Introduction

STM32Cube is an STMicroelectronics original initiative to significantly improve designer's productivity by reducing development effort, time and cost. STM32Cube covers the whole STM32 portfolio.

STM32Cube includes:

- A set of user-friendly software development tools to cover project development from the conception to the realization, among which STM32CubeMX, a graphical software configuration tool, STM32CubeIDE, an all-in-one development tool, STM32CubeProgrammer (STM32CubeProg), a programming tool, and STM32CubeMonitor-Power (STM32CubeMonPwr) monitoring tool.
- STM32Cube MCU and MPU Packages, comprehensive embedded-software platforms specific to each microcontroller and microprocessor series (such as STM32CubeL4 for the STM32L4 Series), which include STM32Cube hardware abstraction layer (HAL), STM32Cube low-layer APIs, a consistent set of middleware components, and all embedded software utilities.
- STM32Cube Expansion Packages, which contain embedded software components that complement the functionalities of the STM32Cube MCU and MPU Packages with middleware extensions and applicative layers, and examples.

For a complete description of STM32Cube, refer to Chapter 2.

The BSP (board support package) drivers are part of the STM32Cube MCU and MPU Packages based on the HAL drivers, and provide a set of high-level APIs relative to the hardware components and features on the Evaluation boards, Discovery kits and Nucleo boards delivered with the STM32Cube MCU and MPU Packages for a given STM32 microcontroller Series.

The BSP drivers allow quick access to the board services using high-level APIs, without any specific configuration as the link with the HAL and the external components is made intrinsically within the drivers. From the project-setting point of view, the user has only to add the necessary driver files in the workspace and call the functions needed from the examples in Level0, Level1 or Level2 in Figure 2. However, some low-level configuration functions may be overridden by the applications if the user wants to change the default behavior of the BSP drivers.

The purpose of this document is to provide the user with guidance for the development of BSP drivers.

It gives an overview of the architecture of BSP drivers (class, component, common and bus) and implementation examples.

1 Documentation conventions

STM32Cube BSP drivers support Arm®-based devices.

1.1 About this document

This document mainly focuses on the BSP architecture, which is designed to be more generic by addressing multi instance components and multi buses and changing the initialization process to be based on the code generated by STM32CubeMX tool.

It details the architecture of BSP drivers (class, component, common and bus) and gives examples of implementation to guide the user developing BSP drivers on a given board.

The user of this document must be familiar with the STM32Cube MCU and MPU Packages.

2 What is STM32Cube?

STM32Cube is an STMicroelectronics original initiative to significantly improve designer’s productivity by reducing development effort, time and cost. STM32Cube covers the whole STM32 portfolio.

STM32Cube includes:

• A set of user-friendly software development tools to cover project development from the conception to the realization, among which:
  – STM32CubeMX, a graphical software configuration tool that allows the automatic generation of C initialization code using graphical wizards
  – STM32CubeIDE, an all-in-one development tool with IP configuration, code generation, code compilation, and debug features
  – STM32CubeProgrammer (STM32CubeProg), a programming tool available in graphical and command line versions
  – STM32CubeMonitor-Power (STM32CubeMonPwr), a monitoring tool to measure and help in the optimization of the power consumption of the MCU

• STM32Cube MCU and MPU Packages, comprehensive embedded-software platforms specific to each microcontroller and microprocessor series (such as STM32CubeL4 for the STM32L4 Series), which include:
  – STM32Cube hardware abstraction layer (HAL), ensuring maximized portability across the STM32 portfolio
  – STM32Cube low-layer APIs, ensuring the best performance and footprints with a high degree of user control over the HW
  – A consistent set of middleware components such as FAT file system, RTOS, USB Host and Device, TCP/IP, Touch library, and Graphics
  – All embedded software utilities with full sets of peripheral and applicative examples

• STM32Cube Expansion Packages, which contain embedded software components that complement the functionalities of the STM32Cube MCU and MPU Packages with:
  – Middleware extensions and applicative layers
  – Examples running on some specific STMicroelectronics development boards
3 BSP driver architecture

The STM32Cube MCU and MPU Packages architecture is described in Figure 1 and Figure 2.

Figure 1. STM32Cube MCU and MPU Packages architecture

Figure 2. STM32Cube MCU and MPU Packages detailed architecture

(1) The set of middleware components depends on the product Series.
The BSP drivers are generally composed of four parts, as presented in Figure 3 and detailed here.

1. Function drivers: This part provides a set of high-level APIs for a specific class or functionality, such as LCD, Audio or Touchscreen.
2. Common driver: The common driver provides a set of friendly APIs for HMI (LEDs, buttons, and joysticks) and COM services.
3. Component drivers: This generic driver, for an external device on the board and independent of the HAL, is the component driver, which provides specific APIs to the external IC component and can be portable on any board. The component driver is composed of the component core files (nnnxxxx.h and nnnxxxx.c), component register files (nnnxxxx_reg.h and nnnxxxx_reg.c) and option configuration file (nnnxxxx_conf.h).
4. Bus IO driver: generic bus interface to provide the transport layer for the components, such as I2C or SPI.

Figure 3. BSP drivers overview
3.1 BSP drivers features

The BSP architecture aims to provide the following features:

- Manage dynamically the MSP part of the generic class functions to customize the low-level part in order to prevent resources conflict between several class drivers.
- Support generic, specific and extended functions categories for BSP class drivers to fit in same time with native STM32 and expansion boards.
- Manage low power mode and allow either STM32 or external components to enter and exit low power mode defined by the user for more power control efficiency.
- Components driver flexibility allowing to customize the component class structure by adding more elementary functions for full external components control.
- Manage multi instance access to components drivers and guarantee unitary functions reentrancy by adding object handles
- Generic argument for each unitary component function to handle specific features offered by different components belonging to the same functionality class.
- Read register and Write registers basic component functions to allow handling more components features from application level.
- Generic BUS IO driver to centralize the low-level transport layer for the components
- Split the component driver into three layers:
  - Component core driver.c or driver.h files
  - Component register driver_reg.c or driver_reg.h files
  - Configuration file
- Flexible use DMA and IT HAL model based on the new HAL register callbacks features

3.2 Hardware configuration

The BSP architecture is designed to support the following hardware configurations:

- Single board: The STM32 and all the used components are on the same board (mother board): Evaluation board, Discovery Kit, Nucleo, specific or user-defined board.

Figure 4. BSP driver repository: single board

- Multi boards: The STM32 and some used components are on the same board (mother board) while additional components are on one or several daughterboards linked to the mother board through GPIOs or communication buses.
Figure 5. BSP driver repository: multi-boards

Note: The BSP class drivers that are exclusively provided by components on the daughterboard must be located in the daughterboard folder. The components on the daughterboard may be linked to the mother board through this formal bus IO services.
3.3 BSP driver repository

The BSP drivers are composed of component drivers that are located in a common folder for all the boards and board specific drivers that are located in a specific folder for each supported board within a STM32 family as shown in Figure 6.

Figure 6. BSP driver repository: overview
The components drivers of a same class are providing the same driver structure as defined in the component header of the class file (class.h) located in the \components\common folder. The class corresponds to the generic functions categories, such as LCD, TS, IO and others.

Figure 7. BSP driver repository: common class headers
3.4 BSP based project repository

This BSP architecture offers two configuration file sets:

- **Component configuration file**: a component may require to be configured by the user to select a specific mode in compile time (Compile-time configurable drivers). In this case, the component folder contains a configuration file with the `_template` suffix. This file must be copied and renamed by removing the `_template` suffix in the user folder.

- **BSP drivers configuration file**: the common and the specific function drivers may need to be configured to select a specific mode or enable specific features. In this case, the board folder contains a configuration file with the `_template` suffix. This file must be copied and renamed by removing the `_template` suffix in the user folder.
Figure 8. BSP driver repository: configuration files

Note: 1  The component configuration files are optional. In some cases, they may be omitted when no specific configuration item needs to be customized.

Note: 2  The BSP drivers configuration file is mandatory and must be always added in the application include folder.
3.5 **BSP inclusion model**

*Figure 9* shows the different inclusion dependencies between the BSP drivers modules. From application side, the common and the class function drivers must be added independently in the workspace and the components and global BSP drivers configuration files must be added physically in the application include folder.

Some BSP drivers services can be used by other BSP common or class driver, thus the former BSP drivers must be added as well in the project workspace. Example: IO BSP driver.

The component configuration files are not available for some components.
4  BSP naming rules

4.1  General rules

The following table summarizes the general naming rules regarding the files, functions and resources exported to the end user.

Table 2. General naming rules

<table>
<thead>
<tr>
<th>-</th>
<th>ST Mother board</th>
<th>ST daughterboard</th>
<th>User specific board</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>File names</strong></td>
<td>stm32tnnnm_boardtype{Function} (c/h) like stm32f413h_discovery.c/h, stm32f4xx_nucleo.c/h, stm32f769i_eval.c</td>
<td>shield name {Function} (c/h) like iks01a2_env_sensors.c/h</td>
<td>user board name{Function} (c/h) like sx1276mb1mas.c/h</td>
</tr>
<tr>
<td><strong>Exported Function name</strong></td>
<td>BSP_CLASS_Function like BSP_AUDIO_OUT_Init(), BSP_LED_Init()</td>
<td>SHIELDNAME_Function like ADAFRUIT_802_JOY_Init() IKS01A2_ENV_SENSOR_Init</td>
<td>USERBOARDNAME_CLASS_Function like USERBOARDNAME_AUDIO_OUT_Init() USERBOARDNAME_LED_Init()</td>
</tr>
<tr>
<td><strong>Structure name</strong></td>
<td>CLASS_STRUCTNAME_Ctx_t (for example AUDIO_IN_Ctx_t)</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Enum name</strong></td>
<td>(CATEGORY/CLASS)_EnumName_t (for example Button_TypeDef/COM_TypeDef)</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>defines</strong></td>
<td>CLASS_DEFINENAME (for example AUDIO_OUT_XXX)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Note: 1**  The category refers to common BSP drivers feature classification ex: JOY, PB, COM, POT, LED...

**Note: 2**  For expansion/extension BSP drivers, the _ex suffix must be added in the files name and ex suffix must be added to the extension driver resources (functions, data structures, enumeration, defines...).

**Note: 3**  For Nucleo, whatever the type (32, 64, 144), we must always use the same common driver, if some resources are different, they must be delimited using the USE_NUCLEO_NN defined in the configuration file.

**Note: 4**  In case several variants of a Nucleo board type are available, a second level of delimitation is used based on the device name (USE_NUCLEO-TnnnMM), for example USE_NUCLEO_H7A3ZI.

**Note: 5**  The environment and motion sensors class are considered as macro classes as they support several unitary sensors subclasses (gyro, magneto...), thus the file names are ending with s but not the name of the class itself. For example, b_l475e_iot01a1_env_sensors.c or b_l475e_iot01a1_env_sensors.h are the file names, and the class name is ENV_SENSOR.
4.2 Board naming rules

The following table summarizes the rules and the difference between the CPN and the firmware used name.

<table>
<thead>
<tr>
<th>ST Board</th>
<th>Board Name</th>
<th>Filename</th>
<th>BSP Folder Name</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>Expansion board</td>
<td>{X/I}-NUCLEO-NNNNNN</td>
<td>nnnnn like iks01a2</td>
<td>NNNNN like IKS01A2</td>
</tr>
</tbody>
</table>
5 BSP common driver

The common driver provides a set of friendly used APIs for HMI devices (LEDs, buttons, and joystick) and the board COM ports. It is available for all the supported boards within a specific series of STM32Cube MCU and MPU Packages.

Figure 10. BSP driver repository: common drivers
5.1 BSP common driver functions

The BSP common services are defined only for the corresponding hardware available on the board. Table 4 gives the list of common services that must be implemented depending on the hardware:

<table>
<thead>

Note: The COM BSP driver must be always defined when the board embeds RS232 connector or when the board supports the VCP USB class through STLINK.
5.2 **BSP common functions implementation**

This section provides examples of common services code implementation. This must be adapted to match the board components.

### 5.2.1 BSP_GetVersion

This API returns the BSP driver revision. The version format is as follows: 0xXYZR (8 bits for each decimal, R for RC)

```c
int32_t BSP_GetVersion (void)
{
    return (int32_t)BOARDNAME_BSP_VERSION;
}
```

The BOARDNAME_BSP_VERSION is defined in the common BSP driver header file as follows:

```c
#define BOARDNAME_BSP_VERSION_X (int32_t) (0x02) /*!< [31:24] main version */
#define BOARDNAME_BSP_VERSION_Y (int32_t) (0x06) /*!< [23:16] sub1 version */
#define BOARDNAME_BSP_VERSION_Z (int32_t) (0x02) /*!< [15:8] sub2 version */
#define BOARDNAME_BSP_VERSION_RC (int32_t) (0x00) /*!< [7:0] release candidate */
#define BOARDNAME_BSP_VERSION ((BOARDNAME_BSP_VERSION_X << 24)
                             |(BOARDNAME_BSP_VERSION_Y << 16)
                             |(BOARDNAME_BSP_VERSION_Z << 8))
```
5.2.2 **BSP_LED_Init**

This API configures the user LED GPIOs (Power and components monitoring LEDs are not included). The number of LEDs (LEDn) is defined by the number of physical LEDs on the board.

```c
int32_t BSP_LED_Init (Led_TypeDef Led)
{
    GPIO_InitTypeDef gpio_init_structure;

    /* Enable the GPIO_LED Clock */
    switch (Led)
    {
        case LED1:
            LED1_GPIO_CLK_ENABLE ();
            break;
        (...)
        case LEDN:
            LEDN_GPIO_CLK_ENABLE ();
            break;
        default:
            break;
    }

    /* configure the GPIO_LED pin */
    gpio_init_structure.Pin = LED_PIN [Led];
    gpio_init_structure.Mode = GPIO_MODE_OUTPUT_PP;
    gpio_init_structure.Pull = GPIO_PULLUP;
    gpio_init_structure.Speed = GPIO_SPEED_FREQ_VERY_HIGH;
    HAL_GPIO_Init (LED_PORT [Led], &gpio_init_structure);

    HAL_GPIO_WritePin (LED_PORT [Led], LED_PIN [Led], GPIO_PIN_RESET);

    return BSP_ERROR_NONE;
}
```
The LEDs enumeration must be defined in the common BSP driver header file as follows:

```c
typedef enum
{
    LED1 = 0,
    LED_GREEN = LED1,
    LED2 = 1,
    LED_ORANGE = LED2,
    LED3 = 2,
    LED_RED = LED3,
    LED4 = 3,
    LED_BLUE = LED4,
    LEDn
} Led_TypeDef;
```

The different literals and defines must be defined in the common BSP driver header file as follows:

```c
#define LEDi_LED_PORT                   ((GPIO_TypeDef*) GPIOx)
#define LEDi_GPIO_CLK_ENABLE ()           __HAL_RCC_GPIOj_CLK_ENABLE ()
#define LEDi_PIN                         ((uint32_t) GPIO_PIN_M)
```

Where 0<= i < N and j = {A, B …}

N: Number of LEDs

{A, B …} GPIO Port

The PIN and GPIO arrays are defined in the BSP common driver source file as follows:

```c
int32_t LED_PIN [LEDn] = {LED1_PIN,
                         LEDi_PIN,
                         ....
                         LEDN_PIN};

GPIO_TypeDef* LED_PORT [LEDn] = {LED1_GPIO_PORT,
                                  LEDi_GPIO_PORT,
                                  ....
                                  LEDN_GPIO_PORT};
```
5.2.3 **BSP_LED_DeInit**

This API turns off the user LED and de-initialize the GPIO peripheral registers to their default reset values.

```c
int32_t BSP_LED_DeInit(Led_TypeDef Led)
{
    GPIO_InitTypeDef gpio_init_structure;

    /* DeInit the GPIO_LED pin */
    gpio_init_structure.Pin = LED_PIN[Led];

    /* Turn off LED */
    HAL_GPIO_WritePin(LED_PORT[Led], LED_PIN[Led], GPIO_PIN_SET);
    HAL_GPIO_DeInit(LED_PORT[Led], gpio_init_structure.Pin);
    return BSP_ERROR_NONE;
}
```

**Note:** The **BSP_LED_DeInit** must not disable the clock of the GPIO port, because it may be used by other modules in the application.

5.2.4 **BSP_LED_On**

This API turns the selected LED on.

```c
int32_t BSP_LED_On(Led_TypeDef Led)
{
    HAL_GPIO_WritePin(LED_PORT[Led], LED_PIN[Led], GPIO_PIN_RESET);
    return BSP_ERROR_NONE;
}
```

5.2.5 **BSP_LED_Off**

This API turns the selected LED off.

```c
int32_t BSP_LED_On(Led_TypeDef Led)
{
    HAL_GPIO_WritePin(LED_PORT[Led], LED_PIN[Led], GPIO_PIN_SET);
    return BSP_ERROR_NONE;
}
```

**Note:** The GPIO PIN state, **GPIO_PIN_SET** / **GPIO_PIN_RESET**, used to turn on/off the LEDs depends on the schematics of the board (the GPIO may drive the anode or the cathode of the LED).
5.2.6 **BSP_LED_Toggle**

This API toggles the state of the selected LED.

```c
int32_t BSP_LED_Toggle (Led_TypeDef Led)
{
    HAL_GPIO_TogglePin (LED_PORT [Led], LED_PIN [Led]);
    return BSP_ERROR_NONE;
}
```

5.2.7 **BSP_LED_GetState**

This API returns the state of the selected LED.

```c
int32_t BSP_LED_GetState (Led_TypeDef Led)
{
    return int32_t) (HAL_GPIO_ReadPin (LED_PORT [Led], LED_PIN [Led]) == GPIO_PIN_RESET);
}
```

**Note:** The GPIO PIN state, GPIO_PIN_SET / GPIO_PIN_RESET, used to turn on/off the LEDs depends on the schematics of the board (the GPIO may drive the anode or the cathode of the LED).

The LEDs are generally driven by GPIOs, on the same port or on different ports. If the same GPIO port is used, the switch case may be simply omitted.

```c
int32_t BSP_LED_Init(Led_TypeDef Led)
{
    GPIO_InitTypeDef gpio_init_structure = {0};

    /* Enable the GPIO_LED Clock */
    LEDx_GPIO_CLK_ENABLE ();

    /* configure the GPIO_LED pin */
    gpio_init_structure.Pin = LED_PIN [Led];
    gpio_init_structure.Mode = GPIO_MODE_OUTPUT_PP;
    gpio_init_structure.Pull = GPIO_PULLUP;
    gpio_init_structure.Speed = GPIO_SPEED_FREQ_VERY_HIGH;
    HAL_GPIO_Init (LED_PORT [Led], &gpio_init_structure);

    HAL_GPIO_WritePin (LED_PORT [Led], LED_PIN [Led], GPIO_PIN_RESET);
    return BSP_ERROR_NONE;
}
```
Where the LEDx_GPIO_CLK_ENABLE is defined in the common BSP driver header file as follows:

```c
#define LEDx_LED_PORT ((GPIO_TypeDef*) GPIOj)
#define LEDx_GPIO_CLK_ENABLE () __HAL_RCC_GPIOx_CLK_ENABLE ()
#define LEDi_PIN ((uint32_t) GPIO_PIN_M)
```

Where 0 <= i < N and j = {A, B ...}

N: Number of LEDs

(A, B ...) GPIO Port
5.2.8  BSP_PB_Init

This API configures the push-button GPIOs and EXTI Line if the button must be used in interrupt mode.

```c
int32_t BSP_PB_Init(Button_TypeDef Button, ButtonMode_TypeDef ButtonMode)
{
    GPIO_InitTypeDef gpio_init_structure;
    static BSP_EXTI_LineCallback ButtonCallback[BUTTONn] =
        (BUTTON_USER_EXTI_Callback);
    static uint32_t  BSP_BUTTON_PRIO [BUTTONn] =
        (BSP_BUTTON_USER_IT_PRIORITY);
    static const uint32_t BUTTON_EXTI_LINE[BUTTONn] =
        (BUTTON_USER_EXTI_LINE);

    /* Enable the GPIO_LED Clock */
    switch (Button)
    {
    case BUTTON_TAMPER:
        BUTTON_TAMPER_GPIO_CLK_ENABLE ();
        break;
    (…)
    case BUTTON_USER:
        BUTTON_USER_GPIO_CLK_ENABLE ();
        break;
    default:
        break;
    }

    gpio_init_structure.Pin = BUTTON_PIN [Button];
    gpio_init_structure.Pull = GPIO_NOPULL;
    gpio_init_structure.Speed = GPIO_SPEED_FREQ_HIGH;

    if (ButtonMode == BUTTON_MODE_GPIO)
    {
        /* Configure Button pin as input */
        gpio_init_structure.Mode = GPIO_MODE_INPUT;
        HAL_GPIO_Init(BUTTON_PORT [Button], &gpio_init_structure);
    }
    else /* (ButtonMode == BUTTON_MODE_EXTI) */
    {
        /* Configure Button pin as input with External interrupt */
        gpio_init_structure.Mode = GPIO_MODE_IT_RISING;
        HAL_GPIO_Init(BUTTON_PORT[Button], &gpio_init_structure);
    }
```
typedef enum
{
    BUTTON_WAKEUP = 0,
    BUTTON_TAMPER = 1,
    BUTTON_USER = 2,
    BUTTONn
} Button_TypeDef;

typedef enum
{
    BUTTON_MODE_GPIO = 0,
    BUTTON_MODE_EXTI = 1
} ButtonMode_TypeDef;

#define BUTTON_NAME_LED_PORT             ((GPIO_TypeDef*) GPIOx)
#define BUTTON_NAME_GPIO_CLK_ENABLE ()    __HAL_RCC_GPIOj_CLK_ENABLE ()
#define BUTTON_NAME_PIN                  ((uint32_t) GPIO_PIN_M)

BUTTON_NAME = BUTTON_WAKEUP or
BUTTON_TAMPER or
BUTTON_USER
N: Number of Buttons
x = {A, B …} GPIO Port

The different literals and defines must be defined in the common BSP driver header file as follows:

typedef enum
{
    BUTTON_WAKEUP = 0,
    BUTTON_TAMPER = 1,
    BUTTON_USER = 2,
    BUTTONn
} Button_TypeDef;

typedef enum
{
    BUTTON_MODE_GPIO = 0,
    BUTTON_MODE_EXTI = 1
} ButtonMode_TypeDef;

#define BUTTON_NAME_LED_PORT             ((GPIO_TypeDef*) GPIOx)
#define BUTTON_NAME_GPIO_CLK_ENABLE ()    __HAL_RCC_GPIOj_CLK_ENABLE ()
#define BUTTON_NAME_PIN                  ((uint32_t) GPIO_PIN_M)

BUTTON_NAME = BUTTON_WAKEUP or
BUTTON_TAMPER or
BUTTON_USER
N: Number of Buttons
x = {A, B …} GPIO Port
The buttons EXTI Lines IRQ priorities are defined in the in the `stm32YNNN_eval_conf.h` file.

```c
#define BSP_BUTTON_NAME_IT_PRIORITY 0x0FU
```

The priority, PIN and GPIO arrays are defined in the BSP common driver C file:

```c
uint32_t BSP_BUTTON_PRIO [BUTTONn] = {
    ..., 
    BSP_BUTTON_NAME_IT_PRIORITY, 
    ..., 
};
```

### 5.2.9 BSP_PB_GetState

This API returns the state of the selected button.

```c
int32_t BSP_PB_GetState (Button_TypeDef Button)
{
    return (int32_t)HAL_GPIO_ReadPin(BUTTON_PORT[Button],
    BUTTON_PIN[Button]);
}
```

**Note:** The GPIO PIN state, GPIO_PIN_SET / GPIO_PIN_RESET, used to return the button state depends on the schematics of the board.
5.2.10 **BSP_COM_Init**

This API configures the COM port available on the board. This function may be used to initialize the LOG via the COM port feature when the USE_BSP_COM_FEATURE and USE_COM_LOG definitions are defined in the BSP configuration file, or prepares one of the board COM port for the user transfer.

```c
UART_HandleTypeDef hcom_uart [COMn];
#ifdef (USE_BSP_COM_FEATURE > 0)
#ifdef (USE_COM_LOG > 0)
static COM_TypeDef COM_ActiveLogPort = COM1;
#endif
#endif
int32_t BSP_COM_Init (COM_TypeDef COM, COM_InitTypeDef *COM_Init)
{
  int32_t ret = BSP_ERROR_NONE;

  if(COM >= COMn)
  {
    ret = BSP_ERROR_WRONG_PARAM;
  }
  else
  {
    #if (USE_HAL_UART_REGISTER_CALLBACKS == 0)
    /* Init the UART Msp */
    UARTx_MspInit(&hcom_uart[COM]);
    #else
    if(IsComMspCbValid[COM] == 0U)
    {
      if(BSP_COM_RegisterDefaultMspCallbacks(COM) != BSP_ERROR_NONE)
      {
        return BSP_ERROR_MSP_FAILURE;
      }
    }
    #endif

    if(MX_USARTx_Init(&hcom_uart[COM], COM_Init) != HAL_OK)
    {
      ret = BSP_ERROR_PERIPH_FAILURE;
    }
  }

  return ret;
}
```
The COMs enumeration must be defined in the common BSP driver header file as follows:

```c
typedef enum
{
    COM1 = 0, (...)
    COMn
} COM_TypeDef;
```

The different literals and defines must be defined in the common BSP driver header file as follows:

```c
#define COMi_UART          USARTi
#define COMi_TX_GPIO_PORT  ((GPIO_TypeDef*) GPIOx)
#define COMi_TX_GPIO_CLK_ENABLE () __HAL_RCC_GPIOj_CLK_ENABLE ()
#define COMi_TX_PIN         ((uint32_t) GPIO_PIN_M)
#define COMi_TX_AF          GPIO_AFx_USARTy
#define COMi_RX_GPIO_PORT  ((GPIO_TypeDef*) GPIOx)
#define COMi_RX_GPIO_CLK_ENABLE () __HAL_RCC_GPIOj_CLK_ENABLE ()
#define COMi_RX_PIN         ((uint32_t) GPIO_PIN_M)
#define COMi_CLK_ENABLE ()  __HAL_RCC_GPIOk_CLK_ENABLE ()
#define COM1_TX_AF          GPIO_AFx_USARTy
```

Where 0<= i < N and j, k = {A, B ...}
N: Number of COMs
(A, B ...) GPIO Port

The arrays' definition are defined in the BSP common driver source file as follows:

```c
USART_TypeDef* COM_USART[COMn] = {COMi_UART};
GPIO_TypeDef* COM_TX_PORT[COMn] = {COMi_TX_GPIO_PORT};
GPIO_TypeDef* COM_RX_PORT[COMn] = {COMi_RX_GPIO_PORT};
const uint16_t COM_TX_PIN[COMn] = {COMi_TX_PIN};
const uint16_t COM_RX_PIN[COMn] = {COMi_RX_PIN};
const uint16_t COM_TX_AF[COMn] = {COMi_TX_AF};
const uint16_t COM_RX_AF[COMn] = {COMi_RX_AF};
```
5.2.11  BSP_COM_SelectLogPort

This API selects a COM port for the printf output when the USE_COM_LOG definition is activated in the BSP configuration file.

```
#if (USE_COM_LOG > 0)
/**
 * @brief Select the active COM port.
 * @param COM COM port to be activated.
 *          This parameter can be COM1
 * @retval BSP status
 */
int32_t BSP_COM_SelectLogPort(COM_TypeDef COM)
{
    if(COM_ActiveLogPort != COM)
    {
        COM_ActiveLogPort = COM;
    }

    return BSP_ERROR_NONE;
}
#endif

#if (USE_COM_LOG > 0)
#ifdef __GNUC__
int __io_putchar (int ch)
#else
int fputc (int ch, FILE *f)
#endif /* __GNUC__ */
{
    (void)HAL_UART_Transmit (&hcom_uart [COM_ActiveLogPort], (uint8_t *)
&ch, 1, COM_POLL_TIMEOUT);
    return ch;
}
#endif /* USE_COM_LOG */
```

Note:1  If the first Port COM is used, the BSP_COM_SelectLogPort may not be called.

Note:2  If there is only one COM port (COMn = 1), the BSP_COM_SelectLogPort function may be omitted.

To be able to use the COM port for the printf output the following putc and putchar functions must be implemented to override the default putc and putchar behavior.
5.2.12  BSP_JOY_Init

This API configures the joystick GPIOs and EXTI Line if the button must be used in interrupt mode.

```c
/* Store Joystick pins initialized */
uint32_t JoyPinsMask = 0;

int32_t BSP_JOY_Init (JOY_TypeDef JOY, JOYMode_TypeDef JoyMode,
                        JOYPin_TypeDef JoyPins)
{
    uint32_t joykey, key_pressed;
    GPIO_InitTypeDef gpio_init_structure;

    static BSP_EXTI_LineCallback JoyCallback[JOY_KEY_NUMBER] = {
        JOY1_SEL_EXTI_Callback,
        JOY1_DOWN_EXTI_Callback,
        JOY1_LEFT_EXTI_Callback,
        JOY1_RIGHT_EXTI_Callback,
        JOY1_UP_EXTI_Callback
    };
    static const uint32_t JOY_EXTI_LINE[JOY_KEY_NUMBER]   = {
        JOY1_SEL_EXTI_LINE,
        JOY1_DOWN_EXTI_LINE,
        JOY1_LEFT_EXTI_LINE,
        JOY1_RIGHT_EXTI_LINE,
        JOY1_UP_EXTI_LINE
    };

    /* Store Joystick pins initialized */
    JoyPinsMask |= JoyPins;

    /* Initialized the Joystick. */
    for (joykey = 0; joykey < JOY_KEY_NUMBER; joykey++)
    {
        key_pressed = 1 << joykey;
        if (key_pressed & JoyPins)
        {
            if (JOY == JOY1)
            {
                /* Enable the JOY clock */
                JOY1_GPIO_CLK_ENABLE(key_pressed);

                gpio_init_structure.Pin = JOY1_PIN[joykey];
                gpio_init_structure.Pull = GPIO_PULLDOWN;
                gpio_init_structure.Speed = GPIO_SPEED_FREQ_VERY_HIGH;
            }
        }
    }
}
```
if (JoyMode == JOY_MODE_GPIO)
{
    /* Configure Joy pin as input */
    gpio_init_structure.Mode = GPIO_MODE_INPUT;
    HAL_GPIO_Init(JOY1_PORT[joykey], &gpio_init_structure);
}
else if (JoyMode == JOY_MODE_EXTI)  
{  
    /* Configure Joy pin as input with External interrupt */
    gpio_init_structure.Mode = GPIO_MODE_IT_RISING;
    HAL_GPIO_Init(JOY1_PORT[joykey], &gpio_init_structure);

    (void)HAL_EXTI_GetHandle(&hjoy_exti[joykey], JOY_EXTI_LINE[joykey]);
    (void)HAL_EXTI_RegisterCallback(&hjoy_exti[joykey],
    HAL_EXTI_COMMON_CB_ID, JoyCallback[joykey]);
    /* Enable and set Joy EXTI Interrupt to the lowest priority */
    HAL_NVIC_SetPriority((IRQn_Type)(JOY1_IRQn[joykey]),
    BSP_JOY1_PRIO[joykey], 0x00);
    HAL_NVIC_EnableIRQ((IRQn_Type)(JOY1_IRQn[joykey]));
}
else if (JOY == JOYx)
{
}

return BSP_ERROR_NONE;
The joystick mode enumeration and keys must be defined in the common BSP driver header file as follows:

```c
typedef enum
{
  JOY_NONE  = 0x00U,
  JOY_SEL   = 0x01U,
  JOY_DOWN  = 0x02U,
  JOY_LEFT  = 0x04U,
  JOY_RIGHT = 0x08U,
  JOY_UP    = 0x10U,
  JOY_ALL   = 0x1FU
} JOYPin_TypeDef;
#define JOY_KEY_NUMBER         5U

typedef enum {
  JOY_MODE_GPIO = 0,
  JOY_MODE_EXTI = 1
}JOYMode_TypeDef;
```

The JOY enumeration must be defined in the common BSP driver header file as follows:

```c
typedef enum
{
  JOY1 = 0, (…)
  JOYN
} JOY_TypeDef;
```

The different literals and defines must be defined in the common BSP driver header file as follows:

```c
#define JOYx_NAME_PIN                       ((uint32_t) GPIO_PIN_M)
#define JOYx_NAME_GPIO_PORT                 ((GPIO_TypeDef*) GPIOy)
#define JOYx_NAME_GPIO_CLK_ENABLE ()        __HAL_RCC_GPIOj_CLK_ENABLE ()
#define JOYx_NAME_GPIO_CLK_DISABLE ()       __HAL_RCC_GPIOj_CLK_DISABLE ()
#define JOYx_NAME_EXTI_IRQn                 EXTIj_IRQn
JOY_NAME = JO_SEL ...JOY_UP
define JOYx_NAME_GPIO_PORT ((GPIO_TypeDef*) GPIOy)
define JOYx_NAME_GPIO_CLK_ENABLE () __HAL_RCC_GPIOj_CLK_ENABLE ()
define JOYx_NAME_GPIO_CLK_DISABLE () __HAL_RCC_GPIOj_CLK_DISABLE ()
define JOYx_NAME_EXTI_IRQn EXTIj_IRQn
N: Number of Joystick instances
y = {A, B …} GPIO Port
x: Joystick instance
```
The Joystick EXTI Lines IRQ priorities are defined in the `boardname_conf.h` file.

```c
#define BSP_JOYx_NAME_IT_PRIORITY 0x0FU
```

The priority, PIN and GPIO arrays are defined in the BSP common driver C file:

```c
uint32_t BSP_JOYx_PRIO[JOY_KEY_NUMBER] = {BSP_JOYx_SEL_IT_PRIORITY,
                                            BSP_JOYx_DOWN_IT_PRIORITY,
                                            BSP_JOYx_LEFT_IT_PRIORITY,
                                            BSP_JOYx_RIGHT_IT_PRIORITY,
                                            BSP_JOYx_UP_IT_PRIORITY};

static GPIO_TypeDef* JOYx_PORT[JOY_KEY_NUMBER] = {JOYx_SEL_GPIO_PORT,
                                                JOYx_DOWN_GPIO_PORT,
                                                JOYx_LEFT_GPIO_PORT,
                                                JOYx_RIGHT_GPIO_PORT,
                                                JOYx_UP_GPIO_PORT};

static const uint16_t JOYx_PIN[JOY_KEY_NUMBER] = {JOYx_SEL_PIN,
                                                JOYx_DOWN_PIN,
                                                JOYx_LEFT_PIN,
                                                JOYx_RIGHT_PIN,
                                                JOYx_UP_PIN};

static const IRQn_Type JOYx_IRQn[JOY_KEY_NUMBER] = {JOYx_SEL_EXTI_IRQn,
                                                JOYx_DOWN_EXTI_IRQn,
                                                JOYx_LEFT_EXTI_IRQn,
                                                JOYx_RIGHT_EXTI_IRQn,
                                                JOYx_UP_EXTI_IRQn};
```
5.2.13  **BSP_JOY_DeInit**

This API de-initializes the GPIO peripheral registers to their default reset values.

```c
int32_t BSP_JOY_DeInit(JOY_TypeDef JOY, JOYPin_TypeDef JoyPins)
{
    uint32_t joykey, key_pressed;

    /* Store Joystick pins initialized */
    JoyPinsMask &= JoyPins;

    /* Initialized the Joystick. */
    for(joykey = 0; joykey < JOY_KEY_NUMBER; joykey++)
    {
        key_pressed = 1 << joykey;
        if (key_pressed & JoyPins)
        {
            if (JOY == JOY1)
            {
                HAL_GPIO_DeInit(JOY1_PORT[joykey], JOY1_PIN[joykey]);
            }
            else if (JOY == JOYx)
            {
            }
        }
    }
    return BSP_ERROR_NONE;
}
```

**Note:** The **BSP_JOY_DeInit** must not disable the clock of the GPIO ports, because they may be used by other modules in the application.
### 5.2.14  BSP_JOY_GetState

This API returns the current joystick state and indicates the joystick key that was pressed.

```c
int32_t BSP_JOY_GetState (JOY_TypeDef JOY)
{
    uint32_t joykey, key_pressed;

    for (joykey = 0; joykey < JOY_KEY_NUMBER; joykey++)
    {
        key_pressed = 1 << joykey;
        if (key_pressed & JoyPinsMask)
        {
            if (JOY == JOY1)
            {
                if (HAL_GPIO_ReadPin(JOY1_PORT[joykey], JOY1_PIN[joykey]) != GPIO_PIN_RESET)
                    /* Return Code Joystick key pressed */
                return key_pressed;
            }
            else if (JOY == JOYx)
            {
            }
        }
    }

    /* No Joystick key pressed */
    return JOY_NONE;
}
```
### 5.2.15 BSP_POT_Init

This API configures the ADC channel associated with the potentiometer.

```c
ADC_HandleTypeDef hpot_adc[POTn];
int32_t BSP_POT_Init(POT_TypeDef POT)
{
    int32_t ret = BSP_ERROR_NONE;

    if(POT >= POTn)
    {
        ret = BSP_ERROR_WRONG_PARAM;
    }
    else
    {
        #if (USE_HAL_ADC_REGISTER_CALLBACKS == 0)
            /* Init the ADC Msp */
            ADCx_MspInit(&hpot_adc[POT]);
        #else
            if(IsPotMspCbValid[POT] == 0U)
            {
                if(BSP_POT_RegisterDefaultMspCallbacks(POT) != BSP_ERROR_NONE)
                {
                    return BSP_ERROR_MSP_FAILURE;
                }
            }
        #endif

        if(MX_ADCx_Init(&hpot_adc[POT]) != HAL_OK)
        {
            ret = BSP_ERROR_PERIPH_FAILURE;
        }
    }

    return ret;
}
```

The POTs enumeration must be defined in the common BSP driver header file as follows:

```c
typedef enum
{
    POT1 = 0, (...)
    POTn
} POT_TypeDef;
```
The different literals and defines must be defined in the common BSP driver header file as follows:

```c
#define POTi_ADC                        ADCx
#define POTi_ADC_CHANNEL_GPIO_PORT      ((GPIO_TypeDef*) GPIOx)
#define POTi_CHANNEL_GPIO_CLK_ENABLE()  __HAL_RCC_GPIOj_CLK_ENABLE()
#define POTi_CHANNEL_GPIO_PIN           ((uint32_t) GPIO_PIN_M)
#define POTi_CLK_ENABLE()               __HAL_RCC_GPIOk_CLK_ENABLE()
```

Where 0\(\leq i < N\) and \(j, k = \{A, B \ldots\}\)

\(N\): Number of POTs

\((A, B \ldots)\) GPIO Port

The arrays definition are defined in the BSP common driver source file as follows:

```c
ADC_TypeDef* POT_ADC [POTn] = {POTi_ADC};
GPIO_TypeDef* POT_CHANNEL_GPIO_PORT [POTn] = {POTi_TX_GPIO_PORT};
const uint16_t POT_CHANNEL_GPIO_PIN [POTn] = {POTi_TX_PIN};
```
5.2.16  **BSP_POT_GetLevel**

This API returns the level of voltage on potentiometer in percentage.

```c
int32_t BSP_POT_GetLevel(POT_TypeDef POT)
{
    int32_t ret = BSP_ERROR_PERIPH_FAILURE;

    if(POT >= POTn)
    {
        ret = BSP_ERROR_WRONG_PARAM;
    }
    else
    {
        if(HAL_ADC_Start(&hpot_adc[POT]) == HAL_OK)
        {
            if(HAL_ADC_PollForConversion(&hpot_adc[POT], POT_ADC_POLL_TIMEOUT) == HAL_OK)
            {
                if(HAL_ADC_GetValue(&hpot_adc[POT]) <= (uint32_t)0xFFF)
                {
                    ret = (int32_t)POT_CONVERT2PERC((uint16_t)HAL_ADC_GetValue(&hpot_adc[POT]));
                }
            }
        }
    }
    return ret;
}
```

With `POT_CONVERT2PERC` defined BSP driver header file as follows:

```c
#define POT_CONVERT2PERC(x) ((((int32_t)x)*100)/(0xFFF))
```

5.2.17  **BSP_POT_DeInit**

This method de-initializes the ADC peripheral registers and related resources to their default reset values.

```c
int32_t BSP_POT_DeInit(POT_TypeDef POT)
{
    int32_t ret = BSP_ERROR_NONE;

    if(POT >= POTn)
    {
        ret = BSP_ERROR_WRONG_PARAM;
    }
    return ret;
}
```
Note: 1 All the BSP Potentiometers functions and resources must be delimited by the USE_BSP_POT_FEATURE in the BSP common driver.

Note: 2 By default, the USE_BSP_POT_FEATURE define is deactivated in the common driver header file.

```c
#endif /* USE_BSP_POT_FEATURE */

#define USE_BSP_POT_FEATURE   0U
#endif
```

### 5.2.18 BSP_POT_RegisterDefaultMspCallbacks

This method registers the default POT Msp callbacks.

```c
int32_t BSP_POT_RegisterDefaultMspCallbacks (POT_TypeDef POT)
{
    int32_t ret = BSP_ERROR_NONE;

    if(POT >= POTn)
    {
        ret = BSP_ERROR_WRONG_PARAM;
    }
    else
    {
        __HAL_ADC_RESET_HANDLE_STATE(&hpot_adc[POT]);
    }
    return ret;
}
```
This method registers the specific user POT Msp callbacks.

```c
/* Register default MspInit/MspDeInit Callback */
if(HAL_ADC_RegisterCallback(&hpot_adc[POT], HAL_ADC_MSPINIT_CB_ID, ADCx_MspInit) != HAL_OK)
{
    ret = BSP_ERROR_PERIPH_FAILURE;
}
else if(HAL_ADC_RegisterCallback(&hpot_adc[POT], HAL_ADC_MSPDEINIT_CB_ID, ADCx_MspDeInit) != HAL_OK)
{
    ret = BSP_ERROR_PERIPH_FAILURE;
}
else
{
    IsPotMspCbValid[POT] = 1U;
}

/* BSP status */
return ret;
```

### 5.2.19 BSP_POT_RegisterMspCallbacks

This method registers the specific user POT Msp callbacks.

```c
int32_t BSP_POT_RegisterMspCallbacks (POT_TypeDef POT, BSP_POT_Cb_t *Callback)
{
    int32_t ret = BSP_ERROR_NONE;

    if(POT >= POTn)
    {
        ret = BSP_ERROR_WRONG_PARAM;
    }
    else
    {
        __HAL_ADC_RESET_HANDLE_STATE(&hpot_adc[POT]);

        /* Register MspInit/MspDeInit Callbacks */
        if(HAL_ADC_RegisterCallback(&hpot_adc[POT], HAL_ADC_MSPINIT_CB_ID, Callback->pMspInitCb) != HAL_OK)
        {
            ret = BSP_ERROR_PERIPH_FAILURE;
        }
    }
```
With the BSP_POT_Cb_t structure defined as

```c
typedef struct {
    void (* pMspInitCb)(ADC_HandleTypeDef *);
    void (* pMspDeInitCb)(ADC_HandleTypeDef *);
} BSP_POT_Cb_t;
```

Note: The register callbacks statement and functions must be delimited by the USE_HAL_ADC_REGISTER_CALLBACKS conditional defined in the HAL configuration file.

```c
#if (USE_HAL_ADC_REGISTER_CALLBACKS == 1)
(…)
#endif /*
```

5.2.20 Using IO expander

On some boards, LED, button or joystick GPIOs may be driven by external IO expander(s) (covered by the BSP IO class driver). The statement based on these GPIOs must be delimited by the use or not of the IO expander and the BSP IO configuration. The GPIOs configuration and use must be implemented as in this LED example:

```c
int32_t BSP_LED_Init(Led_TypeDef Led)
{
    int32_t ret = BSP_ERROR_NONE;

    #if (USE_BSP_IO_CLASS == 1)
        (...)
    #endif /*
```
```c
BSP_IO_Init_t io_init_structure;
#endif /* (USE_BSP_IO_CLASS == 1) */
GPIO_InitTypeDef gpio_init_structure;

if(Led == LED1)
{
    /* Enable the GPIO_LED clock */
    LED1_GPIO_CLK_ENABLE();

    /* Configure the GPIO_LED pin */
    gpio_init_structure.Mode = GPIO_MODE_OUTPUT_PP;
    gpio_init_structure.Pull = GPIO_PULLUP;
    gpio_init_structure.Speed = GPIO_SPEED_FREQ_HIGH;
    gpio_init_structure.Pin = LED_PIN[Led];
    HAL_GPIO_Init(LED_PORT[Led], &gpio_init_structure);
    HAL_GPIO_WritePin(LED_PORT[Led], (uint16_t)LED_PIN[Led],
                      GPIO_PIN_SET);
}
else
{
#if (USE_BSP_IO_CLASS == 1)
    io_init_structure.Pin  = LED_PIN[Led];
    io_init_structure.Pull = IO_PULLUP;
    io_init_structure.Mode = IO_MODE_OUTPUT_PP;
    /* Initialize IO expander */
    if(BSP_IO_Init(0, &io_init_structure) != BSP_ERROR_NONE)
    {
        ret = BSP_ERROR_NO_INIT;
    }
    else
    {
        if(BSP_IO_WritePin(0, LED_PIN[Led], IO_PIN_SET) != BSP_ERROR_NONE)
        {
            ret = BSP_ERROR_NO_INIT;
        }
    }
#endif /* (USE_BSP_IO_CLASS == 1) */
}
return ret;
```

**Note:** 1  
**USE_BSP_IO_CLASS** is not defined by default to reduce the driver footprint of the common BSP driver, as the IO expander BSP driver and the used bus (generally I²C) must be added.
in the project. To enable the IO expander, the `USE_BSP_IO_CLASS` define must be uncommented in the `boardname_conf.h` file.

Note: 2  The `BSP_IO_Init` is built internally to prevent multiple initialization, if the BSP IOE is already initialized, calling the `BSP_IO_Init` has no effect.

Note: 3  If a BSP common function is entirely using the BSP IOE driver, it must be delimited by the `USE_BSP_IO_CLASS` define.
The BSP bus driver `boardname_bus.c` exports the transport functions used by the components IO operations. They can be shared by several IO operations of several external components.

**Figure 11. BSP driver repository: bus drivers**
6.1 BSP bus driver APIs

Each bus available on the board must provide the following APIs:

<table>
<thead>
<tr>
<th>Service</th>
<th>Description</th>
<th>Peripheral</th>
</tr>
</thead>
<tbody>
<tr>
<td>BSP_PPPn_Init</td>
<td>Initialize a bus</td>
<td>All</td>
</tr>
<tr>
<td>BSP_PPPn_DeInit</td>
<td>De-Initialize a bus</td>
<td>All</td>
</tr>
<tr>
<td>BSP_PPPn_IsReady</td>
<td>Return the status of the bus</td>
<td>I²C</td>
</tr>
<tr>
<td>BSP_PPPn_WriteReg</td>
<td>Read registers through a bus (8 bits)</td>
<td>I²C</td>
</tr>
<tr>
<td>BSP_PPPn_ReadReg</td>
<td>Write registers through bus (8 bits)</td>
<td>I²C</td>
</tr>
<tr>
<td>BSP_PPPn_WriteReg16</td>
<td>Read registers through a bus (16 bits)</td>
<td>I²C</td>
</tr>
<tr>
<td>BSP_PPPn_ReadReg16</td>
<td>Write registers through bus (16 bits)</td>
<td>I²C</td>
</tr>
<tr>
<td>BSP_PPPn_Recv</td>
<td>Receive an amount of data through a bus</td>
<td>All</td>
</tr>
<tr>
<td>BSP_PPPn_Send</td>
<td>Send an amount width data through bus</td>
<td>All</td>
</tr>
<tr>
<td>BSP_PPPn_SendRecv</td>
<td>Send and receive an amount of data through bus (Full duplex)</td>
<td>Full duplex like SPI</td>
</tr>
<tr>
<td>BSP_GetTick</td>
<td>Return system tick in ms</td>
<td>Generic</td>
</tr>
<tr>
<td>BSP_PPPn_RegisterMspCallbacks</td>
<td>User register bus Msp callback</td>
<td>All</td>
</tr>
<tr>
<td>BSP_PPPn_RegisterDefaultMspCallbacks</td>
<td>Default register bus Msp callbacks</td>
<td>All</td>
</tr>
</tbody>
</table>

Note: 1 Throughout this section, the address argument is only available for I²C bus.

Note: 2 In BSP bus drivers, only required services are mandatory, others can be omitted.
6.2  BSP bus APIs implementation

6.2.1  BSP_PPPn_Init

The BSP_PPPn_Init() function initializes the bus MSP and HAL parts. To prevent multiple initializations when several components use the same bus, the initialization function must be protected to ensure that a bus initialization is called once. The protection mechanism must be based on the HAL state of the BUS peripheral.

```c
static uint32_t PPPnInitCounter = 0;

int32_t BSP_PPPn_Init(__ARGS__)
{
    int32_t ret = BSP_ERROR_NONE;

    hbus_pppn.Instance = BUS_PPPn;

    if(PPPnInitCounter++ == 0U)
    {
        if(HAL_PPP_GetState(&hbus_pppn) == HAL_PPP_STATE_RESET)
        {
            #if (USE_HAL_PPP_REGISTER_CALLBACKS == 0)
                /* Init the BUS Msp */
                PPPn_MspInit(&hbus_pppn);
            #else
                if(IsPppnMspCbValid == 0U)
                {
                    if(BSP_PPPn_RegisterDefaultMspCallbacks() != BSP_ERROR_NONE)
                    {
                        ret = BSP_ERROR_MSP_FAILURE;
                    }
                }
            #endif
        }
        if(ret == BSP_ERROR_NONE)
        {
            /* Init the BUS peripheral */
            if (MX_PPPn_Init(&hbus_pppn, __ARGS__)) != HAL_OK)
            {
                ret = BSP_ERROR_BUS_FAILURE;
            }
        }
    }
    #endif
}
```

6.2.2 BSP bus MSP default functions

The default MSP functions (Init and Deinit) are defined as follows:

```c
static void PPPn_MspInit(PPP_HandleTypeDef *hppp)
{
    GPIO_InitTypeDef gpio_init;

    /* Enable GPIO clock */
    BUS_PPPn_SIGNALA_GPIO_CLK_ENABLE();
    BUS_PPPn_SIGNALB_GPIO_CLK_ENABLE();

    /* Enable Main peripheral clock */
    BUS_PPPn_CLK_ENABLE();

    /* Configure PPP Signal A as alternate function */
    gpio_init.Pin = BUS_PPPn_SIGNALA_GPIO_PIN;
    gpio_init.Mode = GPIO_MODE_AF_PP;
    gpio_init.Speed = GPIO_SPEED_FREQ_HIGH;
    gpio_init.Pull = GPIO_PULLUP;
    gpio_init.Alternate = BUS_PPPn_SIGNALA_GPIO_AF;
    HAL_GPIO_Init(BUS_PPPn_SIGNALA_GPIO_PORT, &gpio_init);

    /* Configure PPP Signal B as alternate function */
    gpio_init.Pin = BUS_PPPn_SIGNALB_GPIO_PIN;
    gpio_init.Mode = GPIO_MODE_AF_PP;
    gpio_init.Alternate = BUS_PPPn_SIGNALB_GPIO_AF;
    HAL_GPIO_Init(BUS_PPPn_SIGNALB_GPIO_PORT, &gpio_init);
}
```

/* @brief Initialize PPP Msp part
 * @param PPP handle

```c
return ret;
}
__weak HAL_StatusTypeDef MX_PPPn_Init (PPP_HandleTypeDef *hppp , __ARGS__)
{
    /* Init the PPP MSP Part*/
    hppp->Init.param1 = PARAM#1;
    (...) 
    hppp->Init.ParamN = PARAM#N;
    return HAL_PPP_Init (hppp); }
```
The different literals and defines must be defined in the common BSP driver header file as follows:

```c
#define BUS_PPPn                             PPPn
#define BUS_PPPn_SIGNALA_GPIO_PORT           GPIOa
#define BUS_PPPn_SIGNALA_GPIO_CLK_ENABLE ()  __HAL_RCC_GPIOa_CLK_ENABLE ()
#define BUS_PPPn_SIGNALA_GPIO_PIN            GPIO_PIN_A
#define BUS_PPPn_SIGNALA_GPIO_AF             GPIO_AFa_PPPx
#define BUS_PPPn_SIGNALB_GPIO_PORT           GPIOb
#define BUS_PPPn_SIGNALB_GPIO_CLK_ENABLE ()  __HAL_RCC_GPIOb_CLK_ENABLE ()
#define BUS_PPPn_SIGNALB_GPIO_PIN            GPIO_PIN_B
#define BUS_PPPn_SIGNALB_GPIO_AF             GPIO_AFb_PPPy
#define BUS_PPPn_CLK_ENABLE ()               __HAL_RCC_PPPn_CLK_ENABLE ()
#define BUS_PPPn_CLK_DISABLE ()              __HAL_RCC_PPPn_CLK_DISABLE ()
```

Example:

```c
#define BUS_SPI1                        SPI1
#define BUS_SPI1_CLK_ENABLE()           __HAL_RCC_SPI1_CLK_ENABLE()
#define BUS_SPI1_CLK_DISABLE()          __HAL_RCC_SPI1_CLK_DISABLE()
#define BUS_SPI1_SCK_GPIO_PIN           GPIO_PIN_5
#define BUS_SPI1_MISO_GPIO_PIN          GPIO_PIN_6
#define BUS_SPI1_MOSI_GPIO_PIN          GPIO_PIN_7
#define BUS_SPI1_SCK_GPIO_PORT          GPIOA
#define BUS_SPI1_MISO_GPIO_PORT         GPIOA
#define BUS_SPI1_MOSI_GPIO_PORT         GPIOA
#define BUS_SPI1_SCK_GPIO_AF            GPIO_AF5_SPI1
#define BUS_SPI1_MISO_GPIO_AF           GPIO_AF5_SPI1
#define BUS_SPI1_MOSI_GPIO_AF           GPIO_AF5_SPI1
```
Note: `BUS_PPPn_FEATUREx_GPIO_CLK_DISABLE()` macros are not defined as their usage is forbidden by the BSP as they can be shared with other firmware modules.

### 6.2.3 BSP_PPPn_DeInit

The `BSP_PPPn_DeInit()` function de-initializes the bus MSP and HAL parts.

```c
int32_t BSP_PPPn_DeInit(void)
{
    int32_t ret = BSP_ERROR_NONE;

    if (PPPnInitCounter > 0U)
    {
        if (--PPPnInitCounter == 0U)
        {
            #if (USE_HAL_PPP_REGISTER_CALLBACKS == 0)
            PPPn_MspDeInit(&hbus_pppn);
            #endif /* (USE_HAL_PPP_REGISTER_CALLBACKS == 0) */

            /* Init the I2C */
            if (HAL_PPP_DeInit(&hbus_pppn) != HAL_OK)
            {
                ret = BSP_ERROR_BUS_FAILURE;
            }
        }
    }

    return ret;
}
```
6.2.4 **BSP_PPPn_ReadReg{16}**

The **BSP_BUS_RegisterMspCallbacks** allows assigning the Msp callbacks to the bus handles.

```c
int32_t BSP_PPPn_RegisterMspCallbacks(BSP_PPP_Cb_t *Callback)
{
    int32_t ret = BSP_ERROR_NONE;

    __HAL_PPP_RESET_HANDLE_STATE(&hbus_pppn);

    /* Register MspInit/MspDeInit Callbacks */
    if(HAL_PPP_RegisterCallback(&hbus_pppn, HAL_PPP_MSPINIT_CB_ID, Callback->pMspBusInitCb) != HAL_OK)
    {
        ret = BSP_ERROR_PERIPH_FAILURE;
    }
    else if(HAL_PPP_RegisterCallback(&hbus_pppn, HAL_PPP_MSPDEINIT_CB_ID, Callback->pMspBusDeInitCb) != HAL_OK)
    {
        ret = BSP_ERROR_PERIPH_FAILURE;
    }
    else
    {
        IsPppnMspCbValid = 1U;
    }

    /* BSP status */
    return ret;
}
```

6.2.5 **BSP_PPPn_RegisterDefaultMspCallbacks**

The **BSP_BUS_RegisterDefaultMspCallbacks** allows assigning the default callbacks to the bus handles when the user has changed them.
```c
int32_t BSP_PPPn_RegisterDefaultMspCallbacks(void)
{
    int32_t ret = BSP_ERROR_NONE;

    __HAL_PPP_RESET_HANDLE_STATE(&hbus_pppn);

    /* Register default MspInit/MspDeInit Callback */
    if(HAL_PPP_RegisterCallback(&hbus_pppn, HAL_PPP_MSPINIT_CB_ID,
                                 PPPn_MspInit) != HAL_OK)
    {
        ret = BSP_ERROR_PERIPH_FAILURE;
    }
    else if(HAL_PPP_RegisterCallback(&hbus_pppn, HAL_PPP_MSPDEINIT_CB_ID,
                                      PPPn_MspDeInit) != HAL_OK)
    {
        ret = BSP_ERROR_PERIPH_FAILURE;
    }
    else
    {
        IsPppnMspCbValid = 1U;
    }

    /* BSP status */
    return ret;
}
```

**Note:**
The register callbacks statement and functions must be delimited by the `USE_HAL_PPP_REGISTER_CALLBACKS` conditional defined in the HAL configuration file.

```c
#if (USE_HAL_PPP_REGISTER_CALLBACKS == 1)
(....)
#endif /*
```
### 6.2.6 `BSP_PPPn_WriteReg{16}`

The `BSP_PPPn_WriteReg()` function permits to write a register of a specific slave (8/16 bits).

```c
int32_t BSP_PPPn_WriteReg(uint16_t Addr, uint16_t Reg, uint8_t *pData, uint16_t Length)
{
    int32_t ret = BSP_ERROR_NONE;
    uint32_t hal_error = HAL_OK;

    if(HAL_PPP_Transmit(&hbus_pppn, Addr, Reg, pData, Length, PPPn_TIMEOUT) != HAL_OK)
    {
        hal_error = HAL_PPP_GetError(&hbus_pppn);
        if( hal_error == HAL_PPP_ERROR_CODE#N )
        {
            ret = BSP_ERROR_BUS_ERROR_CODE#N;
        }
        if( hal_error == HAL_PPP_ERROR_CODE#M )
        {
            ret = BSP_ERROR_BUS_ERROR_CODE#M;
        }
        else
        {
            ret = BSP_ERROR_PERIPH_FAILURE;
        }
    }

    return ret;
}
```
6.2.7  **BSP_PPPn_ReadReg{16}**

The **BSP_PPPn_ReadReg** functions permit to read a register of a specific slave (8/16 bits).

```c
int32_t BSP_PPPn_ReadReg(uint16_t Addr, uint16_t Reg, uint8_t *pData, uint16_t Length)
{
    int32_t ret = BSP_ERROR_NONE;
    uint32_t hal_error = HAL_OK;

    if(HAL_PPP_Receive(&hbus_pppn, Addr, Reg, pData, Length, PPPn_TIMEOUT) != HAL_OK)
    {
        hal_error = HAL_PPP_GetError(&hbus_pppn);
        if( hal_error == HAL_PPP_ERROR_CODE#N )
        {
            ret = BSP_ERROR_BUS_ERROR_CODE#N;
        }
        if( hal_error == HAL_PPP_ERROR_CODE#M )
        {
            ret = BSP_ERROR_BUS_ERROR_CODE#M;
        }
        else
        {
            ret = BSP_ERROR_PERIPH_FAILURE;
        }
    }
    return ret;
}
```
6.2.8 **BSP_PPPn_Send**

The `BSP_PPPn_Send` function permits to transmit a specific amount of data to a specific slave.

```c
PPP_HandleTypeDef hbus_pppn;
int32_t BSP_PPPn_Send (uint8_t *pdata, uint16_t Length)
{
    int32_t ret = BSP_ERROR_BUS_FAILURE;
    if (HAL_PPP_Transmit (&hbus_pppn, pData, Length, PPPn_TIMEOUT) ==
        HAL_OK)
        {
            ret = Length;
        }
    return ret;
}
```

6.2.9 **BSP_PPPn_Recv**

The `BSP_PPPn_Recv` function permits to receive a specific amount of data from a slave.

```c
PPP_HandleTypeDef hbus_pppn;
int32_t BSP_PPPn_Recv (uint8_t *pdata, uint16_t Length)
{
    int32_t ret = BSP_ERROR_BUS_FAILURE;
    if (HAL_PPP_Receive (&hbus_pppn, pData, Length, PPPn_TIMEOUT) == HAL_OK)
    {
        ret = BSP_ERROR_NONE;
    }
    return ret;
}
```
6.2.10  **BSP_PPPn_SendRecv**

The **BSP_PPPn_SendRecv** function permits to send and receive simultaneously a specific amount of data from and to a slave.

```c
PPP_HandleTypeDef hbus_pppn; int32_t BSP_PPPn_SendRecv (uint8_t *pTxdata, uint8_t *pRxdata, uint16_t Length)
{
    int32_t ret = BSP_ERROR_BUS_FAILURE;
    if (HAL_PPP_SendReceive (&hbus_pppn, pTxData, pRxData, Length, PPPn_TIMEOUT) == HAL_OK)
    {
        ret = BSP_ERROR_NONE;
    }
    return ret;
}
```

6.2.11  **BSP_PPPn_IsReady**

```c
int32_t BSP_PPPn_IsReady(uint16_t DevAddr, uint32_t Trials)
{
    int32_t ret = BSP_ERROR_NONE;

    if(HAL_PPP_IsDeviceReady(&hbus_pppn, DevAddr, Trials, BUS_PPPn_POLL_TIMEOUT) != HAL_OK)
    {
        ret = BSP_ERROR_BUSY;
    }

    return ret;
}
```
### 6.3 BSP bus services

The following table summarizes the most common communication services used by Evaluation, Discovery and Nucleo boards.

**Table 6. Most common communication services**

<table>
<thead>

</tbody>
</table>
### 6.4 BSP SPI bus specific services

The sequence of the SPI initialization is provided as weak function that may be overridden by another configuration that can be generated by CubeMX.

The typical SPI initialization sequence is as follows:

```c
phspi->Init.Mode = SPI_MODE_MASTER;
phspi->Init.Direction = SPI_DIRECTION_2LINES;
phspi->Init.DataSize = SPI_DATASIZE_8BIT;
phspi->Init.CLKPolarity = SPI_POLARITY_LOW;
phspi->Init.CKPhase = SPI_PHASE_1EDGE;
phspi->Init.NSS = SPI_NSS_SOFT;
phspi->Init.BaudRatePrescaler = baudrate_presc;
phspi->Init.FirstBit = SPI_FIRSTBIT_MSB;
phspi->Init.TIMode = SPI_TIMODE_DISABLE;
phspi->Init.CRCCalculation = SPI_CRCCALCULATION_DISABLE;
phspi->Init.CRCPolynomial = 7;
if (HAL_SPI_Init(phspi)!= HAL_OK)
{
    ret = HAL_ERROR;
}
```

---

**Table 6. Most common communication services (continued)**

<table>
<thead>
<tr>
<th>I²C</th>
<th>SPI</th>
<th>UART</th>
</tr>
</thead>
<tbody>
<tr>
<td>int32_t</td>
<td>int32_t BSP_SPIn_RegisterDe</td>
<td>int32_t BSP_UARTn_RegisterDefaultMsp</td>
</tr>
<tr>
<td>BSP_I2Ch_RegisterDefaultMspCallbacks (void);</td>
<td>faultMspCallbacks (void);</td>
<td>Callbacks (void);</td>
</tr>
<tr>
<td>int32_t</td>
<td>int32_t BSP_SPIn_RegisterMspCallbacks</td>
<td>int32_t BSP_UARTn_RegisterMspCallbacks</td>
</tr>
<tr>
<td>BSP_I2Ch_RegisterMspCallbacks (BSP_I2C_Cb_t *Callbacks);</td>
<td>(BSP_SPI_Cb_t *Callbacks);</td>
<td>(BSP_UART_Cb_t *Callbacks);</td>
</tr>
</tbody>
</table>

**Note:** If the UART is used, the bus driver header file must add the following redefinition to inherit the different UART structures already defined in the common.

```c
#include "stm32Tnxx_nucleo.h"
...
#define BUS_UART_InitTypeDef MX_UART_InitTypeDef
```
The SPI baud-rate need to be isolated by the current system clock, a static service is added locally in the BSP BUS driver in order to calculate the prescaler from the wished independent baud rate expressed in Hz. This function is defined as follows:

```c
static uint32_t SPI_GetPrescaler(uint32_t clock_src_hz, uint32_t baudrate_mbps)
{
    uint32_t divisor = 0;
    uint32_t spi_clk = clock_src_hz;
    uint32_t presc = 0;
    static const uint32_t baudrate[] =
    {
        SPI_BAUDRATEPRESCALER_2,
        SPI_BAUDRATEPRESCALER_4,
        SPI_BAUDRATEPRESCALER_8,
        SPI_BAUDRATEPRESCALER_16,
        SPI_BAUDRATEPRESCALER_32,
        SPI_BAUDRATEPRESCALER_64,
        SPI_BAUDRATEPRESCALER_128,
        SPI_BAUDRATEPRESCALER_256,
    };
    while (spi_clk > baudrate_mbps)
    {
        presc = baudrate[divisor];
        if (++divisor > 7)
            break;
        spi_clk = (spi_clk >> 1);
    }
    return presc;
}
```

The MX_SPIn_Init() uses this function to configure the prescaler using only the baud rate as follows:

```c
MX_SPIn_Init (&hbus_spin, SPI_GetPrescaler (HAL_RCC_GetPCLK2Freq(),
BUS_SPIn_BAUDRATE))
```
While the `MX_SPIn_Init` is defined as follows:

```c
__weak HAL_StatusTypeDef MX_SPIn_Init(SPI_HandleTypeDef* phspi, uint32_t baudrate_presc)
{
    HAL_StatusTypeDef ret = HAL_OK;
    phspi->Init.Mode = SPI_MODE_MASTER;
    phspi->Init.Direction = SPI_DIRECTION_2LINES;
    phspi->Init.DataSize = SPI_DATASIZE_8BIT;
    phspi->Init.CLKPolarity = SPI_POLARITY_LOW;
    phspi->Init.CKPhase = SPI_PHASE_1EDGE;
    phspi->Init.NSS = SPI_NSS_SOFT;
    phspi->Init.BaudRatePrescaler = baudrate_presc;
    phspi->Init.FirstBit = SPI_FIRSTBIT_MSB;
    phspi->Init.TIMode = SPI_TIMODE_DISABLE;
    phspi->Init.CRCCalculation = SPI_CRCCALCULATION_DISABLE;
    phspi->Init.CRCPolynomial = 7;
    if (HAL_SPI_Init(phspi)!= HAL_OK)
    {
        ret = HAL_ERROR;
    }
    return ret;
}
```

Note that the baud rate is defined in the BSP bus driver header file as follows:

```c
#ifndef BUS_SPIn_BAUDRATE
#define BUS_SPIn_BAUDRATE 10000000U /* baud rate of SPIn = 10 Mbps*/
#endif
```

```c
// The user can always override the default SPIx baud rate value in the common BSP configuration file.
#define BUS_SPIn_BAUDRATE 16000000U /* baud rate of SPIn = 16 Mbps */
```
6.5  **BSP I²C bus specific services**

The sequence of the I²C initialization is provided as weak function that may be overridden by another configuration that can be generated by CubeMX.

The I²C initialization sequence depends on the I²C peripheral version, it can be as follows for I²C V1 (STM32F1xx, STM32F2xx, STM32F4xx and STM32L1xx):

```c
hi2c.Init.ClockSpeed = #I2Cn_FREQUENCY#;
hi2c.Init.DutyCycle = I2C_DUTYCYCLE_2;
hi2c.Init.OwnAddress1 = 0;
hi2c.Init.AddressingMode = I2C_ADDRESSINGMODE_7BIT;
hi2c.Init.DualAddressMode = I2C_DUALADDRESS_DISABLED;
hi2c.Init.OwnAddress2 = 0;
hi2c.Init.GeneralCallMode = I2C_GENERALCALL_DISABLED;
hi2c.Init.NoStretchMode = I2C_NOSTRETCH_DISABLED;
if (HAL_I2C_Init(hi2c)!= HAL_OK)
{
    ret = HAL_ERROR;
}
```

And for the I²C V2 (TM32F0xx, STM32F3xx, STM32F7xx, STM32L0xx and STM32L4xx) and I²C V3 (STM32H7x):

```c
hi2c->Init.ClockSpeed = #I2Cn_FREQUENCY#;
hi2c->Init.OwnAddress1 = 0;
hi2c->Init.AddressingMode = I2C_ADDRESSINGMODE_7BIT;
hi2c->Init.DualAddressMode = I2C_DUALADDRESS_DISABLE;
hi2c->Init.OwnAddress2 = 0;
hi2c->Init.OwnAddress2Masks = I2C_OA2_NOMASK;
hi2c->Init.GeneralCallMode = I2C_GENERALCALL_DISABLE;
hi2c->Init.NoStretchMode = I2C_NOSTRETCH_DISABLE;
if (HAL_I2C_Init(hi2c)!= HAL_OK)
{
    ret = HAL_ERROR;
}
else if (HAL_I2CEx_ConfigAnalogFilter(hi2c, I2C_ANALOGFILTER_DISABLE)!=
HAL_OK)
{
    ret = HAL_ERROR;
}
else if (HAL_I2CEx_ConfigDigitalFilter(hi2c, 0x02)! = HAL_OK)
{
    ret = HAL_ERROR;
}
```
In both I²C peripheral versions, the frequency must be defined in the BSP bus driver header file as follows:

```
#ifndef BUS_I2Cn_FREQUENCY
#define BUS_I2Cn_FREQUENCY 100000U /* Frequency of I2Cn = 100 kHz*/
#endif
```

The user can always override the default I2Cn baud rate value in the common BSP configuration file.

```
#define BUS_I2Cn_FREQUENCY 400000U /* Frequency of I2Cn = 400 kHz*/
```

For I²C peripheral version I²C v2 and I²C v3, the I²C frequency must be calculated using the system clock and the I²C control register based on the I²C timing. The BSP specification recommends insulating the bus frequency from the system configuration. Thus, a static service is added locally in the BSP BUS driver in order to calculate the timing field from I²C frequency expressed in Hz. This function is defined as follows:

```
#ifndef I2C_VALID_TIMING_NBR
#define I2C_VALID_TIMING_NBR 128U
#endif
#define I2C_SPEED_FREQ_STANDARD 0U /* 100 kHz */
#define I2C_SPEED_FREQ_FAST 1U /* 400 kHz */
#define I2C_SPEED_FREQ_FAST_PLUS 2U /* 1 MHz */
#define I2C_ANALOG_FILTER_DELAY_MIN 50U /* ns */
#define I2C_ANALOG_FILTER_DELAY_MAX 260U /* ns */
#define I2C_USE_ANALOG_FILTER 1U
#define I2C_DIGITAL_FILTER_COEF 0U
#define I2C_PRES_MAX 16U
#define I2C_SCLDEL_MAX 16U
#define I2C_SDADEL_MAX 16U
#define I2C_SCLH_MAX 256U
#define I2C_SCLL_MAX 256U
#define SEC2NSEC 1000000000UL

            uint32_t tscl_l = tafdel_min + dnf_delay + (2U * ti2cclk) + ((scll + 1U) * tpresc);
        }
    }
The MX_I2Cn_Init() function configures the timing using only the I²C frequency as follows:

```c
MX_I2Cn_Init (&hbus_i2cn, I2C_GetTiming ( SystemCoreClock , BUS_I2Cn_FREQUENCY ));
```
While the `MX_I2Cn_Init` is defined as follows:

```c
__weak HAL_StatusTypeDef MX_I2Cn_Init (I2C_HandleTypeDef *hi2c, uint32_t timing)
{
    HAL_StatusTypeDef ret = HAL_OK;
    hi2c->Init.Timing = timing;
    hi2c->Init.OwnAddress1 = 0;
    hi2c->Init.AddressingMode = I2C_ADDRESSINGMODE_7BIT;
    hi2c->Init.DualAddressMode = I2C_DUALADDRESS_DISABLE;
    hi2c->Init.OwnAddress2 = 0;
    hi2c->Init.OwnAddress2Masks = I2C_OA2_NOMASK;
    hi2c->Init.GeneralCallMode = I2C_GENERALCALL_DISABLE;
    hi2c->Init.NoStretchMode = I2C_NOSTRETCH_DISABLE;
    if (HAL_I2C_Init(hi2c) != HAL_OK)
    {
        ret = HAL_ERROR;
    }
    else
    {
        uint32_t analog_filter;

        analog_filter = (I2C_USE_ANALOG_FILTER == 1U) ?
            I2C_ANALOGFILTER_ENABLE : I2C_ANALOGFILTER_DISABLE;
        if (HAL_I2CEx_ConfigAnalogFilter(hI2c, analog_filter) != HAL_OK)
        {
            ret = HAL_ERROR;
        }
        else
        {
            if (HAL_I2CEx_ConfigDigitalFilter(hI2c, I2C_DIGITAL_FILTER_COEF) !=
            HAL_OK)
            {
                ret = HAL_ERROR;
            }
        }
    }
    return ret;
}
```

**Note:** If the user needs to use different I²C timing configuration or system clock, he can simply override the weak `MX_I2Cn_Init()` function by fixing the timing parameters in the user files as follows:
HAL_StatusTypeDef MX_I2Cn_Init (I2C_HandleTypeDef *hi2c, uint32_t timing)
{
    UNUSED (timing);
    HAL_StatusTypeDef ret = HAL_OK;

    hi2c->Init.Timing = TIMING;
    hi2c->Init.OwnAddress1 = 0;
    hi2c->Init.AddressingMode = I2C_ADDRESSINGMODE_7BIT;
    hi2c->Init.DualAddressMode = I2C_DUALADDRESS_DISABLE;
    hi2c->Init.OwnAddress2 = 0;
    hi2c->Init.OwnAddress2Masks = I2C_OA2_NOMASK;
    hi2c->Init.GeneralCallMode = I2C_GENERALCALL_DISABLE;
    hi2c->Init.NoStretchMode = I2C_NOSTRETCH_DISABLE;
    if (HAL_I2C_Init(hi2c) != HAL_OK)
    {
        ret = HAL_ERROR;
    }
    else if (HAL_I2CEx_ConfigAnalogFilter(hi2c, I2C_ANALOGFILTER_DISABLE) != HAL_OK)
    {
        ret = HAL_ERROR;
    }
    else
    {
        if (HAL_I2CEx_ConfigDigitalFilter(hi2c, 0x02) != HAL_OK)
        {
            ret = HAL_ERROR;
        }
    }

    return ret;
}
6.6 **BSP bus multi configuration**

The bus configuration can be different following the attached components requirements. In this case, different configurations are provided by several elementary bus initialization functions following the required configurations.

```c
PPP_HandleTypeDef hbus_pppn;
Int32_t BSP_PPPn_InitA (void)
{
    int32_t ret = BSP_ERROR_BUS_FAILURE;
    hbus_pppn.Instance = BSP_PPPn;

    if (PPPnInitCounter++ == 0U)
    {
        if (HAL_PPP_GetState (&hbus_pppn) == HAL_PPP_STATE_RESET)
        {
            if (HAL_PPP_GetState (&hbus_pppn) == HAL_PPP_STATE_RESET)
            {
                if (HAL_PPP_GetState (&hbus_pppn) == HAL_PPP_STATE_RESET)
                {
                    return BSP_ERROR_BUS_FAILURE;
                }
            }
        }
    }

    if (MX_PPPx_InitA (&hbus_pppn) != HAL_OK)
    {
        ret = BSP_ERROR_BUS_FAILURE;
    }

    return ret;
}

__weak HAL_StatusTypeDef MX_PPPx_InitA (PPP_HandleTypeDef *hppp)
{
    hppp->Init.param1 = PARAM#1A;
    (...
    hppp->Init.ParamN = PARAM#NA;
    return HAL_PPP_Init (hppp);
}

int32_t BSP_PPPn_InitB (void)
{
    int32_t ret = BSP_ERROR_BUS_FAILURE;
    hbus_pppn.Instance = BSP_PPPn;
```
Note: 1 The bus multi-configuration must be avoided, when a common configuration can be found without performance loss. Example if two component require two different I2C frequencies, the lowest frequency can be used if it is accepted by the two components.

Note: 2 The different configuration must be used by the different Read/Write functions to select the right configuration for each component.

6.7 BSP bus customization

The different bus services provided within the BSP drivers are based on polling model, IT and DMA are not supported natively. Moreover, these bus services do not embed internally concurrent access protection mechanism; in case of a busy bus, the BSP bus services return simply the BSP_ERROR_BUSY error that must be managed by the upper layers.

If the bus instance used by a component is not supported by the native mother board or specific bus services are required (interrupt model, DMA) or there is a need to manage concurrent access to bus through mutexes or semaphores, the user must create a bus driver extension file to add the required services in the application folders. Note that for
Nucleo bus driver, no additional bus extension file is required as it is always an application file.

Note: 1 When one of the BSP function needs to be overridden, the native BSP bus driver must be removed from the project setting and the extension file must be used instead without the _ex suffix.

Note: 2 The bus driver extension header file must be included in the board configuration file.
7 BSP component driver

The component driver is the interface for an external device on the board and it is not directly dependent of the HAL. The component driver provides specific unitary services and can be used by any board integrating this external component.

Figure 12. BSP driver repository: component drivers
The component drivers, except memory ones, are split into two drivers set:

- **Component register drivers** (*nnnxxxx_reg.c/.h*): the register file contains the defined component registers, the low layer register Write and Read operations, the unitary functions and the context structure. This file is completely platform independent and may be used with any environment.

- **Component core drivers** (*nnnxxxx.c/.h*): this file contains the component high-level functions based on the unitary register functions.

### 7.1 BSP component register file

The component register file is named always as follows: *nnnxxxx_reg.c* or *nnnxxxx_reg.h*, where nnnxxx is the component part number. This driver provides the set of unitary/elementary functions to set and get the different component registers.

In addition to the functional set/get elementary functions, the component register file must provide the generic read/write functions and the different component register and bit definition.
7.1.1 Component register header file

The component register header file (nnnxxxx_reg.h) looks like:

```c
/* Component Registers definition */
#define NNNXXXX_REG_NAME1 0X06
#define NNNXXXX_REG_NAME2 0X07
#define NNNXXXX_REG_NAME3 0X08
#define NNNXXXX_REG_NAME4 0X09
#define NNNXXXX_REG_NAME5 0X0A
(...)

/* Component Context structure */
typedef int32_t (*NNNXXXX_Write_Func)(void *, uint8_t, uint8_t*,
                                   uint16_t);
typedef int32_t (*NNNXXXX_Read_Func) (void *, uint8_t, uint8_t*,
                                 uint16_t);
typedef struct
  {
    NNNXXXX_Write_Func WriteReg;
    NNNXXXX_Read_Func  ReadReg;
    void *handle;
  } nnnxxxx_ctx_t;

/* Prototypes of Read/Write component functions */
int32_t nnnxxxx_write_reg(nnnxxxx_ctx_t *ctx, uint16_t Reg, uint8_t *Data,
                         uint16_t len);
int32_t nnnxxxx_read_reg(nnnxxxx_ctx_t *ctx, uint16_t Reg, uint8_t *Data,
                         uint16_t len);

/* Component Register's bit definition */
#define NNNXXXX_ITEM_BIT_MASK MASK_VALUE
#define NNNXXXX_ITEM_BIT_POSITION POSITION_VALUE
(...)
/* Prototypes of component elementary functions */
int32_t nnnxxxx_set_item(nnnxxxx_ctx_t *ctx, NNNXXXX_FEATURE_t *value);
int32_t nnnxxxx_get_item(nnnxxxx_ctx_t *ctx, NNNXXXX_FEATURE_t *value);
(...)
```

**Note:** The context structure is always the first argument of the register driver unitary functions. It is a data object required to link the register and core component drivers smoothly and it is always named `nnnxxxx_ctx_t` and defined as above.

7.1.2 Component register source file

In the component register source file (nnnxxxx_reg.c), the Read/Write and elementary functions are implemented as follows:
int32_t nnnxxxx_write_reg(nnnxxxx_ctx_t *ctx, uint16_t reg, uint8_t *pdata, uint16_t len)
{
    return ctx->WriteReg(ctx->handle, Reg, pdata, len);
}

int32_t nnnxxxx_read_reg(nnnxxxx_ctx_t *ctx, uint16_t reg, uint8_t* pdata, uint16_t len)
{
    return ctx->ReadReg(ctx->handle, reg, pdata, len);
}

int32_t nnnxxxx_set_item (nnnxxxx_ctx_t *ctx, uint8_t value)
{
    uint8_t tmp;
    if (nnnxxxx_read_reg(ctx, NNNXXXX_ITEM_REG, &tmp, 1))
        return NNNXXXX_ERROR;
    tmp &= ~ NNNXXXX_ITEM_BIT_MASK;
    tmp |= value << NNNXXXX_ITEM_BIT_POSITION;
    if (nnnxxxx_write_reg(ctx, NNNXXXX_ITEM_REG, &tmp, 1))
        return NNNXXXX_ERROR;
    return NNNXXXX_OK;
}

int32_t nnnxxxx_get_item (nnnxxxx_ctx_t *ctx, uint8_t *value)
{
    if (nnnxxxx_read_reg(ctx, NNNXXXX_ITEM_REG, (uint8_t *)&value, 1))
        return NNNXXXX_ERROR;
    *value &= NNNXXXX_ITEM_BIT_MASK;
    *value = *value >> NNNXXXX_ITEM_BIT_POSITION;
    return NNNXXXX_OK;
}

Note: The exported types, the functions names and their parameters must be defined in lower case to be compatible with Linux environment.
7.2 BSP component core drivers

The component core drivers provide the high-level functions built on top of the component register drivers, it is the main application, middleware and BSP class interface. The component core drivers provide the main component object structure and the different literals associated with enumeration types, in addition to the high-level component function and the class structure.

7.2.1 Component core header file

The component header file provides the component object handle structure definition, the IO structure, the driver structure and the component functions.

```c
#ifndef NNNXXXX_H
#define NNNXXXX_H
#ifdef __cplusplus
extern "C" {
#endif
(...)
typedef struct
{
(...)
} NNNXXXX_Object_t;

typedef struct
{
(...)
} NNNXXXX_IO_t;

typedef struct
{
(...)
} NNNXXXX_Drv_t;
(...)
int32_t (NNNXXXX_Function (NNNXXXX_Object_t * pObj, DRV_ARGS)
(...)
#ifdef __cplusplus
}
#endif
#endif /* NNNXXXX_H */
```
Object structure

The component object structure is used to allow instantiating a component driver to handle several identical components on same hardware platform (board/extension board) and also as a global storage for internal parameters exchanged between the driver modules and functions.

The structure type definition is declared. A typical component object structure is defined as follows:

```c
typedef struct
{
    NNNXXX_IO_t IO;
    nnnxxxx_ctx_t Ctx;
    uint32_t IsInitialized;
    uint32_t Params#1;
    (...)
    uint32_t Params#N;
} NNNXXXX_Object_t;
```

Refer also to Table 7:

<table>
<thead>
<tr>
<th>Object field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IO</td>
<td>IO bus structure</td>
</tr>
<tr>
<td>Ctx</td>
<td>The register driver context structure</td>
</tr>
<tr>
<td>IsInitialized</td>
<td>Set to 1 if the component has already initialized (Must be set during the first component Init call)</td>
</tr>
<tr>
<td>Params#N</td>
<td>Common class component private parameters</td>
</tr>
</tbody>
</table>
IO structure

The IO structure provides the main IO mechanism to link a component to the board that this later is attached to. The IO functions depend on each component and are defined as follows:

```c
typedef int32_t (*NNNXXXX_Init_Func) (void);
typedef int32_t (*NNNXXXX_DeInit_Func) (void);
typedef int32_t (*NNNXXXX_GetTick_Func) (void);
typedef int32_t (*NNNXXXX_WriteReg_Func)(uint16_t, uint16_t, uint8_t*, uint16_t);
typedef int32_t (*NNNXXXX_ReadReg_Func) (uint16_t, uint16_t, uint8_t*, uint16_t);
typedef int32_t (*NNNXXXX_Recv_Func) (uint8_t*, uint16_t);
typedef int32_t (*NNNXXXX_Send_Func) (uint8_t*, uint16_t);
typedef int32_t (*NNNXXXX_SendRecv_Func)(uint8_t*, uint8_t*, uint16_t);
typedef struct
{
    NNNXXXX_Init_Func        Init;
    NNNXXXX_DeInit_Func      DeInit;
    uint16_t                 Address;
    NNNXXXX_WriteReg_Func    WriteReg;
    NNNXXXX_ReadReg_Func     ReadReg;
    NNNXXXX_Send_Func        Write;
    NNNXXXX_Recv_Func        Read;
    NNNXXXX_SendRecv_Func    SendRecv;
    NNNXXXX_GetTick_Func     GetTick;
}NNNXXXX_IO_t;
```
The members of the NNNXXXX_IO_t structure are defined as described in Table 8:

### Table 8. BSP component drivers: IO structure(1)

<table>
<thead>
<tr>
<th>Object field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Address</td>
<td>Device address (may be useless in SPI case)</td>
</tr>
<tr>
<td>Init</td>
<td>Initialize the bus</td>
</tr>
<tr>
<td>DeInit</td>
<td>De-initialize the bus (without modifying the MSP)</td>
</tr>
<tr>
<td>ReadReg</td>
<td>Read specific component registers</td>
</tr>
<tr>
<td>WriteReg</td>
<td>Write specific component registers</td>
</tr>
<tr>
<td>Recv</td>
<td>Receive multiple data</td>
</tr>
<tr>
<td>Send</td>
<td>Send multiple data</td>
</tr>
<tr>
<td>SendRecv</td>
<td>Send and receive multiple data simultaneously (Full duplex)</td>

<td>Return time stamp (may be used for delays and timeout computation)</td>
</tr>
</tbody>
</table>

1. The IO operation functions list highlighted in gray in Table 8 depend on the component requirements.

Here are examples of components IO structure:

1. IO structure for LSM6SDL MEMS component

```c
typedef int32_t (*LSM6DSL_Init_Func) (void);
typedef int32_t (*LSM6DSL_DeInit_Func) (void);
typedef int32_t (*LSM6DSL_GetTick_Func) (void);
typedef int32_t (*LSM6DSL_WriteReg_Func)(uint16_t, uint16_t, uint8_t*, uint16_t);
typedef int32_t (*LSM6DSL_ReadReg_Func) (uint16_t, uint16_t, uint8_t*, uint16_t);
typedef struct
{
    LSM6DSL_Init_Func Init;
    LSM6DSL_DeInit_Func DeInit;
    uint16_t Address;
    LSM6DSL_WriteReg_Func WriteReg;
    LSM6DSL_ReadReg_Func ReadReg;
    LSM6DSL_GetTick_Func GetTick;
} LSM6DSL_IO_t;
```
2. IO structure for ESP8266 WiFi component

```c
typedef int8_t (*ESP8266_Init_Func)(void);
typedef int8_t (*ESP8266_DeInit_Func)(void);
typedef int16_t (*ESP8266_Send_Func)(uint8_t *, uint16_t len, uint32_t);
typedef int16_t (*ESP8266_Receive_Func)(uint8_t *, uint16_t len,
                                 uint32_t);
typedef int32_t (*ESP8266_GetTick_Func)(void);

typedef struct
{
    ESP8266_Init_Func Init;
    ESP8266_DeInit_Func DeInit;
    ESP8266_GetTick_Func GetTick;
    ESP8266_Send_Func Send;
    ESP8266_Receive_Func Receive;
} ESP8266_IO_t;
```

Component driver structure

The component driver structure is an object that holds the most common services and elementary functions offered by the external component for a given class.

A typical component driver structure is defined as follows:

```c
typedef struct
{
    int32_t (* Init) (NNNXXXX_Object_t *, DRV_ARGS);
    int32_t (* DeInit) (NNNXXXX_Object_t *, DRV_ARGS);
    int32_t (* Funct1) (NNNXXXX_Object_t *, DRV_ARGS);
    (...)
    int32_t (* FunctN) (NNNXXXX_Object_t *, DRV_ARGS);
} NNNXXXX_Drv_t;
```
Component driver APIs

The component drivers, contrary to the class driver structure, must provide all the elementary functions that cover all the functionalities and the features that the component may provide. In addition to the component specific functions:

- uint32_t NNNXXXX_Init (NNNXXXX_Object_t* Obj, DRV_ARGS);
- uint32_t NNNXXXX_DeInit (NNNXXXX_Object_t* Obj, DRV_ARGS);
- uint32_t NNNXXXX_Function#x (NNNXXXX_Object_t* Obj, DRV_ARGS);
- uint32_t NNNXXXX_RegisterBusIO (NNNXXXX_Object_t* Obj, NNNXXXX_IO_t *io);
- uint32_t NNNXXXX_ReadID (NNNXXXX_Object_t* Obj, uint32_t* ID);

Each component must provide the following functions:

- uint32_t NNNXXXX_Init (NNNXXXX_Object_t* Obj, DRV_ARGS);
- uint32_t NNNXXXX_DeInit (NNNXXXX_Object_t* Obj, DRV_ARGS);
- uint32_t NNNXXXX_Function#x (NNNXXXX_Object_t* Obj, DRV_ARGS);

Note: The ReadID API may be omitted if the component does not support ID feature.
7.2.2 Component core source file

The component source file provides the component functions’ implementation, the IO registration mechanism, the wrapper functions and the linking of core drivers to register ones.

Wrapper functions

The Write and Read APIs in the component register driver are defined by the component architecture itself and do not depend on the core driver context.

These operations are based on a global component context to fit any platform requirements:

typedef struct
{
    NNNXXX_Write_Func   WriteReg;
    NNNXXX_Read_Func    ReadReg;
    void                  *handle;
} nnnxxxx_ctx_t;

This context must be linked to the component core drivers to fit the board HW constraints. This is insured during the registration phase by calling NNNXXXX_RegisterBusIO API.

The Read and Write functions in the core drivers are more linked to the bus driver IO operations prototypes and the class hardware configuration.

The core driver must use wrapper functions to adapt the IO operation with those from the component register driver.

A typical implementation of wrapper functions is as follows:

static int32_t ReadRegWrap(void *handle, uint8_t Reg, uint8_t* pData, uint16_t len)
{
    NNNXXXX_Object_t *pObj = (NNNXXXX_Object_t *)handle;
    return pObj->IO.ReadReg(pObj->IO.Address, Reg, pData, len);
}

static int32_t WriteRegWrap(void *handle, uint8_t Reg, uint8_t* pData, uint16_t len)
{
    NNNXXXX_Object_t *pObj = (NNNXXXX_Object_t *)handle;
    return pObj->IO.WriteReg(pObj->IO.Address, Reg, pData, len);
}

Register IO API

The NNNXXXX_RegisterBusIO in the component core driver permits to connect a component device to the IO bus defined by the board. It adds a mechanism to link the wrap Write and Read functions and is responsible of initializing the used bus.
Typical `NNNXXXX_RegisterBusIO` implementations is as follows:

```c
uint32_t NNNXXXX_RegisterBusIO (NNNXXXX_Object_t *Obj, NNNXXXX_IO_t *io) {
    if (Obj == NULL) {
        return NNNXXXX_ERROR;
    }

    Obj->IO.Address     = io->Address;
    Obj->IO.Init        = io->Init;
    Obj->IO.DeInit      = io->DeInit;
    Obj->IO.WriteReg    = io->WriteReg;  // Connecting component to IO bus
    Obj->IO.ReadReg     = io->ReadReg;
    Obj->IO.GetTick     = io->GetTick;

    pObj->Ctx.ReadReg   = ReadRegWrap;
    pObj->Ctx.WriteReg  = WriteRegWrap;  // Wrapping mechanism
    pObj->Ctx.handle    = pObj;

    if (pObj->IO.Init) {
        return pObj->IO.Init();  // Bus Initialization
    } else {
        return NNNXXXX_ERROR;
    }
}
```
7.3 Registering components

The IO operations functions are required by the components drivers to have access to transport services of the bus to which they are linked.

Most of the component IO operations are based on the generic bus services exported by the file boardname_bus.h. They can be directly assigned to the component IO structure as shown in the following listing:

```c
NNNXXXX_Object_t ComponentObj;
void MyFunction (void)
{
  (...)
  NNNXXXX_IO_t IO;
  /* Assign the component IO operations */
  IO.DevAddr = DevAddr;
  IO.Init = PPPn_Init;
  IO.ReadReg = PPPn_ReadReg;
  IO.WriteReg = PPPn_WriteReg;
  IO.GetTick = BSP_GetTick;
  NNNXXXX_RegisterBusIO (&ComponentObj, &IO);
  (...)
  NNNXXXX_Init (&ComponentObj, &Init);
}
```

However, some components may need more control signals or need a different IO operations function prototypes, in this case, the component IO operations need to be wrapped to the native BSP bus functions through dedicated functions that are implemented in the class driver or the middleware interface file in case the component services are directly called from middleware.

```c
NNNXXXX_Object_t ComponentObj;
static int32_t CLASS_BUS_Init(void)
{
  GPIO_InitTypeDef GPIO_Init;
  int32_t ret = BSP_ERROR_UNKNOWN_FAILURE;

  if (BSP_PPPn_Init() < 0);
  {
    __HAL_RCC_GPIOy_CLK_ENABLE();
    GPIO_Init.Pin = GPIO_PIN_x;
    (...)
    HAL_GPIO_Init (GPIOy, &GPIO_Init);
    ret = BSP_ERROR_NONE;
  }
  return ret;
}
```
```c
static int32_t CLASS_BUS_DeInit(void)
{
    int32_t ret = BSP_ERROR_UNKNOWN_FAILURE;
    if(BSP_ PPPn_DeInit() < 0);
    {
        HAL_GPIO_DeInit(GPIOy, GPIO_PIN_x);
        ret = BSP_ERROR_NONE;
    }
    return ret;
}

static int32_t CLASS_BUS_WriteReg(uint16_t Addr, uint16_t Reg, uint8_t *pdata, uint16_t len )
{
    int32_t ret = BSP_ERROR_UNKNOWN_FAILURE;
    /* Control signal Enable */
    HAL_GPIO_WritePin(GPIOy, GPIO_PIN_x, GPIO_PIN_RESET);
    /* Format Write data */
    (…)
    if(BSP_PPPn_SendRecv(TxBuffer, RxBuffer, (len + 1)) < 0);
    {
        ret = BSP_ERROR_NONE;
    }
    /* Control signal Disable */
    HAL_GPIO_WritePin(GPIOy, GPIO_PIN_x, GPIO_PIN_SET);
    return ret;
}

static int32_t CLASS_BUS_ReadReg(uint16_t Addr, uint16_t Reg, uint8_t *pdata, uint16_t len )
{
    int32_t ret = BSP_ERROR_UNKNOWN_FAILURE;
    /* Control signal Enable */
    HAL_GPIO_WritePin(GPIOy, GPIO_PIN_x, GPIO_PIN_RESET);
    /* Format Read data */
    (…)
    if(BSP_PPPn_SendRecv(TxBuffer, RxBuffer, (len + 1)) < 0);
    {
        ret = BSP_ERROR_NONE;
    }
    /* Control signal Disable */
    HAL_GPIO_WritePin(GPIOy, GPIO_PIN_x, GPIO_PIN_SET);
    return ret;
}
```
When several components share the same buses, it is highly recommended that dedicated
buses availability and control mechanisms must be used. For example, in case of I²C,
BSP_PPPn_IsReady function must be used before performing any IO operations. This is
already handled in the HAL services internally and if the bus is used, a HAL error is
returned. However, in case of LL, the check on the bus state must be added.
7.4 **BSP component class drivers**

The class header files are located under BSP/Components/Common folder (refer to Figure 6. BSP driver repository: common class headers).

The class header file provides the common class services in the class structure and must only include the ‘stdint.h’ file as the component does not depends on any STM32 platforms neither a specific board.

```c
#ifndef __CLASS_H
#define __CLASS_H
#ifdef __cplusplus
extern "C"
#endif
#include <stdint.h>

typedef struct
{
    int32_t (*Init) (void *, __ARGS_);
    int32_t (*DeInit) (void *, __ARGS_);
    int32_t (*Funct1) (void *, __ARGS_);
    (…)
    int32_t (*FunctN) (void *, __ARGS_);
} CLASS_Drv_t;

#ifdef __cplusplus
}
#endif
#endif /* __CLASS_H */
```
7.5  BSP memory component drivers

The memory component driver is the interface for an external device on the board and it is, contrary to standard components, dependent of the HAL/LL. The component driver provides specific unitary services and may be used by any board integrating this external component.

Figure 14. BSP driver repository: memory component drivers
The memory component driver is simply calling to the main STM32 peripheral, which is linked to, and is providing a set of unitary functions corresponding to the different commands processes required by the memory part number.

The memory component driver may call directly the HAL services (only the common services) and the platform must be selected in the component driver configuration file.

From BSP class driver, the services of the memory component are called in the same way as for the BSP Init model 2) single controller component P/N.

The component requires for the HAL the basic HAL services to build the command structure and execute it. The HAL services required from the component are basically to send command, send and receive data and optionally get status or poll for operation completion depending on the data stage required for each command (No Data, Data IN or Data OUT). As the memory component needs only to execute specific commands, no Init function is required, the memory initialization is done through the STM32 memory peripheral.
Typical example for this memory component architecture is the QSPI; examples of commands are as follows:

```c
int32_t MX25L512_Read4BytesAddr (void *Ctx, uint8_t* pData, uint32_t ReadAddr, uint32_t Size)
{
    QSPI_CommandTypeDef cmd;

    cmd.InstructionMode = QSPI_INSTRUCTION_4_LINES;
    cmd.Instruction = MX25L512_QPI_READ_4_BYTE_ADDR_CMD;
    cmd.AddressMode = QSPI_ADDRESS_4_LINES;
    cmd.AddressSize = QSPI_ADDRESS_32_BITS;
    cmd.Address = ReadAddr;
    (...)

    if (HAL_QSPI_Command(Ctx, &cmd, HAL_QPSI_TIMEOUT_DEFAULT_VALUE) != HAL_OK)
    {
        return MX25L512_ERROR;
    }

    if (pData && !Size)
    {
        /* Reception of the data */
        if (HAL_QSPI_Receive(Ctx, pData, HAL_QPSI_TIMEOUT_DEFAULT_VALUE) != HAL_OK)
        {
            return MX25L512_ERROR;
        }
    }
    return MX25L512_ERROR;
};
```

The memory command driver needs only to provide the unitary function and no common memory class structure is required.
If there is no command to return the characteristics of the memory device (capacity, block/sector size), the driver must provide a function called `NNNN_GetFlashInfo()`. Here is an example:

```c
int32_t MX25L512_GetFlashInfo (MX25L512_Info_t *pInfo)
{
    /* Configure the structure with the memory configuration */
    pInfo->FlashSize          = MX25L512_FLASH_SIZE;
    pInfo->EraseSectorSize    = MX25L512_SUBSECTOR_SIZE;
    pInfo->EraseSectorsNumber = (MX25L512_FLASH_SIZE/MX25L512_SUBSECTOR_SIZE);
    pInfo->ProgPageSize       = MX25L512_PAGE_SIZE;
    pInfo->ProgPagesNumber    = (MX25L512_FLASH_SIZE/MX25L512_PAGE_SIZE);
    return MX25L512_ERROR;
};
```

However the command set and response masks and values must be defined in the memory driver as defines.

```c
/* Identification Operations */
#define MX25L512_ReadIDs_CMD                        0x9F
#define MX25L512_MULTIPLE_IO_READ_ID_CMD            0xAF
#define MX25L512_READ_SERIAL_FLASH_DISCO_PARAM_CMD  0x5A

/* Read Operations */
#define MX25L512_READ_CMD                           0x03
#define MX25L512_Read4BytesAddr_CMD                 0x13
#define MX25L512_FAST_READ_CMD                      0x0B
#define MX25L512_FAST_READ_DTR_CMD                  0x0D
#define MX25L512_FAST_READ_4_BYTE_ADDR_CMD          0x0C
#define MX25L512_FAST_READ_4_BYTE_ADDR_DTR_CMD      0x0E
```

The memory component driver header file must include the platform in use as follows:

```c
#ifndef MX25L512_CONF_H
#define MX25L512_CONF_H
(...)
#include "stm32yyxx_hal.h"
(...)
#endif /* MX25L512_CONF_H */
```
7.6 **BSP component upgrade**

This covers the case of active components built with internal MCU that are upgradeable. The drivers must consequently be associated to a specific firmware version and its container folder must integrate the binaries and the documentations relative to the procedure to perform the firmware upgrade.

The rationale behind this architecture approach is that the features offered by the component may be changed depending on the firmware version.

An example of patchable component folder is shown *Figure 16*.

*Figure 16. Patchable component folder example*
8 BSP class driver

The class drivers provide a set of high-level functions for available classes, such as LCD, AUDIO or Touchscreen, for each board.

Figure 17. BSP driver repository: function drivers

Each class driver may provide three sets of functions:
1. Generic functions: common functions that must be provided by all the drivers for a given class for all the supported board
2. Specific functions: Advanced functions that are relative to specific features in the STM32 or the components available on the boards
3. Extended functions: Advanced services that may extend generic functions to provide more control on component drivers offering advanced features. The extended functions end always with the Ex suffix.
8.1 Generic common functions

The generic common functions provide most common services for a specific class and not depending on specific core or components features. These services are mandatory and must always be provided for all the BSP drivers of the same class.

Even the generic services are specific for each class driver, they must provide the following common services for all classes:

### Table 9. BSP class drivers: generic common functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Example</th>

</tbody>
</table>

8.1.1 BSP_CLASS_Init

This function initializes the main peripheral of each class, for example I2S for audio and LTDC for Display, the associated Msp (GPIO, DMA, NVIC, Clock) and eventually the external components by linking the IO operation functions pointer and initializing the component itself by setting its internal registers to the right configuration.

Typically the BSP_CLASS_Init function, has several implementation scenarios depending on external component type (controller, memory), whether the board may use different components part number and if the external component (if used) may be identified dynamically by a single identifier through a ReadID like function.

**Class with no external component**

This is typically the use case when the STM32 is able to get internally the configuration from an external device and communicate with the device based on a standardized protocol. The BSP_CLASS_Init implementation is as follows:
uint32_t IsPppMspCbValid = 0;
int32_t BSP_CLASS_Init (uint32_t Instance, BSP_CLASS_Init_t *ClassInit)
{
    NNNXXX_Init_t Init;

    (...)
#if (USE_HAL_PPP_REGISTER_CALLBACKS == 0)
    /* Init the PPP Msp */
    PPP_MspInit(&hppp);
#else
    if (IsPppMspCbValid == 0)
    {
        BSP_CLASS_DefaultMspCallbacks (Instance);
    }
#endif
if (MX_PPPx_Init(&hclass_ppp, &Init) != HAL_OK)
{
    return BSP_ERROR_PERIPH_FAILURE;
}
if (MX_PPPx_ClockConfig(&hclass_ppp, Clock)!= HAL_OK)
{
    return BSP_ERROR_CLOCK_FAILURE;
}
return BSP_ERROR_NONE;

Single controller component P/N

This is typically the use case when a STM32 peripheral requires an external controller that drives different signals and different data format; example: LCD controller, Audio CODEC but all board versions have always the same component reference.
Multiple controller component P/N without ID:

This is typically the use case when a STM32 peripheral requires an external controller that drives different signals and different data formats; example: LCD controller, Audio CODEC. The board versions may have different references of components but the components don’t return IDs.
```c
#ifdef BSP_CLASS_USE_NNNXXXXA
    NNNXXXX_A_Object_t ComponentObj;
#else
    #ifdef BSP_CLASS_USE_NNNXXXXB
        NNNXXXX_B_Object_t ComponentObj;
    #endif
#endif

CLASS_DrvTypeDef      *Class_Drv;
void                  *Class_CompObj;

uint32_t BSP_CLASS_Init (uint32_t Instance, BSP_CLASS_Init_t *ClassInit)
{
    (…)
#ifdef BSP_CLASS_USE_NNNXXXXA
    if (NNNXXXX_A_Probe((void *)&CodecAddress, ClassInit))
#else
    #ifdef BSP_CLASS_USE_NNNXXXXB
        if (NNNXXXX_B_Probe((void *)&CodecAddress, ClassInit))
    #endif
#endif
{
    return BSP_ERROR_UNKNOWN_COMPONENT;
}
(…)
}

static int32_t NNNXXXX_A_Probe(void *Ctx, BSP_CLASS_Init_t *ClassInit)
{
    static NNNXXXX_A_Object_t   NNNXXXX_Obj;
    NNNXXXX_A_IO_t           IO;
    NNNXXXX_A_Init_t            Init;

    /* Configure the component */
    IO.DevAddr       = DevAddr;
    IO.DevAddr    = DevAddr;
    IO.Init       = BUS#N_Init;
    IO.ReadReg    = BUS#N_ReadReg;
    IO.WriteReg   = BUS#N_WriteReg;
    IO.GetTick    = BSP_GetTick;
    NNNXXXX_A_RegisterBusIO (&NNNXXXX_Obj, &IO);

    (…)
    If (NNNXXXX_A_Init (&NNNXXXX_Obj, &Init) ==0)
{
    Class_Drv = (CLASS_Drv_t *) &NNNXXXX_drv;
```
Multiple controller component P/N with ID

This is typically the use case when a STM32 peripheral requires an external controller that drives different signals and different data format; example: LCD controller, Audio CODEC. The board versions may have different references of components but the components don’t return IDs.
NNNXXXX_A_Object_t ComponentObjA;
NNNXXXX_B_Object_t ComponentObjB;
CLASS_DrvTypeDef *Class_Drv;
void *Class_CompObj;

uint32_t BSP_CLASS_Init (BSP_CLASS_Init_t *ClassInit)
{
    (…)
    if (NNNXXXX_A_Probe((void *)&CodecAddress, ClassInit))
    {
        return BSP_ERROR_UNKNOWN_COMPONENT;
    }
    else if (NNNXXXX_B_Probe((void *)&CodecAddress, ClassInit))
    {
        return BSP_ERROR_UNKNOWN_COMPONENT;
    }
    (…)
}

static int32_t NNNXXXX_A_Probe(void *Ctx, BSP_CLASS_Init_t *ClassInit)
{
    static NNNXXXX_A_Object_t NNNXXXX_Obj;
    NNNXXXX_A_IO_t IO;
    NNNXXXX_A_Init_t Init;

    /* Configure the component */
    IO.DevAddr = DevAddr;
    IO.Init = BUS#N_Init;
    IO.ReadReg = BUS#N_ReadReg;
    IO.WriteReg = BUS#N_WriteReg;
    IO.GetTick = BSP_GetTick;
    NNNXXXX_A_RegisterBusIO (&NNNXXXX_A_Obj, &IO);

    (…)
    If (NNNXXXX_A_Init (&NNNXXXX_A_Obj, &Init) ==0)
    {
        Class_Drv = (CLASS_Drv_t *)&NNNXXXX_A_drv;
        CompObj = &NNNXXXX_A_Obj;
        return BSP_ERROR_NONE;
    }
    return BSP_ERROR_UNKNOWN_COMPONENT;
}
Specific command based memories

This is typically the use case when the STM32 may interface a standard memory that requires specific part number commands and specific compile time configuration.

The BSP_CLASS_Init() follows the same architecture as the BSP class based on the second component driver model (Single controller component P/N) except there is no need to register IO operation and the component architecture is based on the memory component model.

Below an example of the BSP_QSPI_Init():
```c
int32_t BSP_QSPI_Init(uint32_t Interface)
{
    MX25L512_Info_t Info;
    hqspi.Instance = QUADSPI;

    /* Get QSPI information */
    MX25L512_GetFlashInfo (&Info);
    /* QSPI initialization */
    if (MX_QSPI_Init (&hqspi, Info.FlashSize) != MX25L512_ERROR)
    {
        return BSP_ERROR_PERIPH_FAILURE;
    }

    /* Reset the QSPI */
    if (QSPI_ResetMemory (Interface) != MX25L512_ERROR)
    {
        return BSP_ERROR_COMPONENT_FAILURE;
    }

    /* Put QSPI memory in QPI mode */
    if (MX25L512_EnterQuadMode (&hqspi) < MX25L512_ERROR)
    {
        return BSP_ERROR_COMPONENT_FAILURE;
    }

    /* Set the QSPI memory in 4-bytes address mode */
    if (QSPI_EnterFourBytesAddress(Interface) != MX25L512_ERROR)
    {
        return BSP_ERROR_COMPONENT_FAILURE;
    }

    /* Configuration of the dummy cycles on QSPI memory side */
    if (QSPI_DummyCyclesCfg(Interface) != MX25L512_ERROR)
    {
        return BSP_ERROR_COMPONENT_FAILURE;
    }

    /* Configuration of the Output driver strength on memory side */
    if (QSPI_OutDrvStrengthCfg(Interface) != MX25L512_ERROR)
    {
        return BSP_ERROR_COMPONENT_FAILURE;
    }

    return BSP_ERROR_NONE;
}
```
8.1.2 **BSP_CLASS_DeInit**

This function de-initializes the class main peripheral, for example I2S for audio and LTDC for Display, and the associated Msp (GPIO, DMA, NVIC, Clock). Note that the GPIO port clocks are not disabled as they may be shared by other BSP drivers or the user code. The BSP_CLASS_DeInit implementation, is as follows:

```c
uint32_t BSP_CLASS_DeInit (uint32_t Instance)
{
    int32_t ret = BSP_ERROR_NONE;

#if (USE_HAL_PPP_REGISTER_CALLBACKS == 0)
    /* Init the PPP Msp */
    PPP_MspDeInit(&hclass_ppp);
#else
    IsPppMspCbValid = 0;
#endif

    /* De-initialize the PPP peripheral */
    if (HAL_PPP_DeInit (&hclass_ppp)!= HAL_OK)
    {
        ret = BSP_ERROR_BUS_FAILURE;
    }

    return ret;
}
```

8.1.3 **BSP_CLASS_RegisterDefaultMspCallbacks**

The BSP_CLASS_RegisterDefaultMspCallbacks allows to assign the default callbacks to the main peripherals handles when they are changed by the user.

```c
int32_t BSP_CLASS_RegisterDefaultMspCallbacks (uint32_t Instance)
{
    HAL_PPP_RegisterCallback (&hclass_ppp, HAL_PPP_MSPINIT_CB_ID, PPPx_MspInit);
    HAL_PPP_RegisterCallback (&hclass_ppp, HAL_PPP_MSPDEINIT_CB_ID, PPPx_MspDeInit);
    IsPppMspCbValid = 1;
    return BSP_ERROR_NONE;
}
```

8.1.4 **BSP_CLASS_RegisterMspCallbacks**

The BSP_CLASS_RegisterMspCallbacks allows to assign the Msp callbacks to the main peripherals handles.
8.1.5 RegisterMspCallbacks example

This section gives an example of register Msp callbacks implementation for BUS BSP driver based on I²C peripheral.

```c
int32_t BSP_CLASS_RegisterMspCallbacks (uint32_t Instance, BSP_CLASS_Cb_t *CallBacks)
{
    HAL_PPP_RegisterCallback (&hclass_ppp, HAL_PPP_MSPINIT_CB_ID, CallBacks->pMspInitCb);
    HAL_PPP_RegisterCallback (&hclass_ppp, HAL_PPP_MSPDEINIT_CB_ID, CallBacks->pMspDeInitCb);
    IsPppMspCbValid = 1;
    return BSP_ERROR_NONE;
}
```
uint32_t IsI2c1MspCbValid = 0;
#if (USE_HAL_I2C_REGISTER_CALLBACKS == 1)
/**
 * @brief Default BSP I2C1 Bus Msp Callbacks
 * @param Instance    I2C instance
 * @retval BSP status
 */
int32_t BSP_I2C1_RegisterDefaultMspCallbacks (uint32_t Instance)
{
    /* Prevent unused argument(s) compilation warning */
    UNUSED(Instance);
    __HAL_I2C_RESET_HANDLE_STATE(&hbus_i2c1);

    /* Register MspInit Callback */
    HAL_I2C_RegisterCallback(&hbus_i2c1, HAL_I2C_MSPINIT_CB_ID, I2C1_MspInit);

    /* Register MspDeInit Callback */
    HAL_I2C_RegisterCallback(&hbus_i2c1, HAL_I2C_MSPDEINIT_CB_ID, I2C1_MspDeInit);

    IsI2c1MspCbValid = 1;
    return BSP_ERROR_NONE;
}
/**
 * @brief BSP I2C1 Bus Msp Callback registering
 * @param Instance      I2C instance
 * @param pMspInitCb    pointer to MspInit callback function
 * @param pMspDeInitCb  pointer to MspDeInit callback function
}
In the Init bus function, a check on the Msp registration callback usage must be done:

```c
static uint32_t I2C1InitCounter = 0;
int32_t BSP_I2C1_Init(void)
{
    int32_t ret = BSP_ERROR_NONE;

    hbus_i2c1.Instance = BUS_I2C1;

    if(I2C1InitCounter++ == 0U)
    {
        if(HAL_I2C_GetState(&hbus_i2c1) == HAL_I2C_STATE_RESET)
        {
            #if (USE_HAL_I2C_REGISTER_CALLBACKS == 0)
            /* Init the I2C Msp */
            I2C1_MspInit(&hbus_i2c1);
            #else
            if(IsFmpi2c1MspCbValid == 0U)
            {
                if(BSP_I2C1_RegisterDefaultMspCallbacks() != BSP_ERROR_NONE)
                {
                    ret = BSP_ERROR_I2CMspCallbacks;
                }
            }
            #endif /* USE_HAL_I2C_REGISTER_CALLBACKS */
        }
    }

    return ret;
}
```

```c
static uint32_t I2C1InitCounter = 0;
int32_t BSP_I2C1_Init(void)
{
    int32_t ret = BSP_ERROR_NONE;

    hbus_i2c1.Instance = BUS_I2C1;

    if(I2C1InitCounter++ == 0U)
    {
        if(HAL_I2C_GetState(&hbus_i2c1) == HAL_I2C_STATE_RESET)
        {
            #if (USE_HAL_I2C_REGISTER_CALLBACKS == 0)
            /* Init the I2C Msp */
            I2C1_MspInit(&hbus_i2c1);
            #else
            if(IsFmpi2c1MspCbValid == 0U)
            {
                if(BSP_I2C1_RegisterDefaultMspCallbacks() != BSP_ERROR_NONE)
                {
                    ret = BSP_ERROR_I2CMspCallbacks;
                }
            }
            #endif /* USE_HAL_I2C_REGISTER_CALLBACKS */
        }
    }

    return ret;
}
```
Note: A given bus among BSP bus drivers maybe used by several classes. To insure that Class_A DeInit doesn't affect Class_B, a global variable PPPnInitCounter is used to check whether we must proceed or not for Init or DeInit peripheral operations.
The De-Init bus function must reset the Msp registration callback usage:

```c
int32_t BSP_I2C1_DeInit(void)
{
    int32_t ret = BSP_ERROR_NONE;

    if (I2C1InitCounter > 0U)
    {
        if (--I2C1InitCounter == 0U)
        {
#if (USE_HAL_I2C_REGISTER_CALLBACKS == 0)
            I2C1_MspDeInit(&hbus_i2c1);
#endif /* (USE_HAL_I2C_REGISTER_CALLBACKS == 0) */

            /* Init the I2C */
            if (HAL_I2C_DeInit(&hbus_i2c1) != HAL_OK)
            {
                ret = BSP_ERROR_BUS_FAILURE;
            }
        }
    }

    return ret;
}
```

### 8.1.6 BSP_CLASS_Action

This is the generic name of the class specific functions. Each class must provide frequently used functions to bring the high-level services to the end user, by hiding the main peripheral and the Msp configuration complexity. The prototype for such function is as follows:

```c
int32_t BSP_CLASS_Action (uint32_t Instance, __ARGS__);
```

*Note:* **__ARGS__**: the list of arguments of the **BSP_CLASS_Action** function.

An example of **BSP_CLASS_Action** is:

```c
int32_t BSP_SD_ReadBlocks (uint32_t Instance, uint32_t *pData, uint32_t BlockIdx, uint32_t BlocksNbr)
```
8.2 Specific functions

The specific drivers services are set of advanced functions that are relative to specific features in a STM32 serie or a component:

**Table 10. BSP class drivers: Specific functions**

<table>
<thead>
<tr>
<th>Class</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUDIO_IN</td>
<td>int32_t BSP_AUDIO_IN_RecordChannels(uint32_t Instance, uint8_t **pBuf, uint32_t NbrOfBytes);</td>
</tr>
<tr>
<td>LCD</td>
<td>int32_t BSP_LCD_SetLayerAddress(uint32_t Instance, uint32_t LayerIndex, uint32_t Address)</td>
</tr>
<tr>
<td></td>
<td>int32_t BSP_LCD_SetLayerWindow(uint32_t Instance, uint16_t LayerIndex, uint16_t Xpos, uint16_t Ypos, uint16_t Width, uint16_t Height)</td>
</tr>
<tr>
<td></td>
<td>int32_t BSP_LCD_SetLayerVisible(uint32_t Instance, uint32_t LayerIndex, FunctionalState State)</td>
</tr>
<tr>
<td></td>
<td>int32_t BSP_LCD_ConfigLayer (uint32_t Instance, uint32_t LayerIndex, BSP_LCD_LayerConfig_t *Config)</td>
</tr>
</tbody>
</table>

8.3 Extended functions

The extended functions are implementing a set of advanced services that extend existing generic functions to provide more control on components drivers offering advanced features. Contrary to the specific functions, the extended ones are not mandatory as equivalent services are already covered by the common functions. The extended functions extend the common functions by providing a special services set specific for a function driver.

An example of such services is described in the Table 11 below for LCD driver:

**Table 11. BSP class drivers: Extended functions**

<table>
<thead>
<tr>
<th>Driver</th>
<th>Services</th>
</tr>
</thead>
<tbody>
<tr>
<td>Common</td>
<td>int32_t BSP_LCD_Init(uint32_t Instance, LCD_OrientationTypeDef Orientation)</td>
</tr>
<tr>
<td>Extended</td>
<td>int32_t BSP_LCD_InitEx(uint32_t Instance, uint32_t Orientation, uint32_t PixelFormat, uint32_t Width, uint32_t Height)</td>
</tr>
</tbody>
</table>
## 8.4 BSP classes

This section lists the APIs, for each class, that must be implemented. MX_PPP_Init and MX_PPP_ClockConfig APIs are specially prefixed with "MX_" as they can be generated later by STM32CubeMX tool.

### 8.4.1 BSP AUDIO OUT class APIs

<table>
<thead>
<tr>
<th>Function</th>
<th>Arguments</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>int32_t BSP_AUDIO_OUT_Init</td>
<td>uint32_t Instance, BSP_AUDIO_Init_t *AUDIO_Init</td>
<td>AUDIO OUT Initialization</td>
</tr>
<tr>

<td>Register AUDIO OUT default Msp callbacks</td>
</tr>
</tbody>
</table>
With:

```c
typedef struct {
    uint32_t                    Device;
    uint32_t                    SampleRate;
    uint32_t                    BitsPerSample;
    uint32_t                    ChannelsNbr;
    uint32_t                    Volume;
} BSP_AUDIO_Init_t;
```

**MX_PPP_TypeDef** can be:

```c
typedef struct {
    uint32_t AudioFrequency;
    uint32_t AudioMode;
    uint32_t DataSize;
    uint32_t MonoStereoMode;
    uint32_t ClockStrobing;
    uint32_t Synchro;
    uint32_t OutputDrive;
    uint32_t SynchroExt;
    uint32_t FrameLength;
    uint32_t ActiveFrameLength;
    uint32_t SlotActive;
} MX_SAI_TypeDef;
```

```c
typedef struct {
    uint32_t AudioFrequency;
    uint32_t AudioMode;
    uint32_t FullDuplexMode;
} MX_I2S_TypeDef;
```

```c
#if(USE_PPP_REGISTER_CALLBACKS == 1)
typedef struct {
    void (* pMspInitCb)(PPP_HandleTypeDef *);
    void (* pMspDeInitCb)(PPP_HandleTypeDef *);
} BSP_AUDIO_OUT_Cb_t;
#endif /* (USE_HAL_PPP_REGISTER_CALLBACKS == 1) */
```
### 8.4.2 BSP AUDIO IN class APIs

#### Table 13. BSP AUDIO IN class APIs

<table>

<td>uint32_t Instance</td>
<td>Register AUDIO IN default Msp callbacks</td>
</tr>
</tbody>
</table>
#if(USE_PPP_REGISTER_CALLBACKS == 1)
typedef struct
{
    void (* pMspInitCb)(PPP_HandleTypeDef *);
    void (* pMspDeInitCb)(PPP_HandleTypeDef *);
}BSP_AUDIO_IN_Cb_t;
#endif /* (USE_HAL_PPP_REGISTER_CALLBACKS == 1) */

Note: When using DFSDM IP for recording, the following specific APIs must be implemented:

### Table 14. Specific APIs for recording

<table>
<thead>
<tr>
<th>Function</th>
<th>Arguments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BSP_AUDIO_IN_RecordChannels</td>
<td>uint32_t Instance, uint8_t **pBuf, uint32_t NbrOfBytes</td>
<td>Start recording using digital microphones already initialized. The data is to be processed at application level.</td>
</tr>
<tr>
<td>BSP_AUDIO_IN_StopChannels</td>
<td>uint32_t Instance, uint32_t Device</td>
<td>Stop recording on a given digital microphone</td>
</tr>
<tr>
<td>BSP_AUDIO_IN_PauseChannels</td>
<td>uint32_t Instance, uint32_t Device</td>
<td>Pause recording on a given digital microphone</td>
</tr>
<tr>
<td>BSP_AUDIO_IN_ResumeChannels</td>
<td>uint32_t Instance, uint32_t Device</td>
<td>Resume recording on a given digital microphone</td>
</tr>
</tbody>
</table>

Be aware of DFSDM filters synchronization while developing these APIs.

### 8.4.3 BSP TS class APIs

```

```c
#define BSP_OSPI_RAM_BurstLength_t NNNXXXX_BurstLength_t
```

NNNXXXX: OSPI hyperRAM component
8.5 **BSP class driver context**

BSP driver resources (process variables) must always be stored in a global BSP driver context structure. Note that the class_ppp handle of the BSP class driver main peripheral must always be defined outside the context to export them when needed by the xxxx_it.c file to handle IRQ or by the application if needed to change peripheral parameters.

An example of context structure is defined as below (AUDIO IN):

```c
typedef struct
{
    uint32_t Instance;    /*Audio IN instance*/
    uint32_t Device;      /*Audio IN device to be used*/
    uint32_t SampleRate;  /*Audio IN Sample rate*/
    uint32_t BitsPerSample;  /*Audio IN Sample resolution*/
    uint32_t ChannelsNbr;  /*Audio IN number of channel*/
    uint16_t *pBuff;       /*Audio IN record buffer*/
    uint8_t  **pMultiBuff; /*Audio IN multi-buffer*/
    uint32_t Size;         /*Audio IN record buffer size*/
    uint32_t Volume;       /*Audio IN volume*/
    uint32_t State;        /*Audio IN State*/
    uint32_t IsMultiBuff;  /*Audio IN multi-buffer usage*/
    uint32_t IsMspCallbacksValid;  /*Is Msp Callbacks registered*/
} AUDIO_IN_Ctx_t;
```
8.6 BSP class driver inter dependency

In some cases, one or more BSP drivers may be used by several other BSP class drivers, this typically the case of the IO expander, the BSP IO may be used by the BSP TS, IDD and IO itself.

The BSP class drivers may need to call the BSP_IO_Init() several times internally. To prevent multi initialization the BSP_IO_Init() must manage such multi call by using its internal Is_InitIALIZED variable to check whether or not the IO expander is already called.

The BSP_IO_Init must be defined as below:

```c
int32_t BSP_IO_Init (uint32_t Instance)
{
    int32_t ret = BSP_ERROR_UNKNOWN_FAILURE;
    static uint8_t IO_IsInitialized = 0;

    if (IO_IsInitialized == 0)
    {
        IO_IsInitialized = 1;
        (…)
        ret = BSP_ERROR_NONE;
    }
}
else
{
    ret = BSP_ALREADY_INITIALIZED;
}

return ret;
}
```
8.7 Using driver structure

Typically the class driver structure, defined under /common, is used when we need to use only the generic functions in a component driver in standalone mode or when a BSP class driver may support several component references offering the same services. Typical use of the class driver structure is as follows:

```
NNNXXXX_Object_t ComponentObj;
NNNXXXX_Drv_t    ComponentDrv;

void BSP_CLASS_Init (BSP_CLASS_Init_t *ClassInit)
{
    NNNXXXX_IO_t           IO;
    NNNXXXX_Init_t            Init;
    (…)
    /* Configure the component */
    IO.DevAddr    = DevAddr;
    IO.Init       = BUS#N_Init;
    IO.ReadReg    = BUS#N_ReadReg;
    IO.WriteReg   = BUS#N_WriteReg;
    IO.GetTick    = BSP_GetTick;
    NNNXXXX_RegisterBusIO (&ComponentObj, &IO);
    (…)
    ComponentDrv.Init (&ComponentObj, Init);
    (…)
}
```

Or with dynamic class driver structure assignment using the ReadID function or the component use define in the global BSP configuration files.
NNNXXXX_A_Object_t ComponentObjA;
CLASS_DrvTypeDef *Class_Drv;
void *Class_CompObj;
int32_t BSP_CLASS_Init (BSP_CLASS_Init_t *ClassInit)
{
    (...)  
    if (NNNXXXX_A_Probe((void *)&CodecAddress, ClassInit))
    {
        return BSP_ERROR_UNKNOWN_COMPONENT;
    }
    (...)  
}

static int32_t NNNXXXX_Probe(void *Ctx, BSP_CLASS_Init_t *ClassInit)

    }
    return BSP_ERROR_UNKNOWN_COMPONENT;
}
9 BSP IRQ handlers

9.1 Generic rules

The IRQ handlers associated with the BSP drivers must be defined internally in the BSP driver, it is not recommended to use the BSP peripherals handles in the `stm32yyxxxx_it.c` file using HAL APIs except for raw memory access (SDRAM, SRAM…), that write and read operation require to call HAL services thus need for handles. The BSP IRQ handler naming is following this rule:

```c
void {BOARD_PREFIX}_{CATEGORY/CLASS}_{Mode}_IRQHandler (#INSTANCE#, #SUB_INSTANCE#)
```

And then called in the `stm32yyxxxx_it.c` file, as follows:

```c
void #IRQLINE#_IRQHandler(void)
{
    (BOARD_PREFIX)_{CATEGORY/CLASS}_{Mode}_IRQHandler (#INSTANCE#, #SUB_INSTANCE#);
}
```

The table below provides some examples of the above symbols:

<table>
<thead>
<tr>
<th>BOARD_PREFIX</th>
<th>CLASS</th>
<th>CATEGORY (Common Class Driver)</th>
<th>MODE</th>
<th>INSTANCE</th>
<th>SUBINSTANCE</th>
</tr>
</thead>
<tbody>

<td>JOY1….JOYn</td>
<td>XXX_MIC3</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>XXX_MIC4</td>
</tr>
</tbody>
</table>
Some examples are listed below.

- **Standard board common BSP driver**

```c
void EXTI9_5_IRQHandler(void)
{
    BSP_PB_IRQHandler (BUTTON_USER);
}
void EXTI9_5_IRQHandler(void)
{
    BSP_JOY_IRQHandler (JOY1, JOY_ALL);
}
```

- **Standard board AUDIO BSP driver**

```c
void DMA2_Stream0_IRQHandler(void)
{
    BSP_AUDIO_IN_IRQHandler (0, AUDIO_IN_ANALOG_MIC);
}
void DMA2_Stream1_IRQHandler(void)
{
    BSP_AUDIO_IN_IRQHandler (0, AUDIO_IN_DIGITAL_MIC1);
}
```

- **Shield common BSP driver**

```c
void EXTI9_5_IRQHandler(void)
{
    SxRadioBoard_IRQHandler (RADIO_DIO0);
}
```
9.2 **BSP IRQ Handlers implementation**

As described in the previous section, the BSP IRQ handlers are defined as follows:

```c
void (BOARD_PREFIX)_(CATEGORY/CLASS)_IRQHandler (#INSTANCE#, #SUB_INSTANCE)
```

The BSP IRQ handler function is platform and features agnostic, however the internal implementation depends on the hardware configuration and the BSP IRQ lines configuration.

Typically, the BSP IRQ handler can be managed in two ways following the hardware configuration:

The category/Class sub-instances use each an IRQ line. Example, the different buttons uses different IRQ lines.

```c
void BSP_PB_IRQHandler (Button_TypeDef Button)
{
    HAL_EXTI_IRQHandler (&hpb_exti [Button]);
}
```

And in the BSP Button IRQ Handler is called in the `stm32yyxxx_it.c` file as follows:

```c
void EXTIa_IRQHandler(void)
{
    BSP_PB_IRQHandler (BUTTON_NAME#1);
}
void EXTIb_IRQHandler(void)
{
    BSP_PB_IRQHandler (BUTTON_NAME#2);
}
```

The same IRQ line manages a category/Class sub-instances. Example, the different Joystick keys share the same IRQ line.

```c
void BSP_JOY_IRQHandler (JOY_TypeDef JOY, uint32_t JoyPins)
{
    UNUSED(JoyPins);
    HAL_EXTI_IRQHandler (&hjoy_Exti[JOY]);
}
```

And in the BSP Button IRQ Handler is called in the `stm32yyxxx_it.c` file as follows:
void EXTIa_IRQHandler(void)
{
    BSP_JOY_IRQHandler (JOYi, JOY_ALL);
}

Chapter 10  BSP error management

The common BSP drivers’ module must return specific error to their functions. Each caller to one or more services from this module including the application must make a check on the returned values before using the associated services.

The class drivers are based on dynamic component driver assignment, at user file level, the application must check on the return value of the BSP_CLASS_Init before using the class driver services and inside the BSP services, the functions pointers validity must be always checked and return an error when the function pointer is not valid.

The main rule for the error returned values is as follows:

- Negative values: error codes
- Zero: no error
- Positive values: state, information

Figure 18. BSP error management

Note: In general, returned value by BSP Driver and component functions must always be a pointer, for example:

```c
int32_t BSP_CLASS_Function (uint32_t Instance, uint32_t * value);
```

or

```c
int32_t BSP_CLASS_Function (uint32_t Instance, BSP_ITEM_t * sValue);
```

Exception is made for status check function and Get function type with positive values, for example:

```c
int32_t BSP_I2C1_IsReady (uint16_t DevAddr, uint32_t Trials)
{
    int32_t ret = BSP_ERROR_NONE;
    if(HAL_I2C_IsDeviceReady(&hbus_i2c1, DevAddr, Trials, BUS_I2C1_POLL_TIMEOUT) != HAL_OK)
    {
        ret = BSP_ERROR_BUSY;
    }
    return ret;
}
```
10.1 Component drivers

All the functions of the components drivers must return a component specific error code (int32_t) defined following the scheme above.

For components drivers returned values such as data transfer length or data value must be returned as positive values.

10.2 BSP common drivers

The class drivers, bus drivers and common drivers use common error code defined in the boardname_errno.h file and defined as follows:

```c
/* Common Error codes */
#define BSP_ERROR_NONE 0
#define BSP_ERROR_NO_INIT -1
#define BSP_ERROR_WRONG_PARAM -2
#define BSP_ERROR_BUSY -3
#define BSP_ERROR_PERIPH_FAILURE -4
#define BSP_ERROR_COMPONENT_FAILURE -5
#define BSP_ERROR_UNKNOWN_FAILURE -6
#define BSP_ERROR_UNKNOWN_COMPONENT -7
#define BSP_ERROR_BUS_FAILURE -8
#define BSP_ERROR_CLOCK_FAILURE -9
#define BSP_ERROR_MSP_FAILURE -10
#define BSP_ERROR_FEATURE_NOT_SUPPORTED -11
```

10.3 BSP class drivers

The specific class driver errors are also defined in the boardname_errno.h file as follows:

```c
/* BSP QSPI error codes */
#define BSP_ERROR_QSPI_ASSIGN_FAILURE -20
#define BSP_ERROR_QSPI_SETUP_FAILURE -21
#define BSP_ERROR_QSPI_MMP_LOCK_FAILURE -22
#define BSP_ERROR_QSPI_MMP_UNLOCK_FAILURE -23
/* BSP TS error code */
#define BSP_ERROR_TS_TOUCH_NOT_DETECTED -30
```
10.4 BSP bus drivers

The specific bus drivers’ errors are also defined in the boardname_errno.h file as follows:

/* BSP BUS error code */
#define BSP_ERROR_BUS_TRANSACTION_FAILURE -100
#define BSP_ERROR_BUS_ARBITRATION_LOSS -101
#define BSP_ERROR_BUS_ACKNOWLEDGE_FAILURE -102
#define BSP_ERROR_BUS_PROTOCOL_FAILURE -103
#define BSP_ERROR_BUS_MODE_FAULT -104
#define BSP_ERROR_BUS_FRAME_ERROR -105
#define BSP_ERROR_BUS_CRC_ERROR -106
#define BSP_ERROR_BUS_DMA_FAILURE -107
