

TDE1708DFT in IO-Link applications

1 Introduction

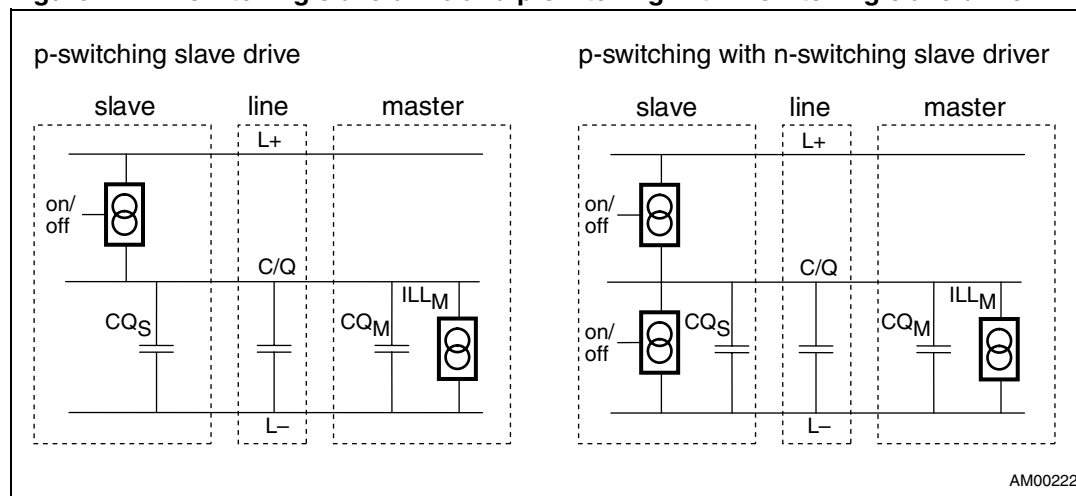

This application note investigates the possibility of using a TDE1708DFT switch for the physical layer transmitter realization of 3-wire IO-Link sensors.

The TDE1708DFT is an integrated power switch especially dedicated to proximity detectors. It can deliver up to 250 mA, enables high-side and low-side configurations and includes a number of protections.

According to the IO-Link Communication Specification (see [Section 8: References -3.](#) and for the TDE1708DFT features - see [Section 8: References - 1.](#)) two basic slave transmitter configurations were tested (see [Figure 1](#)):

- p-switching (high-side) driver
- p-switching driver with an additional n-switching (low-side) driver (push-pull operation)

Figure 1. P-switching slave drive and p-switching with n-switching slave drive

In the following test arrangements the input load current (I_{LLM}) is fixed to 10 mA which represents the average master current sink value specified for a 3-wire system. The master (C_{QM}), slave (C_{QL}), and line capacitances are set together at 4.7 nF, corresponding to the maximum parasitic capacitance of the system.

4 Push-pull configuration with TDE1708DFT

The following push-pull driver configuration was designed based on the previous single driver measurements. In this proposed schematic (see [Figure 14](#)) two additional components (R3, D3) must be added to speed up the turning off of the driver in the low-side configuration. The resistor R3 creates a weak pull-up while the diode D3 separates the low-side output from the high-side. The reason for this being that if the low-side driver is forced high in a short time after turning off then it stays turned on with all the subsequent effects.

Figure 14. Push-pull test configuration schematic

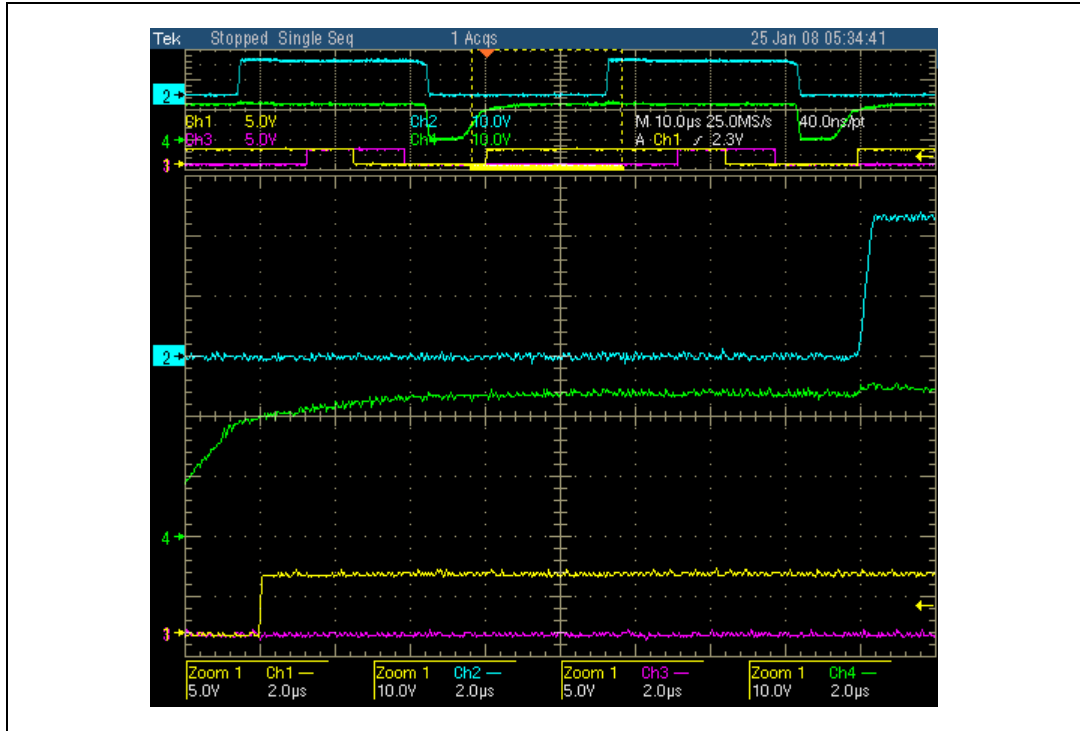

AM00234

The low-side driver helps to reduce the falling time with the capacitive load, the rest of the circuit works exactly the same way as that described in [Section 2.1](#). [Figure 17](#) shows a software timing example in accordance with [Table 2](#) and a dead time between the driver outputs of 1 μs.

6 Alternative driving

The larger temperature propagation turn-on time dependence of the TDE1708DFT, described in the previous section ([Section 5: Performance characteristics](#)), has led to the development of an alternative kind of driving which would not suffer from this problem. The presented driving configuration (see [Figure 20](#)) uses both the input signal “IN” together with the open collector pin “DELAY” (originally dedicated to delay adjustment). The IN signal controls only the turning off of the switch (the output is blocked by the DELAY pin during its high state), while the DELAY signal then controls the turning on of the switch (see [Figure 21](#)). This principle results in more positive temperature characteristics ([Section 6.1: Temperature characteristics](#)).

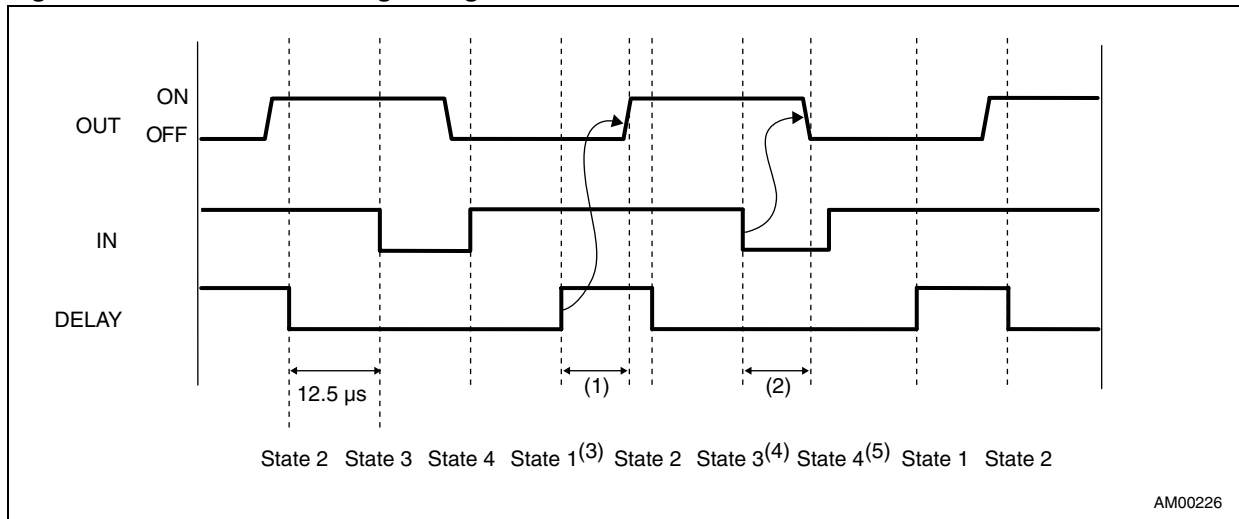

Figure 20. Alternative driving schematics

AM00235

1. The resistor R1 prevents the circuit from the cross conduction between the push-pull output of the generator and the open collector DELAY pin.

AM00226

1. Delay propagation turn-on time (see [Figure 22](#) and [Figure 23](#)).
2. Propagation turn-off time (see [Figure 24](#) and [Figure 25](#)).
3. State 1: DELAY releases the output.
4. State 3: IN goes low and turns off the switch.
5. State 4: IN goes high, the output is blocked by the DELAY signal (the monostable circuit time meanwhile runs).

7 Conclusion

With respect to the results obtained, the TDE1708DFT may be used in the operating mode COM1 (4.8 kBaud) in p-switching (high-side) 3-wire sensors and up to operating mode COM2 (38.4 kBaud) in push-pull 3-wire sensors.

Note: In the case of push-pull configuration a precise compensation of the propagation turn-on time temperature drift ([Figure 18](#)) is necessary to avoid cross conduction of the two switches. The alternative driving configuration ([Section 6: Alternative driving](#)) partially solves this issue for the price of employing two input pins for one switch.
