Hello, and welcome to this presentation of the STM32 Universal Synchronous/Asynchronous Receiver/Transmitter Interface. It covers the main features of this USART interface, which is widely used for serial communications in embedded systems.
The STM32G4 embeds 3 Universal Synchronous Asynchronous Receiver Transmitter (USARTs) and 2 Universal Asynchronous Receiver Transmitter (UARTs). The USART is a very flexible serial interface that supports:

- Asynchronous UART communication,
- SPI (serial peripheral interface) master and slave modes,
- SmartCard ISO 7816 communication
- irDA Serial infra red communication
- LIN (local interconnect network) mode.

It also provides certain features that are useful when implementing Modbus communications.

The UART implements the same features as the USART, except support of synchronous protocols: SPI and SmartCard.

Applications making use of the USART benefit from the
easy and inexpensive connection between devices, which only requires a few pins.
In addition, the USART peripheral is functional in low-power modes. It comes with Transmit and Receive FIFOs and can transmit and receive in stop modes.
The USART is a fully programmable serial interface featuring the following configurable parameters:

- data length,
- parity,
- number of stop bits,
- data order,
- baud rate generator
- and a configurable oversampling mode by 8 or by 16.

The USART can operate in FIFO mode and it comes with two FIFOs: Transmit and Receive FIFOs.

You have the option to use basic RS-232 flow control with CTS (Clear To Send) and RTS (Request To Send) signals.

The RS-485 DE (Driver Enable) signal is also supported. The USART supports a dual clock domain allowing wakeup from Stop mode and baud rate programming independent of the peripheral clock (PCLK).
This also allows the peripheral clock to be throttled along with the core clock without disrupting communications.
The USART features a multi-processor mode which allows the USART to remain idle when it is not addressed. In addition to full-duplex communication, single-wire half-duplex mode is supported. The USART also offers many other features including auto baud rate detection, receiver timeout and supports several modes which will be described later in the presentation.
This table also highlights the differences between the 3 USARTs, the 2 UARTs and the LPUART.
The UART does not support:
- Synchronous mode and SmartCard mode.
The LPUART does not support:
- Synchronous mode
- SmartCard mode
- irDA communication
- LIN mode
- Modbus communication.
This is the USART block diagram.
The USART clock source (usrart_ker_ck) can be selected from several sources: peripheral clock (APB clock PCK), SYSCLK, High Speed Internal 16-MHz oscillator (HSI16), Low Speed External Oscillator (LSE).
The USART clock source is divided by a programmable factor in the USART_PSC register in range 1 to 256.
Tx and Rx pins are used for data transmission and reception.
nCTS and nRTS pins are used for RS-232 hardware flow control.
The Driver Enable pin (DE) which is available on the same I/O as nRTS is used in RS-485 mode.
The clock output (CK) is dual purpose:
➢ When the USART is used in Synchronous Master/Slave mode, the clock provided to the slave device is output/input on the CK pin.
When the USART is used in Smartcard mode, the clock provided to the card is output on the CK pin. Note that the NSS and nCTS signals share the same pin: NSS is the slave selection input applied to the device in synchronous slave mode.
The USART has a flexible clocking scheme. The registers are accessed through the APB bus, and the kernel is clocked with `usart_ker_ck` (prescaled or not) which is independent from the APB clock. In order to pass data from one clock domain to the other one, either 8-data FIFOs are used or single data buffers. The USART block is an APB slave that can rely on DMA requests to transfer data to/from memory buffers. The functions of the TX and RX pins can be swapped. This allows to work in the case of a cross-wired connection to another UART.
The USART receiver implements different user-configurable oversampling techniques for data recovery by discriminating between valid incoming data and noise. This allows a trade-off between the maximum communication speed and noise/clock inaccuracy immunity. Select oversampling by 8 to achieve higher speed (up to `usart_ker_ck_pres` divided by 8) where `usart_ker_ck_pres` is the USART clock source frequency. In this case the maximum receiver tolerance to clock deviation is reduced.

Select Oversampling by 16 (OVER8 = 0) to increase the tolerance of the receiver to clock deviations. In this case, the maximum speed is limited to `usart_ker_ck_pres` divided by 16.

The maximum baud rate that can be reached is 21.25 Mbaud when the clock source is at 170 MHz and oversampling by 8 is configured. With other clock sources, and/or higher oversampling ratio, the maximum speed is limited.
The frame format used in Asynchronous mode consists of a set of data bits in addition to bits for synchronization and optionally a parity bit for error checking. The USART supports 7-, 8- or 9-bit data lengths. A frame starts with one start-bit, where the line is driven low for a one-bit period. This signals the start of a frame, and is used for synchronization. The start bit is followed by 7, 8 or 9 data bits. If Parity Control is enabled, the parity bit is transmitted as the last data bit and is included in the data length count. Finally, a number of stop-bits (0, 1, 1.5 or 2), where the line is driven high, end the frame. Data order is programmable with Most Significant bit-first or Least Significant bit-first shifting.

The standard frame was described in the previous slide. This slide shows an example of 8-bit data frames configured with 1 stop bit. An Idle character is interpreted as an entire frame of “1”s. (The number of “1”s will include the number of stop bits). A Break character is interpreted on receiving “0”s for a frame period. At the end of the break frame, 2 stop bits are inserted.
The USART supports full-duplex communication where Tx and Rx lines are respectively connected with the other interface’s Rx and Tx lines.

The USART can be configured to follow a single-wire half-duplex protocol where the Tx and Rx lines are internally connected.

In this communication mode, only the Tx pin is used for both transmission and reception.

The Tx pin is always released when no data is transmitted, thus, it acts as a standard I/O in idle or reception modes.

This means that the I/O must be configured so that the Tx pin is configured as an alternate function open-drain with an external pull-up.
In RS-232 communication, it is possible to control the serial data flow between 2 devices by using the nCTS input and the nRTS output. These two lines allow the receiver and the transmitter to alert each other of their state. The figure shows how to connect 2 devices in this mode. The idea is to prevent dropped bytes or conflicts in case of half-duplex communication. Both signals are active low.
RS-485 hardware flow control

**RS485 Hardware control mode**

- In RS485 Hardware control mode, the master needs to generate a direction signal to control the transceiver (Physical Layer=PHY)
  - This signal informs the PHY if it must act in send or receive mode
  - It uses the DE (Driver Enable) pin to activate the external RS-485 bus driver
- The DE and nRTS signals are available on the same pin

For serial half-duplex communication protocols like RS-485, the master needs to generate a direction signal to control the transceiver (Physical Layer). This signal informs the Physical Layer if it must act in send or receive mode. In RS-485 mode, a control line is used: the Driver Enable pin is used to activate the external transceiver control. DE shares the pin with nRTS.
To simplify communication between multiple processors, the USART supports a multi-processor mode. In multi-processor communication, it is desirable that only the intended message recipient should actively receive the message. The devices not being addressed are put into Mute mode. The USART can enter or exit from Mute mode using one of two methods:

- Idle line detection
- Address mark detection.
Unlike the UART, the USART can also communicate synchronously. It can operate as a SPI in Master or Slave mode with programmable clock polarity (CPOL) and phase (CPHA) and programmable data order with MSb or LSb first. The clock is output (in case of Master mode) or input (in case of Slave mode) on the CK pin. No clock pulses are provided during the start and stop bits. When the USART is configured in SPI slave mode, it supports the transmit underrun error and the NSS hardware or software management.
Unlike the UART, the USART can be used in Smartcard mode, based on a half-duplex communication. The clock is output to the Smartcard on the CK pin. It supports the T=0 protocol and provides many features allowing support for T=1. Both direct and inverse conventions are supported directly by hardware.
The USART supports IrDA specifications which is a half-duplex communication protocol. The data from and to the USART is represented in a NRZ (Non Return to Zero) format where the signal value is at the same level through the entire bit period. For IrDA, the required format is RZI (Return to Zero Inverted) where a “1” is signaled by holding the line low, and a “0” is signaled by a short high pulse. The Serial InfraRed (SIR) Transmit encoder modulates the Non Return to Zero (NRZ) transmit bit stream output from the USART. The SIR receive decoder demodulates the return-to-zero bit stream from the infrared detector and outputs the received NRZ serial bit stream to the USART. The USART only supports bit rates up to 115.2 Kbits/s for the SIR ENDEC. In normal mode, the transmitted pulse width is specified.
as 3/16 of a bit period.
The USART receiver is able to detect and automatically configure the baud rate based on the reception of one character.

The received character can be:
- Any character starting with a bit at ‘1’
- Any character starting with a 10xx pattern
- 0x7F
- 0x55

The USART is able to automatically determine the baud rate based on the reception of one character.
of bit 0 bit and finally at the end of bit 6. In parallel, another check is performed for each intermediate transition of the RX line.
The USART supports a receiver timeout feature. When the USART doesn’t receive new data for a programmed amount of time, a receiver timeout event is signaled and an interrupt is generated if enabled.

The USART receiver timeout counter starts counting:
- From the end of the first stop bit in case of 1 and 1.5 stop bit configuration.
- From the end of the second stop bit in case of 2 stop bits configuration.
- From the beginning of the stop bit in case of 0.5 stop bit configuration.
The USART can operate in FIFO mode which is enabled/disabled by software. It is disabled by default. The USART comes with a Transmit FIFO (TXFIFO) and a Receive FIFO (RXFIFO), each being 8 data deep. When the IrDA and LIN modes are used, the FIFO mode is not supported. Provided that the TXFIFO and RXFIFO are clocked by the kernel clock, it is possible to transmit and receive data even in Stop mode. It is possible to configure TXFIFO and RXFIFO thresholds, used mainly to avoid underrun/overrun issue while waking up from Stop mode.
The USART is able to wake up the MCU from Stop mode when the USART clock source is:
- HSI
- LSE

The sources of wakeup can be:
- A specific wakeup event triggered by:
  - Start bit
  - Address match
  - Any received data
- Standard RXNE interrupt when FIFO management is disabled
- FIFO event interrupts when FIFO management is enabled:
  - RXFIFO full, TXFIFO empty, RXFIFO/TXFIFO reaches the programmed threshold

The USART is able to wake up the MCU from Stop mode when the USART clock source is the HSI or LSE clock.
The sources of wakeup can be:
- A specific wakeup event which is triggered by either a start bit or an address match or any received data.
- An RXNE interrupt when FIFO management is disabled or
- FIFO event interrupts when FIFO management is enabled:
  - Receive FIFO full interrupt
  - Transmit FIFO empty interrupt
  - Receive FIFO threshold interrupt
  - Transmit FIFO threshold interrupt
This slide and the next two ones provide the list of interrupt events, detailing their cause and indicating whether these events can be used as wakeup requests. Several events can provide an interrupt:

- The Transmit Data Register Empty flag is set when the Transmit Data register is empty and ready to be written.
- The Transmit Complete flag is set when the data transmission is complete and both data and shift registers are empty.
- The CTS flag is set when the nCTS input toggles.
- The Receive Data Register Not Empty flag is set when the Receive Data register contains data.
- The Idle Line flag is set when an idle line is detected.
- The Character Match flag is set when the received data corresponds to the programmed address.

<tr>
<td>Transmission Complete Before Guard Time</td>
<td>This flag is set just after the end of frame transmission and if no NACK has been received from the card (ISO/IEC 7816 mode)</td>
<td>NO</td>
</tr>
</tbody>
</table>
- The Receiver Timeout flag is set when there is no activity on the Rx line for a programmed duration.
- The Transmission Complete Before Guard Time flag is set after the end of frame transmission and if no NACK has been received from the card.
The End of Block flag is set when a complete block is received.
The Wakeup from Stop Mode flag is set when the wakeup event is verified.
The LIN break flag is set when a LIN break frame is detected.
The Transmit FIFO not full flag is set when the Transmit FIFO is not full.
The Transmit FIFO empty flag is set when the Transmit FIFO is empty.
The Transmit FIFO threshold flag is set when programmed threshold is reached.
The Receive FIFO not empty flag is set when the Receive FIFO is not empty.
The Receive FIFO full flag is set when the Receive FIFO is full.
The Receive FIFO threshold flag is set when the programmed threshold is reached.
programmed threshold is reached.
Several errors flags can be generated:

- The Overrun error flag is set when an overrun error occurs.
- The Parity error flag is set when a parity error occurs.
- The Framing error flag is set when a framing error occurs.
- The Noise error flag is set when a noise is detected on the received frame.
- The Auto-baudrate error flag is set when the baudrate measurement failed.
- The Underrun error flag is set when an underrun error occurs in synchronous slave mode.

</tbody>
</table>
The DMA requests can be generated when Receive Buffer Not Empty or Transmit Buffer Empty flags are set when FIFO management is disabled. The DMA requests can also be generated when the Transmit FIFO not full and Receive FIFO not empty flags are set when FIFO management is enabled.
The USART peripheral is active in Run, Sleep and low-power modes.
The USART interrupts cause the device to exit Sleep and Low-power Sleep modes.
The USART is able to wake up the MCU from Stop 0 and Stop 1 modes when the USART clock is set to HSI or LSE.
USART reception is functional in Stop mode, and generates a wakeup interrupt on Start, address match or received frame event.
In Standby and shutdown modes, the peripheral is in power-down, and it must be reinitialized after exiting Standby or Shutdown mode.
This is a list of peripherals related to the USART. Please refer to these trainings for more information if needed.

- General-purpose input/outputs
- Reset and clock controller
- Power controller
- Interrupts controller
- Direct memory access controller
