

Overview of Secure Boot and Secure Firmware Update solution on Arm® TrustZone® STM32 microcontrollers

Introduction

This application note describes how to get a Secure Boot and Secure Firmware Update solution on Arm® TrustZone® STM32 microcontrollers based on the Arm® Cortex®-M33 processor. It also provides a top-level comparison of this solution versus the X-CUBE-SBSFU solution, which applies to non-TrustZone® STM32 microcontrollers based on the Arm® Cortex®-M0, Cortex®-M3, Cortex®-M4, or Cortex®-M7 processors. It provides as well top-level integration guidelines for the Secure Boot and Secure Firmware Update solution.

For Arm® TrustZone® STM32 microcontrollers, a Secure Boot and Secure Firmware Update solution is provided in the corresponding STM32Cube MCU Package. Contrary to the solution proposed in the X-CUBE-SBSFU STM32Cube Expansion Package, it is based on the open-source TF-M (Trusted Firmware for Arm® Cortex®-M) reference implementation.

This application note applies to all TrustZone® STM32 microcontrollers (refer to [Table 1](#)). However, in this document, the [STM32L5 Series](#) is used as an example.

Depending on the TrustZone® STM32 microcontroller, TF-M-based application available in the STM32Cube MCU Package may differ. Refer to the user manual of the TFM application (complete implementation of TF-M) of the considered Arm® TrustZone® STM32 microcontroller (see [Section 2 References](#)) to get a precise description of the solution.

To get more information about the open-source TF-M reference implementation, refer to [\[TF-M\]](#).

Table 1. Applicable products

Type	Product series
Microcontrollers	STM32L5 Series , STM32U5 Series

1 General information

Throughout this application note, the terminology *X-CUBE-SBSFU* refers to the Secure Boot and Secure Firmware Update solution available in the *X-CUBE-SBSFU* STM32Cube Expansion Package, whereas the terminology *SBSFU* refers to the Secure Boot and Secure Firmware Update solution available in the STM32Cube MCU Packages of Arm® TrustZone® STM32 microcontrollers (*STM32CubeL5* is used as an example).

Table 2 presents the definition of acronyms that are relevant for a better understanding of this document.

Table 2. List of acronyms

Acronym	Definition
AEAD	Authenticated encryption with associated data
AES	Advanced encryption standard
CBC	AES cipher block chaining
CTR	AES counter mode
EAT	Entity attestation token
ECDSA	Elliptic curve digital signature algorithm
GCM	AES Galois/counter mode
HDP	Hide protection
HUK	Hardware unique key
ITS	Internal trusted storage
KMS	Key management services
MAC	Message authentication code
MPU	Memory protection unit
OEM	Original equipment manufacturer
OTFDEC	On-the-fly decryption
PKCS	Public-key cryptography standard
PSA	Platform security architecture. Framework for securing devices
RDP	Read protection
RoT	Root of Trust
RSA	Rivest–Shamir–Adleman algorithm
SBSFU	Secure Boot and Secure Firmware Update
SST	Secure storage service. Secure storage service provided by TF-M
TBSA-M	Trusted base system architecture for Arm® Cortex®-M
TF-M	Trusted Firmware for M-class Arm® processors. TF-M provides a reference implementation of secure world software for Armv8-M
TFM	Name of the TF-M-based application with complete functionalities in the STM32Cube MCU Package
TZ	TrustZone®
WRP	Write protection

Note: Arm and TrustZone are registered trademarks of Arm Limited (or its subsidiaries) in the US and or elsewhere.

3 Arm® Trusted Firmware-M (TF-M) introduction

TF-M (refer to [TF-M]) is an Arm Limited driven open-source software framework providing a reference implementation of the PSA standard on the Arm® Cortex®-M33 (TrustZone®) processor:

- PSA immutable RoT (Root of Trust): immutable “Secure Boot and Secure Firmware Update” application executed after any reset. This application is based on MCUboot open source software (refer to [MCUboot]).
- PSA updatable RoT: “secure” application implementing a set of secure services isolated in the secure/privileged environment that can be called by the non-secure application at non-secure application run-time via the PSA APIs (refer to [PSA_API]):
 - Secure storage service: TF-M secure storage (SST) service implements PSA protected storage APIs allowing data encryption and writing the result in a possibly untrusted storage. The SST service implements an AES-GCM based AEAD encryption policy, as a reference, to protect data integrity and authenticity.
 - Internal trusted storage service: TF-M internal trusted storage (ITS) service implements PSA internal trusted storage APIs allowing the writing of data in a microcontroller built-in Flash memory region that will be isolated from non-secure or from unprivileged applications by means of the hardware security protection mechanisms.
 - Cryptography service: the TF-M crypto service implements the PSA Crypto APIs that allow an application to use cryptography primitives such as symmetric and asymmetric ciphers, hash, message authentication codes (MACs), and authenticated encryption with associated data (AEAD). It is based on the mbed-crypto open-source software (refer to [mbed-crypto]).
 - Initial attestation service: the TF-M initial attestation service allows the application to prove the device identity during an authentication process to a verification entity. The initial attestation service can create a token on request, which contains a fix set of device specific data.
- Application updatable RoT: third-party secure services that are isolated in the secure/unprivileged environment and that can be called by the non-secure application at non-secure application run-time.

Figure 1. TF-M overview

4 X-CUBE-SBSFU vs. TF-M comparison

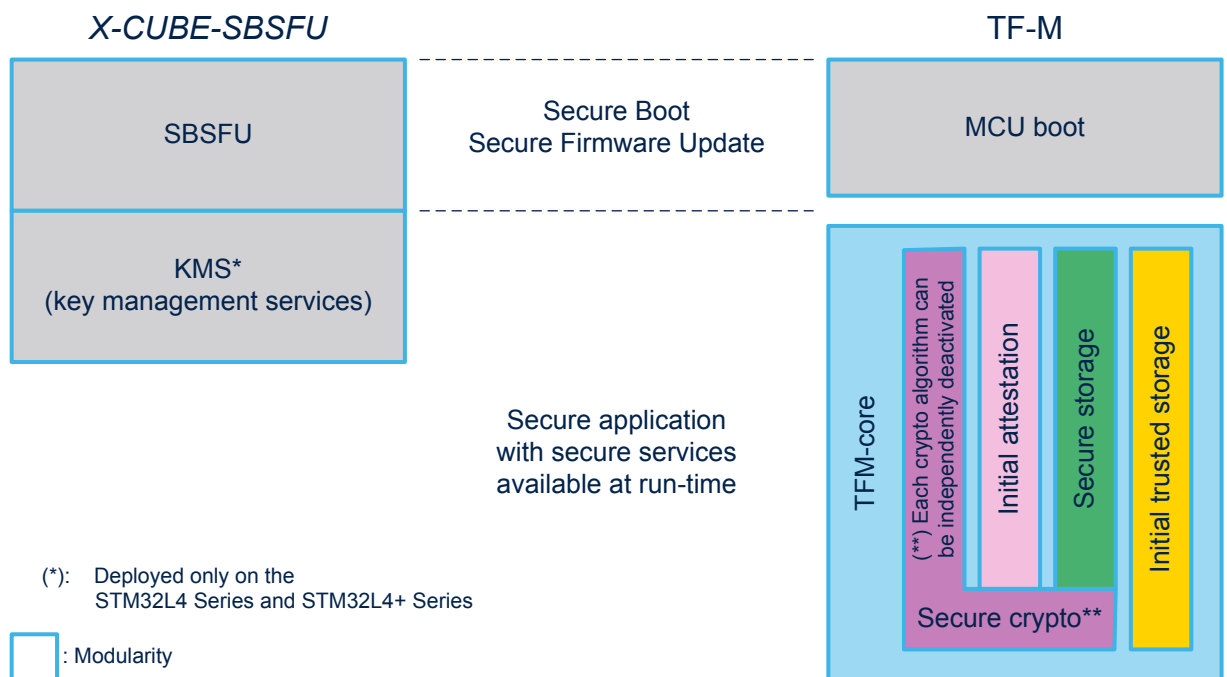

4.1 Overview

X-CUBE-SBSFU provides an STMicroelectronics implementation of Secure Boot and Secure Firmware Update, and optionally for some STM32 series only, secure KMS (key management services) service available at run-time for the user application.

The TF-M reference implementation provides Secure Boot and Secure Firmware Update services based on open-source MCU boot, and a set of secure services available at run-time for the user application.

The high-level comparison between *X-CUBE-SBSFU* and TF-M is shown in Figure 2.

Figure 2. *X-CUBE-SBSFU* vs. TF-M overview

The MCU boot part of the TF-M can be compared to *X-CUBE-SBSFU* (without KMS): it offers similar services. *X-CUBE-SBSFU* KMS supports similar services as TF-M secure crypto services but the lists of cryptographic algorithms or features are not the same and APIs are different even if both are based on an opaque key API concept. Refer to the *X-CUBE-SBSFU* and TF-M APIs documents referenced in the related user manuals ([UM2262] and TFM user manual of the concerned Arm® TrustZone® STM32Cube MCU Package; see Section 2 References) to get more details about the supported features.

4.2 Top-level features

Even if *X-CUBE-SBSFU* and TF-M propose similar services, the features of both solutions are not exactly the same. [Table 5](#) summarizes the differences between *X-CUBE-SBSFU* in *X-CUBE-SBSFU* V2.4.0 and TF-M-based applications in *STM32CubeL5* V1.4.0 as an example.

Table 5. *X-CUBE-SBSFU* vs. TF-M top-level features

Security topic	<i>X-CUBE-SBSFU</i> in <i>X-CUBE-SBSFU</i> V2.4.0 ⁽¹⁾	TF-M in <i>STM32CubeL5</i> V1.4.0 ⁽¹⁾
SBSFU	1 or 2 slots per image. New image via local loader or USER APP. Encrypted image execution in external Flash memory.	1 or 2 slots per image. New image via local loader or USER APP. Encrypted image execution in external Flash memory.
	Single firmware image. Full or partial update.	Single firmware image or multiple (2) firmware images (secure and non-secure) . Full update only.
	Symmetric crypto scheme. Asymmetric crypto scheme (ECDSA) or symmetric crypto scheme , with or without firmware encryption.	Asymmetric crypto scheme (RSA or ECDSA) with or without firmware encryption.
Run-time secure services	Secure services <ul style="list-style-type: none"> • 1 level of isolation • Non-secure interruption managed (STM32L4+ Series only) • Main crypto services (STM32L4 Series and STM32L4+ Series only) 	Secure services <ul style="list-style-type: none"> • 2 levels of isolation • Non-secure interruption managed • Complete crypto services (full SW or mixed SW&HW) • Initial attestation • Secure Storage (data encryption/integrity) • Internal trusted storage (data integrity) • Architecture ready to integrate unprivileged application services

1. Differences are highlighted in bold.

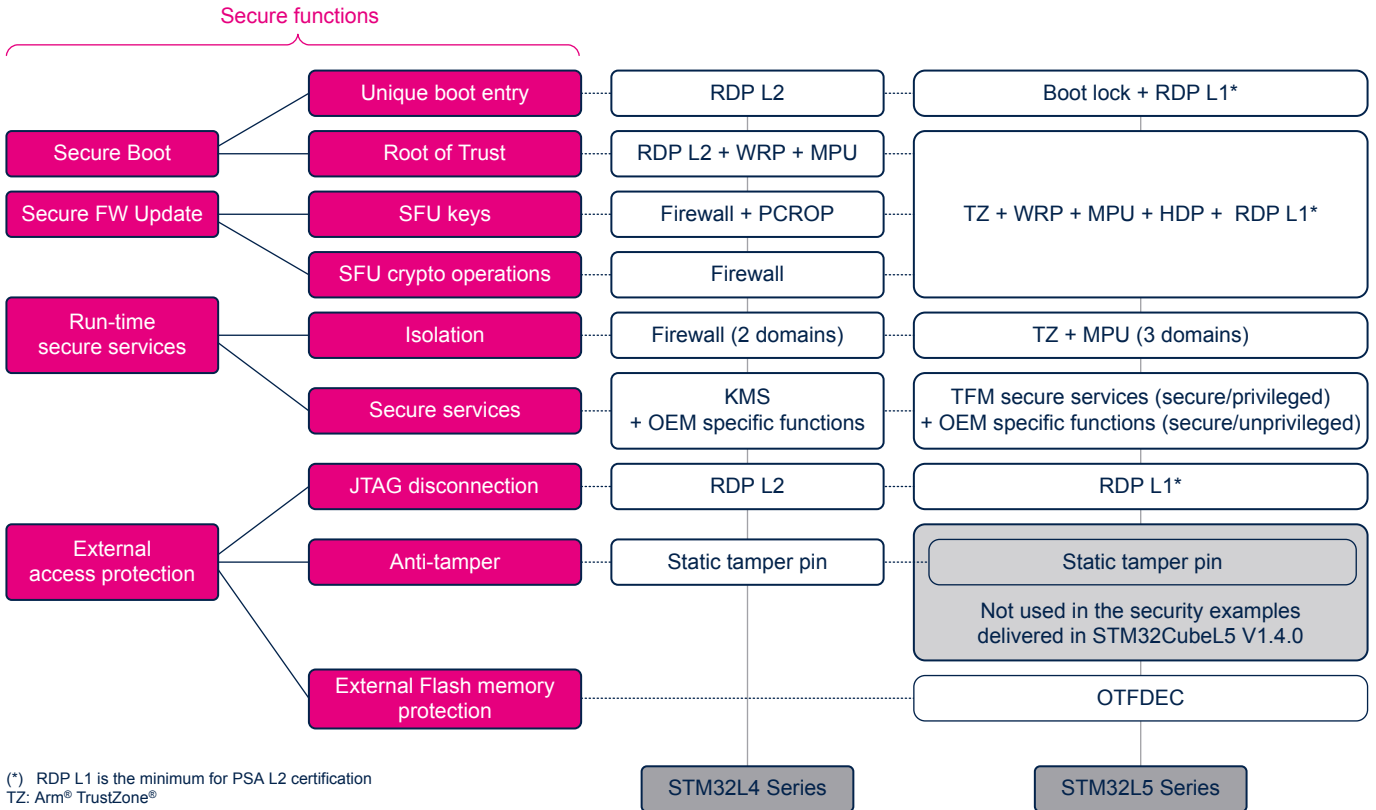

To get an up-to-date view of the feature differences between *X-CUBE-SBSFU* and TF-M-based applications for Arm® TrustZone® STM32 microcontrollers, refer to the latest version of [\[UM2262\]](#) and of the TFM user manual of the concerned Arm® TrustZone® STM32Cube MCU Package (see [Section 2 References](#)).

4.3 Hardware security

The security strategy of the TF-M-based applications is relying on TrustZone® and STM32 microcontroller hardware security features.

Figure 3 shows the comparison of this security strategy (for the STM32L5 Series as an example) with the SBSFU security strategy in X-CUBE-SBSFU (for the STM32L4 Series as example).

Figure 3. X-CUBE-SBSFU (STM32L4 Series) and TF-M (STM32L5 Series) security strategy overview

For more details on security strategy with TF-M, refer to the TFM user manual of the concerned Arm® TrustZone® STM32Cube MCU Package (see Section 2 References).

5 TF-M-based applications

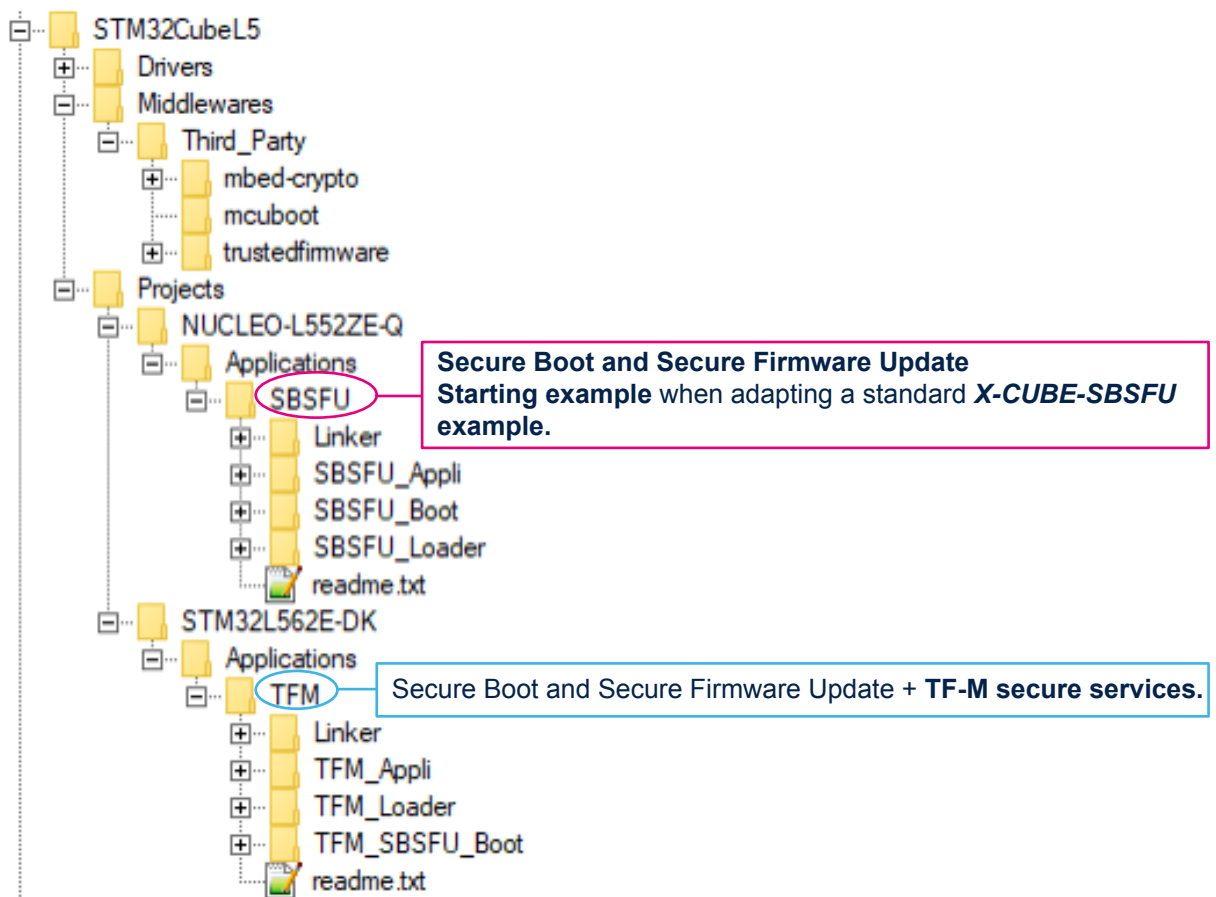

This chapter presents the TF-M-based applications in the STM32Cube MCU Packages of Arm® TrustZone® STM32 microcontrollers.

The Arm® TrustZone® STM32Cube MCU Packages propose two different applications based on the TF-M reference implementation, ported onto the Arm® TrustZone® STM32 microcontrollers to take benefit of the hardware security features.

- **SBSFU**: it consists of the “Secure Boot and Secure Firmware Update” application (named `SBSFU_Boot`) and simple user application example (named `SBSFU_Appli`). A local loader application example (named `SBSFU_Loader`) is also included.
- **TFM**: it consists of the “Secure Boot and Secure Firmware Update” application (named `TFM_SBSFU_Boot`) and user application with TFM secure services at run-time (named `TFM_Appli`). A local loader application example (named `TFM_Loader`) is also included.

Users of *X-CUBE-SBSFU* without KMS are advised to consider the migration to the *SBSFU* application in the Arm® TrustZone® STM32Cube MCU Package of interest. Users of *X-CUBE-SBSFU* with KMS are advised to consider the migration to the TFM application in the Arm® TrustZone® STM32Cube MCU Package of interest (possibly removing some secure services or cryptographic algorithms to fit the application needs).

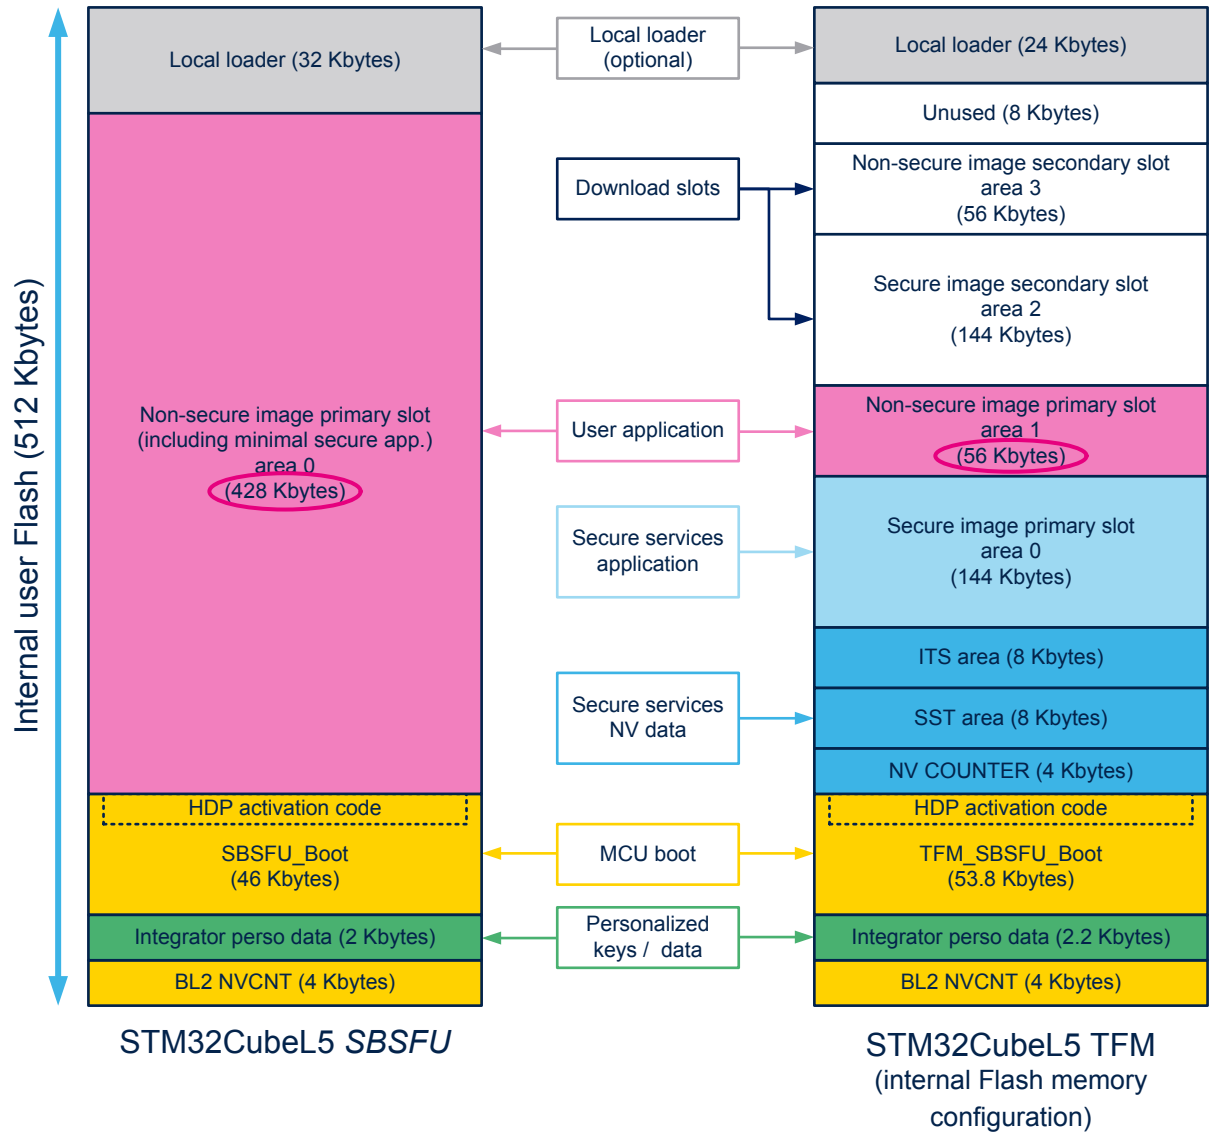

Figure 4. STM32CubeL5 applications based on TF-M

For each application, the memory footprint depends on the configuration (refer to the *Memory layout* section in the TFM user manual of the concerned Arm® TrustZone® STM32Cube MCU Package; see [Section 2 References](#)).

By removing the TF-M secure services at run-time and by proposing one firmware image configuration combined with primary slot only configuration, the *SBSFU* application in the Arm® TrustZone® STM32Cube MCU Package of interest maximizes the amount of internal Flash memory available for the user application as illustrated in Figure 5.

Figure 5. Memory footprint example of STM32CubeL5 applications based on TF-M

For more details on memory mapping, refer to the *Memory layout* section in the TFM user manual of the concerned Arm® TrustZone® STM32Cube MCU Package (see [Section 2 References](#)).

6 SBSFU application

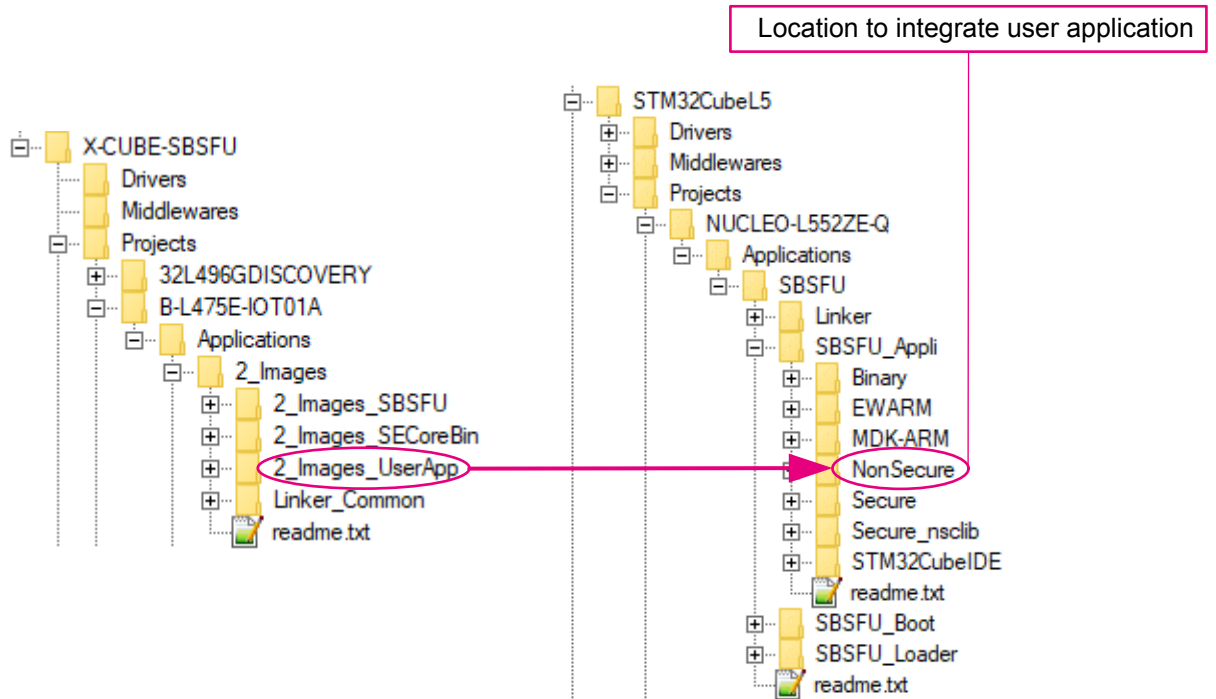

This chapter presents the *SBSFU* application in the STM32Cube MCU Packages of Arm® TrustZone® STM32 microcontrollers.

6.1 User application integration

When migrating from the *X-CUBE-SBSFU* application to the *SBSFU* application in an Arm® TrustZone® STM32Cube MCU Package, the user application must be integrated into the *SBSFU/SBSFU_Appli/NonSecure* folder as shown in Figure 6.

This folder contains a simple user application example.

Figure 6. User application integration

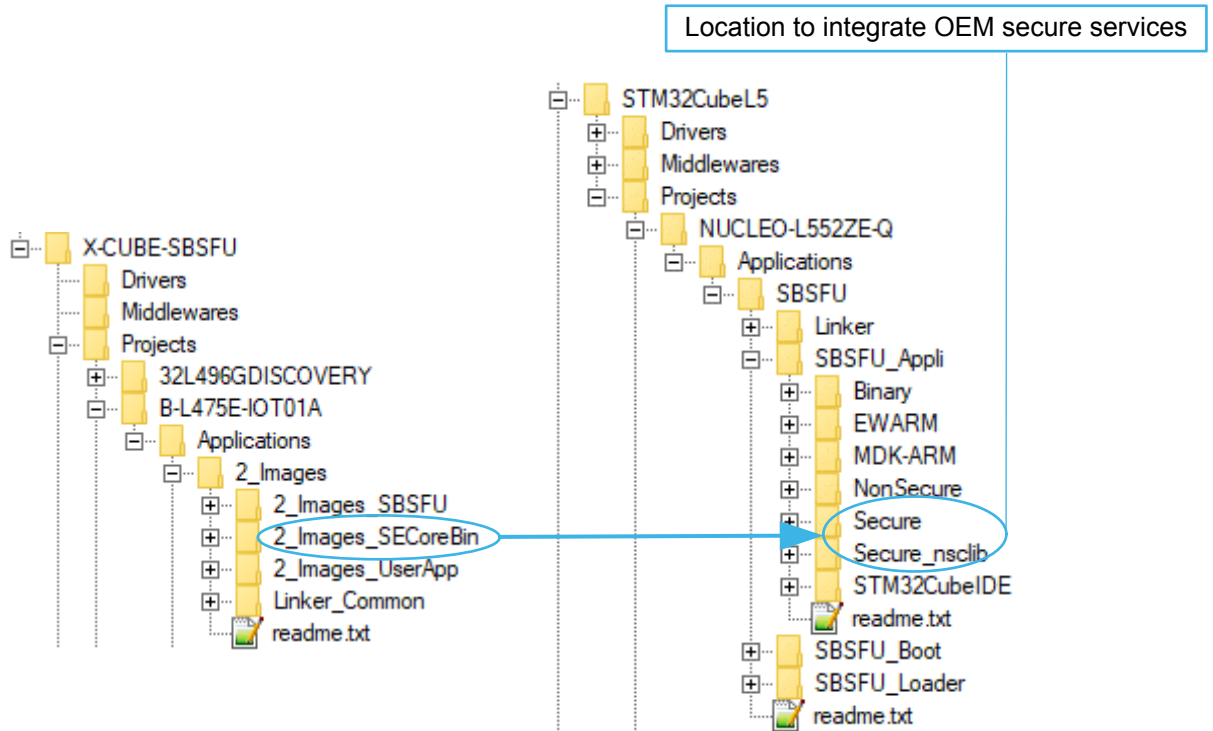

6.2 OEM secure services integration

If OEM own secure services are also implemented in X-CUBE-SBSFU, these OEM secure services must be integrated into the `SBSFU/SBSFU_Appli/Secure` and `SBSFU/SBSFU_Appli/Secure_ncslib` folders, following TrustZone® HAL examples in STM32Cube MCU Packages, as shown in Figure 7.

These folders contain a simple example of OEM secure service: “Secure GPIO Toggle”.

Figure 7. OEM secure services integration (SBSFU)

6.3 Keys personalization

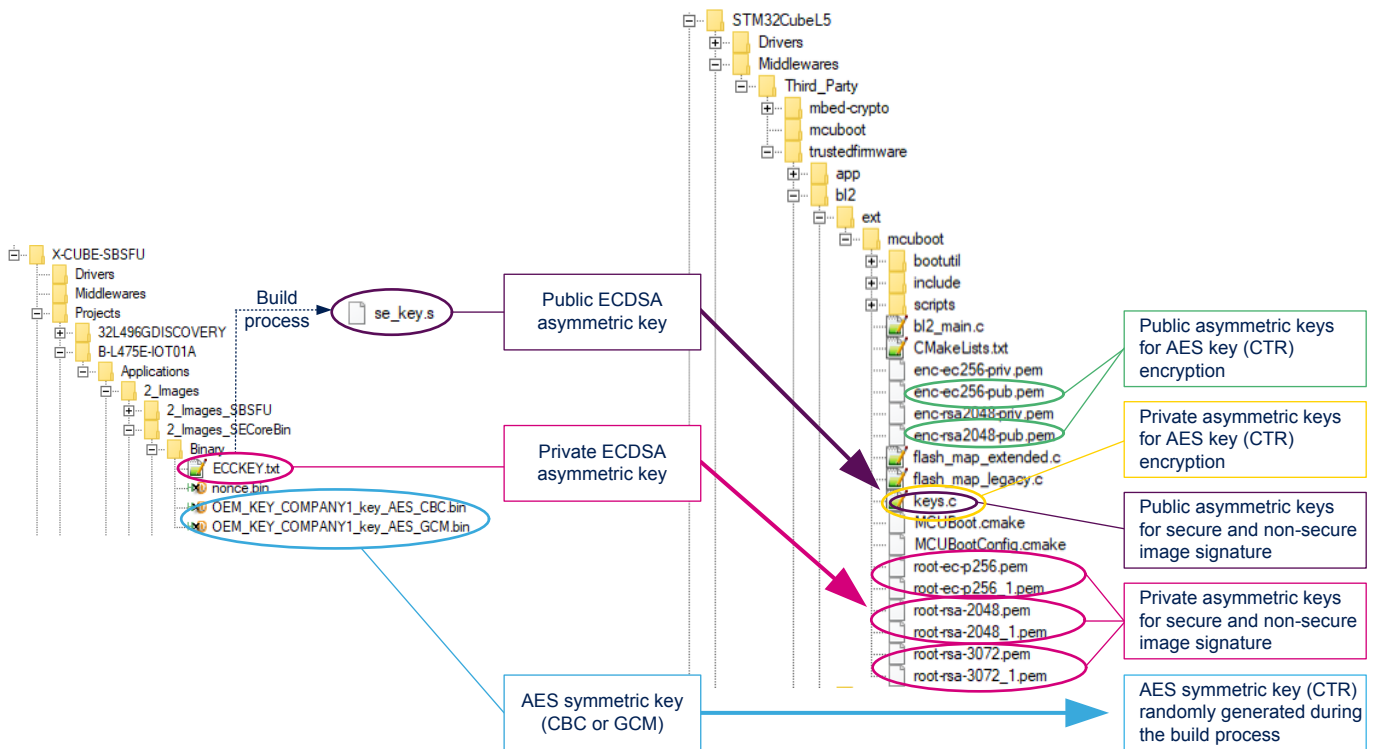

In *X-CUBE-SBSFU*, the personalization data are cryptographic keys:

- ECDSA asymmetric key: for firmware image signature
- AES symmetric key (CBC or GCM): for firmware image encryption

In *SBSFU* in STM32CubeL5 V1.4.0, for firmware image signature, there are two RSA or ECDSA asymmetric keys (one for secure image, and one for non-secure image) to personalize, compared to one ECDSA asymmetric key in *X-CUBE-SBSFU*. It must be noticed that contrary to *X-CUBE-SBSFU*, the public asymmetric keys are not automatically generated during the build process of STM32CubeL5 *SBSFU* but need to be provided by the user together with the private asymmetric keys (refer to Figure 8).

SBSFU in STM32CubeL5 V1.4.0 supports firmware encryption with AES-CTR cryptography. Compared to *X-CUBE-SBSFU*, the AES-CTR key is not present in the personalized data, but is randomly generated during each build process, is encrypted (RSA-OAEP or ECIES-P256) and provided in the firmware image itself. The asymmetric key (RSA or ECDSA) used to encrypt the AES-CTR key is distinct from the asymmetric signature keys. Both public and private asymmetric keys for AES-CTR key encryption must be provided by the user (refer to Figure 8).

Figure 8. Firmware image keys personalization

The two private RSA or ECDSA asymmetric keys used to sign the secure and non-secure firmware images are not embedded in the Flash memory, whereas the two associated public RSA or ECDSA asymmetric keys are present in the build output of the *SBSFU_Boot* project. They are embedded in a dedicated immutable Flash region (personalization data area) as shown in Figure 9.

The public RSA or ECDSA asymmetric key used to encrypt the AES-CTR key is not embedded in the Flash memory, whereas the associated private RSA or ECDSA asymmetric key is present in the build output of `SBSFU_Boot` project, in the personalization data area as well, as shown in Figure 9.

Figure 9. Integrator personalized data area in STM32CubeL5 SBSFU

7 TFM application

This chapter presents the TFM application in the STM32Cube MCU Packages of Arm® TrustZone® STM32 microcontrollers.

The top-level integration guidelines provided in [Section 6 SBSFU application](#) are applicable to the TFM application in STM32Cube MCU Packages. In this section, additional top-level integration guidelines, specific to the TFM application in STM32Cube MCU Packages, are provided.

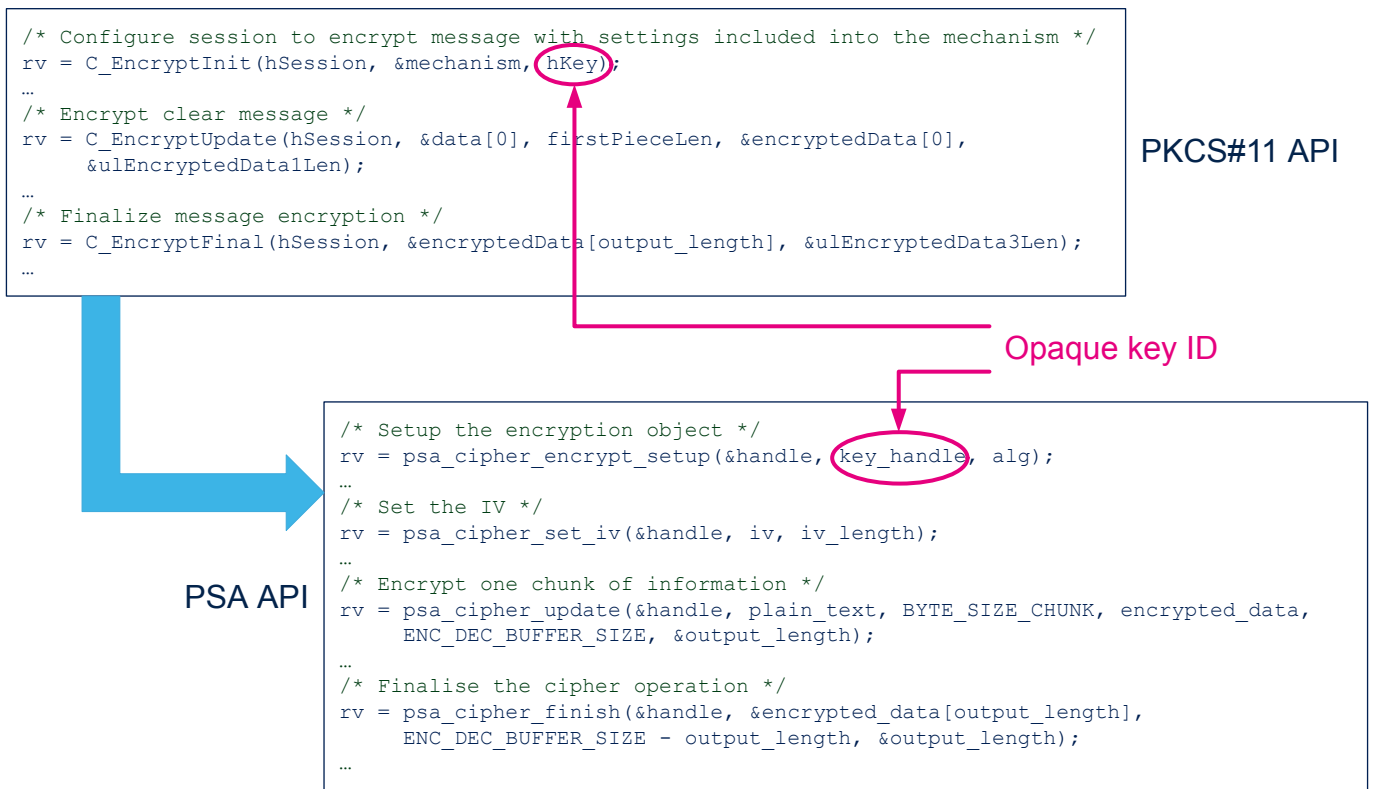

To get more information on the TFM application in STM32Cube MCU Packages, refer to the TFM user manual of the concerned Arm® TrustZone® STM32Cube MCU Package (see [Section 2 References](#)).

7.1 Cryptographic secure services at run-time

In *X-CUBE-SBSFU*, the KMS services are provided to the user application through PKCS#11 APIs. In the TFM application in STM32Cube MCU Packages, the secure cryptography services are provided to the user application through PSA cryptographic APIs. Both are based on an opaque key APIs concept.

[Figure 10](#) shows an example of API usage difference for AES encryption.

Figure 10. PSA API migration example

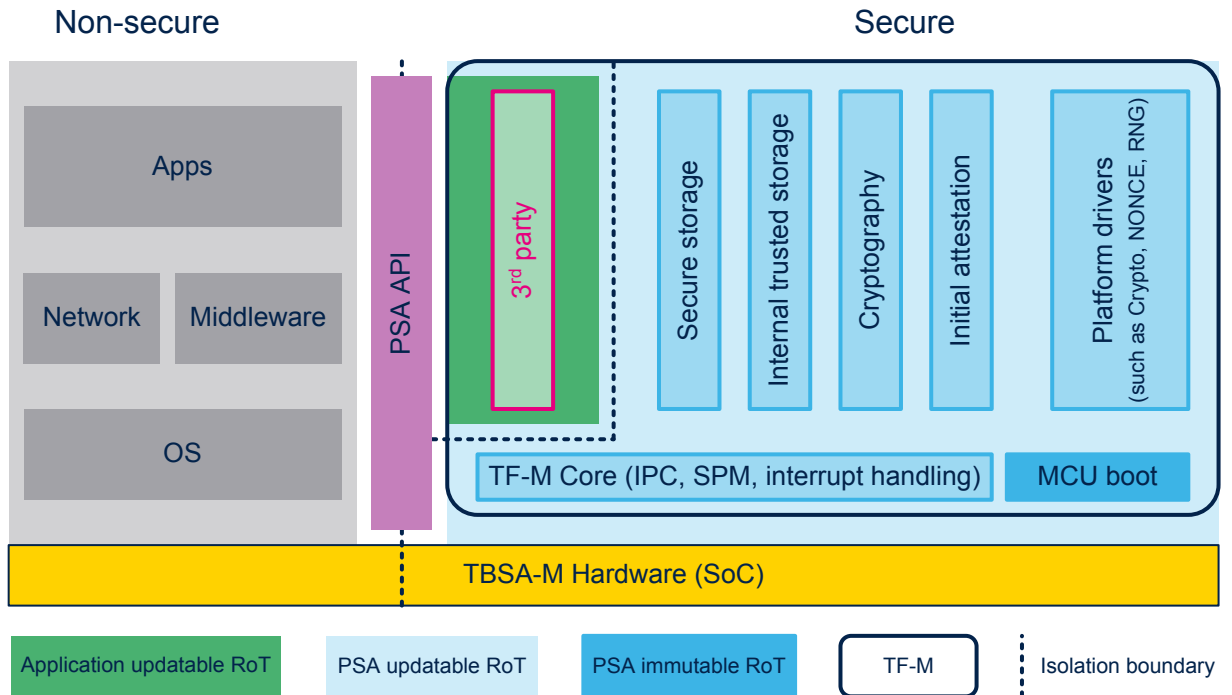

For more information on PSA APIs, refer to TFM user application example and [\[PSA_API\]](#).

7.2 OEM secure services integration

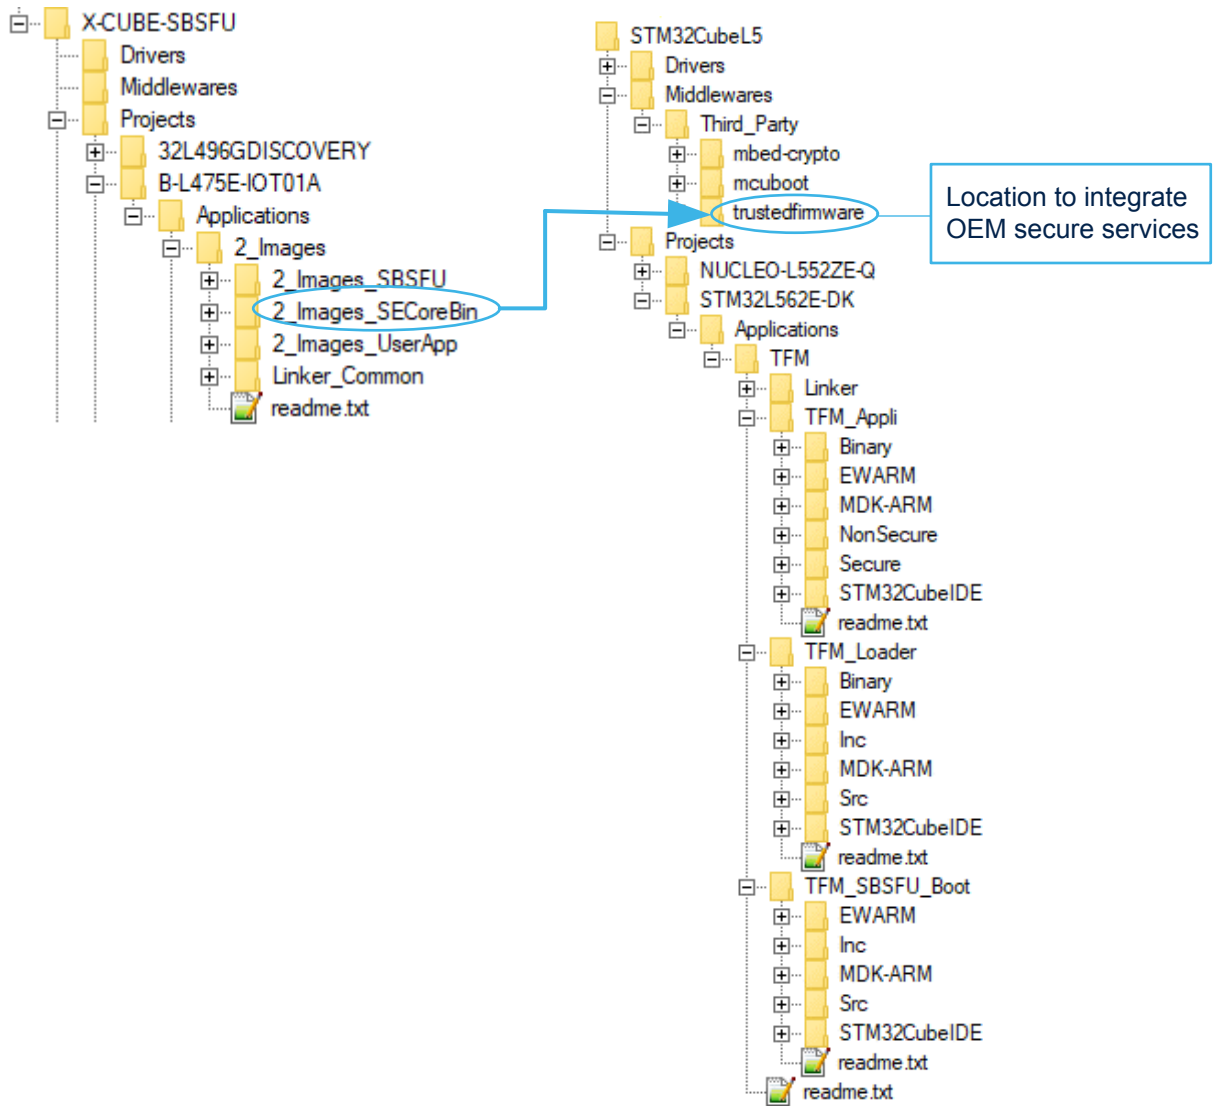

As shown in [Figure 11](#), the OEM secure services must be integrated as third-party secure services in the secure/unprivileged part of the secure application (referred to as “*Application RoT from TFM framework*”). For more information on “*Application RoT from TFM framework*”, refer to the TFM user manual of the concerned Arm® TrustZone® STM32Cube MCU Package (see [Section 2 References](#)).

Figure 11. 3rd party secure services in TF-M

These services must be integrated in the `Middlewares/trustedfirmware` folder as shown in Figure 12. For more information, refer to [TF-M].

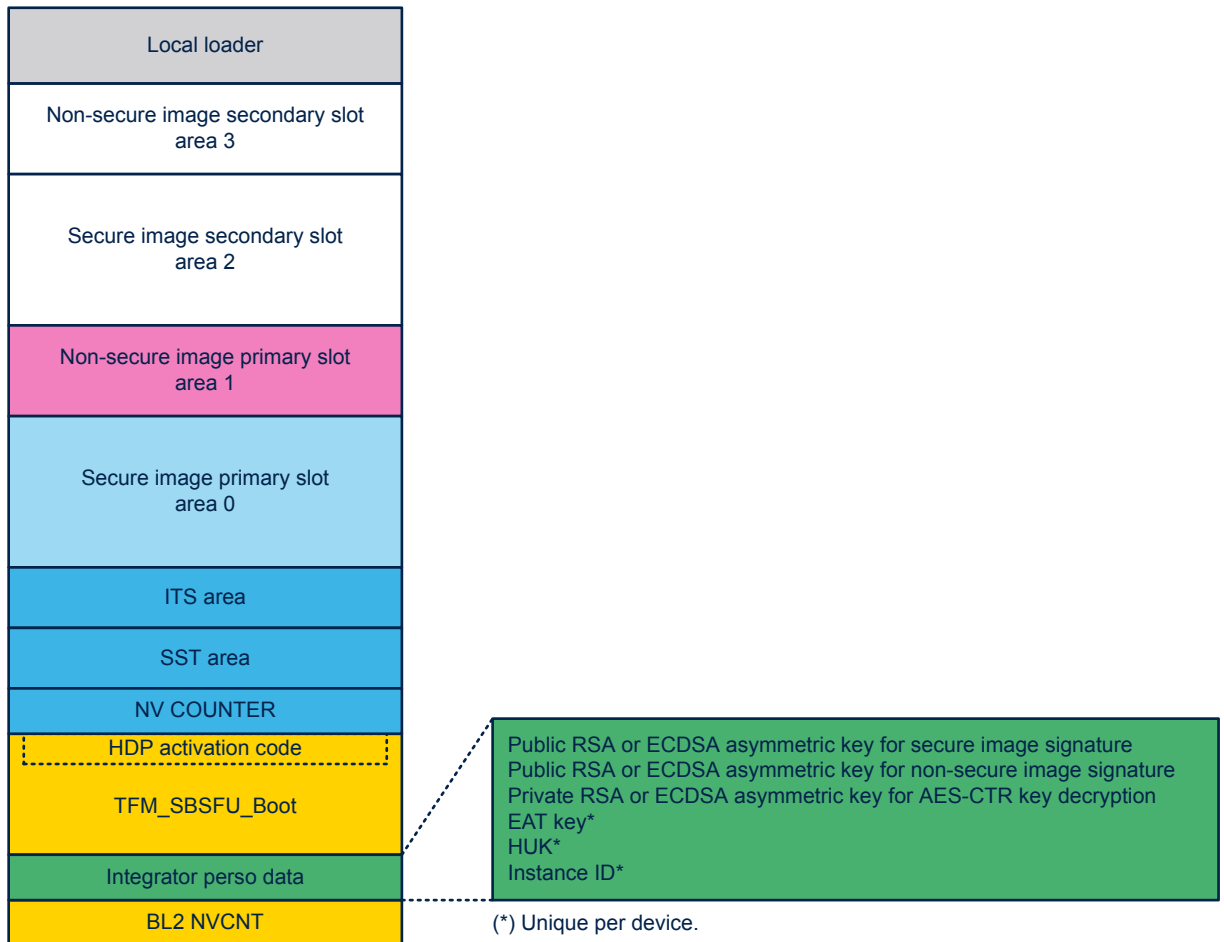

Figure 12. OEM secure services integration (TFM)

7.3 Data personalization

In addition to the firmware image authentication keys, additional data requires personalization for the TFM application: EAT key, HUK, and Instance ID. These data are required for TF-M initial attestation service. They are product-specific (unique per device). These data, together with the asymmetric keys for images signature and AES CTR key decryption (refer to [Section 6.3 Keys personalization](#)), are grouped in the dedicated immutable Flash region (personalization data area), which must be personalized for each device in production, before activating the final security configuration.

Figure 13. Personalization data region

STM32CubeL5 TFM

For more details on personalization data, refer to section *Integrator role description* in the TFM user manual of the concerned Arm® TrustZone® STM32Cube MCU Package (see [Section 2 References](#)).

Revision history

Table 6. Document revision history

Date	Revision	Changes
20-Feb-2020	1	Initial release.
24-Jul-2020	2	Updated the entire document for STM32CubeL5 firmware V1.3.0 release. New features in <code>SBSFU_Boot</code> : image encryption, external Flash memory support with OTFDEC, configurable crypto schemes, configurable image number mode, configurable slot mode, and RSA hardware accelerator. Local loader introduced.
16-Aug-2021	3	<p>Made the document generic to cover all applicable Arm® TrustZone® STM32 microcontrollers and the related STM32Cube MCU Packages, keeping the STM32CubeL5 MCU Package as an example:</p> <ul style="list-style-type: none"> • Updated the document title • Added Table 1. Applicable products and updated Table 3. Document references • Updated Section 4.2 Top-level features and Section 6.3 Keys personalization
