained. In other words, the domain behaves as if it is in power saving mode, while the debugger does not lose the connection.

The emulation mode is programmed in the MCU Debug (DBGMCU) unit. For more information, refer to Section 59.5.8

### Reset of debug infrastructure

The debug components, except for the debug port and access ports, are reset by their respective power domain resets. The debug port (SWJ-DP) is reset by a power-on reset of the D3 domain only.

### 59.4 Debug access port functional description

The debug access port (DAP) is a debug subsystem comprising serial-wire and JTAG debug port (SWJ-DP) and three access ports.

#### 59.4.1 Serial-wire and JTAG debug port (SWJ-DP)

The SWJ-DP is a CoreSight component that implements an external access port for connecting debugging equipment.

The port can be configured as:
- a 5-pin standard JTAG debug port (JTAG-DP)
- a 2-pin (clock + data) “serial-wire” debug port (SW-DP)

The two modes are mutually exclusive, since they share the same IO pins.

By default, the JTAG-DP is selected upon a system or power-on reset. The five IOs are configured by hardware in debug alternative function mode. The SWJ-DP incorporates pull-up resistors on the JTDI, JTMS/SWDIO, and nJTRST lines, as well as a pull-down resistor on the JTCK/SWCLK line.

A debugger can select the SW-DP by transmitting the following serial data sequence on JTMS/SWDIO:

```
...(50 or more ones),...,0,1,1,1,0,0,1,1,1,0,0,1,1,1,...,(50 or more ones),...
```

JTCK/SWCLK must be cycled for each data bit.

In SW-DP mode, the unused JTAG lines JTDI, JTD0 and nJTRST can be used for other functions.
All SWJ port IOs can be reconfigured to other functions by software, in which case debugging is no longer possible.

**Serial wire debug port**

The Serial wire debug protocol uses two pins:
- SWCLK: clock from host to target
- SWDIO: bi-directional serial data (100kΩ pull-up required)

Serial data is transferred LSB first, synchronously with the clock. A transfer comprises three phases:
1. packet request (8 bits) transmitted by the host
2. acknowledge response (3 bits) transmitted by the target
3. data transfer (33 bits) transmitted by the host (in the case of a write) or target (in the case of a read)

The data transfer only occurs if the acknowledge response is OK.

Between each phase, if the direction of the data is reversed, a single clock cycle turn-around time is inserted.

</tbody>
</table>
Figure 819 shows successful write and read transfers.

**Figure 819. SWD successful data transfer**

In the case of a FAULT or WAIT ACK response from the target, the data transfer phase is cancelled, unless overrun detection is enabled, in which case the data will be ignored by the target (in the case of a write), or not driven (in the case of a read).

A line reset must be generated by the host when it is first connected, or following a protocol error. The line reset consists of 50 or more SWCLK cycles with SWDIO high, followed by two SWCLK cycles with SWDIO low.

For more details on the Serial Wire debug protocol, refer to the Arm® Debug Interface Architecture Specification [1].

**Note:** The SWJ-DP implements SWD protocol version 2.
JTAG debug port

Figure 820. JTAG TAP state machine

The JTAG-DP implements a TAP state machine (TAPSM) based on IEEE 1149.1-1990. The state machine is shown in Figure 820. It controls two scan chains, one associated with an instruction register (IR) and one with a number of data registers (DR).

When the TAPSM goes through the Capture-IR state, 0b0001 is transferred onto the instruction register (IR) scan chain. The IR scan chain is connected between JTDI and JTDO.

While the TAPSM is in the Shift-IR state, the IR scan chain shifts one bit for each rising edge of JTCK. This means that on the first tick:
- The LSB of the IR scan chain is output on JTDO.
- Bit [n] of the IR scan chain is transferred to bit [n-1].
- The value on JTDI is transferred to the MSB of the IR scan chain.

When the TAPSM goes through the Update-IR state, the value scanned into the IR scan chain is transferred into the instruction register.

When the TAPSM goes through the Capture-DR state, a value is transferred from one of the data registers onto one of the DR scan chains, connected between JTDI and JTDO.
The value held in the instruction register determines which data register, and associated DR scan chain, is selected.

This data is then shifted while the TAPSM is in the Shift-DR state, in the same manner as the IR shift in the Shift-IR state.

When the TAPSM goes through the Update-DR state, the value scanned into the DR scan chain is transferred into the selected data register.

When the TAPSM is in the Run-Test/Idle state, no special actions occur. The IDCODE instruction is loaded in IR.

When active, the nJTRST signal resets the state machine asynchronously to the Test-Logic-Reset state.

The data registers corresponding to the 4-bit IR instructions are listed in Table 575.

The DR registers are described in more detail in the Arm® Debug Interface Architecture Specification [1].

### Debug port registers

The SW-DP and JTAG-DP both access the debug port (DP) registers. These are listed in Table 576.

The debugger can access the DP registers as follows:

1. Program the SELECT register DPBANKSEL field in the DP to select the register bank to be accessed (see Table 576).
2. Program the A(3:2) field in the DPACC register, if using JTAG, with the register address within the bank. Program the R/W bit to select a read or a write. In the case of a write, program the DATA field with the write data. If using SWD, the A(3:2) and R/W fields are part of the Packet Request word sent to the SW-DP with the APnDP bit reset (see Table 572). The write data is sent in the data phase.

<td>00</td>
<td>R</td>
<td>DP_DPIDR register. It contains the IDCODE for the debug port.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>W</td>
<td>DP_ABORT register(^{(1)}). It aborts the current AP transaction. This register is also used to clear the error flags in the DP_CTRL/STAT register.</td>
</tr>
</tbody>
</table>
| 0x4             | 01          | R/W | If DPBANKSEL[3:0] = 0x0 (DP_SELECT register):  
CTRL/STAT register. It controls the DP and provides status information.  
If DPBANKSEL[3:0] = 0x1 (DP_SELECT register):  
DP_DLCR register\(^{(2)}\). It controls the operating mode of the SWD Data Link.  
If DPBANKSEL[3:0] = 0x2 (DP_SELECT register):  
DP_TARGETID register. It provides target identification information.  
If DPBANKSEL[3:0] = 0x3 (DP_SELECT register):  
DLPIDR register\(^{(2)}\). It provides the SWD protocol version. |
| 0x8             | 10          | R   | RESEND register\(^{(2)}\). It returns the value that was returned by the last AP read or DP_RDBUFF read, used in the event of a corrupted read transfer. |
|                 |             | W   | DP_SELECT register. It selects the access port, access port register bank, and DP register at address 0x4. |
| 0xC             | 11          | R   | DP_RDBUFF register  
Via JTAG-DP, it is used to allow the debugger to get the final result after a sequence of operations (without requesting new JTAG-DP operation).  
Via SW-DP, it contains the result of the preceding AP read access, allowing a new AP access to be avoided. |
|                 |             | W   | DP_TARGETSEL register\(^{(2)}\). On a write to DP_TARGETSEL immediately following a line reset sequence, the target is selected if the following conditions are both met:  
Writing any other value deselects the target. Debug tools must write 0xFFFFFFFF to deselect all targets. This is an invalid DP_TARGETID value. All other invalid DP_TARGETID values are reserved. |

---

1. Access to the AP ABORT register from the JTAG-DP is done using the ABORT instruction.
2. Only accessible via SW-DP. Register is "reserved" via JTAG-DP.

3044/3289 RM0433 Rev 6
Bits 31:28 **REVISION[3:0]**: Revision code
0x6

Bits 27:20 **PARTNO[7:0]**: Part number for the debug port
0xBA

Bits 19:17 Reserved, must be kept at reset value.

Bit 16 **MIN**: Minimal debug port (MINDP) implementation
0: MINDP not implemented (transaction counter and pushed operations are supported)

Bits 15:12 **VERSION[3:0]**: DP architecture version
0x2: DPv2

Bits 11:1 **DESIGNER[10:0]**: JEDEC designer identity code
0x23B: Arm®

Bit 0 Reserved, must be kept at reset value.

**Debug port abort register (DP_ABORT)**

Address offset: 0x0

Reset value: 0x0000 0000

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **ORUNERRCLR**: Overrun error clear bit
0: No effect
1: Clear CTRL/STAT register’s STICKYORUN bit

Bit 3 **WDERRCLR**: Write data error clear bit
0: No effect
1: Clear CTRL/STAT register’s WDATAERR bit
Bit 2 **STKERRCLR**: Sticky error clear bit
- 0: No effect
- 1: Clear CTRL/STAT register’s STICKYERR bit

Bit 1 **STKCMPCLR**: Sticky compare clear bit
- 0: No effect
- 1: Clear CTRL/STAT register’s STICKYCMP bit

Bit 0 **DAPABORT**: Abort current AP transaction
The transaction is aborted if an excessive number of WAIT responses are returned, indicating that the transaction has stalled.
- 0: No effect
- 1: Abort transaction

### Debug port control/status register (DP_CTRL/STAT)

Address offset: 0x4
Reset value: 0x0000 0000

Bit 31 **CSYSPWRUPACK**: System domain power-up status bit - not used in this device
Bit 30 **CSYSPWRUPREQ**: System domain power-up control bit - not used in this device
Bit 29 **CDBGPWRUPACK**: Debug domain power-up status bit
This bit is read-only. It returns the status of the debug domain power-up acknowledge signal from the power controller.
- 0: domain powered down
- 1: domain powered up

Bit 28 **CDBGPWRUPREQ**: Debug domain power-up/down control bit
This bit controls the debug domain power-up/down request signal to the power controller.
- 0: power-down requested
- 1: power-up requested

Bit 27 **CDBGGRSTACK**: Debug domain reset status bit - not used in this device
Bit 26 **CDBGRSTREQ**: Debug domain reset control bit - not used in this device

Bits 25:24 Reserved, must be kept at reset value.

Bits 23:12 **TRNCNT[11:0]**: Transaction counter

To program a sequence of transactions to incremental addresses via an AP, TRNCNT bits are loaded with the number of transactions to perform. It is decremented at the successful completion of each transaction.

Bits 11:8 **MASKLANE[3:0]**: Pushed-compare and pushed-verify masking bits

The field indicates the bytes to be masked in pushed-compare and pushed-verify operations (DP_CTRL/STAT register’s field TRNMODE = 1 or 2). In the pushed operations, the word supplied in an AP write transaction is compared with the current value at the target AP address.

- 0b1XXX: include byte lane 3 in comparisons
- 0bX1XX: include byte lane 2 in comparisons
- 0bXX1X: include byte lane 1 in comparisons
- 0bXXX1: include byte lane 0 in comparisons

Bit 7 **WDATAERR**: Write data error in SW-DP

The bit indicates that
- there is a parity or a framing error on the data phase of a write operation, or
- a write operation that had been accepted by the DP has then be discarded without being submitted to the AP.

This bit is read-only. It is reset by writing 1 to the WDERRCLR bit of the DP_ABORT register.

- 0: No error
- 1: Error has occurred

This bit is reserved in JTAG-DP.

Bit 6 **READOK**: AP read response in SW-DP

This bit indicates the response to the last AP read access. It is read-only.

- 0: Read not OK
- 1: Read OK

This bit is Reserved in JTAG-DP.

Bit 5 **STICKYERR**: Transaction error (read-only in SW-DP, R/W in JTAG-DP)

This bit indicates that an error occurred during an AP transaction.

- 0: No error
- 1: Error has occurred

In the SW-DP, this bit is reset by writing 1 to the STKERRCLR bit of the DP_ABORT register. In the JTAG-DP, this bit is reset by programming it to 1.
Bit 4 **STICKYCMP**: Compare match (read-only in SW-DP, R/W in JTAG-DP)
This bit indicates that a match occurred in a pushed operation.

0: Match if TRNMODE = 0x1; no match if TRNMODE = 0x2
1: No match if TRNMODE = 0x1; match if TRNMODE = 0x2

In the SW-DP, this bit is reset by writing 1 to the STKCMPCLR bit in the DP_ABORT register.
In the JTAG-DP, this bit is reset by programming it to it.

Bits 3:2 **TRNMODE[1:0]**: Transfer mode for AP write operations
For read operations, this field must be set to 0x0.

0x0: Normal operation - AP transactions are passed directly to the AP.
0x1: Pushed-verify operation. The DP stores the write data and performs a read transaction
at the target AP address. The result of the read operation is compared with the stored data. If
they do not match, the STICKYCMP bit is set.
0x2: Pushed-compare operation. The DP stores the write data and performs a read
transaction at the target AP address. The result of the read is compared with the stored data.
If they match, the STICKYCMP bit is set.
0x3: Reserved

In pushed operations, only the data bytes indicated by the MASKLANE field are included in
the comparison.

Bit 1 **STICKYORUN**: Overrun (read-only in SW-DP, R/W in JTAG-DP)
This bit indicates that an overrun occurred (new transaction received before previous
transaction completed). This bit is only set if the ORUNDETECT bit is set.

0: No overrun
1: Overrun occurred

In the SW-DP, this bit is reset by writing 1 to the ABORT register’s ORUNERRCLR bit. In the
JTAG-DP, this bit is reset by writing a 1 to it.

Bit 0 **ORUNDETECT**: Overrun detection mode enable
0: Overrun detection disabled
1: Overrun detection enabled. In the event of an overrun, the STICKYORUN bit will be set
and subsequent transactions will be blocked until the STICKYORUN bit is cleared.

**Debug port data link control register (DP_DLCR)**

Bits 31:28  **TINSTANCE[3:0]**: Target instance number
   These bits define the instance number for this device in a multi-drop system.
   0x0

Bits 27:4  Reserved, must be kept at reset value.

Bits 3:0  **PROT SVN[3:0]**: Serial Wire Debug protocol version
   0x1: Version 2

**Debug port resend register (DP_RESEND)**

Address offset: 0x8

Reset value: 0x0000 0000

![RESEND Register](image)

Bits 31:0  **RESEND[31:0]**: Last AP read or DP RDBUFF read value
   These bits contain the value that was returned by the last AP read or DP RDBUFF read.
   Used in the event of a corrupted read transfer.

**Debug port access port select register (DP_SELECT)**

Address offset: 0x8

Reset value: N/A

![APSELECT Register](image)
Bits 31:28 **APSEL[3:0]**: Access port select bits
These bits select the access port for the next transaction.

- 0x0: AP0 - Cortex-M7 debug access port (AHB-AP)
- 0x1: AP1 - D3 access port (AHB-AP)
- 0x2: AP2 - System debug access port (APB-AP)
- 0x3 to 0xF: Reserved

Bits 27:8 Reserved, must be kept at reset value.

Bits 7:4 **APBANKSEL[3:0]**: AP register bank select bits
These bits select the 4-word register bank on the active AP for the next transaction.

Bits 3:0 **DPBANKSEL[3:0]**: DP register bank select bits
These bits select the register at address 0x4 of the debug port.

- 0x0: CTRL/STAT register
- 0x1: DLCR register
- 0x2: TARGETID register
- 0x3: DLPIRD register
- 0x4 to 0xF: Reserved

**Debug port read buffer register (DP_RDBUFF)**
Address offset: 0xC
Reset value: 0x0000 0000

Bits 31:0 **RDBUFF[31:0]**: Last AP read value
The field contains the value returned by the last AP read access. There are two ways to retrieve the value returned by an AP read access:

- perform a second read access to the same address, which will initiate a new transaction on the corresponding bus, or
- read the value returned by the last AP read access from the DP_RDBUFF register, in which case no new AP transaction occurs
**Debug port target identification register (DP_TARGETSEL)**

Address offset: 0xC

**Bits 31:28** **TINSTANCE[3:0]:** Target instance number

The field defines the instance number for the target device in a multi-drop system. It must be programmed with the same value as TINSTANCE field of DP_DLPIDR register, in order to select this device.

**Bits 27:12** **TPARTNO[15:0]:** Target part number

The field defines the part number for the target device. It must be programmed with the same value as TPARTNO field of DP_TARGETID register, in order to select this device.

**Bits 11:1** **TDESIGNER[10:0]:** Target designer JEDEC code

The field defines the JEDEC code for the target device. It must be programmed with the same value as TDESIGNER field of DP_TARGETID register, in order to select this device.

**Bit 0** Reserved, must be kept at reset value.

### 59.4.2 Access ports

**Figure 821. Debug and access port connections**
There are the following access ports (AP) attached to the DP:

1. AP0: Cortex-M7 access port (AHB-AP). Allows access to the debug and trace features integrated in the Cortex-M7 processor core via an AHB-Lite bus connected to the AHBD port of the processor.

2. AP1: D3 access port (AHB-AP). Allows access to the bus matrix in the D3 domain. This gives visibility of the D3 domain memory and peripherals when the D1 and D2 domains are switched off. No CoreSight components are accessible via this port.

3. AP2: System access port (APB-AP). Allows access to the debug and trace features on the system APB debug bus, that is, all components not included in the processor core.

All access ports are of MEM-AP type, that is, the debug and trace component registers are mapped in the address space of the associated debug bus. The AP is seen by the debugger as a set of 32-bit registers organized in banks of four registers each. Some of these registers are used to configure or monitor the AP itself, while others are used to perform a transfer on the bus. The AP registers are listed in Table 577.

The address of the AP registers is composed of:

- bits [7:4]: contents of the DP_SELECT register’s APBANKSEL field
- bits [3:2]: contents of the A(3:2) field of the APACC data register in the JTAG-DP (see Table 575) or of the SW-DP Packet Request (see Table 572), depending on the debug interface used
- bits [1:0]: Always set to 0

The contents of the SELECT register APSEL field in the DP define which MEM-AP is being accessed.

The debugger can access the AP registers as follows:

1. Program the DP_SELECT register’s APSEL field to choose one of the APs, and the APBANKSEL field to select the register bank to be accessed.

2. Program the A(3:2) field in the APACC register, if using JTAG, with the register address within the bank. Program the RnW bit to select a read or a write. In the case of a write, program the DATA field with the write data. If using SWD, the A(3:2) and RnW fields are part of the Packet Request word sent to the SW-DP with the APnDP bit set (see Table 572). The write data is sent in the data phase.

The debugger can access the memory mapped debug component registers through the MEM-AP registers (using the above AP register access procedure) as follows:

1. Program the transaction target address in the TAR register.

2. Program the CSW register, if necessary, with the transfer parameters (AddrInc for example).

3. Write to or read from the DRW register to initiate a bus transaction at the address held in the TAR register. Alternatively, a read or write to banked data register BDn triggers an access to address TAR[31:4] + n (this allows accessing up to four consecutive addresses without changing the address in the TAR register).

For more detailed information on the MEM-AP, refer to the Arm® Debug Interface Architecture Specification [1]. The usage of MEM-AP to connect the debug port to the debug components (in the example, a processor, an ETM and a ROM table), is in the section 7.1.2.
### MEM-AP registers

Bit 31: Reserved, must be kept at reset value.

Bit 30 SPROT: Secure transfer request bit
- In the APB-AP, this field is reserved. In the AHB-APs, this field sets the protection attribute HPROT[6] of the bus transfer.
  0: If SPIDEN is high, secure transfer. If SPIDEN is low, non-secure transfer.
  1: Non-secure transfer.

Bit 29: Reserved, must be kept at reset value.

Bits 28:24 PROT[4:0]: Bus transfer protection bits
- In the APB-AP, this field is reserved. In the AHB-APs, this field sets the protection attributes HPROT[4:0] of the bus transfer.
- 0bXXXX0: Instruction fetch
- 0bXXXX1: Data access
- 0bXX0XX: User mode
- 0bXX1XX: Privileged mode
- 0b0XXX: Non-bufferable
- 0bXX1XX: Bufferable
- 0bX0XXX: Non-cacheable
- 0bX1XXX: Cacheable
- 0b0XXX: Non-exclusive
- 0b1XXX: Exclusive

Bit 23 SPISTATUS: Status of SPIDEN option bit
- This bit determines whether the debugger can access secure memory. This field is reserved in the APB-AP.
  0: Secure AHB transfers are blocked
  1: Secure AHB transfers are allowed

Bits 22:12: Reserved, must be kept at reset value.

Bits 11:8 MODE[3:0]: Barrier support enabled bit
- These bits define if memory barrier operation is supported.
  0x0: Not supported

Bit 7 TRINPROG: Transfer in progress
- This bit indicates that a bus transfer is in progress on the AP.
  0: No transfer in progress.
  1: Bus transfer in progress.
Bit 6 **DEVICEEN**: Device Enable bit  
This bit defines whether the AP can be accessed or not.  
1: AP access enabled.

Bits 5:4 **ADDRINC[1:0]**: Auto-increment mode bits  
These bits define whether the TAR address is automatically incremented after a transaction.  
0x0: no auto-increment  
0x1: Address is incremented by the size in bytes of the transaction (SIZE field).  
0x2: Packed transfers enabled (Only in AHB-APs - reserved in APB-AP). A 32-bit AP access will give rise to 1 x 32-bit, 2 x 16-bit or 4 x 8-bit bus transactions corresponding to the programmed transaction size. The data will be packed or unpacked accordingly.  
0x3: Reserved

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **SIZE[2:0]**: Size of next memory access transaction (only for AHB-APs)  
0x0: Byte (8-bit)  
0x1: Half-word (16-bit)  
0x2: Word (32-bit)  
0x3-0x7: Reserved

For APB-AP, this field is read-only and fixed at 0x2 (32-bit).

**Access port base address register (AP_BASE)**  
Address offset: 0xF8  
Reset value: 0xE00F E003 (AP0), 0x0000 0002 (AP1), 0xE00E 0003 (AP2)

59.5 Trace and debug subsystem functional description

The trace and debug subsystem features the following CoreSight components:

- System ROM tables
- Global timestamp generator (TSG)
- System cross-trigger interface (CTI)
- Cross-trigger matrix (CTM)
- Trace port interface unit (TPIU)
- Trace bus funnel (CSTF)
- Embedded trace FIFO (ETF)
- Serial wire output (SWO)
- Serial wire output trace funnel (SWTF)

These components are accessible by the debugger via the system APB-AP and its associated APB-D debug bus. They are also accessible by the Cortex-M7 processor.

The MCU debug unit (DBGMCU) is also accessed via the APB-D. This non-CoreSight component contains registers for configuring the behavior of the device in debug mode.

Trace bus replicator branches the trace bus from the CPU’s ITM CoreSight component to ETF and SWO, through trace bus funnels.

59.5.1 System ROM tables

There are two ROM tables on the APB-D bus. The ROM table is a CoreSight component that contains the base addresses of all the CoreSight components on the APB-D bus. These tables allow a debugger to discover the topology of the CoreSight components automatically.

The first table points to the second table, and to the CoreSight components located in D3 power domain: SWO, SWTF, TSG. The DBGMCU is not referenced by the table as it is not a standard CoreSight component. The table occupies a 4-Kbyte, 32-bit wide chunk of APB-D address space, from 0xE00E0000 to 0xE00E0FFC when accessed by the debugger, and from 0x5C000000 to 0x5C000FFC when accessed from the system bus.

<td>See System ROM registers</td>
</tr>
</tbody>
</table>

The top of each ROM table contains a number of read-only registers, including the standard CoreSight component and peripheral identity registers, see section System ROM registers.

Each debug component occupies one or more 4 Kbyte blocks of address space. This block of address space is referred to as the debug register file for the component.

The component address offset field of a ROM Table entry points to the start of the last 4 Kbyte block of the address space of the component. This block always contains the component and peripheral ID registers for the component, starting at offset 0xFD0 from the start of the block. The 4 Kbyte count field PIDR4 [7:4], specifies the number of 4 Kbyte blocks for the component. Therefore, the process for finding the start of the address space for a component is:

1. Read the ROM-table entry for the component and extract its Address_Offset[18:0] from bits [31:12] of the ROM-table entry.
2. Use the address offset, together with the base address of the ROM table, ROM_Base_Address, to calculate the base address of the component:
   \[
   \text{Component\_Base\_Address} = \text{ROM\_Base\_Address} + \text{Address\_Offset}
   \]
   The Component_Base_Address is the start address of the 4 Kbyte block of the address space for the component.
3. Read the peripheral ID4 register for the component. The address of this register is:
   \[
   \text{Peripheral\_ID4\_address} = \text{Component\_Base\_Address} + 0xFD0
   \]
4. Extract the 4 Kbyte count field [7:4] from the value of the Peripheral ID4 Register.
5. Use the 4 Kbyte count field value to calculate the start address of the address space for the component. If the field value is 0b0000, which corresponds to a count value of 1, the address space for the component starts at Component_Base_Address obtained at stage 2.

The topology for the CoreSight components on the APB-D is shown in Figure 822.
For more information on the use of the ROM table, refer to the Arm® Debug Interface Architecture Specification [1].

59.5.2 Global timestamp generator (TSG)

The global timestamp generator contains a 64-bit counter that provides a common timing reference for all of the trace sources in the system, namely the ETM and ITM in the processor core. These components insert timestamps in the trace streams that allow the trace analyzer to recover the chronological order of trace packets, which can be lost when multiple trace sources are multiplexed into one stream at the funnels.

The TSG registers are accessible over the APB-D. This allows the debugger or debug software to:

- start and stop the timestamp incrementing
- read the current timestamp value
- change the current timestamp value
  - The timestamp counter must be halted while it is changed. When the timestamp value is changed, the timestamp generator resynchronizes all the trace sources.
- change the reported timestamp increment

For more information on the global timestamp generator CoreSight component, refer to the Arm® CoreSight™ SoC-400 Technical Reference Manual [2].

The timestamp generator is located in the D3 power domain, and the timestamp is distributed to the Cortex-M7. To simplify the distribution over power domain boundaries, the 64-bit timestamp is encoded in seven bits, then decoded in the destination power domain, and interpolated to increase its resolution if the processor clock is significantly faster than the generator clock. The timestamp distribution is shown in Figure 823.

Figure 823. Global timestamp distribution
TSG registers

TSG counter control register (TSG_CNTCR)

Address offset: 0x000
Reset value: 0x0000 0000

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **HDBG**: Halt on debug
- 0: Normal operation
- 1: Halt counter when system-wide debug state is detected - not implemented

Bit 0 **EN**: Enable
- 0: Counter disabled
- 1: Counter enabled and incrementing

TSG counter status register (TSG_CNTSR)

Address offset: 0x004
Reset value: 0x0000 0000

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **DBGH**: Debug halt
- 0: Normal operation
- 1: Counter halted due to system-wide debug state

Bit 0 Reserved, must be kept at reset value.
**TSG current counter value lower register (TSG_CNTCVL)**

Address offset: 0x008
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bits 31:0</th>
<th>CNTCVL[31:16]</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw</td>
</tr>
<tr>
<td>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:0 **CNTCVL[31:0]**: TSG current counter value field, bits[31:0]
To change the current timestamp value, write the lower 32 bits of the new value to this register before writing the upper 32 bits to CNTCVU. The timestamp value is not changed until the CNTVCVU register is written to. Note: The TSG_CNTCR register’s EN bit must be cleared before writing to this register.

**TSG current counter value upper register (TSG_CNTCVU)**

Address offset: 0x00C
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bits 31:0</th>
<th>CNTCVU[31:16]</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw</td>

<th>CNTCVU[15:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw</td>
</tr>
</tbody>
</table>

Bits 31:0 **CNTCVU[31:0]**: TSG current counter value field, bits[63:32]
To change the current timestamp value, write the lower 32 bits of the new value to CNTCVL before writing the upper 32 bits to this register. The 64-bit timestamp value is updated with the value from both writes when this register is written to. Note: The TSG_CNTCR register’s EN bit must be cleared before writing to this register.

**TSG base frequency ID register (TSG_CNTFID0)**

Address offset: 0x020
Reset value: 0x0000 0000

59.5.3 Cross trigger interfaces (CTI) and matrix (CTM)

The cross trigger interfaces (CTI) and cross trigger matrix (CTM) together form the CoreSight embedded cross trigger feature. There are two CTI components, one at system
level and one dedicated to the Cortex-M7. The two CTIs are connected to each other via the CTM. The system-level CTI is accessible to the debugger via the system access port and associated APB-D. The Cortex-M7 CTI is physically integrated in the Cortex-M7 core, and is accessible via the Cortex-M7 access port and associated AHBD.

The CTIs allow events from various sources to trigger debug and/or trace activity. For example, a transition detected on an external trigger input can start code trace.

Each CTI has up to 8 trigger inputs and 8 trigger outputs. Any input can be connected to any output, on the same CTI, or on another CTI via the CTM.

The trigger input and output signals for each CTI are listed in Table 582 to Table 585.

</tr>
</tbody>
</table>
There are four event channels in the cross trigger matrix, which allows up to four parallel bidirectional connections between trigger inputs and outputs on different CTIs. To connect input number \( m \) on CTI \( x \) to output number \( n \) on CTI \( y \), the input must be connected to an event channel \( p \) using the CTIINEN\( m \) register of CTI \( x \). The same channel \( p \) must be connected to the output using the CTIOUTEN\( n \) register of CTI \( y \). Note: this applies even if the input and output belong to the same CTI.

An input can be connected to more than one channel (up to four), so an input can be routed to several outputs. Similarly, an output can be connected to several inputs. It is also possible to connect several inputs/outputs to the same channel.

- **Bits 31:3** Reserved, must be kept at reset value.
- **Bit 2** LOCKTYPE: Size of the CTI_LAR register
  0: 32-bit
- **Bit 1** LOCKGRANT: Current status of lock
  This bit always returns zero when read by an external debugger.
  0: Write access is permitted
  1: Write access is blocked. Only read access is permitted.
- **Bit 0** LOCKEXIST: Existence of lock control mechanism
  The bit indicates whether a lock control mechanism exists. It always returns zero when read by an external debugger.
  0: No lock control mechanism exists
  1: Lock control mechanism is implemented

59.5.4 Trace funnel (CSTF)

The trace funnel is a CoreSight component that combines the ATB buses from two trace sources into one single ATB. The CSTF has two ATB slave ports, and one ATB master port. An arbiter selects the slave ports according to a programmable priority.

The slave ports are connected as follows:
- S0: Cortex-M7 ETM
- S1: Cortex-M7 ITM

The CSTF registers allow the slave ports to be individually enabled, and their priority settings to be configured. The priorities can be modified only when trace is disabled. The arbitration works as follows:
- The arbiter selects the slave port with the highest assigned priority that has data valid
- Up to min_hold_time transfers are passed from the selected slave to the master port, where min_hold_time is programmable in the CONTROL register.
- A new arbitration is then performed

High priority should be assigned to slave ports connected to sources with a small amount of buffering, or where data loss cannot be tolerated. Low priority should be assigned to less critical sources or those with large buffers.

For more information on the ATB Funnel CoreSight component, refer to the Arm® CoreSight™ SoC-400 Technical Reference Manual [2].

### CSTF claim tag set register (CSTF_CLAIMSET)

Address offset: 0xFA0
Reset value: 0x0000 000F
Bits 31:4  Reserved, must be kept at reset value.

Bits 3:0  **CLAIMSET[3:0]**: Set claim tag bits

Write:
- 0000: No effect
- xxx1: Set bit 0
- xx1x: Set bit 1
- x1xx: Set bit 2
- 1xxx: Set bit 3

Read:
- 0xF: Indicates there are four bits in claim tag

### CSTF claim tag clear register (CSTF_CLAIMCLR)

**Address offset**: 0xFA4

**Reset value**: 0x0000 0000

<table>
<thead>
<tr>

**ClaimsCLR[3:0]**

Bits 31:4  Reserved, must be kept at reset value.

Bits 3:0  **CLAIMCLR[3:0]**: Reset claim tag bits

Write:
- 0000: No effect
- xxx1: Clear bit 0
- xx1x: Clear bit 1
- x1xx: Clear bit 2
- 1xxx: Clear bit 3

Read: Returns current value of claim tag

### CSTF lock access register (CSTF_LAR)

**Address offset**: 0xFB0

**Reset value**: N/A

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **LOCKTYPE**: Size of the CSTF_LAR register
0: 32-bit

Bit 1 **LOCKGRANT**: Current status of lock
This bit always returns zero when read by an external debugger.

0: Write access is permitted
1: Write access is blocked. Only read access is permitted.

Bit 0 **LOCKEXIST**: Existence of lock control mechanism
The bit indicates whether a lock control mechanism exists. It always returns zero when read by an external debugger.

0: No lock control mechanism exists
1: Lock control mechanism is implemented

59.5.5 Embedded trace FIFO (ETF)

The ETF is an 4 Kbyte memory that captures trace data from two trace sources, namely the ETM and ITM of the CPU core. The ETF is a design configuration of the CoreSight™ trace memory controller component.

The ETF can be used in three modes (selected in the mode register):

1. Hardware FIFO mode

   The trace memory is used as a FIFO that is drained through the ATB master interface. Trace data is captured into the trace RAM and when full, the incoming trace stream is stalled. When the Trace buffer is not empty, trace data is drained out through the ATB master interface to the TPIU.

   In this mode, the role of the FIFO is to smooth the flow of trace information arriving at the trace port. Since the trace data can be very bursty in nature, the peak data rate can easily exceed the port capability, resulting in an overflow. The ETF allows a steady data rate at the trace port, which can then be sized according to the average rate rather than...
the peak. The trace is stored off-chip in real time by the trace port analyzer tool, and so the trace log can be very big.

2. Software FIFO mode

The trace memory is used as a FIFO that can be read through the RRD Register while trace is being captured. Trace data is captured into the trace RAM and when full, the incoming trace stream is stalled.

This mode allows the trace to be transferred by DMA into the system memory, or to a high speed interface (SPI, USB etc), or even monitored by software. Note that unlike the hardware FIFO mode, this mode is invasive, since it uses system resources which are shared by the processor.

3. Circular buffer mode

The trace memory is used as a circular buffer. Trace data is captured into the Trace memory starting from the location pointed to by the write pointer register. Even when the trace memory is full, incoming trace data continues to be overwritten into the trace memory until a stop condition occurs.

In this mode, the ETF stores the trace data on-chip, so the trace log size is limited to that of the ETF SRAM, 4 Kbytes in this case. Being a circular buffer, if the FIFO becomes full, incoming trace data overwrites the oldest stored data and the oldest stored data is lost. Therefore the contents of the trace buffer represent the most recent activity of the processor, up to the point when the buffer was stopped, rather than all the activity since the trace was started.

There are three possible methods to read out the buffer contents once the trace stops:

- via the Trace port - with the TPIU enabled, the contents of the buffer are output over the Trace port. This can be done by setting the DRAINBUF bit in the ETF_FFCR register.
- via the Debug port - the debugger can read the buffer via the RRD register that is accessible over the system APB-D.
- by software - the processor can read the buffer via the RRD register, since the APB-D is accessible from the system bus.

The ETF can transition between the following states:

- **Disabled**
  This state is entered after a reset, or when trace capture is disabled. The ETF must only be programmed in this state.

- **Running**
  Trace capture is performed in this state. It is entered by enabling trace capture while in Disabled state.

- **Stopped**
  Trace capture is stopped in this state, but the contents of the buffer can be read out or drained. This state is entered after a stop event (trigger or flush).

- **Disabling**
  This is a transitional state while disabling trace capture.

- **Stopping**
  This is a transitional state while stopping trace capture.

- **Draining**
  This state is entered while draining the buffer in Stopped state.

The state transition diagram is shown in Figure 826.

</tbody>
</table>

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 EMPTY: Trace FIFO empty
This bit is valid only when the TCEN bit of the ETF_CTL register is high. This bit reads as zero when TCEN is low.

0: Trace FIFO contains data
1: Trace FIFO is empty.

Note: Empty trace FIFO does not mean that the ETF pipeline is empty. The latter is indicated by the FTEMPY bit.

Bit 3 FTEMPY: Formatter empty
This bit is set when trace capture has stopped, and all internal pipelines and buffers have drained. Unlike READY, it is not affected by buffer drains. The ACQCOMP output reflects the value of this bit.

Bit 2 READY: ETF ready
This bit is set when trace capture has stopped and all internal pipelines and buffers have drained (Stopped or Disabled state)

Bit 1 TRIGD: Triggered
The Triggered bit is set when trace capture is in progress and the TMC has detected a Trigger Event. This bit is cleared when leaving Disabled state.
This bit is operational only in the Circular buffer mode. In all other modes, this bit is always low.
This bit does not indicate that a trigger has been embedded in the formatted output trace data from the TMC. Trigger indication on the output trace stream is determined by the programming of the Formatter and Flush Control Register, ETF_FFCR.

Bit 0 FULL: Trace buffer full
In circular buffer mode, this flag is set when the RAM write pointer wraps around the top of the buffer, and remains set until the TCEN bit of the ETF_CTL register is cleared and set. In software and hardware FIFO modes, this flag indicates that the current space in the trace memory is less than or equal to the value programmed in the ETF_BUFWM Register, that is, Fill level >= MEM_SIZE - BUFWM.
This bit is cleared when leaving Disabled state. The FULL output reflects the value of this register bit.

**Bits 31:0**  
**RRD[31:0]: RAM Read Data.**

Circular buffer mode:
When in Stopped state and the buffer is not empty, reading this register returns the next word of data from the trace buffer. When all of the trace buffer has been read, the Empty bit in the ETF_STS Register is set, and subsequent reads return 0xFFFFFFFF. Reading this register when not in Stopped state returns 0xFFFFFFFF.

Software FIFO mode:
Reading this register returns data from the FIFO. If this register is read when the FIFO is empty, the data returned is 0xFFFFFFFF.

Hardware FIFO mode:
Reading this register returns 0xFFFFFFFF.

**Bits 31:13**  
Reserved, must be kept at reset value.

**Bits 12:0**  
**RRP[12:0]: RAM Read Pointer**

The RAM Read Pointer Register contains the value of the read pointer that is used to read entries from the trace memory over the APB interface via the ETF_RRD register. The pointer can be programmed with a byte address, 64-bit aligned (that is, bits 0 to 3 should be zero). The pointer is incremented by 8 each time a full 64-bit FIFO entry has been written. When the pointer reaches its maximum value, it wraps around.

This register can only be written in Disabled state. It can be read in Disabled state, in Stopped state in circular buffer mode and SW FIFO mode, and also in Running and Stopping states in SW FIFO mode.
**ETF RAM write pointer register (ETF_RWP)**

Address offset: 0x018  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>

<td>Read/Write (no programming but must be kept at reset value)</td>
</tr>
<tr>
<td>12:0</td>
<td>RAM write pointer RWP[12:0]</td>
<td>Read/Write</td>
</tr>
</tbody>
</table>

The RAM write pointer register contains the value of the write pointer that is used to write entries into the trace memory over the APB interface via the ETF_RWD register. The pointer can be programmed with a byte address, 64-bit aligned (that is, bits 0 to 3 should be zero). The pointer is incremented by 8 each time a full 64-bit FIFO entry has been read. When the pointer reaches its maximum value, it wraps around.

This register can only be written in Disabled state. It can be read in Disabled state, in Stopped state in circular buffer mode and SW FIFO mode, and also in Running and Stopping states in SW FIFO mode.

**ETF trigger counter register (ETF_TRG)**

Address offset: 0x01C  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Access</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:13</td>
<td>Reserved</td>
<td>Read/Write (no programming but must be kept at reset value)</td>
</tr>
<tr>
<td>10:0</td>
<td>Trigger counter TRG[10:0]</td>
<td>Read/Write</td>
</tr>
</tbody>
</table>

The ETF trigger counter register contains the value of the trigger counter, which is used to detect when a specific condition has been met in order to trigger the ETF mechanism. This register can only be written in Disabled state. It can be read in Disabled state, in Stopped state in circular buffer mode and SW FIFO mode, and also in Running and Stopping states in SW FIFO mode.
RM0433 Debug infrastructure

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:0 **TRG[10:0]:** Trigger counter

In Circular buffer mode, specifies the number of 32-bit words to capture in the trace RAM following the detection of either a rising edge on the TRIGIN input or a trigger packet in the incoming trace stream, ATID = 7’h7D. On capturing the specified number of data words, a trigger event occurs. The effect of a trigger event on the ETF behavior is controlled by the FFCR Register.

The number of 32-bit words written into the trace RAM following the trigger is the value stored in this register, plus one. This register is ignored when the ETF is in Software FIFO mode or Hardware FIFO mode. When the trigger counter starts counting, any additional triggers, either on TRIGIN or in the incoming trace stream, are ignored until the counter reaches zero. When the trigger counter has reached zero, it remains at zero until it is re-programmed with a write to this register.

This register is cleared when READY goes high, so that the state of the counter when trace capture has stopped does not affect a subsequent trace capture session. Writing to this register when not in Disabled state results in unpredictable behavior.

A read access to this register is permitted at any time when in Disabled state, or in Circular buffer mode. A read access returns the current value of the trigger counter.

**ETF control register (ETF_CTL)**

Address offset: 0x020

Reset value: 0x0000 0000

Bits 31:2  Reserved, must be kept at reset value.

Bits 1:0  **MODE[1:0]**: Operation mode
00b: Circular buffer mode
In this mode, the trace memory is used as a circular buffer. Trace data is captured into the Trace memory starting from the location pointed to by the write pointer register. Even when the trace memory is full, incoming trace data continues to be overwritten into the trace memory until a stop condition has occurred.

01b: Software FIFO mode
In this mode, the trace memory is used as a FIFO that can be read through the RRD Register while trace is being captured. Trace data is captured into the trace RAM and when full, the incoming trace stream is stalled.

10b: Hardware FIFO mode
In this mode, the trace memory is used as a FIFO that is drained through the ATB master interface. Trace data is captured into the trace RAM and when full, the incoming trace stream is stalled. When the Trace buffer is non-empty, trace data is drained out through the ATB master interface to the TPIU.

11b: Reserved

</tr>
</tbody>
</table>

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **LBUFLEVEL[11:0]**: Latched buffer fill level

Reading this register returns the maximum fill level of the trace memory in 32-bit words since this register was last read. Reading this register also results in its contents being updated to the current fill level.

When entering Disabled state, this register retains its last value. While in Disabled state, reads from this register do not affect its value. When exiting Disabled state, the LBUFLEVEL Register is cleared.

This register is used for performance analysis of the trace system.

<td>0</td>
</tr>
</tbody>
</table>

**Bits 31:11**  Reserved, must be kept at reset value.

**Bits 10:0**  **BUFWM[10:0]:** Buffer level watermark

The value programmed into this register indicates the required threshold vacancy level in 32-bit words in the trace memory. When the space in the FIFO is less than or equal to this value, that is, Fill level >= MEM_SIZE - BUFWM, the FULL output is pulled high and the FULL bit in the STS Register is set.

This register is used only in Software FIFO and Hardware FIFO modes. In Circular buffer mode, this functionality can be obtained by programming the RWP to the required vacancy trigger level, so that when the pointer wraps around, the FULL bit is set indicating that the vacancy level has fallen below the required level.

The maximum value that can be written into this register is MEM_SIZE - 1. In this case, the FULL bit output is asserted after the first 32-bit word is written to trace memory.

Writing to this register other than when in disabled state results in unpredictable behavior.

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **DRAINBUF**: Drain buffer

This bit is used to enable draining of the trace data through the ATB master interface after the formatter has stopped. This is useful in Circular buffer mode to capture trace data into trace memory and then to drain the captured trace through the ATB master interface.

Writing a one to this bit when in Stopped state starts the drain of the contents of the trace buffer through the ATB Master interface. This bit always reads as zero. The READY bit in the ETF_STS register goes low while the drain is in progress.

This bit is functional only when the ETF is in Circular buffer mode and formatting is enabled, that is, the ENFT bit in the ETF_FFCR register is set. Setting this bit when the ETF is in any other mode, or when not in Stopped state, results in Unpredictable behavior.

When trace capture is complete in Circular buffer mode, all of the captured trace must be retrieved from the trace memory through the same mechanism, either read all trace data out through RRD reads, or drain all trace data by setting the DRAINBUF bit. Setting the DRAINBUF bit after some of the captured trace has been read out through RRD results in unpredictable behavior.

Bit 13 **STPONTRGEV**: Stop on trigger event

0: No effect
1: Stop trace capture when a trigger event occurs

Enabling the ETF in Software FIFO mode or Hardware FIFO mode with this bit set results in unpredictable behavior.
Bit 12 **STOPONFL**: Stop on flush
   0: No effect
   1: Stop trace capture when flush is completed

   If a flush is initiated by the ATB master interface, its completion does not lead to a formatter stop regardless of the value programmed in this bit.

Bit 11 Reserved, must be kept at reset value.

Bit 10 **TRIGONFL**: Trigger on flush
   0: No effect
   1: Indicate a trigger in the trace stream when flush is completed

   If ENFT and ENTI are both clear, this bit is ignored and no trigger is inserted into the trace stream.
   If a flush is initiated by the ATB master interface, its completion does not lead to a trigger indication regardless of the value programmed in this bit.

Bit 9 **TRGONTRGEV**: Trigger on trigger event
   0: No effect
   1: Indicate a trigger in the trace stream when trigger event occurs

   If ENFT and ENTI are both clear, this bit is ignored and no trigger is inserted into the trace stream.
   This bit is not supported in Software FIFO mode or Hardware FIFO mode.

Bit 8 **TRGONTRGIN**: Trigger on trigger in
   0: No effect
   1: Indicate a trigger in the trace stream when a rising edge is detected on the TRIGIN input.

   If ENFT and ENTI are both clear, this bit is ignored and no trigger is inserted into the trace stream.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **FLUSHMAN**: Manual flush
   0: No effect
   1: Flush the trace FIFO and pipeline

   This bit is cleared automatically when the flush completes. If the TCEN bit in the ETF_CTL register is 0, writes to this bit are ignored.

Bit 5 **FONTRGEV**: Flush on trigger event
   0: No effect
   1: Flush the trace FIFO and pipeline if a trigger event occurs

   This bit is not supported in Software FIFO mode or Hardware FIFO mode. If STPONTRGEV is set, this bit is ignored.

Bit 4 **FONFLIN**: Flush on flush in
   0: No effect
   1: Flush the trace FIFO and pipeline when a rising edge is detected on the FLUSHIN input
Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **ENTI**: Enable trigger insertion

Setting this bit enables the insertion of triggers in the formatted trace stream. A trigger is indicated by inserting one byte of data 8'h00 with ATID 7'h7D in the trace stream. Trigger indication on the trace stream is additionally controlled by the register bits TRIGONFL, TRGONTRGEV, and TRGONTRIGIN in the FFCR Register. This bit can only be changed when READY is high, and TCEN is low. This bit takes effect only when the ENFT register bit in this register is set. If ENTI bit is set to high when ENFT is low, it results in formatting being enabled.

Bit 0 **ENFT**: Enable formatting.

0: Formatting is disabled. Incoming trace data is assumed to be from a single trace source.
1: Formatting is enabled.

If multiple ATIDs are received by the ETF when trace capture is enabled and the formatter is disabled, it results in interleaving of trace data. Disabling of formatting is supported only in Circular buffer mode. If the ETF is enabled in a mode other than Circular buffer mode with ENFT low, it results in formatting being enabled. If ENTI bit is set to high when ENFT is low, it results in formatting being enabled.

This bit is ignored when in Disabled state.

**ETF periodic synchronization counter register (ETF_PSCR)**

Address offset: 0x308

Reset value: 0x0000 000A

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **LOCKTYPE**: Size of the ETF_LAR register
0: 32-bit

Bit 1 **LOCKGRANT**: Current status of lock
This bit always returns zero when read by an external debugger.

0: Write access is permitted
1: Write access is blocked. Only read access is permitted.

Bit 0 **LOCKEXIST**: Existence of lock control mechanism
The bit indicates whether a lock control mechanism exists. It always returns zero when read by an external debugger.

0: No lock control mechanism exists
1: Lock control mechanism is implemented

59.5.6 Trace port interface unit (TPIU)

The TPIU is a CoreSight™ component that formats the trace stream and outputs it on the external trace port signals. The TPIU has a single ATB slave port for incoming trace data. The trace port is a synchronous parallel port, comprising a clock output, TRACECK, and four data outputs, TRACED(7:0). The trace port width is programmable in the range 1 to 8. Using a smaller port width reduces the number of test points/connector pins needed, and frees up IOs for other purposes. However it restricts the bandwidth of the trace port and hence the quantity of trace information that can be output in real time. The TRACECK output must be enabled by setting the TRACECLKEN bit in the DBGMCU.CR register before trace is sent to the TPIU. Furthermore, the TRACECK frequency can be programmed in the RCC.

For more information on the Trace port interface CoreSight™ component, refer to the Arm® CoreSight™ SoC-400 technical reference manual [2].
TPIU registers

TPIU supported port size register (TPIU_SUPPSIZE)
Address offset: 0x000
Reset value: 0x0000 000F

<table>
<thead>
<tr>
<th>Bits 31:16</th>
<th>PORTSIZE[31:16]</th>
</tr>
</thead>
<tbody>
<tr>
<td>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16</td>
<td>r r r r r r r r r r r r r r r</td>
</tr>
<tr>
<td>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</td>
<td>r r r r r r r r r r r r r r r</td>
</tr>
</tbody>
</table>

Bits 31:0 PORTSIZE[31:0]: Indicates supported trace port sizes, from 1 to 32 pins. Bit n-1 when set indicates that port size n is supported.
0x0000 000F: Port sizes 1 to 4 supported

TPIU current port size register (TPIU_CURPSIZE)
Address offset: 0x004
Reset value: 0x0000 0001

<table>
<thead>
<tr>
<th>Bits 31:16</th>
<th>PORTSIZE[31:16]</th>
</tr>
</thead>
<tbody>
<tr>
<td>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16</td>
<td>rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw</td>

<tr>
<td>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</td>
<td>rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw</td>
</tr>
</tbody>
</table>

Bits 31:0 PORTSIZE[31:0]: Indicates current trace port size
Bit n-1 when set indicates that the current port size is n pins. The value of n must be within the range of supported port sizes (1-4). Only one bit can be set, or unpredictable behavior may result. This register should only be modified when the formatter is stopped.

TPIU supported trigger modes register (TPIU_SUPTRGM)
Address offset: 0x100
Reset value: 0x0000 011F

<table>
<thead>
<tr>
<th>Bits 31:16</th>

</tbody>
</table>

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 TRIGCOUNT[7:0]: Enable trigger delay indication  
Enables delaying the indication of triggers to any external connected trace capture or storage devices. This counter is only eight bits wide and is intended to be used only with the counter multipliers in the Trigger multiplier register, 0x108. When a trigger is started, this value, in combination with the multiplier, is the number of words before the trigger is indicated. When the trigger counter reaches 0, the value written here is reloaded. Writing to this register causes the trigger counter value to reset but does not reset any values on the multiplier. Reading this register returns the preset value, not the current count.
### TPIU trigger multiplier register (TPIU_TRGMULT)

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **TCPRESENT**: TRACECTL output pin availability
Indicates whether the optional TRACECTL output pin is available for use.

0: TRACECTL pin is not present in this device.

Bit 1 **FTSTOPPED**: Formatter stopped
The formatter has received a stop request signal and all trace data and post-amble is sent. Any additional trace data on the ATB interface is ignored.

0: Formatter has not stopped
1: Formatter has stopped

Bit 0 **FLINPROG**: Flush in progress
Indicates whether a flush on the ATB slave port is in progress. This bit reflects the status of the AFVALIDS output. A flush can be initiated by the flush control bits in the TPIU_FFCR register.

0: No flush in progress
1: Flush in progress

Bit 8  **TRIGIN**: Trigger on trigger in
0: No effect
1: Indicate a trigger in the trace stream when the TRIGIN input from the system CTI is asserted.

Bit 7  Reserved, must be kept at reset value.

Bit 6  **FONMAN**: Generate a manual flush
0: No effect
1: Flush the trace

This bit is cleared automatically when the flush completes.

Bit 5  **FONTRIG**: Flush on trigger event
A trigger event occurs when the trigger counter reaches 0, or, if the trigger counter is 0, when the TRIGIN input from the system CTI is high.

0: No effect
1: Flush the trace if a trigger event occurs

Bit 4  **FONFLIN**: Flush on flush in
0: No effect
1: Flush the trace if the FLUSHIN input from the system CTI is asserted

Bits 3:2  Reserved, must be kept at reset value.

Bit 1  **ENFCONT**: Enable continuous formatting
0: Continuous formatting is disabled
1: Continuous formatting is enabled

Bit 0  **ENFTC**: Enable the embedding of triggers in formatted trace
0: Formatting is disabled
1: Formatting is enabled

**TPIU formatter synchronization counter register (TPIU_FSCR)**

Address offset: 0x400

Reset value: 0x0000 0040

<table>

<th>1</th>
<th>0</th>
</tr>
</thead>
</table>
Bits 31:12  Reserved, must be kept at reset value.

Bits 11:0  CYCCOUNT[11:0]: Enables effective use of TPAs
Enables effective use of different-sized TPAs without wasting large amounts of storage capacity of the capture device. This counter contains the number of formatter frames since the last synchronization packet of 128 bits. It is a 12-bit counter with a maximum count value of 4096. This equates to synchronization every 65536 bytes, that is, 4096 packets x 16 bytes per packet. The default is set up for a synchronization packet every 1024 bytes, that is, every 64 formatter frames. If the formatter is configured for continuous mode, full and half-word sync frames are inserted during normal operation. Under these circumstances, the count value is the maximum number of complete frames between full synchronization packets.

TPIU claim tag set register (TPIU_CLAIMSET)
Address offset: 0xFA0
Reset value: 0x0000 000F

</thead>
</table>

Bits 31:0  ACCESS_W[31:0]: TPIU register access enable
Enables write access to some TPIU registers by processor cores (debuggers do not need to unlock the component)
0xC5ACCE55: Enable write access
Other values: Disable write access
Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **LOCKTYPE**: Size of the TPIU_LAR register
- 0: 32-bit

Bit 1 **LOCKGRANT**: Current status of lock
- This bit always returns zero when read by an external debugger.
  - 0: Write access is permitted
  - 1: Write access is blocked. Only read access is permitted.

Bit 0 **LOCKEXIST**: Existence of lock control mechanism
- The bit indicates whether a lock control mechanism exists. It always returns zero when read by an external debugger.
  - 0: No lock control mechanism exists
  - 1: Lock control mechanism is implemented

Bits 31:11  Reserved, must be kept at reset value.

Bit 11 SWOUARTNRZ: Support of SWO UART or NRZ
Indicates whether serial wire output, UART or NRZ, is supported.

0: Not supported

Bit 10 SWOMAN: Support of SWO Manchester format
Indicates whether serial wire output, Manchester encoded format, is supported.

0: Not supported

Bit 9 TCLKDATA: Support of trace clock plus data
0: Not supported

Bits 8:6 FIFO_SIZE[2:0]: FIFO size in powers of 2
0x2: FIFO size = 4 (16 bytes)

Bit 5 CLKRELAT: ATB clock and TRACECLKIN relation
Indicates the relationship between the ATB clock and TRACECLKIN (synchronous or asynchronous)

1: Asynchronous

Bits 4:0 MAXNUM[4:0]: Number/type of ATB input port multiplexing
0x0: None

Table 589. TPIU register map and reset values (continued)
### 59.5.7 Serial wire output (SWO) and SWO trace funnel (SWTF)

The SWO is a CoreSight component that formats the trace stream from the processor ITM and outputs it on the single wire TRACESWO output. The SWO trace funnel (SWTF) must be programmed to enable the trace bus from the Cortex-M7 ITM before trace is enabled. The SWTF registers are listed in Table 591.

Compared to the TPIU, the SWO contains:
- no formatter
- no pattern generator
- an 8-bit ATB input
- no synchronous trace output, that is, no TRACEDATA or TRACECLK pins
- no support for flush, because this is not required
- no support for triggering

The SWO output supports Manchester encoded and UART NRZ formats.
For more information about the serial wire output CoreSight™ component, refer to the Arm® CoreSight™ Components Technical Reference Manual [4].

**SWO registers**

**SWO current output divisor register (SWO_CODR)**

Address offset: 0x010
Reset value: 0x0000 0000

**PRESCALER[12:0]**

Bits 31:13 Reserved, must be kept at reset value.

Bits 12:0 **PRESCALER[12:0]**: SWO baud rate scaling
The baud rate is the trace clock frequency divided by (PRESCALER - 1). The baud rate changes instantly, so it is recommended to stop the trace source and wait until the port is idle before writing to this register.

**SWO selected pin protocol register (SWO_SPPR)**

Address offset: 0x0F0
Reset value: 0x0000 0001

</tr>
</thead>
</table>

Bits 31:4  Reserved, must be kept at reset value.

Bit 3  **FTNONSTOP**: Change of settings without stopping formatter  
1: Change of settings is allowed with formatter running

Bit 2  **TCPRESENT**: TRACECTL pin present on SWO  
0: TRACECTL pin not present

Bit 1  **FTSTOPPED**: Formatter stopped  
0: Formatter running  
The bit always returns 0 as the SWO formatter cannot be stopped in this device.

Bit 0  **FLINPROG**: Flush in progress  
0: Flush is not in progress  
The bit always returns 0 as SWO flushing is not supported in this device.

Bits 31:3 Reserved, must be kept at reset value.

- **Bit 2** **LOCKTYPE**: Size of the SWO_LAR register  
  0: 32-bit

- **Bit 1** **LOCKGRANT**: Current status of lock  
  This bit always returns zero when read by an external debugger.
  
  0: Write access is permitted  
  1: Write access is blocked - only read access is permitted

- **Bit 0** **LOCKEXIST**: Existence of lock control mechanism  
  The bit indicates whether a lock control mechanism exists. It always returns zero when read by an external debugger.
  
  0: No lock control mechanism exists  
  1: Lock control mechanism is implemented

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **LOCKTYPE**: Size of the SWTF_LAR register
0: 32-bit

Bit 1 **LOCKGRANT**: Current status of lock
This bit always returns zero when read by an external debugger.

0: Write access is permitted
1: Write access is blocked - only read access is permitted

Bit 0 **LOCKEXIST**: Existence of lock control mechanism
The bit indicates whether a lock control mechanism exists. It always returns zero when read by an external debugger.

0: No lock control mechanism exists
1: Lock control mechanism is implemented

59.5.8  Microcontroller debug unit (DBGMCU)

The DBGMCU component contains a number of registers that control the power and clock behavior in debug mode. Specifically it allows the debugger, or debug software, to:

- maintain the clock and power to the processor cores when in low-power modes (sleep, stop or standby)
- maintain the clock and power to the system debug and trace components when in low power modes
- stop the clock to certain peripherals (CAN, SMBUS timeout, Watchdogs, Timers, RTC) when either processor core is stopped in debug mode. For timers having complementary outputs, the outputs are disabled (as if the MOE bit was reset) for safety purposes when the counter is stopped (TIM1/8/15/16/17 = 1 in DBGMCU_APB2FZ1).

The DBGMCU registers are not reset by a system reset, only by a power on reset. They are accessible to the debugger via the APB-D bus at base address 0xE00E1000. They are also accessible by the processor core at base address 0x5C001000.

Note: the DBGMCU is not a standard CoreSight component. Therefore, it does not appear in the system ROM table.

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **TRGOEN**: External trigger output enable
This bit controls the direction of the bi-directional trigger pin, TRGIO.

0: Input - TRGIO is connected to TRGIN
1: Output - TRGIO is connected to TRGOUT

Bits 27:23 Reserved, must be kept at reset value.

Bit 22 **D3DBGCKEN**: D3 debug clock enable
This bit allows the debug components in the D3 domain (excluding the DAPCLK domain) to be switched off if they are not needed.

0: Disabled - D3 domain debug components are disabled and their clocks gated
1: Enabled - D3 domain debug components are clocked whenever the corresponding domain clock (CK_HCLK_D3) is active

Bit 21 **D1DBGCKEN**: D1 debug clock enable
This bit allows the debug components in the D1 domain (excluding those in the processor core) to be switched off if they are not needed.

0: Disabled - D1 domain debug components are disabled and their clocks gated
1: Enabled - D1 domain debug components are clocked whenever the corresponding domain clock (CK_HCLK_D1) is active

Bit 20 **TRACECLKEN**: Trace port clock enable
This bit enables the trace port clock, TRACECLK.

0: Disabled - TRACECLK is disabled
1: Enabled - TRACECLK is active

Bits 19:9 Reserved, must be kept at reset value.

Bit 8 **DBGSTBY_D3**: Allow debug in D3 Standby mode
0: Normal operation - all clocks are disabled and the domain powered down automatically in Standby mode(1).
1: Automatic clock stop/power-down disabled - all active clocks and oscillators continue to run during Standby mode, and the domain supply is maintained, allowing full debug capability. On exit from Standby mode, a system reset is performed.
DBGMCU APB3 peripheral freeze register (DBGMCU_APB3FZ1)

Address offset: 0x034
Reset value: 0x0000 0000

Bit 7  **DBGSTOP_D3**: Allow debug in D3 Stop mode
- 0: Normal operation - domain clocks are disabled automatically in Stop mode\(^{(2)}\)
- 1: Automatic clock stop/power-down disabled - all active clocks and oscillators continue to run during Stop mode. On exit from Stop mode, the clock settings is set to the Stop mode exit state.

Bits 6:3 Reserved, must be kept at reset value.

Bit 2  **DBGSTBY_D1**: Allow D1 domain debug in Standby mode
- 0: Normal operation - all clocks is disabled and the domain powered down automatically in Standby mode.
- 1: Automatic clock stop/power-down disabled - all active clocks and oscillators continue to run during Standby mode, and the domain supply is maintained, allowing full debug capability. On exit from Standby mode, a domain reset is performed.

Bit 1  **DBGSTOP_D1**: Allow D1 domain debug in Stop mode
- 0: Normal operation - all clocks are disabled automatically in Stop mode
- 1: Automatic clock stop disabled - all active clocks and oscillators continue to run during Stop mode, allowing full debug capability. On exit from Stop mode, the clock settings is set to the Stop mode exit state.

Bit 0  **DBGSLEEP_D1**: Allow D1 domain debug in Sleep mode
- 0: Normal operation - processor clock is stopped automatically in Sleep mode
- 1: Automatic clock stop disabled - processor clock continues to run, allowing full debug capability

1. If CDBGPWRUPREQ in the debug port Control/Stat register is asserted, D3 will remain powered up and the DAPCLK active in Standby mode, even if DBGSTBY_D3 is reset. However the remaining D3 domain clocks will be switched off.

2. If CDBGPWRUPREQ in the debug port Control/Stat register is asserted, D3 will remain powered up and the DAPCLK active in Stop mode, even if DBGSTOP_D3 is reset. However the remaining D3 domain clocks will be switched off.

       0: Normal operation - I2C4 SMBUS timeout continues to operate while the core is in debug mode
       1: Stop in debug - I2C4 SMBUS timeout is frozen while the core is in debug mode

Bits 6:0  Reserved, must be kept at reset value.
59.6 Cortex-M7 debug functional description

The Cortex-M7 subsystem features the following CoreSight™ components:

- ROM tables
- System control space (SCS)
- Breakpoint unit (FPB)
- Data watchpoint and trace unit (DWT)
- Instrumentation trace macrocell (ITM)
- Embedded trace macrocell (ETM)
- Cross trigger interface (CTI)
These components are accessible by the debugger via the Cortex-M7 AHB-AP and its associated AHBD bus.

59.6.1 Cortex-M7 ROM tables

The ROM table is a CoreSight™ component that contains the base addresses of all the CoreSight debug components accessible via the AHBD. These tables allow a debugger to discover the topology of the CoreSight system automatically.

There are two ROM tables in the Cortex-M7 sub-system:

- Cortex-M7 CPU ROM table
  This table is pointed to by the BASE register in the Cortex-M7 AHB-AP. It contains the base address pointers for the ETM and CTI, as well as for the Cortex-M7 CPU ROM table.

- Cortex-M7 PPB (private peripheral bus) ROM table
  This table contains pointers to the Cortex-M7 System Control Space registers allowing the debugger to identify the CPU core, as well as to the remaining CoreSight components in the Cortex-M7 subsystem: FPB, DWT and ITM.

The CPU ROM table occupies a 4-Kbyte, 32-bit wide chunk of AHBD address space, from 0xE00FE000 to 0xE00FEFFC.

<table>

59.6.2 Cortex-M7 data watchdog and trace unit (DWT)

The DWT provides four comparators that can be used as:
- watchpoint
- ETM trigger
- PC sampling trigger
- data address sampling trigger
- data comparator (comparator 1 only)
- clock cycle counter comparator (comparator 0 only)

It also contains counters for:
- clock cycles
- folded instructions
- load store unit (LSU) operations
- sleep cycles
- number of cycles per instruction
- interrupt overhead
A DWT comparator compares one of the following with the value held in its DWT_COMP register:

- a data address
- an instruction address
- a data value
- the cycle count value, for comparator 0 only.

For address matching, the comparator can use a mask, so it matches a range of addresses.

On a successful match, the comparator generates one of the following:

- one or more DWT data trace packets, containing one or more of:
  - the address of the instruction that caused a data access
  - an address offset, bits[15:0] of the data access address
  - the matched data value
- a watchpoint debug event, on either the PC value or the accessed data address
- a CMPMATCH[N] event that signals the match outside the DWT unit

A watchpoint debug event either generates a DebugMonitor exception, or causes the processor to halt execution and enter Debug state.

For more details on how to use the DWT, refer to the Arm®v7-M Architecture Reference Manual [5].

**Cortex-M7 DWT registers**

**DWT control register (M7_DWT_CTRL)**

Address offset: 0x000

Reset value: 0x4000 0000

Bit 24  **NOPRFCNT**: Profiling counter support (read-only)
   0: Supported
   1: Not supported

Bit 23  Reserved, must be kept at reset value.

Bit 22  **CYCEVTENA**: Enable for POSTCNT underflow event counter packet generation
   0: Disabled
   1: Enabled

Bit 21  **FOLDEVTENA**: Enable for folded instruction counter overflow event generation
   0: Disabled
   1: Enabled

Bit 20  **LSUEVTENA**: Enable for LSU counter overflow event generation
   0: Disabled
   1: Enabled

Bit 19  **SLEEPEVTENA**: Enable for sleep counter overflow event generation
   0: Disabled
   1: Enabled

Bit 18  **EXCEVTENA**: Enable for exception overhead counter overflow event generation
   0: Disabled
   1: Enabled

Bit 17  **CPIEVTENA**: Enable for CPI counter overflow event generation
   0: Disabled
   1: Enabled

Bit 16  **EXTRCENA**: Enable for exception trace generation
   0: Disabled
   1: Enabled

Bits 15:13  Reserved, must be kept at reset value.

Bit 12  **PCSAMPLENA**: POSTCNT counter use enable
   Enables use of POSTCNT counter as a timer for Periodic PC sample packet generation.
   0: Disabled
   1: Enabled

Bits 11:10  **SYNCTAP[1:0]**: Position of synchronization packet counter tap on CYCCNT counter
   This selection determines the synchronization packet rate.
   0x0: Disabled - no synchronization packets
   0x1: Tap at CYCCNT[24]
   0x2: Tap at CYCCNT[26]
   0x3: Tap at CYCCNT[28]

Bit 9  **CYCTAP**: Position of the POSTCNT tap on the CYCCNT counter
   0: Tap at CYCCNT[6]
   1: Tap at CYCCNT[10]
Bits 8:5 **POSTINIT[3:0]**: Initial value of the POSTCNT counter
Write to this field are ignored if POSTCNT counter is enabled (that is, CYCEVTENA or PCSAMPLENA must be reset prior to writing POSTINIT).

Bits 4:1 **POSTPRESET[3:0]**: Reload value of the POSTCNT counter.

Bit 0 **CYCCNTENA**: CYCCNT counter enable
0: Disabled
1: Enabled

</tbody>
</table>
Bits 19:16 **DATAVADDR[3:0]**: Comparator number of a second comparator
When the DATAVMATCH and LNK1ENA bits are both 1, this field can hold the comparator number of a second comparator to use for linked address comparison.

Bits 15:12 **DATAVADDR[3:0]**: Comparator number of a comparator
When the DATAVMATCH and LNK1ENA bits are both 1, this field can hold the comparator number of a comparator to use for linked address comparison.

Bits 11:10 **DATAVSIZE[1:0]**: Size of required data comparison
For data value matching, specifies the size of the required data comparison.

- 0x0: Byte
- 0x1: Half word
- 0x2: Word
- 0x3: Reserved

Bit 9 **LNK1ENA**: Support of a second linked comparator (read-only)
Indicates whether use of a second linked comparator is supported (read-only).

- 1: Supported

Bit 8 **DATAVMATCH**: Cycle comparison enable
- 0: Perform address comparison
- 1: Perform data value comparison

Bit 7 **CYCMATCH**: Cycle count comparison enable on comparator 0
This field is reserved for other comparators.

- 0: No cycle count comparison
- 1: Compare DWT_COMP0 with the cycle counter, DWT_CYCCNT

Bit 6 Reserved, must be kept at reset value.

Bit 5 **EMITRANGE**: Data trace address offset packet enable
Enables generation of data trace address offset packets (containing data address bits 0 to 15)

- 0: Disabled
- 1: Enabled

Bit 4 Reserved, must be kept at reset value.

Bits 3:0 **FUNCTION[3:0]**: Action on comparator match
The meaning of this bit field depends on the setting of the DATAVMATCH and CYCMATCH fields. See [5].

**DWT CoreSight peripheral identity register 4 (M7_DWT_PIDR4)**

Address offset: 0xFD0
Reset value: 0x0000 0004

**Note:** The registers and their descriptions are provided in the context of Cortex-M7 DWT (Dynamic Window Tracker) and their reset values.
3248

59.6.3  Cortex-M7 instrumentation trace macrocell (ITM)

The ITM generates trace information as packets. There are four sources that can generate packets. If multiple sources generate packets at the same time, the ITM arbitrates the order in which packets are output. The four sources in decreasing order of priority are:

1. Software trace

Software can write directly to any of 32 x 32-bit ITM stimulus registers to generate packets. The permission level for each port can be programmed. When software writes to an enabled stimulus port, the ITM combines the identity of the port, the size of the write access, and the data written, into a packet that it writes to a FIFO. The ITM
outputs packets from the FIFO onto the trace bus. Reading a stimulus port register returns the status of the stimulus register (empty or pending) in bit 0.

2. Hardware trace
The DWT generates trace packets in response to a data trace event, a PC sample or a performance profiling counter wraparound. The ITM outputs these packets on the trace bus.

3. Local timestamping
The ITM contains a 21-bit counter clocked by the (pre-divided) processor clock. The counter value is output in a timestamp packet on the trace bus. The counter is reset to zero every time a timestamp packet is generated. The timestamps thus indicate the time elapsed since the previous timestamp packet.

4. Global system timestamping
Timestamps can also be generated using the system-wide 64-bit count value coming from the Timestamp Generator component.

Cortex-M7 ITM registers

ITM stimulus register x (M7_ITM_STIMx)
Address offset: 0x000 + x * 0x4 (x = 0 to 31)
Reset value: Undefined

```
 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
STIMULUS[31:16]
   rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw
 15 14 13 12 11 10  9  8  7  6  5  4  3  2  1  0
STIMULUS[15:0]
   rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw
```

Bits 31:0 **STIMULUS[31:0]**: Software event packet / FIFOREADY
Write data is output on the trace bus as a software event packet. When reading, bit 0 is a FIFOREADY indicator:

0: Stimulus port buffer is full (or port is disabled)
1: Stimulus port can accept new write data

ITM trace enable register (M7_ITM_TER)
Address offset: 0xE00
Reset value: 0x00000000

```
 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
STIMENA[31:16]
   rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw
 15 14 13 12 11 10  9  8  7  6  5  4  3  2  1  0
STIMENA[15:0]
   rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw
```

3200/3289  RM0433 Rev 6
Bits 31:0  **STIMENA[31:0]**: Stimulus port enable
   Each bit n (0:31) enables the stimulus port associated with the M7_ITM_STIMn register.
   0: Port disabled
   1: Port enabled

**ITM trace privilege registers (M7_ITM_TPR)**
Address offset: 0xE40
Reset value: 0x00000000

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16  

Bits 31:24  Reserved, must be kept at reset value.

Bit 23  **BUSY**: ITM busy
Indicates whether the ITM is currently processing events (read-only):

0: Not busy
1: Busy

Bits 22:16  **TRACEBUSID[6:0]**: Identifier for multi-source trace stream formatting
If multi-source trace is in use, the debugger must write a non-zero value to this field. Note:
different IDs must be used for each trace source in the system.

Bits 15:12  Reserved, must be kept at reset value.

Bits 11:10  **GTSFREQ[1:0]**: Global timestamp frequency
Defines how often the ITM generates a global timestamp, based on the global timestamp
clock frequency, or disables generation of global timestamps. The possible values are:

0x0: Disable generation of global timestamps
0x1: Generate timestamp request whenever the ITM detects a change in global timestamp
counter bits [63:7]; this is approximately every 128 cycles
0x2: Generate timestamp request whenever the ITM detects a change in global timestamp
counter bits [63:13]; this is approximately every 8192 cycles
0x3: Generate a timestamp after every packet, if the output FIFO is empty

Bits 9:8  **TSPRESCALE[1:0]**: Local timestamp prescale
Prescale used with the trace packet reference clock. The possible values are:

0x0: No prescaling
0x1: Divide by 4
0x2: Divide by 16
0x3: Divide by 64

Bits 7:5  Reserved, must be kept at reset value.

Bit 4  **SWOENA**: Asynchronous clocking enable for the timestamp counter (read-only)
0: Timestamp counter uses processor clock

Bit 3  **TXENA**: Hardware event packet forwarding enable
Enables forwarding of hardware event packets from the DWT unit to the trace port.

0: Disabled
1: Enabled

Bit 2  **SYNCENA**: Synchronization packet transmission enable
If a debugger sets this bit it must also configure the DWT_CTRL register SYNCTAP field in
the DWT for the correct synchronization speed.

0: Disabled
1: Enabled

Bit 1  **TSENA**: Local timestamp generation enable
0: Disabled
1: Enabled

Bit 0  **ITMENA**: ITM enable
0: Disabled
1: Enabled

Cortex-M7 ITM register map and reset values
The ITM registers are located at address range 0xE0000000 to 0xE0000FFC, on the AHBD.

Table 598. Cortex-M7 ITM register map and reset values
59.6.4 Cortex-M7 breakpoint unit (FPB)

The FPB allows hardware breakpoints to be set. It contains eight comparators which monitor the instruction fetch address and return a breakpoint instruction when a match is detected. The Cortex-M7 FPB does not support flash patch functionality.

Table 598. Cortex-M7 ITM register map and reset values (continued)
Bits 31:15  Reserved, must be kept at reset value.

Bits 14:12 **NUM_CODE[6:4]**: Instruction address comparator number field, three MSBs
This read-only field holds the three MSBs of the number of instruction address comparators supported.

0x0: the MSBs of the number are all 0

Bits 11:8 **NUM_LIT[3:0]**: Number of literal address comparators supported (read-only).
0x0: No literal comparators supported.

Bits 7:4 **NUM_CODE[3:0]**: Instruction address comparator number field, four LSBs
This read-only field holds the four LSBs of the number of instruction address comparators supported.

0x8: 8 instruction comparators supported

Bit 1  **KEY**: Write protect key
A write to M7_FPB_CTRL register will be ignored if this bit is not set to 1.

Bits 0  **ENABLE**: FPB enable
0: Disable
1: Enable

**FPB remap register (M7_FPB_REMAP)**

Address offset: 0x004
Reset value: 0x0000 0000

Bits 31:30  Reserved, must be kept at reset value.

Bit 29  **RMPSPT**: Flash patch remap support (read-only)
0: Remapping not supported

Bits 28:5  **REMAP[23:0]**: Reserved - not supported

Bits 4:0  Reserved, must be kept at reset value.
**FPB comparator registers (M7_FPB_COMPx)**

Address offset: 0x008 + x * 0x4 (for x = 0 to 7)

Reset value: 0x00000000

---

### REPLACE[1:0]

Behavior upon COMP versus instruction fetch address match

- 0x0: Reserved
- 0x1: Breakpoint on lower half-word, upper half-word is unaffected.
- 0x2: Breakpoint on upper half-word, lower half-word is unaffected.
- 0x3: Breakpoint on both upper and lower half-words.

Bit 29 Reserved, must be kept at reset value.

### COMP[26:0]

Value to compare with code memory access address

Value to compare with address bits 28:2 of accesses to instruction code memory (0x00000000 to 0x1FFFFFFF). If a match occurs, the action to take is defined by the REPLACE field.

Bit 1 Reserved, must be kept at reset value.

Bit 0 **ENABLE**: Comparator enable

The comparator is only enabled if both this bit and the FPB ENABLE bit in the M7_FPB_CTRL register are set.

0: Disabled

1: Enabled

---

**FPB CoreSight peripheral identity register 4 (M7_FPB_PIDR4)**

Address offset: 0xFD0

Reset value: 0x00000004

59.6.5  **Cortex-M7 embedded trace macrocell (ETM)**

The Cortex-M7 ETM is a CoreSight™ component closely coupled to the CPU. The ETM generates trace packets that allow the execution of the Cortex-M7 core to be traced. In the STM32H7, the ETM is configured for instruction trace only, so data accesses are not included in the trace information.

The ETM receives information from the CPU over the processor trace interface, including:

- The number of instructions executed in the same cycle
- Changes in program flow
- The current processor instruction state
- The addresses of memory locations accessed by load and store instructions
- The type, direction and size of a transfer
- Condition code information
- Exception information
- Wait for interrupt state information

For more information, refer to the Arm® CoreSight™ ETM™-M7 technical reference manual [6].

### Bits 31:18  Reserved, must be kept at reset value.

- **Bit 17 DV**: Data value tracing (read-only)  
  0: Disabled
- **Bit 16 DA**: Data address tracing (read-only)  
  0: Disabled

### Bits 15:13  Reserved, must be kept at reset value.

- **Bit 12 RS**: Return stack enable  
  0: Disabled  
  1: Enabled
- **Bit 11 TS**: Global timestamp tracing  
  0: Disabled  
  1: Enabled

### Bits 10:8  COND[2:0]: Conditional instruction tracing

- 0x0: Conditional instruction tracing disabled
- 0x1: Conditional load instructions are traced
- 0x2: Conditional store instructions are traced
- 0x3: Conditional load and store instructions are traced
- 0x7: All conditional instructions are traced

Other: Reserved

### Bits 7:5  Reserved, must be kept at reset value.

- **Bit 4 CCI**: Cycle counting in instruction trace  
  0: Disabled  
  1: Enabled
- **Bit 3 BB**: Branch broadcast mode  
  0: Disabled  
  1: Enabled

### Bits 2:1  INSTP[1:0]: Determines which instructions are P0 instructions (read-only)

- 0x0: Only branches are P0 instructions

### Bit 0  Reserved, must be kept at reset value.
ETM event control 0 register (M7_ETM_EVENTCTL0)

Only accepts writes when trace unit is disabled
Address offset: 0x020
Reset value: 0x0000 0000

0x00: Reserved  
0x01 to 0x6F: Valid ID  
0x70 to 0x7F: Reserved
ETM ViewInst main control register (M7_ETM_VICTL)

Address offset: 0x080
Reset value: 0x0000 0000

| Bit 31:20 | Reserved, must be kept at reset value. |
| Bit 19 | EXLEVEL_S3: Trace disable, exception level 3 |
| | Disables tracing in the specified exception level in Secure state for exception level 3. |
| | 0: Enable ViewInst in this exception level |
| | 1: Disable ViewInst in this exception level |
| Bit 18:17 | Reserved, must be kept at reset value. |
| Bit 16 | EXLEVEL_S0: Trace disable, exception level 0 |
| | Disables tracing in the specified exception level in Secure state for exception level 0. |
| | 0: Enable ViewInst in this exception level |
| | 1: Disable ViewInst in this exception level |
| Bit 15:12 | Reserved, must be kept at reset value. |
| Bit 11 | TRCERR: Tracing of system error exception |
| | Selects whether a system error exception must always be traced. |
| | 0: System error exception is traced only if the instruction or exception immediately before the system error exception is traced |
| | 1: System error exception is always traced regardless of the value of ViewInst |
| Bit 10 | TRCRESET: Tracing of reset exception |
| | Selects whether a reset exception must always be traced. |
| | 0: Reset exception is traced only if the instruction or exception immediately before the reset exception is traced |
| | 1: Reset exception is always traced regardless of the value of ViewInst |
| Bit 9 | SSSTATUS: Current status of the start/stop logic |
| | 0: Stop state |
| | 1: Started state |
| Bit 8 | Reserved, must be kept at reset value. |
Bit 7 **TYPE**: Resource type
   0: Single selected resource
   1: Boolean combined resource pair

Bits 6:4  Reserved, must be kept at reset value.

Bits 3:0 **SEL[3:0]**: Resource / Boolean combined resource pair
   When TYPE is 0, selects a single selected resource from 0-15 defined by bits[3:0]
   When TYPE is 1, selects a Boolean combined resource pair from 0-7 defined by bits[2:0]

Bits 31:3 Reserved, must be kept at reset value.

- **Bit 2** LOCKTYPE: Size of the M7_ETM_LAR register
  - 0: 32-bit

- **Bit 1** LOCKGRANT: Current status of lock
  - This bit always returns zero when read by an external debugger.
  - 0: Write access is permitted
  - 1: Write access is blocked. Only read access is permitted.

- **Bit 0** LOCKEXIST: Existence of lock control mechanism
  - The bit indicates whether a lock control mechanism exists. It always returns zero when read by an external debugger.
  - 0: No lock control mechanism exists
  - 1: Lock control mechanism is implemented

60  **Device electronic signature**

The electronic signature is stored in the Flash memory area. It can be read using the JTAG/SWD or the CPU. It contains factory-programmed identification data that allow the user firmware or other external devices to automatically match its interface to the characteristics of the STM32H742/743/53xx and STM32H750xB microcontrollers.

60.1  **Unique device ID register (96 bits)**

The unique device identifier is ideally suited:
- for use as serial numbers (for example USB string serial numbers or other end applications)
- for use as security keys in order to increase the security of code in Flash memory while using and combining this unique ID with software cryptographic primitives and protocols before programming the internal Flash memory
- to activate secure boot processes, etc.

The 96-bit unique device identifier provides a reference number which is unique for any device and in any context. These bits can never be altered by the user.

The 96-bit unique device identifier can also be read in single bytes/half-words/words in different ways and then be concatenated using a custom algorithm.

Bits 15:0  F_SIZE: Flash memory size  
This bitfield indicates the size of the device Flash memory expressed in Kbytes.  
As an example, 0x0400 corresponds to 1024 Kbytes.

60.3 Package data register

Refer to SYSCFG package register (SYSCFG_PKGR) for package identification. The SYSCFG clock should be enabled first in the RCC_APB4ENR register.

<td>Initial release.</td>
</tr>
</tbody>
</table>
| 26-May-2017| 2        | **Section 2** renamed Memory and bus architecture. Updated Section: Embedded bootloader.  
**Section 3: Embedded Flash memory (FLASH)**  
Updated Section: Flash sector erase, Section: Standard Flash bank erase, Section: Flash bank erase with automatic protection removal and Section: Flash mass erase.  
Added Section: Flash mass erase with automatic protection removal.  
Updated Table 16: FLASH register map and reset value:  
– FLASH_BOOT7_CURR/PRG (add offset = 0x140/0x144) available only on RM0399.  
– Added FLASH_CRCEADD2R at add offset = 0x158  
– Added FLASH_CRCEADD2R at add offset = 0x15C  
**Section 6: Power control (PWR)**  
Updated Section 6.3.1: PWR pins and internal signals.  
Updated VBAT in Section 6.4: Power supplies.  
Updated Figure 13: Power supply overview and Figure 15: Device startup with VCORE supplied from voltage regulator.  
Removed VCORE in Section 6.5: Power supply supervision.  
Updated Figure 24: VCORE voltage scaling versus system power modes and Figure 25: Power control modes detailed state diagram.  
**Section 8: Reset and Clock Control (RCC)**  
Names of all clock source selection bits changed from XXSCR to XXSEL.  
RC48 renamed HSI48.  
VSWRST bit renamed BDRST in RCC_BDCR and bit description modified.  
CAMITFEN renamed DCMIEN in RCC_AHB2ENR; and CAMITFLPEN renamed DCMILPEN in RCC_AHB2LPENR.  
FLITFLPEN bit renamed FLASHLPEN in RCC_AHB3LPENR.  
HDMICECLPEN renamed CECLPEN in RCC_APB1LLPENR.  
Updated peripheral kernel clock names in the whole document.  
Updated Figure 34: System reset circuit to remove VDDA.  
Updated maximum frequency for ADC1, 2, 3 in Table 51: Kernel clock distribution overview.  
Removed lsi_ck as USBxOTG clock in Section: Peripherals dedicated to control and data transfer. |
Section 8: Reset and Clock Control (RCC) (continued)
Renamed USART7RST/EN/LPEN bits into UART7RST/EN/LPEN, and
USART8RST/EN/LPEN bits into UART8RST/EN/LPEN in Section 8.7.31: RCC
APB1 Peripheral Reset Register
(RCC_APB1RSTR), Section 8.7.43: RCC APB1 Clock Register
(RCC_APB1LENR) and Section 8.7.52: RCC APB1 Low Sleep Clock Register
(RCC_APB1LLPENR).

Section 10: Hardware semaphore (HSEM)
Renamed pclk into hsem_hclk in the whole document.
Updated COREID bit description in Section 10.4.1: HSEM register (HSEM_R0 -
HSEM_R31).

Section 11: General-purpose I/Os (GPIO)
Table 84: GPIO register map and reset values:
– updated GPIOx_MODER reset values
– changed index to A to K for GPIOx_AFRH.
– added GPIOC..K_PUPDR

Section 12: System configuration controller (SYSCFG)
Updated SYSCFG_UR3 register.

Section 13: Block interconnect
In Table 92: DMAMUX1, DMA1 and DMA2 connections, renamed dac1_dma
and dac2_dma into dac_ch1_dma and dac_ch2_dma, respectively.
Updated several source and destination signals in Table 88: Peripherals
interconnect matrix details and Table 89: EXTI wakeup inputs.

Section 17: DMA request multiplexer (DMAMUX)
Updated resources in Table 110: DMAMUX1: assignment of multiplexer inputs
to resources to Table 112: DMAMUX1: assignment of synchronization inputs to
resources.

Section 19: Nested Vectored Interrupt Controllers
Added LCD-TFT interrupts (ltdc_it and ltdc_err_it) in Table 130: NVIC.
Extended interrupt and event controller (EXIT)
Replaced DMA1 by BDMA for events 66 to 73 in Table 133: EXTI Event input
mapping.
Table 601. Document revision history (continued)

<table>
<thead>
<tr>
<th>Date</th>
<th>Revision</th>
<th>Changes</th>
</tr>
</thead>
</table>
| 26-May-2017| 2 (continued) | Section 22: Flexible memory controller (FMC)
- Updated internal signals in Figure 86: FMC block diagram
- HCLK renamed fmc_hclk
- KCK_FMC renamed fmc_ker_ck
Updated Section 22.5: AXI interface to add 32-bit accesses.
Read FIFO depth changed to 6x64 bits. AXI bus width correct (64 bits instead of 32 bits).
All waveforms made generic for what regards data bus and NBL bits.
In Section: SRAM/NOR-Flash chip-select timing registers 1..4 (FMC_BTR1..4), modified DATAST example and updated BURSTURN description. In Section: SRAM/NOR-Flash write timing registers 1..4 (FMC_BWTR1..4): updated BURSTURN description. Updated Section: SDRAM Control registers 1,2 (FMC_SDCR1,2) to add bitfield width.
Added missing FMC_SDCR2 bits in Table 181: FMC register map.

Section 23: Quad-SPI interface (QUADSPI)
Updated internal signals in Figure 115: QUADSPI block diagram when dual-flash mode is disabled and Figure 116: QUADSPI block diagram when dual-flash mode is enabled. Added Section 23.3.2: QUADSPI pins and internal signals. Modified error type for access by Cortex CPU in Section 23.3.7: QUADSPI memory-mapped mode.
Added Section 23.3.8: QUADSPI Free running clock mode as well as FRCM bit in Section 23.5.6: QUADSPI communication configuration register (QUADSPI_CCR). Updated Section 23.5.1: QUADSPI control register (QUADSPI_CR). In Table 185: QUADSPI register map and reset values, changed DMAEN bit to reserved for QUADSPI_CR register.

Section 24: Delay block (DLYB)
Added internal signals in Figure 123: DLYB block diagram and added Section 24.3.2: DLYB pins and internal signals.

Section 25: Analog-to-digital converters (ADC)
Number of ADCs changed to 3 in Section 25.1: Introduction.
Added internal signals in Section 25.3.1: ADC block diagram.
Changed ADCx_IN[19:0] into ADCx_INP[19:0] and ADCx_INN[19:0] in Figure 124: ADC block diagram and Table 190: ADC input/output pins. Changed ADC_CLK into adc_ker_ck.
Updated Figure 126: ADC1 connectivity, Figure 127: ADC2 connectivity and Figure 128: ADC3 connectivity and added note below figure. Updated Figure 175: Dual ADC block diagram(1).
Updated notes in Section: Dual clock domain architecture.
Updated Section 25.3.11: Channel selection (SQRx, JSQRx) and Section 25.3.12: Channel preselection register (ADCx_PCSEL).
Table 601. Document revision history (continued)

</tr>
</thead>
</table>
| 26-May-2017| 2 (continued) | **Section 25: Analog-to-digital converters (ADC) (continued)**  
Examples given for 24 MHz instead of 72 MHz in Section 25.3.13: Channel-wise programmable sampling time (SMRP1, SMRP2) and Section 25.3.17: Timing.  
6-bit resolution removed and updated Table 195: TSAR timings depending on resolution in Section 25.3.23: Programmable resolution (RES) - fast conversion mode.  
Updated notes in Section: Combined regular/injected simultaneous mode and Section: Combined regular simultaneous + alternate trigger mode.  
Added Section: DFSDM mode in dual ADC simultaneous mode.  
Changed ADC3_IN18 into ADC3 VINP[18] in Section 25.3.33: Temperature sensor.  
Changed ADC3_IN17 into ADC3 VINP[17] in Section 25.3.34: VBAT supply monitoring.  
Changed ADC3_IN19 into ADC3 VINP[19] in Section 25.3.35: Monitoring the internal voltage reference.  
Changed all bit access type to ‘r’ in Section 25.5.15: ADC x regular Data Register (ADCx_DR) (x=1 to 3).  
Updated Table 206: ADC register map and reset values (master and slave ADC common registers) offset =0x300).  
**Section 26: Digital-to-analog converter (DAC)**  
Updated/added internal signals in Figure 194: DAC channel block diagram.  
Added Section 26.3.2: DAC pins and internal signals.. APB1 clock and LSI clock replaced by dac_pclk and by lsi_ck in the whole document.  
**Section 28: Comparator (COMP)**  
Replaced COMP_IFCR by COMP_ICFR in Section 28.7.1: Comparator status register (COMP_SR).  
**Section 29: Operational amplifiers (OPAMP)**  
Replaced all occurrences of DACx_int by dac_outx (x = 1, 2).  
Updated VP_SEL bit description in Section 29.6.1: OPAMP1 control/status register (OPAMP1_CSR) register.  
**Section 31: Digital camera interface (DCMI)**  
Section DCMI pins merged with Section 31.4.4: DCMI physical interface.  
External signals HSYNC, VSYNC and PIXCLK standardized to DCMI_HSYNC, DCMI_VSYNC and DCIM_PIXCLK in the whole document. Updated Figure 224: DCMI block diagram and Figure 225: Top level block diagram.  
**Section 32: LCD-TFT Display Controller (LTDC)**  
LCD-TFT pins and signal interface renamed LCD-TFT pins and external signal interface.  
Internal signal names updated in Figure 233: LTDC block diagram. ck_axi_d1 renamed ltdc_aclk in the whole document.  
Updated Section 32.3.4: LTDC reset and clocks.  
Updated CFBP bitfield size in Section 32.7.23: LTDC Layerx Color Frame Buffer Length Register (LTDC_LxCFBLR) (where x=1..2).
26-May-2017 2 (continued)

</table>
| 26-May-2017| 2 (continued) | **Section 46: Real-time clock (RTC)**  
Added Figure 527: RTC block overview.  
Updated title of Figure 528: Detailed RTC block diagram.  
Added Section 46.3.2: RTC pins and internal signals. Updated Table 353: RTC pins and internal signals.  
Updated Section 46.3.3: GPIOs controlled by the RTC.  
Updated Section 46.6.16: RTC tamper configuration register (RTC_TAMPCR).  |
|            |          | **Section 47: Inter-integrated circuit (I2C) interface**  
Updated OA1[7:1] and OA2[7:1] bit description in Section 47.7.3: Own address 1 register (I2C_OAR1) and Section 47.7.4: Own address 2 register (I2C_OAR2).  
Replaced HSI16 by HSI or CSI or internal oscillator in Section 47.4.14: Wakeup from Stop mode on address match.  |
|            |          | **Section 48: Universal synchronous asynchronous receiver transmitter (USART)**  
Section 48.5.14: USART synchronous mode: removed Figure RX data setup/hold time, added reference to synchronous master mode in Figure 574: USART data clock timing diagram in synchronous master mode (M bits = '00') and Figure 575: USART data clock timing diagram in synchronous master mode (M bits = '01') and figure contents updated to mention two M bits instead of one.  
Updated Figure 586: Wakeup event verified (wakeup event = address match, FIFO disabled) in Section 48.5.21: USART low-power management.  |
|            |          | **Section 51: Serial audio interface (SAI)**  
Updated SYNCIN bitfield description in Section 51.5.1: Global configuration register (SAI_GCR).  |
|            |          | **Section 50: Serial peripheral interface (SPI)**  
Updated note in Section : Simplex communications.  
Added note about the PCM long and short frame definition in Section : PCM standard. Added Section 50.9.3: Bits and fields usable in I2S/PCM mode description and Table 391: Bit fields usable in PCM/I2S mode.  
Updated WSINV in Section 50.11.14: SPI/I2S configuration register (SPI_I2SCGFR) and Section 50.12: SPI register map and reset values.  |
|            |          | **Section 52: SPDIF receiver interface (SPDIFRX)**  
Added internal signals in Section Figure 658.: SPDIFRX block diagram and added Section 52.3.1: SPDIFRX pins and internal signals.  |
<table>
<thead>
<tr>
<th>Date</th>
<th>Revision</th>
<th>Changes</th>
</tr>
</thead>
</table>
| 26-May-2017| 2 (continued) | **Section 55: Secure digital input/output MultiMediaCard interface (SDMMC)**  
- Renamed internal signals in the whole section; updated  
  *Figure 694: SDMMC block diagram*; added Section 55.4.2:SDMMC pins and internal signals  
- Added Section 55.4.7: MDMA request generation  
- Removed SDMMC_VER, SDMMC_ID, SDMMC_SID  
- Updated SDMMC_STAR bit 12 and 13 in *Table 449: SDMMC register map*.  
**Section 56: FD Controller Area Network (FDCAN)**  
ASC (asynchronous serial communication) removed from the whole section.  
Added F0OM bit (bit 31) and F1OM bit (bit 31) in *FDCAN Rx FIFO 0 Configuration Register (FDCAN_RXF0C)* and *FDCAN Rx FIFO 1 Configuration Register (FDCAN_RXF1C)*, respectively.  
**Section 57: USB on-the-go high-speed (OTG_HS)**  
Added Section 57.4.2: USB OTG pin and internal signals.  
**Section 60: Debug infrastructure**  
Updated Section 60.5.8: Microcontroller debug unit (DBGMCU).  
Replaced in all DBGMCU register names:  
- D1APB1 by APB3  
- D2APB1 by APB1  
- D2APB2 by APB2  
- D3APB4 by APB4  
WDGLSD2 bit changed to reserved in Section : DBGMCU APB4 peripheral freeze register CPU *(DBGMCU_APB4FZ1)*DBGMCU_APB4FZ1.  
Removed reserved registers in *Table 578: DBGMCU register map and reset values*.  
**Section 2.3: Embedded SRAM**  
Added Section : Error code correction (ECC).  
**Section 12: System configuration controller (SYSCFG)**  
Changed 2.5 to 2.7 V in HSLV bit description of SYSCFG compensation cell control/status register (SYSCFG_CCCSR) and IO_HSLV of SYSCFG user register 17 (SYSCFG_URI17).  
**Section 3: Embedded Flash memory (FLASH)**  
In *Table 16: FLASH register map and reset value*:  
- Updated FLASH_OPTSR_CUR at address offset 0x11C.  
- Updated FLASH_OPTSR_PRG at address offset 0x120.  
Changed 2.5 to 2.7 V in IO_HSLV bit description of FLASH option status register (current value) (FLASH_OPTSR_CUR) and FLASH option status register (value to program) (FLASH_OPTSR_PRG). |

**Section 6: Power control (PWR)**
Replace AIEC by EXTI and wait VDD11 by Wait VCORE in Figure 27: Dynamic voltage scaling behavior with D1, D2 and system in Stop mode. Figure 28: Dynamic Voltage Scaling D1, D2, system Standby mode and Figure 29: Dynamic voltage scaling behavior with D1 and D2 in DStandby mode and D3 in autonomous mode.
Updated Section 6.4.7: USB regulator.
Updated Section 6.4: Entering Stop mode.

**Section 7: Low-power D3 domain**
Replaced VDD11 by VCORE.

**Section 8: Reset and Clock Control (RCC)**
Updated maximum frequency for ADC1, 2, 3 in Table 51: Kernel clock distribution overview.

**Section 10: Hardware semaphore (HSEM)**
Whole section updated to align with the product features.

**Section 14: MDMA controller (MDMA)**
Removed iterator in MDMA_CxISR and MDMA_CxIFCR bit names.

**Section 19: Nested Vectored Interrupt Controllers**
Changed usart4_gbl_it into uart4_gbl_it in Table 130: NVIC.

**Section 21: Cyclic redundancy check calculation unit (CRC)**
Updated first two features of Section 21.2: CRC main features.

**Section 25: Analog-to-digital converters (ADC)**
Section 25.2: ADC main features: suppressed ADC supply requirements.
Renamed VTS into VSENSE in the whole section.
Updated Figure 124: ADC block diagram, Figure 126: ADC1 connectivity, Figure 127: ADC2 connectivity and Figure 128: ADC3 connectivity.
VINN connected to ADC_INN instead of ADC_INN-1 in Table 190: ADC input/output pins.

Section 19: I/O analog switches voltage booster: voltage booster enable bit renamed BOOTSE (instead of BOOTSEN) and corresponding register renamed SYSCFG_PMCR (instead of SYSCFG_CFGR1).

</table>
| 11-Aug-2017| 3 (continued) | **Section 25: Analog-to-digital converters (ADC) (continued)**  
Added note related to software trigger selection in *Section 25.3.16: Starting conversions (ADSTART, JADSTART).*  
Updated *Figure 136: Triggers are shared between ADC master and ADC slave,* *Figure 191: Temperature sensor channel block diagram,* *Figure 192: VBAT channel block diagram* and *Figure 193: VREFINT channel block diagram.*  
Updated *Section : Analog watchdog.*  
Updated software notification by interrupt at end of conversion in *Section : Interleaved mode with independent injected;* updated *Figure 178: Interleaved mode on 1 channel in continuous conversion mode: dual ADC mode* and *Figure 179: Interleaved mode on 1 channel in single conversion mode: dual ADC mode.*  
Removed temperature sensor precision and replaced ambient by junction temperature in *Section 25.3.33: Temperature sensor.*  
*Section 25.6.2: ADC x common control register (ADCx_CCR) (x=12 or 3):*  
– VBATEN bit description made generic  
– TSEN renamed VSENSEEN and description made generic  
– Updated *Table 203: DELAY bits versus ADC resolution.*  
*ADCx.OR register suppressed since all bits are reserved.*  
*Renamed ADCx.LHTR1 into ADCx.HTR1.*  
*Changed ADCx.ISR bit access type to rc_w1.*  
*Updated iterators for all ADC common registers.* |
|           |          | **Section 26: Digital-to-analog converter (DAC)**  
Updated VREF+ range in *Table 207: DAC input/output pins.*  
Updated *Section 26.3.5: DAC conversion.*  
Added note related to ENx limitation when CENx is set in *Section 26.3.12: DAC channel buffer calibration.*  
Added case of accesses to DHRxxxD for wave generation in *Section 26.3.13: Dual DAC channel conversion (if available).*  
*Renamed DAC_M_ID into DAC_SIDR and M_ID bits into SID.* |
|           |          | **Section 26: Digital-to-analog converter (DAC) (continued)**  
*Added Section 26.5: DAC interrupts*  
*Section 26.6.1: DAC x control register (DACx.CR) (x=1 to 2):*  
– TEN2 bit: replaced DACx.DHRy by DACx.DHR2  
– TEN1 bit: replaced DACx.DHRy by DACx.DHR1.  
– TSELx bits: updated information on trigger selection/mapping  
*Section 26.6.16: DAC x mode control register (DACx.MCR) (x=1 to 2):* added note related to ENx bit for MODEx bit description.  
*Section 26.6.19: DAC x Sample and Hold hold time register (DACx.SHHR)(x=1 to 2):* added notes related to THOLDx modification when ENx=0.  
*Section 26.6.20: DAC x Sample and Hold refresh time register (DACx.SHRR)(x=1 to 2):* added note related to TREFRESHx modification when ENx=0.  
*Suppressed DAC.OR register.* |

<thead>
<tr>
<th>Date</th>
<th>Revision</th>
<th>Changes</th>
</tr>
</thead>
</table>
| 11-Aug-2017| 3 (continued) | Section 29: Operational amplifiers (OPAMP)  
Updated OPAMP1_VINM internal connection in Table 225: Operational amplifier possible connections.  

Section 37: High-Resolution Timer (HRTIM)  
Updated Note 1. in Table 289: External events mapping and associated features.  

Section 44: System window watchdog (WWDG)  
Corrected math equations used to calculate the WWDG period.  

Section 47: Inter-integrated circuit (I2C) interface  
Updated NACKCF bit definition in Section 47.7.8: Interrupt clear register (I2C_ICR) register.  

Section 51: Serial audio interface (SAI)  
SAIXEN bit renamed SAIEN in SAI_xCR register.  
Updated Figure 643: PDM typical connection and timing to make the block diagram independent from the number of data and clock lines.  
Updated Figure 644: Detailed PDM interface block diagram to add “n” and “p” indexes (n being the number of data lines and p the number of microphone pairs).  

Section 52: SPDIF receiver interface (SPDIFRX)  
Updated Figure 658: SPDIFRX block diagram.  

Section 59: HDMI-CEC controller (HDMI-CEC)  
Updated  
– Section 59.2: HDMI-CEC controller main features  
– Updated Figure 798: HDMI-CEC block diagram  

Section 61: Device electronic signature  
Updated Unique device ID register base address in Section 61.1: Unique device ID register (96 bits).  
Updated Flash size base address in Section 61.2: Flash size.  
Replaced package data register description by reference to SYSCFG_PKGR in Section 61.3: Package data register.

</table>
Section 18: Chrom-Art Accelerator™ controller (DMA2D)
Added Section 18.4.8: DMA2D output FIFO byte reordering.
Added Section: Memory-to-memory with PFC, blending and fixed color FG and
Section: Memory-to-memory with PFC, blending and fixed color BG.
Updated Section 18.6.1: DMA2D control register (DMA2D_CR):
Added bit 6 LOM
Updated Section 18.6.5: DMA2D foreground offset register (DMA2D_FGOR)
LO[15:0] bit description. Updated Section 18.6.7: DMA2D background offset
register (DMA2D_BGOR) LO[15:0] bit description. Updated Section 18.6.9:
DMA2D foreground color register (DMA2D_FGCOLR). Updated Section
18.6.11: DMA2D background color register (DMA2D_BGCOLR). Updated
Section 18.6.14: DMA2D output PFC control register (DMA2D_OPFCCR)
adding SB bit 6 description. Updated Section 18.6.17: DMA2D output offset
register (DMA2D_OOR) LO[15:0] bit description.
Added identification registers: DMA2D_VERR, DMA2D_IPIDR, DMA2D_SIDR.

Section 20: Nested Vectored Interrupt Controllers (NVIC1 and NVIC2)
Updated Table 138: NVIC and Section 20.1.1: SysTick calibration value register.

Section 21: Extended interrupt and event controller (EXTI)
Added note related to WKUP1 to 6 in Table 155: EXTI Event input mapping

Section 23: Flexible memory controller (FMC)
Updated Figure 106: FMC memory banks (default mapping) and Table 147:
FMC bank mapping options to change Bank 4 to *not used by FMC).
Updated Section: General transaction rules.

Section 15: Quad-SPI interface (QUADSPI)
Updated access types in Section 15.5.1: QUADSPI control register
(QUADSPI_CR) and Section 15.5.4: QUADSPI flag clear register
(QUADSPI_FCR).

Section 28: Analog-to-digital converters (ADC)
\( f_{ADC} \) and TADC replaced by \( f_{ADC\_ker\_ck} \) and \( f_{ADC\_ker\_ck} \) in the whole IP user
specification. Added \( f_{ADC\_ker\_ck} \) in Figure 179: ADC clock scheme. FHCLK
replaced by \( f_{ADC\_hclk} \) in Section: Clock ratio constraint between ADC clock and
AHB clock.
Replaced EXTSEL by JEXTSEL and adc_ext_trg0/1 by adc_jext_trg0/1 in Table
202: ADC1, ADC2 and ADC3 - External triggers for injected channels.
Updated note for JE0IE in Section 28.6.2: ADC interrupt enable register
(ADC_IER).

</table>
| 28-Jun-2018| 4 (continued) | **Section 28: Analog-to-digital converters (ADC) (continued)**  
Updated conditions for programming ADC_JSQR register in Section 28.4.10:  
Constraints when writing the ADC control bits, Section 28.4.11: Channel selection (SQRx, JSQRx), as well as in notes related to all Section 28.6.16: ADC injected sequence register (ADC_JSQR) bitfields (product errata sheets updated accordingly).  
Updated note related to offset correction in Section : Single ADC operating modes support when oversampling.  
Updated Section 28.6.8: ADC channel preselection register (ADC_PCSEL).  
Removed calibration value in Section 28.6.26: ADC calibration factors register (ADC_CALFACT).  

**Section 30: Digital-to-analog converter (DAC)**  
Changed data register indexing scheme in the whole document.  
Updated Figure 252: Dual-channel DAC block diagram.  
Added Section 30.3: DAC implementation.  
Section : Sample and Hold mode:  
Replaced SAMx by TSAMPEX.  
Replaced CL by CSH.  
Replaced TSAMx by TSAMPLEX.  
Replaced TREFx by TREFRESHx/  
Replaced tsampling by tSAMP.  
Replaced tstab-BON and tstab-BOFF by 7 µs and 3 µs, respectively.  
Replace Tofftrimmax by tTRIM.  
DAC status register (DAC_SR): for DAC1RDY and DAC1RDYbits, replaced DAC.CH1 and DAC.CH2 by DAC channel 1 and DAC channel 2, respectively.  

**Section 32: Digital filter for sigma delta modulators (DFSDM)**  
Updated Section 32.4.3: DFSDM reset and clocks and Section 32.4.4: Serial channel transceivers.  

**Section 33: Digital camera interface (DCMI)**  
Added 10-12-14-bit progressive video format in Section 33.5.1: Data formats.  

**Section 21: True random number generator (RNG)**  
BYP removed in the register description and map register.  

**Section 37: Hash processor (HASH)**  
In the whole document:  
Replaced SHA1, SHA224, SHA256 by SHA-1, SHA-224, SHA-256.  
Replaced HASH_Hx by HASH_HRx  
Updated Section 37.1: Introduction  
Updated Section 37.2: HASH main features  
Updated Section 37.3.3: About secure hash algorithms

**Section 24: Advanced-control timers (TIM1)**
Updated procedure in Section: External clock source mode 1, Section 24.3.7: Input capture mode, Section 24.3.8: PWM input mode and Section 24.3.20: One-pulse mode. Updated Section 24.3.16: Using the break function, including Figure 191: Break and Break2 circuitry overview.

**Section 25: General-purpose timer (TIM2)**
Added TIM4 timer input selection register (TIM4_TISEL)

**Section 26: General-purpose timers (TIM16/TIM17)**

**Section 27: Low-power timer (LPTIM)**
Added Section 27.4.15: Debug mode.

**Section 31: System window watchdog (WWDG)**
Updated Figure 290: Watchdog block diagram and Figure 291: Window watchdog timing diagram. Updated Section 31.3.2: Enabling the watchdog and Section 31.3.6: Debug mode. Updated Table 174: WWDG register map and reset values.

**Section 32: Inter-integrated circuit (I2C) interface**
Updated Figure 292: I2C block diagram.
Updated Section 32.4.5: I2C initialization removing the reference to RCC and modified Figure 294: Setup and hold timings.
Updated Table 189: Effect of low-power modes on the I2C.
Updated Section 32.6: I2C interrupts.
Updated note in Section: Master communication initialization (address phase).
Updated START bit 13 description in Section 32.7.2: I2C control register 2 (I2C_CR2).

**Section 33: Universal synchronous/asynchronous receiver transmitter (USART/UART)**
Section title updated to include UART
Added DWU formula in Section 33.5.8: Tolerance of the USART receiver to clock deviation.
Updated Section 33.5.21: USART low-power management
Added Section: Determining the maximum USART baud rate that allows to correctly wake up the microcontroller from low-power mode.
Replaced undocumented w_r0 access type by w access type in Section 33.7.8: USART request register (USART_RQR). Updated notes related to reserved bit/bitfield depending on USART feature in USART control register 1 [alternate] (USART_CR1), USART control register 2 (USART_CR2), USART control register 3 (USART_CR3), USART interrupt and status register [alternate] (USART_ISR) and USART interrupt flag clear register (USART_ICR).
Section 34: Low-power universal asynchronous receiver transmitter (LPUART)
Updated Section: Determining the maximum LPUART baud rate that allows to correctly wake up the MCU from low-power mode.
Transmit data register (LPUART_TDR) and Receive data register (LPUART_RDR) reset value changed from undefined to 0x0000 0000.
Updated notes related to reserved bit/bitfield depending on LPUART feature in Control register 3 (LPUART_CR3) and Interrupt and status register [alternate] (LPUART_ISR).

Section 36: Serial audio interface (SAI)
Updated Section: Clock generator programming in SPDIF generator mode.

Section 54: SPDIF receiver interface (SPDIFRX)
Suppressed references to spdifr_x_symb_ck in the whole section.
Removed SPDIFRX_VERR/IDR/SIDR registers.

Section 57: FD controller area network (FDCAN)
Changed fdcan_ker_ck max value from 500 MHz to 100 MHz.
Major section update.

Section 57: USB on-the-go high-speed (OTG)
Major section update.

Section 61: Ethernet (ETH): Gigabit media access control (GMAC) with DMA controller
Updated Rx flow control sequence in Section: Receive flow control.
Removed column “Behavior of the sbd_perch_tx_intr_o[] and sbd_perch_rx_intr_o[]” in Table 523: Transfer complete interrupt behavior.
Remove all references to non-user internal signals in register descriptions.
Updated SARC[2:0] configurations in Operating mode configuration register (ETH_MACCR). Updated DZPO bit description in Tx Queue 0 flow control register (ETH_MACQ0TXFCR). Changed bit 21 to reserved in LPI control status register (ETH_MACLCSR). Changed bits 1:2 to reserved in Interrupt enable register (ETH_MACIER). Changed bits 1, 2 and 15 to reserved in Interrupt status register (ETH_MACISR). Changed bit 28 to reserved in L3 and L4 control 1 register (ETH_MACL3L4C1R). Removed ETH_MTLRxQ1OMR register description and updated Rx queue i operating mode register (ETH_MTLRXQIOMR) to support both Queue 0 and 1. Changed bits 20:16 to reserved in MMC Rx interrupt mask register (ETH_MMC_RX_INTERRUPT_MASK).
### Table 601. Document revision history (continued)

<table>
<thead>
<tr>

<th>Revision</th>
<th>Changes</th>
</tr>
</thead>
</table>
| 28-Jun-2018| 4 (continued) | **Section 63: Debug infrastructure**  
  Updated Section 63.5.1: System ROM tables.  
  Renamed CSTF_TYPID register into CSTF_DEVTYPE.  
  Updated CSTF_CTRL and CSTF_PRIORITY priority in Table 607: CSTF register map and reset values.  
  Renamed MAXNUM bit into MUXNUM in TPIU device configuration register (TPIU_DEVID).  
  Renamed SWTF_TYPEID register into SWTF_DEVTYPE.  
  Updated DBGMCU identity code register (DBGMCU_IDC) reset value and added revision X.  
  Updated ITM trace privilege registers (M7_ITM_TPR).  
  Removed M7_ETM_DEVID register.  
  Updated Debug port target identification register (DP_TARGETID).  
  DBGMCU_APB1HFZ1 removed. |
| 25-Jun-2018| 5        | Added STM32H750xB microcontrollers:  
  Update cover page including Related documents  
  Updated Table 2: Bus-master-to-bus-slave interconnect  
  Updated Figure 1: System architecture for STM32H743/53xx and STM32H750xB devices  
  Updated Section 4.3.4: Flash memory architecture and usage.  
  Specified that parallel operations are not possible on STM32H750xB devices in Section 4.3.11: FLASH parallel operations (STM32H743/753 devices only).  
  Specified that bank swapping is not available on STM32H750xB devices in Section 4.3.15: Flash bank and register swapping (STM32H743/753 devices only) and notes added for bit SWAP_BANK and SWPA_BANK_OPT in FLASH_OPTCR and FLASH_OPTCR_PRG register, respectively.  
  Section 61: Ethernet (ETH): Gigabit media access control (GMAC) with DMA controller:  
  Added Figure 735: Supported PHY interfaces.  
  Updated Remote wakeup packet filter register (ETH_MACRWKPFR) description to replace wkuppktfilter_reg by ETH_MACRWKPFR and restrict the number of filters to 4. |

Table 601. Document revision history (continued)

<table>
<thead>
<tr>
<th>Date</th>
<th>Revision</th>
<th>Changes</th>
</tr>
</thead>
</table>
| 04-Apr-2019| 6 (continued) | **Section 5: Power control (PWR)**
Added case of device startup with $V_{\text{CORE}}$ supplied in Bypass mode in Section 5.4.1: System supply startup.
Added VOS0 in Section 5.4.2: Core domain, Section 5.4.3: PWR external supply and Section 5.6.2: Voltage scaling. Added Section: VOS0 activation/desactivation sequence.
Updated Section 5.5.5: Battery voltage thresholds.
Updated Section 5.5.6: Temperature thresholds to indicate that the thresholds are available only when the backup regulator is enabled.
Added note related to VOS0 activation in Section: Entering Stop mode and Section: Entering Standby mode.
Added Section 5.7.11: Monitoring low-power modes.
Added note related to $V_{\text{BAT}}$ and temperature monitoring availability for MONEN bit of Section 5.8.3: PWR control register 2 (PWR_CR2).
SCUEN bit is no more read-only in Section 5.8.4: PWR control register 3 (PWR_CR3) register description.

**Section 7: Reset and Clock Control (RCC)**
Changed adc_ker_ck to adc_ker_ck_input in the whole section.
Updated Section: HSE oscillator, Section: LSE oscillator and Figure 43: HSE/LSE clock source.
Changed maximum frequency to 480 MHz in Figure 46: Core and bus clock generation.
Updated Table 55: Kernel clock distribution overview.
Specified that RCC Internal Clock Source Calibration Register (RCC_ICSCR) is available only on revision Y and added RCC HSI configuration register (RCC_HSICFGR).
Specified that RCC Clock Recovery RC Register (RCC_CRRCR) is available only on revision Y and added RCC CSI configuration register (RCC_CSICFGR).
Updated DIVP1[6:0] in RCC PLL1 Dividers Configuration Register (RCC_PLL1DIVR).
Renamed BKPSRAMAMEN into BKPRAMAMEN in RCC D3 Autonomous mode Register (RCC_D3AMR).
Added USB2OTGHSULPIEN in RCC AHB1 Clock Register (RCC_AHB1ENR), and USB2OTGHSULPILPEN in RCC AHB1 Sleep Clock Register (RCC_AHB1LPENR).
Renamed HDMICECRST into CECRST in RCC APB1 Peripheral Reset Register (RCC_APB1LRSTR), and HDMICECEN to CECEN in RCC APB1 Clock Register (RCC_APB1LENR).
Changed CPURST bit to in RCC AHB3 Sleep Clock Register (RCC_AHB3LPENR).

**Section 10: General-purpose I/Os (GPIO)**
Updated Figure 73: Analog inputs connected to ADC inputs to specify that the analog switch status depends on PyxSO reset value in SYSCFG_PMCR.
MODER reset state changed to analog mode in Section 10.4.1: GPIO port mode register (GPIOx_MODER) (x =A to K).
Table 601. Document revision history (continued)

<table>
<thead>
<tr>
<th>Date</th>
<th>Revision</th>
<th>Changes</th>
</tr>
</thead>
</table>
| 04-Apr-2019 | 6 (continued) | **Section 11: System configuration controller (SYSCFG)**  
Added BOOSTVDDSEL bit in SYSCFG peripheral mode configuration register (SYSCFG_PMCR).  
Added note related to CSI clock required for setting READY bit in SYSCFG configuration register (SYSCFG_CFR). Added SYSCFG power control register (SYSCFG_PWRCR).  

**Section 15: Basic direct memory access controller (BDMA)**  
Updated Section : Channel state and disabling a channel.  

**Section 16: DMA request multiplexer (DMAMUX)**  
Removed references to security and privileged/unprivileged access control in Section 16.6.4: DMAMUX2 request line multiplexer interrupt channel status register (DMAMUX2_CSR), Section 16.6.6: DMAMUX2 request line multiplexer interrupt clear flag register (DMAMUX2_CFR) and Section 16.6.8: DMAMUX2 request generator channel x configuration register (DMAMUX2_RGxCR).  

**Section 17: Chrom-Art Accelerator™ controller (DMA2D)**  
Replaced DMA2D_FGPFCR by DMA2D_FGPFCR in Section : Memory-to-memory with PFC, blending and fixed color FG. Replaced DMA2D_BGPFCR by DMA2D_BGPFCR in Section : Memory-to-memory with PFC, blending and fixed color BG.  
Updated Section 17.6.9: DMA2D foreground color register (DMA2D_FGCOLR). Added Section 17.6.21: DMA2D foreground CLUT (DMA2D_FGCLUT[y]) and Section 17.6.22: DMA2D background CLUT (DMA2D_BGCLUT[y]).  
Table 137: DMA2D register map and reset values: changed APLHA[7:0] to reserved for DMA2D_FGCOLR and APLHA[7:0] to reserved for DMA2D_BGCOLR.  

**Section 21: Flexible memory controller (FMC)**  
Replaced BCH8 by Hamming in Section 21.8.6: Computation of the error correction code (ECC) in NAND Flash memory.  
Updated Figure 106: Mode D write access waveforms.  

**Section 23: Delay block (DLYB)**  
Updated Section 23.1: Introduction to specify that the DLYB output clock can be used to clock the data received by Quad-SPI interface.
### Table 601. Document revision history (continued)

<table>
<thead>
<tr>
<th>Date</th>
<th>Revision</th>
<th>Changes</th>
</tr>
</thead>
</table>
| 04-Apr-2019| 6 (continued) | **Section 24: Analog-to-digital converters (ADC)**  
Renamed `adc_ker_ck` into `adc_ker_ck_input` in the hole section.  
Renamed `OVSR` into `OVR`, `OSR` into `OSVR[9:0]` and `AUTODLY` into `AUTDLY`.  
Added **Section 24.3: ADC implementation**.  
For all ADC internal channels connected to `V_{BAT}`, `V_{SENSE}`, `V_{REFINT}`, and DAC internal channels, changed ADC channel name from `ADCx_INPy/INMy` to `ADCx VINP[y]/VINM[y]`.  
Updated **Figure 133: ADC clock scheme** to distinguish between revision Y (without `F_{adc_ker_ck_input}` divider and revision V without `F_{adc_ker_ck_input}` divider.  
Updated **Table 205: Offset computation versus data resolution**, Section : **16-bit and 8-bit signed format management: RSHIFTx, SSATE** and **Table 209: Analog watchdog 1,2,3 comparison**.  
Removed reference to ALIGN bit in the note related to data alignment in **Section : Single ADC operating modes support when oversampling**.  
Updated **Section 24.6.3: ADC control register (ADC_CR)** to distinguish between revision Y with one BOOST bit and revision V with two BOOST bits.  
Updated **Section 24.6.4: ADC configuration register (ADC_CFGR)** to change `RES[2:0]` value corresponding to 8-bit format.  
**Section 28: Operational amplifiers (OPAMP)**  
Removed references to `OPAMODE` in **Section 28.6.1: OPAMP1 control/status register (OPAMP1_CSR)**. Changed `OPAMODE` bitfield to reserved in **Section 28.6.1: OPAMP1 control/status register (OPAMP1_CSR)**.  
**Section 31: LCD-TFT display controller (LTDC)**  
**Section 31.4.1: LTDC global configuration parameters / Synchronous timing** updated.  
**Section 32: JPEG codec (JPEG)**  
**Table 269: JPEG codec register map and reset values:**  
– `JPEG_CR`: added `HPDIE` (bit 6)  
– Renamed `JPEG_HWCFR1/2` into `JPEG_HWCFGR1/2`  
**Section 33: True random number generator (RNG)**  
Updated **Section 33.2: RNG main features**, **Section 33.4: RNG interrupts**, **Section 33.6: RNG entropy source validation** and **Table 270: RNG internal input/output signals**. |

| 04-Apr-2019 | 6 (continued) | **Section 46: Inter-integrated circuit (I2C) interface**  
Updated Section 46.3: I2C implementation.  
Updated Section 46.7.2: I2C control register 2 (I2C_CR2), Section 46.7.3: I2C own address 1 register (I2C_OAR1), and Section 46.7.8: I2C interrupt clear register (I2C_ICR).  
**Section 42: Low-power timer (LPTIM)**  
Updated Section 42.4.9: Timeout function.  
Updated WAVE bit description in Section 42.7.4: LPTIM configuration register (LPTIM_CFG).  
**Section 47: Universal synchronous/asynchronous receiver transmitter (USART/UART)**  
Replaced DSI_NSS by DIS_NSS in USART_CR1.  
Changed USART_TDR into USART_RDR in Figure 589: Reception using DMA.  
Updated Section 47.5.4: USART FIFOs and thresholds.  
Updated RTO bitfield description in Section 47.7.7: USART receiver timeout register (USART_RTOR).  
Section 47.7.9: USART interrupt and status register [alternate] (USART_ISR):  
– Updated ABRF, IDLE bit descriptions  
– For FIFO disabled only: updated RXNE and ORE bit descriptions  
Changed NFCF to NECF in Section 47.7.11: USART interrupt flag clear register (USART_ICR).  
Table 395: USART register map and reset values:  
– USART_CR1: bit 12 changed to M0, bit 7 changed to TXEIE/TXFNFIE, bit 5 changed to RXNEIE/RXFNEIE.  
– USART_ISR: changed TXE bit to TXE/TXFNF and RXNE into RXNE/RXFNE  
Corrected USART_ISR/TCGBT reset value for FIFO disabled.  
**Section 48: Low-power universal asynchronous receiver transmitter (LPUART)**  
Changed LPUART_TDR into LPUART_RDR in Figure 603: Reception using DMA.  
Updated Section 47.5.4: USART FIFOs and thresholds.  
Updated Section 48.5.1: Control register 1 [alternate] (LPUART_CR1).  
Corrected WUS bitfield length and changed RXFTCFG to TXFTCFG (bit 31 to 29) in Section 48.5.4: Control register 3 (LPUART_CR3).  
Section 48.5.8: Interrupt and status register [alternate] (LPUART_ISR):  
– Updated IDLE bit descriptions  
– FIFO enabled only: updated reset value  
Changed NFCF to NECF in Section 48.5.9: Interrupt flag clear register (LPUART_ICR).  
Table 401: LPUART register map and reset values:  
– LPUART_CR1: bit 12 changed to M0, bit 5 changed to RXNEIE/RXFNEIE.  
– LPUART_ISR: changed TXE bit to TXE/TXFNF  
– Corrected LPUART_ISR reset value and bits 7 and 5 names. |

| 04-Apr-2019| 6 (continued) | **Section 49: Serial peripheral interface (SPI)**<br>
|            |          | Table 409: SPI register map and reset values:<br>
|            |          | – SPI2S_SR: Changed bit 7 to CRCE.<br>
|            |          | – SPI2S_I2SCFGR: added DATFMT (bit 14)<br>
|            |          | **Section 53: Management data input/output (MDIOS)**<br>
|            |          | In Table 436: MDIOS register map and reset values, for MDIOS_CR register, changed bit 3 to EIE and added DPC (bit 7).<br>
|            |          | **Section 54: Secure digital input/output MultiMediaCard interface (SDMMC)**<br>
|            |          | Replaced HOLD by DHOLD in the whole document.<br>
|            |          | Updated Figure 701: SDMMC block diagram and Table 440: SDMMC pins.<br>
|            |          | Updated Figure 710: CLKMUX unit.<br>
|            |          | Updated Wait_S in Section : Data path and Table 450: Data path status flags and clear bits.<br>
|            |          | Updated Section 54.4.3: General description.<br>
|            |          | Updated Section : Stream operation and CMD12.<br>
|            |          | Added Section 54.7: SDMMC interrupts.<br>
|            |          | Updated Section 54.8.10: SDMMC data counter register (SDMMC_DCNTR), Section 54.8.11: SDMMC status register (SDMMC_STAR) and Section 54.8.15: SDMMC data FIFO registers x (SDMMC_FIFORx).<br>
|            |          | Updated Table 462: SDMMC register map.<br>
|            |          | **Section 55: Controller area network with flexible data rate (FDCAN)**<br>
|            |          | Updated Section 55.4.7: FDCAN nominal bit timing and prescaler register (FDCAN_NBTP), Section 55.4.12: FDCAN error counter register (FDCAN_ECR), Section 55.4.15: FDCAN interrupt register (FDCAN_IR), Section 55.4.37: FDCAN Tx buffer request pending register (FDCAN_TXBRP) and Section 55.4.64: FDCAN TT trigger select register (FDCAN_TTTS).<br>
|            |          | Updated Table 489: FDCAN register map and reset values.<br>
|            |          | Updated FDCAN_TEST, FDCAN_TSCC, FDCAN_ECR, FDCAN_TDCR, FDCAN_XIDFC, FDCAN_RXF0A, FDCAN_RXF1A, FDCAN_TXESC, FDCAN_TXEFS, FDCAN_TTMCC, FDCAN_TTOCN and FDCAN_TTIR in Table 489: FDCAN register map and reset values.<br>
|            |          | Updated FCCAN_CCU_CCFG in Table 490: CCU register map and reset values.<br>
|            |          | **Section 57: Ethernet (ETH): media access control (MAC) with DMA controller**<br>
|            |          | Added Figure 788: Supported PHY interfaces.<br>
|            |          | Removed reference to AV standard in Section 57.1: Ethernet introduction.
Table 601. Document revision history (continued)

<table>
<thead>
<tr>

</thead>
</table>
| 04-Apr-2019| 6 (continued) | **Section 59: Debug infrastructure**  
changed ETF RAM size to 4 Kbytes in *Section 59.5.5: Embedded trace FIFO (ETF)* and *Section: ETF RAM size register (ETF_RSZ)*.  
added revision V and updated reset value in *Section: DBGMCU identity code register (DBGMCU_IDC)*.  
renamed WDGLSD1 into DBG_IWDG1 in *Section: DBGMCU APB4 peripheral freeze register (DBGMCU_APB4FZ1)*.  
prefixed all bits names in *Section: DBGMCU APB1L peripheral freeze register (DBGMCU_APB1LIFZ1)*, *Section: DBGMCU APB2 peripheral freeze register (DBGMCU_APB2FZ1)* and *Section: DBGMCU APB4 peripheral freeze register (DBGMCU_APB4FZ1)* by 'DBG_'. |
