Application note

VIpower: auxiliary BIAS power supply using VIPer20A-E

Introduction

This application note describes a bias power supply to meet the needs of powering up Power MOSFETs as well as providing standby power when the main unit is off.

The VIPer20ADIP-E, a part of STMicroelectronics proprietary VIpower (Vertical Intelligent Power), is a current mode PWM with a 700 V avalanche rugged Power MOSFET. It uses a fabrication process which allows the integration of analog control circuits with a vertical power device on the same chip. It can provide an output of 10 W power capability for wide range input, or 20 W for single input voltage range.

1 Key features of the VIPer20ADIP-E

- Adjustable switching frequency up to 200 kHz
- Current mode control
- Burst mode operation in standby mode, meets “Blue Angel” standards
- Undervoltage lock-out with hysteresis
- Integrated start-up supply
- Avalanche rugged
- Overtemperature protection
- Primary or secondary regulation general circuit description

2 General circuit description

This demo board (see schematic in [Figure 1](#)) is a 110 to 375 V_{DC} input discontinuous flyback, working at 100 kHz. The output can deliver 12 V at 0.5 A continuous. This circuit can be powered from the main bulk capacitors of an off-line power supply, power factor correction output stage, or the AC line with the addition of a low current bridge rectifier. It benefits from the EMI filter present in a typical power supply. The output uses a Schottky diode for better efficiency. C7 is a low ESR capacitor which manages the ripple current. IC2 provides the reference and the feedback to tightly regulate the output. CS5, CS6, and RS3 form the feedback loop compensation to optimize stability during transients. The demoboard can be tested with convection air. Depending on the final application, air flow might be needed to keep the VIPer20ADIP-E under the thermal shutdown limit.

Figure 1. Schematic

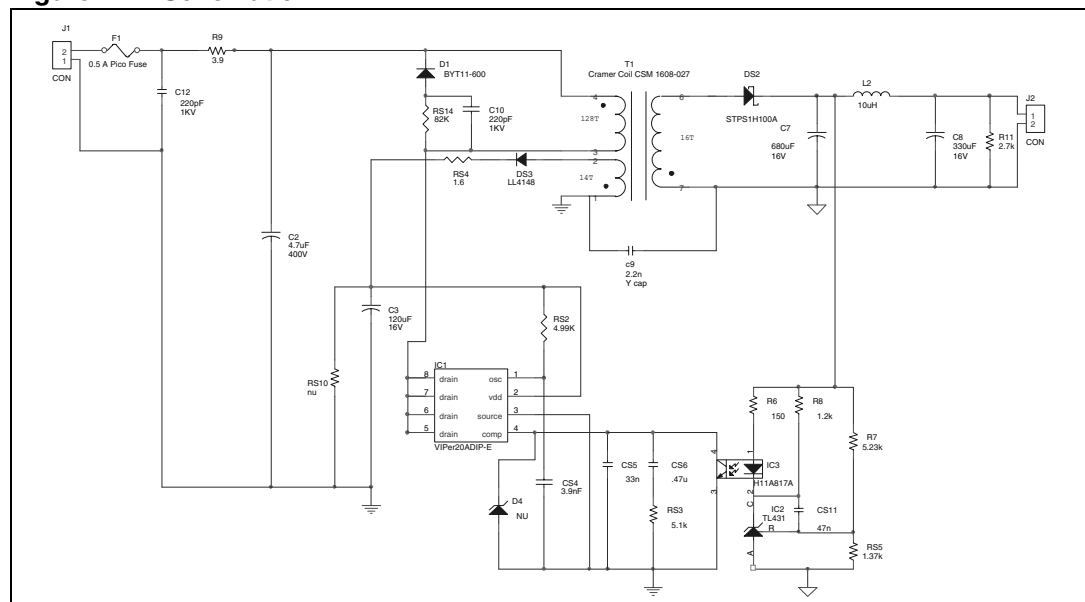

Table 1. Electrical specification from measured results

Parameter	Results
Input voltage range J1	110 to 375 V _{DC}
Output J2	12 V from 0 to 0.5 A
Load regulation (0 to 0.5 A) from setpoint	+/-25 mV or +/-0.2%
Line regulation (at max load)	+/-1 mV
Efficiency	84% at 120 V _{DC} and 79% at 375 V _{DC}
Output ripple voltage	35 mV MAX
Input power at no load	0.65 W MAX
Transient response, 50% load step	+/-60 mV typical

3 Connecting the demo board

This demo board has two connectors. Connect a DC voltage source capable of delivering up to 400 volts DC to connector J1. Be sure to connect the positive source to the + terminal of J1 and the negative to the terminal before turning on the input power. The minimum voltage to operate this demo board is 110 V_{DC}. Connect an electronic load or resistive load to J2.

4 Layout considerations

Some simple rules to improve performance and minimize noise should be followed:

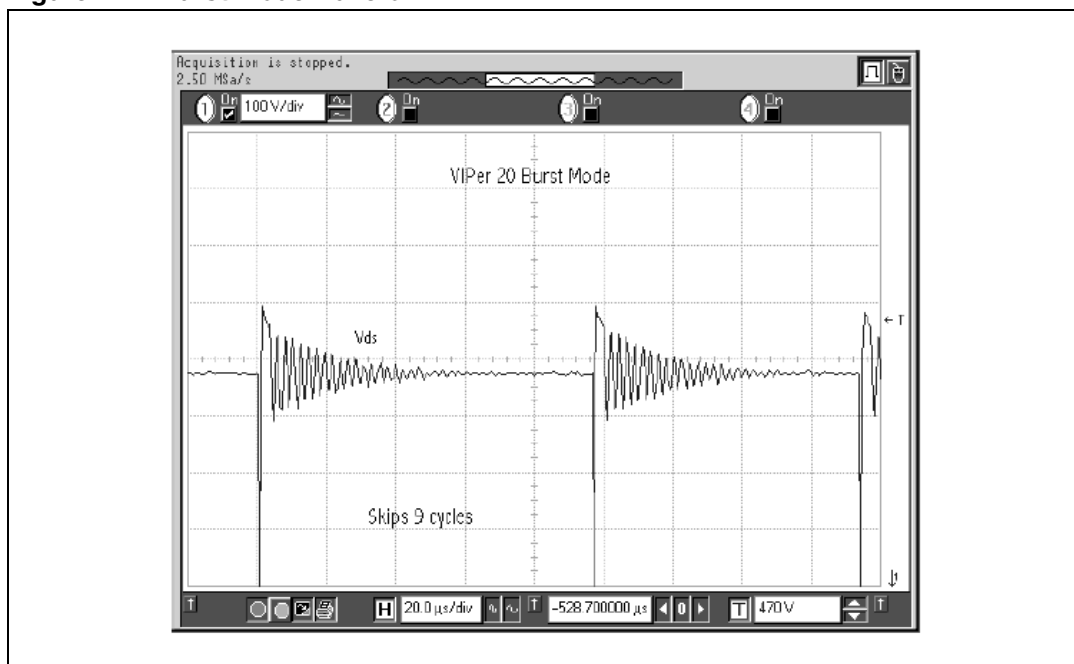

1. Minimize power loops. The switched power current paths inner loop area must be as small as possible. This can be accomplished by careful layout of the printed circuit board and the use of surface mount components. This avoids radiated and conducted EMI noise, and improves the efficiency by eliminating parasitic inductance, thus reducing or eliminating the need for snubbers and EMI filtering.
2. Use separate tracks for low level signal and power traces carrying fast switching pulses. This can be seen on the VIPer20ADIP-E pin 3 on the printed circuit lay out. When signal paths share the same trace as a power path, instabilities may result. The compensation components, CS6, RS3, and CS4 are on a separate trace connected directly to the source of the device.

5 Burst mode

When the output current is too low, the burst mode operation takes over automatically. This results in missing cycles as shown on the following scope waveform (*Figure 4*). V_{in} is 375 V_{DC} I_{OUT} is at no load.

As can be seen, there is one pulse out of ten pulses to reduce power consumption. The output ripple is negligible.

Figure 4. Burst mode waveform
