Introduction

The aim of this document is to give a supplementary description for serial boot modes in addition to the description in RM0046, rev. 3 (see Section Appendix A). It is described the hardware configuration to allow the right selection of the serial boot mode with autobaud by means of autoscan and the RX pins configuration of serial communication peripherals (FlexCAN and LINFlex).

1 Hardware configuration to select boot mode

The SPC560P34x/SPC560P40x devices detect the serial boot mode based on external pins.

To enter boot mode via FlexCAN or LINFlex, the device must be forced into an Alternate Boot Loader Mode via the FAB (Force Alternate Boot Mode), which must be asserted before initiating the reset sequence. The type of alternate boot mode is selected according to the ABS (Alternate Boot Selector) pins (see Table 1).

Boot configuration pins are:

1. During reset the boot configuration pins are weak pull down.

Note: PAD A[2] - ABS[0] is not bonded on SPC560P34x/SPC560P40x LQFP64 so for this package the option 'FlexCAN without Autobaud ' is not available and the internal pull-down on PAD A[2] assures that it is at low logical value at reset.”

1.1 SPC560P34x/SPC560P40x boot pins

The TX/RX pin (LINFlex_0 and FlexCAN_0) used for serial boot and configuration boot pins to select the serial boot mode are described in the Table 2 for LQFP64 and LQFP100 packages.

Hardware configuration to select boot mode

1.2 Autobaud feature

SPC560P34x/SPC560P40x devices implement the autobaud feature via FlexCAN or LINFlex selecting the active serial communication peripheral by means of an autoscan routine.

When autobaud configuration is selected by ABS and FAB pins, the autoscan routine starts and listens to the active bus protocol. Initially the LinFlex_0 RX pin and FlexCAN_0 RX pin are configured as GPIO inputs:

- for LQFP100 internal weak pull-up enabled for both RX pins,
- for LQFP64 internal weak pull-up enabled only for FlexCAN_0 RX pin.

The autoscan routine waits in polling for the first LOW level to select which routine will be executed:

- FlexCAN Autobaud routine
- LinFlex Autobaud routine

Then the measurement baud rate is computed to configure the serial communication at the right rate. In the end of baud rate measurement, LinFlex_0 RX pin and FlexCAN_0 RX pin switches to work as dedicated pin.

Baud rate measurement is using the System Timer Module (STM) which is driven by the system clock. Measurement itself is performed by software polling the related inputs as general purpose IO’s, resulting in a detection granularity that is directly related to the execution speed of the software.

One main difference of the autobaud feature is that the system clock is not driven directly by the external oscillator, but it is driven by the FMPLL output. The reason is that to have an optimum resolution for baud rate measurement, the system clock needs to be nearer to the maximum allowed device’s frequency.

This is achieved with the following two steps:

1. using the Clock Monitor Unit (CMU) and the internal RC oscillator (IRC), the external frequency is measured using the IRC as reference to determine this frequency.
2. Based on the result of this measurement, the FMPLL is programmed to generate a system clock that is configured to be near, but lower, to the maximum allowed frequency.

After setting up the system clock, the BAM autoscan code configures the FlexCAN RX pin (B[1] on all packages) and LINFlex RX pin (B[3] on LQFP100 or B[7] on LQFP64) as GPIO inputs and searches for FlexCAN RX pin level to verify if CAN is connected or not.
Then continuously waits in polling on change of RX pins level. The FlexCAN RX pin level takes precedence. First signal found at low level selects the serial boot routine that will be executed.

In case a low level is detected on any input, the corresponding autobaud measurement functionality is started:

- when FlexCAN RX (corresponds to pin B[1]) level is low, the CAN autobaud measurement starts and then sets up the FlexCAN baud rate accordingly;
- when UART RX (corresponds to pin B[3] on LQFP100 or B[7] on LQFP64) level is low, the UART autobaud measurement starts and then sets up the LINFlex baud rate accordingly.

After performing the autobaud measurement and setting up the baud rate, the corresponding RX input is reconfigured and the related standard download process is started; in case of a detected CAN transmission a download using the CAN protocol as described in section “Bootstrap with FlexCAN—autobaud disabled” of RM0046, rev. 3 (see Section Appendix A), and in case of a detected UART transmission a download using the UART protocol as described in Section “Boot from UART—autobaud disabled” of RM0046, rev.3 (see Section Appendix A).

The following Figure 1 identifies the corresponding flow and steps.

**Note:** When autobaud scan is selected, initially both LINFlex_0 RX pin and FlexCAN_0 RX pin should be at high level. No external circuity should pull-down them to allow right autoscan.
Figure 1. BAM Autoscan code flow

FlexCAN RX and LINFlex RX configured as GPIO inputs

FlexCAN RX == 1

NO

FlexCAN RX == 0

YES

Both RDX pins have to be at high level.
Avoid to connect them to external pull-down resistor.

If CAN is connected, after reset CAN_RX has to be at high level

detected

Autobaud measurement for FlexCAN
Set matching baud rate
Continue with FlexCAN download

Autobaud measurement for LINFlex
Set matching baud rate
Continue with LINFlex download

LINFlex RX == 0

Continue with LINFlex download
