Introduction

This reference manual targets application developers. It provides complete information on how to use the STM32L4+ Series microcontrollers memory and peripherals.

The STM32L4+ Series is a family of microcontrollers with different memory sizes, packages and peripherals.

For ordering information, mechanical and electrical device characteristics, refer to the corresponding datasheets.

For information on the Arm® Cortex®-M4 core, refer to the Cortex®-M4 Technical Reference Manual.

  5.4.9 Power Port A pull-down control register (PWR_PDCRA) .............. 226
  5.4.10 Power Port B pull-up control register (PWR_PUCRB) ............... 226
  5.4.11 Power Port B pull-down control register (PWR_PDCRB) ............. 227
  5.4.12 Power Port C pull-up control register (PWR_PUCRC) ............... 227
  5.4.13 Power Port C pull-down control register (PWR_PDCRC) ............. 228
  5.4.14 Power Port D pull-up control register (PWR_PUCRD) ............... 228
  5.4.15 Power Port D pull-down control register (PWR_PDCRD) ............. 229
  5.4.16 Power Port E pull-up control register (PWR_PUCRE) ............... 229
  5.4.17 Power Port E pull-down control register (PWR_PDCRE) ............. 230
  5.4.18 Power Port F pull-up control register (PWR_PUCRF) ............... 230
  5.4.19 Power Port F pull-down control register (PWR_PDCRF) ............. 231
  5.4.20 Power Port G pull-up control register (PWR_PUCRG) ............... 231
  5.4.21 Power Port G pull-down control register (PWR_PDCRG) ............. 232
  5.4.22 Power Port H pull-up control register (PWR_PUCH) ................. 232
  5.4.23 Power Port H pull-down control register (PWR_PDCHR) ............. 233
6 Reset and clock control (RCC) .................................................. 238

6.1 Reset .................................................. 238
6.1.1 Power reset ........................................... 238
6.1.2 System reset .......................................... 238
6.1.3 Backup domain reset ................................... 239

6.2 Clocks ................................................. 240
6.2.1 HSE clock ........................................... 246
6.2.2 HSI16 clock .......................................... 247
6.2.3 MSI clock ........................................... 248
6.2.4 HSI48 clock .......................................... 248
6.2.5 PLL .................................................. 249
6.2.6 LSE clock ........................................... 250
6.2.7 LSI clock ........................................... 250
6.2.8 System clock (SYSCLK) selection .............. 251
6.2.9 Clock source frequency versus voltage scaling 251
6.2.10 Clock security system (CSS) .................. 252
6.2.11 Clock security system on LSE ................. 252
6.2.12 ADC clock ........................................ 253
6.2.13 RTC clock ........................................ 253
6.2.14 Timer clock ........................................ 253
6.2.15 Watchdog clock ................................... 253
6.2.16 Clock-out capability ......................... 254
6.2.17 Internal/external clock measurement with TIM15/TIM16/TIM17 254
6.2.18 Peripheral clock enable register (RCC_AHBxENR, RCC_APBxENRx) 257

6.3 Low-power modes ....................................... 257

6.4 RCC registers ........................................ 258
6.4.1 Clock control register (RCC_CR) .............. 258
6.4.2 Internal clock sources calibration register (RCC_ICSCR) 261
6.4.3 Clock configuration register (RCC_CFGR) .......... 261
6.4.4 PLL configuration register (RCC_PLLCFGR) ........ 264
6.4.5 PLLSAI1 configuration register (RCC_PLLASAI1CFGR) 266
6.4.6 PLLSAI2 configuration register (RCC_PLLSAI2CFGR) .......................... 270
6.4.7 Clock interrupt enable register (RCC_CIER) ............................... 272
6.4.8 Clock interrupt flag register (RCC_CIFR) ................................. 274
6.4.9 Clock interrupt clear register (RCC_CICR) .............................. 275
6.4.10 AHB1 peripheral reset register (RCC_AHB1RSTR) ....................... 277
6.4.11 AHB2 peripheral reset register (RCC_AHB2RSTR) ....................... 278
6.4.12 AHB3 peripheral reset register (RCC_AHB3RSTR) ....................... 280
6.4.13 APB1 peripheral reset register 1 (RCC_APB1RSTR1) ................. 281
6.4.14 APB1 peripheral reset register 2 (RCC_APB1RSTR2) ................. 283
6.4.15 APB2 peripheral reset register (RCC_APB2RSTR) ....................... 284
6.4.16 AHB1 peripheral clock enable register (RCC_AHB1ENR) .............. 286
6.4.17 AHB2 peripheral clock enable register (RCC_AHB2ENR) .............. 287
6.4.18 AHB3 peripheral clock enable register (RCC_AHB3ENR) .............. 289
6.4.19 APB1 peripheral clock enable register 1 (RCC_APB1ENR1) .......... 290
6.4.20 APB1 peripheral clock enable register 2 (RCC_APB1ENR2) .......... 292
6.4.21 APB2 peripheral clock enable register (RCC_APB2ENR) .............. 294
6.4.22 AHB1 peripheral clocks enable in Sleep and Stop modes register (RCC_AHB1SMENR) .................................................. 295
6.4.23 AHB2 peripheral clocks enable in Sleep and Stop modes register (RCC_AHB2SMENR) .................................................. 297
6.4.24 AHB3 peripheral clocks enable in Sleep and Stop modes register (RCC_AHB3SMENR) .................................................. 299
6.4.25 APB1 peripheral clocks enable in Sleep and Stop modes register 1 (RCC_APB1SMENR1) ................................................. 300
6.4.26 APB1 peripheral clocks enable in Sleep and Stop modes register 2 (RCC_APB1SMENR2) ................................................. 303
6.4.27 APB2 peripheral clocks enable in Sleep and Stop modes register (RCC_APB2SMENR) .................................................. 304
6.4.28 Peripherals independent clock configuration register (RCC_CCIPR) 305
6.4.29 Backup domain control register (RCC_BDCR) .......................... 308
6.4.30 Control/status register (RCC_CSR) ......................................... 310
6.4.31 Clock recovery RC register (RCC_CRRCR) ............................... 312
6.4.32 Peripherals independent clock configuration register (RCC_CCIPR2) 313
6.4.33 OCTOSPI delay configuration register (RCC_DLYCFGR) ............. 315
6.4.34 RCC register map ................................................................. 316

7 Clock recovery system (CRS) ....................................................... 321
7.1 Introduction ............................................................................. 321
7.2 CRS main features ................................................................. 321
### Contents

7.3 CRS implementation ........................................... 321

    8.3.12 Analog configuration ....................................... 340
    8.3.13 Using the HSE or LSE oscillator pins as GPIOs .......... 340
    8.3.14 Using the GPIO pins in the RTC supply domain ............ 340
    8.3.15 Using PH3 as GPIO .......................................... 341
  8.4 GPIO registers ................................................ 341
8.4.1 GPIO port mode register (GPIOx_MODER) (x = A to I) ........................................ 341
8.4.2 GPIO port output type register (GPIOx_OTYPER) (x = A to I) ........................................ 342
8.4.3 GPIO port output speed register (GPIOx_OSPEEDR) (x = A to I) ........................................ 342
8.4.4 GPIO port pull-up/pull-down register (GPIOx_PUPDR) (x = A to I) ........................................ 343
8.4.5 GPIO port input data register (GPIOx_IDR) (x = A to I) ........................................ 343
8.4.6 GPIO port output data register (GPIOx_ODR) (x = A to I) ........................................ 344
8.4.7 GPIO port bit set/reset register (GPIOx_BSRR) (x = A to I) ........................................ 344
8.4.8 GPIO port configuration lock register (GPIOx_LCKR) (x = A to I) ........................................ 344
8.4.9 GPIO alternate function low register (GPIOx_AFRL) (x = A to I) ........................................ 346
8.4.10 GPIO alternate function high register (GPIOx_AFRH) (x = A to I) ........................................ 346
8.4.11 GPIO port bit reset register (GPIOx_BRR) (x = A to I) ........................................ 347
8.4.12 GPIO register map ........................................ 348

9 System configuration controller (SYSCFG) ........................................ 350
9.1 SYSCFG main features ........................................ 350
9.2 SYSCFG registers ........................................ 350
  9.2.1 SYSCFG memory remap register (SYSCFG_MEMRMP) ........................................ 350
  9.2.2 SYSCFG configuration register 1 (SYSCFG_CFRG1) ........................................ 351
  9.2.3 SYSCFG external interrupt configuration register 1 (SYSCFG_EXTICR1) ........................................ 353
  9.2.4 SYSCFG external interrupt configuration register 2 (SYSCFG_EXTICR2) ........................................ 355
  9.2.5 SYSCFG external interrupt configuration register 3 (SYSCFG_EXTICR3) ........................................ 356
  9.2.6 SYSCFG external interrupt configuration register 4 (SYSCFG_EXTICR4) ........................................ 358
  9.2.7 SYSCFG SRAM2 control and status register (SYSCFG_SCSR) ........................................ 359
  9.2.8 SYSCFG configuration register 2 (SYSCFG_CFGR2) ........................................ 360
  9.2.9 SYSCFG SRAM2 write protection register (SYSCFG_SWPR) ........................................ 361
  9.2.10 SYSCFG SRAM2 key register (SYSCFG_SKR) ........................................ 361
  9.2.11 SYSCFG SRAM2 write protection register 2 (SYSCFG_SWPR2) ........................................ 362
10 Peripherals interconnect matrix ................................................. 365
  10.1 Introduction ............................................................... 365
  10.2 Connection summary ..................................................... 365
  10.3 Interconnection details .................................................. 366
    10.3.1 From timer (TIM1/TIM2/TIM3/TIM4/TIM5/TIM8/TIM15/TIM16/TIM17)
      to timer (TIM1/TIM2/TIM3/TIM4/TIM5/TIM8/TIM15) ..................... 366
    10.3.2 From timer (TIM1/TIM2/TIM3/TIM6/TIM8/TIM15) and EXTI
      to ADC (ADC1) ............................................................ 367
    10.3.3 From ADC to timer (TIM1/TIM8) .................................... 368
    10.3.4 From timer (TIM2/TIM4/TIM5/TIM6/TIM7/TIM8/LPTIM1/LPTIM2)
      and EXTI to DAC (internal channel 1 and channel 2) ................. 368
    10.3.5 From timer (TIM1/TIM3/TIM4/TIM6/TIM7/TIM8/LPTIM1/LPTIM2)
      and EXTI to DFSDM1 ................................................... 368
    10.3.6 From DFSDM1 to timer (TIM1/TIM8/TIM15/TIM16/TIM17) .......... 369
    10.3.7 From HSE, LSE, LSI, MSI, MCO, RTC to timer
      (TIM2/TIM15/TIM16/TIM17) ........................................... 369
    10.3.8 From RTC, COMP1, COMP2 to low-power timer (LPTIM1/LPTIM2) . 370
    10.3.9 From timer (TIM1/TIM2/TIM3/TIM8/TIM15) to comparators
      (COMP1/COMP2) ...................................................... 370
    10.3.10 From ADC (ADC1) to ADC (ADC2) ................................ 370
    10.3.11 From USB to timer (TIM2) ........................................ 371
    10.3.12 From internal analog source to ADC and OPAMP
      (OPAMP1/OPAMP2) ................................................... 371
    10.3.13 From comparators (COMP1/COMP2) to timers
      (TIM1/TIM2/TIM3/TIM8/TIM15/TIM16/TIM17) .......................... 372
    10.3.14 From system errors to timers (TIM1/TIM8/TIM15/TIM16/TIM17) ... 372
    10.3.15 From timers (TIM16/TIM17) to IRTIM ............................ 373
    10.3.16 From ADC (ADC1/ADC2) to DFSDM ................................ 373

11 Direct memory access controller (DMA) .................................... 374
  11.1 Introduction .............................................................. 374
  11.2 DMA main features ....................................................... 374
  11.3 DMA implementation ..................................................... 375
    11.3.1 DMA1 and DMA2 .................................................... 375
    11.3.2 DMA request mapping ............................................. 375
  11.4 DMA functional description ............................................ 375
    11.4.1 DMA block diagram ................................................ 375
11.4.2 DMA pins and internal signals ........................................ 377
11.4.3 DMA transfers .......................................................... 377
11.4.4 DMA arbitration .......................................................... 378
11.4.5 DMA channels ............................................................ 378
11.4.6 DMA data width, alignment and endianness ...................... 382
11.4.7 DMA error management ............................................... 383
11.5 DMA interrupts ............................................................ 384
11.6 DMA registers .............................................................. 384
  11.6.1 DMA interrupt status register (DMA_ISR) ...................... 384
  11.6.2 DMA interrupt flag clear register (DMA_IFCR) ............... 387
  11.6.3 DMA channel x configuration register (DMA_CCRx) .......... 388
  11.6.4 DMA channel x number of data to transfer register (DMA_CNDTRx) .................................................. 391
  11.6.5 DMA channel x peripheral address register (DMA_CPARx) .. 391
  11.6.6 DMA channel x memory address register (DMA_CMARx) ...... 392
  11.6.7 DMA register map .................................................... 392

12 DMA request multiplexer (DMAMUX) .................................. 395
  12.1 Introduction ............................................................. 395
  12.2 DMAMUX main features ............................................... 396
  12.3 DMAMUX implementation ............................................. 396
    12.3.1 DMAMUX instantiation ........................................... 396
    12.3.2 DMAMUX mapping ................................................ 396
  12.4 DMAMUX functional description .................................. 402
    12.4.1 DMAMUX block diagram .......................................... 402
    12.4.2 DMAMUX signals ................................................ 403
    12.4.3 DMAMUX channels ............................................... 403
    12.4.4 DMAMUX request line multiplexer .......................... 403
    12.4.5 DMAMUX request generator .................................... 406
  12.5 DMAMUX interrupts .................................................. 407
  12.6 DMAMUX registers ................................................... 408
    12.6.1 DMAMUX request line multiplexer channel x configuration register (DMAMUX_CxCR) .............. 408
    12.6.2 DMAMUX request line multiplexer interrupt channel status register (DMAMUX_CSR) .................... 409
    12.6.3 DMAMUX request line multiplexer interrupt clear flag register (DMAMUX_CFR) ......................... 409
12.6.4 DMAMUX request generator channel x configuration register (DMAMUX_RGxCR) ........................................... 410
12.6.5 DMAMUX request generator interrupt status register (DMAMUX_RGSR) .................................................. 411
12.6.6 DMAMUX request generator interrupt clear flag register (DMAMUX_RGCFR) ........................................... 411

13 Chrom-ART Accelerator controller (DMA2D) ......................... 414
13.1 DMA2D introduction ............................................................... 414
13.2 DMA2D main features ........................................................... 414
13.3 DMA2D functional description ................................................. 415
   13.3.1 DMA2D block diagram .................................................. 415
   13.3.2 DMA2D control ............................................................ 416
   13.3.3 DMA2D foreground and background FIFOs ....................... 416
   13.3.4 DMA2D foreground and background pixel format converter (PFC) ... 417
   13.3.5 DMA2D foreground and background CLUT interface ............ 419
   13.3.6 DMA2D blender .......................................................... 420
   13.3.7 DMA2D output PFC .................................................... 421
   13.3.8 DMA2D output FIFO .................................................. 421
   13.3.9 DMA2D output FIFO byte reordering ............................... 422
   13.3.10 DMA2D AHB master port timer ..................................... 423
   13.3.11 DMA2D transactions .................................................. 424
   13.3.12 DMA2D configuration .................................................. 424
   13.3.13 DMA2D transfer control (start, suspend, abort and completion) ... 428
   13.3.14 Watermark ............................................................. 428
   13.3.15 Error management ..................................................... 428
   13.3.16 AHB dead time ....................................................... 428
13.4 DMA2D interrupts ............................................................... 429
13.5 DMA2D registers ............................................................... 430
   13.5.1 DMA2D control register (DMA2D_CR) ............................... 430
   13.5.2 DMA2D interrupt status register (DMA2D_ISR) ................. 432
   13.5.3 DMA2D interrupt flag clear register (DMA2D_IFCR) ............. 433
   13.5.4 DMA2D foreground memory address register (DMA2D_FGMAR) ... 433
   13.5.5 DMA2D foreground offset register (DMA2D_FGOR) ................ 434
   13.5.6 DMA2D background memory address register (DMA2D_BGMAR) ... 434
   13.5.7 DMA2D background offset register (DMA2D_BGOR) ............... 435
13.5.8 DMA2D foreground PFC control register (DMA2D_FGPFCCR) ............. 436
13.5.9 DMA2D foreground color register (DMA2D_FGCOLR) .................. 438
13.5.10 DMA2D background PFC control register (DMA2D_BGPFCCR) ....... 439
13.5.11 DMA2D background color register (DMA2D_BGCOLR) ............... 441
13.5.12 DMA2D foreground CLUT memory address register (DMA2D_FGCMAR) .................................................. 441
13.5.13 DMA2D background CLUT memory address register (DMA2D_BGCMAR) .................................................. 442
13.5.14 DMA2D output PFC control register (DMA2D_OPFCCR) .............. 442
13.5.15 DMA2D output color register (DMA2D_OCOLR) ....................... 443
13.5.16 DMA2D output memory address register (DMA2D_OMAR) .......... 445
13.5.17 DMA2D output offset register (DMA2D_OOR) .......................... 445
13.5.18 DMA2D number of line register (DMA2D_NLR) ....................... 446
13.5.19 DMA2D line watermark register (DMA2D_LWR) ....................... 446
13.5.20 DMA2D AHB master timer configuration register (DMA2D_AMTCR) 447
13.5.21 DMA2D foreground CLUT (DMA2D_FGCLUT[y]) ...................... 447
13.5.22 DMA2D background CLUT (DMA2D_BGCLUT[y]) ...................... 448
13.5.23 DMA2D register map .................................................. 449

14 Chrom-GRC (GFXMMU) ......................................................... 451
14.1 Introduction ............................................................... 451
14.2 GFXMMU main features .................................................. 451
14.3 GFXMMU functional and architectural description ...................... 452
  14.3.1 Virtual memory ..................................................... 452
  14.3.2 MMU architecture ................................................... 454
14.4 GFXMMU interrupts ....................................................... 458
14.5 GFXMMU registers .......................................................... 459
  14.5.1 GFXMMU configuration register (GFXMMU_CR) ...................... 459
  14.5.2 GFXMMU status register (GFXMMU_SR) ............................ 460
  14.5.3 GFXMMU flag clear register (GFXMMU_FCR) ..................... 460
  14.5.4 GFXMMU default value register (GFXMMU_DVR) ................. 461
  14.5.5 GFXMMU buffer 0 configuration register (GFXMMU_B0CR) .... 461
  14.5.6 GFXMMU buffer 1 configuration register (GFXMMU_B1CR) ...... 462
  14.5.7 GFXMMU buffer 2 configuration register (GFXMMU_B2CR) .... 462
  14.5.8 GFXMMU buffer 3 configuration register (GFXMMU_B3CR) ...... 463
  14.5.9 GFXMMU LUT entry x low (GFXMMU_LUTxL) ..................... 463
  14.5.10 GFXMMU LUT entry x high (GFXMMU_LUTxH) ................... 463
## Contents

14.5.11 GFXMMU register map ........................................... 465

15 **Nested vectored interrupt controller (NVIC)** .................. 466
   15.1 NVIC main features ............................................. 466
   15.2 SysTick calibration value register ......................... 466
   15.3 Interrupt and exception vectors ............................. 467

16 **Extended interrupts and events controller (EXTI)** ............. 475
   16.1 Introduction .................................................. 475
   16.2 EXTI main features ............................................ 475
   16.3 EXTI functional description ................................. 475
      16.3.1 EXTI block diagram ...................................... 476
      16.3.2 Wakeup event management ............................... 476
      16.3.3 Peripherals asynchronous Interrupts .................. 477
      16.3.4 Hardware interrupt selection .......................... 477
      16.3.5 Hardware event selection ................................ 477
      16.3.6 Software interrupt/event selection .................... 477
   16.4 EXTI interrupt/event line mapping ........................... 477
   16.5 EXTI registers ................................................ 480
      16.5.1 Interrupt mask register 1 (EXTI_IMR1) ............... 480
      16.5.2 Event mask register 1 (EXTI_EMR1) .................... 480
      16.5.3 Rising trigger selection register 1 (EXTI_RTSR1) .... 480
      16.5.4 Falling trigger selection register 1 (EXTI_FTSR1) ... 481
      16.5.5 Software interrupt event register 1 (EXTI_SWIER1) .. 482
      16.5.6 Pending register 1 (EXTI_PR1) .......................... 483
      16.5.7 Interrupt mask register 2 (EXTI_IMR2) ................ 483
      16.5.8 Event mask register 2 (EXTI_EMR2) .................... 484
      16.5.9 Rising trigger selection register 2 (EXTI_RTSR2) ..... 484
      16.5.10 Falling trigger selection register 2 (EXTI_FTSR2) ... 485
      16.5.11 Software interrupt event register 2 (EXTI_SWIER2) .. 485
      16.5.12 Pending register 2 (EXTI_PR2) .......................... 486
      16.5.13 EXTI register map ....................................... 487

17 **Cyclic redundancy check calculation unit (CRC)** ............... 488
   17.1 Introduction .................................................. 488
   17.2 CRC main features ............................................ 488
17.3 CRC functional description ........................................... 489
  17.3.1 CRC block diagram ................................................. 489
  17.3.2 CRC internal signals .............................................. 489
  17.3.3 CRC operation ..................................................... 489
17.4 CRC registers .......................................................... 491
  17.4.1 CRC data register (CRC_DR) ...................................... 491
  17.4.2 CRC independent data register (CRC_IDR) ....................... 491
  17.4.3 CRC control register (CRC_CR) ................................... 492
  17.4.4 CRC initial value (CRC_INIT) .................................... 493
  17.4.5 CRC polynomial (CRC_POL) ...................................... 493
  17.4.6 CRC register map .................................................. 494

18 Flexible static memory controller (FSMC) .......................... 495
  18.1 Introduction .......................................................... 495
  18.2 FMC main features .................................................. 495
  18.3 FMC implementation ................................................ 496
  18.4 FMC block diagram .................................................. 496
  18.5 AHB interface ........................................................ 497
    18.5.1 Supported memories and transactions ......................... 497
  18.6 External device address mapping ................................ 498
    18.6.1 NOR/PSRAM address mapping ................................ 499
    18.6.2 NAND Flash memory address mapping ....................... 500
  18.7 NOR Flash/PSRAM controller ....................................... 501
    18.7.1 External memory interface signals ......................... 502
    18.7.2 Supported memories and transactions ....................... 504
    18.7.3 General timing rules ......................................... 505
    18.7.4 NOR Flash/PSRAM controller asynchronous transactions .... 506
    18.7.5 Synchronous transactions ................................... 524
    18.7.6 NOR/PSRAM controller registers .............................. 531
  18.8 NAND Flash controller .............................................. 539
    18.8.1 External memory interface signals ......................... 540
    18.8.2 NAND Flash supported memories and transactions .......... 542
    18.8.3 Timing diagrams for NAND Flash memory .................... 542
    18.8.4 NAND Flash operations ...................................... 543
    18.8.5 NAND Flash prewait functionality ............................ 544
18.8.6 Computation of the error correction code (ECC) in NAND Flash memory ............................................. 545
18.8.7 NAND Flash controller registers ............................................. 546
18.8.8 FMC register map ............................................. 552

19 Octo-SPI interface (OCTOSPI) ............................................. 554

19.1 Introduction ............................................. 554
19.2 OCTOSPI main features ............................................. 554
19.3 OCTOSPI implementation ............................................. 555
19.4 OCTOSPI functional description ............................................. 556
  19.4.1 OCTOSPI block diagram ............................................. 556
  19.4.2 OCTOSPI interface to memory modes ............................................. 557
  19.4.3 OCTOSPI Regular-command protocol ............................................. 557
  19.4.4 OCTOSPI Regular-command protocol signal interface ............................................. 561
  19.4.5 HyperBus protocol ............................................. 564
  19.4.6 Specific features ............................................. 568
  19.4.7 OCTOSPI operating modes introduction ............................................. 569
  19.4.8 OCTOSPI Indirect mode ............................................. 570
  19.4.9 OCTOSPI Automatic status-polling mode ............................................. 571
  19.4.10 OCTOSPI Memory-mapped mode ............................................. 572
  19.4.11 OCTOSPI configuration introduction ............................................. 573
  19.4.12 OCTOSPI system configuration ............................................. 573
  19.4.13 OCTOSPI device configuration ............................................. 573
  19.4.14 OCTOSPI Regular-command mode configuration ............................................. 574
  19.4.15 OCTOSPI HyperBus protocol configuration ............................................. 577
  19.4.16 OCTOSPI error management ............................................. 578
  19.4.17 OCTOSPI BUSY and ABORT ............................................. 578
  19.4.18 OCTOSPI reconfiguration or deactivation ............................................. 579
  19.4.19 NCS behavior ............................................. 579
19.5 Address alignment and data number ............................................. 581
19.6 OCTOSPI interrupts ............................................. 582
19.7 OCTOSPI registers ............................................. 582
  19.7.1 OCTOSPI control register (OCTOSPI_CR) ............................................. 582
  19.7.2 OCTOSPI device configuration register 1 (OCTOSPI_DCR1) ............................................. 585
  19.7.3 OCTOSPI device configuration register 2 (OCTOSPI_DCR2) ............................................. 586
  19.7.4 OCTOSPI device configuration register 3 (OCTOSPI_DCR3) ............................................. 587
  19.7.5 OCTOSPI device configuration register 4 (OCTOSPI_DCR4) ............................................. 588

21 Analog-to-digital converters (ADC) ........................................... 616

21.1 Introduction ................................................................. 616
21.2 ADC main features .......................................................... 617
21.3 ADC implementation .......................................................... 618
21.4 ADC functional description .................................................. 619
  21.4.1 ADC block diagram ..................................................... 619
  21.4.2 ADC pins and internal signals ........................................ 620
  21.4.3 ADC clocks .............................................................. 621
  21.4.4 ADC1/2 connectivity ................................................... 623
  21.4.5 Slave AHB interface .................................................... 625
  21.4.6 ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN) .................................................. 625
  21.4.7 Single-ended and differential input channels ....................... 625
  21.4.8 Calibration (ADCAL, ADCALDIFF, ADC_CALFACT) ............... 626
  21.4.9 ADC on-off control (ADEN, ADDIS, ADRDY) ....................... 629
  21.4.10 Constraints when writing the ADC control bits ................... 630
  21.4.11 Channel selection (SQRx, JSQRx) .................................. 631
  21.4.12 Channel-wise programmable sampling time (SMPR1, SMPR2) ..... 632
  21.4.13 Single conversion mode (CONT=0) .................................. 633
  21.4.14 Continuous conversion mode (CONT=1) ............................ 633
  21.4.15 Starting conversions (ADSTART, JADSTART) ..................... 634
  21.4.16 ADC timing ............................................................ 635
  21.4.17 Stopping an ongoing conversion (ADSTP, JADSTP) ............... 635
  21.4.18 Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN) ........................................ 637
  21.4.19 Injected channel management ......................................... 639
  21.4.20 Discontinuous mode (DISCEN, DISCNUM, JDISCEN) .............. 641
  21.4.21 Queue of context for injected conversions ......................... 642
  21.4.22 Programmable resolution (RES) - Fast conversion mode ........ 650
  21.4.23 End of conversion, end of sampling phase (EOC, JEOC, EOSMP) .. 651
  21.4.24 End of conversion sequence (EOS, JEOS) ........................ 651
  21.4.25 Timing diagrams example (single/continuous modes, hardware/software triggers) ........................................ 652
  21.4.26 Data management ..................................................... 654
  21.4.27 Managing conversions using the DFSDM .......................... 659
21.4.28 Dynamic low-power features ................................................................. 660
21.4.29 Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx) .... 665
21.4.30 Oversampler .......................................................... 669
21.4.31 Dual ADC modes ................................................................. 675
21.4.32 Temperature sensor ................................................................. 688
21.4.33 VBAT supply monitoring ................................................................. 690
21.4.34 Monitoring the internal voltage reference ........................................ 691
21.5 ADC interrupts ................................................................. 692
21.6 ADC registers (for each ADC) ................................................................. 694
  21.6.1 ADC interrupt and status register (ADC_ISR) ................................. 694
  21.6.2 ADC interrupt enable register (ADC_IER) ....................................... 696
  21.6.3 ADC control register (ADC_CR) ..................................................... 698
  21.6.4 ADC configuration register (ADC_CFGR) ........................................ 701
  21.6.5 ADC configuration register 2 (ADC_CFGR2) .................................... 705
  21.6.6 ADC sample time register 1 (ADC_SMPR1) ..................................... 707
  21.6.7 ADC sample time register 2 (ADC_SMPR2) ..................................... 708
  21.6.8 ADC watchdog threshold register 1 (ADC_TR1) .............................. 709
  21.6.9 ADC watchdog threshold register 2 (ADC_TR2) .............................. 710
  21.6.10 ADC watchdog threshold register 3 (ADC_TR3) .............................. 710
  21.6.11 ADC regular sequence register 1 (ADC_SQR1) .............................. 711
  21.6.12 ADC regular sequence register 2 (ADC_SQR2) .............................. 712
  21.6.13 ADC regular sequence register 3 (ADC_SQR3) .............................. 713
  21.6.14 ADC regular sequence register 4 (ADC_SQR4) .............................. 714
  21.6.15 ADC regular data register (ADC_DR) ........................................... 715
  21.6.16 ADC injected sequence register (ADC_JSQR) .................................. 715
  21.6.17 ADC offset y register (ADC_OFRy) ............................................. 717
  21.6.18 ADC injected channel y data register (ADC_JDRy) ......................... 718
  21.6.19 ADC analog watchdog 2 configuration register (ADC_AWD2CR) ....... 718
  21.6.20 ADC analog watchdog 3 configuration register (ADC_AWD3CR) ....... 719
  21.6.21 ADC differential mode selection register (ADC_DIFSEL) ............... 719
  21.6.22 ADC calibration factors (ADC_CALFACT) ..................................... 720
21.7 ADC common registers ................................................................. 720
  21.7.1 ADC common status register (ADC_CSR) ....................................... 720
  21.7.2 ADC common control register (ADC_CCR) ...................................... 722
  21.7.3 ADC common regular data register for dual mode (ADC_CDR) .......... 725
21.8 ADC register map ................................................................. 725
22 Digital-to-analog converter (DAC) ............................................. 729
  22.1 Introduction ......................................................... 729
  22.2 DAC main features .................................................. 729
  22.3 DAC implementation .................................................. 730
  22.4 DAC functional description ......................................... 731
    22.4.1 DAC block diagram ............................................. 731
    22.4.2 DAC channel enable ........................................... 732
    22.4.3 DAC data format .............................................. 732
    22.4.4 DAC conversion ................................................ 734
    22.4.5 DAC output voltage .......................................... 734
    22.4.6 DAC trigger selection ....................................... 735
    22.4.7 DMA requests ................................................ 736
    22.4.8 Noise generation ............................................ 736
    22.4.9 Triangle-wave generation .................................... 738
    22.4.10 DAC channel modes ......................................... 739
    22.4.11 DAC channel buffer calibration ............................ 742
    22.4.12 Dual DAC channel conversion modes (if dual channels are available) ................................................. 743
  22.5 DAC low-power modes ............................................... 747
  22.6 DAC interrupts ...................................................... 748
  22.7 DAC registers .......................................................... 749

# DSI Host (DSI) applied to STM32L4R9xx and STM32L4S9xx only

## 30 Introduction

### 30.1 Introduction

### 30.2 Standard and references

### 30.3 DSI Host main features

### 30.4 DSI Host functional description

#### 30.4.1 General description

#### 30.4.2 DSI Host pins and internal signals

#### 30.4.3 Supported resolutions and frame rates

#### 30.4.4 System level architecture

### 30.5 Functional description: video mode on LTDC interface

#### 30.5.1 Video transmission mode

#### 30.5.2 Updating the LTDC interface configuration in video mode

### 30.6 Functional description: adapted command mode on LTDC interface

### 30.7 Functional description: APB slave generic interface

#### 30.7.1 Packet transmission using the generic interface

### 30.8 Functional description: timeout counters

#### 30.8.1 Contention error detection timeout counters

#### 30.8.2 Peripheral response timeout counters

### 30.9 Functional description: transmission of commands

#### 30.9.1 Transmission of commands in video mode

#### 30.9.2 Transmission of commands in low-power mode

#### 30.9.3 Transmission of commands in high-speed

#### 30.9.4 Read command transmission

#### 30.9.5 Clock lane in low-power mode

### 30.10 Functional description: virtual channels

### 30.11 Functional description: video mode pattern generator

#### 30.11.1 Color bar pattern

#### 30.11.2 Color coding

#### 30.11.3 BER testing pattern

#### 30.11.4 Video mode pattern generator resolution

### 30.12 Functional description: D-PHY management

#### 30.12.1 D-PHY configuration

#### 30.12.2 Special D-PHY operations

#### 30.12.3 Special low-power D-PHY functions

#### 30.12.4 DSI PLL control

### 33 True random number generator (RNG) applied to STM32L4P5xx and STM32L4Q5xx only

#### 33.1 Introduction

#### 33.2 RNG main features

#### 33.3 RNG functional description

- 33.3.1 RNG block diagram
- 33.3.2 RNG internal signals
- 33.3.3 Random number generation
- 33.3.4 RNG initialization
- 33.3.5 RNG operation
- 33.3.6 RNG clocking
- 33.3.7 Error management
- 33.3.8 RNG low-power usage

#### 33.4 RNG interrupts

#### 33.5 RNG processing time

#### 33.6 RNG entropy source validation

- 33.6.1 Introduction
- 33.6.2 Validation conditions
- 33.6.3 Data collection

#### 33.7 RNG registers

- 33.7.1 RNG control register (RNG_CR)
- 33.7.2 RNG status register (RNG_SR)
- 33.7.3 RNG data register (RNG_DR)
- 33.7.4 RNG health test control register (RNG_HTCR)
- 33.7.5 RNG register map

1.1 General information

The STM32L4+ Series devices have an Arm\textsuperscript{\textregistered}(a) Cortex\textsuperscript{\textregistered}-M4 core.

1.2 List of abbreviations for registers

The following abbreviations(b) are used in register descriptions:

- **read/write (rw)**: Software can read and write to this bit.
- **read-only (r)**: Software can only read this bit.
- **write-only (w)**: Software can only write to this bit. Reading this bit returns the reset value.
- **read/clear write0 (rc\_w0)**: Software can read as well as clear this bit by writing 0. Writing 1 has no effect on the bit value.
- **read/clear write1 (rc\_w1)**: Software can read as well as clear this bit by writing 1. Writing 0 has no effect on the bit value.
- **read/clear write (rc\_w)**: Software can read as well as clear this bit by writing to the register. The value written to this bit is not important.
- **read/clear by read (rc\_r)**: Software can read this bit. Reading this bit automatically clears it to 0. Writing this bit has no effect on the bit value.
- **read/set by read (rs\_r)**: Software can read this bit. Reading this bit automatically sets it to 1. Writing this bit has no effect on the bit value.
- **read/set (rs)**: Software can read as well as set this bit. Writing 0 has no effect on the bit value.
- **read/write once (rwo)**: Software can only write once to this bit and can also read it at any time. Only a reset can return the bit to its reset value.
- **toggle (t)**: The software can toggle this bit by writing 1. Writing 0 has no effect.
- **read-only write trigger (rt\_w1)**: Software can read this bit. Writing 1 triggers an event but has no effect on the bit value.
- **Reserved (Res.)**: Reserved bit, must be kept at reset value.

---

a. Arm is a registered trademark of Arm Limited (or its subsidiaries) in the US and/or elsewhere.
b. This is an exhaustive list of all abbreviations applicable to STMicroelectronics microcontrollers, some of them may not be used in the current document.
1.3 Glossary

This section gives a brief definition of acronyms and abbreviations used in this document:

- **Word**: data of 32-bit length.
- **Half-word**: data of 16-bit length.
- **Byte**: data of 8-bit length.
- **IAP (in-application programming)**: IAP is the ability to re-program the Flash memory of a microcontroller while the user program is running.
- **ICP (in-circuit programming)**: ICP is the ability to program the Flash memory of a microcontroller using the JTAG protocol, the SWD protocol or the bootloader while the device is mounted on the user application board.
- **Option bytes**: product configuration bits stored in the Flash memory.
- **OBL**: option byte loader.
- **AHB**: advanced high-performance bus.
- **APB**: advanced peripheral bus.

1.4 Availability of peripherals

For availability of peripherals and their number across all sales types, refer to the particular device datasheet.
2 System and memory overview

2.1 System architecture

The main system consists of 32-bit multilayer AHB bus matrix that interconnects:

- **Up to nine masters:**
  - Cortex®-M4 with FPU core I-bus
  - Cortex®-M4 with FPU core D-bus
  - Cortex®-M4 with FPU core S-bus
  - DMA1
  - DMA2
  - DMA2D (Chrom-Art Accelerator™) memory bus
  - LCD-TFT controller DMA-bus
  - SDMMC1 bus
  - SDMMC2 bus (only for STM32L4P5xx and STM32L4Q5xx devices)
  - GFXMMU (Chrom-GRC™) bus (only for STM32L4Sxxx and STM32L4R5xxx devices)

- **Up to eleven slaves:**
  - Internal Flash memory on the I-Code bus
  - Internal Flash memory on D-Code bus
  - Internal SRAM1 (192 Kbytes for STM32L4Rxxx and STM32Sxxx devices and 128 Kbytes for STM32L4P5xx and STM32Q5xx devices)
  - Internal SRAM2 (64 Kbytes)
  - Internal SRAM3 (384 Kbytes for STM32L4Rxxx and STM32L4Sxxx devices and 128 Kbytes for STM32L4P5xx and STM32L4Q5xx devices)
  - GFXMMU (Chrom-GRC™) (only for STM32L4Rxxx and STM32L4Sxxx devices)
  - AHB1 peripherals including AHB to APB bridges and APB peripherals (connected to APB1 and APB2)
  - AHB2 peripherals
  - Flexible memory controller (FMC)
  - OCTOSPI1
  - OCTOSPI2

The bus matrix provides access from a master to a slave, enabling concurrent access and efficient operation even when several high-speed peripherals work simultaneously. This architecture is shown in Figure 1:
Figure 1. System architecture for STM32L4Rxxx and STM32L4Sxxx
2.1.1 I-bus

This bus connects the instruction bus of the Cortex®-M4 core to the BusMatrix. This bus is used by the core to fetch instructions. The target of this bus is a memory containing code (either internal Flash memory, internal SRAM or external memories through the FMC or OCTOSPIs).

2.1.2 D-bus

This bus connects the data bus of the Cortex®-M4 core to the BusMatrix. This bus is used by the core for literal load and debug access. The target of this bus is a memory containing code (either internal Flash memory, internal SRAM or external memories through the FMC or OCTOSPIs).

2.1.3 S-bus

This bus connects the system bus of the Cortex®-M4 core to the BusMatrix. This bus is used by the core to access data located in a peripheral or SRAM area. The targets of this bus are the internal SRAM, the AHB1 peripherals including the APB1 and APB2.
peripherals, the AHB2 peripherals and the external memories through the OCTOSPI or the FMC.

The SRAM2 is also accessible on this bus to allow continuous mapping with SRAM1 and SRAM3.

2.1.4 DMA-bus

This bus connects the AHB master interface of the DMA to the BusMatrix. The targets of this bus are the SRAM1, SRAM2 and SRAM3, the AHB1 peripherals including the APB1 and APB2 peripherals, the AHB2 peripherals and the external memories through the OCTOSPI or the FMC.

2.1.5 DMA2D-bus

This bus connects the AHB master interface of the DMA2D to the BusMatrix. The targets of this bus are the SRAM1, SRAM2 and SRAM3 and external memories through the OCTOSPI or the FMC.

2.1.6 LCD-TFT controller DMA bus

This bus connects the LCD controller DMA master interface to the BusMatrix. The targets of this bus are data memories: internal SRAMs (SRAM1, SRAM2, SRAM3), internal Flash memory or external memories through FMC or OCTOSPI.

2.1.7 SDMMC1 controller DMA bus

This bus connects the SDMMC1 DMA master interface to the BusMatrix. This bus is used only by the SDMMC1 DMA to load/store data from/to memory. The targets of this bus are data memories: internal SRAMs (SRAM1, SRAM2, SRAM3), internal Flash memory or external memories through FMC or OCTOSPI.

2.1.8 SDMMC2 controller DMA bus (only for STM32L4P5xx and STM32L4Q5xx devices)

This bus connects the SDMMC2 DMA master interface to the BusMatrix. This bus is used only by the SDMMC2 DMA to load/store data from/to memory. The targets of this bus are data memories: internal SRAMs (SRAM1, SRAM2, SRAM3), internal Flash memory or external memories through FMC or OCTOSPI.

2.1.9 GFXMMU-bus (only for STM32L4Rxxx and STM32L4Sxxx devices)

This bus connects the GFXMMU (Chrom-GRC™) AHB master interface to the BusMatrix. The targets of this bus are data memories: internal SRAMs (SRAM1, SRAM2, SRAM3), internal Flash memory or external memories through FMC or OCTOSPI.

2.1.10 BusMatrix

The BusMatrix manages the access arbitration between masters. The arbitration uses a Round Robin algorithm.
For STM32L4Rxxx and STM32L4Sxxx devices, the BusMatrix is composed of:

- up to nine masters:
  - CPU AHB system bus, D-Code bus, I-Code bus, DMA1, DMA2, DMA2D, SDMMC1, LCD-TFT and GFXMMU
- up to eleven slaves:
  - FLASH, SRAM1, SRAM2, SRAM3, AHB1 (including APB1 and APB2), AHB2, GFXMMU, OCTOSTPI1, OCTOSPI2 and FMC

For STM32L4P5xx and STM32Q5xx devices, the BusMatrix is composed of:

- nine masters:
  - CPU AHB system bus, D-Code bus, I-Code bus, DMA1, DMA2, DMA2D, SDMMC1, SDMMC2 and LCD-TFT
- ten slaves:
  - FLASH, SRAM1, SRAM2, SRAM3, AHB1 (including APB1 and APB2), AHB2, OCTOSTPI1, OCTOSPI2 and FMC.

AHB/APB bridges

The two AHB/APB bridges provide full synchronous connections between the AHB and the two APB buses, allowing flexible selection of the peripheral frequency.

Refer to Section 2.2.2: Memory map and register boundary addresses on page 94 for the address mapping of the peripherals connected to this bridge.

After each device reset, all peripheral clocks are disabled (except for the SRAM1/2 and Flash memory interface). Before using a peripheral you have to enable its clock in the RCC_AHBxENR and the RCC_APBxENR registers.

Note: When a 16- or 8-bit access is performed on an APB register, the access is transformed into a 32-bit access: the bridge duplicates the 16- or 8-bit data to feed the 32-bit vector.
2.2 Memory organization

2.2.1 Introduction

Program memory, data memory, registers and I/O ports are organized within the same linear 4-Gbyte address space.

The bytes are coded in memory in Little Endian format. The lowest numbered byte in a word is considered the word’s least significant byte and the highest numbered byte the most significant.

The addressable memory space is divided into eight main blocks, of 512 Mbytes each.
2.2.2 Memory map and register boundary addresses

Figure 3. Memory map for STM32L4Rxxx and STM32L4Sxxx

2.3 Bit banding

The Cortex®-M4 with FPU memory map includes two bit-band regions. These regions map each word in an alias region of memory to a bit in a bit-band region of memory. Writing to a word in the alias region has the same effect as a read-modify-write operation on the targeted bit in the bit-band region.

In the STM32L4+ Series devices both the peripheral registers and the SRAM1 are mapped to a bit-band region, so that single bit-band write and read operations are allowed. The operations are only available for Cortex®-M4 with FPU accesses, and not from other bus masters (such as DMA).
A mapping formula shows how to reference each word in the alias region to a corresponding bit in the bit-band region. The mapping formula is:

\[ \text{bit\_word\_addr} = \text{bit\_band\_base} + (\text{byte\_offset} \times 32) + (\text{bit\_number} \times 4) \]

where:
- \( \text{bit\_word\_addr} \) is the address of the word in the alias memory region that maps to the targeted bit
- \( \text{bit\_band\_base} \) is the starting address of the alias region
- \( \text{byte\_offset} \) is the number of the byte in the bit-band region that contains the targeted bit
- \( \text{bit\_number} \) is the bit position (0-7) of the targeted bit

**Example**

The following example shows how to map bit 2 of the byte located at SRAM1 address 0x20000300 to the alias region:

\[ 0x22006008 = 0x22000000 + (0x300 \times 32) + (2 \times 4) \]

Writing to address 0x22006008 has the same effect as a read-modify-write operation on bit 2 of the byte at SRAM1 address 0x20000300.

Reading address 0x22006008 returns the value (0x01 or 0x00) of bit 2 of the byte at SRAM1 address 0x20000300 (0x01: bit set; 0x00: bit reset).

For more information on bit-banding, refer to the Cortex®-M4 programming manual (see Related documents on page 1).

### 2.4 Embedded SRAM

The STM32L4Rxox and STM32L4Sxxx devices feature up to 640 Kbytes SRAM:
- 192 Kbytes SRAM1
- 64 Kbytes SRAM2
- 384 Kbytes SRAM3

The STM32L4P5xx and STM32L4Q5xx devices feature up to 320 Kbytes SRAM:
- 128 Kbytes SRAM1
- 64 Kbytes SRAM2
- 128 Kbytes SRAM3

These SRAM can be accessed as bytes, half-words (16 bits) or full words (32 bits). These memories can be addressed at maximum system clock frequency without wait state and thus by both CPU and DMA.

The CPU can access the SRAM1 through the system bus or through the ICode/DCode buses when boot from SRAM1 is selected or when physical remap is selected (Section 9.2.1: SYSCFG memory remap register (SYSCFG_MEMRMP) in the SYSCFG controller). To get the maximum performance on SRAM1 execution, physical remap should be selected (boot or software selection).

Execution can be performed from SRAM2 with maximum performance without any remap thanks to access through ICode bus.

The SRAM2 is aliased at address 0x2003 0000 for STM32L4Rxox and STM32L4Sxxx devices and at address 0x2002 0000 for STM32L4P5xx and STM32L4Q5xx devices,
offering a continuous address space with the SRAM1 and SRAM3.

2.4.1 SRAM2 parity check

The user can enable the SRAM2 parity check using the option bit SRAM2_PE in the user option byte (refer to Section 3.4.1: Option bytes description).

The data bus width is 36 bits because 4 bits are available for parity check (1 bit per byte) in order to increase memory robustness, as required for instance by Class B or SIL norms.

The parity bits are computed and stored when writing into the SRAM2. Then, they are automatically checked when reading. If one bit fails, an NMI is generated. The same error can also be linked to the BRK_IN Break input of TIM1/TIM8/TIM15/TIM16/TIM17, with the SPL control bit in the SYSCFG configuration register 2 (SYSCFG_CFGR2). The SRAM2 Parity Error flag (SPF) is available in the SYSCFG configuration register 2 (SYSCFG_CFGR2).

Note: When enabling the RAM parity check, it is advised to initialize by software the whole RAM memory at the beginning of the code, to avoid getting parity errors when reading non-initialized locations.

2.4.2 SRAM2 Write protection

The SRAM2 can be write protected with a page granularity of 1 Kbyte.

</table>
2.4.3 SRAM2 Read protection

The SRAM2 is protected with the Read protection (RDP). Refer to Section 3.5.1: Read protection (RDP) for more details.

2.4.4 SRAM2 Erase

The SRAM2 can be erased with a system reset using the option bit SRAM2_RST in the user option byte (refer to Section 3.4.1: Option bytes description).

The SRAM2 erase can also be requested by software by setting the bit SRAM2ER in the SYSCFG SRAM2 control and status register (SYSCFG_SCSR).

2.5 Flash memory overview

The Flash memory is composed of two distinct physical areas:

- The main Flash memory block. It contains the application program and user data if necessary.
- The information block. It is composed of three parts:
  - Option bytes for hardware and memory protection user configuration.
  - System memory that contains the ST proprietary code.
  - OTP (one-time programmable) area

The Flash interface implements instruction access and data access based on the AHB protocol. It also implements the logic necessary to carry out the Flash memory operations.
(program/erase) controlled through the Flash registers. Refer to Section 3: Embedded Flash memory (FLASH) for more details.

### 2.6 Boot configuration

#### 2.6.1 Boot configuration

Three different boot modes can be selected through the BOOT0 pin or the nBOOT0 bit into the FLASH_OPTR register (if the nSWBOOT0 bit is cleared into the FLASH_OPTR register), and nBOOT1 bit in FLASH_OPTR register, as shown in the following table.

<table>

</tr>
</tbody>
</table>

1. A Flash empty check mechanism is implemented to force the boot from system Flash if the first Flash memory location is not programmed (0xFFFF FFFF) and if the boot selection was configured to boot from the main Flash.

The values on both BOOT0 pin (coming from the pin or the option bit) and nBOOT1 bit are latched upon reset release. It is up to the user to set nBOOT1 and BOOT0 to select the required boot mode.

The BOOT0 pin or user option bit (depending on the nSWBOOT0 bit value in the FLASH_OPTR register), and nBOOT1 bit are also re-sampled when exiting from Standby mode. Consequently, they must be kept in the required Boot mode configuration in Standby mode. After this startup delay has elapsed, the CPU fetches the top-of-stack value from address 0x0000 0000, then starts code execution from the boot memory at 0x0000 0004.

Depending on the selected boot mode, main Flash memory, system memory or SRAM1 is accessible as follows:

- Boot from main Flash memory: the main Flash memory is aliased in the boot memory space (0x0000 0000), but still accessible from its original memory space
(0x0800 0000). In other words, the Flash memory contents can be accessed starting from address 0x0000 0000 or 0x0800 0000.

- Boot from system memory: the system memory is aliased in the boot memory space (0x0000 0000), but still accessible from its original memory space (0x1FFF 0000).
- Boot from the embedded SRAM1: the SRAM1 is aliased in the boot memory space (0x0000 0000), but it is still accessible from its original memory space (0x2000 0000).

PH3/BOOT0 GPIO is configured in:

- Input mode during the complete reset phase if the option bit nSWBOOT0 is set into the FLASH_OPTR register and then switches automatically in analog mode after reset is released (BOOT0 pin).
- Input mode from the reset phase to the completion of the option byte loading if the bit nSWBOOT0 is cleared into the FLASH_OPTR register (BOOT0 value coming from the option bit). It switches then automatically to the analog mode even if the reset phase is not complete.

Note: When the device boots from SRAM, in the application initialization code, you have to relocate the vector table in SRAM using the NVIC exception table and the offset register.

When booting from the main Flash memory, the application software can either boot from bank 1 or from bank 2. By default, boot from bank 1 is selected.

To select boot from Flash memory bank 2, set the BFB2 bit in the user option bytes. When this bit is set and the boot pins are in the boot from main Flash memory configuration, the device boots from system memory, and the boot loader jumps to execute the user application programmed in Flash memory bank 2. For further details, please refer to AN2606.

Physical remap

Once the boot pins mode is selected, the application software can modify the memory accessible in the code area (in this way the code can be executed through the ICode bus in place of the System bus). This modification is performed by programming the SYSCFG memory remap register (SYSCFG_MEMRMP) in the SYSCFG controller.

The following memories can thus be remapped:

- Main Flash memory
- System memory
- Embedded SRAM1 (192 Kbytes for STM32L4Rxxx and STM32L4Sxxx devices and 128 Kbytes for STM32L4P5xx and STM32L4Q5xx devices)
- FSMC bank 1 (NOR/PSRAM 1 and 2)
- OctoSPI (OCTOSPI1 or OSCTOSPI2) memory

</tbody>
</table>

1. Reserved areas highlighted in gray.
2. When the FSMC is remapped at address 0x0000 0000, only the first two regions of bank 1 memory controller (bank 1 NOR/PSRAM 1 and NOR/PSRAM 2) can be remapped. When the OCTOSPI is remapped at address 0x0000 0000, only 128 Mbytes are remapped. In remap mode, the CPU can access the external memory via ICode bus instead of system bus, which boosts up the performance.
3. Even when aliased in the boot memory space, the related memory is still accessible at its original memory space.
4. 2 Mbytes for STM32L4Rxxx and STM32L4Sxxx devices and 1 Mbyte for STM32L4P5xx and STM32L4Q5xx devices.
3 Embedded Flash memory (FLASH)

3.1 Introduction

The Flash memory interface manages CPU AHB ICode and DCode accesses to the Flash memory. It implements the erase and program Flash memory operations and the read and write protection mechanisms.

The Flash memory interface accelerates code execution with a system of instruction prefetch and cache lines.

3.2 FLASH main features

- Up to 2 Mbytes of Flash memory with dual-bank architecture supporting read-while-write capability (RWW).
- Flash memory read operations with two data width modes supported:
  - Single-bank mode DBANK=0: read access of 128 bits
  - Dual-bank mode DBANK=1: read access of 64 bits
- Page erase, bank erase and mass erase (both banks)

Flash memory interface features:
- Flash memory read operations
- Flash memory program/erase operations
- Read protection activated by option (RDP)
- 4 Write protection areas (2 per bank when DBANK=1 and 4 for full memory when DBANK=0)
- 2 proprietary code read protection areas (1 per bank when DBANK=1, 2 for all memory when DBANK=0)
- Flash empty check
- Prefetch on ICODE
- Instruction Cache: 32 cache lines of 4 x 64 or 2 x 128 bits on ICode (1 Kbyte RAM)
- Data Cache: 8 cache lines of 4 x 64 bits or 2 x 128 on DCode (256 bytes RAM)
- Error Code Correction ECC: 8 bits per 64-bit double-word
  - DBANK=1: 8 + 64 = 72 bits, 2 bits detection, 1 bit correction
  - DBANK=0: (8+64) + (8+64) = 144 bits, 2 bits detection, 1 bit correction
- Option byte loader
- Low-power mode
3.3 FLASH functional description

3.3.1 Flash memory organization

The Flash memory has the following main features:

- Capacity up to 2 Mbytes, in Single-bank mode (read width of 128 bits) or in Dual-bank mode (read width of 64-bits)
- Supports dual boot mode thanks to the BFB2 option bit (only in Dual-bank mode)
- Dual-bank mode when DBANK bit is set:
  - 2 Mbytes organized in 2 banks for main memory
  - Page size of 4 Kbytes
  - 72 bits wide data read (64 bits plus 8 ECC bits)
  - Bank and Mass erase
- Single-bank mode when DBANK is reset:
  - 2 Mbytes organized in one single-bank for main memory
  - Page size of 8 Kbytes
  - 144 bits wide data read (128 bits plus 2x8 ECC bits)
  - Mass erase

The Flash memory is organized as follows:

For STM32L4Rxxx and STM32L4Sxxx devices:

- A main memory block organized depending on the dual-bank configuration bit:
  - When dual-bank is enabled (DBANK bit set), the Flash is divided in 2 banks of 1 Mbyte, and each bank is organized as follows:
    The main memory block containing 256 pages of 4 Kbytes
    Each page is composed of 8 rows of 512 bytes
  - When dual-bank is disabled (DBANK bit reset), the main memory block is organized as one single-bank of 2 Mbytes as follows:
    The main memory block containing 256 pages of 8 Kbytes
    Each page is composed of 8 rows of 1024 bytes

- Dual-bank organization on 1 Mbyte devices
  The dual-bank feature on 1 Mbyte devices is enabled by setting the DB1M option bit. The dual-bank memory organization is different from the single-bank: the single-bank memory contains 128 pages of 8 Kbytes whereas the dual-bank memory each bank contains 128 pages of 4 Kbytes.
  For erase operation, the right page numbering and address must be considered according to the DB1M option bit.
  - When the DB1M bit is reset, the erase operation must be performed on the Bank 1.
  - When the DB1M bit is set, to perform an erase operation on Bank 2, the page number must be programmed (page number from 0 to 127) on Bank 2.

For STM32L4P5xx and STM32L4Q5xx devices:

- A main memory block organized depending on the dual-bank configuration bit:
  - When dual-bank is enabled (DBANK bit set), the Flash is divided in 2 banks of 512 Kbytes, and each bank is organized as follows:
The main memory block containing 128 pages of 4 Kbytes
Each page is composed of 8 rows of 512 bytes
- When dual-bank is disabled (DBANK bit reset), the main memory block is
  organized as one single-bank of 1 Mbyte as follows:
  The main memory block containing 128 pages of 8 Kbytes
  Each page is composed of 8 rows of 1024 bytes
- Dual-bank organization on 512 Kbytes devices
  The dual-bank feature on 512 Kbytes devices is enabled by setting the DB1M option
  bit. The dual-bank memory organization is different from the single-bank: the single-
  bank memory contains 128 pages of 8 Kbytes whereas the dual-bank memory each
  bank contains 64 pages of 4 Kbytes.

Refer to Table 8: Flash module - 1 Mbyte dual-bank organization, DB1M = 1 (64 bits read
width) and Table 9: Flash module - 1 Mbyte single-bank organization, DB1M = 0 (128 bits
read width) for details on 1 Mbyte single-bank and 1 Mbyte dual-bank organizations.

Refer to Table 10: Flash module - 512 Kbytes dual-bank organization, DB1M = 1 (64 bits
read width) and Table 11: Flash module - 512 Kbytes single-bank organization DB1M = 0
(128 bits read width) for details on 512 Kbytes single-bank and 512 Kbytes dual-bank
organizations.

For all STM32L4+ Series:
- An Information block containing:
  - System memory from which the device boots in System memory boot mode. The
    area is reserved for use by STMicroelectronics and contains the bootloader that is
    used to reprogram the Flash memory through one of the following interfaces:
    USART1, USART2, USART3, USB (DFU), I2C1, I2C2, I2C3, SPI1, SPI2, SPI3. It
    is programmed by STMicroelectronics when the device is manufactured, and
    protected against spurious write/erase operations. For further details, please refer
  - 1 Kbyte (128 double word) OTP (one-time programmable) bytes for user data. The
    OTP area is available in Bank 1 only. The OTP data cannot be erased and can be
    written only once. If only one bit is at 0, the entire double word cannot be written
    anymore, even with the value 0x0000 0000 0000 0000.
  - Option bytes for user configuration.

The memory organization is based on a main area and an information block as shown in the
tables below.

</table>
3.3.2 Error code correction (ECC)

Dual-bank mode (DBANK=1, 64-bits data width)

Data in Flash memory are 72-bits words: 8 bits are added per double word (64 bits). The ECC mechanism supports:

- One error detection and correction
- Two errors detection

When one error is detected and corrected, the flag ECCC (ECC correction) is set in Flash ECC register (FLASH_ECCR). If ECCCIE is set, an interrupt is generated.

When two errors are detected, a flag ECCD (ECC detection) is set in FLASH_ECCR register. In this case, a NMI is generated.

When an ECC error is detected, the address of the failing double word and its associated bank are saved in ADDR_ECC[20:0] and BK_ECC in the FLASH_ECCR register. ADDR_ECC[2:0] are always cleared.
When ECCC or ECCD is set, ADDR_ECC and BK_ECC are not updated if a new ECC error occurs. FLASH_ECCR is updated only when ECC flags are cleared.

**Note:** For a virgin data: $0xFF$ FFFF FFFF FFFF FFF F, one error is detected and corrected but two errors detection is not supported.

When an ECC error is reported, a new read at the failing address may not generate an ECC error if the data is still present in the current buffer, even if ECCC and ECCD are cleared.

**Single-bank mode (DBANK=0, 128-bits data width)**

Data in Flash memory are 144-bits words: 8 bits are added per each double word. The ECC mechanism supports:

- One error detection and correction
- Two errors detection per 64 double words

The user must first check the SYSF_ECC bit, and if it is set, the user must refer to the DBANK=1 programming model (because system Flash is always on 2 banks). If the bit is not set, the user must refer to the following programing model:

Each double word (bits 63:0 and bits 127:64) has ECC.

When one error is detected in 64 LSB bits (bits 63:0) and corrected, a flag ECCC (ECC correction) is set in the FLASH_ECCR register.

When one error is detected in 64 MSB bits (bits 127:64) and corrected, a flag ECCC2 (ECC2 correction) is set in the FLASH_ECCR register.

If the ECCCIE is set, an interrupt is generated. The user has to read ECCC and ECCC2 to see which part of the 128-bits data has been corrected (either 63:0, 127:64 or both).

When two errors are detected in 64 LSB bits, a flag ECCD (ECC detection) is set in the FLASH_ECCR register.

When two errors are detected in 64 MSB bits (bits 127:64), a flag ECCD2 (ECC2 detection) is set in the FLASH_ECCR register.

In this case, a NMI is generated. The user has to read ECCD and ECCD2 to see which part of the 128-bits data has error detection (either 63:0, 127:64 or both).

When an ECC error is detected, the address of the failing the 2 times double word is saved into ADDR_ECC[20:0] in FLASH_ECCR. ADDR_ECC[20:0] contains an address of a 2 times double word.

The ADDR_ECC[3:0] are always cleared. BK_ECC is not used in this mode.

When ECCC/ECCC2 or ECCD/ECCD2 is/are set, if a new ECC error occurs, the ADDR_ECC is not updated. The FLASH_ECCR is updated only if the ECC flags (ECCC/ECCC2/ECCD/ECCD2) are cleared.

**Note:** For a virgin data: $0xFF$ FFFF FFFF FFFF FFF F, one error is detected and corrected but two errors detection is not supported.

When an ECC error is reported, a new read at the failing address may not generate an ECC error if the data is still present in the current buffer, even if ECCC and ECCD are cleared.

**3.3.3 Read access latency**

To correctly read data from Flash memory, the number of wait states (LATENCY) must be correctly programmed in the **Flash access control register (FLASH_ACR)** according to the
frequency of the CPU clock (HCLK) and the internal voltage range of the device V\textsubscript{CORE}.
Refer to Section 5.1.8: Dynamic voltage scaling management. Table 12 shows the correspondence between wait states and CPU clock frequency.

Table 12. Number of wait states according to CPU clock (HCLK) frequency

<table>
<thead>
<tr>
<th>Wait states (WS) (Latency)</th>
<th>HCLK (MHz)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>V\textsubscript{CORE} Range 1 boost</td>
</tr>
<tr>
<td>0 WS (1 CPU cycles)</td>
<td>≤20</td>
</tr>
<tr>
<td>1 WS (2 CPU cycles)</td>
<td>≤40</td>
</tr>
<tr>
<td>2 WS (3 CPU cycles)</td>
<td>≤60</td>
</tr>
<tr>
<td>3 WS (4 CPU cycles)</td>
<td>≤80</td>
</tr>
<tr>
<td>4 WS (5 CPU cycles)</td>
<td>≤100</td>
</tr>
<tr>
<td>5 WS (6 CPU cycles)</td>
<td>≤120</td>
</tr>
</tbody>
</table>

After reset, the CPU clock frequency is 4 MHz and 0 wait state (WS) is configured in the FLASH_ACR register.

When changing the CPU frequency, the following software sequences must be applied in order to tune the number of wait states needed to access the Flash memory:

**Increasing the CPU frequency:**

1. Program the new number of wait states to the LATENCY bits in the *Flash access control register (FLASH_ACR)*.
2. Check that the new number of wait states is taken into account to access the Flash memory by reading the FLASH_ACR register.
3. Modify the CPU clock source by writing the SW bits in the RCC_CFGR register.
4. If needed, modify the CPU clock prescaler by writing the HPRE bits in RCC_CFGR.
5. Check that the new CPU clock source or/and the new CPU clock prescaler value is/are taken into account by reading the clock source status (SWS bits) or/and the AHB prescaler value (HPRE bits), respectively, in the RCC_CFGR register.

**Decreasing the CPU frequency:**

1. Modify the CPU clock source by writing the SW bits in the RCC_CFGR register.
2. If needed, modify the CPU clock prescaler by writing the HPRE bits in RCC_CFGR.
3. Check that the new CPU clock source or/and the new CPU clock prescaler value is/are taken into account by reading the clock source status (SWS bits) or/and the AHB prescaler value (HPRE bits), respectively, in the RCC_CFGR register.
4. Program the new number of wait states to the LATENCY bits in *Flash access control register (FLASH_ACR)*.
5. Check that the new number of wait states is used to access the Flash memory by reading the FLASH_ACR register.
3.3.4 Adaptive real-time memory accelerator (ART Accelerator)

The proprietary Adaptive real-time (ART) memory accelerator is optimized for STM32 industry-standard Arm® Cortex®-M4 with FPU processors. It balances the inherent performance advantage of the Arm® Cortex®-M4 with FPU over Flash memory technologies, which normally requires the processor to wait for the Flash memory at higher operating frequencies.

To release the processor full performance, the accelerator implements an instruction prefetch queue and branch cache which increases program execution speed from the 64-bit Flash memory. Based on CoreMark benchmark, the performance achieved thanks to the ART accelerator is equivalent to 0 wait state program execution from Flash memory at a CPU frequency up to 120 MHz.

Instruction prefetch

The Cortex®-M4 fetches the instruction over the ICode bus and the literal pool (constant/data) over the DCode bus. The prefetch block aims at increasing the efficiency of ICode bus accesses.

In case of Single-bank mode (DBANK option bit is reset), each Flash memory read operation provides 128 bits from either four instructions of 32 bits or eight instructions of 16 bits depending on the launched program. This 128-bits current instruction line is saved in a current buffer, and in case of sequential code, at least four CPU cycles are needed to execute the previous read instruction line.

When in Dual-bank mode (DBANK option bit is set), each Flash memory read operation provides 64 bits from either two instructions of 32 bits or four instructions of 16 bits depending on the launched program. This 64-bits current instruction line is saved in a current buffer, and in case of sequential code, at least two CPU cycles are needed to execute the previous read instruction line.

Prefetch on the ICode bus can be used to read the next sequential instruction line from the Flash memory while the current instruction line is being requested by the CPU.

Prefetch is enabled by setting the PRFTEN bit in the Flash access control register (FLASH_ACR). This feature is useful if at least one wait state is needed to access the Flash memory.

*Figure 5* shows the execution of sequential 16-bit instructions with and without prefetch when 3 WS are needed to access the Flash memory.
Figure 5. Sequential 16-bit instructions execution (64-bit read data width)

When the code is not sequential (branch), the instruction may not be present in the currently used instruction line or in the prefetched instruction line. In this case (miss), the penalty in terms of number of cycles is at least equal to the number of wait states.
If a loop is present in the current buffer, no new Flash access is performed.

**Instruction cache memory (I-Cache)**

To limit the time lost due to jumps, it is possible to retain 32 lines of 4 x 64 bits in Dual-bank mode or 32 lines of 2 x 128 bits in Single-bank mode in an instruction cache memory. This feature can be enabled by setting the instruction cache enable (ICEN) bit in the **Flash access control register (FLASH_ACR)**. Each time a miss occurs (requested data not present in the currently used instruction line, in the prefetched instruction line or in the instruction cache memory), the line read is copied into the instruction cache memory. If some data contained in the instruction cache memory are requested by the CPU, they are provided without inserting any delay. Once all the instruction cache memory lines have been filled, the LRU (least recently used) policy is used to determine the line to replace in the instruction memory cache. This feature is particularly useful in case of code containing loops.

The Instruction cache memory is enable after system reset.

**Data cache memory (D-Cache)**

Literal pools are fetched from Flash memory through the DCode bus during the execution stage of the CPU pipeline. Each DCode bus read access fetches 64 or 128 bits which are saved in a current buffer. The CPU pipeline is consequently stalled until the requested literal pool is provided. To limit the time lost due to literal pools, accesses through the AHB databus DCode have priority over accesses through the AHB instruction bus ICode.

If some literal pools are frequently used, the data cache memory can be enabled by setting the data cache enable (DCEN) bit in the **Flash access control register (FLASH_ACR)**. This feature works like the instruction cache memory, but the retained data size is limited to 8 rows of 4x64 bits in Dual-bank mode and to 8 rows of 2x128 bits in Single-bank mode.

The Data cache memory is enable after system reset.

*Note:* The D-Cache is active only when data is requested by the CPU (not by DMA1 and DMA2). Data in option bytes block are not cacheable.

### 3.3.5 Flash program and erase operations

The STM32L4+ Series embedded Flash memory can be programmed using in-circuit programming or in-application programming.

The **in-circuit programming (ICP)** method is used to update the entire contents of the Flash memory, using the JTAG, SWD protocol or the bootloader to load the user application into the microcontroller. ICP offers quick and efficient design iterations and eliminates unnecessary package handling or socketing of devices.

In contrast to the ICP method, **in-application programming (IAP)** can use any communication interface supported by the microcontroller (I/Os, USB, CAN, UART, I²C, SPI, etc.) to download programming data into memory. IAP allows the user to re-program the Flash memory while the application is running. Nevertheless, part of the application has to have been previously programmed in the Flash memory using ICP.

*Note:* The contents of the Flash memory are not guaranteed if a device reset occurs during a Flash memory operation.

An on-going Flash memory operation will not block the CPU as long as the CPU does not access the same Flash memory bank. Code or data fetches are possible on one bank while
a write/erase operation is performed to the other bank (refer to Section 3.3.8: Read-while-write (RWW) available only in Dual-bank mode (DBANK=1)). The Flash erase and programming is only possible in the voltage scaling range 1. The VOS[1:0] bits in the PWR_CR1 must be programmed to 01b.

On the contrary, during a program/erase operation to the Flash memory, any attempt to read the same Flash memory bank will stall the bus. The read operation will proceed correctly once the program/erase operation has completed.

Unlocking the Flash memory

After reset, write is not allowed in the Flash control register (FLASH_CR) to protect the Flash memory against possible unwanted operations due, for example, to electric disturbances. The following sequence is used to unlock this register:

1. Write KEY1 = 0x45670123 in the Flash key register (FLASH_KEYR)
2. Write KEY2 = 0xCDEF89AB in the FLASH_KEYR register.

Any wrong sequence will lock up the FLASH_CR register until the next system reset. In the case of a wrong key sequence, a bus error is detected and a Hard Fault interrupt is generated.

The FLASH_CR register can be locked again by software by setting the LOCK bit in the FLASH_CR register.

Note: The FLASH_CR register cannot be written when the BSY bit in the Flash status register (FLASH_SR) is set. Any attempt to write to it with the BSY bit set will cause the AHB bus to stall until the BSY bit is cleared.

3.3.6 Flash main memory erase sequences

The Flash memory erase operation can be performed at page level, bank level or on the whole Flash memory (Mass Erase). Mass Erase does not affect the Information block (system Flash, OTP and option bytes).

Page erase

To erase a page, follow the procedure below:

1. Check that no Flash memory operation is ongoing by checking the BSY bit in the Flash status register (FLASH_SR).
2. Check and clear all error programming flags due to a previous programming. If not, PGSERR is set.
3. In Dual-bank mode (DBANK option bit is set), set the PER bit and select the page to erase (PNB) with the associated bank (BKER) in the Flash control register (FLASH_CR). In Single-bank mode (DBANK option bit is reset), set the PER bit and select the page to erase (PNB). The BKER bit in the Flash control register (FLASH_CR) must be kept cleared.
4. Set the STRT bit in the FLASH_CR register.
5. Wait for the BSY bit to be cleared in the FLASH_SR register.

Note: The internal oscillator HSI16 (16 MHz) is enabled automatically when STRT bit is set, and disabled automatically when STRT bit is cleared, except if the HSI16 is previously enabled with HSION in RCC_CR register.

If the page erase is part of write-protected area (by WRP or PCROP), WRPERR is set and the page erase request is aborted.
Bank 1, Bank 2 Mass erase (available only in Dual-bank mode when DBANK=1)

To perform a bank Mass Erase, follow the procedure below:
1. Check that no Flash memory operation is ongoing by checking the BSY bit in the FLASH_SR register.
2. Check and clear all error programming flags due to a previous programming. If not, PGSERR is set.
3. Set the MER1 bit or MER2 (depending on the bank) in the Flash control register (FLASH_CR). Both banks can be selected in the same operation, in that case it corresponds to a mass erase.
4. Set the STRT bit in the FLACH_CR register.
5. Wait for the BSY bit to be cleared in the Flash status register (FLASH_SR).

Mass erase

To perform a Mass erase, follow the procedure below:
1. Check that no Flash memory operation is ongoing by checking the BSY bit in the FLASH_SR register.
2. Check and clear all error programming flags due to a previous programming. If not, PGSERR is set.
3. Set the MER1 bit and MER2 in the Flash control register (FLASH_CR).
4. Set the STRT bit in the FLACH_CR register.
5. Wait for the BSY bit to be cleared in the Flash status register (FLASH_SR).

Note: The internal oscillator HSI16 (16 MHz) is enabled automatically when STRT bit is set, and disabled automatically when STRT bit is cleared, except if the HSI16 is previously enabled with HSION in RCC_CR register.

When DBANK=0, if only the MERA or the MERB bit is set, PGSERR is set and no erase operation is performed.

If the bank to erase or if one of the banks to erase contains a write-protected area (by WRP or PCROP), WRPERR is set and the mass erase request is aborted (for both banks if both are selected).

3.3.7 Flash main memory programming sequences

The Flash memory is programmed 72 bits at a time (64 bits + 8 bits ECC).

Programming in a previously programmed address is not allowed except if the data to write is full zero, and any attempt will set PROGERR flag in the Flash status register (FLASH_SR).

It is only possible to program double word (2 x 32-bit data).

- Any attempt to write byte or half-word will set SIZERR flag in the FLASH_SR register.
- Any attempt to write a double word which is not aligned with a double word address will set PGAERR flag in the FLASH_SR register.

Standard programming

The Flash memory programming sequence in standard mode is as follows:
1. Check that no Flash main memory operation is ongoing by checking the BSY bit in the Flash status register (FLASH_SR).

2. Check and clear all error programming flags due to a previous programming. If not, PGSERR is set.

3. Set the PG bit in the Flash control register (FLASH_CR).

4. Perform the data write operation at the desired memory address, inside main memory block or OTP area. Only double word can be programmed.
   - Write a first word in an address aligned with double word
   - Write the second word

5. Wait until the BSY bit is cleared in the FLASH_SR register.

6. Check that EOP flag is set in the FLASH_SR register (meaning that the programming operation has succeed), and clear it by software.

7. Clear the PG bit in the FLASH_SR register if there no more programming request anymore.

Note: When the Flash interface has received a good sequence (a double word), programming is automatically launched and BSY bit is set. The internal oscillator HSI16 (16 MHz) is enabled automatically when PG bit is set, and disabled automatically when PG bit is cleared, except if the HSI16 is previously enabled with HSION in RCC_CR register.

If the user needs to program only one word, double word must be completed with the erase value 0xFFFF FFFF to launch automatically the programming.
ECC is calculated from the double word to program.

**Fast programming for a row (64 double words if DBANK=1) or for half row (64 double words if DBANK=0)**

This mode allows to program a row (64 double words if DBANK=1) or half row (64 double words if DBANK=0), and to reduce the page programming time by eliminating the need for verifying the Flash locations before they are programmed and to avoid rising and falling time of high voltage for each double word. During fast programming, the CPU clock frequency (HCLK) must be at least 8 MHz.

Only the main memory can be programmed in fast programming mode.

The Flash main memory programming sequence in standard mode is as follows:

1. In Single-bank mode (DBANK=0), perform a mass erase. If not, PGSERR is set. The Fast programing can be performed only if the code is executed from RAM or from bootloader. In Dual-bank mode (DBANK=1), perform a mass erase of the bank to program. If not, PGSERR is set.

2. Check that no Flash main memory operation is ongoing by checking the BSY bit in the Flash status register (FLASH_SR).

3. Check and clear all error programming flag due to a previous programming.

4. Set the FSTPG bit in Flash control register (FLASH_CR).

5. Write the 64 double words to program a row or half row. Only double words can be programmed:
   - Write a first word in an address aligned with double word
   - Write the second word.
6. Wait until the BSY bit is cleared in the FLASH_SR register.
7. Check that EOP flag is set in the FLASH_SR register (meaning that the programming operation has succeed), and clear it by software.
8. Clear the FSTPG bit in the FLASH_SR register if there no more programming request anymore.

Note: If the Flash is attempted to be written in fast programming mode while a read operation is on going in the same bank, the programming is aborted without any system notification (no error flag is set).

When the Flash interface has received the first double word, programming is automatically launched. The BSY bit is set when the high voltage is applied for the first double word, and it is cleared when the last double word has been programmed or in case of error. The internal oscillator HSI16 (16 MHz) is enabled automatically when FSTPG bit is set, and disabled automatically when FSTPG bit is cleared, except if the HSI16 is previously enabled with HSION in RCC_CR register.

The 64 double word must be written successively. The high voltage is kept on the Flash for all the programming (around 2 x 25 us). Maximum time between two double words write requests is the time programming. If a second double word arrives after this time programming, fast programming is interrupted and MISSERR is set.

High voltage mustn’t exceed 8 ms for a full row between 2 erases. This is guaranteed by the sequence of 64 double words successively written with a clock system greater or equal to 8MHz. An internal time-out counter counts 7ms when fast programming is set and stops the programming when time-out is over. In this case the FASTERR bit is set.

If an error occurs, high voltage is stopped and next double word to programmed is not programmed. Anyway, all previous double words have been properly programmed.
Programming errors

Several kind of errors can be detected. In case of error, the Flash operation (programming or erasing) is aborted.

- **PROGERR**: Programming error
  In standard programming: PROGERR is set if the word to write is not previously erased (except if the value to program is full zero).

- **SIZERR**: Size programming error
  In standard programming or in fast programming: only double word can be programmed and only 32-bit data can be written. SIZERR is set if a byte or an half-word is written.

- **PGAERR**: Alignment programming error
  PGAERR is set if one of the following conditions occurs:
  - In standard programming: the first word to be programmed is not aligned with a double word address, or the second word doesn’t belong to the same double word address.
  - In fast programming: the data to program does not belong to the same row than the previous programmed double words, or the address to program is not greater than the previous one.

- **PGSERR**: Programming sequence error
  PGSERR is set if one of the following conditions occurs:
  - In the standard programming sequence or the fast programming sequence: a data is written when PG and FSTPG are cleared.
  - In the standard programming sequence or the fast programming sequence: MER1, MER2, and PER are not cleared when PG or FSTPG is set.
  - In the fast programming sequence: the Mass erase is not performed before setting FSTPG bit.
  - In the mass erase sequence: PG, FSTPG, and PER are not cleared when MER1 or MER2 is set.
  - In the page erase sequence: PG, FSTPG, MER1 and MER2 are not cleared when PER is set.
  - PGSERR is set also if PROGERR, SIZERR, PGAERR, WRPERR, MISSERR, FASTERR or PGSERR is set due to a previous programming error.
  - When DBANK=0, in the case that only either MER1 or MER2 is set, PGSERR is set (bank mass erase is not allowed).

- **WRPERR**: Write protection error
  WRPERR is set if one of the following conditions occurs:
  - Attempt to program or erase in a write protected area (WRP) or in a PCROP area.
  - Attempt to perform a bank erase when one page or more is protected by WRP or PCROP.
  - The debug features are connected or the boot is executed from SRAM or from System Flash when the read protection (RDP) is set to Level 1.
  - Attempt to modify the option bytes when the read protection (RDP) is set to Level 2.

- **MISSERR**: Fast programming data miss error
  In fast programming: all the data must be written successively. MISSERR is set if the
previous data programmation is finished and the next data to program is not written yet.

- **FASTERR**: Fast programming error
  
  In fast programming: FASTERR is set if one of the following conditions occurs:
  
  - When FSTPG bit is set for more than 7ms which generates a time-out detection.
  - When the fast programming has been interrupted by a MISSERR, PGAERR, WRPERR or SIZERR.

If an error occurs during a program or erase operation, one of the following error flags is set in the FLASH_SR register:

- PROGERR, SIZERR, PGAERR, PGSERR, MISSERR (Program error flags), WRPERR (Protection error flag)

In this case, if the error interrupt enable bit ERRIE is set in the Flash status register (FLASH_SR), an interrupt is generated and the operation error flag OPERR is set in the FLASH_SR register.

**Note:** If several successive errors are detected (for example, in case of DMA transfer to the Flash memory), the error flags cannot be cleared until the end of the successive write requests.

### Programming and caches

If a Flash memory write access concerns some data in the data cache, the Flash write access modifies the data in the Flash memory and the data in the cache.

If an erase operation in Flash memory also concerns data in the data or instruction cache, you have to make sure that these data are rewritten before they are accessed during code execution. If this cannot be done safely, it is recommended to flush the caches by setting the DCRST and ICRST bits in the Flash access control register (FLASH_ACR).

**Note:** The I/D cache should be flushed only when it is disabled (I/DCEN = 0).

#### 3.3.8 Read-while-write (RWW) available only in Dual-bank mode (DBANK=1)

The Dual-bank mode is available only when the DBANK option bit is reset, allowing read-while-write operations. This feature allows to perform a read operation from one bank while erase or program operation is performed to the other bank.

**Note:** Write-while-write operations are not allowed. As an example, it is not possible to perform an erase operation on one bank while programming the other one.

### Read from bank 1 while page erasing in bank 2 (or vice versa)

While executing a program code from bank 1, it is possible to perform a page erase operation on bank 2 (and vice versa). Follow the procedure below:

1. Check that no Flash memory operation is ongoing by checking the BSY bit in the Flash status register (FLASH_SR) (BSY is active when erase/program operation is on going in bank 1 or bank 2).
2. Set PER bit, PSB to select the page and BKER to select the bank in the Flash control register (FLASH_CR).
3. Set the STRT bit in the FLASH_CR register.
4. Wait for the BSY bit to be cleared (or use the EOP interrupt).
Read from bank 1 while mass erasing bank 2 (or vice versa)

While executing a program code from bank 1, it is possible to perform a mass erase operation on bank 2 (and vice versa). Follow the procedure below:

1. Check that no Flash memory operation is ongoing by checking the BSY bit in the Flash status register (FLASH_SR) (BSY is active when erase/program operation is ongoing in bank 1 or bank 2).
2. Set MER1 or MER2 to in the Flash control register (FLASH_CR).
3. Set the STRT bit in the FLASH_CR register.
4. Wait for the BSY bit to be cleared (or use the EOP interrupt).

Read from bank 1 while programming bank 2 (or vice versa)

While executing a program code from bank 1, it is possible to perform a program operation on the bank 2. (and vice versa). Follow the procedure below:

1. Check that no Flash memory operation is ongoing by checking the BSY bit in the Flash status register (FLASH_SR) (BSY is active when erase/program operation is ongoing on bank 1 or bank 2).
2. Set the PG bit in the Flash control register (FLASH_CR).
3. Perform the data write operations at the desired address memory inside the main memory block or OTP area.
4. Wait for the BSY bit to be cleared (or use the EOP interrupt).
3.4 FLASH option bytes

3.4.1 Option bytes description

The option bytes are configured by the end user depending on the application requirements. As a configuration example, the watchdog may be selected in hardware or software mode (refer to Section 3.4.2: Option bytes programming).

A double word is split up as follows in the option bytes:

Table 13. Option byte format

<table>
<thead>
<tr>
<th>63-24</th>
<th>23-16</th>
<th>15-8</th>
<th>7-0</th>
<th>31-24</th>
<th>23-16</th>
<th>15-8</th>
<th>7-0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The organization of these bytes inside the information block is as shown in Table 14.

The option bytes can be read from the memory locations listed in Table 14 or from the Option byte registers:

- Flash option register (FLASH_OPTR)
- Flash PCROP1 Start address register (FLASH_PCROP1SR)
- Flash PCROP1 End address register (FLASH_PCROP1ER)
- Flash WRP1 area A address register (FLASH_WRP1AR)
- Flash WRP1 area B address register (FLASH_WRP1BR)
- Flash PCROP2 Start address register (FLASH_PCROP2SR)
- Flash PCROP2 End address register (FLASH_PCROP2ER)
- Flash WRP2 area A address register (FLASH_WRP2AR)
- Flash WRP2 area B address register (FLASH_WRP2BR).

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 nBOOT0: nBOOT0 option bit
0: nBOOT0 = 0
1: nBOOT0 = 1

Bit 26 nSWBOOT0: Software BOOT0
0: BOOT0 taken from the option bit nBOOT0
1: BOOT0 taken from PH3/BOOT0 pin

Bit 25 SRAM2_RST: SRAM2 Erase when system reset
0: SRAM2 erased when a system reset occurs
1: SRAM2 is not erased when a system reset occurs

Bit 24 SRAM2_PE: SRAM2 parity check enable
0: SRAM2 parity check enable
1: SRAM2 parity check disable

Bit 23 nBOOT1: Boot configuration
Together with the BOOT0 pin, this bit selects boot mode from the Flash main memory, SRAM1 or the System memory. Refer to Section 2.6: Boot configuration.
Bit 22 DBANK:
  0: Single-bank mode with 128 bits data read width
  1: Dual-bank mode with 64 bits data
This bit can be written only when PCROP1/2 is disabled.
Note: For 1-Mbyte and 512-Kbyte Flash memory devices, do not care about DBANK.

Bit 21 DB1M:
  For STM32L4Rxxx and STM32L4Sxxx devices:
  Dual-bank on 1-Mbyte Flash memory devices
  0: 1 Mbyte single Flash contiguous address in Bank1
  1: 1 Mbyte dual-bank Flash with contiguous addresses
  For STM32L4P5xx and STM32L4Q5xx devices:
  Dual-bank on 512 Kbytes Flash memory devices
  0: 512 Kbytes single Flash contiguous address in Bank1
  1: 512 Kbytes Dual-bank Flash with contiguous addresses
Note: For 2-Mbytes Flash memory devices, do not care about DB1M.

Bit 20 BFB2: Dual-bank boot
  0: Dual-bank boot disable
  1: Dual-bank boot enable

Bit 19 WWDG_SW: Window watchdog selection
  0: Hardware window watchdog
  1: Software window watchdog

Bit 18 IWDG_STDBY: Independent watchdog counter freeze in Standby mode
  0: Independent watchdog counter is frozen in Standby mode
  1: Independent watchdog counter is running in Standby mode

Bit 17 IWDG_STOP: Independent watchdog counter freeze in Stop mode
  0: Independent watchdog counter is frozen in Stop mode
  1: Independent watchdog counter is running in Stop mode

Bit 16 IDWG_SW: Independent watchdog selection
  0: Hardware independent watchdog
  1: Software independent watchdog

Bit 15 Reserved, must be kept at reset value.

Bit 14 nRST_SHDW:
  0: Reset generated when entering the Shutdown mode
  1: No reset generated when entering the Shutdown mode

Bit 13 nRST_STDBY
  0: Reset generated when entering the Standby mode
  1: No reset generate when entering the Standby mode

Bit 12 nRST_STOP
  0: Reset generated when entering the Stop mode
  1: No reset generated when entering the Stop mode
Bit 11  Reserved, must be kept at reset value.

Bits 10:8  **BOR_LEV**: BOR reset Level

These bits contain the VDD supply level threshold that activates/releases the reset.

- 000: BOR Level 0. Reset level threshold is around 1.7 V
- 001: BOR Level 1. Reset level threshold is around 2.0 V
- 010: BOR Level 2. Reset level threshold is around 2.2 V
- 011: BOR Level 3. Reset level threshold is around 2.5 V
- 100: BOR Level 4. Reset level threshold is around 2.8 V

Bits 7.0  **RDP**: Read protection level

- 0xAA: Level 0, read protection not active
- 0xCC: Level 2, chip read protection active
- Others: Level 1, memories read protection active

### PCROP1 Start address option bytes

Flash memory address: 0x1FF0 0008

ST production value: 0xFFFF FFFF

```
Embedded Flash memory (FLASH)

Bit 31  **PCROP_RDP**: PCROP area preserved when RDP level decreased
This bit is set only. It is reset after a full mass erase due to a change of RDP from Level 1 to Level 0.
0: PCROP area is not erased when the RDP level is decreased from Level 1 to Level 0.
1: PCROP area is erased when the RDP level is decreased from Level 1 to Level 0 (full mass erase).

Bits 30:17  Reserved, must be kept at reset value.

Bits 16:0  **PCROP1_END**: Bank 1 PCROP area end offset
- **DBANK=1**: PCROP1_END contains the last double-word of the bank 1 PCROP area.
- **DBANK=0**: PCROP1_END contains the last 2x double-word PCROP area for all memory.

### WRP Area A address option bytes

3.4.2 Option bytes programming

After reset, the options related bits in the Flash control register (FLASH_CR) are write-protected. To run any operation on the option bytes page, the option lock bit OPTLOCK in the Flash control register (FLASH_CR) must be cleared. The following sequence is used to unlock this register:

1. Unlock the FLASH_CR with the LOCK clearing sequence (refer to Unlocking the Flash memory).
2. Write OPTKEY1 = 0x08192A3B in the Flash option key register (FLASH_OPTKEYR).
3. Write OPTKEY2 = 0x4C5D6E7F in the FLASH_OPTKEYR register.

The user options can be protected against unwanted erase/program operations by setting the OPTLOCK bit by software.

Note: If LOCK is set by software, OPTLOCK is automatically set too.

Modifying user options

The option bytes are programmed differently from a main memory user address. It is not possible to modify independently user options of bank 1 or bank 2. The users Options of the bank 1 are modified first.

To modify the user options value, follow the procedure below:

1. Check that no Flash memory operation is on going by checking the BSY bit in the Flash status register (FLASH_SR).
2. Clear OPTLOCK option lock bit with the clearing sequence described above.
3. Write the desired options value in the options registers: Flash option register (FLASH_OPR), Flash PCROP1 Start address register (FLASH_PCROP1SR), Flash PCROP1 End address register (FLASH_PCROP1ER), Flash WRP1 area A address register (FLASH_WRP1AR), Flash WRP1 area B address register (FLASH_WRP1BR),

Bits 31:24  Reserved, must be kept at reset value.

Bits 23:16  WRP2B_END: WRP second area “B” end offset
   
   DBANK=1
   
   WRP2B_END contains the last page of the WRP second area for bank2.
   
   DBANK=0
   
   WRP2B_END contains the last page of the WRP fourth area for all memory.

Bits 15:8  Reserved, must be kept at reset value.

Bits 7:0  WRP2B_STRT: WRP second area “B” start offset
   
   DBANK=1
   
   WRP2B_STRT contains the first page of the WRP second area for bank2.
   
   DBANK=0
   
   WRP2B_STRT contains the first page of the WRP second area for all memory.
4. Set the Options Start bit OPTSTRT in the Flash control register (FLASH_CR).

5. Wait for the BSY bit to be cleared.

Note: Any modification of the value of one option is automatically performed by erasing both user option bytes pages first (bank 1 and bank 2) and then programming all the option bytes with the values contained in the Flash option registers.

Option byte loading

After the BSY bit is cleared, all new options are updated into the Flash but they are not applied to the system. They will have effect on the system when they are loaded. Option bytes loading (OBL) is performed in two cases:

- when OBL_LAUNCH bit is set in the Flash control register (FLASH_CR).
- after a power reset (BOR reset or exit from Standby/Shutdown modes).

Option byte loader performs a read of the options block and stores the data into internal option registers. These internal registers configure the system and cannot be read with by software. Setting OBL_LAUNCH generates a reset so the option byte loading is performed under system reset.

Each option bit has also its complement in the same double word. During option loading, a verification of the option bit and its complement allows to check the loading has correctly taken place.

During option byte loading, the options are read by double word with ECC. If the word and its complement are matching, the option word/byte is copied into the option register.

If the comparison between the word and its complement fails, a status bit OPTVERR is set.

Mismatch values are forced into the option registers:

- For USR OPT option, the value of mismatch is all options at ‘1’, except for BOR_LEV which is “000” (lowest threshold)
- For WRP option, the value of mismatch is the default value “No protection”
- For RDP option, the value of mismatch is the default value “Level 1”
- For PCROP, the value of mismatch is “all memory protected”

On system reset rising, internal option registers are copied into option registers which can be read and written by software (FLASH_OPTR, FLASH_PCROP1/2SR, FLASH_PCROP1/2ER, FLASH_WRP1/2AR, FLASH_WRP1/2BR). These registers are also used to modify options. If these registers are not modified by user, they reflect the options states of the system. See Section : Modifying user options for more details.

Activating Dual-bank mode (switching from DBANK=0 to DBANK=1)

When switching from one Flash mode to another (for example from single to dual-bank) it is recommended to execute the code from the SRAM or use the bootloader. To avoid reading
corrupted data from the Flash when the memory organization is changed, any access (either CPU or DMAs) to Flash memory should be avoided before reprogramming.

- Disable Instruction/data caches and/or prefetch if they are enabled (reset PRFTEN and ICEN/DCEN bits in the FLASH_ACR register).
- Flush instruction and data cache by setting the DCRST/ICRST bits in the FLASH_ACR register.
- Set the DBANK option bit and clear all the WRP write protection (follow user option modification and option bytes loader procedure).
  - Once OBL is done with DBANK=1, perform a mass erase.
  - Start a new programming of code in 64 bits mode with DBANK=1 memory mapping.
  - Set the new WRP/PCROP with DBANK=1 scheme if needed.
  - Set PRFTEN and ICEN/DCEN if needed.

The new software is ready to be run using the bank configuration.

**De-activating Dual-bank mode (switching from DBANK=1 to DBANK=0)**

When switching from one Flash mode to another (for example from single to dual-bank) it is recommended to execute the code from the SRAM or use the bootloader. To avoid reading corrupted data from the Flash when the memory organization is changed, any access (either CPU or DMAs) to Flash memory should be avoided before reprogramming.

- Disable Instruction/data caches and/or prefetch if they are enabled (reset PRFTEN and ICEN/DCEN bits in the FLASH_ACR register).
- Flush instruction and data cache by setting the DCRST/ICRST bits in the FLASH_ACR register.
- Clear the DBANK option bit and all WRP write protection (follow user option modification and option bytes loader procedure).
  - Once OBL is done with DBANK=0, perform a mass erase.
  - Start a new programming of code in 128 bits mode with DBANK=0 memory mapping
  - Set the new WRP/PCROP with DBANK=0 scheme if needed. Set PRFTEN and ICEN/DCEN if needed.

The new software is ready to be run using the bank configuration.
3.5 **FLASH memory protection**

The Flash main memory can be protected against external accesses with the Read protection (RDP). The pages of the Flash memory can also be protected against unwanted write due to loss of program counter contexts. The write-protection (WRP) granularity is one page (2 KByte). Apart of the Flash memory can also be protected against read and write from third parties (PCROP). The PCROP granularity is double word (64-bit).

### 3.5.1 Read protection (RDP)

The read protection is activated by setting the RDP option byte and then, by applying a system reset to reload the new RDP option byte. The read protection protects to the Flash main memory, the option bytes, the backup registers (RTC_BKPxR in the RTC) and the SRAM2.

*Note:* If the read protection is set while the debugger is still connected through JTAG/SWD, apply a POR (power-on reset) instead of a system reset.

There are three levels of read protection from no protection (level 0) to maximum protection or no debug (level 2).

The Flash memory is protected when the RDP option byte and its complement contain the pair of values shown in Table 15.

<table>
<thead>
<tr>
<th>RDP byte value</th>
<th>RDP complement value</th>
<th>Read protection level</th>
</tr>
</thead>
<tbody>
<tr>
<td>0xAA</td>
<td>0x55</td>
<td>Level 0</td>
</tr>
<tr>
<td>Any value except 0xAA or 0xCC</td>
<td>Any value (not necessarily complementary) except 0x55 and 0x33</td>
<td>Level 1 (default)</td>
</tr>
<tr>
<td>0xCC</td>
<td>0x33</td>
<td>Level 2</td>
</tr>
</tbody>
</table>

The System memory area is read accessible whatever the protection level. It is never accessible for program/erase operation.

**Level 0: no protection**

Read, program and erase operations into the Flash main memory area are possible. The option bytes, the SRAM2 and the backup registers are also accessible by all operations.
Level 1: Read protection

This is the default protection level when RDP option byte is erased. It is defined as well when RDP value is at any value different from 0xAA and 0xCC, or even if the complement is not correct.

- **User mode**: Code executing in user mode (Boot Flash) can access Flash main memory, option bytes, SRAM2 and backup registers with all operations.
- **Debug, boot RAM and bootloader modes**: In debug mode or when code is running from boot RAM or bootloader, the Flash main memory, the backup registers (RTC_BKPxR in the RTC) and the SRAM2 are totally inaccessible. In these modes, a read or write access to the Flash generates a bus error and a Hard Fault interrupt.

**Caution:** In case the Level 1 is configured and no PCROP area is defined, it is mandatory to set PCROP_RDP bit to 1 (full mass erase when the RDP level is decreased from Level 1 to Level 0). In case the Level 1 is configured and a PCROP area is defined, if user code needs to be protected by RDP but not by PCROP, it must not be placed in a page containing a PCROP area.

Level 2: No debug

In this level, the protection level 1 is guaranteed. In addition, the Cortex®-M4 debug port, the boot from RAM (boot RAM mode) and the boot from System memory (bootloader mode) are no more available. In user execution mode (boot FLASH mode), all operations are allowed on the Flash main memory. On the contrary, only read operations can be performed on the option bytes.

Option bytes cannot be programmed nor erased. Thus, the level 2 cannot be removed at all: it is an irreversible operation. When attempting to modify the options bytes, the protection error flag WRPERR is set in the Flash_SR register and an interrupt can be generated.

**Note:** The debug feature is also disabled under reset.

STMicroelectronics is not able to perform analysis on defective parts on which the level 2 protection has been set.

Changing the Read protection level

It is easy to move from level 0 to level 1 by changing the value of the RDP byte to any value (except 0xCC). By programming the 0xCC value in the RDP byte, it is possible to go to level 2 either directly from level 0 or from level 1. Once in level 2, it is no more possible to modify the Read protection level.

When the RDP is reprogrammed to the value 0xAA to move from Level 1 to Level 0, a mass erase of the Flash main memory is performed if PCROP_RDP is set in the Flash PCROP1 End address register (FLASH_PCROP1ER). The backup registers (RTC_BKPxR in the RTC) and the SRAM2 are also erased. The user options except PCROP protection are set to their previous values copied from FLASH_OPTR, FLASH_WRPxyR (x=1, 2 and y =A or B). PCROP is disable. The OTP area is not affected by mass erase and remains unchanged.

If the bit PCROP_RDP is cleared in the FLASH_PCROP1ER, the full mass erase is replaced by a partial mass erase that is successive page erases in the bank where PCROP is active, except for the pages protected by PCROP. This is done in order to keep the PCROP code. If PCROP is active for both banks, both banks are erased by page erases. Only when both banks are erased, options are re-programmed with their previous values. This is also true for FLASH_PCROPxSR and FLASH_PCROPxER registers (x=1,2).
**Note:** Full Mass Erase or Partial Mass Erase is performed only when Level 1 is active and Level 0 requested. When the protection level is increased (0->1, 1->2, 0->2) there is no mass erase.

To validate the protection level change, the option bytes must be reloaded through the OBL_LAUNCH bit in Flash control register.

3.5.2 Proprietary code readout protection (PCROP)

Apart of the Flash memory can be protected against read and write from third parties. The protected area is execute-only: it can only be reached by the STM32 CPU, as an instruction code, while all other accesses (DMA, debug and CPU data read, write and erase) are strictly prohibited. Depending of the DBANK mode, it allows either to specify one PCROP zone per bank in Dual-bank mode or to specify two PCROP zones for all memory. An additional option bit (PCROP_RDP) allows to select if the PCROP area is erased or not when the RDP protection is changed from Level 1 to Level 0 (refer to Changing the Read protection level).

Each PCROP area is defined by a start page offset and an end page offset related to the physical Flash bank base address. These offsets are defined in the PCROP address registers Flash PCROP1 Start address register (FLASH_PCROP1SR), Flash PCROP1 End address register (FLASH_PCROP1ER), Flash PCROP2 Start address register (FLASH_PCROP2SR), Flash PCROP2 End address register (FLASH_PCROP2ER).

In Single-bank mode (DBANK=0):
- The PCROPx (x = 1, 2) area is defined from the address: base address + [PCROPx_STRT x 16] (included) to the address: base address + [(PCROPx_END+1) x 16] (excluded). The minimum PCROP area size is two 2 x double-words (256 bits).

In Dual-bank mode (DBANK=1)
- The PCROPx (x = 1, 2) area is defined from the address: bank “x” base address + [PCROPx_STRT x 0x8] (included) to the address: bank “x” base address + [(PCROPx_END+1) x 0x8] (excluded). The minimum PCROP area size is two double-words (128 bits).

1. When the protection level 2 is active, the Debug port, the boot from RAM and the boot from system memory are disabled.
2. The system memory is only read-accessible, whatever the protection level (0, 1 or 2) and execution mode.
3. The Flash main memory is erased when the RDP option byte is programmed with all level protections disabled (0xAA).
4. OTP can only be written once.
5. The backup registers are erased when RDP changes from level 1 to level 0.
6. The SRAM2 is erased when RDP changes from level 1 to level 0.
For example, to protect by PCROP from the address 0x0806 2F80 (included) to the address 0x0807 0004 (included):

- if boot in Flash is done in Bank 1, FLASH_PCROP1SR and FLASH_PCROP1ER registers must be programmed with:
  - PCROP1_STRT = 0xC5F0.
  - PCROP1_END = 0xE000.
- if the two banks are swapped, the protection must apply to bank 2, and FLASH_PCROP2SR and FLASH_PCROP2ER register must be programmed with:
  - PCROP2_STRT = 0xC5F0.
  - PCROP2_END = 0xE000.

Any read access performed through the D-bus to a PCROP protected area will trigger RDERR flag error.

Any PCROP protected address is also write protected and any write access to one of these addresses will trigger WRPERR.

Any PCROP area is also erase protected. Consequently, any erase to a page in this zone is impossible (including the page containing the start address and the end address of this zone). Moreover, a software mass erase cannot be performed if one zone is PCROP protected.

For previous example, due to erase by page, all pages from page 0x62 to 0x70 are protected in case of page erase. (All addresses from 0x0806 2000 to 0x080 70FFF cannot be erased).

Deactivation of PCROP can only occurs when the RDP is changing from level 1 to level 0. If the user options modification tries to clear PCROP or to decrease the PCROP area, the options programming is launched but PCROP area stays unchanged. On the contrary, it is possible to increase the PCROP area.

When option bit PCROP_RDP is cleared, when the RDP is changing from level 1 to level 0, Full Mass Erase is replaced by Partial Mass Erase in order to keep the PCROP area (refer to Changing the Read protection level). In this case, PCROP1/2_STRT and PCROP1/2_END are also not erased.

Note: It is recommended to align PCROP area with page granularity when using PCROP_RDP, or to leave free the rest of the page where PCROP zone starts or ends.

### Table 17. PCROP protection(1)

<table>
<thead>
<tr>

</tr>
<tr>
<td></td>
<td>- PCROPx_offset_end with a higher value.</td>
</tr>
</tbody>
</table>
3.5.3 Write protection (WRP)

The user area in Flash memory can be protected against unwanted write operations. Depending on the DBANK option bit configuration, it allows either to specify:

- In Single-bank mode (DBANK=0): four write-protected (WRP) areas can be defined in each bank, with page size (8 KByte) granularity.
- In Dual-bank mode (DBANK=1): two write-protected (WRP) areas can be defined in each bank, with page (4 KByte) granularity.

Each area is defined by a start page offset and an end page offset related to the physical Flash bank base address. These offsets are defined in the WRP address registers: Flash WRP1 area A address register (FLASH_WRP1AR), Flash WRP1 area B address register (FLASH_WRP1BR), Flash WRP2 area A address register (FLASH_WRP2AR), Flash WRP2 area B address register (FLASH_WRP2BR).

Dual-bank mode (DBANK=1)

The bank “x” WRP “y” area (x=1,2 and y=A,B) is defined from the address: Bank “x” Base address + [WRPxy_STRT x 0x1000] (included) to the address: Bank “x” Base address + [(WRPxy_END+1) x 0x1000] (excluded).

Single-bank mode (DBANK=0)

The WRPx “y” area (x=1,2 and y=A,B) is defined from the address: Base address + [WRPy_STRT x 0x2000] (included) to the address: Base address + [(WRPy_END+1) x 0x2000] (excluded).

For example, to protect by WRP from the address 0x0806 2800 (included) to the address 0x0807 07FF (included):

- If boot in Flash is done in Bank 1, FLASH_WRP1AR register must be programmed with:
  - WRP1A_STRT = 0x62.
  - WRP1A.END = 0x70.
  - WRP1B_STRT and WRP1B.END in FLASH_WRP1BR can be used instead (area “B” in Bank 1).
- If the two banks are swapped, the protection must apply to bank 2, and FLASH_WRP2AR register must be programmed with:
  - WRP2A_STRT = 0x62.
  - WRP2A.END = 0x70.
  - WRP2A_STRT = 0xC5.
  - WRP2A.END = 0xE0.
  - WRP2B_STRT and WRP2B.END in FLASH_WRP2BR can be used instead (area “B” in Bank 2).
When WRP is active, it cannot be erased or programmed. Consequently, a software mass erase cannot be performed if one area is write-protected.

If an erase/program operation to a write-protected part of the Flash memory is attempted, the write protection error flag (WRPERR) is set in the FLASH_SR register. This flag is also set for any write access to:
- OTP area part of the Flash memory that can never be written like the ICP
- PCROP area.

**Note:** When the memory read protection level is selected (RDP level = 1), it is not possible to program or erase Flash memory if the CPU debug features are connected (JTAG or single wire) or boot code is being executed from RAM or System Flash, even if WRP is not activated.

**Note:** To validate the WRP options, the option bytes must be reloaded through the OBL_LAUNCH bit in Flash control register.

**Note:** When DBANK=0, it is the user’s responsibility to make sure that no overlapping occurs on the WRP zone.

### Table 18. WRP protection

</table>

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **SLEEP_PD**: Flash Power-down mode during Sleep or Low-power sleep mode  
This bit determines whether the Flash memory is in Power-down mode or idle mode when the device is in Sleep or Low-power sleep mode.  
0: Flash in idle mode during Sleep and Low-power sleep modes  
1: Flash in Power-down mode during Sleep and Low-power sleep modes  

**Caution**: The Flash must not be put in power-down while a program or an erase operation is on-going.

Bit 13 **RUN_PD**: Flash Power-down mode during Run or Low-power run mode  
This bit is write-protected with FLASH_PDKEYR.  
This bit determines whether the Flash memory is in Power-down mode or idle mode when the device is in Run or Low-power run mode. The Flash memory can be put in Power-down mode only when the code is executed from RAM. The Flash must not be accessed when RUN_PD is set.  
0: Flash in idle mode  
1: Flash in Power-down mode  

**Caution**: The Flash must not be put in power-down while a program or an erase operation is on-going.

Bit 12 **DCRST**: Data cache reset  
0: Data cache is not reset  
1: Data cache is reset  
This bit can be written only when the data cache is disabled.

Bit 11 **ICRST**: Instruction cache reset  
0: Instruction cache is not reset  
1: Instruction cache is reset  
This bit can be written only when the instruction cache is disabled.

Bit 10 **DCEN**: Data cache enable  
0: Data cache is disabled  
1: Data cache is enabled
3.7.2 Flash Power-down key register (FLASH_PDKEYR)

Bits 31:0 PDKEYR: Power-down in Run mode Flash key
The following values must be written consecutively to unlock the RUN_PD bit in FLASH_ACR:
PDKEY1: 0x0415 2637
PDKEY2: 0xFAFB FCFD
### 3.7.3 Flash key register (FLASH_KEYR)

- **Address offset**: 0x08
- **Reset value**: 0x0000 0000
- **Access**: no wait state, word access

<table>
<thead>
<tr>
<th>Key frame (31:16)</th>
</tr>
</thead>
<tbody>
<tr>
<td>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16</td>
</tr>
<tr>
<td>w  w  w  w  w  w  w  w  w  w  w  w  w  w  w  w</td>
</tr>
<tr>
<td>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</td>
</tr>
</tbody>
</table>

Bits 31:0 **KEYR**: Flash key  
The following values must be written consecutively to unlock the FLACH_CR register allowing Flash programming/erasing operations:  
KEY1: 0x4567 0123  
KEY2: 0xCDEF 89AB

### 3.7.4 Flash option key register (FLASH_OPTKEYR)

- **Address offset**: 0x0C
- **Reset value**: 0x0000 0000
- **Access**: no wait state, word access

<table>
<thead>
<tr>
<th>Option key frame (31:16)</th>
</tr>
</thead>
<tbody>
<tr>
<td>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16</td>
</tr>
<tr>
<td>w  w  w  w  w  w  w  w  w  w  w  w  w  w  w  w</td>
</tr>
<tr>
<td>15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0</td>
</tr>
</tbody>
</table>

Bits 31:0 **OPTKEYR**: Option byte key  
The following values must be written consecutively to unlock the FLACH_OPTR register allowing option byte programming/erasing operations:  
KEY1: 0x0819 2A3B  
KEY2: 0x4C5D 6E7F
### 3.7.5 Flash status register (FLASH_SR)

Address offset: 0x10  
Reset value: 0x0000 0000  
Access: no wait state, word, half-word and byte access

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:18</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
</tbody>
</table>
| 17 | **PEMPTY**: Program EMPTY  
Set by hardware on power-on reset or after OBL_LAUNCH command execution if the Flash is not programmed and the user intends to boot from the main Flash. Cleared by hardware on power-on reset or after OBL_LAUNCH command execution if the Flash is programmed and the user intends to boot from main Flash. This bit can also be set and cleared by software.  
1: The bit value is toggling  
0: No effect  
This bit can be set to clear the Program Empty bit if an OBL_LAUNCH is done by software after Flash programming (boot in main Flash selected). It finally forces the boot in the main Flash, without loosing the debugger connection. |
| 16 | **BSY**: Busy  
This indicates that a Flash operation is in progress. This is set on the beginning of a Flash operation and reset when the operation finishes or when an error occurs. |
| 15 | **OPTVERR**: Option validity error  
Set by hardware when the options read may not be the one configured by the user. If option haven't been properly loaded, OPTVERR is set again after each system reset.  
Cleared by writing 1. |
| 14 | **RDERR**: PCROP read error  
Set by hardware when an address to be read through the D-bus belongs to a read protected area of the Flash (PCROP protection). An interrupt is generated if RDERRIE is set in FLASH_CR.  
Cleared by writing 1. |
| 13:10 | Reserved, must be kept at reset value. |
| 9 | **FASTERR**: Fast programming error  
Set by hardware when a fast programming sequence (activated by FSTPG) is interrupted due to an error (alignment, size, write protection or data miss). The corresponding status bit (PGAERR, SIZERR, WRPERR or MISSERR) is set at the same time.  
Cleared by writing 1. |
Bit 8 **MISERR**: Fast programming data miss error
In fast programming mode, 32 double words must be sent to Flash successively, and the new data must be sent to the Flash logic control before the current data is fully programmed. MISSERR is set by hardware when the new data is not present in time.
Cleared by writing 1.

Bit 7 **PGSERR**: Programming sequence error
Set by hardware when a write access to the Flash memory is performed by the code while PG or FSTPG have not been set previously. Set also by hardware when PROGERR, SIZERR, PGAERR, WRPERR, MISSERR or FASTERR is set due to a previous programming error.
Set also when trying to perform bank erase when DBANK=0.
Cleared by writing 1.

Bit 6 **SIZERR**: Size error
Set by hardware when the size of the access is a byte or half-word during a program or a fast program sequence. Only double word programming is allowed (consequently: word access).
Cleared by writing 1.

Bit 5 **PGAERR**: Programming alignment error
Set by hardware when the data to program cannot be contained in the same 64-bit Flash memory row in case of standard programming, or if there is a change of page during fast programming.
Cleared by writing 1.

Bit 4 **WRPERR**: Write protection error
Set by hardware when an address to be erased/programmed belongs to a write-protected part (by WRP, PCROP or RDP level 1) of the Flash memory.
Cleared by writing 1.

Bit 3 **PROGERR**: Programming error
Set by hardware when a double-word address to be programmed contains a value different from ‘0xFFFF FFFF’ before programming, except if the data to write is ‘0x0000 0000’.
Cleared by writing 1.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **OPERR**: Operation error
Set by hardware when a Flash memory operation (program / erase) completes unsuccessfully.
This bit is set only if error interrupts are enabled (ERRIE = 1).
Cleared by writing ‘1’.

Bit 0 **EOP**: End of operation
Set by hardware when one or more Flash memory operation (programming / erase) has been completed successfully.
This bit is set only if the end of operation interrupts are enabled (EOPIE = 1).
Cleared by writing 1.
3.7.6 Flash control register (FLASH_CR)

Address offset: 0x14
Reset value: 0xC000 0000
Access: no wait state when no Flash memory operation is on going, word, half-word and byte access

Bit 31  **LOCK**: FLASH_CR Lock
- This bit is set only. When set, the FLASH_CR register is locked. It is cleared by hardware after detecting the unlock sequence.
- In case of an unsuccessful unlock operation, this bit remains set until the next system reset.

Bit 30  **OPTLOCK**: Options Lock
- This bit is set only. When set, all bits concerning user option in FLASH_CR register and so option page are locked. This bit is cleared by hardware after detecting the unlock sequence. The LOCK bit must be cleared before doing the unlock sequence for OPTLOCK bit.
- In case of an unsuccessful unlock operation, this bit remains set until the next reset.

Bits 29:28  Reserved, must be kept at reset value.

Bit 27  **OBL_LAUNCH**: Force the option byte loading
- When set to 1, this bit forces the option byte reloading. This bit is cleared only when the option byte loading is complete. It cannot be written if OPTLOCK is set.
  0: Option byte loading complete
  1: Option byte loading requested

Bit 26  **RDERRIE**: PCROP read error interrupt enable
- This bit enables the interrupt generation when the RDERR bit in the FLASH_SR is set to 1.
  0: PCROP read error interrupt disabled
  1: PCROP read error interrupt enabled

Bit 25  **ERRIE**: Error interrupt enable
- This bit enables the interrupt generation when the OPERR bit in the FLASH_SR is set to 1.
  0: OPERR error interrupt disabled
  1: OPERR error interrupt enabled

Bit 24  **EOPIE**: End of operation interrupt enable
- This bit enables the interrupt generation when the EOP bit in the FLASH_SR is set to 1.
  0: EOP Interrupt disabled
  1: EOP Interrupt enabled
Bits 23:19  Reserved, must be kept at reset value

Bit 18 **FSTPG**: Fast programming
- 0: Fast programming disabled
- 1: Fast programming enabled

Bit 17 **OPTSTRT**: Options modification start
- This bit triggers an options operation when set.
- This bit is set only by software, and is cleared when the BSY bit is cleared in FLASH_SR.

Bit 16 **START**: Start
- This bit triggers an erase operation when set. If MER1, MER2 and PER bits are reset and the STRT bit is set, an unpredictable behavior may occur without generating any error flag. This condition should be forbidden.
- This bit is set only by software, and is cleared when the BSY bit is cleared in FLASH_SR.

Bit 15 **MER2**: Bank 2 Mass erase
- This bit triggers the bank 2 mass erase (all bank 2 user pages) when set.

Bits 14:12  Reserved, must be kept at reset value.

Bit 11 **BKER**: Bank erase
- DBANK=1
- 0: Bank 1 is selected for page erase
- 1: Bank 2 is selected for page erase
- DBANK=0
- Reserved, must be kept cleared

Bits 10:3 **PNB[7:0]**: Page number selection
- These bits select the page to erase:
  - 00000000: page 0
  - 00000001: page 1
  - ...
  - 11111111: page 255

Bit 2 **MER1**: Bank 1 Mass erase
- This bit triggers the bank 1 mass erase (all bank 1 user pages) when set.

Bit 1 **PER**: Page erase
- 0: page erase disabled
- 1: page erase enabled

Bit 0 **PG**: Programming
- 0: Flash programming disabled
- 1: Flash programming enabled
### 3.7.7 Flash ECC register (FLASH_ECCR)

Address offset: 0x18  
Reset value: 0x0000 0000  
Access: no wait state when no Flash memory operation is on going, word, half-word and byte access

ADDR_ECC[15:0]  
| r | r | r | r | r | r | r | r | r | r | r | r | r | r | r |

#### Bit 31 ECCD: ECC detection
- **DBANK=0**
  - Set by hardware when two ECC errors have been detected (only if ECCC/ECCC2/ECCD/ ECD2 are previously cleared). When this bit is set, a NMI is generated.
  - Cleared by writing 1.
- **DBANK=1**
  - Set by hardware when two ECC errors have been detected on 64-bits LSB (bits 63:0) (only if ECCC/ECCC2/ECCD/ ECD2 are previously cleared). When this bit is set, a NMI is generated.
  - Cleared by writing 1.

#### Bit 30 ECCC: ECC correction
- Set by hardware when one ECC error has been detected and corrected (only if ECCC/ECCC2/ECCD/ECD2 are previously cleared). An interrupt is generated if ECCIE is set.
- Cleared by writing 1.

#### Bit 29 ECCD2: ECC2 detection
- **DBANK=0**
  - Set by hardware when two ECC errors have been detected on 64-bits MSB (bits 127:64). This bit is set (only if ECCC/ECCC2/ECCD/ECD2 are previously cleared). When this bit is set, a NMI is generated.
  - Cleared by writing 1.
- **DBANK=1**
  - Reserved, must be kept at reset value.

#### Bit 28 ECCC2: ECC correction
- **DBANK=0**
  - Set by hardware when one ECC error has been detected and corrected on 64-bits MSB (bits 127:64). This bit is set (only if ECCC/ECCC2/ECCD/ECD2 are previously cleared). An interrupt is generated if ECCIE is set.
  - Cleared by writing 1.
- **DBANK=1**
  - Reserved, must be kept at reset value.

Bits 27:25 Reserved, must be kept at reset value.
Bit 24 **ECCIE**: ECC correction interrupt enable
- 0: ECCC interrupt disabled
- 1: ECCC interrupt enabled.

DBANK=0
This bit enables the interrupt generation when the ECCC or ECCC2 bits in the FLASH_ECCR register are set.
DBANK=1
This bit enables the interrupt generation when the ECCC bit in the FLASH_ECCR register is set.

Bit 23 Reserved, must be kept at reset value.

Bit 22 **SYSF_ECC**: System Flash ECC fail
This bit indicates that the ECC error correction or double ECC error detection is located in the System Flash.

Bit 21 **BK_ECC**: ECC fail bank
DBANK=1
This bit indicates which bank is concerned by the ECC error correction or by the double ECC error detection.
0: bank 1
1: bank 2
DBANK=0
If SYSF_ECC is 1, it indicates which bank is concerned by the ECC error.
If SYSF_ECC is 0, reserved, must be kept cleared.

Bits 20:0 **ADDR_ECC**: ECC fail address
DBANK=0
This field indicates which address in the Flash memory is concerned by the ECC error correction or by the double ECC error detection.
DBANK=1
This field indicates which address in the bank is concerned by the ECC error correction or by the double ECC error detection.

### 3.7.8 Flash option register (FLASH_OPTR)

**Address offset**: 0x20

**Reset value**: 0xFFEF F8AA. Register bits are loaded with values from Flash memory at OBL.

**Access**: no wait state when no Flash memory operation is on going; word, half-word and byte access

158/2298   RM0432 Rev 8
Bits 31:28  Reserved, must be kept at reset value.

Bit 27  **nBOOT0**: nBOOT0 option bit
0: nBOOT0 = 0
1: nBOOT0 = 1

Bit 26  **nSWBOOT0**: Software BOOT0
0: BOOT0 taken from the option bit nBOOT0
1: BOOT0 taken from PH3/BOOT0 pin

Bit 25  **SRAM2_RST**: SRAM2 Erase when system reset
0: SRAM2 erased when a system reset occurs
1: SRAM2 is not erased when a system reset occurs

Bit 24  **SRAM2_PE**: SRAM2 parity check enable
0: SRAM2 parity check enable
1: SRAM2 parity check disable

Bit 23  **nBOOT1**: Boot configuration
Together with the BOOT0 pin, this bit selects boot mode from the Flash main memory, SRAM1 or the System memory. Refer to Section 2.6: Boot configuration.

Bit 22  **DBANK**:  
0: Single-bank mode with 128 bits data read width
1: Dual-bank mode with 64 bits data
This bit can only be written when PCROPA/B is disabled.

Bit 21  **DB1M**:  
*For STM32L4Rxxx and STM32L4Sxxx devices:* Dual-bank on 1 Mbyte Flash memory devices
0: 1 Mbyte single Flash contiguous address in Bank 1
1: 1 Mbyte dual-bank Flash with contiguous addresses
When DB1M is set, a hard fault is generated when the requested address goes over 1 Mbyte.

*For STM32L4P5xx and STM32L4Q5xx devices:* Dual-bank on 512 Kbytes Flash memory devices
0: 512 Kbytes single Flash contiguous address in bank1
1: 512 Kbytes dual-bank Flash with contiguous addresses
When DB1M is set, a hard fault is generated when the requested address goes over 512 Kbytes.

Bit 20  **BFB2**: Dual-bank boot
0: Dual-bank boot disable
1: Dual-bank boot enable

Bit 19  **WWDG_SW**: Window watchdog selection
0: Hardware window watchdog
1: Software window watchdog

Bit 18  **IWDG_STDBY**: Independent watchdog counter freeze in Standby mode
0: Independent watchdog counter is frozen in Standby mode
1: Independent watchdog counter is running in Standby mode

Bit 17  **IWDG_STOP**: Independent watchdog counter freeze in Stop mode
0: Independent watchdog counter is frozen in Stop mode
1: Independent watchdog counter is running in Stop mode
3.7.9 Flash PCROP1 Start address register (FLASH_PCROP1SR)

Address offset: 0x24

Reset value: 0xFFFXX XXXX. Register bits are loaded with values from Flash memory at OBL.

Access: no wait state when no Flash memory operation is on going; word access.

**PCROP1_START[16:0]**

**Res.**

- Bit 16 **IDWG_SW**: Independent watchdog selection
  - 0: Hardware independent watchdog
  - 1: Software independent watchdog

- Bit 15 **nRST_SHDW**: Reset generated when entering the Shutdown mode
  - 0: No reset generated when entering the Shutdown mode

- Bit 14 **nRST_STDDBY**: Reset generated when entering the Standby mode
  - 0: No reset generated when entering the Standby mode

- Bit 13 **nRST_STOP**: Reset generated when entering the Stop mode
  - 0: No reset generated when entering the Stop mode

- Bit 12 **nRST_SUSP**: Reset generated when entering the Standby mode
  - 0: No reset generated when entering the Standby mode

- Bit 11 **nRST_STOP**: Reset generated when entering the Stop mode
  - 0: No reset generated when entering the Stop mode

- Bits 10:8 **BOR_LEV**: BOR reset Level
  - These bits contain the VDD supply level threshold that activates/releases the reset.
  - 000: BOR Level 0. Reset level threshold is around 1.7 V
  - 001: BOR Level 1. Reset level threshold is around 2.0 V
  - 010: BOR Level 2. Reset level threshold is around 2.2 V
  - 011: BOR Level 3. Reset level threshold is around 2.5 V
  - 100: BOR Level 4. Reset level threshold is around 2.8 V

- Bits 7:0 **RDP**: Read protection level
  - 0xAA: Level 0, read protection not active
  - 0xCC: Level 2, chip read protection active
  - Others: Level 1, memories read protection active

**Note**: Take care about PCROP_RDP configuration in Level 1. Refer to Section: Level 1: Read protection for more details.

3.7.9 Flash PCROP1 Start address register (FLASH_PCROP1SR)
Bits 31:17 Reserved, must be kept

Bits 16:0 \textbf{PCROP1\_STRT}: PCROP area start offset
\begin{itemize}
  \item DBANK=1
  \item PCROP1\_STRT contains the first double-word of the PCROP area for bank 1.
  \item DBANK=0
  \item PCROP1\_STRT contains the first 2×double-word of the PCROP area for all memory.
\end{itemize}

3.7.10 \textbf{Flash PCROP1 End address register (FLASH\_PCROP1ER)}

Address offset: 0x28

Reset value: 0xXXXX XXXX. Register bits are loaded with values from Flash memory at OBL.

Access: no wait state when no Flash memory operation is on going; word, half-word access. PCROP\_RDP bit can be accessed with byte access.

Bit 31 \textbf{PCROP\_RDP}: PCROP area preserved when RDP level decreased
This bit is set only. It is reset after a full mass erase due to a change of RDP from Level 1 to Level 0.

0: PCROP area is not erased when the RDP level is decreased from Level 1 to Level 0.
1: PCROP area is erased when the RDP level is decreased from Level 1 to Level 0 (full mass erase).

Bits 30:17 Reserved, must be kept cleared

Bits 16:0 \textbf{PCROP1\_END}: Bank 1 PCROP area end offset
\begin{itemize}
  \item DBANK=1
  \item PCROP1\_END contains the last double-word of the bank 1 PCROP area.
  \item DBANK=0
  \item PCROP1\_END contains the last 2×double-word PCROP area for all memory.
\end{itemize}
### 3.7.11 Flash WRP1 area A address register (FLASH_WRP1AR)

Address offset: 0x2C

Reset value: 0xFFXX FFXX. Register bits are loaded with values from Flash memory at OBL.

Access: no wait state when no Flash memory operation is on going; word, half-word and byte access

Bits 31:24  Reserved, must be kept cleared

Bits 23:16 **WRP1A_END**: WRP first area “A” end offset

- DBANK=1
  - WRP1A_END contains the last page of WRP first area in bank1.
- DBANK=0
  - WRP1A_END contains the last page of WRP first area for all memory.

Bits 15:8  Reserved, must be kept cleared

Bits 7:0 **WRP1A_START**: WRP first area “A” start offset

- DBANK=1
  - WRP1A_START contains the first page of WRP first area for bank1.
- DBANK=0
  - WRP1A_START contains the first page of WRP first area for all memory.

### 3.7.12 Flash WRP2 area A address register (FLASH_WRP2AR)

Bits 31:24  Reserved, must be kept cleared

Bits 23:16 **WRP2A_END**: WRP first area “A” end offset

- DBANK=1
  - WRP2A_END contains the last page of WRP first area in bank1.
- DBANK=0
  - WRP2A_END contains the last page of WRP first area for all memory.

Bits 15:8  Reserved, must be kept cleared

Bits 7:0 **WRP2A_START**: WRP first area “A” start offset

- DBANK=1
  - WRP2A_START contains the first page of WRP first area for bank1.
- DBANK=0
  - WRP2A_START contains the first page of WRP first area for all memory.
Bits 31:24  Reserved, must be kept cleared

Bits 23:16  **WRP2A_END**: WRP first area “A” end offset  
          - **DBANK=1**: WRP2A_END contains the last page of the WRP first area for bank2.  
          - **DBANK=0**: WRP2A_END contains the last page of the WRP third area for all memory.

Bits 15:8  Reserved, must be kept cleared

Bits 7:0  **WRP2A_STRT**: WRP first area “A” start offset  
          - **DBANK=1**: WRP2A_STRT contains the first page of the WRP first area for bank2.  
          - **DBANK=0**: WRP2A_STRT contains the first page of the WRP third area for all memory.

### 3.7.13 Flash PCROP2 Start address register (FLASH_PCROP2SR)

Address offset: 0x44  
Reset value: 0xFFFF XXXX  
Access: no wait state when no Flash memory operation is on going; word access.

<td>LVEN: Low voltage enable</td>
<td>rw</td>
</tr>
</tbody>
</table>

- This bit is set and cleared by software. This bit must be used only in case of external SMPS.
  - 0: Flash low voltage disable
  - 1: Flash low voltage enabled. Before setting this bit, it is recommended to:
    - Switch the voltage scaling to range 2
    - Ensure that the minimum VDD12 is 1.08 V
    - When the external SMPS is ON, the LVEN bit can be set.

Refer to Section 2.2 on page 93 for the register boundary addresses.
4 Firewall (FW)

4.1 Introduction

The Firewall is made to protect a specific part of code or data into the Non-Volatile Memory, and/or to protect the Volatile data into the SRAM1 from the rest of the code executed outside the protected area.

4.2 Firewall main features

- The code to protect by the Firewall (Code Segment) may be located in:
  - The Flash memory map
  - The SRAM1 memory, if declared as an executable protected area during the Firewall configuration step.
- The data to protect can be located either
  - in the Flash memory (non-volatile data segment)
  - in the SRAM1 memory (volatile data segment)

The software can access these protected areas once the Firewall is opened. The Firewall can be opened or closed using a mechanism based on “call gate” (Refer to Opening the Firewall).

The start address of each segment and its respective length must be configured before enabling the Firewall (Refer to Section 4.3.5: Firewall initialization).

Each illegal access into these protected segments (if the Firewall is enabled) generates a reset which immediately kills the detected intrusion.

Any DMA access to protected segments is forbidden whatever the Firewall state (opened or closed). It is considered as an illegal access and generates a reset.
4.3 Firewall functional description

4.3.1 Firewall AMBA bus snoop

The Firewall peripheral is snooping the AMBA buses on which the memories (volatile and non-volatile) are connected. A global architecture view is illustrated in Figure 7.

Figure 7. STM32L4+ Series firewall connection schematics

4.3.2 Functional requirements

There are several requirements to guaranty the highest security level by the application code/data which needs to be protected by the Firewall and to avoid unwanted Firewall alarm (reset generation).

Debug consideration

In debug mode, if the Firewall is opened, the accesses by the debugger to the protected segments are not blocked. For this reason, the Read out level 2 protection must be active in conjunction with the Firewall implementation.

If the debug is needed, it is possible to proceed in the following way:

- A dummy code having the same API as the protected code may be developed during the development phase of the final user code. This dummy code may send back coherent answers (in terms of function and potentially timing if needed), as the protected code should do in production phase.
- In the development phase, the protected code can be given to the customer-end under NDA agreement and its software can be developed in level 0 protection. The customer-
end code needs to embed an IAP located in a write protected segment in order to allow future code updates when the production parts will be Level 2 ROP.

**Write protection**

In order to offer a maximum security level, the following points need to be respected:

- It is mandatory to keep a write protection on the part of the code enabling the Firewall. This activation code should be located outside the segments protected by the Firewall.
- The write protection is also mandatory on the code segment protected by the Firewall.
- The page including the reset vector must be write-protected.

**Interrupts management**

The code protected by the Firewall must not be interruptible. It is up to the user code to disable any interrupt source before executing the code protected by the Firewall. If this constraint is not respected, if an interrupt comes while the protected code is executed (Firewall opened), the Firewall will be closed as soon as the interrupt subroutine is executed. When the code returns back to the protected code area, a Firewall alarm will raise since the “call gate” sequence will not be applied and a reset will be generated.

Concerning the interrupt vectors and the first user page in the Flash memory:

- If the first user page (including the reset vector) is protected by the Firewall, the NVIC vector should be reprogrammed outside the protected segment.
- If the first user page is not protected by the Firewall, the interrupt vectors may be kept at this location.

There is no interrupt generated by the Firewall.

**4.3.3 Firewall segments**

The Firewall has been designed to protect three different segment areas:

**Code segment**

This segment is located into the Flash memory. It should contain the code to execute which requires the Firewall protection. The segment must be reached using the “call gate” entry sequence to open the Firewall. A system reset is generated if the “call gate” entry sequence is not respected (refer to *Opening the Firewall*) and if the Firewall is enabled using the FWDIS bit in the system configuration register. The length of the segment and the segment base address must be configured before enabling the Firewall (refer to *Section 4.3.5: Firewall initialization*).

**Non-volatile data segment**

This segment contains non-volatile data used by the protected code which must be protected by the Firewall. The access to this segment is defined into *Section 4.3.4: Segment accesses and properties*. The Firewall must be opened before accessing the data in this area. The Non-Volatile data segment should be located into the Flash memory. The segment length and the base address of the segment must be configured before enabling the Firewall (refer to *Section 4.3.5: Firewall initialization*).
Volatile data segment

Volatile data used by the protected code located into the code segment must be defined into the SRAM1 memory. The access to this segment is defined into the Section 4.3.4: Segment accesses and properties. Depending on the Volatile data segment configuration, the Firewall must be opened or not before accessing this segment area. The segment length and the base address of the segment as well as the segment options must be configured before enabling the Firewall (refer to Section 4.3.5: Firewall initialization).

The Volatile data segment can also be defined as executable (for the code execution) or shared using two bit of the Firewall configuration register (bit VDS for the volatile data sharing option and bit VDE for the volatile data execution capability). For more details, refer to Table 21.

4.3.4 Segment accesses and properties

All DMA accesses to the protected segments are forbidden, whatever the Firewall state, and generate a system reset.

Segment access depending on the Firewall state

Each of the three segments has specific properties which are presented in Table 21.

Table 21. Segment accesses according to the Firewall state

<table>
<thead>
<tr>
<th>Segment</th>
<th>Firewall opened access allowed</th>
<th>Firewall closed access allowed</th>
<th>Firewall disabled access allowed</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td></td>
<td></td>
<td>to open the Firewall at first.</td>
<td></td>
</tr>
</tbody>
</table>
The Volatile data segment is a bit different from the two others. The segment can be:

- **Shared (VDS bit in the register)**
  
  It means that the area and the data located into this segment can be shared between the protected code and the user code executed in a non-protected area. The access is allowed whether the Firewall is opened or closed or disabled. The VDS bit gets priority over the VDE bit, this last bit value being ignored in such a case. It means that the Volatile data segment can execute parts of code located there without any need to open the Firewall before executing the code.

- **Execute**
  
  The VDE bit is considered as soon as the VDS bit = 0 in the FW_CR register. If the VDS bit = 1, refer to the description above on the Volatile data segment sharing. If VDS = 0 and VDE = 1, the Volatile data segment is executable. To avoid a system reset generation from the Firewall, the “call gate” sequence should be applied on the Volatile data segment to open the Firewall as an entry point for the code execution.

### Segments properties

Each segment has a specific length register to define the segment size to be protected by the Firewall: CSL register for the Code segment length register, NVDSL for the Non-volatile data segment length register, and VDSL register for the Volatile data segment length register. Granularity and area ranges for each of the segments are presented in Table 22.

<table>
<thead>
<tr>
<th>Segment</th>
<th>Granularity</th>
<th>Area range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Code segment</td>
<td>256 byte</td>
<td>2048 Kbytes - 256 bytes</td>
</tr>
<tr>
<td>Non-volatile data segment</td>
<td>256 byte</td>
<td>2048 Kbytes - 256 bytes</td>
</tr>
<tr>
<td>Volatile data segment</td>
<td>64 byte</td>
<td>192 Kbyte - 64 bytes</td>
</tr>
</tbody>
</table>

### 4.3.5 Firewall initialization

The initialization phase should take place at the beginning of the user code execution (refer to the *Write protection*).

The initialization phase consists of setting up the addresses and the lengths of each segment which needs to be protected by the Firewall. It must be done before enabling the Firewall, because the enabling bit can be written once. Thus, when the Firewall is enabled, it cannot be disabled anymore until the next system reset.

Once the Firewall is enabled, the accesses to the address and length segments are no longer possible. All write attempts are discarded.

A segment defined with a length equal to 0 is not considered as protected by the Firewall. As a consequence, there is no reset generation from the Firewall when an access to the base address of this segment is performed.

After a reset, the Firewall is disabled by default (FWDIS bit in the SYSCFG register is set). It has to be cleared to enable the Firewall feature.
Below is the initialization procedure to follow:

1. Configure the RCC to enable the clock to the Firewall module
2. Configure the RCC to enable the clock of the system configuration registers
3. Set the base address and length of each segment (CSSA, CSL, NVDSSA, NVDSL, VDSSA, VDSL registers)
4. Set the configuration register of the Firewall (FW_CR register)
5. Enable the Firewall clearing the FWDIS bit in the system configuration register.

The Firewall configuration register (FW_CR register) is the only one which can be managed in a dynamic way even if the Firewall is enabled:

- when the Non-Volatile data segment is undefined (meaning the NVDSL register is equal to 0), the accesses to this register are possible whatever the Firewall state (opened or closed).
- when the Non-Volatile data segment is defined (meaning the NVDSL register is different from 0), the accesses to this register are only possible when the Firewall is opened.

### 4.3.6 Firewall states

The Firewall has three different states as shown in Figure 8:

- Disabled: The FWDIS bit is set by default after the reset. The Firewall is not active.
- Closed: The Firewall protects the accesses to the three segments (Code, Non-volatile data, and Volatile data segments).
- Opened: The Firewall allows access to the protected segments as defined in Section 4.3.4: Segment accesses and properties.

![Figure 8. Firewall functional states](MS32390V4)
Opening the Firewall

As soon as the Firewall is enabled, it is closed. It means that most of the accesses to the protected segments are forbidden (refer to Section 4.3.4: Segment accesses and properties). In order to open the Firewall to interact with the protected segments, it is mandatory to apply the “call gate” sequence described hereafter.

“call gate” sequence

The “call gate” is composed of 3 words located on the first three 32-bit addresses of the base address of the code segment and of the Volatile data segment if it is declared as not shared (VDS = 0) and executable (VDE = 1).

- 1st word: Dummy 32-bit words always closed in order to protect the “call gate” opening from an access due to a prefetch buffer.
- 2nd and 3rd words: 2 specific 32-bit words called “call gate” and always opened.

To open the Firewall, the code currently executed must jump to the 2nd word of the “call gate” and execute the code from this point. The 2nd word and 3rd word execution must not be interrupted by any intermediate instruction fetch; otherwise, the Firewall is not considered open and comes back to a close state. Then, executing the 3rd word after receiving the intermediate instruction fetch would generate a system reset as a consequence.

As soon as the Firewall is opened, the protected segments can be accessed as described in Section 4.3.4: Segment accesses and properties.

Closing the Firewall

The Firewall is closed immediately after it is enabled (clearing the FWDIS bit in the system configuration register).

To close the Firewall, the protected code must:
- Write the correct value in the Firewall Pre Arm Flag into the FW_CR register.
- Jump to any executable location outside the Firewall segments.

If the Firewall Pre Arm Flag is not set when the protected code jumps to a non protected segment, a reset is generated. This control bit is an additional protection to avoid an undesired attempt to close the Firewall with the private information not yet cleaned (see the note below).

For security reasons, following the application for which the Firewall is used, it is advised to clean all private information from CPU registers and hardware cells.
### 4.4 Firewall registers

#### 4.4.1 Code segment start address (FW_CSSA)

Address offset: 0x00  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31:24</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits 23:8</td>
<td><strong>ADD[23:8]</strong>: code segment start address</td>
</tr>
<tr>
<td></td>
<td>The LSB bits of the start address (bit 7:0) are reserved and forced to 0 in order to allow a 256-byte granularity.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong>: These bits can be written only before enabling the Firewall. Refer to Section 4.3.5: Firewall initialization.</td>
</tr>
<tr>
<td>Bits 7:0</td>
<td>Reserved, must be kept at the reset value.</td>
</tr>
</tbody>
</table>

#### 4.4.2 Code segment length (FW_CSL)

Address offset: 0x04  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31:22</th>
<th>Reserved, must be kept at the reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits 21:8</td>
<td><strong>LENG[21:8]</strong>: code segment length</td>
</tr>
<tr>
<td></td>
<td><strong>LENG[21:8]</strong> selects the size of the code segment expressed in bytes but is a multiple of 256 bytes.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong>: If LENG[21:8] = 0 after enabling the Firewall, this segment is not defined, thus not protected by the Firewall. These bits can only be written before enabling the Firewall. Refer to Section 4.3.5: Firewall initialization.</td>
</tr>
<tr>
<td>Bits 7:0</td>
<td>Reserved, must be kept at the reset value.</td>
</tr>
</tbody>
</table>
4.4.3 Non-volatile data segment start address (FW_NVDSSA)

Address offset: 0x08
Reset value: 0x0000 0000

Bits 31:24 Reserved, must be kept at the reset value.

Bits 23:8 **ADD[23:8]**: Non-volatile data segment start address

The LSB bits of the start address (bit 7:0) are reserved and forced to 0 in order to allow a 256-byte granularity.

*Note: These bits can only be written before enabling the Firewall. Refer to Section 4.3.5: Firewall initialization.*

Bits 7:0 Reserved, must be kept at the reset value.

4.4.4 Non-volatile data segment length (FW_NVDSL)

Address offset: 0x0C
Reset value: 0x0000 0000

Bits 31:22 Reserved, must be kept at the reset value.

Bits 21:8 **LENG[21:8]**: Non-volatile data segment length

**LENG[21:8]** selects the size of the Non-volatile data segment expressed in bytes but is a multiple of 256 bytes.

The segment area is defined from {ADD[23:8],0x00} to {ADD[23:8]+LENG[21:8], 0x00} - 0x01

*Note: If **LENG[21:8]** = 0 after enabling the Firewall, this segment is not defined, thus not protected by the Firewall.*

*These bits can only be written before enabling the Firewall. Refer to Section 4.3.5: Firewall initialization.*

Bits 7:0 Reserved, must be kept at the reset value.
4.4.5 Volatile data segment start address (FW_VDSSA)

Address offset: 0x10
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>
<th>23</th>
<th>22</th>
<th>21</th>
<th>20</th>
<th>19</th>
<th>18</th>
<th>17</th>
<th>16</th>
</tr>
</thead>
</table>

Bits 31:18 Reserved, must be kept at the reset value.

Bit 17 ADD[17]: Volatile data segment start address

Bits 16:6 ADD[16:6]: Volatile data segment start address

The LSB bits of the start address (bit 5:0) are reserved and forced to 0 in order to allow a 64-byte granularity.

Note: These bits can only be written before enabling the Firewall. Refer to Section 4.3.5: Firewall initialization

Bits 5:0 Reserved, must be kept at the reset value.

4.4.6 Volatile data segment length (FW_VDSL)

Address offset: 0x14
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>
<th>23</th>
<th>22</th>
<th>21</th>
<th>20</th>
<th>19</th>
<th>18</th>
<th>17</th>
<th>16</th>
</tr>
</thead>
</table>

Bits 31:18 Reserved, must be kept at the reset value.

Bits 17:16 LENG[17:16]: Volatile data segment length

Note: These bits can only be written before enabling the Firewall. Refer to Section 4.3.5: Firewall initialization

Bits 5:0 Reserved, must be kept at the reset value.
Bits 31:18  Reserved, must be kept at the reset value.

Bit 17  **LENG[17]**: volatile data segment length

Bits 16:6  **LENG[16:6]**: volatile data segment length

LENG[16:6] selects the size of the volatile data segment expressed in bytes but is a multiple of 64 bytes.

The segment area is defined from \( \{\text{ADD}[16:6],0x00\} \) to \( \{\text{ADD}[16:6]+\text{LENG}[16:6], 0x00\} - 0x01 \)

*Note:* If **LENG[17:6]** = 0 after enabling the Firewall, this segment is not defined, thus not protected by the Firewall.

*These bits can only be written before enabling the Firewall.* Refer to Section 4.3.5: Firewall initialization.

Bits 5:0  Reserved, must be kept at the reset value.

### 4.4.7 Configuration register (FW_CR)

**Address offset:** 0x20

**Reset value:** 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>
<th>23</th>
<th>22</th>
<th>21</th>
<th>20</th>
<th>19</th>
<th>18</th>
<th>17</th>
<th>16</th>
</tr>
</thead>
<tbody>
<tr>
<td>15</td>
<td>14</td>
<td>13</td>
<td>12</td>
<td>11</td>
<td>10</td>
<td>9</td>
<td>8</td>
<td>7</td>
<td>6</td>
<td>5</td>
<td>4</td>
<td>3</td>
<td>2</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>
<th>23</th>
<th>22</th>
<th>21</th>
<th>20</th>
<th>19</th>
<th>18</th>
<th>17</th>
<th>16</th>
</tr>
</thead>
<tbody>
<tr>
<td>VDE</td>
<td>VDS</td>
<td>FPA</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:3  Reserved, must be kept at the reset value.
This register is protected in the same way as the Non-volatile data segment (refer to Section 4.3.5: Firewall initialization).

Bit 2 **VDE:** Volatile data execution
- 0: Volatile data segment cannot be executed if VDS = 0
- 1: Volatile data segment is declared executable whatever VDS bit value

When VDS = 1, this bit has no meaning. The Volatile data segment can be executed whatever the VDE bit value.

If VDS = 1, the code can be executed whatever the Firewall state (opened or closed)
If VDS = 0, the code can only be executed if the Firewall is opened or applying the “call gate” entry sequence if the Firewall is closed.
Refer to **Segment access depending on the Firewall state.**

Bit 1 **VDS:** Volatile data shared
- 0: Volatile data segment is not shared and cannot be hit by a non protected executable code when the Firewall is closed. If it is accessed in such a condition, a system reset will be generated by the Firewall.
- 1: Volatile data segment is shared with non protected application code. It can be accessed whatever the Firewall state (opened or closed).
Refer to **Segment access depending on the Firewall state.**

Bit 0 **FPA:** Firewall prearm
- 0: any code executed outside the protected segment when the Firewall is opened will generate a system reset.
- 1: any code executed outside the protected segment will close the Firewall.
Refer to **Closing the Firewall.**

This register is protected in the same way as the Non-volatile data segment (refer to Section 4.3.5: Firewall initialization).
### 4.4.8 Firewall register map

The table below provides the Firewall register map and reset values.

**Table 23. Firewall register map and reset values**

| Offset | Register   | 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|--------|------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| 0x0    | FW_CSSA    | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
|        | Reset Value| 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| 0x4    | FW_CSL     | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
|        |            | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| 0x8    | FW_NVDSA   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
|        | Reset Value| 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| 0xC    | FW_NVDSL   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
|        |            | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| 0x10   | FW_VDSSA   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
|        | Reset Value| 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| 0x14   | FW_VDSL    | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
|        |            | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

Refer to *Section 2.2 on page 93* for the register boundary addresses.
5 Power control (PWR)

5.1 Power supplies

The STM32L4+ Series devices require a 1.71 V to 3.6 V operating supply voltage (VDD). Several peripherals are supplied through independent power domains: VDDA, VDDIO2, VDDUSB, VDDDSI. Those supplies must not be provided without a valid operating supply on the VDD pin.

- VDD = 1.71 V to 3.6 V
  VDD is the external power supply for the I/Os, the internal regulator and the system analog such as reset, power management and internal clocks. It is provided externally through VDD pins.

- VDDA = 1.62 V (ADCs/COMPs) / 1.8 V (DACs/OPAMPs) / 2.4 V (VREFBUF) to 3.6 V
  VDDA is the external analog power supply for A/D converters, D/A converters, voltage reference buffer, operational amplifiers and comparators. The VDDA voltage level is independent from the VDD voltage. VDDA should be preferably connected to VDD when these peripherals are not used.

- VDD12 = 1.05 to 1.32 V
  VDD12 is the external power supply bypassing the internal regulator when connected to an external SMPS. It is provided externally through VDD12 pins and only available on packages with the external SMPS supply option. VDD12 does not require any external decoupling capacitance and cannot support any external load.

- VDDUSB = 3.0 V to 3.6 V
  VDDUSB is the external independent power supply for USB transceivers. The VDDUSB voltage level is independent from the VDD voltage. VDDUSB should be preferably connected to VDD when the USB is not used. The VDDUSB power supply may not be present as a dedicated pin, but to be internally bonded to VDD. For such devices, VDD has to respect the VDDUSB supply range when the USB is used.

- VDDIO2 = 1.08 V to 3.6 V
  VDDIO2 is the external power supply for 14 I/Os (Port G[15:2]). The VDDIO2 voltage level is independent from the VDD voltage and should preferably be connected to VDD when PG[15:2] are not used.

- VDDDSI is an independent DSI power supply dedicated to the DSI regulator and the MIPI DPHY. This supply must be connected to the global VDD.

- VCAPDSI pin is the output of the DSI regulator (1.2 V) which must be connected externally to VDD12DSI.

- VDD12DSI pin is used to supply the MIPI D-PHY, and to supply the clock and data lanes pins. An external capacitor of 2.2 uF must be connected on VDD12DSI pin.

- VBAT = 1.55 V to 3.6 V
  VBAT is the power supply for RTC, external clock 32 kHz oscillator and backup registers (through power switch) when VDD is not present. VBAT is internally bonded to VDD for small packages without dedicated pin.

- VREF-, VREF+
  VREF+ is the input reference voltage for ADCs and DACs. It is also the output of the internal voltage reference buffer when enabled.
When $V_{DDA} < 2$ V, $V_{REF+}$ must be equal to $V_{DDA}$.
When $V_{DDA} \geq 2$ V, $V_{REF+}$ must be between 2 V and $V_{DDA}$.
$V_{REF+}$ can be grounded when ADC and DAC are not active.
The internal voltage reference buffer supports two output voltages, which are
configured with VRS bit in the VREFBUF_CSR register:
- $V_{REF+}$ around 2.048 V. This requires $V_{DDA}$ equal to or higher than 2.4 V.
- $V_{REF+}$ around 2.5 V. This requires $V_{DDA}$ equal to or higher than 2.8 V.
$V_{REF-}$ and $V_{REF+}$ pins are not available on all packages. When not available on the
package, they are bonded to $V_{SSA}$ and $V_{DDA}$, respectively.
When the $V_{REF+}$ is double-bonded with $V_{DDA}$ in a package, the internal voltage
reference buffer is not available and must be kept disable (refer to related device
datasheet for packages pinout description).
$V_{REF-}$ must always be equal to $V_{SSA}$.

An embedded linear voltage regulator is used to supply the internal digital power $V_{CORE}$.
$V_{CORE}$ is the power supply for digital peripherals and memories.

Figure 9. STM32L4P5xx/Q5xx, STM32L4S5xx/R5xx and STM32L4S7xx/L4R7xx
power supply overview
5.1.1 Independent analog peripherals supply

To improve ADC and DAC conversion accuracy and to extend the supply flexibility, the analog peripherals have an independent power supply which can be separately filtered and shielded from noise on the PCB.

- The analog peripherals voltage supply input is available on a separate VDDA pin.
- An isolated supply ground connection is provided on VSSA pin.

The VDDA supply voltage can be different from VDD. The presence of VDDA must be checked before enabling any of the analog peripherals supplied by VDDA (A/D converter, D/A converter, comparators, operational amplifiers, voltage reference buffer).

The VDDA supply can be monitored by the Peripheral Voltage Monitoring, and compared with two thresholds (1.65 V for PVM3 or 2.2 V for PVM4), refer to Section 5.2.3: Peripheral Voltage Monitoring (PVM) for more details.

When a single supply is used, VDDA can be externally connected to VDD through the external filtering circuit in order to ensure a noise-free VDDA reference voltage.
ADC and DAC reference voltage

To ensure a better accuracy on low-voltage inputs and outputs, the user can connect to 
VREF+, a separate reference voltage lower than VDDA. VREF+ is the highest voltage, 
represented by the full scale value, for an analog input (ADC) or output (DAC) signal. 
VREF+ can be provided either by an external reference of by an internal buffered voltage 
reference (VREFBUF).

The internal voltage reference is enabled by setting the ENVR bit in the Section 23.3.1: 
VREFBUF control and status register (VREFBUF_CSR). The voltage reference is set to 
2.5 V when the VRS bit is set and to 2.048 V when the VRS bit is cleared. The internal 
voltage reference can also provide the voltage to external components through VREF+ pin. 
Refer to the device datasheet and to Section 23: Voltage reference buffer (VREFBUF) for 
further information.

5.1.2 Independent I/O supply rail

Some I/Os from Port G (PG[15:2]) are supplied from a separate supply rail. The power 
supply for this rail can range from 1.08 V to 3.6 V and is provided externally through the 
VDDIO2 pin. The VDDIO2 voltage level is completely independent from VDD or VDDA. The 
VDDIO2 pin is available only for some packages. Refer to the pinout diagrams or tables in the 
related device datasheet(s) for I/O list(s).

After reset, the I/Os supplied by VDDIO2 are logically and electrically isolated and therefore 
are not available. The isolation must be removed before using any I/O from PG[15:2], by 
setting the IOSV bit in the PWR_CR2 register, once the VDDIO2 supply is present.

The VDDIO2 supply is monitored by the Peripheral Voltage Monitoring (PVM2) and compared 
with the internal reference voltage (3/4 VREFINT, around 0.9V), refer to Section 5.2.3: 
Peripheral Voltage Monitoring (PVM) for more details.

5.1.3 Independent USB transceivers supply

The USB transceivers are supplied from a separate VDDUSB power supply pin. VDDUSB 
range is from 3.0 V to 3.6 V and is completely independent from VDD or VDDA. 
After reset, the USB features supplied by VDDUSB are logically and electrically isolated and 
therefore are not available. The isolation must be removed before using the USB OTG 
peripheral, by setting the USV bit in the PWR_CR2 register, once the VDDUSB supply is 
present.

The VDDUSB supply is monitored by the Peripheral Voltage Monitoring (PVM1) and 
compared with the internal reference voltage (VREFINT, around 1.2 V), refer to Section 5.2.3: 
Peripheral Voltage Monitoring (PVM) for more details.

5.1.4 Independent DSI supply

The DSI (Display Serial Interface) sub-system uses several power supply pins which are 
independent from the other supply pins:

- VDDDSI is an independent DSI power supply dedicated for DSI Regulator and MIPI 
  D-PHY. This supply must be connected to global VDD.
- VCAPDSI pin is the output of DSI Regulator (1.2V) which must be connected externally 
  to VDD12DSI.
- VDD12DSI pin is used to supply the MIPI D-PHY, and to supply clock and data lanes
pins. An external capacitor of 2.2 uF must be connected on VDD12DSI pin.
• VSSDSI pin is an isolated supply ground used for DSI sub-system.

If DSI functionality is not used at all, then:
• VDDDSI pin must be connected to global VDD.
• VCAPDSI pin must be connected externally to VDD12DSI but the external capacitor is no more needed. If the VDD12DSI is not available on a package, the VCAPDSI to be kept floating.
• VSSDSI pin must be grounded.

Note: VDDDSI and VDD12DSI pins are not available on all packages. When not available, they are bonded to VDD and VCAPDSI, respectively.

5.1.5 Battery backup domain

To retain the content of the Backup registers and supply the RTC function when V_DD is turned off, the VBAT pin can be connected to an optional backup voltage supplied by a battery or by another source.

The VBAT pin powers the RTC unit, the LSE oscillator and the PC13 to PC15 I/Os, allowing the RTC to operate even when the main power supply is turned off. The switch to the V_BAT supply is controlled by the power-down reset embedded in the Reset block.

Warning: During t_RSTTEMPO (temporization at V_DD startup) or after a PDR has been detected, the power switch between V_BAT and V_DD remains connected to V_BAT. During the startup phase, if V_DD is established in less than t_RSTTEMPO (refer to the datasheet for the value of t_RSTTEMPO) and V_DD > V_BAT + 0.6 V, a current may be injected into V_BAT through an internal diode connected between V_DD and the power switch (V_BAT). If the power supply/battery connected to the VBAT pin cannot support this current injection, it is strongly recommended to connect an external low-drop diode between this power supply and the VBAT pin.

If no external battery is used in the application, it is recommended to connect V_BAT externally to V_DD with a 100 nF external ceramic decoupling capacitor.

When the backup domain is supplied by V_DD (analog switch connected to V_DD), the following pins are available:
• PC13, PC14 and PC15, which can be used as GPIO pins
• PC13, PC14 and PC15, which can be configured by RTC or LSE (refer to Section 46.3: RTC functional description on page 1546)
• PA0/RTC_TAMP2 and PE6/RTC_TAMP3 when they are configured by the RTC as tamper pins

Note: Due to the fact that the analog switch can transfer only a limited amount of current (3 mA), the use of GPIO PC13 to PC15 in output mode is restricted: the speed has to be limited to 2 MHz with a maximum load of 30 pF and these I/Os must not be used as a current source (e.g. to drive a LED).
When the backup domain is supplied by V_BAT (analog switch connected to V_BAT because V_DD is not present), the following functions are available:

- PC13, PC14 and PC15 can be controlled only by RTC or LSE (refer to Section 46.3: RTC functional description)
- PA0/RTC_TAMP2 and PE6/RTC_TAMP3 when they are configured by the RTC as tamper pins

**Backup domain access**

After a system reset, the backup domain (RTC registers and backup registers) is protected against possible unwanted write accesses. To enable access to the backup domain, proceed as follows:

1. Enable the power interface clock by setting the PWREN bits in the APB1 peripheral clock enable register 1 (RCC_APB1ENR1)
2. Set the DBP bit in the Power control register 1 (PWR_CR1) to enable access to the backup domain
3. Select the RTC clock source in the Backup domain control register (RCC_BDCR).

**VBAT battery charging**

When VDD is present, it is possible to charge the external battery on V_BAT through an internal resistance.

The V_BAT charging is done either through a 5 kOhm resistor or through a 1.5 kOhm resistor depending on the VBRS bit value in the PWR_CR4 register.

The battery charging is enabled by setting VBE bit in the PWR_CR4 register. It is automatically disabled in VBAT mode.

### 5.1.6 Voltage regulator

Two embedded linear voltage regulators supply all the digital circuitries, except for the Standby circuitry and the backup domain. The main regulator output voltage (V_CORE) can be programmed by software to two different power ranges (Range 1 and Range 2) in order to optimize the consumption depending on the system’s maximum operating frequency (refer to Section 6.2.9: Clock source frequency versus voltage scaling and to Section 3.3.3: Read access latency).

The voltage regulators are always enabled after a reset. Depending on the application modes, the V_CORE supply is provided either by the main regulator (MR) or by the low-power regulator (LPR):

- In Run, Sleep and Stop 0 modes, both regulators are enabled and the main regulator (MR) supplies full power to the V_CORE domain (core, memories and digital peripherals).
- In Low-power run and Low-power sleep modes, the main regulator is off and the low-power regulator (LPR) supplies low-power to the V_CORE domain, preserving the contents of the registers, SRAM1, SRAM2 and SRAM3.
- In Stop 1 and Stop 2 modes, the main regulator is off and the low-power regulator (LPR) supplies low-power to the V_CORE domain, preserving the contents of the registers, SRAM1, SRAM2 and SRAM3.
- In Standby mode, the SRAM2 content can be fully or partially (see note below)
preserved (depending on RRS[1:0] bits in the PWR_CR3 register). The main regulator (MR) is off and the low-power regulator (LPR) provides the supply only to SRAM2. The core, digital peripherals (except Standby circuitry and backup domain) and SRAM1 are powered off.

**Note:** For STM32L4RxXX and STM32L4Sxxx devices it is only possible to preserve the full SRAM2 content depending on RRS bit in the PWR_CR3 register. For STM32L4P5xx and STM32L4Q5xx devices it is possible to preserve the full (64 Kbytes) or partial (4 Kbytes) SRAM2 content depending on RRS[1:0] bits in the PWR_CR3 register.

- In Standby mode, both regulators are powered off. The contents of the registers, SRAM1, SRAM2 and SRAM3 is lost except for the Standby circuitry and the backup domain.
- In Shutdown mode, both regulators are powered off. When exiting from Shutdown mode, a power-on reset is generated. Consequently, the contents of the registers, SRAM1, SRAM2 and SRAM3 is lost, except for the backup domain.

### 5.1.7 VDD12 domain

VDD12 is intended to be connected with external SMPS (switched-mode power supply) to generate the $V_{\text{CORE}}$ logic supply in Run, Sleep and Stop 0 modes only.

VDD12 pins correspond to the internal $V_{\text{CORE}}$ powering the digital part of Core, RAMs, FLASH and peripherals. This significantly improves the power consumption with a gain from 50% or more depending of the SMPS performances.

The main benefit occurs in Run and Sleep modes whereas in Stop 0 mode, the gain is less significant.

The figure below shows a schematic to understand how the internal regulator stops supplying $V_{\text{CORE}}$ when an external voltage VDD12 is provided.

As VDD12 shares the same pin as output of the internal regulator, applying a slightly higher voltage (typically +50 mV) on the VDD12 blocks, the PMOS and the regulator consumption is negligible.

**Figure 11. Internal main regulator overview**

![Figure 11. Internal main regulator overview](image)

A switch, controlled by the chosen GPIO, is inserted between the SMPS output and VDD12.
There are two possible states:

- **Connected:** Switch is closed so SMPS powers VDD12
- **Disconnected:** Switch is open and VDD12 is disconnected from SMPS output

Proper software management through GPIOs to enable/disable SMPS and to connect/disconnect SMPS through the switch, is required to conform with the rules described below. See also Section 5.1.8: Dynamic voltage scaling management.

It is mandatory to respect the following rules to avoid any damage or instability on either digital parts or internal regulators:

- **In Run, Sleep and Stop 0 modes, VDD12 can be connected and should respect**
  - $V_{DD12} < 1.32 \text{ V}$
  - $V_{DD12} \geq V_{CORE} + 50 \text{ mV}$ giving for main regulator
    - Range 1 boost mode, $V_{CORE} = 1.28 \text{ V}$ so $V_{DD12}$ should be greater than $1.33 \text{ V}$, but this cannot match previous rule $V_{DD12} < 1.32 \text{ V}$, so it is not a functional use case with an external SMPS.
    - Range 1 normal mode, $V_{CORE} = 1.2 \text{ V}$ so $V_{DD12}$ should be greater than $1.25 \text{ V}$.
    - Range 2, $V_{CORE} = 1.0 \text{ V}$ so $V_{DD12}$ should be greater than $1.05 \text{ V}$
  - $V_{DD12} \geq 1.08 \text{ V}$ in Range 2 when $80 \text{ MHz} \geq \text{SYSCLK}$ frequency $\geq 26 \text{ MHz}$
  - $V_{DD12} \geq 1.14 \text{ V}$ in Range 2 when $\text{SYSCLK}$ frequency $> 80 \text{ MHz}$

- **In all other modes, such as LPRun, LPSleep, Stop 1, Stop 2, Standby and Shutdown modes, VDD12 must be disconnected from SMPS output. This means that the pin must be connected to an high impedance output:**
  - $V_{DD12}$ connected to HiZ (voltage is provided by internal regulators)

- **Transitions of VDD12 from connected to disconnected is only allowed when SYSCLK frequency $\leq 26 \text{ MHz}$ to avoid big voltage drop on main regulator side.**

**Note:** In case of asynchronous reset while having the $V_{DD12} \leq 1.25 \text{ V}$, $V_{DD12}$ should switch to HiZ in less than regulator switching time from Range 2 to Range 1 (~1 us).

**Note:** On STM32L4P5xx and STM32L4Q5xx devices, $V_{DD12}$ Range 2 is extended down to $1.00 \text{ V}$ for better efficiency, thus following formula applies when bit EXT_SMPS_ON in the Power control register 4 (PWR_CR4) is set:
- Range 2, $V_{CORE} = 0.95 \text{ V}$ so $V_{DD12}$ should be greater than $1.00 \text{ V}$

**Note:** For more details on VDD12 management, refer to AN4978 “Design recommendations for STM32L4xxxx with external SMPS, for ultra-low-power applications with high performance”.

### 5.1.8 Dynamic voltage scaling management

The dynamic voltage scaling is a power management technique which consists in increasing or decreasing the voltage used for the digital peripherals ($V_{CORE}$), according to the application performance and power consumption needs.

Dynamic voltage scaling to increase $V_{CORE}$ is known as overvoltage. It allows to improve the device performance.

Dynamic voltage scaling to decrease $V_{CORE}$ is known as undervoltage. It is performed to save power, particularly in laptop and other mobile devices where the energy comes from a battery and is thus limited.

- Range 1: High-performance range.
In Range1, the main regulator operates in two modes following the R1MODE bit in the PWR_CR5 register:

- **Main regulator Range 1 normal mode:** provides a typical output voltage at 1.2 V. It is used when the system clock frequency is up to 80 MHz. The Flash access time for read access is minimum, write and erase operations are possible.
- **Main regulator Range 1 boost mode:** provides a typical output voltage at 1.28 V. It is used when the system clock frequency is up to 120 MHz. The Flash access time for read access is minimum, write and erase operations are possible. To optimize the power consumption it is recommended to select the range1 boost mode when the system clock frequency is greater than 80 MHz. See Table 24.

**Table 24. Range 1 boost mode configuration**

<table>
<thead>
<tr>
<th>System frequency</th>
<th>26 MHz &lt; SYSCLK ≤ 80 MHz</th>
<th>80 MHz &lt; SYSCLK ≤ 120 MHz</th>
</tr>
</thead>
<tbody>
<tr>
<td>R1MODE bit configuration</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

- **Range 2:** Low-power range.

The main regulator provides a typical output voltage at 1.0 V. The system clock frequency can be up to 26 MHz. The Flash access time for a read access is increased as compared to Range 1; write and erase operations are not possible.

Voltage scaling is selected through the VOS bit in the PWR.CR1 register.

The sequence to go from Range 1 (Normal/Boost) to Range 2 is:

1. In case of switching from Range 1 boost mode to Range 2, the system clock must be divided by 2 using the AHB prescaler before switching to a lower system frequency for at least 1us and then reconfigure the AHB prescaler.
2. Reduce the system frequency to a value lower than 26 MHz
3. Adjust number of wait states according to new frequency target in Range 2 (LATENCY bits in the FLASH_ACR).
4. Program the VOS bits to “10” in the PWR.CR1 register.
The sequence to go from Range 2 to Range 1 (normal/boost mode) is:

1. Program the VOS bits to “01” in the PWR_CR1 register.
2. Wait until the VOSF flag is cleared in the PWR_SR2 register.
3. Adjust number of wait states according new frequency target in Range 1 (LATENCY bits in the FLASH_ACR).
4. Increase the system frequency by following below procedure:
   - If the system frequency is 26 MHz < SYSCLK ≤ 80 MHz:
     - Select the Range 1 normal mode by setting R1MODE bit in the PWR_CR5 register.
     - Configure and switch to PLL for a new system frequency.
   - If the system frequency is SYSCLK > 80 MHz:
     - The system clock must be divided by 2 using the AHB prescaler before switching to a higher system frequency.
     - Select the Range 1 boost mode by clearing the R1MODE bit is in the PWR_CR5 register,
     - Configure and switch to PLL for a new system frequency.
     - Wait for at least 1us and then reconfigure the AHB prescaler to get the needed HCLK clock frequency.

The sequence to switch from Range1 normal mode to Range1 boost mode is:

1. The system clock must be divided by 2 using the AHB prescaler before switching to a higher system frequency.
2. Clear the R1MODE bit is in the PWR_CR5 register,
3. Adjust the number of wait states according to the new frequency target in range1 boost mode
4. Configure and switch to new system frequency.
5. Wait for at least 1 1us and then reconfigure the AHB prescaler to get the needed HCLK clock frequency.

The sequence to switch from Range1 boost mode to Range1 normal mode is:

1. Set the R1MODE bit is in the PWR_CR5 register.
2. Adjust the number of wait states according new frequency target in Range1 default mode
3. Configure and switch to new system frequency.

When supplying VDD12 with an external SMPS, three states can be configured:

- **SMPS Range 1**: main regulator is in normal Range 1, $V_{CORE}$ is supplied by external SMPS and higher than 1.25 V. SYSCLK frequency can be up to 120 MHz.
- **SMPS Range 2 high**: main regulator is in Range 2, $V_{CORE}$ is supplied by external SMPS and higher than
  - 1.08 V when SYSCLK frequency ≤ 80 MHz
  - 1.14 V when SYSCLK frequency > 80MHz
- **SMPS Range 2 low**: main regulator is in Range 2, $V_{CORE}$ is supplied by external SMPS and higher than 1.05 V. Max SYSCLK frequency is 26 MHz without Flash write/erase operations.
In order to match the upper rules described in Section 5.1.7: VDD12 domain, the transition sequences can only be one of the following:

- **Range 1 to SMPS Range 1:**
  1. Start SMPS converter (if not always enabled by HW).
  2. Check that SMPS converter output is at the correct level, like $1.25 \text{ V} \leq \text{VDD12} < 1.32 \text{ V}$.
  3. Connect VDD12 to external SMPS converter through the switch.

- **Range 2 to SMPS Range 2 low and high:**
  1. Start SMPS (if not always enabled by HW).
  2. Check that SMPS output is at the correct level like $1.05 \text{ V} \leq \text{VDD12} < 1.32 \text{ V}$.
  3. Connect VDD12 to external SMPS converter through the switch.
  
    - If $1.08 \text{ V} \leq \text{VDD12}$ (like *SMPS Range 2 high*), then the following steps can be applied:
      1. Set register FLASH_CFG bit LVEN to 1.
      2. Adjust the number of wait states in the FLASH_ACR (up to max frequency of Range 1 refer to Section 3.3.3: Read access latency).
      3. Increase the system frequency up to the maximum allowed value for voltage Range 1 (like 80 MHz when $1.08 \text{ V} < \text{VDD12} < 1.14 \text{ V}$ or 120 MHz when $\text{VDD12} > 1.14 \text{ V}$).

- **SMPS Range 1 to Range 1 or SMPS Range 2 low and high to Range 2:**
  1. If in Range 1, reduce the system frequency to a value lower or equal to 26 MHz.
  2. Adjust number of wait states according new frequency target corresponding to voltage range (LATENCY bits in the FLASH_ACR).
  3. Set register FLASH_CFG bit LVEN to 0.
  4. Disconnect VDD12 by opening the switch.
  5. Stop SMPS (if required and not kept always enabled).

## 5.2 Power supply supervisor

### 5.2.1 Power-on reset (POR) / power-down reset (PDR) / brown-out reset (BOR)

The device has an integrated power-on reset (POR) / power-down reset (PDR), coupled with a brown-out reset (BOR) circuitry. The BOR is active in all power modes except Shutdown mode, and cannot be disabled.

Five BOR thresholds can be selected through option bytes.

During power-on, the BOR keeps the device under reset until the supply voltage $V_{DD}$ reaches the specified $V_{BORX}$ threshold. When $V_{DD}$ drops below the selected threshold, a device reset is generated. When $V_{DD}$ is above the $V_{BORX}$ upper limit, the device reset is released and the system can start.

For more details on the brown-out reset thresholds, refer to the electrical characteristics section in the datasheet.
5.2.2 Programmable voltage detector (PVD)

You can use the PVD to monitor the VDD power supply by comparing it to a threshold selected by the PLS[2:0] bits in the Power control register 2 (PWR\_CR2).

The PVD is enabled by setting the PVDE bit.

A PVDO flag is available, in the Power status register 2 (PWR\_SR2), to indicate if VDD is higher or lower than the PVD threshold. This event is internally connected to the EXTI line 16 and can generate an interrupt if enabled through the EXTI registers. The rising/falling edge sensitivity of the EXTI Line 16 should be configured according to PVD output behavior i.e. if the EXTI line 16 is configured to rising edge sensitivity, the interrupt will be generated when VDD drops below the PVD threshold. As an example the service routine could perform emergency shutdown tasks.
5.2.3 Peripheral Voltage Monitoring (PVM)

Only \( V_{DD} \) is monitored by default, as it is the only supply required for all system-related functions. The other supplies (\( V_{DDA}, V_{DDIO2} \) and \( V_{DDUSB} \)) can be independent from \( V_{DD} \) and can be monitored with four Peripheral Voltage Monitoring (PVM).

Each of the four \( \text{PVM}_x \) (\( x=1, 2, 3, 4 \)) is a comparator between a fixed threshold \( V_{PVMx} \) and the selected power supply. \( \text{PVMO}_x \) flags indicate if the independent power supply is higher or lower than the \( \text{PVM}_x \) threshold: \( \text{PVMO}_x \) flag is cleared when the supply voltage is above the \( \text{PVM}_x \) threshold, and is set when the supply voltage is below the \( \text{PVM}_x \) threshold.

Each PVM output is connected to an EXTI line and can generate an interrupt if enabled through the EXTI registers. The PVMx output interrupt is generated when the independent power supply drops below the \( \text{PVM}_x \) threshold and/or when it rises above the \( \text{PVM}_x \) threshold, depending on EXTI line rising/falling edge configuration.

Each PVM can remain active in Stop 0, Stop 1 and Stop 2 modes, and the PVM interrupt can wake up from the Stop mode.

<table>
<thead>
<tr>
<th>PVM</th>
<th>Power supply</th>
<th>PVM threshold</th>
<th>EXTI line</th>
</tr>
</thead>
<tbody>
<tr>
<td>PVM1</td>

<td>( V_{PVM4} ) (around 2.2 V)</td>
<td>38</td>
</tr>
</tbody>
</table>

The independent supplies (\( V_{DDA}, V_{DDIO2} \) and \( V_{DDUSB} \)) are not considered as present by default, and a logical and electrical isolation is applied to ignore any information coming from the peripherals supplied by these dedicated supplies.

- If these supplies are shorted externally to \( V_{DD} \), the application should assume they are available without enabling any Peripheral Voltage Monitoring.
- If these supplies are independent from \( V_{DD} \), the Peripheral Voltage Monitoring (PVM) can be enabled to confirm whether the supply is present or not.

The following sequence must be done before using the USB OTG peripheral:

1. If \( V_{DDUSB} \) is independent from \( V_{DD} \):
   a) Enable the PVM1 by setting PVME1 bit in the \textit{Power control register 2 (PWR\_CR2)}.
   b) Wait for the PVM1 wakeup time
   c) Wait until PVMO1 bit is cleared in the \textit{Power status register 2 (PWR\_SR2)}.
   d) Optional: Disable the PVM1 for consumption saving.

2. Set the USV bit in the \textit{Power control register 2 (PWR\_CR2)} to remove the \( V_{DDUSB} \) power isolation.

The following sequence must be done before using any I/O from PG[15:2]:

1. If \( V_{DDIO2} \) is independent from \( V_{DD} \):
   a) Enable the PVM2 by setting PVME2 bit in the Power control register 2 (PWR_CR2).
   b) Wait for the PVM2 wakeup time
   c) Wait until PVMO2 bit is cleared in the Power status register 2 (PWR_SR2).
   d) Optional: Disable the PVM2 for consumption saving.
2. Set the IOSV bit in the Power control register 2 (PWR_CR2) to remove the \( V_{DDIO2} \) power isolation.

The following sequence must be done before using any of these analog peripherals: analog to digital converters, digital to analog converters, comparators, operational amplifiers, voltage reference buffer:

1. If \( V_{DDA} \) is independent from \( V_{DD} \):
   a) Enable the PVM3 (or PVM4) by setting PVME3 (or PVME4) bit in the Power control register 2 (PWR_CR2).
   b) Wait for the PVM3 (or PVM4) wakeup time
   c) Wait until PVMO3 (or PVMO4) bit is cleared in the Power status register 2 (PWR_SR2).
   d) Optional: Disable the PVM3 (or PVM4) for consumption saving.
2. Enable the analog peripheral, which automatically removes the \( V_{DDA} \) isolation.

### 5.3 Low-power modes

By default, the microcontroller is in Run mode after a system or a power Reset. Several low-power modes are available to save power when the CPU does not need to be kept running, for example when waiting for an external event. It is up to the user to select the mode that gives the best compromise between low-power consumption, short startup time and available wakeup sources.

The device features seven low-power modes:

- **Sleep mode**: CPU clock off, all peripherals including Cortex®-M4 core peripherals such as NVIC, SysTick, etc. can run and wake up the CPU when an interrupt or an event occurs. Refer to Section 5.3.4: Sleep mode.

- **Low-power run mode**: This mode is achieved when the system clock frequency is reduced below 2 MHz. The code is executed from the SRAM or the Flash memory. The regulator is in low-power mode to minimize the regulator's operating current. Refer to Section 5.3.2: Low-power run mode (LP run).

- **Low-power sleep mode**: This mode is entered from the Low-power run mode: Cortex®-M4 is off. Refer to Section 5.3.5: Low-power sleep mode (LP sleep).

- **Stop 0, Stop 1 and Stop 2 modes**: SRAM1, SRAM2, SRAM3 and all registers content are retained. All clocks in the VCORE domain are stopped, the PLL, the MSI, the HSI16 and the HSE are disabled. The LSI and the LSE can be kept running. The RTC can remain active (Stop mode with RTC, Stop mode without RTC). Some peripherals with the wakeup capability can enable the HSI16 RC during the Stop mode to detect their wakeup condition.

In Stop 2 mode, most of the VCORE domain is put in a lower leakage mode. To further reduce the current consumption during Stop 2, it is possible to switch OFF the SRAM3:

- Stop 2 mode with SRAM3 content lost when the RRSTP bit is cleared in...
PWR_CR1 register (default setting).

Stop 2 mode with SRAM3 retention when the RRSTP bit is set in PWR_CR1 register. Stop 1 offers the largest number of active peripherals and wakeup sources, a smaller wakeup time but a higher consumption than Stop 2. In Stop 0 mode, the main regulator remains ON, which allows the fastest wakeup time but with much higher consumption. The active peripherals and wakeup sources are the same as in Stop 1 mode.

The system clock, when exiting from Stop 0, Stop 1 or Stop 2 mode, can be either MSI up to 48 MHz or HSI16, depending on the software configuration.

Refer to Section 5.3.6: Stop 0 mode and Section 5.3.8: Stop 2 mode.

- Standby mode: $V_{\text{CORE}}$ domain is powered off. However, it is possible to preserve the SRAM2 contents:
  
  For STM32L4Rxxy and STM32L4Sxx devices:
  - Standby mode with SRAM2 retention when the bit RRS is set in PWR_CR3 register. In this case, SRAM2 is supplied by the low-power regulator.
  - Standby mode when the bit RRS is cleared in PWR_CR3 register. In this case the main regulator and the low-power regulator are powered off.
  
  For STM32L4P5xx and STM32L4Q5xx devices:
  - Standby mode with full or only the upper 4 Kbytes of SRAM2 retention when the RRS[1:0] bits are set to ‘01’ or ‘10’ respectively in the PWR_CR3 register. In this case, the SRAM2 is supplied by the low-power regulator.
  - Standby mode when the RRS[1:0] bits are cleared in PWR_CR3 register. In this case the main regulator and the low-power regulator are powered off.

All clocks in the $V_{\text{CORE}}$ domain are stopped, the PLL, the MSI, the HSI16 and the HSE are disabled. The LSI and the LSE can be kept running. The RTC can remain active (Standby mode with RTC, Standby mode without RTC). The system clock, when exiting Standby modes, is MSI from 1 MHz up to 8 MHz.

Refer to Section 5.3.9: Standby mode.

- Shutdown mode: $V_{\text{CORE}}$ domain is powered off. All clocks in the $V_{\text{CORE}}$ domain are stopped, the PLL, the MSI, the HSI16, the LSI and the HSE are disabled. The LSE can be kept running. The system clock, when exiting the Shutdown mode, is MSI at 4 MHz. In this mode, the supply voltage monitoring is disabled and the product behavior is not guaranteed in case of a power voltage drop. Refer to Section 5.3.10: Shutdown mode.

In addition, the power consumption in Run mode can be reduced by one of the following means:

- Slowing down the system clocks
- Gating the clocks to the APB and AHB peripherals when they are unused.

</table>

2. The Flash can be configured in Power-down mode. By default, it is not in Power-down mode.
3. The SRAM clock can be gated on or off.
4. For STM32L4Rx6x and STM32L4Sxxx, SRAM2 content is preserved when the bit RRS is set in PWR.CR3 register. For STM32L4P5xx and STM32L4Q5xx, 4 Kbytes or full SRAM2 content is preserved depending on RRS[1:0] bits configuration in PWR.CR3 register.
5. Some peripherals with wakeup from Stop capability can request HSI16 to be enabled. In this case, HSI16 is woken up by the peripheral, and only feeds the peripheral which requested it. HSI16 is automatically put off when the peripheral does not need it anymore.
6. PSSI is available only on STM32L4P5xx and STM32L4Q5xx devices.
7. UART and LPUART reception is functional in Stop mode, and generates a wakeup interrupt on Start, address match or received frame event.
8. I2C address detection is functional in Stop mode, and generates a wakeup interrupt in case of address match.
Debug mode

By default, the debug connection is lost if the application puts the MCU in Stop 0, Stop1, Stop 2, Standby or Shutdown mode while the debug features are used. This is due to the fact that the Cortex®-M4 core is no longer clocked.

However, by setting some configuration bits in the DBGMCU_CR register, the software can be debugged even when using the low-power modes extensively. For more details, refer to Section 57.16.1: Debug support for low-power modes.

5.3.1 Run mode

Slowing down system clocks

In Run mode, the speed of the system clocks (SYSCLK, HCLK, PCLK) can be reduced by programming the prescaler registers. These prescalers can also be used to slow down the peripherals before entering the Sleep mode.

For more details, refer to Section 6.4.3: Clock configuration register (RCC_CFGR).

Peripheral clock gating

In Run mode, the HCLK and PCLK for individual peripherals and memories can be stopped at any time to reduce the power consumption.

To further reduce the power consumption in Sleep mode, the peripheral clocks can be disabled prior to executing the WFI or WFE instructions.

The peripheral clock gating is controlled by the RCC_AHBxENR and RCC_APBxENR registers.

Disabling the peripherals clocks in Sleep mode can be performed automatically by resetting the corresponding bit in the RCC_AHBxSMENR and RCC_APBxSMENR registers.

5.3.2 Low-power run mode (LP run)

To further reduce the consumption when the system is in Run mode, the regulator can be configured in low-power mode. In this mode, the system frequency should not exceed 2 MHz.

Please refer to the product datasheet for more details on voltage regulator and peripherals operating conditions.

I/O states in Low-power run mode

In Low-power run mode, all I/O pins keep the same state as in Run mode.

Entering the Low-power run mode

To enter the Low-power run mode, proceed as follows:
1. Optional: Jump into the SRAM and power-down the Flash by setting the RUN_PD bit in
the Flash access control register (FLASH_ACR).
2. Decrease the system clock frequency below 2 MHz.
3. Force the regulator in low-power mode by setting the LPR bit in the PWR_CR1 register.
Refer to Table 28: Low-power run on how to enter the Low-power run mode.

**Exiting the Low-power run mode**

To exit the Low-power run mode, proceed as follows:
1. Force the regulator in main mode by clearing the LPR bit in the PWR_CR1 register.
2. Wait until REGLPF bit is cleared in the PWR_SR2 register.
3. Increase the system clock frequency.

Refer to Table 28: Low-power run on how to exit the Low-power run mode.

<table>
<thead>
<tr>

<td>LPR = 0 Wait until REGLPF = 0 Increase the system clock frequency</td>
</tr>
<tr>
<td>Wakeup latency</td>
<td>Regulator wakeup time from low-power mode</td>
</tr>
</tbody>
</table>

**5.3.3 Low-power modes**

**Entering low-power mode**

Low-power modes are entered by the MCU by executing the WFI (Wait For Interrupt), or
WFE (Wait for Event) instructions, or when the SLEEPONEXIT bit in the Cortex®-M4
System Control register is set on Return from ISR.

Entering Low-power mode through WFI or WFE will be executed only if no interrupt is
pending or no event is pending.

**Exiting low-power mode**

From Sleep modes, and Stop modes the MCU exit low-power mode depending on the way
the low-power mode was entered:

- If the WFI instruction or Return from ISR was used to enter the low-power mode, any
  peripheral interrupt acknowledged by the NVIC can wake up the device.
- If the WFE instruction is used to enter the low-power mode, the MCU exits the low-
  power mode as soon as an event occurs. The wakeup event can be generated either
  by:
    - NVIC IRQ interrupt.
    - When SEVONPEND = 0 in the Cortex®-M4 System Control register. By enabling
      an interrupt in the peripheral control register and in the NVIC. When the MCU
      resumes from WFE, the peripheral interrupt pending bit and the NVIC peripheral
IRQ channel pending bit (in the NVIC interrupt clear pending register) have to be cleared.

Only NVIC interrupts with sufficient priority will wakeup and interrupt the MCU.

- When SEVONPEND = 1 in the Cortex®-M4 System Control register.

By enabling an interrupt in the peripheral control register and optionally in the NVIC. When the MCU resumes from WFE, the peripheral interrupt pending bit and when enabled the NVIC peripheral IRQ channel pending bit (in the NVIC interrupt clear pending register) have to be cleared.

All NVIC interrupts will wakeup the MCU, even the disabled ones. Only enabled NVIC interrupts with sufficient priority will wakeup and interrupt the MCU.

- Event

Configuring a EXTI line in event mode. When the CPU resumes from WFE, it is not necessary to clear the EXTI peripheral interrupt pending bit or the NVIC IRQ channel pending bit as the pending bits corresponding to the event line is not set.

It may be necessary to clear the interrupt flag in the peripheral.

From Standby modes, and Shutdown modes the MCU exit low-power mode through an external reset (NRST pin), an IWDG reset, a rising edge on one of the enabled WKUPx pins or a RTC event occurs (see Figure 456: RTC block diagrams).

After waking up from Standby or Shutdown mode, program execution restarts in the same way as after a Reset (boot pin sampling, option bytes loading, reset vector is fetched, etc.).

5.3.4 Sleep mode

I/O states in Sleep mode

In Sleep mode, all I/O pins keep the same state as in Run mode.

Entering the Sleep mode

The Sleep mode is entered according Section : Entering low-power mode, when the SLEEPDEEP bit in the Cortex®-M4 System Control register is clear.

Refer to Table 29: Sleep for details on how to enter the Sleep mode.

Exiting the Sleep mode

The Sleep mode is exit according Section : Exiting low-power mode.

Refer to Table 29: Sleep for more details on how to exit the Sleep mode.
Low-power sleep mode (LP sleep)

Please refer to the product datasheet for more details on voltage regulator and peripherals operating conditions.

I/O states in Low-power sleep mode

In Low-power sleep mode, all I/O pins keep the same state as in Run mode.

Entering the Low-power sleep mode

The Low-power sleep mode is entered from Low-power run mode according Section : Entering low-power mode, when the SLEEPDEEP bit in the Cortex®-M4 System Control register is clear.

Refer to Table 30: Low-power sleep for details on how to enter the Low-power sleep mode.

Exiting the Low-power sleep mode

The low-power Sleep mode is exit according Section : Exiting low-power mode. When exiting the Low-power sleep mode by issuing an interrupt or an event, the MCU is in Low-power run mode.

Refer to Table 30: Low-power sleep for details on how to exit the Low-power sleep mode.
5.3.6 Stop 0 mode

The Stop 0 mode is based on the Cortex®-M4 Deepsleep mode combined with the peripheral clock gating. The voltage regulator is configured in main regulator mode. In Stop 0 mode, all clocks in the \(V_{CORE}\) domain are stopped; the PLL, the MSI, the HSI16 and the HSE oscillators are disabled. Some peripherals with the wakeup capability (I2Cx \(x=1,2,3\), U(S)ARTx \(x=1,2...5\) and LPUART) can switch on the HSI16 to receive a frame, and switch off the HSI16 after receiving the frame if it is not a wakeup frame. In this case, the HSI16 clock is propagated only to the peripheral requesting it.

SRAM1, SRAM2, SRAM3 and register contents are preserved.

The BOR is always available in Stop 0 mode. The consumption is increased when thresholds higher than \(V_{BOR0}\) are used.

I/O states in Stop 0 mode

In the Stop 0 mode, all I/O pins keep the same state as in the Run mode.

Entering the Stop 0 mode

The Stop 0 mode is entered according Section : Entering low-power mode, when the SLEEPDEEP bit in the Cortex®-M4 System Control register is set.
Refer to Table 31: Stop 0 mode for details on how to enter the Stop 0 mode.

If Flash memory programming is ongoing, the Stop 0 mode entry is delayed until the memory access is finished.

If an access to the APB domain is ongoing, The Stop 0 mode entry is delayed until the APB access is finished.

In Stop 0 mode, the following features can be selected by programming individual control bits:

- Independent watchdog (IWDG): the IWDG is started by writing to its Key register or by hardware option. Once started, it cannot be stopped except by a Reset. See Section 44.3: IWDG functional description.
- real-time clock (RTC): this is configured by the RTCECN bit in the Backup domain control register (RCC_BDCR)
- Internal RC oscillator (LSI): this is configured by the LSION bit in the Control/status register (RCC_CSR).
- External 32.768 kHz oscillator (LSE): this is configured by the LSEON bit in the Backup domain control register (RCC_BDCR).

Several peripherals can be used in Stop 0 mode and can add consumption if they are enabled and clocked by LSI or LSE, or when they request the HSI16 clock: LPTIM1, LPTIM2, I2Cx (x=1,2,3,4) UARTx(x=1,2...5), LPUART.

The DACx (x=1,2), the OPAMPs and the comparators can be used in Stop 0 mode, the PVMx (x=1,2,3,4) and the PVD as well. If they are not needed, they must be disabled by software to save their power consumptions.

The ADCx (x=1,2,3), temperature sensor and VREFBUF buffer can consume power during the Stop 0 mode, unless they are disabled before entering this mode.

**Exiting the Stop 0 mode**

The Stop 0 mode is exit according Section: Entering low-power mode.

Refer to Table 31: Stop 0 mode for details on how to exit Stop 0 mode.

When exiting Stop 0 mode by issuing an interrupt or a wakeup event, the HSI16 oscillator is selected as system clock if the bit STOPWUCK is set in Clock configuration register (RCC_CFGR). The MSI oscillator is selected as system clock if the bit STOPWUCK is cleared. The wakeup time is shorter when HSI16 is selected as wakeup system clock. The MSI selection allows wakeup at higher frequency, up to 48 MHz.

When the voltage regulator operates in low-power mode, an additional startup delay is incurred when waking up from Stop 0 mode with HSI16. By keeping the internal regulator ON during Stop 0 mode, the consumption is higher although the startup time is reduced.

When exiting the Stop 0 mode, the MCU is either in Run mode (Range 1 or Range 2 depending on VOS bit in PWR_CR1) or in Low-power run mode if the bit LPR is set in the PWR_CR1 register.
5.3.7 Stop 1 mode

The Stop 1 mode is the same as Stop 0 mode except that the main regulator is OFF, and only the low-power regulator is ON. Stop 1 mode can be entered from Run mode and from Low-power run mode.

Refer to **Table 32: Stop 1 mode** for details on how to enter and exit Stop 1 mode.
### 5.3.8 Stop 2 mode

The Stop 2 mode is based on the Cortex®-M4 Deepsleep mode combined with peripheral clock gating. In Stop 2 mode, all clocks in the V\textsubscript{CORE} domain are stopped, the PLL, the MSI, the HSI16 and the HSE oscillators are disabled. Some peripherals with wakeup capability (I2C3 and LPUART) can switch on the HSI16 to receive a frame, and switch off the HSI16 after receiving the frame if it is not a wakeup frame. In this case the HSI16 clock is propagated only to the peripheral requesting it.

SRAM1, SRAM2, SRAM3 and register contents are preserved. The SRAM3 content is preserved or lost following the RRSTP bit configuration in the PWR\_CR1 register. By default, after reset, the RRSTP bit is reset thus the SRAM3 content is lost during Stop 2.

The BOR is always available in Stop 2 mode. The consumption is increased when thresholds higher than V\textsubscript{BOR0} are used.

#### Table 32. Stop 1 mode

<table>
<thead>
<tr>
<th>Stop 1 mode</th>
<th>Description</th>
</tr>
</thead>
</table>
| Mode entry  | WIFI (Wait for Interrupt) or WFE (Wait for Event) while:  
  - SLEEPDEEP bit is set in Cortex®-M4 System Control register  
  - No interrupt (for WIFI) or event (for WFE) is pending  
  - LPMS = "001" in PWR\_CR1  
  On Return from ISR while:  
  - SLEEPDEEP bit is set in Cortex®-M4 System Control register  
  - SLEEPONEXIT = 1  
  - No interrupt is pending  
  - LPMS = "001" in PWR\_CR1  
  Note: To enter Stop 1 mode, all EXTI Line pending bits (in Pending register 1 (EXTI\_PR1)), and the peripheral flags generating wakeup interrupts must be cleared. Otherwise, the Stop 1 mode entry procedure is ignored and program execution continues. |
| Mode exit   | If WIFI or Return from ISR was used for entry  
  Any EXTI Line configured in interrupt mode (the corresponding EXTI Interrupt vector must be enabled in the NVIC). The interrupt source can be external interrupts or peripherals with wakeup capability. Refer to Table 76: STM32L4Rxxx and STM32L4Sxxx vector table.  
  If WFE was used for entry and SEVONPEND = 0:  
  Any EXTI Line configured in event mode. Refer to Section 16.3.2: Wakeup event management.  
  If WFE was used for entry and SEVONPEND = 1:  
  Any EXTI Line configured in interrupt mode (even if the corresponding EXTI Interrupt vector is disabled in the NVIC). The interrupt source can be external interrupts or peripherals with wakeup capability. Refer to Table 76: STM32L4Rxxx and STM32L4Sxxx vector table.  
  Wakeup event: refer to Section 16.3.2: Wakeup event management |
| Wakeup latency | Longest wakeup time between: MSI or HSI16 wakeup time and regulator wakeup time from Low-power mode + Flash wakeup time from Stop 1 mode. |
**Note:** The comparators outputs, the LPUART outputs and the LPTIM1 outputs are forced to low speed (OSPEEDy=00) during the Stop 2 mode.

**I/O states in Stop 2 mode**

In the Stop 2 mode, all I/O pins keep the same state as in the Run mode.

**Entering Stop 2 mode**

The Stop 2 mode is entered according [Section : Entering low-power mode](#), when the SLEEPDEEP bit in the Cortex®-M4 System Control register is set.

Refer to [Table 33: Stop 2 mode](#) for details on how to enter the Stop 2 mode.

Stop 2 mode can only be entered from Run mode. It is not possible to enter Stop 2 mode from the Low-power run mode.

If Flash memory programming is ongoing, the Stop 2 mode entry is delayed until the memory access is finished.

If an access to the APB domain is ongoing, The Stop 2 mode entry is delayed until the APB access is finished.

In Stop 2 mode, the following features can be selected by programming individual control bits:

- Independent watchdog (IWDG): the IWDG is started by writing to its Key register or by hardware option. Once started it cannot be stopped except by a Reset. See [Section 44.3: IWDG functional description](#) in [Section 44: Independent watchdog (IWDG)](#).
- Real-time clock (RTC): this is configured by the RTCEN bit in the [Backup domain control register](#).
- Internal RC oscillator (LSI): this is configured by the LSION bit in the [Control/status register](#).
- External 32.768 kHz oscillator (LSE): this is configured by the LSEON bit in the [Backup domain control register](#).

Several peripherals can be used in Stop 2 mode and can add consumption if they are enabled and clocked by LSI or LSE, or when they request the HSI16 clock: LPTIM1, I2C3, LPUART.

The comparators can be used in Stop 2 mode, the PVMx (x=1,2,3,4) and the PVD as well. If they are not needed, they must be disabled by software to save their power consumptions.

The ADCx, OPAMPx, DACx, temperature sensor and VREFBUF buffer can consume power during Stop 2 mode, unless they are disabled before entering this mode.

All the peripherals which cannot be enabled in Stop 2 mode must be either disabled by clearing the Enable bit in the peripheral itself, or put under reset state by setting the corresponding bit in the [AHB1 peripheral reset register](#), [AHB2 peripheral reset register](#), [AHB3 peripheral reset register](#), [APB1 peripheral reset register 1](#), [APB1 peripheral reset register 2](#), [APB2 peripheral reset register](#).

**Exiting Stop 2 mode**

The Stop 2 mode is exit according [Section : Exiting low-power mode](#).
Refer to Table 33: Stop 2 mode for details on how to exit Stop 2 mode.

When exiting Stop 2 mode by issuing an interrupt or a wakeup event, the HSI16 oscillator is selected as system clock if the bit STOPWUCK is set in Clock configuration register (RCC_CFR). The MSI oscillator is selected as system clock if the bit STOPWUCK is cleared. The wakeup time is shorter when HSI16 is selected as wakeup system clock. The MSI selection allows wakeup at higher frequency, up to 48 MHz.

When exiting the Stop 2 mode, the MCU is in Run mode (Range 1 or Range 2 depending on VOS bit in PWR_CR1).

</tbody>
</table>

### 5.3.9 Standby mode

The Standby mode allows to achieve the lowest power consumption with BOR. It is based on the Cortex-M4 Deepsleep mode, with the voltage regulators disabled (except when
SRAM2 content is preserved. The PLL, the HSI16, the MSI and the HSE oscillators are also switched off.

SRAM1 and register contents are lost except for registers in the Backup domain and Standby circuitry (see Figure 9). SRAM2 content can be partially (only for STM32L4P5xx and STM32L4Q5xx) or fully preserved depending on RRS[1:0] bits configuration in PWR_CR3 register. In this case the Low-power regulator is ON and provides the supply to SRAM2 only.

The BOR is always available in Standby mode. The consumption is increased when thresholds higher than $V_{BOR0}$ are used.

I/O states in Standby mode

In the Standby mode, the I/O’s are by default in floating state. If the APC bit of PWR_CR3 register has been set, the I/Os can be configured either with a pull-up (refer to PWR_PUCRx registers ($x=A,B,C,D,E,F,G,H$)), or with a pull-down (refer to PWR_PDCRx registers ($x=A,B,C,D,E,F,G,H$)), or can be kept in analog state if none of the PWR_PUCRx or PWR_PDCRx register has been set. The pull-down configuration has highest priority over pull-up configuration in case both PWR_PUCRx and PWR_PDCRx are set for the same IO.

Some I/Os (listed in Section 8.3.1: General-purpose I/O (GPIO)) are used for JTAG/SW debug and can only be configured to their respective reset pull-up or pull-down state during Standby mode setting their respective bit in the PWR_PUCRx or PWR_PDCRx registers to ‘1’, or will be configured to floating state if the bit is kept at ‘0’.

The RTC outputs on PC13 are functional in Standby mode. PC14 and PC15 used for LSE are also functional. 5 wakeup pins (WKUPx, $x=1,2...5$) and the 3 RTC tampers are available.

Entering Standby mode

The Standby mode is entered according Section : Entering low-power mode, when the SLEEPDEEP bit in the Cortex®-M4 System Control register is set.

Refer to Table 34: Standby mode for details on how to enter Standby mode.

In Standby mode, the following features can be selected by programming individual control bits:

- Independent watchdog (IWDG): the IWDG is started by writing to its Key register or by hardware option. Once started it cannot be stopped except by a reset. See Section 44.3: IWDG functional description in Section 44: Independent watchdog (IWDG).
- real-time clock (RTC): this is configured by the RTCEN bit in the Backup domain control register (RCC_BDCR)
- Internal RC oscillator (LSI): this is configured by the LSION bit in the Control/status register (RCC_CSR).
- External 32.768 kHz oscillator (LSE): this is configured by the LSEON bit in the Backup domain control register (RCC_BDCR)

Exiting Standby mode

The Standby mode is exited according Section : Entering low-power mode. The SBF status flag in the Power control register 3 (PWR_CR3) indicates that the MCU was in Standby mode. All registers are reset after wakeup from Standby except for Power control register 3 (PWR_CR3).
Refer to Table 34: Standby mode for more details on how to exit Standby mode.

When exiting Standby mode, I/O’s that were configured with pull-up or pull-down during Standby through registers PWR_PUCRx or PWR_PDCRx will keep this configuration upon exiting Standby mode until the bit APC of PWR_CR3 register has been cleared. Once the bit APC is cleared, they will be either configured to their reset values or to the pull-up/pull-down state according the GPIOx_PUPDR registers. The content of the PWR_PUCRx or PWR_PDCRx registers however is not lost and can be re-used for a sub-sequent entering into Standby mode.

Some I/Os (listed in Section 8.3.1: General-purpose I/O (GPIO)) are used for JTAG/SW debug and have internal pull-up or pull-down activated after reset so will be configured at this reset value as well when exiting Standby mode.

For IO’s, with a pull-up or pull-down pre-defined after reset (some JTAG/SW IO’s) or with GPIOx_PUPDR programming done after exiting from Standby, in case those programming is different from the PWR_PUCRx or PWR_PDCRx programmed value during Standby, both a pull-down and pull-up will be applied until the bit APC is cleared, releasing the PWR_PUCRx or PWR_PDCRx programmed value.

</tbody>
</table>
5.3.10 Shutdown mode

The Shutdown mode allows to achieve the lowest power consumption. It is based on the Deepsleep mode, with the voltage regulator disabled. The V\text{CORE} domain is consequently powered off. The PLL, the HSI16, the MSI, the LSI and the HSE oscillators are also switched off.

SRAM1, SRAM2, SRAM3 and register contents are lost except for registers in the Backup domain. The BOR is not available in Shutdown mode. No power voltage monitoring is possible in this mode, therefore the switch to Backup domain is not supported.

I/O states in Shutdown mode

In the Shutdown mode, are by default in floating state. If the APC bit of PWR\_CR3 register has been set, the I/Os can be configured either with a pull-up (refer to PWR\_PUCRx registers \((x=A,B,C,D,E,F,G,H)\), or with a pull-down (refer to PWR\_PDCRx registers \((x=A,B,C,D,E,F,G,H)\)), or can be kept in analog state if none of the PWR\_PUCRx or PWR\_PDCRx register has been set. The pull-down configuration has highest priority over pull-up configuration in case both PWR\_PUCRx and PWR\_PDCRx are set for the same IO. However this configuration is lost when exiting the Shutdown mode due to the power-on reset.

Some I/Os (listed in Section 8.3.1: General-purpose I/O (GPIO)) are used for JTAG/SW debug and can only be configured to their respective reset pull-up or pull-down state during Standby mode setting their respective bit in the PWR\_PUCRx or PWR\_PDCRx registers to ‘1’, or will be configured to floating state if the bit is kept at ‘0’.

The RTC outputs on PC13 are functional in Shutdown mode. PC14 and PC15 used for LSE are also functional. 5 wakeup pins (WKUPx, \(x=1,2...5\)) and the 3 RTC tampers are available.

Entering Shutdown mode

The Shutdown mode is entered according Entering low-power mode, when the SLEEPDEEP bit in the Cortex\textsuperscript{\textregistered}\textsuperscript{-}M4 System Control register is set.

Refer to Table 35: Shutdown mode for details on how to enter Shutdown mode.

In Shutdown mode, the following features can be selected by programming individual control bits:

- real-time clock (RTC): this is configured by the RTCEN bit in the Backup domain control register (RCC\_BDCR). Caution: in case of VDD power-down the RTC content will be lost.
- external 32.768 kHz oscillator (LSE): this is configured by the LSEON bit in the Backup domain control register (RCC\_BDCR)

Exiting Shutdown mode

The Shutdown mode is exit according Section : Exiting low-power mode. A power-on reset occurs when exiting from Shutdown mode. All registers (except for the ones in the Backup domain) are reset after wakeup from Shutdown.

Refer to Table 35: Shutdown mode for more details on how to exit Shutdown mode.

When exiting Shutdown mode, I/Os that were configured with pull-up or pull-down during Shutdown through registers PWR\_PUCRx or PWR\_PDCRx will lose their configuration and
will be configured in floating state or to their pull-up pull-down reset value (for some I/Os listed in Section 8.3.1: General-purpose I/O (GPIO)).

### 5.3.11 Auto-wakeup from low-power mode

The RTC can be used to wakeup the MCU from low-power mode without depending on an external interrupt (Auto-wakeup mode). The RTC provides a programmable time base for waking up from Stop (0, 1 or 2) or Standby mode at regular intervals. For this purpose, two of the three alternative RTC clock sources can be selected by programming the RTCSEL[1:0] bits in the Backup domain control register (RCC_BDCR):

- Low-power 32.768 kHz external crystal oscillator (LSE OSC)
  This clock source provides a precise time base with very low-power consumption.
- Low-power internal RC Oscillator (LSI)
  This clock source has the advantage of saving the cost of the 32.768 kHz crystal. This internal RC Oscillator is designed to add minimum power consumption.

To wakeup from Stop mode with an RTC alarm event (or RTC SSRU event which is only available on STM32L4P5xx and STM32L4Q5xx devices), it is necessary to:

- Configure the EXTI Line 18 to be sensitive to rising edge
- Configure the RTC to generate the RTC alarm

To wakeup from Standby mode, there is no need to configure the EXTI Line 18.

To wakeup from Stop mode with an RTC wakeup event, it is necessary to:

- Configure the EXTI Line 20 to be sensitive to rising edge
- Configure the RTC to generate the RTC alarm

To wakeup from Standby mode, there is no need to configure the EXTI Line 20.
5.4 PWR registers

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

5.4.1 Power control register 1 (PWR_CR1)

Address offset: 0x00

Reset value: 0x0000 0200 (This register is reset after wakeup from Standby mode)

<table>

5.4.2 Power control register 2 (PWR_CR2)

Address offset: 0x04

Reset value: 0x0000 0000 (This register is reset when exiting the Standby mode)

<table>
<thead>
<tr>
<th>Bits 31:11</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
</table>
| Bit 10 USV | VDDUSB USB supply valid
This bit is used to validate the VDDUSB supply for electrical and logical isolation purpose. Setting this bit is mandatory to use the USB OTG_FS peripheral. If VDDUSB is not always present in the application, the PVM can be used to determine whether this supply is ready or not.

0: VDDUSB is not present. Logical and electrical isolation is applied to ignore this supply.
1: VDDUSB is valid. |
| Bit 9 IOSV | VDDIO2 Independent I/Os supply valid
This bit is used to validate the VDDIO2 supply for electrical and logical isolation purpose. Setting this bit is mandatory to use PG[15:2]. If VDDIO2 is not always present in the application, the PVM can be used to determine whether this supply is ready or not.

0: VDDIO2 is not present. Logical and electrical isolation is applied to ignore this supply.
1: VDDIO2 is valid. |
| Bit 8 Reserved, must be kept at reset value. |
| Bit 7 PVME4 | Peripheral voltage monitoring 4 enable: VDDA vs. 2.2V
0: PVM4 (VDDA monitoring vs. 2.2V threshold) disable.
1: PVM4 (VDDA monitoring vs. 2.2V threshold) enable. |
Bit 6 **PVME3**: Peripheral voltage monitoring 3 enable: $V_{DDA}$ vs. 1.62V
0: PVM3 ($V_{DDA}$ monitoring vs. 1.62V threshold) disable.
1: PVM3 ($V_{DDA}$ monitoring vs. 1.62V threshold) enable.

Bit 5 **PVME2**: Peripheral voltage monitoring 2 enable: $V_{DDIO2}$ vs. 0.9V
0: PVM2 ($V_{DDIO2}$ monitoring vs. 0.9V threshold) disable.
1: PVM2 ($V_{DDIO2}$ monitoring vs. 0.9V threshold) enable.

Bit 4 **PVME1**: Peripheral voltage monitoring 1 enable: $V_{DDUSB}$ vs. 1.2V
0: PVM1 ($V_{DDUSB}$ monitoring vs. 1.2V threshold) disable.
1: PVM1 ($V_{DDUSB}$ monitoring vs. 1.2V threshold) enable.

Bits 3:1 **PLS[2:0]**: Power voltage detector level selection.
These bits select the voltage threshold detected by the power voltage detector:
000: $V_{PVD0}$ around 2.0 V
001: $V_{PVD1}$ around 2.2 V
010: $V_{PVD2}$ around 2.4 V
011: $V_{PVD3}$ around 2.5 V
100: $V_{PVD4}$ around 2.6 V
101: $V_{PVD5}$ around 2.8 V
110: $V_{PVD6}$ around 2.9 V
111: External input analog voltage PVD_IN (compared internally to VREFINT)

**Note:** These bits are write-protected when the bit PVDL (PVD Lock) is set in the SYSCFG_CBR register.
These bits are reset only by a system reset.

Bit 0 **PVDE**: Power voltage detector enable
0: Power voltage detector disable.
1: Power voltage detector enable.

**Note:** This bit is write-protected when the bit PVDL (PVD Lock) is set in the SYSCFG_CBR register.
This bit is reset only by a system reset.

### 5.4.3 Power control register 3 (PWR_CR3)

Address offset: 0x08

Reset value: 0x0000 8000 (This register is not reset when exiting Standby modes and with the PWR_RST bit in the RCC_APB1RSTR1 register)

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).
Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **EIWUL**: Enable internal wakeup line
0: Internal wakeup line disable.
1: Internal wakeup line enable.

Bits 14:13 Reserved, must be kept at reset value.

Bit 12 **DSIPDEN**: Enable Pull-down activation on DSI pins
1: Pull-Down is enabled on DSI pins.
0: Pull-Down is disabled on DSI pins.

Bit 11 **ENULP**: Enable ULP sampling
When this bit is set, the BORL, BORH and PVD are periodically sampled instead continuous monitoring to reduce power consumption. Fast supply drop between two sample/compare phases is not detected in this mode. This bit has impact only on STOP2, Standby and shutdown low power modes.

*Note*: Available on STM32L4P5xx and STM32L4Q5xx only.

Bit 10 **APC**: Apply pull-up and pull-down configuration
When this bit is set, the I/O pull-up and pull-down configurations defined in the PWR_PUCRx and PWR_PDCRx registers are applied. When this bit is cleared, the PWR_PUCRx and PWR_PDCRx registers are not applied to the I/Os, instead the I/Os will be in floating mode during Standby or configured according GPIO controller GPIOx_PUPDR register during Run mode.

Bit 9:8 **RRS[1:0]**: SRAM2 retention in Standby mode
*For STM32L4Rxxx and STM32L4Sxxx devices bit 9 is reserved*
0: SRAM2 is powered off in Standby mode (SRAM2 content is lost).
1: SRAM2 is powered by the low-power regulator in Standby mode (SRAM2 content is kept).
*For STM32L4P5xx and STM32L4Q5xx devices:
00: SRAM2 is powered off in Standby mode (SRAM2 content is lost).
01: Full SRAM2 is powered by the low-power regulator in Standby mode (SRAM2 full content is kept).
10: Only 4 Kbytes of SRAM2 is powered by the low-power regulator in Standby mode (4 Kbytes of SRAM2 content is kept)
11: reserved.*

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **EWUP5**: Enable Wakeup pin WKUP5
When this bit is set, the external wakeup pin WKUP5 is enabled and triggers a wakeup from Standby or Shutdown event when a rising or a falling edge occurs. The active edge is configured via the WP5 bit in the PWR_CR4 register.

Bit 3 **EWUP4**: Enable Wakeup pin WKUP4
When this bit is set, the external wakeup pin WKUP4 is enabled and triggers a wakeup from Standby or Shutdown event when a rising or a falling edge occurs. The active edge is configured via the WP4 bit in the PWR_CR4 register.
Bit 2 **EWUP3**: Enable Wakeup pin WKUP3
When this bit is set, the external wakeup pin WKUP3 is enabled and triggers a wakeup from Standby or Shutdown event when a rising or a falling edge occurs. The active edge is configured via the WP3 bit in the PWR_CR4 register.

Bit 1 **EWUP2**: Enable Wakeup pin WKUP2
When this bit is set, the external wakeup pin WKUP2 is enabled and triggers a wakeup from Standby or Shutdown event when a rising or a falling edge occurs. The active edge is configured via the WP2 bit in the PWR_CR4 register.

Bit 0 **EWUP1**: Enable Wakeup pin WKUP1
When this bit is set, the external wakeup pin WKUP1 is enabled and triggers a wakeup from Standby or Shutdown event when a rising or a falling edge occurs. The active edge is configured via the WP1 bit in the PWR_CR4 register.

### 5.4.4 Power control register 4 (PWR_CR4)

Address offset: 0xOC

Reset value: 0x0000 0000 (This register is not reset when exiting Standby modes and with the PWRRST bit in the RCC_APB1RSTR1 register)

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

</table>

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **EXT_SMPS_ON**: external SMPS on.
This bit informs the internal regulator about external SMPS switch status to decrease regulator output to 0.95 V in Range 2, allowing the external SMPS output down to 1.00 V.
0: the external SMPS switch is open.
1: the external SMPS switch is closed, internal regulator output is set to 0.95 V.

*Note: This bit is only available on STM32L4P5xx and STM32L4Q5xx devices.*

Bits 12:10 Reserved, must be kept at reset value.

Bit 9 **VBR5**: \(V_{\text{BAT}}\) battery charging resistor selection
0: Charge \(V_{\text{BAT}}\) through a 5 kOhms resistor
1: Charge \(V_{\text{BAT}}\) through a 1.5 kOhms resistor

Bit 8 **VBE**: \(V_{\text{BAT}}\) battery charging enable
0: \(V_{\text{BAT}}\) battery charging disable
1: \(V_{\text{BAT}}\) battery charging enable

Bits 7:5 Reserved, must be kept at reset value.
Bit 4 **WP5**: Wakeup pin WKUP5 polarity  
This bit defines the polarity used for an event detection on external wake-up pin, WKUP5  
0: Detection on high level (rising edge)  
1: Detection on low level (falling edge)

Bit 3 **WP4**: Wakeup pin WKUP4 polarity  
This bit defines the polarity used for an event detection on external wake-up pin, WKUP4  
0: Detection on high level (rising edge)  
1: Detection on low level (falling edge)

Bit 2 **WP3**: Wakeup pin WKUP3 polarity  
This bit defines the polarity used for an event detection on external wake-up pin, WKUP3  
0: Detection on high level (rising edge)  
1: Detection on low level (falling edge)

Bit 1 **WP2**: Wakeup pin WKUP2 polarity  
This bit defines the polarity used for an event detection on external wake-up pin, WKUP2  
0: Detection on high level (rising edge)  
1: Detection on low level (falling edge)

Bit 0 **WP1**: Wakeup pin WKUP1 polarity  
This bit defines the polarity used for an event detection on external wake-up pin, WKUP1  
0: Detection on high level (rising edge)  
1: Detection on low level (falling edge)

### 5.4.5 Power status register 1 (PWR_SR1)

**Address offset**: 0x10

**Reset value**: 0x0000 0000 (This register is not reset when exiting Standby modes and with the PWRRST bit in the RCC_APB1RSTR1 register)

**Access**: 2 additional APB cycles are needed to read this register vs. a standard APB read.

</tbody>
</table>
Bits 31:16  Reserved, must be kept at reset value.

Bit 15  **PVMO4**: Peripheral voltage monitoring output: $V_{DDA}$ vs. 2.2 V
0: $V_{DDA}$ voltage is above PVM4 threshold (around 2.2 V).
1: $V_{DDA}$ voltage is below PVM4 threshold (around 2.2 V).

*Note:* PVMO4 is cleared when PVM4 is disabled (PVME4 = 0). After enabling PVM4, the PVM4 output is valid after the PVM4 wakeup time.

Bit 14  **PVMO3**: Peripheral voltage monitoring output: $V_{DDA}$ vs. 1.62 V
0: $V_{DDA}$ voltage is above PVM3 threshold (around 1.62 V).
1: $V_{DDA}$ voltage is below PVM3 threshold (around 1.62 V).

*Note:* PVMO3 is cleared when PVM3 is disabled (PVME3 = 0). After enabling PVM3, the PVM3 output is valid after the PVM3 wakeup time.

Bit 13  **PVMO2**: Peripheral voltage monitoring output: $V_{DDIO2}$ vs. 0.9 V
0: $V_{DDIO2}$ voltage is above PVM2 threshold (around 0.9 V).
1: $V_{DDIO2}$ voltage is below PVM2 threshold (around 0.9 V).

*Note:* PVMO2 is cleared when PVM2 is disabled (PVME2 = 0). After enabling PVM2, the PVM2 output is valid after the PVM2 wakeup time.

Bit 12  **PVMO1**: Peripheral voltage monitoring output: $V_{DDUSB}$ vs. 1.2 V
0: $V_{DDUSB}$ voltage is above PVM1 threshold (around 1.2 V).
1: $V_{DDUSB}$ voltage is below PVM1 threshold (around 1.2 V).

*Note:* PVMO1 is cleared when PVM1 is disabled (PVME1 = 0). After enabling PVM1, the PVM1 output is valid after the PVM1 wakeup time.

Bit 11  **PVDO**: Power voltage detector output
0: $V_{DD}$ is above the selected PVD threshold
1: $V_{DD}$ is below the selected PVD threshold

Bit 10  **VOSF**: Voltage scaling flag
A delay is required for the internal regulator to be ready after the voltage scaling has been changed. VOSF indicates that the regulator reached the voltage level defined with VOS bits of the PWR_CR1 register.
0: The regulator is ready in the selected voltage range
1: The regulator output voltage is changing to the required voltage level

Bit 9  **REGLPF**: Low-power regulator flag
This bit is set by hardware when the MCU is in Low-power run mode. When the MCU exits from the Low-power run mode, this bit remains at 1 until the regulator is ready in main mode. A polling on this bit must be done before increasing the product frequency.
This bit is cleared by hardware when the regulator is ready.
0: The regulator is ready in main mode (MR)
1: The regulator is in low-power mode (LPR)

Bit 8  **REGLPS**: Low-power regulator started
This bit provides the information whether the low-power regulator is ready after a power-on reset or a Standby/Shutdown. If the Standby mode is entered while REGLPS bit is still cleared, the wakeup from Standby mode time may be increased.
0: The low-power regulator is not ready
1: The low-power regulator is ready

Bits 7:0  Reserved, must be kept at reset value.

### 5.4.7  Power status clear register (PWR_SCR)

Address offset: 0x18
Power control (PWR)

Reset value: 0x0000 0000

Access: 3 additional APB cycles are needed to write this register vs. a standard APB write.

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 PD14: Port A pull-down bit 14
When set, this bit activates the pull-down on PA[14] when APC bit is set in PWR_CR3 register.

Bit 13 Reserved, must be kept at reset value.

Bits 12:0 PDy: Port A pull-down bit y (y=0...12)
When set, this bit activates the pull-down on PA[y] when APC bit is set in PWR_CR3 register.

5.4.10 Power Port B pull-up control register (PWR_PUCRB)

Address offset: 0x28.

Reset value: 0x0000 0000 (This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register)

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).
5.4.11 Power Port B pull-down control register (PWR_PDCRB)

Address offset: 0x2C.

Reset value: 0x0000 0000 (This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register)

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **PDy**: Port B pull-down bit y (y=0..15)
When set, this bit activates the pull-down on PB[y] when APC bit is set in PWR_CR3 register.
The pull-down is not activated if the corresponding PDy bit is also set.

5.4.12 Power Port C pull-up control register (PWR_PUCRC)

Address offset: 0x30.

Reset value: 0x0000 0000 (This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register)

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).
### 5.4.13 Power Port C pull-down control register (PWR_PDCRC)

Address offset: 0x34.

Reset value: 0x0000 0000 (This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register)

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

</table>

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:0  **PUy**: Port C pull-up bit y (y=0..15)

When set, this bit activates the pull-up on PC[y] when APC bit is set in PWR_CR3 register.

The pull-up is not activated if the corresponding PDy bit is also set.

### 5.4.14 Power Port D pull-up control register (PWR_PUCRD)

Address offset: 0x38.

Reset value: 0x0000 0000 (This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register)

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:0  **PDy**: Port C pull-down bit y (y=0..15)

When set, this bit activates the pull-down on PC[y] when APC bit is set in PWR_CR3 register.
5.4.15 Power Port D pull-down control register (PWR_PDCRD)

Address offset: 0x3C.

Reset value: 0x0000 0000 (This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register)

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **PDy**: Port D pull-down bit y (y=0..15)
- When set, this bit activates the pull-down on PD[y] when APC bit is set in PWR_CR3 register.
- The pull-down is not activated if the corresponding PDy bit is also set.

5.4.16 Power Port E pull-up control register (PWR_PUCRE)

Address offset: 0x20.

Reset value: 0x0000 0000 (This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register)

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).
5.4.17 Power Port E pull-down control register (PWR_PDCRE)

Address offset: 0x44.

Reset value: 0x0000 0000 (This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register)

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **PDy**: Port E pull-down bit y (y=0..15)
When set, this bit activates the pull-down on PE[y] when APC bit is set in PWR_CR3 register.
The pull-down is not activated if the corresponding PDy bit is also set.

5.4.18 Power Port F pull-up control register (PWR_PUCRF)

Address offset: 0x48.

Reset value: 0x0000 0000 (This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register)

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).
5.4.19 Power Port F pull-down control register (PWR_PDCRF)

Address offset: 0x4C.

Reset value: 0x0000 0000 (This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register)

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 PDy: Port F pull-down bit y (y=0..15)
When set, this bit activates the pull-down on PF[y] when APC bit is set in PWR_CR3 register.
The pull-down is not activated if the corresponding PDy bit is also set.

5.4.20 Power Port G pull-up control register (PWR_PUCRG)

Address offset: 0x50.

Reset value: 0x0000 0000 (This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register)

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).
5.4.21 **Power Port G pull-down control register (PWR_PDCRG)**

Address offset: 0x54.

Reset value: 0x0000 0000 (This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register)

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **PDy**: Port G pull-down bit y (y=0..15)

When set, this bit activates the pull-down on PG[y] when APC bit is set in PWR_CR3 register.

The pull-down is not activated if the corresponding PDy bit is also set.

5.4.22 **Power Port H pull-up control register (PWR_PUCRH)**

Address offset: 0x58.

Reset value: 0x0000 0000 (This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register)

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **PUy**: Port G pull-up bit y (y=0..15)

When set, this bit activates the pull-up on PG[y] when APC bit is set in PWR_CR3 register.
Power control (PWR)

5.4.23 Power Port H pull-down control register (PWR_PDCRH)

Address offset: 0x5C.

Reset value: 0x0000 0000 (This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register)

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0  PDy: Port H pull-down bit y (y=0..15)
When set, this bit activates the pull-down on PH[y] when APC bit is set in PWR_CR3 register.
The pull-down is not activated if the corresponding PDy bit is also set.

5.4.24 Power Port I pull-up control register (PWR_PUCRI)

Address offset: 0x60.

Reset value: 0x0000 0000 (This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register)

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).
### 5.4.25 Power Port I pull-down control register (PWR_PDCRI)

Address offset: 0x64.

- **Reset value**: 0x0000 0000 (This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register)
- **Access**: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

- **Bits 31:16**: Reserved, must be kept at reset value.
- **Bits 11:0**: **PDy**: Port I pull-down bit y (y=0..11)
  - When set, this bit activates the pull-down on PI[y] when APC bit is set in PWR_CR3 register.
Bits 31:9  Reserved, must be kept at reset value.

Bit 8  **R1MODE**: Main regulator Range 1 mode

This bit is only valid for the main regulator in Range 1 and has no effect on Range 2. It is recommended to reset this bit when the system frequency is greater than 80 MHz. Refer to Table 24: Range 1 boost mode configuration.

0: Main regulator in Range 1 boost mode.
1: Main regulator in Range 1 normal mode.

Bits 7:0  Reserved, must be kept at reset value.

1. The availability of this bit/bitfield depends on product part numbers. For additional information refer to Section 1.4: Availability of peripherals.
6 Reset and clock control (RCC)

6.1 Reset

There are three types of reset, defined as system reset, power reset and backup domain reset.

6.1.1 Power reset

A power reset is generated when one of the following events occurs:

1. a Brown-out reset (BOR).
2. when exiting from Standby mode.
3. when exiting from Shutdown mode.

A Brown-out reset, including power-on or power-down reset (POR/PDR), sets all registers to their reset values except the Backup domain.

When exiting Standby mode, all registers in the \( V_{\text{CORE}} \) domain are set to their reset value. Registers outside the \( V_{\text{CORE}} \) domain (RTC, WKUP, IWDG, and Standby/Shutdown modes control) are not impacted.

When exiting Shutdown mode, a Brown-out reset is generated, resetting all registers except those in the Backup domain.

6.1.2 System reset

A system reset sets all registers to their reset values except the reset flags in the clock control/status register (RCC_CSR) and the registers in the Backup domain.

A system reset is generated when one of the following events occurs:

1. A low level on the NRST pin (external reset)
2. Window watchdog event (WWDG reset)
3. Independent watchdog event (IWDG reset)
4. A firewall event (FIREWALL reset)
5. A software reset (SW reset) (see Software reset)
6. Low-power mode security reset (see Low-power mode security reset)
7. Option byte loader reset (see Option byte loader reset)
8. A Brown-out reset

The reset source can be identified by checking the reset flags in the Control/Status register, RCC_CSR (see Section 6.4.30: Control/status register (RCC_CSR)).

These sources act on the NRST pin and it is always kept low during the delay phase. The RESET service routine vector is fixed at address 0x0000_0004 in the memory map.

The system reset signal provided to the device is output on the NRST pin. The pulse generator guarantees a minimum reset pulse duration of 20 µs for each internal reset source. In case of an external reset, the reset pulse is generated while the NRST pin is asserted low.

In case of an internal reset, the internal pull-up \( R_{\text{PU}} \) is deactivated in order to save the power consumption through the pull-up resistor.
Software reset

The SYSRESETREQ bit in Cortex®-M4 Application Interrupt and Reset Control Register must be set to force a software reset on the device (refer to the STM32F3, STM32F4, STM32L4 and STM32L4+ Series Cortex®-M4 (PM0214)).

Low-power mode security reset

To prevent that critical applications mistakenly enter a low-power mode, two low-power mode security resets are available. If enabled in option bytes, the resets are generated in the following conditions:

1. Entering Standby mode: this type of reset is enabled by resetting nRST_STDBY bit in User option Bytes. In this case, whenever a Standby mode entry sequence is successfully executed, the device is reset instead of entering Standby mode.
2. Entering Stop mode: this type of reset is enabled by resetting nRST_STOP bit in User option bytes. In this case, whenever a Stop mode entry sequence is successfully executed, the device is reset instead of entering Stop mode.
3. Entering Shutdown mode: this type of reset is enabled by resetting nRST_SHDW bit in User option bytes. In this case, whenever a Shutdown mode entry sequence is successfully executed, the device is reset instead of entering Shutdown mode.

For further information on the User Option Bytes, refer to Section 3.4.1: Option bytes description.

Option byte loader reset

The option byte loader reset is generated when the OBL_LAUNCH bit (bit 27) is set in the FLASH_CR register. This bit is used to launch the option byte loading by software.

6.1.3 Backup domain reset

The backup domain has two specific resets.

A backup domain reset is generated when one of the following events occurs:
1. Software reset, triggered by setting the BDRST bit in the *Backup domain control register (RCC_BDCR)*.

2. \( V_{DD} \) or \( V_{BAT} \) power on, if both supplies have previously been powered off.

A backup domain reset only affects the LSE oscillator, the RTC, the Backup registers and the RCC Backup domain control register.

### 6.2 Clocks

Four different clock sources can be used to drive the system clock (SYSCLK):

- HSI16 (high speed internal) 16 MHz RC oscillator clock
- MSI (multispeed internal) RC oscillator clock
- HSE oscillator clock, from 4 to 48 MHz
- PLL clock

The MSI is used as system clock source after startup from Reset, configured at 4 MHz.

The devices have the following additional clock sources:

- 32 kHz low speed internal RC (LSI RC) which drives the independent watchdog and optionally the RTC used for Auto-wake up from Stop and Standby modes.
- 32.768 kHz low speed external crystal (LSE crystal) which optionally drives the real-time clock (RTCCCLK).
- RC 48 MHz internal clock sources (HSI48) to potentially drive the USB FS, the SDMMC and the RNG.

Each clock source can be switched on or off independently when it is not used, to optimize power consumption.

Several prescalers can be used to configure the AHB frequency, the APB1 and APB2 domains. The maximum frequency of the AHB, the APB1 and the APB2 domains is 120 MHz.
All the peripheral clocks are derived from their bus clock (HCLK, PCLK1 or PCLK2) except:

- The 48 MHz clock, used for USB OTG FS, SDMMC and RNG. This clock is derived (selected by software) from one of the four following sources:
  - main PLL VCO (PLL48M1CLK)
  - PLLSAI1 VCO (PLL48M2CLK)
  - MSI clock
  - HSI48 internal oscillator

When the MSI clock is auto-trimmed with the LSE, it can be used by the USB OTG FS device.

When available, the HSI48 48 MHz clock can be coupled to the clock recovery system allowing adequate clock connection for the USB OTG FS (Crystal less solution).

- The ADCs clock which is derived (selected by software) from one of the following sources:
  - system clock (SYSCLK)
  - PLLSAI1 VCO (PLLADC1CLK)

- The U(S)ARTs clocks which are derived (selected by software) from one of the four following sources:
  - system clock (SYSCLK)
  - HSI16 clock
  - LSE clock
  - APB1 or APB2 clock (PCLK1 or PCLK2 depending on which APB is mapped the U(S)ART)

The wakeup from Stop mode is supported only when the clock is HSI16 or LSE.

- The I2Cs clocks which are derived (selected by software) from one of the three following sources:
  - system clock (SYSCLK)
  - HSI16 clock
  - APB1 clock (PCLK1)

The wakeup from Stop mode is supported only when the clock is HSI16.

- The SAI1 and SAI2 clocks which are derived (selected by software) from one of the following sources:
  - an external clock mapped on SAI1_EXTCLK for SAI1 and SAI2_EXTCLK for SAI2
  - PLLSAI1 VCO (PLLSAI1CLK)
  - PLLSAI2 VCO (PLLSAI2CLK)
  - main PLL VCO (PLLSAI3CLK)
  - HSI16 clock

- The DFSDM audio clock which is derived (selected by software) from one of the following sources:
  - SAI1 clock
  - HSI clock
  - MSI clock

- The LTDC clock. The LTDC clock is generated from a specific PLL (PLLSAI2).

- The DSI clock. To generate the DSI clocks, the high-speed external crystal (HSE) must be available.
- The DSI lanebyteclk clock: DSI Lane byte clock (high-speed clock divided by 8) which is output from the DSI-PHY or from a specific output of PLLSAI2 (frequency lower than 62.5 MHz) in the case when the DSI-PHY is off.
- The DSI host rxclksesc clock. The DSI RX escape mode clock is output from DSI-PHY (generated from DP0/DN0 even if the DSI-PHY is not clocked).
- The OctoSPI kernel clock which is derived (selected by software) from one of the following sources:
  - System clock,
  - PLL48M1CLK
  - MSI clock
- The low-power timers (LPTIMx) clock which are derived (selected by software) from one of the five following sources:
  - LSI clock
  - LSE clock
  - HSI16 clock
  - APB1 clock (PCLK1)
  - External clock mapped on LPTIMx_IN1
  The functionality in Stop mode (including wakeup) is supported only when the clock is LSI or LSE, or in external clock mode.
- The RTC clock which is derived (selected by software) from one of the three following sources:
  - LSE clock
  - LSI clock
  - HSE clock divided by 32
  The functionality in Stop mode (including wakeup) is supported only when the clock is LSI or LSE.
- The IWDG clock which is always the LSI clock.

The RCC feeds the Cortex® System Timer (SysTick) external clock with the AHB clock (HCLK) divided by 8. The SysTick can work either with this clock or directly with the Cortex® clock (HCLK), configurable in the SysTick Control and Status Register.

FCLK acts as Cortex®-M4 free-running clock. For more details refer to the STM32F3, STM32F4, STM32L4 and STM32L4+ Series Cortex®-M4 programming manual (PM0214).
Figure 16. Clock tree for STM32L4Rxxx and STM32L4Sxxx devices
1. For full details about the internal and external clock source characteristics, please refer to the “Electrical characteristics” section in your device datasheet.

2. The ADC clock can be derived from the AHB clock of the ADC bus interface, divided by a programmable factor (1, 2 or 4). When the programmable factor is ‘1’, the AHB prescaler must be equal to ‘1’.

Figure 17. DSI clock tree

DSI clock control bits (IDF, ODF, NDIV, TXECKDIV and TOCKDIV) are configured by DSIHOST registers.
Figure 18. Clock tree for STM32L4P5xx and STM32L4Q5xx devices

- **SYSCLK**: System clock
- **MCO**: Main clock output
- **LSE OSC**: 32.768 kHz oscillator
- **HSI16**: High-speed 16 MHz internal oscillator
- **HSE**: High-speed external oscillator
- **PLLSAI1**: PLL clock source
- **PLLSAI2**: PLL clock source
- **PLL48M1CLK**: PLL 48 MHz clock source
- **PLL48M2CLK**: PLL 48 MHz clock source

- **FCLK**: Cortex free running clock
- **HCLK**: AHB bus clock
- **PCLK1**: APB1 prescaler
- **PCLK2**: APB2 prescaler
- **AHB**: Advanced high-performance bus
- **APB**: Advanced peripheral bus
- **HSE**: High-speed external oscillator
- **LSI**: Low-speed internal oscillator
- **RTC**: Real-time clock
- **PWR**: Power management
- **IWDG**: Independent watchdog
- **USART**: Universal asynchronous receive/transmit
- **OCTOSPI**: Octospi
- **LTDC**: Low-resolution display controller
- **OCTOSPI**: Octospi
- **DFSDM**: Digital filter for sound processing

Clock sources and their relationships are shown in the diagram, including various PLL settings and prescaler configurations.
6.2.1 HSE clock

The high speed external clock signal (HSE) can be generated from two possible clock sources:

- HSE external crystal/ceramic resonator
- HSE user external clock

The resonator and the load capacitors have to be placed as close as possible to the oscillator pins in order to minimize output distortion and startup stabilization time. The loading capacitance values must be adjusted according to the selected oscillator.

**Figure 19. HSE/ LSE clock sources**

<td>External clock</td>
<td>![External clock diagram]</td>
</tr>
<tr>
<td>Crystal/Ceramic resonators</td>
<td>![Crystal/Ceramic resonators diagram]</td>
</tr>
</tbody>
</table>
External crystal/ceramic resonator (HSE crystal)

The 4 to 48 MHz external oscillator has the advantage of producing a very accurate rate on the main clock.

The associated hardware configuration is shown in Figure 19. Refer to the electrical characteristics section of the datasheet for more details.

The HSERDY flag in the Clock control register (RCC_CR) indicates if the HSE oscillator is stable or not. At startup, the clock is not released until this bit is set by hardware. An interrupt can be generated if enabled in the Clock interrupt enable register (RCC_CIER).

The HSE Crystal can be switched on and off using the HSEON bit in the Clock control register (RCC_CR).

External source (HSE bypass)

In this mode, an external clock source must be provided. It can have a frequency of up to 48 MHz. You select this mode by setting the HSEBYP and HSEON bits in the Clock control register (RCC_CR). The external clock signal (square, sinus or triangle) with ~40-60 % duty cycle depending on the frequency (refer to the datasheet) has to drive the OSC_IN pin while the OSC_OUT pin can be used a GPIO. See Figure 19.

6.2.2 HSI16 clock

The HSI16 clock signal is generated from an internal 16 MHz RC Oscillator.

The HSI16 RC oscillator has the advantage of providing a clock source at low cost (no external components). It also has a faster startup time than the HSE crystal oscillator however, even with calibration the frequency is less accurate than an external crystal oscillator or ceramic resonator.

The HSI16 clock can be selected as system clock after wakeup from Stop modes (Stop 0, Stop 1 or Stop 2). Refer to Section 6.3: Low-power modes. It can also be used as a backup clock source (auxiliary clock) if the HSE crystal oscillator fails. Refer to Section 6.2.10: Clock security system (CSS).

Calibration

RC oscillator frequencies can vary from one chip to another due to manufacturing process variations, this is why each device is factory calibrated by ST for 1 % accuracy at TA=25°C.

After reset, the factory calibration value is loaded in the HSICAL[7:0] bits in the Internal clock sources calibration register (RCC_ICSCR).

If the application is subject to voltage or temperature variations this may affect the RC oscillator speed. You can trim the HSI16 frequency in the application using the HSITRIM[6:0] in the Internal clock sources calibration register (RCC_ICSCR).

For more details on how to measure the HSI16 frequency variation, refer to Section 6.2.17: Internal/external clock measurement with TIM15/TIM16/TIM17.

The HSIRDY flag in the Clock control register (RCC_CR) indicates if the HSI16 RC is stable or not. At startup, the HSI16 RC output clock is not released until this bit is set by hardware.

The HSI16 RC can be switched on and off using the HSION bit in the Clock control register (RCC_CR).
The HSI16 signal can also be used as a backup source (Auxiliary clock) if the HSE crystal oscillator fails. Refer to Section 6.2.10: Clock security system (CSS) on page 252.

### 6.2.3 MSI clock

The MSI clock signal is generated from an internal RC oscillator. Its frequency range can be adjusted by software using the MSIRANGE[3:0] bits in the Clock control register (RCC_CR). Twelve frequency ranges are available: 100 kHz, 200 kHz, 400 kHz, 800 kHz, 1 MHz, 2 MHz, 4 MHz (default value), 8 MHz, 16 MHz, 24 MHz, 32 MHz and 48 MHz.

The MSI clock is used as system clock after restart from Reset, wake-up from Standby and Shutdown low-power modes. After restart from Reset, the MSI frequency is set to its default value 4 MHz. Refer to Section 6.3: Low-power modes.

The MSI clock can be selected as system clock after a wake-up from Stop mode (Stop 0, Stop 1 or Stop 2). Refer to Section 6.3: Low-power modes. It can also be used as a backup clock source (auxiliary clock) if the HSE crystal oscillator fails. Refer to Section 6.2.10: Clock security system (CSS).

The MSI RC oscillator has the advantage of providing a low-cost (no external components) low-power clock source. In addition, when used in PLL-mode with the LSE, it provides a very accurate clock source which can be used by the USB OTG FS device, and feed the main PLL to run the system at the maximum speed.

The MSIRDY flag in the Clock control register (RCC_CR) indicates whether the MSI RC is stable or not. At startup, the MSI RC output clock is not released until this bit is set by hardware. The MSI RC can be switched on and off by using the MSION bit in the Clock control register (RCC_CR).

#### Hardware auto calibration with LSE (PLL-mode)

When a 32.768 kHz external oscillator is present in the application, it is possible to configure the MSI in a PLL-mode by setting the MSIPLLLEN bit in the Clock control register (RCC_CR). When configured in PLL-mode, the MSI automatically calibrates itself thanks to the LSE. This mode is available for all MSI frequency ranges. At 48 MHz, the MSI in PLL-mode can be used for the USB OTG FS device, saving the need of an external high-speed crystal.

#### Software calibration

The MSI RC oscillator frequency can vary from one chip to another due to manufacturing process variations, this is why each device is factory calibrated by ST for 1% accuracy at an ambient temperature, TA, of 25 °C. After reset, the factory calibration value is loaded in the MSICAL[7:0] bits in the Internal clock sources calibration register (RCC_ICSCR). If the application is subject to voltage or temperature variations, this may affect the RC oscillator speed. You can trim the MSI frequency in the application by using the MSITRIM[7:0] bits in the RCC_ICSCR register. For more details on how to measure the MSI frequency variation please refer to Section 6.2.17: Internal/external clock measurement with TIM15/TIM16/TIM17.

### 6.2.4 HSI48 clock

The HSI48 clock signal is generated from an internal 48 MHz RC oscillator and can be used directly for USB and for random number generator (RNG) as well as SDMMC.

The internal 48 MHz RC oscillator is mainly dedicated to provide a high precision clock to the USB peripheral by means of a special Clock Recovery System (CRS) circuitry. The CRS
can use the USB SOF signal, the LSE or an external signal to automatically and quickly adjust the oscillator frequency on-fly. It is disabled as soon as the system enters Stop or Standby mode. When the CRS is not used, the HSI48 RC oscillator runs on its default frequency which is subject to manufacturing process variations.

For more details on how to configure and use the CRS peripheral please refer to Section 7: Clock recovery system (CRS).

The HSI48RDY flag in the Clock recovery RC register (RCC_CRRCR) indicates whether the HSI48 RC oscillator is stable or not. At startup, the HSI48 RC oscillator output clock is not released until this bit is set by hardware.

The HSI48 can be switched on and off using the HSI48ON bit in the Clock recovery RC register (RCC_CRRCR).

### 6.2.5 PLL

The device embeds 3 PLLs: PLL, PLLSAI1, PLLSAI2. Each PLL provides up to three independent outputs. The internal PLLs can be used to multiply the HSI16, HSE or MSI output clock frequency. The PLLs input frequency must be between 4 and 16 MHz. The selected clock source is divided by a programmable factor PLLM from 1 to 8 to provide a clock frequency in the requested input range. Refer to Figure 16: Clock tree for STM32L4Rxxx and STM32L4Sxxx devices and PLL configuration register (RCC_PLLCFGR).

The PLLs configuration (selection of the input clock and multiplication factor) must be done before enabling the PLL. Once the PLL is enabled, these parameters cannot be changed.

To modify the PLL configuration, proceed as follows:

1. Disable the PLL by setting PLLON to 0 in Clock control register (RCC_CR).
2. Wait until PLLRDY is cleared. The PLL is now fully stopped.
3. Change the desired parameter.
4. Enable the PLL again by setting PLLON to 1.
5. Enable the desired PLL outputs by configuring PLLPEN, PLLQEN, PLLREN in PLL configuration register (RCC_PLLCFGR).

An interrupt can be generated when the PLL is ready, if enabled in the Clock interrupt enable register (RCC_CIER).

The same procedure is applied for changing the configuration of the PLLSAI1 or PLLSAI2:

1. Disable the PLLSAI1/PLLSAI2 by setting PLLSAI1ON/PLLSAI2ON to 0 in Clock control register (RCC_CR).
2. Wait until PLLSAI1RDY/PLLSAI2RDY is cleared. The PLLSAI1/PLLSAI2 is now fully stopped.
3. Change the desired parameter.
4. Enable the PLLSAI1/PLLSAI2 again by setting PLLSAI1ON/PLLSAI2ON to 1.
5. Enable the desired PLL outputs by configuring PLLSAI1PEN/PLLSAI2PEN, PLLSAI1QEN/PLLSAI2QEN, PLLSAI1REN/PLLSAI2REN in PLLSAI1 configuration register (RCC_PLLSAI1CFGR) and PLLSAI2 configuration register (RCC_PLLSAI2CFGR).

The PLL output frequency must not exceed 120 MHz.
The enable bit of each PLL output clock (PLLPEN, PLLQEN, PLLREN, PLLSAI1PEN, PLLSAI1QEN, PLLSAI1REN, PLLSAI2PEN and PLLSAI2REN) can be modified at any time without stopping the corresponding PLL. PLLREN cannot be cleared if PLLCLK is used as system clock.

6.2.6 LSE clock

The LSE crystal is a 32.768 kHz Low Speed External crystal or ceramic resonator. It has the advantage of providing a low-power but highly accurate clock source to the real-time clock peripheral (RTC) for clock/calendar or other timing functions.

The LSE crystal is switched on and off using the LSEON bit in Backup domain control register (RCC_BDCR). The crystal oscillator driving strength can be changed at runtime using the LSEDRV[1:0] bits in the Backup domain control register (RCC_BDCR) to obtain the best compromise between robustness and short start-up time on one side and low-power-consumption on the other side. The LSE drive can be decreased to the lower drive capability (LSEDRV=00) when the LSE is ON. However, once LSEDRV is selected, the drive capability cannot be increased if LSEON=1.

The LSERDY flag in the Backup domain control register (RCC_BDCR) indicates whether the LSE crystal is stable or not. At startup, the LSE crystal output clock signal is not released until this bit is set by hardware. An interrupt can be generated if enabled in the Clock interrupt enable register (RCC_CIER).

Distribution of the external 32 kHz clock (LSE) outside the RTC block could be disabled by setting LSESYSDIS bit in Backup domain control register (RCC_BDCR) to reduce power consumption. Propagation is stopped regardless the use of LSE by other peripherals. This feature is present only on STM32L4P5xx and STM32L4Q5xx devices.

External source (LSE bypass)

In this mode, an external clock source must be provided. It can have a frequency of up to 1 MHz. You select this mode by setting the LSEBYP and LSEON bits in the AHB1 peripheral clocks enable in Sleep and Stop modes register (RCC_AHB1SMENR). The external clock signal (square, sinus or triangle) with ~50 % duty cycle has to drive the OSC32_IN pin while the OSC32_OUT pin can be used as GPIO. See Figure 19.

6.2.7 LSI clock

The LSI RC acts as a low-power clock source that can be kept running in Stop and Standby mode for the independent watchdog (IWDG) RTC. The clock frequency is 32 kHz. For more details, refer to the electrical characteristics section of the datasheets.

The LSI RC can be switched on and off using the LSION bit in the Control/status register (RCC_CSR).

The LSIRDY flag in the Control/status register (RCC_CSR) indicates if the LSI oscillator is stable or not. At startup, the clock is not released until this bit is set by hardware. An interrupt can be generated if enabled in the Clock interrupt enable register (RCC_CIER).
6.2.8 System clock (SYSCLK) selection

Four different clock sources can be used to drive the system clock (SYSCLK):
- MSI oscillator
- HSI16 oscillator
- HSE oscillator
- PLL

The system clock maximum frequency is 120 MHz. After a system reset, the MSI oscillator, at 4 MHz, is selected as system clock. When a clock source is used directly or through the PLL as a system clock, it is not possible to stop it.

A switch from one clock source to another occurs only if the target clock source is ready (clock stable after startup delay or PLL locked). If a clock source which is not yet ready is selected, the switch will occur when the clock source becomes ready. Status bits in the \textit{internal clock sources calibration register (RCC\_ICSCR)} indicate which clock(s) is (are) ready and which clock is currently used as a system clock.

To switch from low speed to high speed or from high speed to low speed system clock, it is recommended to use a transition state with medium speed clock, for at least 1us.

Clock source switching conditions:
- Switching from HSE or HSI or MSI to PLL with AHB frequency (HCLK) higher than 80 MHz
- Switching from PLL with HCLK higher than 80 MHz to HSE or HSI or MSI

Transition state:
- Set the AHB prescaler HPRE[3:0] bits to divide the system frequency by 2
- Switch system clock to PLL
- Wait for at least 1us and then reconfigure AHB prescaler bits to the needed HCLK frequency

6.2.9 Clock source frequency versus voltage scaling

The following table gives the different clock source frequencies depending on the product voltage range.

6.2.10 Clock security system (CSS)

Clock Security System can be activated by software. In this case, the clock detector is enabled after the HSE oscillator startup delay, and disabled when this oscillator is stopped.

If a failure is detected on the HSE clock, the HSE oscillator is automatically disabled, a clock failure event is sent to the break input of the advanced-control timers (TIM1/TIM8 and TIM15/16/17) and an interrupt is generated to inform the software about the failure (Clock Security System Interrupt CSSI), allowing the MCU to perform rescue operations. The CSSI is linked to the Cortex®-M4 NMI (Non-Maskable Interrupt) exception vector.

*Note:* Once the CSS is enabled and if the HSE clock fails, the CSS interrupt occurs and a NMI is automatically generated. The NMI will be executed indefinitely unless the CSS interrupt pending bit is cleared. As a consequence, in the NMI ISR user must clear the CSS interrupt by setting the CSSC bit in the Clock interrupt clear register (RCC_CICR).

If the HSE oscillator is used directly or indirectly as the system clock (indirectly means: it is used as PLL input clock, and the PLL clock is used as system clock), a detected failure causes a switch of the system clock to the MSI or the HSI16 oscillator depending on the STOPWUCK configuration in the Clock configuration register (RCC_CFGR), and the disabling of the HSE oscillator. If the HSE clock (divided or not) is the clock entry of the PLL used as system clock when the failure occurs, the PLL is disabled too.

6.2.11 Clock security system on LSE

A Clock Security System on LSE can be activated by software writing the LSECSSON bit in the Backup domain control register (RCC_BDCR). This bit can be disabled only by a hardware reset or RTC software reset, or after a failure detection on LSE. LSECSSON must be written after LSE and LSI are enabled (LSEON and LSION enabled) and ready (LSERDY and LSIRDY set by hardware), and after the RTC clock has been selected by RTCSEL and LSIPREDIV is disabled.

*Note:* LSIPREDIV bit is available only on STM32L4P5xx and STM32L4Q5xx devices.

The CSS on LSE is working in all modes except VBAT. It is working also under system reset (excluding power on reset). If a failure is detected on the external 32 kHz oscillator, the LSE clock is no longer supplied to the RTC but no hardware action is made to the registers. If the MSI was in PLL-mode, this mode is disabled.

In Standby mode a wakeup is generated. In other modes an interrupt can be sent to wakeup the software (see Clock interrupt enable register (RCC_CIER), Clock interrupt flag register (RCC_CIFR), Clock interrupt clear register (RCC_CICR)).

The software MUST then disable the LSECSSON bit, stop the defective 32 kHz oscillator (disabling LSEON), and change the RTC clock source (no clock or LSI or HSE, with RTCSEL), or take any required action to secure the application.

The frequency of LSE oscillator have to be higher than 30 kHz to avoid false positive CSS detection.
6.2.12 ADC clock

The ADC clock is derived from the system clock, or from the PLLSAI1 output. It can reach 120 MHz and can be divided by the following prescalers values: 1, 2, 4, 6, 8, 10, 12, 16, 32, 64, 128 or 256 by configuring the ADC1_CCR register. It is asynchronous to the AHB clock. Alternatively, the ADC clock can be derived from the AHB clock of the ADC bus interface, divided by a programmable factor (1, 2 or 4). This programmable factor is configured using the CKMODE bit fields in the ADC123_CCR.

If the programmed factor is ‘1’, the AHB prescaler must be set to ‘1’.

6.2.13 RTC clock

The RTCCCLK clock source can be either the HSE/32, LSE or LSI clock. It is selected by programming the RTCSEL[1:0] bits in the Backup domain control register (RCC_BDCR). This selection cannot be modified without resetting the Backup domain. The system must always be configured so as to get a PCLK frequency greater than or equal to the RTCCCLK frequency for a proper operation of the RTC.

The LSE clock is in the Backup domain, whereas the HSE and LSI clocks are not. Consequently:

- If LSE is selected as RTC clock:
  - The RTC continues to work even if the VDD supply is switched off, provided the VBAT supply is maintained.
- If LSI is selected as the RTC clock:
  - The RTC state is not guaranteed if the VDD supply is powered off.
- If the HSE clock divided by a prescaler is used as the RTC clock:
  - The RTC state is not guaranteed if the VDD supply is powered off or if the internal voltage regulator is powered off (removing power from the VCORE domain).

When the RTC clock is LSE or LSI, the RTC remains clocked and functional under system reset.

6.2.14 Timer clock

The timer clock frequencies are automatically defined by hardware. There are two cases:

1. If the APB prescaler equals 1, the timer clock frequencies are set to the same frequency as that of the APB domain.
2. Otherwise, they are set to twice (×2) the frequency of the APB domain.

6.2.15 Watchdog clock

If the Independent watchdog (IWDG) is started by either hardware option or software access, the LSI oscillator is forced ON and cannot be disabled. After the LSI oscillator temporization, the clock is provided to the IWDG.
6.2.16 Clock-out capability

- **MCO**
  The microcontroller clock output (MCO) capability allows the clock to be output onto the external MCO pin. One of eight clock signals can be selected as the MCO clock.
  - LSI
  - LSE
  - SYSCLK
  - HSI16
  - HSI48
  - HSE
  - PLLCLK
  - MSI
  The selection is controlled by the MCOSEL[3:0] bits of the *Clock configuration register (RCC_CFR)*. The selected clock can be divided with the MCOPRE[2:0] field of the *Clock configuration register (RCC_CFR)*.

- **LSCO**
  Another output (LSCO) allows a low speed clock to be output onto the external LSCO pin:
  - LSI
  - LSE
  This output remains available in Stop (Stop 0, Stop 1 and Stop 2) and Standby modes. The selection is controlled by the LSCOSEL, and enabled with the LSCOEN in the *Backup domain control register (RCC_BDCR)*.

The MCO clock output requires the corresponding alternate function selected on the MCO pin, the LSCO pin should be left in default POR state.

6.2.17 Internal/external clock measurement with TIM15/TIM16/TIM17

It is possible to indirectly measure the frequency of all on-board clock sources by mean of the TIM15, TIM16 or TIM17 channel 1 input capture, as represented on *Figure 20, Figure 21* and *Figure 22*.

![Figure 20. Frequency measurement with TIM15 in capture mode](image-url)
The input capture channel of the Timer 15 can be a GPIO line or an internal clock of the MCU. This selection is performed through the TI1_RMP bit in the TIM15_OR register. The possibilities are the following ones:

- TIM15 Channel1 is connected to the GPIO. Refer to the alternate function mapping in the device datasheets.
- TIM15 Channel1 is connected to the LSE.

Figure 21. Frequency measurement with TIM16 in capture mode

The input capture channel of the Timer 16 can be a GPIO line or an internal clock of the MCU. This selection is performed through the TI1_RMP[1:0] bits in the TIM16_OR register. The possibilities are the following ones:

- TIM16 Channel1 is connected to the GPIO. Refer to the alternate function mapping in the device datasheets.
- TIM16 Channel1 is connected to the LSI clock.
- TIM16 Channel1 is connected to the LSE clock.
- TIM16 Channel1 is connected to the RTC wakeup interrupt signal. In this case the RTC interrupt should be enabled.
- TIM16 Channel1 is connected to the MSI clock.
- TIM16 Channel1 is connected to the HSE/32 clock.
- TIM16 Channel1 is connected to the MCO clock.

Figure 22. Frequency measurement with TIM17 in capture mode
The input capture channel of the Timer 17 can be a GPIO line or an internal clock of the MCU. This selection is performed through the TI1_RMP[1:0] bits in the TIM17_OR register. The possibilities are the following ones:

- TIM17 Channel1 is connected to the GPIO. Refer to the alternate function mapping in the device datasheets.
- TIM17 Channel1 is connected to the MSI Clock.
- TIM17 Channel1 is connected to the HSE/32 Clock.
- TIM17 Channel1 is connected to the microcontroller clock output (MCO), this selection is controlled by the MCOSEL[3:0] bits of the Clock configuration register (RCC_CFGGR).

**Calibration of the HSI16 and the MSI**

For TIM15 and TIM16, the primary purpose of connecting the LSE to the channel 1 input capture is to be able to precisely measure the HSI16 and MSI system clocks (for this, either the HSI16 or MSI should be used as the system clock source). The number of HSI16 (MSI, respectively) clock counts between consecutive edges of the LSE signal provides a measure of the internal clock period. Taking advantage of the high precision of LSE crystals (typically a few tens of ppm's), it is possible to determine the internal clock frequency with the same resolution, and trim the source to compensate for manufacturing, process, temperature and/or voltage related frequency deviations.

The MSI and HSI16 oscillator both have dedicated user-accessible calibration bits for this purpose.

The basic concept consists in providing a relative measurement (e.g. the HSI16/LSE ratio): the precision is therefore closely related to the ratio between the two clock sources. The higher the ratio is, the better the measurement will be.

If LSE is not available, HSE/32 will be the better option in order to reach the most precise calibration possible.

It is however not possible to have a good enough resolution when the MSI clock is low (typically below 1 MHz). In this case, it is advised to:

- accumulate the results of several captures in a row
- use the timer’s input capture prescaler (up to 1 capture every 8 periods)
- use the RTC wakeup interrupt signal (when the RTC is clocked by the LSE) as the input for the channel1 input capture. This improves the measurement precision. For this purpose the RTC wakeup interrupt must be enable.

**Calibration of the LSI**

The calibration of the LSI will follow the same pattern that for the HSI16, but changing the reference clock. It will be necessary to connect LSI clock to the channel 1 input capture of the TIM16. Then define the HSE as system clock source, the number of his clock counts between consecutive edges of the LSI signal provides a measure of the internal low speed clock period.

The basic concept consists in providing a relative measurement (e.g. the HSE/LSI ratio): the precision is therefore closely related to the ratio between the two clock sources. The higher the ratio is, the better the measurement will be.
6.2.18 Peripheral clock enable register  
(RCC_AHBxENR, RCC_APBxENRy)

Each peripheral clock can be enabled by the xxxxEN bit of the RCC_AHBxENR, 
RCC_APBxENRy registers.

When the peripheral clock is not active, the peripheral registers read or write accesses are 
not supported.

The enable bit has a synchronization mechanism to create a glitch free clock for the 
peripheral. After the enable bit is set, there is a 2 clock cycles delay before the clock be 
active.

Caution: Just after enabling the clock for a peripheral, software must wait for a delay before 
accessing the peripheral registers.

6.3 Low-power modes

• AHB and APB peripheral clocks, including DMA clock, can be disabled by software.
• Sleep and Low Power Sleep modes stops the CPU clock. The memory interface clocks 
  (Flash, SRAM1, SRAM2 and SRAM3 interfaces) can be stopped by software during 
sleep mode. The AHB to APB bridge clocks are disabled by hardware during Sleep 
mode when all the clocks of the peripherals connected to them are disabled.
• Stop modes (Stop 0, Stop 1 and Stop 2) stops all the clocks in the V_CORE domain and 
disables the three PLL, the HSI16, the MSI and the HSE oscillators. 
  All U(S)ARTs, LPUARTs and I²Cs have the capability to enable the HSI16 oscillator 
even when the MCU is in Stop mode (if HSI16 is selected as the clock source for that 
peripheral).
  All U(S)ARTs and LPUARTs can also be driven by the LSE oscillator when the system 
is in Stop mode (if LSE is selected as clock source for that peripheral) and the LSE 
oscillator is enabled (LSEON). In that case the LSE remains always ON in Stop mode 
they do not have the capability to turn on the LSE oscillator).
• Standby and Shutdown modes stops all the clocks in the V_CORE domain and disables 
the PLL, the HSI16, the MSI and the HSE oscillators.

The CPU’s deepsleep mode can be overridden for debugging by setting the DBG_STOP or 
DBG_STANDBY bits in the DBGMCU_CR register.

When leaving the Stop modes (Stop 0, Stop 1 or Stop 2), the system clock is either MSI or 
HSI16, depending on the software configuration of the STOPWUCK bit in the RCC_CFGR 
register. The frequency (range and user trim) of the MSI oscillator is the one configured 
before entering Stop mode. The user trim of HSI16 is kept. If the MSI was in PLL-mode 
before entering Stop mode, the PLL-mode stabilization time must be waited for after wakeup 
even if the LSE was kept ON during the Stop mode.

When leaving the Standby and Shutdown modes, the system clock is MSI. The MSI 
frequency at wakeup from Standby mode is configured with the MSISRANGE is the 
RCC_CSR register, from 1 to 8 MHz. The MSI frequency at wakeup from Shutdown mode is 
4 MHz. The user trim is lost.

If a Flash memory programming operation is on going, Stop, Standby and Shutdown modes 
entry is delayed until the Flash memory interface access is finished. If an access to the APB 
domain is ongoing, Stop, Standby and Shutdown modes entry is delayed until the APB 
access is finished.
6.4 RCC registers

6.4.1 Clock control register (RCC_CR)

Address offset: 0x00

Reset value: 0x0000 0063. HSEBYP is not affected by reset.

Access: no wait state, word, half-word and byte access

| Bit 31:30 | Reset, must be kept at reset value. |
| Bit 29   | PLLSAI2RDY: SAI2 PLL clock ready flag |
| Bit 28   | PLLSAI2ON: SAI2 PLL enable |
| Bit 27   | PLLSAI1RDY: SAI1 PLL clock ready flag |
| Bit 26   | PLLSAI1ON: SAI1 PLL enable |
| Bit 25   | PLLRDY: Main PLL clock ready flag |
| Bit 24   | PLLON: Main PLL enable |
| Bits 23:20 | Reserved, must be kept at reset value. |

### Clock Control Register (RCC_CR)

| Bit 31:30 | Reserved, must be kept at reset value. |
| Bit 29   | PLLSAI2RDY: SAI2 PLL clock ready flag |
| Bit 28   | PLLSAI2ON: SAI2 PLL enable |
| Bit 27   | PLLSAI1RDY: SAI1 PLL clock ready flag |
| Bit 26   | PLLSAI1ON: SAI1 PLL enable |
| Bit 25   | PLLRDY: Main PLL clock ready flag |
| Bit 24   | PLLON: Main PLL enable |
| Bits 23:20 | Reserved, must be kept at reset value. |
Bit 19  **CSSON**: Clock security system enable
Set by software to enable the clock security system. When CSSON is set, the clock detector is enabled by hardware when the HSE oscillator is ready, and disabled by hardware if a HSE clock failure is detected. This bit is set only and is cleared by reset.
0: Clock security system OFF (clock detector OFF)
1: Clock security system ON (Clock detector ON if the HSE oscillator is stable, OFF if not).

Bit 18  **HSEBYP**: HSE crystal oscillator bypass
Set and cleared by software to bypass the oscillator with an external clock. The external clock must be enabled with the HSEON bit set, to be used by the device. The HSEBYP bit can be written only if the HSE oscillator is disabled.
0: HSE crystal oscillator not bypassed
1: HSE crystal oscillator bypassed with external clock

Bit 17  **HSERDY**: HSE clock ready flag
Set by hardware to indicate that the HSE oscillator is stable.
0: HSE oscillator not ready
1: HSE oscillator ready

*Note: Once the HSEON bit is cleared, HSERDY goes low after 6 HSE clock cycles.*

Bit 16  **HSEON**: HSE clock enable
Set and cleared by software.
Cleared by hardware to stop the HSE oscillator when entering Stop, Standby or Shutdown mode. This bit cannot be reset if the HSE oscillator is used directly or indirectly as the system clock.
0: HSE oscillator OFF
1: HSE oscillator ON

Bits 15:12 Reserved, must be kept at reset value.

Bit 11  **HSIASFS**: HSI16 automatic start from Stop
Set and cleared by software. When the system wakeup clock is MSI, this bit is used to wakeup the HSI16 is parallel of the system wakeup.
0: HSI16 oscillator is not enabled by hardware when exiting Stop mode with MSI as wakeup clock.
1: HSI16 oscillator is enabled by hardware when exiting Stop mode with MSI as wakeup clock.

Bit 10  **HSIRDY**: HSI16 clock ready flag
Set by hardware to indicate that HSI16 oscillator is stable. This bit is set only when HSI16 is enabled by software by setting HSION.
0: HSI16 oscillator not ready
1: HSI16 oscillator ready

*Note: Once the HSION bit is cleared, HSIRDY goes low after 6 HSI16 clock cycles.*

Bit 9  **HSIKERON**: HSI16 always enable for peripheral kernels.
Set and cleared by software to force HSI16 ON even in Stop modes. The HSI16 can only feed USARTs and I2Cs peripherals configured with HSI16 as kernel clock. Keeping the HSI16 ON in Stop mode allows to avoid slowing down the communication speed because of the HSI16 startup time. This bit has no effect on HSION value.
0: No effect on HSI16 oscillator.
1: HSI16 oscillator is forced ON even in Stop mode.
Bit 8 **HSION**: HSI16 clock enable
Set and cleared by software.
Cleared by hardware to stop the HSI16 oscillator when entering Stop, Standby or Shutdown mode.
Set by hardware to force the HSI16 oscillator ON when STOPWUCK=1 or HSIASFS = 1 when leaving Stop modes, or in case of failure of the HSE crystal oscillator.
This bit is set by hardware if the HSI16 is used directly or indirectly as system clock.
0: HSI16 oscillator OFF
1: HSI16 oscillator ON

Bits 7:4 **MSIRANGE[3:0]**: MSI clock ranges
These bits are configured by software to choose the frequency range of MSI when MSIRGSEL is set. 12 frequency ranges are available:
0000: range 0 around 100 kHz
0001: range 1 around 200 kHz
0010: range 2 around 400 kHz
0011: range 3 around 800 kHz
0100: range 4 around 1M Hz
0101: range 5 around 2 MHz
0110: range 6 around 4 MHz (reset value)
0111: range 7 around 8 MHz
1000: range 8 around 16 MHz
1001: range 9 around 24 MHz
1010: range 10 around 32 MHz
1011: range 11 around 48 MHz
others: not allowed (hardware write protection)

Note: Warning: MSIRANGE can be modified when MSI is OFF (MSION=0) or when MSI is ready (MSIRDY=1). MSIRANGE must NOT be modified when MSI is ON and NOT ready (MSION=1 and MSIRDY=0)

Bit 3 **MSIRGSEL**: MSI clock range selection
Set by software to select the MSI clock range with MSIRANGE[3:0]. Write 0 has no effect.
After a standby or a reset MSIRGSEL is at 0 and the MSI range value is provided by MSISRANGE in CSR register.
0: MSI Range is provided by MSISRANGE[3:0] in RCC_CSR register
1: MSI Range is provided by MSIRANGE[3:0] in the RCC_CR register

Bit 2 **MSIPLLEN**: MSI clock PLL enable
Set and cleared by software to enable/disable the PLL part of the MSI clock source.
MSIPLLEN must be enabled after LSE is enabled (LSEON enabled) and ready (LSERDY set by hardware). There is a hardware protection to avoid enabling MSIPLLEN if LSE is not ready.
This bit is cleared by hardware when LSE is disabled (LSEON = 0) or when the Clock Security System on LSE detects a LSE failure (refer to RCC_CSR register).
0: MSI PLL OFF
1: MSI PLL ON

Bit 1 **MSIRDY**: MSI clock ready flag
This bit is set by hardware to indicate that the MSI oscillator is stable.
0: MSI oscillator not ready
1: MSI oscillator ready

Note: Once the MSION bit is cleared, MSIRDY goes low after 6 MSI clock cycles.
Bit 0 **MSION**: MSI clock enable

This bit is set and cleared by software.

Cleared by hardware to stop the MSI oscillator when entering Stop, Standby or Shutdown mode.

Set by hardware to force the MSI oscillator ON when exiting Standby or Shutdown mode.

Set by hardware to force the MSI oscillator ON when STOPWUCK=0 when exiting from Stop modes, or in case of a failure of the HSE oscillator.

Set by hardware when used directly or indirectly as system clock.

0: MSI oscillator OFF
1: MSI oscillator ON

### 6.4.2 Internal clock sources calibration register (RCC_ICSCR)

Address offset: 0x04

Reset value: 0x40XX 00XX where X is factory-programmed.

Access: no wait state, word, half-word and byte access.

### 6.4.3 Clock configuration register (RCC_CFRG)

Address offset: 0x08

Reset value: 0x0000 0000
Reset and clock control (RCC)

Access: $0 \leq \text{wait state} \leq 2$, word, half-word and byte access

1 or 2 wait states inserted only if the access occurs during clock source switch.

From 0 to 15 wait states inserted if the access occurs when the APB or AHB prescalers values update is on going.

| Bit 14 | Reserved, must be kept at reset value. |
Bits 13:11 **PPRE2[2:0]**: APB high-speed prescaler (APB2)
Set and cleared by software to control the division factor of the APB2 clock (PCLK2).
- 0xx: HCLK not divided
- 100: HCLK divided by 2
- 101: HCLK divided by 4
- 110: HCLK divided by 8
- 111: HCLK divided by 16

Bits 10:8 **PPRE1[2:0]**: APB low-speed prescaler (APB1)
Set and cleared by software to control the division factor of the APB1 clock (PCLK1).
- 0xx: HCLK not divided
- 100: HCLK divided by 2
- 101: HCLK divided by 4
- 110: HCLK divided by 8
- 111: HCLK divided by 16

Bits 7:4 **HPRE[3:0]**: AHB prescaler
Set and cleared by software to control the division factor of the AHB clock.

**Caution:** Depending on the device voltage range, the software has to set correctly these bits to ensure that the system frequency does not exceed the maximum allowed frequency (for more details please refer to *Section 5.1.8: Dynamic voltage scaling management*). After a write operation to these bits and before decreasing the voltage range, this register must be read to be sure that the new value has been taken into account.
- 0xxx: SYSCLK not divided
- 1000: SYSCLK divided by 2
- 1001: SYSCLK divided by 4
- 1010: SYSCLK divided by 8
- 1011: SYSCLK divided by 16
- 1100: SYSCLK divided by 64
- 1101: SYSCLK divided by 128
- 1110: SYSCLK divided by 256
- 1111: SYSCLK divided by 512

Bits 3:2 **SWS[1:0]**: System clock switch status
Set and cleared by hardware to indicate which clock source is used as system clock.
- 00: MSI oscillator used as system clock
- 01: HSI16 oscillator used as system clock
- 10: HSE used as system clock
- 11: PLL used as system clock

Bits 1:0 **SW[1:0]**: System clock switch
Set and cleared by software to select system clock source (SYSCLK).
Configured by HW to force MSI oscillator selection when exiting Standby or Shutdown mode.
Configured by HW to force MSI or HSI16 oscillator selection when exiting Stop mode or in case of failure of the HSE oscillator, depending on STOPWUCK value.
- 00: MSI selected as system clock
- 01: HSI16 selected as system clock
- 10: HSE selected as system clock
- 11: PLL selected as system clock
### 6.4.4 PLL configuration register (RCC_PLLCFGR)

Address offset: 0x0C  
Reset value: 0x0000 1000  
Access: no wait state, word, half-word and byte access

This register is used to configure the PLL clock outputs according to the formulas:

- \( f(\text{VCO clock}) \) = \( f(\text{PLL clock input}) \times (\text{PLLN} / \text{PLLM}) \)
- \( f(\text{PLL}_P) \) = \( f(\text{VCO clock}) / \text{PLLP} \)
- \( f(\text{PLL}_Q) \) = \( f(\text{VCO clock}) / \text{PLLQ} \)
- \( f(\text{PLL}_R) \) = \( f(\text{VCO clock}) / \text{PLLR} \)

Bits 31:27 PLLPDIV[4:0]: Main PLLP division factor for PLLSAI3CLK  
Set and cleared by software to control the SAI1 or SAI2 clock frequency. PLLSAI3CLK output clock frequency = VCO frequency / PLLPDIV.  
00000: PLLSAI3CLK is controlled by the bit PLLP  
00001: Reserved.  
00010: PLLSAI3CLK = VCO / 2  
....  
11111: PLLSAI3CLK = VCO / 31

Bits 26:25 PLLR[1:0]: Main PLL division factor for PLLCLK (system clock)  
Set and cleared by software to control the frequency of the main PLL output clock PLLCLK. This output can be selected as system clock. These bits can be written only if PLL is disabled.  
PLLCLK output clock frequency = VCO frequency / PLLR with PLLR = 2, 4, 6, or 8  
00: PLLR = 2  
01: PLLR = 4  
10: PLLR = 6  
11: PLLR = 8

**Caution:** The software has to set these bits correctly not to exceed 120 MHz on this domain.

Bit 24 PLLREN: Main PLL PLLCLK output enable  
Set and reset by software to enable the PLLCLK output of the main PLL (used as system clock). This bit cannot be written when PLLCLK output of the PLL is used as System Clock. In order to save power, when the PLLCLK output of the PLL is not used, the value of PLLREN should be 0.  
0: PLLCLK output disable  
1: PLLCLK output enable

Bit 23 Reserved, must be kept at reset value.
Bits 22:21  **PLLQ[1:0]**: Main PLL division factor for PLL48M1CLK (48 MHz clock).
   Set and cleared by software to control the frequency of the main PLL output clock
   PLL48M1CLK. This output can be selected for USB, RNG, SDMMC (48 MHz clock). These
   bits can be written only if PLL is disabled.
   PLL48M1CLK output clock frequency = VCO frequency / PLLQ with PLLQ = 2, 4, 6, or 8
   00: PLLQ = 2
   01: PLLQ = 4
   10: PLLQ = 6
   11: PLLQ = 8
   **Caution:** The software has to set these bits correctly not to exceed 120 MHz on
   this domain.

Bit 20  **PLLQEN**: Main PLL PLL48M1CLK output enable
   Set and reset by software to enable the PLL48M1CLK output of the main PLL.
   In order to save power, when the PLL48M1CLK output of the PLL is not used, the value of
   PLLQEN should be 0.
   0: PLL48M1CLK output disable
   1: PLL48M1CLK output enable

Bits 19:18  **Reserved**, must be kept at reset value.

Bit 17  **PLLP**: Main PLL division factor for PLLSAI3CLK (SAI1 and SAI2 clock) or SDMMC clock.
   Set and cleared by software to control the frequency of the main PLL output clock
   PLLSAI3CLK. This output can be selected for SAI1 or SAI2 or SDMMC. These bits can be
   written only if PLL is disabled.
   When the PLLPDIV[4:0] is set to `00000'PLLSAI3CLK output clock frequency = VCO
   frequency / PLLP with PLLP =7, or 17
   0: PLLP = 7
   1: PLLP = 17
   **Caution:** The software has to set these bits correctly not to exceed 120 MHz on
   this domain.

Bit 16  **PLLPEN**: Main PLL PLLSAI3CLK output enable
   Set and reset by software to enable the PLLSAI3CLK output of the main PLL.
   In order to save power, when the PLLSAI3CLK output of the PLL is not used, the value of
   PLLPEN should be 0.
   0: PLLSAI3CLK output disable
   1: PLLSAI3CLK output enable

Bit 15  Reserved, must be kept at reset value.
6.4.5 PLLSAI1 configuration register (RCC_PLLSAI1CFGR)

Address offset: 0x10
Reset value: 0x0000 1000
Access: no wait state, word, half-word and byte access

This register is used to configure the PLLSAI1 clock outputs according to the formulas:
- \( f(VCOSAI1\_P) = f(VCOSAI1\_clock) \div PLLSAI1PDIV \)
- \( f(VCOSAI1\_Q) = f(VCOSAI1\_clock) \div PLLSAI1Q \)
- \( f(VCO) = f(VCOSAI1\_clock) \times (PLLSAI1N / PLLSAI1M) \)

Bits 14:8 PLLN[6:0]: Main PLL multiplication factor for VCO
Set and cleared by software to control the multiplication factor of the VCO. These bits can be written only when the PLL is disabled.
VCO output frequency = VCO input frequency \( \times \) PLLN with \( 8 \leq PLLN \leq 127 \)
0000000: PLLN = 0 wrong configuration
0000001: PLLN = 1 wrong configuration
... 0000111: PLLN = 7 wrong configuration
0001000: PLLN = 8
0001001: PLLN = 9
... 1111111: PLLN = 127
Caution: The software has to set correctly these bits to assure that the VCO output frequency is between 64 and 344 MHz.

Bits 7:4 PLLM: Division factor for the main PLL input clock
Set and cleared by software to divide the PLL input clock before the VCO. These bits can be written only when all PLLs are disabled.
VCO input frequency = PLL input clock frequency \( \div \) PLLM with \( 1 \leq PLLM \leq 16 \)
0000: PLLM = 1
0001: PLLM = 2
0010: PLLM = 3
0011: PLLM = 4
0100: PLLM = 5
0101: PLLM = 6
0110: PLLM = 7
0111: PLLM = 8
Caution: The software has to set these bits correctly to ensure that the VCO input frequency ranges from 2.66 MHz to 8 MHz.

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 PLLSRC: Main PLL entry clock source
Set and cleared by software to select PLL clock source. These bits can be written only when PLL disabled.
In order to save power, when no PLL is used, the value of PLLSRC should be 00.
00: No clock sent to PLL
01: MSI clock selected as PLL clock entry
10: HSI16 clock selected as PLL clock entry
11: HSE clock selected as PLL clock entry

Caution: The software has to set correctly these bits to assure that the VCO input frequency is between 64 and 344 MHz.
• \( f(\text{PLLSAI1}_R) = \frac{f(\text{VCOSAI1 clock})}{\text{PLLSAI1R}} \)

Note: This bit can be written only when the PLLSAI1 is disabled.

Bits 26:25 PLLSAI1R[1:0]: PLLSAI1 division factor for PLLADC1CLK (ADC clock)

Set and cleared by software to control the frequency of the PLLSAI1 output clock PLLADC1CLK. This output can be selected as ADC clock. These bits can be written only if PLLSAI1 is disabled.

PLLADC1CLK output clock frequency = VCOSAI1 frequency / PLLSAI1R with PLLSAI1R = 2, 4, 6, or 8

00: PLLSAI1R = 2
01: PLLSAI1R = 4
10: PLLSAI1R = 6
11: PLLSAI1R = 8

Bit 24 PLLSAI1REN: PLLSAI1 PLLADC1CLK output enable

Set and reset by software to enable the PLLADC1CLK output of the PLLSAI1 (used as clock for ADC).

In order to save power, when the PLLADC1CLK output of the PLLSAI1 is not used, the value of PLLSAI1REN should be 0.

0: PLLADC1CLK output disable
1: PLLADC1CLK output enable

Bit 23 Reserved, must be kept at reset value.

Bits 22:21 PLLSAI1Q[1:0]: PLLSAI1 division factor for PLL48M2CLK (48 MHz clock)

Set and cleared by software to control the frequency of the PLLSAI1 output clock PLL48M2CLK. This output can be selected for USB, RNG, SDMMC (48 MHz clock). These bits can be written only if PLLSAI1 is disabled.

PLL48M2CLK output clock frequency = VCOSAI1 frequency / PLLSAI1Q with PLLSAI1Q = 2, 4, 6, or 8

00: PLLSAI1Q = 2
01: PLLSAI1Q = 4
10: PLLSAI1Q = 6
11: PLLSAI1Q = 8

Caution: The software has to set these bits correctly not to exceed 120 MHz on this domain.
Bit 20 **PLLSAI1QEN**: PLLSAI1 PLL48M2CLK output enable

Set and reset by software to enable the PLL48M2CLK output of the PLLSAI1.

In order to save power, when the PLL48M2CLK output of the PLLSAI1 is not used, the value of PLLSAI1QEN should be 0.

0: PLL48M2CLK output disable
1: PLL48M2CLK output enable

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **PLLSAI1P**: PLLSAI1 division factor for PLLSAI1CLK (SAI1 or SAI2 clock).

Set and cleared by software to control the frequency of the PLLSAI1 output clock PLLSAI1CLK. This output can be selected for SAI1 or SAI2. These bits can be written only if PLLSAI1 is disabled.

When the PLLSAI1PDIV[4:0] is set to "00000", PLLSAI1CLK output clock frequency = VCOSAI1 frequency / PLLSAI1P with PLLSAI1P = 7, or 17

0: PLLSAI1P = 7
1: PLLSAI1P = 17

Bit 16 **PLLSAI1PEN**: PLLSAI1 PLLSAI1CLK output enable

Set and reset by software to enable the PLLSAI1CLK output of the PLLSAI1.

In order to save power, when the PLLSAI1CLK output of the PLLSAI1 is not used, the value of PLLSAI1PEN should be 0.

0: PLLSAI1CLK output disable
1: PLLSAI1CLK output enable

Bit 15 Reserved, must be kept at reset value.
Bits 14:8 **PLLSAI1N[6:0]**: PLLSAI1 multiplication factor for VCO
Set and cleared by software to control the multiplication factor of the VCO. These bits can be written only when the PLLSAI1 is disabled.

VCOSAI1 output frequency = VCOSAI1 input frequency x PLLSAI1N
with 8 <= PLLSAI1N <= 127
0000000: PLLSAI1N = 0 wrong configuration
0000001: PLLSAI1N = 1 wrong configuration
...
0000111: PLLSAI1N = 7 wrong configuration
0001000: PLLSAI1N = 8
0001001: PLLSAI1N = 9
...
1111111: PLLSAI1N = 127

**Caution:** The software has to set correctly these bits to ensure that the VCO output frequency is between 64 and 344 MHz.

Bits 7:4 **PLLSAI1M**: Division factor for PLLSAI1 input clock
Set and reset by software to divide the PLLSAI1 input clock before the VCO. These bits can be written only when PLLSAI1 is disabled.

VCO input frequency = PLLSAI1 input clock frequency / PLLSAI1M with 1 <= PLLSAI1M <= 16
0000: PLLSAI1M = 1
0001: PLLSAI1M = 2
0010: PLLSAI1M = 3
0011: PLLSAI1M = 4
0100: PLLSAI1M = 5
0101: PLLSAI1M = 6
0110: PLLSAI1M = 7
0111: PLLSAI1M = 8
1000: PLLSAI1M = 9
...
1111: PLLSAI1M = 16

**Caution:** The software has to set these bits correctly to ensure that the VCO input frequency ranges from 2.66 to 8 MHz.

Bits 3:0 Reserved, must be kept at reset value.
6.4.6 PLLSAI2 configuration register (RCC_PLLSAI2CFGR)

Address offset: 0x14
Reset value: 0x0000 1000
Access: no wait state, word, half-word and byte access

This register is used to configure the PLLSAI2 clock outputs according to the formulas:

- \( f(\text{VCOSAI2 clock}) = f(\text{PLL clock input}) \times (\text{PLLSAI2N} / \text{PLLSAI2M}) \)
- \( f(\text{PLLSAI2}_P) = f(\text{VCOSAI2 clock}) / \text{PLLSAI2PDIV} \)
- \( f(\text{PLLSAI2}_R) = f(\text{VCOSAI2 clock}) / \text{PLLSAI2R} \)

### Bits 31:27 PLLSAI2PDIV[4:0]: PLLSAI2 division factor for PLLSAI2CLK

- Set and cleared by software to control the SAI1 or SAI2 clock frequency. PLLSAI2CLK output clock frequency = VCOSAI2 frequency / PLLSAI2PDIV.
- 00000: PLLSAI2CLK is controlled by the bit PLLSAI2P
- 00001: Reserved.
- 00010: PLLSAI2CLK = VCOSAI2 / 2
- ....
- 11111: PLLSAI2CLK = VCOSAI2 / 31

### Bits 26:25 PLLSAI2R[1:0]: PLLSAI2 division factor for PLLLCDCLK (LTDC clock)

- Set and cleared by software to control the frequency of the PLLSAI2 output clock PLLLCDCLK. This output can be selected as ADC clock. These bits can be written only if PLLSAI2 is disabled.
- PLLLCDCLK output clock frequency = VCOSAI2 frequency / PLLSAI2R with PLLSAI2R = 2, 4, 6, or 8
- 00: PLLSAI2R = 2
- 01: PLLSAI2R = 4
- 10: PLLSAI2R = 6
- 11: PLLSAI2R = 8

### Bit 24 PLLSAI2REN: PLLSAI2 PLLLCDCLK output enable

- Set and reset by software to enable the PLLLCDCLK output of the PLLSAI2 (used as clock for ADC).
- In order to save power, when the PLLLCDCLK output of the PLLSAI2 is not used, the value of PLLSAI2REN should be 0.
- 0: PLLLCDCLK output disable
- 1: PLLLCDCLK output enable

### Bit 23 Reserved, must be kept at reset value.
Bits 22:21 **PLLSAI2Q[1:0]**: PLLSAI2 PLLDSICLK output enable.
Set and cleared by software to control the frequency of the DSI clock.
These bits can be written only if PLLSAI2 is disabled.
PLLDSICLK output clock frequency = VCOSAI2 frequency / PLLSAI2Q with PLLSAI2Q = 2, 4, 6, or 8
00: PLLSAI2Q = 2
01: PLLSAI2Q = 4
10: PLLSAI2Q = 6
11: PLLSAI2Q = 8

Bit 20 **PLLSAI2QEN**: PLLSAI2 division factor for PLLDSICLK (DSI clock).
Set and reset by software to enable the PLLDSICLK (DSI clock) output of the PLLSAI2
(used as USB clock).
In order to save power, when the PLLDSICLK output of the PLLSAI2 is not used, the value of PLLSAI2PEN should be 0.
0: PLLDSICLK output disable
1: PLLDSICLK output enable

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **PLLSAI2P**: PLLSAI2 division factor for PLLSAI2CLK (SAI1 or SAI2 clock).
Set and cleared by software to control the frequency of the PLLSAI2 output clock
PLLSAI2CLK. This output can be selected for SAI1 or SAI2. These bits can be written only if PLLSAI2 is disabled.
(when the PLLSAI2PDIV[4:0] is set to "00000"), PLLSAI2CLK output clock frequency = VCOSAI2 frequency / PLLSAI2P with PLLSAI2P =7, or 17
0: PLLSAI2P = 7
1: PLLSAI2P = 17

Bit 16 **PLLSAI2PEN**: PLLSAI2 PLLSAI2CLK output enable
Set and reset by software to enable the PLLSAI2CLK output of the PLLSAI2.
In order to save power, when the PLLSAI2CLK output of the PLLSAI2 is not used, the value of PLLSAI2PEN should be 0.
0: PLLSAI2CLK output disable
1: PLLSAI2CLK output enable

Bit 15 Reserved, must be kept at reset value.
Bits 14:8 **PLLSAI2N[6:0]**: PLLSAI2 multiplication factor for VCO
Set and cleared by software to control the multiplication factor of the VCO. These bits can be written only when the PLLSAI2 is disabled.

VCO\(S\)AI2 output frequency = VCO\(S\)AI2 input frequency x PLLSAI2N
with 8 <= PLLSAI2N <= 127
0000000: PLLSAI2N = 0 wrong configuration
0000001: PLLSAI2N = 1 wrong configuration
...
0000111: PLLSAI2N = 7 wrong configuration
0001000: PLLSAI2N = 8
0001001: PLLSAI2N = 9
...
1111111: PLLSAI2N = 127

**Caution:** The software has to set correctly these bits to ensure that the VCO output frequency is between 64 and 344 MHz.

Bits 7:4 **PLLSAI2M**: Division factor for PLLSAI2 input clock
Set and reset by software to divide the PLLSAI2 input clock before the VCO. These bits can be written only when PLLSAI2 is disabled.

VCO input frequency = PLLSAI2 input clock frequency / PLLM with 1 <= PLLSAI2M <= 16
0000: PLLSAI2M = 1
0001: PLLSAI2M = 2
0010: PLLSAI2M = 3
0011: PLLSAI2M = 4
0100: PLLSAI2M = 5
0101: PLLSAI2M = 6
0110: PLLSAI2M = 7
0111: PLLSAI2M = 8
1000: PLLSAI2M = 9
...
1111: PLLSAI2M = 16

**Caution:** The software has to set these bits correctly to ensure that the VCO input frequency ranges from 2.66 to 8 MHz.

Bits 3:0 Reserved, must be kept at reset value.

### 6.4.7 Clock interrupt enable register (RCC\_CIER)

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **HSI48RDYIE**: HSI48 ready interrupt enable
Set and cleared by software to enable/disable interrupt caused by the internal HSI48 oscillator.
0: HSI48 ready interrupt disabled
1: HSI48 ready interrupt enabled

Bit 9 **LSECSSIE**: LSE clock security system interrupt enable
Set and cleared by software to enable/disable interrupt caused by the clock security system on LSE.
0: Clock security interrupt caused by LSE clock failure disabled
1: Clock security interrupt caused by LSE clock failure enabled

Bit 8 Reserved, must be kept at reset value.

Bit 7 **PLLSAI2RDYIE**: PLLSAI2 ready interrupt enable
Set and cleared by software to enable/disable interrupt caused by PLLSAI2 lock.
0: PLLSAI2 lock interrupt disabled
1: PLLSAI2 lock interrupt enabled

Bit 6 **PLLSAI1RDYIE**: PLLSAI1 ready interrupt enable
Set and cleared by software to enable/disable interrupt caused by PLLSAI1 lock.
0: PLLSAI1 lock interrupt disabled
1: PLLSAI1 lock interrupt enabled

Bit 5 **PLLRDYIE**: PLL ready interrupt enable
Set and cleared by software to enable/disable interrupt caused by PLL lock.
0: PLL lock interrupt disabled
1: PLL lock interrupt enabled

Bit 4 **HSERDYIE**: HSE ready interrupt enable
Set and cleared by software to enable/disable interrupt caused by the HSE oscillator stabilization.
0: HSE ready interrupt disabled
1: HSE ready interrupt enabled

Bit 3 **HSIRDYIE**: HSI16 ready interrupt enable
Set and cleared by software to enable/disable interrupt caused by the HSI16 oscillator stabilization.
0: HSI16 ready interrupt disabled
1: HSI16 ready interrupt enabled
Bit 2 **MSIRDYIE**: MSI ready interrupt enable
- Set and cleared by software to enable/disable interrupt caused by the MSI oscillator stabilization.
- 0: MSI ready interrupt disabled
- 1: MSI ready interrupt enabled

Bit 1 **LSERDYIE**: LSE ready interrupt enable
- Set and cleared by software to enable/disable interrupt caused by the LSE oscillator stabilization.
- 0: LSE ready interrupt disabled
- 1: LSE ready interrupt enabled

Bit 0 **LSIRDYIE**: LSI ready interrupt enable
- Set and cleared by software to enable/disable interrupt caused by the LSI oscillator stabilization.
- 0: LSI ready interrupt disabled
- 1: LSI ready interrupt enabled

**Bits 31:11** Reserved, must be kept at reset value.

**Bit 10** **HSI48RDYF**: HSI48 ready interrupt flag
- Set by hardware when the HSI48 clock becomes stable and HSI48RDYIE is set in a response to setting the HSI48ON (refer to Clock recovery RC register (RCC_CRRCR)).
- Cleared by software setting the HSI48RDYC bit.
- 0: No clock ready interrupt caused by the HSI48 oscillator
- 1: Clock ready interrupt caused by the HSI48 oscillator

**Bit 9** **LSECSSSF**: LSE Clock security system interrupt flag
- Set by hardware when a failure is detected in the LSE oscillator.
- Cleared by software setting the LSECSSC bit.
- 0: No clock security interrupt caused by LSE clock failure
- 1: Clock security interrupt caused by LSE clock failure

**Bit 8** **CSSF**: Clock security system interrupt flag
- Set by hardware when a failure is detected in the HSE oscillator.
- Cleared by software setting the CSSC bit.
- 0: No clock security interrupt caused by HSE clock failure
- 1: Clock security interrupt caused by HSE clock failure
Bit 7 **PLLSAI2RDYF**: PLLSAI2 ready interrupt flag
Set by hardware when the PLLSAI2 locks and PLLSAI2RDYDIE is set.
Cleared by software setting the PLLSAI2RDYC bit.
0: No clock ready interrupt caused by PLLSAI2 lock
1: Clock ready interrupt caused by PLLSAI2 lock

Bit 6 **PLLSAI1RDYF**: PLLSAI1 ready interrupt flag
Set by hardware when the PLLSAI1 locks and PLLSAI1RDYDIE is set.
Cleared by software setting the PLLSAI1RDYC bit.
0: No clock ready interrupt caused by PLLSAI1 lock
1: Clock ready interrupt caused by PLLSAI1 lock

Bit 5 **PLLRDYF**: PLL ready interrupt flag
Set by hardware when the PLL locks and PLLRDYDIE is set.
Cleared by software setting the PLLRDYC bit.
0: No clock ready interrupt caused by PLL lock
1: Clock ready interrupt caused by PLL lock

Bit 4 **HSERDYF**: HSE ready interrupt flag
Set by hardware when the HSE clock becomes stable and HSERDYDIE is set.
Cleared by software setting the HSERDYC bit.
0: No clock ready interrupt caused by the HSE oscillator
1: Clock ready interrupt caused by the HSE oscillator

Bit 3 **HSIRDYF**: HSI16 ready interrupt flag
Set by hardware when the HSI16 clock becomes stable and HSIRDYDIE is set in a response to setting the HSION (refer to Clock control register (RCC_CR)). When HSION is not set but the HSI16 oscillator is enabled by the peripheral through a clock request, this bit is not set and no interrupt is generated.
Cleared by software setting the HSIRDYC bit.
0: No clock ready interrupt caused by the HSI16 oscillator
1: Clock ready interrupt caused by the HSI16 oscillator

Bit 2 **MSIRDYF**: MSI ready interrupt flag
Set by hardware when the MSI clock becomes stable and MSIRDYDIE is set.
Cleared by software setting the MSIRDYC bit.
0: No clock ready interrupt caused by the MSI oscillator
1: Clock ready interrupt caused by the MSI oscillator

Bit 1 **LSERDYF**: LSE ready interrupt flag
Set by hardware when the LSE clock becomes stable and LSERDYDIE is set.
Cleared by software setting the LSERDYC bit.
0: No clock ready interrupt caused by the LSE oscillator
1: Clock ready interrupt caused by the LSE oscillator

Bit 0 **LSIRDYF**: LSI ready interrupt flag
Set by hardware when the LSI clock becomes stable and LSIRDYDIE is set.
Cleared by software setting the LSIRDYC bit.
0: No clock ready interrupt caused by the LSI oscillator
1: Clock ready interrupt caused by the LSI oscillator

6.4.9 Clock interrupt clear register (RCC_CICR)
Address offset: 0x20
Reset value: 0x0000 0000
### Reset and clock control (RCC) RM0432

**Access:** no wait state, word, half-word and byte access

**Bits 31:11** Reserved, must be kept at reset value.

- **Bit 10** **HSI48RDYC**: HSI48 oscillator ready interrupt clear
  
  This bit is set by software to clear the HSI48RDYF flag.
  
  0: No effect
  
  1: Clear the HSI48RDYC flag

- **Bit 9** **LSECSSC**: LSE Clock security system interrupt clear
  
  This bit is set by software to clear the LSECSSF flag.
  
  0: No effect
  
  1: Clear LSECSSF flag

- **Bit 8** **CSSC**: Clock security system interrupt clear
  
  This bit is set by software to clear the CSSF flag.
  
  0: No effect
  
  1: Clear CSSF flag

- **Bit 7** **PLLSAI2RDYC**: PLLSAI2 ready interrupt clear
  
  This bit is set by software to clear the PLLSAI2RDYF flag.
  
  0: No effect
  
  1: Clear PLLSAI2RDYC flag

- **Bit 6** **PLLSAI1RDYC**: PLLSAI1 ready interrupt clear
  
  This bit is set by software to clear the PLLSAI1RDYF flag.
  
  0: No effect
  
  1: Clear PLLSAI1RDYC flag

- **Bit 5** **PLLRDYC**: PLL ready interrupt clear
  
  This bit is set by software to clear the PLLRDYF flag.
  
  0: No effect
  
  1: Clear PLLRDYC flag

- **Bit 4** **HSERDYC**: HSE ready interrupt clear
  
  This bit is set by software to clear the HSERDYF flag.
  
  0: No effect
  
  1: Clear HSERDYC flag

- **Bit 3** **HSIRDYC**: HSI16 ready interrupt clear
  
  This bit is set by software to clear the HSIRDYF flag.
  
  0: No effect
  
  1: Clear HSIRDYC flag
Bit 2 **MSIRDYC**: MSI ready interrupt clear
   This bit is set by software to clear the MSIRDYF flag.
   0: No effect
   1: MSIRDYF cleared

Bit 1 **LSERDYC**: LSE ready interrupt clear
   This bit is set by software to clear the LSERDYF flag.
   0: No effect
   1: LSERDYF cleared

Bit 0 **LSIRDYC**: LSI ready interrupt clear
   This bit is set by software to clear the LSIRDYF flag.
   0: No effect
   1: LSIRDYF cleared

Bits 31:24  Reserved, must be kept at reset value.

Bit 23  **SDMMC2RST**: SDMMC2 reset
Set and cleared by software.
0: No effect
1: Reset SDMMC2

Bit 22  **SDMMC1RST**: SDMMC1 reset
Set and cleared by software.
0: No effect
1: Reset SDMMC1

Bit 21  Reserved, must be kept at reset value.
Bit 20 **OSPIMRST**: OctoSPI IO manager reset  
Set and cleared by software.  
0: No effect  
1: Reset OctoSPI IO manager

Bit 19 Reserved, must be kept at reset value.

Bit 18 **RNGRST**: Random number generator reset  
Set and cleared by software.  
0: No effect  
1: Reset RNG

Bit 17 **HASHRST**: Hash reset  
Set and cleared by software.  
0: No effect  
1: Reset HASH

Bit 16 **AESRST**: AES hardware accelerator reset  
Set and cleared by software.  
0: No effect  
1: Reset AES

Bit 15 **PKARST**: PKA reset  
Set and cleared by software.  
0: No effect  
1: Reset PKA

Bit 14 **DCMIRST**: DCMI or PSSI reset (DCMI or PSSI depending on which interface is active)  
Set and cleared by software  
0: No effect  
1: Reset DCMI/PSSI interface

Bit 13 **ADCRST**: ADC reset  
Set and cleared by software.  
0: No effect  
1: Reset ADC interface

Bit 12 **OTGFSRST**: USB OTG FS reset  
Set and cleared by software.  
0: No effect  
1: Reset USB OTG FS

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **GPIOIRST**: IO port I reset  
Set and cleared by software  
0: No effect  
1: Reset IO port I

Bit 7 **GPIOHRST**: IO port H reset  
Set and cleared by software.  
0: No effect  
1: Reset IO port H
Bit 6  **GPIOGRST**: IO port G reset
Set and cleared by software.
0: No effect
1: Reset IO port G

Bit 5  **GPIOFRST**: IO port F reset
Set and cleared by software.
0: No effect
1: Reset IO port F

Bit 4  **GPIOERST**: IO port E reset
Set and cleared by software.
0: No effect
1: Reset IO port E

Bit 3  **GPIODRST**: IO port D reset
Set and cleared by software.
0: No effect
1: Reset IO port D

Bit 2  **GPIOCRST**: IO port C reset
Set and cleared by software.
0: No effect
1: Reset IO port C

Bit 1  **GPIOBRST**: IO port B reset
Set and cleared by software.
0: No effect
1: Reset IO port B

Bit 0  **GPIOARST**: IO port A reset
Set and cleared by software.
0: No effect
1: Reset IO port A

  - 0: GFXMMU clocks disabled by the clock gating\(^{(1)}\) during Sleep and Stop modes
  - 1: GFXMMU clocks enabled by the clock gating\(^{(1)}\) during Sleep and Stop modes

#### Bit 17 DMA2DSMEN: DMA2D clock enable during Sleep and Stop modes
- **Set and cleared by software**
  - 0: DMA2D clocks disabled by the clock gating\(^{(1)}\) during Sleep and Stop modes
  - 1: DMA2D clocks enabled by the clock gating\(^{(1)}\) during Sleep and Stop modes

#### Bit 16 TSCSMEN: Touch Sensing Controller clocks enable during Sleep and Stop modes
- **Set and cleared by software**
  - 0: TSC clocks disabled by the clock gating\(^{(1)}\) during Sleep and Stop modes
  - 1: TSC clocks enabled by the clock gating\(^{(1)}\) during Sleep and Stop modes

#### Bits 15:13 Reserved, must be kept at reset value.

#### Bit 12 CRCSMEN: CRC clocks enable during Sleep and Stop modes
- **Set and cleared by software**
  - 0: CRC clocks disabled by the clock gating\(^{(1)}\) during Sleep and Stop modes
  - 1: CRC clocks enabled by the clock gating\(^{(1)}\) during Sleep and Stop modes

#### Bits 11:10 Reserved, must be kept at reset value.

#### Bit 9 SRAM1SMEN: SRAM1 interface clocks enable during Sleep and Stop modes
- **Set and cleared by software**
  - 0: SRAM1 interface clocks disabled by the clock gating\(^{(1)}\) during Sleep and Stop modes
  - 1: SRAM1 interface clocks enabled by the clock gating\(^{(1)}\) during Sleep and Stop modes

#### Bit 8 FLASHSMEN: Flash memory interface clocks enable during Sleep and Stop modes
- **Set and cleared by software**
  - 0: Flash memory interface clocks disabled by the clock gating\(^{(1)}\) during Sleep and Stop modes
  - 1: Flash memory interface clocks enabled by the clock gating\(^{(1)}\) during Sleep and Stop modes

#### Bits 7:3 Reserved, must be kept at reset value.
Bit 2 **DMAMUX1SMEN**: DMAMUX1 clock enable during Sleep and Stop modes.
Set and cleared by software.
0: DMAMUX1 clocks disabled by the clock gating(1) during Sleep and Stop modes
1: DMAMUX1 clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 1 **DMA2SMEN**: DMA2 clocks enable during Sleep and Stop modes
Set and cleared by software during Sleep mode.
0: DMA2 clocks disabled by the clock gating(1) during Sleep and Stop modes
1: DMA2 clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 0 **DMA1SMEN**: DMA1 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: DMA1 clocks disabled by the clock gating(1) during Sleep and Stop modes
1: DMA1 clocks enabled by the clock gating(1) during Sleep and Stop modes

1. This register only configures the clock gating, not the clock source itself. Most of the peripherals are clocked by a single clock (AHB or APB clock), which is always disabled in Stop mode. In this case setting the bit has no effect in Stop mode.

Set and cleared by software.
0: OCTOOSPIM clocks disabled by the clock gating(1) during Sleep and Stop modes
1: OCTOOSPIM clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 19 Reserved, must be kept at reset value.
Bit 18 **RNGSMEN**: Random Number Generator clocks enable during Sleep and Stop modes
   
   Set and cleared by software.
   
   0: Random Number Generator clocks disabled by the clock gating during Sleep and Stop modes
   1: Random Number Generator clocks enabled by the clock gating during Sleep and Stop modes

Bit 17 **HASHSMEN**: HASH clock enable during Sleep and Stop modes
   
   Set and cleared by software.
   
   0: HASH clocks disabled by the clock gating during Sleep and Stop modes
   1: HASH clocks enabled by the clock gating during Sleep and Stop modes

Bit 16 **AESSMEN**: AES accelerator clocks enable during Sleep and Stop modes
   
   Set and cleared by software.
   
   0: AES clocks disabled by the clock gating during Sleep and Stop modes
   1: AES clocks enabled by the clock gating during Sleep and Stop modes

Bit 15 **PKASMEN**: PKA clocks enable during Sleep and Stop modes
   
   Set and cleared by software.
   
   0: PKA clocks disabled by the clock gating during Sleep and Stop modes
   1: PKA clocks enabled by the clock gating during Sleep and Stop modes

Bit 14 **DCMISMEN**: DCMI or PSSI clock enable during Sleep and Stop modes. (DCMI or PSSI depending on which interface is active)
   
   Set and cleared by software.
   
   0: DCMI/PSSI clocks disabled by the clock gating during Sleep and Stop modes
   1: DCMI/PSSI clocks enabled by the clock gating during Sleep and Stop modes

Bit 13 **ADCSMEN**: ADC clocks enable during Sleep and Stop modes
   
   Set and cleared by software.
   
   0: ADC clocks disabled by the clock gating during Sleep and Stop modes
   1: ADC clocks enabled by the clock gating during Sleep and Stop modes

Bit 12 **OTGFSSMEN**: OTG full speed clocks enable during Sleep and Stop modes
   
   Set and cleared by software.
   
   0: USB OTG full speed clocks disabled by the clock gating during Sleep and Stop modes
   1: USB OTG full speed clocks enabled by the clock gating during Sleep and Stop modes

Bits 11 Reserved, must be kept at reset value.

Bit 10 **SRAM3SMEN**: SRAM2 interface clocks enable during Sleep and Stop modes
   
   Set and cleared by software.
   
   0: SRAM3 interface clocks disabled by the clock gating during Sleep and Stop modes
   1: SRAM3 interface clocks enabled by the clock gating during Sleep and Stop modes

Bit 9 **SRAM2SMEN**: SRAM2 interface clocks enable during Sleep and Stop modes
   
   Set and cleared by software.
   
   0: SRAM2 interface clocks disabled by the clock gating during Sleep and Stop modes
   1: SRAM2 interface clocks enabled by the clock gating during Sleep and Stop modes

Bit 8 **GPIOISMEN**: IO port I clocks enable during Sleep and Stop modes
   
   Set and cleared by software.
   
   0: IO port I clocks disabled by the clock gating during Sleep and Stop modes
   1: IO port I clocks enabled by the clock gating during Sleep and Stop modes
Bit 7 **GPIOHSMEN**: IO port H clocks enable during Sleep and Stop modes  
Set and cleared by software.  
0: IO port H clocks disabled by the clock gating(1) during Sleep and Stop modes  
1: IO port H clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 6 **GPIOGSMEN**: IO port G clocks enable during Sleep and Stop modes  
Set and cleared by software.  
0: IO port G clocks disabled by the clock gating(1) during Sleep and Stop modes  
1: IO port G clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 5 **GPIOFSMEN**: IO port F clocks enable during Sleep and Stop modes  
Set and cleared by software.  
0: IO port F clocks disabled by the clock gating(1) during Sleep and Stop modes  
1: IO port F clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 4 **GPIOESMEN**: IO port E clocks enable during Sleep and Stop modes  
Set and cleared by software.  
0: IO port E clocks disabled by the clock gating(1) during Sleep and Stop modes  
1: IO port E clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 3 **GPIODSMEN**: IO port D clocks enable during Sleep and Stop modes  
Set and cleared by software.  
0: IO port D clocks disabled by the clock gating(1) during Sleep and Stop modes  
1: IO port D clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 2 **GPIOCSMEN**: IO port C clocks enable during Sleep and Stop modes  
Set and cleared by software.  
0: IO port C clocks disabled by the clock gating(1) during Sleep and Stop modes  
1: IO port C clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 1 **GPIOBSMEN**: IO port B clocks enable during Sleep and Stop modes  
Set and cleared by software.  
0: IO port B clocks disabled by the clock gating(1) during Sleep and Stop modes  
1: IO port B clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 0 **GPIOASMEN**: IO port A clocks enable during Sleep and Stop modes  
Set and cleared by software.  
0: IO port A clocks disabled by the clock gating(1) during Sleep and Stop modes  
1: IO port A clocks enabled by the clock gating(1) during Sleep and Stop modes

1. This register only configures the clock gating, not the clock source itself. Most of the peripherals are clocked by a single clock (AHB or APB clock), which is always disabled in Stop mode. In this case setting the bit has no effect in Stop mode.

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 OCTOSP: OctoSPI2 memory interface clocks enable during Sleep and Stop modes
Set and cleared by software.
0: OctoSPI2 clocks disabled by the clock gating(1) during Sleep and Stop modes
1: OctoSPI2 clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 8 OSP1SMEN: OctoSPI1 memory interface clocks enable during Sleep and Stop modes
Set and cleared by software.
0: OctoSPI1 clocks disabled by the clock gating(1) during Sleep and Stop modes
1: OctoSPI1 clocks enabled by the clock gating(1) during Sleep and Stop modes

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 FMC: Flexible memory controller clocks enable during Sleep and Stop modes
Set and cleared by software.
0: FMC clocks disabled by the clock gating(1) during Sleep and Stop modes
1: FMC clocks enabled by the clock gating(1) during Sleep and Stop modes

1. This register only configures the clock gating, not the clock source itself. Most of the peripherals are clocked by a single clock (AHB or APB clock), which is always disabled in Stop mode. In this case setting the bit has no effect in Stop mode.

Bit 31 LPTIM1SMEN: Low power timer 1 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: LPTIM1 clocks disabled by the clock gating(1) during Sleep and Stop modes
1: LPTIM1 clocks enabled by the clock gating(1) during Sleep and Stop modes
Bit 30 **OPAMPSMEN**: OPAMP interface clocks enable during Sleep and Stop modes
- Set and cleared by software.
- 0: OPAMP interface clocks disabled by the clock gating\(^{(1)}\) during Sleep and Stop modes
- 1: OPAMP interface clocks enabled by the clock gating\(^{(1)}\) during Sleep and Stop modes

Bit 29 **DAC1SMEN**: DAC1 interface clocks enable during Sleep and Stop modes
- Set and cleared by software.
- 0: DAC1 interface clocks disabled by the clock gating\(^{(1)}\) during Sleep and Stop modes
- 1: DAC1 interface clocks enabled by the clock gating\(^{(1)}\) during Sleep and Stop modes

Bit 28 **PWRSMEN**: Power interface clocks enable during Sleep and Stop modes
- Set and cleared by software.
- 0: Power interface clocks disabled by the clock gating\(^{(1)}\) during Sleep and Stop modes
- 1: Power interface clocks enabled by the clock gating\(^{(1)}\) during Sleep and Stop modes

Bit 27 **Reserved, must be kept at reset value.**

Bit 25 **CAN1SMEN**: CAN1 clocks enable during Sleep and Stop modes
- Set and cleared by software.
- 0: CAN1 clocks disabled by the clock gating\(^{(1)}\) during Sleep and Stop modes
- 1: CAN1 clocks enabled by the clock gating\(^{(1)}\) during Sleep and Stop modes

Bit 24 **CRSSMEN**: CRS clock enable during Sleep and Stop modes
- Set and cleared by software.
- 0: CRS clocks disabled by the clock gating\(^{(1)}\) during Sleep and Stop modes
- 1: CRS clocks enabled by the clock gating\(^{(1)}\) during Sleep and Stop modes

Bit 23 **I2C3SMEN**: I2C3 clocks enable during Sleep and Stop modes
- Set and cleared by software.
- 0: I2C3 clocks disabled by the clock gating\(^{(1)}\) during Sleep and Stop modes
- 1: I2C3 clocks enabled by the clock gating\(^{(1)}\) during Sleep and Stop modes

Bit 22 **I2C2SMEN**: I2C2 clocks enable during Sleep and Stop modes
- Set and cleared by software.
- 0: I2C2 clocks disabled by the clock gating\(^{(1)}\) during Sleep and Stop modes
- 1: I2C2 clocks enabled by the clock gating\(^{(1)}\) during Sleep and Stop modes

Bit 21 **I2C1SMEN**: I2C1 clocks enable during Sleep and Stop modes
- Set and cleared by software.
- 0: I2C1 clocks disabled by the clock gating\(^{(1)}\) during Sleep and Stop modes
- 1: I2C1 clocks enabled by the clock gating\(^{(1)}\) during Sleep and Stop modes

Bit 20 **UART5SMEN**: UART5 clocks enable during Sleep and Stop modes
- Set and cleared by software.
- 0: UART5 clocks disabled by the clock gating\(^{(1)}\) during Sleep and Stop modes
- 1: UART5 clocks enabled by the clock gating\(^{(1)}\) during Sleep and Stop modes

Bit 19 **UART4SMEN**: UART4 clocks enable during Sleep and Stop modes
- Set and cleared by software.
- 0: UART4 clocks disabled by the clock gating\(^{(1)}\) during Sleep and Stop modes
- 1: UART4 clocks enabled by the clock gating\(^{(1)}\) during Sleep and Stop modes

Bit 18 **USART3SMEN**: USART3 clocks enable during Sleep and Stop modes
- Set and cleared by software.
- 0: USART3 clocks disabled by the clock gating\(^{(1)}\) during Sleep and Stop modes
- 1: USART3 clocks enabled by the clock gating\(^{(1)}\) during Sleep and Stop modes
Bit 17 **USART2SMEN**: USART2 clocks enable during Sleep and Stop modes
   Set and cleared by software.
   - 0: USART2 clocks disabled by the clock gating(1) during Sleep and Stop modes
   - 1: USART2 clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 16 Reserved, must be kept at reset value.

Bit 15 **SPI3SMEN**: SPI3 clocks enable during Sleep and Stop modes
   Set and cleared by software.
   - 0: SPI3 clocks disabled by the clock gating(1) during Sleep and Stop modes
   - 1: SPI3 clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 14 **SPI2SMEN**: SPI2 clocks enable during Sleep and Stop modes
   Set and cleared by software.
   - 0: SPI2 clocks disabled by the clock gating(1) during Sleep and Stop modes
   - 1: SPI2 clocks enabled by the clock gating(1) during Sleep and Stop modes

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **WWDGSMEN**: Window watchdog clocks enable during Sleep and Stop modes
   Set and cleared by software. This bit is forced to ‘1’ by hardware when the hardware WWDG option is activated.
   - 0: Window watchdog clocks disabled by the clock gating(1) during Sleep and Stop modes
   - 1: Window watchdog clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 10 **RTCAPBSMEN**: RTC APB clock enable during Sleep and Stop modes
   Set and cleared by software.
   - 0: RTC APB clock disabled by the clock gating(1) during Sleep and Stop modes
   - 1: RTC APB clock enabled by the clock gating(1) during Sleep and Stop modes

Bits 6 Reserved, must be kept at reset value.

Bit 5 **TIM7SMEN**: TIM7 timer clocks enable during Sleep and Stop modes
   Set and cleared by software.
   - 0: TIM7 clocks disabled by the clock gating(1) during Sleep and Stop modes
   - 1: TIM7 clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 4 **TIM6SMEN**: TIM6 timer clocks enable during Sleep and Stop modes
   Set and cleared by software.
   - 0: TIM6 clocks disabled by the clock gating(1) during Sleep and Stop modes
   - 1: TIM6 clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 3 **TIM5SMEN**: TIM5 timer clocks enable during Sleep and Stop modes
   Set and cleared by software.
   - 0: TIM5 clocks disabled by the clock gating(1) during Sleep and Stop modes
   - 1: TIM5 clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 2 **TIM4SMEN**: TIM4 timer clocks enable during Sleep and Stop modes
   Set and cleared by software.
   - 0: TIM4 clocks disabled by the clock gating(1) during Sleep and Stop modes
   - 1: TIM4 clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 1 **TIM3SMEN**: TIM3 timer clocks enable during Sleep and Stop modes
   Set and cleared by software.
   - 0: TIM3 clocks disabled by the clock gating(1) during Sleep and Stop modes
   - 1: TIM3 clocks enabled by the clock gating(1) during Sleep and Stop modes
Bit 0  **TIM2SMEN**: TIM2 timer clocks enable during Sleep and Stop modes  
   Set and cleared by software.  
   0: TIM2 clocks disabled by the clock gating\(^1\) during Sleep and Stop modes  
   1: TIM2 clocks enabled by the clock gating\(^1\) during Sleep and Stop modes  

1. This register only configures the clock gating, not the clock source itself. Most of the peripherals are clocked by a single clock (AHB or APB clock), which is always disabled in Stop mode. In this case setting the bit has no effect in Stop mode.

6.4.26 APB1 peripheral clocks enable in Sleep and Stop modes register 2  
(RCC_APB1SMENR2)

Bits 31:6  Reserved, must be kept at reset value.

Bit 5  **LPTIM2SMEN**: Low power timer 2 clocks enable during Sleep and Stop modes  
   Set and cleared by software.  
   0: LPTIM2 clocks disabled by the clock gating\(^1\) during Sleep and Stop modes  
   1: LPTIM2 clocks enabled by the clock gating\(^1\) during Sleep and Stop modes

Bits 4:  Reserved, must be kept at reset value.

Bit 1  **I2C4SMEN**: I2C4 clocks enable during Sleep and Stop modes  
   Set and cleared by software.  
   0: I2C4 clocks disabled by the clock gating\(^1\) during Sleep and Stop modes  
   1: I2C4 clocks enabled by the clock gating\(^1\) during Sleep and Stop modes

Bit 0  **LPUART1SMEN**: Low power UART 1 clocks enable during Sleep and Stop modes  
   Set and cleared by software.  
   0: LPUART1 clocks disabled by the clock gating\(^1\) during Sleep and Stop modes  
   1: LPUART1 clocks enabled by the clock gating\(^1\) during Sleep and Stop modes

1. This register only configures the clock gating, not the clock source itself. Most of the peripherals are clocked by a single clock (AHB or APB clock), which is always disabled in Stop mode. In this case setting the bit has no effect in Stop mode.
6.4.27 APB2 peripheral clocks enable in Sleep and Stop modes register (RCC_APB2SMENR)

Address: 0x80
Reset value: 0x0D67 7801
Access: word, half-word and byte access

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **DSISMEN**: DSI clocks enable during Sleep and Stop modes
Set and cleared by software.
0: DSI clocks disabled by the clock gating(1) during Sleep and Stop modes
1: DSI clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 26 **LTDCSMEN**: LCD-TFT timer clocks enable during Sleep and Stop modes
Set and cleared by software.
0: LCD-TFT clocks disabled by the clock gating(1) during Sleep and Stop modes
1: LCD-TFT clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 25 Reserved, must be kept at reset value.

Bit 24 **DFSDM1SMEN**: DFSDM1 timer clocks enable during Sleep and Stop modes
Set and cleared by software.
0: DFSDM1 clocks disabled by the clock gating(1) during Sleep and Stop modes
1: DFSDM1 clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 23 Reserved, must be kept at reset value.

Bit 22 **SAI2SMEN**: SAI2 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: SAI2 clocks disabled by the clock gating(1) during Sleep and Stop modes
1: SAI2 clocks enabled by the clock gating(1) during Sleep and Stop modes

Bit 21 **SAI1SMEN**: SAI1 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: SAI1 clocks disabled by the clock gating(1) during Sleep and Stop modes
1: SAI1 clocks enabled by the clock gating(1) during Sleep and Stop modes

Bits 20:19 Reserved, must be kept at reset value.

Bit 18 **TIM17SMEN**: TIM17 timer clocks enable during Sleep and Stop modes
Set and cleared by software.
0: TIM17 timer clocks disabled by the clock gating(1) during Sleep and Stop modes
1: TIM17 timer clocks enabled by the clock gating(1) during Sleep and Stop modes
Bit 17 **TIM16SMEN**: TIM16 timer clocks enable during Sleep and Stop modes
   Set and cleared by software.
   0: TIM16 timer clocks disabled by the clock gating\(^{(1)}\) during Sleep and Stop modes
   1: TIM16 timer clocks enabled by the clock gating\(^{(1)}\) during Sleep and Stop modes

Bit 16 **TIM15SMEN**: TIM15 timer clocks enable during Sleep and Stop modes
   Set and cleared by software.
   0: TIM15 timer clocks disabled by the clock gating\(^{(1)}\) during Sleep and Stop modes
   1: TIM15 timer clocks enabled by the clock gating\(^{(1)}\) during Sleep and Stop modes

Bit 15 Reserved, must be kept at reset value.

Bit 14 **USART1SMEN**: USART1 clocks enable during Sleep and Stop modes
   Set and cleared by software.
   0: USART1 clocks disabled by the clock gating\(^{(1)}\) during Sleep and Stop modes
   1: USART1 clocks enabled by the clock gating\(^{(1)}\) during Sleep and Stop modes

Bit 13 **TIM8SMEN**: TIM8 timer clocks enable during Sleep and Stop modes
   Set and cleared by software.
   0: TIM8 timer clocks disabled by the clock gating\(^{(1)}\) during Sleep and Stop modes
   1: TIM8 timer clocks enabled by the clock gating\(^{(1)}\) during Sleep and Stop modes

Bit 12 **SPI1SMEN**: SPI1 clocks enable during Sleep and Stop modes
   Set and cleared by software.
   0: SPI1 clocks disabled by the clock gating\(^{(1)}\) during Sleep and Stop modes
   1: SPI1 clocks enabled by the clock gating\(^{(1)}\) during Sleep and Stop modes

Bit 11 **TIM1SMEN**: TIM1 timer clocks enable during Sleep and Stop modes
   Set and cleared by software.
   0: TIM1 timer clocks disabled by the clock gating\(^{(1)}\) during Sleep and Stop modes
   1: TIM1P timer clocks enabled by the clock gating\(^{(1)}\) during Sleep and Stop modes

Bits 10:1 Reserved, must be kept at reset value.

Bit 0 **SYSCFGSMEN**: SYSCFG + COMP + VREFBUF clocks enable during Sleep and Stop modes
   Set and cleared by software.
   0: SYSCFG + COMP + VREFBUF clocks disabled by the clock gating\(^{(1)}\) during Sleep and Stop modes
   1: SYSCFG + COMP + VREFBUF clocks enabled by the clock gating\(^{(1)}\) during Sleep and Stop modes

---

1. This register only configures the clock gating, not the clock source itself. Most of the peripherals are clocked by a single clock (AHB or APB clock), which is always disabled in Stop mode. In this case setting the bit has no effect in Stop mode.

### 6.4.28 Peripherals independent clock configuration register (RCC_CCIPR)

Address: 0x88

Reset value: 0x0000 0000

Access: no wait states, word, half-word and byte access
Bit 31 Reserved, must be kept at reset value.

Bit 30 Reserved, must be kept at reset value.

Bits 29:28 **ADCSel[1:0]**: ADCs clock source selection

These bits are set and cleared by software to select the clock source used by the ADC interface.

00: No clock selected
01: PLLSAI1 "R" clock (PLLADC1CLK) selected as ADC clock
10: Reserved
11: System clock selected as ADCs clock

Bits 27:26 **CLK48Sel[1:0]**: 48 MHz clock source selection

These bits are set and cleared by software to select the 48 MHz clock source used by USB OTG FS, RNG and SDMMC.

00: HSI48 clock selected as 48 MHz clock
01: PLLSAI1 "Q" clock (PLL48M2CLK) selected as 48 MHz clock
10: PLL "Q" clock (PLL48M1CLK) selected as 48 MHz clock
11: MSI clock selected as 48 MHz clock

Bits 22:25 Reserved, must be kept at reset value.

Bits 21:20 **LPTIM2Sel[1:0]**: Low power timer 2 clock source selection

These bits are set and cleared by software to select the LPTIM2 clock source.

00: PCLK selected as LPTIM2 clock
01: LSI clock selected as LPTIM2 clock
10: HSI16 clock selected as LPTIM2 clock
11: LSE clock selected as LPTIM2 clock

Bits 19:18 **LPTIM1Sel[1:0]**: Low power timer 1 clock source selection

These bits are set and cleared by software to select the LPTIM1 clock source.

00: PCLK selected as LPTIM1 clock
01: LSI clock selected as LPTIM1 clock
10: HSI16 clock selected as LPTIM1 clock
11: LSE clock selected as LPTIM1 clock

Bits 17:16 **I2C3Sel[1:0]**: I2C3 clock source selection

These bits are set and cleared by software to select the I2C3 clock source.

00: PCLK selected as I2C3 clock
01: System clock (SYSCLK) selected as I2C3 clock
10: HSI16 clock selected as I2C3 clock
11: Reserved

6.4.29 Backup domain control register (RCC_BDCR)

Address offset: 0x90
Reset value: 0x0000 0000, reset by Backup domain Reset, except LSCOSEL, LSCOEN and BDRST which are reset only by Backup domain power-on reset.
Access: 0 ≤ wait state ≤ 3, word, half-word and byte access
Wait states are inserted in case of successive accesses to this register.

Note: The bits of the Backup domain control register (RCC_BDCR) are outside of the V_{CORE} domain. As a result, after Reset, these bits are write-protected and the DBP bit in the Section 5.4.1: Power control register 1 (PWR_CR1) has to be set before these can be modified. Refer to Section 5.1.5: Battery backup domain on page 186 for further information. These bits (except LSCOSEL, LSCOEN and BDRST) are only reset after a Backup domain Reset (see Section 6.1.3: Backup domain reset). Any internal or external Reset will not have any effect on these bits.

</table>

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **LSCOSEL**: Low speed clock output selection
Set and cleared by software.
0: LSI clock selected
1: LSE clock selected

Bit 24 **LSCOEN**: Low speed clock output enable
Set and cleared by software.
0: Low speed clock output (LSCO) disable
1: Low speed clock output (LSCO) enable

Bits 23:17 Reserved, must be kept at reset value.

Bit 16 **BDRST**: Backup domain software reset
Set and cleared by software.
0: Reset not activated
1: Reset the entire Backup domain

Bit 15 **RTCEN**: RTC clock enable
Set and cleared by software.
0: RTC clock disabled
1: RTC clock enabled

Bits 14:10 Reserved, must be kept at reset value.
Bits 9:8  **RTCSEL[1:0]: RTC clock source selection**

Set by software to select the clock source for the RTC. Once the RTC clock source has been selected, it cannot be changed anymore unless the Backup domain is reset, or unless a failure is detected on LSE (LSECSSD is set). The BDRST bit can be used to reset them.

- **00**: No clock
- **01**: LSE oscillator clock used as RTC clock
- **10**: LSI oscillator clock used as RTC clock
- **11**: HSE oscillator clock divided by 32 used as RTC clock

Bit 7  **LSESYSDIS**: Disable the Clock LSE propagation to the system

Set by software to disable the Clock LSE propagation to the system. Only RTC is clocked by LSE when this bit is set.

- **1**: No clock LSE propagation
- **0**: Clock LSE propagation enabled

*Note: This bit is available only on STM32L4P5xx and STM32L4Q5xx.*

Bit 6  **LSECSSD**: CSS on LSE failure detection

Set by hardware to indicate when a failure has been detected by the clock security system on the external 32 kHz oscillator (LSE).

- **0**: No failure detected on LSE (32 kHz oscillator)
- **1**: Failure detected on LSE (32 kHz oscillator)

Bit 5  **LSECSSON**: CSS on LSE enable

Set by software to enable the Clock Security System on LSE (32 kHz oscillator). LSECSSON must be enabled after the LSE oscillator is enabled (LSEON bit enabled) and ready (LSERDY flag set by hardware), and after the RTCSEL bit is selected and LSIPREDIV (see note below) is disabled.

Once enabled this bit cannot be disabled, except after a LSE failure detection (LSECSSD =1). In that case the software MUST disable the LSECSSON bit.

- **0**: CSS on LSE (32 kHz external oscillator) OFF
- **1**: CSS on LSE (32 kHz external oscillator) ON

*Note: LSIPREDIV bit is available only on STM32L4P5xx and STM32L4Q5xx.*

Bits 4:3  **LSEDRV[1:0]** LSE oscillator drive capability

Set by software to modulate the LSE oscillator’s drive capability.

- **00**: ‘Xtal mode’ lower driving capability
- **01**: ‘Xtal mode’ medium low driving capability
- **10**: ‘Xtal mode’ medium high driving capability
- **11**: ‘Xtal mode’ higher driving capability

The oscillator is in Xtal mode when it is not in bypass mode.
Bit 2 **LSEBYP**: LSE oscillator bypass
Set and cleared by software to bypass oscillator in debug mode. This bit can be written only when the external 32 kHz oscillator is disabled (LSEON=0 and LSERDY=0).
0: LSE oscillator not bypassed
1: LSE oscillator bypassed

Bit 1 **LSERDY**: LSE oscillator ready
Set and cleared by hardware to indicate when the external 32 kHz oscillator is stable. After the LSEON bit is cleared, LSERDY goes low after 6 external low-speed oscillator clock cycles.
0: LSE oscillator not ready
1: LSE oscillator ready

Bit 0 **LSEON**: LSE oscillator enable
Set and cleared by software.
0: LSE oscillator OFF
1: LSE oscillator ON

### 6.4.30 Control/status register (RCC_CSR)

Address: 0x94

Reset value: 0x0C00 0600, reset by system Reset, except reset flags by power Reset only.

Access: 0 ≤ wait state ≤ 3, word, half-word and byte access

Wait states are inserted in case of successive accesses to this register.

**Bit 31** **LPWRRSTF**: Low-power reset flag
Set by hardware when a reset occurs due to illegal Stop, Standby or Shutdown mode entry. Cleared by writing to the RMVF bit.
0: No illegal mode reset occurred
1: Illegal mode reset occurred

**Bit 30** **WWDGRSTF**: Window watchdog reset flag
Set by hardware when a window watchdog reset occurs. Cleared by writing to the RMVF bit.
0: No window watchdog reset occurred
1: Window watchdog reset occurred

**Bit 29** **IWDRSTF**: Independent window watchdog reset flag
Set by hardware when an independent watchdog reset domain occurs. Cleared by writing to the RMVF bit.
0: No independent watchdog reset occurred
1: Independent watchdog reset occurred
Bit 28  **SFTRSTF**: Software reset flag
Set by hardware when a software reset occurs.
Cleared by writing to the RMVF bit.
0: No software reset occurred
1: Software reset occurred

Bit 27  **BORSTF**: BOR flag
Set by hardware when a BOR occurs.
Cleared by writing to the RMVF bit.
0: No BOR occurred
1: BOR occurred

Bit 26  **PINRSTF**: Pin reset flag
Set by hardware when a reset from the NRST pin occurs.
Cleared by writing to the RMVF bit.
0: No reset from NRST pin occurred
1: Reset from NRST pin occurred

Bit 25  **OB LRSTF**: Option byte loader reset flag
Set by hardware when a reset from the Option Byte loading occurs.
Cleared by writing to the RMVF bit.
0: No reset from Option Byte loading occurred
1: Reset from Option Byte loading occurred

Bit 24  **FWRSTF**: Firewall reset flag
Set by hardware when a reset from the firewall occurs.
Cleared by writing to the RMVF bit.
0: No reset from the firewall occurred
1: Reset from the firewall occurred

Bit 23  **RMVF**: Remove reset flag
Set by software to clear the reset flags.
0: No effect
1: Clear the reset flags

Bits 22:12  Reserved, must be kept at reset value.

Bits 11:8  **MSISRANGE[3:0]** MSI range after Standby mode
Set by software to chose the MSI frequency at startup. This range is used after exiting Standby mode until MSIRGSEL is set. After a pad or a power-on reset, the range is always 4 MHz. MSISRANGE can be written only when MSIRGSEL = ‘1’.
0100: Range 4 around 1 MHz
0101: Range 5 around 2 MHz
0110: Range 6 around 4 MHz (reset value)
0111: Range 7 around 8 MHz
others: Reserved

*Note:*  Changing the MSISRANGE does not change the current MSI frequency.

Bits 7:5  Reserved, must be kept at reset value.
6.4.31 Clock recovery RC register (RCC_CRRCR)

Address: 0x98

Reset value: 0x0000 XXX0 where X is factory-programmed.

Access: no wait state, word, half-word and byte access

Bits 31:16 Reserved, must be kept at reset value

Bits 15:7 HSI48CAL[8:0]: HSI48 clock calibration

These bits are initialized at startup with the factory-programmed HSI48 calibration trim value. They are ready only.
### 6.4.32 Peripherals independent clock configuration register (RCC_CCIPR2)

Address: 0x9C

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access

Wait states are inserted in case of successive accesses to this register.

</thead>
</table>
Bit 14 **SDMMCSEL**: SDMMC clock selection
Set and reset by software.
This bit allows to select the SDMMC kernel clock source between PLLP clock (PLLSAI3CLK) or clock from internal multiplexor.
It is recommended to change this bit only after reset and before enabling the SDMMC module.
- 0: 48 MHz clock is selected as SDMMC kernel clock
- 1: PLLSAI3CLK is selected as SDMMC kernel clock, used in case higher frequency than 48MHz is needed (for SDR50 mode).

Bit 13 Reserved, must be kept at reset value.

Bit 12 **DSISEL** clock selection
Set and reset by software.
This bit allows to select the DSI byte lane clock source between PLLDSICLK clock or clock from DSI-PHY.
It is recommended to change this bit only after reset and before to enable the DSI module.
- 0: DSI-PHY is selected as DSI byte lane clock source (usual case)
- 1: PLLDSICLK is selected as DSI byte lane clock source, used in case DSI PLL and DSI-PHY are off (low-power mode).

Bit 11 Reserved, must be kept at reset value.

Bits 10:8 **SAI2SEL**: SAI2 clock source selection
Set and reset by software.
If the selected clock is the external clock and this clock is stopped it is not possible to switch to another clock. The user must switch to another clock before stopping the external clock.
- 000: PLLSAI1CLK clock is selected as SAI2 clock
- 001: PLLSAI2CLK clock is selected as SAI2 clock
- 010: PLLSAI3CLK clock is selected as SAI2 clock
- 011: External clock SAI2_EXTCLK is selected as SAI2 clock
- 100: HSI clock selected as SAI2 clock
Other configuration are reserved.

Bits 7:5 **SAI1SEL**: SAI1 clock source selection
Set and reset by software.
If the selected clock is the external clock and this clock is stopped it is not possible to switch to another clock.
The user must switch to another clock before stopping the external clock.
- 000: PLLSAI1CLK clock is selected as SAI1 clock
- 001: PLLSAI2CLK clock is selected as SAI1 clock
- 010: PLLSAI3CLK clock is selected as SAI1 clock
- 011: External clock SAI1_EXTCLK is selected as SAI1 clock
- 100: HSI clock selected as SAI1 clock
Other configuration are reserved.
6.4.33  **OCTOSPI delay configuration register (RCC_DLYCFGR)**

Address: 0xA4

Reset value: 0x0000 0000h

Access: no wait state, word, half-word and byte access

This register allows to configure OCTOSPI’s delay cell.

Bits 31:8  Reserved, must be kept at reset value.

Bits 7:4  **OCTOSPI2_DLY:** Delay sampling configuration on OCTOSPI2 to be used for internal sampling clock (called feedback clock) or for DQS data strobe.
Set and reset by software.
0000: 1 unitary delay
0001: 2 unitary delays
0010: 3 unitary delays
...
1111: 16 unitary delays

Bits 3:0  **OCTOSPI1_DLY:** Delay sampling configuration on OCTOSPI1 to be used for internal sampling clock (called feedback clock) or for DQS data strobe.
Set and reset by software.
0000: 1 unitary delay
0001: 2 unitary delays
0010: 3 unitary delays
...
1111: 16 unitary delays

### 6.4.34 RCC register map

The following table gives the RCC register map and the reset values.

| Off- set | Register | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

Refer to Section 2.2 on page 93 for the register boundary addresses.
7 Clock recovery system (CRS)

7.1 Introduction

The clock recovery system (CRS) is an advanced digital controller acting on the internal fine-granularity trimmable RC oscillator HSI48. The CRS provides powerful means for oscillator output frequency evaluation, based on comparison with a selectable synchronization signal. It is capable of doing automatic adjustment of oscillator trimming based on the measured frequency error value, while keeping the possibility of a manual trimming.

The CRS is ideally suited to provide a precise clock to the USB peripheral. In such case, the synchronization signal can be derived from the start-of-frame (SOF) packet signalization on the USB bus, which is sent by a USB host at 1 ms intervals.

The synchronization signal can also be derived from the LSE oscillator output or it can be generated by user software.

7.2 CRS main features

- Selectable synchronization source with programmable prescaler and polarity:
  - External pin
  - LSE oscillator output
  - USB SOF packet reception
- Possibility to generate synchronization pulses by software
- Automatic oscillator trimming capability with no need of CPU action
- Manual control option for faster start-up convergence
- 16-bit frequency error counter with automatic error value capture and reload
- Programmable limit for automatic frequency error value evaluation and status reporting
- Maskable interrupts/events:
  - Expected synchronization (ESYNC)
  - Synchronization OK (SYNCOK)
  - Synchronization warning (SYNCWARN)
  - Synchronization or trimming error (ERR)

7.3 CRS implementation

7.4 CRS functional description

7.4.1 CRS block diagram

Figure 23. CRS block diagram

7.4.2 Synchronization input

The CRS synchronization (SYNC) source, selectable through the CRS_CFRGR register, can be the signal from the LSE clock or the USB SOF signal. For a better robustness of the SYNC input, a simple digital filter (2 out of 3 majority votes, sampled by the RC48 clock) is implemented to filter out any glitches. This source signal also has a configurable polarity and can then be divided by a programmable binary prescaler to obtain a synchronization signal in a suitable frequency range (usually around 1 kHz).

For more information on the CRS synchronization source configuration, refer to Section 7.7.2: CRS configuration register (CRS_CFRGR).

It is also possible to generate a synchronization event by software, by setting the SWSYNC bit in the CRS_CR register.
7.4.3 Frequency error measurement

The frequency error counter is a 16-bit down/up counter which is reloaded with the RELOAD value on each SYNC event. It starts counting down till it reaches the zero value, where the ESYNC (expected synchronization) event is generated. Then it starts counting up to the OUTRANGE limit where it eventually stops (if no SYNC event is received) and generates a SYNCMISS event. The OUTRANGE limit is defined as the frequency error limit (FELIM field of the CRS_CFRGR register) multiplied by 128.

When the SYNC event is detected, the actual value of the frequency error counter and its counting direction are stored in the FECAP (frequency error capture) field and in the FEDIR (frequency error direction) bit of the CRS_ISR register. When the SYNC event is detected during the downcounting phase (before reaching the zero value), it means that the actual frequency is lower than the target (and so, that the TRIM value must be incremented), while when it is detected during the upcounting phase it means that the actual frequency is higher (and that the TRIM value must be decremented).

Figure 24. CRS counter behavior

![Diagram showing CRS counter behavior.](image-url)
7.4.4 Frequency error evaluation and automatic trimming

The measured frequency error is evaluated by comparing its value with a set of limits:
- TOLERANCE LIMIT, given directly in the FELIM field of the CRS_CFGR register
- WARNING LIMIT, defined as 3 * FELIM value
- OUTRANGE (error limit), defined as 128 * FELIM value

The result of this comparison is used to generate the status indication and also to control the automatic trimming which is enabled by setting the AUTOTRIMEN bit in the CRS_CR register:

- When the frequency error is below the tolerance limit, it means that the actual trimming value in the TRIM field is the optimal one, hence no trimming action is needed.
  - SYNCOK status indicated
  - TRIM value not changed in AUTOTRIM mode

- When the frequency error is below the warning limit but above or equal to the tolerance limit, it means that some trimming action is necessary but that adjustment by one trimming step is enough to reach the optimal TRIM value.
  - SYNCWARN status indicated
  - TRIM value adjusted by one trimming step in AUTOTRIM mode

- When the frequency error is above or equal to the warning limit but below the error limit, it means that a stronger trimming action is necessary, and there is a risk that the optimal TRIM value is not reached for the next period.
  - SYNCWARN status indicated
  - TRIM value adjusted by two trimming steps in AUTOTRIM mode

- When the frequency error is above or equal to the error limit, it means that the frequency is out of the trimming range. This can also happen when the SYNC input is not clean or when some SYNC pulse is missing (for example when one USB SOF is corrupted).
  - SYNCERR or SYMCMISS status indicated
  - TRIM value not changed in AUTOTRIM mode

Note: If the actual value of the TRIM field is so close to its limits that the automatic trimming would force it to overflow or underflow, then the TRIM value is set just to the limit and the TRIMOVF status is indicated.

In AUTOTRIM mode (AUTOTRIMEN bit set in the CRS_CR register), the TRIM field of CRS_CR is adjusted by hardware and is read-only.

7.4.5 CRS initialization and configuration

RELOAD value

The RELOAD value must be selected according to the ratio between the target frequency and the frequency of the synchronization source after prescaling. It is then decreased by one to reach the expected synchronization on the zero value. The formula is the following:

\[
\text{RELOAD} = \left( \frac{f_{\text{TARGET}}}{f_{\text{SYNC}}} \right) - 1
\]

The reset value of the RELOAD field corresponds to a target frequency of 48 MHz and a synchronization signal frequency of 1 kHz (SOF signal from USB).
FELIM value

The selection of the FELIM value is closely coupled with the HSI48 oscillator characteristics and its typical trimming step size. The optimal value corresponds to half of the trimming step size, expressed as a number of HSI48 oscillator clock ticks. The following formula can be used:

$$FELIM = \frac{f_{TARGET}}{f_{SYNC}} \times \frac{STEP\%}{100\%} / 2$$

The result must be always rounded up to the nearest integer value to obtain the best trimming response. If frequent trimming actions are not needed in the application, the hysteresis can be increased by slightly increasing the FELIM value.

The reset value of the FELIM field corresponds to $(f_{TARGET} / f_{SYNC}) = 48000$ and to a typical trimming step size of 0.14%.

Caution: There is no hardware protection from a wrong configuration of the RELOAD and FELIM fields which can lead to an erratic trimming response. The expected operational mode requires proper setup of the RELOAD value (according to the synchronization source frequency), which is also greater than 128 * FELIM value (OUTRANGE limit).

7.5 CRS low-power modes

Bits 31:15  Reserved, must be kept at reset value.

Bits 14:8  TRIM[6:0]: HSI48 oscillator smooth trimming
For product supporting the 7-bit TRIM width (see Section 7.3), the default value of the HSI48 oscillator smooth trimming is 64, which corresponds to the middle of the trimming interval. For products supporting the 6-bit TRIM width (see Section 7.3) this bit is reserved, must be kept at reset value.

Bit 7  SWSYNC: Generate software SYNC event
This bit is set by software in order to generate a software SYNC event. It is automatically cleared by hardware.
0: No action
1: A software SYNC event is generated.

Bit 6  AUTOTRIMEN: Automatic trimming enable
This bit enables the automatic hardware adjustment of TRIM bits according to the measured frequency error between two SYNC events. If this bit is set, the TRIM bits are read-only. The TRIM value can be adjusted by hardware by one or two steps at a time, depending on the measured frequency error value. Refer to Section 7.4.4 for more details.
0: Automatic trimming disabled, TRIM bits can be adjusted by the user.
1: Automatic trimming enabled, TRIM bits are read-only and under hardware control.

Bit 5  CEN: Frequency error counter enable
This bit enables the oscillator clock for the frequency error counter.
0: Frequency error counter disabled
1: Frequency error counter enabled
When this bit is set, the CRS_CFGR register is write-protected and cannot be modified.

Bit 4  Reserved, must be kept at reset value.

Bit 3  ESYNCE: Expected SYNC interrupt enable
0: Expected SYNC (ESYNCF) interrupt disabled
1: Expected SYNC (ESYNCF) interrupt enabled
Bit 2 **ERRIE**: Synchronization or trimming error interrupt enable
0: Synchronization or trimming error (ERRF) interrupt disabled
1: Synchronization or trimming error (ERRF) interrupt enabled

Bit 1 **SYNCWARNIE**: SYNC warning interrupt enable
0: SYNC warning (SYNCWARNF) interrupt disabled
1: SYNC warning (SYNCWARNF) interrupt enabled

Bit 0 **SYNCKIE**: SYNC event OK interrupt enable
0: SYNC event OK (SYNCKOF) interrupt disabled
1: SYNC event OK (SYNCKOF) interrupt enabled

### 7.7.2 CRS configuration register (CRS_CFGR)

This register can be written only when the frequency error counter is disabled (CEN bit is cleared in CRS_CR). When the counter is enabled, this register is write-protected.

Address offset: 0x04

Reset value: 0x2022 BB7F

**Bit 31** **SYNCPOL**: SYNC polarity selection
This bit is set and cleared by software to select the input polarity for the SYNC signal source.
0: SYNC active on rising edge (default)
1: SYNC active on falling edge

**Bit 30** Reserved, must be kept at reset value.

**Bits 29:28** **SYNCSRC[1:0]**: SYNC signal source selection
These bits are set and cleared by software to select the SYNC signal source.
00: GPIO selected as SYNC signal source
01: LSE selected as SYNC signal source
10: USB SOF selected as SYNC signal source (default).
11: Reserved

*Note: When using USB LPM (Link Power Management) and the device is in Sleep mode, the periodic USB SOF is not generated by the host. No SYNC signal is therefore provided to the CRS to calibrate the HSI48 oscillator on the run. To guarantee the required clock precision after waking up from Sleep mode, the LSE or reference clock on the GPIOs should be used as SYNC signal.*

**Bit 27** Reserved, must be kept at reset value.
Bits 26:24 **SYNCDIV[2:0]**: SYNC divider
These bits are set and cleared by software to control the division factor of the SYNC signal.
- 000: SYNC not divided (default)
- 001: SYNC divided by 2
- 010: SYNC divided by 4
- 011: SYNC divided by 8
- 100: SYNC divided by 16
- 101: SYNC divided by 32
- 110: SYNC divided by 64
- 111: SYNC divided by 128

Bits 23:16 **FELIM[7:0]**: Frequency error limit
FELIM contains the value to be used to evaluate the captured frequency error value latched in the FECAP[15:0] bits of the CRS_ISR register. Refer to Section 7.4.4 for more details about FECAP evaluation.

Bits 15:0 **RELOAD[15:0]**: Counter reload value
RELOAD is the value to be loaded in the frequency error counter with each SYNC event. Refer to Section 7.4.3 for more details about counter behavior.

</tbody>
</table>

Bits 31:16 **FECAP[15:0]**: Frequency error capture
FECAP is the frequency error counter value latched in the time of the last SYNC event. Refer to Section 7.4.4 for more details about FECAP usage.

Bit 15 **FEDIR**: Frequency error direction
FEDIR is the counting direction of the frequency error counter latched in the time of the last SYNC event. It shows whether the actual frequency is below or above the target.
- 0: Upcounting direction, the actual frequency is above the target.
- 1: Downcounting direction, the actual frequency is below the target.

Bits 14:11 Reserved, must be kept at reset value.

Bit 10 **TRIMOVF**: Trimming overflow or underflow
This flag is set by hardware when the automatic trimming tries to over- or under-flow the TRIM value. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.
- 0: No trimming error signalized
- 1: Trimming error signalized
Bit 9  **SYNCMISS**: SYNC missed
This flag is set by hardware when the frequency error counter reached value FELIM * 128
and no SYNC was detected, meaning either that a SYNC pulse was missed or that the
frequency error is too big (internal frequency too high) to be compensated by adjusting the
TRIM value, and that some other action has to be taken. At this point, the frequency error
counter is stopped (waiting for a next SYNC) and an interrupt is generated if the ERRIE bit is
set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR
register.
0: No SYNC missed error signalized
1: SYNC missed error signalized

Bit 8  **SYNCERR**: SYNC error
This flag is set by hardware when the SYNC pulse arrives before the ESYNC event and the
measured frequency error is greater than or equal to FELIM * 128. This means that the
frequency error is too big (internal frequency too low) to be compensated by adjusting the
TRIM value, and that some other action has to be taken. An interrupt is generated if the
ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in
the CRS_ICR register.
0: No SYNC error signalized
1: SYNC error signalized

Bits 7:4  Reserved, must be kept at reset value.

Bit 3  **ESYNC**: Expected SYNC flag
This flag is set by hardware when the frequency error counter reached a zero value. An
interrupt is generated if the ESYNCIE bit is set in the CRS_CR register. It is cleared by
software by setting the ESYNCC bit in the CRS_ICR register.
0: No expected SYNC signalized
1: Expected SYNC signalized

Bit 2  **ERRF**: Error flag
This flag is set by hardware in case of any synchronization or trimming error. It is the logical
OR of the TRIMOVF, SYNCMISS and SYNCERR bits. An interrupt is generated if the ERRIE
bit is set in the CRS_CR register. It is cleared by software in reaction to setting the ERRC bit
in the CRS_ICR register, which clears the TRIMOVF, SYNCMISS and SYNCERR bits.
0: No synchronization or trimming error signalized
1: Synchronization or trimming error signalized

Bit 1  **SYN CWARNF**: SYNC warning flag
This flag is set by hardware when the measured frequency error is greater than or equal to
FELIM * 3, but smaller than FELIM * 128. This means that to compensate the frequency
error, the TRIM value must be adjusted by two steps or more. An interrupt is generated if the
SYNCWARNIE bit is set in the CRS_CR register. It is cleared by software by setting the
SYNCWARNC bit in the CRS_ICR register.
0: No SYNC warning signalized
1: SYNC warning signalized

Bit 0  **SYNCOKF**: SYNC event OK flag
This flag is set by hardware when the measured frequency error is smaller than FELIM * 3.
This means that either no adjustment of the TRIM value is needed or that an adjustment by
one trimming step is enough to compensate the frequency error. An interrupt is generated if the
SYNCOKE bit is set in the CRS_CR register. It is cleared by software by setting the
SYNCOKCI bit in the CRS_ICR register.
0: No SYNC event OK signalized
1: SYNC event OK signalized
### 7.7.4 CRS interrupt flag clear register (CRS_ICR)

Address offset: 0x0C  
Reset value: 0x0000 0000

| Bit 31:4 Reserved, must be kept at reset value. |
| Bit 3 ESYNCC: Expected SYNC clear flag |
| Writing 1 to this bit clears the ESYNCF flag in the CRS_ISR register. |
| Bit 2 ERRC: Error clear flag |
| Writing 1 to this bit clears TRIMOVF, SYNCMISS and SYNCERR bits and consequently also the ERRF flag in the CRS_ISR register. |
| Bit 1 SYNCWARNC: SYNC warning clear flag |
| Writing 1 to this bit clears the SYNCWARNF flag in the CRS_ISR register. |
| Bit 0 SYNCOKC: SYNC event OK clear flag |
| Writing 1 to this bit clears the SYNCOKF flag in the CRS_ISR register. |

1. The TRIM bitfield can be one bit less. Refer to Section 7.3: CRS implementation for details.

Refer to Section 2.2 on page 93 for the register boundary addresses.
8 General-purpose I/Os (GPIO)

8.1 Introduction

Each general-purpose I/O port has four 32-bit configuration registers (GPIOx_MODER, GPIOx_OTYPE, GPIOx_OSPEEDR and GPIOx_PUPDR), two 32-bit data registers (GPIOx_IDR and GPIOx_ODR) and a 32-bit set/reset register (GPIOx_BSRR). In addition all GPIOs have a 32-bit locking register (GPIOx_LCKR) and two 32-bit alternate function selection registers (GPIOx_AFRH and GPIOx_AFRL).

8.2 GPIO main features

- Output states: push-pull or open drain + pull-up/down
- Output data from output data register (GPIOx_ODR) or peripheral (alternate function output)
- Speed selection for each I/O
- Input states: floating, pull-up/down, analog
- Input data to input data register (GPIOx_IDR) or peripheral (alternate function input)
- Bit set and reset register (GPIOx_BSRR) for bitwise write access to GPIOx_ODR
- Locking mechanism (GPIOx_LCKR) provided to freeze the I/O port configurations
- Analog function
- Alternate function selection registers
- Fast toggle capable of changing every two clock cycles
- Highly flexible pin multiplexing allows the use of I/O pins as GPIOs or as one of several peripheral functions

8.3 GPIO functional description

Subject to the specific hardware characteristics of each I/O port listed in the datasheet, each port bit of the general-purpose I/O (GPIO) ports can be individually configured by software in several modes:

- Input floating
- Input pull-up
- Input-pull-down
- Analog
- Output open-drain with pull-up or pull-down capability
- Output push-pull with pull-up or pull-down capability
- Alternate function push-pull with pull-up or pull-down capability
- Alternate function open-drain with pull-up or pull-down capability

Each I/O port bit is freely programmable, however the I/O port registers have to be accessed as 32-bit words, half-words or bytes. The purpose of the GPIOx_BSRR register is to allow atomic read/modify accesses to any of the GPIOx_ODR registers. In this way, there is no risk of an IRQ occurring between the read and the modify access.
Figure 25 and Figure 26 show the basic structures of a standard and a 5-Volt tolerant I/O port bit, respectively. Table 43 gives the possible port bit configurations.

1. \( V_{\text{DD, FT}} \) is a potential specific to 5-Volt tolerant I/Os and different from \( V_{\text{DD}} \).
Table 43. Port bit configuration table\(^{(1)}\)

1. GP = general-purpose, PP = push-pull, PU = pull-up, PD = pull-down, OD = open-drain, AF = alternate function.
8.3.1 General-purpose I/O (GPIO)

During and just after reset, the alternate functions are not active and most of the I/O ports are configured in analog mode.

The debug pins are in AF pull-up/pull-down after reset:
- PA15: JTDI in pull-up
- PA14: JTCK/SWCLK in pull-down
- PA13: JTMS/SWDAT in pull-up
- PB4: NJTRST in pull-up
- PB3: JTDO in floating state no pull-up/pull-down

PH3/BOOT0 is in input mode during the reset until at least the end of the option byte loading phase. See Section 8.3.15: Using PH3 as GPIO.

When the pin is configured as output, the value written to the output data register (GPIOx_ODR) is output on the I/O pin. It is possible to use the output driver in push-pull mode or open-drain mode (only the low level is driven, high level is HI-Z).

The input data register (GPIOx_IDR) captures the data present on the I/O pin at every AHB clock cycle.

All GPIO pins have weak internal pull-up and pull-down resistors, which can be activated or not depending on the value in the GPIOx_PUPDR register.

8.3.2 I/O pin alternate function multiplexer and mapping

The device I/O pins are connected to on-board peripherals/modules through a multiplexer that allows only one peripheral alternate function (AF) connected to an I/O pin at a time. In this way, there can be no conflict between peripherals available on the same I/O pin.

Each I/O pin has a multiplexer with up to sixteen alternate function inputs (AF0 to AF15) that can be configured through the GPIOx_AFRL (for pin 0 to 7) and GPIOx_AFRH (for pin 8 to 15) registers:
- After reset the multiplexer selection is alternate function 0 (AF0). The I/Os are configured in alternate function mode through GPIOx_MODER register.
- The specific alternate function assignments for each pin are detailed in the device datasheet.

In addition to this flexible I/O multiplexing architecture, each peripheral has alternate functions mapped onto different I/O pins to optimize the number of peripherals available in smaller packages.

To use an I/O in a given configuration, the user has to proceed as follows:
- **Debug function:** after each device reset these pins are assigned as alternate function pins immediately usable by the debugger host
- **GPIO:** configure the desired I/O as output, input or analog in the GPIOx_MODER register.
- **Peripheral alternate function:**
  - Connect the I/O to the desired AFx in one of the GPIOx_AFRL or GPIOx_AFRH register.
  - Select the type, pull-up/pull-down and output speed via the GPIOx_OTYPER, GPIOx_PUPDR and GPIOx_OSPEEDER registers, respectively.
– Configure the desired I/O as an alternate function in the GPIOx_MODER register.

- **Additional functions:**
  - For the ADC, DAC, OPAMP and COMP, configure the desired I/O in analog mode in the GPIOx_MODER register and configure the required function in the ADC, DAC, OPAMP, and COMP registers.
  - For the additional functions like RTC, WKUPx and oscillators, configure the required function in the related RTC, PWR and RCC registers. These functions have priority over the configuration in the standard GPIO registers.

Refer to the “Alternate function mapping” table in the device datasheet for the detailed mapping of the alternate function I/O pins.

### 8.3.3 I/O port control registers

Each of the GPIO ports has four 32-bit memory-mapped control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR) to configure up to 16 I/Os. The GPIOx_MODER register is used to select the I/O mode (input, output, AF, analog). The GPIOx_OTYPER and GPIOx_OSPEEDR registers are used to select the output type (push-pull or open-drain) and speed. The GPIOx_PUPDR register is used to select the pull-up/pull-down whatever the I/O direction.

### 8.3.4 I/O port data registers

Each GPIO has two 16-bit memory-mapped data registers: input and output data registers (GPIOx_IDR and GPIOx_ODR). GPIOx_ODR stores the data to be output, it is read/write accessible. The data input through the I/O are stored into the input data register (GPIOx_IDR), a read-only register.

See Section 8.4.5: GPIO port input data register (GPIOx_IDR) (x = A to I) and Section 8.4.6: GPIO port output data register (GPIOx_ODR) (x = A to I) for the register descriptions.

### 8.3.5 I/O data bitwise handling

The bit set reset register (GPIOx_BSRR) is a 32-bit register which allows the application to set and reset each individual bit in the output data register (GPIOx_ODR). The bit set reset register has twice the size of GPIOx_ODR.

To each bit in GPIOx_ODR, correspond two control bits in GPIOx_BSRR: BS(i) and BR(i). When written to 1, bit BS(i) sets the corresponding ODR(i) bit. When written to 1, bit BR(i) resets the ODR(i) corresponding bit.

Writing any bit to 0 in GPIOx_BSRR does not have any effect on the corresponding bit in GPIOx_ODR. If there is an attempt to both set and reset a bit in GPIOx_BSRR, the set action takes priority.

Using the GPIOx_BSRR register to change the values of individual bits in GPIOx_ODR is a “one-shot” effect that does not lock the GPIOx_ODR bits. The GPIOx_ODR bits can always be accessed directly. The GPIOx_BSRR register provides a way of performing atomic bitwise handling.

There is no need for the software to disable interrupts when programming the GPIOx_ODR at bit level: it is possible to modify one or more bits in a single atomic AHB write access.
8.3.6 GPIO locking mechanism

It is possible to freeze the GPIO control registers by applying a specific write sequence to the GPIOx_LCKR register. The frozen registers are GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL and GPIOx_AFRH.

To write the GPIOx_LCKR register, a specific write / read sequence has to be applied. When the right LOCK sequence is applied to bit 16 in this register, the value of LCKR[15:0] is used to lock the configuration of the I/Os (during the write sequence the LCKR[15:0] value must be the same). When the LOCK sequence has been applied to a port bit, the value of the port bit can no longer be modified until the next MCU reset or peripheral reset. Each GPIOx_LCKR bit freezes the corresponding bit in the control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL and GPIOx_AFRH.

The LOCK sequence (refer to Section 8.4.8: GPIO port configuration lock register (GPIOx_LCKR) (x = A to I)) can only be performed using a word (32-bit long) access to the GPIOx_LCKR register due to the fact that GPIOx_LCKR bit 16 has to be set at the same time as the [15:0] bits.

For more details refer to LCKR register description in Section 8.4.8: GPIO port configuration lock register (GPIOx_LCKR) (x = A to I).

8.3.7 I/O alternate function input/output

Two registers are provided to select one of the alternate function inputs/outputs available for each I/O. With these registers, the user can connect an alternate function to some other pin as required by the application.

This means that a number of possible peripheral functions are multiplexed on each GPIO using the GPIOx_AFRL and GPIOx_AFRH alternate function registers. The application can thus select any one of the possible functions for each I/O. The AF selection signal being common to the alternate function input and alternate function output, a single channel is selected for the alternate function input/output of a given I/O.

To know which functions are multiplexed on each GPIO pin refer to the device datasheet.

8.3.8 External interrupt/wakeup lines

All ports have external interrupt capability. To use external interrupt lines, the port can be configured in input, output or alternate function mode (the port must not be configured in analog mode).

Refer to Section 16: Extended interrupts and events controller (EXTI) and to Section 16.3.2: Wakeup event management.
8.3.9 Input configuration

When the I/O port is programmed as input:

- The output buffer is disabled
- The Schmitt trigger input is activated
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle
- A read access to the input data register provides the I/O state

*Figure 27* shows the input configuration of the I/O port bit.

**Figure 27. Input floating/pull up/pull down configurations**

8.3.10 Output configuration

When the I/O port is programmed as output:

- The output buffer is enabled:
  - Open drain mode: A “0” in the Output register activates the N-MOS whereas a “1” in the Output register leaves the port in Hi-Z (the P-MOS is never activated)
  - Push-pull mode: A “0” in the Output register activates the N-MOS whereas a “1” in the Output register activates the P-MOS
- The Schmitt trigger input is activated
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle
- A read access to the input data register gets the I/O state
- A read access to the output data register gets the last written value
Figure 28 shows the output configuration of the I/O port bit.

**Figure 28. Output configuration**

8.3.11 **Alternate function configuration**

When the I/O port is programmed as alternate function:

- The output buffer can be configured in open-drain or push-pull mode
- The output buffer is driven by the signals coming from the peripheral (transmitter enable and data)
- The Schmitt trigger input is activated
- The weak pull-up and pull-down resistors are activated or not depending on the value in the GPIOx_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle
- A read access to the input data register gets the I/O state

Figure 29 shows the alternate function configuration of the I/O port bit.

**Figure 29. Alternate function configuration**
8.3.12 Analog configuration

When the I/O port is programmed as analog configuration:

- The output buffer is disabled
- The Schmitt trigger input is deactivated, providing zero consumption for every analog value of the I/O pin. The output of the Schmitt trigger is forced to a constant value (0).
- The weak pull-up and pull-down resistors are disabled by hardware
- Read access to the input data register gets the value "0"

*Figure 30* shows the high-impedance, analog-input configuration of the I/O port bits.

8.3.13 Using the HSE or LSE oscillator pins as GPIOs

When the HSE or LSE oscillator is switched OFF (default state after reset), the related oscillator pins can be used as normal GPIOs.

When the HSE or LSE oscillator is switched ON (by setting the HSEON or LSEON bit in the RCC_CSR register) the oscillator takes control of its associated pins and the GPIO configuration of these pins has no effect.

When the oscillator is configured in a user external clock mode, only the pin is reserved for clock input and the OSC_OUT or OSC32_OUT pin can still be used as normal GPIO.

8.3.14 Using the GPIO pins in the RTC supply domain

The PC13/PC14/PC15 GPIO functionality is lost when the core supply domain is powered off (when the device enters Standby mode). In this case, if their GPIO configuration is not bypassed by the RTC configuration, these pins are set in an analog input mode.

For details about I/O control by the RTC, refer to *Section 46.3: RTC functional description.*
8.3.15 Using PH3 as GPIO

PH3 may be used as boot pin (BOOT0) or as a GPIO. Depending on the nSWBOOT0 bit in the user option byte, it switches from the input mode to the analog input mode:

- After the option byte loading phase if nSWBOOT0 = 1.
- After reset if nSWBOOT0 = 0.

8.4 GPIO registers

For a summary of register bits, register address offsets and reset values, refer to Table 44. The peripheral registers can be written in word, half word or byte mode.

8.4.1 GPIO port mode register (GPIOx_MODER) (x = A to I)

Address offset: 0x00

Reset value: 0xABFF FFFF (for port A)
Reset value: 0xFFFF FEBF (for port B)
Reset value: 0xFFFF FFFF (for ports C..G)
Reset value: 0x0000 000F (for port H)

Bits 31:16 BR[15:0]: Port x reset I/O pin y (y = 15 to 0)  
These bits are write-only. A read to these bits returns the value 0x0000.  
0: No action on the corresponding ODx bit  
1: Resets the corresponding ODx bit  
*Note:* If both BSx and BRx are set, BSx has priority.

Bits 15:0 BS[15:0]: Port x set I/O pin y (y = 15 to 0)  
These bits are write-only. A read to these bits returns the value 0x0000.  
0: No action on the corresponding ODx bit  
1: Sets the corresponding ODx bit

8.4.8 GPIO port configuration lock register (GPIOx_LCKR)  
(x = A to I)

This register is used to lock the configuration of the port bits when a correct write sequence is applied to bit 16 (LCKK). The value of bits [15:0] is used to lock the configuration of the GPIO. During the write sequence, the value of LCKR[15:0] must not change. When the
LOCK sequence has been applied on a port bit, the value of this port bit can no longer be modified until the next MCU reset or peripheral reset.

**Note:** A specific write sequence is used to write to the GPIOx_LCKR register. Only word access (32-bit long) is allowed during this locking sequence.

Each lock bit freezes a specific configuration register (control and alternate function registers).

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **LCKK**: Lock key

This bit can be read any time. It can only be modified using the lock key write sequence.

0: Port configuration lock key not active
1: Port configuration lock key active. The GPIOx_LCKR register is locked until the next MCU reset or peripheral reset.

LOCK key write sequence:

WR LCKR[16] = 1 + LCKR[15:0]
WR LCKR[16] = 0 + LCKR[15:0]
WR LCKR[16] = 1 + LCKR[15:0]
RD LCKR
RD LCKR[16] = 1 (this read operation is optional but it confirms that the lock is active)

**Note:** During the LOCK key write sequence, the value of LCK[15:0] must not change. Any error in the lock sequence aborts the lock.

After the first lock sequence on any bit of the port, any read access on the LCKK bit returns 1 until the next MCU reset or peripheral reset.

Bits 15:0 **LCK[15:0]**: Port x lock I/O pin y (y = 15 to 0)

These bits are read/write but can only be written when the LCKK bit is 0.

0: Port configuration not locked
1: Port configuration locked

Refer to Section 2.2 on page 93 for the register boundary addresses.
9 System configuration controller (SYSCFG)

9.1 SYSCFG main features

The STM32L4+ Series devices feature a set of configuration registers. The main purposes of the system configuration controller are the following:

- Remapping memory areas
- Managing the external interrupt line connection to the GPIOs
- Managing robustness feature
- Setting SRAM2 write protection and software erase
- Configuring FPU interrupts
- Enabling the firewall
- Enabling /disabling I2C Fast-mode Plus driving capability on some I/Os and voltage booster for I/Os analog switches.

9.2 SYSCFG registers

9.2.1 SYSCFG memory remap register (SYSCFG_MEMRMP)

This register is used for specific configurations on memory remap.

Address offset: 0x00

Reset value: 0x0000 000X (X is the memory mode selected by the BOOT0 pin and BOOT1 option bit)

<table>
<thead>

</table>
Note: When the FSMC is remapped at address 0x0000 0000, only the first two regions of Bank 1 memory controller (Bank1 NOR/PSRAM 1 and NOR/PSRAM 2) can be remapped. In remap mode, the CPU can access the external memory via ICode bus instead of System bus which boosts up the performance.

### 9.2.2 SYSCFG configuration register 1 (SYSCFG_CFGR1)

Address offset: 0x04

Reset value: 0x7C00 0001
Bits 31:26  **FPU_IE[5..0]**: Floating point unit interrupts enable bits
- **FPU_IE[5]**: Inexact interrupt enable
- **FPU_IE[4]**: Input denormal interrupt enable
- **FPU_IE[3]**: Overflow interrupt enable
- **FPU_IE[2]**: Underflow interrupt enable
- **FPU_IE[1]**: Divide-by-zero interrupt enable
- **FPU_IE[0]**: Invalid operation interrupt enable

Bits 25:24  Reserved, must be kept at reset value.

Bit 23  **I2C4_FMP**: Fast-mode Plus driving capability activation
This bit enables the Fm+ driving mode on I2C4 pins selected through AF selection bits.
- 0: Fm+ mode is not enabled on I2C4 pins selected through AF selection bits
- 1: Fm+ mode is enabled on I2C4 pins selected through AF selection bits.

Bit 22  **I2C3_FMP**: I2C3 Fast-mode Plus driving capability activation
This bit enables the Fm+ driving mode on I2C3 pins selected through AF selection bits.
- 0: Fm+ mode is not enabled on I2C3 pins selected through AF selection bits
- 1: Fm+ mode is enabled on I2C3 pins selected through AF selection bits.

Bit 21  **I2C2_FMP**: I2C2 Fast-mode Plus driving capability activation
This bit enables the Fm+ driving mode on I2C2 pins selected through AF selection bits.
- 0: Fm+ mode is not enabled on I2C2 pins selected through AF selection bits
- 1: Fm+ mode is enabled on I2C2 pins selected through AF selection bits.

Bit 20  **I2C1_FMP**: I2C1 Fast-mode Plus driving capability activation
This bit enables the Fm+ driving mode on I2C1 pins selected through AF selection bits.
- 0: Fm+ mode is not enabled on I2C1 pins selected through AF selection bits
- 1: Fm+ mode is enabled on I2C1 pins selected through AF selection bits.

Bit 19  **I2C_PB9_FMP**: Fast-mode Plus (Fm+) driving capability activation on PB9
This bit enables the Fm+ driving mode for PB9.
- 0: PB9 pin operates in standard mode.
- 1: Fm+ mode enabled on PB9 pin, and the Speed control is bypassed.

Bit 18  **I2C_PB8_FMP**: Fast-mode Plus (Fm+) driving capability activation on PB8
This bit enables the Fm+ driving mode for PB8.
- 0: PB8 pin operates in standard mode.
- 1: Fm+ mode enabled on PB8 pin, and the Speed control is bypassed.

Bit 17  **I2C_PB7_FMP**: Fast-mode Plus (Fm+) driving capability activation on PB7
This bit enables the Fm+ driving mode for PB7.
- 0: PB7 pin operates in standard mode.
- 1: Fm+ mode enabled on PB7 pin, and the Speed control is bypassed.

Bit 16  **I2C_PB6_FMP**: Fast-mode Plus (Fm+) driving capability activation on PB6
This bit enables the Fm+ driving mode for PB6.
- 0: PB6 pin operates in standard mode.
- 1: Fm+ mode enabled on PB6 pin, and the Speed control is bypassed.

Bits 15:10  Reserved, must be kept at reset value.
Table 45 describes when the bit 9 (ANASWVDD) and the bit 8 (BOOSTEN) should be set or reset depending on the voltage settings.

9.2.3 SYSCFG external interrupt configuration register 1 (SYSCFG_EXTICR1)

Address offset: 0x08

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>VDD</th>
<th>VDDA</th>

</table>

**Table 45. BOOSTEN and ANASWVDD set/reset (when at least one analog peripheral supplied by VDDA is enabled)**
Bits 31:16  Reserved, must be kept at reset value.

Bits 15:12 **EXTI3[3:0]:** EXTI 3 configuration bits
   These bits are written by software to select the source input for the EXTI3 external interrupt.
   0000: PA[3] pin
   0001: PB[3] pin
   0100: PE[3] pin
   0101: PF[3] pin
   0111: PH[3] pin
   1000: PI[3] pin

Bits 11:8 **EXTI2[3:0]:** EXTI 2 configuration bits
   These bits are written by software to select the source input for the EXTI2 external interrupt.
   0000: PA[2] pin
   0001: PB[2] pin
   0100: PE[2] pin
   0101: PF[2] pin
   0111: PH[2] pin
   1000: PI[2] pin

Bits 7:4 **EXTI1[3:0]:** EXTI 1 configuration bits
   These bits are written by software to select the source input for the EXTI1 external interrupt.
   0000: PA[1] pin
   0001: PB[1] pin
   0010: PC[1] pin
   0011: PD[1] pin

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **EXTI7[3:0]**: EXTI 7 configuration bits

These bits are written by software to select the source input for the EXTI7 external interrupt.

- 0000: PA[7] pin
- 0001: PB[7] pin
- 0101: PF[7] pin
- 0111: PH[7] pin
- 1000: PI[7] pin
Bits 11:8 **EXTI6[3:0]**: EXTI 6 configuration bits
These bits are written by software to select the source input for the EXTI6 external interrupt.
- 0000: PA[6] pin

Bits 7:4 **EXTI5[3:0]**: EXTI 5 configuration bits
These bits are written by software to select the source input for the EXTI5 external interrupt.
- 0000: PA[5] pin

Bits 3:0 **EXTI4[3:0]**: EXTI 4 configuration bits
These bits are written by software to select the source input for the EXTI4 external interrupt.
- 0000: PA[4] pin

Note: Some of the I/O pins mentioned in the above register may not be available on small packages.

9.2.5 SYSCFG external interrupt configuration register 3
(SYSCFG_EXTICR3)
Address offset: 0x10
Reset value: 0x0000 0000
Bits 31:16  Reserved, must be kept at reset value.

Bits 15:12  **EXTI11[3:0]**: EXTI 11 configuration bits
These bits are written by software to select the source input for the EXTI11 external interrupt.

Bits 11:8  **EXTI10[3:0]**: EXTI 10 configuration bits
These bits are written by software to select the source input for the EXTI10 external interrupt.
0000: PA[10] pin
0001: PB[10] pin
0010: PC[10] pin
0011: PD[10] pin
0100: PE[10] pin
0101: PF[10] pin
0110: PG[10] pin
0111: PH[10] pin
1000: PI[10] pin

Bits 7:4  **EXTI9[3:0]**: EXTI 9 configuration bits
These bits are written by software to select the source input for the EXTI9 external interrupt.
0000: PA[9] pin
0001: PB[9] pin
0010: PC[9] pin
0100: PE[9] pin
0101: PF[9] pin
0110: PG[9] pin
0111: PH[9] pin
1000: PI[9] pin

Bits 3:0  **EXTI8[3:0]**: EXTI 8 configuration bits
These bits are written by software to select the source input for the EXTI8 external interrupt.
0000: PA[8] pin
0001: PB[8] pin
0010: PC[8] pin
0011: PD[8] pin
0100: PE[8] pin
0101: PF[8] pin
0110: PG[8] pin
0111: PH[8] pin
1000: PI[8] pin

**Note:** Some of the I/O pins mentioned in the above register may not be available on small packages.

Note: Some of the I/O pins mentioned in the above register may not be available on small packages.
Bit 31:2  Reserved, must be kept at reset value

Bit 1  **SRAM2BSY:** SRAM2 busy by erase operation
0: No SRAM2 erase operation is on going.
1: SRAM2 erase operation is on going.

Bit 0  **SRAM2ER:** SRAM2 Erase
Setting this bit starts a hardware SRAM2 erase operation. This bit is automatically cleared at the end of the SRAM2 erase operation.

*Note:* This bit is write-protected: setting this bit is possible only after the correct key sequence is written in the SYSCFG_SKR register.

### 9.2.8  SYSCFG configuration register 2 (SYSCFG_CFGR2)

Address offset: 0x1C
System reset value: 0x0000 0000

</table>
```

Bits 31:9  Reserved, must be kept at reset value

Bit 8  **SPF:** SRAM2 parity error flag
This bit is set by hardware when an SRAM2 parity error is detected. It is cleared by software by writing '1'.
0: No SRAM2 parity error detected
1: SRAM2 parity error detected

Bits 7:4  Reserved, must be kept at reset value

Bit 3  **ECCL:** ECC Lock
This bit is set by software and cleared only by a system reset. It can be used to enable and lock the Flash ECC error connection to TIM1/8/15/16/17 Break input.
0: ECC error disconnected from TIM1/8/15/16/17 Break input.
1: ECC error connected to TIM1/8/15/16/17 Break input.
9.2.9 SYSCFG SRAM2 write protection register (SYSCFG_SWPR)

</table>

Bits 31:0 PxWP (x = 0 to 31): SRAM2 page x write protection
These bits are set by software and cleared only by a system reset.
0: Write protection of SRAM2 page x is disabled.
1: Write protection of SRAM2 page x is enabled.

9.2.10 SYSCFG SRAM2 key register (SYSCFG_SKR)

Address offset: 0x24

System reset value: 0x0000 0000
9.2.11 SYSCFG SRAM2 write protection register 2 (SYSCFG_SWPR2)

Address offset: 0x28
System reset value: 0x0000 0000

Bits 31:8 Reserved, must be kept at reset value

Bits 7:0 **KEY[7:0]:** SRAM2 write protection key for software erase

The following steps are required to unlock the write protection of the SRAM2ER bit in the SYSCFG_CFRGR2 register.
1. Write “0xCA” into Key[7:0]
2. Write “0x53” into Key[7:0]
Writing a wrong key reactivates the write protection.

Bits 31:0 **PxWP** (x= 32 to 63): SRAM2 page x write protection

These bits are set by software and cleared only by a system reset.
0: Write protection of SRAM2 page x is disabled.
1: Write protection of SRAM2 page x is enabled.
### 9.2.12 SYSCFG register map

Refer to Section 2.2 on page 93 for the register boundary addresses.
10 Peripherals interconnect matrix

10.1 Introduction

Several peripherals have direct connections between them. This allows autonomous communication and or synchronization between peripherals, saving CPU resources thus power supply consumption.

In addition, these hardware connections remove software latency and allow design of predictable system.

Depending on peripherals, these interconnections can operate in Run, Sleep, Low-power run and sleep, Stop 0, Stop 1 and Stop 2 modes.

10.3 Interconnection details

10.3.1 From timer (TIM1/TIM2/TIM3/TIM4/TIM5/TIM8/TIM15/TIM16/TIM17) to timer (TIM1/TIM2/TIM3/TIM4/TIM5/TIM8/TIM15)

**Purpose**

Some of the TIMx timers are linked together internally for timer synchronization or chaining. When one timer is configured in Master Mode, it can reset, start, stop or clock the counter of another timer configured in Slave Mode.

A description of the feature is provided in: Section 38.3.19: Timer synchronization.

</table>

1. Numbers in table are links to corresponding detailed sub-section in Section 10.3: Interconnection details.
2. The "-" symbol in grayed cells means no interconnect.
3. ADC2 is only available on STM32L4P5xx and STM32L4Q5xx devices.
4. DAC channel 1.
5. DAC channel 2.
The modes of synchronization are detailed in:

- Section 37.3.26: Timer synchronization for advanced-control timers (TIM1/TIM8)
- Section 38.3.18: Timers and external trigger synchronization for general-purpose timers (TIM2/TIM3/TIM4/TIM5)
- Section 39.4.19: External trigger synchronization (TIM15 only) for general-purpose timer (TIM15)

**Triggering signals**

The output (from Master) is on signal TIMx_TRGO (and TIMx_TRGO2 for TIM1/TIM8) following a configurable timer event.

The input (to slave) is on signals TIMx_ITR0/ITR1/ITR2/ITR3

The input and output signals for TIM1/TIM8 are shown in Figure 282: Advanced-control timer block diagram.

The possible master/slave connections are given in:

- Table 279: TIMx internal trigger connection
- Table 284: TIMx internal trigger connection
- Table 288: TIMx Internal trigger connection

**Active power mode**

Run, Sleep, Low-power run, Low-power sleep.

10.3.2 From timer (TIM1/TIM2/TIM3/TIM4/TIM6/TIM8/TIM15) and EXTI to ADC (ADC1)

**Purpose**

General-purpose timers (TIM2/TIM3/TIM4), basic timer (TIM6), advanced-control timers (TIM1/TIM8), general-purpose timer (TIM15) and EXTI can be used to generate an ADC triggering event.

TIMx synchronization is described in: Section 37.3.27: ADC synchronization (TIM1/TIM8).

ADC synchronization is described in: Section 21.4.18: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN).

**Triggering signals**

The output (from timer) is on signal TIMx_TRGO, TIMx_TRGO2 or TIMx_CCx event. The input (to ADC) is on signal EXT[15:0], JEXT[15:0].

The connection between timers and ADC is provided in:

- Table 131: ADC1 - External triggers for regular channels
- Table 132: ADC1 - External trigger for injected channels

**Active power mode**

Run, Sleep, Low-power run, Low-power sleep.
10.3.3 From ADC to timer (TIM1/TIM8)

**Purpose**
ADC1 can provide trigger event through watchdog signals to advanced-control timers (TIM1/TIM8).

A description of the ADC analog watchdog setting is provided in: *Section 21.4.29: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)*.

Trigger settings on the timer are provided in: *Section 37.3.4: External trigger input*.

**Triggering signals**
The output (from ADC) is on signals ADCn_AWDx_OUT n = 1, 2 (for ADC1, 2) x = 1, 2, 3 (3 watchdog per ADC) and the input (to timer) on signal TIMx_ETR (external trigger).

**Active power mode**
Run, Sleep, Low-power run, Low-power sleep.

10.3.4 From timer (TIM2/TIM4/TIM5/TIM6/TIM7/TIM8/LPTIM1/LPTIM2) and EXTI to DAC (internal channel 1 and channel 2)

**Purpose**
General-purpose timers (TIM2/TIM4/TIM5), basic timers (TIM6, TIM7), advanced-control timers (TIM8), low power timers (LPTIM1, LPTIM2) and EXTI can be used as triggering event to start a DAC conversion.

**Triggering signals**
The output (from timer) is on signal TIMx_TRGO directly connected to corresponding DAC inputs.

Selection of input triggers on DAC is provided in *Section 22.4.6: DAC trigger selection* (single and dual mode).

**Active power mode**
Run, Sleep, Low-power run, Low-power sleep.

10.3.5 From timer (TIM1/TIM3/TIM4/TIM6/TIM7/TIM8/TIM16/LPTIM1/LPTIM2) and EXTI to DFSDM1

**Purpose**
General-purpose timers (TIM3/TIM4), basic timers (TIM6/TIM7), advanced-control timers (TIM1/TIM8), general-purpose timer (TIM16), low power timers (LPTIM1/LPTIM2) and EXTI can be used to generate a triggering event on DFSDM1 module (on each possible data block DFSDM1_FLT0/DFSDM1_FLT1/DFSDM1_FLT2/DFSDM1_FLT3) and start an ADC conversion.

DFSDM triggered conversion feature is described in: *Section 28.4.15: Launching conversions*. 
Triggering signals

The output (from timer) is on signal TIMx_TRGO/TIMx_TRGO2 or TIM16_OC1.

The input (on DFSDM1) is on signal DFSDM1_INTRG[0:8].

The connection between timers, EXTI and DFSDM1 is provided in Table 187: DFSDM triggers connection.

Active power mode

Run, Sleep, Low-power run, Low-power sleep.

10.3.6 From DFSDM1 to timer (TIM1/TIM8/TIM15/TIM16/TIM17)

Purpose

DFSDM1 can generate a timer break on advanced-control timers (TIM1/TIM8) and general-purpose timers (TIM15/TIM16/TIM17) when a watchdog is activated (minimum or maximum threshold value crossed by analog signal) or when a short-circuit detection is made.

DFSDM1 watchdog is described in Section 28.4.10: Analog watchdog.

DFSDM1 short-circuit detection is described in Section 28.4.11: Short-circuit detector.

Timer break is described in:

- Section 37.3.16: Using the break function (TIM1/TIM8)
- Section 39.4.13: Using the break function (TIM15/TIM16/TIM17)

Triggering signals

The output (from DFSDM1) is on signals dfsdm1_break[0:3] directly connected to timer and 'Ored' with other break input signals of the timer.

Active power mode

Run, Sleep, Low-power run, Low-power sleep.

10.3.7 From HSE, LSE, LSI, MSI, MCO, RTC to timer (TIM2/TIM15/TIM16/TIM17)

Purpose

External clocks (HSE, LSE), internal clocks (LSI, MSI), microcontroller output clock (MCO), GPIO and RTC wakeup interrupt can be used as input to general-purpose timer (TIM15/16/17) channel 1.

This allows to calibrate the HSI16/MSI system clocks (with TIM15/TIM16 and LSE) or LSI (with TIM16 and HSE). This is also used to precisely measure LSI (with TIM16 and HSI16) or MSI (with TIM17 and HSI16) oscillator frequency.

When Low Speed External (LSE) oscillator is used, no additional hardware connections are required.

This feature is described in Section 6.2.17: Internal/external clock measurement with TIM15/TIM16/TIM17.
External clock LSE can be used as input to general-purpose timers (TIM2) on TIM2_ETR pin, see Section 38.4.22: TIM2 option register 1 (TIM2_OR1).

**Active power mode**
Run, Sleep, Low-power run, Low-power sleep.

### 10.3.8 From RTC, COMP1, COMP2 to low-power timer (LPTIM1/LPTIM2)

**Purpose**
RTC alarm A/B, RTC_TAMP1/2/3 input detection, COMP1/2_OUT can be used as trigger to start LPTIM counters (LPTIM1/2).

**Triggering signals**
This trigger feature is described in Section 41.4.7: Trigger multiplexer and following sections.

The input selection is described in Table 297: LPTIM1 external trigger connection.

**Active power mode**
Run, Sleep, Low-power run, Low-power sleep, Stop 0, Stop 1, Stop 2 (LPTIM1 only).

### 10.3.9 From timer (TIM1/TIM2/TIM3/TIM8/TIM15) to comparators (COMP1/COMP2)

**Purpose**
Advanced-control timers (TIM1/TIM8), general-purpose timers (TIM2/TIM3) and general-purpose timer (TIM15) can be used as blanking window input to COMP1/COMP2

The blanking function is described in Section 26.3.7: Comparator output blanking function.

The blanking sources are given in:
- Section 26.6.1: Comparator 1 control and status register (COMP1_CSR) bits 20:18 BLANKING[2:0]
- Section 26.6.2: Comparator 2 control and status register (COMP2_CSR) bits 20:18 BLANKING[2:0]

**Triggering signals**
Timer output signal TIMx_Ocx are the inputs to blanking source of COMP1/COMP2.

**Active power mode**
Run, Sleep, Low-power run, Low-power sleep.

### 10.3.10 From ADC (ADC1) to ADC (ADC2)

**Purpose**
ADC1 can be used as a “master” to trigger ADC2 “slave” start of conversion.

In dual ADC mode, the converted data of the master and slave ADCs can be read in parallel.
A description of dual ADC mode is provided in: Section 21.4.31: Dual ADC modes.

**Triggering signals**
Internal to the ADCs.

**Active power mode**
Run, Sleep, Low-power run, Low-power sleep.

### 10.3.11 From USB to timer (TIM2)

**Purpose**
USB (OTG_FS SOF) can generate a trigger to general-purpose timer (TIM2).

Connection of USB to TIM2 is described in Table 284: TIMx internal trigger connection.

**Triggering signals**
Internal signal generated by USB FS Start Of Frame.

**Active power mode**
Run, Sleep.

### 10.3.12 From internal analog source to ADC and OPAMP (OPAMP1/OPAM2)

**Purpose**
Internal temperature sensor ($V_{TS}$) and $V_{BAT}$ monitoring channel are connected to ADC1 input channels.

Internal reference voltage ($V_{REFINT}$) is connected to ADC1 input channels.

OPAMP1 and OPAMP2 outputs can be connected to ADC1 or ADC2 input channels through the GPIO.

DAC1\_OUT1 can be connected to OPAMP1\_VINP.

DAC1\_OUT2 can be connected to OPAMP2\_VINP.

This is according:
- Section 21.2: ADC main features
- Section 21.4.11: Channel selection (SQRx, JSQRx)
- Figure 89: ADC1 connectivity
- Table 179: Operational amplifier possible connections

**Active power mode**
Run, Sleep, Low-power run, Low-power sleep.
10.3.13 From comparators (COMP1/COMP2) to timers (TIM1/TIM2/TIM3/TIM8/TIM15/TIM16/TIM17)

**Purpose**

Comparators (COMP1/COMP2) output values can be connected to timers (TIM1/TIM2/TIM3/TIM8/TIM15/TIM16/TIM17) input captures or TIMx_ETR signals.

The connection to ETR is described in Section 37.3.4: External trigger input.

Comparators (COMP1/COMP2) output values can also generate break input signals for timers (TIM1/TIM8) on input pins TIMx_BKIN or TIMx_BKIN2 through GPIO alternate function selection using open drain connection of IO, see Section 37.3.17: Bidirectional break inputs.

The possible connections are given in:
- Section 37.4.23: TIM1 option register 1 (TIM1_OR1)
- Section 37.4.24: TIM8 option register 1 (TIM8_OR1)
- Section 38.4.22: TIM2 option register 1 (TIM2_OR1)
- Section 38.4.23: TIM3 option register 1 (TIM3_OR1)
- Section 38.4.26: TIMx register map
- Section 38.4.25: TIM3 option register 2 (TIM3_OR2)
- Section 39.3: TIM16/TIM17 main features

**Active power mode**

Run, Sleep, Low-power run, Low-power sleep.

10.3.14 From system errors to timers (TIM1/TIM8/TIM15/TIM16/TIM17)

**Purpose**

CSS, CPU hardfault, RAM parity error, FLASH ECC double error detection, PVD can generate system errors in the form of timer break toward timers (TIM1/TIM8/TIM15/TIM16/TIM17).

The purpose of the break function is to protect power switches driven by PWM signals generated by the timers.

List of possible source of break are described in:
- Section 37.3.16: Using the break function (TIM1/TIM8)
- Section 39.4.13: Using the break function (TIM15/TIM16/TIM17)
- Figure 393: TIM15 block diagram
- Figure 394: TIM16/TIM17 block diagram

**Active power mode**

Run, Sleep, Low-power run, Low-power sleep.
10.3.15 From timers (TIM16/TIM17) to IRTIM

**Purpose**

General-purpose timer (TIM16/TIM17) output channel TIMx_OC1 are used to generate the waveform of infrared signal output.

The functionality is described in *Section 43: Infrared interface (IRTIM)*.

**Active power mode**

Run, Sleep, Low-power run, Low-power sleep.

10.3.16 From ADC (ADC1/ADC2) to DFSDM

**Purpose**

Up to 2 internal ADC results can be directly connected through a parallel bus to DFSDM input in order to use DFSDM filtering capabilities.

The feature is described as part of DFSDM peripheral description in *Section 28.4.6: Parallel data inputs - Input from internal ADC*

The possible connections are given in:

- *Section 28.7.1: DFSDM channel y configuration register (DFSDM_CHyCFGR1)*
  - Bits 13:12 DATMPX[1:0]: Input data multiplexer for channel y

- *Section 28.7.5: DFSDM channel y data input register (DFSDM_CHyDATINR)*
  - Bits 31:16 INDAT0[15:0]: Input data for channel y or channel y+1
  - Bits 15:0 INDAT0[15:0]: Input data for channel y

**Active power mode**

Run, Sleep, Low-power run, Low-power sleep.
11 Direct memory access controller (DMA)

11.1 Introduction

The direct memory access (DMA) controller is a bus master and system peripheral. The DMA is used to perform programmable data transfers between memory-mapped peripherals and/or memories, upon the control of an off-loaded CPU.

The DMA controller features a single AHB master architecture.

There are two instances of DMA, DMA1 and DMA2.

Each channel is dedicated to managing memory access requests from one or more peripherals. Each DMA includes an arbiter for handling the priority between DMA requests.

11.2 DMA main features

- Single AHB master
- Peripheral-to-memory, memory-to-peripheral, memory-to-memory and peripheral-to-peripheral data transfers
- Access, as source and destination, to on-chip memory-mapped devices such as Flash memory, SRAM, and AHB and APB peripherals
- All DMA channels independently configurable:
  - Each channel is associated either with a DMA request signal coming from a peripheral, or with a software trigger in memory-to-memory transfers. This configuration is done by software.
  - Priority between the requests is programmable by software (4 levels per channel: very high, high, medium, low) and by hardware in case of equality (such as request to channel 1 has priority over request to channel 2).
  - Transfer size of source and destination are independent (byte, half-word, word), emulating packing and unpacking. Source and destination addresses must be aligned on the data size.
  - Support of transfers from/to peripherals to/from memory with circular buffer management
  - Programmable number of data to be transferred: 0 to $2^{16} - 1$
- Generation of an interrupt request per channel. Each interrupt request is caused from any of the three DMA events: transfer complete, half transfer, or transfer error.
11.3 DMA implementation

11.3.1 DMA1 and DMA2

DMA1 and DMA2 are implemented with the hardware configuration parameters shown in the table below.

<table>
<thead>
<tr>
<th>Feature</th>
<th>DMA1</th>
<th>DMA2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of channels</td>
<td>7</td>
<td>7</td>
</tr>
</tbody>
</table>

11.3.2 DMA request mapping

The DMA controller is connected to DMA requests from the AHB/APB peripherals through the DMAMUX peripheral.

For the mapping of the different requests, refer to the Section 12.3: DMAMUX implementation.

11.4 DMA functional description

11.4.1 DMA block diagram
The DMA block diagram is shown in the figure below.

**Figure 31. DMA block diagram**

The DMA controller performs direct memory transfer by sharing the AHB system bus with other system masters. The bus matrix implements round-robin scheduling. DMA requests may stop the CPU access to the system bus for a number of bus cycles, when CPU and DMA target the same destination (memory or peripheral).
According to its configuration through the AHB slave interface, the DMA controller arbitrates between the DMA channels and their associated received requests. The DMA controller also schedules the DMA data transfers over the single AHB port master.

The DMA controller generates an interrupt per channel to the interrupt controller.

### 11.4.2 DMA pins and internal signals

**Table 49. DMA internal input/output signals**

<table>
<thead>
<tr>

<tr>
<td>dma_it[x]</td>
<td>Output</td>
<td>DMA channel x interrupt</td>
</tr>
</tbody>
</table>

### 11.4.3 DMA transfers

The software configures the DMA controller at channel level, in order to perform a block transfer, composed of a sequence of AHB bus transfers.

A DMA block transfer may be requested from a peripheral, or triggered by the software in case of memory-to-memory transfer.

After an event, the following steps of a single DMA transfer occur:

1. The peripheral sends a single DMA request signal to the DMA controller.
2. The DMA controller serves the request, depending on the priority of the channel associated to this peripheral request.
3. As soon as the DMA controller grants the peripheral, an acknowledge is sent to the peripheral by the DMA controller.
4. The peripheral releases its request as soon as it gets the acknowledge from the DMA controller.
5. Once the request is de-asserted by the peripheral, the DMA controller releases the acknowledge.

The peripheral may order a further single request and initiate another single DMA transfer.

The request/acknowledge protocol is used when a peripheral is either the source or the destination of the transfer. For example, in case of memory-to-peripheral transfer, the peripheral initiates the transfer by driving its single request signal to the DMA controller. The DMA controller reads then a single data in the memory and writes this data to the peripheral.

For a given channel x, a DMA block transfer consists of a repeated sequence of:

- a single DMA transfer, encapsulating two AHB transfers of a single data, over the DMA AHB bus master:
  - a single data read (byte, half-word or word) from the peripheral data register or a location in the memory, addressed through an internal current peripheral/memory address register. The start address used for the first single transfer is the base address of the peripheral or memory, and is programmed in the DMA_CPARx or DMA_CMARx register.
  - a single data write (byte, half-word or word) to the peripheral data register or a location in the memory, addressed through an internal current peripheral/memory address register.
address register.
The start address used for the first transfer is the base address of the peripheral or memory, and is programmed in the DMA_CPARx or DMA_CMARx register.

- post-decrementing of the programmed DMA_CNDTRx register
  This register contains the remaining number of data items to transfer (number of AHB 'read followed by write' transfers).

This sequence is repeated until DMA_CNDTRx is null.

*Note:* The AHB master bus source/destination address must be aligned with the programmed size of the transferred single data to the source/destination.

### 11.4.4 DMA arbitration

The DMA arbiter manages the priority between the different channels.

When an active channel x is granted by the arbiter (hardware requested or software triggered), a single DMA transfer is issued (such as a AHB 'read followed by write' transfer of a single data). Then, the arbiter considers again the set of active channels and selects the one with the highest priority.

The priorities are managed in two stages:

- software: priority of each channel is configured in the DMA_CCRx register, to one of the four different levels:
  - very high
  - high
  - medium
  - low
- hardware: if two requests have the same software priority level, the channel with the lowest index gets priority. For example, channel 2 gets priority over channel 4.

When a channel x is programmed for a block transfer in memory-to-memory mode, re arbitration is considered between each single DMA transfer of this channel x. Whenever there is another concurrent active requested channel, the DMA arbiter automatically alternates and grants the other highest-priority requested channel, which may be of lower priority than the memory-to-memory channel.

### 11.4.5 DMA channels

Each channel may handle a DMA transfer between a peripheral register located at a fixed address, and a memory address. The amount of data items to transfer is programmable. The register that contains the amount of data items to transfer is decremented after each transfer.

A DMA channel is programmed at block transfer level.

#### Programmable data sizes

The transfer sizes of a single data (byte, half-word, or word) to the peripheral and memory are programmable through, respectively, the PSIZE[1:0] and MSIZE[1:0] fields of the DMA_CCRx register.
**Pointer incrementation**

The peripheral and memory pointers may be automatically incremented after each transfer, depending on the PINC and MINC bits of the DMA_CCRx register.

If the **incremented mode** is enabled (PINC or MINC set to 1), the address of the next transfer is the address of the previous one incremented by 1, 2 or 4, depending on the data size defined in PSIZE[1:0] or MSIZE[1:0]. The first transfer address is the one programmed in the DMA_CPARx or DMA_CMARx register. During transfers, these registers keep the initially programmed value. The current transfer addresses (in the current internal peripheral/memory address register) are not accessible by software.

If the channel x is configured in **non-circular mode**, no DMA request is served after the last data transfer (once the number of single data to transfer reaches zero). The DMA channel must be disabled in order to reload a new number of data items into the DMA_CNDTRx register.

**Note:** If the channel x is disabled, the DMA registers are not reset. The DMA channel registers (DMA_CCRx, DMA_CPARx and DMA_CMARx) retain the initial values programmed during the channel configuration phase.

In **circular mode**, after the last data transfer, the DMA_CNDTRx register is automatically reloaded with the initially programmed value. The current internal address registers are reloaded with the base address values from the DMA_CPARx and DMA_CMARx registers.

**Channel configuration procedure**

The following sequence is needed to configure a DMA channel x:

1. Set the peripheral register address in the DMA_CPARx register.
   The data is moved from/to this address to/from the memory after the peripheral event, or after the channel is enabled in memory-to-memory mode.

2. Set the memory address in the DMA_CMARx register.
   The data is written to/read from the memory after the peripheral event or after the channel is enabled in memory-to-memory mode.

3. Configure the total number of data to transfer in the DMA_CNDTRx register.
   After each data transfer, this value is decremented.

4. Configure the parameters listed below in the DMA_CCRx register:
   - the channel priority
   - the data transfer direction
   - the circular mode
   - the peripheral and memory incremented mode
   - the peripheral and memory data size
   - the interrupt enable at half and/or full transfer and/or transfer error

5. Activate the channel by setting the EN bit in the DMA_CCRx register.

A channel, as soon as enabled, may serve any DMA request from the peripheral connected to this channel, or may start a memory-to-memory block transfer.

**Note:** The two last steps of the channel configuration procedure may be merged into a single access to the DMA_CCRx register, to configure and enable the channel.
Channel state and disabling a channel

A channel \( x \) in active state is an enabled channel (read \( \text{DMA	extunderscore CCR}x.\text{EN} = 1 \)). An active channel \( x \) is a channel that must have been enabled by the software (\( \text{DMA	extunderscore CCR}x.\text{EN} \) set to 1) and afterwards with no occurred transfer error (\( \text{DMA	extunderscore ISR}.\text{TEIF}x = 0 \)). In case there is a transfer error, the channel is automatically disabled by hardware (\( \text{DMA	extunderscore CCR}x.\text{EN} = 0 \)).

The three following use cases may happen:

- **Suspend and resume a channel**
  This corresponds to the two following actions:
  - An active channel is disabled by software (writing \( \text{DMA	extunderscore CCR}x.\text{EN} = 0 \) whereas \( \text{DMA	extunderscore CCR}x.\text{EN} = 1 \)).
  - The software enables the channel again (\( \text{DMA	extunderscore CCR}x.\text{EN} \) set to 1) without reconfiguring the other channel registers (such as \( \text{DMA	extunderscore CNDTR}x, \text{DMA	extunderscore CPAR}x \) and \( \text{DMA	extunderscore CMAR}x \)).

  This case is not supported by the DMA hardware, that does not guarantee that the remaining data transfers are performed correctly.

- **Stop and abort a channel**
  If the application does not need any more the channel, this active channel can be disabled by software. The channel is stopped and aborted but the \( \text{DMA	extunderscore CNDTR}x \) register content may not correctly reflect the remaining data transfers versus the aborted source and destination buffer/register.

- **Abort and restart a channel**
  This corresponds to the software sequence: disable an active channel, then reconfigure the channel and enable it again.
  This is supported by the hardware if the following conditions are met:
  - The application guarantees that, when the software is disabling the channel, a DMA data transfer is not occurring at the same time over its master port. For example, the application can first disable the peripheral in DMA mode, in order to ensure that there is no pending hardware DMA request from this peripheral.
  - The software must operate separated write accesses to the same \( \text{DMA	extunderscore CCR}x \) register: First disable the channel. Second reconfigure the channel for a next block transfer including the \( \text{DMA	extunderscore CCR}x \) if a configuration change is needed. There are read-only \( \text{DMA	extunderscore CCR}x \) register fields when \( \text{DMA	extunderscore CCR}x.\text{EN} = 1 \). Finally enable again the channel.

When a channel transfer error occurs, the \( \text{EN} \) bit of the \( \text{DMA	extunderscore CCR}x \) register is cleared by hardware. This \( \text{EN} \) bit can not be set again by software to re-activate the channel \( x \), until the \( \text{TEIF}x \) bit of the \( \text{DMA	extunderscore ISR} \) register is set.

Circular mode (in memory-to-peripheral/peripheral-to-memory transfers)

The circular mode is available to handle circular buffers and continuous data flows (such as ADC scan mode). This feature is enabled using the \( \text{CIRC} \) bit in the \( \text{DMA	extunderscore CCR}x \) register.

*Note:* The circular mode must not be used in memory-to-memory mode. Before enabling a channel in circular mode (\( \text{CIRC} = 1 \)), the software must clear the \( \text{MEM2MEM} \) bit of the \( \text{DMA	extunderscore CCR}x \) register. When the circular mode is activated, the amount of data to transfer is
automatically reloaded with the initial value programmed during the channel configuration phase, and the DMA requests continue to be served.

In order to stop a circular transfer, the software needs to stop the peripheral from generating DMA requests (such as quit the ADC scan mode), before disabling the DMA channel. The software must explicitly program the DMA_CNDTRx value before starting/enabling a transfer, and after having stopped a circular transfer.

**Memory-to-memory mode**

The DMA channels may operate without being triggered by a request from a peripheral. This mode is called memory-to-memory mode, and is initiated by software.

If the MEM2MEM bit in the DMA_CCRx register is set, the channel, if enabled, initiates transfers. The transfer stops once the DMA_CNDTRx register reaches zero.

*Note:* The memory-to-memory mode must not be used in circular mode. Before enabling a channel in memory-to-memory mode (MEM2MEM = 1), the software must clear the CIRC bit of the DMA_CCRx register.

**Peripheral-to-peripheral mode**

Any DMA channel can operate in peripheral-to-peripheral mode:

- when the hardware request from a peripheral is selected to trigger the DMA channel
  This peripheral is the DMA initiator and paces the data transfer from/to this peripheral to/from a register belonging to another memory-mapped peripheral (this one being not configured in DMA mode).
- when no peripheral request is selected and connected to the DMA channel
  The software configures a register-to-register transfer by setting the MEM2MEM bit of the DMA_CCRx register.

**Programming transfer direction, assigning source/destination**

The value of the DIR bit of the DMA_CCRx register sets the direction of the transfer, and consequently, it identifies the source and the destination, regardless the source/destination type (peripheral or memory):

- **DIR = 1** defines typically a memory-to-peripheral transfer. More generally, if DIR = 1:
  - The source attributes are defined by the DMA_MARx register, the MSIZE[1:0] field and MINC bit of the DMA_CCRx register.
    Regardless of their usual naming, these ‘memory’ register, field and bit are used to define the source peripheral in peripheral-to-peripheral mode.
  - The destination attributes are defined by the DMA_PARx register, the PSIZE[1:0] field and PINC bit of the DMA_CCRx register.
    Regardless of their usual naming, these ‘peripheral’ register, field and bit are used to define the destination memory in memory-to-memory mode.

- **DIR = 0** defines typically a peripheral-to-memory transfer. More generally, if DIR = 0:
  - The source attributes are defined by the DMA_PARx register, the PSIZE[1:0] field and PINC bit of the DMA_CCRx register.
    Regardless of their usual naming, these ‘peripheral’ register, field and bit are used to define the source memory in memory-to-memory mode.
  - The destination attributes are defined by the DMA_MARx register, the MSIZE[1:0] field and MINC bit of the DMA_CCRx register.
Regardless of their usual naming, these ‘memory’ register, field and bit are used to define the destination peripheral in peripheral-to-peripheral mode.

### 11.4.6 DMA data width, alignment and endianness

When PSIZE[1:0] and MSIZE[1:0] are not equal, the DMA controller performs some data alignments as described in the table below.

<table>
<thead>
<tr>
<th>Source port width (MSIZE if DIR = 1, else PSIZE)</th>
<th>Destination port width (PSIZE if DIR = 1, else MSIZE)</th>
<th>Number of data items to transfer (NDT)</th>
<th>Source content: address / data (DMA_CMARx if DIR = 1, else DMA_CPARx)</th>
<th>DMA transfers</th>
<th>Destination content: address / data (DMA_CPARx if DIR = 1, else DMA_CMARx)</th>
</tr>
</thead>
<tbody>

Addressing AHB peripherals not supporting byte/half-word write transfers

When the DMA controller initiates an AHB byte or half-word write transfer, the data are duplicated on the unused lanes of the AHB master 32-bit data bus (HWDATA[31:0]).

When the AHB slave peripheral does not support byte or half-word write transfers and does not generate any error, the DMA controller writes the 32 HWDATA bits as shown in the two examples below:

- To write the half-word 0xABCD, the DMA controller sets the HWDATA bus to 0xABCDABCD with a half-word data size (HSIZE = HalfWord in AHB master bus).
- To write the byte 0xAB, the DMA controller sets the HWDATA bus to 0xABABABAB with a byte data size (HSIZE = Byte in the AHB master bus).

Assuming the AHB/APB bridge is an AHB 32-bit slave peripheral that does not take into account the HSIZE data, any AHB byte or half-word transfer is changed into a 32-bit APB transfer as described below:

- An AHB byte write transfer of 0xB0 to one of the 0x0, 0x1, 0x2 or 0x3 addresses, is converted to an APB word write transfer of 0xB0B0B0B0 to the 0x0 address.
- An AHB half-word write transfer of 0xB1B0 to the 0x0 or 0x2 addresses, is converted to an APB word write transfer of 0xB1B0B1B0 to the 0x0 address.

11.4.7 DMA error management

A DMA transfer error is generated when reading from or writing to a reserved address space. When a DMA transfer error occurs during a DMA read or write access, the faulty channel x is automatically disabled through a hardware clear of its EN bit in the corresponding DMA_CCRx register.

The TEIFx bit of the DMA_ISR register is set. An interrupt is then generated if the TEIE bit of the DMA_CCRx register is set.

The EN bit of the DMA_CCRx register can not be set again by software (channel x re-activated) until the TEIFx bit of the DMA_ISR register is cleared (by setting the CTEIFx bit of the DMA_IFCR register).

When the software is notified with a transfer error over a channel which involves a peripheral, the software has first to stop this peripheral in DMA mode, in order to disable any pending or future DMA request. Then software may normally reconfigure both DMA and the peripheral in DMA mode for a new transfer.
11.5 DMA interrupts

An interrupt can be generated on a half transfer, transfer complete or transfer error for each DMA channel x. Separate interrupt enable bits are available for flexibility.

11.6 DMA registers

Refer to Section 1.2 for a list of abbreviations used in register descriptions.

The DMA registers have to be accessed by words (32-bit).

11.6.1 DMA interrupt status register (DMA_ISR)

Address offset: 0x00
Reset value: 0x0000 0000

Every status bit is cleared by hardware when the software sets the corresponding clear bit or the corresponding global clear bit CGIFx, in the DMA_IFCR register.

Bit 0  **GIF1**: global interrupt flag for channel 1  
0: no TE, HT or TC event  
1: a TE, HT or TC event occurred
### 11.6.2 DMA interrupt flag clear register (DMA_IFCR)

Address offset: 0x04
Reset value: 0x0000 0000

Setting the global clear bit CGIfx of the channel x in this DMA_IFCR register, causes the DMA hardware to clear the corresponding GIFx bit and any individual flag among TEIfx, HTIfx, TCIfx, in the DMA_ISR register.

Setting any individual clear bit among CTEIfx, CHTIfx, CTCIfx in this DMA_IFCR register, causes the DMA hardware to clear the corresponding individual flag and the global flag GIFx in the DMA_ISR register, provided that none of the two other individual flags is set.

Writing 0 into any flag clear bit has no effect.

Bits 31:28 Reserved, must be kept at reset value.

- Bit 27 **CTEIF7**: transfer error flag clear for channel 7
- Bit 26 **CHTIF7**: half transfer flag clear for channel 7
- Bit 25 **CTCIF7**: transfer complete flag clear for channel 7
- Bit 24 **CGIF7**: global interrupt flag clear for channel 7
- Bit 23 **CTEIF6**: transfer error flag clear for channel 6
- Bit 22 **CHTIF6**: half transfer flag clear for channel 6
- Bit 21 **CTCIF6**: transfer complete flag clear for channel 6
- Bit 20 **CGIF6**: global interrupt flag clear for channel 6
- Bit 19 **CTEIF5**: transfer error flag clear for channel 5
- Bit 18 **CHTIF5**: half transfer flag clear for channel 5
- Bit 17 **CTCIF5**: transfer complete flag clear for channel 5
- Bit 16 **CGIF5**: global interrupt flag clear for channel 5
- Bit 15 **CTEIF4**: transfer error flag clear for channel 4
- Bit 14 **CHTIF4**: half transfer flag clear for channel 4
- Bit 13 **CTCIF4**: transfer complete flag clear for channel 4
- Bit 12 **CGIF4**: global interrupt flag clear for channel 4
- Bit 11 **CTEIF3**: transfer error flag clear for channel 3
- Bit 10 **CHTIF3**: half transfer flag clear for channel 3
- Bit 9  **CTCIF3**: transfer complete flag clear for channel 3
Bit 8  CGIF3: global interrupt flag clear for channel 3
Bit 7  CTEIF2: transfer error flag clear for channel 2
Bit 6  CHTIF2: half transfer flag clear for channel 2
Bit 5  CTCIF2: transfer complete flag clear for channel 2
Bit 4  CGIF2: global interrupt flag clear for channel 2
Bit 3  CTEIF1: transfer error flag clear for channel 1
Bit 2  CHTIF1: half transfer flag clear for channel 1
Bit 1  CTCIF1: transfer complete flag clear for channel 1
Bit 0  CGIF1: global interrupt flag clear for channel 1

11.6.3 DMA channel x configuration register (DMA_CCRx)

Address offset: 0x08 + 0x14 * (x - 1), (x = 1 to 7)
Reset value: 0x0000 0000

The register fields/bits MEM2MEM, PL[1:0], MSIZE[1:0], PSIZE[1:0], MINC, PINC, and DIR are read-only when EN = 1.

The states of MEM2MEM and CIRC bits must not be both high at the same time.

Bits 31:15 Reserved, must be kept at reset value.

Bit 14  MEM2MEM: memory-to-memory mode
0: disabled
1: enabled

Note: this bit is set and cleared by software.
It must not be written when the channel is enabled (EN = 1).
It is read-only when the channel is enabled (EN = 1).

Bits 13:12  PL[1:0]: priority level
00: low
01: medium
10: high
11: very high

Note: this field is set and cleared by software.
It must not be written when the channel is enabled (EN = 1).
It is read-only when the channel is enabled (EN = 1).
Bits 11:10 **MSIZE[1:0]:** memory size
- Defines the data size of each DMA transfer to the identified memory.
  - In memory-to-memory mode, this field identifies the memory source if DIR = 1 and the memory destination if DIR = 0.
  - In peripheral-to-peripheral mode, this field identifies the peripheral source if DIR = 1 and the peripheral destination if DIR = 0.
  - 00: 8 bits
  - 01: 16 bits
  - 10: 32 bits
  - 11: reserved
- **Note:** this field is set and cleared by software.
  - It must not be written when the channel is enabled (EN = 1).
  - It is read-only when the channel is enabled (EN = 1).

Bits 9:8 **PSIZE[1:0]:** peripheral size
- Defines the data size of each DMA transfer to the identified peripheral.
  - In memory-to-memory mode, this field identifies the memory destination if DIR = 1 and the memory source if DIR = 0.
  - In peripheral-to-peripheral mode, this field identifies the peripheral destination if DIR = 1 and the peripheral source if DIR = 0.
  - 00: 8 bits
  - 01: 16 bits
  - 10: 32 bits
  - 11: reserved
- **Note:** this field is set and cleared by software.
  - It must not be written when the channel is enabled (EN = 1).
  - It is read-only when the channel is enabled (EN = 1).

Bit 7 **MINC:** memory increment mode
- Defines the increment mode for each DMA transfer to the identified memory.
  - In memory-to-memory mode, this field identifies the memory source if DIR = 1 and the memory destination if DIR = 0.
  - In peripheral-to-peripheral mode, this field identifies the peripheral source if DIR = 1 and the peripheral destination if DIR = 0.
  - 0: disabled
  - 1: enabled
- **Note:** this bit is set and cleared by software.
  - It must not be written when the channel is enabled (EN = 1).
  - It is read-only when the channel is enabled (EN = 1).

Bit 6 **PINC:** peripheral increment mode
- Defines the increment mode for each DMA transfer to the identified peripheral.
  - In memory-to-memory mode, this field identifies the memory destination if DIR = 1 and the memory source if DIR = 0.
  - In peripheral-to-peripheral mode, this field identifies the peripheral destination if DIR = 1 and the peripheral source if DIR = 0.
  - 0: disabled
  - 1: enabled
- **Note:** this bit is set and cleared by software.
  - It must not be written when the channel is enabled (EN = 1).
  - It is read-only when the channel is enabled (EN = 1).
Bit 5 **CIRC**: circular mode
0: disabled
1: enabled

*Note: this bit is set and cleared by software.*

*It must not be written when the channel is enabled (EN = 1).*

*It is not read-only when the channel is enabled (EN = 1).*

Bit 4 **DIR**: data transfer direction
This bit must be set only in memory-to-peripheral and peripheral-to-memory modes.
0: read from peripheral
   - Source attributes are defined by PSIZE and PINC, plus the DMA_CPARx register.
     This is still valid in a memory-to-memory mode.
   - Destination attributes are defined by MSIZE and MINC, plus the DMA_CMARx register. This is still valid in a peripheral-to-peripheral mode.
1: read from memory
   - Destination attributes are defined by PSIZE and PINC, plus the DMA_CPARx register. This is still valid in a memory-to-memory mode.
   - Source attributes are defined by MSIZE and MINC, plus the DMA_CMARx register. This is still valid in a peripheral-to-peripheral mode.

*Note: this bit is set and cleared by software.*

*It must not be written when the channel is enabled (EN = 1).*

*It is read-only when the channel is enabled (EN = 1).*

Bit 3 **TEIE**: transfer error interrupt enable
0: disabled
1: enabled

*Note: this bit is set and cleared by software.*

*It must not be written when the channel is enabled (EN = 1).*

*It is not read-only when the channel is enabled (EN = 1).*

Bit 2 **HTIE**: half transfer interrupt enable
0: disabled
1: enabled

*Note: this bit is set and cleared by software.*

*It must not be written when the channel is enabled (EN = 1).*

*It is not read-only when the channel is enabled (EN = 1).*

Bit 1 **TCIE**: transfer complete interrupt enable
0: disabled
1: enabled

*Note: this bit is set and cleared by software.*

*It must not be written when the channel is enabled (EN = 1).*

*It is not read-only when the channel is enabled (EN = 1).*

Bit 0 **EN**: channel enable
When a channel transfer error occurs, this bit is cleared by hardware. It can not be set again by software (channel x re-activated) until the TEIFx bit of the DMA_ISR register is cleared (by setting the CTEIFx bit of the DMA_IFCR register).
0: disabled
1: enabled

*Note: this bit is set and cleared by software.*
11.6.4 DMA channel x number of data to transfer register (DMA_CNDTRx)

Address offset: 0x0C + 0x14 * (x - 1), (x = 1 to 7)
Reset value: 0x0000 0000

| Bits 31:16 | Reserved, must be kept at reset value. |
| Bits 15:0 | NDT[15:0]: number of data to transfer (0 to $2^{16} - 1$) |

- This field is updated by hardware when the channel is enabled:
  - It is decremented after each single DMA ‘read followed by write’ transfer, indicating the remaining amount of data items to transfer.
  - It is kept at zero when the programmed amount of data to transfer is reached, if the channel is not in circular mode (CIRC = 0 in the DMA_CCRx register).
  - It is reloaded automatically by the previously programmed value, when the transfer is complete, if the channel is in circular mode (CIRC = 1).

If this field is zero, no transfer can be served whatever the channel status (enabled or not).

Note: this field is set and cleared by software.
It must not be written when the channel is enabled (EN = 1).
It is read-only when the channel is enabled (EN = 1).

11.6.5 DMA channel x peripheral address register (DMA_CPARx)

Address offset: 0x10 + 0x14 * (x - 1), (x = 1 to 7)
Reset value: 0x0000 0000
11.6.6 DMA channel x memory address register (DMA_CMARx)

Address offset: 0x14 + 0x14 * (x - 1), (x = 1 to 7)

Reset value: 0x0000 0000

| Bits 31:0 | PA[31:0]: peripheral address |
|-----------|
| It contains the base address of the peripheral data register from/to which the data will be read/written. |
| When PSIZE[1:0] = 01 (16 bits), bit 0 of PA[31:0] is ignored. Access is automatically aligned to a half-word address. |
| When PSIZE = 10 (32 bits), bits 1 and 0 of PA[31:0] are ignored. Access is automatically aligned to a word address. |
| In memory-to-memory mode, this register identifies the memory destination address if DIR = 1 and the memory source address if DIR = 0. |
| In peripheral-to-peripheral mode, this register identifies the peripheral destination address DIR = 1 and the peripheral source address if DIR = 0. |
| Note: this register is set and cleared by software. |
| It must not be written when the channel is enabled (EN = 1). |
| It is not read-only when the channel is enabled (EN = 1). |

11.6.7 DMA register map

The table below gives the DMA register map and reset values.

Refer to Section 2.2 for the register boundary addresses.
12 DMA request multiplexer (DMAMUX)

12.1 Introduction

A peripheral indicates a request for DMA transfer by setting its DMA request signal. The DMA request is pending until it is served by the DMA controller that generates a DMA acknowledge signal, and the corresponding DMA request signal is deasserted.

In this document, the set of control signals required for the DMA request/acknowledge protocol is not explicitly shown or described, and it is referred to as DMA request line.

The DMAMUX request multiplexer enables routing a DMA request line between the peripherals and the DMA controllers of the product. The routing function is ensured by a programmable multi-channel DMA request line multiplexer. Each channel selects a unique DMA request line, unconditionally or synchronously with events from its DMAMUX synchronization inputs. The DMAMUX may also be used as a DMA request generator from programmable events on its input trigger signals.

The number of DMAMUX instances and their main characteristics are specified in Section 12.3.1.

The assignment of DMAMUX request multiplexer inputs to the DMA request lines from peripherals and to the DMAMUX request generator outputs, the assignment of DMAMUX request multiplexer outputs to DMA controller channels, and the assignment of DMAMUX synchronizations and trigger inputs to internal and external signals depend on the product implementation, and are detailed in Section 12.3.2.
12.2 DMAMUX main features

- 14-channel programmable DMA request line multiplexer output
- 4-channel DMA request generator
- 26 trigger inputs to DMA request generator
- 26 synchronization inputs
- Per DMA request generator channel:
  - DMA request trigger input selector
  - DMA request counter
  - Event overrun flag for selected DMA request trigger input
- Per DMA request line multiplexer channel output:
  - 89 (STM32L4Rxxx and STM32L4Sxxx devices) or 90 (STM32L4P5xx and STM32L4Q5xx devices) input DMA request lines from peripherals
  - One DMA request line output
  - Synchronization input selector
  - DMA request counter
  - Event overrun flag for selected synchronization input
  - One event output, for DMA request chaining

12.3 DMAMUX implementation

12.3.1 DMAMUX instantiation

DMAMUX is instantiated with the hardware configuration parameters listed in the following table.

<table>
<thead>
<tr>
<th>Feature</th>
<th>DMAMUX</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of DMAMUX output request channels</td>
<td>14</td>
</tr>
<tr>
<td>Number of DMAMUX request generator channels</td>
<td>4</td>
</tr>
<tr>
<td>Number of DMAMUX request trigger inputs</td>
<td>26</td>
</tr>
<tr>
<td>Number of DMAMUX synchronization inputs</td>
<td>26</td>
</tr>
<tr>
<td>Number of DMAMUX peripheral request inputs</td>
<td>89 (STM32L4Rxxx and STM32L4Sxxx devices) or 90 (STM32L4P5xx and STM32L4Q5xx devices)</td>
</tr>
</tbody>
</table>

12.3.2 DMAMUX mapping

The mapping of resources to DMAMUX is hardwired.

DMAMUX is used with DMA1 and DMA2:
- DMAMUX channels 0 to 6 are connected to DMA1 channels 0 to 6
- DMAMUX channels 7 to 13 are connected to DMA2 channels 0 to 6

12.4 DMAMUX functional description

12.4.1 DMAMUX block diagram

*Figure 32* shows the DMAMUX block diagram.

**Figure 32. DMAMUX block diagram**

DMAMUX features two main sub-blocks: the request line multiplexer and the request line generator.

The implementation assigns:

- DMAMUX request multiplexer sub-block inputs (dmamux_reqx) from peripherals (dmamux_req_inx) and from channels of the DMAMUX request generator sub-block (dmamux_req_genx)
- DMAMUX request outputs to channels of DMA controllers (dmamux_req_outx)
- Internal or external signals to DMA request trigger inputs (dmamux_trgx)
- Internal or external signals to synchronization inputs (dmamux_syncx)
12.4.2 DMAMUX signals

Table 60 lists the DMAMUX signals.

12.4.3 DMAMUX channels

A DMAMUX channel is a DMAMUX request multiplexer channel that may include, depending on the selected input of the request multiplexer, an additional DMAMUX request generator channel.

A DMAMUX request multiplexer channel is connected and dedicated to one single channel of DMA controller(s).

Channel configuration procedure

Follow the sequence below to configure both a DMAMUX x channel and the related DMA channel y:

1. Set and configure completely the DMA channel y, except enabling the channel y.
2. Set and configure completely the related DMAMUX y channel.
3. Last, activate the DMA channel y by setting the EN bit in the DMA y channel register.

12.4.4 DMAMUX request line multiplexer

The DMAMUX request multiplexer with its multiple channels ensures the actual routing of DMA request/acknowledge control signals, named DMA request lines.

Each DMA request line is connected in parallel to all the channels of the DMAMUX request line multiplexer.

A DMA request is sourced either from the peripherals or from the DMAMUX request generator.

The DMAMUX request line multiplexer channel x selects the DMA request line number as configured by the DMAREQ_ID field in the DMAMUX_CxCR register.

Note: The null value in the field DMAREQ_ID corresponds to no DMA request line selected.
Caution: A same non-null DMAREQ_ID can be assigned to two different channels only if the application ensures that these channels are not requested to be served at the same time. In other words, if two different channels receive a same asserted hardware request at the same time, an unpredictable DMA hardware behavior occurs.

On top of the DMA request selection, the synchronization mode and/or the event generation may be configured and enabled, if required.

Synchronization mode and channel event generation

Each DMAMUX request line multiplexer channel x can be individually synchronized by setting the synchronization enable (SE) bit in the DMAMUX_CxCR register.

DMAMUX has multiple synchronization inputs. The synchronization inputs are connected in parallel to all the channels of the request multiplexer.

The synchronization input is selected via the SYNC_ID field in the DMAMUX_CxCR register of a given channel x.

When a channel is in this synchronization mode, the selected input DMA request line is propagated to the multiplexer channel output, once is detected a programmable rising/falling edge on the selected input synchronization signal, via the SPOL[1:0] field of the DMAMUX_CxCR register.

Additionally, there is a programmable DMA request counter, internally to the DMAMUX request multiplexer, which may be used for the channel request output generation and also possibly for an event generation. An event generation on the channel x output is enabled through the EGE bit (event generation enable) of the DMAMUX_CxCR register.

As shown in Figure 34, upon the detected edge of the synchronization input, the pending selected input DMA request line is connected to the DMAMUX multiplexer channel x output.

Note: If a synchronization event occurs while there is no pending selected input DMA request line, it is discarded. The following asserted input request lines is not connected to the DMAMUX multiplexer channel output until a synchronization event occurs again.

From this point on, each time the connected DMAMUX request is served by the DMA controller (a served request is deasserted), the DMAMUX request counter is decremented. At its underrun, the DMA request counter is automatically loaded with the value in NBREQ field of the DMAMUX_CxCR register and the input DMA request line is disconnected from the multiplexer channel x output.

Thus, the number of DMA requests transferred to the multiplexer channel x output following a detected synchronization event, is equal to the value in NBREQ field, plus one.

Note: The NBREQ field value shall only be written by software when both synchronization enable bit SE and event generation enable EGE bit of the corresponding multiplexer channel x are disabled.
If EGE is enabled, the multiplexer channel generates a channel event, as a pulse of one AHB clock cycle, when its DMA request counter is automatically reloaded with the value of the programmed NBREQ field, as shown in Figure 33 and Figure 34.
Note: If EGE is enabled and NBREQ = 0, an event is generated after each served DMA request.

Note: A synchronization event (edge) is detected if the state following the edge remains stable for more than two AHB clock cycles.

Upon writing into DMAMUX_CxCR register, the synchronization events are masked during three AHB clock cycles.

Synchronization overrun and interrupt

If a new synchronization event occurs before the request counter underrun (the internal request counter programmed via the NBREQ field of the DMAMUX_CxCR register), the synchronization overrun flag bit SOFx is set in the DMAMUX_CSR status register.

Note: The request multiplexer channel x synchronization must be disabled (DMAMUX_CxCR.SE = 0) at the completion of the use of the related channel of the DMA controller. Else, upon a new detected synchronization event, there is a synchronization overrun due to the absence of a DMA acknowledge (that is, no served request) received from the DMA controller.

The overrun flag SOFx is reset by setting the associated clear synchronization overrun flag bit CSOFx in the DMAMUX_CFR register.

Setting the synchronization overrun flag generates an interrupt if the synchronization overrun interrupt enable bit SOIE is set in the DMAMUX_CxCR register.

12.4.5 DMAMUX request generator

The DMAMUX request generator produces DMA requests following trigger events on its DMA request trigger inputs.

The DMAMUX request generator has multiple channels. DMA request trigger inputs are connected in parallel to all channels.

The outputs of DMAMUX request generator channels are inputs to the DMAMUX request line multiplexer.

Each DMAMUX request generator channel x has an enable bit GE (generator enable) in the corresponding DMAMUX_RGxCR register.

The DMA request trigger input for the DMAMUX request generator channel x is selected through the SIG_ID (trigger signal ID) field in the corresponding DMAMUX_RGxCR register.

Trigger events on a DMA request trigger input can be rising edge, falling edge or either edge. The active edge is selected through the GPOL (generator polarity) field in the corresponding DMAMUX_RGxCR register.

Upon the trigger event, the corresponding generator channel starts generating DMA requests on its output. Each time the DMAMUX generated request is served by the connected DMA controller (a served request is deasserted), a built-in (inside the DMAMUX request generator) DMA request counter is decremented. At its underrun, the request generator channel stops generating DMA requests and the DMA request counter is automatically reloaded to its programmed value upon the next trigger event.

Thus, the number of DMA requests generated after the trigger event is GNBREQ + 1.
Note: The GNBREQ field value must be written by software only when the enable GE bit of the corresponding generator channel x is disabled.

A trigger event (edge) is detected if the state following the edge remains stable for more than two AHB clock cycles.

Upon writing into DMAMUX_RGxCR register, the trigger events are masked during three AHB clock cycles.

Trigger overrun and interrupt

If a new DMA request trigger event occurs before the DMAMUX request generator counter underrun (the internal counter programmed via the GNBREQ field of the DMAMUX_RGxCR register), and if the request generator channel x was enabled via GE, then the request trigger event overrun flag bit OFx is asserted by the hardware in the status DMAMUX_RGSR register.

Note: The request generator channel x must be disabled (DMAMUX_RGxCR.GE = 0) at the completion of the usage of the related channel of the DMA controller. Else, upon a new detected trigger event, there is a trigger overrun due to the absence of an acknowledge (that is, no served request) received from the DMA.

The overrun flag OFx is reset by setting the associated clear overrun flag bit COFx in the DMAMUX_RGCFR register.

Setting the DMAMUX request trigger overrun flag generates an interrupt if the DMA request trigger event overrun interrupt enable bit OIE is set in the DMAMUX_RGxCR register.

12.5 DMAMUX interrupts

An interrupt can be generated upon:
- a synchronization event overrun in each DMA request line multiplexer channel
- a trigger event overrun in each DMA request generator channel

For each case, per-channel individual interrupt enable, status and clear flag register bits are available.

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SYNC_ID[4:0]: Synchronization identification**

Selects the synchronization input (see Table 58: DMAMUX: assignment of synchronization inputs to resources (STM32L4Rxxx and STM32L4Sxxx devices) and Table 59: DMAMUX: assignment of synchronization inputs to resources (STM32L4P5xx and STM32L4Q5xx devices)).

Bits 23:19 **NBREQ[4:0]: Number of DMA requests minus 1 to forward**

Defines the number of DMA requests to forward to the DMA controller after a synchronization event, and/or the number of DMA requests before an output event is generated.

This field shall only be written when both SE and EGE bits are low.

Bits 18:17 **SPOL[1:0]: Synchronization polarity**

Defines the edge polarity of the selected synchronization input:

00: No event, i.e. no synchronization nor detection.

01: Rising edge

10: Falling edge

11: Rising and falling edges

Bit 16 **SE: Synchronization enable**

0: synchronization disabled

1: synchronization enabled

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **EGE: Event generation enable**

0: event generation disabled

1: event generation enabled

Bit 8 **SOIE: Synchronization overrun interrupt enable**

0: interrupt disabled

1: interrupt enabled
12.6.2 **DMAMUX request line multiplexer interrupt channel status register**

0: Interrupt on a trigger overrun event occurrence is disabled  
1: Interrupt on a trigger overrun event occurrence is enabled |
| 7:5 | Reserved, must be kept at reset value. |
| 4:0 | **SIG_ID[4:0]**: Signal identification  
Selects the DMA request trigger input used for the channel x of the DMA request generator |
12.6.5 DMAMUX request generator interrupt status register (DMAMUX_RGSR)

Address offset: 0x140
Reset value: 0x0000 0000

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 OF[3:0]: Trigger overrun event flag
   * The flag is set when a new trigger event occurs on DMA request generator channel x, before the request counter underrun (the internal request counter programmed via the GNBREQ field of the DMAMUX_RGxCR register).
   * The flag is cleared by writing 1 to the corresponding COFx bit in the DMAMUX_RGCFR register.

12.6.6 DMAMUX request generator interrupt clear flag register (DMAMUX_RGCFR)

Address offset: 0x144
Reset value: 0x0000 0000

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 COF[3:0]: Clear trigger overrun event flag
   * Writing 1 in each bit clears the corresponding overrun flag OFx in the DMAMUX_RGSR register.
12.6.7 **DMAMUX register map**

The following table summarizes the DMAMUX registers and reset values. Refer to the register boundary address table for the DMAMUX register base address.

Refer to Section 2.2 on page 93 for the register boundary addresses.
13 Chrom-ART Accelerator controller (DMA2D)

13.1 DMA2D introduction

The Chrom-ART Accelerator (DMA2D) is a specialized DMA dedicated to image manipulation. It can perform the following operations:

- Filling a part or the whole of a destination image with a specific color
- Copying a part or the whole of a source image into a part or the whole of a destination image
- Copying a part or the whole of a source image into a part or the whole of a destination image with a pixel format conversion
- Blending a part and/or two complete source images with different pixel format and copy the result into a part or the whole of a destination image with a different color format.

All the classical color coding schemes are supported from 4-bit up to 32-bit per pixel with indexed or direct color mode. The DMA2D has its own dedicated memories for CLUTs (color look-up tables).

13.2 DMA2D main features

The main DMA2D features are:

- Single AHB master bus architecture.
- AHB slave programming interface supporting 8/16/32-bit accesses (except for CLUT accesses which are 32-bit).
- User programmable working area size
- User programmable offset for sources and destination areas expressed in pixels or bytes
- User programmable sources and destination addresses on the whole memory space
- Up to 2 sources with blending operation
- Alpha value can be modified (source value, fixed value or modulated value)
- User programmable source and destination color format
- Up to 11 color formats supported from 4-bit up to 32-bit per pixel with indirect or direct color coding
- 2 internal memories for CLUT storage in indirect color mode
- Automatic CLUT loading or CLUT programming via the CPU
- User programmable CLUT size
- Internal timer to control AHB bandwidth
- 6 operating modes: register-to-memory, memory-to-memory, memory-to-memory with pixel format conversion, memory-to-memory with pixel format conversion and blending, memory-to-memory with pixel format conversion, blending and fixed color foreground, and memory-to-memory with pixel format conversion, blending and fixed color background.
• Area filling with a fixed color
• Copy from an area to another
• Copy with pixel format conversion between source and destination images
• Copy from two sources with independent color format and blending
• Output buffer byte swapping to support refresh of displays through parallel interface
• Abort and suspend of DMA2D operations
• Watermark interrupt on a user programmable destination line
• Interrupt generation on bus error or access conflict
• Interrupt generation on process completion

13.3 DMA2D functional description

13.3.1 DMA2D block diagram

The DMA2D controller performs direct memory transfer. As an AHB master, it can take the control of the AHB bus matrix to initiate AHB transactions.

The DMA2D can operate in the following modes:
• Register-to-memory
• Memory-to-memory
• Memory-to-memory with Pixel Format Conversion
• Memory-to-memory with Pixel Format Conversion and Blending
• Memory-to memory with pixel format conversion, blending and fixed color foreground
• Memory-to memory with pixel format conversion, blending and fixed color background

The AHB slave port is used to program the DMA2D controller.

The block diagram of the DMA2D is shown in Figure 35: DMA2D block diagram.
13.3.2 DMA2D control

The DMA2D controller is configured through the DMA2D Control Register (DMA2D_CR) which allows selecting:

The user application can perform the following operations:
- Select the operating mode
- Enable/disable the DMA2D interrupt
- Start/suspend/abort ongoing data transfers

13.3.3 DMA2D foreground and background FIFOs

The DMA2D foreground (FG) FG FIFO and background (BG) FIFO fetch the input data to be copied and/or processed.

The FIFOs fetch the pixels according to the color format defined in their respective pixel format converter (PFC).
They are programmed through a set of control registers:
- DMA2D foreground memory address register (DMA2D_FGMAR)
- DMA2D foreground offset register (DMA2D_FGOR)
- DMA2D background memory address register (DMA2D_BGMAR)
- DMA2D background offset register (DMA2D_BGBOR)
- DMA2D number of lines register (number of lines and pixel per lines) (DMA2D_NLR)

When the DMA2D operates in register-to-memory mode, none of the FIFOs is activated.

When the DMA2D operates in memory-to-memory mode (no pixel format conversion nor blending operation), only the FG FIFO is activated and acts as a buffer.

When the DMA2D operates in memory-to-memory operation with pixel format conversion (no blending operation), the BG FIFO is not activated.

### 13.3.4 DMA2D foreground and background pixel format converter (PFC)

DMA2D foreground pixel format converter (PFC) and background pixel format converter perform the pixel format conversion to generate a 32-bit per pixel value. The PFC can also modify the alpha channel.

The first stage of the converter converts the color format. The original color format of the foreground pixel and background pixels are configured through the CM[3:0] bits of the DMA2D_FGPFCCR and DMA2D_BGPFCR, respectively.

The supported input formats are given in Table 63: Supported color mode in input.

<table>
<thead>
<tr>
<th>CM[3:0]</th>

</tr>
<tr>
<td>1001</td>
<td>A8</td>
</tr>
<tr>
<td>1010</td>
<td>A4</td>
</tr>
</tbody>
</table>

Table 63. Supported color mode in input
The color format are coded as follows:
- Alpha value field: transparency
  0xFF value corresponds to an opaque pixel and 0x00 to a transparent one.
- R field for Red
- G field for Green
- B field for Blue
- L field: luminance
  This field is the index to a CLUT to retrieve the three/four RGB/ARGB components.

If the original format was direct color mode (ARGB/RGB), then the extension to 8-bit per channel is performed by copying the MSBs into the LSBs. This ensures a perfect linearity of the conversion.

If the original format is indirect color mode (L/AL), a CLUT is required and each pixel format converter is associated with a 256 entry 32-bit CLUT.

If the original format does not include an alpha channel, the alpha value is automatically set to 0xFF (opaque).

For the specific alpha mode A4 and A8, no color information is stored nor indexed. The color to be used for the image generation is fixed and is defined in the DMA2D_FGCOLR for foreground pixels and in the DMA2D_BGCOLR register for background pixels.

The order of the fields in the system memory is defined in Table 64: Data order in memory.

<table>
<thead>
<tr>
<th>Color Mode</th>
<th>@ + 3</th>
<th>@ + 2</th>
<th>@ + 1</th>
<th>@ + 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARGB888</td>
<td>A0[7:0]</td>
<td>R0[7:0]</td>
<td>G0[7:0]</td>
<td>B0[7:0]</td>
</tr>
<tr>
<td>RGB888</td>
<td>B1[7:0]</td>
<td>R0[7:0]</td>
<td>G0[7:0]</td>
<td>B0[7:0]</td>
</tr>
<tr>
<td></td>
<td>R3[7:0]</td>
<td>G3[7:0]</td>
<td>B3[7:0]</td>
<td>R2[7:0]</td>
</tr>
<tr>
<td>L8</td>
<td>L1[7:0]</td>
<td>L2[7:0]</td>
<td>L3[7:0]</td>
<td>L0[7:0]</td>
</tr>
<tr>
<td>AL88</td>
<td>A1[7:0]</td>
<td>L1[7:0]</td>
<td>A0[7:0]</td>
<td>L0[7:0]</td>
</tr>
</tbody>
</table>

The 24-bit RGB888 aligned on 32-bit is supported through the ARGB8888 mode.

Once the 32-bit value is generated, the alpha channel can be modified according to the AM[1:0] field of the DMA2D_FGPFCR/DMA2D_BGPFCR registers as shown in Table 65: Alpha mode configuration.
The alpha channel can be:
- kept as it is (no modification),
- replaced by the ALPHA[7:0] value of DMA2D_FGPFCCR/DMA2D_BGPFCCR,
- or replaced by the original alpha value multiplied by the ALPHA[7:0] value of DMA2D_FGPFCCR/DMA2D_BGPFCCR divided by 255.

Table 65. Alpha mode configuration

<table>
<thead>
<tr>
<th>AM[1:0]</th>
<th>Alpha mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>No modification</td>
</tr>
<tr>
<td>01</td>
<td>Replaced by value in DMA2D_xxPFCCR</td>
</tr>
<tr>
<td>10</td>
<td>Replaced by original value multiplied by the value in DMA2D_xxPFCCR / 255</td>
</tr>
<tr>
<td>11</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

Note: To support the alternate format, the incoming alpha value can be inverted setting the AI bit of the DMA2D_FGPFCCR/DMA2D_BGPFCCR registers. This applies also to the Alpha value stored in the DMA2D_FGPFCCR/DMA2D_BGPFCCR and in the CLUT.

The R and B fields can also be swapped setting the RBS bit of the DMA2D_FGPFCCR/DMA2D_BGPFCCR registers. This applies also to the RGB order used in the CLUT and in the DMA2D_FGCOLR/DMA2D_BGCOLR registers.

13.3.5 DMA2D foreground and background CLUT interface

The CLUT interface manages the CLUT memory access and the automatic loading of the CLUT.

Three kinds of accesses are possible:
- CLUT read by the PFC during pixel format conversion operation
- CLUT accessed through the AHB slave port when the CPU is reading or writing data into the CLUT
- CLUT written through the AHB master port when an automatic loading of the CLUT is performed

The CLUT memory loading can be done in two different ways:
- Automatic loading

The following sequence must be followed to load the CLUT:

a) Program the CLUT address into the DMA2D_FGCMAR register (foreground CLUT) or DMA2D_BGCMAR register (background CLUT)

b) Program the CLUT size in the CS[7:0] field of the DMA2D_FGPFCCR register (foreground CLUT) or DMA2D_BGPFCCR register (background CLUT).

c) Set the START bit of the DMA2D_FGPFCCR register (foreground CLUT) or DMA2D_BGPFCCR register (background CLUT) to start the transfer. During this automatic loading process, the CLUT is not accessible by the CPU. If a conflict
occurs, a CLUT access error interrupt is raised assuming CAEIE is set to ‘1’ in DMA2D_CR.

- **Manual loading**

  The application has to program the CLUT manually through the DMA2D AHB slave port to which the local CLUT memory is mapped. The foreground CLUT is located at address offset 0x0400 and the background CLUT at address offset 0x0800.

The CLUT format is 24 or 32 bits. It is configured through the CCM bit of the DMA2D_FGPFCCR register (foreground CLUT) or DMA2D_BGPFCCR register (background CLUT) as shown in Table 66: Supported CLUT color mode.

<table>

### 13.3.6 DMA2D blender

The DMA2D blender blends the source pixels by pair to compute the resulting pixel.

The blending is performed according to the following equation:

\[
\alpha_{\text{OUT}} = \alpha_{\text{FG}} + \alpha_{\text{BG}} - \alpha_{\text{Mult}}
\]

\[
C_{\text{OUT}} = \frac{C_{\text{FG}} \cdot \alpha_{\text{FG}} + C_{\text{BG}} \cdot \alpha_{\text{BG}} - C_{\text{BG}} \cdot \alpha_{\text{Mult}}}{\alpha_{\text{OUT}}} \quad \text{with } C = R \text{ or } G \text{ or } B
\]

Division is rounded to the nearest lower integer

No configuration register is required by the blender. The blender usage depends on the DMA2D operating mode defined in MODE[2:0] field of the DMA2D_CR register.
13.3.7 DMA2D output PFC

The output PFC performs the pixel format conversion from 32 bits to the output format defined in the CM[2:0] field of the DMA2D output pixel format converter configuration register (DMA2D_OPFCCR).

The supported output formats are given in Table 68: Supported color mode in output.

<table>
<thead>
<tr>
<th>CM[2:0]</th>
<th>Color mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>ARGB8888</td>
</tr>
<tr>
<td>001</td>

<td>RGB565</td>
</tr>
<tr>
<td>011</td>
<td>ARGB1555</td>
</tr>
<tr>
<td>100</td>
<td>ARGB4444</td>
</tr>
</tbody>
</table>

**Note:** To support the alternate format, the calculated alpha value is inverted setting the AI bit of the DMA2D_OPFCCR registers. This applies also to the Alpha value used in the DMA2D_OCOLR.

The R and B fields can also be swapped setting the RBS bit of the DMA2D_OPFCCR registers. This applies also to the RGB order used in the DMA2D_OCOLR.

13.3.8 DMA2D output FIFO

The output FIFO programs the pixels according to the color format defined in the output PFC.

The destination area is defined through a set of control registers:
- DMA2D output memory address register (DMA2D_OMAR)
- DMA2D output offset register (DMA2D_OOR)
- DMA2D number of lines register (number of lines and pixel per lines) (DMA2D_NLR)

If the DMA2D operates in register-to-memory mode, the configured output rectangle is filled by the color specified in the DMA2D output color register (DMA2D_OCOLR) which contains a fixed 32-bit, 24-bit or 16-bit value. The format is selected by the CM[2:0] field of the DMA2D_OPFCCR register.

The data are stored into the memory in the order defined in Table 69: Data order in memory.

<table>
<thead>

<td>$B_3[7:0]$</td>
<td>$R_2[7:0]$</td>
</tr>
</tbody>
</table>
The RGB888 aligned on 32-bit is supported through the ARGB8888 mode.

13.3.9 DMA2D output FIFO byte reordering

The output FIFO bytes is reordered to support display frame buffer update through a parallel interface (F(S)MC) directly from the DMA2D.

The reordering of bytes can be done using:
- RBS bit to swap Red and Blue component
- SB bit to swap byte two by two in the output FIFO

When the byte swapping is activated (SB field of the DMA2D_OPFCR is set), the number of pixel per line (PL field of the DMA2D_NLR) must be even and the output memory address (MA field of the DMA2D_OMAR) must be even, and the output line offset computed in bytes (resulting from LOM field of DMA2D_CR and LO field of DMA2D_OOR values) must be even. If not a configuration error is detected.

13.3.10 DMA2D AHB master port timer

An 8-bit timer is embedded into the AHB master port to provide an optional limitation of the bandwidth on the crossbar.

This timer is clocked by the AHB clock and counts a dead time between two consecutive accesses. This limits the bandwidth usage.

The timer enabling and the dead time value are configured through the AHB master port timer configuration register (DMA2D_AMPTCR).
13.3.11 DMA2D transactions

DMA2D transactions consist of a sequence of a given number of data transfers. The number of data and the width can be programmed by software.

Each DMA2D data transfer is composed of up to 4 steps:
1. Data loading from the memory location pointed by the DMA2D_FGMAR register and pixel format conversion as defined in DMA2D_FGCR.
2. Data loading from a memory location pointed by the DMA2D_BGMAR register and pixel format conversion as defined in DMA2D_BGCR.
3. Blending of all retrieved pixels according to the alpha channels resulting of the PFC operation on alpha values.
4. Pixel format conversion of the resulting pixels according to the DMA2D_OCR register and programming of the data to the memory location addressed through the DMA2D_OMAR register.

13.3.12 DMA2D configuration

Both source and destination data transfers can target peripherals and memories in the whole 4 Gbyte memory area, at addresses ranging between 0x0000 0000 and 0xFFFF FFFF.

The DMA2D can operate in any of the four following modes selected through MODE[2:0] bits of the DMA2D_CR register:
- Register-to-memory
- Memory-to-memory
- Memory-to-memory with PFC
- Memory-to-memory with PFC and blending
- Memory-to-memory with PFC, blending and fixed FG color
- Memory-to-memory with PFC, blending and fixed BG color

Register-to-memory

The register-to-memory mode is used to fill a user defined area with a predefined color. The color format is set in the DMA2D_OPFCCR.

The DMA2D does not perform any data fetching from any source. It just writes the color defined in the DMA2D_OCOLR register to the area located at the address pointed by the DMA2D_OMAR and defined in the DMA2D_NLR and DMA2D_OOR.

Memory-to-memory

In memory-to-memory mode, the DMA2D does not perform any graphical data transformation. The foreground input FIFO acts as a buffer and the data are transferred from the source memory location defined in DMA2D_FGMAR to the destination memory location pointed by DMA2D_OMAR.

The color mode programmed in the CM[3:0] bits of the DMA2D_FGPFCCR register defines the number of bits per pixel for both input and output.

The size of the area to be transferred is defined by the DMA2D_NLR and DMA2D_FGOR registers for the source, and by DMA2D_NLR and DMA2D_OOR registers for the destination.
Memory-to-memory with PFC

In this mode, the DMA2D performs a pixel format conversion of the source data and stores them in the destination memory location.

The size of the areas to be transferred are defined by the DMA2D_NLR and DMA2D_FGOR registers for the source, and by DMA2D_NLR and DMA2D_OOR registers for the destination.

Data are fetched from the location defined in the DMA2D_FGMAR register and processed by the foreground PFC. The original pixel format is configured through the DMA2D_FGPFCCR register.

If the original pixel format is direct color mode, then the color channels are all expanded to 8 bits.

If the pixel format is indirect color mode, the associated CLUT has to be loaded into the CLUT memory.

The CLUT loading can be done automatically by following the sequence below:
1. Set the CLUT address into the DMA2D_FGCMAR.
2. Set the CLUT size in the CS[7:0] bits of the DMA2D_FGPFCCR register.
3. Set the CLUT format (24 or 32 bits) in the CCM bit of the DMA2D_FGPFCCR register.
4. Start the CLUT loading by setting the START bit of the DMA2D_FGPFCCR register.

Once the CLUT loading is complete, the CTCIF flag of the DMA2D_IFR register is raised, and an interrupt is generated if the CTCIE bit is set in DMA2D_CR. The automatic CLUT loading process can not work in parallel with classical DMA2D transfers.

The CLUT can also be filled by the CPU or by any other master through the APB port. The access to the CLUT is not possible when a DMA2D transfer is ongoing and uses the CLUT (indirect color format).

In parallel to the color conversion process, the alpha value is added or changed depending on the value programmed in the DMA2D_FGPFCCR register. If the original image does not have an alpha channel, a default alpha value of 0xFF is automatically added to obtain a fully opaque pixel. The alpha value is modified according to the AM[1:0] bits of the DMA2D_FGPFCCR register:

- It can be unchanged.
- It can be replaced by the value defined in the ALPHA[7:0] value of the DMA2D_FGPFCCR register.
- It can be replaced by the original value multiplied by the ALPHA[7:0] value of the DMA2D_FGPFCCR register divided by 255.

The resulting 32-bit data are encoded by the OUT PFC into the format specified by the CM[2:0] field of the DMA2D_OPFCCR register. The output pixel format cannot be the indirect mode since no CLUT generation process is supported.

The processed data are written into the destination memory location pointed by DMA2D_OMAR.

Memory-to-memory with PFC and blending

In this mode, 2 sources are fetched in the foreground FIFO and background FIFO from the memory locations defined by DMA2D_FGMAR and DMA2D_BGMAR.
The two pixel format converters have to be configured as described in the memory-to-memory mode. Their configurations can be different as each pixel format converter are independent and have their own CLUT memory.

Once each pixel has been converted into 32 bits by their respective PFCs, they are blended according to the equation below:

$$\alpha_{\text{Mult}} = \frac{\alpha_{\text{FG}} \cdot \alpha_{BG}}{255}$$

$$\alpha_{\text{OUT}} = \alpha_{\text{FG}} + \alpha_{BG} - \alpha_{\text{Mult}}$$

$$C_{\text{OUT}} = \frac{C_{\text{FG}} \cdot \alpha_{FG} + C_{BG} \cdot \alpha_{BG} - C_{BG} \cdot \alpha_{Mult}}{\alpha_{\text{OUT}}} \quad \text{with } C = R \text{ or } G \text{ or } B$$

Division are rounded to the nearest lower integer.

The resulting 32-bit pixel value is encoded by the output PFC according to the specified output format, and the data are written into the destination memory location pointed by DMA2D_OMAR.

Memory-to-memory with PFC, blending and fixed color FG

In this mode, only 1 source is fetched in the background FIFO from the memory location defined by DMA2D_BGMAR.

The value of the foreground color is given by the DMA2D_FGCOLOR register and the alpha value is set to 0xFF (opaque).

The alpha value can be replaced or modified according to the AM[1:0] and ALPHA[7:0] fields of the DMA2D_FGPFCR.

The two pixel format converters have to be configured as described in the memory-to-memory mode. Their configurations can be different as each pixel format converter are independent and have their own CLUT memory.

Once each pixel has been converted into 32 bits by their respective PFCs, they are blended together, and the resulting 32-bit pixel value is encoded by the output PFC according to the specified output format, and the data are written into the destination memory location pointed by DMA2D_OMAR.

Memory-to-memory with PFC, blending and fixed color BG

In this mode, only 1 source is fetched in the foreground FIFO from the memory location defined by DMA2D_FGMAR.

The value of the background color is given by the DMA2D_BGCOLOR register and the alpha value is set to 0xFF (opaque).

The alpha value can be replaced or modified according to the AM[1:0] and ALPHA[7:0] fields of the DMA2D_BGPFCR.

The two pixel format converters have to be configured as described in the memory-to-memory mode. Their configurations can be different as each pixel format converter are independent and have their own CLUT memory.
Once each pixel has been converted into 32 bits by their respective PFCs, they are blended together, and the resulting 32-bit pixel value is encoded by the output PFC according to the specified output format, and the data are written into the destination memory location pointed by DMA2D_OMAR.

**Configuration error detection**

The DMA2D checks that the configuration is correct before any transfer. The configuration error interrupt flag is set by hardware when a wrong configuration is detected when a new transfer/automatic loading starts. An interrupt is then generated if the CEIE bit of the DMA2D_CR is set.

The wrong configurations that can be detected are listed below:

- Foreground CLUT automatic loading: MA bits of DMA2D_FGCMAR are not aligned with CCM of DMA2D_FGPFCCR.
- Background CLUT automatic loading: MA bits of DMA2D_BGCMAR are not aligned with CCM of DMA2D_BGPFCCR.
- Memory transfer (except in register-to-memory mode and except in memory-to-memory mode with blending and fixed color FG): MA bits of DMA2D_FGMAR are not aligned with CM of DMA2D_FGPFCCR.
- Memory transfer (except in register-to-memory mode and except in memory-to-memory mode with blending and fixed color FG): CM bits of DMA2D_FGPFCCR are invalid.
- Memory transfer (except in register-to-memory mode and except in memory-to-memory mode with blending and fixed color FG): PL bits of DMA2D_NLR are odd while CM of DMA2D_FGPFCCR is A4 or L4.
- Memory transfer (except in register-to-memory mode and except in memory-to-memory mode with blending and fixed color FG): LO bits of DMA2D_FGOR are odd while CM of DMA2D_FGPFCCR is A4 or L4 and LOM bit of the DMA2D_CR is pixel mode.
- Memory transfer (only in blending mode and except in memory-to-memory mode with blending and fixed color FG): MA bits of DMA2D_BGMAR are not aligned with the CM of DMA2D_BGPFCCR.
- Memory transfer: (only in blending mode and in blending with fixed color FG mode) CM bits of DMA2D_BGPFCCR are invalid.
- Memory transfer (only in blending mode and in blending with fixed color FG mode): PL bits of DMA2D_NLR odd while CM of DMA2D_BGPFCCR is A4 or L4.
- Memory transfer (only in blending mode and in blending with fixed color FG mode): LO bits of DMA2D_BGOR are odd while CM of DMA2D_BGPFCCR is A4 or L4 and LOM bit of the DMA2D_CR is pixel mode.
- Memory transfer (except in memory to memory mode): MA bits of DMA2D_OMAR are not aligned with CM bits of DMA2D_OPFCCR.
- Memory transfer (except in memory to memory mode): CM bits of DMA2D_OPFCCR are invalid.
- Memory transfer with byte swapping: PL bits of DMA2D_NLR are odd or MA bits of the DMA2D_OMAR are odd or LO in bytes (resulting from LOM bit of the DMA2D_CR and LO bits of DMA2D_OOR values) are odd while SB bit of DMA2D_OPFCCR is set.
- Memory transfer: NL bits of DMA2D_NLR = 0.
13.3.13 DMA2D transfer control (start, suspend, abort and completion)

Once the DMA2D is configured, the transfer can be launched by setting the START bit of the DMA2D_CR register. Once the transfer is completed, the START bit is automatically reset and the TCIF flag of the DMA2D_ISR register is raised. An interrupt can be generated if the TCIE bit of the DMA2D_CR is set.

The user application can suspend the DMA2D at any time by setting the SUSP bit of the DMA2D_CR register. The transaction can then be aborted by setting the ABORT bit of the DMA2D_CR register or can be restarted by resetting the SUSP bit of the DMA2D_CR register.

The user application can abort at any time an ongoing transaction by setting the ABORT bit of the DMA2D_CR register. In this case, the TCIF flag is not raised.

Automatic CLUT transfers can also be aborted or suspended by using the ABORT or the SUSP bit of the DMA2D_CR register.

13.3.14 Watermark

A watermark can be programmed to generate an interrupt when the last pixel of a given line has been written to the destination memory area.

The line number is defined in the LW[15:0] field of the DMA2D_LWR register.

When the last pixel of this line has been transferred, the TWIF flag of the DMA2D_ISR register is raised and an interrupt is generated if the TWIE bit of the DMA2D_CR is set.

13.3.15 Error management

Two kind of errors can be triggered:

- AHB master port errors signaled by the TEIF flag of the DMA2D_ISR register.
- Conflicts caused by CLUT access (CPU trying to access the CLUT while a CLUT loading or a DMA2D transfer is ongoing) signalled by the CAEIF flag of the DMA2D_ISR register.

Both flags are associated to their own interrupt enable flag in the DMA2D_CR register to generate an interrupt if need be (TEIE and CAEIE).

13.3.16 AHB dead time

To limit the AHB bandwidth usage, a dead time between two consecutive AHB accesses can be programmed.

This feature can be enabled by setting the EN bit in the DMA2D_AMTCR register.

The dead time value is stored in the DT[7:0] field of the DMA2D_AMTCR register. This value represents the guaranteed minimum number of cycles between two consecutive transactions on the AHB bus.

The update of the dead time value while the DMA2D is running is taken into account for the next AHB transfer.
13.4 DMA2D interrupts

An interrupt can be generated on the following events:

- Configuration error
- CLUT transfer complete
- CLUT access error
- Transfer watermark reached
- Transfer complete
- Transfer error

Separate interrupt enable bits are available for flexibility.

|           | 0: CTC interrupt disable |
|           | 1: CTC interrupt enable |
| Bit 11   | **CAEIE:** CLUT access error interrupt enable |
|           | This bit is set and cleared by software. |
|           | 0: CAE interrupt disable |
|           | 1: CAE interrupt enable |
| Bit 10   | **TWIE:** Transfer watermark interrupt enable |
|           | This bit is set and cleared by software. |
|           | 0: TW interrupt disable |
|           | 1: TW interrupt enable |
Bit 9  **TCIE**: Transfer complete interrupt enable
This bit is set and cleared by software.
0: TC interrupt disable
1: TC interrupt enable

Bit 8  **TEIE**: Transfer error interrupt enable
This bit is set and cleared by software.
0: TE interrupt disable
1: TE interrupt enable

Bit 7  Reserved, must be kept at reset value.

Bit 6  **LOM**: Line Offset Mode
This bit configures how is expressed the line offset (pixels or bytes) for the foreground, background and output.
This bit is set and cleared by software. It can not be modified while a transfer is on going.
0: Line offsets are expressed in pixels
1: Line offsets are expressed in bytes

Bits 5:3  Reserved, must be kept at reset value.

Bit 2  **ABORT**: Abort
This bit can be used to abort the current transfer. This bit is set by software and is automatically reset by hardware when the START bit is reset.
0: No transfer abort requested
1: Transfer abort requested

Bit 1  **SUSP**: Suspend
This bit can be used to suspend the current transfer. This bit is set and reset by software. It is automatically reset by hardware when the START bit is reset.
0: Transfer not suspended
1: Transfer suspended

Bit 0  **START**: Start
This bit can be used to launch the DMA2D according to the parameters loaded in the various configuration registers. This bit is automatically reset by the following events:
- At the end of the transfer
- When the data transfer is aborted by the user application by setting the ABORT bit in DMA2D CR
- When a data transfer error occurs
- When the data transfer has not started due to a configuration error or another transfer operation already ongoing (automatic CLUT loading).

Programming this bit to 1 clears the CTCIF flag in the DMA2D_ISR register

Bit 3  **CAECIF**: Clear CLUT access error interrupt flag
Programming this bit to 1 clears the CAEIF flag in the DMA2D_ISR register

Bit 2  **CTWIF**: Clear transfer watermark interrupt flag
Programming this bit to 1 clears the TWIF flag in the DMA2D_ISR register

Bit 1  **CTCIF**: Clear transfer complete interrupt flag
Programming this bit to 1 clears the TCIF flag in the DMA2D_ISR register

Bit 0  **CTEIF**: Clear Transfer error interrupt flag
Programming this bit to 1 clears the TEIF flag in the DMA2D_ISR register

13.5.4  DMA2D foreground memory address register (DMA2D_FGMAR)

Address offset: 0x000C
Reset value: 0x0000 0000

Bits 31:0  **MA[31:0]**: Memory address
Address of the data used for the foreground image. This register can only be written when data transfers are disabled. Once the data transfer has started, this register is read-only.

The address alignment must match the image format selected e.g. a 32-bit per pixel format must be 32-bit aligned, a 16-bit per pixel format must be 16-bit aligned and a 4-bit per pixel format must be 8-bit aligned.
13.5.5 DMA2D foreground offset register (DMA2D_FGOR)

Address offset: 0x0010
Reset value: 0x0000 0000

</tr>
</thead>
</table>

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **LO[15:0]:** Line offset

The line offset used for the foreground image, expressed in pixel when the LOM bit is reset and in byte when the LOM bit is set.

When expressed in pixels, only LO[13:0] is considered, LO[15:14] are ignored.

This value is used for the address generation. It is added at the end of each line to determine the starting address of the next line.

These bits can only be written when data transfers are disabled. Once data transfer has started, they become read-only.

If the image format is 4-bit per pixel, the line offset must be even.

13.5.6 DMA2D background memory address register (DMA2D_BGMAR)

Bits 31:16 **MA[31:16]:** Memory address

Address of the data used for the background image. This register can only be written when data transfers are disabled. Once a data transfer has started, this register is read-only.

The address alignment must match the image format selected e.g. a 32-bit per pixel format must be 32-bit aligned, a 16-bit per pixel format must be 16-bit aligned and a 4-bit per pixel format must be 8-bit aligned.
13.5.7 DMA2D background offset register (DMA2D_BGOR)

Address offset: 0x0018
Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **LO[15:0]**: Line offset

The line offset used for the background image, expressed in pixels when the LOM bit is reset and in byte when the LOM bit is set.

When expressed in pixels, only LO[13:0] is considered, LO[15:14] are ignored.

This value is used for the address generation. It is added at the end of each line to determine the starting address of the next line.

These bits can only be written when data transfers are disabled. Once data transfer has started, they become read-only.

If the image format is 4-bit per pixel, the line offset must be even.
13.5.8 DMA2D foreground PFC control register (DMA2D_FGPFCCR)

Address offset: 0x001C
Reset value: 0x0000 0000

| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 |
|-----------------------------------|------------------|-----------|------------------|-----------|
| rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:24 ALPHA[7:0]: Alpha value
These bits define a fixed alpha channel value which can replace the original alpha value or be multiplied by the original alpha value according to the alpha mode selected through the AM[1:0] bits.
These bits can only be written when data transfers are disabled. Once a transfer has started, they become read-only.

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 RBS: Red Blue Swap
This bit allows to swap the R & B to support BGR or ABGR color formats. Once the transfer has started, this bit is read-only.
0: Regular mode (RGB or ARGB)
1: Swap mode (BGR or ABGR)

Bit 20 AI: Alpha Inverted
This bit inverts the alpha value. Once the transfer has started, this bit is read-only.
0: Regular alpha
1: Inverted alpha

Bits 19:18 Reserved, must be kept at reset value.

Bits 17:16 AM[1:0]: Alpha mode
These bits select the alpha channel value to be used for the foreground image. They can only be written data the transfer are disabled. Once the transfer has started, they become read-only.
00: No modification of the foreground image alpha channel value
01: Replace original foreground image alpha channel value by ALPHA[7:0]
10: Replace original foreground image alpha channel value by ALPHA[7:0] multiplied with original alpha channel value
other configurations are meaningless

Bits 15:8 CS[7:0]: CLUT size
These bits define the size of the CLUT used for the foreground image. Once the CLUT transfer has started, this field is read-only.
The number of CLUT entries is equal to CS[7:0] + 1.

Bits 7:6 Reserved, must be kept at reset value.
Bit 5 **START**: Start
This bit can be set to start the automatic loading of the CLUT. It is automatically reset:
- at the end of the transfer
- when the transfer is aborted by the user application by setting the ABORT bit in DMA2D_CR
- when a transfer error occurs
- when the transfer has not started due to a configuration error or another transfer operation already ongoing (data transfer or automatic background CLUT transfer).

Bit 4 **CCM**: CLUT color mode
This bit defines the color format of the CLUT. It can only be written when the transfer is disabled. Once the CLUT transfer has started, this bit is read-only.
0: ARGB8888
1: RGB888
others: meaningless

Bits 3:0 **CM[3:0]**: Color mode
These bits define the color format of the foreground image. They can only be written when data transfers are disabled. Once the transfer has started, they are read-only.
0000: ARGB8888
0001: RGB888
0010: RGB565
0011: ARGB1555
0100: ARGB4444

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **RED[7:0]**: Red value  
These bits defines the red value for the A4 or A8 mode of the foreground image. They can only be written when data transfers are disabled. Once the transfer has started, they are read-only.  
Used also for fixed color FG in memory-to-memory with blending and fixed color FG (BG fetch only with FG and BG PFC active) mode.

Bits 15:8 **GREEN[7:0]**: Green value  
These bits defines the green value for the A4 or A8 mode of the foreground image. They can only be written when data transfers are disabled. Once the transfer has started, They are read-only.  
Used also for fixed color FG in memory-to-memory with blending and fixed color FG (BG fetch only with FG and BG PFC active) mode.

Bits 7:0 **BLUE[7:0]**: Blue value  
These bits defines the blue value for the A4 or A8 mode of the foreground image. They can only be written when data transfers are disabled. Once the transfer has started, They are read-only.  
Used also for fixed color FG in memory-to-memory with blending and fixed color FG (BG fetch only with FG and BG PFC active) mode.
13.5.10 DMA2D background PFC control register (DMA2D_BGPFCCR)

Address offset: 0x0024

These bits define a fixed alpha channel value which can replace the original alpha value or be multiplied with the original alpha value according to the alpha mode selected with bits AM[1:0]. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 RBS: Red Blue Swap
This bit allows to swap the R & B to support BGR or ABGR color formats. Once the transfer has started, this bit is read-only.
0: Regular mode (RGB or ARGB)
1: Swap mode (BGR or ABGR)

Bit 20 AI: AI: Alpha Inverted
This bit inverts the alpha value. Once the transfer has started, this bit is read-only.
0: Regular alpha
1: Inverted alpha

Bits 19:18 Reserved, must be kept at reset value.

Bits 17:16 AM[1:0]: Alpha mode
These bits define which alpha channel value to be used for the background image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.
00: No modification of the foreground image alpha channel value
01: Replace original background image alpha channel value by ALPHA[7:0]
10: Replace original background image alpha channel value by ALPHA[7:0] multiplied with original alpha channel value
others: meaningless

Bits 15:8 CS[7:0]: CLUT size
These bits define the size of the CLUT used for the BG. Once the CLUT transfer has started, this field is read-only.
The number of CLUT entries is equal to CS[7:0] + 1.

Bits 7:6 Reserved, must be kept at reset value.
Bit 5 **START**: Start

This bit is set to start the automatic loading of the CLUT. This bit is automatically reset:
- at the end of the transfer
- when the transfer is aborted by the user application by setting the ABORT bit in the DMA2D_CR
- when a transfer error occurs
- when the transfer has not started due to a configuration error or another transfer operation already ongoing (data transfer or automatic foreground CLUT transfer).

Bit 4 **CCM**: CLUT Color mode

These bits define the color format of the CLUT. This register can only be written when the transfer is disabled. Once the CLUT transfer has started, this bit is read-only.
0: ARGB8888
1: RGB888
others: meaningless

Bits 3:0 **CM[3:0]**: Color mode

These bits define the color format of the foreground image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.
0000: ARGB8888
0001: RGB888
0010: RGB565

Bits 15:0  **MA[15:0]:**

RM0432 Rev 8  441/2298
13.5.13 DMA2D background CLUT memory address register (DMA2D_BGCMAR)

Address offset: 0x0030
Reset value: 0x0000 0000

Bits 31:0 MA[31:0]: Memory Address
Address of the data used for the CLUT address dedicated to the foreground image. This register can only be written when no transfer is ongoing. Once the CLUT transfer has started, this register is read-only.
If the foreground CLUT format is 32-bit, the address must be 32-bit aligned.

13.5.14 DMA2D output PFC control register (DMA2D_OPFCCR)

Address offset: 0x0034
Reset value: 0x0000 0000

Bits 31:0 MA[31:0]: Memory address
Address of the data used for the CLUT address dedicated to the background image.
This register can only be written when no transfer is on going. Once the CLUT transfer has started, this register is read-only.
If the background CLUT format is 32-bit, the address must be 32-bit aligned.
13.5.15 DMA2D output color register (DMA2D_OCOLR)

Address offset: 0x0038
Reset value: 0x0000 0000

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **RBS**: Red Blue Swap

This bit allows to swap the R & B to support BGR or ABGR color formats. Once the transfer has started, this bit is read-only.

0: Regular mode (RGB or ARGB)
1: Swap mode (BGR or ABGR)

Bit 20 **AI**: Alpha Inverted

This bit inverts the alpha value. Once the transfer has started, this bit is read-only.

0: Regular alpha
1: Inverted alpha

Bits 19:10 Reserved, must be kept at reset value.

Bit 9 **SB**: Swap Bytes

When set, the bytes in the output FIFO are swapped two by two.

When this bit is set, the number of pixel per line (PL) must be even, and the output memory address (OMAR) must be even.

This register can only be written when the transfer is disabled. Once the transfer has started, this register is read-only.

0: Bytes in regular order in the output FIFO
1: Bytes are swapped two by two in the output FIFO

Bits 8:3 Reserved, must be kept at reset value.

Bits 2:0 **CM[2: 0]**: Color mode

These bits define the color format of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

ARGB8888 or RGB888 color mode

Bits 31:24  ALPHA[7:0]: Alpha channel value in ARGB8888 mode otherwise reserved
These bits define the alpha channel of the output color. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 23:16  RED[7:0]: Red value in ARGB8888 or RGB888 mode otherwise reserved
These bits define the red value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 15:8  GREEN[7:0]: Green value in ARGB8888 or RGB888
These bits define the green value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 7:0  BLUE[7:0]: Blue value in ARGB8888 or RGB888
These bits define the blue value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

RGB565 color mode

Bits 15:11  RED[4:0]: Red value in RGB565 mode
These bits define the red value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 12:5  GREEN[5:0]: Green value in RGB565 mode
These bits define the green value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 4:0  BLUE[4:0]: Blue value in RGB565 mode
These bits define the blue value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

ARGB1555 color mode

Bit 15  A: Alpha channel value in ARGB1555 mode
This bit defines the alpha channel of the output color. This bit can only be written when data transfers are disabled. Once the transfer has started, it is read-only.

Bits 14:10  RED[4:0]: Red value in ARGB1555 mode
These bits define the red value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 9:5  GREEN[4:0]: Green value in ARGB1555 mode
These bits define the green value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 4:0  BLUE[4:0]: Blue value in ARGB1555 mode
These bits define the blue value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

ARGB4444 color mode

Bits 15:12  ALPHA[3:0]: Alpha channel value in ARGB4444
This bit defines the alpha channel of the output color. This bit can only be written when data transfers are disabled. Once the transfer has started, it is read-only.
13.5.16 DMA2D output memory address register (DMA2D_OMAR)

Bits 11:8 **RED[3:0]: Red value in ARGB4444 mode**
These bits define the red value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 7:4 **GREEN[3:0]: Green value in ARGB4444 mode**
These bits define the green value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 3:0 **BLUE[3:0]: Blue value in ARGB4444 mode**
These bits define the blue value of the output image. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Bits 31:30  Reserved, must be kept at reset value.

Bits 29:16  PL[13:0]: Pixel per lines
Number of pixels per lines of the area to be transferred. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.
If any of the input image format is 4-bit per pixel, pixel per lines must be even.

Bits 15:0  NL[15:0]: Number of lines
Number of lines of the area to be transferred. These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

13.5.19 DMA2D line watermark register (DMA2D_LWR)

</table>

Bits 31:30  Reserved, must be kept at reset value.

Bits 29:16  LW[15:0]: Line offset
The line offset used for the output expressed in pixel when the LOM bit is reset and in byte when the LOM bit is set.
When expressed in pixels, only LO[13:0] is considered, LO[15:14] are ignored.
This value is used for the address generation. It is added at the end of each line to determine the starting address of the next line.
These bits can only be written when data transfers are disabled. Once data transfer has started, they become read-only.
13.5.20 DMA2D AHB master timer configuration register (DMA2D_AMTCR)

Address offset: 0x004C  
Reset value: 0x0000 0000

</table>

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 LW[15:0]: Line watermark
These bits allow to configure the line watermark for interrupt generation.  
An interrupt is raised when the last pixel of the watermarked line has been transferred.  
These bits can only be written when data transfers are disabled. Once the transfer has started, they are read-only.

Refer to Section 2.2 on page 93 for the register boundary addresses.
14 Chrom-GRC (GFXMMU)

14.1 Introduction
The Chrom-GRC (GFXMMU) is a graphical oriented memory management unit aimed to optimize memory usage according to the display shape.

14.2 GFXMMU main features
- Fully programmable display shape to physically store only the visible pixel
- Up to 4 virtual buffers
- Each virtual buffer have 3072 or 4096 bytes per line and 1024 lines
- Each virtual buffer can be physically mapped to any system memory
- Interrupt in case of buffer overflow (1 per buffer)
- Interrupt in case of memory transfer error
14.3  GFXMMU functional and architectural description

The GFXMMU is responsible of address resolution to convert the virtual buffer address into the physical buffer address.

![Figure 38. GFXMMU block diagram](image)

14.3.1 Virtual memory

The GFXMMU provides a virtual memory space seen by the system masters\(^{(a)}\). This virtual memory space is divided into four virtual buffers.

**Virtual buffer**

A virtual buffer is seen by any system master as a continuous memory space representing a virtual frame buffer of 1024 lines.

Each line is divided into 192 or 256 16-byte blocks depending on the 192BM bit of the GFXMMU configuration register (GFXMMU_CR).

Depending on the display shape and size, only the necessary blocks are mapped to a physical memory location. This mapping is done programming the LUT entry for each line:

- The enable of the line
- The number of the first “visible” block
- The number of the last “visible” block
- The address offset of the line within the physical buffer

The “visible” blocks can be arranged in the physical buffer in a continuous way programming the address offset of each line.

The LUT is common to all the buffers i.e. all the buffers have the same “shape”.

---

\(^{(a)}\) Refer to section “System architecture” for system masters accessing GFXMMU.
Virtual buffer overview

For a frame buffer coded in 32 bpp or 16 bpp, the virtual buffer can be configured to have 192 or 256 blocks. This results in a virtual frame buffer of 768 x 1024 or 1024 x 1024 pixels for 32 bpp and 1536 x 1024 or 2048 x 1024 for 16 bpp.

For a frame buffer coded in 24 bpp, the virtual buffer must be configured to have 192 blocks to have an integer number of pixel per lines. This results in a virtual frame buffer of 1024 x 1024 pixels for 24 bpp.

Each buffer can be physically mapped anywhere in the physical memory thanks to:

- The physical buffer base address (PBBA) field of the GFXMMU buffer x configuration register (GFXMMU_BxCR). It configures the physical location of the 8-Mbyte area where the buffer is mapped.
- The physical buffer location respective to the physical buffer base address is defined by the physical buffer offset (PBO) field of the GFXMMU buffer x configuration register (GFXMMU_BxCR).
The buffer can not overflow the 8-Mbyte boundary of the zone defined by its base address. In case of overflow, the buffer x overflow flag (BxOF) of the GFXMMU status register (GFXMMU_SR) is set and an interrupt is generated if the buffer x overflow interrupt enable (BxOIE) bit of the GFXMMU configuration register (GFXMMU_CR) is set.

**Virtual buffer application use case**

As the physical locations are independently configurable, the four virtual buffers can be physically mapped to non continuous locations. This would allow for example to have the four buffers mapped on to four different SDRAM banks and avoid extra precharge cycles accessing the SDRAM.

As a consequence, one buffer must be used by the CPU/Chrom ART for frame buffer calculation while an other one must be used by the LTDC.

The two remaining buffers can be used as a graphical library requiring extra drawing buffers.

### 14.3.2 MMU architecture

The MMU block is responsible of the address resolution. It receives the 24-bit address and returns the physical 23-bit address and a valid signals to indicate the address is physically mapped or not. The MMU also checks overflow of a area boundary.
The MMU LUT is implemented as a 1024 x 35-bit RAM

**Figure 41. MMU block diagram**

**Line block decoder**

The line block decoder is generating the block number and the line number according the address.

**Look up RAM**

The look up RAM is a 1024 x 35-bit RAM with the following fields:

- 1-bit line enable
- 8-bit first valid block
- 8-bit last valid block
- 18-bit for line offset

As the RAM is bigger than a word, each entry is split into two words on the memory map. The write access are done in two steps:

1. Write the first word with enable/first valid block/last valid block in the GFXMMU_LUTxL memory location (internally buffered).
2. Write the second word with line offset in the GFXMMU_LUTxH memory location (effective write into the memory together with the internally buffered value).

A write in the LUT can happen any time but it can lead to inconsistencies if a master is using the MMU at the same time. As the CPU has the priority during LUT programming, this may slow down MMU calculation.

There is no restriction during read operations, but this may slow down CPU as the MMU has the priority on LUT accesses.

**Block validation/comparator**

This block is checking if the block is valid.
A block is considered as valid (physically mapped) when:
- Line is enable.
- The block number is greater or equal to the first valid block.
- The block number is lower or equal to the last valid block.

When the block is valid, the physical address generated is considered as correct.

If the result of the MMU evaluation is not valid, the write operations are ignored, and read operations return the default 32-bit value stored in the default value (DV) field of the GFXMMU default value register (GFXMMU_DVR).

**Block offset address calculation within the buffer**

The block number is added to the line offset to get the offset of the block within the physical buffer.

As a consequence, the line offset stored in the LUT is given by the following formula:

\[
\text{Line offset} = (\text{Number of visible blocks already used}) - (1^{st} \text{ visible block}) \times \text{block size}
\]

with:
- The maximum value for the line offset is when all the block of all the line are used. As the consequence the line offset for the last line can be maximum: \(1023 \times 256 \times 6 = 0x3F:F00x\)
- The minimum value for the line offset is when the last block of the first line is the first valid block: \(-255*16 = -0xFFx \text{ i.e } 0x3F:F01x\)

As the consequence the full range of the line offset entry of the LUT is used.

Carry is not taken into account as this stage to be able to perform negative offset calculations (values from 0x3F:F01x to 0x3F:FFFx)

As the block offset is within a 4-Mbyte buffer, the address generated is 22-bit wide.

**Block offset address calculation**

Once the offset of the block within the buffer as been calculated, this value is added to the offset of the block respective to the physical buffer base address.

The offset of the blocks are defined in registers as shown in Figure 42:

![Figure 42. Block validation/comparator implementation](MSv43803V1)

The resulting address and the buffer offset address must be on 23-bit.

The carry is taken into account to trigger address overflow. The carry is propagated to the GFXMMU status register (GFXMMU_SR) to set the buffer x overflow flag (BxOF).
Example of calculation

We are considering the following configuration for virtual buffer 0:
- First visible block of line 0: block 7
- Number of visible block in line 0: 10
- First visible block of line 1: block 6
- Number of visible block in line 1: 12
- Address of the physical buffer: 0xC020:0000

The configuration must be:
- The base address of the physical buffer 0: 0xC000:0000
- The offset of buffer 0: 0x20:0000
- First visible block of line 0: block 7
- Last visible block of line 0: block 16
- Block 0 offset of line 0: (0 - 7) x 0x10 = -0x70 = 0x3F:FF90
- First visible block of line 1: block 6
- Last visible block of line 1: block 17
- Block 0 offset of line 1: (10 - 6) x 0x10 = (0xA - 0x6) x 0x10 = 0x40

As a consequence:
- the physical address of block 7 of line 0 is:
  0xC000:0000 + 0x20:0000 + (0x3F:FF90 + 0x70 without carry) = 0xC020:0000
- the physical address of block 16 of line 0 is:
  0xC000:0000 + 0x20:0000 + (0x3F:FF90 + 0x100 without carry) = 0xC020:0090
- the physical address of block 6 of line 1 is:
  0xC000:0000 + 0x20:0000 + (0x40 + 0x60 without carry) = 0xC020:00A0
- the physical address of block 17 of line 1 is:
  0xC000:0000 + 0x20:0000 + (0x40 + 0x110 without carry) = 0xC020:0150
14.4 GFXMMU interrupts

An interrupt can be produced on the following events:
- Buffer 0 overflow
- Buffer 1 overflow
- Buffer 2 overflow
- Buffer 3 overflow
- AHB master error

Separate interrupt enable bits are available for flexibility.

Bits 31:5 Reserved, must be kept at reset value.

- **Bit 4 AMEF**: AHB master error flag  
  This bit is set when an AHB error happens during a transaction. It is cleared by writing 1 to CAMEF.

- **Bit 3 B3OF**: Buffer 3 overflow flag  
  This bit is set when an overflow occurs during the offset calculation of the buffer 3. It is cleared by writing 1 to CB3OF.

- **Bit 2 B2OF**: Buffer 2 overflow flag  
  This bit is set when an overflow occurs during the offset calculation of the buffer 2. It is cleared by writing 1 to CB2OF.

- **Bit 1 B1OF**: Buffer 1 overflow flag  
  This bit is set when an overflow occurs during the offset calculation of the buffer 1. It is cleared by writing 1 to CB1OF.

- **Bit 0 B0OF**: Buffer 0 overflow flag  
  This bit is set when an overflow occurs during the offset calculation of the buffer 0. It is cleared by writing 1 to CB0OF.

Refer to Section 2.2 on page 93 for the register boundary addresses.
15 Nested vectored interrupt controller (NVIC)

15.1 NVIC main features

- 95 maskable interrupt channels (not including the sixteen Cortex®-M4 with FPU interrupt lines)
- 16 programmable priority levels (4 bits of interrupt priority are used)
- Low-latency exception and interrupt handling
- Power management control
- Implementation of System Control Registers

The NVIC and the processor core interface are closely coupled, which enables low latency interrupt processing and efficient processing of late arriving interrupts.

All interrupts including the core exceptions are managed by the NVIC. For more information on exceptions and NVIC programming, refer to the PM0214 programming manual for Cortex™-M4 products.

15.2 SysTick calibration value register

The SysTick calibration value is set to 0x4000 3A97, which gives a reference time base of 1 ms with the SysTick clock set to 15 MHz (max f_HCLK/8).
### 15.3 Interrupt and exception vectors

The gray rows in the following tables describe the vectors without specific position.

16 Extended interrupts and events controller (EXTI)

16.1 Introduction

The EXTI main features are as follows:

- Generation of up to 39 event/interrupt requests
  - 26 configurable lines
  - 13 direct lines
- Independent mask on each event/interrupt line
- Configurable rising or falling edge (configurable lines only)
- Dedicated status bit (configurable lines only)
- Emulation of event/interrupt requests (configurable lines only)

16.2 EXTI main features

The extended interrupts and events controller (EXTI) manages the external and internal asynchronous events/interrupts and generates the event request to the CPU/Interrupt Controller and a wake-up request to the Power Controller.

The EXTI allows the management of up to 39 event lines which can wake up from the Stop 0 and Stop 1 modes. Not all events can wake up from the Stop 2 mode (refer to Table 78: EXTI lines connections).

The lines are either configurable or direct:

- The lines are configurable: the active edge can be chosen independently, and a status flag indicates the source of the interrupt. The configurable lines are used by the I/Os external interrupts, and by few peripherals.
- The lines are direct: they are used by some peripherals to generate a wake-up from Stop event or interrupt. The status flag is provided by the peripheral.

Each line can be masked independently for an interrupt or an event generation.

This controller also allows to emulate events or interrupts by software, multiplexed with the corresponding hardware event line, by writing to a dedicated register.

16.3 EXTI functional description

For the configurable interrupt lines, the interrupt line should be configured and enabled in order to generate an interrupt. This is done by programming the two trigger registers with the desired edge detection and by enabling the interrupt request by writing a ‘1’ to the corresponding bit in the interrupt mask register. When the selected edge occurs on the interrupt line, an interrupt request is generated. The pending bit corresponding to the interrupt line is also set. This request is cleared by writing a ‘1’ in the pending register.

For the direct interrupt lines, the interrupt is enabled by default in the interrupt mask register and there is no corresponding pending bit in the pending register.

To generate an event, the event line should be configured and enabled. This is done by programming the two trigger registers with the desired edge detection and by enabling the event request by writing a ‘1’ to the corresponding bit in the event mask register. When the
selected edge occurs on the event line, an event pulse is generated. The pending bit corresponding to the event line is not set.

For the configurable lines, an interrupt/event request can also be generated by software by writing a ‘1’ in the software interrupt/event register.

Note: The interrupts or events associated to the direct lines are triggered only when the system is in Stop mode. If the system is still running, no interrupt/event is generated by the EXTI.

16.3.1 EXTI block diagram

The extended interrupt/event block diagram is shown on Figure 43.

16.3.2 Wakeup event management

The STM32L4+ Series devices are able to handle external or internal events in order to wake up the core (WFE). The wakeup event can be generated either by:

- enabling an interrupt in the peripheral control register but not in the NVIC, and enabling the SEVONPEND bit in the Cortex™-M4 System Control register. When the MCU resumes from WFE, the EXTI peripheral interrupt pending bit and the peripheral NVIC IRQ channel pending bit (in the NVIC interrupt clear pending register) have to be cleared
- or by configuring an EXTI line in event mode. When the CPU resumes from WFE, it is not necessary to clear the peripheral interrupt pending bit or the NVIC IRQ channel pending bit as the pending bit corresponding to the event line is not set.
16.3.3 Peripherals asynchronous Interrupts

Some peripherals are able to generate events when the system is in run mode and also when the system is in Stop mode, allowing to wake up the system from Stop mode.

To accomplish this, the peripheral generates both a synchronized (to the system clock, e.g. APB clock) and an asynchronous version of the event. This asynchronous event is connected to an EXTI direct line.

Note: Few peripherals with wakeup from Stop capability are connected to an EXTI configurable line. In this case, the EXTI configuration is necessary to allow the wakeup from Stop mode.

16.3.4 Hardware interrupt selection

To configure a line as an interrupt source, use the following procedure:
1. Configure the corresponding mask bit in the EXTI_IMR register.
2. Configure the Trigger Selection bits of the Interrupt line (EXTI_RTSR and EXTI_FTSR).
3. Configure the enable and mask bits that control the NVIC IRQ channel mapped to the EXTI so that an interrupt coming from one of the EXTI lines can be correctly acknowledged.

Note: The direct lines do not require any EXTI configuration.

16.3.5 Hardware event selection

To configure a line as an event source, use the following procedure:
1. Configure the corresponding mask bit in the EXTI_EMR register.
2. Configure the Trigger Selection bits of the Event line (EXTI_RTSR and EXTI_FTSR).

16.3.6 Software interrupt/event selection

Any of the configurable lines can be configured as a software interrupt/event line. The procedure to generate a software interrupt is as follows:
1. Configure the corresponding software interrupt bit (EXTI_IMR, EXTI_EMR).
2. Set the required bit of the software interrupt register (EXTI_SWIER).

16.4 EXTI interrupt/event line mapping

In the STM32L4+ Series, 39 interrupt/event lines are available. The GPIOs are connected to 16 configurable interrupt/event lines (see Figure 44).
The GPIOs PI12 to PI15 are not available.

The EXTI lines are connected as shown in Table 78: EXTI lines connections.

1. All the lines can wake up from the Stop 0 and Stop 1 modes. All the lines, except the ones mentioned above, can wake up from the Stop 2 mode.
2. This line source cannot wake up from the Stop 2 mode.
3. SSRU is only available on STM32L4P5xx and STM32L4Q5xx devices.
4. LPTIM2 can wakeup from the Stop 2 mode only on STM32L4P5xx and STM32L4Q5xx devices.
16.5 EXTI registers

Refer to Section 1.2 on page 86 for a list of abbreviations used in register descriptions.

The peripheral registers have to be accessed by words (32-bit).

16.5.1 Interrupt mask register 1 (EXTI_IMR1)

Address offset: 0x00
Reset value: 0xFF82 0000

<table>
<thead>
<tr>

</tbody>
</table>

Bits 31:0 EMx: Event mask on line x (x = 31 to 0)
0: Event request from line x is masked
1: Event request from line x is not masked

16.5.3 Rising trigger selection register 1 (EXTI_RTSR1)

Address offset: 0x08
Reset value: 0x0000 0000
Note: The configurable wakeup lines are edge-triggered. No glitch must be generated on these lines. If a rising edge on a configurable interrupt line occurs during a write operation in the EXTI_RTSR register, the pending bit is not set.

Rising and falling edge triggers can be set for the same interrupt line. In this case, both generate a trigger condition.

### 16.5.4 Falling trigger selection register 1 (EXTI_FTSR1)

Address offset: 0x0C
Reset value: 0x0000 0000

</tr>
</tbody>
</table>

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:18 FTx: Falling trigger event configuration bit of line x (x = 22 to 18)
0: Falling trigger disabled (for Event and Interrupt) for input line
1: Falling trigger enabled (for Event and Interrupt) for input line

Bit 17 Reserved, must be kept at reset value.

Bits 16:0 FTx: Falling trigger event configuration bit of line x (x = 16 to 0)
0: Falling trigger disabled (for Event and Interrupt) for input line
1: Falling trigger enabled (for Event and Interrupt) for input line
**Note:** The configurable wakeup lines are edge-triggered. No glitch must be generated on these lines. If a falling edge on a configurable interrupt line occurs during a write operation to the EXTI_FTSR register, the pending bit is not set.

Rising and falling edge triggers can be set for the same interrupt line. In this case, both generate a trigger condition.

### 16.5.5 Software interrupt event register 1 (EXTI_SWIER1)

Address offset: 0x10

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31:23</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits 22: 18 SWIx: Software interrupt on line x (x = 22 o 18)</td>
<td></td>
</tr>
<tr>
<td>If the interrupt is enabled on this line in the EXTI_IMR, writing a '1' to this bit when it is at '0' sets the corresponding pending bit in EXTI_PR resulting in an interrupt request generation.</td>
<td></td>
</tr>
<tr>
<td>This bit is cleared by clearing the corresponding bit in the EXTI_PR register (by writing a '1' into the bit).</td>
<td></td>
</tr>
</tbody>
</table>

| Bit 17 | Reserved, must be kept at reset value. |
| Bits 16:0 SWIx: Software interrupt on line x (x = 16 to 0) |
| If the interrupt is enabled on this line in the EXTI_IMR, writing a '1' to this bit when it is at '0' sets the corresponding pending bit in EXTI_PR resulting in an interrupt request generation. |
| This bit is cleared by clearing the corresponding bit of EXTI_PR (by writing a '1' into the bit). |
16.5.6 Pending register 1 (EXTI_PR1)

Address offset: 0x14
Reset value: undefined

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:18 **PIFx**: Pending interrupt flag on line x (x = 22 to 18)
0: No trigger request occurred
1: Selected trigger request occurred
This bit is set when the selected edge event arrives on the interrupt line. This bit is cleared by writing a ‘1’ to the bit.

Bit 17 Reserved, must be kept at reset value.

Bits 16:0 **PIFx**: Pending interrupt flag on line x (x = 16 to 0)
0: No trigger request occurred
1: Selected trigger request occurred
This bit is set when the selected edge event arrives on the interrupt line. This bit is cleared by writing a ‘1’ to the bit.

16.5.7 Interrupt mask register 2 (EXTI_IMR2)

Address offset: 0x20
Reset value: 0x0000 0187

Bits 31:8 Reserved, must be kept at reset value

Bits 8:0 **IMx**: Interrupt mask on line x (x = 40 to 32)
0: Interrupt request from line x is masked
1: Interrupt request from line x is not masked

Note: The reset value for the direct lines (line 17, lines from 23 to 34, line 39, line 40) is set to ‘1’ in order to enable the interrupt by default.
### 16.5.8 Event mask register 2 (EXTI_EMR2)

STI
17  Cyclic redundancy check calculation unit (CRC)

17.1  Introduction

The CRC (cyclic redundancy check) calculation unit is used to get a CRC code from 8-, 16- or 32-bit data word and a generator polynomial.

Among other applications, CRC-based techniques are used to verify data transmission or storage integrity. In the scope of the functional safety standards, they offer a means of verifying the Flash memory integrity. The CRC calculation unit helps compute a signature of the software during runtime, to be compared with a reference signature generated at link time and stored at a given memory location.

17.2  CRC main features

- Uses CRC-32 (Ethernet) polynomial: 0x4C11DB7
  \[ X^{32} + X^{26} + X^{23} + X^{16} + X^{12} + X^{11} + X^{10} + X^{8} + X^{7} + X^{5} + X^{4} + X^{2} + X + 1 \]
- Alternatively, uses fully programmable polynomial with programmable size (7, 8, 16, 32 bits)
- Handles 8-, 16-, 32-bit data size
- Programmable CRC initial value
- Single input/output 32-bit data register
- Input buffer to avoid bus stall during calculation
- CRC computation done in 4 AHB clock cycles (HCLK) for the 32-bit data size
- General-purpose 8-bit register (can be used for temporary storage)
- Reversibility option on I/O data
17.3 CRC functional description

17.3.1 CRC block diagram

The CRC calculation unit has a single 32-bit read/write data register (CRC_DR). It is used to input new data (write access), and holds the result of the previous CRC calculation (read access).

Each write operation to the data register creates a combination of the previous CRC value (stored in CRC_DR) and the new one. CRC computation is done on the whole 32-bit data word or byte by byte depending on the format of the data being written.

The CRC_DR register can be accessed by word, right-aligned half-word and right-aligned byte. For the other registers only 32-bit access is allowed.

The duration of the computation depends on data width:
- 4 AHB clock cycles for 32-bit
- 2 AHB clock cycles for 16-bit
- 1 AHB clock cycles for 8-bit

An input buffer allows a second data to be immediately written without waiting for any wait states due to the previous CRC calculation.

The data size can be dynamically adjusted to minimize the number of write accesses for a given number of bytes. For instance, a CRC for 5 bytes can be computed with a word write followed by a byte write.

### Table 80. CRC internal input/output signals

<table>
<thead>
<tr>
<th>Signal name</th>
<th>Signal type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>crc_hclk</td>
<td>Digital input</td>
<td>AHB clock</td>
</tr>
</tbody>
</table>
The input data can be reversed, to manage the various endianness schemes. The reversing operation can be performed on 8 bits, 16 bits and 32 bits depending on the REV_IN[1:0] bits in the CRC_CR register.

For example: input data 0x1A2B3C4D is used for CRC calculation as:
- 0x58D43CB2 with bit-reversal done by byte
- 0xD458B23C with bit-reversal done by half-word
- 0xB23CD458 with bit-reversal done on the full word

The output data can also be reversed by setting the REV_OUT bit in the CRC_CR register. The operation is done at bit level: for example, output data 0x11223344 is converted into 0x22CC4488.

The CRC calculator can be initialized to a programmable value using the RESET control bit in the CRC_CR register (the default value is 0xFFFFFFFF).

The initial CRC value can be programmed with the CRC_INIT register. The CRC_DR register is automatically initialized upon CRC_INIT register write access.

The CRC_IDR register can be used to hold a temporary value related to CRC calculation. It is not affected by the RESET bit in the CRC_CR register.

**Polynomial programmability**

The polynomial coefficients are fully programmable through the CRC_POL register, and the polynomial size can be configured to be 7, 8, 16 or 32 bits by programming the POLYSIZE[1:0] bits in the CRC_CR register. Even polynomials are not supported.

If the CRC data is less than 32-bit, its value can be read from the least significant bits of the CRC_DR register.

To obtain a reliable CRC calculation, the change on-fly of the polynomial value or size can not be performed during a CRC calculation. As a result, if a CRC calculation is ongoing, the application must either reset it or perform a CRC_DR read before changing the polynomial.

The default polynomial value is the CRC-32 (Ethernet) polynomial: 0x4C11DB7.
17.4 CRC registers

17.4.1 CRC data register (CRC_DR)

Address offset: 0x00
Reset value: 0xFFFF FFFF

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **REV_OUT**: Reverse output data
   - This bit controls the reversal of the bit order of the output data.
   - 0: Bit order not affected
   - 1: Bit-reversed output format

Bits 6:5 **REV_IN[1:0]**: Reverse input data
   - These bits control the reversal of the bit order of the input data
   - 00: Bit order not affected
   - 01: Bit reversal done by byte
   - 10: Bit reversal done by half-word
   - 11: Bit reversal done by word

Bits 4:3 **POLYSIZE[1:0]**: Polynomial size
   - These bits control the size of the polynomial.
   - 00: 32 bit polynomial
   - 01: 16 bit polynomial
   - 10: 8 bit polynomial
   - 11: 7 bit polynomial

Bits 2:1 Reserved, must be kept at reset value.

Bit 0 **RESET**: RESET bit
   - This bit is set by software to reset the CRC calculation unit and set the data register to the value stored in the CRC_INIT register. This bit can only be set, it is automatically cleared by hardware
## 17.4.4 CRC initial value (CRC_INIT)

Refer to *Section 2.2 on page 93* for the register boundary addresses.
18 Flexible static memory controller (FSMC)

18.1 Introduction

The flexible static memory controller (FSMC) includes two memory controllers:
- The NOR/PSRAM memory controller
- The NAND memory controller

This memory controller is also named flexible memory controller (FMC).

18.2 FMC main features

The FMC functional block makes the interface with: synchronous and asynchronous static memories, and NAND Flash memory. Its main purposes are:
- to translate AHB transactions into the appropriate external device protocol
- to meet the access time requirements of the external memory devices

All external memories share the addresses, data and control signals with the controller. Each external device is accessed by means of a unique chip select. The FMC performs only one access at a time to an external device.

The main features of the FMC controller are the following:
- Interface with static-memory mapped devices including:
  - Static random access memory (SRAM)
  - NOR Flash memory/OneNAND Flash memory
  - PSRAM (4 memory banks)
  - Ferroelectric RAM (FRAM)
  - NAND Flash memory with ECC hardware to check up to 8 Kbytes of data
- Interface with parallel LCD modules, supporting Intel 8080 and Motorola 6800 modes.
- Burst mode support for faster access to synchronous devices such as NOR Flash memory, PSRAM
- Programmable continuous clock output for asynchronous and synchronous accesses
- 8-, 16-bit wide data bus
- Independent chip select control for each memory bank
- Independent configuration for each memory bank
- Write enable and byte lane select outputs for use with PSRAM, SRAM devices
- External asynchronous wait control
- Write FIFO with 16 x32-bit depth

The Write FIFO is common to all memory controllers and consists of:
- a Write Data FIFO which stores the AHB data to be written to the memory (up to 32 bits) plus one bit for the AHB transfer (burst or not sequential mode)
- a Write Address FIFO which stores the AHB address (up to 28 bits) plus the AHB data size (up to 2 bits). When operating in burst mode, only the start address is stored except when crossing a page boundary (for PSRAM). In this case, the AHB burst is broken into two FIFO entries.
The Write FIFO can be disabled by setting the WFDIS bit in the FMC_BCR1 register.

At startup the FMC pins must be configured by the user application. The FMC I/O pins which are not used by the application can be used for other purposes.

The FMC registers that define the external device type and associated characteristics are usually set at boot time and do not change until the next reset or power-up. However, the settings can be changed at any time.

### 18.3 FMC implementation

### 18.4 FMC block diagram

The FMC consists of the following main blocks:
- The AHB interface (including the FMC configuration registers)
- The NOR Flash/PSRAM/SRAM controller
- The external device interface
- The NAND Flash controller

The block diagram is shown in the figure below.
18.5 AHB interface

The AHB slave interface allows internal CPUs and other bus master peripherals to access the external memories.

AHB transactions are translated into the external device protocol. In particular, if the selected external memory is 16- or 8-bit wide, 32-bit wide transactions on the AHB are split into consecutive 16- or 8-bit accesses. The FMC chip select (FMC_NEx) does not toggle between the consecutive accesses except in case of Access mode D when the Extended mode is enabled.

The FMC generates an AHB error in the following conditions:
- When reading or writing to an FMC bank (Bank 1 to 4) which is not enabled.
- When reading or writing to the NOR Flash bank while the FACCEN bit is reset in the FMC_BCRx register.

The effect of an AHB error depends on the AHB master which has attempted the R/W access:
- If the access has been attempted by the Cortex®-M4 CPU, a hard fault interrupt is generated.
- If the access has been performed by a DMA controller, a DMA transfer error is generated and the corresponding DMA channel is automatically disabled.

The AHB clock (HCLK) is the reference clock for the FMC.

18.5.1 Supported memories and transactions

General transaction rules

The requested AHB transaction data size can be 8-, 16- or 32-bit wide whereas the accessed external device has a fixed data width. This may lead to inconsistent transfers. Therefore, some simple transaction rules must be followed:
- AHB transaction size and memory data size are equal
  There is no issue in this case.
- AHB transaction size is greater than the memory size:
  In this case, the FMC splits the AHB transaction into smaller consecutive memory accesses to meet the external data width. The FMC chip select (FMC_NEx) does not toggle between the consecutive accesses. If the bus turnaround timings is configured...
to any other value than 0, the FMC chip select (FMC_NEx) toggles between the consecutive accesses. This feature is required when interfacing with FRAM memory.

- **AHB transaction size is smaller than the memory size:**
  
  The transfer may or not be consistent depending on the type of external device:
  
  - Accesses to devices that have the byte select feature (SRAM, ROM, PSRAM)
    
    In this case, the FMC allows read/write transactions and accesses the right data through its byte lanes NBL[1:0].
    
    Bytes to be written are addressed by NBL[1:0].
    
    All memory bytes are read (NBL[1:0] are driven low during read transaction) and the useless ones are discarded.
    
  - Accesses to devices that do not have the byte select feature (NOR and NAND Flash memories)
    
    This situation occurs when a byte access is requested to a 16-bit wide Flash memory. Since the device cannot be accessed in Byte mode (only 16-bit words can be read/written from/to the Flash memory), Write transactions and Read transactions are allowed (the controller reads the entire 16-bit memory word and uses only the required byte).

**Wrap support for NOR Flash/PSRAM**

Wrap burst mode for synchronous memories is not supported. The memories must be configured in Linear burst mode of undefined length.

**Configuration registers**

The FMC can be configured through a set of registers. Refer to Section 18.7.6, for a detailed description of the NOR Flash/PSRAM controller registers. Refer to Section 18.8.7, for a detailed description of the NAND Flash registers.

### 18.6 External device address mapping

From the FMC point of view, the external memory is divided into fixed-size banks of 256 Mbytes each (see Figure 47):

- **Bank 1 used to address up to 4 NOR Flash memory or PSRAM devices.** This bank is split into 4 NOR/PSRAM subbanks with 4 dedicated chip selects, as follows:
  
  - Bank 1 - NOR/PSRAM 1
  - Bank 1 - NOR/PSRAM 2
  - Bank 1 - NOR/PSRAM 3
  - Bank 1 - NOR/PSRAM 4

- **Bank 3 used to address NAND Flash memory devices.** The MPU memory attribute for this space must be reconfigured by software to Device.

For each bank the type of memory to be used can be configured by the user application through the Configuration register.
18.6.1 NOR/PSRAM address mapping

HADDR[27:26] bits are used to select one of the four memory banks as shown in Table 83.

Table 83. NOR/PSRAM bank selection

<table>
<thead>
<tr>
<th>HADDR[27:26]</th>
<th>Selected bank</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Bank 1 - NOR/PSRAM 1</td>
</tr>
<tr>
<td>01</td>
<td>Bank 1 - NOR/PSRAM 2</td>
</tr>
<tr>
<td>10</td>
<td>Bank 1 - NOR/PSRAM 3</td>
</tr>
<tr>
<td>11</td>
<td>Bank 1 - NOR/PSRAM 4</td>
</tr>
</tbody>
</table>

1. HADDR are internal AHB address lines that are translated to external memory.

The HADDR[25:0] bits contain the external memory address. Since HADDR is a byte address whereas the memory is addressed at word level, the address actually issued to the memory varies according to the memory data width, as shown in the following table.

Table 84. NOR/PSRAM External memory address

<table>
<thead>
<tr>
<th>Memory width</th>
<th>Data address issued to the memory</th>
<th>Maximum memory capacity (bits)</th>
</tr>
</thead>
<tbody>
<tr>
<td>8-bit</td>
<td>HADDR[25:0]</td>
<td>64 Mbytes x 8 = 512 Mbit</td>
</tr>
<tr>
<td>16-bit</td>
<td>HADDR[25:1] &gt;&gt; 1</td>
<td>64 Mbytes/2 x 16 = 512 Mbit</td>
</tr>
</tbody>
</table>

1. In case of a 16-bit external memory width, the FMC internally uses HADDR[25:1] to generate the address for external memory FMC_A[24:0]. Whatever the external memory width, FMC_A[0] should be connected to external memory address A[0].
18.6.2 NAND Flash memory address mapping

The NAND bank is divided into memory areas as indicated in Table 85.

Table 85. NAND memory mapping and timing registers

<table>
<thead>
<tr>
<th>Start address</th>
<th>End address</th>
<th>FMC bank</th>
<th>Memory space</th>
<th>Timing register</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x8800 0000</td>
<td>0x8BFF FFFF</td>
<td>Bank 3 - NAND Flash</td>
<td>Attribute</td>
<td>FMC_PATT (0x8C)</td>
</tr>
<tr>
<td>0x8000 0000</td>
<td>0x83FF FFFF</td>
<td>Common</td>
<td>Common</td>
<td>FMC_PMEM (0x88)</td>
</tr>
</tbody>
</table>

For NAND Flash memory, the common and attribute memory spaces are subdivided into three sections (see in Table 86 below) located in the lower 256 Kbytes:

- Data section (first 64 Kbytes in the common/attribute memory space)
- Command section (second 64 Kbytes in the common / attribute memory space)
- Address section (next 128 Kbytes in the common / attribute memory space)

Table 86. NAND bank selection

<table>
<thead>
<tr>
<th>Section name</th>
<th>HADDR[17:16]</th>
<th>Address range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Address section</td>
<td>1X</td>
<td>0x020000-0x03FFFF</td>
</tr>
<tr>
<td>Command section</td>
<td>01</td>
<td>0x010000-0x01FFFF</td>
</tr>
<tr>
<td>Data section</td>
<td>00</td>
<td>0x000000-0x0FFFF</td>
</tr>
</tbody>
</table>

The application software uses the 3 sections to access the NAND Flash memory:

- To sending a command to NAND Flash memory, the software must write the command value to any memory location in the command section.
- To specify the NAND Flash address that must be read or written, the software must write the address value to any memory location in the address section. Since an address can be 4 or 5 bytes long (depending on the actual memory size), several consecutive write operations to the address section are required to specify the full address.
- To read or write data, the software reads or writes the data from/to any memory location in the data section.

Since the NAND Flash memory automatically increments addresses, there is no need to increment the address of the data section to access consecutive memory locations.
18.7 **NOR Flash/PSRAM controller**

The FMC generates the appropriate signal timings to drive the following types of memories:

- Asynchronous SRAM, FRAM and ROM
  - 8 bits
  - 16 bits
- PSRAM (CellularRAM™)
  - Asynchronous mode
  - Burst mode for synchronous accesses
  - Multiplexed or non-multiplexed
- NOR Flash memory
  - Asynchronous mode
  - Burst mode for synchronous accesses
  - Multiplexed or non-multiplexed

The FMC outputs a unique chip select signal, NE[4:1], per bank. All the other signals (addresses, data and control) are shared.

The FMC supports a wide range of devices through a programmable timings among which:

- Programmable wait states (up to 15)
- Programmable bus turnaround cycles (up to 15)
- Programmable output enable and write enable delays (up to 15)
- Independent read and write timings and protocol to support the widest variety of memories and timings
- Programmable continuous clock (FMC_CLK) output.

The FMC Clock (FMC_CLK) is a submultiple of the HCLK clock. It can be delivered to the selected external device either during synchronous accesses only or during asynchronous and synchronous accesses depending on the CCKEN bit configuration in the FMC_BCR1 register:

- If the CCLKEN bit is reset, the FMC generates the clock (CLK) only during synchronous accesses (Read/write transactions).
- If the CCLKEN bit is set, the FMC generates a continuous clock during asynchronous and synchronous accesses. To generate the FMC_CLK continuous clock, Bank 1 must be configured in Synchronous mode (see Section 18.7.6: NOR/PSRAM controller registers). Since the same clock is used for all synchronous memories, when a continuous output clock is generated and synchronous accesses are performed, the AHB data size has to be the same as the memory data width (MWID) otherwise the FMC_CLK frequency is changed depending on AHB data transaction (refer to Section 18.7.5: Synchronous transactions for FMC_CLK divider ratio formula).

The size of each bank is fixed and equal to 64 Mbytes. Each bank is configured through dedicated registers (see Section 18.7.6: NOR/PSRAM controller registers).

The programmable memory parameters include access times (see Table 87) and support for wait management (for PSRAM and NOR Flash accessed in Burst mode).
18.7.1 External memory interface signals

Table 88, Table 89 and Table 90 list the signals that are typically used to interface with NOR Flash memory, SRAM and PSRAM.

**Note:** The prefix “N” identifies the signals that are active low.

### NOR Flash memory, non-multiplexed I/Os

### 18.7.3 General timing rules

**Signals synchronization**

- All controller output signals change on the rising edge of the internal clock (HCLK).
- In Synchronous mode (read or write), all output signals change on the rising edge of HCLK. Whatever the CLKDIV value, all outputs change as follows:
  - NOEL/NWEL/ NEL/NADVH/ NADV / NBLL/ Address valid outputs change on the falling edge of FMC_CLK clock.
  - NOEH/ NWEH / NEH/ NOEH/NBLH/ Address invalid outputs change on the rising edge of FMC_CLK clock.

18.7.4 NOR Flash/PSRAM controller asynchronous transactions

Asynchronous static memories (NOR Flash, PSRAM, SRAM, FRAM)

- Signals are synchronized by the internal clock HCLK. This clock is not issued to the memory.
- The FMC always samples the data before de-asserting the NOE signal. This guarantees that the memory data hold timing constraint is met (minimum Chip Enable high to data transition is usually 0 ns).
- If the Extended mode is enabled (EXTMOD bit is set in the FMC_BCRx register), up to four extended modes (A, B, C and D) are available. It is possible to mix A, B, C and D modes for read and write operations. For example, read operation can be performed in mode A and write in mode B.
- If the Extended mode is disabled (EXTMOD bit is reset in the FMC_BCRx register), the FMC can operate in mode 1 or mode 2 as follows:
  - Mode 1 is the default mode when SRAM/PSRAM memory type is selected (MTYP = 0x0 or 0x01 in the FMC_BCRx register).
  - Mode 2 is the default mode when NOR memory type is selected (MTYP = 0x10 in the FMC_BCRx register).

Mode 1 - SRAM/FRAM/PSRAM (CRAM)

The next figures show the read and write transactions for the supported modes followed by the required configuration of FMC_BCRx, and FMC_BTRx/FMC_BWTRx registers.

![Mode 1 read access waveforms](image-url)
The DATAHLD time at the end of the read and write transactions guarantee the address and data hold time after the NOE/NWE rising edge. The DATAST value must be greater than zero (DATAST > 0).

WAIT management in asynchronous accesses

If the asynchronous memory asserts the WAIT signal to indicate that it is not yet ready to accept or to provide data, the ASYNCCWAIT bit has to be set in FMC_BCRx register.

If the WAIT signal is active (high or low depending on the WAITPOL bit), the second access phase (Data setup phase), programmed by the DATAST bits, is extended until WAIT becomes inactive. Unlike the data setup phase, the first access phases (Address setup and Address hold phases), programmed by the ADDSET and ADDHLD bits, are not WAIT sensitive and so they are not prolonged.

The data setup phase must be programmed so that WAIT can be detected 4 HCLK cycles before the end of the memory transaction. The following cases must be considered:

</table>
1. The memory asserts the WAIT signal aligned to NOE/NWE which toggles:

\[
\text{DATAST} \geq (4 \times \text{HCLK}) + \text{max\_wait\_assertion\_time}
\]

2. The memory asserts the WAIT signal aligned to NEx (or NOE/NWE not toggling):

\[
\text{if } \quad \text{max\_wait\_assertion\_time} > \text{address\_phase} + \text{hold\_phase}
\]

then:

\[
\text{DATAST} \geq (4 \times \text{HCLK}) + (\text{max\_wait\_assertion\_time} \text{– address\_phase} \text{– hold\_phase})
\]

otherwise

\[
\text{DATAST} \geq 4 \times \text{HCLK}
\]

where max_wait Assertion Time is the maximum time taken by the memory to assert the WAIT signal once NEx/NOE/NWE is low.

*Figure 61* and *Figure 62* show the number of HCLK clock cycles that are added to the memory access phase after WAIT is released by the asynchronous memory (independently of the above cases).

**Figure 61. Asynchronous wait during a read access waveforms**
Figure 62. Asynchronous wait during a write access waveforms

CellularRAM™ (PSRAM) refresh management

The CellularRAM™ does not allow maintaining the chip select signal (NE) low for longer than the $t_{CEM}$ timing specified for the memory device. This timing can be programmed in the FMC_PCSCNTR register. It defines the maximum duration of the NE low pulse in HCLK cycles for asynchronous accesses and FMC_CLK cycles for synchronous accesses.

18.7.5 Synchronous transactions

The memory clock, FMC_CLK, is a submultiple of HCLK. It depends on the value of CLKDIV and the MWID/ AHB data size, following the formula given below:

$$FMC\_CLK\ \text{divider ratio} = \max(CLKDIV + 1, MWID(\text{AHB data size}))$$

Whatever MWID size: 16 or 8-bit, the FMC_CLK divider ratio is always defined by the programmed CLKDIV value.

Example:
- If CLKDIV=1, MWID = 16 bits, AHB data size=8 bits, FMC_CLK=HCLK/2.

NOR Flash memories specify a minimum time from NADV assertion to CLK high. To meet this constraint, the FMC does not issue the clock to the memory during the first internal clock cycle of the synchronous access (before NADV assertion). This guarantees that the rising edge of the memory clock occurs in the middle of the NADV low pulse.
Data latency versus NOR memory latency

The data latency is the number of cycles to wait before sampling the data. The DATLAT value must be consistent with the latency value specified in the NOR Flash configuration register. The FMC does not include the clock cycle when NADV is low in the data latency count.

**Caution:** Some NOR Flash memories include the NADV Low cycle in the data latency count, so that the exact relation between the NOR Flash latency and the FMC DATLAT parameter can be either:

- NOR Flash latency = (DATLAT + 2) CLK clock cycles
- or NOR Flash latency = (DATLAT + 3) CLK clock cycles

Some recent memories assert NWAIT during the latency phase. In such cases DATLAT can be set to its minimum value. As a result, the FMC samples the data and waits long enough to evaluate if the data are valid. Thus the FMC detects when the memory exits latency and real data are processed.

Other memories do not assert NWAIT during latency. In this case the latency must be set correctly for both the FMC and the memory, otherwise invalid data are mistaken for good data, or valid data are lost in the initial phase of the memory access.

**Single-burst transfer**

When the selected bank is configured in Burst mode for synchronous accesses, if for example an AHB single-burst transaction is requested on 16-bit memories, the FMC performs a burst transaction of length 1 (if the AHB transfer is 16 bits), or length 2 (if the AHB transfer is 32 bits) and de-assert the chip select signal when the last data is strobed.

Such transfers are not the most efficient in terms of cycles compared to asynchronous read operations. Nevertheless, a random asynchronous access would first require to re-program the memory access mode, which would altogether last longer.

**Cross boundary page for CellularRAM™ 1.5**

CellularRAM™ 1.5 does not allow burst access to cross the page boundary. The FMC controller allows to split automatically the burst access when the memory page size is reached by configuring the CPSIZE bits in the FMC_BCR1 register following the memory page size.

**Wait management**

For synchronous NOR Flash memories, NWAIT is evaluated after the programmed latency period, which corresponds to (DATLAT+2) CLK clock cycles.

If NWAIT is active (low level when WAITPOL = 0, high level when WAITPOL = 1), wait states are inserted until NWAIT is inactive (high level when WAITPOL = 0, low level when WAITPOL = 1).

When NWAIT is inactive, the data is considered valid either immediately (bit WAITCFG = 1) or on the next clock edge (bit WAITCFG = 0).

During wait-state insertion via the NWAIT signal, the controller continues to send clock pulses to the memory, keeping the chip select and output enable signals valid. It does not consider the data as valid.
In Burst mode, there are two timing configurations for the NOR Flash NWAIT signal:

- The Flash memory asserts the NWAIT signal one data cycle before the wait state (default after reset).
- The Flash memory asserts the NWAIT signal during the wait state

The FMC supports both NOR Flash wait state configurations, for each chip select, thanks to the WAITCFG bit in the FMC_BCRx registers (x = 0..3).

18.7.6 NOR/PSRAM controller registers

SRAM/NOR-Flash chip-select control register for bank x (FMC_BCRx) (x = 1 to 4)

Address offset: 8 * (x – 1), (x = 1 to 4)
Reset value: Bank 1: 0x0000 30DB
Reset value: Bank 2: 0x0000 30D2
Reset value: Bank 3: 0x0000 30D2
Reset value: Bank 4: 0x0000 30D2

This register contains the control information of each memory bank, used for SRAMs, PSRAM, FRAM and NOR Flash memories.

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:22 **NBLSET[1:0]:** Byte lane (NBL) setup

These bits configure the NBL setup timing from NBLx low to chip select NEx low.
00: NBL setup time is 0 AHB clock cycle
01: NBL setup time is 1 AHB clock cycle
10: NBL setup time is 2 AHB clock cycles
11: NBL setup time is 3 AHB clock cycles

Bit 21 **WFDIS:** Write FIFO disable

This bit disables the Write FIFO used by the FMC controller.
0: Write FIFO enabled (Default after reset)
1: Write FIFO disabled

Note: The WFDIS bit of the FMC_BCR2..4 registers is don’t care. It is only enabled through the FMC_BCR1 register.
Bit 20 **CCLKEN**: Continuous clock enable

This bit enables the FMC_CLK clock output to external memory devices.

0: The FMC_CLK is only generated during the synchronous memory access (read/write transaction). The FMC_CLK clock ratio is specified by the programmed CLKDIV value in the FMC_BCRx register (default after reset).

1: The FMC_CLK is generated continuously during asynchronous and synchronous access. The FMC_CLK clock is activated when the CCLKEN is set.

*Note: The CCLKEN bit of the FMC_BCR2..4 registers is don't care. It is only enabled through the FMC_BCR1 register. Bank 1 must be configured in Synchronous mode to generate the FMC_CLK continuous clock.*

*Note: If CCLKEN bit is set, the FMC_CLK clock ratio is specified by CLKDIV value in the FMC_BTR1 register. CLKDIV in FMC_BWTR1 is don't care.*

*Note: If the Synchronous mode is used and CCLKEN bit is set, the synchronous memories connected to other banks than Bank 1 are clocked by the same clock (the CLKDIV value in the FMC_BTR2..4 and FMC_BWTR2..4 registers for other banks has no effect.)*

Bit 19 **CBURSTRW**: Write burst enable

For PSRAM (CRAM) operating in Burst mode, the bit enables synchronous accesses during write operations. The enable bit for synchronous read accesses is the BURSTEN bit in the FMC_BCRx register.

0: Write operations are always performed in Asynchronous mode.

1: Write operations are performed in Synchronous mode.

Bits 18:16 **CPSIZE[2:0]**: CRAM page size

These are used for CellularRAM™ 1.5 which does not allow burst access to cross the address boundaries between pages. When these bits are configured, the FMC controller splits automatically the burst access when the memory page size is reached (refer to memory datasheet for page size).

- 000: No burst split when crossing page boundary (default after reset)
- 001: 128 bytes
- 010: 256 bytes
- 011: 512 bytes
- 100: 1024 bytes
- Others: reserved

Bit 15 **ASYNCWAIT**: Wait signal during asynchronous transfers

This bit enables/disables the FMC to use the wait signal even during an asynchronous protocol.

0: NWAIT signal is not taken into account when running an asynchronous protocol (default after reset).

1: NWAIT signal is taken into account when running an asynchronous protocol.

Bit 14 **EXTMOD**: Extended mode enable

This bit enables the FMC to program the write timings for non multiplexed asynchronous accesses inside the FMC_BWTR register, thus resulting in different timings for read and write operations.

0: values inside FMC_BWTR register are not taken into account (default after reset)

1: values inside FMC_BWTR register are taken into account

*Note: When the Extended mode is disabled, the FMC can operate in mode 1 or mode 2 as follows:*

- Mode 1 is the default mode when the SRAM/PSRAM memory type is selected (MTYP = 0x0 or 0x01)
- Mode 2 is the default mode when the NOR memory type is selected (MTYP = 0x10).
Bit 13 **WAITEN**: Wait enable bit

This bit enables/disables wait-state insertion via the NWAIT signal when accessing the memory in Synchronous mode.

0: NWAIT signal is disabled (its level not taken into account, no wait state inserted after the programmed Flash latency period).

1: NWAIT signal is enabled (its level is taken into account after the programmed latency period to insert wait states if asserted) (default after reset).

Bit 12 **WREN**: Write enable bit

This bit indicates whether write operations are enabled/disabled in the bank by the FMC.

0: Write operations are disabled in the bank by the FMC, an AHB error is reported.

1: Write operations are enabled for the bank by the FMC (default after reset).

Bit 11 **WAITCFG**: Wait timing configuration

The NWAIT signal indicates whether the data from the memory are valid or if a wait state must be inserted when accessing the memory in Synchronous mode. This configuration bit determines if NWAIT is asserted by the memory one clock cycle before the wait state or during the wait state:

0: NWAIT signal is active one data cycle before wait state (default after reset).

1: NWAIT signal is active during wait state (not used for PSRAM).

Bit 10 Reserved, must be kept at reset value.

Bit 9 **WAITPOL**: Wait signal polarity bit

Defines the polarity of the wait signal from memory used for either in Synchronous or Asynchronous mode.

0: NWAIT active low (default after reset)

1: NWAIT active high

Bit 8 **BURSTEN**: Burst enable bit

This bit enables/disables synchronous accesses during read operations. It is valid only for synchronous memories operating in Burst mode.

0: Burst mode disabled (default after reset). Read accesses are performed in Asynchronous mode.

1: Burst mode enabled. Read accesses are performed in Synchronous mode.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **FACCEN**: Flash access enable

Enables NOR Flash memory access operations.

0: Corresponding NOR Flash memory access is disabled.

1: Corresponding NOR Flash memory access is enabled (default after reset).

Bits 5:4 **MWID[1:0]**: Memory data bus width

Defines the external memory device width, valid for all type of memories.

00: 8 bits

01: 16 bits (default after reset)

10: reserved

11: reserved
Bits 3:2 **MTYP[1:0]**: Memory type

Defines the type of external memory attached to the corresponding memory bank.

- **00**: SRAM/FRAM (default after reset for Bank 2...4)
- **01**: PSRAM (CRAM) / FRAM
- **10**: NOR Flash/OneNAND Flash (default after reset for Bank 1)
- **11**: reserved

Bit 1 **MUXEN**: Address/data multiplexing enable bit

When this bit is set, the address and data values are multiplexed on the data bus, valid only with NOR and PSRAM memories:

- **0**: Address/data non multiplexed
- **1**: Address/data multiplexed on databus (default after reset)

Bit 0 **MBKEN**: Memory bank enable bit

Enables the memory bank. After reset Bank1 is enabled, all others are disabled. Accessing a disabled bank causes an ERROR on AHB bus.

- **0**: Corresponding memory bank is disabled.
- **1**: Corresponding memory bank is enabled.

### SRAM/NOR-Flash chip-select timing register for bank x (FMC_BTRx)

**Address offset**: 0x04 + 8 * (x – 1), (x = 1 to 4)

**Reset value**: 0x0FFF FFFF

This register contains the control information of each memory bank, used for SRAMs, PSRAM and NOR Flash memories. If the **EXTMOD** bit is set in the FMC_BCRx register, then this register is partitioned for write and read access, that is, 2 registers are available: one to configure read accesses (this register) and one to configure write accesses (FMC_BWTRx registers).

Bits 31:30 **DATAHLD[1:0]**: Data hold phase duration

These bits are written by software to define the duration of the data hold phase in HCLK cycles (refer to Figure 48 to Figure 60), used in asynchronous accesses:

For read accesses

- **00**: DATAHLD phase duration = 0 × HCLK clock cycle (default)
- **01**: DATAHLD phase duration = 1 × HCLK clock cycle
- **10**: DATAHLD phase duration = 2 × HCLK clock cycle
- **11**: DATAHLD phase duration = 3 × HCLK clock cycle

For write accesses

- **00**: DATAHLD phase duration = 1 × HCLK clock cycle (default)
- **01**: DATAHLD phase duration = 2 × HCLK clock cycle
- **10**: DATAHLD phase duration = 3 × HCLK clock cycle
- **11**: DATAHLD phase duration = 4 × HCLK clock cycle
**ACCMOD[1:0]: Access mode**

Specifies the asynchronous access modes as shown in the timing diagrams. These bits are taken into account only when the EXTMOD bit in the FMC_BCRx register is 1.

- **00**: Access mode A
- **01**: Access mode B
- **10**: Access mode C
- **11**: Access mode D

**DATLAT[3:0]:** (see note below bit descriptions): Data latency for synchronous memory

For synchronous access with read/write Burst mode enabled (BURSTEN / CBURSTRW bits set), defines the number of memory clock cycles (+2) to issue to the memory before reading/writing the first data:

- This timing parameter is not expressed in HCLK periods, but in FMC_CLK periods.
- For asynchronous access, this value is don't care.
- **0000**: Data latency of 2 CLK clock cycles for first burst access
- **1111**: Data latency of 17 CLK clock cycles for first burst access (default value after reset)

**CLKDIV[3:0]: Clock divide ratio (for FMC_CLK signal)**

Defines the period of FMC_CLK clock output signal, expressed in number of HCLK cycles:

- **0000**: FMC_CLK period = 1x HCLK period
- **0001**: FMC_CLK period = 2 x HCLK periods
- **0010**: FMC_CLK period = 3 x HCLK periods
- **1111**: FMC_CLK period = 16 x HCLK periods (default value after reset)

In asynchronous NOR Flash, SRAM or PSRAM accesses, this value is don't care.

*Note: Refer to Section 18.7.5: Synchronous transactions for FMC_CLK divider ratio formula*

**BUSTURN[3:0]: Bus turnaround phase duration**

These bits are written by software to add a delay at the end of current read or write transaction to next transaction on the same bank.

This delay allows to match the minimum time between consecutive transactions (t\textsubscript{EHEL} from NEx high to NEx low) and the maximum time needed by the memory to free the data bus after a read access (t\textsubscript{EHQZ}, chip enable high to output Hi-Z). This delay is recommended for mode D and muxed mode. For non-muxed memory, the bus turnaround delay can be set to minimum value.

\[(BUSTURN + 1)HCLK period \geq \max(t_{EHEL} \text{ min}, t_{EHQZ} \text{ max})\]

For FRAM memories, the bus turnaround delay should be configured to match the minimum t\textsubscript{PC} (precharge time) timings. The bus turnaround delay is inserted between any consecutive transactions on the same bank (read/read, write/write, read/write and write/read) to match the t\textsubscript{PC} memory timing. The chip select is toggling between any consecutive accesses.

\[(BUSTURN + 1)HCLK period \geq t_{PC} \text{ min}\]

- **0000**: BUSTURN phase duration = 1 HCLK clock cycle added
- **1111**: BUSTURN phase duration = 16 x HCLK clock cycles added (default value after reset)
Bits 15:8 DATAST[7:0]: Data-phase duration
These bits are written by software to define the duration of the data phase (refer to Figure 48 to Figure 60), used in asynchronous accesses:
0000 0000: Reserved
0000 0001: DATAST phase duration = 1 × HCLK clock cycles
0000 0010: DATAST phase duration = 2 × HCLK clock cycles
...
1111 1111: DATAST phase duration = 255 × HCLK clock cycles (default value after reset)
For each memory type and access mode data-phase duration, refer to the respective figure (Figure 48 to Figure 60).
Example: Mode 1, write access, DATAST=1: Data-phase duration= DATAST+1 = 2 HCLK clock cycles.
Note: In synchronous accesses, this value is don’t care.

Bits 7:4 ADDHLD[3:0]: Address-hold phase duration
These bits are written by software to define the duration of the address hold phase (refer to Figure 48 to Figure 60), used in mode D or multiplexed accesses:
0000: Reserved
0001: ADDHLD phase duration =1 × HCLK clock cycle
0010: ADDHLD phase duration = 2 × HCLK clock cycle
...
1111: ADDHLD phase duration = 15 × HCLK clock cycles (default value after reset)
For each access mode address-hold phase duration, refer to the respective figure (Figure 48 to Figure 60).
Note: In synchronous accesses, this value is not used, the address hold phase is always 1 memory clock period duration.

Bits 3:0 ADDSET[3:0]: Address setup phase duration
These bits are written by software to define the duration of the address setup phase (refer to Figure 48 to Figure 60), used in SRAMs, ROMs, asynchronous NOR Flash and PSRAM:
0000: ADDSET phase duration = 0 × HCLK clock cycles
...
1111: ADDSET phase duration = 15 × HCLK clock cycles (default value after reset)
For each access mode address setup phase duration, refer to the respective figure (Figure 48 to Figure 60).
Note: In synchronous accesses, this value is don’t care.
In Muxed mode or mode D, the minimum value for ADDSET is 1.
In mode 1 and PSRAM memory, the minimum value for ADDSET is 1.

Note: PSRAMs (CRAMs) have a variable latency due to internal refresh. Therefore these memories issue the NWAIT signal during the whole latency phase to prolong the latency as needed.
With PSRAMs (CRAMs) the filled DATLAT must be set to 0, so that the FMC exits its latency phase soon and starts sampling NWAIT from memory, then starts to read or write when the memory is ready.
This method can be used also with the latest generation of synchronous Flash memories that issue the NWAIT signal, unlike older Flash memories (check the datasheet of the specific Flash memory being used).
SRAM/NOR-Flash write timing registers x (FMC_BWTRx)

Address offset: 0x104 + 8 * (x – 1), (x = 1 to 4)

Reset value: 0x0FFF FFFF

This register contains the control information of each memory bank. It is used for SRAMs, PSRAMs and NOR Flash memories. When the EXTMOD bit is set in the FMC_BCRx register, then this register is active for write access.

Bits 31:30  **DATAHLD[1:0]:** Data hold phase duration

These bits are written by software to define the duration of the data hold phase in HCLK cycles (refer to Figure 48 to Figure 60), used in asynchronous write accesses:

- 00: DATAHLD phase duration = 1 × HCLK clock cycle (default)
- 01: DATAHLD phase duration = 2 × HCLK clock cycle
- 10: DATAHLD phase duration = 3 × HCLK clock cycle
- 11: DATAHLD phase duration = 4 × HCLK clock cycle

Bits 29:28  **ACCMOD[1:0]:** Access mode.

Specifies the asynchronous access modes as shown in the next timing diagrams. These bits are taken into account only when the EXTMOD bit in the FMC_BCRx register is 1.

- 00: Access mode A
- 01: Access mode B
- 10: Access mode C
- 11: Access mode D

Bits 27:20  Reserved, must be kept at reset value.

Bits 19:16  **BUSTURN[3:0]:** Bus turnaround phase duration

These bits are written by software to add a delay at the end of current write transaction to next transaction on the same bank.

For FRAM memories, the bus turnaround delay should be configured to match the minimum tPC (precharge time) timings. The bus turnaround delay is inserted between any consecutive transactions on the same bank (read/read, write/write, read/write and write/read). The chip select is toggling between any consecutive accesses.

(BUSTURN + 1)HCLK period ≥ tPC min

- 0000: BUSTURN phase duration = 1 HCLK clock cycle added
- ...  
- 1111: BUSTURN phase duration = 16 × HCLK clock cycles added (default value after reset)
Flexible static memory controller (FSMC) RM0432

PSRAM chip select counter register (FMC_PCSCNTR)

Address offset: 0x20
Reset value: 0x0000 0000

This register contains the PSRAM chip select counter value for Synchronous and Asynchronous modes. The chip select counter is common to all banks and can be enabled separately on each bank. During PSRAM read or write accesses, this value is loaded into a timer which is decremented while the NE signal is held low. When the timer reaches 0, the PSRAM controller splits the current access, toggles NE to allow PSRAM device refresh, and restarts a new access. The programmed counter value guarantees a maximum NE pulse width ($t_{CEM}$) as specified for PSRAM devices. The counter is reloaded and starts decrementing each time a new access is started by a transition of NE from high to low.

Note: In synchronous NOR Flash accesses, this value is not used, the address hold phase is always 1 Flash clock period duration.

Note: In synchronous accesses, this value is not used, the address setup phase is always 1 Flash clock period duration. In muxed mode, the minimum ADDSET value is 1.
18.8 NAND Flash controller

The FMC generates the appropriate signal timings to drive the following types of device:
- 8- and 16-bit NAND Flash memories

The NAND bank is configured through dedicated registers (Section 18.8.7). The programmable memory parameters include access timings (shown in Table 113) and ECC configuration.

18.8.3 Timing diagrams for NAND Flash memory

The NAND Flash memory bank is managed through a set of registers:
- Control register: FMC_PCR
- Interrupt status register: FMC_SR
- ECC register: FMC_ECCR
- Timing register for Common memory space: FMC_PMEM
- Timing register for Attribute memory space: FMC_PATT

Each timing configuration register contains three parameters used to define number of HCLK cycles for the three phases of any NAND Flash access, plus one parameter that defines the timing for starting driving the data bus when a write access is performed. *Figure 66* shows the timing parameter definitions for common memory accesses, knowing that Attribute memory space access timings are similar.
**18.8.4 NAND Flash operations**

The command latch enable (CLE) and address latch enable (ALE) signals of the NAND Flash memory device are driven by address signals from the FMC controller. This means that to send a command or an address to the NAND Flash memory, the CPU has to perform a write to a specific address in its memory space.

A typical page read operation from the NAND Flash device requires the following steps:

1. Program and enable the corresponding memory bank by configuring the FMC_PCR and FMC_PMEM (and for some devices, FMC_PATT, see Section 18.8.5: NAND Flash prewait functionality) registers according to the characteristics of the NAND Flash memory (PWID bits for the data bus width of the NAND Flash, PTYP = 1, PWAITEN = 0 or 1 as needed, see Section 18.6.2: NAND Flash memory address mapping for timing configuration).

2. The CPU performs a byte write to the common memory space, with data byte equal to one Flash command byte (for example 0x00 for Samsung NAND Flash devices). The LE input of the NAND Flash memory is active during the write strobe (low pulse on NWE), thus the written byte is interpreted as a command by the NAND Flash memory. Once the command is latched by the memory device, it does not need to be written again for the following page read operations.

3. The CPU can send the start address (STARTAD) for a read operation by writing four bytes (or three for smaller capacity devices), STARTAD[7:0], STARTAD[16:9], STARTAD[24:17] and finally STARTAD[25] (for 64 Mb x 8 bit NAND Flash memories) in the common memory or attribute space. The ALE input of the NAND Flash device is active during the write strobe (low pulse on NWE), thus the written bytes are interpreted as the start address for read operations. Using the attribute memory space makes it possible to use a different timing configuration of the FMC, which can be used
to implement the prewait functionality needed by some NAND Flash memories (see details in Section 18.8.5: NAND Flash prewait functionality).

4. The controller waits for the NAND Flash memory to be ready (R/NB signal high), before starting a new access to the same or another memory bank. While waiting, the controller holds the NCE signal active (low).

5. The CPU can then perform byte read operations from the common memory space to read the NAND Flash page (data field + Spare field) byte by byte.

6. The next NAND Flash page can be read without any CPU command or address write operation. This can be done in three different ways:
   - by simply performing the operation described in step 5
   - a new random address can be accessed by restarting the operation at step 3
   - a new command can be sent to the NAND Flash device by restarting at step 2

18.8.5 NAND Flash prewait functionality

Some NAND Flash devices require that, after writing the last part of the address, the controller waits for the R/NB signal to go low. (see Figure 67).

Figure 67. Access to non ‘CE don’t care’ NAND-Flash

1. CPU wrote byte 0x00 at address 0x7001 0000.
2. CPU wrote byte A7~A0 at address 0x7002 0000.
3. CPU wrote byte A16~A9 at address 0x7002 0000.
4. CPU wrote byte A24~A17 at address 0x7002 0000.
5. CPU wrote byte A25 at address 0x7002 0000: FMC performs a write access using FMC_PATT timing definition, where ATTHOLD ≥ 7 (providing that (7+1) × HCLK = 112 ns > tWB max). This guarantees that NCE remains low until R/NB goes low and high again (only requested for NAND Flash memories where NCE is not don’t care).
When this functionality is required, it can be ensured by programming the MEMHOLD value to meet the $t_{WB}$ timing. However any CPU read access to the NAND Flash memory has a hold delay of ($MEMHOLD + 2$) HCLK cycles and CPU write access has a hold delay of ($MEMHOLD$) HCLK cycles inserted between the rising edge of the NWE signal and the next access.

To cope with this timing constraint, the attribute memory space can be used by programming its timing register with an ATTHOLD value that meets the $t_{WB}$ timing, and by keeping the MEMHOLD value at its minimum value. The CPU must then use the common memory space for all NAND Flash read and write accesses, except when writing the last address byte to the NAND Flash device, where the CPU must write to the attribute memory space.

### 18.8.6 Computation of the error correction code (ECC) in NAND Flash memory

The FMC NAND Card controller includes two error correction code computation hardware blocks, one per memory bank. They reduce the host CPU workload when processing the ECC by software.

These two ECC blocks are identical and associated with Bank 2 and Bank 3. As a consequence, no hardware ECC computation is available for memories connected to Bank 4.

The ECC algorithm implemented in the FMC can perform 1-bit error correction and 2-bit error detection per 256, 512, 1024, 2048, 4096 or 8192 bytes read or written from/to the NAND Flash memory. It is based on the Hamming coding algorithm and consists in calculating the row and column parity.

The ECC modules monitor the NAND Flash data bus and read/write signals (NCE and NWE) each time the NAND Flash memory bank is active.

The ECC operates as follows:

- When accessing NAND Flash memory bank 2 or bank 3, the data present on the D[15:0] bus is latched and used for ECC computation.
- When accessing any other address in NAND Flash memory, the ECC logic is idle, and does not perform any operation. As a result, write operations to define commands or addresses to the NAND Flash memory are not taken into account for ECC computation.

Once the desired number of bytes has been read/written from/to the NAND Flash memory by the host CPU, the FMC_ECCR registers must be read to retrieve the computed value. Once read, they should be cleared by resetting the ECCEN bit to ‘0’. To compute a new data block, the ECCEN bit must be set to one in the FMC_PCR registers.
To perform an ECC computation:
1. Enable the ECCEN bit in the FMC_PCR register.
2. Write data to the NAND Flash memory page. While the NAND page is written, the ECC block computes the ECC value.
3. Read the ECC value available in the FMC_ECCR register and store it in a variable.
4. Clear the ECCEN bit and then enable it in the FMC_PCR register before reading back the written data from the NAND page. While the NAND page is read, the ECC block computes the ECC value.
5. Read the new ECC value available in the FMC_ECCR register.
6. If the two ECC values are the same, no correction is required, otherwise there is an ECC error and the software correction routine returns information on whether the error can be corrected or not.

18.8.7 NAND Flash controller registers

NAND Flash control registers (FMC_PCR)

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:17 **ECCPS[2:0]**: ECC page size
Defines the page size for the extended ECC:
000: 256 bytes
001: 512 bytes
010: 1024 bytes
011: 2048 bytes
100: 4096 bytes
101: 8192 bytes

Bits 16:13 **TAR[3:0]**: ALE to RE delay
Sets time from ALE low to RE low in number of AHB clock cycles (HCLK).
Time is: $t_{ar} = (TAR + SET + 2) \times THCLK$ where $THCLK$ is the HCLK clock period
0000: 1 HCLK cycle (default)
1111: 16 HCLK cycles

*Note: SET is MEMSET or ATTSET according to the addressed space.*
Bits 12:9 **TCLR[3:0]**: CLE to RE delay
Sets time from CLE low to RE low in number of AHB clock cycles (HCLK).
Time is \( t_{\text{clr}} = (TCLR + SET + 2) \times THCLK \) where THCLK is the HCLK clock period
- 0000: 1 HCLK cycle (default)
- 1111: 16 HCLK cycles
*Note: SET is MEMSET or ATTSET according to the addressed space.*

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **ECCEN**: ECC computation logic enable bit
- 0: ECC logic is disabled and reset (default after reset),
- 1: ECC logic is enabled.

Bits 5:4 **PWID[1:0]**: Data bus width
Defines the external memory device width.
- 00: 8 bits
- 01: 16 bits (default after reset).
- 10: reserved.
- 11: reserved.

Bit 3 **PTYP**: Memory type
Defines the type of device attached to the corresponding memory bank:
- 0: Reserved, must be kept at reset value
- 1: NAND Flash (default after reset)

Bit 2 **PBKEN**: NAND Flash memory bank enable bit
Enables the memory bank. Accessing a disabled memory bank causes an ERROR on AHB bus
- 0: Corresponding memory bank is disabled (default after reset)
- 1: Corresponding memory bank is enabled

Bit 1 **PWAITEN**: Wait feature enable bit
Enables the Wait feature for the NAND Flash memory bank:
- 0: disabled
- 1: enabled

Bit 0 Reserved, must be kept at reset value.
FIFO status and interrupt register (FMC_SR)

Address offset: 0x84
Reset value: 0x0000 0040

This register contains information about the FIFO status and interrupt. The FMC features a FIFO that is used when writing to memories to transfer up to 16 words of data from the AHB.

This is used to quickly write to the FIFO and free the AHB for transactions to peripherals other than the FMC, while the FMC is draining its FIFO into the memory. One of these register bits indicates the status of the FIFO, for ECC purposes.

The ECC is calculated while the data are written to the memory. To read the correct ECC, the software must consequently wait until the FIFO is empty.

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **FEMPT**: FIFO empty
Read-only bit that provides the status of the FIFO
0: FIFO not empty
1: FIFO empty

Bit 5 **IFEN**: Interrupt falling edge detection enable bit
0: Interrupt falling edge detection request disabled
1: Interrupt falling edge detection request enabled

Bit 4 **ILEN**: Interrupt high-level detection enable bit
0: Interrupt high-level detection request disabled
1: Interrupt high-level detection request enabled

Bit 3 **IREN**: Interrupt rising edge detection enable bit
0: Interrupt rising edge detection request disabled
1: Interrupt rising edge detection request enabled

Bit 2 **IFS**: Interrupt falling edge status
The flag is set by hardware and reset by software.
0: No interrupt falling edge occurred
1: Interrupt falling edge occurred
*Note: If this bit is written by software to 1 it is set.*

Bit 1 **ILS**: Interrupt high-level status
The flag is set by hardware and reset by software.
0: No Interrupt high-level occurred
1: Interrupt high-level occurred
Bit 0  **IRS:** Interrupt rising edge status
   The flag is set by hardware and reset by software.
   0: No interrupt rising edge occurred
   1: Interrupt rising edge occurred
   *Note:* If this bit is written by software to 1 it is set.

**Common memory space timing register (FMC_PMEM)**

Address offset: Address: 0x88
Reset value: 0xFCFC FCFC

The FMC_PMEM read/write register contains the timing information for NAND Flash memory bank. This information is used to access either the common memory space of the NAND Flash for command, address write access and data read/write access.

Flexible static memory controller (FSMC) RM0432

Bits 7:0 **MEMSET[7:0]**: Common memory x setup time
Defines the number of HCLK (+1) clock cycles to set up the address before the command assertion (NWE, NOE), for NAND Flash read or write access to common memory space on socket x:
- 0000 0000: 1 HCLK cycle
- 1111 1110: 255 HCLK cycles
- 1111 1111: reserved

Attribute memory space timing register (FMC_PATT)
Address offset: 0x8C
Reset value: 0xFCFC FCFC

The FMC_PATT read/write register contains the timing information for NAND Flash memory bank. It is used for 8-bit accesses to the attribute memory space of the NAND Flash for the last address write access if the timing must differ from that of previous accesses (for Ready/Busy management, refer to *Section 18.8.5: NAND Flash prewait functionality*).

<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 31:24 **ATTHZ[7:0]**: Attribute memory data bus Hi-Z time
Defines the number of HCLK clock cycles during which the data bus is kept in Hi-Z after the start of a NAND Flash write access to attribute memory space on socket. Only valid for write transaction:
- 0000 0000: 0 HCLK cycle
- 1111 1110: 255 HCLK cycles
- 1111 1111: reserved.

Bits 23:16 **ATTHOLD[7:0]**: Attribute memory hold time
Defines the number of HCLK clock cycles for write access and HCLK (+2) clock cycles for read access during which the address is held (and data for write access) after the command deassertion (NWE, NOE), for NAND Flash read or write access to attribute memory space on socket:
- 0000 0000: reserved
- 0000 0001: 1 HCLK cycle for write access / 3 HCLK cycles for read access
- 1111 1110: 254 HCLK cycles for write access / 256 HCLK cycles for read access
- 1111 1111: reserved.

Bits 15:8 **ATTWAIT[7:0]**: Attribute memory wait time
Defines the minimum number of HCLK (+1) clock cycles to assert the command (NWE, NOE), for NAND Flash read or write access to attribute memory space on socket x. The duration for command assertion is extended if the wait signal (NWAIT) is active (low) at the end of the programmed value of HCLK:
- 0000 0000: reserved
- 0000 0001: 2 HCLK cycles (+ wait cycle introduced by deassertion of NWAIT)
- 1111 1110: 255 HCLK cycles (+ wait cycle introduced by deasserting NWAIT)
- 1111 1111: reserved.
Bits 7:0 ATTSET[7:0]: Attribute memory setup time
Defines the number of HCLK (+1) clock cycles to set up address before the command assertion (NWE, NOE), for NAND Flash read or write access to attribute memory space on socket:
0000 0000: 1 HCLK cycle
1111 1110: 255 HCLK cycles
1111 1111: reserved.

ECC result registers (FMC_ECCR)
Address offset: 0x94
Reset value: 0x0000 0000
This register contain the current error correction code value computed by the ECC computation modules of the FMC NAND controller. When the CPU reads the data from a NAND Flash memory page at the correct address (refer to Section 18.8.6: Computation of the error correction code (ECC) in NAND Flash memory), the data read/written from/to the NAND Flash memory are processed automatically by the ECC computation module. When X bytes have been read (according to the ECCPS field in the FMC_PCR registers), the CPU must read the computed ECC value from the FMC_ECC registers. It then verifies if these computed parity data are the same as the parity value recorded in the spare area, to determine whether a page is valid, and, to correct it otherwise. The FMC_ECCR register should be cleared after being read by setting the ECCEN bit to 0. To compute a new data block, the ECCEN bit must be set to 1.

Refer to Section 2.2 on page 93 for the register boundary addresses.
19 Octo-SPI interface (OCTOSPI)

19.1 Introduction

The OCTOSPI supports most external serial memories such as serial PSRAMs, serial NAND and serial NOR Flash memories, HyperRAM™ and HyperFlash™ memories, with the following functional modes:

- Indirect mode: all the operations are performed using the OCTOSPI registers to preset commands, addresses, data and transfer parameters.
- Automatic status-polling mode: the external memory status register is periodically read and an interrupt can be generated in case of flag setting.
- Memory-mapped mode: the external memory is memory mapped and it is seen by the system as if it was an internal memory, supporting both read and write operations.

The OCTOSPI supports the following protocols with associated frame formats:

- the Regular-command frame format with the command, address, alternate byte, dummy cycles and data phase
- the HyperBus™ frame format

19.2 OCTOSPI main features

- Functional modes: Indirect, Automatic status-polling, and Memory-mapped
- Read and write support in Memory-mapped mode
- External (P)SRAM memory support
- Support for single, dual, quad and octal communication
- Dual-quad configuration, where eight bits can be sent/received simultaneously by accessing two quad memories in parallel
- SDR (single-data rate) and DTR (double-transfer rate) support
- Data strobe support
- Fully programmable opcode
- Fully programmable frame format
- Support wrapped-type access to memory in read direction
- HyperBus support
- Integrated FIFO for reception and transmission
- Asynchronous bus clock versus kernel clock support
- 8-, 16-, and 32-bit data accesses allowed
- DMA channel for Indirect mode operations
- Interrupt generation on FIFO threshold, timeout, operation complete, and access error
- AHB interface with transaction acceptance limited to one: the interface accepts the next transfer on AHB bus only once the previous is completed on memory side.
19.3 OCTOSPI implementation

The table below describes the OCTOSPI implementation on STM32L4+ Series devices. The full list of features is implemented in STM32L4P5xx and STM32L4Q5xx devices, while STM32L4Rxxx and STM32L4Sxxx devices support a reduced set of features.

1. The CLK cycles are up to 64 when extended CSHT timeout feature is supported, and up to 8 when it is not supported.
19.4 OCTOSPI functional description

19.4.1 OCTOSPI block diagram

Figure 68. OCTOSPI block diagram in octal configuration

Figure 69. OCTOSPI block diagram in quad configuration
19.4.2 OCTOSPI interface to memory modes

The OCTOSPI supports the following protocols:
- Regular-command protocol
- HyperBus protocol

The OCTOSPI uses from 6 to 12 signals to interface with a memory, depending on the functional mode:
- NCS: chip-select
- CLK: communication clock
- NCLK: inverted clock used only in the 1.8 V HyperBus protocol
- DQS: data strobe used only in Regular-command protocol as input only
- IO[3:0]: data bus LSB
- IO[7:4]: data bus MSB used in dual-quad and octal configurations

19.4.3 OCTOSPI Regular-command protocol

When in Regular-command protocol, the OCTOSPI communicates with the external device using commands. Each command can include the following phases:
- Instruction phase
- Address phase
- Alternate-byte phase
- Dummy-cycle phase
- Data phase

Any of these phases can be configured to be skipped, but at least one of the instruction, address, alternate byte, or data phases must be present.
The NCS falls before the start of each command and rises again after each command finishes.

In Memory-mapped mode, both read and write operations are supported: as a consequence, some of the configuration registers are duplicated to specify write operations (read operations are configured using regular registers).

**Instruction phase**

During this phase, a 1- to 4-byte instruction is sent to the external device specifying the type of operation to be performed. The size of the instruction to be sent is configured in ISIZE[1:0] of OCTOSPI_CCR and the instruction is programmed in INSTRUCTION[31:0] of OCTOSPI_IR.

The instruction phase can optionally send:
- 1 bit at a time from the IO0/SO signal (Single-SPI mode)
- 2 bits at a time (over IO0/IO1 in Dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in Quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in Octal-SPI mode).

This can be configured using IMODE[2:0] of OCTOSPI_CCR.

The instruction can be sent in DTR (double-transfer rate) mode on each rising and falling edge of the clock, by setting IDTR in OCTOSPI_CCR.

When IMODE[2:0] = 000 in OCTOSPI_CCR, the instruction phase is skipped, and the command sequence starts with the address phase, if present.

In Memory-mapped mode, the instruction used for the write operation is specified in OCTOSPI_WIR and the instruction format is specified in OCTOSPI_WCCR. The instruction used for the read operation and the instruction format are specified in OCTOSPI_IR and OCTOSPI_CCR.

**Address phase**

In the address phase, 1 to 4 bytes are sent to the external device, to indicate the address of the operation. The number of address bytes to be sent is configured in ADSIZE[1:0] of OCTOSPI_CCR.

In Indirect and Automatic status-polling modes, the address bytes to be sent are specified in ADDRESS[31:0] of OCTOSPI_AR. In Memory-mapped mode, the address is given directly via the AHB (from any master in the system).
The address phase can send:
- 1 bit at a time (over SOI in Single-SPI mode)
- 2 bits at a time (over IO0/IO1 in Dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in Quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in Octal-SPI mode)

This can be configured using ADMODE[2:0] of OCTOSPI_CCR.

The address can be sent in DTR mode (on each rising and falling edge of the clock) setting ADDTR of OCTOSPI_CCR.

When ADMODE[2:0] = 000, the address phase is skipped and the command sequence proceeds directly to the next phase, if any.

In Memory-mapped mode, the address format for the write operation is specified in OCTOSPI_WCCR. The address format for the read operation is specified in OCTOSPI_CCR.

**Alternate-bytes phase**

In the alternate-bytes phase, 1 to 4 bytes are sent to the external device, generally to control the mode of operation. The number of alternate bytes to be sent is configured in ABSIZE[1:0] of OCTOSPI_CCR. The bytes to be sent are specified in OCTOSPI_ABR.

The alternate-byte phase can send:
- 1 bit at a time (over SOI in Single-SPI mode)
- 2 bits at a time (over IO0/IO1 in Dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in Quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in Octal-SPI mode)

This can be configured using ABMODE[2:0] of OCTOSPI_CCR.

The alternate bytes can be sent in DTR mode (on each rising and falling edge of the clock) setting ABDTR of OCTOSPI_CCR.

When ABMODE[2:0] = 000, the alternate-bytes phase is skipped and the command sequence proceeds directly to the next phase, if any.

There may be times when only a single nibble needs to be sent during the alternate-byte phase rather than a full byte, such as when the Dual-SPI mode is used and only two cycles are used for the alternate bytes.

In this case, the firmware can use the Quad-SPI mode (ABMODE[2:0] = 011) and send a byte with bits 7 and 3 of ALTERNATE[31:0] set to 1 (keeping the IO3 line high), and bits 6 and 2 set to 0 (keeping the IO2 line low), in OCTOSPI_IR.

The upper two bits of the nibble to be sent are then placed in bits 4:3 of ALTERNATE[31:0] while the lower two bits are placed in bits 1:0. For example, if the nibble 2 (0010) is to be sent over IO0/IO1, then ALTERNATE[31:0] must be set to 0x8A (1000_1010).

In Memory-mapped mode, the alternate bytes used for the write operation are specified in OCTOSPI_WABR and the alternate byte format is specified in OCTOSPI_WCCR. The alternate bytes used for read operation and the alternate byte format are specified in OCTOSPI_ABR and OCTOSPI_CCR.
Dummy-cycle phase

In the dummy-cycle phase, 1 to 31 cycles are given without any data being sent or received, in order to give the external device, the time to prepare for the data phase when the higher clock frequencies are used. The number of cycles given during this phase is specified in DCYC[4:0] of OCTOSPI_TCR. In both SDR and DTR modes, the duration is specified as a number of full CLK cycles.

When DCYC[4:0] = 00000, the dummy-cycle phase is skipped, and the command sequence proceeds directly to the data phase, if present.

In order to assure enough “turn-around” time for changing the data signals from the output mode to the input mode, there must be at least one dummy cycle when using the Dual-SPI, the Quad-SPI or the Octal-SPI mode, to receive data from the external device.

In Memory-mapped mode, the dummy cycles for the write operations are specified in OCTOSPI_WTCR. The dummy cycles for the read operation are specified in OCTOSPI_TCR.

Data phase

During the data phase, any number of bytes can be sent to or received from the external device.

In Indirect mode, the number of bytes to be sent/received is specified in OCTOSPI_DLR. In this mode, the data to be sent to the external device must be written to OCTOSPI_DR, while in Indirect-read mode the data received from the external device is obtained by reading OCTOSPI_DR.

In Automatic status-polling mode, the number of bytes to be received is specified in OCTOSPI_DLR and the data received from the external device can be obtained by reading OCTOSPI_DR.

In Memory-mapped mode, the data read or written, is sent or received directly over the AHB to the Cortex core or to a DMA.

The data phase can send/receive:

- 1 bit at a time (over SO/SI in Single-SPI mode)
- 2 bits at a time (over IO0/IO1 in Dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in Quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in Octal-SPI mode)

This can be configured using DMODE[2:0] of OCTOSPI_CCR.

The data can be sent or received in DTR mode (on each rising and falling edge of the clock) setting DDTR of OCTOSPI_CCR.

When DMODE[2:0] = 000, the data phase is skipped, and the command sequence finishes immediately by raising the NCS. This configuration must be used only in Indirect-write mode.

In Memory-mapped mode, the data format for the write operation is specified in OCTOSPI_WCCR. The data format for the read operation is specified in OCTOSPI_CCR.

DQS usage

The DQS signal can be used for data strobing during the read transactions when the device toggles the DQS aligned with the data.
The DQS management can be enabled by setting DQSE of OCTOSPI_CCR.

**Figure 72. DTR read in Octal-SPI mode with DQS (Macronix mode) example**

19.4.4 OCTOSPI Regular-command protocol signal interface

**Single-SPI mode**

The legacy SPI mode allows just a single bit to be sent/received serially. In this mode, the data is sent to the external device over the SO signal (whose I/Os are shared with IO0). The data received from the external device arrives via SI (whose I/Os are shared with IO1).

The different phases can each be configured separately to use this Single-bit mode by setting to 001 the IMODE, ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase configured in Single-SPI mode:
- IO0 (SO) is in output mode.
- IO1 (SI) is in input mode (high impedance).
- IO2 is in output mode and forced to 0 (to deactivate the “write protect” function).
- IO3 is in output mode and forced to 1 (to deactivate the “hold” function).
- IO4 to IO7 are in output mode and forced to 0.

This is the case even for the dummy phase if DMODE[2:0] = 001.

**Dual-SPI mode**

In Dual-SPI mode, two bits are sent/received simultaneously over the IO0/IO1 signals.

The different phases can each be configured separately to use Dual-SPI mode by setting to 010 the IMODE, ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase configured in Dual-SPI mode:
- IO0/IO1 are at high-impedance (input) during the data phase for the read operations, and outputs in all other cases.
- IO2 is in output mode and forced to 0.
- IO3 is in output mode and forced to 1.
- IO4 to IO7 are in output mode and forced to 0.
In the dummy phase when DMODE[2:0] = 010, IO0/IO1 are always high-impedance.

**Quad-SPI mode**

In Quad-SPI mode, four bits are sent/received simultaneously over the IO0/IO1/IO2/IO3 signals.

The different phases can each be configured separately to use the Quad-SPI mode by setting to 011 the IMODE,ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase configured in Quad-SPI mode:
- IO0 to IO3 are all at high-impedance (inputs) during the data phase for the read operations, and outputs in all other cases.
- IO4 to IO7 are in output mode and forced to 0.

In the dummy phase when DMODE[2:0] = 011, IO0 to IO3 are all high-impedance.

IO2 and IO3 are used only in Quad-SPI mode. If none of the phases are configured to use the Quad-SPI mode, then the pins corresponding to IO2 and IO3 can be used for other functions even while the OCTOSPI is active.

**Octal-SPI mode**

In regular Octal-SPI mode, the eight bits are sent/received simultaneously over the IO[0:7] signals.

The different phases can each be configured separately to use the Octal-SPI mode by setting to 100 the IMODE,ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase that is configured in Octal-SPI mode, IO[0:7] are all at high-impedance (input) during the data phase for read operations, and outputs in all other cases.

In the dummy phase when DMODE[2:0] = 100, IO[0:7] are all high-impedance.

IO[4:7] are used only in Octal-SPI mode. If none of the phases are configured to use Octal-SPI mode, then the pins corresponding to IO[4:7] can be used for other functions even while the OCTOSPI is active.

**Single-data rate (SDR) mode**

By default, all the phases operate in Single-data rate (SDR) mode.

In SDR mode, when the OCTOSPI drives the IO0/SO, IO1 to IO7 signals, these signals transition only with the falling edge of CLK.

When receiving data in SDR mode, the OCTOSPI assumes that the external devices also send the data using CLK falling edge. By default (when SSHIFT = 0 in OCTOSPI_TCR), the signals are sampled using the following (rising) edge of CLK.
Double-transfer rate (DTR) mode

Each of the instruction, address, alternate-byte and data phases can be configured to operate in DTR mode setting IDTR, ADDTR, ABDTR, and DDTR in OCTOSPI_CCR.

In Memory-mapped mode, the DTR mode for each phase of the write operations is specified in OCTOSPI_WCCR. The DTR mode for each phase of the read operations is specified in OCTOSPI_CCR.

In DTR mode, when the OCTOSPI drives the IO0/So and IO1to IO7 signals in the instruction, address, and alternate-byte phases, a bit is sent or received on each of the falling and rising edges of CLK.

When receiving data in DTR mode, the OCTOSPI assumes that the external devices also send the data using both CLK rising and falling edges. When DDTR = 1 in OCTOSPI_CCR, the software must clear SSHIFT in OCTOSPI_TCR. Thus, the signals are sampled one half of a CLK cycle later (on the following, opposite edge).

In DTR mode, it is recommended to set DHQC of OCTOSPI_TCR, to shift the outputs by a quarter of cycle and avoid to hold issues on the memory side.

Note: DHQC must not be set when the prescaler value is 0, as this action leads to unpredictable behavior.

Dual-quad configuration

When DMM = 1 in OCTOSPI_CR, the OCTOSPI is in dual-memory configuration: if DMODE = 100, two external Quad-SPI devices (device A and device B) are used in order to send/receive eight bits (or 16 bits in DTR mode) every cycle, effectively doubling the throughput.

Each device (A or B) uses the same CLK and NCS signals, but each has separate IO0 to IO3 signals.
The dual-quad configuration can be used in conjunction with the Single-SPI, Dual-SPI, and Quad-SPI modes, as well as with either the SDR or DTR mode.

The device size, as specified in DEVSIZE[4:0] of OCTOSPI_DCR1, must reflect the total external device capacity, that is the double of the size of one individual component.

If address X is even, then the byte that the OCTOSPI gives for address X is the byte at the address X/2 of device A, and the byte that the OCTOSPI gives for address X + 1 is the byte at the address X/2 of device B. In other words, the bytes at even addresses are all stored in device A and the bytes at odd addresses are all stored in device B.

When reading the status registers of the devices in dual-quad configuration, twice as many bytes must be read compared to the same read in Regular-command protocol: if each device gives eight valid bits after the instruction for fetching the status register, then the OCTOSPI must be configured with a data length of 2 bytes (16 bits), and the OCTOSPI receives one byte from each device.

If each device gives a status of 16 bits, then the OCTOSPI must be configured to read 4 bytes to get all the status bits of both devices in dual-quad configuration. The least-significant byte of the result (in the data register) is the least-significant byte of device A status register. The next byte is the least-significant byte of device B status register. Then, the third byte of the data register is the device A second byte. The forth byte is the device B second byte (if devices have 16-bit status registers).

An even number of bytes must always be accessed in dual-quad configuration. For this reason, bit 0 of DL[31:0] in OCTOSPI_DLR is stuck at 1 when DMM = 1.

In dual-quad configuration, the behavior of device A interface signals is basically the same as in normal mode. Device B interface signals have exactly the same waveforms as device A ones during the instruction, address, alternate-byte, and dummy-cycle phases. In other words, each device always receives the same instruction and the same address.

Then, during the data phase, the AIOx and the BIOx buses both transfer data in parallel, but the data that is sent to (or received from) device A is distinct than the one from device B.

### 19.4.5 HyperBus protocol

The OCTOSPI can communicate with the external device using the HyperBus protocol.

The HyperBus uses 11 to 12 pins depending on the operating voltage:

- IO[7:0] as bidirectional data bus
- RWDS for read and write data strobe and latency insertion (mapped on DQS pin)
- NCS
- CLK
- NCLK for 1.8 V operations

The HyperBus does not require any command specification nor any alternate bytes. As a consequence, a separate register set is used to define the timing of the transaction.

The HyperBus frame is composed of the following phases:

- Command/address phase
- Data phase

The NCS falls before the start of a transaction and rises again after each transaction finishes.
The specific HyperBus features are configured through the registers in the 0x0200-0x02FC offset range.

**Command/address phase**

During this initial phase, the OCTOSPI sends 48 bits over IO[7:0] to specify the operations to be performed with the external device.

</tbody>
</table>

The address space is configured through the memory type MTYP[2:0] of OCTOSPI_DCR1.

The total size of the device is configured in DEVSIZE[4:0] of OCTOSPI_DCR1. In case of multi-chip product (MCP), the device size is the sum of all the sizes of all the MCP dies.

**Read/write operation with initial latency**

The HyperBus read and write operations need to respect two timings:
- \( t_{\text{RWR}} \): minimal read/write recovery time for the device (defined in TRWR[7:0] of OCTOSPI_HLCR)
- \( t_{\text{ACC}} \): access time for the device (defined in TAC[7:0] of OCTOSPI_HLCR)
During the read operation, the RWDS is used by the device, in two ways (see Figure 75):
- during the command/address phase, to request an additional latency
- during the data phase, for data strobing

During the write operation the RWDS is used:
- by the device, during the command/address phase, to request an additional latency.
- by the OCTOSPI, during the data phase, for write data masking.

**Figure 76. HyperBus write operation with initial latency**

Read/write operation with additional latency

If the device needs an additional latency (during refresh period of a SDRAM for example), RWDS must be tied to one during one of the RWDS signals, during the command/address phase.

An additional $t_{ACC}$ duration is added by the OCTOSPI to meet the device request.

**Figure 77. HyperBus read operation with additional latency**
Fixed-latency mode

Some devices or some applications may not want to operate with a variable latency time as described above.

The latency can be forced to $2 \times t_{ACC}$ by setting LM of OCTOSPI_HLCR.

In this OCTOSPI latency mode, the state of the RWDS signal is not taken into account by the OCTOSPI and an additional latency is always added, leading to a fixed $2 \times t_{ACC}$ latency time.

Write operation with no latency

Some devices can also require a zero latency for the write operations. This write-zero latency can be forced by setting WZL in OCTOSPI_HLCR.
Latency on page-crossing during the read operations

An additional latency can be needed by some devices for the read operation when crossing pages.

The initial latency must be respected for any page access, as a consequence, when the first access is close to the page boundary, a latency is automatically added at the page crossing to respect the tACC time.

![Figure 80. HyperBus read operation page crossing with latency](image)

19.4.6 Specific features

The OCTOSPI supports some specific features, such as:

- Wrap support
- NCS boundary and refresh
- Communication regulation

Wrap support

The OCTOSPI supports an hybrid wrap as defined by the HyperBus protocol. An hybrid wrap is also supported in the Regular-command protocol.

In hybrid wrap, the transaction can continue after the initial wrap with an incremental access.

The wrap size supported by the target memory is configured by WRAPSIZE in OCTOSPI_DCR2.

Wrap is supported only in memory-read direction and only for data size = 4 bytes. Wrapped reads are supported for both HyperBus and Regular-command protocols. To enable wrapped-read accesses, the dedicated registers OCTOSPI_WPxxx must be programmed according to the wrapped-read access characteristics. The dedicated OCTOSPI_WPxxx registers apply for both HyperBus and Regular-command protocols.

If the target memory is not supporting the hybrid wrap, WRAPSIZE must be set to 0.

NCS boundary and refresh

Two processes can be activated to regulate the OCTOSPI transactions:

- NCS boundary
- Refresh

The NCS boundary feature limits a transaction to a boundary of aligned addresses. The size of the address to be aligned with, is configured in CSBOUND[4:0] of OCTOSPI_DCR3 and it is equal to 2^{CSBOUND}.
As an example, if CSBOUND(4:0] = 0x4, the boundary is set to \(2^4 = 16\) bytes. As a consequence, the NCS is released each time that the LSB address is equal to 0xF and each time that a new transaction is issued to address the next data.

If CSBOUND[4:0] = 0, the feature is disabled and a minimum value of 3 is recommended.

The NCS boundary feature cannot be used for Flash memory devices in write mode since a command is necessary to program another page of the Flash memory.

The refresh feature limits the duration of the transactions to the value programmed in REFRESH[31:0] of OCTOSPI_DCR4. The duration is expressed in number of cycles. This allows an external RAM to perform its internal refresh operation regularly.

The refresh value must be greater than the minimal transaction size in terms of number of cycles including the command/address/alternate/dummy phases.

If NCS boundary and refresh are enabled at the same time, the NCS is released on the first condition met.

Communication regulation

The communication regulation feature limits the maximum length of a transaction to the value programmed in MAXTRAN[7:0] of OCTOSPI_DCR3.

If the number of clock cycles reach the MAXTRAN + 1 value, and if the second OCTOSPI requests an access, the NCS is released and a new transaction is issued to address the next data. If the second OCTOSPI does not request an access, the transaction is not stopped and the NCS is not released.

If MAXTRAN[7:0] = 0, no limitation occurs.

The MAXTRAN[7:0] value must be greater than the minimal transaction size in terms of number of cycles including the command, address, alternate, and dummy phases.

Note: The communication regulation feature cannot be used in write mode for the Flash memory devices that require extra command to re-enable the write operation after the NCS is active again.

If NCS boundary, refresh and communication regulation are enabled at the same time, the NCS is released on the first condition met.

Re-starting after an interrupted transfer

When a read or write operation is interrupted by a timeout or communication regulation feature, the Octo-SPI interface, as soon as possible after getting back the port ownership, re-issues the initial command sequence together with the address following the last address actually accessed before interruption. The transfer initially set goes on and ends seamlessly.

19.4.7 OCTOSPI operating modes introduction

The OCTOSPI has the following operating modes regardless of the low-level protocol used (either Regular-command or HyperBus):

- Indirect mode (read or write)
- Automatic status-polling mode
- Memory-mapped mode
19.4.8 OCTOSPI Indirect mode

In Indirect mode, the commands are started by writing to the OCTOSPI registers and the data is transferred by writing or reading the data register, in a similar way to other communication peripherals.

When FMODE[1:0] = 0 in OCTOSPI_CR, the OCTOSPI is in Indirect-write mode: bytes are sent to the external device during the data phase. Data is provided by writing to OCTOSPI_DR.

When FMODE[1:0] = 01, the OCTOSPI is in Indirect-read mode: bytes are received from the external device during the data phase. Data is recovered by reading OCTOSPI_DR.

In Indirect mode, when the OCTOSPI is configured in DTR mode over eight lanes with DQS disabled, the given starting address and the data length must be even.

Note: The OCTOSPI_AR register must be updated even if the start address is the same as the start address of the previous indirect access.

The number of bytes to be read/written is specified in OCTOSPI_DLR:

- If DL[31:0] = 0xFFFF FFFF, the data length is considered undefined and the OCTOSPI simply continues to transfer data until it reaches the end of the external device (as defined by DEVSIZE). If no bytes are to be transferred, DMODE[2:0] must be set to 0 in OCTOSPI_CCR.

- If DL[31:0] = 0xFFFF FFFFF and DEVSIZE[4:0] = 0x1F (its maximum value indicating at 4-Gbyte device), the transfers continue indefinitely, stopping only after an abort request or after the OCTOSPI is disabled. After the last memory address is read (at address 0xFFFF FFFF), reading continues with address = 0x0000 0000.

When the programmed number of bytes to be transmitted or received is reached, TCF bit is set in OCTOSPI_SR and an interrupt is generated if TCIE = 1 in OCTOSPI_CR. In the case of an undefined number of data, TCF is set when the limit of the external SPI memory is reached, according to the device size defined in OCTOSPI_DCR1.

Triggering the start of a transfer in Regular-command protocol

Depending on the OCTOSPI configuration, there are three different ways to trigger the start of a transfer in Indirect mode when using Regular-command protocol. In general, the start of transfer is triggered as soon as the software gives the last information that is necessary for the command. More specifically in Indirect mode, a transfer starts when one of the following sequence of events occurs:

- If no address is necessary (ADMODE[2:0] = 000) and if no data needs to be provided by the software (FMODE[1:0] = 01 or DMODE[2:0] = 000), and at the moment when a write is performed to INSTRUCTION[31:0] in OCTOSPI_IR

- If an address is necessary (when ADMODE[2:0] ≠ 000) and if no data needs to be provided by the software (when FMODE[1:0] = 01 or DMODE[2:0] = 000), and at the moment when a write is performed to ADDRESS[31:0] in OCTOSPI_AR

- If an address is necessary (when ADMODE[2:0] ≠ 000) and if data needs to be provided by the software (when FMODE[1:0] = 00 and DMODE[2:0] ≠ 000), and at the moment when a write is performed to DATA[31:0] in OCTOSPI_DR

A write to OCTOSPI_ABR never triggers the communication start. If alternate bytes are required, they must have been programmed before.

As soon as a command is started, the BUSY bit is automatically set in OCTOSPI_SR.
Triggering the start of a transfer in HyperBus protocol

Depending on the OCTOSPI configuration, there are different ways to trigger the start of a command in Indirect mode. In general, it is triggered as soon as the firmware gives the last information that is necessary for the transfer to start, and more specifically, a communication in Indirect mode is triggered by one of the following register settings, when it is the last one to be executed:

• when a write is performed to ADDRESS[31:0] (OCTOSPI_AR) in Indirect-read mode (when FMODE = 01).
• when a write is performed to DATA[31:0] (OCTOSPI_DR) in Indirect-write mode (when FMODE = 00).
• when a write is performed to INSTRUCTION[31:0] (OCTOSPI_IR) for both Indirect read and write modes

Note: In case of HyperBus, a (dummy) write to OCTOSPI_IR is required to trigger the transfer, as for Regular-command protocol.

As soon as a transfer is started, the BUSY bit (OCTOSPI_SR[5]) is automatically set.

FIFO and data management

Data in Indirect mode passes through a 32-byte FIFO that is internal to the OCTOSPI. FLEVEL in OCTOSPI_SR indicates how many bytes are currently being held in the FIFO.

AHB burst transactions are supported. Data of the burst are successively written in OCTOSPI_DR and immediately transferred in the internal FIFO.

In Indirect-write mode (FMODE[1:0] = 00), the software adds data to the FIFO when it writes in OCTOSPI_DR. A word write adds 4 bytes to the FIFO, an half-word write adds 2 bytes, and a byte write adds only 1 byte. If the software adds too many bytes to the FIFO (more than indicated in DL[31:0]), the extra bytes are flushed from the FIFO at the end of the write operation (when TCF is set).

The byte/half-word accesses to OCTOSPI_DR must be done only to the least significant byte/halfword of the 32-bit register.

FTHRES is used to define a FIFO threshold after which point the FIFO threshold flag, FTF, gets set. In Indirect-read mode, FTF is set when the number of valid bytes to be read from the FIFO is above the threshold. FTF is also set if there is any data left in the FIFO after the last byte is read from the external device, regardless of FTHRES setting. In Indirect-write mode, the FTF is set when the number of empty bytes in the FIFO is above the threshold.

If FTIE = 1, there is an interrupt when the FTF is set. If DMAEN = 1, a DMA transfer is initiated when the FTF is set. The FTF is cleared by hardware as soon as the threshold condition is no longer true (after enough data has been transferred by the CPU or DMA).

The last data read in RX FIFO remains valid as long as there is no request for the next line. This means that, when the application reads several times in a row at the same location, the data is provided from the RX FIFO and not read again from the distant memory.

19.4.9 OCTOSPI Automatic status-polling mode

In Automatic status-polling mode, the OCTOSPI periodically starts a command to read a defined number of status bytes (up to four). The received bytes can be masked to isolate some status bits and an interrupt can be generated when the selected bits have a defined value.
The access to the device begins in the same manner as in Indirect-read mode. BUSY in OCTOSPI_SR goes high at this point and stays high even between the periodic accesses.

The content of MASK[31:0] in OCTOSPI_PSMAR is used to mask the data from the external device in Automatic status-polling mode:

- If the MASK[n] = 0, then bit n of the result is masked and not considered.
- If MASK[n] = 1, and the content of bit[n] is the same as MATCH[n] in OCTOSPI_PSMAR, then there is a match for bit n.

If PMM = 0 in OCTOSPI_CR, the AND-match mode is activated: SMF is set in OCTOSPI_SR only when there is a match on all of the unmasked bits.

If PMM = 1 in OCTOSPI_CR, the OR-match mode is activated: SMF gets set if there is a match on any of the unmasked bits.

An interrupt is called when SMF = 1 if SMIE = 1.

If APMS is set in OCTOSPI_CR, the operation stops and BUSY goes to 0 as soon as a match is detected. Otherwise, BUSY stays at 1 and the periodic accesses continue until there is an abort or until the OCTOSPI is disabled (EN = 0).

OCTOSPI_DR contains the latest received status bytes (FIFO deactivated). The content of this register is not affected by the masking used in the matching logic. FTF in OCTOSPI_SR is set as soon as a new reading of the status is complete. FTF is cleared as soon as the data is read.

In Automatic status-polling mode, variable latency is not supported. As a consequence, the memory must be configured in fixed latency.

19.4.10 OCTOSPI Memory-mapped mode

When configured in Memory-mapped mode, the external SPI device is seen as an internal memory.

Note: More than 256 Mbytes can be addressed even if the external device capacity is larger.

If an access is made to an address outside of the range defined by DEVSIZE[4:0] but still within the 256 Mbytes range, then an AHB error is given. The effect of this error depends on the AHB master that attempted the access:

- If it is the Cortex CPU, a hard-fault interrupt is generated.
- If it is a DMA, a DMA transfer error is generated and the corresponding DMA channel is automatically disabled.

Byte, half-word, and word access types are all supported.

A support for execute in place (XIP) operation is implemented, where the OCTOSPI continues to load the bytes to the addresses following the most recent access. If subsequent accesses are continuous to the bytes that follow, then these operations ends up quickly since their results were pre-fetched.

By default, the OCTOSPI never stops its prefetch operation, it either keeps the previous read operation active with the NCS maintained low or it relaunches a new transfer, even if no access to the external device occurs for a long time.

Since external devices tend to consume more when the NCS is held low, the application may want to activate the timeout counter (TCEN = 1 in OCTOSPI_CR): the NCS is released after a period defined by TIMEOUT[15:0] in OCTOSPI_LPTR, when x cycles have elapsed without an access since the clock is inactive.
BUSY goes high as soon as the first memory-mapped access occurs. Because of the prefetch operations, BUSY does not fall until there is an abort, or the peripheral is disabled.

19.4.11 OCTOSPI configuration introduction

The OCTOSPI configuration is done in three steps:
1. OCTOSPI system configuration
2. OCTOSPI device configuration
3. OCTOSPI mode configuration

19.4.12 OCTOSPI system configuration

The OCTOSPI is configured using OCTOSPI_CR. The user must program:
- Functional mode with FMODE[1:0]
- Automatic status-polling mode behavior if needed with PMM and APMS
- FIFO level with FTHRES
- DMA usage with DMAEN
- Timeout counter usage with TCEN
- Dual-quad configuration, if needed, with DMM (only for Quad-SPI mode)

In case of an interrupt usage, the respective enable bit can also be set during this phase.

If the timeout counter is used, the timeout value is programmed in OCTOSPI_LPTR.

The DMA channel must not be enabled during the OCTOSPI configuration: it must be enabled only when the operation is fully configured, to avoid any unexpected request generation.

The DMA and OCTOSPI must be configured in a coherent manner regarding data length: FTHRES value must reflect the DMA burst size.

19.4.13 OCTOSPI device configuration

The parameters related to the external device targeted are configured through OCTOSPI_DCR1 and OCTOSPI_DCR2. The user must program:
- Device size with DEVSIZE[4:0]
- Chip-select minimum high time with CSHT[5:0]
- Clock mode with FRCK and CKMODE
- Device frequency with PRESCALER[7:0]

MTYP[2:0] defines the memory type to be used for 8-line modes:
- Micron mode with D0/D1 ordering in 8-data-bit mode (DMODE[2:0] = 100)
- Macronix mode with D1/D0 ordering in 8-data-bit mode (DMODE[2:0] = 100)
- HyperBus memory mode: the protocol follows the HyperBus specification, and an 8-data-bit DTR mode must be selected.
- HyperBus register mode, addressing register space: the memory-mapped accesses in this mode must be non-cacheable, or the Indirect read/write modes must be used.
DEVSIZE[4:0] defines the size of external memory using the following formula:

\[ \text{Number of bytes in the device} = 2^{(\text{DEVSIZE}+1)} \]

where DEVSIZE+1 is the number of address bits required to address the external device. The external device capacity can go up to 4 Gbytes (addressed using 32 bits) in Indirect mode, but the addressable space in Memory-mapped mode is limited to 256 Mbytes.

If DMM = 1, DEVSIZE[4:0] indicates the total capacity of the two devices together.

When the OCTOSPI executes two commands, one immediately after the other, it raises the chip-select signal (NCS) high between the two commands for only one CLK cycle by default.

If the external device requires more time between commands, the chip-select high time CSHT[5:0] can be used to specify the minimum number of CLK cycles for which the NCS must remain high.

CKMODE indicates the level that the CLK takes between commands (when NCS = 1).

In HyperBus protocol, the device timing (tACC and tRWR) and the Latency mode must be configured in OCTOSPI_HLCR.

19.4.14 OCTOSPI Regular-command mode configuration

Indirect mode configuration

When FMODE[1:0] = 00, the Indirect-write mode is selected and data can be sent to the external device. When FMODE[1:0] = 01, the Indirect-read mode is selected and data can be read from the external device.

When the OCTOSPI is used in Indirect mode, the frames are constructed in the following way:

1. Specify a number of data bytes to read or write in OCTOSPI_DLR.
2. Specify the frame timing in OCTOSPI_TCR.
3. Specify the frame format in OCTOSPI_CCR.
4. Specify the instruction in OCTOSPI_IR.
5. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_ABR.
6. Specify the targeted address in OCTOSPI_AR.
7. Enable the DMA channel if needed.
8. Read/write the data from/to the FIFO through OCTOSPI_DR (if no DMA usage).

If neither the address register (OCTOSPI_AR) nor the data register (OCTOSPI_DR) need to be updated for a particular command, then the command sequence starts as soon as OCTOSPI_IR is written. This is the case when both ADMODE[2:0] and DMODE[2:0] equal 000, or if just ADMODE[2:0] = 000 when in Indirect-read mode (FMODE[1:0] = 01).

When an address is required (ADMODE[2:0] ≠ 000) and the data register does not need to be written (FMODE[1:0] = 01 or DMODE[2:0] = 000), the command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.

In case of data transmission (FMODE[1:0] = 00 and DMODE[2:0] ≠ 000), the communication start is triggered by a write in the FIFO through OCTOSPI_DR.
Automatic status-polling mode configuration

The Automatic status-polling mode is enabled by setting FMODE[1:0] = 10. In this mode, the programmed frame is sent and the data is retrieved periodically.

The maximum amount of data read in each frame is 4 bytes. If more data is requested in OCTOSPI_DLR, it is ignored and only 4 bytes are read. The periodicity is specified in OCTOSPI_PIR.

Once the status data has been retrieved, the following can be processed:

- Set SMF (an interrupt is generated if enabled).
- Stop automatically the periodic retrieving of the status bytes.

The received value can be masked with the value stored in OCTOSPI_PSMKR, and can be ORed or ANDed with the value stored in OCTOSPI_PSMAR.

In case of a match, SMF is set and an interrupt is generated if enabled; The OCTOSPI can be automatically stopped if AMPS is set. In any case, the latest retrieved value is available in OCTOSPI_DR.

When the OCTOSPI is used in Automatic status-polling mode, the frames are constructed in the following way:

1. Specify the input mask in OCTOSPI_PSMKR.
2. Specify the comparison value in OCTOSPI_PSMAR.
3. Specify the read period in OCTOSPI_PIR.
4. Specify a number of data bytes to read in OCTOSPI_DLR.
5. Specify the frame timing in OCTOSPI_TCR.
6. Specify the frame format in OCTOSPI_CCR.
7. Specify the instruction in OCTOSPI_IR.
8. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_ABR.
9. Specify the optional targeted address in OCTOSPI_AR.

If the address register (OCTOSPI_AR) does not need to be updated for a particular command, then the command sequence starts as soon as OCTOSPI_CCR is written. This is the case when ADMODE[2:0] = 000.

When an address is required (ADMODE[2:0] ≠ 000), the command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.

Memory-mapped mode configuration

In Memory-mapped mode, the external device is seen as an internal memory but with some latency during accesses. Read and write operations are allowed to the external device in this mode.

It is not recommended to program the Flash memory using memory-mapped writes, as the internal flags for erase or programming status have to be polled.

Memory-mapped mode is entered by setting FMODE[1:0] = 11 in OCTOSPI_CR.

The programmed instruction and frame are sent when an AHB master accesses the memory mapped space.

The FIFO is used as a prefetch buffer to anticipate any linear reads. Any access to OCTOSPI_DR in this mode returns zero.
The data length register (OCTOSPI_DLR) has no meaning in Memory-mapped mode.

When the OCTOSPI is used in Memory-mapped mode, the frames are constructed in the following way:

1. Specify the frame timing in OCTOSPI_TCR for read operation.
2. Specify the frame format in OCTOSPI_CCR for read operation.
3. Specify the instruction in OCTOSPI_IR.
4. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_ABR for read operation.
5. Specify the frame timing in OCTOSPI_WTCR for write operation.
6. Specify the frame format in OCTOSPI_WCCR for write operation.
7. Specify the instruction in OCTOSPI_WIR.
8. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_WABR for read operation.

All the configuration operations must be completed before the first access to the memory area. On the first access, the OCTOSPI becomes busy, and no further configuration is allowed.

**OCTOSPI delayed data sampling when no DQS is used**

By default, when no DQS is used, the OCTOSPI samples the data driven by the external device one half of a CLK cycle after the external device drives the signal.

In case of any external signal delays, it may be useful to sample the data later. Using SSHIFT in OCTOSPI_TCR, the sampling of the data can be shifted by half of a CLK cycle.

The firmware must clear SSHIFT when the data phase is configured in DTR mode (DDTR = 1).

**OCTOSPI delayed data sampling when DQS is used**

When external DQS is used as a sampling clock, it can be shifted in time to compensate the data propagation delay. This shift is performed by an external delay block located outside the OCTOSPI. The control of this feature depends on the device implementation (see the product reference manual for more details).

In certain configuration cases, this external delay block is implemented but is not useful, so it can be bypassed by setting DLYBYP in OCTOSPI_DCR1.

**Sending the instruction only once (SIOO)**

A Flash memory can provide a mode where an instruction must be sent only with the first command sequence, while subsequent commands start directly with the address. The user can take advantage of this type of features using SIOO in OCTOSPI_CCR.

SIOO is valid for Memory-mapped mode only. If this bit is set, the instruction is sent only for the first command following a write to OCTOSPI_CCR.

Subsequent command sequences skip the instruction phase, until there is a write to OCTOSPI_CCR. SIOO has no effect when IMODE[1:0] = 00 (no instruction).

SIOO mode is not supported when any of the communication regulation, NCS boundary or refresh features are used.
19.4.15 OCTOSPI HyperBus protocol configuration

Indirect mode configuration

When FMODE[1:0] = 00, the Indirect-write mode is selected and data can be sent to the external device. When FMODE[1:0] = 01, the Indirect-read mode is selected where data can be read from the external device.

When the OCTOSPI is used in Indirect mode, the frames are constructed in the following way:

1. Specify a number of data bytes to read or write in OCTOSPI_DLR.
2. Specify the targeted address in OCTOSPI_AR.
3. Make a write operation in OCTOSPI_IR and enable the DMA channel if needed.
4. Read/write the data from/to the FIFO through OCTOSPI_DR (if no DMA usage).

In Indirect-read mode, the command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.

In Indirect-write mode, the communication start is triggered by a write in the FIFO through OCTOSPI_DR.

Automatic status-polling mode configuration

The Automatic status-polling mode is enabled setting FMODE[1:0] = 10. In this mode, the programmed frame is sent and the data is retrieved periodically.

The maximum amount of data read in each frame is 4 bytes. If more data is requested in OCTOSPI_DLR, it is ignored and only 4 bytes are read. The periodicity is specified in OCTOSPI_PIR.

Once the status data has been retrieved, it can be internally processed to:

- Set SMF (an interrupt is generated if enabled).
- Stop automatically the periodic retrieving of the status bytes.

The received value can be masked with the value stored in OCTOSPI_PSMKR and can be ORed or ANDed with the value stored in OCTOSPI_PSMAR.

In case of a match, SMF is set and an interrupt is generated if enabled. The OCTOSPI can be automatically stopped if AMPS is set.

In any case, the latest retrieved value is available in OCTOSPI_DR.

When the OCTOSPI is used in Automatic status-polling mode, the frames are constructed in the following way:

1. Specify the input mask in OCTOSPI_PSMKR.
2. Specify the comparison value in OCTOSPI_PSMAR.
3. Specify the read period in OCTOSPI_PIR.
4. Specify a number of data bytes to read in OCTOSPI_DLR.
5. Specify the targeted address in OCTOSPI_AR.

The command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.
Memory-mapped mode configuration

In Memory-mapped mode, the external device is seen as an internal memory but with some latency during the accesses. Read and write operations are allowed to the external device in this mode.

The Memory-mapped mode is entered by setting FMODE[1:0] = 11. The programmed instruction and frame is sent when an AHB master accesses the memory mapped space.

The FIFO is used as a prefetch buffer to anticipate any linear reads. Any access to OCTOSPI_DR in this mode returns zero.

The data length register (OCTOSPI_DLR) has no meaning in Memory-mapped mode.

All the configuration operation must be completed prior to the first access to the memory area. On the first access, the OCTOSPI becomes busy, and no configuration is allowed.

19.4.16 OCTOSPI error management

A error can be generated in the following cases:

- in Indirect or Automatic status-polling mode, when a wrong address has been programmed in OCTOSPI_AR (according to the device size defined by DEVSIZE[4:0]). This sets TEF and an interrupt is generated if enabled.
- in Indirect mode, if the address plus the data length exceed the device size. TEF is set as soon as the access is triggered.
- in Memory-mapped mode when an out-of-range access is done by an AHB master. This generates an AHB error as a response to the faulty AHB request.
- when the Memory-mapped mode is disabled. An access to the memory-mapped area generates an AHB error as a response to the faulty AHB request.

The OCTOSPI generates an AHB slave error in the following situations:

- Memory-mapped mode is disabled and an AHB read request occurs.
- Read or write address exceeds the size of the external memory.
- Abort is received while a read or write burst is ongoing.
- OCTOSPI is disabled while a read or write burst is ongoing.
- Write wrap burst is received.
- Write request is received while DQSE = 0 in OCTOSPI_WCCR, which means that the DQS output is disabled.
- Write request is received while DMODE[2:0] = 000 (no data phase), except when MTYP[2:0] is HyperBus.
- Illegal access size when wrap read burst. This means the HSIZE is different from 4 bytes (only for Memory-mapped mode).
- Illegal wrap size when receiving read wrap burst with size different from 4 bytes (only for Memory-mapped mode).

19.4.17 OCTOSPI BUSY and ABORT

Once the OCTOSPI starts an operation with the external device, BUSY is automatically set in OCTOSPI_SR.

In Indirect mode, BUSY is reset once the OCTOSPI has completed the requested command sequence and the FIFO is empty.
In Automatic status-polling mode, BUSY goes low only after the last periodic access is complete, due to a match when APMS = 1 or due to an abort.

After the first access in Memory-mapped mode, BUSY goes low only on an abort.

Any operation can be aborted by setting ABORT in OCTOSPI_CR. Once the abort is completed, BUSY and ABORT are automatically reset, and the FIFO is flushed.

Before setting ABORT, the software must ensure that all the current transactions are finished using the synchronization barriers.

**Note:** Some devices may misbehave if a write operation to a status register is aborted.

### 19.4.18 OCTOSPI reconfiguration or deactivation

Prior to any OCTOSPI reconfiguration, the software must ensure that all the transactions are completed:

- After a Memory-mapped write, the software must perform a dummy read followed by a synchronization barrier, then an abort.
- After a Memory-mapped read, the software must perform a synchronization barrier then an abort.

### 19.4.19 NCS behavior

By default, NCS is high, deselecting the external device. NCS falls before an operation begins and rises as soon as it finishes.

When CKMODE = 0 (Mode 0: CLK stays low when no operation is in progress), NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final rising CLK edge (see the figure below).

**Figure 81. NCS when CKMODE = 0 (T = CLK period)**

![Figure 81. NCS when CKMODE = 0](MSv44100V1)
When CKMODE = 1 (Mode 3: CLK goes high when no operation is in progress) and when in SDR mode, NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final rising CLK edge (see the figure below).

**Figure 82. NCS when CKMODE = 1 in SDR mode (T = CLK period)**

![Figure 82](image1)

When the CKMODE = 1 (Mode 3) and DDTR = 1 (data DTR mode), NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final active rising CLK edge (see the figure below). Because the DTR operations must finish with a falling edge, CLK is low when NCS rises, and CLK rises back up one half of a CLK cycle afterwards.

**Figure 83. NCS when CKMODE = 1 in DTR mode (T = CLK period)**

![Figure 83](image2)

When the FIFO stays full during a read operation, or if the FIFO stays empty during a write operation, the operation stalls and CLK stays low until the software services the FIFO. If an abort occurs when an operation is stalled, NCS rises just after the abort is requested and then CLK rises one half of a CLK cycle later (see the figure below).

**Figure 84. NCS when CKMODE = 1 with an abort (T = CLK period)**

![Figure 84](image3)

When not in dual-quad configuration (DMM = 0), only device A is accessed and thus the BNCS stays high. In dual-quad configuration, the BNCS behaves exactly the same as the ANCS. Thus, if there is a device B and if the application always stays in dual-quad...
configuration, then the device B may use the ANCS and the pin outputting BNCS can be used for other functions.

19.5 **Address alignment and data number**

The following table summarizes the effect of the address alignment and programmed data number depending on the use case.

<table>

</table>

1. To be respected by the software.
2. IND = Indirect mode.
3. MM = Memory-mapped mode
4. RDS = read data strobe, WDM = write data mask.
19.6 OCTOSPI interrupts

An interrupt can be produced on the following events:
- Timeout
- Status match
- FIFO threshold
- Transfer complete
- Transfer error

Separate interrupt enable bits are available to provide more flexibility.

<table>

</tbody>
</table>

Bits 31:30 Reserved, must be kept at reset value.
Bits 29:28  **FMODE[1:0]**: Functional mode
   
   This field defines the OCTOSPI functional mode of operation.
   
   00: Indirect-write mode
   01: Indirect-read mode
   10: Automatic status-polling mode
   11: Memory-mapped mode

   If DMAEN = 1 already, then the DMA controller for the corresponding channel must be
disabled before changing the FMODE[1:0] value. If FMODE[1:0] and FTHRES[4:0] are
wrongly updated while DMAEN = 1, the DMA request signal automatically goes to inactive
state.

Bits 27:24  Reserved, must be kept at reset value.

Bit 23  **PMM**: Polling match mode

   This bit indicates which method must be used to determine a match during the Automatic
status-polling mode.

   0: AND-match mode, SMF is set if all the unmasked bits received from the device match the
   corresponding bits in the match register.
   1: OR-match mode, SMF is set if any of the unmasked bits received from the device matches
   its corresponding bit in the match register.

Bit 22  **APMS**: Automatic status-polling mode stop

   This bit determines if the Automatic status-polling mode is stopped after a match.
   
   0: Automatic status-polling mode is stopped only by abort or by disabling the OCTOSPI.
   1: Automatic status-polling mode stops as soon as there is a match.

Bit 21  Reserved, must be kept at reset value.

Bit 20  **TOIE**: Timeout interrupt enable

   This bit enables the timeout interrupt.
   
   0: Interrupt disabled
   1: Interrupt enabled

Bit 19  **SMIE**: Status match interrupt enable

   This bit enables the status match interrupt.
   
   0: Interrupt disabled
   1: Interrupt enabled

Bit 18  **FTIE**: FIFO threshold interrupt enable

   This bit enables the FIFO threshold interrupt.
   
   0: Interrupt disabled
   1: Interrupt enabled

Bit 17  **TCIE**: Transfer complete interrupt enable

   This bit enables the transfer complete interrupt.
   
   0: Interrupt disabled
   1: Interrupt enabled

Bit 16  **TEIE**: Transfer error interrupt enable

   This bit enables the transfer error interrupt.
   
   0: Interrupt disabled
   1: Interrupt enabled

Bits 15:13  Reserved, must be kept at reset value.
Bits 12:8 \textbf{FTHRES}[4:0]: FIFO threshold level
This field defines, in Indirect mode, the threshold number of bytes in the FIFO that causes the FIFO threshold flag FTF in OCTOSPI\_SR, to be set.
00000: FTF is set if there are one or more free bytes available to be written to in the FIFO in Indirect-write mode, or if there are one or more valid bytes can be read from the FIFO in Indirect-read mode.
00001: FTF is set if there are two or more free bytes available to be written to in the FIFO in Indirect-write mode, or if there are two or more valid bytes can be read from the FIFO in Indirect-read mode.
...
11111: FTF is set if there are 32 free bytes available to be written to in the FIFO in Indirect-write mode, or if there are 32 valid bytes can be read from the FIFO in Indirect-read mode.

\textit{Note:} If DMAEN = 1, the DMA controller for the corresponding channel must be disabled before changing the FTHRES[4:0] value.

Bit 7 \textbf{MSEL}: Flash select
This bit selects the Flash memory to be addressed in Single-, Dual-, Quad-SPI mode in single-memory configuration (when DMM = 0).
0: FLASH 1 selected (data exchanged over IO[3:0])
1: FLASH 2 selected (data exchanged over IO[7:4])
This bit is ignored when DMM = 1 or when Octal-SPI mode is selected.

Bit 6 \textbf{DMM}: Dual-memory configuration
This bit activates the dual-memory configuration, where two external devices are used simultaneously to double the throughput and the capacity
0: Dual-quad configuration disabled
1: Dual-quad configuration enabled

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 \textbf{TCEN}: Timeout counter enable
This bit is valid only when the Memory-mapped mode (FMODE[1:0] = 11) is selected. This bit enables the timeout counter.
0: Timeout counter is disabled, and thus the chip-select (NCS) remains active indefinitely after an access in Memory-mapped mode.
1: Timeout counter is enabled, and thus the chip-select is released in the Memory-mapped mode after TIMEOUT[15:0] cycles of external device inactivity.

Bit 2 \textbf{DMAEN}: DMA enable
In Indirect mode, the DMA can be used to input or output data via OCTOSPI\_DR. DMA transfers are initiated when FTF is set.
0: DMA disabled for Indirect mode
1: DMA enabled for Indirect mode

\textit{Note:} Resetting the DMAEN bit while a DMA transfer is ongoing, breaks the handshake with the DMA. Do not write this bit during DMA operation.

Bit 1 \textbf{ABORT}: Abort request
This bit aborts the on-going command sequence. It is automatically reset once the abort is completed. This bit stops the current transfer.
0: No abort requested
1: Abort requested

\textit{Note:} This bit is always read as 0.
Bit 0  EN: Enable
   This bit enables the OCTOSPI.
   0: OCTOSPI disabled
   1: OCTOSPI enabled

   Note: The DMA request can be aborted without having received the ACK in case this EN bit is
   cleared during the operation.
   In case this bit is set to 0 during a DMA transfer, the REQ signal to DMA returns to
   inactive state without waiting for the ACK signal from DMA to be active.

19.7.2 OCTOSPI device configuration register 1 (OCTOSPI_DCR1)

Address offset: 0x0008
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

<table>

</tr>
</tbody>
</table>

Bits 31:27  Reserved, must be kept at reset value.

Bits 26:24  MTYP[2:0]: Memory type
   This bit indicates the type of memory to be supported.
   000: Micron mode, D0/D1 ordering in DTR 8-data-bit mode. Regular-command protocol in
   Single-, Dual-, Quad- and Octal-SPI modes.
   Note: In this mode, DQS signal polarity is inverted with respect to the memory clock signal.
   This is the default value and care must be taken to change MTYP[2:0] for memories different
   from Micron.
   001: Macronix mode, D1/D0 ordering in DTR 8-data-bit mode. Regular-command protocol in
   Single-, Dual-, Quad- and Octal-SPI modes.
   010: Standard mode
   011: Macronix RAM mode, D1/D0 ordering in DTR 8-data-bit mode. Regular-command
   protocol in Single-, Dual-, Quad- and Octal-SPI modes with dedicated address mapping.
   100: HyperBus memory mode, the protocol follows the HyperBus specification. 8-data-bit
   DTR mode must be selected.
   101: HyperBus register mode, addressing register space. The memory-mapped accesses in
   this mode must be non-cacheable, or Indirect read/write modes must be used.
   Others: Reserved

Bits 23:21  Reserved, must be kept at reset value.
19.7.3 OCTOSPI device configuration register 2 (OCTOSPI_DCR2)

Address offset: 0x000C
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.
Bits 31:19  Reserved, must be kept at reset value.

Bits 18:16  **WRAPSIZE[2:0]**: Wrap size

This field indicates the wrap size to which the memory is configured. For memories which have a separate command for wrapped instructions, this field indicates the wrap-size associated with the command held in the OCTOSPI1_WPIR register.

000: Wrapped reads are not supported by the memory.
001: Reserved
010: External memory supports wrap size of 16 bytes.
011: External memory supports wrap size of 32 bytes.
100: External memory supports wrap size of 64 bytes.
101: External memory supports wrap size of 128 bytes.
110-111: Reserved

Bits 15:8  Reserved, must be kept at reset value.

Bits 7:0  **PRESCALER[7:0]**: Clock prescaler

This field defines the scaler factor for generating the CLK based on the kernel clock (value + 1).

0: \( F_{CLK} = F_{KERNEL} \), kernel clock used directly as OCTOSPI CLK (prescaler bypassed). In this case, if the DTR mode is used, it is mandatory to provide to the OCTOSPI a kernel clock that has 50% duty-cycle.
1: \( F_{CLK} = F_{KERNEL}/2 \)
2: \( F_{CLK} = F_{KERNEL}/3 \)
...
255: \( F_{CLK} = F_{KERNEL}/256 \)

For odd clock division factors, the CLK duty cycle is not 50%. The clock signal remains low one cycle longer than it stays high.

### 19.7.4 OCTOSPI device configuration register 3 (OCTOSPI_DCR3)

Address offset: 0x0010

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.
Bits 31:21  Reserved, must be kept at reset value.

Bits 20:16 **CSBOUND[4:0]**: NCS boundary
- This field enables the transaction boundary feature. When active, a minimum value of 3 is recommended.
- The NCS is released on each boundary of $2^{\text{CSBOUND}}$ bytes.
- 0: NCS boundary disabled
- others: NCS boundary set to $2^{\text{CSBOUND}}$ bytes

Bits 15:8  Reserved, must be kept at reset value.

Bits 7:0 **MAXTRAN[7:0]**: Maximum transfer
- This field enables the communication regulation feature.
- The NCS is released every MAXTRAN + 1 clock cycles when the other OCTOSPI request the access to the bus.
- 0: Maximum communication disabled
- others: Maximum communication is set to MAXTRAN + 1 bytes

### 19.7.5 OCTOSPI device configuration register 4 (OCTOSPI_DCR4)

Address offset: 0x0014

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

<table>
<thead>
<tr>

</tbody>
</table>

Bits 31:0 **REFRESH[31:0]**: Refresh rate
- This field enables the refresh rate feature.
- The NCS is released every REFRESH + 1 clock cycles for writes, and REFRESH + 4 clock cycles for reads.

**Note:** These two values can be extended with few clock cycles when refresh occurs during a byte transmission in Single-, Dual- or Quad-SPI mode, because the byte transmission must be completed.

- 0: Refresh disabled
- others: Maximum communication length is set to REFRESH + 1 clock cycles.
19.7.6 OCTOSPI status register (OCTOSPI_SR)

Address offset: 0x0020
Reset value: 0x0000 0000

<table>

</tbody>
</table>

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:8 **FLEVEL[5:0]**: FIFO level
This field gives the number of valid bytes that are being held in the FIFO. FLEVEL = 0 when the FIFO is empty, and 32 when it is full.
In Automatic status-polling mode, FLEVEL is zero.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **BUSY**: Busy
This bit is set when an operation is ongoing. It is cleared automatically when the operation with the external device is finished and the FIFO is empty.

Bit 4 **TOF**: Timeout flag
This bit is set when timeout occurs. It is cleared by writing 1 to CTOF.

Bit 3 **SMF**: Status match flag
This bit is set in Automatic status-polling mode when the unmasked received data matches the corresponding bits in the match register (OCTOSPI_PSMAR).
It is cleared by writing 1 to CSMF.

Bit 2 **FTF**: FIFO threshold flag
In Indirect mode, this bit is set when the FIFO threshold has been reached, or if there is any data left in the FIFO after the reads from the external device are complete.
It is cleared automatically as soon as the threshold condition is no longer true.
In Automatic status-polling mode, this bit is set every time the status register is read, and the bit is cleared when the data register is read.

Bit 1 **TCF**: Transfer complete flag
This bit is set in Indirect mode when the programmed number of data has been transferred or in any mode when the transfer has been aborted. It is cleared by writing 1 to CTCF.

Bit 0 **TEF**: Transfer error flag
This bit is set in Indirect mode when an invalid address is being accessed in Indirect mode.
It is cleared by writing 1 to CTEF.
19.7.7 OCTOSPI flag clear register (OCTOSPI_FCR)

ADDRESS[31:16]

Bits 31:0 ADDRESS[31:0]: Address
Address to be sent to the external device. In HyperBus protocol, this field must be even as this protocol is 16-bit word oriented. In dual-memory configuration, AR[0] is forced to 1. Writes to this field are ignored when BUSY = 1 or when FMODE = 11 (Memory-mapped mode).
19.7.10 OCTOSPI data register (OCTOSPI_DR)

Address offset: 0x0050
Reset value: 0x0000 0000

Bits 31:0 DATA[31:0]: Data
Data to be sent/received to/from the external SPI device
In Indirect-write mode, data written to this register is stored on the FIFO before it is sent to the external device during the data phase. If the FIFO is too full, a write operation is stalled until the FIFO has enough space to accept the amount of data being written.
In Indirect-read mode, reading this register gives (via the FIFO) the data that was received from the external device. If the FIFO does not have as many bytes as requested by the read operation and if BUSY = 1, the read operation is stalled until enough data is present or until the transfer is complete, whichever happens first.
In Automatic status-polling mode, this register contains the last data read from the external device (without masking).
Word, half-word, and byte accesses to this register are supported. In Indirect-write mode, a byte write adds 1 byte to the FIFO, a half-word write 2 bytes, and a word write 4 bytes. Similarly, in Indirect-read mode, a byte read removes 1 byte from the FIFO, a halfword read 2 bytes, and a word read 4 bytes. Accesses in Indirect mode must be aligned to the bottom of this register: A byte read must read DATA[7:0] and a half-word read must read DATA[15:0].

19.7.11 OCTOSPI polling status mask register (OCTOSPI_PSMKR)

Address offset: 0x0080
Reset value: 0x0000 0000
This register can be modified only when BUSY = 0.
Bits 31:0 **MASK[31:0]**: Status mask
Mask to be applied to the status bytes received in Automatic status-polling mode
For bit n:
0: Bit n of the data received in Automatic status-polling mode is masked and its value is not considered in the matching logic.
1: Bit n of the data received in Automatic status-polling mode is unmasked and its value is considered in the matching logic.

### 19.7.12 OCTOSPI polling status match register (OCTOSPI_PSMAR)
Address offset: 0x0088
Reset value: 0x0000 0000
This register can be modified only when BUSY = 0.

<table>

Bit 30 Reserved, must be kept at reset value.

Bit 29 DQSE: DQS enable
This bit enables the data strobe management.
0: DQS disabled
1: DQS enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 DDTR: Data double transfer rate
This bit sets the DTR mode for the data phase.
0: DTR mode disabled for data phase
1: DTR mode enabled for data phase

Bits 26:24 DMODE[2:0]: Data mode
This field defines the data phase mode of operation.
000: No data
001: Data on a single line
010: Data on two lines
011: Data on four lines
100: Data on eight lines
101-111: Reserved

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 ABSIZE[1:0]: Alternate bytes size
This bit defines alternate bytes size.
00: 8-bit alternate bytes
01: 16-bit alternate bytes
10: 24-bit alternate bytes
11: 32-bit alternate bytes
Bit 19 **ABDTR**: Alternate bytes double transfer rate
This bit sets the DTR mode for the alternate bytes phase.
0: DTR mode disabled for alternate bytes phase
1: DTR mode enabled for alternate bytes phase
This field can be written only when BUSY = 0.

Bits 18:16 **ABMODE[2:0]**: Alternate-byte mode
This field defines the alternate-byte phase mode of operation.
000: No alternate bytes
001: Alternate bytes on a single line
010: Alternate bytes on two lines
011: Alternate bytes on four lines
100: Alternate bytes on eight lines
101-111: Reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ADSIZE[1:0]**: Address size
This field defines address size.
00: 8-bit address
01: 16-bit address
10: 24-bit address
11: 32-bit address

Bit 11 **ADDTR**: Address double transfer rate
This bit sets the DTR mode for the address phase.
0: DTR mode disabled for address phase
1: DTR mode enabled for address phase

Bits 10:8 **ADMODE[2:0]**: Address mode
This field defines the address phase mode of operation.
000: No address
001: Address on a single line
010: Address on two lines
011: Address on four lines
100: Address on eight lines
101-111: Reserved

Bits 7:6 Reserved, must be kept at reset value.
Bits 5:4 **ISIZE[1:0]:** Instruction size  
This bit defines instruction size.  
00: 8-bit instruction  
01: 16-bit instruction  
10: 24-bit instruction  
11: 32-bit instruction

Bit 3 **IDTR: Instruction double transfer rate**  
This bit sets the DTR mode for the instruction phase.  
0: DTR mode disabled for instruction phase  
1: DTR mode enabled for instruction phase

Bits 2:0 **IMODE[2:0]:** Instruction mode  
This field defines the instruction phase mode of operation.  
000: No instruction  
001: Instruction on a single line  
010: Instruction on two lines  
011: Instruction on four lines  
100: Instruction on eight lines  
101-111: Reserved

### 19.7.15 OCTOSPI timing configuration register (OCTOSPI_TCR)

Address offset: 0x0108  
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

Bit 31 Reserved, must be kept at reset value.

Bit 30 **SShift:** Sample shift  
By default, the OCTOSPI samples data 1/2 of a CLK cycle after the data is driven by the external device.  
This bit allows the data to be sampled later in order to consider the external signal delays.  
0: No shift  
1: 1/2 cycle shift  
The software must ensure that SShift = 0 when the data phase is configured in DTR mode (when DDTR = 1.)

Bit 29 Reserved, must be kept at reset value.
Bit 28  **DHQC**: Delay hold quarter cycle  
0: No delay hold  
1: 1/4 cycle hold  

Bits 27:5  Reserved, must be kept at reset value.  

Bits 4:0  **DCYC[4:0]**: Number of dummy cycles  
This field defines the duration of the dummy phase.  
In both SDR and DTR modes, it specifies a number of CLK cycles (0-31).  
It is recommended to have at least six dummy cycles when using memories with DQS activated.

### 19.7.16 OCTOSPI instruction register (OCTOSPI_IR)

Address offset: 0x0110  
Reset value: 0x0000 0000  
This register can be modified only when BUSY = 0.

</table>

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 TIMEOUT[15: 0]: Timeout period
After each access in Memory-mapped mode, the OCTOSPI prefetches the subsequent bytes and hold them in the FIFO.
This field indicates how many CLK cycles the OCTOSPI waits after the clock becomes inactive and until it raises the NCS, putting the external device in a lower-consumption state.

19.7.19 OCTOSPI wrap communication configuration register (OCTOSPI_WPCCR)

Address offset: 0x0140
Reset value: 0x0000 0000
This register can be modified only when BUSY = 0.

Bits 31:30  Reserved, must be kept at reset value.

Bit 29 **DQSE**: DQS enable

This bit enables the data strobe management.

0: DQS disabled
1: DQS enabled

Bit 28  Reserved, must be kept at reset value.

Bit 27 **DDTR**: data double transfer rate

This bit sets the DTR mode for the data phase.

0: DTR mode disabled for data phase
1: DTR mode enabled for data phase

Bits 26:24 **DMODE[2:0]**: Data mode

This field defines the data phase mode of operation.

000: No data
001: Data on a single line
010: Data on two lines
011: Data on four lines
100: Data on eight lines
101-111: Reserved

Bits 23:22  Reserved, must be kept at reset value.

Bits 21:20 **ABSIZE[1:0]**: Alternate bytes size

This field defines alternate bytes size:

00: 8-bit alternate bytes
01: 16-bit alternate bytes
10: 24-bit alternate bytes
11: 32-bit alternate bytes

Bit 19 **ABDTR**: Alternate bytes double transfer rate

This bit sets the DTR mode for the alternate-bytes phase.

0: DTR mode disabled for alternate-bytes phase
1: DTR mode enabled for alternate-bytes phase
Bits 18:16 **ABMODE[2:0]**: Alternate-byte mode

This field defines the alternate-byte phase mode of operation.

- 000: No alternate bytes
- 001: Alternate bytes on a single line
- 010: Alternate bytes on two lines
- 011: Alternate bytes on four lines
- 100: Alternate bytes on eight lines
- 101-111: Reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ADSIZE[1:0]**: Address size

This field defines address size.

- 00: 8-bit address
- 01: 16-bit address
- 10: 24-bit address
- 11: 32-bit address

Bit 11 **ADDTR**: Address double transfer rate

This bit sets the DTR mode for the address phase.

- 0: DTR mode disabled for address phase
- 1: DTR mode enabled for address phase

Bits 10:8 **ADMODE[2:0]**: Address mode

This field defines the address phase mode of operation.

- 000: No address
- 001: Address on a single line
- 010: Address on two lines
- 011: Address on four lines
- 100: Address on eight lines
- 101-111: Reserved

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **ISIZE[1:0]**: Instruction size

This bit defines instruction size:

- 00: 8-bit instruction
- 01: 16-bit instruction
- 10: 24-bit instruction
- 11: 32-bit instruction

Bit 3 **IDTR**: Instruction double transfer rate

This bit sets the DTR mode for the instruction phase.

- 0: DTR mode disabled for instruction phase
- 1: DTR mode enabled for instruction phase

Bits 2:0 **IMODE[2:0]**: Instruction mode

This field defines the instruction phase mode of operation.

- 000: No instruction
- 001: Instruction on a single line
- 010: Instruction on two lines
- 011: Instruction on four lines
- 100: Instruction on eight lines
- 101-111: Reserved
19.7.24 OCTOSPI write timing configuration register (OCTOSPI_WTCR)

Address offset: 0x0188
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

Bits 31:5 Reserved, must be kept at reset value.

Bits 4:0 DCYC[4:0]: Number of dummy cycles
This field defines the duration of the dummy phase.
In both SDR and DTR modes, it specifies a number of CLK cycles (0-31). It is recommended to have at least 5 dummy cycles when using memories with DQS activated.

19.7.25 OCTOSPI write instruction register (OCTOSPI_WIR)

Address offset: 0x0190
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

</table>

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 TRWR[7:0]: Read write recovery time
Device read write recovery time expressed in number of communication clock cycles

Bits 15:8 TACC[7:0]: Access time
Device access time expressed in number of communication clock cycles
Bits 7:2 Reserved, must be kept at reset value.

Bit 1 WZL: Write zero latency
This bit enables zero latency on write operations.
- 0: Latency on write accesses
- 1: No latency on write accesses

Bit 0 LM: Latency mode
This bit selects the Latency mode.
- 0: Variable initial latency
- 1: Fixed latency

### 19.7.28 OCTOSPI register map

20 OCTOSPI I/O manager (OCTOSPIM)

20.1 Introduction
The OCTOSPI I/O manager is a low-level interface that enables:
- An efficient OCTOSPI pin assignment with a full I/O Matrix (before alternate function map)
- Multiplex of single/dual/quad/octal SPI interfaces over the same bus

20.2 OCTOSPIM main features
- Supports up to two single/dual/quad/octal SPI interfaces
- Supports up to two ports for pin assignment
- Fully programmable I/O matrix for pin assignment by function (data/control/clock)

20.3 OCTOSPIM implementation
The table below describes the OCTOSPIM implementation on STM32L4+ Series devices. The full list of features is implemented in STM32L4P5xx and STM32L4Q5xx devices, while STM32L4Rxxx and STM32L4Sxxx devices support a reduced set of features.

20.4 OCTOSPIM functional description

20.4.1 OCTOSPIM block diagram
The block diagram of the OCTOSPI I/O manager is shown in Figure 85.
1. The number of ports (n) is 2.
2. Arbitration is possible for both I/O matrix input ports.

1. The number of ports (n) is 2.
20.4.2 OCTOSPIM matrix

The OCTOSPI I/O manager matrix allows the user to set a fully programmable pre-mapping of functions:

- Any OCTOSPIM_Pn_CLK / OCTOSPIM_Pn_NCLK pair can be mapped independently to OCTOSPI1_CLK/OCTOSPI1_NCLK or OCTOSPI2_CLK/OCTOSPI2_NCLK
- Any OCTOSPIM_Pn_DQS can be mapped independently to OCTOSPI1_DQS or OCTOSPI2_DQS
- Any OCTOSPIM_Pn_NCS can be mapped independently to OCTOSPI1_NCS or OCTOSPI2_NCS
- Any OCTOSPIM_Pn_IO[3:0] and OCTOSPIM_Pn_IO[7:4] can be mapped independently to OCTOSPI1_IO[3:0], OCTOSPI1_IO[7:4], OCTOSPI2_IO1[3:0] or OCTOSPI2_IO[7:4]

For each OCTOSPI I/O manager port, individual signal enables and mapping are configured through the corresponding OCTOSPI I/O manager Port n configuration register (OCTOSPIM_PnCR).

When several I/O pins have the same configuration, and are enabled at the same time, the result can be unpredictable.

In the default out-of-reset configuration, all the OCTOSPI1 and OCTOSPI2 signals are mapped, respectively, on Port 1 and on Port 2.

The OCTOSPIM configuration can be changed only when both OCTOSPI1 and OCTOSPI2 are disabled.
20.4.3 OCTOSPIM multiplexed mode

When this mode is set the two OCTOSPIs are time-multiplexed over the same bus. Both OCTOSPIs get the ownership of the bus (in turn) through a request/acknowledge protocol with REQ/ACK signals.

The time-multiplexing is enabled by setting the MUXEN bit of the configuration register OCTOSPIM_CR.

The fairness counter (MAXTRAN) of each OCTOSPI can be used to accurately manage the maximum duration for which a given OCTOSPI takes the bus: this feature ensures a maximum bus access latency for the other OCTOSPIs. When the bus is released by one OCTOSPI, an arbitration phase occurs, which is round-robin: when the other OCTOSPI requests the bus, it gets it.

When the multiplexed mode is enabled, either the fairness counter or the refresh timeout counter of both OCTOSPI interfaces must be activated.

OCTOSPI1_nCS are not part of the multiplexing. Only OCTOSPI1_IOs, OCTOSPI1_DQS and OCTOSPI1_CLK / OCTOSPI1_NCLK are multiplexed.

When the multiplexed mode is used, only clock mode 0 is supported on the OCTOSPIs.

Due to arbitration and bus sharing, the auto polling interval time of the OCTOSPI, when used, may be increased.

The OCTOSPIM configuration can be changed only when both OCTOSPI1 and OCTOSPI2 are disabled.

Minimum switching duration

The minimum number of cycles needed to switch from an OCTOSPI to another can be configured.

This internal timer guarantees a latency between the falling edge of the REQ signal of the active OCTOSPI (the active OCTOSPI releases the bus), and the rising edge of the ACK signal to the requesting OCTOSPI (the bus is granted to the requesting OCTOSPI).

The duration is defined by the REQ2ACK_TIME fields of the configuration register OCTOSPIM_CR.

Pin mapping in Multiplexed mode

In Multiplexed mode, the mapping of the bus is done as described below:

- OCTOSPI1_nCS and OCTOSPI2_NCS work in the same way, then in Non-multiplexed mode they have to be assigned to their respective OCTOSPIM_Pn_NCS.
- All the other signals are seen by the I/O matrix as if they were seen from OCTOSPI1.
20.5 OCTOSPIM registers

20.5.1 OCTOSPIM control register (OCTOSPIM_CR)

Address offset: 0x0000
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Address offset: 0x0000 + 0x04*n (n=1 to 2)</th>
<th>Reset value: 0x0301 0111, 0x0705 0333</th>
</tr>
</thead>
</table>

- **Bits 31:24**: Reserved, must be kept at reset value.
- **Bits 23:16**: `REQ2ACK_TIME[7:0]`: REQ to ACK time
  - In Multiplexed mode (MUXEN = 1), this field defines the time between two transactions.
  - The value is the number of OCTOSPI clock cycles - 1
- **Bits 15:1**: Reserved, must be kept at reset value.
- **Bit 0**: `MUXEN`: Multiplexed mode enable
  - This bit enables the multiplexing of the two OCTOSPIs.
  - 0: No multiplexing, hence no arbitration
  - 1: OCTOSP1 and OCTOSP12 are multiplexed over the same bus.

20.5.2 OCTOSPIM Port n configuration register (OCTOSPIM_PnCR)

Address offset: 0x0000 + 0x04*n (n=1 to 2)
Reset value: 0x0301 0111, 0x0705 0333

<table>
<thead>
<tr>
<th>Address offset: 0x0000 + 0x04*n (n=1 to 2)</th>
<th>Reset value: 0x0301 0111, 0x0705 0333</th>
</tr>
</thead>
</table>

- **Bits 31:27**: Reserved, must be kept at reset value.
  - This bits select the source of Port n IO[7:4].
  - 00: OCTOSP1_IO[3:0] in non multiplexed mode / multiplexed_IO[3:0] in multiplexed mode
  - 10: OCTOSP12_IO[3:0] in non multiplexed mode / unused in multiplexed mode
  - 11: OCTOSP12_IO[7:4] in non multiplexed mode / unused in multiplexed mode
Bit 24  **IOHEN**: IO[7:4] enable for Port n
This bit enables the Port n IO[7:4].
0: IO[7:4] for Port n disabled
1: IO[7:4] for Port n enabled

Bits 23:19  Reserved, must be kept at reset value.

Bits 18:17  **IOLSRC[1:0]**: IO[3:0] source for Port n
This bits select the source of Port n IO[3:0].
00: OCTOSPI1_IO[3:0] in non multiplexed mode / multiplexed_IO[3:0] in multiplexed mode
10: OCTOSPI2_IO[3:0] in non multiplexed mode / unused in multiplexed mode
11: OCTOSPI2_IO[7:4] in non multiplexed mode / unused in multiplexed mode

Bit 16  **IOLEN**: IO[3:0] enable for Port n
This bit enables the Port n IO[3:0].
0: IO[3:0] for Port n disabled
1: IO[3:0] for Port n enabled

Bits 15:10  Reserved, must be kept at reset value.

Bit 9  **NCSSRC**: nCS source for Port n
This bit selects the source of Port n nCS.
0: OCTOSPI1_nCS
1: OCTOSPI2_nCS

Bit 8  **NCSEN**: nCS enable for Port n
This bit enables the Port n nCS.
0: nCS for Port n is disabled
1: nCS for Port n is enabled

Bits 7:6  Reserved, must be kept at reset value.

Bit 5  **DQSSRC**: DQS source for Port n
This bit selects the source of Port n DQS.
0: OCTOSPI1_DQS in non multiplexed mode / multiplexed_DQS in multiplexed mode
1: OCTOSPI2_DQS in non multiplexed mode / unused port in multiplexed mode

Bit 4  **DQSEN**: DQS enable for Port n
This bit enables the Port n DQS.
0: DQS for Port n is disabled
1: DQS for Port n is enabled

Bits 3:2  Reserved, must be kept at reset value.

Bit 1  **CLKSRC**: CLK/CLKn source for Port n
This bit selects the source of Port n CLK/CLKn.
0: OCTOSPI1_CLK/CLKn in non multiplexed mode / multiplexed_CLK/CLKn in multiplexed mode
1: OCTOSPI2_CLK/CLKn in non multiplexed mode / unused port in multiplexed mode

Bit 0  **CLKEN**: CLK/CLKn enable for Port n
This bit enables the Port n CLK/CLKn.
0: CLK/CLKn for Port n is disabled
1: CLK/CLKn for Port n is enabled
20.5.3 OCTOSPIM register map

The following table summarizes the OCTOSPIM I/O manager registers.

| Offset | Register name     | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|--------|-------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 0x0000 | OCTOSPIM _CR     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | Reset value      | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| 0x0004 | OCTOSPIM _P1CR   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | Reset value      | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| 0x0008 | OCTOSPIM _P2CR   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | Reset value      | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |

Refer to Section 2.2 on page 93 for the register boundary addresses.
21 Analog-to-digital converters (ADC)

21.1 Introduction

This section describes the implementation of up to 2 ADCs:

- ADC1 and ADC2 are tightly coupled and can operate in dual mode (ADC1 is master).

Each ADC consists of a 12-bit successive approximation analog-to-digital converter.

Each ADC has up to 19 multiplexed channels. A/D conversion of the various channels can be performed in single, continuous, scan or discontinuous mode. The result of the ADC is stored in a left-aligned or right-aligned 16-bit data register.

The ADCs are mapped on the AHB bus to allow fast data handling.

The analog watchdog features allow the application to detect if the input voltage goes outside the user-defined high or low thresholds.

A built-in hardware oversampler allows to improve analog performance while off-loading the related computational burden from the CPU.

An efficient low-power mode is implemented to allow very low consumption at low frequency.
21.2 ADC main features

- **High-performance features**
  - Up to 2 ADCs which can operate in dual mode:
    - ADC1 is connected to 16 external channels + 3 internal channels
    - ADC2 is connected to 16 external channels + 2 internal channels
  - 12, 10, 8 or 6-bit configurable resolution
  - ADC conversion time is independent from the AHB bus clock frequency
  - Faster conversion time by lowering resolution
  - Manage single-ended or differential inputs
  - AHB slave bus interface to allow fast data handling
  - Self-calibration
  - Channel-wise programmable sampling time
  - Up to four injected channels (analog inputs assignment to regular or injected channels is fully configurable)
  - Hardware assistant to prepare the context of the injected channels to allow fast context switching
  - Data alignment with in-built data coherency
  - Data can be managed by DMA for regular channel conversions
  - Data can be routed to DFSDM for post processing
  - 4 dedicated data registers for the injected channels

- **Oversampler**
  - 16-bit data register
  - Oversampling ratio adjustable from 2 to 256
  - Programmable data shift up to 8-bit

- **Low-power features**
  - Speed adaptive low-power mode to reduce ADC consumption when operating at low frequency
  - Allows slow bus frequency application while keeping optimum ADC performance
  - Provides automatic control to avoid ADC overrun in low AHB bus clock frequency application (auto-delayed mode)

- **Number of external analog input channels per ADC**
  - Up to 5 fast channels from GPIO pads
  - Up to 11 slow channels from GPIO pads

- **In addition, there are several internal dedicated channels**
  - The internal reference voltage (V_{REFINT}), connected to ADC1
  - The internal temperature sensor (V_{TS}), connected to ADC1
  - The V_{BAT} monitoring channel (V_{BAT}/3), connected to ADC1
  - DAC1 and DAC2 internal channels, connected to ADC2

- **Start-of-conversion can be initiated:**
  - By software for both regular and injected conversions
  - By hardware triggers with configurable polarity (internal timers events or GPIO input events) for both regular and injected conversions
• Conversion modes
  – Each ADC can convert a single channel or can scan a sequence of channels
  – Single mode converts selected inputs once per trigger
  – Continuous mode converts selected inputs continuously
  – Discontinuous mode
• Dual ADC mode for ADC1 and 2
• Interrupt generation at ADC ready, the end of sampling, the end of conversion (regular or injected), end of sequence conversion (regular or injected), analog watchdog 1, 2 or 3 or overrun events
• 3 analog watchdogs per ADC
• ADC input range: $V_{\text{REF}}^- \leq V_{\text{IN}} \leq V_{\text{REF}}^+$

21.4.3 ADC clocks

Dual clock domain architecture

The dual clock-domain architecture means that the ADC clock is independent from the AHB bus clock.

The input clock is the same for all ADCs and can be selected between two different clock sources (see Figure 88: ADC clock scheme):

1. The ADC clock can be a specific clock source, derived from the following clock sources:
   - The system clock
   - PLLSAI1 (single ADC implementation)
   Refer to RCC Section for more information on how to generate ADC dedicated clock.
   To select this scheme, bits CKMODE[1:0] of the ADCx_CCR register must be reset.

2. The ADC clock can be derived from the AHB clock of the ADC bus interface, divided by a programmable factor (1, 2 or 4). In this mode, a programmable divider factor can be selected (/1, 2 or 4 according to bits CKMODE[1:0]).
   To select this scheme, bits CKMODE[1:0] of the ADCx_CCR register must be different from “00”.

Note: For option 2), a prescaling factor of 1 (CKMODE[1:0]=01) can be used only if the AHB prescaler is set to 1 (HPRE[3:0] = 0xxx in RCC_CFGR register).

Option 1) has the advantage of reaching the maximum ADC clock frequency whatever the AHB clock scheme selected. The ADC clock can eventually be divided by the following ratio: 1, 2, 4, 6, 8, 12, 16, 32, 64, 128, 256; using the prescaler configured with bits PRESC[3:0] in the ADCx_CCR register.

Option 2) has the advantage of bypassing the clock domain resynchronizations. This can be useful when the ADC is triggered by a timer and if the application requires that the ADC is precisely triggered without any uncertainty (otherwise, an uncertainty of the trigger instant time is added by the resynchronizations between the two clock domains).

Clock ratio constraint between ADC clock and AHB clock

There are generally no constraints to be respected for the ratio between the ADC clock and the AHB clock except if some injected channels are programmed. In this case, it is mandatory to respect the following ratio:

- \( F_{\text{HCLK}} \geq F_{\text{ADC}} / 4 \) if the resolution of all channels are 12-bit or 10-bit
- \( F_{\text{HCLK}} \geq F_{\text{ADC}} / 3 \) if there are some channels with resolutions equal to 8-bit (and none with lower resolution)
- \( F_{\text{HCLK}} \geq F_{\text{ADC}} / 2 \) if there are some channels with resolutions equal to 6-bit
21.4.4 ADC1/2 connectivity

ADC1 and ADC2 are tightly coupled and share some external channels as described in the below figures.

Figure 89. ADC1 connectivity
Figure 90. ADC2 connectivity
21.4.5 Slave AHB interface

The ADCs implement an AHB slave port for control/status register and data access. The features of the AHB interface are listed below:

- Word (32-bit) accesses
- Single cycle response
- Response to all read/write accesses to the registers with zero wait states.

The AHB slave interface does not support split/retry requests, and never generates AHB errors.

21.4.6 ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)

By default, the ADC is in Deep-power-down mode where its supply is internally switched off to reduce the leakage currents (the reset state of bit DEEPPWD is 1 in the ADC_CR register).

To start ADC operations, it is first needed to exit Deep-power-down mode by setting bit DEEPPWD=0.

When ADC operations are complete, the ADC can be disabled (ADEN=0). It is possible to save power by also disabling the ADC voltage regulator. This is done by writing bit ADVREGEN=0.

Then, to save more power by reducing the leakage currents, it is also possible to re-enter in ADC Deep-power-down mode by setting bit DEEPPWD=1 into ADC_CR register. This is particularly interesting before entering Stop mode.

Note: Writing DEEPPWD=1 automatically disables the ADC voltage regulator and bit ADVREGEN is automatically cleared.

When the internal voltage regulator is disabled (ADVREGEN=0), the internal analog calibration is kept.

In ADC Deep-power-down mode (DEEPPWD=1), the internal analog calibration is lost and it is necessary to either relaunch a calibration or re-apply the calibration factor which was previously saved (refer to Section 21.4.8: Calibration (ADCAL, ADCALDIF, ADC_CALFACT)).

21.4.7 Single-ended and differential input channels

Channels can be configured to be either single-ended input or differential input by programming DIFSEL[i] bits in the ADC_DIFSEL register. This configuration must be written while the ADC is disabled (ADEN=0). Note that the DIFSEL[i] bits corresponding to single-ended channels are always programmed at 0.

In single-ended input mode, the analog voltage to be converted for channel “i” is the difference between the ADCy_INPx external voltage equal to VINP[i] (positive input) and VREF− (negative input).

In differential input mode, the analog voltage to be converted for channel “i” is the difference between the ADCy_INPx external voltage positive input equal to VINP[i], and the ADCy_INNx negative input equal to VINN[i].

The input voltage in differential mode ranges from VREF− to VREF+, which makes a full scale range of 2xVREF+. When VINP[i] equals VREF−, VINN[i] equals VREF+, and the maximum
negative input differential voltage (VREF-) corresponds to 0x000 ADC output. When V_{INP[i]} equals V_{REF+}, V_{INN[i]} equals V_{REF-}, and the maximum positive input differential voltage (V_{REF+}) corresponds to 0xFFF ADC output. When V_{INP[i]} and V_{INN[i]} are connected together, the zero input differential voltage corresponds to 0x800 ADC output.

The ADC sensitivity in differential mode is twice smaller than in single-ended mode.

When ADC is configured as differential mode, both inputs should be biased at (V_{REF+}) / 2 voltage. Refer to the device datasheet for the allowed common mode input voltage V_{CMIN}.

The input signals are supposed to be differential (common mode voltage should be fixed). Internal channels (such as V_{TS} and V_{REFINT}) are used in single-ended mode only.

For a complete description of how the input channels are connected for each ADC, refer to Section 21.4.4: ADC1/2 connectivity.

Caution: When configuring the channel "i" in differential input mode, its negative input voltage V_{INN[i]} is connected to another channel. As a consequence, this channel is no longer usable in single-ended mode or in differential mode and must never be configured to be converted. Some channels are shared between ADC1/ADC2: this can make the channel on the other ADC unusable. Only exception is interleaved mode for ADC master and the slave.

21.4.8 Calibration (ADCAL, ADCALDIF, ADC_CALFACT)

Each ADC provides an automatic calibration procedure which drives all the calibration sequence including the power-on/off sequence of the ADC. During the procedure, the ADC calculates a calibration factor which is 7-bit wide and which is applied internally to the ADC until the next ADC power-off. During the calibration procedure, the application must not use the ADC and must wait until calibration is complete.

Calibration is preliminary to any ADC operation. It removes the offset error which may vary from chip to chip due to process or bandgap variation.

The calibration factor to be applied for single-ended input conversions is different from the factor to be applied for differential input conversions:

- Write ADCALDIF=0 before launching a calibration which will be applied for single-ended input conversions.
- Write ADCALDIF=1 before launching a calibration which will be applied for differential input conversions.

The calibration is then initiated by software by setting bit ADCAL=1. Calibration can only be initiated when the ADC is disabled (when ADEN=0). ADCAL bit stays at 1 during all the calibration sequence. It is then cleared by hardware as soon the calibration completes. At this time, the associated calibration factor is stored internally in the analog ADC and also in the bits CALFACT_S[6:0] or CALFACT_D[6:0] of ADC_CALFACT register (depending on single-ended or differential input calibration).

The internal analog calibration is kept if the ADC is disabled (ADEN=0). However, if the ADC is disabled for extended periods, then it is recommended that a new calibration cycle is run before re-enabling the ADC.

The internal analog calibration is lost each time the power of the ADC is removed (example, when the product enters in Standby or VBAT mode). In this case, to avoid spending time recalibrating the ADC, it is possible to re-write the calibration factor into the ADC_CALFACT register without recalibrating, supposing that the software has previously saved the calibration factor delivered during the previous calibration.
The calibration factor can be written if the ADC is enabled but not converting (ADEN=1 and ADSTART=0 and JADSTART=0). Then, at the next start of conversion, the calibration factor will automatically be injected into the analog ADC. This loading is transparent and does not add any cycle latency to the start of the conversion. It is recommended to recalibrate when $V_{REF+}$ voltage changed more than 10%.

**Software procedure to calibrate the ADC**

1. Ensure DEEPPWD=0, ADVREGEN=1 and that ADC voltage regulator startup time has elapsed.
2. Ensure that ADEN=0.
3. Select the input mode for this calibration by setting ADCALDIF=0 (single-ended input) or ADCALDIF=1 (differential input).
4. Set ADCAL=1.
5. Wait until ADCAL=0.
6. The calibration factor can be read from ADC_CALFACT register.

**Software procedure to re-inject a calibration factor into the ADC**

1. Ensure ADEN=1 and ADSTART=0 and JADSTART=0 (ADC enabled and no conversion is ongoing).
2. Write CALFACT_S and CALFACT_D with the new calibration factors.
3. When a conversion is launched, the calibration factor will be injected into the analog ADC only if the internal analog calibration factor differs from the one stored in bits CALFACT_S for single-ended input channel or bits CALFACT_D for differential input channel.
If the ADC is supposed to convert both differential and single-ended inputs, two calibrations must be performed, one with ADCALDIF=0 and one with ADCALDIF=1. The procedure is the following:

1. Disable the ADC.
2. Calibrate the ADC in single-ended input mode (with ADCALDIF=0). This updates the register CALFACT_S[6:0].
3. Calibrate the ADC in differential input modes (with ADCALDIF=1). This updates the register CALFACT_D[6:0].
4. Enable the ADC, configure the channels and launch the conversions. Each time there is a switch from a single-ended to a differential inputs channel (and vice-versa), the calibration will automatically be injected into the analog ADC.
21.4.9 ADC on-off control (ADEN, ADDIS, ADRDY)

First of all, follow the procedure explained in Section 21.4.6: ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)).

Once DEEPPWD=0 and ADVREGEN=1, the ADC can be enabled and the ADC needs a stabilization time of $t_{STAB}$ before it starts converting accurately, as shown in Figure 94. Two control bits enable or disable the ADC:

- ADEN=1 enables the ADC. The flag ADRDY will be set once the ADC is ready for operation.
- ADDIS=1 disables the ADC. ADEN and ADDIS are then automatically cleared by hardware as soon as the analog ADC is effectively disabled.

Regular conversion can then start either by setting ADSTART=1 (refer to Section 21.4.18: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN)) or when an external trigger event occurs, if triggers are enabled.

Injected conversions start by setting JADSTART=1 or when an external injected trigger event occurs, if injected triggers are enabled.

**Software procedure to enable the ADC**

1. Clear the ADRDY bit in the ADC_ISR register by writing ‘1’.
2. Set ADEN=1.
3. Wait until ADRDY=1 (ADRDY is set after the ADC startup time). This can be done using the associated interrupt (setting ADRDYIE=1).
4. Clear the ADRDY bit in the ADC_ISR register by writing ‘1’ (optional).

**Caution:** ADEN bit cannot be set when ADCAL is set and during four ADC clock cycles after the ADCAL bit is cleared by hardware (end of the calibration).

**Software procedure to disable the ADC**

1. Check that both ADSTART=0 and JADSTART=0 to ensure that no conversion is ongoing. If required, stop any regular and injected conversion ongoing by setting ADSTP=1 and JADSTP=1 and then wait until ADSTP=0 and JADSTP=0.
2. Set ADDIS=1.
3. If required by the application, wait until ADEN=0, until the analog ADC is effectively disabled (ADDIS will automatically be reset once ADEN=0).
21.4.10 Constraints when writing the ADC control bits

The software is allowed to write the RCC control bits to configure and enable the ADC clock (refer to RCC Section), the DIFSEL[i] control bits in the ADC_DIFSEL register and the control bits ADCAL and ADEN in the ADC_CR register, only if the ADC is disabled (ADEN must be equal to 0).

The software is then allowed to write the control bits ADSTART, JADSTART and ADDIS of the ADC_CR register only if the ADC is enabled and there is no pending request to disable the ADC (ADEN must be equal to 1 and ADDIS to 0).

For all the other control bits of the ADC_CFRG, ADC_SMPRx, ADC_SQRy, ADC_JDRy, ADC_OFRy, ADC_OFCHRy and ADC_IER registers:
- For control bits related to configuration of regular conversions, the software is allowed to write them only if the ADC is enabled (ADEN=1) and if there is no regular conversion ongoing (ADSTART must be equal to 0).
- For control bits related to configuration of injected conversions, the software is allowed to write them only if the ADC is enabled (ADEN=1) and if there is no injected conversion ongoing (JADSTART must be equal to 0).

The software is allowed to write the ADSTP or JADSTP control bits of the ADC_CR register only if the ADC is enabled, possibly converting, and if there is no pending request to disable the ADC (ADSTART or JADSTART must be equal to 1 and ADDIS to 0).

The software can write the register ADC_JSQR at any time, when the ADC is enabled (ADEN=1). Refer to Section 21.6.16: ADC injected sequence register (ADC_JSQR) for additional details.

Note: There is no hardware protection to prevent these forbidden write accesses and ADC behavior may become in an unknown state. To recover from this situation, the ADC must be disabled (clear ADEN=0 as well as all the bits of ADC_CR register).
21.4.11 Channel selection (SQRx, JSQRx)

There are up to 19 multiplexed channels per ADC:

- 5 fast analog inputs coming from GPIO pads (ADCx_INP/INN[1:5])
- Up to 11 slow analog inputs coming from GPIO pads (ADCx_INP/INN[6:16])
- The ADCs are connected to the following internal analog inputs:
  - The internal reference voltage (VREFINT) is connected to ADC1_INP0.
  - The internal temperature sensor (VTS) is connected to ADC1_INP17.
  - The VBAT monitoring channel (VBAT/3) is connected to ADC1_INP18.
  - The DAC1 internal channel 1 is connected to ADC2_INP17.
  - The DAC1 internal channel 2 is connected to ADC2_INP18.

Note: To convert one of the internal analog channels, the corresponding analog sources must first be enabled by programming bits VREFEN, CH17SEL or CH18SEL in the ADCx_CCR registers.

It is possible to organize the conversions in two groups: regular and injected. A group consists of a sequence of conversions that can be done on any channel and in any order. For instance, it is possible to implement the conversion sequence in the following order: ADCx_INP/INN3, ADCx_INP/INN8, ADCx_INP/INN2, ADCx_INN/INP2, ADCx_INP/INN0, ADCx_INP/INN2, ADCx_INP/INN2, ADCx_INP/INN15.

- A regular group is composed of up to 16 conversions. The regular channels and their order in the conversion sequence must be selected in the ADC_SQRy registers. The total number of conversions in the regular group must be written in the L[3:0] bits in the ADC_SQR1 register.

- An injected group is composed of up to 4 conversions. The injected channels and their order in the conversion sequence must be selected in the ADC_JSQR register. The total number of conversions in the injected group must be written in the L[1:0] bits in the ADC_JSQR register.

ADC_SQRy registers must not be modified while regular conversions can occur. For this, the ADC regular conversions must be first stopped by writing ADSTP=1 (refer to Section 21.4.17: Stopping an ongoing conversion (ADSTP, JADSTP)).

The software is allowed to modify on-the-fly the ADC_JSQR register when JADSTART is set to 1 (injected conversions ongoing) only when the context queue is enabled (JQDIS=0 in ADC_CFGR register). Refer to Section 21.4.21: Queue of context for injected conversions.
21.4.12 Channel-wise programmable sampling time (SMPR1, SMPR2)

Before starting a conversion, the ADC must establish a direct connection between the voltage source under measurement and the embedded sampling capacitor of the ADC. This sampling time must be enough for the input voltage source to charge the embedded capacitor to the input voltage level.

Each channel can be sampled with a different sampling time which is programmable using the SMP[2:0] bits in the ADC_SMPR1 and ADC registers. It is therefore possible to select among the following sampling time values:

- SMP = 000: 2.5 ADC clock cycles
- SMP = 001: 6.5 ADC clock cycles
- SMP = 010: 12.5 ADC clock cycles
- SMP = 011: 24.5 ADC clock cycles
- SMP = 100: 47.5 ADC clock cycles
- SMP = 101: 92.5 ADC clock cycles
- SMP = 110: 247.5 ADC clock cycles
- SMP = 111: 640.5 ADC clock cycles

The total conversion time is calculated as follows:

\[ T_{\text{CONV}} = \text{Sampling time} + 12.5 \text{ ADC clock cycles} \]

Example:

With \( F_{\text{ADC.CLK}} = 30 \text{ MHz} \) and a sampling time of 2.5 ADC clock cycles:

\[ T_{\text{CONV}} = (2.5 + 12.5) \text{ ADC clock cycles} = 15 \text{ ADC clock cycles} = 500 \text{ ns} \]

The ADC notifies the end of the sampling phase by setting the status bit EOSMP (only for regular conversion).

Constraints on the sampling time

For each channel, SMP[2:0] bits must be programmed to respect a minimum sampling time as specified in the ADC characteristics section of the datasheets.

I/O analog switches voltage booster

The I/O analog switches resistance increases when the VDDA voltage is too low. This requires to have the sampling time adapted accordingly (cf datasheet for electrical characteristics). This resistance can be minimized at low VDDA by enabling an internal voltage booster with BOOSTEN bit in the SYSCFG_CFGR1 register.

SMPPLUS control bit

When a sampling time of 2.5 ADC clock cycles is selected, the total conversion time becomes 15 cycles in 12-bit mode. If the dual interleaved mode is used (see Section: Interleaved mode with independent injected), the sampling interval cannot be equal to the value specified since an even number of cycles is required for the conversion. The SMPPLUS bit can be used to change the sampling time 2.5 ADC clock cycles into 3.5 ADC clock cycles. In this way, the total conversion time becomes 16 clock cycles, thus making possible to interleave every 8 cycles.
21.4.13 Single conversion mode (CONT=0)

In Single conversion mode, the ADC performs once all the conversions of the channels. This mode is started with the CONT bit at 0 by either:

- Setting the ADSTART bit in the ADC_CR register (for a regular channel)
- Setting the JADSTART bit in the ADC_CR register (for an injected channel)
- External hardware trigger event (for a regular or injected channel)

Inside the regular sequence, after each conversion is complete:

- The converted data are stored into the 16-bit ADC_DR register
- The EOC (end of regular conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

Inside the injected sequence, after each conversion is complete:

- The converted data are stored into one of the four 16-bit ADC_JDRy registers
- The JEOC (end of injected conversion) flag is set
- An interrupt is generated if the JEOCIE bit is set

After the regular sequence is complete:

- The EOS (end of regular sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

After the injected sequence is complete:

- The JEOS (end of injected sequence) flag is set
- An interrupt is generated if the JEOSIE bit is set

Then the ADC stops until a new external regular or injected trigger occurs or until bit ADSTART or JADSTART is set again.

Note: To convert a single channel, program a sequence with a length of 1.

21.4.14 Continuous conversion mode (CONT=1)

This mode applies to regular channels only.

In continuous conversion mode, when a software or hardware regular trigger event occurs, the ADC performs once all the regular conversions of the channels and then automatically restarts and continuously converts each conversion of the sequence. This mode is started with the CONT bit at 1 either by external trigger or by setting the ADSTART bit in the ADC_CR register.

Inside the regular sequence, after each conversion is complete:

- The converted data are stored into the 16-bit ADC_DR register
- The EOC (end of conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

After the sequence of conversions is complete:

- The EOS (end of sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

Then, a new sequence restarts immediately and the ADC continuously repeats the conversion sequence.
Note: To convert a single channel, program a sequence with a length of 1.

It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN=1 and CONT=1.

Injected channels cannot be converted continuously. The only exception is when an injected channel is configured to be converted automatically after regular channels in continuous mode (using JAUTO bit), refer to Auto-injection mode section).

21.4.15 Starting conversions (ADSTART, JADSTART)

Software starts ADC regular conversions by setting ADSTART=1.

When ADSTART is set, the conversion starts:
- Immediately: if EXTEN[1:0] = 00 (software trigger)
- At the next active edge of the selected regular hardware trigger: if EXTEN[1:0] is not equal to 00

Software starts ADC injected conversions by setting JADSTART=1.

When JADSTART is set, the conversion starts:
- Immediately, if JEXTEN[1:0] = 00 (software trigger)
- At the next active edge of the selected injected hardware trigger: if JEXTEN[1:0] is not equal to 00

Note: In auto-injection mode (JAUTO=1), use ADSTART bit to start the regular conversions followed by the auto-injected conversions (JADSTART must be kept cleared).

ADSTART and JADSTART also provide information on whether any ADC operation is currently ongoing. It is possible to re-configure the ADC while ADSTART=0 and JADSTART=0 are both true, indicating that the ADC is idle.

ADSTART is cleared by hardware:
- In single mode with software regular trigger (CONT=0, EXTSEL=0x0)
  - At any end of regular conversion sequence (EOS assertion) or at any end of subgroup processing if DISCEN = 1
- In all cases (CONT=x, EXTSEL=x)
  - After execution of the ADSTP procedure asserted by the software.

Note: In continuous mode (CONT=1), ADSTART is not cleared by hardware with the assertion of EOS because the sequence is automatically relaunched.

When a hardware trigger is selected in single mode (CONT=0 and EXTSEL≠0x00), ADSTART is not cleared by hardware with the assertion of EOS to help the software which does not need to reset ADSTART again for the next hardware trigger event. This ensures that no further hardware triggers are missed.

JADSTART is cleared by hardware:
- In single mode with software injected trigger (JEXTSEL = 0x0)
  - At any end of injected conversion sequence (JEOS assertion) or at any end of subgroup processing if JDISCEN = 1
- In all cases (JEXTSEL=x)
  - After execution of the JADSTP procedure asserted by the software.

Note: When the software trigger is selected, ADSTART bit should not be set if the EOC flag is still high.
21.4.16 ADC timing

The elapsed time between the start of a conversion and the end of conversion is the sum of the configured sampling time plus the successive approximation time depending on data resolution:

\[ T_{\text{CONV}} = T_{\text{SMPL}} + T_{\text{SAR}} = [2.5 \text{ min} + 12.5 \text{ 12bit}] \times T_{\text{ADC_CLK}} \]

\[ T_{\text{CONV}} = T_{\text{SMPL}} + T_{\text{SAR}} = 83.33 \text{ ns min} + 416.67 \text{ ns 12bit} = 500.0 \text{ ns (for } F_{\text{ADC_CLK}} = 30 \text{ MHz)} \]

![Figure 95. Analog to digital conversion time](image)

1. \( T_{\text{SMPL}} \) depends on \( \text{SMP}[2:0] \).
2. \( T_{\text{SAR}} \) depends on \( \text{RES}[2:0] \).

21.4.17 Stopping an ongoing conversion (ADSTP, JADSTP)

The software can decide to stop regular conversions ongoing by setting ADSTP=1 and injected conversions ongoing by setting JADSTP=1.

Stopping conversions will reset the ongoing ADC operation. Then the ADC can be reconfigured (ex: changing the channel selection or the trigger) ready for a new operation.

Note that it is possible to stop injected conversions while regular conversions are still operating and vice-versa. This allows, for instance, re-configuration of the injected conversion sequence and triggers while regular conversions are still operating (and vice-versa).

When the ADSTP bit is set by software, any ongoing regular conversion is aborted with partial result discarded (ADC_DR register is not updated with the current conversion).

When the JADSTP bit is set by software, any ongoing injected conversion is aborted with partial result discarded (ADC_JDRy register is not updated with the current conversion). The scan sequence is also aborted and reset (meaning that relaunching the ADC would restart a new sequence).

Once this procedure is complete, bits ADSTP/ADSTART (in case of regular conversion), or JADSTP/JADSTART (in case of injected conversion) are cleared by hardware and the software must poll ADSTART (or JADSTART) until the bit is reset before assuming the ADC is completely stopped.
Note: In auto-injection mode (JAUTO=1), setting ADSTP bit aborts both regular and injected conversions (JADSTP must not be used).

21.4.18 Conversion on external trigger and trigger polarity
(EXTSEL, EXTEN, JEXTSEL, JEXTEN)

A conversion or a sequence of conversions can be triggered either by software or by an external event (e.g. timer capture, input pins). If the EXTEN[1:0] control bits (for a regular conversion) or JEXTEN[1:0] bits (for an injected conversion) are different from 0b00, then external events are able to trigger a conversion with the selected polarity.

When the Injected Queue is enabled (bit JQDIS=0), injected software triggers are not possible.

The regular trigger selection is effective once software has set bit ADSTART=1 and the injected trigger selection is effective once software has set bit JADSTART=1.

Any hardware triggers which occur while a conversion is ongoing are ignored.
- If bit ADSTART=0, any regular hardware triggers which occur are ignored.
- If bit JADSTART=0, any injected hardware triggers which occur are ignored.

Table 129 provides the correspondence between the EXTEN[1:0] and JEXTEN[1:0] values and the trigger polarity.

Table 129. Configuring the trigger polarity for regular external triggers

<table>
<thead>
<tr>

</tbody>
</table>

Note: The polarity of the regular trigger cannot be changed on-the-fly.

Table 130. Configuring the trigger polarity for injected external triggers

<table>
<thead>
<tr>
<th>JEXTEN[1:0]</th>
<th>Source</th>
</tr>
</thead>
</table>
| 00          | – If JQDIS=1 (Queue disabled): Hardware trigger detection disabled, software trigger detection enabled  
              – If JQDIS=0 (Queue enabled), Hardware and software trigger detection disabled |
| 01          | Hardware Trigger with detection on the rising edge            |
| 10          | Hardware Trigger with detection on the falling edge            |
| 11          | Hardware Trigger with detection on both the rising and falling edges |

Note: The polarity of the injected trigger can be anticipated and changed on-the-fly when the queue is enabled (JQDIS=0). Refer to Section 21.4.21: Queue of context for injected conversions.

The EXTSEL and JEXTSEL control bits select which out of 16 possible events can trigger conversion for the regular and injected groups.

A regular group conversion can be interrupted by an injected trigger.
Note: The regular trigger selection cannot be changed on-the-fly. The injected trigger selection can be anticipated and changed on-the-fly. Refer to Section 21.4.21: Queue of context for injected conversions on page 642.

Each ADC master shares the same input triggers with its ADC slave as described in Figure 98.

Figure 98. Triggers sharing between ADC master and ADC slave

Table 131 to Table 132 give all the possible external triggers of the three ADCs for regular and injected conversions.

21.4.19 Injected channel management

Triggered injection mode

To use triggered injection, the JAUTO bit in the ADC_CFRG register must be cleared.

1. Start the conversion of a group of regular channels either by an external trigger or by setting the ADSTART bit in the ADC_CR register.
2. If an external injected trigger occurs, or if the JADSTART bit in the ADC_CR register is set during the conversion of a regular group of channels, the current conversion is...
reset and the injected channel sequence switches are launched (all the injected channels are converted once).

3. Then, the regular conversion of the regular group of channels is resumed from the last interrupted regular conversion.

4. If a regular event occurs during an injected conversion, the injected conversion is not interrupted but the regular sequence is executed at the end of the injected sequence. Figure 99 shows the corresponding timing diagram.

**Note:** When using triggered injection, one must ensure that the interval between trigger events is longer than the injection sequence. For instance, if the sequence length is 30 ADC clock cycles (that is two conversions with a sampling time of 2.5 clock periods), the minimum interval between triggers must be 31 ADC clock cycles.

**Auto-injection mode**

If the JAUTO bit in the ADC_CFGR register is set, then the channels in the injected group are automatically converted after the regular group of channels. This can be used to convert a sequence of up to 20 conversions programmed in the ADC_SQRy and ADC_JSQR registers.

In this mode, the ADSTART bit in the ADC_CR register must be set to start regular conversions, followed by injected conversions (JADSTART must be kept cleared). Setting the ADSTP bit aborts both regular and injected conversions (JADSTP bit must not be used).

In this mode, external trigger on injected channels must be disabled.

If the CONT bit is also set in addition to the JAUTO bit, regular channels followed by injected channels are continuously converted.

**Note:** It is not possible to use both the auto-injected and discontinuous modes simultaneously.

When the DMA is used for exporting regular sequencer’s data in JAUTO mode, it is necessary to program it in circular mode (CIRC bit set in DMA_CCRx register). If the CIRC bit is reset (single-shot mode), the JAUTO sequence will be stopped upon DMA Transfer Complete event.
21.4.20 Discontinuous mode (DISCEN, DISCNUM, JDISCEN)

Regular group mode

This mode is enabled by setting the DISCEN bit in the ADC_CFGR register.

It is used to convert a short sequence (subgroup) of n conversions (n ≤ 8) that is part of the sequence of conversions selected in the ADC_SQRy registers. The value of n is specified by writing to the DISCNUM[2:0] bits in the ADC_CFGR register.

When an external trigger occurs, it starts the next n conversions selected in the ADC_SQRy registers until all the conversions in the sequence are done. The total sequence length is defined by the L[3:0] bits in the ADC_SQR1 register.

Example:
- DISCEN=1, n=3, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10, 11
  - 1st trigger: channels converted are 1, 2, 3 (an EOC event is generated at each conversion).
  - 2nd trigger: channels converted are 6, 7, 8 (an EOC event is generated at each conversion).
  - 3rd trigger: channels converted are 9, 10, 11 (an EOC event is generated at each conversion) and an EOS event is generated after the conversion of channel 11.
  - 4th trigger: channels converted are 1, 2, 3 (an EOC event is generated at each conversion).
  - ...
- DISCEN=0, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10, 11
  - 1st trigger: the complete sequence is converted: channel 1, then 2, 3, 6, 7, 8, 9, 10 and 11. Each conversion generates an EOC event and the last one also generates an EOS event.
  - All the next trigger events will relaunch the complete sequence.

1. The maximum latency value can be found in the electrical characteristics of the device datasheet.
Note: The channel numbers referred to in the above example might not be available on all microcontrollers.

When a regular group is converted in discontinuous mode, no rollover occurs (the last subgroup of the sequence can have less than n conversions).

When all subgroups are converted, the next trigger starts the conversion of the first subgroup. In the example above, the 4th trigger reconverts the channels 1, 2 and 3 in the 1st subgroup.

It is not possible to have both discontinuous mode and continuous mode enabled. In this case (if DISCEN=1, CONT=1), the ADC behaves as if continuous mode was disabled.

**Injected group mode**

This mode is enabled by setting the JDISCEN bit in the ADC_CFGR register. It converts the sequence selected in the ADC_JSQR register, channel by channel, after an external injected trigger event. This is equivalent to discontinuous mode for regular channels where ‘n’ is fixed to 1.

When an external trigger occurs, it starts the next channel conversions selected in the ADC_JSQR registers until all the conversions in the sequence are done. The total sequence length is defined by the JL[1:0] bits in the ADC_JSQR register.

Example:
- JDISCEN=1, channels to be converted = 1, 2, 3
  - 1st trigger: channel 1 converted (a JEOC event is generated)
  - 2nd trigger: channel 2 converted (a JEOC event is generated)
  - 3rd trigger: channel 3 converted and a JEOC event + a JEOS event are generated
  - ...

Note: The channel numbers referred to in the above example might not be available on all microcontrollers.

When all injected channels have been converted, the next trigger starts the conversion of the first injected channel. In the example above, the 4th trigger reconverts the 1st injected channel 1.

It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

### 21.4.21 Queue of context for injected conversions

A queue of context is implemented to anticipate up to 2 contexts for the next injected sequence of conversions. JQDIS bit of ADC_CFGR register must be reset to enable this feature. Only hardware-triggered conversions are possible when the context queue is enabled.

This context consists of:
- Configuration of the injected triggers (bits JEXTEN[1:0] and JEXTSEL bits in ADC_JSQR register)
- Definition of the injected sequence (bits JSQx[4:0] and JL[1:0] in ADC_JSQR register)
All the parameters of the context are defined into a single register ADC_JSQR and this register implements a queue of 2 buffers, allowing the bufferization of up to 2 sets of parameters:

- The JSQR register can be written at any moment even when injected conversions are ongoing.
- Each data written into the JSQR register is stored into the Queue of context.
- At the beginning, the Queue is empty and the first write access into the JSQR register immediately changes the context and the ADC is ready to receive injected triggers.
- Once an injected sequence is complete, the Queue is consumed and the context changes according to the next JSQR parameters stored in the Queue. This new context is applied for the next injected sequence of conversions.
- A Queue overflow occurs when writing into register JSQR while the Queue is full. This overflow is signaled by the assertion of the flag JQOVF. When an overflow occurs, the write access of JSQR register which has created the overflow is ignored and the queue of context is unchanged. An interrupt can be generated if bit JQOVFIE is set.
- Two possible behaviors are possible when the Queue becomes empty, depending on the value of the control bit JQM of register ADC_CFG:
  - If JQM=0, the Queue is empty just after enabling the ADC, but then it can never be empty during run operations: the Queue always maintains the last active context and any further valid start of injected sequence will be served according to the last active context.
  - If JQM=1, the Queue can be empty after the end of an injected sequence or if the Queue is flushed. When this occurs, there is no more context in the queue and hardware triggers are disabled. Therefore, any further hardware injected triggers are ignored until the software re-writes a new injected context into JSQR register.
- Reading JSQR register returns the current JSQR context which is active at that moment. When the JSQR context is empty, JSQR is read as 0x0000.
- The Queue is flushed when stopping injected conversions by setting JADSTP=1 or when disabling the ADC by setting ADDIS=1:
  - If JQM=0, the Queue is maintained with the last active context.
  - If JQM=1, the Queue becomes empty and triggers are ignored.

Note: When configured in discontinuous mode (bit JDISCEN=1), only the last trigger of the injected sequence changes the context and consumes the Queue. The 1st trigger only consumes the queue but others are still valid triggers as shown by the discontinuous mode example below (length = 3 for both contexts):

- 1st trigger, discontinuous. Sequence 1: context 1 consumed, 1st conversion carried out
- 2nd trigger, disc. Sequence 1: 2nd conversion.
- 3rd trigger, discontinuous. Sequence 1: 3rd conversion.
- 4th trigger, discontinuous. Sequence 2: context 2 consumed, 1st conversion carried out.
- 5th trigger, discontinuous. Sequence 2: 2nd conversion.
- 6th trigger, discontinuous. Sequence 2: 3rd conversion.
Behavior when changing the trigger or sequence context

The Figure 100 and Figure 101 show the behavior of the context Queue when changing the sequence or the triggers.

**Figure 100. Example of JSQR queue of context (sequence change)**

<table>
<thead>

<td>EMPTY</td>
<td>P1</td>
<td>P1</td>
</tr>
<tr>
<td>ADC state</td>
<td>RDY</td>
<td>Conversion1</td>
<td>Conversion2</td>
</tr>
</tbody>
</table>

1. Parameters:
P1: sequence of 2 conversions, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 2
P3: sequence of 4 conversions, hardware trigger 1
Queue of context: Behavior when a queue overflow occurs

The Figure 102 and Figure 103 show the behavior of the context Queue if an overflow occurs before or during a conversion.

**Figure 102. Example of JSQR queue of context with overflow before conversion**

1. Parameters:
P1: sequence of 2 conversions, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 2
P3: sequence of 3 conversions, hardware trigger 1
P4: sequence of 4 conversions, hardware trigger 1

**Figure 103. Example of JSQR queue of context with overflow during conversion**

1. Parameters:
P1: sequence of 2 conversions, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 2
P3: sequence of 3 conversions, hardware trigger 1
P4: sequence of 4 conversions, hardware trigger 1
It is recommended to manage the queue overflows as described below:

- After each P context write into JSQR register, flag JQOVF shows if the write has been ignored or not (an interrupt can be generated).
- Avoid Queue overflows by writing the third context (P3) only once the flag JEOS of the previous context P2 has been set. This ensures that the previous context has been consumed and that the queue is not full.

**Queue of context: Behavior when the queue becomes empty**

*Figure 104* and *Figure 105* show the behavior of the context Queue when the Queue becomes empty in both cases JQM=0 or 1.

*Figure 104. Example of JSQR queue of context with empty queue (case JQM=0)*

<table>
<thead>
<tr>
<th>Write JSQR</th>
<th>P1</th>
<th>P2</th>
<th>P3</th>
<th>The queue is not empty and maintains P2 because JQM=0</th>
<th>Queue not empty (P3 maintained)</th>
</tr>
</thead>
<tbody>
<tr>
<td>JSQR queue</td>
<td>EMPTY</td>
<td>P1</td>
<td>P1, P2</td>
<td>P2</td>

<td>P1</td>
<td>P2</td>
<td>P3</td>
<td></td>
</tr>
<tr>
<td>ADC state</td>
<td>RDY</td>
<td>Conversion1</td>
<td>RDY</td>
<td>Conversion1</td>
<td>RDY</td>
</tr>
</tbody>
</table>

1. Parameters:
- P1: sequence of 1 conversion, hardware trigger 1
- P2: sequence of 1 conversion, hardware trigger 1
- P3: sequence of 1 conversion, hardware trigger 1

**Note:** When writing P3, the context changes immediately. However, because of internal resynchronization, there is a latency and if a trigger occurs just after or before writing P3, it can happen that the conversion is launched considering the context P2. To avoid this situation, the user must ensure that there is no ADC trigger happening when writing a new context that applies immediately.
Flushing the queue of context

The figures below show the behavior of the context Queue in various situations when the queue is flushed.

**Figure 105. Example of JSQR queue of context with empty queue (case JQM=1)**

1. Parameters:
   - P1: sequence of 1 conversion, hardware trigger 1
   - P2: sequence of 1 conversion, hardware trigger 1
   - P3: sequence of 1 conversion, hardware trigger 1

   Queue becomes empty and triggers are ignored because JQM=1

**Figure 106. Flushing JSQR queue of context by setting JADSTP=1 (JQM=0). Case when JADSTP occurs during an ongoing conversion.**

1. Parameters:
   - P1: sequence of 1 conversion, hardware trigger 1
   - P2: sequence of 1 conversion, hardware trigger 1
   - P3: sequence of 1 conversion, hardware trigger 1

   Queue is flushed and maintains the last active context (P2 is lost)
Figure 107. Flushing JSQR queue of context by setting JADSTP=1 (JQM=0). Case when JADSTP occurs during an ongoing conversion and a new trigger occurs.

<table>

</tbody>
</table>

Queue is flushed and maintains the last active context (P2 is lost)

1. Parameters:
P1: sequence of 1 conversion, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 1
P3: sequence of 1 conversion, hardware trigger 1
**Figure 109. Flushing JSQR queue of context by setting JADSTP=1 (JQM=1)**

1. Parameters:
   - P1: sequence of 1 conversion, hardware trigger 1
   - P2: sequence of 1 conversion, hardware trigger 1
   - P3: sequence of 1 conversion, hardware trigger 1

**Figure 110. Flushing JSQR queue of context by setting ADDIS=1 (JQM=0)**

1. Parameters:
   - P1: sequence of 1 conversion, hardware trigger 1
   - P2: sequence of 1 conversion, hardware trigger 1
   - P3: sequence of 1 conversion, hardware trigger 1
Queue of context: Starting the ADC with an empty queue

The following procedure must be followed to start ADC operation with an empty queue, in case the first context is not known at the time the ADC is initialized. This procedure is only applicable when JQM bit is reset:

5. Write a dummy JSQR with JEXTEN[1:0] not equal to 00 (otherwise triggering a software conversion)
6. Set JADSTART
7. Set JADSTP
8. Wait until JADSTART is reset
9. Set JADSTART.

Disabling the queue

It is possible to disable the queue by setting bit JQDIS=1 into the ADC_CFRGR register.

21.4.22 Programmable resolution (RES) - Fast conversion mode

It is possible to perform faster conversion by reducing the ADC resolution.

The resolution can be configured to be either 12, 10, 8, or 6 bits by programming the control bits RES[1:0]. Figure 116, Figure 117, Figure 118 and Figure 119 show the conversion result format with respect to the resolution as well as to the data alignment.

Lower resolution allows faster conversion time for applications where high-data precision is not required. It reduces the conversion time spent by the successive approximation steps according to Table 133.
21.4.23 End of conversion, end of sampling phase (EOC, JEOC, EOSMP)

The ADC notifies the application for each end of regular conversion (EOC) event and each injected conversion (JEOC) event.

The ADC sets the EOC flag as soon as a new regular conversion data is available in the ADC_DR register. An interrupt can be generated if bit EOCIE is set. EOC flag is cleared by the software either by writing 1 to it or by reading ADC_DR.

The ADC sets the JEOC flag as soon as a new injected conversion data is available in one of the ADC_JDRy register. An interrupt can be generated if bit JEOCIE is set. JEOC flag is cleared by the software either by writing 1 to it or by reading the corresponding ADC_JDRy register.

The ADC also notifies the end of Sampling phase by setting the status bit EOSMP (for regular conversions only). EOSMP flag is cleared by software by writing 1 to it. An interrupt can be generated if bit EOSMPIE is set.

21.4.24 End of conversion sequence (EOS, JEOS)

The ADC notifies the application for each end of regular sequence (EOS) and for each end of injected sequence (JEOS) event.

The ADC sets the EOS flag as soon as the last data of the regular conversion sequence is available in the ADC_DR register. An interrupt can be generated if bit EOSIE is set. EOS flag is cleared by the software either by writing 1 to it.

The ADC sets the JEOS flag as soon as the last data of the injected conversion sequence is complete. An interrupt can be generated if bit JEOSIE is set. JEOS flag is cleared by the software either by writing 1 to it.

1. TRGx is selected as trigger source, EXTEN[1:0] = 10, CONT = 1
2. Channels selected = 1, 2, 3, 4; AUTDLY=0.
21.4.26 Data management

Data register, data alignment and offset (ADC_DR, OFFSETy, OFFSETy.CH, ALIGN)

Data and alignment

At the end of each regular conversion channel (when EOC event occurs), the result of the converted data is stored into the ADC_DR data register which is 16 bits wide.

At the end of each injected conversion channel (when JEOC event occurs), the result of the converted data is stored into the corresponding ADC_JDRy data register which is 16 bits wide.

The ALIGN bit in the ADC_CFGR register selects the alignment of the data stored after conversion. Data can be right- or left-aligned as shown in Figure 116, Figure 117, Figure 118 and Figure 119.

Special case: when left-aligned, the data are aligned on a half-word basis except when the resolution is set to 6-bit. In that case, the data are aligned on a byte basis as shown in Figure 118 and Figure 119.

Note: Left-alignment is not supported in oversampling mode. When ROVSE and/or JOVSE bit is set, the ALIGN bit value is ignored and the ADC only provides right-aligned data.

Offset

An offset y (y=1,2,3,4) can be applied to a channel by setting the bit OFFSETy.EN=1 into ADC_OfRy register. The channel to which the offset will be applied is programmed into the bits OFFSETy.CH[4:0] of ADC_OfRy register. In this case, the converted value is decreased by the user-defined offset written in the bits OFFSETy[11:0]. The result may be a negative value so the read data is signed and the SEXT bit represents the extended sign value.

Note: Offset correction is not supported in oversampling mode. When ROVSE and/or JOVSE bit is set, the value of the OFFSETy.EN bit in ADC_OfRy register is ignored (considered as reset).

Table 136 describes how the comparison is performed for all the possible resolutions for analog watchdog 1.

<table>

**MS31016V1**

**MS31017V1**
The overrun flag (OSR) notifies of that a buffer overrun event occurred when the regular converted data has not been read (by the CPU or the DMA) before new converted data became available.

The OVR flag is set if the EOC flag is still 1 at the time when a new conversion completes. An interrupt can be generated if bit OVRIE=1.

When an overrun condition occurs, the ADC is still operating and can continue converting unless the software decides to stop and reset the sequence by setting bit ADSTP=1.

OVR flag is cleared by software by writing 1 to it.

It is possible to configure if data is preserved or overwritten when an overrun event occurs by programming the control bit OVRMOD:

- **OVRMOD=0**: The overrun event preserves the data register from being overrun: the old data is maintained and the new conversion is discarded and lost. If OVR remains at 1, any further conversions will occur but the result data will be also discarded.
- **OVRMOD=1**: The data register is overwritten with the last conversion result and the previous unread data is lost. If OVR remains at 1, any further conversions will operate normally and the ADC_DR register will always contain the latest converted data.
Analog-to-digital converters (ADC) RM0432

Figure 120. Example of overrun (OVR)

Note: There is no overrun detection on the injected channels since there is a dedicated data register for each of the four injected channels.

Managing a sequence of conversions without using the DMA

If the conversions are slow enough, the conversion sequence can be handled by the software. In this case the software must use the EOC flag and its associated interrupt to handle each data. Each time a conversion is complete, EOC is set and the ADC_DR register can be read. OVRMOD should be configured to 0 to manage overrun events as an error.

Managing conversions without using the DMA and without overrun

It may be useful to let the ADC convert one or more channels without reading the data each time (if there is an analog watchdog for instance). In this case, the OVRMOD bit must be configured to 1 and OVR flag should be ignored by the software. An overrun event will not prevent the ADC from continuing to convert and the ADC_DR register will always contain the latest conversion.

Managing conversions using the DMA

Since converted channel values are stored into a unique data register, it is useful to use DMA for conversion of more than one channel. This avoids the loss of the data already stored in the ADC_DR register.

When the DMA mode is enabled (DMAEN bit set to 1 in the ADC_CFGR register in single ADC mode or MDMA different from 0b00 in dual ADC mode), a DMA request is generated after each conversion of a channel. This allows the transfer of the converted data from the ADC_DR register to the destination location selected by the software.
Despite this, if an overrun occurs (OVR=1) because the DMA could not serve the DMA transfer request in time, the ADC stops generating DMA requests and the data corresponding to the new conversion is not transferred by the DMA. Which means that all the data transferred to the RAM can be considered as valid.

Depending on the configuration of OVRMOD bit, the data is either preserved or overwritten (refer to Section : ADC overrun (OVR, OVRMOD)).

The DMA transfer requests are blocked until the software clears the OVR bit.

Two different DMA modes are proposed depending on the application use and are configured with bit DMACFG of the ADC_CFGR register in single ADC mode, or with bit DMACFG of the ADC_CCR register in dual ADC mode:

- DMA one shot mode (DMACFG=0).
  This mode is suitable when the DMA is programmed to transfer a fixed number of data.
- DMA circular mode (DMACFG=1)
  This mode is suitable when programming the DMA in circular mode.

**DMA one shot mode (DMACFG=0)**

In this mode, the ADC generates a DMA transfer request each time a new conversion data is available and stops generating DMA requests once the DMA has reached the last DMA transfer (when DMA_EOT interrupt occurs - refer to DMA paragraph) even if a conversion has been started again.

When the DMA transfer is complete (all the transfers configured in the DMA controller have been done):

- The content of the ADC data register is frozen.
- Any ongoing conversion is aborted with partial result discarded.
- No new DMA request is issued to the DMA controller. This avoids generating an overrun error if there are still conversions which are started.
- Scan sequence is stopped and reset.
- The DMA is stopped.

**DMA circular mode (DMACFG=1)**

In this mode, the ADC generates a DMA transfer request each time a new conversion data is available in the data register, even if the DMA has reached the last DMA transfer. This allows configuring the DMA in circular mode to handle a continuous analog input data stream.

**21.4.27 Managing conversions using the DFSDM**

The ADC conversion results can be transferred directly to the Digital filter for sigma delta modulators (DFSDM).

In this case, the DFSDMCFG bit must be set to 1 and DMAEN bit must be cleared to 0. The ADC transfers all the 16 bits of the regular data register to the DFSDM and resets the EOC flag once the transfer is complete.
The data format must be 16-bit signed:

\[
\begin{align*}
\text{ADC\_DR}[15:12] &= \text{sign extended} \\
\text{ADC\_DR}[11] &= \text{sign} \\
\text{ADC\_DR}[11:0] &= \text{data}
\end{align*}
\]

To obtain 16-bit signed format in 12-bit ADC mode, the software needs to configure the \text{OFFSET}\_y[11:0] to 0x800 after having set \text{OFFSET}\_y\_EN to 1.

Only right aligned data format is available for the DFSDM interface (see Figure 117: Right alignment (offset enabled, signed value)).

### 21.4.28 Dynamic low-power features

#### Auto-delayed conversion mode (AUTDLY)

The ADC implements an auto-delayed conversion mode controlled by the AUTDLY configuration bit. Auto-delayed conversions are useful to simplify the software as well as to optimize performance of an application clocked at low frequency where there would be risk of encountering an ADC overrun.

When AUTDLY=1, a new conversion can start only if all the previous data of the same group has been treated:

- For a regular conversion: once the ADC\_DR register has been read or if the EOC bit has been cleared (see Figure 121).
- For an injected conversion: when the JEOS bit has been cleared (see Figure 122).

This is a way to automatically adapt the speed of the ADC to the speed of the system which will read the data.

The delay is inserted after each regular conversion (whatever DISCEN=0 or 1) and after each sequence of injected conversions (whatever JDISCEN=0 or 1).

**Note:** There is no delay inserted between each conversions of the injected sequence, except after the last one.

During a conversion, a hardware trigger event (for the same group of conversions) occurring during this delay is ignored.

**Note:** This is not true for software triggers where it remains possible during this delay to set the bits ADSTART or JADSTART to restart a conversion: it is up to the software to read the data before launching a new conversion.

No delay is inserted between conversions of different groups (a regular conversion followed by an injected conversion or conversely):

- If an injected trigger occurs during the automatic delay of a regular conversion, the injected conversion starts immediately (see Figure 122).
- Once the injected sequence is complete, the ADC waits for the delay (if not ended) of the previous regular conversion before launching a new regular conversion (see Figure 124).

The behavior is slightly different in auto-injected mode (JAUTO=1) where a new regular conversion can start only when the automatic delay of the previous injected sequence of conversion has ended (when JEOS has been cleared). This is to ensure that the software can read all the data of a given sequence before starting a new sequence (see Figure 125).
To stop a conversion in continuous auto-injection mode combined with autodelay mode (JAUTO=1, CONT=1 and AUTDLY=1), follow the following procedure:
1. Wait until JEOS=1 (no more conversions are restarted)
2. Clear JEOS,
3. Set ADSTP=1
4. Read the regular data.

If this procedure is not respected, a new regular sequence can restart if JEOS is cleared after ADSTP has been set.

In AUTDLY mode, a hardware regular trigger event is ignored if it occurs during an already ongoing regular sequence or during the delay that follows the last regular conversion of the sequence. It is however considered pending if it occurs after this delay, even if it occurs during an injected sequence of the delay that follows it. The conversion then starts at the end of the delay of the injected sequence.

In AUTDLY mode, a hardware injected trigger event is ignored if it occurs during an already ongoing injected sequence or during the delay that follows the last injected conversion of the sequence.

21.4.29 Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)

The three AWD analog watchdogs monitor whether some channels remain within a configured voltage range (window).

**Figure 126. Analog watchdog guarded area**

![Analog watchdog guarded area](MS45396V1)

**AWDx flag and interrupt**

An interrupt can be enabled for each of the 3 analog watchdogs by setting AWDxIE in the ADC_IER register (x=1,2,3).

AWDx (x=1,2,3) flag is cleared by software by writing 1 to it.

The ADC conversion result is compared to the lower and higher thresholds before alignment.

**Description of analog watchdog 1**

The AWD analog watchdog 1 is enabled by setting the AWD1EN bit in the ADC_CFGR register. This watchdog monitors whether either one selected channel or all enabled channels remain within a configured voltage range (window).

*Table 135* shows how the ADC_CFGR registers should be configured to enable the analog watchdog on one or more channels.

**Table 135. Analog watchdog channel selection**

</tbody>
</table>

1. Selected by the AWD1CH[4:0] bits. The channels must also be programmed to be converted in the appropriate regular or injected sequence.

The AWD1 analog watchdog status bit is set if the analog voltage converted by the ADC is below a lower threshold or above a higher threshold.
These thresholds are programmed in bits HT1[11:0] and LT1[11:0] of the ADC_TR1 register for the analog watchdog 1. When converting data with a resolution of less than 12 bits (according to bits RES[1:0]), the LSB of the programmed thresholds must be kept cleared because the internal comparison is always performed on the full 12-bit raw converted data (left aligned).

*Table 136* describes how the comparison is performed for all the possible resolutions for analog watchdog 1.

</tbody>
</table>

**Description of analog watchdog 2 and 3**

The second and third analog watchdogs are more flexible and can guard several selected channels by programming the corresponding bits in AWDxCH[18:0] (x=2,3).

The corresponding watchdog is enabled when any bit of AWDxCH[18:0] (x=2,3) is set.

They are limited to a resolution of 8 bits and only the 8 MSBs of the thresholds can be programmed into HTx[7:0] and LTx[7:0]. *Table 137* describes how the comparison is performed for all the possible resolutions.

ADCy_AWDx_OUT signal output generation

Each analog watchdog is associated to an internal hardware signal ADCy_AWDx_OUT (y=ADC number, x=watchdog number) which is directly connected to the ETR input (external trigger) of some on-chip timers. Refer to the on-chip timers section to understand how to select the ADCy_AWDx_OUT signal as ETR.

ADCy_AWDx_OUT is activated when the associated analog watchdog is enabled:

- ADCy_AWDx_OUT is set when a guarded conversion is outside the programmed thresholds.
- ADCy_AWDx_OUT is reset after the end of the next guarded conversion which is inside the programmed thresholds (It remains at 1 if the next guarded conversions are still outside the programmed thresholds).
- ADCy_AWDx_OUT is also reset when disabling the ADC (when setting ADDIS=1). Note that stopping regular or injected conversions (setting ADSTP=1 or JADSTP=1) has no influence on the generation of ADCy_AWDx_OUT.

Note: AWDx flag is set by hardware and reset by software: AWDx flag has no influence on the generation of ADCy_AWDx_OUT (ex: ADCy_AWDx_OUT can toggle while AWDx flag remains at 1 if the software did not clear the flag).

Figure 127. ADCy_AWDx_OUT signal generation (on all regular channels)

21.4.30 Oversampler

The oversampling unit performs data pre-processing to offload the CPU. It is able to handle multiple conversions and average them into a single data with increased data width, up to 16-bit.

It provides a result with the following form, where N and M can be adjusted:

\[
\text{Result} = \frac{1}{M} \times \sum_{n=0}^{n-N-1} \text{Conversion}(t_n)
\]

It allows to perform by hardware the following functions: averaging, data rate reduction, SNR improvement, basic filtering.

The oversampling ratio N is defined using the OVFS[2:0] bits in the ADC_CFGR2 register, and can range from 2x to 256x. The division coefficient M consists of a right bit shift up to 8 bits, and is defined using the OVSS[3:0] bits in the ADC_CFGR2 register.

The summation unit can yield a result up to 20 bits (256x 12-bit results), which is first shifted right. It is then truncated to the 16 least significant bits, rounded to the nearest value using the least significant bits left apart by the shifting, before being finally transferred into the ADC_DR data register.

Note: If the intermediary result after the shifting exceeds 16-bit, the result is truncated as is, without saturation.

![Figure 131. 20-bit to 16-bit result truncation](https://example.com/fig131)

Figure 131 gives a numerical example of the processing, from a raw 20-bit accumulated data to the final 16-bit result.

![Figure 132. Numerical example with 5-bit shift and rounding](https://example.com/fig132)

Figure 132 gives a numerical example of the processing, from a raw 20-bit accumulated data to the final 16-bit result.

![Table 138](https://example.com/tbl138)

Table 138 gives the data format for the various N and M combinations, for a raw conversion data equal to 0xFFF.
There are no changes for conversion timings in oversampled mode: the sample time is maintained equal during the whole oversampling sequence. A new data is provided every N conversions, with an equivalent delay equal to $N \times T_{CONV} = N \times (t_{SMPL} + t_{SAR})$. The flags are set as follows:

- The end of the sampling phase (EOSMP) is set after each sampling phase
- The end of conversion (EOC) occurs once every N conversions, when the oversampled result is available
- The end of sequence (EOS) occurs once the sequence of oversampled data is completed (i.e. after $N \times$ sequence length conversions total)

**ADC operating modes supported when oversampling (single ADC mode)**

In oversampling mode, most of the ADC operating modes are maintained:

- Single or continuous mode conversions
- ADC conversions start either by software or with triggers
- ADC stop during a conversion (abort)
- Data read via CPU or DMA with overrun detection
- Low-power modes (AUTDLY)
- Programmable resolution: in this case, the reduced conversion values (as per RES[1:0] bits in ADC_CFGR1 register) are accumulated, truncated, rounded and shifted in the same way as 12-bit conversions are

**Note:** The alignment mode is not available when working with oversampled data. The ALIGN bit in ADC_CFGR1 is ignored and the data are always provided right-aligned.

Offset correction is not supported in oversampling mode. When ROVSE and/or JOVSE bit is set, the value of the OFFSETy_EN bit in ADC_OFRy register is ignored (considered as reset).
Analog watchdog

The analog watchdog functionality is maintained (AWDSGL and AWDEN bits), with the following difference:

- The RES[1:0] bits are ignored, comparison is always done using the full 12-bit values HT[11:0] and LT[11:0]
- The comparison is performed on the most significant 12-bit of the 16-bit oversampled results ADC_DR[15:4]

Note: Care must be taken when using high shifting values, this will reduce the comparison range. For instance, if the oversampled result is shifted by 4 bits, thus yielding a 12-bit data right-aligned, the effective analog watchdog comparison can only be performed on 8 bits. The comparison is done between ADC_DR[11:4] and HT[0:7] / LT[0:7], and HT[11:8] / LT[11:8] must be kept reset.

Triggered mode

The averager can also be used for basic filtering purpose. Although not a very powerful filter (slow roll-off and limited stop band attenuation), it can be used as a notch filter to reject constant parasitic frequencies (typically coming from the mains or from a switched mode power supply). For this purpose, a specific discontinuous mode can be enabled with TROVS bit in ADC_CFGR2, to be able to have an oversampling frequency defined by a user and independent from the conversion time itself.

Figure 133 below shows how conversions are started in response to triggers during discontinuous mode.

If the TROVS bit is set, the content of the DISCEN bit is ignored and considered as 1.

Figure 133. Triggered regular oversampling mode (TROVS bit = 1)

In oversampling mode, it is possible to have differentiated behavior for injected and regular sequencers. The oversampling can be enabled for both sequencers with some limitations if they have to be used simultaneously (this is related to a unique accumulation unit).
Oversampling regular channels only

The regular oversampling mode bit ROVSM defines how the regular oversampling sequence is resumed if it is interrupted by injected conversion:

- In continued mode, the accumulation restarts from the last valid data (prior to the conversion abort request due to the injected trigger). This ensures that oversampling will be complete whatever the injection frequency (providing at least one regular conversion can be complete between triggers);
- In resumed mode, the accumulation restarts from 0 (previous conversion results are ignored). This mode allows to guarantee that all data used for oversampling were converted back-to-back within a single timeslot. Care must be taken to have a injection trigger period above the oversampling period length. If this condition is not respected, the oversampling cannot be complete and the regular sequencer will be blocked.

Figure 134 gives examples for a 4x oversampling ratio.

**Figure 134. Regular oversampling modes (4x ratio)**

Oversampling Injected channels only

The Injected oversampling mode bit JOVSE enables oversampling solely for conversions in the injected sequencer.
Oversampling regular and injected channels

It is possible to have both ROVSE and JOVSE bits set. In this case, the regular oversampling mode is forced to resumed mode (ROVSM bit ignored), as represented on Figure 135 below.

**Figure 135. Regular and injected oversampling modes used simultaneously**

<table>
<thead>
<tr>
<th>ROVSE = 1, JOVSE = 1, ROVSM = X, TROVS = 0</th>
</tr>
</thead>
</table>

Triggered regular oversampling with injected conversions

It is possible to have triggered regular mode with injected conversions. In this case, the injected mode oversampling mode must be disabled, and the ROVSM bit is ignored (resumed mode is forced). The JOVSE bit must be reset. The behavior is represented on Figure 136 below.

**Figure 136. Triggered regular oversampling with injection**

<table>
<thead>
<tr>
<th>ROVSE = 1, JOVSE = 0, ROVSM = X, TROVS = 1</th>
</tr>
</thead>
</table>
Auto-injected mode

It is possible to oversample auto-injected sequences and have all conversions results stored in registers to save a DMA resource. This mode is available only with both regular and injected oversampling active: \( \text{JAUTO} = 1, \text{ROVSE} = 1 \) and \( \text{JOVSE} = 1 \), other combinations are not supported. The ROVSM bit is ignored in auto-injected mode. The Figure 137 below shows how the conversions are sequenced.

Figure 137. Oversampling in auto-injected mode

It is possible to have also the triggered mode enabled, using the TROVS bit. In this case, the ADC must be configured as following: \( \text{JAUTO} = 1, \text{DISCEN} = 0, \text{JDISCEN} = 0, \text{ROVSE} = 1, \text{JOVSE} = 1 \) and \( \text{TROVSE} = 1 \).

Dual ADC modes supported when oversampling

It is possible to have oversampling enabled when working in dual ADC configuration, for the injected simultaneous mode and regular simultaneous mode. In this case, the two ADCs must be programmed with the very same settings (including oversampling).

All other dual ADC modes are not supported when either regular or injected oversampling is enabled (\( \text{ROVSE} = 1 \) or \( \text{JOVSE} = 1 \)).

Combined modes summary

The Table 139 below summarizes all combinations, including modes not supported.

</table>
21.4.31 Dual ADC modes

Dual ADC modes can be used in devices with two ADCs or more (see Figure 138).

In dual ADC mode the start of conversion is triggered alternately or simultaneously by the ADCx master to the ADC slave, depending on the mode selected by the bits DUAL[4:0] in the ADCx_CCR register.

Four possible modes are implemented:

- Injected simultaneous mode
- Regular simultaneous mode
- Interleaved mode
- Alternate trigger mode

It is also possible to use these modes combined in the following ways:

- Injected simultaneous mode + Regular simultaneous mode
- Regular simultaneous mode + Alternate trigger mode
- Injected simultaneous mode + Interleaved mode

In dual ADC mode (when bits DUAL[4:0] in ADCx_CCR register are not equal to zero), the bits CONT, AUTDLY, DISCEN, DISCNUM[2:0], JDISCEN, JQM, JAUTO of the ADC_CFGR register are shared between the master and slave ADC: the bits in the slave ADC are always equal to the corresponding bits of the master ADC.

To start a conversion in dual mode, the user must program the bits EXTEN[1:0], EXTSEL, JEXTEN[1:0], JEXTSEL of the master ADC only, to configure a software or hardware trigger, and a regular or injected trigger. (the bits EXTEN[1:0] and JEXTEN[1:0] of the slave ADC are don’t care).

In regular simultaneous or interleaved modes: once the user sets bit ADSTART or bit ADSTP of the master ADC, the corresponding bit of the slave ADC is also automatically set. However, bit ADSTART or bit ADSTP of the slave ADC is not necessary cleared at the same time as the master ADC bit.

In injected simultaneous or alternate trigger modes: once the user sets bit JADSTART or bit JADSTP of the master ADC, the corresponding bit of the slave ADC is also automatically set. However, bit JADSTART or bit JADSTP of the slave ADC is not necessary cleared at the same time as the master ADC bit.

In dual ADC mode, the converted data of the master and slave ADC can be read in parallel, by reading the ADC common data register (ADCx_CDR). The status bits can be also read in parallel by reading the dual-mode status register (ADCx_CSR).
1. External triggers also exist on slave ADC but are not shown for the purposes of this diagram.

2. The ADC common data register (ADCx_CDR) contains both the master and slave ADC regular converted data.
**Injected simultaneous mode**

This mode is selected by programming bits DUAL[4:0]=00101

This mode converts an injected group of channels. The external trigger source comes from the injected group multiplexer of the master ADC (selected by the JEXTSEL bits in the ADC_JSQR register).

**Note:** Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).

In simultaneous mode, one must convert sequences with the same length or ensure that the interval between triggers is longer than the longer of the 2 sequences. Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

Regular conversions can be performed on one or all ADCs. In that case, they are independent of each other and are interrupted when an injected event occurs. They are resumed at the end of the injected conversion group.

- At the end of injected sequence of conversion event (JEOS) on the master ADC, the converted data is stored into the master ADC_JDRy registers and a JEOS interrupt is generated (if enabled)
- At the end of injected sequence of conversion event (JEOS) on the slave ADC, the converted data is stored into the slave ADC_JDRy registers and a JEOS interrupt is generated (if enabled)
- If the duration of the master injected sequence is equal to the duration of the slave injected one (like in Figure 139), it is possible for the software to enable only one of the two JEOS interrupt (ex: master JEOS) and read both converted data (from master ADC_JDRy and slave ADC_JDRy registers).

**Figure 139. Injected simultaneous mode on 4 channels: dual ADC mode**

![Diagram](MS31900V1)

If JDISCEN=1, each simultaneous conversion of the injected sequence requires an injected trigger event to occur.

This mode can be combined with AUTDLY mode:

- Once a simultaneous injected sequence of conversions has ended, a new injected trigger event is accepted only if both JEOS bits of the master and the slave ADC have been cleared (delay phase). Any new injected trigger events occurring during the ongoing injected sequence and the associated delay phase are ignored.
- Once a regular sequence of conversions of the master ADC has ended, a new regular trigger event of the master ADC is accepted only if the master data register (ADC_DR) has been read. Any new regular trigger events occurring for the master ADC during the
ongoing regular sequence and the associated delay phases are ignored. There is the same behavior for regular sequences occurring on the slave ADC.

**Regular simultaneous mode with independent injected**

This mode is selected by programming bits DUAL[4:0] = 00110.

This mode is performed on a regular group of channels. The external trigger source comes from the regular group multiplexer of the master ADC (selected by the EXTSEL bits in the ADC_CFGR register). A simultaneous trigger is provided to the slave ADC.

In this mode, independent injected conversions are supported. An injection request (either on master or on the slave) will abort the current simultaneous conversions, which are restarted once the injected conversion is completed.

*Note:* Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).

In regular simultaneous mode, one must convert sequences with the same length or ensure that the interval between triggers is longer than the longer conversion time of the 2 sequences. Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

Software is notified by interrupts when it can read the data:

- At the end of each conversion event (EOC) on the master ADC, a master EOC interrupt is generated (if EOCIE is enabled) and software can read the ADC_DR of the master ADC.
- At the end of each conversion event (EOC) on the slave ADC, a slave EOC interrupt is generated (if EOCIE is enabled) and software can read the ADC_DR of the slave ADC.
- If the duration of the master regular sequence is equal to the duration of the slave one (like in Figure 140), it is possible for the software to enable only one of the two EOC interrupt (ex: master EOC) and read both converted data from the Common Data register (ADCx_CDR).

It is also possible to read the regular data using the DMA. Two methods are possible:

- Using two DMA channels (one for the master and one for the slave). In this case bits MDMA[1:0] must be kept cleared.
  - Configure the DMA master ADC channel to read ADC_DR from the master. DMA requests are generated at each EOC event of the master ADC.
  - Configure the DMA slave ADC channel to read ADC_DR from the slave. DMA requests are generated at each EOC event of the slave ADC.
- Using MDMA mode, which leaves one DMA channel free for other uses:
  - Configure MDMA[1:0]=0b10 or 0b11 (depending on resolution).
  - A single DMA channel is used (the one of the master). Configure the DMA master ADC channel to read the common ADC register (ADCx_CDR)
  - A single DMA request is generated each time both master and slave EOC events have occurred. At that time, the slave ADC converted data is available in the upper half-word of the ADCx_CDR 32-bit register and the master ADC converted data is available in the lower half-word of ADCx_CCR register.
  - Both EOC flags are cleared when the DMA reads the ADCx_CCR register.

*Note:* In MDMA mode (MDMA[1:0]=0b10 or 0b11), the user must program the same number of conversions in the master’s sequence as in the slave’s sequence. Otherwise, the remaining conversions will not generate a DMA request.
Figure 140. Regular simultaneous mode on 16 channels: dual ADC mode

If DISCEN=1 then each “n” simultaneous conversions of the regular sequence require a regular trigger event to occur (“n” is defined by DISCNUM).

This mode can be combined with AUTDLY mode:

- Once a simultaneous conversion of the sequence has ended, the next conversion in the sequence is started only if the common data register, ADCx_CDR (or the regular data register of the master ADC) has been read (delay phase).
- Once a simultaneous regular sequence of conversions has ended, a new regular trigger event is accepted only if the common data register (ADCx_CDR) has been read (delay phase). Any new regular trigger events occurring during the ongoing regular sequence and the associated delay phases are ignored.

It is possible to use the DMA to handle data in regular simultaneous mode combined with AUTDLY mode, assuming that multi-DMA mode is used: bits MDMA must be set to 0b10 or 0b11.

When regular simultaneous mode is combined with AUTDLY mode, it is mandatory for the user to ensure that:

- The number of conversions in the master’s sequence is equal to the number of conversions in the slave’s.
- For each simultaneous conversions of the sequence, the length of the conversion of the slave ADC is inferior to the length of the conversion of the master ADC. Note that the length of the sequence depends on the number of channels to convert and the sampling time and the resolution of each channels.

Note: This combination of regular simultaneous mode and AUTDLY mode is restricted to the use case when only regular channels are programmed: it is forbidden to program injected channels in this combined mode.

Interleaved mode with independent injected

This mode is selected by programming bits DUAL[4:0] = 00111.

This mode can be started only on a regular group (usually one channel). The external trigger source comes from the regular channel multiplexer of the master ADC.

After an external trigger occurs:

- The master ADC starts immediately.
- The slave ADC starts after a delay of several-ADC clock cycles after the sampling phase of the master ADC has complete.

The minimum delay which separates two conversions in interleaved mode is configured in the DELAY bits in the ADCx_CCR register. This delay starts counting one half cycle after the end of the sampling phase of the master conversion. This way, an ADC cannot start a
conversion if the complementary ADC is still sampling its input (only one ADC can sample the input signal at a given time).

- The minimum possible DELAY is 1 to ensure that there is at least one cycle time between the opening of the analog switch of the master ADC sampling phase and the closing of the analog switch of the slave ADC sampling phase.
- The maximum DELAY is equal to the number of cycles corresponding to the selected resolution. However the user must properly calculate this delay to ensure that an ADC does not start a conversion while the other ADC is still sampling its input.

If the CONT bit is set on both master and slave ADCs, the selected regular channels of both ADCs are continuously converted.

The software is notified by interrupts when it can read the data at the end of each conversion event (EOC) on the slave ADC. A slave and master EOC interrupts are generated (if EOCIE is enabled) and the software can read the ADC_DR of the slave/master ADC.

**Note:** It is possible to enable only the EOC interrupt of the slave and read the common data register (ADCx_CDR). But in this case, the user must ensure that the duration of the conversions are compatible to ensure that inside the sequence, a master conversion is always followed by a slave conversion before a new master conversion restarts. It is recommended to use the MDMA mode.

It is also possible to have the regular data transferred by DMA. In this case, individual DMA requests on each ADC cannot be used and it is mandatory to use the MDMA mode, as following:

- Configure MDMA[1:0]=0b10 or 0b11 (depending on resolution).
- A single DMA channel is used (the one of the master). Configure the DMA master ADC channel to read the common ADC register (ADCx_CDR).
- A single DMA request is generated each time both master and slave EOC events have occurred. At that time, the slave ADC converted data is available in the upper half-word of the ADCx_CDR 32-bit register and the master ADC converted data is available in the lower half-word of ADCx_CCR register.
- Both EOC flags are cleared when the DMA reads the ADCx_CCR register.

**Figure 141. Interleaved mode on 1 channel in continuous conversion mode: dual ADC mode**
If DISCEN=1, each “n” simultaneous conversions (“n” is defined by DISCNUM) of the regular sequence require a regular trigger event to occur.

In this mode, injected conversions are supported. When injection is done (either on master or on slave), both the master and the slave regular conversions are aborted and the sequence is restarted from the master (see Figure 143 below).

**Alternate trigger mode**

This mode is selected by programming bits DUAL[4:0] = 01001.

This mode can be started only on an injected group. The source of external trigger comes from the injected group multiplexer of the master ADC.

This mode is only possible when selecting hardware triggers: JEXTEN[1:0] must not be 00.

**Injected discontinuous mode disabled (JDISCEN=0 for both ADC)**
1. When the 1st trigger occurs, all injected master ADC channels in the group are converted.
2. When the 2nd trigger occurs, all injected slave ADC channels in the group are converted.
3. And so on.

A JEOS interrupt, if enabled, is generated after all injected channels of the master ADC in the group have been converted.

A JEOS interrupt, if enabled, is generated after all injected channels of the slave ADC in the group have been converted.

JEOC interrupts, if enabled, can also be generated after each injected conversion.

If another external trigger occurs after all injected channels in the group have been converted then the alternate trigger process restarts by converting the injected channels of the master ADC in the group.

Figure 144. Alternate trigger: injected group of each ADC

Note: Regular conversions can be enabled on one or all ADCs. In this case the regular conversions are independent of each other. A regular conversion is interrupted when the ADC has to perform an injected conversion. It is resumed when the injected conversion is finished.

The time interval between 2 trigger events must be greater than or equal to 1 ADC clock period. The minimum time interval between 2 trigger events that start conversions on the same ADC is the same as in the single ADC mode.

Injected discontinuous mode enabled (JDISCEN=1 for both ADC)
If the injected discontinuous mode is enabled for both master and slave ADCs:

- When the 1st trigger occurs, the first injected channel of the master ADC is converted.
- When the 2nd trigger occurs, the first injected channel of the slave ADC is converted.
- And so on.

A JEOS interrupt, if enabled, is generated after all injected channels of the master ADC in the group have been converted.

A JEOS interrupt, if enabled, is generated after all injected channels of the slave ADC in the group have been converted.

JEOC interrupts, if enabled, can also be generated after each injected conversions.

If another external trigger occurs after all injected channels in the group have been converted then the alternate trigger process restarts.

**Figure 145. Alternate trigger: 4 injected channels (each ADC) in discontinuous mode**

**Combined regular/injected simultaneous mode**

This mode is selected by programming bits DUAL[4:0] = 00001.

It is possible to interrupt the simultaneous conversion of a regular group to start the simultaneous conversion of an injected group.

*Note*: *In combined regular/injected simultaneous mode, one must convert sequences with the same length or ensure that the interval between triggers is longer than the long conversion time of the 2 sequences. Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.*

**Combined regular simultaneous + alternate trigger mode**

This mode is selected by programming bits DUAL[4:0]=00010.

It is possible to interrupt the simultaneous conversion of a regular group to start the alternate trigger conversion of an injected group. **Figure 146** shows the behavior of an alternate trigger interrupting a simultaneous regular conversion.

The injected alternate conversion is immediately started after the injected event. If a regular conversion is already running, in order to ensure synchronization after the injected conversion, the regular conversion of all (master/slave) ADCs is stopped and resumed synchronously at the end of the injected conversion.
Note: In combined regular simultaneous + alternate trigger mode, one must convert sequences with the same length or ensure that the interval between triggers is longer than the long conversion time of the 2 sequences. Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

**Figure 146. Alternate + regular simultaneous**

If a trigger occurs during an injected conversion that has interrupted a regular conversion, the alternate trigger is served. **Figure 147** shows the behavior in this case (note that the 6th trigger is ignored because the associated alternate conversion is not complete).

**Figure 147. Case of trigger occurring during injected conversion**

**Combined injected simultaneous plus interleaved**

This mode is selected by programming bits DUAL[4:0]=00011

It is possible to interrupt an interleaved conversion with a simultaneous injected event.

In this case the interleaved conversion is interrupted immediately and the simultaneous injected conversion starts. At the end of the injected sequence the interleaved conversion is resumed. When the interleaved regular conversion resumes, the first regular conversion which is performed is always the master’s one. **Figure 148, Figure 149** and **Figure 150** show the behavior using an example.

**Caution:** In this mode, it is mandatory to use the Common Data Register to read the regular data with a single read access. On the contrary, master-slave data coherency is not guaranteed.
Figure 148. Interleaved single channel CH0 with injected sequence CH11, CH12

Figure 149. Two Interleaved channels (CH1, CH2) with injected sequence CH11, CH12
- case 1: Master interrupted first

Figure 150. Two Interleaved channels (CH1, CH2) with injected sequence CH11, CH12
- case 2: Slave interrupted first
### DMA requests in dual ADC mode

In all dual ADC modes, it is possible to use two DMA channels (one for the master, one for the slave) to transfer the data, like in single mode (refer to Figure 151: DMA Requests in regular simultaneous mode when MDMA=0b00).

**Figure 151. DMA Requests in regular simultaneous mode when MDMA=0b00**

<tr>
<td>ADC Slave EOC</td>
<td>Trigger, DMA request, DMA reads Slave</td>
</tr>
</tbody>
</table>

In simultaneous regular and interleaved modes, it is also possible to save one DMA channel and transfer both data using a single DMA channel. For this MDMA bits must be configured in the ADCx_CCR register:

- **MDMA=0b10**: A single DMA request is generated each time both master and slave EOC events have occurred. At that time, two data items are available and the 32-bit register ADCx_CDR contains the two half-words representing two ADC-converted data items. The slave ADC data take the upper half-word and the master ADC data take the lower half-word.  
  This mode is used in interleaved mode and in regular simultaneous mode when resolution is 10-bit or 12-bit.

**Example:**

Interleaved dual mode: a DMA request is generated each time 2 data items are available:

1st DMA request: ADCx_CDR[31:0] = SLV_ADC_DR[15:0] | MST_ADC_DR[15:0]  
2nd DMA request: ADCx_CDR[31:0] = SLV_ADC_DR[15:0] | MST_ADC_DR[15:0]
Figure 152. DMA requests in regular simultaneous mode when MDMA=0b10

Figure 153. DMA requests in interleaved mode when MDMA=0b10
Analog-to-digital converters (ADC)  

**Note:** When using MDMA mode, the user must take care to configure properly the duration of the master and slave conversions so that a DMA request is generated and served for reading both data (master + slave) before a new conversion is available.

- **MDMA=0b11:** This mode is similar to the MDMA=0b10. The only differences are that on each DMA request (two data items are available), two bytes representing two ADC converted data items are transferred as a half-word.
  
  This mode is used in interleaved and regular simultaneous mode when resolution is 6-bit or when resolution is 8-bit and data is not signed (offsets must be disabled for all the involved channels).

  **Example:**
  
  Interleaved dual mode: a DMA request is generated each time 2 data items are available:
  
  1st DMA request: \( \text{ADCx}_\text{CDR}[15:0] = \text{SLV}_{\text{ADC}}\_\text{DR}[7:0] | \text{MST}_{\text{ADC}}\_\text{DR}[7:0] \)
  
  2nd DMA request: \( \text{ADCx}_\text{CDR}[15:0] = \text{SLV}_{\text{ADC}}\_\text{DR}[7:0] | \text{MST}_{\text{ADC}}\_\text{DR}[7:0] \)

**Overrun detection**

In dual ADC mode (when DUAL[4:0] is not equal to b00000), if an overrun is detected on one of the ADCs, the DMA requests are no longer issued to ensure that all the data transferred to the RAM are valid (this behavior occurs whatever the MDMA configuration). It may happen that the EOC bit corresponding to one ADC remains set because the data register of this ADC contains valid data.

**DMA one shot mode/ DMA circular mode when MDMA mode is selected**

When MDMA mode is selected (0b10 or 0b11), bit DMACFG of the ADCx_CCR register must also be configured to select between DMA one shot mode and circular mode, as explained in section "Section : Managing conversions using the DMA" (bits DMACFG of master and slave ADC_CFGR are not relevant).

**Stopping the conversions in dual ADC modes**

The user must set the control bits ADSTP/JADSTP of the master ADC to stop the conversions of both ADC in dual ADC mode. The other ADSTP control bit of the slave ADC has no effect in dual ADC mode.

Once both ADC are effectively stopped, the bits ADSTART/JADSTART of the master and slave ADCs are both cleared by hardware.

**21.4.32 Temperature sensor**

The temperature sensor can be used to measure the junction temperature (Tj) of the device. The temperature sensor is internally connected to the ADC input channels which are used to convert the sensor output voltage to a digital value. When not in use, the sensor can be put in power down mode. It support the temperature range –40 to 125 °C.

*Figure 154* shows the block diagram of connections between the temperature sensor and the ADC.

The temperature sensor output voltage changes linearly with temperature. The offset of this line varies from chip to chip due to process variation (up to 45 °C from one chip to another).
The uncalibrated internal temperature sensor is more suited for applications that detect
temperature variations instead of absolute temperatures. To improve the accuracy of the
temperature sensor measurement, calibration values are stored in system memory for each
device by ST during production.

During the manufacturing process, the calibration data of the temperature sensor and the
internal voltage reference are stored in the system memory area. The user application can
then read them and use them to improve the accuracy of the temperature sensor or the
internal reference (refer to the datasheet for additional information).

The temperature sensor is internally connected to the ADC input channel which is used to
convert the sensor’s output voltage to a digital value. Refer to the electrical characteristics
section of the device datasheet for the sampling time value to be applied when converting
the internal temperature sensor.

When not in use, the sensor can be put in power-down mode.

*Figure 154* shows the block diagram of the temperature sensor.

### Reading the temperature

To use the sensor:

1. Select the ADC input channels that is connected to $V_{TS}$.
2. Program with the appropriate sampling time (refer to electrical characteristics section of
   the device datasheet).
3. Set the CH17SEL bit in the ADCx_CCR register to wake up the temperature sensor
   from power-down mode.
4. Start the ADC conversion.
5. Read the resulting $V_{TS}$ data in the ADC data register.
6. Calculate the actual temperature using the following formula:

   \[
   \text{Temperature (in °C)} = \frac{\text{TS\_CAL2\_TEMP} - \text{TS\_CAL1\_TEMP}}{\text{TS\_CAL2} - \text{TS\_CAL1}} \times (\text{TS\_DATA} - \text{TS\_CAL1}) + 30 \text{ °C}
   \]
Where:
- TS_CAL2 is the temperature sensor calibration value acquired at TS_CAL2_TEMP.
- TS_CAL1 is the temperature sensor calibration value acquired at TS_CAL1_TEMP.
- TS_DATA is the actual temperature sensor output value converted by ADC.

Refer to the device datasheet for more information about TS_CAL1 and TS_CAL2 calibration points.

Note: The sensor has a startup time after waking from power-down mode before it can output $V_{TS}$ at the correct level. The ADC also has a startup time after power-on, so to minimize the delay, the ADEN and CH17SEL bits should be set at the same time.

The above formula is given for TS_DATA measurement done with the same $V_{REF+}$ voltage as TS_CAL1/TS_CAL2 values. If $V_{REF+}$ is different, the formula must be adapted. For example if $V_{REF+} = 3.3 \, \text{V}$ and TS_CAL data are acquired at $V_{REF+} = 3.0 \, \text{V}$, TS_DATA must be replaced by $TS\_DATA \times (3.3/3.0)$.

### 21.4.33 V\_BAT supply monitoring

The CH18SEL bit in the ADCx_CCR register is used to switch to the battery voltage. As the $V_{BAT}$ voltage could be higher than $V_{DDA}$, to ensure the correct operation of the ADC, the $V_{BAT}$ pin is internally connected to a bridge divider by 3. This bridge is automatically enabled when CH18SEL is set, to connect $V_{BAT}/3$ to the ADC input channels. As a consequence, the converted digital value is one third of the $V_{BAT}$ voltage. To prevent any unwanted consumption on the battery, it is recommended to enable the bridge divider only when needed, for ADC conversion.

Refer to the electrical characteristics of the device datasheet for the sampling time value to be applied when converting the $V_{BAT}/3$ voltage.

The figure below shows the block diagram of the $V_{BAT}$ sensing feature.

**Figure 155. V\_BAT channel block diagram**

1. The CH18SEL bit must be set to enable the conversion of internal channel for $V_{BAT}/3$. 

---

MSv37245V1
21.4.34 Monitoring the internal voltage reference

It is possible to monitor the internal voltage reference ($V_{\text{REFINT}}$) to have a reference point for evaluating the ADC $V_{\text{REF}+}$ voltage level.

The internal voltage reference is internally connected to the input channel 0 of the ADC1 (ADC1_INP0).

Refer to the electrical characteristics section of the product datasheet for the sampling time value to be applied when converting the internal voltage reference voltage.

*Figure 156* shows the block diagram of the $V_{\text{REFINT}}$ sensing feature.

### Figure 156. $V_{\text{REFINT}}$ channel block diagram

1. The VREFEN bit into ADCx_CCR register must be set to enable the conversion of internal channels ($V_{\text{REFINT}}$).

#### Calculating the actual $V_{\text{REF}+}$ voltage using the internal reference voltage

The power supply voltage applied to the device may be subject to variations or not precisely known. When $V_{\text{DDA}}$ is connected to $V_{\text{REF}+}$, it is possible to compute the actual $V_{\text{DDA}}$ voltage using the embedded internal reference voltage ($V_{\text{REFINT}}$). $V_{\text{REFINT}}$ and its calibration data, acquired by the ADC during the manufacturing process at $V_{\text{DDA}_{\text{Charac}}}$, can be used to evaluate the actual $V_{\text{DDA}}$ voltage level.

The following formula gives the actual $V_{\text{REF}+}$ voltage supplying the device:

$$V_{\text{REF}+} = V_{\text{REF+}_{\text{Charac}}} \times \frac{V_{\text{REFINT}_{\text{CAL}}}}{V_{\text{REFINT}_{\text{DATA}}}}$$

Where:

- $V_{\text{REF+}_{\text{Charac}}}$ is the value of $V_{\text{REF+}}$ voltage characterized at $V_{\text{REFINT}}$ during the manufacturing process. It is specified in the device datasheet.
- $V_{\text{REFINT}_{\text{CAL}}}$ is the $V_{\text{REFINT}}$ calibration value
- $V_{\text{REFINT}_{\text{DATA}}}$ is the actual $V_{\text{REFINT}}$ output value converted by ADC

#### Converting a supply-relative ADC measurement to an absolute voltage value

The ADC is designed to deliver a digital value corresponding to the ratio between $V_{\text{REF}+}$ and the voltage applied on the converted channel.

For most applications $V_{\text{DDA}}$ value is unknown and ADC converted values are right-aligned. In this case, it is necessary to convert this ratio into a voltage independent from $V_{\text{DDA}}$.
Analog-to-digital converters (ADC) RM0432

By replacing $V_{REF+}$ by the formula provided above, the absolute voltage value is given by the following formula:

$$V_{CHANNELx} = \frac{V_{REF+}}{FULL_{\_SCALE}} \times ADC_{\_DATA}$$

For applications where $V_{REF+}$ is known and ADC converted values are right-aligned, the absolute voltage value can be obtained by using the following formula:

$$V_{CHANNELx} = \frac{V_{REF+_{\_Charac}} \times V_{REFINT_{\_CAL}} \times ADC_{\_DATA}}{V_{REFINT_{\_DATA}} \times FULL_{\_SCALE}}$$

Where:
- $V_{REF+_{\_Charac}}$ is the value of $V_{REF+}$ voltage characterized at $V_{REFINT}$ during the manufacturing process.
- $V_{REFINT_{\_CAL}}$ is the $V_{REFINT}$ calibration value
- $ADC_{\_DATA}$ is the value measured by the ADC on channel $x$ (right-aligned)
- $V_{REFINT_{\_DATA}}$ is the actual $V_{REFINT}$ output value converted by the ADC
- $FULL_{\_SCALE}$ is the maximum digital value of the ADC output. For example with 12-bit resolution, it will be $2^{12} - 1 = 4095$ or with 8-bit resolution, $2^8 - 1 = 255$.

Note: If ADC measurements are done using an output format other than 16-bit right-aligned, all the parameters must first be converted to a compatible format before the calculation is done.

21.5 ADC interrupts

For each ADC, an interrupt can be generated:
- After ADC power-up, when the ADC is ready (flag ADRDY)
- On the end of any conversion for regular groups (flag EOC)
- On the end of a sequence of conversion for regular groups (flag EOS)
- On the end of any conversion for injected groups (flag JEOC)
- On the end of a sequence of conversion for injected groups (flag JEOS)
- When an analog watchdog detection occurs (flag AWD1, AWD2 and AWD3)
- When the end of sampling phase occurs (flag EOSMP)
- When the data overrun occurs (flag OVR)
- When the injected sequence context queue overflows (flag JQOVF)

Separate interrupt enable bits are available for flexibility.

Bits 31:11  Reserved, must be kept at reset value.

Bit 10  **JQOVF**: Injected context queue overflow

This bit is set by hardware when an Overflow of the Injected Queue of Context occurs. It is cleared by software writing 1 to it. Refer to *Section 21.4.21: Queue of context for injected conversions* for more information.

0: No injected context queue overflow occurred (or the flag event was already acknowledged and cleared by software)

1: Injected context queue overflow has occurred

Bit 9  **AWD3**: Analog watchdog 3 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT3[7:0] and HT3[7:0] of ADC_TR3 register. It is cleared by software writing 1 to it.

0: No analog watchdog 3 event occurred (or the flag event was already acknowledged and cleared by software)

1: Analog watchdog 3 event occurred

Bit 8  **AWD2**: Analog watchdog 2 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT2[7:0] and HT2[7:0] of ADC_TR2 register. It is cleared by software writing 1 to it.

0: No analog watchdog 2 event occurred (or the flag event was already acknowledged and cleared by software)

1: Analog watchdog 2 event occurred

Bit 7  **AWD1**: Analog watchdog 1 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT1[11:0] and HT1[11:0] of ADC_TR1 register. It is cleared by software, writing 1 to it.

0: No analog watchdog 1 event occurred (or the flag event was already acknowledged and cleared by software)

1: Analog watchdog 1 event occurred

Bit 6  **JEOS**: Injected channel end of sequence flag

This bit is set by hardware at the end of the conversions of all injected channels in the group. It is cleared by software writing 1 to it.

0: Injected conversion sequence not complete (or the flag event was already acknowledged and cleared by software)

1: Injected conversions complete
Bit 5 **JEOC**: Injected channel end of conversion flag

This bit is set by hardware at the end of each injected conversion of a channel when a new data is available in the corresponding ADC_JDRy register. It is cleared by software writing 1 to it or by reading the corresponding ADC_JDRy register.

- 0: Injected channel conversion not complete (or the flag event was already acknowledged and cleared by software)
- 1: Injected channel conversion complete

Bit 4 **OVR**: ADC overrun

This bit is set by hardware when an overrun occurs on a regular channel, meaning that a new conversion has completed while the EOC flag was already set. It is cleared by software writing 1 to it.

- 0: No overrun occurred (or the flag event was already acknowledged and cleared by software)
- 1: Overrun has occurred

Bit 3 **EOS**: End of regular sequence flag

This bit is set by hardware at the end of the conversions of a regular sequence of channels. It is cleared by software writing 1 to it.

- 0: Regular Conversions sequence not complete (or the flag event was already acknowledged and cleared by software)
- 1: Regular Conversions sequence complete

Bit 2 **EOC**: End of conversion flag

This bit is set by hardware at the end of each regular conversion of a channel when a new data is available in the ADC_DR register. It is cleared by software writing 1 to it or by reading the ADC_DR register.

- 0: Regular channel conversion not complete (or the flag event was already acknowledged and cleared by software)
- 1: Regular channel conversion complete

Bit 1 **EOSMP**: End of sampling flag

This bit is set by hardware during the conversion of any channel (only for regular channels), at the end of the sampling phase.

- 0: not at the end of the sampling phase (or the flag event was already acknowledged and cleared by software)
- 1: End of sampling phase reached

Bit 0 **ADRDY**: ADC ready

This bit is set by hardware after the ADC has been enabled (bit ADEN=1) and when the ADC reaches a state where it is ready to accept conversion requests. It is cleared by software writing 1 to it.

- 0: ADC not yet ready to start conversion (or the flag event was already acknowledged and cleared by software)
- 1: ADC is ready to start conversion
### 21.6.2 ADC interrupt enable register (ADC_IER)

Bit 31 ADCAL: ADC calibration
This bit is set by software to start the calibration of the ADC. Program first the bit ADCALDIF to determine if this calibration applies for single-ended or differential inputs mode.
It is cleared by hardware after calibration is complete.
0: Calibration complete
1: Write 1 to calibrate the ADC. Read at 1 means that a calibration in progress.
Note: The software is allowed to launch a calibration by setting ADCAL only when ADEN=0.
The software is allowed to update the calibration factor by writing ADC_CALFACT only when ADEN=1 and ADSTART=0 and JADSTART=0 (ADC enabled and no conversion is ongoing).

Bit 30 ADCALDIF: Differential mode for calibration
This bit is set and cleared by software to configure the single-ended or differential inputs mode for the calibration.
0: Writing ADCAL will launch a calibration in single-ended inputs mode.
1: Writing ADCAL will launch a calibration in differential inputs mode.
Note: The software is allowed to write this bit only when the ADC is disabled and is not calibrating (ADCAL=0, JADSTART=0, ADSTP=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

Bit 29 DEEPPWD: Deep-power-down enable
This bit is set and cleared by software to put the ADC in Deep-power-down mode.
0: ADC not in Deep-power down
1: ADC in Deep-power-down (default reset state)
Note: The software is allowed to write this bit only when the ADC is disabled (ADCAL=0, JADSTART=0, JADSTP=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

Bit 28 ADVREGEN: ADC voltage regulator enable
This bits is set by software to enable the ADC voltage regulator.
Before performing any operation such as launching a calibration or enabling the ADC, the ADC voltage regulator must first be enabled and the software must wait for the regulator start-up time.
0: ADC Voltage regulator disabled
1: ADC Voltage regulator enabled.
For more details about the ADC voltage regulator enable and disable sequences, refer to Section 21.4.6: ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN).
The software can program this bit field only when the ADC is disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).
Bits 27:6  Reserved, must be kept at reset value.

Bit 5  **JADSTP**: ADC stop of injected conversion command

This bit is set by software to stop and discard an ongoing injected conversion (JADSTP Command).

It is cleared by hardware when the conversion is effectively discarded and the ADC injected sequence and triggers can be re-configured. The ADC is then ready to accept a new start of injected conversions (JADSTART command).

0: No ADC stop injected conversion command ongoing
1: Write 1 to stop injected conversions ongoing. Read 1 means that an ADSTP command is in progress.

**Note:** The software is allowed to set JADSTP only when JADSTART=1 and ADDIS=0 (ADC is enabled and eventually converting an injected conversion and there is no pending request to disable the ADC)

*In Auto-injection mode (JAUTO=1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP)*

Bit 4  **ADSTP**: ADC stop of regular conversion command

This bit is set by software to stop and discard an ongoing regular conversion (ADSTP Command).

It is cleared by hardware when the conversion is effectively discarded and the ADC regular sequence and triggers can be re-configured. The ADC is then ready to accept a new start of regular conversions (ADSTART command).

0: No ADC stop regular conversion command ongoing
1: Write 1 to stop regular conversions ongoing. Read 1 means that an ADSTP command is in progress.

**Note:** The software is allowed to set ADSTP only when ADSTART=1 and ADDIS=0 (ADC is enabled and eventually converting a regular conversion and there is no pending request to disable the ADC).

*In auto-injection mode (JAUTO=1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP)*

Bit 3  **JADSTART**: ADC start of injected conversion

This bit is set by software to start ADC conversion of injected channels. Depending on the configuration bits JEXTEN[1:0], a conversion will start immediately (software trigger configuration) or once an injected hardware trigger event occurs (hardware trigger configuration).

It is cleared by hardware:

– in single conversion mode when software trigger is selected (JEXTSEL=0x0): at the assertion of the End of Injected Conversion Sequence (JEOS) flag.
– in all cases: after the execution of the JADSTP command, at the same time that JADSTP is cleared by hardware.

0: No ADC injected conversion is ongoing.
1: Write 1 to start injected conversions. Read 1 means that the ADC is operating and eventually converting an injected channel.

**Note:** The software is allowed to set JADSTART only when ADEN=1 and ADDIS=0 (ADC is enabled and there is no pending request to disable the ADC).

*In auto-injection mode (JAUTO=1), regular and auto-injected conversions are started by setting bit ADSTART (JADSTART must be kept cleared)*
Bit 2 **ADSTART**: ADC start of regular conversion

This bit is set by software to start ADC conversion of regular channels. Depending on the configuration bits EXTEN[1:0], a conversion will start immediately (software trigger configuration) or once a regular hardware trigger event occurs (hardware trigger configuration).

It is cleared by hardware:

- in single conversion mode when software trigger is selected (EXTSEL=0x0): at the assertion of the End of Regular Conversion Sequence (EOS) flag.
- in all cases: after the execution of the ADSTP command, at the same time that ADSTP is cleared by hardware.

0: No ADC regular conversion is ongoing.
1: Write 1 to start regular conversions. Read 1 means that the ADC is operating and eventually converting a regular channel.

**Note:** The software is allowed to set ADSTART only when ADEN=1 and ADDIS=0 (ADC is enabled and there is no pending request to disable the ADC)

In auto-injection mode (JAUTO=1), regular and auto-injected conversions are started by setting bit ADSTART (JADSTART must be kept cleared)

Bit 1 **ADDIS**: ADC disable command

This bit is set by software to disable the ADC (ADDIS command) and put it into power-down state (OFF state).

It is cleared by hardware once the ADC is effectively disabled (ADEN is also cleared by hardware at this time).

0: no ADDIS command ongoing
1: Write 1 to disable the ADC. Read 1 means that an ADDIS command is in progress.

**Note:** The software is allowed to set ADDIS only when ADEN=1 and both ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing)

Bit 0 **ADEN**: ADC enable control

This bit is set by software to enable the ADC. The ADC will be effectively ready to operate once the flag ADRDY has been set.

It is cleared by hardware when the ADC is disabled, after the execution of the ADDIS command.

0: ADC is disabled (OFF state)
1: Write 1 to enable the ADC.

**Note:** The software is allowed to set ADEN only when all bits of ADC_CR registers are 0 (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0) except for bit ADVREGEN which must be 1 (and the software must have wait for the startup time of the voltage regulator)
### 21.6.4 ADC configuration register (ADC_CFGR)

Bit 31 **JQDIS**: Injected Queue disable  
These bits are set and cleared by software to disable the Injected Queue mechanism:  
0: Injected Queue enabled  
1: Injected Queue disabled  

*Note:* The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no regular nor injected conversion is ongoing).  
A set or reset of JQDIS bit causes the injected queue to be flushed and the JSQR register is cleared.

Bits 30:26 **AWD1CH[4:0]**: Analog watchdog 1 channel selection  
These bits are set and cleared by software. They select the input channel to be guarded by the analog watchdog.  
00000: ADC analog input channel 0 monitored by AWD1 (available on ADC1 only)  
00001: ADC analog input channel 1 monitored by AWD1  
....  
10010: ADC analog input channel 18 monitored by AWD1  
others: reserved, must not be used  

*Note:* Some channels are not connected physically. Keep the corresponding AWD1CH[4:0] setting to the reset value.  
The channel selected by AWD1CH must be also selected into the SQRi or JSQRi registers. The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

Bit 25 **JAUTO**: Automatic injected group conversion  
This bit is set and cleared by software to enable/disable automatic injected group conversion after regular group conversion.  
0: Automatic injected group conversion disabled  
1: Automatic injected group conversion enabled  

*Note:* The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no regular nor injected conversion is ongoing).  
When dual mode is enabled (DUAL bits in ADCx_CCR register are not equal to zero), the bit JAUTO of the slave ADC is no more writable and its content is equal to the bit JAUTO of the master ADC.
Bit 24  **JAWD1EN**: Analog watchdog 1 enable on injected channels  
This bit is set and cleared by software  
0: Analog watchdog 1 disabled on injected channels  
1: Analog watchdog 1 enabled on injected channels  
_Note: The software is allowed to write this bit only when JADSTART=0 (which ensures that no injected conversion is ongoing)._  

Bit 23  **AWD1EN**: Analog watchdog 1 enable on regular channels  
This bit is set and cleared by software  
0: Analog watchdog 1 disabled on regular channels  
1: Analog watchdog 1 enabled on regular channels  
_Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing)._  

Bit 22  **AWD1SGL**: Enable the watchdog 1 on a single channel or on all channels  
This bit is set and cleared by software to enable the analog watchdog on the channel identified by the AWD1CH[4:0] bits or on all the channels  
0: Analog watchdog 1 enabled on all channels  
1: Analog watchdog 1 enabled on a single channel  
_Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing)._  

Bit 21  **JQM**: JSQR queue mode  
This bit is set and cleared by software.  
It defines how an empty Queue is managed.  
0: JSQR mode 0: The Queue is never empty and maintains the last written configuration into JSQR.  
1: JSQR mode 1: The Queue can be empty and when this occurs, the software and hardware triggers of the injected sequence are both internally disabled just after the completion of the last valid injected sequence.  
Refer to Section 21.4.21: Queue of context for injected conversions for more information.  
_Note: The software is allowed to write this bit only when JADSTART=0 (which ensures that no injected conversion is ongoing)._  
When dual mode is enabled (DUAL bits in ADCx_CCR register are not equal to zero), the bit JQM of the slave ADC is no more writable and its content is equal to the bit JQM of the master ADC.  

Bit 20  **JDISCEN**: Discontinuous mode on injected channels  
This bit is set and cleared by software to enable/disable discontinuous mode on the injected channels of a group.  
0: Discontinuous mode on injected channels disabled  
1: Discontinuous mode on injected channels enabled  
_Note: The software is allowed to write this bit only when JADSTART=0 (which ensures that no injected conversion is ongoing)._  
It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.  
When dual mode is enabled (bits DUAL of ADCx_CCR register are not equal to zero), the bit JDISCEN of the slave ADC is no more writable and its content is equal to the bit JDISCEN of the master ADC.
Bits 19:17 **DISCNUM[2:0]**: Discontinuous mode channel count

These bits are written by software to define the number of regular channels to be converted in discontinuous mode, after receiving an external trigger.

- 000: 1 channel
- 001: 2 channels
- ...
- 111: 8 channels

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

When dual mode is enabled (DUAL bits in ADCx_CCR register are not equal to zero), the bits DISCNUM[2:0] of the slave ADC are no more writable and their content is equal to the bits DISCNUM[2:0] of the master ADC.

Bit 16 **DISCEN**: Discontinuous mode for regular channels

This bit is set and cleared by software to enable/disable Discontinuous mode for regular channels.

- 0: Discontinuous mode for regular channels disabled
- 1: Discontinuous mode for regular channels enabled

*Note:* It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN=1 and CONT=1.

It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).

When dual mode is enabled (DUAL bits in ADCx_CCR register are not equal to zero), the bit DISCEN of the slave ADC is no more writable and its content is equal to the bit DISCEN of the master ADC.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **AUTDLY**: Delayed conversion mode

This bit is set and cleared by software to enable/disable the Auto Delayed Conversion mode.

- 0: Auto-delayed conversion mode off
- 1: Auto-delayed conversion mode on

*Note:* The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

When dual mode is enabled (DUAL bits in ADCx_CCR register are not equal to zero), the bit AUTDLY of the slave ADC is no more writable and its content is equal to the bit AUTDLY of the master ADC.

Bit 13 **CONT**: Single / continuous conversion mode for regular conversions

This bit is set and cleared by software. If it is set, regular conversion takes place continuously until it is cleared.

- 0: Single conversion mode
- 1: Continuous conversion mode

*Note:* It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN=1 and CONT=1.

The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).

When dual mode is enabled (DUAL bits in ADCx_CCR register are not equal to zero), the bit CONT of the slave ADC is no more writable and its content is equal to the bit CONT of the master ADC.
Bit 12 **OVRMOD**: Overrun mode

This bit is set and cleared by software and configure the way data overrun is managed.
- 0: ADC_DR register is preserved with the old data when an overrun is detected.
- 1: ADC_DR register is overwritten with the last conversion result when an overrun is detected.

*Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bits 11:10 **EXTEN[1:0]**: External trigger enable and polarity selection for regular channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of a regular group.
- 00: Hardware trigger detection disabled (conversions can be launched by software)
- 01: Hardware trigger detection on the rising edge
- 10: Hardware trigger detection on the falling edge
- 11: Hardware trigger detection on both the rising and falling edges

*Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bits 9:6 **EXTSEL[3:0]**: External trigger selection for regular group

These bits select the external event used to trigger the start of conversion of a regular group:
- 0000: Event 0
- 0001: Event 1
- 0010: Event 2
- 0011: Event 3
- 0100: Event 4
- 0101: Event 5
- 0110: Event 6
- 0111: Event 7
- ... 1111: Event 15

*Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bit 5 **ALIGN**: Data alignment

This bit is set and cleared by software to select right or left alignment. Refer to Section : Data register, data alignment and offset (ADC_DR, OFFSETy, OFFSETy_CH, ALIGN)
- 0: Right alignment
- 1: Left alignment

*Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

Bits 4:3 **RES[1:0]**: Data resolution

These bits are written by software to select the resolution of the conversion.
- 00: 12-bit
- 01: 10-bit
- 10: 8-bit
- 11: 6-bit

*Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*
Bit 2  **DFSDMCFG**: DFSDM mode configuration

This bit is set and cleared by software to enable the DFSDM mode. It is effective only when DMAEN=0.

0: DFSDM mode disabled
1: DFSDM mode enabled

*Note:* To make sure no conversion is ongoing, the software is allowed to write this bit only when ADSTART= 0 and JADSTART= 0.

Bit 1  **DMACFG**: Direct memory access configuration

This bit is set and cleared by software to select between two DMA modes of operation and is effective only when DMAEN=1.

0: DMA One Shot mode selected
1: DMA Circular mode selected

For more details, refer to *Section : Managing conversions using the DMA*

*Note:* The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

In dual-ADC modes, this bit is not relevant and replaced by control bit DMACFG of the ADCx_CCR register.

Bit 0  **DMAEN**: Direct memory access enable

This bit is set and cleared by software to enable the generation of DMA requests. This allows to use the DMA to manage automatically the converted data. For more details, refer to *Section : Managing conversions using the DMA*.

0: DMA disabled
1: DMA enabled

*Note:* The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

In dual-ADC modes, this bit is not relevant and replaced by control bits MDMA[1:0] of the ADCx_CCR register.

### 21.6.5 ADC configuration register 2 (ADC_CFGR2)

Bits 31:28  Reserved, must be kept at reset value.

Bits 27:17  Reserved, must be kept at reset value.

Bits 16:11  Reserved, must be kept at reset value.
Bit 10  **ROVSM**: Regular Oversampling mode
This bit is set and cleared by software to select the regular oversampling mode.
0: Continued mode: When injected conversions are triggered, the oversampling is temporary stopped and continued after the injection sequence (oversampling buffer is maintained during injected sequence)
1: Resumed mode: When injected conversions are triggered, the current oversampling is aborted and resumed from start after the injection sequence (oversampling buffer is zeroed by injected sequence start)
*Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no conversion is ongoing).*

Bit 9  **TROVS**: Triggered Regular Oversampling
This bit is set and cleared by software to enable triggered oversampling
0: All oversampled conversions for a channel are done consecutively following a trigger
1: Each oversampled conversion for a channel needs a new trigger
*Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no conversion is ongoing).*

Bits 8:5  **OVSS[3:0]**: Oversampling shift
This bitfield is set and cleared by software to define the right shifting applied to the raw oversampling result.
0000: No shift
0001: Shift 1-bit
0010: Shift 2-bits
0011: Shift 3-bits
0100: Shift 4-bits
0101: Shift 5-bits
0110: Shift 6-bits
0111: Shift 7-bits
1000: Shift 8-bits
Other codes reserved
*Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no conversion is ongoing).*
Bits 4:2 **OVSR[2:0]**: Oversampling ratio
This bitfield is set and cleared by software to define the oversampling ratio.
- 000: 2x
- 001: 4x
- 010: 8x
- 011: 16x
- 100: 32x
- 101: 64x
- 110: 128x
- 111: 256x

*Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no conversion is ongoing).*

Bit 1 **JOVSE**: Injected Oversampling Enable
This bit is set and cleared by software to enable injected oversampling.
- 0: Injected Oversampling disabled
- 1: Injected Oversampling enabled

*Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

Bit 0 **ROVSE**: Regular Oversampling Enable
This bit is set and cleared by software to enable regular oversampling.
- 0: Regular Oversampling disabled
- 1: Regular Oversampling enabled

*Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

Bit 31 **SMPPLUS**: Addition of one clock cycle to the sampling time.
- 1: 2.5 ADC clock cycle sampling time becomes 3.5 ADC clock cycles for the ADC_SMPR1 and ADC_SMPR2 registers.
- 0: The sampling time remains set to 2.5 ADC clock cycles remains

*To make sure no conversion is ongoing, the software is allowed to write this bit only when ADSTART= 0 and JADSTART= 0.*

Bit 30 Reserved, must be kept at reset value.

Bits 29:0 **SMP[9:0][2:0]**: Channel x sampling time selection

These bits are written by software to select the sampling time individually for each channel. During sample cycles, the channel selection bits must remain unchanged.

- 000: 2.5 ADC clock cycles
- 001: 6.5 ADC clock cycles
- 010: 12.5 ADC clock cycles
- 011: 24.5 ADC clock cycles
- 100: 47.5 ADC clock cycles
- 101: 92.5 ADC clock cycles
- 110: 247.5 ADC clock cycles
- 111: 640.5 ADC clock cycles

*Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing). Some channels are not connected physically. Keep the corresponding SMPx[2:0] setting to the reset value.*
Bits 31:27  Reserved, must be kept at reset value.

Bits 26:0  **SMP[18:10][2:0]: Channel x sampling time selection**
These bits are written by software to select the sampling time individually for each channel.
During sampling cycles, the channel selection bits must remain unchanged.
- 000: 2.5 ADC clock cycles
- 001: 6.5 ADC clock cycles
- 010: 12.5 ADC clock cycles
- 011: 24.5 ADC clock cycles
- 100: 47.5 ADC clock cycles
- 101: 92.5 ADC clock cycles
- 110: 247.5 ADC clock cycles
- 111: 640.5 ADC clock cycles

*Note:* The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).
Some channels are not connected physically. Keep the corresponding SMPx[2:0] setting to the reset value.

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **HT3[7:0]:** Analog watchdog 3 higher threshold

These bits are written by software to define the higher threshold for the analog watchdog 3.

Refer to Section 21.4.29: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)

Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **LT3[7:0]:** Analog watchdog 3 lower threshold

These bits are written by software to define the lower threshold for the analog watchdog 3.

Refer to Section 21.4.29: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)

Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).
Bits 31:24  Reserved, must be kept at reset value.

Bits 23:16  **HT3[7:0]**: Analog watchdog 3 higher threshold
These bits are written by software to define the higher threshold for the analog watchdog 3.
Refer to Section 21.4.29: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)

Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

Bits 15:8  Reserved, must be kept at reset value.

Bits 7:0  **LT3[7:0]**: Analog watchdog 3 lower threshold
These bits are written by software to define the lower threshold for the analog watchdog 3.
This watchdog compares the 8-bit of LT3 with the 8 MSB of the converted data.

Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

**Bits 31:29**  Reserved, must be kept at reset value.

**Bits 28:24**  **SO4[4:0]**: 4th conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 4th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

**Bit 23**  Reserved, must be kept at reset value.

**Bits 22:18**  **SO3[4:0]**: 3rd conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 3rd in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

**Bit 17**  Reserved, must be kept at reset value.

**Bits 16:12**  **SO2[4:0]**: 2nd conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 2nd in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

**Bit 11**  Reserved, must be kept at reset value.
Bits 10:6 **SQ1[4:0]:** 1st conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 1st in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bits 5:4 Reserved, must be kept at reset value.

Bits 3:0 **L[3:0]:** Regular channel sequence length
These bits are written by software to define the total number of conversions in the regular channel conversion sequence.

0000: 1 conversion
0001: 2 conversions
...
1111: 16 conversions

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

*Note:* Some channels are not connected physically and must not be selected for conversion.

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ9[4:0]:** 9th conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 9th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ8[4:0]:** 8th conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 8th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ7[4:0]:** 7th conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 7th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).
Bit 11 Reserved, must be kept at reset value.

Bits 10:6 \textbf{SQ6[4:0]}: 6th conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 6th in the regular conversion sequence.

\textbf{Note}: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 \textbf{SQ5[4:0]}: 5th conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 5th in the regular conversion sequence.

\textbf{Note}: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

\textbf{Note}: Some channels are not connected physically and must not be selected for conversion.

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 \textbf{SQ14[4:0]}: 14th conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 14th in the regular conversion sequence.

\textbf{Note}: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 \textbf{SQ13[4:0]}: 13th conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 13th in the regular conversion sequence.

\textbf{Note}: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 \textbf{SQ12[4:0]}: 12th conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 12th in the regular conversion sequence.

\textbf{Note}: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.
Bits 10:6 **SQ11[4:0]**: 11th conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 11th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **SQ10[4:0]**: 10th conversion in regular sequence
These bits are written by software with the channel number (0 to 18) assigned as the 10th in the regular conversion sequence.

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.

<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bit 31 Reserved, must be kept at reset value.  

Bits 30:26 **JSQ2[4:0]**: 4th conversion in the injected sequence  
These bits are written by software with the channel number (0 to 18) assigned as the 4th in the injected conversion sequence.  
**Note:** The software is allowed to write these bits only when JADSTART=0 (which ensures that no injected conversion is ongoing).

Bit 25 Reserved, must be kept at reset value.  

Bits 24:20 **JSQ3[4:0]**: 3rd conversion in the injected sequence  
These bits are written by software with the channel number (0 to 18) assigned as the 3rd in the injected conversion sequence.  
**Note:** The software is allowed to write these bits only when JADSTART=0 (which ensures that no injected conversion is ongoing).

Bit 19 Reserved, must be kept at reset value.
Bits 18:14  JSQ2[4:0]: 2nd conversion in the injected sequence
These bits are written by software with the channel number (0 to 18) assigned as the 2nd in the injected conversion sequence.

Note: The software is allowed to write these bits only when JADSTART=0 (which ensures that no injected conversion is ongoing).

Bit 13  Reserved, must be kept at reset value.

Bits 12:8  JSQ1[4:0]: 1st conversion in the injected sequence
These bits are written by software with the channel number (0 to 18) assigned as the 1st in the injected conversion sequence.

Note: The software is allowed to write these bits only when JADSTART=0 (which ensures that no injected conversion is ongoing).

Bits 7:6  JEXTEN[1:0]: External Trigger Enable and Polarity Selection for injected channels
These bits are set and cleared by software to select the external trigger polarity and enable the trigger of an injected group.
00: If JQDIS=0 (queue enabled), Hardware and software trigger detection disabled
00: If JQDIS=1 (queue disabled), Hardware trigger detection disabled (conversions can be launched by software)
01: Hardware trigger detection on the rising edge
10: Hardware trigger detection on the falling edge
11: Hardware trigger detection on both the rising and falling edges

Note: The software is allowed to write these bits only when JADSTART=0 (which ensures that no injected conversion is ongoing).

If JQM=1 and if the Queue of Context becomes empty, the software and hardware triggers of the injected sequence are both internally disabled (refer to Section 21.4.21: Queue of context for injected conversions)

Bits 5:2  JEXTSEL[3:0]: External Trigger Selection for injected group
These bits select the external event used to trigger the start of conversion of an injected group:
0000: Event 0
0001: Event 1
0010: Event 2
0011: Event 3
0100: Event 4
0101: Event 5
0110: Event 6
0111: Event 7
...
1111: Event 15

Note: The software is allowed to write these bits only when JADSTART=0 (which ensures that no injected conversion is ongoing).

Bits 1:0  JL[1:0]: Injected channel sequence length
These bits are written by software to define the total number of conversions in the injected channel conversion sequence.
00: 1 conversion
01: 2 conversions
10: 3 conversions
11: 4 conversions

Note: The software is allowed to write these bits only when JADSTART=0 (which ensures that no injected conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.
21.6.17 ADC offset y register (ADC_OFRy)

</tbody>
</table>

**Bit 31** **OFFSETy_EN**: Offset y enable
This bit is written by software to enable or disable the offset programmed into bits OFFSETy[11:0].

*Note*: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

**Bits 30:26** **OFFSETy_CH[4:0]**: Channel selection for the data offset y
These bits are written by software to define the channel to which the offset programmed into bits OFFSETy[11:0] will apply.

*Note*: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

Some channels are not connected physically and must not be selected for the data offset y.

**Bits 25:12** Reserved, must be kept at reset value.

**Bits 11:0** **OFFSETy[11:0]**: Data offset y for the channel programmed into bits OFFSETy_CH[4:0]
These bits are written by software to define the offset y to be subtracted from the raw converted data when converting a channel (can be regular or injected). The channel to which applies the data offset y must be programmed in the bits OFFSETy_CH[4:0]. The conversion result can be read from in the ADC_DR (regular conversion) or from in the ADC_JDRyi registers (injected conversion).

*Note*: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

If several offset (OFFSETy) point to the same channel, only the offset with the lowest x value is considered for the subtraction.

Ex: if OFFSET1_CH[4:0]=4 and OFFSET2_CH[4:0]=4, this is OFFSET1[11:0] which is subtracted when converting channel 4.
21.6.18 ADC injected channel y data register (ADC_JDRy)

Address offset: 0x80 + 0x04 * (y - 1), (y = 1 to 4)
Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 JDATA[15:0]: Injected data
These bits are read-only. They contain the conversion result from injected channel y. The data are left- or right-aligned as described in Section 21.4.26: Data management.

21.6.19 ADC analog watchdog 2 configuration register (ADC_AWD2CR)

Address offset: 0xA0
Reset value: 0x0000 0000

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:0 AWD2CH[18:0]: Analog watchdog 2 channel selection
These bits are set and cleared by software. They enable and select the input channels to be guarded by the analog watchdog 2.

AWD2CH[i] = 0: ADC analog input channel i is not monitored by AWD2
AWD2CH[i] = 1: ADC analog input channel i is monitored by AWD2
When AWD2CH[18:0] = 000...0, the analog watchdog 2 is disabled

Note: The channels selected by AWD2CH must be also selected into the SQRi or JSQRi registers. The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

Some channels are not connected physically and must not be selected for the analog watchdog.
21.6.20 ADC analog watchdog 3 configuration register (ADC_AWD3CR)

Address offset: 0xA4
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Address offset: 0xA4</th>
<th>Reset value: 0x0000 0000</th>

</thead>
<tbody>
<tr>
<td>AWD3CH[18:16]</td>
<td>rw</td>
</tr>
<tr>
<td>AWD3CH[15:0]</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:0 AWD3CH[18:0]: Analog watchdog 3 channel selection
- These bits are set and cleared by software. They enable and select the input channels to be guarded by the analog watchdog 3.
  - AWD3CH[i] = 0: ADC analog input channel i is not monitored by AWD3
  - AWD3CH[i] = 1: ADC analog input channel i is monitored by AWD3
- When AWD3CH[18:0] = 000..0, the analog watchdog 3 is disabled
  - Note: The channels selected by AWD3CH must be also selected into the SQRi or JSQRi registers.
  - The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).
  - Some channels are not connected physically and must not be selected for the analog watchdog.

21.6.21 ADC differential mode selection register (ADC_DIFSEL)

Address offset: 0xB0
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Address offset: 0xB0</th>

</tr>
<tr>
<td>DIFSEL[15:0]</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:0 DIFSEL[18:0]: Differential mode for channels 18 to 0.
- These bits are set and cleared by software. They allow to select if a channel is configured as single-ended or differential mode.
  - DIFSEL[i] = 0: ADC analog input channel is configured in single ended mode
  - DIFSEL[i] = 1: ADC analog input channel i is configured in differential mode
- Note: The DIFSEL bits corresponding to channels that are either connected to a single-ended I/O port or to an internal channel must be kept their reset value (single-ended input mode).
  - The software is allowed to write these bits only when the ADC is disabled (ADCAL=0, JADSTART=0, ADSTP=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).
21.6.22 ADC calibration factors (ADC_CALFACT)

</tr>
</tbody>
</table>

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:16 CALFACT_D[6:0]: Calibration Factors in differential mode

These bits are written by hardware or by software.
Once a differential inputs calibration is complete, they are updated by hardware with the calibration factors.
Software can write these bits with a new calibration factor. If the new calibration factor is different from the current one stored into the analog ADC, it will then be applied once a new differential calibration is launched.

Note: The software is allowed to write these bits only when ADEN=1, ADSTART=0 and JADSTART=0 (ADC is enabled and no calibration is ongoing and no conversion is ongoing).

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:0 CALFACT_S[6:0]: Calibration Factors In single-ended mode

These bits are written by hardware or by software.
Once a single-ended inputs calibration is complete, they are updated by hardware with the calibration factors.
Software can write these bits with a new calibration factor. If the new calibration factor is different from the current one stored into the analog ADC, it will then be applied once a new single-ended calibration is launched.

Note: The software is allowed to write these bits only when ADEN=1, ADSTART=0 and JADSTART=0 (ADC is enabled and no calibration is ongoing and no conversion is ongoing).

21.7 ADC common registers

These registers define the control and status registers common to master and slave ADCs:

21.7.1 ADC common status register (ADC_CSR)

Address offset: 0x00 (this offset address is relative to the master ADC base address + 0x300)
Reset value: 0x0000 0000

This register provides an image of the status bits of the different ADCs. Nevertheless it is read-only and does not allow to clear the different status bits. Instead each status bit must be cleared by writing 0 to it in the corresponding ADC_ISR register.

Bits 31:27 Reserved, must be kept at reset value.

- **Bit 26 JQOVF_SLV**: Injected Context Queue Overflow flag of the slave ADC
  - This bit is a copy of the JQOVF bit in the corresponding ADC_ISR register.

- **Bit 25 AWD3_SLV**: Analog watchdog 3 flag of the slave ADC
  - This bit is a copy of the AWD3 bit in the corresponding ADC_ISR register.

- **Bit 24 AWD2_SLV**: Analog watchdog 2 flag of the slave ADC
  - This bit is a copy of the AWD2 bit in the corresponding ADC_ISR register.

- **Bit 23 AWD1_SLV**: Analog watchdog 1 flag of the slave ADC
  - This bit is a copy of the AWD1 bit in the corresponding ADC_ISR register.

- **Bit 22 JEOS_SLV**: End of injected sequence flag of the slave ADC
  - This bit is a copy of the JEOS bit in the corresponding ADC_ISR register.

- **Bit 21 JEOC_SLV**: End of injected conversion flag of the slave ADC
  - This bit is a copy of the JEOC bit in the corresponding ADC_ISR register.

- **Bit 20 OVR_SLV**: Overrun flag of the slave ADC
  - This bit is a copy of the OVR bit in the corresponding ADC_ISR register.

- **Bit 19 EOS_SLV**: End of regular sequence flag of the slave ADC. This bit is a copy of the EOS bit in the corresponding ADC_ISR register.

- **Bit 18 EOC_SLV**: End of regular conversion of the slave ADC
  - This bit is a copy of the EOC bit in the corresponding ADC_ISR register.

- **Bit 17 EOSMP_SLV**: End of Sampling phase flag of the slave ADC
  - This bit is a copy of the EOSMP2 bit in the corresponding ADC_ISR register.

- **Bit 16 ADRDY_SLV**: Slave ADC ready
  - This bit is a copy of the ADRDY bit in the corresponding ADC_ISR register.

Bits 15:11 Reserved, must be kept at reset value.

- **Bit 10 JQOVF_MST**: Injected Context Queue Overflow flag of the master ADC
  - This bit is a copy of the JQOVF bit in the corresponding ADC_ISR register.

- **Bit 9 AWD3_MST**: Analog watchdog 3 flag of the master ADC
  - This bit is a copy of the AWD3 bit in the corresponding ADC_ISR register.

- **Bit 8 AWD2_MST**: Analog watchdog 2 flag of the master ADC
  - This bit is a copy of the AWD2 bit in the corresponding ADC_ISR register.

- **Bit 7 AWD1_MST**: Analog watchdog 1 flag of the master ADC
  - This bit is a copy of the AWD1 bit in the corresponding ADC_ISR register.

- **Bit 6 JEOS_MST**: End of injected sequence flag of the master ADC
  - This bit is a copy of the JEOS bit in the corresponding ADC_ISR register.
Bit 5 **JEOC** _MST_: End of injected conversion flag of the master ADC
This bit is a copy of the JEOC bit in the corresponding ADC_ISR register.

Bit 4 **OVR** _MST_: Overrun flag of the master ADC
This bit is a copy of the OVR bit in the corresponding ADC_ISR register.

Bit 3 **EOS** _MST_: End of regular sequence flag of the master ADC
This bit is a copy of the EOS bit in the corresponding ADC_ISR register.

Bit 2 **EOC** _MST_: End of regular conversion of the master ADC
This bit is a copy of the EOC bit in the corresponding ADC_ISR register.

Bit 1 **EOSMP** _MST_: End of Sampling phase flag of the master ADC
This bit is a copy of the EOSMP bit in the corresponding ADC_ISR register.

Bit 0 **ADRDY** _MST_: Master ADC ready
This bit is a copy of the ADRDY bit in the corresponding ADC_ISR register.

### 21.7.2 ADC common control register (ADC_CCR)

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **CH18SEL**: CH18 selection
This bit is set and cleared by software to control channel 18.
0: VBAT channel disabled.
1: VBAT channel enabled

Bit 23 **CH17SEL**: CH17 selection
This bit is set and cleared by software to control channel 17.
0: Temperature sensor channel disabled
1: Temperature sensor channel enabled

Bit 22 **VREFEN**: VREFINT enable
This bit is set and cleared by software to enable/disable the VREFINT channel.
0: VREFINT channel disabled
1: VREFINT channel enabled
Bits 21:18  **PRESC[3:0]**: ADC prescaler

These bits are set and cleared by software to select the frequency of the clock to the ADC. The clock is common for all the ADCs.

- **0000**: input ADC clock not divided
- **0001**: input ADC clock divided by 2
- **0010**: input ADC clock divided by 4
- **0011**: input ADC clock divided by 6
- **0100**: input ADC clock divided by 8
- **0101**: input ADC clock divided by 10
- **0110**: input ADC clock divided by 12
- **0111**: input ADC clock divided by 16
- **1000**: input ADC clock divided by 32
- **1001**: input ADC clock divided by 64
- **1010**: input ADC clock divided by 128
- **1011**: input ADC clock divided by 256
- other: reserved

*Note:* The software is allowed to write these bits only when the ADC is disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0). The ADC prescaler value is applied only when CKMODE[1:0] = 0b00.

Bits 17:16  **CKMODE[1:0]**: ADC clock mode

These bits are set and cleared by software to define the ADC clock scheme (which is common to both master and slave ADCs):

- **00**: CK_ADCx (x=123) (Asynchronous clock mode), generated at product level (refer to Section 6: Reset and clock control (RCC))
- **01**: HCLK/1 (Synchronous clock mode). This configuration must be enabled only if the AHB clock prescaler is set to 1 (HPRE[3:0] = 0xxx in RCC_CFGFR register) and if the system clock has a 50% duty cycle.
- **10**: HCLK/2 (Synchronous clock mode)
- **11**: HCLK/4 (Synchronous clock mode)

In all synchronous clock modes, there is no jitter in the delay from a timer trigger to the start of a conversion.

*Note:* The software is allowed to write these bits only when the ADCs are disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

Bits 15:14  **MDMA[1:0]**: Direct memory access mode for dual ADC mode

This bitfield is set and cleared by software. Refer to the DMA controller section for more details.

- **00**: MDMA mode disabled
- **01**: Enable dual interleaved mode to output to the master channel of DFSDM interface both Master and the Slave result (16-bit data width)
- **10**: MDMA mode enabled for 12 and 10-bit resolution
- **11**: MDMA mode enabled for 8 and 6-bit resolution

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 13  **DMACFG**: DMA configuration (for dual ADC mode)

This bit is set and cleared by software to select between two DMA modes of operation and is effective only when DMAEN=1.

- **0**: DMA One Shot mode selected
- **1**: DMA Circular mode selected

For more details, refer to Section : Managing conversions using the DMA

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).
Bit 12 Reserved, must be kept at reset value.

Bits 11:8 **DELAY**: Delay between 2 sampling phases

These bits are set and cleared by software. These bits are used in dual interleaved modes. Refer to Table 141 for the value of ADC resolution versus DELAY bits values.

*Note: The software is allowed to write these bits only when the ADCs are disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).*

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DUAL[4:0]**: Dual ADC mode selection

These bits are written by software to select the operating mode. All the ADCs independent:

00000: Independent mode

00001 to 01001: Dual mode, master and slave ADCs working together

00010: Combined regular simultaneous + injected simultaneous mode

00011: Combined regular simultaneous + alternate trigger mode

00011: Combined Interleaved mode + injected simultaneous mode

00100: Reserved

00101: Injected simultaneous mode only

00110: Regular simultaneous mode only

00111: Interleaved mode only

01001: Alternate trigger mode only

All other combinations are reserved and must not be programmed.

*Note: The software is allowed to write these bits only when the ADCs are disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).*

Refer to Section 2.2 on page 93 for the register boundary addresses.
22 Digital-to-analog converter (DAC)

22.1 Introduction

The DAC module is a 12-bit, voltage output digital-to-analog converter. The DAC can be configured in 8- or 12-bit mode and may be used in conjunction with the DMA controller. In 12-bit mode, the data could be left- or right-aligned. The DAC features two output channels, each with its own converter. In dual DAC channel mode, conversions could be done independently or simultaneously when both channels are grouped together for synchronous update operations. An input reference pin, $V_{REF+}$ (shared with others analog peripherals) is available for better resolution. An internal reference can also be set on the same input. Refer to voltage reference buffer ($V_{REFBUF}$) section.

The DACx_OUTy pin can be used as general purpose input/output (GPIO) when the DAC output is disconnected from output pad and connected to on chip peripheral. The DAC output buffer can be optionally enabled to allow a high drive output current. An individual calibration can be applied on each DAC output channel. The DAC output channels support a low power mode, the Sample and hold mode.

22.2 DAC main features

The DAC main features are the following (see Figure 157: Dual-channel DAC block diagram)

- One DAC interface, maximum two output channels
- Left or right data alignment in 12-bit mode
- Synchronized update capability
- Noise-wave and Triangular-wave generation
- Dual DAC channel for independent or simultaneous conversions
- DMA capability for each channel including DMA underrun error detection
- External triggers for conversion
- DAC output channel buffered/unbuffered modes
- Buffer offset calibration
- Each DAC output can be disconnected from the DACx_OUTy output pin
- DAC output connection to on chip peripherals
- Sample and hold mode for low power operation in Stop mode
- Input voltage reference, $V_{REF+}$

*Figure 157* shows the block diagram of a DAC channel and *Table 146* gives the pin description.

22.4 DAC functional description

22.4.1 DAC block diagram

Figure 157. Dual-channel DAC block diagram

1. MODE\textsubscript{x} bits in the DAC\_MCR control the output mode and allow switching between the Normal mode in buffer/unbuffered configuration and the Sample and hold mode.

2. Refer to Section 22.3: DAC implementation for channel2 availability.
The DAC includes:

- Up to two output channels
- The DACx_OUTy can be disconnected from the output pin and used as an ordinary GPIO
- The DAC_OUTx can use an internal pin connection to on-chip peripherals such as comparator, operational amplifier and ADC (if available).
- DAC output channel buffered or non buffered
- Sample and hold block and registers operational in Stop mode, using the LSI clock source for static conversion.

The DAC includes up to two separate output channels. Each output channel can be connected to on-chip peripherals such as comparator, operational amplifier and ADC (if available). In this case, the DAC output channel can be disconnected from the DACx_OUTy output pin and the corresponding GPIO can be used for another purpose.

The DAC output can be buffered or not. The Sample and hold block and its associated registers can run in Stop mode using the LSI clock source.

#### 22.4.2 DAC channel enable

Each DAC channel can be powered on by setting its corresponding ENx bit in the DAC_CR register. The DAC channel is then enabled after a \( t_{WAKEUP} \) startup time.

*Note:* The ENx bit enables the analog DAC channelx only. The DAC channelx digital interface is enabled even if the ENx bit is reset.

#### 22.4.3 DAC data format

Depending on the selected configuration mode, the data have to be written into the specified register as described below:

- Single DAC channel
  
  There are three possibilities:
  
  - 8-bit right alignment: the software has to load data into the DAC_DHR8Rx[7:0] bits (stored into the DHRx[11:4] bits)
  
  - 12-bit left alignment: the software has to load data into the DAC_DHR12Lx[15:4] bits (stored into the DHRx[11:0] bits)
  
  - 12-bit right alignment: the software has to load data into the DAC_DHR12Rx[11:0] bits (stored into the DHRx[11:0] bits)

Depending on the loaded DAC_DHRyyxyx register, the data written by the user is shifted and stored into the corresponding DHRx (data holding registerx, which are internal non-memory-
mapped registers). The DHRx register is then loaded into the DORx register either automatically, by software trigger or by an external event trigger.

**Figure 158. Data registers in single DAC channel mode**

| 12-bit right aligned |

- Dual DAC channels (when available)

  There are three possibilities:
  - 8-bit right alignment: data for DAC channel1 to be loaded into the DAC_DHR8RD [7:0] bits (stored into the DHR1[11:4] bits) and data for DAC channel2 to be loaded into the DAC_DHR8RD [15:8] bits (stored into the DHR2[11:4] bits)
  - 12-bit left alignment: data for DAC channel1 to be loaded into the DAC_DHR12LD [15:4] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC_DHR12LD [31:20] bits (stored into the DHR2[11:0] bits)
  - 12-bit right alignment: data for DAC channel1 to be loaded into the DAC_DHR12RD [11:0] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC_DHR12RD [27:16] bits (stored into the DHR2[11:0] bits)

Depending on the loaded DAC_DHRyyyD register, the data written by the user is shifted and stored into DHR1 and DHR2 (data holding registers, which are internal non-memory-mapped registers). The DHR1 and DHR2 registers are then loaded into the DAC_DOR1 and DOR2 registers, respectively, either automatically, by software trigger or by an external event trigger.

22.4.4 DAC conversion

The DAC_DORx cannot be written directly and any data transfer to the DAC channelx must be performed by loading the DAC_DHRx register (write operation to DAC_DHR8Rx, DAC_DHR12Lx, DAC_DHR12Rx, DAC_DHR8RD, DAC_DHR12RD or DAC_DHR12LD).

Data stored in the DAC_DHRx register are automatically transferred to the DAC_DORx register after one APB1 clock cycle, if no hardware trigger is selected (TENx bit in DAC_CR register is reset). However, when a hardware trigger is selected (TENx bit in DAC_CR register is set) and a trigger occurs, the transfer is performed three APB1 clock cycles after the trigger signal.

When DAC_DORx is loaded with the DAC_DHRx contents, the analog output voltage becomes available after a time $t_{\text{SETTLING}}$ that depends on the power supply voltage and the analog output load.

HFSEL bit of DAC_CR must be set when APB1 clock speed is faster than 80 MHz. It adds an extra delay of three APB1 clock cycles to the transfer from DAC_DHRx register to DAC_DORx register ($t_{\text{SETTLING}}$).

The DAC_DORx update rate is limited to 1/3 of APB1 clock frequency. When HFSEL bit is set, this rate is limited to 1/8 of the APB1 clock frequency.

When HFSEL is set, it is not allowed to write the DHRx register during a period of eight clock cycles after the ENx bit is set. During this period, making software/hardware triggering is not allowed either.

![Figure 160. Timing diagram for conversion with trigger disabled TEN = 0](image)

22.4.5 DAC output voltage

Digital inputs are converted to output voltages on a linear conversion between 0 and $V_{\text{REF+}}$.

The analog output voltages on each DAC channel pin are determined by the following equation:

$$\text{DACoutput} = V_{\text{REF}} \times \frac{\text{DOR}}{4096}$$
22.4.6 DAC trigger selection

If the TENx control bit is set, the conversion can then be triggered by an external event (timer counter, external interrupt line). The TSELx[3:0] control bits determine which out of 16 possible events triggers the conversion as shown in TSELx[3:0] bits of the DAC_CR register. These events can be either the software trigger or hardware triggers. Refer to Table 147: DAC trigger selection.

Each time a DAC interface detects a rising edge on the selected trigger source (refer to the table below), the last data stored into the DAC_DHRx register are transferred into the DAC_DORx register. The DAC_DORx register is updated three APB1 cycles after the trigger occurs.

If the software trigger is selected, the conversion starts once the SWTRIG bit is set. SWTRIG is reset by hardware once the DAC_DORx register has been loaded with the DAC_DHRx register contents.

Note: TSELx[3:0] bit cannot be changed when the ENx bit is set.
When software trigger is selected, the transfer from the DAC_DHRx register to the DAC_DORx register takes only one APB1 clock cycle.

22.4.7 DMA requests

Each DAC channel has a DMA capability. Two DMA channels are used to service DAC channel DMA requests.

When an external trigger (but not a software trigger) occurs while the DMAENx bit is set, the value of the DAC_DHRx register is transferred into the DAC_DORx register when the transfer is complete, and a DMA request is generated.

In dual mode, if both DMAENx bits are set, two DMA requests are generated. If only one DMA request is needed, only the corresponding DMAENx bit must be set. In this way, the application can manage both DAC channels in dual mode by using one DMA request and a unique DMA channel.

As DAC_DHRx to DAC_DORx data transfer occurred before the DMA request, the very first data has to be written to the DAC_DHRx before the first trigger event occurs.

DMA underrun

The DAC DMA request is not queued so that if a second external trigger arrives before the acknowledgment for the first external trigger is received (first request), then no new request is issued and the DMA channelx underrun flag DMAUDRx in the DAC_SR register is set, reporting the error condition. The DAC channelx continues to convert old data.

The software must clear the DMAUDRx flag by writing 1, clear the DMAEN bit of the used DMA stream and re-initialize both DMA and DAC channelx to restart the transfer correctly. The software must modify the DAC trigger conversion frequency or lighten the DMA workload to avoid a new DMA underrun. Finally, the DAC conversion could be resumed by enabling both DMA data transfer and conversion trigger.

For each DAC channelx, an interrupt is also generated if its corresponding DMAUDRIEx bit in the DAC_CR register is enabled.

22.4.8 Noise generation

In order to generate a variable-amplitude pseudonoise, an LFSR (linear feedback shift register) is available. DAC noise generation is selected by setting WAVEx[1:0] to 01. The preloaded value in LFSR is 0xAAA. This register is updated three APB1 clock cycles after each trigger event, following a specific calculation algorithm.
The LFSR value, that may be masked partially or totally by means of the MAMPx[3:0] bits in the DAC.CR register, is added up to the DAC.DHRx contents without overflow and this value is then transferred into the DAC.DORx register.

If LFSR is 0x0000, a ‘1’ is injected into it (anti-lock-up mechanism).

It is possible to reset LFSR wave generation by resetting the WAVEx[1:0] bits.

Note: The DAC trigger must be enabled for noise generation by setting the TENx bit in the DAC.CR register.
22.4.9 Triangle-wave generation

It is possible to add a small-amplitude triangular waveform on a DC or slowly varying signal. DAC triangle-wave generation is selected by setting WAVEx[1:0] to 10\(^{\text{b}}\). The amplitude is configured through the MAMPx[3:0] bits in the DAC_CR register. An internal triangle counter is incremented three APB1 clock cycles after each trigger event. The value of this counter is then added to the DAC_DHRx register without overflow and the sum is transferred into the DAC_DORx register. The triangle counter is incremented as long as it is less than the maximum amplitude defined by the MAMPx[3:0] bits. Once the configured amplitude is reached, the counter is decremented down to 0, then incremented again and so on.

It is possible to reset triangle wave generation by resetting the WAVEx[1:0] bits.

![Figure 163. DAC triangle wave generation](image)

![Figure 164. DAC conversion (SW trigger enabled) with triangle wave generation](image)

**Note:** The DAC trigger must be enabled for triangle wave generation by setting the TENx bit in the DAC_CR register.

The MAMPx[3:0] bits must be configured before enabling the DAC, otherwise they cannot be changed.
22.4.10 DAC channel modes

Each DAC channel can be configured in Normal mode or Sample and hold mode. The output buffer can be enabled to allow a high drive capability. Before enabling output buffer, the voltage offset needs to be calibrated. This calibration is performed at the factory (loaded after reset) and can be adjusted by software during application operation.

Normal mode

In Normal mode, there are four combinations, by changing the buffer state and by changing the DACx_OUTy pin interconnections.

To enable the output buffer, the MODEx[2:0] bits in DAC_MCR register must be:
- 000: DAC is connected to the external pin
- 001: DAC is connected to external pin and to on-chip peripherals

To disable the output buffer, the MODEx[2:0] bits in DAC_MCR register must be:
- 010: DAC is connected to the external pin
- 011: DAC is connected to on-chip peripherals

Sample and hold mode

In Sample and hold mode, the DAC core converts data on a triggered conversion, and then holds the converted voltage on a capacitor. When not converting, the DAC cores and buffer are completely turned off between samples and the DAC output is tri-stated, therefore reducing the overall power consumption. A stabilization period, which value depends on the buffer state, is required before each new conversion.

In this mode, the DAC core and all corresponding logic and registers are driven by the LSI low-speed clock in addition to the APB1 clock, allowing to use the DAC channels in deep low power modes such as Stop mode.

The LSI low-speed clock must not be stopped when the Sample and hold mode is enabled.

The sample/hold mode operations can be divided into 3 phases:

1. Sample phase: the sample/hold element is charged to the desired voltage. The charging time depends on capacitor value (internal or external, selected by the user). The sampling time is configured with the TSAMPLEx[9:0] bits in DAC_SHSRx register. During the write of the TSAMPLEx[9:0] bits, the BWSTx bit in DAC_SR register is set to 1 to synchronize between both clocks domains (APB and low speed clock) and allowing the software to change the value of sample phase during the DAC channel operation.

2. Hold phase: the DAC output channel is tri-stated, the DAC core and the buffer are turned off, to reduce the current consumption. The hold time is configured with the THOLDx[9:0] bits in DAC_SHHR register.

3. Refresh phase: the refresh time is configured with the TREFRESHx[7:0] bits in DAC_SHRR register.

The timings for the three phases above are in units of LSI clock periods. As an example, to configure a sample time of 350 µs, a hold time of 2 ms and a refresh time of 100 µs assuming LSI ~32 KHz is selected:

- 12 cycles are required for sample phase: TSAMPLEx[9:0] = 11,
- 62 cycles are required for hold phase: THOLDx[9:0] = 62,
- and 4 cycles are required for refresh period: TREFRESHx[7:0] = 4.
In this example, the power consumption is reduced by almost a factor of 15 versus Normal modes.

The formulas to compute the right sample and refresh timings are described in the table below, the Hold time depends on the leakage current.

**Table 148. Sample and refresh timings**

<table>
<thead>
<tr>
<th>Buffer State</th>
<th>$t_{\text{SAMP}}$&lt;sup&gt;(1)(2)&lt;/sup&gt;</th>
<th>$t_{\text{REFRESH}}$&lt;sup&gt;(2)(3)&lt;/sup&gt;</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable</td>
<td>$7 \mu \text{s} + (10 \times R_{\text{BON}} \times C_{\text{SH}})$</td>
<td>$7 \mu \text{s} + (R_{\text{BON}} \times C_{\text{SH}}) \times \ln(2 \times N_{\text{LSB}})$</td>
</tr>
<tr>
<td>Disable</td>
<td>$3 \mu \text{s} + (10 \times R_{\text{BOFF}} \times C_{\text{SH}})$</td>
<td>$3 \mu \text{s} + (R_{\text{BOFF}} \times C_{\text{SH}}) \times \ln(2 \times N_{\text{LSB}})$</td>
</tr>
</tbody>
</table>

1. In the above formula the settling to the desired code value with ½ LSB or accuracy requires 10 constant time for 12 bits resolution. For 8 bits resolution, the settling time is 7 constant time.
2. $C_{\text{SH}}$ is the capacitor in Sample and hold mode.
3. The tolerated voltage drop during the hold phase “$V_d$” is represented by the number of LSBs after the capacitor discharging with the output leakage current. The settling back to the desired value with ½ LSB error accuracy requires $\ln(2 \times N_{\text{LSB}})$ constant time of the DAC.

**Example of the sample and refresh time calculation with output buffer on**

The values used in the example below are provided as indication only. Please refer to the product datasheet for product data.

$C_{\text{SH}} = 100 \ \text{nF}$

$V_{\text{DDA}} = 3.0 \ \text{V}$

**Sampling phase:**

$t_{\text{SAMP}} = 7 \mu \text{s} + (10 \times 2000 \times 100 \times 10^{-9}) = 2.007 \ \text{ms}$

(where $R_{\text{BON}} = 2 \ \text{kΩ}$)

**Refresh phase:**

$t_{\text{REFRESH}} = 7 \mu \text{s} + (2000 \times 100 \times 10^{-9}) \times \ln(2 \times 10) = 606.1 \ \mu\text{s}$

(where $N_{\text{LSB}} = 10$ (10 LSB drop during the hold phase))

**Hold phase:**

$D_v = i_{\text{leak}} \times t_{\text{hold}} / C_{\text{SH}} = 0.0073 \ \text{V} \ (10 \ \text{LSB of 12bit at 3 \ \text{V}})$

$i_{\text{leak}} = 150 \ \text{nA} \ \text{(worst case on the IO leakage on all the temperature range)}$

$t_{\text{hold}} = 0.0073 \times 100 \times 10^{-9} / (150 \times 10^{-9}) = 4.867 \ \text{ms}$
Like in Normal mode, the Sample and hold mode has different configurations.

To enable the output buffer, MODEx[2:0] bits in DAC_MCR register must be set to:
- 100: DAC is connected to the external pin
- 101: DAC is connected to external pin and to on chip peripherals

To disabled the output buffer, MODEx[2:0] bits in DAC_MCR register must be set to:
- 110: DAC is connected to external pin and to on chip peripherals
- 111: DAC is connected to on chip peripherals

When MODEx[2:0] bits are equal to 111, an internal capacitor, \( C_{\text{Lint}} \), holds the voltage output of the DAC core and then drive it to on-chip peripherals.

All Sample and hold phases are interruptible, and any change in DAC_DHRx immediately triggers a new sample phase.

22.4.11 DAC channel buffer calibration

The transfer function for an N-bit digital-to-analog converter (DAC) is:

\[ V_{out} = \left( \frac{D}{2^N - 1} \right) \times G \times V_{ref} + V_{os} \]

Where \( V_{OUT} \) is the analog output, \( D \) is the digital input, \( G \) is the gain, \( V_{ref} \) is the nominal full-scale voltage, and \( V_{os} \) is the offset voltage. For an ideal DAC channel, \( G = 1 \) and \( V_{os} = 0 \).

Due to output buffer characteristics, the voltage offset may differ from part-to-part and introduce an absolute offset error on the analog output. To compensate the \( V_{os} \), a calibration is required by a trimming technique.

The calibration is only valid when the DAC channel is operating with buffer enabled (MODEx[2:0] = 000b or 001b or 100b or 101b). If applied in other modes when the buffer is off, it has no effect. During the calibration:

- The buffer output is disconnected from the pin internal/external connections and put in tristate mode (HiZ).
- The buffer acts as a comparator to sense the middle-code value 0x800 and compare it to \( V_{REF+}/2 \) signal through an internal bridge, then toggle its output signal to 0 or 1 depending on the comparison result (CAL_FLAGx bit).

Two calibration techniques are provided:

- Factory trimming (default setting)
  The DAC buffer offset is factory trimmed. The default value of OTRIMx[4:0] bits in DAC_CCR register is the factory trimming value and it is loaded once DAC digital interface is reset.
- User trimming
  The user trimming can be done when the operating conditions differs from nominal factory trimming conditions and in particular when \( V_{DDA} \) voltage, temperature, \( V_{REF+} \) values change and can be done at any point during application by software.

**Note:** Refer to the datasheet for more details of the Nominal factory trimming conditions

In addition, when \( V_{DD} \) is removed (example the device enters in STANDBY or VBAT modes) the calibration is required.

The steps to perform a user trimming calibration are as below:
1. If the DAC channel is active, write 0 to ENx bit in DAC_CR to disable the channel.
2. Select a mode where the buffer is enabled, by writing to DAC_MCR register, MODEx[2:0] = 000b or 001b or 100b or 101b.
3. Start the DAC channelx calibration, by setting the CENx bit in DAC_CR register to 1.
4. Apply a trimming algorithm:
   a) Write a code into OTRIMx[4:0] bits, starting by 00000b.
   b) Wait for tTRIM delay.
   c) Check if CAL_FLAGx bit in DAC_SR is set to 1.
   d) If CAL_FLAGx is set to 1, the OTRIMx[4:0] trimming code is found and can be used during device operation to compensate the output value, else increment OTRIMx[4:0] and repeat sub-steps from (a) to (d) again.

The software algorithm may use either a successive approximation or dichotomy techniques to compute and set the content of OTRIMx[4:0] bits in a faster way.

The commutation/toggle of CAL_FLAGx bit indicates that the offset is correctly compensated and the corresponding trim code must be kept in the OTRIMx[4:0] bits in DAC_CCR register.

Note: A tTRIM delay must be respected between the write to the OTRIMx[4:0] bits and the read of the CAL_FLAGx bit in DAC_SR register in order to get a correct value. This parameter is specified into datasheet electrical characteristics section.

If VDDA, VREF+ and temperature conditions do not change during device operation while it enters more often in standby and VBAT mode, the software may store the OTRIMx[4:0] bits found in the first user calibration in the flash or in back-up registers. then to load/write them directly when the device power is back again thus avoiding to wait for a new calibration time. When CENx bit is set, it is not allowed to set ENx bit.

22.4.12 Dual DAC channel conversion modes (if dual channels are available)

To efficiently use the bus bandwidth in applications that require the two DAC channels at the same time, three dual registers are implemented: DHR8RD, DHR12RD and DHR12LD. A unique register access is then required to drive both DAC channels at the same time. For the wave generation, no accesses to DHRxxxD registers are required. As a result, two output channels can be used either independently or simultaneously.

11 conversion modes are possible using the two DAC channels and these dual registers. All the conversion modes can nevertheless be obtained using separate DHRx registers if needed.

All modes are described in the paragraphs below.

Independent trigger without wave generation

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).
When a DAC channel 1 trigger arrives, the DHR1 register is transferred into DAC_DOR1 (three APB1 clock cycles later).

When a DAC channel 2 trigger arrives, the DHR2 register is transferred into DAC_DOR2 (three APB1 clock cycles later).

**Independent trigger with single LFSR generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and the same LFSR mask value in the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel 1 trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three APB1 clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel 2 trigger arrives, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three APB1 clock cycles later). Then the LFSR2 counter is updated.

**Independent trigger with different LFSR generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and set different LFSR masks values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel 1 trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three APB1 clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel 2 trigger arrives, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three APB1 clock cycles later). Then the LFSR2 counter is updated.
Independent trigger with single triangle generation

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and the same maximum amplitude value in the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the DAC channel1 triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three APB1 clock cycles later). The DAC channel1 triangle counter is then updated.

When a DAC channel2 trigger arrives, the DAC channel2 triangle counter, with the same triangle amplitude, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three APB1 clock cycles later). The DAC channel2 triangle counter is then updated.

Independent trigger with different triangle generation

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bits.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and set different maximum amplitude values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the DAC channel1 triangle counter, with a triangle amplitude configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three APB1 clock cycles later). The DAC channel1 triangle counter is then updated.

When a DAC channel2 trigger arrives, the DAC channel2 triangle counter, with a triangle amplitude configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three APB1 clock cycles later). The DAC channel2 triangle counter is then updated.

Simultaneous software start

To configure the DAC in this conversion mode, the following sequence is required:
• Load the dual DAC channel data to the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

In this configuration, one APB1 clock cycle later, the DHR1 and DHR2 registers are transferred into DAC_DOR1 and DAC_DOR2, respectively.

Simultaneous trigger without wave generation

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Load the dual DAC channel data to the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DHR1 and DHR2 registers are transferred into DAC_DOR1 and DAC_DOR2, respectively (after three APB1 clock cycles).

**Simultaneous trigger with single LFSR generation**

1. To configure the DAC in this conversion mode, the following sequence is required:
2. Set the two DAC channel trigger enable bits TEN1 and TEN2.
3. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
4. Configure the two DAC channel WAVE[1:0] bits as 01 and the same LFSR mask value in the MAMPx[3:0] bits.
5. Load the dual DAC channel data to the desired DHR register (DHR12RD, DHR12LD or DHR8RD).

When a trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three APB1 clock cycles later). The LFSR1 counter is then updated. At the same time, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three APB1 clock cycles later). The LFSR2 counter is then updated.

**Simultaneous trigger with different LFSR generation**

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVE[1:0] bits as 01 and set different LFSR mask values using the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three APB1 clock cycles later). The LFSR1 counter is then updated. At the same time, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three APB1 clock cycles later). The LFSR2 counter is then updated.

**Simultaneous trigger with single triangle generation**

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVE[1:0] bits as 1x and the same maximum amplitude value using the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DAC channel1 triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three APB1 clock cycles later). The DAC channel1 triangle counter is then updated.

At the same time, the DAC channel2 triangle counter, with the same triangle amplitude, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three APB1 clock cycles later). The DAC channel2 triangle counter is then updated.

**Simultaneous trigger with different triangle generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVE[1:0] bits as 1x and set different maximum amplitude values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DAC channel1 triangle counter, with a triangle amplitude configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three APB clock cycles later). Then the DAC channel1 triangle counter is updated.

At the same time, the DAC channel2 triangle counter, with a triangle amplitude configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three APB1 clock cycles later). Then the DAC channel2 triangle counter is updated.

### 22.5 DAC low-power modes

<table>
<thead>

Bit 31 Reserved, must be kept at reset value.

Bit 30 **CEN2**: DAC channel2 calibration enable

This bit is set and cleared by software to enable/disable DAC channel2 calibration, it can be written only if EN2 bit is set to 0 into DAC_CR (the calibration mode can be entered/exit only when the DAC channel is disabled) Otherwise, the write operation is ignored.

0: DAC channel2 in Normal operating mode
1: DAC channel2 in calibration mode

*Note: This bit is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.*

Bit 29 **DMAUDRIE2**: DAC channel2 DMA underrun interrupt enable

This bit is set and cleared by software.

0: DAC channel2 DMA underrun interrupt disabled
1: DAC channel2 DMA underrun interrupt enabled

*Note: This bit is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.*

Bit 28 **DMAEN2**: DAC channel2 DMA enable

This bit is set and cleared by software.

0: DAC channel2 DMA mode disabled
1: DAC channel2 DMA mode enabled

*Note: This bit is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.*
Bits 27:24  **MAMP2[3:0]**: DAC channel2 mask/amplitude selector

These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.

- 0000: Unmask bit0 of LFSR/ triangle amplitude equal to 1
- 0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3
- 0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7
- 0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15
- 0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31
- 0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63
- 0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127
- 0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255
- 1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511
- 1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023
- 1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047
- ≥ 1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095

*Note:* These bits are available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Bits 23:22  **WAVE2[1:0]**: DAC channel2 noise/triangle wave generation enable

These bits are set/reset by software.

- 00: wave generation disabled
- 01: Noise wave generation enabled
- 1x: Triangle wave generation enabled

*Note:* Only used if bit TEN2 = 1 (DAC channel2 trigger enabled)

These bits are available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Bits 21:18  **TSEL2[3:0]**: DAC channel2 trigger selection

These bits select the external event used to trigger DAC channel2

- 0000: SWTRIG2
- 0001: dac_ch2_trg1
- 0010: dac_ch2_trg2
- ...
- 1111: dac_ch2_trg15

Refer to the trigger selection tables in Section 22.4.6: DAC trigger selection for details on trigger configuration and mapping.

*Note:* Only used if bit TEN2 = 1 (DAC channel2 trigger enabled).

These bits are available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Bit 17  **TEN2**: DAC channel2 trigger enable

This bit is set and cleared by software to enable/disable DAC channel2 trigger

- 0: DAC channel2 trigger disabled and data written into the DAC_DHR2 register are transferred one APB1 clock cycle later to the DAC_DOR2 register
- 1: DAC channel2 trigger enabled and data from the DAC_DHR2 register are transferred three APB1 clock cycles later to the DAC_DOR2 register

*Note:* When software trigger is selected, the transfer from the DAC_DHR2 register to the DAC_DOR2 register takes only one APB1 clock cycle.

These bits are available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.
Bit 16  **EN2**: DAC channel2 enable
This bit is set and cleared by software to enable/disable DAC channel2.
0: DAC channel2 disabled
1: DAC channel2 enabled

*Note:* These bits are available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Bit 15  **HFSEL**: High frequency interface mode enable
This bit is set and cleared by software to enable/disable DAC interface high speed mode
This bit need to be set when APB1 clock frequency is higher than 80 MHz.
0: High frequency interface mode disabled
1: High frequency interface mode enabled

Bit 14  **CEN1**: DAC channel1 calibration enable
This bit is set and cleared by software to enable/disable DAC channel1 calibration, it can be written only if bit EN1=0 into DAC_CR (the calibration mode can be entered/exit only when the DAC channel is disabled) Otherwise, the write operation is ignored.
0: DAC channel1 in Normal operating mode
1: DAC channel1 in calibration mode

Bit 13  **DMAUDRIE1**: DAC channel1 DMA Underrun Interrupt enable
This bit is set and cleared by software.
0: DAC channel1 DMA Underrun Interrupt disabled
1: DAC channel1 DMA Underrun Interrupt enabled

Bit 12  **DMAEN1**: DAC channel1 DMA enable
This bit is set and cleared by software.
0: DAC channel1 DMA mode disabled
1: DAC channel1 DMA mode enabled

Bits 11:8  **MAMP1[3:0]**: DAC channel1 mask/amplitude selector
These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.
0000: Unmask bit0 of LFSR/ triangle amplitude equal to 1
0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3
0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7
0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15
0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31
0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63
0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127
0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255
1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511
1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023
1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047
≥1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095

Bits 7:6  **WAVE1[1:0]**: DAC channel1 noise/triangle wave generation enable
These bits are set and cleared by software.
00: wave generation disabled
01: Noise wave generation enabled
1x: Triangle wave generation enabled
Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).
22.7.2 DAC software trigger register (DAC_SWTRGR)

Address offset: 0x04
Reset value: 0x0000 0000

**Bits 5:2 TSEL1[3:0]: DAC channel1 trigger selection**

These bits select the external event used to trigger DAC channel1

0000: SWTRIG1
0001: dac_ch1_trg1
0010: dac_ch1_trg2
...
1111: dac_ch1_trg15

Refer to the trigger selection tables in Section 22.4.6: DAC trigger selection for details on trigger configuration and mapping.

*Note: Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).*

**Bit 1 TEN1: DAC channel1 trigger enable**

This bit is set and cleared by software to enable/disable DAC channel1 trigger.

0: DAC channel1 trigger disabled and data written into the DAC_DHR1 register are transferred one APB1 clock cycle later to the DAC_DOR1 register
1: DAC channel1 trigger enabled and data from the DAC_DHR1 register are transferred three APB1 clock cycles later to the DAC_DOR1 register

*Note: When software trigger is selected, the transfer from the DAC_DHR1 register to the DAC_DOR1 register takes only one APB1 clock cycle.*

**Bit 0 EN1: DAC channel1 enable**

This bit is set and cleared by software to enable/disable DAC channel1.

0: DAC channel1 disabled
1: DAC channel1 enabled
Bits 31:2 Reserved, must be kept at reset value.

**Bit 1 SWTRIG2**: DAC channel2 software trigger  
This bit is set by software to trigger the DAC in software trigger mode.  
0: No trigger  
1: Trigger  
*Note*: This bit is cleared by hardware (one APB1 clock cycle later) once the DAC_DHR2 register value has been loaded into the DAC_DOR2 register.  
This bit is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

**Bit 0 SWTRIG1**: DAC channel1 software trigger  
This bit is set by software to trigger the DAC in software trigger mode.  
0: No trigger  
1: Trigger  
*Note*: This bit is cleared by hardware (one APB1 clock cycle later) once the DAC_DHR1 register value has been loaded into the DAC_DOR1 register.

Bits 31:20 **DAC2DHR[11:0]**: DAC channel2 12-bit left-aligned data
These bits are written by software which specifies 12-bit data for DAC channel2.

Bits 19:16  Reserved, must be kept at reset value.

Bits 15:4 **DAC1DHR[11:0]**: DAC channel1 12-bit left-aligned data
These bits are written by software which specifies 12-bit data for DAC channel1.

Bits 3:0  Reserved, must be kept at reset value.
22.7.11 Dual DAC 8-bit right aligned data holding register (DAC_DHR8RD)

Address offset: 0x28
Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **DAC2DHR[7:0]**: DAC channel2 8-bit right-aligned data
These bits are written by software which specifies 8-bit data for DAC channel2.

Bits 7:0 **DAC1DHR[7:0]**: DAC channel1 8-bit right-aligned data
These bits are written by software which specifies 8-bit data for DAC channel1.

22.7.12 DAC channel1 data output register (DAC_DOR1)

Address offset: 0x2C
Reset value: 0x0000 0000

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **DAC1DOR[11:0]**: DAC channel1 data output
These bits are read-only, they contain data output for DAC channel1.
# Digital-to-analog converter (DAC)

## 22.7.13 DAC channel2 data output register (DAC_DOR2)

This register is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Address offset: 0x30

Reset value: 0x0000 0000

Bits 31:2 DAC1 and DAC2 status
These bits are read-only, they contain status for DAC channel1 and channel2.
Bit 31 **BWST2**: DAC channel2 busy writing sample time flag
This bit is systematically set just after Sample and hold mode enable. It is set each time the software writes the register DAC_SHSR2. It is cleared by hardware when the write operation of DAC_SHSR2 is complete. (It takes about 3 LSI periods of synchronization).
0: There is no write operation of DAC_SHSR2 ongoing; DAC_SHSR2 can be written
1: There is a write operation of DAC_SHSR2 ongoing; DAC_SHSR2 cannot be written

*Note:* This bit is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Bit 30 **CAL_FLAG2**: DAC channel2 calibration offset status
This bit is set and cleared by hardware
0: Calibration trimming value is lower than the offset correction value
1: Calibration trimming value is equal or greater than the offset correction value

*Note:* This bit is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Bit 29 **DMAUDR2**: DAC channel2 DMA underrun flag
This bit is set by hardware and cleared by software (by writing it to 1).
0: No DMA underrun error condition occurred for DAC channel2
1: DMA underrun error condition occurred for DAC channel2 (the currently selected trigger is driving DAC channel2 conversion at a frequency higher than the DMA service capability rate).

*Note:* This bit is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Bit 28 Reserved, must be kept at reset value.

Bit 27 Reserved, must be kept at reset value.

Bits 26:16 Reserved, must be kept at reset value.

Bit 15 **BWST1**: DAC channel1 busy writing sample time flag
This bit is systematically set just after Sample and hold mode enable and is set each time the software writes the register DAC_SHSR1. It is cleared by hardware when the write operation of DAC_SHSR1 is complete. (It takes about 3 LSI periods of synchronization).
0: There is no write operation of DAC_SHSR1 ongoing; DAC_SHSR1 can be written
1: There is a write operation of DAC_SHSR1 ongoing; DAC_SHSR1 cannot be written

Bit 14 **CAL_FLAG1**: DAC channel1 calibration offset status
This bit is set and cleared by hardware
0: Calibration trimming value is lower than the offset correction value
1: Calibration trimming value is equal or greater than the offset correction value

Bit 13 **DMAUDR1**: DAC channel1 DMA underrun flag
This bit is set by hardware and cleared by software (by writing it to 1).
0: No DMA underrun error condition occurred for DAC channel1
1: DMA underrun error condition occurred for DAC channel1 (the currently selected trigger is driving DAC channel1 conversion at a frequency higher than the DMA service capability rate)

Bit 12 Reserved, must be kept at reset value.

Bit 11 Reserved, must be kept at reset value.

Bits 10:0 Reserved, must be kept at reset value.
22.7.15 DAC calibration control register (DAC_CCR)
Address offset: 0x38
Reset value: 0x00XX 00XX

<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 Reserved, must be kept at reset value.

Bit 24 Reserved, must be kept at reset value.

Bits 23:19 Reserved, must be kept at reset value.
Bits 18:16 **MODE2[2:0]**: DAC channel2 mode

These bits can be written only when the DAC is disabled and not in the calibration mode (when bit EN2=0 and bit CEN2 =0 in the DAC_CR register). If EN2=1 or CEN2 =1 the write operation is ignored.

They can be set and cleared by software to select the DAC channel2 mode:

- DAC channel2 in Normal mode
  - 000: DAC channel2 is connected to external pin with Buffer enabled
  - 001: DAC channel2 is connected to external pin and to on chip peripherals with buffer enabled
  - 010: DAC channel2 is connected to external pin with buffer disabled
  - 011: DAC channel2 is connected to on chip peripherals with Buffer disabled

- DAC channel2 in Sample and hold mode
  - 100: DAC channel2 is connected to external pin with Buffer enabled
  - 101: DAC channel2 is connected to external pin and to on chip peripherals with Buffer enabled
  - 110: DAC channel2 is connected to external pin and to on chip peripherals with Buffer disabled
  - 111: DAC channel2 is connected to on chip peripherals with Buffer disabled

*Note: This register can be modified only when EN2=0.*

Refer to Section 22.3: DAC implementation for the availability of DAC channel2.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:10 Reserved, must be kept at reset value.

Bit 9 Reserved, must be kept at reset value.

Bit 8 Reserved, must be kept at reset value.

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **MODE1[2:0]**: DAC channel1 mode

These bits can be written only when the DAC is disabled and not in the calibration mode (when bit EN1=0 and bit CEN1 =0 in the DAC_CR register). If EN1=1 or CEN1 =1 the write operation is ignored.

They can be set and cleared by software to select the DAC channel1 mode:

- DAC channel1 in Normal mode
  - 000: DAC channel1 is connected to external pin with Buffer enabled
  - 001: DAC channel1 is connected to external pin and to on chip peripherals with Buffer enabled
  - 010: DAC channel1 is connected to external pin with buffer disabled
  - 011: DAC channel1 is connected to on chip peripherals with Buffer disabled

- DAC channel1 in Sample & hold mode
  - 100: DAC channel1 is connected to external pin with Buffer enabled
  - 101: DAC channel1 is connected to external pin and to on chip peripherals with Buffer enabled
  - 110: DAC channel1 is connected to external pin and to on chip peripherals with Buffer disabled
  - 111: DAC channel1 is connected to on chip peripherals with Buffer disabled

*Note: This register can be modified only when EN1=0.*
22.7.17 DAC channel1 sample and hold sample time register
(DAC_SHSR1)

Address offset: 0x40
Reset value: 0x0000 0000

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 **TSAMPLE1[9:0]**: DAC channel1 sample time (only valid in Sample and Hold mode)
These bits can be written when the DAC channel1 is disabled or also during normal operation.
In the latter case, the write can be done only when BWST1 of DAC_SR register is low. If BWST1=1, the write operation is ignored.

**Note:** It represents the number of LSI clocks to perform a sample phase. Sampling time = (TSAMPLE1[9:0] + 1) x LSI clock period.

22.7.18 DAC channel2 sample and hold sample time register
(DAC_SHSR2)

This register is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Address offset: 0x44
Reset value: 0x0000 0000

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 **TSAMPLE2[9:0]**: DAC channel2 sample time (only valid in Sample and Hold mode)
These bits can be written when the DAC channel2 is disabled or also during normal operation.
In the latter case, the write can be done only when BWST2 of DAC_SR register is low. If BWST2=1, the write operation is ignored.

**Note:** It represents the number of LSI clocks to perform a sample phase. Sampling time = (TSAMPLE2[9:0] + 1) x LSI clock period.
22.7.19 DAC sample and hold time register (DAC_SHHR)

Address offset: 0x48
Reset value: 0x0001 0001

<table>
<thead>
<tr>
<th>31</th>

<td>0</td>
</tr>
</tbody>
</table>

Bits 31:26  Reserved, must be kept at reset value.

Bits 25:16 THOLD2[9:0]: DAC channel2 hold time (only valid in Sample and hold mode).

Hold time = (THOLD2[9:0]) x LSI clock period

Note: This register can be modified only when EN2=0.

These bits are available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:0 THOLD1[9:0]: DAC channel1 hold time (only valid in Sample and hold mode)

Hold time = (THOLD1[9:0]) x LSI clock period

Note: This register can be modified only when EN1=0.

Note: These bits can be written only when the DAC channel is disabled and in Normal operating mode (when bit ENx=0 and bit CENx=0 in the DAC_CR register). If ENx=1 or CENx=1 the write operation is ignored.

22.7.20 DAC sample and hold refresh time register (DAC_SHRR)

Bits 31:26  Reserved, must be kept at reset value.

Bits 25:16 TREFRESH2[7:0]: DAC channel2 refresh time (only valid in Sample and hold mode).

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:0 TREFRESH1[7:0]: DAC channel1 refresh time (only valid in Sample and hold mode)

Note: This register can be modified only when EN2=0.

These bits are available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.
Bits 31:24  Reserved, must be kept at reset value.

Bits 23:16  TREFRESH2[7:0]: DAC channel2 refresh time (only valid in Sample and hold mode)
            Refresh time= (TREFRESH[7:0]) x LSI clock period
            Note:  This register can be modified only when EN2=0.
            These bits are available only on dual-channel DACs. Refer to Section 22.3: DAC
            implementation.

Bits 15:8  Reserved, must be kept at reset value.

Bits 7:0  TREFRESH1[7:0]: DAC channel1 refresh time (only valid in Sample and hold mode)
            Refresh time= (TREFRESH[7:0]) x LSI clock period
            Note:  This register can be modified only when EN1=0.

Note:  These bits can be written only when the DAC channel is disabled and in Normal operating
mode (when bit ENx=0 and bit CENx=0 in the DAC_CR register). If ENx=1 or CENx=1 the
write operation is ignored.

Refer to Section 2.2 on page 93 for the register boundary addresses.
23 Voltage reference buffer (VREFBUF)

23.1 Introduction

The devices embed a voltage reference buffer which can be used as voltage reference for ADCs, DACs and also as voltage reference for external components through the VREF+ pin. When the VREF+ pin is double-bonded with VDDA pin in a package, the voltage reference buffer is not available and must be kept disabled (refer to datasheet for packages pinout description).

23.2 VREFBUF functional description

The internal voltage reference buffer supports two voltages\(^{(a)}\), which are configured with VRS bits in the VREFBUF_CSR register:

- $V_{RS} = 0$: $V_{REF\_OUT1}$ around 2.048 V.
- $V_{RS} = 1$: $V_{REF\_OUT2}$ around 2.5 V.

The internal voltage reference can be configured in four different modes depending on ENVR and HIZ bits configuration. These modes are provided in the table below:

<table>
<thead>
<tr>
<th>ENVR</th>
<th>HIZ</th>
<th>VREF buffer configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>VREFBUF buffer off mode:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>$V_{REF+}$ pin pulled-down to $V_{SSA}$</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>External voltage reference mode (default value):</td>
</tr>
<tr>
<td></td>
<td></td>
<td>$V_{REFBUF}$ buffer off</td>
</tr>
<tr>
<td></td>
<td></td>
<td>$V_{REF+}$ pin input mode</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>Internal voltage reference mode:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>$V_{REFBUF}$ buffer on</td>
</tr>
<tr>
<td></td>
<td></td>
<td>$V_{REF+}$ pin connected to VREFBUF buffer output</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Hold mode:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>$V_{REFBUF}$ buffer off</td>
</tr>
<tr>
<td></td>
<td></td>
<td>$V_{REF+}$ pin floating. The voltage is held with the external capacitor</td>
</tr>
<tr>
<td></td>
<td></td>
<td>VRR detection disabled and VRR bit keeps last state</td>
</tr>
</tbody>
</table>

After enabling the VREFBUF by setting ENVR bit and clearing HIZ bit in the VREFBUF_CSR register, the user must wait until VRR bit is set, meaning that the voltage reference output has reached its expected value.

---

\(^{(a)}\) The minimum $V_{DDA}$ voltage depends on VRS setting, refer to the product datasheet.
23.3 VREFBUF registers

23.3.1 VREFBUF control and status register (VREFBUF_CSR)

Address offset: 0x00
Reset value: 0x0000 0002

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:4 Reserved, must be kept at reset value.

- **Bit 3 VRR**: Voltage reference buffer ready
  - 0: the voltage reference buffer output is not ready.
  - 1: the voltage reference buffer output reached the requested level.

- **Bit 2 VRS**: Voltage reference scale
  - This bit selects the value generated by the voltage reference buffer.
  - 0: Voltage reference set to VREF_OUT1 (around 2.048 V).
  - 1: Voltage reference set to VREF_OUT2 (around 2.5 V).

- **Bit 1 HIZ**: High impedance mode
  - This bit controls the analog switch to connect or not the VREF+ pin.
  - 0: VREF+ pin is internally connected to the voltage reference buffer output.
  - 1: VREF+ pin is high impedance.
  - Refer to Table 153: VREF buffer modes for the mode descriptions depending on ENVR bit configuration.

- **Bit 0 ENVR**: Voltage reference buffer mode enable
  - This bit is used to enable the voltage reference buffer mode.
  - 0: Internal voltage reference mode disable (external voltage reference mode).
  - 1: Internal voltage reference mode (reference buffer enable or hold mode) enable.
23.3.2 VREFBUF calibration control register (VREFBUF_CCR)

Address offset: 0x04
Reset value: 0x0000 00XX

<table>
<thead>
<tr>
<th>Offset</th>
<th>Register name</th>
<th>31</th>
<th>30</th>

</tr>
</tbody>
</table>

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 TRIM[5:0]: Trimming code

These bits are automatically initialized after reset with the trimming value stored in the Flash memory during the production test. Writing into these bits allows the tuning of the internal reference buffer voltage.

Note: If the user application performs the trimming, the trimming code must start from 000000 to 111111 in ascending order.

23.3.3 VREFBUF register map

The following table gives the VREFBUF register map and the reset values.

Refer to Section 2.2 on page 93 for the register boundary addresses.
24 Digital camera interface (DCMI)

24.1 Introduction

The digital camera is a synchronous parallel interface able to receive a high-speed data flow from an external 8-, 10-, 12- or 14-bit CMOS camera module. It supports different data formats: YCbCr4:2:2/RGB565 progressive video and compressed data (JPEG).

24.2 DCMI main features

- 8-, 10-, 12- or 14-bit parallel interface
- Embedded/external line and frame synchronization
- Continuous or snapshot mode
- Crop feature
- Supports the following data formats:
  - 8/10/12/14-bit progressive video: either monochrome or raw Bayer
  - YCbCr 4:2:2 progressive video
  - RGB 565 progressive video
  - Compressed data: JPEG

24.3 DCMI functional description

The digital camera interface is a synchronous parallel interface that can receive high-speed data flows. It consists of up to 14 data lines (DCMI_D[13:0]) and a pixel clock line (DCMI_PIXCLK). The pixel clock has a programmable polarity, so that data can be captured on either the rising or the falling edge of the pixel clock.

The data are packed into a 32-bit data register (DCMI_DR) and then transferred through a general-purpose DMA channel. The image buffer is managed by the DMA, not by the camera interface.

The data received from the camera can be organized in lines/frames (raw YUB/RGB/Bayer modes) or can be a sequence of JPEG images. To enable JPEG image reception, the JPEG bit (bit 3 of DCMI_CR register) must be set.

The data flow is synchronized either by hardware using the optional DCMI_HSYNC (horizontal synchronization) and DCMI_VSYNC (vertical synchronization) signals or by synchronization codes embedded in the data flow.
24.3.1 DCMI block diagram

Figure 166 shows the DCMI block diagram.

![DCMI block diagram](image)

<tr>
<td></td>
<td>DCMI_VSYNC</td>
<td>Input</td>
<td>Vertical synchronization</td>
</tr>
</tbody>
</table>

24.3.2 DCMI pins

The following table shows DCMI pins.

![Top-level block diagram](image)

24.3.3 DCMI clocks

The digital camera interface uses two clock domains, DCMI_PIXCLK and HCLK. The signals generated with DCMI_PIXCLK are sampled on the rising edge of HCLK once they are stable. An enable signal is generated in the HCLK domain, to indicate that data coming
from the camera are stable and can be sampled. The maximum DCMI_PIXCLK period must be higher than 2.5 HCLK periods.

### 24.3.4 DCMI DMA interface

The DMA interface is active when the CAPTURE bit of the DCMI_CR register is set. A DMA request is generated each time the camera interface receives a complete 32-bit data block in its register.

### 24.3.5 DCMI physical interface

The interface is composed of 11/13/15/17 inputs. Only the Slave mode is supported.

The camera interface can capture 8-bit, 10-bit, 12-bit or 14-bit data depending on the EDM[1:0] bits of the DCMI_CR register. If less than 14 bits are used, the unused input pins must be connected to ground.

DCMI pins are shown in Table 155.

The data are synchronous with DCMI_PIXCLK and change on the rising/falling edge of the pixel clock depending on the polarity.

The DCMI_HSYNC signal indicates the start/end of a line.

The DCMI_VSYNC signal indicates the start/end of a frame

---

#### Figure 168. DCMI signal waveforms

1. The capture edge of DCMI_PIXCLK is the falling edge, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.
2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.

#### 8-bit data

When EDM[1:0] = 00 in DCMI_CR the interface captures 8 LSBs at its input (DCMI_D[7:0]) and stores them as 8-bit data. The DCMI_D[13:8] inputs are ignored. In this case, to capture a 32-bit word, the camera interface takes four pixel clock cycles.

The first captured data byte is placed in the LSB position in the 32-bit word and the 4th captured data byte is placed in the MSB position in the 32-bit word. The table below gives an example of the positioning of captured data bytes in two 32-bit words.
When EDM[1:0] = 01 in DCMI_CR, the camera interface captures 10-bit data at its input DCMI_D[9:0] and stores them as the 10 least significant bits of a 16-bit word. The remaining most significant bits of the DCMI_DR register (bits 11 to 15) are cleared to zero. So, in this case, a 32-bit data word is made up every two pixel clock cycles. The first captured data are placed in the LSB position in the 32-bit word and the 2\textsuperscript{nd} captured data are placed in the MSB position in the 32-bit word as shown in the table below.

<table>
<thead>
<tr>
<th>Byte address</th>
<th>31:24</th>
<th>23:16</th>
<th>15:8</th>
<th>7:0</th>
</tr>
</thead>
<tbody>
<tr>

<td>$D_{n+5}[7:0]$</td>
<td>$D_{n+4}[7:0]$</td>
</tr>
</tbody>
</table>

Table 157. Positioning of captured data bytes in 32-bit words (10-bit width)

When EDM[1:0] = 10 in DCMI_CR, the camera interface captures the 12-bit data at its input DCMI_D[11:0] and stores them as the 12 least significant bits of a 16-bit word. The remaining most significant bits are cleared to zero. So, in this case a 32-bit data word is made up every two pixel clock cycles. The first captured data are placed in the LSB position in the 32-bit word and the 2\textsuperscript{nd} captured data are placed in the MSB position in the 32-bit word as shown in the table below.

Table 159. Positioning of captured data bytes in 32-bit words (14-bit width)
24.3.6 DCMI synchronization

The digital camera interface supports embedded or hardware (DCMI_HSYNC and DCMI_VSYNC) synchronization. When embedded synchronization is used, it is up to the digital camera module to make sure that the 0x00 and 0xFF values are used ONLY for synchronization (not in data). Embedded synchronization codes are supported only for the 8-bit parallel data interface width (that is, in the DCMI_CR register, the EDM[1:0] bits must be cleared).

For compressed data, the DCMI supports only the hardware synchronization mode. In this case, DCMI_VSYNC is used as a start/end of the image, and DCMI_HSYNC is used as a Data Valid signal. Figure 169 shows the corresponding timing diagram.

**Hardware synchronization mode**

In hardware synchronization mode, the two synchronization signals (DCMI_HSYNC/DCMI_VSYNC) are used.

Depending on the camera module/mode, data may be transmitted during horizontal/vertical synchronization periods. The DCMI_HSYNC/DCMI_VSYNC signals act like blanking signals since all the data received during DCMI_HSYNC/DCMI_VSYNC active periods are ignored.

In order to correctly transfer images into the DMA/RAM buffer, data transfer is synchronized with the DCMI_VSYNC signal. When the hardware synchronization mode is selected, and

**Figure 169. Timing diagram**

[Diagram showing timing diagram, including symbols for Beginning of JPEG stream, Padding data at the end of the JPEG stream, Programmable JPEG packet size, and Packet dispatching depends on the image content.]

Packet dispatching depends on the image content. This results in a variable blanking duration.

JPEG packet data
capture is enabled (CAPTURE bit set in DCMI.CR), data transfer is synchronized with the
deactivation of the DCMI.VSYNC signal (next start of frame).

Transfer can then be continuous, with successive frames transferred by DMA to successive
buffers or the same/circular buffer. To allow the DMA management of successive frames, a
VSIF (Vertical synchronization interrupt flag) is activated at the end of each frame.

**Embedded data synchronization mode**

In this synchronization mode, the data flow is synchronized using 32-bit codes embedded in
the data flow. These codes use the 0x00/0xFF values that are not used in data anymore.
There are 4 types of codes, all with a 0xFF0000XY format. The embedded synchronization
codes are supported only in 8-bit parallel data width capture (in the DCMI.CR register, the
EDM[1:0] bits must be cleared). For other data widths, this mode generates unpredictable
results and must not be used.

*Note:* Camera modules can have 8 such codes (in interleaved mode). For this reason, the
interleaved mode is not supported by the camera interface (otherwise, every other
half-frame would be discarded).

- **Mode 2**
  Four embedded codes signal the following events
  - Frame start (FS)
  - Frame end (FE)
  - Line start (LS)
  - Line end (LE)

  The XY values in the 0xFF0000XY format of the four codes are programmable (see
  Section 24.5.7: DCMI embedded synchronization code register (DCMI_ESCR)).

  A 0xFF value programmed as a “frame end” means that all the unused codes are
  interpreted as valid frame end codes.

  In this mode, once the camera interface has been enabled, the frame capture starts
  after the first occurrence of the frame end (FE) code followed by a frame start (FS)
  code.

- **Mode 1**
  An alternative coding is the camera mode 1. This mode is ITU656 compatible.

  The codes signal another set of events:
  - SAV (active line) - line start
  - EAV (active line) - line end
  - SAV (blanking) - end of line during interframe blanking period
  - EAV (blanking) - end of line during interframe blanking period

  This mode can be supported by programming the following codes:
  - FS ≤ 0xFF
  - FE ≤ 0xFF
  - LS ≤ SAV (active)
  - LE ≤ EAV (active)

  An embedded unmask code is also implemented for frame/line start and frame/line end
codes. Using it, it is possible to compare only the selected unmasked bits with the
programmed code. A bit can therefore be selected to compare in the embedded code and
detect a frame/line start or frame/line end. This means that there can be different codes for the frame/line start and frame/line end with the unmasked bit position remaining the same.

Example

FS = 0xA5

Unmask code for FS = 0x10

In this case the frame start code is embedded in the bit 4 of the frame start code.

24.3.7 DCMI capture modes

This interface supports two types of capture: snapshot (single frame) and continuous grab.

Snapshot mode (single frame)

In this mode, a single frame is captured (CM = 1 of the DCMI_CR register). After the CAPTURE bit is set in DCMI_CR, the interface waits for the detection of a start of frame before sampling the data. The camera interface is automatically disabled (CAPTURE bit cleared in DCMI_CR) after receiving the first complete frame. An interrupt is generated (IT_FRAME) if it is enabled.

In case of an overrun, the frame is lost and the CAPTURE bit is cleared.

Continuous grab mode

In this mode (CM bit = 0 in DCMI_CR), once the CAPTURE bit has been set in DCMI_CR, the grabbing process starts on the next DCMI_VSYNC or embedded frame start depending on the mode. The process continues until the CAPTURE bit is cleared in DCMI_CR. Once the CAPTURE bit has been cleared, the grabbing process continues until the end of the current frame.
In continuous grab mode, the FCRC\[1:0\] bits in DCMI_CR can be configured to grab all pictures, every second picture or one out of four pictures to decrease the frame capture rate.

Note: In the hardware synchronization mode (ESS = 0 in DCMI_CR), the IT_VSYNC interrupt is generated (if enabled) even when CAPTURE = 0 in DCMI_CR so, to reduce the frame capture rate even further, the IT_VSYNC interrupt can be used to count the number of frames between 2 captures in conjunction with the Snapshot mode. This is not allowed by embedded data synchronization mode.

24.3.8 DCMI crop feature

With the crop feature, the camera interface can select a rectangular window from the received image. The start (upper left corner) coordinates and size (horizontal dimension in number of pixel clocks and vertical dimension in number of lines) are specified using two 32-bit registers (DCMI_CWSTRT and DCMI_CWSIZE). The size of the window is specified in number of pixel clocks (horizontal dimension) and in number of lines (vertical dimension).

These registers specify the coordinates of the starting point of the capture window as a line number (in the frame, starting from 0) and a number of pixel clocks (on the line, starting from 0), and the size of the window as a line number and a number of pixel clocks. The CAPCNT value can only be a multiple of 4 (two least significant bits are forced to 0) to allow the correct transfer of data through the DMA.
If the DCMI_VSYNC signal goes active before the number of lines is specified in the DCMI_CWSIZE register, then the capture stops and an IT_FRAME interrupt is generated when enabled.

Figure 173. Data capture waveforms

1. Here, the active state of DCMI_HSYNC and DCMI_VSYNC is 1.
2. DCMI_HSYNC and DCMI_VSYNC can change states at the same time.

24.3.9 DCMI JPEG format

To allow JPEG image reception, it is necessary to set the JPEG bit of the DCMI_CR register. JPEG images are not stored as lines and frames, so the DCMI_VSYNC signal is used to start the capture while DCMI_HSYNC serves as a data enable signal. The number of bytes in a line may not be a multiple of 4. This case must be carefully handled since a DMA request is generated each time a complete 32-bit word has been constructed from the captured data. When an end of frame is detected and the 32-bit word to be transferred has not been completely received, the remaining data are padded with zeros and a DMA request is generated.

The crop feature and embedded synchronization codes cannot be used in JPEG format.

24.3.10 DCMI FIFO

A 8-word FIFO is implemented to manage data rate transfers on the AHB. The DCMI features a simple FIFO controller with a read pointer incremented each time the camera interface reads from the AHB, and a write pointer incremented each time the camera interface writes to the FIFO. There is no overrun protection to prevent the data from being overwritten if the AHB interface does not sustain the data transfer rate.

In case of overrun or errors in the synchronization signals, the FIFO is reset and the DCMI interface waits for a new start of frame.
24.3.11 DCMI data format description

Data formats

Three types of data are supported:
- 8/10/12/14-bit progressive video: either monochrome or raw Bayer format
- YCbCr 4:2:2 progressive video
- RGB565 progressive video. A pixel coded in 16 bits (5 bits for blue, 5 bits for red, 6 bits for green) takes two clock cycles to be transferred.

Compressed data: JPEG

For B&W (black and white), YCbCr or RGB data, the maximum input size is 2048 × 2048 pixels. No limit in JPEG compressed mode.

For monochrome, RGB and YCbCr, the frame buffer is stored in raster mode. 32-bit words are used. Only the little-endian format is supported.

Monochrome format

Characteristics:
- Raster format
- 8 bits per pixel

The table below shows how the data are stored.

| Table 160. Data storage in monochrome progressive video format |
|------------------|------------------|------------------|------------------|------------------|
| **Byte address** | **31:24**        | **23:16**        | **15:8**         | **7:0**          |
| 0                 | n + 3            | n + 2            | n + 1            | n                |
| 4                 | n + 7            | n + 6            | n + 5            | n + 4            |

RGB format

Characteristics:
- Raster format
- RGB
- Interleaved: one buffer: R, G and B interleaved (such as BRGBRGBRG)
- Optimized for display output
The RGB planar format is compatible with standard OS frame buffer display formats.

Only 16 BPP (bits per pixel): RGB565 (2 pixels per 32-bit word) is supported.

The 24 BPP (palletized format) and gray-scale formats are not supported. Pixels are stored in a raster scan order, that is from top to bottom for pixel rows, and from left to right within a pixel row. Pixel components are R (red), G (green) and B (blue). All components have the same spatial resolution (4:4:4 format). A frame is stored in a single part, with the components interleaved on a pixel basis.

The table below shows how the data are stored.

**Table 161. Data storage in RGB progressive video format**

<table>
<thead>
<tr>
<th>Byte address</th>
<th>31:27</th>
<th>26:21</th>
<th>20:16</th>
<th>15:11</th>
<th>10:5</th>
<th>4:0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Red n + 1</td>
<td>Green n + 1</td>
<td>Blue n + 1</td>
<td>Red n</td>
<td>Green n</td>
<td>Blue n</td>
</tr>
<tr>
<td>4</td>
<td>Red n + 4</td>
<td>Green n + 3</td>
<td>Blue n + 3</td>
<td>Red n + 2</td>
<td>Green n + 2</td>
<td>Blue n + 2</td>
</tr>
</tbody>
</table>

**YCbCr format**

Characteristics:
- Raster format
- YCbCr 4:2:2
- Interleaved: one buffer: Y, Cb and Cr interleaved (such as CbYCrYCbYCr)

Pixel components are Y (luminance or "luma"), Cb and Cr (chrominance or "chroma" blue and red). Each component is encoded in 8 bits. Luma and chroma are stored together (interleaved) as shown in the table below.

**Table 162. Data storage in YCbCr progressive video format**

<table>
<thead>
<tr>
<th>Byte address</th>
<th>31:24</th>
<th>23:16</th>
<th>15:8</th>

<td>Cb n</td>
</tr>
<tr>
<td>4</td>
<td>Y n + 3</td>
<td>Cr n + 2</td>
<td>Y n + 2</td>
<td>Cb n + 2</td>
</tr>
</tbody>
</table>

**YCbCr format - Y only**

Characteristics:
- Raster format
- YCbCr 4:2:2
- The buffer only contains Y information - monochrome image

Pixel components are Y (luminance or "luma"), Cb and Cr (chrominance or "chroma" blue and red). In this mode, the chroma information is dropped. Only the luma component of each pixel, encoded in 8 bits, is stored as shown in Table 163.

The result is a monochrome image having the same resolution as the original YCbCr data.
Half resolution image extraction

This is a modification of the previous reception modes, being applicable to monochrome, RGB or Y extraction modes.

This mode is used to only store a half resolution image. It is selected through OELS and LSM control bits.

24.4 DCMI interrupts

Five interrupts are generated. All interrupts are maskable by software. The global interrupt (DCMI_IT) is the OR of all the individual interrupts. The table below gives the list of all interrupts.

<table>
<thead>
<tr>

</tbody>
</table>

Bits 31:21 Reserved, must be kept at reset value.

- **Bit 20**: **OELS**: Odd/Even Line Select (Line Select Start)
  
  This bit works in conjunction with the LSM field (LSM = 1).
  
  0: Interface captures first line after the frame start, second one being dropped.
  
  1: Interface captures second line from the frame start, first one being dropped.

- **Bit 19**: **LSM**: Line Select mode
  
  0: Interface captures all received lines.
  
  1: Interface captures one line out of two.

- **Bit 18**: **OEBS**: Odd/Even Byte Select (Byte Select Start)
  
  This bit works in conjunction with BSM field (BSM ≠ 00).
  
  0: Interface captures first data (byte or double byte) from the frame/line start, second one being dropped.
  
  1: Interface captures second data (byte or double byte) from the frame/line start, first one being dropped.

- **Bits 17:16**: **BSM[1:0]**: Byte Select mode
  
  00: Interface captures all received data.
  
  01: Interface captures every other byte from the received data.
  
  10: Interface captures one byte out of four.
  
  11: Interface captures two bytes out of four.

  *Note: This mode only works for EDM[1:0] = 00. For all other EDM values, this field must be programmed to the reset value.*

- **Bit 15**: Reserved, must be kept at reset value.

- **Bit 14**: **ENABLE**: DCMI enable
  
  0: DCMI disabled
  
  1: DCMI enabled

  *Note: The DCMI configuration registers must be programmed correctly before enabling this bit.*

Bits 13:12 Reserved, must be kept at reset value.
Bits 11:10 **EDM[1:0]:** Extended data mode
00: Interface captures 8-bit data on every pixel clock.
01: Interface captures 10-bit data on every pixel clock.
10: Interface captures 12-bit data on every pixel clock.
11: Interface captures 14-bit data on every pixel clock.

Bits 9:8 **FCRC[1:0]:** Frame capture rate control
These bits define the frequency of frame capture. They are meaningful only in Continuous grab mode. They are ignored in snapshot mode.
00: All frames are captured.
01: Every alternate frame captured (50% bandwidth reduction)
10: One frame out of four captured (75% bandwidth reduction)
11: reserved

Bit 7 **VSPOL:** Vertical synchronization polarity
This bit indicates the level on the DCMI_VSYNC pin when the data are not valid on the parallel interface.
0: DCMI_VSYNC active low
1: DCMI_VSYNC active high

Bit 6 **HSPOL:** Horizontal synchronization polarity
This bit indicates the level on the DCMI_HSYNC pin when the data are not valid on the parallel interface.
0: DCMI_HSYNC active low
1: DCMI_HSYNC active high

Bit 5 **PCKPOL:** Pixel clock polarity
This bit configures the capture edge of the pixel clock.
0: Falling edge active
1: Rising edge active

Bit 4 **ESS:** Embedded synchronization select
0: Hardware synchronization data capture (frame/line start/stop) is synchronized with the DCMI_HSYNC/DCMI_VSYNC signals.
1: Embedded synchronization data capture is synchronized with synchronization codes embedded in the data flow.

*Note: Valid only for 8-bit parallel data. HSPOL/VSPOL are ignored when the ESS bit is set.*
This bit is disabled in JPEG mode.

Bit 3 **JPEG:** JPEG format
0: Uncompressed video format
1: This bit is used for JPEG data transfers. The DCMI_HSYNC signal is used as data enable. The crop and embedded synchronization features (ESS bit) cannot be used in this mode.

Bit 2 **CROP:** Crop feature
0: The full image is captured. In this case the total number of bytes in an image frame must be a multiple of four.
1: Only the data inside the window specified by the crop register is captured. If the size of the crop window exceeds the picture size, then only the picture size is captured.

Bit 1 **CM:** Capture mode
0: Continuous grab mode - The received data are transferred into the destination memory through the DMA. The buffer location and mode (linear or circular buffer) is controlled through the system DMA.
1: Snapshot mode (single frame) - Once activated, the interface waits for the start of frame and then transfers a single frame through the DMA. At the end of the frame, the CAPTURE bit is automatically reset.
Bit 0 **CAPTURE**: Capture enable
- 0: Capture disabled
- 1: Capture enabled

The camera interface waits for the first start of frame, then a DMA request is generated to transfer the received data into the destination memory.

In snapshot mode, the CAPTURE bit is automatically cleared at the end of the first frame received.

In continuous grab mode, if the software clears this bit while a capture is ongoing, the bit is effectively cleared after the frame end.

*Note*: The DMA controller and all DCMI configuration registers must be programmed correctly before enabling this bit.

### 24.5.2 DCMI status register (DCMI_SR)

Bits 31:3 Reserved, must be kept at reset value.

- **Bit 2 FNE**: FIFO not empty
  - This bit gives the status of the FIFO.
  - 1: FIFO contains valid data.
  - 0: FIFO empty

- **Bit 1 VSYNC**: Vertical synchronization
  - This bit gives the state of the DCMI_VSYNC pin with the correct programmed polarity. When embedded synchronization codes are used, the meaning of this bit is the following:
  - 0: active frame
  - 1: synchronization between frames
  - In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in DCMI_CR is set.

- **Bit 0 HSYNC**: Horizontal synchronization
  - This bit gives the state of the DCMI_HSYNC pin with the correct programmed polarity. When embedded synchronization codes are used, the meaning of this bit is the following:
  - 0: active line
  - 1: synchronization between lines
  - In case of embedded synchronization, this bit is meaningful only if the CAPTURE bit in DCMI_CR is set.
24.5.3 DCMI raw interrupt status register (DCMI_RIS)

DCMI_RIS gives the raw interrupt status and is accessible in read only. When read, this register returns the status of the corresponding interrupt before masking with the DCMI_IER register value.

Address offset: 0x08
Reset value: 0x0000 0000

<table>
<thead>
<tr>

</tr>
<tr>
<td>r r r r r r</td>
</tr>
</tbody>
</table>

Bits 31:5 Reserved, must be kept at reset value.

- **Bit 4 LINE_RIS**: Line raw interrupt status
  - This bit gets set when the DCMI_HSYNC signal changes from the inactive state to the active state. It goes high even if the line is not valid.
  - In the case of embedded synchronization, this bit is set only if the CAPTURE bit in DCMI_CR is set.
  - It is cleared by setting the LINE_ISC bit of the DCMI_ICR register.

- **Bit 3 VSYNC_RIS**: DCMI_VSYNC raw interrupt status
  - This bit is set when the DCMI_VSYNC signal changes from the inactive state to the active state.
  - In the case of embedded synchronization, this bit is set only if the CAPTURE bit is set in DCMI_CR.
  - It is cleared by setting the VSYNC_ISC bit of the DCMI_ICR register.

- **Bit 2 ERR_RIS**: Synchronization error raw interrupt status
  - 0: No synchronization error detected
  - 1: Embedded synchronization characters are not received in the correct order.
  - This bit is valid only in the embedded synchronization mode. It is cleared by setting the ERR_ISC bit of the DCMI_ICR register.
  - **Note**: *This bit is available only in embedded synchronization mode.*

- **Bit 1 OVR_RIS**: Overrun raw interrupt status
  - 0: No data buffer overrun occurred
  - 1: A data buffer overrun occurred and the data FIFO is corrupted.
  - The bit is cleared by setting the OVR_ISC bit of the DCMI_ICR register.

- **Bit 0 FRAME_RIS**: Capture complete raw interrupt status
  - 0: No new capture
  - 1: A frame has been captured.
  - This bit is set when a frame or window has been captured.
  - In case of a cropped window, this bit is set at the end of line of the last line in the crop. It is set even if the captured frame is empty (e.g. window cropped outside the frame).
  - The bit is cleared by setting the FRAME_ISC bit of the DCMI_ICR register.
### 24.5.4 DCMI interrupt enable register (DCMI_IER)

The DCMI_IER register is used to enable interrupts. When one of the DCMI_IER bits is set, the corresponding interrupt is enabled. This register is accessible in both read and write.

*Address offset: 0x0C*

*Reset value: 0x0000 0000*

24.5.5  DCMI masked interrupt status register (DCMI_MIS)

This DCMI_MIS register is a read-only register. When read, it returns the current masked status value (depending on the value in DCMI_IER) of the corresponding interrupt. A bit in this register is set if the corresponding enable bit in DCMI_IER is set and the corresponding bit in DCMI_RIS is set.

Address offset: 0x10
Reset value: 0x0000 0000

</tbody>
</table>

Bits 31:5  Reserved, must be kept at reset value.

**Bit 4  LINE_MIS**: Line masked interrupt status
This bit gives the status of the masked line interrupt.
0: No interrupt generation when the line is received
1: An Interrupt is generated when a line has been completely received and the LINE_IE bit is set in DCMI_IER.

**Bit 3  VSYNC_MIS**: VSYNC masked interrupt status
This bit gives the status of the masked VSYNC interrupt.
0: No interrupt is generated on DCMI_VSYNC transitions.
1: An interrupt is generated on each DCMI_VSYNC transition from the inactive to the active state and the VSYNC_IE bit is set in DCMI_IER.
The active state of the DCMI_VSYNC signal is defined by the VSPOL bit.

**Bit 2  ERR_MIS**: Synchronization error masked interrupt status
This bit gives the status of the masked synchronization error interrupt.
0: No interrupt is generated on a synchronization error.
1: An interrupt is generated if the embedded synchronization codes are not received in the correct order and the ERR_IE bit in DCMI_IER is set.
*Note: This bit is available only in embedded synchronization mode.*

**Bit 1  OVR_MIS**: Overrun masked interrupt status
This bit gives the status of the masked overflow interrupt.
0: No interrupt is generated on overrun.
1: An interrupt is generated if the DMA was not able to transfer the last data before new data (32-bit) are received and the OVR_IE bit is set in DCMI_IER.

**Bit 0  FRAME_MIS**: Capture complete masked interrupt status
This bit gives the status of the masked capture complete interrupt
0: No interrupt is generated after a complete capture.
1: An interrupt is generated at the end of each received frame/crop window (in crop mode) and the FRAME_IE bit is set in DCMI_IER.
### 24.5.6 DCMI interrupt clear register (DCMI_ICR)

The DCMI_ICR register is write-only. Setting a bit of this register clears the corresponding flag in the DCMI_RIS and DCMI_MIS registers. Writing 0 has no effect.

Bits 31:5 Reserved, must be kept at reset value.

- **Bit 4** `LINE_ISC`: line interrupt status clear  
  Setting this bit clears the LINE_RIS flag in the DCMI_RIS register.

- **Bit 3** `VSYNC_ISC`: Vertical Synchronization interrupt status clear  
  Setting this bit clears the VSYNC_RIS flag in the DCMI_RIS register.

- **Bit 2** `ERR_ISC`: Synchronization error interrupt status clear  
  Setting this bit clears the ERR_RIS flag in the DCMI_RIS register.  
  **Note:** This bit is available only in embedded synchronization mode.

- **Bit 1** `OVR_ISC`: Overrun interrupt status clear  
  Setting this bit clears the OVR_RIS flag in the DCMI_RIS register.

- **Bit 0** `FRAME_ISC`: Capture complete interrupt status clear  
  Setting this bit clears the FRAME_RIS flag in the DCMI_RIS register.

**FEC[7:0]**  
**LEC[7:0]**  
**LSC[7:0]**  
**FSC[7:0]**
Bits 31:24 **FEC[7:0]**: Frame end delimiter code
This byte specifies the code of the frame end delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, FEC.
If FEC is programmed to 0xFF, all the unused codes (0xFF0000XY) are interpreted as frame end delimiters.

Bits 23:16 **LEC[7:0]**: Line end delimiter code
This byte specifies the code of the line end delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, LEC.

Bits 15:8 **LSC[7:0]**: Line start delimiter code
This byte specifies the code of the line start delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, LSC.

Bits 7:0 **FSC[7:0]**: Frame start delimiter code
This byte specifies the code of the frame start delimiter. The code consists of 4 bytes in the form of 0xFF, 0x00, 0x00, FSC.
If FSC is programmed to 0xFF, no frame start delimiter is detected. But, the first occurrence of LSC after an FEC code is interpreted as a start of frame delimiter.

24.5.9 DCMI crop window start (DCMI_CWSTRT)

Address offset: 0x20
Reset value: 0x0000 0000

Bits 31:24 **FEU[7:0]**: Frame end delimiter unmask
This byte specifies the mask to be applied to the code of the frame end delimiter.
0: The corresponding bit in the FEC byte in DCMI_ESCR is masked while comparing the frame end delimiter with the received data.
1: The corresponding bit in the FEC byte in DCMI_ESCR is compared while comparing the frame end delimiter with the received data.

Bits 23:16 **LEU[7:0]**: Line end delimiter unmask
This byte specifies the mask to be applied to the code of the line end delimiter.
0: The corresponding bit in the LEC byte in DCMI_ESCR is masked while comparing the line end delimiter with the received data.
1: The corresponding bit in the LEC byte in DCMI_ESCR is compared while comparing the line end delimiter with the received data.

Bits 15:8 **LSU[7:0]**: Line start delimiter unmask
This byte specifies the mask to be applied to the code of the line start delimiter.
0: The corresponding bit in the LSC byte in DCMI_ESCR is masked while comparing the line start delimiter with the received data.
1: The corresponding bit in the LSC byte in DCMI_ESCR is compared while comparing the line start delimiter with the received data.

Bits 7:0 **FSU[7:0]**: Frame start delimiter unmask
This byte specifies the mask to be applied to the code of the frame start delimiter.
0: The corresponding bit in the FSC byte in DCMI_ESCR is masked while comparing the frame start delimiter with the received data.
1: The corresponding bit in the FSC byte in DCMI_ESCR is compared while comparing the frame start delimiter with the received data.

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:16 **VST[12:0]**: Vertical start line count
The image capture starts with this line number. Previous line data are ignored.
0x0000: line 1
0x0001: line 2
0x0002: line 3
....

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:0 **HOFFCNT[13:0]**: Horizontal offset count
This value gives the number of pixel clocks to count before starting a capture.
# DCMI crop window size (DCMI_CWSIZE)

## Section 2.2
Refer to Section 2.2 for the register boundary addresses.
25 Parallel synchronous slave interface (PSSI) applied to STM32L4P5xx and STM32LQ5xx only

The PSSI peripheral and the DCMI (digital camera interface) use the same circuitry. As a result, these two peripherals cannot be used at the same time: when using the PSSI, the DCMI registers cannot be accessed, and vice-versa.

In addition, the PSSI and the DCMI share the same alternate functions and interrupt vector (see Section 25.3.2: PSSI pins and internal signals).

25.1 Introduction

The PSSI is a generic synchronous 8/16-bit parallel data input/output slave interface. It enables the transmitter to send a data valid signal that indicates when the data is valid, and the receiver to output a flow control signal that indicates when it is ready to sample the data.

25.2 PSSI main features

The PSSI peripheral main features are the following:

- Slave mode operation
- 8-bit or 16-bit parallel data input or output
- 8-word (32-byte) FIFO
- Data enable (PSSI_DE) alternate function input and Ready (PSSI_RDY) alternate function output
  When selected, these signals can either enable the transmitter to indicate when the data is valid, allow the receiver to indicate when it is ready to sample the data, or both.

25.3 PSSI functional description

The PSSI is a synchronous parallel slave interface that can send or receive high-speed data flows. It consists of up to 16 data lines (PSSI_D[15:0]) plus a clock line (PSSI_PDCK). The clock polarity can be configured so that data can be captured or transmitted on either the clock rising or falling edge.

Usually, a general-purpose DMA channel is used to pass 32-bit packed data via the data register (PSSI_DR).

The data flow can either be continuous or synchronized by hardware using the optional PSSI_DE (Data enable), and PSSI_RDY (Ready) signals.

*Figure 175* shows the PSSI block diagram.
25.3.1 PSSI block diagram

Figure 175. PSSI block diagram

Figure 176. Top-level block diagram

25.3.2 PSSI pins and internal signals

The PSSI interface is composed of 19 pins, though nine signals are enough to transfer parallel data. Table 166 shows the PSSI pins.

When the PSSI ENABLE bit (bit 14 of PSSI_CR) is set to 1, the alternate functions and the interrupt vector are associated with the PSSI. Otherwise, they are associated with the DCMI. The DCMI ENABLE bit (bit 15 of DCMI_CR) and the PSSI ENABLE bit (bit 14 of PSSI_CR) must not be set to 1 at the same time. As an example, if a GPIO is configured to use the alternate function PSSI_PDCK/DCMI_PIXCK, it is the PSSI_PDCK function which becomes active if PSSI_CR/ENABLE is set to 1.
25.3.3 PSSI clock

The AHB clock frequency must be at least 2.5 times higher than the PSSI_PDCK frequency. At frequency ratios lower than 2.5, data might be corrupted or lost during transfers.

Data transfers are synchronous with PSSI_PDCK. The PSSI_PDCK polarity can be configured as follows, through CKPOL bit (bit 5 of PSSI_CR):

- When CKPOL = 0
  - Input pins are sampled on PSSI_PDCK falling edge
  - Output pins are driven on PSSI_PDCK rising edge
- When CKPOL = 1
  - Input pins are sampled on PSSI_PDCK rising edge
  - Output pins are driven on PSSI_PDCK falling edge

25.3.4 PSSI data management

Data direction

The direction of data transfers is configured through the OUTEN control bit (bit 31 of PSSI_CR):

- When OUTEN is cleared to 0 (default setting), the PSSI operates in receive mode and the data is input on the data pins.
- When OUTEN is set to 1, the peripheral operates in transmit mode and the data is output on the data pins.

OUTEN can be modified only when the ENABLE bit is cleared to 0.
Data register and DMA

Data are transferred from/to the FIFO using the PSSI_DR data register:
- In receive mode, data must be read from the FIFO by reading PSSI_DR.
- In transmit mode, data must be written to the FIFO by writing into PSSI_DR.

Word (32-bit) accesses to PSSI_DR and half-word (16-bit) accesses to PSSI_DR[15:0] are permitted in all modes. Byte (8-bit) accesses to PSSI_DR[7:0] are permitted only when the PSSI is configured to transfer 8 bits at a time (EDM=00 in the PSSI_CR register).

To reduce the load on the CPU, it is recommended to use the DMA to transfer data from/to the PSSI FIFO. When it is used, the DMA must be configured to transfer data via the PSSI_DR register. Using 32-bit transfers optimizes bandwidth and reduces the bus load. However, 8-bit and 16-bit transfers are also permitted.

To use the DMA, set the PSSI DMA enable bit (DMAEN in PSSI_CR) to 1 (default setting). When DMAEN is set to 1, a DMA transfer is initiated when the FIFO is ready for a 32-bit transfer (four valid bytes in receive mode or four empty bytes in transmit mode). As a result, in receive mode, no DMA transfers are initiated if there are three bytes or fewer in the FIFO, even if the DMA is configured to perform 8-bit transfers.

The RTT4B and RTT1B status bits (PSSI_SR) are useful when the CPU directly perform transfers to and from the FIFO. RTT4B set to 1 indicates that the FIFO is ready to transfer four bytes: at least four valid bytes in the FIFO in receive mode or at least four free bytes in transmit mode. RTT1B set to 1 indicates that the FIFO is ready to transfer one byte: at least one valid byte in the FIFO in receive mode or at least one free byte in transmit mode.

8-bit data

The PSSI parallel interface can transfer either 8-bit (using D[7:0]) or 16-bit data (using D[15:0]) depending on the EDM[1:0] control bits (bits 11:10 of PSSI_CR). If the 8-bit configuration is selected (EDM[1:0] set to 00), the unused D[15:0] pins can be used for GPIO or other functions.

When EDM[1:0] in PSSI_CR are programmed to 00, the interface transfers 8 bits using the D[7:0] pins. In this case, D[15:8] are not used and four PSSI_PDCK cycles are required to transfer a 32-bit word.

The least-significant byte (bits 7:0) correspond to the first byte transferred, and the most-significant byte (bits 31:28) corresponds to the forth byte transferred. Table 168 illustrates the positioning of the data bytes in two 32-bit words.

<table>

<td>D_{n+5}[7:0]</td>
<td>D_{n+4}[7:0]</td>
</tr>
</tbody>
</table>
Parallel synchronous slave interface (PSSI) applied to STM32L4P5xx and STM32LQ5xx only

16-bit data

When EDM[1:0] in PSSI_CR are programmed to 11, the interface transfers 16 bits using the D[15:0] pins. In this case, two PSSI_PDCK cycles are required to transfer a 32-bit word.

The least-significant half word (bits 15:0) correspond to the first half word transferred, and the most-significant half-word (bits 31:16) corresponds to the second half word transferred. Table 169 illustrates the positioning of the data in two 32-bit words.

</tbody>
</table>

FIFO data buffer and error conditions

An eight-word FIFO helps improving performance and avoids overruns and underruns.

If the ready signal (PSSI_RDY) is disabled in receive mode, an overrun error is generated when a clock active edge occurs when the FIFO is full. In this case, the input data is lost.

If the data enable signal (PSSI_DE) is disabled in transmit mode, an underrun error is generated when a clock active edge occurs when the FIFO is empty. In this case, unpredictable data are output.

The OVR_RIS status bit indicates that either an overrun or an underrun occurred. An interrupt can be generated when these events occur.

25.3.5 PSSI optional control signals

Data Enable (PSSI_DE) alternate function input

The data enable signal, PSSI_DE, is an optional signal. It is driven by the data source/transmitter in order to indicate that the data is valid to be transferred during the current cycle. When PSSI_DE is inactive, it means that the data must not be sampled by the receiver at the next clock edge.

This alternate function signal can be enabled using the DERDYCFG (bits 20:18 of PSSI_CR) control bits. PSSI_DE polarity is configured through DEPOL control bit (bit 6 of PSSI_CR). PSSI_DE is active low when DEPOL is cleared to 0, and high when DEPOL is set to 1.

The direction of the PSSI_DE signal is defined by the OUTEN value. It is the same as the data direction.

If the PSSI_DE alternate function input is enabled (through DERDYCFG) in receive mode (OUTEN cleared to 0), the PSSI samples PSSI_DE on the same PSSI_PDCK edge as the one used for sampling the data (D[15:0]). If PSSI_DE is active, the sampled data is saved in the FIFO. Otherwise, the sampled data is considered invalid and discarded. The transmitting device can use PSSI_DE as a data valid signal, driving it inactive when the data in the current cycle is not valid. This flow control function allows avoiding underrun errors.
If the PSSI_DE alternate output function is enabled (through DERDYCFG) in transmit mode (OUTEN=1), the PSSI drives PSSI_DE on the same PSSI_PDCK edge that the one used to drive the data (D[15:0]). If a new 8 or 16-bit data (as programmed in the EDM[1:0] control bits in PSSI_CR) is available for transmission in the internal FIFO, this data is output on the data outputs (D[15:0]) and the PSSI_DE output becomes active on the current PSSI_PDCK edge. Otherwise (if the TX FIFO is empty), the D[15:0] outputs remains unchanged on the next clock edge and the PSSI_DE output becomes inactive.

**Figure 177. Data enable in receive mode waveform diagram (CKPOL=0)**

![Waveform diagram](MSv48846V2)

Ready (PSSI_RDY) alternate function output

The ready signal, PSSI_RDY, is an optional signal. It is driven by the receiving device and indicates whether data is being accepted in the current cycle. When PSSI_RDY is inactive, it means that the data must not be sampled by the receiver at the next clock edge.

This alternate function signal can be enabled using the DERDYCFG control bits (bits 20:18 of PSSI_CR). PSSI_RDY polarity is configured through the RDYPOL control bit (bit 6 of PSSI_CR). PSSI_RDY is active low when RDYPOL is cleared to 0, and high when RDYPOL set to 1.

The direction of the PSSI_RDY signal is defined by the OUTEN (bit 31 of PSSI_CR). It is set in the opposite direction compared to the PSSI_DE and data signals.

If the PSSI_RDY alternate output function is enabled (through DERDYCFG) in receive mode (OUTEN=0), the PSSI drives PSSI_RDY one PSSI_PDCK half cycle after it samples...
the data (D[15:0]). If the FIFO has enough free space to receive more data, the PSSI drives the PSSI_RDY signal active. Otherwise, if the FIFO is full and cannot accept more data, the PSSI drives the PSSI_RDY signal inactive. The transmitting device must repeat the current data in the next cycle when it detects that PSSI_RDY is inactive. This flow control function allows the PSSI to avoid overrun errors when the system (via the DMA) is unable to keep up with the data flow.

**Figure 179. Ready in receive mode waveform diagram (CKPOL=0)**

If the PSSI_RDY alternate input function is enabled (through DERDYCFG) in transmit mode (OUTEN=1), the PSSI samples the PSSI_RDY signal on the opposite PSSI_PDCK edge to the one at which D[15:0] are driven. If the PSSI_RDY signal is inactive, the PSSI keeps the same data (D[15:0]) and PSSI DE signals that valid data are available during the next PSSI_PDCK clock cycle. Otherwise, if PSSI_RDY signal is sampled as active, the next data from the TX FIFO (if available) is output on the data outputs (D[15:0]). If no new data are available in the TX FIFO, the PSSI keeps the data output values and outputs the PSSI_DE signal as inactive (if enabled).

The receiving device uses the PSSI_RDY to control the data flow and avoid overrun errors when the system (via the DMA) is unable to keep up with the data flow.

**Bidirectional PSSI_DE/PSSI_RDY signal**

A single pin can be used for both data enable (PSSI_DE) and ready (PSSI_RDY) functions if DEPOL and RDYPOL are both set to 1 and DERDYCFG is set to 111 or 100 in the PSSI_CR register. In this case, the GPIO corresponding to selected alternate function (PSSI_DE when DERDYCFG=111 or PSSI_RDY when DERDYCFG=100) must be configured as open-drain. The other device must also be configured to drive the line as open-drain, and a weak pull-up must be applied to the line.

The signal thus becomes bidirectional. If either the sender drives the line low (to indicate that the data is not valid) or the receiver drives the line low (to indicate that it is not sampling the current data), then both devices know that the data is not being transferred in the current cycle.
The PSSI generates only one interrupt (IT_OVR). It is consequently equivalent to the global interrupt (pssi_it). Refer to Table 170 for the list of interrupts.

The PSSI and the DCMI share the same interrupt vector. When the PSSI ENABLE bit (bit 14 of PSSI_CR) is set to 1, these interrupts are triggered by the PSSI. Otherwise, they are controlled by the DCMI.

The DCMI ENABLE bit (bit 14 of DCMI_CR) and PSSI ENABLE bit must not be set to 1 at the same time.

Bits 31  OUTEN: Data direction selection bit
0: Receive mode: data is input synchronously with PSSI_PDCK
1: Transmit mode: data is output synchronously with PSSI_PDCK

Bits 30  DMAEN: DMA enable bit
0: DMA transfers are disabled. The user application can directly access the PSSI_DR register when DMA transfers are disabled.
1: DMA transfers are enabled (default configuration). A DMA channel in the general-purpose DMA controller must be configured to perform transfers from/to PSSI_DR.

Bits 29:21 Reserved, must be kept at reset value.

Bits 20:18 DERDYCFG: Data enable and ready configuration
000: PSSI_DE and PSSI_RDY both disabled
001: Only PSSI_RDY enabled
010: Only PSSI_DE enabled
011: Both PSSI_RDY and PSSI_DE alternate functions enabled
100: Both PSSI_RDY and PSSI_DE features enabled - bidirectional on PSSI_RDY pin (see Bidirectional PSSI_DE/PSSI_RDY signal on page 800)
101: Only PSSI_RDY function enabled, but mapped to PSSI_DE pin
110: Only PSSI_DE function enabled, but mapped to PSSI_RDY pin
111: Both PSSI_RDY and PSSI_DE features enabled - bidirectional on PSSI_DE pin (see Bidirectional PSSI_DE/PSSI_RDY signal on page 800)

When the PSSI_RDY function is mapped to the PSSI_DE pin (settings 101 or 111), it is still the RDYPOL bit which determines its polarity. Similarly, when the PSSI_DE function is mapped to the PSSI_RDY pin (settings 110 or 111), it is still the DEPOL bit which determines its polarity.

Bits 17:15 Reserved, must be kept at reset value.
Parallel synchronous slave interface (PSSI) applied to STM32L4P5xx and STM32LQ5xx

Bit 14 **ENABLE**: PSSI enable
0: PSSI disabled
1: PSSI enabled
The contents of the FIFO are flushed when ENABLE is cleared to 0.

**Note**: When ENABLE=1, the content of PSSI_CR must not be changed, except for the ENABLE bit itself. All configuration bits can change as soon as ENABLE changes from 0 to 1.

The DMA controller and all PSSI configuration registers must be programmed correctly before setting the ENABLE bit to 1.
The ENABLE bit and the DCMI ENABLE bit (bit 15 of DCMI_CR) must not be set to 1 at the same time.

Bits 13:12 Reserved, must be kept at reset value.

Bits 11:10 **EDM[1:0]**: Extended data mode
00: Interface captures 8-bit data on every parallel data clock
01: Reserved, must not be selected
10: Reserved, must not be selected
11: The interface captures 16-bit data on every parallel data clock

Bit 9 Reserved, must be kept at reset value.

Bit 8 **RDYPOL**: Ready (PSSI_RDY) polarity
This bit indicates the level on the PSSI_RDY pin when the data are not valid on the parallel interface.
0: PSSI_RDY active low (0 indicates that the receiver is ready to receive)
1: PSSI_RDY active high (1 indicates that the receiver is ready to receive)

Bit 7 Reserved, must be kept at reset value.

Bit 6 **DEPOL**: Data enable (PSSI_DE) polarity
This bit indicates the level on the PSSI_DE pin when the data are not valid on the parallel interface.
0: PSSI_DE active low (0 indicates that data is valid)
1: PSSI_DE active high (1 indicates that data is valid)

Bit 5 **CKPOL**: Parallel data clock polarity
This bit configures the capture edge of the parallel clock or the edge used for driving outputs, depending on OUTEN.
0: Falling edge active for inputs or rising edge active for outputs
1: Rising edge active for inputs or falling edge active for outputs.

Bits 4:0 Reserved, must be kept at reset value.
25.5.2 **PSSI status register (PSSI_SR)**

Address offset: 0x04

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **RTT1B**: FIFO is ready to transfer one byte

1: FIFO is ready for a one-byte (32-bit) transfer. In receive mode, this means that at least one valid data byte is in the FIFO. In transmit mode, this means that there is at least one byte free in the FIFO.

0: FIFO is not ready for a 1-byte transfer

Bit 2 **RTT4B**: FIFO is ready to transfer four bytes

1: FIFO is ready for a four-byte (32-bit) transfer. In receive mode, this means that at least four valid data bytes are in the FIFO. In transmit mode, this means that there are at least four bytes free in the FIFO.

0: FIFO is not ready for a four-byte transfer

Bits 1:0 Reserved, must be kept at reset value.

25.5.3 **PSSI raw interrupt status register (PSSI_RIS)**

Address offset: 0x08

Reset value: 0x0000 0000

PSSI_RIS gives the raw interrupt status. This register is read-only. When read, it returns the status of the corresponding interrupt before masking with the PSSI_IER register value.

OVR_RIS

Bits 1:0 Reserved, must be kept at reset value.
25.5.4 PSSI interrupt enable register (PSSI_IER)

Address offset: 0x0C
Reset value: 0x0000 0000

The PSSI_IER register is used to enable interrupts. When one of the PSSI_IER bits is set, the corresponding interrupt is enabled. This register is accessible both in read and write modes.

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 OVR_RIS: Data buffer overrun/underrun raw interrupt status
0: No overrun/underrun occurred
1: An overrun/underrun occurred: overrun in receive mode, underrun in transmit mode.
This bit is cleared by writing a 1 to the OVR_ISC bit in PSSI_ICR.

Bit 0 Reserved, must be kept at reset value.
25.5.5 **PSSI masked interrupt status register (PSSI_MIS)**

This PSSI_MIS register is read-only. When read, it returns the current masked status value of the corresponding interrupt (depending on the value in PSSI_IER). A bit in this register is set if the corresponding enable bit in PSSI_IER is set and the corresponding bit in PSSI_RIS is set.

Address offset: 0x10

</tbody>
</table>
25.5.7 PSSI data register (PSSI_DR)

Address offset: 0x28
Reset value: 0x0000 0000

In receive mode (OUTEN=0), the DMA controller must read the received data from this register. Write operations to PSSI_DR result in an error response. When more bytes than the number of valid bytes are read in the FIFO, the invalid bytes return zeros.

In transmit mode (OUTEN=1), the DMA controller must write the data to be transmitted into this register. Read operations to PSSI_DR result in an error response.

32-bit, 16-bit, and 8-bit accesses are all supported for PSSI_DR. For instance, 16-bit read/write operations remove/add two bytes from/to the FIFO. However, 8-bit accesses are permitted only when the PSSI is configured to transfer 8 data bits at a time (EDM=00 in PSSI_CR). 8-bit accesses to PSSI_DR when EDM is not set to 0 result in an error response.

All accesses must include byte 0: 8-bit accesses must be performed to bits 7 to 0 and 16-bit accesses from bits 15 to 0. Accesses that do not include byte 0 results in an error response.

Accessing PSSI_DR when ENABLE bit in PSSI_CR is set to 0 results in an error response.

Refer to Section 2.2 on page 93 for the register boundary addresses.
26 Comparator (COMP)

26.1 Introduction

The device embeds two ultra-low-power comparators COMP1, and COMP2. The comparators can be used for a variety of functions including:

- Wakeup from low-power mode triggered by an analog signal,
- Analog signal conditioning,
- Cycle-by-cycle current control loop when combined with a PWM output from a timer.

26.2 COMP main features

- Each comparator has configurable plus and minus inputs used for flexible voltage selection:
  - Multiplexed I/O pins
  - DAC Channel1 and Channel2
  - Internal reference voltage and three submultiple values (1/4, 1/2, 3/4) provided by scaler (buffered voltage divider)
- Programmable hysteresis
- Programmable speed / consumption
- The outputs can be redirected to an I/O or to timer inputs for triggering:
  - Break events for fast PWM shutdowns
- Comparator outputs with blanking source
- The two comparators can be combined in a window comparator
- Each comparator has interrupt generation capability with wakeup from Sleep and Stop modes (through the EXTI controller)
26.3 COMP functional description

26.3.1 COMP block diagram

The block diagram of the comparators is shown in Figure 182.

**Figure 182. Comparator block diagram**

26.3.2 COMP pins and internal signals

The I/Os used as comparators inputs must be configured in analog mode in the GPIOs registers.

The comparator output can be connected to the I/Os using the alternate function channel given in “Alternate function mapping” table in the datasheet.

The output can also be internally redirected to a variety of timer input for the following purposes:

- Emergency shut-down of PWM signals, using BKin and BKin2 inputs
- Cycle-by-cycle current control, using OCREF_CLR inputs
- Input capture for timing measures

It is possible to have the comparator output simultaneously redirected internally and externally.

26.3.3 COMP reset and clocks

The COMP clock provided by the clock controller is synchronous with the APB2 clock. There is no clock enable control bit provided in the RCC controller. Reset and clock enable bits are common for COMP and SYSCFG.

**Important:** The polarity selection logic and the output redirection to the port works independently from the APB2 clock. This allows the comparator to work even in Stop mode.

26.3.4 Comparator LOCK mechanism

The comparators can be used for safety purposes, such as over-current or thermal protection. For applications having specific functional safety requirements, it is necessary to insure that the comparator programming cannot be altered in case of spurious register access or program counter corruption.
For this purpose, the comparator control and status registers can be write-protected (read-only).

Once the programming is completed, the COMPx LOCK bit can be set to 1. This causes the whole register to become read-only, including the COMPx LOCK bit.

The write protection can only be reset by a MCU reset.

### 26.3.5 Window comparator

The purpose of window comparator is to monitor the analog voltage if it is within specified voltage range defined by lower and upper threshold.

Two embedded comparators can be utilized to create window comparator. The monitored analog voltage is connected to the non-inverting (plus) inputs of comparators connected together and the upper and lower threshold voltages are connected to the inverting (minus) inputs of the comparators. Two non-inverting inputs can be connected internally together by enabling WINMODE bit to save one IO for other purposes.

![Figure 183. Window mode](image)

### 26.3.6 Hysteresis

The comparator includes a programmable hysteresis to avoid spurious output transitions in case of noisy signals. The hysteresis can be disabled if it is not needed (for instance when exiting from low-power mode) to be able to force the hysteresis value using external components.
26.3.7 Comparator output blanking function

The purpose of the blanking function is to prevent the current regulation to trip upon short current spikes at the beginning of the PWM period (typically the recovery current in power switches anti parallel diodes). It consists of a selection of a blanking window which is a timer output compare signal. The selection is done by software (refer to the comparator register description for possible blanking signals). Then, the complementary of the blanking signal is ANDed with the comparator output to provide the wanted comparator output. See the example provided in the figure below.

Figure 184. Comparator hysteresis

![Comparator hysteresis](MS19584V1)

Figure 185. Comparator output blanking

![Comparator output blanking](MS30964V1)
26.3.8 COMP power and speed modes

COMP1 and COMP2 power consumption versus propagation delay can be adjusted to have the optimum trade-off for a given application.

The bits PWRMODE[1:0] in COMPx_CSR registers can be programmed as follows:
- 00: High speed / full power
- 01 or 10: Medium speed / medium power
- 11: Low speed / ultra-low-power

26.4 COMP low-power modes

### Table 176. Comparator behavior in the low power modes

<table>
<thead>

<td>Stop 2</td>
<td>The COMP registers are powered down and must be reinitialized after exiting Standby or Shutdown mode.</td>
</tr>
</tbody>
</table>

26.5 COMP interrupts

The comparator outputs are internally connected to the Extended interrupts and events controller. Each comparator has its own EXTI line and can generate either interrupts or events. The same mechanism is used to exit from low-power modes.

Refer to Interrupt and events section for more details.

To enable COMPx interrupt, it is required to follow this sequence:
1. Configure and enable the EXTI line corresponding to the COMPx output event in interrupt mode and select the rising, falling or both edges sensitivity
2. Configure and enable the NVIC IRQ channel mapped to the corresponding EXTI lines
3. Enable COMPx.
The COMP1_CSR is the Comparator 1 control/status register. It contains all the bits/flags related to comparator1.

Address offset: 0x00

System reset value: 0x0000 0000

</table>
Bit 22 **BRGEN**: Scalar bridge enable

This bit is set and cleared by software (only if LOCK not set). This bit enable the bridge of the scaler.

0: Scalar resistor bridge disable (if BRGEN bit of COMP2_CSR register is also reset)
1: Scalar resistor bridge enable

If SCALEN is set and BRGEN is reset, BG voltage reference is available but not 1/4 BGAP, 1/2 BGAP, 3/4 BGAP. BGAP value is sent instead of 1/4 BGAP, 1/2 BGAP, 3/4 BGAP.

If SCALEN and BRGEN are set, 1/4 BGAP 1/2 BGAP 3/4 BGAP and BGAP voltage references are available.

Bit 21 Reserved, must be kept at reset value

Bits 20:18 **BLANKING[2:0]**: Comparator 1 blanking source selection bits

These bits select which timer output controls the comparator 1 output blanking.

000: No blanking
001: TIM1 OC5 selected as blanking source
010: TIM2 OC3 selected as blanking source
All other values: reserved

Bits 17:16 **HYST[1:0]**: Comparator 1 hysteresis selection bits

These bits are set and cleared by software (only if LOCK not set). They select the hysteresis voltage of the comparator 1.

00: No hysteresis
01: Low hysteresis
10: Medium hysteresis
11: High hysteresis

Bit 15 **POLARITY**: Comparator 1 polarity selection bit

This bit is set and cleared by software (only if LOCK not set). It inverts Comparator 1 polarity.

0: Comparator 1 output value not inverted
1: Comparator 1 output value inverted

Bits 14: Reserved, must be kept at reset value.

Bit 7 **INPSEL**: Comparator 1 input plus selection bit

This bit is set and cleared by software (only if LOCK not set).

0: external IO - PC5
1: PB2

Bits 6:4 **INMSEL**: Comparator 1 input minus selection bits

These bits are set and cleared by software (only if LOCK not set). They select which input is connected to the input minus of comparator 1.

000 = 1/4 VREFINT
001 = 1/2 VREFINT
010 = 3/4 VREFINT
011 = VREFINT
100 = DAC Channel1
101 = DAC Channel2

<td>Comparator 1 switched ON</td>
</tr>
</tbody>
</table>
Bit 22  **BRGEN**: Scaler bridge enable
This bit is set and cleared by software (only if LOCK not set). This bit enable the bridge of the scaler.
0: Scaler resistor bridge disable (if BRGEN bit of COMP1_CSR register is also reset)
1: Scaler resistor bridge enable
If SCALEN is set and BRGEN is reset, BG voltage reference is available but not 1/4 BGAP, 1/2 BGAP, 3/4 BGAP. BGAP value is sent instead of 1/4 BGAP, 1/2 BGAP, 3/4 BGAP.
If SCALEN and BRGEN are set, 1/4 BGAP 1/2 BGAP 3/4 BGAP and BGAP voltage references are available.

Bit 21  Reserved, must be kept at reset value

Bits 20:18  **BLANKING[2:0]**: Comparator 2 blanking source selection bits
These bits select which timer output controls the comparator 2 output blanking.
000: No blanking
100: TIM15 OC1 selected as blanking source
All other values: reserved

Bits 17:16  **HYST[1:0]**: Comparator 2 hysteresis selection bits
These bits are set and cleared by software (only if LOCK not set). Select the hysteresis voltage of the comparator 2.
00: No hysteresis
01: Low hysteresis
10: Medium hysteresis
11: High hysteresis

Bit 15  **POLARITY**: Comparator 2 polarity selection bit
This bit is set and cleared by software (only if LOCK not set). It inverts Comparator 2 polarity.
0: Comparator 2 output value not inverted
1: Comparator 2 output value inverted

Bits 14:10  Reserved, must be kept at reset value.

Bit 9  **WINMODE**: Windows mode selection bit
This bit is set and cleared by software (only if LOCK not set). This bit selects the window mode of the comparators. If set, both positive inputs of comparators will be connected together.
0: Input plus of Comparator 2 is not connected to Comparator 1
1: Input plus of Comparator 2 is connected with input plus of Comparator 1

Bit 8  Reserved, must be kept at reset value.

Bit 7  **INPSEL**: Comparator 1 input plus selection bit
This bit is set and cleared by software (only if LOCK not set).
0: PB4
1: PB6
Bits 6:4 **INMSEL**: Comparator 2 input minus selection bits
These bits are set and cleared by software (only if LOCK not set). They select which input is connected to the input minus of comparator 2.
- 000 = 1/4 VREFINT
- 001 = 1/2 VREFINT
- 010 = 3/4 VREFINT
- 011 = VREFINT
- 100 = DAC Channel1
- 101 = DAC Channel2
- 110 = PB3
- 111 = PB7

Bits 3:2 **PWRMODE[1:0]**: Power Mode of the comparator 2
These bits are set and cleared by software (only if LOCK not set). They control the power/speed of the Comparator 2.
- 00: High speed
- 01 or 10: Medium speed
- 11: Ultra low power

Bit 1 Reserved, must be kept cleared.

Bit 0 **EN**: Comparator 2 enable bit
This bit is set and cleared by software (only if LOCK not set). It switches on comparator 2.
- 0: Comparator 2 switched OFF
- 1: Comparator 2 switched ON
### 26.6.3 COMP register map

The following table summarizes the comparator registers.

| Offset | Register   | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

Refer to *Section 2.2 on page 93* for the register boundary addresses.
27 Operational amplifiers (OPAMP)

27.1 Introduction

The device embeds two operational amplifiers with two inputs and one output each. The three I/Os can be connected to the external pins, this enables any type of external interconnections. The operational amplifier can be configured internally as a follower or as an amplifier with a non-inverting gain ranging from 2 to 16.

The positive input can be connected to the internal DAC.

The output can be connected to the internal ADC.

27.2 OPAMP main features

- Rail-to-rail input and output voltage range
- Low input bias current (down to 1 nA)
- Low input offset voltage (1.5 mV after calibration, 3 mV with factory calibration)
- Low-power mode (current consumption reduced to 30 µA instead of 100 µA)
- Fast wakeup time (10 µs in normal mode, 30 µs in low-power mode)
- Gain bandwidth of 1.6 MHz

27.3 OPAMP functional description

The OPAMP has several modes.

Each OPAMP can be individually enabled, when disabled the output is high-impedance.

When enabled, it can be in calibration mode, all input and output of the OPAMP are then disconnected, or in functional mode.

There are two functional modes, the low-power mode or the normal mode. In functional mode the inputs and output of the OPAMP are connected as described in the Section 27.3.3: Signal routing.

27.3.1 OPAMP reset and clocks

The operational amplifier clock is necessary for accessing the registers. When the application does not need to have read or write access to those registers, the clock can be switched off using the peripheral clock enable register (see OPAMPEN bit in Section 6.2.18: Peripheral clock enable register (RCC_AHBxENR, RCC_APBxENRx)).

The bit OPAEN enables and disables the OPAMP operation. The OPAMP registers configurations should be changed before enabling the OPAEN bit in order to avoid spurious effects on the output.

When the output of the operational amplifier is no more needed the operational amplifier can be disabled to save power. All the configurations previously set (including the calibration) are maintained while OPAMP is disabled.
27.3.2 Initial configuration

The default configuration of the operational amplifier is a functional mode where the three IOs are connected to external pins. In the default mode the operational amplifier uses the factory trimming values. See electrical characteristics section of the datasheet for factory trimming conditions, usually the temperature is 30 °C and the voltage is 3 V. The trimming values can be adjusted, see Section 27.3.5: Calibration for changing the trimming values. The default configuration uses the normal mode, which provides the highest performance. Bit OPALPM can be set in order to switch the operational amplifier to low-power mode and reduced performance. Both normal and low-power mode characteristics are defined in the section “electrical characteristics” of the datasheet. Before utilization, the bit OPA_RANGE of OPAMP_CSR must be set to 1 if VDDA is above 2.4V, or kept at 0 otherwise.

As soon as the OPAEN bit in OPAMP_CSR register is set, the operational amplifier is functional. The two input pins and the output pin are connected as defined in Section 27.3.3: Signal routing and the default connection settings can be changed.

Note: The inputs and output pins must be configured in analog mode (default state) in the corresponding GPIOx_MODER register.

27.3.3 Signal routing

The routing for the operational amplifier pins is determined by OPAMP_CSR register.

The connections of the two operational amplifiers (OPAMP1 and OPAMP2) are described in the table below.

<table>
<thead>
<tr>
<th>Signal</th>
<th>Pin</th>
<th>Internal</th>
<th>comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>OPAMP1_VINM</td>
<td>PA1 or dedicated pin(1)</td>
<td>OPAMP1_OUT or PGA</td>
<td>Controlled by bits OPAMODE and VM_SEL.</td>
</tr>
<tr>
<td>OPAMP1_VINP</td>
<td>PA0</td>
<td>DAC1_OUT1</td>
<td>Controlled by bit VP_SEL.</td>
</tr>
<tr>
<td>OPAMP1_VOUT</td>
<td>PA3</td>
<td>ADC1_IN8</td>
<td>The pin is connected when the OPAMP is enabled. The ADC input is controlled by ADC.</td>
</tr>
<tr>
<td>OPAMP2_VINM</td>
<td>PA7 or dedicated pinChapter 1.</td>
<td>OPAMP2_OUT or PGA</td>
<td>Controlled by bits OPAMODE and VM_SEL.</td>
</tr>
<tr>
<td>OPAMP2_VINP</td>
<td>PA6</td>
<td>DAC1_OUT2</td>
<td>Controlled by bit VP_SEL.</td>
</tr>
<tr>
<td>OPAMP2_VOUT</td>
<td>PB0</td>
<td>ADC1_IN15</td>
<td>The pin is connected when the OPAMP is enabled. The ADC input is controlled by ADC.</td>
</tr>
</tbody>
</table>

1. The dedicated pin is only available on BGA132 and BGA169 package. This configuration provides the lowest input bias current (see datasheet).
27.3.4 OPAMP modes

The operational amplifier inputs and outputs are all accessible on terminals. The amplifiers can be used in multiple configuration environments:

- Standalone mode (external gain setting mode)
- Follower configuration mode
- PGA modes

*Note:* The amplifier output pin is directly connected to the output pad to minimize the output impedance. It cannot be used as a general purpose I/O, even if the amplifier is configured as a PGA and only connected to the ADC channel.

*Note:* The impedance of the signal must be maintained below a level which avoids the input leakage to create significant artifacts (due to a resistive drop in the source). Please refer to the electrical characteristics section in the datasheet for further details.

**Standalone mode (external gain setting mode)**

The procedure to use the OPAMP in standalone mode is presented hereafter.

Starting from the default value of OPAMP_CSR, and the default state of GPIOx_MODER, configure bit OPA_RANGE according the VDDA voltage. As soon as the OPAEN bit is set, the two input pins and the output pin are connected to the operational amplifier.

This default configuration uses the factory trimming values and operates in normal mode (highest performance). The behavior of the OPAMP can be changed as follows:

- **OPALPM** can be set to “operational amplifier low-power” mode in order to save power.
- **USERTRIM** can be set to modify the trimming values for the input offset.

![Figure 186. Standalone mode: external gain setting mode](image)
Follower configuration mode

The procedure to use the OPAMP in follower mode is presented hereafter.

- configure OPAMODE bits as “internal follower”
- configure VP_SEL bits as “GPIO connected to VINP”.
- As soon as the OPAEN bit is set, the signal on pin OPAMP_VINP is copied to pin OPAMP_VOUT.

Note: The pin corresponding to OPAMP_VINM is free for another usage.

Note: The signal on the operational amplifier output is also seen as an ADC input. As a consequence, the OPAMP configured in follower mode can be used to perform impedance adaptation on input signals before feeding them to the ADC input, assuming the input signal frequency is compatible with the operational amplifier gain bandwidth specification.

Figure 187. Follower configuration
Programmable Gain Amplifier mode

The procedure to use the OPAMP to amplify the amplitude of an input signal is presented hereafter.

- configure OPAMODE bits as “internal PGA enabled”,
- configure PGA_GAIN bits as “internal PGA Gain 2, 4, 8 or 16”,
- configure VM_SEL bits as “inverting not externally connected”,
- configure VP_SEL bits as “GPIO connected to VINP”.

As soon as the OPAEN bit is set, the signal on pin OPAMP_VINP is amplified by the selected gain and visible on pin OPAMP_VOUT.

Note: To avoid saturation, the input voltage should stay below \( V_{DDA} \div \) divided by the selected gain.

Figure 188. PGA mode, internal gain setting (x2/x4/x8/x16), inverting input not used
Programmable Gain Amplifier mode with external filtering

The procedure to use the OPAMP to amplify the amplitude of an input signal, with an external filtering, is presented hereafter.

- configure OPAMODE bits as “internal PGA enabled”;
- configure PGA_GAIN bits as “internal PGA Gain 2, 4, 8 or 16”;
- configure VM_SEL bits as “GPIO connected to VINM”;
- configure VP_SEL bits as “GPIO connected to VINV”.

Any external connection on VINP can be used in parallel with the internal PGA, for example a capacitor can be connected between VOUT and VINM for filtering purpose (see datasheet for the value of resistors used in the PGA resistor network).

Figure 189. PGA mode, internal gain setting (x2/x4/x8/x16), inverting input used for filtering

1. The gain depends on the cut-off frequency.

27.3.5 Calibration

At startup, the trimming values are initialized with the preset ‘factory’ trimming value.

Each operational amplifier offset can be trimmed by the user. Specific registers allow to have different trimming values for normal mode and for low-power mode.

The aim of the calibration is to cancel as much as possible the OPAMP inputs offset voltage. The calibration circuitry allows to reduce the inputs offset voltage to less than +/-1.5 mV within stable voltage and temperature conditions.

For each operational amplifier and each mode two trimming values need to be trimmed, one for N differential pair and one for P differential pair.

There are two registers for trimming the offsets for each operational amplifiers, one for normal mode (OPAMP_OTR) and one low-power mode (OPAMP_LPOTR). Each register is composed of five bits for P differential pair trimming and five bits for N differential pair trimming. These are the ‘user’ values.
The user is able to switch from ‘factory’ values to ‘user’ trimmed values using the USERTRIM bit in the OPAMP_CSR register. This bit is reset at startup and so the ‘factory’ value are applied by default to the OPAMP trimming registers.

User is liable to change the trimming values in calibration or in functional mode.

The offset trimming registers are typically configured after the calibration operation is initialized by setting bit CALON to 1. When CALON = 1 the inputs of the operational amplifier are disconnected from the functional environment.

- Setting CALSEL to 1 initializes the offset calibration for the P differential pair (low voltage reference used).
- Resetting CALSEL to 0 initializes the offset calibration for the N differential pair (high voltage reference used).

When CALON = 1, the bit CALOUT will reflect the influence of the trimming value selected by CALSEL and OPALPM. When the value of CALOUT switches between two consecutive trimming values, this means that those two values are the best trimming values. The CALOUT flag needs up to 1 ms after the trimming value is changed to become steady (see tOFFTRIMmax delay specification in the electrical characteristics section of the datasheet).

Note: The closer the trimming value is to the optimum trimming value, the longer it takes to stabilize (with a maximum stabilization time remaining below 1 ms in any case).

</tbody>
</table>
Calibration procedure

Here are the steps to perform a full calibration of either one of the operational amplifiers:

1. Select correct OPA_RANGE in OPAMP_CSR, then set the OPAEN bit in OPAMP_CSR to 1 to enable the operational amplifier.
2. Set the USERTRIM bit in the OPAMP_CSR register to 1.
3. Choose a calibration mode (refer to Table 180: Operating modes and calibration). The steps 3 to 4 will have to be repeated 4 times. For the first iteration select
   – Normal mode, offset cal high (N differential pair)
   The above calibration mode correspond to OPALPM=0 and CALSEL=0 in the OPAMP_CSR register.
4. Increment TRIMOFFSETN[4:0] in OPAMP_OTR starting from 00000b until CALOUT changes to 1 in OPAMP_CSR.

Note: CALOUT will switch from 0 to 1 for offset cal high and from 1 to 0 for offset cal low.

Note: Between the write to the OPAMP_OTR register and the read of the CALOUT value, make sure to wait for the tOFFTRIMmax delay specified in the electrical characteristics section of the datasheet, to get the correct CALOUT value.

The commutation means that the offset is correctly compensated and that the corresponding trim code must be saved in the OPAMP_OTR register.

Repeat steps 3 to 4 for:
   – Normal mode and offset cal low
   – Low power mode and offset cal high
   – Low power mode and offset cal low

If a mode is not used it is not necessary to perform the corresponding calibration.

All operational amplifier can be calibrated at the same time.

Note: During the whole calibration phase the external connection of the operational amplifier output must not pull up or down currents higher than 500 µA.

During the calibration procedure, it is necessary to set up OPAMODE bits as 00 or 01 (PGA disable) or 11 (internal follower).

#### Bit 31 OPA_RANGE: Operational amplifier power supply range for stability

- All AOP must be in power down to allow AOP-RANGE bit write. It applies to all AOP embedded in the product.
  - 0: Low range (VDDA < 2.4V)
  - 1: High range (VDDA > 2.4V)

#### Bits 30:16 Reserved, must be kept at reset value.

#### Bit 15 CALOUT: Operational amplifier calibration output

- During calibration mode offset is trimmed when this signal toggle.

#### Bit 14 USERTRIM: allows to switch from ‘factory’ AOP offset trimmed values to AOP offset ‘user’ trimmed values

- This bit is active for both mode normal and low-power.
  - 0: ‘factory’ trim code used
  - 1: ‘user’ trim code used

#### Bit 13 CALSEL: Calibration selection

- 0: NMOS calibration (200mV applied on OPAMP inputs)
- 1: PMOS calibration (VDDA-200mV applied on OPAMP inputs)

#### Bit 12 CALON: Calibration mode enabled

- 0: Normal mode
- 1: Calibration mode (all switches opened by HW)

#### Bit 11 Reserved, must be kept at reset value.

#### Bit 10 VP_SEL: Non inverted input selection

- 0: GPIO connected to VINP
- 1: DAC connected to VINP

28 Digital filter for sigma delta modulators (DFSDM)

28.1 Introduction

Digital filter for sigma delta modulators (DFSDM) is a high-performance module dedicated to interface external ΣΔ modulators. It is featuring up to 8 external digital serial interfaces (channels) and up to 4 digital filters with flexible Sigma Delta stream digital processing options to offer up to 24-bit final ADC resolution. DFSDM also features optional parallel data stream input from internal ADC peripherals or from device memory.

An external ΣΔ modulator provides digital data stream of converted analog values from the external ΣΔ modulator analog input. This digital data stream is sent into a DFSDM input channel through a serial interface. DFSDM supports several standards to connect various ΣΔ modulator outputs: SPI interface and Manchester coded 1-wire interface (both with adjustable parameters). DFSDM module supports the connection of up to 8 multiplexed input digital serial channels which are shared with up to 4 DFSDM modules. DFSDM module also supports alternative parallel data inputs from up to 8 internal 16-bit data channels (from internal ADCs or from device memory).

DFSDM is converting an input data stream into a final digital data word which represents an analog input value on a ΣΔ modulator analog input. The conversion is based on a configurable digital process: the digital filtering and decimation of the input serial data stream.

The conversion speed and resolution are adjustable according to configurable parameters for digital processing: filter type, filter order, length of filter, integrator length. The maximum output data resolution is up to 24 bits. There are two conversion modes: single conversion mode and continuous mode. The data can be automatically stored in a system RAM buffer through DMA, thus reducing the software overhead.

A flexible timer triggering system can be used to control the start of conversion of DFSDM. This timing control is capable of triggering simultaneous conversions or inserting a programmable delay between conversions.

DFSDM features an analog watchdog function. Analog watchdog can be assigned to any of the input channel data stream or to final output data. Analog watchdog has its own digital filtering of input data stream to reach the required speed and resolution of watched data.

To detect short-circuit in control applications, there is a short-circuit detector. This block watches each input channel data stream for occurrence of stable data for a defined time duration (several 0’s or 1’s in an input data stream).

An extremes detector block watches final output data and stores maximum and minimum values from the output data values. The extremes values stored can be restarted by software.

Two power modes are supported: normal mode and stop mode.
28.2 DFSDM main features

- Up to 8 multiplexed input digital serial channels:
  - configurable SPI interface to connect various ΣΔ modulators
  - configurable Manchester coded 1 wire interface support
  - clock output for ΣΔ modulator(s)
- Alternative inputs from up to 8 internal digital parallel channels:
  - inputs with up to 16 bit resolution
  - internal sources: ADCs data or memory (CPU/DMA write) data streams
- Adjustable digital signal processing:
  - \text{Sinc}^x filter: filter order/type (1..5), oversampling ratio (up to 1..1024)
  - integrator: oversampling ratio (1..256)
- Up to 24-bit output data resolution:
  - right bit-shifter on final data (0..31 bits)
- Signed output data format
- Automatic data offset correction (offset stored in register by user)
- Continuous or single conversion
- Start-of-conversion synchronization with:
  - software trigger
  - internal timers
  - external events
  - start-of-conversion synchronously with first DFSDM filter (DFSDM_FLT0)
- Analog watchdog feature:
  - low value and high value data threshold registers
  - own configurable \text{Sinc}^x digital filter (order = 1..3, oversampling ratio = 1..32)
  - input from output data register or from one or more input digital serial channels
  - continuous monitoring independently from standard conversion
- Short-circuit detector to detect saturated analog input values (bottom and top ranges):
  - up to 8-bit counter to detect 1..256 consecutive 0’s or 1’s on input data stream
  - monitoring continuously each channel (8 serial channel transceiver outputs)
- Break generation on analog watchdog event or short-circuit detector event
- Extremes detector:
  - store minimum and maximum values of output data values
  - refreshed by software
- Pulse skipper feature to support beamforming applications (delay line like behavior)
- DMA may be used to read the conversion data
- Interrupts: end of conversion, overrun, analog watchdog, short-circuit, channel clock absence
- “regular” or “injected” conversions:
  - “regular” conversions can be requested at any time or even in continuous mode without having any impact on the timing of “injected” conversions
  - “injected” conversions for precise timing and with high conversion priority
28.3 **DFSDM implementation**

28.4.3 DFSDM reset and clocks

DFSDM on-off control

The DFSDM interface is globally enabled by setting DFSDMEN=1 in the DFSDM_CH0CFGR1 register. Once DFSDM is globally enabled, all input channels (y=0..7) and digital filters DFSDM_FLTx (x=0..3) start to work if their enable bits are set (channel enable bit CHEN in DFSDM_CHyCFGR1 and DFSDM_FLTx enable bit DFEN in DFSDM_FLTxCR1).

Digital filter x DFSDM_FLTx (x=0..3) is enabled by setting DFEN=1 in the DFSDM_FLTxCR1 register. Once DFSDM_FLTx is enabled (DFEN=1), both Sincx digital filter unit and integrator unit are reinitialized.

By clearing DFEN, any conversion which may be in progress is immediately stopped and DFSDM_FLTx is put into stop mode. All register settings remain unchanged except DFSDM_FLTxAWSR and DFSDM_FLTxISR (which are reset).

Channel y (y=0..7) is enabled by setting CHEN=1 in the DFSDM_CHyCFGR1 register. Once the channel is enabled, it receives serial data from the external ΣΔ modulator or parallel internal data sources (ADCs or CPU/DMA wire from memory).

DFSDM must be globally disabled (by DFSDMEN=0 in DFSDM_CH0CFGR1) before stopping the system clock to enter in the STOP mode of the device.

DFSDM clocks

The internal DFSDM clock \( f_{\text{DFSDMCLK}} \), which is used to drive the channel transceivers, digital processing blocks (digital filter, integrator) and next additional blocks (analog watchdog, short-circuit detector, extremes detector, control block) is generated by the RCC block and is derived from the system clock SYSCLK or peripheral clock PCLK2 (see Section 6.4.32: Peripherals independent clock configuration register (RCC_CCIPR2)). The DFSDM clock is automatically stopped in stop mode (if DFEN = 0 for all DFSDM_FLTx, \( x=0..3 \)).

The DFSDM serial channel transceivers can receive an external serial clock to sample an external serial data stream. The internal DFSDM clock must be at least 4 times faster than the external serial clock if standard SPI coding is used, and 6 times faster than the external serial clock if Manchester coding is used.

DFSDM can provide one external output clock signal to drive external \( \Sigma \Delta \) modulator(s) clock input(s). It is provided on CKOUT pin. This output clock signal must be in the range specified in given device datasheet and is derived from DFSDM clock or from audio clock (see CKOUTSRC bit in DFSDM_CH0CFGR1 register) by programmable divider in the range 2 - 256 (CKOUTDIV in DFSDM_CH0CFGR1 register). Audio clock source is SAI1 clock selected by SAI1SEL[1:0] field in RCC configuration (see Section 6.4.32: Peripherals independent clock configuration register (RCC_CCIPR2)).

28.4.4 Serial channel transceivers

There are 8 multiplexed serial data channels which can be selected for conversion by each filter or Analog watchdog or Short-circuit detector. Those serial transceivers receive data stream from external \( \Sigma \Delta \) modulator. Data stream can be sent in SPI format or Manchester coded format (see SITP[1:0] bits in DFSDM_CHyCFGR1 register).

The channel is enabled for operation by setting CHEN=1 in DFSDM_CHyCFGR1 register.

Channel inputs selection

Serial inputs (data and clock signals) from DATINy and CKINy pins can be redirected from the following channel pins. This serial input channel redirection is set by CHINSEL bit in DFSDM_CHyCFGR1 register.

Channel redirection can be used to collect audio data from PDM (pulse density modulation) stereo microphone type. PDM stereo microphone has one data and one clock signal. Data signal provides information for both left and right audio channel (rising clock edge samples for left channel and falling clock edge samples for right channel).
Configuration of serial channels for PDM microphone input:

- PDM microphone signals (data, clock) will be connected to DFSDM input serial channel y (DATINy, CKOUT) pins.
- Channel y will be configured: CHINSEL = 0 (input from given channel pins: DATINy, CKINy).
- Channel (y-1) (modulo 8) will be configured: CHINSEL = 1 (input from the following channel ((y-1)+1) pins: DATINy, CKINy).
- Channel y: SITP[1:0] = 0 (rising edge to strobe data) => left audio channel on channel y.
- Channel (y-1): SITP[1:0] = 1 (falling edge to strobe data) => right audio channel on channel y-1.
- Two DFSDM filters will be assigned to channel y and channel (y-1) (to filter left and right channels from PDM microphone).

Figure 191. Input channel pins redirection
Output clock generation

A clock signal can be provided on CKOUT pin to drive external ΣΔ modulator clock inputs. The frequency of this CKOUT signal is derived from DFSDM clock or from audio clock (see CKOUTSRC bit in DFSDM_CH0CFGR1 register) divided by a prescaler (see CKOUTDIV bits in DFSDM_CH0CFGR1 register). If the output clock is stopped, then CKOUT signal is set to low state (output clock can be stopped by CKOUTDIV=0 in DFSDM_CHyCFGR1 register or by DFSDMEN=0 in DFSDM_CH0CFGR1 register). The output clock stopping is performed:

- 4 system clocks after DFSDMEN is cleared (if CKOUTSRC=0)
- 1 system clock and 3 audio clocks after DFSDMEN is cleared (if CKOUTSRC=1)

Before changing CKOUTSRC the software has to wait for CKOUT being stopped to avoid glitch on CKOUT pin. The output clock signal frequency must be in the range 0 - 20 MHz.

SPI data input format operation

In SPI format, the data stream is sent in serial format through data and clock signals. Data signal is always provided from DATIny pin. A clock signal can be provided externally from CKIny pin or internally from a signal derived from the CKOUT signal source.

In case of external clock source selection (SPICKSEL[1:0]=0) data signal (on DATIny pin) is sampled on rising or falling clock edge (of CKIny pin) according SITP[1:0] bits setting (in DFSDM_CHyCFGR1 register).

Internal clock sources - see SPICKSEL[1:0] in DFSDM_CHyCFGR1 register:

- CKOUT signal:
  - For connection to external ΣΔ modulator which uses directly its clock input (from CKOUT) to generate its output serial communication clock.
  - Sampling point: on rising/falling edge according SITP[1:0] setting.

- CKOUT/2 signal (generated on CKOUT rising edge):
  - For connection to external ΣΔ modulator which divides its clock input (from CKOUT) by 2 to generate its output serial communication clock (and this output clock change is active on each clock input rising edge).
  - Sampling point: on each second CKOUT falling edge.

- CKOUT/2 signal (generated on CKOUT falling edge):
  - For connection to external ΣΔ modulator which divides its clock input (from CKOUT) by 2 to generate its output serial communication clock (and this output clock change is active on each clock input falling edge).
  - Sampling point: on each second CKOUT rising edge.

Note: An internal clock source can only be used when the external ΣΔ modulator uses CKOUT signal as a clock input (to have synchronous clock and data operation).

Internal clock source usage can save CKIny pin connection (CKIny pins can be used for other purpose).

The clock source signal frequency must be in the range 0 - 20 MHz for SPI coding and less than fDFSDMCLK/4.

Manchester coded data input format operation

In Manchester coded format, the data stream is sent in serial format through DATIny pin only. Decoded data and clock signal are recovered from serial stream after Manchester
decoding. There are two possible settings of Manchester codings (see SITP[1:0] bits in DFSDM_CHyCFGR1 register):

- signal rising edge = log 0; signal falling edge = log 1
- signal rising edge = log 1; signal falling edge = log 0

The recovered clock signal frequency for Manchester coding must be in the range 0 - 10 MHz and less than f_{DFSDMCLK}/6.

To correctly receive Manchester coded data, the CKOUTDIV divider (in DFSDM_CH0CFGR1 register) must be set with respect to expected Manchester data rate according formula:

\[(\frac{(\text{CKOUTDIV} + 1) \times T_{\text{SYSCLK}}}{T_{\text{Manchester clock}}} < (2 \times \text{CKOUTDIV} \times T_{\text{SYSCLK}})\]

  - 0 0 1 1 0
Clock absence detection

Channels serial clock inputs can be checked for clock absence/presence to ensure the correct operation of conversion and error reporting. Clock absence detection can be enabled or disabled on each input channel \( y \) by bit \( 
CKABEN \) in DFSDM_CHyCFGR1 register. If enabled, then this clock absence detection is performed continuously on a given channel. A clock absence flag is set \( (CKABF[y] = 1) \) and an interrupt can be invoked (if \( CKABIE=1 \)) in case of an input clock error (see \( CKABF[7:0] \) in DFSDM_FLT0ISR register and \( CKABEN \) in DFSDM_CHyCFGR1). After a clock absence flag clearing (by CLRCKABF in DFSDM_FLT0ICR register), the clock absence flag is refreshed. Clock absence status bit \( CKABF[y] \) is set also by hardware when corresponding channel \( y \) is disabled (if \( CHEN[y] = 0 \) then \( CKABF[y] \) is held in set state).

When a clock absence event has occurred, the data conversion (and/or analog watchdog and short-circuit detector) provides incorrect data. The user should manage this event and discard given data while a clock absence is reported.

The clock absence feature is available only when the system clock is used for the CKOUT signal (\( CKOUTSRC=0 \) in DFSDM_CH0CFGR1 register).

When the transceiver is not yet synchronized, the clock absence flag is set and cannot be cleared by CLRCKABF[y] bit (in DFSDM_FLT0ICR register). The software sequence concerning clock absence detection feature should be:

- Enable given channel by \( CHEN = 1 \)
- Try to clear the clock absence flag (by CLRCKABF = 1) until the clock absence flag is really cleared (\( CKABF = 0 \)). At this time, the transceiver is synchronized (signal clock is valid) and is able to receive data.
- Enable the clock absence feature \( CKABEN = 1 \) and the associated interrupt \( CKABIE = 1 \) to detect if the SPI clock is lost or Manchester data edges are missing.

If SPI data format is used, then the clock absence detection is based on the comparison of an external input clock with an output clock generation (CKOUT signal). The external input clock signal into the input channel must be changed at least once per 8 signal periods of CKOUT signal (which is controlled by CKOUTDIV field in DFSDM_CH0CFGR1 register).

Figure 193. Clock absence timing diagram for SPI

If Manchester data format is used, then the clock absence means that the clock recovery is unable to perform from Manchester coded signal. For a correct clock recovery, it is first necessary to receive data with 1 to 0 or 0 to 1 transition (see Figure 195 for Manchester synchronization).
The detection of a clock absence in Manchester coding (after a first successful synchronization) is based on changes comparison of coded serial data input signal with output clock generation (CKOUT signal). There must be a voltage level change on DATINy pin during 2 periods of CKOUT signal (which is controlled by CKOUTDIV bits in DFSDM.CH0CFGR1 register). This condition also defines the minimum data rate to be able to correctly recover the Manchester coded data and clock signals.

The maximum data rate of Manchester coded data must be less than the CKOUT signal.

So to correctly receive Manchester coded data, the CKOUTDIV divider must be set according the formula:

\[
((\text{CKOUTDIV} + 1) \times T_{\text{SYSCLK}}) < T_{\text{Manchester clock}} < (2 \times \text{CKOUTDIV} \times T_{\text{SYSCLK}})
\]

A clock absence flag is set (CKABF[y] = 1) and an interrupt can be invoked (if CKABIE=1) in case of an input clock recovery error (see CKABF[7:0] in DFSDMFLT0ISR register and CKABEN in DFSDM.CHyCFGR1). After a clock absence flag clearing (by CLRCKABF in DFSDMFLT0ICR register), the clock absence flag is refreshed.

**Figure 194. Clock absence timing diagram for Manchester coding**
Manchester/SPI code synchronization

The Manchester coded stream must be synchronized the first time after enabling the channel (CHEN=1 in DFSDM_CHyCFGR1 register). The synchronization ends when a data transition from 0 to 1 or from 1 to 0 (to be able to detect valid data edge) is received. The end of the synchronization can be checked by polling CKABF[y]=0 for a given channel after it has been cleared by CLRCKABF[y] in DFSDM_FLT0ICR, following the software sequence detailed hereafter:

CKABF[y] flag is cleared by setting CLRCKABF[y] bit. If channel y is not yet synchronized the hardware immediately set the CKABF[y] flag. Software is then reading back the CKABF[y] flag and if it is set then perform again clearing of this flag by setting CLRCKABF[y] bit. This software sequence (polling of CKABF[y] flag) continues until CKABF[y] flag is set (signalizing that Manchester stream is synchronized). To be able to synchronize/receive Manchester coded data the CKOUTDIV divider (in DFSDM_CH0CFGR1 register) must be set with respect to expected Manchester data rate according the formula below.

\[
(((\text{CKOUTDIV} + 1) \times T_{\text{SYSCLK}}) < T_{\text{Manchester clock}} < (2 \times \text{CKOUTDIV} \times T_{\text{SYSCLK}})
\]

SPI coded stream is synchronized after first detection of clock input signal (valid rising/falling edge).

**Note:** *When the transceiver is not yet synchronized, the clock absence flag is set and cannot be cleared by CLRCKABF[y] bit (in DFSDM_FLT0ICR register).*
External serial clock frequency measurement

The measuring of a channel serial clock input frequency provides a real data rate from an external ΣΔ modulator, which is important for application purposes.

An external serial clock input frequency can be measured by a timer counting DFSDM clocks \( f_{DFSDMCLK} \) during one conversion duration. The counting starts at the first input data clock after a conversion trigger (regular or injected) and finishes by last input data clock before conversion ends (end of conversion flag is set). Each conversion duration (time between first serial sample and last serial sample) is updated in counter CNVCNT[27:0] in register DFSDM_FLTxCNVTIMR when the conversion finishes (JEOCF=1 or REOCF=1). The user can then compute the data rate according to the digital filter settings (FORD, FOSR, IOSR, FAST). The external serial frequency measurement is stopped only if the filter is bypassed (FOSR=0, only integrator is active, CNVCNT[27:0]=0 in DFSDM_FLTxCNVTIMR register).

In case of parallel data input (Section 28.4.6: Parallel data inputs) the measured frequency is the average input data rate during one conversion.
**Note:** When conversion is interrupted (e.g. by disabling/enabling the selected channel) the interruption time is also counted in CNVCNT[27:0]. Therefore it is recommended to not interrupt the conversion for correct conversion duration result.

Conversion times:

**injected conversion or regular conversion with FAST = 0 (or first conversion if FAST=1):**

for Sinc\(^x\) filters (x=1..5):

\[ t = \frac{\text{CNVCNT}/f_{DFSDMCLK}}{F_{OSR} \times (I_{OSR} - 1 + F_{ORD})} \]

for FastSinc filter:

\[ t = \frac{\text{CNVCNT}/f_{DFSDMCLK}}{F_{OSR} \times (I_{OSR} - 1 + 4) + 2} \]

**regular conversion with FAST = 1 (except first conversion):**

for Sinc\(^x\) and FastSinc filters:

\[ t = \frac{\text{CNVCNT}/f_{DFSDMCLK}}{F_{OSR} \times I_{OSR}} \]

in case if \( F_{OSR} = F_{OSR}[9:0] + 1 = 1 \) (filter bypassed, active only integrator):

\[ t = \frac{I_{OSR}}{f_{CKIN}} \]

where:

- \( f_{CKIN} \) is the channel input clock frequency (on given channel CKINy pin) or input data rate (in case of parallel data input)
- \( F_{OSR} \) is the filter oversampling ratio: \( F_{OSR} = F_{OSR}[9:0] + 1 \) (see DFSDM_FLTxFCR register)
- \( I_{OSR} \) is the integrator oversampling ratio: \( I_{OSR} = I_{OSR}[7:0] + 1 \) (see DFSDM_FLTxFCR register)
- \( F_{ORD} \) is the filter order: \( F_{ORD} = F_{ORD}[2:0] \) (see DFSDM_FLTxFCR register)

**Channel offset setting**

Each channel has its own offset setting (in register) which is finally subtracted from each conversion result (injected or regular) from a given channel. Offset correction is performed after the data right bit shift. The offset is stored as a 24-bit signed value in OFFSET[23:0] field in DFSDM_CHyCFGR2 register.

**Data right bit shift**

To have the result aligned to a 24-bit value, each channel defines a number of right bit shifts which will be applied on each conversion result (injected or regular) from a given channel. The data bit shift number is stored in DTRBS[4:0] bits in DFSDM_CHyCFGR2 register.

The right bit-shift is rounding the result to nearest integer value. The sign of shifted result is maintained, in order to have valid 24-bit signed format of result data.

**Pulses skipper**

Purpose of the pulses skipper is to implement delay line like behavior for given input channel(s). Given number of samples from input serial data stream (serial stream only) can be discarded before they enter into the filter. This data discarding is performed by skipping given number of sampling input clock pulses (given serial data samples are then not sampled by filter). The sampling clock is gated by pulses skipper function for given number of clock pulses. When given clock pulses are skipped then the filtering continues for following input data. With comparison to non skipped data stream this operation causes that
the final output sample (and next samples) from filter will be calculated from later input data. This final sample then looks a bit in forward - because it is calculated from newer input samples than the “non-skipped” sample. The final “skipped sample” is converted later because the skipped input data samples must be replaced by followed input data samples. The final data buffers behavior (skipped and non-skipped output data buffers comparison) looks like the non-skipped data stream is a bit delayed - both data buffers will be phase shifted.

Number of clock pulses to be skipped should be written into PLSSKP[5:0] field in DFSDM_CHyDLYR register. Once PLSSKP[5:0] field is written the execution of pulses skipping is started on given channel. PLSSKP[5:0] field can be read in order to check the progress of pulses skipper. When PLSSKP[5:0]=0 means that pulses skipping has been executed.

Up to 63 clock pulses can be skip with a single write operation into PLSSKP[5:0]. If more pulses need to be skipped, then user has to write several times into the PLSSKP[5:0] field. The application software should handle cumulative skipped clock number per each filter.

28.4.5 Configuring the input serial interface

The following parameters must be configured for the input serial interface:

- **Output clock predivider.** There is a programmable predivider to generate the output clock from DFSDM clock (2 - 256). It is defined by CKOUTDIV[7:0] bits in DFSDM_CH0CFGR1 register.

- **Serial interface type and input clock phase.** Selection of SPI or Manchester coding and sampling edge of input clock. It is defined by SITP [1:0] bits in DFSDM_CHyCFGR1 register.

- **Input clock source.** External source from CKINy pin or internal from CKOUT pin. It is defined by SPICKSEL[1:0] field in DFSDM_CHyCFGR1 register.

- **Final data right bit-shift.** Defines the final data right bit shift to have the result aligned to a 24-bit value. It is defined by DTRBS[4:0] in DFSDM_CHyCFGR2 register.

- **Channel offset per channel.** Defines the analog offset of a given serial channel (offset of connected external ΣΔ modulator). It is defined by OFFSET[23:0] bits in DFSDM_CHyCFGR2 register.

- **short-circuit detector and clock absence per channel enable.** To enable or disable the short-circuit detector (by SCDEN bit) and the clock absence monitoring (by CKABEN bit) on a given serial channel in register DFSDM_CHyCFGR1.

- **Analog watchdog filter and short-circuit detector threshold settings.** To configure channel analog watchdog filter parameters and channel short-circuit detector parameters. Configurations are defined in DFSDM_CHyAWSCDR register.

28.4.6 Parallel data inputs

Each input channel provides a register for 16-bit parallel data input (besides serial data input). Each 16-bit parallel input can be sourced from internal data sources only:

- internal ADC results
- direct CPU/DMA writing.

The selection for using serial or parallel data input for a given channel is done by field DATMPX[1:0] of DFSDM_CHyCFGR1 register. In DATMPX[1:0] is also defined the parallel data source: internal ADC or direct write by CPU/DMA.
Each channel contains a 32-bit data input register DFSDM_CHyDATINR in which it can be written a 16-bit data. Data are in 16-bit signed format. Those data can be used as input to the digital filter which is accepting 16-bit parallel data.

If serial data input is selected (DATMPX[1:0] = 0), the DFSDM_CHyDATINR register is write protected.

**Input from internal ADC**

In case of ADC data parallel input (DATMPX[1:0]=1) the ADC[y+1] result is assigned to channel y input (ADC1 is filling DFSDM_CHDATIN0R register, ADC2 is filling DFSDM_CHDATIN1R register, ... , ADC8 is filling DFSDM_CHDATIN7R register). End of conversion event from ADC[y+1] causes update of channel y data (parallel data from ADC[y+1] are put as next sample to digital filter). Data from ADC[y+1] is written into DFSDM_CHyDATINR register (field INDAT0[15:0]) when end of conversion event occurred.

The setting of data packing mode (DATPACK[1:0] in the DFSDM_CHyCFGR1 register) has no effect in case of ADC data input.

**Input from memory (direct CPU/DMA write)**

The direct data write into DFSDM_CHyDATINR register by CPU or DMA (DATMPX[1:0]=2) can be used as data input in order to process digital data streams from memory or peripherals.

Data can be written by CPU or DMA into DFSDM_CHyDATINR register:

1. **CPU data write:**
   - Input data are written directly by CPU into DFSDM_CHyDATINR register.

2. **DMA data write:**
   - The DMA should be configured in memory-to-memory transfer mode to transfer data from memory buffer into DFSDM_CHyDATINR register. The destination memory address is the address of DFSDM_CHyDATINR register. Data are transferred at DMA transfer speed from memory to DFSDM parallel input.
   - This DMA transfer is different from DMA used to read DFSDM conversion results. Both DMA can be used at the same time - first DMA (configured as memory-to-memory transfer) for input data writings and second DMA (configured as peripheral-to-memory transfer) for data results reading.

The accesses to DFSDM_CHyDATINR can be either 16-bit or 32-bit wide, allowing to load respectively one or two samples in one write operation. 32-bit input data register (DFSDM_CHyDATINR) can be filled with one or two 16-bit data samples, depending on the data packing operation mode defined in field DATPACK[1:0] of DFSDM_CHyCFGR1 register:

1. **Standard mode (DATPACK[1:0]=0):**
   - Only one sample is stored in field INDAT0[15:0] of DFSDM_CHyDATINR register which is used as input data for channel y. The upper 16 bits (INDAT1[15:0]) are ignored and write protected. The digital filter must perform one input sampling (from INDAT0[15:0]) to empty data register after it has been filled by CPU/DMA. This mode is used together with 16-bit CPU/DMA access to DFSDM_CHyDATINR register to load one sample per write operation.

2. **Interleaved mode (DATPACK[1:0]=1):**
   - DFSDM_CHyDATINR register is used as a two sample buffer. The first sample is stored in INDAT0[15:0] and the second sample is stored in INDAT1[15:0]. The digital
filter must perform two input samplings from channel y to empty DFSDM_CHyDATINR register. This mode is used together with 32-bit CPU/DMA access to DFSDM_CHyDATINR register to load two samples per write operation.

3. **Dual mode (DATPACK[1:0]=2):**

Two samples are written into DFSDM_CHyDATINR register. The data INDAT0[15:0] is for channel y, the data in INDAT1[15:0] is for channel y+1. The data in INDAT1[15:0] is automatically copied INDAT0[15:0] of the following (y+1) channel data register DFSDM_CH[y+1]DATINR). The digital filters must perform two samplings - one from channel y and one from channel (y+1) - in order to empty DFSDM_CHyDATINR registers.

Dual mode setting (DATPACK[1:0]=2) is available only on even channel numbers (y = 0, 2, 4, 6). If odd channel (y = 1, 3, 5, 7) is set to Dual mode then both INDAT0[15:0] and INDAT1[15:0] parts are write protected for this channel. If even channel is set to Dual mode then the following odd channel must be set into Standard mode (DATPACK[1:0]=0) for correct cooperation with even channels.

See [Figure 196](#) for DFSDM_CHyDATINR registers data modes and assignments of data samples to channels.

The write into DFSDM_CHyDATINR register to load one or two samples must be performed after the selected input channel (channel y) is enabled for data collection (starting conversion for channel y). Otherwise written data are lost for next processing.

For example: for single conversion and interleaved mode, do not start writing pair of data samples into DFSDM_CHyDATINR before the single conversion is started (any data present in the DFSDM_CHyDATINR before starting a conversion is discarded).

#### 28.4.7 Channel selection

There are 8 multiplexed channels which can be selected for conversion using the injected channel group and/or using the regular channel.

The **injected channel group** is a selection of any or all of the 8 channels. JCHG[7:0] in the DFSDM_FLTxJCHGR register selects the channels of the injected group, where JCHG[y]=1 means that channel y is selected.
Injected conversions can operate in scan mode (JSCAN=1) or single mode (JSCAN=0). In scan mode, each of the selected channels is converted, one after another. The lowest channel (channel 0, if selected) is converted first, followed immediately by the next higher channel until all the channels selected by JCHG[7:0] have been converted. In single mode (JSCAN=0), only one channel from the selected channels is converted, and the channel selection is moved to the next channel. Writing to JCHG[7:0] if JSCAN=0 resets the channel selection to the lowest selected channel.

Injected conversions can be launched by software or by a trigger. They are never interrupted by regular conversions.

The regular channel is a selection of just one of the 8 channels. RCH[2:0] in the DFSDM_FLTxCr1 register indicates the selected channel.

Regular conversions can be launched only by software (not by a trigger). A sequence of continuous regular conversions is temporarily interrupted when an injected conversion is requested.

Performing a conversion on a disabled channel (CHEN=0 in DFSDM_ChxCFGR1 register) causes that the conversion will never end - because no input data is provided (with no clock signal). In this case, it is necessary to enable a given channel (CHEN=1 in DFSDM_ChxCFGR1 register) or to stop the conversion by DFEN=0 in DFSDM_FLTxCr1 register.

28.4.8 Digital filter configuration

DFSDM contains a Sincx type digital filter implementation. This Sincx filter performs an input digital data stream filtering, which results in decreasing the output data rate (decimation) and increasing the output data resolution. The Sincx digital filter is configurable in order to reach the required output data rates and required output data resolution. The configurable parameters are:

- Filter order/type: (see FORD[2:0] bits in DFSDM_FLTxFCR register):
  - FastSinc
  - Sinc
  - Sinc
  - Sinc
  - Sinc
  - Sinc
- Filter oversampling/decimation ratio (see FOSR[9:0] bits in DFSDM_FLTxFCR register):
  - FOSR = 1-1024 - for FastSinc filter and Sinc<sup>x</sup> filter x = FORD = 1..3
  - FOSR = 1-215 - for Sinc<sup>x</sup> filter x = FORD = 4
  - FOSR = 1-73 - for Sinc<sup>x</sup> filter x = FORD = 5

The filter has the following transfer function (impulse response in H domain):

- Sinc<sup>x</sup> filter type: 
  \[ H(z) = \left( \frac{1 - z^{-FOSR}}{1 - z^{-1}} \right)^x \]

- FastSinc filter type: 
  \[ H(z) = \left( \frac{1 - z^{-FOSR}}{1 - z^{-1}} \right)^2 \cdot (1 + z^{-2 \cdot FOSR}) \]
Figure 197. Example: Sinc\(^3\) filter response

For more information about Sinc filter type properties and usage, it is recommended to study the theory about digital filters (more resources can be downloaded from internet).

28.4.9 Integrator unit

The integrator performs additional decimation and a resolution increase of data coming from the digital filter. The integrator simply performs the sum of data from a digital filter for a given number of data samples from a filter.

The integrator oversampling ratio parameter defines how many data counts will be summed to one data output from the integrator. IOSR can be set in the range 1-256 (see IOSR[7:0] bits description in DFSDM_FLTxFCR register).
The analog watchdog purpose is to trigger an external signal (break or interrupt) when an analog signal reaches or crosses given maximum and minimum threshold values. An interrupt/event/break generation can then be invoked.

Each analog watchdog will supervise serial data receiver outputs (after the analog watchdog filter on each channel) or data output register (current injected or regular conversion result) according to AWFSEL bit setting (in DFSDM_FLTxCR1 register). The input channels to be monitored or not by the analog watchdog x will be selected by AWDCH[7:0] in DFSDM_FLTxCR2 register.

Analog watchdog conversions on input channels are independent from standard conversions. In this case, the analog watchdog uses its own filters and signal processing on each input channel independently from the main injected or regular conversions. Analog watchdog conversions are performed in a continuous mode on the selected input channels in order to watch channels also when main injected or regular conversions are paused (RCIP = 0, JCIP = 0).

There are high and low threshold registers which are compared with given data values (set by AWHT[23:0] bits in DFSDM_FLTxAWHTR register and by AWLT[23:0] bits in DFSDM_FLTxAWLTR register).

#### 28.4.10 Analog watchdog

The analog watchdog purpose is to trigger an external signal (break or interrupt) when an analog signal reaches or crosses given maximum and minimum threshold values. An interrupt/event/break generation can then be invoked.

Each analog watchdog will supervise serial data receiver outputs (after the analog watchdog filter on each channel) or data output register (current injected or regular conversion result) according to AWFSEL bit setting (in DFSDM_FLTxCR1 register). The input channels to be monitored or not by the analog watchdog x will be selected by AWDCH[7:0] in DFSDM_FLTxCR2 register.

Analog watchdog conversions on input channels are independent from standard conversions. In this case, the analog watchdog uses its own filters and signal processing on each input channel independently from the main injected or regular conversions. Analog watchdog conversions are performed in a continuous mode on the selected input channels in order to watch channels also when main injected or regular conversions are paused (RCIP = 0, JCIP = 0).

There are high and low threshold registers which are compared with given data values (set by AWHT[23:0] bits in DFSDM_FLTxAWHTR register and by AWLT[23:0] bits in DFSDM_FLTxAWLTR register).
There are 2 options for comparing the threshold registers with the data values

- Option 1: in this case, the input data are taken from final output data register (AWFSEL=0). This option is characterized by:
  - high input data resolution (up to 24-bits)
  - slow response time - inappropriate for fast response applications like overcurrent detection
  - for the comparison the final data are taken after bit shifting and offset data correction
  - final data are available only after main regular or injected conversions are performed
  - can be used in case of parallel input data source (DATMPX[1:0] ≠ 0 in DFSDM_CHANCFG register)

- Option 2: in this case, the input data are taken from any serial data receivers output (AWFSEL=1). This option is characterized by:
  - input serial data are processed by dedicated analog watchdog Sinc² channel filters with configurable oversampling ratio (1..32) and filter order (1..3) (see AWFOSR[4:0] and AWFORD[1:0] bits setting in DFSDM_CHANAWSCDR register)
  - lower resolution (up to 16-bit)
  - fast response time - appropriate for applications which require a fast response like overcurrent/overvoltage detection
  - data are available in continuous mode independently from main regular or injected conversions activity

In case of input channels monitoring (AWFSEL=1), the data for comparison to threshold is taken from channels selected by AWDCH[7:0] field (DFSDM_FLTXCR2 register). Each of the selected channels filter result is compared to one threshold value pair (AWHT[23:0] / AWLT[23:0]). In this case, only higher 16 bits (AWHT[23:8] / AWLT[23:8]) define the 16-bit threshold compared with the analog watchdog filter output because data coming from the analog watchdog filter is up to a 16-bit resolution. Bits AWHT[7:0] / AWLT[7:0] are not taken into comparison in this case (AWFSEL=1).

Parameters of the analog watchdog filter configuration for each input channel are set in DFSDM_CHANAWSCDR register (filter order AWFORD[1:0] and filter oversampling ratio AWFOSR[4:0]).

Each input channel has its own comparator which compares the analog watchdog data (from analog watchdog filter) with analog watchdog threshold values (AWHT/AWLT). When several channels are selected (field AWDCCH[7:0] field of DFSDM_FLTXCR2 register), several comparison requests may be received simultaneously. In this case, the channel request with the lowest number is managed first and then continuing to higher selected channels. For each channel, the result can be recorded in a separate flag (fields AWHTF[7:0], AWLTF[7:0] of DFSDM_FLTXAWSR register). Each channel request is executed in 8 DFSDM clock cycles. So, the bandwidth from each channel is limited to 8 DFSDM clock cycles (if AWDCCH[7:0] = 0xFF). Because the maximum input channel sampling clock frequency is the DFSDM clock frequency divided by 4, the configuration AWFOSR = 0 (analog watchdog filter is bypassed) cannot be used for analog watchdog feature at this input clock speed. Therefore user must properly configure the number of watched channels and analog watchdog filter parameters with respect to input sampling clock speed and DFSDM frequency.
Analog watchdog filter data for given channel y is available for reading by firmware on field WDATA[15:0] in DFSDM_CHyWDATR register. That analog watchdog filter data is converted continuously (if CHEN=1 in DFSDM_CHyCFGR1 register) with the data rate given by the analog watchdog filter setting and the channel input clock frequency.

The analog watchdog filter conversion works like a regular Fast Continuous Conversion without the integrator. The number of serial samples needed for one result from analog watchdog filter output (at channel input clock frequency f_{CKIN}):

first conversion:
   for Sinc^x filters (x=1..5): number of samples = \[F_{OSR} \times F_{ORD} + F_{ORD} + 1\]
   for FastSinc filter: number of samples = \[F_{OSR} \times 4 + 2 + 1\]

next conversions:
   for Sinc^x and FastSinc filters: number of samples = \[F_{OSR} \times I_{OSR}\]

where:

F_{OSR} ....... filter oversampling ratio: F_{OSR} = AWFOSR[4:0]+1 (see DFSDM_CHyAWSCDR register)
F_{ORD} ....... the filter order: F_{ORD} = AWFORD[1:0] (see DFSDM_CHyAWSCDR register)

In case of output data register monitoring (AWFSEL=0), the comparison is done after a right bit shift and an offset correction of final data (see OFFSET[23:0] and DTRBS[4:0] fields in DFSDM_CHyCFGR2 register). A comparison is performed after each injected or regular end of conversion for the channels selected by AWDCH[7:0] field (in DFSDM_FLTxCICR register).

The status of an analog watchdog event is signalized in DFSDM_FLTxAWSR register where a given event is latched. AWHTF[y]=1 flag signalizes crossing AWHT[23:0] value on channel y. AWLTF[y]=1 flag signalizes crossing AWLT[23:0] value on channel y. Latched events in DFSDM_FLTxAWSR register are cleared by writing '1' into the corresponding clearing bit CLRAWHTF[y] or CLRAWLTF[y] in DFSDM_FLTxAWCFR register.

The global status of an analog watchdog is signalized by the AWDF flag bit in DFSDM_FLTxCISR register (it is used for the fast detection of an interrupt source). AWDF=1 signals that at least one watchdog occurred (AWHTF[y]=1 or AWLTF[y]=1 for at least one channel). AWDF bit is cleared when all AWHTF[7:0] and AWLTF[7:0] are cleared.

An analog watchdog event can be assigned to break output signal. There are four break outputs to be assigned to a high or low threshold crossing event (dfsdm_break[3:0]). The break signal assignment to a given analog watchdog event is done by BKAWH[3:0] and BKAWL[3:0] fields in DFSDM_FLTxAWHTR and DFSDM_FLTxAWLTR register.

28.4.11 Short-circuit detector

The purpose of a short-circuit detector is to signalize with a very fast response time if an analog signal reached saturated values (out of full scale ranges) and remained on this value given time. This behavior can detect short-circuit or open circuit errors (e.g. overcurrent or overvoltage). An interrupt/event/break generation can be invoked.

Input data into a short-circuit detector is taken from channel transceiver outputs.

There is an upcounting counter on each input channel which is counting consecutive 0’s or 1’s on serial data receiver outputs. A counter is restarted if there is a change in the data stream received - 1 to 0 or 0 to 1 change of data signal. If this counter reaches a short-circuit threshold register value (SCDT[7:0] bits in DFSDM_CHyAWSCDR register), then a short-
circuit event is invoked. Each input channel has its short-circuit detector. Any channel can be selected to be continuously monitored by setting the SCDEN bit (in DFSDM_CHyCFGR1 register) and it has its own short-circuit detector settings (threshold value in SCDT[7:0] bits, status bit SCDF[7:0], status clearing bits CLRSCDF[7:0]). Status flag SCDF[y] is cleared also by hardware when corresponding channel y is disabled (CHEN[y] = 0).

On each channel, a short-circuit detector event can be assigned to break output signal dfsdm_break[3:0]. There are four break outputs to be assigned to a short-circuit detector event. The break signal assignment to a given channel short-circuit detector event is done by BKSCD[3:0] field in DFSDM_CHyAWSMCR register.

Short circuit detector cannot be used in case of parallel input data channel selection (DATMPX[1:0] ≠ 0 in DFSDM_CHyCFGR1 register).

Four break outputs are totally available (shared with the analog watchdog function).

28.4.12 Extreme detector

The purpose of an extremes detector is to collect the minimum and maximum values of final output data words (peak to peak values).

If the output data word is higher than the value stored in the extremes detector maximum register (EXMAX[23:0] bits in DFSDM_FLTxEXMAX register), then this register is updated with the current output data word value and the channel from which the data is stored is in EXMAXCH[2:0] bits (in DFSDM_FLTxEXMAX register).

If the output data word is lower than the value stored in the extremes detector minimum register (EXMIN[23:0] bits in DFSDM_FLTxEXMIN register), then this register is updated with the current output data word value and the channel from which the data is stored is in EXMINCH[2:0] bits (in DFSDM_FLTxEXMIN register).

The minimum and maximum register values can be refreshed by software (by reading given DFSDM_FLTxEXMAX or DFSDM_FLTxEXMIN register). After refresh, the extremes detector minimum data register DFSDM_FLTxEXMIN is filled with 0x7FFFFFFF (maximum positive value) and the extremes detector maximum register DFSDM_FLTxEXMAX is filled with 0x80000000 (minimum negative value).

The extremes detector performs a comparison after a right bit shift and an offset data correction. For each extremes detector, the input channels to be considered into computing the extremes value are selected in EXCH[7:0] bits (in DFSDM_FLTxCR2 register).

28.4.13 Data unit block

The data unit block is the last block of the whole processing path: External ΣΔ modulators - Serial transceivers - Sinc filter - Integrator - Data unit block.

The output data rate depends on the serial data stream rate, and filter and integrator settings. The maximum output data rate is:

\[
\text{Datarate[samples/s]} = \frac{f_{\text{CKIN}}}{F_{\text{OSR}} \cdot (I_{\text{OSR}} - 1 + F_{\text{ORD}}) + (F_{\text{ORD}} + 1)} \quad \text{...FAST} = 0, \text{ Sincx filter}
\]

\[
\text{Datarate[samples/s]} = \frac{f_{\text{CKIN}}}{F_{\text{OSR}} \cdot (I_{\text{OSR}} - 1 + 4) + (2 + 1)} \quad \text{...FAST} = 0, \text{ FastSinc filter}
\]
Digital filter for sigma delta modulators (DFSDM)

or

\[
\text{Datarate [samples/s]} = \frac{f_{\text{CKIN}}}{F_{\text{OSR}} \cdot I_{\text{OSR}}} \quad \text{...FAST} = 1
\]

Maximum output data rate in case of parallel data input:

\[
\text{Datarate [samples/s]} = \frac{f_{\text{DATAIN RATE}}}{F_{\text{OSR}} \cdot (I_{\text{OSR}} - 1 + F_{\text{ORD}}) + (F_{\text{ORD}} + 1)} \quad \text{...FAST} = 0, \text{ Sincx filter}
\]

or

\[
\text{Datarate [samples/s]} = \frac{f_{\text{DATAIN RATE}}}{F_{\text{OSR}} \cdot (I_{\text{OSR}} - 1 + 4) + (2 + 1)} \quad \text{...FAST} = 0, \text{ FastSinc filter}
\]

or

\[
\text{Datarate [samples/s]} = \frac{f_{\text{DATAIN RATE}}}{F_{\text{OSR}} \cdot I_{\text{OSR}}} \quad \text{...FAST=1 or any filter bypass case (F_{\text{OSR}} = 1)}
\]

where: \( f_{\text{DATAIN RATE}} \) -- input data rate from ADC or from CPU/DMA

The right bit-shift of final data is performed in this module because the final data width is 24-bit and data coming from the processing path can be up to 32 bits. This right bit-shift is configurable in the range 0-31 bits for each selected input channel (see DTRBS[4:0] bits in DFSDM_CHyCFGR2 register). The right bit-shift is rounding the result to nearest integer value. The sign of shifted result is maintained - to have valid 24-bit signed format of result data.

In the next step, an offset correction of the result is performed. The offset correction value (OFFSET[23:0] stored in register DFSDM_CHyCFGR2) is subtracted from the output data for a given channel. Data in the OFFSET[23:0] field is set by software by the appropriate calibration routine.

Due to the fact that all operations in digital processing are performed on 32-bit signed registers, the following conditions must be fulfilled not to overflow the result:

\[
F_{\text{OSR}} \cdot F_{\text{ORD}} \cdot I_{\text{OSR}} \cdot 1 \leq 2^{31} \quad \text{...FAST = 1 or any filter bypass case}
\]

\[
2 \cdot F_{\text{OSR}} \cdot I_{\text{OSR}} \cdot 1 \leq 2^{31} \quad \text{...FAST = 0, Sincx filter}
\]

\[
21 \cdot F_{\text{OSR}} \cdot I_{\text{OSR}} \cdot 1 \leq 2^{31} \quad \text{...FAST = 0, FastSinc filter}
\]

Note: In case of filter and integrator bypass (IOSR[7:0]=0, FOSR[9:0]=0), the input data rate \( f_{\text{DATAIN RATE}} \) must be limited to be able to read all output data:

\[
f_{\text{DATAIN RATE}} \leq f_{\text{APB}}
\]

where \( f_{\text{APB}} \) is the bus frequency to which the DFSDM peripheral is connected.

28.4.14 Signed data format

Each DFSDM input serial channel can be connected to one external \( \Sigma\Delta \) modulator. An external \( \Sigma\Delta \) modulator can have 2 differential inputs (positive and negative) which can be used for a differential or single-ended signal measurement.

A \( \Sigma\Delta \) modulator output is always assumed in a signed format (a data stream of zeros and ones from a \( \Sigma\Delta \) modulator represents values -1 and +1).
**Signed data format in registers:** Data is in a signed format in registers for final output data, analog watchdog, extremes detector, offset correction. The msb of output data word represents the sign of value (two’s complement format).

### 28.4.15 Launching conversions

**Injected conversions** can be launched using the following methods:

- **Software:** writing ‘1’ to JSWSTART in the DFSDMFLTxxCR1 register.
- **Trigger:** JEXTSEL[4:0] selects the trigger signal while JEXTEN activates the trigger and selects the active edge at the same time (see the DFSDMFLTxxCR1 register).
- **Synchronous with DFSDMFLT0 if JSYNC=1:** for DFSDMFLTxx (x>0), an injected conversion is automatically launched when in DFSDMFLT0; the injected conversion is started by software (JSWSTART=1 in DFSDMFLT0CR2 register). Each injected conversion in DFSDMFLTxx (x>0) is always executed according to its local configuration settings (JSAN, JCHG, etc.).

If the scan conversion is enabled (bit JSCAN=1) then, each time an injected conversion is triggered, all of the selected channels in the injected group (JCHG[7:0] bits in DFSDMFLTxxJCHGR register) are converted sequentially, starting with the lowest channel (channel 0, if selected).

If the scan conversion is disabled (bit JSCAN=0) then, each time an injected conversion is triggered, only one of the selected channels in the injected group (JCHG[7:0] bits in DFSDMFLTxxJCHGR register) is converted and the channel selection is then moved to the next selected channel. Writing to the JCHG[7:0] bits when JSCAN=0 sets the channel selection to the lowest selected injected channel.

Only one injected conversion can be ongoing at a given time. Thus, any request to launch an injected conversion is ignored if another request for an injected conversion has already been issued but not yet completed.

**Regular conversions** can be launched using the following methods:

- **Software:** by writing ‘1’ to RSWSTART in the DFSDMFLTxxCR1 register.
- **Synchronous with DFSDMFLT0 if RSYNC=1:** for DFSDMFLTxx (x>0), a regular conversion is automatically launched when in DFSDMFLT0; a regular conversion is started by software (RSWSTART=1 in DFSDMFLT0CR2 register). Each regular conversion in DFSDMFLTxx (x>0) is always executed according to its local configuration settings (RCONT, RCH, etc.).

Only one regular conversion can be pending or ongoing at a given time. Thus, any request to launch a regular conversion is ignored if another request for a regular conversion has already been issued but not yet completed. A regular conversion can be pending if it was interrupted by an injected conversion or if it was started while an injected conversion was in progress. This pending regular conversion is then delayed and is performed when all injected conversion are finished. Any delayed regular conversion is signalized by RPEND bit in DFSDMFLTxxRDATAR register.

### 28.4.16 Continuous and fast continuous modes

Setting RCONT in the DFSDMFLTxxCR1 register causes regular conversions to execute in continuous mode. RCONT=1 means that the channel selected by RCH[2:0] is converted repeatedly after ‘1’ is written to RSWSTART.
The regular conversions executing in continuous mode can be stopped by writing '0' to RCONT. After clearing RCONT, the on-going conversion is stopped immediately.

In continuous mode, the data rate can be increased by setting the FAST bit in the DFSDM_FLTxCR1 register. In this case, the filter does not need to be refilled by new fresh data if converting continuously from one channel because data inside the filter is valid from previously sampled continuous data. The speed increase depends on the chosen filter order. The first conversion in fast mode (FAST=1) after starting a continuous conversion by RSWSTART=1 takes still full time (as when FAST=0), then each subsequent conversion is finished in shorter intervals.

Conversion time in continuous mode:

- If FAST = 0 (or first conversion if FAST=1):
  - For Sinc\(x\) filters:
    \[ t = \frac{CNVCNT}{f_{DFSDMCLK}} = \frac{[FOSR \cdot (IOSR-1 + FORD) + FORD]}{f_{CKIN}} \]
  - For FastSinc filter:
    \[ t = \frac{CNVCNT}{f_{DFSDMCLK}} = \frac{[FOSR \cdot (IOSR-1 + 4) + 2]}{f_{CKIN}} \]

- If FAST = 1 (except first conversion):
  - For Sinc\(x\) and FastSinc filters:
    \[ t = \frac{CNVCNT}{f_{DFSDMCLK}} = \frac{[FOSR \cdot IOSR]}{f_{CKIN}} \]
  - In case FOSR = FOSR[9:0]+1 = 1 (filter bypassed, only integrator active):
    \[ t = \frac{IOSR}{f_{CKIN}} \]

Continuous mode is not available for injected conversions. Injected conversions can be started by timer trigger to emulate the continuous mode with precise timing.

If a regular continuous conversion is in progress (RCONT=1) and if a write access to DFSDM_FLTxCR1 register requesting regular continuous conversion (RCONT=1) is performed, then regular continuous conversion is restarted from the next conversion cycle (like new regular continuous conversion is applied for new channel selection - even if there is no change in DFSDM_FLTxCR1 register).

### 28.4.17 Request precedence

An injected conversion has a higher precedence than a regular conversion. A regular conversion which is already in progress is immediately interrupted by the request of an injected conversion; this regular conversion is restarted after the injected conversion finishes.

An injected conversion cannot be launched if another injected conversion is pending or already in progress: any request to launch an injected conversion (either by JSWSTART or by a trigger) is ignored as long as bit JCIP is ‘1’ (in the DFSDM_FLTxISR register).

Similarly, a regular conversion cannot be launched if another regular conversion is pending or already in progress: any request to launch a regular conversion (using RSWSTART) is ignored as long as bit RCIP is ‘1’ (in the DFSDM_FLTxISR register).

However, if an injected conversion is requested while a regular conversion is already in progress, the regular conversion is immediately stopped and an injected conversion is launched. The regular conversion is then restarted and this delayed restart is signalized in bit RPEND.

Injected conversions have precedence over regular conversions in that a injected conversion can temporarily interrupt a sequence of continuous regular conversions. When
the sequence of injected conversions finishes, the continuous regular conversions start again if RCONT is still set (and RPEND bit will signalize the delayed start on the first regular conversion result).

Precedence also matters when actions are initiated by the same write to DFSDM, or if multiple actions are pending at the end of another action. For example, suppose that, while an injected conversion is in process (JCIP=1), a single write operation to DFSDM_FLTxCRR1 writes ‘1’ to RSWSTART, requesting a regular conversion. When the injected sequence finishes, the precedence dictates that the regular conversion is performed next and its delayed start is signalized in RPEND bit.

28.4.18 Power optimization in run mode

In order to reduce the consumption, the DFSDM filter and integrator are automatically put into idle when not used by conversions (RCIP=0, JCIP=0).

28.5 DFSDM interrupts

In order to increase the CPU performance, a set of interrupts related to the CPU event occurrence has been implemented:

- **End of injected conversion interrupt:**
  - enabled by JEOCIE bit in DFSDM_FLTxCRR2 register
  - indicated in JEOCF bit in DFSDM_FLTxCISR register
  - cleared by reading DFSDM_FLTxCJDATAR register (injected data)
  - indication of which channel end of conversion occurred, reported in JDATACH[2:0] bits in DFSDM_FLTxCJDATAR register

- **End of regular conversion interrupt:**
  - enabled by REOCIE bit in DFSDM_FLTxCRR2 register
  - indicated in REOCF bit in DFSDM_FLTxCISR register
  - cleared by reading DFSDM_FLTxCRDATAR register (regular data)
  - indication of which channel end of conversion occurred, reported in RDATACH[2:0] bits in DFSDM_FLTxCRDATAR register

- **Data overrun interrupt for injected conversions:**
  - occurred when injected converted data were not read from DFSDM_FLTxCJDATAR register (by CPU or DMA) and were overwritten by a new injected conversion
  - enabled by JOVRIE bit in DFSDM_FLTxCRR2 register
  - indicated in JOVRF bit in DFSDM_FLTxCISR register
  - cleared by writing ‘1’ into CLRJOVRF bit in DFSDM_FLTxCICR register

- **Data overrun interrupt for regular conversions:**
  - occurred when regular converted data were not read from DFSDM_FLTxCRDATAR register (by CPU or DMA) and were overwritten by a new regular conversion
  - enabled by ROVRIE bit in DFSDM_FLTxCRR2 register
  - indicated in ROVRF bit in DFSDM_FLTxCISR register
  - cleared by writing ‘1’ into CLRROVRF bit in DFSDM_FLTxCICR register

- **Analog watchdog interrupt:**
occurred when converted data (output data or data from analog watchdog filter - according to AWFSEL bit setting in DFSDM_FLTxCR1 register) crosses over/under high/low thresholds in DFSDM_FLTxAWHTR / DFSDM_FLTxAWLTR registers

- enabled by AWDie bit in DFSDM_FLTxCR2 register (on selected channels AWDCH[7:0])
- indicated in AWDF bit in DFSDM_FLTxISR register
- separate indication of high or low analog watchdog threshold error by AWHTF[7:0] and AWLTF[7:0] fields in DFSDM_FLTxAWSR register
- cleared by writing ‘1’ into corresponding CLRAWHTF[7:0] or CLRAWLTF[7:0] bits in DFSDM_FLTxAWCFR register

- Short-circuit detector interrupt:
  - occurred when the number of stable data crosses over thresholds in DFSDM_CYAWSCDR register
  - enabled by SCDie bit in DFSDM_FLTxCR2 register (on channel selected by SCDEN bit in DFSDM_CYCFG1 register)
  - indicated in SCDF[7:0] bits in DFSDM_FLTxISR register (which also reports the channel on which the short-circuit detector event occurred)
  - cleared by writing ‘1’ into the corresponding CLRSCDF[7:0] bit in DFSDM_FLTxICR register

- Channel clock absence interrupt:
  - occurred when there is clock absence on CKINy pin (see Clock absence detection in Section 28.4.4: Serial channel transceivers)
  - enabled by CKABIE bit in DFSDM_FLTxCR2 register (on channels selected by CKABEN bit in DFSDM_CYCFG1 register)
  - indicated in CKABF[y] bit in DFSDM_FLTxISR register
  - cleared by writing ‘1’ into CLRCKABF[y] bit in DFSDM_FLTxICR register

</tbody>
</table>
28.6 DFSDM DMA transfer

To decrease the CPU intervention, conversions can be transferred into memory using a DMA transfer. A DMA transfer for injected conversions is enabled by setting bit JDMAEN=1 in DFSDM_FLTxCr1 register. A DMA transfer for regular conversions is enabled by setting bit RDMAEN=1 in DFSDM_FLTxCr1 register.

Note: With a DMA transfer, the interrupt flag is automatically cleared at the end of the injected or regular conversion (JEOCF or REOCF bit in DFSDM_FLTxISR register) because DMA is reading DFSDM_FLTxJDATAR or DFSDM_FLTxRDATAR register.

28.7 DFSDM channel y registers (y=0..7)

Word access (32-bit) must be used for registers write access except DFSDM_CHyDATINR register. Write access to DFSDM_CHyDATINR register can be either word access (32-bit) or half-word access (16-bit).

28.7.1 DFSDM channel y configuration register (DFSDM_CHyCFGR1)

This register specifies the parameters used by channel y.

Address offset: 0x00 + 0x20 * y, (y = 0 to 7)

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>DFSDMEN</th>
<th>Global enable for DFSDM interface</th>
</tr>
</thead>
<tbody>
<tr>
<td>0:</td>
<td>DFSDM interface disabled</td>
<td></td>
</tr>
<tr>
<td>1:</td>
<td>DFSDM interface enabled</td>
<td></td>
</tr>
</tbody>
</table>

If DFSDM interface is enabled, then it is started to operate according to enabled y channels and enabled x filters settings (CHEN bit in DFSDM_CHyCFGR1 and DFEN bit in DFSDM_FLTxCr1).

Data cleared by setting DFSDMEN=0:

–all registers DFSDM_FLTxISR are set to reset state (x = 0..3)
–all registers DFSDM_FLTxAWSR are set to reset state (x = 0..3)

Note: DFSDMEN is present only in DFSDM_CH0CFGR1 register (channel y=0)

<table>
<thead>
<tr>
<th>Bit 30</th>

</tr>
</tbody>
</table>

–SAI1 clock selected by SAI1SEL[1:0] field in RCC configuration (see Section 6.4.32: Peripherals independent clock configuration register (RCC_CCIPR2))

This value can be modified only when DFSDMEN=0 (in DFSDM_CH0CFGR1 register).

Note: CKOUTSRC is present only in DFSDM_CH0CFGR1 register (channel y=0)

Bits 29:24 Reserved, must be kept at reset value.
Bits 23:16 **CKOUTDIV[7:0]**: Output serial clock divider

- 0: Output clock generation is disabled (CKOUT signal is set to low state)
- 1: 255: Defines the division of system clock for the serial clock output for CKOUT signal in range 2 - 256 (Divider = CKOUTDIV+1).

CKOUTDIV also defines the threshold for a clock absence detection. This value can only be modified when DFSDMEN=0 (in DFSDM_CH0CFGR1 register).

If DFSDMEN=0 (in DFSDM_CH0CFGR1 register) then CKOUT signal is set to low state (setting is performed one DFSDM clock cycle after DFSDMEN=0).

*Note: CKOUTDIV is present only in DFSDM_CH0CFGR1 register (channel y=0)*

Bits 15:14 **DATPACK[1:0]**: Data packing mode in DFSDM_CHyDATINR register.

- 0: Standard: input data in DFSDM_CHyDATINR register are stored only in INDAT0[15:0]. To empty DFSDM_CHyDATINR register one sample must be read by the DFSDM filter from channel y.
- 1: Interleaved: input data in DFSDM_CHyDATINR register are stored as two samples:
  - first sample in INDAT0[15:0] (assigned to channel y)
  - second sample INDAT1[15:0] (assigned to channel y)

To empty DFSDM_CHyDATINR register, two samples must be read by the digital filter from channel y (INDAT0[15:0] part is read as first sample and then INDAT1[15:0] part is read as next sample).

- 2: Dual: input data in DFSDM_CHyDATINR register are stored as two samples:
  - first sample INDAT0[15:0] (assigned to channel y)
  - second sample INDAT1[15:0] (assigned to channel y+1)

To empty DFSDM_CHyDATINR register, first sample must be read by the digital filter from channel y and second sample must be read by another digital filter from channel y+1. Dual mode is available only on even channel numbers (y = 0, 2, 4, 6), for odd channel numbers (y = 1, 3, 5, 7) DFSDM_CHyDATINR is write protected. If an even channel is set to dual mode then the following odd channel must be set into standard mode (DATPACK[1:0]=0) for correct cooperation with even channel.

- 3: Reserved
  This value can be modified only when CHEN=0 (in DFSDM_CHyCFGR1 register).

Bits 13:12 **DATMPX[1:0]**: Input data multiplexer for channel y

- 0: Data to channel y are taken from external serial inputs as 1-bit values. DFSDM_CHyDATINR register is write protected.
- 1: Data to channel y are taken from internal analog to digital converter ADCy+1 output register update as 16-bit values (if ADCy+1 is available). Data from ADCs are written into INDAT0[15:0] part of DFSDM_CHyDATINR register.

- 2: Data to channel y are taken from internal DFSDM_CHyDATINR register by direct CPU/DMA write.
  There can be written one or two 16-bit data samples according DATPACK[1:0] bit field setting.
- 3: Reserved
  This value can be modified only when CHEN=0 (in DFSDM_CHyCFGR1 register).

Bits 11:9 Reserved, must be kept at reset value.

**Bit 8 CHINSEL**: Channel inputs selection

- 0: Channel inputs are taken from pins of the same channel y.
- 1: Channel inputs are taken from pins of the following channel (channel (y+1) modulo 8).

This value can be modified only when CHEN=0 (in DFSDM_CHyCFGR1 register).

**Bit 7 CHEN**: Channel y enable

- 0: Channel y disabled
- 1: Channel y enabled

If channel y is enabled, then serial data receiving is started according to the given channel setting.
Bit 6 **CKABEN**: Clock absence detector enable on channel y
0: Clock absence detector disabled on channel y
1: Clock absence detector enabled on channel y

Bit 5 **SCDEN**: Short-circuit detector enable on channel y
0: Input channel y will not be guarded by the short-circuit detector
1: Input channel y will be continuously guarded by the short-circuit detector

Bit 4 Reserved, must be kept at reset value.

Bits 3:2 **SPICKSEL[1:0]**: SPI clock select for channel y
0: Clock coming from external CKINy input - sampling point according SITP[1:0]
1: Clock coming from internal CKOUT output - sampling point according SITP[1:0]
2: Clock coming from internal CKOUT - sampling point on each second CKOUT falling edge.
   For connection to external ΣΔ modulator which divides its clock input (from CKOUT) by 2 to generate its output serial communication clock (and this output clock change is active on each clock input rising edge).
3: Clock coming from internal CKOUT output - sampling point on each second CKOUT rising edge.
   For connection to external ΣΔ modulator which divides its clock input (from CKOUT) by 2 to generate its output serial communication clock (and this output clock change is active on each clock input falling edge).
   This value can be modified only when CHEN=0 (in DFSDM_CHyCFGR1 register).

Bits 1:0 **SITP[1:0]**: Serial interface type for channel y
00: SPI with rising edge to strobe data
01: SPI with falling edge to strobe data
10: Manchester coded input on DATINy pin: rising edge = logic 0, falling edge = logic 1
11: Manchester coded input on DATINy pin: rising edge = logic 1, falling edge = logic 0
   This value can only be modified when CHEN=0 (in DFSDM_CHyCFGR1 register).

### 28.7.2 DFSDM channel y configuration register (DFSDM_CHyCFGR2)

This register specifies the parameters used by channel y.

Address offset: \(0x04 + 0x20 \times y\), \((y = 0 \text{ to } 7)\)

Reset value: 0x0000 0000

WDATA[15:0]

Bits 15:0 INDAT1[15:0]: Input channel y watchdog data

Data converted by the analog watchdog filter for input channel y. This data is continuously converted (no trigger) for this channel, with a limited resolution (OSR=1..32/sinc order = 1..3).

28.7.5 DFSDM channel y data input register (DFSDM_CHyDATINR)

This register contains 16-bit input data to be processed by DFSDM filter module. Write access can be either word access (32-bit) or half-word access (16-bit).

Address offset: 0x10 + 0x20 * y, (y = 0 to 7)

</table>

INDAT0[15:0]

Bits 31:16 Reserved, must be kept at reset value.
Bits 31:16  **INDAT1[15:0]**: Input data for channel y or channel y+1

Input parallel channel data to be processed by the digital filter if DATMPX[1:0]=1 or DATMPX[1:0]=2. Data can be written by CPU/DMA (if DATMPX[1:0]=2) or directly by internal ADC (if DATMPX[1:0]=1).

If DATPACK[1:0]=0 (standard mode)
- INDAT0[15:0] is write protected (not used for input sample).

If DATPACK[1:0]=1 (interleaved mode)
- Second channel y data sample is stored into INDAT1[15:0]. First channel y data sample is stored into INDAT0[15:0]. Both samples are read sequentially by DFSDM_FLTx filter as two channel y data samples.

If DATPACK[1:0]=2 (dual mode).
- For even y channels: channel y data sample is stored into INDAT1[15:0] is automatically copied into INDAT0[15:0] of channel (y+1).
- For odd y channels: INDAT1[15:0] is write protected.

See Section 28.4.6: Parallel data inputs for more details.

INDAT0[15:1] is in the 16-bit signed format.

Bits 15:0  **INDAT0[15:0]**: Input data for channel y

Input parallel channel data to be processed by the digital filter if DATMPX[1:0]=1 or DATMPX[1:0]=2. Data can be written by CPU/DMA (if DATMPX[1:0]=2) or directly by internal ADC (if DATMPX[1:0]=1).

If DATPACK[1:0]=0 (standard mode)
- Channel y data sample is stored into INDAT0[15:0].

If DATPACK[1:0]=1 (interleaved mode)
- First channel y data sample is stored into INDAT0[15:0]. Second channel y data sample is stored into INDAT1[15:0]. Both samples are read sequentially by DFSDM_FLTx filter as two channel y data samples.

If DATPACK[1:0]=2 (dual mode).
- For even y channels: Channel y data sample is stored into INDAT0[15:0].
- For odd y channels: INDAT0[15:0] is write protected.

See Section 28.4.6: Parallel data inputs for more details.

INDAT0[15:0] is in the 16-bit signed format.

### 28.7.6 DFSDM channel y delay register (DFSDM_CHyDLYR)

Address offset: 0x14 + 0x20 * y, (y = 0 to 7)

Reset value: 0x0000 0000

STI
28.8  DFSDM filter x module registers (x=0..3)

Word access (32-bit) must be used for registers write access except DFSDM_CHyDATINR register.

28.8.1  DFSDM filter x control register 1 (DFSDM_FLTxCR1)

Address offset: 0x100 + 0x80 * x, (x = 0 to 3)

Reset value: 0x0000 0000

| Bit 31:6 | Reserved, must be kept at reset value. |
| Bit 5:0 | PLSSKP[5:0]: Pulses to skip for input data skipping function |
| Note: User can update PLSSKP[5:0] also when PLSSKP[5:0] is not zero. |

### Bits 28:27

Reserved, must be kept at reset value.

### Bits 28:27

**AWFSEL**: Analog watchdog fast mode select

0: Analog watchdog on data output value (after the digital filter). The comparison is done after offset correction and shift

1: Analog watchdog on channel transceivers value (after watchdog filter)

### Bits 29

**FAST**: Fast conversion mode selection for regular conversions

0: Fast conversion mode disabled

1: Fast conversion mode enabled

When converting a regular conversion in continuous mode, having enabled the fast mode causes each conversion (except the first) to execute faster than in standard mode. This bit has no effect on conversions which are not continuous.

This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).

If FAST=0 (or first conversion in continuous mode if FAST=1):

\[
t = \frac{\text{FOSR} \times (\text{IOSR} + 1)}{\text{fCKIN}}
\]

for Sincx filters

\[
t = \frac{\text{FOSR} \times (\text{IOSR} + 4)}{\text{fCKIN}},
\]

for FastSinc filter

If FAST=1 in continuous mode (except first conversion):

\[
t = \frac{\text{FOSR}}{\text{fCKIN}}
\]

in case if FOSR = FOSR[9:0]+1 = 1 (filter bypassed, active only integrator):

\[
t = \frac{\text{IOSR}}{\text{fCKIN}},
\]

where: \(f_{\text{CKIN}}\) is the channel input clock frequency (on given channel CKINy pin) or input data rate in case of parallel data input.

### Notes:

- **User can update PLSSKP[5:0] also when PLSSKP[5:0] is not zero.**
Bits 26:24 **RCH[2:0]**: Regular channel selection
- 0: Channel 0 is selected as the regular channel
- 1: Channel 1 is selected as the regular channel
- ...
- 7: Channel 7 is selected as the regular channel
Writing these bits when RCIP=1 takes effect when the next regular conversion begins. This is especially useful in continuous mode (when RCONT=1). It also affects regular conversions which are pending (due to ongoing injected conversion).

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **RDMAEN**: DMA channel enabled to read data for the regular conversion
- 0: The DMA channel is not enabled to read regular data
- 1: The DMA channel is enabled to read regular data
This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).

Bit 20 Reserved, must be kept at reset value.

Bit 19 **RSYNC**: Launch regular conversion synchronously with DFSDMFLT0
- 0: Do not launch a regular conversion synchronously with DFSDMFLT0
- 1: Launch a regular conversion in this DFSDMFLTx at the very moment when a regular conversion is launched in DFSDMFLT0
This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).

Bit 18 **RCONT**: Continuous mode selection for regular conversions
- 0: The regular channel is converted just once for each conversion request
- 1: The regular channel is converted repeatedly after each conversion request
Writing '0' to this bit while a continuous regular conversion is already in progress stops the continuous mode immediately.

Bit 17 **RSWSTART**: Software start of a conversion on the regular channel
- 0: Writing '0' has no effect
- 1: Writing '1' makes a request to start a conversion on the regular channel and causes RCIP to become '1'. If RCIP=1 already, writing to RSWSTART has no effect. Writing '1' has no effect if RSYNC=1.
This bit is always read as '0'.

Bits 16:15 Reserved, must be kept at reset value.

Bits 14:13 **JEXTEN[1:0]**: Trigger enable and trigger edge selection for injected conversions
- 00: Trigger detection is disabled
- 01: Each rising edge on the selected trigger makes a request to launch an injected conversion
- 10: Each falling edge on the selected trigger makes a request to launch an injected conversion
- 11: Both rising edges and falling edges on the selected trigger make requests to launch injected conversions
This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).
Bits 12:8 **JEXTSEL[4:0]**: Trigger signal selection for launching injected conversions

0x0-0x1F: Trigger inputs selected by the following table (internal or external trigger).

This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).

*Note:* synchronous trigger has latency up to one $f_{DFSDMCLK}$ clock cycle (with deterministic jitter), asynchronous trigger has latency 2-3 $f_{DFSDMCLK}$ clock cycles (with jitter up to 1 cycle).

\[
\text{DFSDM_FLTx}
\]

- 0x00 dfsdm_jtrg0
- 0x01 dfsdm_jtrg1
- ...
- 0x1E dfsdm_jtrg30
- 0x1F dfsdm_jtrg31

Refer to **Table 187: DFSDM triggers connection**.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **JDMAEN**: DMA channel enabled to read data for the injected channel group

0: The DMA channel is not enabled to read injected data
1: The DMA channel is enabled to read injected data

This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).

Bit 4 **JSCAN**: Scanning conversion mode for injected conversions

0: One channel conversion is performed from the injected channel group and next the selected channel from this group is selected.
1: The series of conversions for the injected group channels is executed, starting over with the lowest selected channel.

This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).

Writing JCHG if JSCAN=0 resets the channel selection to the lowest selected channel.

Bit 3 **JSYNC**: Launch an injected conversion synchronously with the DFSDM_FLT0 JSWSTART trigger

0: Do not launch an injected conversion synchronously with DFSDM_FLT0
1: Launch an injected conversion in this DFSDM_FLTx at the very moment when an injected conversion is launched in DFSDM_FLT0 by its JSWSTART trigger

This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).

Bit 2 Reserved, must be kept at reset value.

Bit 1 **JSWSTART**: Start a conversion of the injected group of channels

0: Writing ‘0’ has no effect.
1: Writing ‘1’ makes a request to convert the channels in the injected conversion group, causing JCIP to become ‘1’ at the same time. If JCIP=1 already, then writing to JSWSTART has no effect. Writing ‘1’ has no effect if JSYNC=1.

This bit is always read as ‘0’.

Bit 0 **DFEN**: DFSDM_FLTx enable

0: DFSDM_FLTx is disabled. All conversions of given DFSDM_FLTx are stopped immediately and all DFSDM_FLTx functions are stopped.
1: DFSDM_FLTx is enabled. If DFSDM_FLTx is enabled, then DFSDM_FLTx starts operating according to its setting.

Data which are cleared by setting DFEN=0:

- register DFSDM_FLTxISR is set to the reset state
- register DFSDM_FLTxAWSR is set to the reset state
28.8.2  **DFSDM filter x control register 2 (DFSDM_FLTxCR2)**

Address offset: 0x104 + 0x80 * x, (x = 0 to 3)

Reset value: 0x0000 0000

</tbody>
</table>

Bits 31:24  Reserved, must be kept at reset value.

Bits 23:16  **AWDCH[7:0]**: Analog watchdog channel selection
These bits select the input channel to be guarded continuously by the analog watchdog.
AWDCH[y] = 0: Analog watchdog is disabled on channel y
AWDCH[y] = 1: Analog watchdog is enabled on channel y

Bits 15:8  **EXCH[7:0]**: Extremes detector channel selection
These bits select the input channels to be taken by the Extremes detector.
EXCH[y] = 0: Extremes detector does not accept data from channel y
EXCH[y] = 1: Extremes detector accepts data from channel y

Bit 7  Reserved, must be kept at reset value.

Bit 6  **CKABIE**: Clock absence interrupt enable
0: Detection of channel input clock absence interrupt is disabled
1: Detection of channel input clock absence interrupt is enabled
Please see the explanation of CKABF[7:0] in DFSDM_FLTxISR.

*Note:* **CKABIE is present only in DFSDM_FLT0CR2 register (filter x=0)**

Bit 5  **SCDIE**: Short-circuit detector interrupt enable
0: short-circuit detector interrupt is disabled
1: short-circuit detector interrupt is enabled
Please see the explanation of SCDF[7:0] in DFSDM_FLTxISR.

*Note:* **SCDIE is present only in DFSDM_FLT0CR2 register (filter x=0)**

Bit 4  **AWDIE**: Analog watchdog interrupt enable
0: Analog watchdog interrupt is disabled
1: Analog watchdog interrupt is enabled
Please see the explanation of AWDF in DFSDM_FLTxISR.

Bit 3  **ROVRIE**: Regular data overrun interrupt enable
0: Regular data overrun interrupt is disabled
1: Regular data overrun interrupt is enabled
Please see the explanation of ROVRF in DFSDM_FLTxISR.
Bit 2 **JOVRIE**: Injected data overrun interrupt enable
0: Injected data overrun interrupt is disabled
1: Injected data overrun interrupt is enabled
Please see the explanation of JOVRF in DFSDM_FLTxISR.

Bit 1 **REOCIE**: Regular end of conversion interrupt enable
0: Regular end of conversion interrupt is disabled
1: Regular end of conversion interrupt is enabled
Please see the explanation of REOCF in DFSDM_FLTxISR.

Bit 0 **JEOCIE**: Injected end of conversion interrupt enable
0: Injected end of conversion interrupt is disabled
1: Injected end of conversion interrupt is enabled
Please see the explanation of JEOCF in DFSDM_FLTxISR.

### 28.8.3 DFSDM filter x interrupt and status register (DFSDM_FLTxISR)

#### Bits 31:24 **SCDF[7:0]**: short-circuit detector flag
SDCF[y]=0: No short-circuit detector event occurred on channel y
SDCF[y]=1: The short-circuit detector counter reaches, on channel y, the value programmed in the DFSDM_CHyAWSHCDR registers
This bit is set by hardware. It can be cleared by software using the corresponding CLRSCDF[y] bit in the DFSDM_FLTxICR register. SDCF[y] is cleared also by hardware when CHEN[y] = 0 (given channel is disabled).

*Note: SDCF[7:0] is present only in DFSDMFLT0ISR register (filter x=0)*

#### Bits 23:16 **CKABF[7:0]**: Clock absence flag
CKABF[y]=0: Clock signal on channel y is present.
CKABF[y]=1: Clock signal on channel y is not present.
Given y bit is set by hardware when clock absence is detected on channel y. It is held at CKABF[y]=1 state by hardware when CHEN=0 (see DFSDM_CHyAWSHCDR1 register). It is held at CKABF[y]=1 state by hardware when the transceiver is not yet synchronized. It can be cleared by software using the corresponding CLRCKABF[y] bit in the DFSDM_FLTxICR register.

*Note: CKABF[7:0] is present only in DFSDMFLT0ISR register (filter x=0)*

Bit 15 Reserved, must be kept at reset value.

Bit 14 **RCIP**: Regular conversion in progress status
0: No request to convert the regular channel has been issued
1: The conversion of the regular channel is in progress or a request for a regular conversion is pending
A request to start a regular conversion is ignored when RCIP=1.
Bit 13  **JCIP**: Injected conversion in progress status

- 0: No request to convert the injected channel group (neither by software nor by trigger) has been issued.
- 1: The conversion of the injected channel group is in progress or a request for a injected conversion is pending, due either to ‘1’ being written to JSWSTART or to a trigger detection.

A request to start an injected conversion is ignored when JCIP=1.

Bits 12:5  Reserved, must be kept at reset value.

Bit 4  **AWDF**: Analog watchdog

- 0: No Analog watchdog event occurred
- 1: The analog watchdog block detected voltage which crosses the value programmed in the DFSDM_FLTxAWLTR or DFSDM_FLTxAWHTR registers.

This bit is set by hardware. It is cleared by software by clearing all source flag bits AWHTF[7:0] and AWLTF[7:0] in DFSDM_FLTxAWSR register (by writing ‘1’ into the clear bits in DFSDM_FLTxAWCFR register).

Bit 3  **ROVRF**: Regular conversion overrun flag

- 0: No regular conversion overrun has occurred
- 1: A regular conversion overrun has occurred, which means that a regular conversion finished while REOCF was already ‘1’. RDATAR is not affected by overruns.

This bit is set by hardware. It can be cleared by software using the CLRROVRF bit in the DFSDM_FLTxICR register.

Bit 2  **JOVRF**: Injected conversion overrun flag

- 0: No injected conversion overrun has occurred
- 1: An injected conversion overrun has occurred, which means that an injected conversion finished while JEOCF was already ‘1’. JDATAR is not affected by overruns.

This bit is set by hardware. It can be cleared by software using the CLRJOVRF bit in the DFSDM_FLTxICR register.

Bit 1  **REOCF**: End of regular conversion flag

- 0: No regular conversion has completed
- 1: A regular conversion has completed and its data may be read

This bit is set by hardware. It is cleared when the software or DMA reads DFSDM_FLTxRDATAR.

Bit 0  **JEOCF**: End of injected conversion flag

- 0: No injected conversion has completed
- 1: An injected conversion has completed and its data may be read

This bit is set by hardware. It is cleared when the software or DMA reads DFSDM_FLTxJDATAR.

**Note:** For each of the flag bits, an interrupt can be enabled by setting the corresponding bit in DFSDM_FLTxCR2. If an interrupt is called, the flag must be cleared before exiting the interrupt service routine.

All the bits of DFSDM_FLTxISR are automatically reset when DFEN=0.
28.8.4 **DFSDM filter x interrupt flag clear register (DFSDM_FLTxICR)**

Address offset: 0x10C + 0x80 * x, (x = 0 to 3)

*Note: The bits of DFSDM_FLTxICR are always read as ‘0’.*
28.8.5 DFSDM filter x injected channel group selection register
(DFSDM_FLTxJCHGR)

Address offset: 0x110 + 0x80 * x, (x = 0 to 3)
Reset value: 0x0000 0001

| 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16 |
|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|    |
| 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |

**JCHG[7:0]**

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **JCHG[7:0]**: Injected channel group selection
   - JCHG[y]=0: channel y is not part of the injected group
   - JCHG[y]=1: channel y is part of the injected group

If JSCAN=1, each of the selected channels is converted, one after another. The lowest channel (channel 0, if selected) is converted first and the sequence ends at the highest selected channel.
If JSCAN=0, then only one channel is converted from the selected channels, and the channel selection is moved to the next channel. Writing JCHG, if JSCAN=0, resets the channel selection to the lowest selected channel.
At least one channel must always be selected for the injected group. Writes causing all JCHG bits to be zero are ignored.

28.8.6 DFSDM filter x control register (DFSDM_FLTxFCR)

<td>13</td>
</tr>
</tbody>
</table>

Bits 31:29 **FORD[2:0]**: Sinc filter order
- 0: FastSinc filter type
- 1: Sinc\(^1\) filter type
- 2: Sinc\(^2\) filter type
- 3: Sinc\(^3\) filter type
- 4: Sinc\(^4\) filter type
- 5: Sinc\(^5\) filter type
- 6-7: Reserved

Sinc\(^x\) filter type transfer function:
\[ H(z) = \left(1 - z^{-FOSR}\right)^x \]

FastSinc filter type transfer function:
\[ H(z) = \left(1 - z^{-1}\right)^2 \cdot \left(1 + z^{-2 \cdot FOSR}\right) \]

This bit can only be modified when DFEN=0 (DFSDM_FLTxCR1).

Bits 28:26 Reserved, must be kept at reset value.

Bits 25:16 **FOSR[9:0]**: Sinc filter oversampling ratio (decimation rate)
- 0 - 1023: Defines the length of the Sinc type filter in the range 1 - 1024 (FOSR = FOSR[9:0] + 1). This number is also the decimation ratio of the output data rate from filter.

This bit can only be modified when DFEN=0 (DFSDM_FLTxCR1)

*Note: If FOSR = 0, then the filter has no effect (filter bypass).*

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **IOSR[7:0]**: Integrator oversampling ratio (averaging length)
- 0 - 255: The length of the Integrator in the range 1 - 256 (IOSR + 1). Defines how many samples from Sinc filter will be summed into one output data sample from the integrator. The output data rate from the integrator will be decreased by this number (additional data decimation ratio).

This bit can only be modified when DFEN=0 (DFSDM_FLTxCR1)

*Note: If IOSR = 0, then the Integrator has no effect (Integrator bypass).*
28.8.8 DFSDM filter x data register for the regular channel (DFSDM_FLTxRDATAR)

Address offset: 0x11C + 0x80 * x, (x = 0 to 3)
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bits 31:8</th>
<th>RDATA[23:0]: Regular channel conversion data</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>When each regular conversion finishes, its data is stored in this register. The data is valid when REOCF=1. Reading this register clears the corresponding REOCF.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Bits 7:5</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit 4</td>
<td>RPEND: Regular channel pending data</td>
</tr>
<tr>
<td></td>
<td>Regular data in RDATA[23:0] was delayed due to an injected channel trigger during the conversion</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Bits 2:0</th>
<th>RDATA[2:0]: Regular channel most recently converted</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>When each regular conversion finishes, RDATA[2:0] is updated to indicate which channel was converted (because regular channel selection RCH[2:0] in DFSDM_FLTxCR1 register can be updated during regular conversion). Thus RDATA[23:0] holds the data that corresponds to the channel indicated by RDATA[2:0].</td>
</tr>
</tbody>
</table>

Note: Half-word accesses may be used to read only the MSBs of conversion data.
Reading this register also clears REOCF in DFSDM_FLTxISR.
28.8.9  DFSDM filter x analog watchdog high threshold register
(DFSDM_FLTxAWHTR)

Address offset: 0x120 + 0x80 * x, (x = 0 to 3)
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Address offset: 0x120 + 0x80 * x, (x = 0 to 3)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reset value: 0x0000 0000</td>
</tr>
</tbody>
</table>

Bits 31:8  **AWHT[23:0]**: Analog watchdog high threshold
These bits are written by software to define the high threshold for the analog watchdog.

*Note:* In case channel transceivers monitor (AWFSEL=1), the higher 16 bits (AWHT[23:8]) define the 16-bit threshold as compared with the analog watchdog filter output (because data coming from the analog watchdog filter are up to a 16-bit resolution). Bits AWHT[7:0] are not taken into comparison in this case.

Bits 7:4  Reserved, must be kept at reset value.

Bits 3:0  **BKAWH[3:0]**: Break signal assignment to analog watchdog high threshold event

- **BKAWH[i]** = 0: Break i signal is not assigned to an analog watchdog high threshold event
- **BKAWH[i]** = 1: Break i signal is assigned to an analog watchdog high threshold event

28.8.10  DFSDM filter x analog watchdog low threshold register
(DFSDM_FLTxAWLTR)

Address offset: 0x124 + 0x80 * x, (x = 0 to 3)
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Address offset: 0x124 + 0x80 * x, (x = 0 to 3)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reset value: 0x0000 0000</td>
</tr>
</tbody>
</table>
Digital filter for sigma delta modulators (DFSDM)

28.8.11 DFSDM filter x analog watchdog status register
(DFSDM_FLTxAWSR)

Address offset: 0x128 + 0x80 * x, (x = 0 to 3)
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31:24</th>

<td>r</td>
<td>r</td>
<td>r</td>
</tr>
</tbody>
</table>

Bits 31:8 **AWLT[23:0]**: Analog watchdog low threshold
These bits are written by software to define the low threshold for the analog watchdog.

*Note*: In case channel transceivers monitor (AWFSEL=1), only the higher 16 bits (AWLT[23:8]) define the 16-bit threshold as compared with the analog watchdog filter output (because data coming from the analog watchdog filter are up to a 16-bit resolution). Bits AWLT[7:0] are not taken into comparison in this case.

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **BKAWL[3:0]**: Break signal assignment to analog watchdog low threshold event

- **BKAWL[i]** = 0: Break i signal is not assigned to an analog watchdog low threshold event
- **BKAWL[i]** = 1: Break i signal is assigned to an analog watchdog low threshold event

**Note**: All the bits of DFSDM_FLTxAWSR are automatically reset when DFEN=0.
### 28.8.12 DFSDM filter x analog watchdog clear flag register (DFSDM_FLTxAWCFR)

Address offset: 0x12C + 0x80 * x, (x = 0 to 3)

Reset value: 0x0000 0000

| Bit 31:6 Reserved, must be kept at reset value. |
| Bit 15:8 | CLRRAWHTF[7:0]: Clear the analog watchdog high threshold flag |
| CLRRAWHTF[y]=0: Writing ‘0’ has no effect |
| CLRRAWHTF[y]=1: Writing ‘1’ to position y clears the corresponding AWHTF[y] bit in the DFSDM_FLTxAWSR register |
| Bit 7:0 | CLRRAWLTF[7:0]: Clear the analog watchdog low threshold flag |
| CLRRAWLTF[y]=0: Writing ‘0’ has no effect |
| CLRRAWLTF[y]=1: Writing ‘1’ to position y clears the corresponding AWLTF[y] bit in the DFSDM_FLTxAWSR register |

### 28.8.13 DFSDM filter x extremes detector maximum register (DFSDM_FLTxEXMAX)

Address offset: 0x130 + 0x80 * x, (x = 0 to 3)

Reset value: 0x8000 0000

| Bit 31:8 EXMAX[23:0]: Extremes detector maximum value |
| These bits are set by hardware and indicate the highest value converted by DFSDM_FLTx. |
| EXMAX[23:0] bits are reset to value (0x800000) by reading of this register. |
| Bit 7:3 Reserved, must be kept at reset value. |
| Bit 2:0 EXMAXCH[2:0]: Extremes detector maximum data channel. |
| These bits contain information about the channel on which the data is stored into EXMAX[23:0]. |
| Bits are cleared by reading of this register. |
28.8.14  DFSDM filter x extremes detector minimum register (DFSDM_FLTxEXMIN)

Address offset: 0x134 + 0x80 * x, (x = 0 to 3)

Reset value: 0x7FFF FF00

Bits 31:8 **EXMIN[23:0]**: Extremes detector minimum value
These bits are set by hardware and indicate the lowest value converted by DFSDM_FLTx. EXMIN[23:0] bits are reset to value (0x7FFFFF) by reading of this register.

Bits 7:3  Reserved, must be kept at reset value.

Bits 2:0 **EXMINCH[2:0]**: Extremes detector minimum data channel
These bits contain information about the channel on which the data is stored into EXMIN[23:0]. Bits are cleared by reading of this register.

28.8.15  DFSDM filter x conversion timer register (DFSDM_FLTxCNVTIMR)

Address offset: 0x138 + 0x80 * x, (x = 0 to 3)

29 LCD-TFT display controller (LTDC)

29.1 Introduction
The LCD-TFT (liquid crystal display - thin film transistor) display controller provides a parallel digital RGB (red, green, blue) and signals for horizontal, vertical synchronization, pixel clock and data enable as output to interface directly to a variety of LCD and TFT panels.

29.2 LTDC main features
- 24-bit RGB parallel pixel output; 8 bits-per-pixel (RGB888)
- 2 display layers with dedicated FIFO (64x32-bit)
- Color look-up table (CLUT) up to 256 color (256x24-bit) per layer
- Programmable timings for different display panels
- Programmable background color
- Programmable polarity for HSYNC, VSYNC and data enable
- Up to 8 input color formats selectable per layer:
  - ARGB8888
  - RGB888
  - RGB565
  - ARGB1555
  - ARGB4444
  - L8 (8-bit luminance or CLUT)
  - AL44 (4-bit alpha + 4-bit luminance)
  - AL88 (8-bit alpha + 8-bit luminance)
- Pseudo-random dithering output for low bits per channel
  - Dither width 2 bits for red, green, blue
- Flexible blending between two layers using alpha value (per pixel or constant)
- Color keying (transparency color)
- Programmable window position and size
- Supports thin film transistor (TFT) color displays
- AHB master interface with burst of 16 words
- Up to 4 programmable interrupt events

29.3 LTDC implementation

29.4 LTDC functional description

29.4.1 LTDC block diagram

The block diagram of the LTDC is shown in the figure below.

**Figure 198. LTDC block diagram**

Layer FIFO: One FIFO 64x32-bit per layer.

PFC: pixel format converter, performing the pixel format conversion from the selected input pixel format of a layer to words.

AHB interface: for data transfer from memories to the FIFO.

Blending, dithering unit and timings generator: Refer to Section 29.5.1 and Section 29.5.2.

29.4.2 LTDC pins and external signal interface

The table below summarizes the LTDC signal interface.

<table>
<thead>
<tr>
<th>LCD-TFT signals</th>
<th>I/O</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>LCD_B[7:0]</td>
<td>O</td>
<td>Data: 8-bit blue data</td>
</tr>
</tbody>
</table>
The LTDC-TFT controller pins must be configured by the user application. The unused pins can be used for other purposes.

For LTDC outputs up to 24 bits (RGB888), if less than 8 bpp are used to output for example RGB565 or RGB666 to interface on 16- or 18-bit displays, the RGB display data lines must be connected to the MSB of the LCD-TFT controller RGB data lines. As an example, in the case of an LCD-TFT controller interfacing with a RGB565 16-bit display, the LCD display R[4:0], G[5:0] and B[4:0] data lines pins must be connected to LCD-TFT controller LCD_R[7:3], LCD_G[7:2] and LCD_B[7:3].

### 29.4.3 LTDC reset and clocks

The LCD-TFT controller peripheral uses the following clock domains:

- **AHB clock domain (HCLK)**
  This domain contains the LCD-TFT AHB master interface for data transfer from the memories to the Layer FIFO and the frame buffer configuration register

- **APB2 clock domain (PCLK2):**
  This domain contains the global configuration registers and the interrupt register.

- **Pixel clock domain (LCD_CLK)**
  This domain contains the pixel data generation, the layer configuration register as well as the LCD-TFT interface signal generator. The LCD_CLK output must be configured following the panel requirements. The LCD_CLK is generated from a specific PLL output (refer to the reset and clock control section).

The table below summarizes the clock domain for each register.

<table>
<thead>
<tr>
<th>LTDC register</th>
<th>Clock domain</th>
</tr>
</thead>
<tbody>
<tr>
<td>LTDC_LxCR</td>
<td>HCLK</td>
</tr>
<tr>
<td>LTDC_LxCFBAR</td>
<td></td>
</tr>
<tr>
<td>LTDC_LxCFBLR</td>
<td></td>
</tr>
<tr>
<td>LTDC_LxCFBLNR</td>
<td></td>
</tr>
<tr>
<td>LTDC_SRCR</td>
<td></td>
</tr>
<tr>
<td>LTDC_IER</td>
<td>PCLK2</td>
</tr>
<tr>
<td>LTDC_ISR</td>
<td></td>
</tr>
<tr>
<td>LTDC_ICR</td>
<td></td>
</tr>
</tbody>
</table>
Care must be taken while accessing the LTDC registers, the APB2 bus is stalled during:

- 6 PCKL2 periods + 5 LCD_CLK periods (five HCLK periods for register on AHB clock domain) for register write access and update
- 7 PCKL2 periods + 5 LCD_CLK periods (five HCLK periods for register on AHB clock domain) for register read access

For registers on PCLK2 clock domain, APB2 bus is stalled for six PCKL2 periods during the register write accesses, and for seven PCKL2 periods during read accesses.

The LCD controller can be reset by setting the corresponding bit in the RCC_APB2RSTR register. It resets the three clock domains.

### 29.5 LTDC programmable parameters

The LCD-TFT controller provides flexible configurable parameters. It can be enabled or disabled through the LTDC_GCR register.

### 29.5.1 LTDC global configuration parameters

#### Synchronous timings

*Figure 199* presents the configurable timing parameters generated by the synchronous timings generator block presented in the block diagram *Figure 198*. It generates the
horizontal and vertical synchronization timings panel signals, the pixel clock and the data enable signals.

**Figure 199. LCD-TFT synchronous timings**

Note: The HBP and HFP are respectively the horizontal back porch and front porch period. The VBP and the VFP are respectively the vertical back porch and front porch period.

The LCD-TFT programmable synchronous timings are the following:

- HSYNC and VSYNC width: horizontal and vertical synchronization width, configured by programming a value of HSYNC width - 1 and VSYNC width - 1 in the LTDC_SSCR register.
- HBP and VBP: horizontal and vertical synchronization back porch width, configured by programming the accumulated value HSYNC width + HBP - 1 and the accumulated value VSYNC width + VBP - 1 in the LTDC_BPCR register.
- Active width and active height: the active width and active height are configured by programming the accumulated value HSYNC width + HBP + active width - 1 and the accumulated value VSYNC width + VBP + active height - 1 in the LTDC_AWCR register.
- Total width: the total width is configured by programming the accumulated value HSYNC width + HBP + active width + HFP - 1 in the LTDC_TWCR register. The HFP is the horizontal front porch period.
- Total height: the total height is configured by programming the accumulated value VSYNC height + VBP + active height + VFP - 1 in the LTDC_TWCR register. The VFP is the vertical front porch period.

**Note:** When the LTDC is enabled, the timings generated start with X/Y=0/0 position as the first horizontal synchronization pixel in the vertical synchronization area and following the back
porch, active data display area and the front porch.
When the LTDC is disabled, the timing generator block is reset to X = total width - 1, 
Y = total height - 1 and held the last pixel before the vertical synchronization phase and the 
FIFO are flushed. Therefore only blanking data is output continuously.

Example of synchronous timings configuration

LCD-TFT timings (must be extracted from panel datasheet):
- horizontal and vertical synchronization width: 0xA pixels and 0x2 lines
- horizontal and vertical back porch: 0x14 pixels and 0x2 lines
- active width and active height: 0x140 pixels, 0xF0 lines (320x240)
- horizontal front porch: 0xA pixels
- vertical front porch: 0x4 lines

The programmed values in the LTDC timings registers are:
- LTDC_SSCR register to be programmed to 0x00090001
  (HSW[11:0] is 0x9 and VSH[10:0] is 0x1)
- LTDC_BPCR register to be programmed to 0x001D0003
  (AHBP[11:0] is 0x1D (0xA+ 0x13) and AVBP[10:0]A is 0x3 (0x2 + 0x1))
- LTDC_AWCR register to be programmed to 0x015D00F3
  (AAW[11:0] is 0x15D (0xA +0x14 +0x13F) and AAH[10:0] is 0xF3 (0x2 + 0x2 + 0xEF))
- LTDC_TWCR register to be programmed to 0x00000167
  (TOTALW[11:0] is 0x167 (0xA +0x14 +0x140 + 0x9))
- LTDC_THCR register to be programmed to 0x000000F7
  (TOTALH[10:0] is 0xF7 (0x2 +0x2 + 0xF0 + 3))

Programmable polarity

The horizontal and vertical synchronization, data enable and pixel clock output signals 
polarity can be programmed to active high or active low through the LTDC_GCR register.

Background color

A constant background color (RGB888) can programmed through the LTDC_BCCR register.
It is used for blending with the bottom layer.

Dithering

The dithering pseudo-random technique using an LFSR is used to add a small random 
value (threshold) to each pixel color channel (R, G or B) value, thus rounding up the MSB in 
some cases when displaying a 24-bit data on 18-bit display. Thus the dithering technique is 
used to round data which is different from one frame to the other.

The dithering pseudo-random technique is the same as comparing LSBs against a 
threshold value and adding a 1 to the MSB part only, if the LSB part is ≥ the threshold. The 
LSBs are typically dropped once dithering was applied.

The width of the added pseudo-random value is two bits for each color channel: two bits for 
red, two bits for green and two bits for blue.

Once the LCD-TFT controller is enabled, the LFSR starts running with the first active pixel 
and it is kept running even during blanking periods and when dithering is switched off. If the 
LTDC is disabled, the LFSR is reset.
The dithering can be switched on and off on the fly through the LTDC_GCR register.

**Reload shadow registers**

Some configuration registers are shadowed. The shadow registers values can be reloaded immediately to the active registers when writing to these registers or at the beginning of the vertical blanking period following the configuration in the LTDC_SRCR register. If the immediate reload configuration is selected, the reload must be activated only when all new registers have been written.

The shadow registers must not be modified again before the reload is done. Reading from the shadow registers returns the actual active value. The new written value can only be read after the reload has taken place.

A register reload interrupt can be generated if enabled in the LTDC_IER register.

The shadowed registers are all layer1 and layer2 registers except LTDC_LxCLUTWR.

**Interrupt generation event**

Refer to [Section 29.6: LTDC interrupts](#) for the interrupt configuration.

### 29.5.2 Layer programmable parameters

Up to two layers can be enabled, disabled and configured separately. The layer display order is fixed and it is bottom up. If two layers are enabled, the layer2 is the top displayed window.

**Windowing**

Every layer can be positioned and resized and it must be inside the active display area.

The window position and size are configured through the top-left and bottom-right X/Y positions and the internal timing generator that includes the synchronous, back porch size and the active data area. Refer to LTDC_LxWHPCR and LTDC_WVPCR registers.
The programmable layer position and size defines the first/last visible pixel of a line and the first/last visible line in the window. It allows to display either the full image frame or only a part of the image frame (see the figure below):

- The first and the last visible pixel in the layer are set by configuring the WHSTPOS[11:0] and WHSPPOS[11:0] in the LTDC_LxWHPCR register.
- The first and the last visible lines in the layer are set by configuring the WVSTPOS[10:0] and WVSPPOS[10:0] in the LTDC_LxWVPCR register.

**Figure 200. Layer window programmable parameters**

### Pixel input format

The programmable pixel format is used for the data stored in the frame buffer of a layer. Up to height input pixel formats can be configured for every layer through the LTDC_LxPFCR register.

The pixel data is read from the frame buffer and then transformed to the internal 8888 (ARGB) format as follows: components having a width of less than 8 bits get expanded to 8 bits by bit replication. The selected bit range is concatenated multiple times until it is longer than 8 bits. Of the resulting vector, the 8 MSB bits are chosen. Example: 5 bits of an RGB565 red channel become (bit positions) 43210432 (the three LSBs are filled with the three MSBs of the five bits)

The table below describes the pixel data mapping depending on the selected format.

**Table 196. Pixel data mapping versus color format**

**Table 196. Pixel data mapping versus color format (continued)**
**Color look-up table (CLUT)**

The CLUT can be enabled at run-time for every layer through the LTDC_LxCR register and it is only useful in case of indexed color when using the L8, AL44 and AL88 input pixel format.

First, the CLUT must be loaded with the R, G and B values that replace the original R, G, B values of that pixel (indexed color). Each color (RGB value) has its own address that is the position within the CLUT.

The R, G and B values and their own respective address are programmed through the LTDC_LxCLUTWR register:

- In case of L8 and AL88 input pixel format, the CLUT must be loaded by 256 colors. The address of each color is configured in the CLUTADD bits in the LTDC_LxCLUTWR register.
- In case of AL44 input pixel format, the CLUT must be loaded by only 16 colors. The address of each color must be filled by replicating the 4-bit L channel to 8-bit as follows:
  - L0 (indexed color 0), at address 0x00
  - L1, at address 0x11
  - L2, at address 0x22
  - ...
  - L15, at address 0xFF

**Color frame buffer address**

Every layer has a start address for the color frame buffer configured through the LTDC_LxCFBAR register.

When a layer is enabled, the data is fetched from the color frame buffer.

**Color frame buffer length**

Every layer has a total line length setting for the color frame buffer in bytes and a number of lines in the frame buffer configurable in the LTDC_LxCFBLR and LTDC_LxCFBLNR register respectively.

The line length and the number of lines settings are used to stop the prefetching of data to the layer FIFO at the end of the frame buffer:

- If it is set to less bytes than required, a FIFO underrun interrupt is generated if it has been previously enabled.
- If it is set to more bytes than actually required, the useless data read from the FIFO is discarded. The useless data is not displayed.

**Color frame buffer pitch**

Every layer has a configurable pitch for the color frame buffer, that is the distance between the start of one line and the beginning of the next line in bytes. It is configured through the LTDC_LxCFBLR register.
Layer blending

The blending is always active and the two layers can be blended following the blending factors configured through the LTDC_LxBFCR register.

The blending order is fixed and it is bottom up. If two layers are enabled, first the Layer1 is blended with the Background color, then the layer2 is blended with the result of blended color of layer1 and the background. Refer to the figure below.

![Figure 201. Blending two layers with background](image)

Default color

Every layer can have a default color in the format ARGB which is used outside the defined layer window or when a layer is disabled.

The default color is configured through the LTDC_LxDCCR register.

The blending is always performed between the two layers even when a layer is disabled. To avoid displaying the default color when a layer is disabled, keep the blending factors of this layer in the LTDC_LxBFCR register to their reset value.

Color keying

A color key (RGB) can be configured to be representative for a transparent pixel.

If the color keying is enabled, the current pixels (after format conversion and before CLUT respectively blending) are compared to the color key. If they match for the programmed RGB value, all channels (ARGB) of that pixel are set to 0.

The color key value can be configured and used at run-time to replace the pixel RGB value.

The color keying is enabled through the LTDC_LxCKCR register.

The color keying is configured through the LTDC_LxCKCR register. The programmed value depends on the pixel format as it is compared to current pixel after pixel format conversion to ARGB888.

**Example:** if the a mid-yellow color (50 % red + 50 % green) is used as the transparent color key:

- In RGB565, the mid-yellow color is 0x8400. Set the LTDC_LxCKCR to 0x848200.
- In ARGB8888, the mid-yellow color is 0x808000. Set LTDC_LxCKCR to 0x808000.
- In all CLUT-based color modes (L8, AL88, AL44), set one of the palette entry to the mid-yellow color 0x808000 and set the LTDC_LxCKCR to 0x808000.
29.6 LTDC interrupts

The LTDC provides four maskable interrupts logically ORed to two interrupt vectors. The interrupt sources can be enabled or disabled separately through the LTDC_IER register. Setting the appropriate mask bit to 1 enables the corresponding interrupt.

The two interrupts are generated on the following events:

- Line interrupt: generated when a programmed line is reached. The line interrupt position is programmed in the LTDC_LIPCR register
- Register reload interrupt: generated when the shadow registers reload is performed during the vertical blanking period
- FIFO underrun interrupt: generated when a pixel is requested from an empty layer FIFO
- Transfer error interrupt: generated when an AHB bus error occurs during data transfer

Those interrupts events are connected to the NVIC controller as described in the figure below.

![Figure 202. Interrupt events](ms19678v1.png)

29.7 **LTDC programming procedure**

The steps listed below are needed to program the LTDC:

1. Enable the LTDC clock in the RCC register.
2. Configure the required pixel clock following the panel datasheet.
3. Configure the synchronous timings: VSYNC, HSYNC, vertical and horizontal back porch, active data area and the front porch timings following the panel datasheet as described in the [Section 29.5.1: LTDC global configuration parameters](#).
4. Configure the synchronous signals and clock polarity in the LTDC_GCR register.
5. If needed, configure the background color in the LTDC_BCCR register.
6. Configure the needed interrupts in the LTDC_IER and LTDC_LIPCR register.
7. Configure the layer1/2 parameters by:
   - programming the layer window horizontal and vertical position in the LTDC_LxWHPCR and LTDC_WVPCR registers. The layer window must be in the active data area.
   - programming the pixel input format in the LTDC_LxPFCR register
   - programming the color frame buffer start address in the LTDC_LxCFBAR register
   - programming the line length and pitch of the color frame buffer in the LTDC_LxCFBLR register
   - programming the number of lines of the color frame buffer in the LTDC_LxCFBLNR register
   - if needed, loading the CLUT with the RGB values and its address in the LTDC_LxCLUTWR register
   - If needed, configuring the default color and the blending factors respectively in the LTDC_LxDCCR and LTDC_LxBFCR registers
8. Enable layer1/2 and if needed the CLUT in the LTDC_LxCR register.
9. If needed, enable dithering and color keying respectively in the LTDC_GCR and LTDC_LxCKCR registers. They can be also enabled on the fly.
10. Reload the shadow registers to active register through the LTDC_SRCR register.
11. Enable the LCD-TFT controller in the LTDC_GCR register.
12. All layer parameters can be modified on the fly except the CLUT. The new configuration must be either reloaded immediately or during vertical blanking period by configuring the LTDC_SRCR register.

*Note:* All layer's registers are shadowed. Once a register is written, it must not be modified again before the reload has been done. Thus, a new write to the same register overrides the previous configuration if not yet reloaded.
29.8 LTDC registers

29.8.1 LTDC synchronization size configuration register (LTDC_SSCR)

This register defines the number of horizontal synchronization pixels minus 1 and the number of vertical synchronization lines minus 1. Refer to Figure 199 and Section 29.5: LTDC programmable parameters for an example of configuration.

Address offset: 0x08

Reset value: 0x0000 0000

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **HSW[11:0]**: horizontal synchronization width (in units of pixel clock period)
These bits define the number of Horizontal Synchronization pixel minus 1.

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:0 **VSH[10:0]**: vertical synchronization height (in units of horizontal scan line)
These bits define the vertical Synchronization height minus 1. It represents the number of horizontal synchronization lines.
29.8.2 LTDC back porch configuration register (LTDC_BPCR)

This register defines the accumulated number of horizontal synchronization and back porch pixels minus 1 (HSYNC width + HBP - 1) and the accumulated number of vertical synchronization and back porch lines minus 1 (VSYNC height + VBP - 1). Refer to Figure 199 and Section 29.5: LTDC programmable parameters for an example of configuration.

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **AHBP[11:0]**: accumulated horizontal back porch (in units of pixel clock period)

These bits define the accumulated horizontal back porch width that includes the horizontal synchronization and horizontal back porch pixels minus 1.

The horizontal back porch is the period between horizontal synchronization going inactive and the start of the active display part of the next scan line.

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:0 **AVBP[10:0]**: accumulated Vertical back porch (in units of horizontal scan line)

These bits define the accumulated vertical back porch width that includes the vertical synchronization and vertical back porch lines minus 1.

The vertical back porch is the number of horizontal scan lines at a start of frame to the start of the first active scan line of the next frame.
29.8.3 LTDC active width configuration register (LTDC_AWCR)

This register defines the accumulated number of horizontal synchronization, back porch and active pixels minus 1 (HSYNC width + HBP + active width - 1) and the accumulated number of vertical synchronization, back porch lines and active lines minus 1 (VSYNC height + BVBP + active height - 1). Refer to Figure 199 and Section 29.5: LTDC programmable parameters for an example of configuration.

Bits 31:28 Reserved, must be kept at reset value.
Bits 27:16 **AAW[11:0]**: accumulated active width (in units of pixel clock period)
These bits define the accumulated active width which includes the horizontal synchronization, horizontal back porch and active pixels minus 1.
The active width is the number of pixels in active display area of the panel scan line.
Refer to device datasheet for maximum active width supported following maximum pixel clock.

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:0 **AAH[10:0]**: accumulated active height (in units of horizontal scan line)
These bits define the accumulated height which includes the vertical synchronization, vertical back porch and the active height lines minus 1. The active height is the number of active lines in the panel.
Refer to device datasheet for maximum active height supported following maximum pixel clock.
29.8.4 LTDC total width configuration register (LTDC_TWCR)

This register defines the accumulated number of horizontal synchronization, back porch, active and front porch pixels minus 1 (HSYNC width + HBP + active width + HFP - 1) and the accumulated number of vertical synchronization, back porch lines, active and front lines minus 1 (VSYNC height + BVBP + active height + VFP - 1). Refer to Figure 199 and Section 29.5: LTDC programmable parameters for an example of configuration.

VBR  IMR
rw  rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 VBR: vertical blanking reload
This bit is set by software and cleared only by hardware after reload (it cannot be cleared through register write once it is set).
0: no effect
1: The shadow registers are reloaded during the vertical blanking period (at the beginning of the first line after the active display area).

Bit 0 IMR: immediate reload
This bit is set by software and cleared only by hardware after reload.
0: no effect
1: The shadow registers are reloaded immediately.

Note: The shadow registers read back the active values. Until the reload has been done, the 'old' value is read.

29.8.7 LTDC background color configuration register (LTDC_BCCR)

This register defines the background color (RGB888).

Address offset: 0x2C
Reset value: 0x0000 0000

Note: The shadow registers read back the active values. Until the reload has been done, the 'old' value is read.
Bits 31:24  Reserved, must be kept at reset value.

Bits 23:16  **BCRED[7:0]**: background color red value
These bits configure the background red value.

Bits 15:8  **BCGREEN[7:0]**: background color green value
These bits configure the background green value.

Bits 7:0  **BCBLUE[7:0]**: background color blue value
These bits configure the background blue value.

### 29.8.8  LTDC interrupt enable register (LTDC_IER)

This register determines which status flags generate an interrupt request by setting the corresponding bit to 1.

Address offset: 0x34

Reset value: 0x0000 0000

<table>

914/2298  
RM0432 Rev 8
29.8.11 LTDC line interrupt position configuration register (LTDC_LIPCR)

This register defines the position of the line interrupt. The line value to be programmed depends on the timings parameters. Refer to Figure 199.

Address offset: 0x40

Reset value: 0x0000 0000

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:0 LIPOS[10:0]: line interrupt position

These bits configure the line interrupt position.

29.8.12 LTDC current position status register (LTDC_CPSR)

Address offset: 0x44

Reset value: 0x0000 0000

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 CRRIF: clears register reload interrupt flag
0: no effect
1: clears the RRIF flag in the LTDC_ISR register

Bit 2 CTERRIF: clears the transfer error interrupt flag
0: no effect
1: clears the TERRIF flag in the LTDC_ISR register.

Bit 1 CFUIF: clears the FIFO underrun interrupt flag
0: no effect
1: clears the FUDERRIF flag in the LTDC_ISR register.

Bit 0 CLIF: clears the line interrupt flag
0: no effect
1: clears the LIF flag in the LTDC_ISR register.
29.8.13 LTDC current display status register (LTDC_CDSR)

This register returns the status of the current display phase which is controlled by the HSYNC, VSYNC, and horizontal/vertical DE signals.

Example: if the current display phase is the vertical synchronization, the VSYNCS bit is set (active high). If the current display phase is the horizontal synchronization, the HSYNCS bit is active high.

Address offset: 0x48
Reset value: 0x0000 000F

| Bits 31:16 | CXPOS[15:0]: current X position |
| These bits return the current X position. |
| Bits 15:0 | CYPOS[15:0]: current Y position |
| These bits return the current Y position. |

| Bits 31:4 | Reserved, must be kept at reset value. |
| Bit 3 | HSYNCS: horizontal synchronization display status |
| 0: active low |
| 1: active high |
| Bit 2 | VSYNCS: vertical synchronization display status |
| 0: active low |
| 1: active high |
| Bit 1 | HDES: horizontal data enable display status |
| 0: active low |
| 1: active high |
| Bit 0 | VDES: vertical data enable display status |
| 0: active low |
| 1: active high |

Note: The returned status does not depend on the configured polarity in the LTDC_GCR register, instead it returns the current active display phase.

29.8.14 LTDC layer x control register (LTDC_LxCR)

Address offset: 0x84 + 0x80 * (x - 1), (x = 1 to 2)
Reset value: 0x0000 0000
# 29.8.15 LTDC layer x window horizontal position configuration register (LTDC_LxWHPCR)

This register defines the horizontal position (first and last pixel) of the layer 1 or 2 window.

The first visible pixel of a line is the programmed value of AHBP[11:0] bits + 1 in the LTDC_BPCR register.

The last visible pixel of a line is the programmed value of AAW[11:0] bits in the LTDC_AWCR register.

Address offset: 0x88 + 0x80 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

| Bit 31:5 | Reserved, must be kept at reset value. |
| Bit 4   | **CLUTEN**: color look-up table enable |
|         | This bit is set and cleared by software. |
|         | 0: color look-up table disable |
|         | 1: color look-up table enable |
|         | The CLUT is only meaningful for L8, AL44 and AL88 pixel format. Refer to [Color look-up table (CLUT)](link) |
| Bit 3:2 | Reserved, must be kept at reset value. |
| Bit 1   | **COLKEN**: color keying enable |
|         | This bit is set and cleared by software. |
|         | 0: color keying disable |
|         | 1: color keying enable |
| Bit 0   | **LEN**: layer enable |
|         | This bit is set and cleared by software. |
|         | 0: layer disable |
|         | 1: layer enable |

The LTDC_BPCR register is configured to 0x000E0005 (AHBP[11:0] is 0xE) and the LTDC_AWCR register is configured to 0x028E01E5 (AAW[11:0] is 0x28E). To configure the horizontal position of a window size of 630x460, with horizontal start offset of 5 pixels in the active data area:

1. layer window first pixel, WHSTPOS[11:0], must be programmed to 0x14 (0xE+1+0x5)
2. layer window last pixel, WHSPPOS[11:0], must be programmed to 0x28A.

29.8.16 LTDC layer x window vertical position configuration register (LTDC_LxWVPCR)

This register defines the vertical position (first and last line) of the layer1 or 2 window.

The first visible line of a frame is the programmed value of AVBP[10:0] bits + 1 in the register LTDC_BPCR register.

The last visible line of a frame is the programmed value of AAH[10:0] bits in the LTDC_AWCR register.

Address offset: 0x8C + 0x80 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bits 31:27 Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits 26:16 WVSPPOS[10:0]: window vertical stop position</td>
</tr>
<tr>
<td>These bits configure the last visible line of the layer window.</td>
</tr>
<tr>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>Bits 15:11 Reserved, must be kept at reset value.</td>
</tr>
<tr>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>Bits 10:0 WVSTPOS[10:0]: window vertical start position</td>
</tr>
<tr>
<td>These bits configure the first visible line of the layer window.</td>
</tr>
<tr>
<td>WVSTPOS[10:0] must be ≤ AAH[10:0] bits (programmed in LTDC_AWCR register).</td>
</tr>
</tbody>
</table>
**Example:**

The LTDC_BPCR register is configured to 0x000E0005 (AVBP[10:0] is 0x5) and the LTDC_AWCR register is configured to 0x028E01E5 (AAH[10:0] is 0x1E5).

To configure the vertical position of a window size of 630x460, with vertical start offset of 8 lines in the active data area:
1. layer window first line: WVSTPOS[10:0] must be programmed to 0xE (0x5 + 1 + 0x8).
2. layer window last line: WVSTPOS[10:0] must be programmed to 0x1DA.

### 29.8.17 LTDC layer x color keying configuration register (LTDC_LxCKCR)

This register defines the color key value (RGB), that is used by the color keying.

**Address offset:** 0x90 + 0x80 * (x - 1), (x = 1 to 2)

**Reset value:** 0x0000 0000

Bits 31:24  Reserved, must be kept at reset value.

Bits 23:16  **CKRED[7:0]:** color key red value

Bits 15:8  **CKGREEN[7:0]:** color key green value

Bits 7:0  **CKBLUE[7:0]:** color key blue value

### 29.8.18 LTDC layer x pixel format configuration register (LTDC_LxPFCR)

This register defines the pixel format that is used for the stored data in the frame buffer of a layer. The pixel data is read from the frame buffer and then transformed to the internal format 8888 (ARGB).

**Address offset:** 0x94 + 0x80 * (x - 1), (x = 1 to 2)

**Reset value:** 0x0000 0000

</tbody>
</table>
This register defines the constant alpha value (divided by 255 by hardware), that is used in the alpha blending. Refer to LTDC_LxBFCR register.

Address offset: 0x98 + 0x80 * (x - 1), (x = 1 to 2)
Reset value: 0x0000 00FF

### Bits 2:0 PF[2:0]: pixel format

These bits configure the pixel format:
- 000: ARGB8888
- 001: RGB888
- 010: RGB565
- 011: ARGB1555
- 100: ARGB4444
- 101: L8 (8-bit luminance)
- 110: AL44 (4-bit alpha, 4-bit luminance)
- 111: AL88 (8-bit alpha, 8-bit luminance)

### 29.8.19 LTDC layer x constant alpha configuration register (LTDC_LxCACR)

This register defines the constant alpha value (divided by 255 by hardware), that is used in the alpha blending. Refer to LTDC_LxBFCR register.

Address offset: 0x98 + 0x80 * (x - 1), (x = 1 to 2)
Reset value: 0x0000 00FF

<table>

</tbody>
</table>

### Bits 7:0 CONSTA[7:0]: constant alpha

These bits configure the constant alpha used for blending. The constant alpha is divided by 255 by hardware.

Example: if the programmed constant alpha is 0xFF, the constant alpha value is 255 / 255 = 1.
29.8.20  LTDC layer x default color configuration register (LTDC_LxDCCR)

This register defines the default color of a layer in the format ARGB. The default color is used outside the defined layer window or when a layer is disabled. The reset value of 0x00000000 defines a transparent black color.

Address offset: 0x9C + 0x80 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

</table>

- Bits 31:24  **DCALPHA[7:0]**: default color alpha
  These bits configure the default alpha value.

- Bits 23:16  **DCRED[7:0]**: default color red
  These bits configure the default red value.

- Bits 15:8  **DCGREEN[7:0]**: default color green
  These bits configure the default green value.

- Bits 7:0  **DCBLUE[7:0]**: default color blue
  These bits configure the default blue value.
29.8.21 LTDC layer x blending factors configuration register (LTDC_LxBFCR)

This register defines the blending factors F1 and F2.

The general blending formula is: \( BC = BF1 \times C + BF2 \times Cs \)

- \( BC = \) blended color
- \( BF1 = \) blend factor 1
- \( C = \) current layer color
- \( BF2 = \) blend factor 2
- \( Cs = \) subjacent layers blended color

Address offset: \( 0xA0 + 0x80 \times (x - 1) \), \( x = 1 \) to 2

Reset value: 0x0000 0607

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:8 **BF1[2:0]**: blending factor 1

These bits select the blending factor F1.
- 000: reserved
- 001: reserved
- 010: reserved
- 011: reserved
- 100: constant alpha
- 101: reserved
- 110: pixel alpha x constant alpha
- 111: reserved

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **BF2[2:0]**: blending factor 2

These bits select the blending factor F2
- 000: reserved
- 001: reserved
- 010: reserved
- 011: reserved
- 100: reserved
- 101: 1 - constant alpha
- 110: reserved
- 111: 1 - (pixel alpha x constant alpha)
Note: The constant alpha value, is the programmed value in the LxCACR register divided by 255 by hardware.

Example: Only layer1 is enabled, BF1 configured to constant alpha. BF2 configured to 1 - constant alpha. The constant alpha programmed in the LxCACR register is 240 (0xF0). Thus, the constant alpha value is 240/255 = 0.94. C: current layer color is 128. Cs: background color is 48. Layer1 is blended with the background color. 
BC = constant alpha x C + (1 - Constant Alpha) x Cs = 0.94 x 128 + (1- 0.94) x 48 = 123.

29.8.22 LTDC layer x color frame buffer address register (LTDC_LxCFBAR)

This register defines the color frame buffer start address which has to point to the address where the pixel data of the top left pixel of a layer is stored in the frame buffer.

Address offset: 0xAC + 0x80 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

CFBADD[15:0]

Bits 31:0 CFBADD[31:0]: color frame buffer start address
These bits define the color frame buffer start address.

29.8.23 LTDC layer x color frame buffer length register (LTDC_LxCFBLR)

This register defines the color frame buffer line length and pitch.

Address offset: 0xB0 + 0x80 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

| Res | Res | Res | CFBLL[12:0] |
| rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:16 CFBP[12:0]: color frame buffer pitch in bytes
These bits define the pitch that is the increment from the start of one line of pixels to the start of the next line in bytes.

Bits 15:13 Reserved, must be kept at reset value.
Example:

- A frame buffer having the format RGB565 (2 bytes per pixel) and a width of 256 pixels (total number of bytes per line is 256 * 2 = 512), where pitch = line length requires a value of 0x02000203 to be written into this register.
- A frame buffer having the format RGB888 (3 bytes per pixel) and a width of 320 pixels (total number of bytes per line is 320 * 3 = 960), where pitch = line length requires a value of 0x03C003C3 to be written into this register.

29.8.24 LTDC layer x color frame buffer line number register (LTDC\_LxCFBLNR)

This register defines the number of lines in the color frame buffer.

Address offset: 0xB4 + 0x80 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

Bits 12:0 CFBLL[12:0]: color frame buffer line length

These bits define the length of one line of pixels in bytes + 3.

The line length is computed as follows:

active high width * number of bytes per pixel + 3.

Note:

The number of lines and line length settings define how much data is fetched per frame for every layer. If it is configured to less bytes than required, a FIFO underrun interrupt is generated if enabled.

The start address and pitch settings on the other hand define the correct start of every line in memory.
29.8.25 LTDC layer x CLUT write register (LTDC_LxCLUTWR)

This register defines the CLUT address and the RGB value.
Address offset: 0xC4 + 0x80 * (x - 1), (x = 1 to 2)
Reset value: 0x0000 0000

Note: The CLUT write register must be configured only during blanking period or if the layer is disabled. The CLUT can be enabled or disabled in the LTDC_LxCR register. The CLUT is only meaningful for L8, AL44 and AL88 pixel format.

29.8.26 LTDC register map

Table 198. LTDC register map and reset values

| Offset | Register name | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| 0x010  | LTDC_AWCR     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| Reset value | | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 0x014  | LTDC_TWCR     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| Reset value | | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

Bits 31:24 CLUTADD[7:0]: CLUT address
These bits configure the CLUT address (color position within the CLUT) of each RGB value.

Bits 23:16 RED[7:0]: red value
These bits configure the red value.

Bits 15:8 GREEN[7:0]: green value
These bits configure the green value.

Bits 7:0 BLUE[7:0]: blue value
These bits configure the blue value.

Note: The CLUT write register must be configured only during blanking period or if the layer is disabled. The CLUT can be enabled or disabled in the LTDC_LxCR register. The CLUT is only meaningful for L8, AL44 and AL88 pixel format.
