Introduction

This reference manual targets application developers. It provides complete information on how to use the STM32L552xx and STM32L562xx microcontrollers memory and peripherals.

STM32L552xx and STM32L562xx belong to the STM32L5x2 line of microcontrollers with different memory sizes, packages and peripherals.

For ordering information, mechanical and electrical device characteristics please refer to the corresponding datasheets.

For information on the Arm® Cortex®-M33 core, refer to the Cortex®-M33 Technical Reference manual.

13 Peripherals interconnect matrix ................................. 472
13.1 Introduction ...................................................... 472
13.2 Connection summary ............................................. 472
13.3 Interconnection details .......................................... 473
  13.3.1 From timer (TIM1/TIM2/TIM3/TIM4/TIM5/TIM8/TIM15/TIM16/TIM17) to timer (TIM1/TIM2/TIM3/TIM4/TIM5/TIM8/TIM15) .......... 473
  13.3.2 From timer (TIM1/TIM2/TIM3/TIM4/TIM5/TIM8/TIM15) and EXTI to ADC (ADC1/ADC2) ............................................. 474
  13.3.3 From ADC1/ADC2 to timer (TIM1/TIM8) ....................... 474
  13.3.4 From timer (TIM2/TIM4/TIM5/TIM6/TIM7/TIM8) and EXTI to DAC (DAC1/DAC2) ..................................................... 475
  13.3.5 From timer (TIM1/TIM3/TIM4/TIM6/TIM8/TIM16/LPTIM1) and EXTI to DFSDM1 ......................................................... 475
  13.3.6 From DFSDM1 to timer (TIM1/TIM8/TIM15/TIM16/TIM17) ..... 476
  13.3.7 From HSE, LSE, LSI, MSI, MCO, RTC to timer (TIM2/TIM15/TIM16/TIM17) ...................................................... 476
  13.3.8 From RTC, COMP1, COMP2 to low-power timer (LPTIM1/LPTIM2/LPTIM3) ...................................................... 477
  13.3.9 From timer (TIM1/TIM2/TIM3/TIM8/TIM15) to comparators (COMP1/COMP2) ..................................................... 477
  13.3.10 From ADC (ADC1) to ADC (ADC2) .......................... 477
  13.3.11 From USB to timer (TIM2) ................................... 478
  13.3.12 From internal analog source to ADC (ADC1/ADC2) and OPAMP (OPAMP1/OPAM2) .................................................. 478
  13.3.13 From comparators (COMP1/COMP2) to timers (TIM1/TIM2/TIM3/TIM8/TIM15/TIM16/TIM17) ........................................ 478
  13.3.14 From system errors to timers (TIM1/TIM8/TIM15/TIM16/TIM17) .... 479
  13.3.15 From timers (TIM16/TIM17) to IRTIM ....................... 479
  13.3.16 From ADC (ADC1/ADC2) to DFSDM .......................... 480

14 Direct memory access controller (DMA) ......................... 481
14.1 Introduction ...................................................... 481
14.2 DMA main features ............................................... 481
14.3 DMA implementation ............................................. 482
  14.3.1 DMA1 and DMA2 ............................................. 482
  14.3.2 DMA request mapping ....................................... 482
14.4 DMA functional description ........................................ 483
14.4.1 DMA block diagram ........................................... 483
14.4.2 DMA pins and internal signals ............................... 484
14.4.3 DMA transfers .................................................. 484
14.4.4 DMA arbitration ............................................... 485
14.4.5 DMA channels .................................................. 486
14.4.6 DMA data width, alignment and endianness ............... 491
14.4.7 DMA error management ....................................... 492
14.5 DMA interrupts .................................................. 493
14.6 DMA registers .................................................... 493
14.6.1 DMA interrupt status register (DMA_ISR) .................. 493
14.6.2 DMA interrupt flag clear register (DMA_IFCR) .......... 497
14.6.3 DMA channel x configuration register (DMA_CCRx) ..... 498
14.6.4 DMA channel x number of data to transfer register (DMA_CNDTRx) . 503
14.6.5 DMA channel x peripheral address register (DMA_CPARx) ........ 504
14.6.6 DMA channel x memory 0 address register (DMA_CM0ARx) .... 504
14.6.7 DMA channel x memory 1 address register (DMA_CM1ARx) .... 505
14.6.8 DMA register map ............................................ 505

15 DMA request multiplexer (DMAMUX) .............................. 509
15.1 Introduction ..................................................... 509
15.2 DMAMUX main features ........................................ 510
15.3 DMAMUX implementation ....................................... 510
15.3.1 DMAMUX instantiation ...................................... 510
15.3.2 DMAMUX mapping .......................................... 511
15.4 DMAMUX functional description ................................ 514
15.4.1 DMAMUX block diagram .................................... 514
15.4.2 DMAMUX signals ............................................. 515
15.4.3 DMAMUX channels .......................................... 515
15.4.4 DMAMUX secure/non-secure channels ..................... 516
15.4.5 DMAMUX privileged / unprivileged channels ............. 516
15.4.6 DMAMUX request line multiplexer ......................... 516
15.4.7 DMAMUX request generator ................................. 519
15.5 DMAMUX interrupts ............................................. 520
15.6 DMAMUX registers .............................................. 522
15.6.1 DMAMUX request line multiplexer channel x configuration register (DMAMUX_CxCR) ................................................. 522
15.6.2 DMAMUX request line multiplexer interrupt channel status register (DMAMUX_CSR) ........................................... 523
15.6.3 DMAMUX request line multiplexer interrupt channel clear flag register (DMAMUX_CCFR) ........................................ 523
15.6.4 DMAMUX request generator channel x configuration register (DMAMUX_RGxCR) ..................................................... 524
15.6.5 DMAMUX request generator interrupt status register (DMAMUX_RGSR) ................................................................. 525
15.6.6 DMAMUX request generator interrupt clear flag register (DMAMUX_RGCFR) ......................................................... 526
15.6.7 DMAMUX register map ................................................................. 527

16 Nested vectored interrupt controller (NVIC) ......................... 529
16.1 NVIC main features ................................................................. 529
16.2 SysTick calibration value register ........................................... 529
16.3 Interrupt and exception vectors ............................................ 530

17 Extended interrupts and event controller (EXTI) .................... 534
17.1 EXTI main features ............................................................... 534
17.2 EXTI block diagram ............................................................. 535
17.2.1 EXTI connections between peripherals and CPU ................. 536
17.2.2 EXTI interrupt/event mapping ............................................. 536
17.3 EXTI functional description .................................................... 538
17.3.1 EXTI configurable event input wakeup ............................... 538
17.3.2 EXTI direct event input wakeup ........................................... 540
17.3.3 EXTI mux selection ............................................................ 540
17.4 EXTI functional behavior ....................................................... 541
17.5 EXTI event protection ........................................................... 542
17.5.1 EXTI security protection ..................................................... 542
17.5.2 EXTI privilege protection ................................................... 543
17.6 EXTI registers ..................................................................... 544
17.6.1 EXTI rising trigger selection register (EXTI_RTSR1) .......... 544
17.6.2 EXTI falling trigger selection register (EXTI_FTSR1) ............ 545
17.6.3 EXTI software interrupt event register (EXTI_SWIER1) ........ 546
17.6.4 EXTI rising edge pending register (EXTI_RPR1) ................. 547
17.6.5 EXTI falling edge pending register (EXTI_FPR1) ................. 548
18 Cyclic redundancy check calculation unit (CRC) ................. 564

  18.4 CRC registers ............................................... 567
    18.4.1 CRC data register (CRC_DR) ............................ 567
    18.4.2 CRC independent data register (CRC_IDR) ............... 567
    18.4.3 CRC control register (CRC_CR) .......................... 568
    18.4.4 CRC initial value (CRC_INIT) ........................... 569
    18.4.5 CRC polynomial (CRC_POL) ............................... 569
    18.4.6 CRC register map ........................................ 570

19 Flexible static memory controller (FSMC) ....................... 571
  19.1 Introduction ................................................. 571
  19.2 FMC main features .......................................... 571
  19.3 FMC block diagram .......................................... 572
## AHB interface

19.4.1 Supported memories and transactions .......................... 573

## External device address mapping

19.5.1 NOR/PSRAM address mapping ................................. 575
19.5.2 NAND Flash memory address mapping ....................... 576

## NOR Flash/PSRAM controller

19.6.1 External memory interface signals .......................... 578
19.6.2 Supported memories and transactions ...................... 580
19.6.3 General timing rules ........................................ 581
19.6.4 NOR Flash/PSRAM controller asynchronous transactions 582
19.6.5 Synchronous transactions .................................. 599
19.6.6 NOR/PSRAM controller registers ............................ 606

## NAND Flash controller

19.7.1 External memory interface signals .......................... 615
19.7.2 NAND Flash supported memories and transactions ........ 617
19.7.3 Timing diagrams for NAND Flash memory .................. 617
19.7.4 NAND Flash operations ...................................... 618
19.7.5 NAND Flash prewait functionality .......................... 619
19.7.6 Computation of the error correction code (ECC) in NAND Flash memory .......................... 620
19.7.7 NAND Flash controller registers ............................ 621
19.7.8 FMC register map ........................................... 627

## Octo-SPI interface (OCTOSPI)

20.1 Introduction ...................................................... 629
20.2 OCTOSPI main features ........................................ 629
20.3 OCTOSPI implementation ....................................... 630
20.4 OCTOSPI functional description ................................ 631
20.4.1 OCTOSPI block diagram .................................... 631
20.4.2 OCTOSPI interface to memory modes ....................... 632
20.4.3 OCTOSPI Regular-command protocol ....................... 632
20.4.4 OCTOSPI Regular-command protocol signal interface .... 636
20.4.5 HyperBus protocol ........................................... 639
20.4.6 Specific features ............................................. 643
20.4.7 OCTOSPI operating modes introduction .................... 644
20.4.8 OCTOSPI Indirect mode ..................................... 644
20.4.9 OCTOSPI Automatic status-polling mode ................. 646
20.4 Memory-mapped mode
20.4.10 OCTOSPI Memory-mapped mode ................................................. 647
20.4.11 OCTOSPI configuration introduction ........................................... 647
20.4.12 OCTOSPI system configuration ..................................................... 648
20.4.13 OCTOSPI device configuration ...................................................... 648
20.4.14 OCTOSPI Regular-command mode configuration ......................... 649
20.4.15 OCTOSPI HyperBus protocol configuration ................................. 652
20.4.16 OCTOSPI error management ......................................................... 653
20.4.17 OCTOSPI BUSY and ABORT ......................................................... 653
20.4.18 OCTOSPI reconfiguration or deactivation .................................... 654
20.4.19 NCS behavior ............................................................................ 654

20.5 Address alignment and data number .................................................. 656

20.6 OCTOSPI interrupts .......................................................................... 657

20.7 OCTOSPI registers ............................................................................ 657
20.7.1 OCTOSPI control register (OCTOSPI_CR) ...................................... 657
20.7.2 OCTOSPI device configuration register 1 (OCTOSPI_DCR1) ........... 660
20.7.3 OCTOSPI device configuration register 2 (OCTOSPI_DCR2) ........... 661
20.7.4 OCTOSPI device configuration register 3 (OCTOSPI_DCR3) ........... 662
20.7.5 OCTOSPI device configuration register 4 (OCTOSPI_DCR4) ........... 663
20.7.6 OCTOSPI status register (OCTOSPI_SR) ........................................ 663
20.7.7 OCTOSPI flag clear register (OCTOSPI_FCR) .................................. 664
20.7.8 OCTOSPI data length register (OCTOSPI_DLR) ............................... 665
20.7.9 OCTOSPI address register (OCTOSPI_AR) ..................................... 666
20.7.10 OCTOSPI data register (OCTOSPI_DR) .......................................... 666
20.7.11 OCTOSPI polling status mask register (OCTOSPI_PSMKR) ........... 667
20.7.12 OCTOSPI polling status match register (OCTOSPI_PSMAR) ........... 667
20.7.13 OCTOSPI polling interval register (OCTOSPI_PIR) ......................... 668
20.7.14 OCTOSPI communication configuration register (OCTOSPI_CCR) ... 668
20.7.15 OCTOSPI timing configuration register (OCTOSPI_TCR) ............... 670
20.7.16 OCTOSPI instruction register (OCTOSPI_IR) .................................. 671
20.7.17 OCTOSPI alternate bytes register (OCTOSPI_ABR) ....................... 672
20.7.18 OCTOSPI low-power timeout register (OCTOSPI_LPTR) ............... 672
20.7.19 OCTOSPI wrap communication configuration register (OCTOSPI_WPCCR) ............................................................... 673
20.7.20 OCTOSPI wrap timing configuration register (OCTOSPI_WPTCR) ... 675
20.7.21 OCTOSPI wrap instruction register (OCTOSPI_WPIR) ................... 676
20.7.22 OCTOSPI wrap alternate bytes register (OCTOSPI_WPABR) .......... 676
20.7.23 OCTOSPI write communication configuration register (OCTOSPI_WCCR) .......................... 677
20.7.24 OCTOSPI write timing configuration register (OCTOSPI_WTCR) . . . . 679
20.7.25 OCTOSPI write instruction register (OCTOSPI_WIR) ......................... 679
20.7.26 OCTOSPI write alternate bytes register (OCTOSPI_WABR) ............... 680
20.7.27 OCTOSPI HyperBus latency configuration register (OCTOSPI_HLCR) .................... 680
20.7.28 OCTOSPI register map ................................................. 681

21 Analog-to-digital converters (ADC) ............................................. 684
21.1 Introduction ............................................................... 684
21.2 ADC main features .................................................... 685
21.3 ADC implementation .................................................... 686
21.4 ADC functional description ............................................. 687
  21.4.1 ADC block diagram .................................................. 687
  21.4.2 ADC pins and internal signals ..................................... 688
  21.4.3 ADC clocks ........................................................... 689
  21.4.4 ADC1/2 connectivity ................................................ 691
  21.4.5 Slave AHB interface .................................................. 693
  21.4.6 ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN) .................................................. 693
  21.4.7 Single-ended and differential input channels ....................... 693
  21.4.8 Calibration (ADCAL, ADCALDIF, ADC_CALFACT) .................. 694
  21.4.9 ADC on-off control (ADEN, ADDIS, ADRDY) ....................... 697
  21.4.10 Constraints when writing the ADC control bits ................... 698
  21.4.11 Channel selection (SQRx, JSQRx) .................................. 699
  21.4.12 Channel-wise programmable sampling time (SMPR1, SMPR2) ......... 700
  21.4.13 Single conversion mode (CONT=0) .................................. 700
  21.4.14 Continuous conversion mode (CONT=1) .................................. 701

# Advanced-control timers (TIM1/TIM8)

## 33.1 TIM1/TIM8 introduction

## 33.2 TIM1/TIM8 main features

## 33.3 TIM1/TIM8 functional description

### 33.3.1 Time-base unit

### 33.3.2 Counter modes

### 33.3.3 Repetition counter

### 33.3.4 External trigger input

### 33.3.5 Clock selection

### 33.3.6 Capture/compare channels

### 33.3.7 Input capture mode

### 33.3.8 PWM input mode

### 33.3.9 Forced output mode

### 33.3.10 Output compare mode

### 33.3.11 PWM mode

### 33.3.12 Asymmetric PWM mode

### 33.3.13 Combined PWM mode

### 33.3.14 Combined 3-phase PWM mode

### 33.3.15 Complementary outputs and dead-time insertion

### 33.3.16 Using the break function

### 33.3.17 Bidirectional break inputs

### 33.3.18 Clearing the OCxREF signal on an external event

### 33.3.19 6-step PWM generation

### 33.3.20 One-pulse mode

### 33.3.21 Retriggerable one pulse mode

### 33.3.22 Encoder interface mode

### 33.3.23 UIF bit remapping

### 33.3.24 Timer input XOR function

### 33.3.25 Interfacing with Hall sensors

### 33.3.26 Timer synchronization

### 33.3.27 ADC synchronization

### 33.3.28 DMA burst mode

### 33.3.29 Debug mode

## 33.4 TIM1/TIM8 registers

### 33.4.1 TIMx control register 1 (TIMx_CR1)(x = 1, 8)

### 33.4.2 TIMx control register 2 (TIMx_CR2)(x = 1, 8)
33.4.3 TIMx slave mode control register (TIMx_SMCR)(x = 1, 8) .............. 1140
33.4.4 TIMx DMA/interrupt enable register (TIMx_DIER)(x = 1, 8) .......... 1142
33.4.5 TIMx status register (TIMx_SR)(x = 1, 8) ........................... 1144
33.4.6 TIMx event generation register (TIMx_EGR)(x = 1, 8) ............... 1146
33.4.7 TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1)(x = 1, 8) .................................................. 1147
33.4.8 TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1)(x = 1, 8) .................................................. 1148
33.4.9 TIMx capture/compare mode register 2 [alternate] (TIMx_CCMR2)(x = 1, 8) .................................................. 1151
33.4.10 TIMx capture/compare mode register 2 [alternate] (TIMx_CCMR2)(x = 1, 8) .................................................. 1152
33.4.11 TIMx capture/compare enable register (TIMx_CCER)(x = 1, 8) ........ 1154
33.4.12 TIMx counter (TIMx_CNT)(x = 1, 8) .................................. 1157
33.4.13 TIMx prescaler (TIMx_PSC)(x = 1, 8) ................................. 1157
33.4.14 TIMx auto-reload register (TIMx_ARR)(x = 1, 8) ...................... 1157
33.4.15 TIMx repetition counter register (TIMx_RCR)(x = 1, 8) .............. 1158
33.4.16 TIMx capture/compare register 1 (TIMx_CCR1)(x = 1, 8) ............ 1158
33.4.17 TIMx capture/compare register 2 (TIMx_CCR2)(x = 1, 8) ............ 1159
33.4.18 TIMx capture/compare register 3 (TIMx_CCR3)(x = 1, 8) ............ 1159
33.4.19 TIMx capture/compare register 4 (TIMx_CCR4)(x = 1, 8) ............ 1160
33.4.20 TIMx break and dead-time register (TIMx_BDTR)(x = 1, 8) .......... 1160
33.4.21 TIMx DMA control register (TIMx_DCR)(x = 1, 8) .................... 1164
33.4.22 TIMx DMA address for full transfer (TIMx_DMAR)(x = 1, 8) ........ 1165
33.4.23 TIM1 option register 1 (TIM1_OR1) .................................... 1166
33.4.24 TIM8 option register 1 (TIM8_OR1) .................................... 1166
33.4.25 TIMx capture/compare mode register 3 (TIMx_CCMR3)(x = 1, 8) ........ 1167
33.4.26 TIMx capture/compare register 5 (TIMx_CCR5)(x = 1, 8) ............ 1168
33.4.27 TIMx capture/compare register 6 (TIMx_CCR6)(x = 1, 8) ............ 1169
33.4.28 TIM1 option register 2 (TIM1_OR2) .................................... 1169
33.4.29 TIM1 option register 3 (TIM1_OR3) .................................... 1171
33.4.30 TIM8 option register 2 (TIM8_OR2) .................................... 1172
33.4.31 TIM8 option register 3 (TIM8_OR3) .................................... 1174

## 46 Serial peripheral interface (SPI) ........................................... 1699

46.1 Introduction ......................................................... 1699
46.2 SPI main features ................................................... 1699
46.3 SPI implementation .................................................. 1699
46.4 SPI functional description ........................................... 1700
  46.4.1 General description ........................................... 1700
  46.4.2 Communications between one master and one slave ............... 1701
  46.4.3 Standard multi-slave communication ................................ 1703
  46.4.4 Multi-master communication .................................... 1704
  46.4.5 Slave select (NSS) pin management .............................. 1705
  46.4.6 Communication formats ........................................ 1706
  46.4.7 Configuration of SPI .......................................... 1708
  46.4.8 Procedure for enabling SPI .................................... 1709
  46.4.9 Data transmission and reception procedures ..................... 1709
  46.4.10 SPI status flags ............................................. 1719
  46.4.11 SPI error flags ............................................. 1720
  46.4.12 NSS pulse mode ............................................... 1721
  46.4.13 TI mode ..................................................... 1721
  46.4.14 CRC calculation .............................................. 1722
46.5 SPI interrupts ....................................................... 1724
46.6 SPI registers ........................................................... 1725
  46.6.1 SPI control register 1 (SPIx_CR1) ................................ 1725
  46.6.2 SPI control register 2 (SPIx_CR2) ................................ 1727
  46.6.3 SPI status register (SPIx_SR) .................................. 1729
  46.6.4 SPI data register (SPIx_DR) .................................... 1730
  46.6.5 SPI CRC polynomial register (SPIx_CRCPR) ....................... 1731
  46.6.6 SPI Rx CRC register (SPIx_RXCRCR) ............................ 1731
  46.6.7 SPI Tx CRC register (SPIx_TXCRCR) ............................ 1731
  46.6.8 SPI register map ............................................... 1733

## 47 Serial audio interface (SAI) .............................................. 1734

47.1 Introduction ......................................................... 1734
47.2 SAI main features ................................................... 1734
47.3 SAI implementation .................................................. 1735
47.4 SAI functional description .......................................... 1735
  47.4.1 SAI block diagram ............................................ 1735
### SAI pins and internal signals

**47.4.2**  SAI pins and internal signals ............................................. 1737

### Main SAI modes

**47.4.3**  Main SAI modes ................................................................. 1737

### SAI synchronization mode

**47.4.4**  SAI synchronization mode .................................................. 1738

### Audio data size

**47.4.5**  Audio data size ................................................................. 1739

### Frame synchronization

**47.4.6**  Frame synchronization ....................................................... 1740

### Slot configuration

**47.4.7**  Slot configuration .............................................................. 1743

### SAI clock generator

**47.4.8**  SAI clock generator ........................................................... 1745

### Internal FIFOs

**47.4.9**  Internal FIFOs ................................................................. 1748

### PDM Interface

**47.4.10**  PDM Interface ................................................................. 1750

### AC'97 link controller

**47.4.11**  AC'97 link controller ....................................................... 1758

### SPDIF output

**47.4.12**  SPDIF output ................................................................. 1760

### Specific features

**47.4.13**  Specific features ............................................................ 1763

### Error flags

**47.4.14**  Error flags ................................................................. 1767

### Disabling the SAI

**47.4.15**  Disabling the SAI ............................................................ 1770

### SAI DMA interface

**47.4.16**  SAI DMA interface ........................................................... 1770

### SAI interrupts

**47.5**  SAI interrupts ................................................................. 1771

### SAI registers

**47.6**  SAI registers ................................................................. 1773

#### SAI global configuration register (SAI_GCR)

**47.6.1**  SAI global configuration register (SAI_GCR) ............................ 1773

#### SAI configuration register 1 (SAI_ACR1)

**47.6.2**  SAI configuration register 1 (SAI_ACR1) ................................ 1773

#### SAI configuration register 1 (SAI_BCR1)

**47.6.3**  SAI configuration register 1 (SAI_BCR1) ................................ 1776

#### SAI configuration register 2 (SAI_ACR2)

**47.6.4**  SAI configuration register 2 (SAI_ACR2) ................................ 1779

#### SAI configuration register 2 (SAI_BCR2)

**47.6.5**  SAI configuration register 2 (SAI_BCR2) ................................ 1781

#### SAI frame configuration register (SAI_AFRCR)

**47.6.6**  SAI frame configuration register (SAI_AFRCR) ........................... 1783

#### SAI frame configuration register (SAI_BFRCR)

**47.6.7**  SAI frame configuration register (SAI_BFRCR) ........................... 1784

#### SAI slot register (SAI_A SLOT R)

**47.6.8**  SAI slot register (SAI_A SLOT R) ........................................ 1785

#### SAI slot register (SAI_B SLOT R)

**47.6.9**  SAI slot register (SAI_B SLOT R) ........................................ 1786

#### SAI interrupt mask register (SAI_AIM)

**47.6.10**  SAI interrupt mask register (SAI_AIM) ................................... 1787

#### SAI interrupt mask register (SAI_BIM)

**47.6.11**  SAI interrupt mask register (SAI_BIM) ................................... 1789

#### SAI status register (SAI_ASR)

**47.6.12**  SAI status register (SAI_ASR) ........................................... 1790

#### SAI status register (SAI_BSR)

**47.6.13**  SAI status register (SAI_BSR) ........................................... 1792

#### SAI clear flag register (SAI_ACLRFR)

**47.6.14**  SAI clear flag register (SAI_ACLRFR) .................................... 1794

#### SAI clear flag register (SAI_BCLRFR)

**47.6.15**  SAI clear flag register (SAI_BCLRFR) .................................... 1795

#### SAI data register (SAI_ADR)

**47.6.16**  SAI data register (SAI_ADR) ............................................. 1796

#### SAI data register (SAI_BDR)

**47.6.17**  SAI data register (SAI_BDR) ............................................. 1797

#### SAI PDM control register (SAI_PDMCR)

**47.6.18**  SAI PDM control register (SAI_PDMCR) .................................. 1797

#### SAI PDM delay register (SAI_PDMDLY)

**47.6.19**  SAI PDM delay register (SAI_PDMDLY) .................................. 1798

#### SAI register map

**47.6.20**  SAI register map ............................................................. 1801
Secure digital input/output MultiMediaCard interface (SDMMC) . . 1803

48.1 SDMMC main features ............................................. 1803

### 50 Universal serial bus full-speed device interface (USB) 1948

- **50.1 Introduction** 1948
- **50.2 USB main features** 1948
- **50.3 USB implementation** 1948
- **50.4 USB functional description** 1949
  - **50.4.1 Description of USB blocks** 1950
- **50.5 Programming considerations** 1951
  - **50.5.1 Generic USB device programming** 1951
50.5.2 System and power-on reset ........................................... 1952
50.5.3 Double-buffered endpoints ........................................ 1957
50.5.4 Isochronous transfers .................................................. 1959
50.5.5 Suspend/Resume events .............................................. 1960

50.6 USB and USB SRAM registers ............................................. 1963
50.6.1 Common registers ...................................................... 1963
50.6.2 Buffer descriptor table ............................................... 1976
50.6.3 USB register map ........................................................ 1979

51 USB Type-C™ / USB Power Delivery interface (UCPD) ............. 1981
51.1 Introduction .............................................................. 1981
51.2 UCPD main features ...................................................... 1981
51.3 UCPD implementation .................................................... 1981
51.4 UCPD functional description .......................................... 1982
  51.4.1 UCPD block diagram .................................................. 1983
  51.4.2 UCPD reset and clocks .............................................. 1984
  51.4.3 Physical layer protocol ............................................. 1985
  51.4.4 UCPD BMC transmitter .............................................. 1992
  51.4.5 UCPD BMC receiver .................................................. 1993
  51.4.6 UCPD Type-C pull-ups (Rp) and pull-downs (Rd) .............. 1995
  51.4.7 UCPD Type-C voltage monitoring and de-bouncing .......... 1995
  51.4.8 UCPD fast role swap (FRS) signaling and detection .......... 1995
  51.4.9 UCPD DMA Interface ................................................ 1996
  51.4.10 Wakeup from Stop mode .......................................... 1996
  51.4.11 UCPD programming sequences .................................... 1996
51.5 UCPD low-power modes .................................................. 2000
51.6 UCPD interrupts .......................................................... 2001
51.7 UCPD registers ............................................................ 2002
  51.7.1 UCPD configuration register 1 (UCPD_CFG1R) .................. 2002
  51.7.2 UCPD configuration register 2 (UCPD_CFG2R) .................. 2004
  51.7.3 UCPD configuration register 3 (UCPD_CFG3R) .................. 2004
  51.7.4 UCPD control register (UCPD_CR) .............................. 2005
  51.7.5 UCPD interrupt mask register (UCPD_IMR) ..................... 2007
  51.7.6 UCPD status register (UCPD_SR) ................................... 2009
  51.7.7 UCPD interrupt clear register (UCPD_ICR) ..................... 2012
  51.7.8 UCPD Tx ordered set type register (UCPD_TX_ORDSETR) ...... 2013
52 Debug support (DBG) ........................................... 2020
  52.1 Introduction ............................................ 2020
  52.2 DBG functional description ......................... 2021
    52.2.1 DBG block diagram ............................... 2021
    52.2.2 DBG pins and internal signals ................. 2021
    52.2.3 DBG reset and clocks ......................... 2022
    52.2.4 DBG power domains ............................. 2022
    52.2.5 Debug and low-power modes ................. 2022
    52.2.6 Security ........................................ 2023
    52.2.7 Serial-wire and JTAG debug port (SWJ-DP) .... 2024
    52.2.8 JTAG debug port ................................ 2025
    52.2.9 Serial-wire debug port ....................... 2027
    52.2.10 Debug port registers ......................... 2028
    52.2.11 Debug port register map and reset values ... 2036
  52.3 Access ports .......................................... 2037
    52.3.1 Access port registers ........................... 2037
    52.3.2 Access port register map and reset values ... 2042
  52.4 ROM tables ............................................ 2043
    52.4.1 MCU ROM table registers ..................... 2046
    52.4.2 MCU ROM table register map and reset values 2051
    52.4.3 Processor ROM table registers ............... 2052
    52.4.4 Processor ROM table register map and reset values 2057
  52.5 Data watchpoint and trace unit (DWT) ............ 2058
    52.5.1 DWT registers .................................. 2059
    52.5.2 DWT register map and reset values ........... 2074
  52.6 Instrumentation trace macrocell (ITM) .............. 2076
52.6.1 ITM registers ............................................. 2077
52.6.2 ITM register map and reset values ..................... 2086
52.7 Breakpoint unit (BPU) ........................................... 2087
  52.7.1 BPU registers ............................................. 2088
  52.7.2 BPU register map and reset values ..................... 2095
52.8 Embedded Trace Macrocell™ (ETM) ......................... 2096
  52.8.1 ETM registers ............................................. 2097
  52.8.2 ETM register map and reset values ..................... 2123

1  Documentation conventions

1.1  General information

The STM32L552xx and STM32L562xx devices have an Arm®(a) Cortex®-M33 core.

1.2  List of abbreviations for registers

The following abbreviations(b) are used in register descriptions:

read/write (rw)  Software can read and write to this bit.
read-only (r)  Software can only read this bit.
write-only (w)  Software can only write to this bit. Reading this bit returns the reset value.
read/clear write0 (rc_w0)  Software can read as well as clear this bit by writing 0. Writing 1 has no effect on the bit value.
read/clear write1 (rc_w1)  Software can read as well as clear this bit by writing 1. Writing 0 has no effect on the bit value.
read/clear write (rc_w)  Software can read as well as clear this bit by writing to the register. The value written to this bit is not important.
read/clear by read (rc_r)  Software can read this bit. Reading this bit automatically clears it to 0. Writing this bit has no effect on the bit value.
read/set by read (rs_r)  Software can read this bit. Reading this bit automatically sets it to 1. Writing this bit has no effect on the bit value.
read/set (rs)  Software can read as well as set this bit. Writing 0 has no effect on the bit value.
read/write once (rwo)  Software can only write once to this bit and can also read it at any time. Only a reset can return the bit to its reset value.
toggle (t)  The software can toggle this bit by writing 1. Writing 0 has no effect.
read-only write trigger (rt_w1)  Software can read this bit. Writing 1 triggers an event but has no effect on the bit value.
Reserved (Res.)  Reserved bit, must be kept at reset value.

---

a. Arm is a registered trademark of Arm Limited (or its subsidiaries) in the US and/or elsewhere.
b. This is an exhaustive list of all abbreviations applicable to STMicroelectronics microcontrollers, some of them may not be used in the current document.
1.3 Glossary

This section gives a brief definition of acronyms and abbreviations used in this document:

- **Word**: data of 32-bit length.
- **Half-word**: data of 16-bit length.
- **Byte**: data of 8-bit length.
- **IAP (in-application programming)**: IAP is the ability to re-program the Flash memory of a microcontroller while the user program is running.
- **ICP (in-circuit programming)**: ICP is the ability to program the Flash memory of a microcontroller using the JTAG protocol, the SWD protocol or the bootloader while the device is mounted on the user application board.
- **Option bytes**: product configuration bits stored in the Flash memory.
- **OBL**: option byte loader.
- **AHB**: advanced high-performance bus.
- **APB**: advanced peripheral bus.
- **RAZ**: read-as-zero.
- **WI**: writes ignored.
- **RAZ/WI**: read-as-zero, writes ignored.

1.4 Availability of peripherals

For availability of peripherals and their number across all sales types, refer to the particular device datasheet.
2 Memory and bus architecture

The STM32L552xx and STM32L562xx devices are ultra-low-power microcontrollers (STM32L5 Series) based on the high-performance Arm® Cortex®-M33 32-bit RISC core. They operate at frequencies up to 110 MHz.

The Cortex®-M33 processor delivers a high computational performance with low-power consumption and an advanced response to interrupts. It features:

- Arm® TrustZone® technology, using the Armv8-M main extension supporting secure and non-secure states
- Memory protection units (MPUs), supporting 8 regions for secure world and 8 regions for non-secure world.
- Configurable security attribution unit (SAU) supporting up to 8 memory regions
- Floating-point arithmetic functionality with support for single precision arithmetic

The Cortex®-M33 processor supports the following bus interfaces:

- System AHB bus: the system AHB (S_AHB) bus interface is used for any instruction fetch and data access to the memory-mapped SRAM, peripherals, external RAM and external devices, or Vendor_SYS regions of the Armv8-M memory map.
- Code AHB bus: the Code AHB (C_AHB) bus interface is used for any instruction fetch and data access to the code region of the Armv8-M memory map.

2.1 System architecture

The main system consists of 32-bit multilayer AHB bus matrix that interconnects:

- Up to six masters:
  - Fast C-bus, connecting Cortex®-M33 with TrustZone and FPU core C-bus to the internal memories through the ART (instruction cache)
  - Slow C-bus, connecting Cortex®-M33 with TrustZone and FPU core C-bus to the external memories through the ART (instruction cache)
  - Cortex®-M33 with TrustZone and FPU core S-bus
  - DMA1
  - DMA2
  - SDMMC1 bus
- Up to seven slaves:
  - Internal Flash memory on the fast C-bus
  - Internal SRAM1 (192 Kbytes)
  - Internal SRAM2 (64 Kbytes)
  - AHB1 peripherals including AHB to APB bridges and APB peripherals (connected to APB1 and APB2)
  - AHB2 peripherals
  - Flexible static memory controller (FSMC)
  - OCTOSPI1 memory controller
The bus matrix provides access from a master to a slave, enabling concurrent access and efficient operation even when several high-speed peripherals work simultaneously. This architecture is shown in **Figure 1**:  

**Figure 1. System architecture**

2.1.1 **Fast C-bus**  
This bus connects the C-bus of the Cortex\(^{\text{\textregistered}}\)-M33 core to the BusMatrix via the instruction cache. This bus is used for instruction fetch and data access to the internal memories mapped in code region. The target of this bus are the internal Flash and internal SRAMs.

2.1.2 **Slow C-bus**  
This bus connects the C-bus of the Cortex\(^{\text{\textregistered}}\)-M33 core to the BusMatrix via the instruction cache. This bus is used for instruction fetch and data access to the external memories mapped in code region. The target of this bus are the external memories (FSMC and OCTOSPI).

2.1.3 **S-bus**  
This bus connects the system bus of the Cortex\(^{\text{\textregistered}}\)-M33 core to the BusMatrix. This bus is used by the core to access data located in a peripheral or SRAM area. The targets of this bus are the internal SRAMs, the AHB1 peripherals including the APB1 and APB2.
peripherals, the AHB2 peripherals and the external memories through the OCTOSPI or the FSMC.

The SRAM2 is also accessible on this bus to allow continuous mapping with SRAM1.

### 2.1.4 DMA-bus

This bus connects the AHB master interface of the DMA to the BusMatrix. The targets of this bus are the SRAM1 and SRAM2, the AHB1 peripherals including the APB1 and APB2 peripherals, the AHB2 peripherals and the external memories through the OCTOSPI or the FSMC.

### 2.1.5 SDMMC controller DMA bus

This bus connects the SDMMC1 DMA master interface to the BusMatrix. This bus is used only by the SDMMC1 DMA to load/store data from/to memory. The targets of this bus are data memories: internal SRAMs (SRAM1, SRAM2), internal Flash memory or external memories through FSMC or OCTOSPI.

### 2.1.6 BusMatrix

The BusMatrix manages the access arbitration between masters. The arbitration uses a Round Robin algorithm. The BusMatrix is composed of up to six masters (CPU AHB, system bus, Fast C-bus, Slow C-bus, DMA1, DMA2, SDMMC1) and up to seven slaves (FLASH, SRAM1, SRAM2, AHB1 (including APB1 and APB2), AHB2, OCTOSPI1 and FSMC).

#### AHB/APB bridges

The two AHB/APB bridges provide full synchronous connections between the AHB and the two APB buses, allowing flexible selection of the peripheral frequency.

Refer to Section 2.3.2: Memory map and register boundary addresses on page 88 for the address mapping of the peripherals connected to this bridge.

After each device reset, all peripheral clocks are disabled (except for the SRAM1/2 and Flash memory interface). Before using a peripheral the user has to enable its clock in the RCC_AHBxENR and the RCC_APBxENR registers.

**Note:** When a 16- or 8-bit access is performed on an APB register, the access is transformed into a 32-bit access: the bridge duplicates the 16- or 8-bit data to feed the 32-bit vector.

### 2.2 TrustZone® security architecture

The security architecture is based on Arm® TrustZone® with the Armv8-M Main Extension. The TrustZone security is activated by the TZEN option bit in the FLASH_OPTR register.

When the TrustZone is enabled, the SAU (security attribution unit) and IDAU (implementation defined attribution unit) define the memory access permissions based on secure or non-secure state of the processor.

- **SAU:** Up to eight SAU configurable regions are available for security attribution.
- **IDAU:** It provides a first memory partition between non-secure and non-secure-callable regions. The IDAU memory map partition is not configurable and fixed by hardware
implementation (refer to Figure 2). It is then combined with the results from the SAU security attribution and the most secure level between the two is selected.

Based on IDAU security attribution, the Flash, system SRAMs and peripherals memory space is aliased twice for secure and non-secure state. However, the external memories space is not aliased.

*Table 1* shows an example of typical eight SAU regions mapping based on IDAU regions. The user can split and choose the secure, non-secure or NSC regions for external memories as needed.
### Table 1. Example of memory map security attribution versus SAU regions configuration

</tbody>
</table>

1. Different colors highlights the different configurations

- Pink: Non-secure
- Green: NSC (non-secure callable)
- Lighter green: Secure or non-secure or NSC
2.2.1 Default TrustZone security state

When the TrustZone security is activated by the TZEN option bit in the FLASH_OPTR, the default system security state is:

- **CPU:**
  - Cortex-M33 is in secure state after reset. The boot address must be in secure address (i.e. belonging to the secure part of the memory map).

- **Memory map:**
  - SAU: is fully secure after reset. Consequently, the memory map is fully secure. Up to 8 SAU configurable regions are available for security attribution.

- **Flash:**
  - Flash secure regions are defined by watermark user options.
  - Flash interface blocks (i.e. pages) are all Non-Secure after reset (but the watermark configuration supersedes the block-based one in case of overlap).

- **SRAMs:**
  - All SRAMs are secure after reset. MPCBB (memory protection block based controller) is configured as fully secure.

- **External memories:**
  - FSMC, OCTOSPI banks are secure after reset. MPCWM (memory protection watermark based controller) is secure

- **All peripherals (except GPIOs) are non secure after reset. For TrustZone-aware peripherals, their secure configuration registers are secure.**

**Note:** Refer to Table 2 and Table 3 for a list of Securable and TrustZone-aware peripherals.

- **All GPIO are secure after reset.**

- **Interrupts:**
  - NVIC: All interrupts are secure after reset. NVIC is banked for secure and non-secure state.
  - TZIC: All illegal access interrupts are disabled after reset.

2.2.2 TrustZone peripheral classification

When the TrustZone security is active, a peripheral can be either Securable or TrustZone-aware type as defined below:

- **Securable:** a peripheral is protected by an AHB/APB firewall gate that is controlled from TZSC controller to define security properties.

- **TrustZone-aware:** a peripheral connected directly to AHB or APB bus and implementing a specific TrustZone behavior such as a subset of registers being secure. TrustZone-aware AHB masters always drive HNONSEC signal according to their security mode (as CM33 core and DMA).

Refer to Section 5.2.1: GTZC TrustZone system architecture

Table 2 and Table 3 summarize the list of Securable and TrustZone aware peripherals within the system.

1. Always secure when TZEN = 1.
2.3 Memory organization

2.3.1 Introduction

Program memory, data memory, registers and I/O ports are organized within the same linear 4-Gbyte address space.

The bytes are coded in memory in Little Endian format. The lowest numbered byte in a word is considered the word’s least significant byte and the highest numbered byte the most significant.
2.3.2 Memory map and register boundary addresses

Figure 2. Memory map based on IDAU mapping
All the memory map areas that are not allocated to memories and peripherals are considered "Reserved". For the detailed mapping of available memory and register areas, refer to the following table.

The following table gives the boundary addresses of the peripherals available in the devices.

2.4 Embedded SRAM

The STM32L552xx and STM32L562xx devices feature up to 256 Kbytes SRAM:

- 192 Kbytes SRAM1
- 64 Kbytes SRAM2

These SRAM can be accessed as bytes, half-words (16 bits) or full words (32 bits). These memories can be addressed at maximum system clock frequency without wait state and thus by both CPU and DMA.

The CPU can access the SRAM1 and SRAM2 through the system bus or through the C-bus depending on the selected address.

Either 64 Kbytes or upper 4 Kbytes of SRAM2 can be retained in Standby mode.

When the TrustZone security is enabled, all SRAMs are secure after reset. The SRAM can be programmed as non-secure with a block granularity, using MPCBB (memory protection controller block configuration based) in GTZC controller. The granularity of SRAM secure/non-secure block-based is a page of 256 bytes.

2.4.1 SRAM2 parity check

The user can enable the SRAM2 parity check using the option bit SRAM2_PE in the OPTR user option register (refer to Section 6.4.1: Option bytes description).

The data bus width is 36 bits because 4 bits are available for parity check (1 bit per byte) in order to increase memory robustness, as required for instance by Class B or SIL safety standards.

The parity bits are computed and stored when writing into the SRAM2. Then, they are automatically checked when reading. If one bit fails, an NMI is generated. The same error can also be linked to the BRK_IN Break input of TIM1/TIM8/TIM15/TIM16/TIM17 with the SPL control bit in the SYSCFG configuration register 2 (SYSCFG_CFGR2). The SRAM2 Parity Error flag (SPF) is available in the SYSCFG configuration register 2 (SYSCFG_CFGR2).
Note: When enabling the RAM parity check, it is advised to initialize by software the whole RAM memory at the beginning of the code, to avoid getting parity errors when reading non-initialized locations.

2.4.2 SRAM2 Write protection

The SRAM2 can be write protected with a page granularity of 1 Kbyte.

</tbody>
</table>
The write protection can be enabled in *SYSCFG SRAM2 write protection register (SYSCFG_SWPR)* in the SYSCFG block. This is a register with write ‘1’ once mechanism, which means that writing ‘1’ on a bit will setup the write protection for that page of SRAM and it can be removed/cleared by a system reset only.

2.4.3 SRAM2 Read protection

The SRAM2 is protected with the Read protection (RDP). Refer to *Section 6.7.2: Readout protection (RDP)* for more details.

2.4.4 SRAM2 Erase

The SRAM2 can be erased with a system reset using the option bit SRAM2_RST in the OPTR user option register (refer to *Section 6.4.1: Option bytes description*).

The SRAM2 erase can also be requested by software by setting the bit SRAM2ER in the *SYSCFG SRAM2 control and status register (SYSCFG_SCSR)*.

The SRAM2 is also erased by a Backup domain reset.

2.5 Flash memory overview

The Flash memory is composed of two distinct physical areas:

- The main Flash memory block. It contains the application program and user data if necessary.
- The information block. It is composed of three parts:
  - Option bytes for hardware and memory protection user configuration.
  - System memory that contains the ST proprietary code.
  - OTP (one-time programmable) area

The Flash interface implements instruction access and data access based on the AHB protocol. It also implements the logic necessary to carry out the Flash memory operations (program/erase) controlled through the Flash registers plus security access control features. Refer to *Section 6: Embedded Flash memory (FLASH)* for more details.
3 Boot configuration

At startup, a BOOT0 pin, nBOOT0 and NSBOOTADDx[24:0] / SECBOOTADD0[24:0] option bytes are used to select the boot memory address which includes:

- Boot from any address in user Flash
- Boot from system memory bootloader
- Boot from any address in embedded SRAM
- Boot from Root Security service (RSS)

The BOOT0 value may come from the PH3-BOOT0 pin or from an option bit depending on the value of a user option bit to free the GPIO pad if needed.

Refer to Table 6 and Table 7 for boot modes when TrustZone is disabled and enabled respectively.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

When TrustZone is enabled by setting the TZEN option bit, the boot space must be in secure area. The SECBOOTADD0[24:0] option bytes are used to select the boot secure memory address.

A unique boot entry option can be selected by setting the BOOT_LOCK option bit. All other boot options are ignored.

The boot address option-bytes enables the possibility to program any boot memory address. However, the allowed address space depends on Flash read protection RDP level.

If the programmed boot memory address is out of the allowed memory mapped area when RDP level is 0.5 or more, the default boot fetch address is forced to:
- 0x0800 0000 (when TZEN = 0)
- RSS (when TZEN = 1)

Refer to the Table 8.

Table 8. Boot space versus RDP protection

</table>
| 1   | Boot address only in:  
  RSS: 0x0FF80000  
  or secure Flash: 0x0C000000 - 0x0C07 FFFF | N/A |
| 2   | Otherwise the boot address is forced to RSS  
  Boot address only in Flash 0x0800 0000 - 0x0807 FFFF | Otherwise the forced boot address is: 0x0800 0000(1) |
The BOOT0 value (either coming from the pin or the option bit) is latched upon reset release. It is up to the user to set nBOOT0 or BOOT0 values to select the required boot mode.

The BOOT0 pin or user option bit (depending on the nSWBOOT0 bit value in the FLASH_OPTR register) is also re-sampled when exiting from Standby mode. Consequently, they must be kept in the required Boot mode configuration in Standby mode. After startup delay, the selection of the boot area is done before releasing the processor reset.

PH3/BOOT0 GPIO is configured in:

- Input mode during the complete reset phase if the option bit nSWBOOT0 is set into the FLASH_OPTR register and then switches automatically in analog mode after reset is released (BOOT0 pin).
- Input mode from the reset phase to the completion of the option byte loading if the bit nSWBOOT0 is cleared into the FLASH_OPTR register (BOOT0 value coming from the option bit). It switches then automatically to the analog mode even if the reset phase is not complete.

**Embedded bootloader and RSS**

The bootloader is located in the system memory. It is used to reprogram the Flash memory by using USART, I2C, SPI, FDCAN or USB FS in device mode through the DFU (device firmware upgrade). It is programmed by ST during production. Refer to AN2606, STM32 microcontroller system memory boot mode.

The root secure services (RSS) are embedded in a Flash memory area named secure information block, programmed during ST production.

The RSS enables for example the secure firmware installation (SFI) thanks to the RSS extension firmware (RSSe SFI).

This feature allows the customers to protect the confidentiality of the firmware to be provisioned into the STM32 device when the production is subcontracted to a third party.

The RSS is available on all devices, after enabling the TrustZone through the TZEN option bit. Refer to AN5428, STM32L5 Series microcontroller system memory RSS services.
4 System security

4.1 Introduction

The STM32L552xx and STM32L562xx have been designed with a comprehensive set of security features, some of which being based on standard Arm TrustZone® technology. These security features should simplify the process of evaluating IoT devices against security standards. They also significantly reduce the cost and complexity of software development for OEMs and third party developers by facilitating the re-use, improving the interoperability, and minimizing the API fragmentation.

This section explains the different security features available on the STM32L552xx and STM32L562xx devices.
4.2 Key security features

- Resource isolation using Armv8-M mainline security extension of Cortex®-M33, extended to securable I/Os, memories and peripherals
- Secure firmware installation (SFI) with device unique cryptographic key pair
  - Leveraging the on-chip immutable bootloader that supports the download of image through USART, USB, I2C, SPI, FDCAN and JTAG
- Enabled for secure boot thanks to unique boot entry feature and hide protect area (HDP) mechanism.
- Secure storage, featuring:
  - Non-volatile on-chip secure storage, protected with secure & HDP areas
  - Battery-powered volatile secure storage, automatically erased in case of tamper
  - Write-only key registers in AES engine
  - STM32L552xx and STM32L562xx Unique ID (96 bits)
- General purpose cryptographic acceleration (AES and PKA only in STM32L562xx)
  - AES 256-bit engine, supporting ECB, CBC, CTR, GCM and CCM chaining modes
  - HASH processor, supporting MD5/SHA-1 checksums and SHA-2 secure hash
  - Public key accelerator (PKA) for RSA/DH (up to 3136 bits) and ECC (up to 640 bits)
  - True random number generator (RNG), NIST SP800-90B pre-certified
- On-the-fly decryption of encrypted image stored on external Flash memory connected through OCTOSPI (STM32L562xx only)
  - Almost-zero latency with standard NOR Flash memories
  - Can be used to encrypt the image using device unique secret keys
  - Automatic key erase in case of tamper
- Flexible lifecycle scheme with readout protection (RDP), including support for product decommissioning (auto-erase)
  - Debug protection, depending on the readout protection level
- Protected firmware distribution scheme, using TrustZone®, on-the-fly decryption and RDP level 0.5
- Active tamper and protection against temperature, voltage and frequency attacks
  - 3 active inputs, 1 active output tamper pin available in all power modes

4.3 Secure install

Secure firmware install (SFI) is an immutable secure service embedded by STMicroelectronics in STM32L552xx and STM32L562xx devices. It allows secure and counted installation of OEM firmware in untrusted production environment (such as OEM contract manufacturer).

The confidentiality of the installed images written either in internal Flash memory or encrypted in external Flash memory is also protected, using AES.
The SFI native service leverages the following hardware security features:

- Secure boot (see Section 4.4)
- Resource isolation using TrustZone® (see Section 4.6)
- Temporal isolation using hide protection (see Section 4.7.1)
- Secure execution (see Section 4.8)
- Secure storage, with associated cryptographic engines (see Section 4.9 and Section 4.10)

Further information can be found in application note AN4992 - Overview secure firmware install (SFI) available on www.st.com.

4.4 Secure boot

4.4.1 Introduction

Secure boot is an immutable code that is always executed after a system reset. As a root of trust, this code checks the STM32L552xx and STM32L562xx static protections and activates available STM32L552xx and STM32L562xx runtime protections, reducing the risk that invalid or malicious code runs on the platform. As root of trust, secure boot also checks integrity and authenticity of the next level firmware before executing it.

The actual functions of secure boot depend on availability of TrustZone® features, and the firmware stored in the device. However it would typically initializes secure storage, and install on-the-fly decryption keys in OTFDEC to be able to use encrypted firmware stored in external Flash memory.

The STM32L552xx and STM32L562xx Trusted Firmware-M (TFM) application, supported by the STM32 ecosystem, provides a root of trust solution including secure boot functions. For more information, refer to user manual UM2671 - Getting started with STM32CubeL5 TFM application available from www.st.com.

In the STM32L552xx and STM32L562xx devices, the secure boot takes benefit of hardware security features such as:

- Resource isolation using TrustZone® (see Section 4.6)
- Temporal isolation using hide protection (see Section 4.7.1)
- Secure execution (see Section 4.8)
- Secure install and update (see Section 4.3 and Section 4.5)
- Secure storage, with associated cryptographic engines if available (see Section 4.9 and Section 4.10)

This section describes the features specifically designed for secure boot.

4.4.2 Unique boot entry and BOOT_LOCK

When TrustZone® is activated (TZEN=1) and BOOT_LOCK secure option bit is cleared the application selects a boot entry point located either in system Flash memory (see Section 4.4.3) or in secure user Flash memory, at the address defined by SECBOOTADD0 option bytes.

When TrustZone® is activated (TZEN=1) and BOOT_LOCK secure option bit is set the device unique boot entry is the secure address defined by SECBOOTADD0 option bytes. These option bytes cannot be modified by the application anymore.
Note: As long as it is cleared, the BOOT_LOCK option byte can be set without any constraint. But once set the BOOT_LOCK option bit cannot be cleared.

For more information on STM32L552xx and STM32L562xx boot mechanisms, refer to Section 3: Boot configuration.

4.4.3 Immutable root of trust in system Flash memory

The first usage of the immutable root of trust code stored in STM32L552xx and STM32L562xx system Flash memory is to perform secure firmware install (SFI), allowing secure and counted installation of OEM firmware in untrusted production environment (such as OEM contract manufacturer). See Section 4.4.2 for more details.

STMicroelectronics immutable code also includes secure runtime services that can be called at runtime when secure application sets the SYSCFG_RSSCMDR register to a non-null value before triggering a system reset. This runtime feature is deactivated when BOOT_LOCK secure option bit is set.

4.5 Secure update

Secure firmware update is a secure service that runs after a secure boot. Its actual functions depend on availability of TrustZone® features, and the firmware stored in the device.

The STM32L552xx and STM32L562xx Trusted Firmware-M (TFM) application, supported by the STM32 ecosystem, allows the update of the microcontroller built-in program with new firmware versions, adding new features and correcting potential issues. The update process is performed in a secure way to prevent unauthorized updates and access to confidential on-device data.

A firmware update can be done either on a single firmware image including both secure and non-secure parts, or on the secure (respectively non-secure) part of the firmware image, independently.

In the STM32L552xx and STM32L562xx devices, the secure update application leverages the same hardware security as the firmware install described in Section 4.3.

For more information, refer to user manual UM2671 - Getting started with STM32CubeL5 TFM application available on www.st.com.

4.6 Resource isolation using TrustZone®

4.6.1 Introduction

In the STM32L552xx and STM32L562xx devices, the hardware and software resources can be partitioned so that they exist either in the secure world or in the non-secure world, as shown on Figure 3.

Note: The initial partitioning of the platform is under the responsibility of the secure firmware executed after reset of the device.

Thanks to this resource isolation technology, the secure world can be used to protect critical code against intentional or unintentional tampering from the more exposed code running in the non-secure world.
Note: Typically secure code is small and rarely modified, while non-secure code is more exposed, and prone to firmware updates.

Figure 3. Secure/non-secure partitioning using TrustZone® technology

4.6.2 TrustZone® security architecture

Armv8-M TrustZone® technology is a comprehensive hardware architecture that proposes to developers a comprehensive, holistic protection across the entire processor and system. In this device TrustZone® hardware features include:

- The Armv8-M mainline security extension of Cortex®-M33, enabling a new processor secure state, with its associated secure interrupts
- The dynamic allocation of memory and peripherals to TrustZone® using eight security attribution unit (SAU) regions of Cortex®-M33
- A global TrustZone® framework (GTZC), extending TrustZone® protection against transactions coming from other masters in the system than the Cortex®-M33.
- TrustZone®-aware embedded Flash memory and peripherals

Note: TrustZone® security is activated by the TZEN option bit in the FLASH_OPTR register

Each of the elements above are described in the following subsections.

4.6.3 Armv8-M security extension of Cortex®-M33

The Arm security extension of the Cortex®-M33 is an evolution, not a revolution. It is using the programmer’s model you find in earlier Cortex® M subfamilies like Cortex®-M4. Indeed, Armv8-M is architecturally similar to Armv7-M, using the same 32-bit architecture, the same memory mapped resources protected with an MPU, and it also uses the Nested Vectored Interrupt Controller (NVIC).
Armv8-M TrustZone® implementation in STM32L552xx and STM32L562xx is composed of the following features:

- A new processor state, with almost no additional code/cycle overhead as opposed to Armv8-A TrustZone® that uses a dedicated exception routine for triggering a secure/non-secure world change
- Two memory map views of a shared 4 Gbytes address space
- A low interrupt latency for both secure and non-secure domains. It also includes a new interrupt configuration for security grouping and priority setting.
- Separated exception vector tables for the secure and non-secure exceptions
- Micro-coded context preservation
- Banking of specific registers across secure/non-secure states, including stack pointers with stack-limit checkers
- Banking of following Cortex®-M33 programmable components (two separate units for secure and non-secure):
  - SysTick timer
  - MPU configuration registers (eight MPU regions in secure, eight in non-secure)
  - Some of the system control block (SCB) registers
- New system exception (SecureFault) for handling of security violations
- Configurable debug support, as defined in Section 4.12: Access controlled debug

For more information please refer to Cortex®-M33 programming manual (PM0264).

4.6.4 Memory and peripheral allocation using IDAU/SAU

Security attributes

As illustrated on Figure 4, Armv8-M non-secure memory view is similar to Armv7-M (that can be found in Cortex® M4), with the difference that secure memory is hidden. The secure memory view shows Flash memory, SRAM and peripherals that are only accessible while the Cortex® processor executes in Secure state.

Note: Figure 4 shows the 32-bit address space viewed after SAU has been configured by the secure code.
The Cortex® processor state (and associated rights) depends on the security attribute assigned to the memory region where it is executing. More specifically:

- A processor in a non-secure state only executes from non-secure (NS) program memory, while a processor in a secure state only executes from secure (S) program memory.
- While running in secure state the processor can access data from both S and NS memories. Running in non-secure state the CPU is limited to non-secure memories.

In order to manage transitions to secure world, developers must create non-secure callable (NSC) regions that contain valid entry points to the secure libraries. The first instruction in these entry points must be the new secure gate (SG) instruction, used by non-secure code to call a secure function. It is illustrated on Figure 5.

**Figure 4. Sharing memory map between CPU in secure and non-secure state**

The memory map shows the different memory regions and their access permissions for both secure and non-secure states. (*) Aliased addresses

**Figure 5. Secure world transition and memory partitioning**

This diagram illustrates the secure and non-secure memory views, showing how non-secure callable regions are used to transition to secure libraries. The transitions are managed through secure gate instructions.
Programming security attributes

In Cortex®-M33 the static implementation defined attribution unit (IDAU) works in conjunction with the programmable security attribution unit (SAU) to assign a specific security attribute (S, NS or NSC) to a specific address, as shown on Table 9.

Table 9. Configuring security attributes with IDAU and SAU

<table>
<thead>
<tr>
<th>IDAU security attribution</th>
<th>SAU security attribution(1)</th>
<th>Final security attribution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-secure</td>
<td>Secure</td>
<td>Secure</td>
</tr>
<tr>
<td></td>
<td>Secure-NSC</td>
<td>Secure-NSC</td>
</tr>
<tr>
<td></td>

<td>Non-secure</td>
</tr>
<tr>
<td>Secure-NSC</td>
<td>Secure</td>
<td>Secure</td>
</tr>
<tr>
<td></td>
<td>Non-secure</td>
<td>Secure-NSC</td>
</tr>
</tbody>
</table>

1. Defined regions are aligned to 32-byte boundaries.

The SAU can only be configured by the Cortex®-M33 in the secure privileged state. When TrustZone® is enabled, the SAU defaults all addresses as secure (S). A secure boot application can then program SAU to create NSC or NS regions, as shown in Table 9. The SAU/IDAU settings are applicable to only the Cortex®-M33. The other masters like DMA are not affected by those policies.

For more information on memory security attribution using IDAU/SAU on STM32L552xx and STM32L562xx, please refer to AN5347 on STMicroelectronics website.

4.6.5 Memory and peripheral allocation using GTZC

Global Trustzone® framework architecture

On top of Armv8-M TrustZone® security extension in Cortex®-M33, the STM32L552xx and STM32L562xx devices come with complementary security features that reinforce in a flexible way the isolation between the secure and the non-secure worlds. Unlike the SAU/IDAU, the GTZC can protect legacy memories and peripherals against non-secure transactions coming from other masters than the Cortex-M33.
Securing peripherals with TZSC

When the TrustZone® security is active, a peripheral is either securable through global TrustZone® controller (GTZC) or is natively TrustZone®-aware, as shown in Figure 6. More specifically:

- A securable peripheral or memory is protected by an AHB/APB firewall gate that is controlled by the TrustZone® security controller (TZSC).
- A TrustZone®-aware peripheral or memory is connected directly to AHB or APB interconnect, implementing a specific TrustZone® behavior such as a subset of secure registers or a secure memory area.

When a securable peripheral is made secure-only with GTZC, if this peripheral is master on the interconnect it automatically issues secure transactions. SDMMC is an example of securable master. TrustZone®-aware AHB masters like Cortex®-M33 or DMAs drive secure signal in the AHB interconnect according to their security mode, independently to the GTZC.

Note: Like with TrustZone®, a peripheral can be made privileged-only with TZSC. In this case, if this peripheral is master on the interconnect, it automatically issues privileged transactions.
Securing memories with TZSC and MPCBB

The TZSC block in GTZC provides the capability to manage the security for all securable external memories (including SRAM devices), programming the MPCWM instances as defined in Table 10.

<table>
<thead>
<tr>
<th>Memory</th>
<th>MPC instance</th>
<th>Type of filtering</th>
<th>Number of regions</th>
<th>Default security</th>
<th>on-the-fly decryption</th>
</tr>
</thead>
<tbody>

<td></td>
<td>1</td>
<td></td>
<td>no</td>
</tr>
</tbody>
</table>

1. Using OTDEC peripheral.
2. Assuming TrustZone\(^{®}\) is activated on the device, non-secure otherwise.

The MPCBB instances in GTZC provide the capability to configure the security of embedded SRAM blocks, as defined in Table 11.

<table>
<thead>
<tr>
<th>Memory</th>
<th>MPC instance</th>
<th>Type of filtering</th>
<th>Memory size (kBytes)</th>
<th>Block size (Bytes)</th>
<th>Number of blocks</th>
<th>Default security</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>SRAM2</td>
<td>MPCBB2</td>
<td></td>
<td>64</td>
<td>256</td>
<td>256</td>
<td></td>
</tr>
</tbody>
</table>

1. Blocks are grouped in superblo cks of 32 consecutive blocks, to manage configuration locking.
2. Assuming TrustZone\(^{®}\) is activated on the device, non-secure otherwise.

Applying GTZC configurations

The TZSC and MPCBB blocks can be used in one of the following ways:
- Statically programmed during secure boot, locked and not changed afterwards.
- Dynamically re-programmed using specific application code or real-time kernel.

When dynamic option is selected and the configuration is not locked:
- MPCBB secure blocks or MPCWM non-secure regions size can be changed by secure software.
- Secure (respectively privilege) state of each peripheral can be changed writing to GTZC\_TZSC\_SECCFRGx (respectively GTZC\_TZSC\_PRIVCFGRx) registers.

Securing peripherals with TZSC

The TZSC block in GTZC provides the capability to manage the security and the privilege for all securable peripherals. The list of those peripherals can be found in Section 5: Global TrustZone\(^{®}\) controller (GTZC).

Note: When TrustZone\(^{®}\) is deactivated, resource isolation hardware GTZC can still be used to isolate peripherals to privileged code only.
When TrustZone® is activated, peripherals are set as non-secure and non-privilege after reset.

TrustZone®-aware peripheral list

STM32L552xx and STM32L562xx devices include the following TrustZone®-aware peripherals. The way illegal accesses to those peripherals are monitored through TZIC registers is described in Section 5: Global TrustZone® controller (GTZC).

- GPIOA to GPIOH
- MPCBB1 (SRAM1) and MPCBB2 (SRAM2)
- TZIC and TZSC (GTZC blocks)
- OTFDEC, writable only in secure if TZEN=1
- EXTI
- Flash memory
- RCC and PWR
- DMA1, DMA2 and DMAMUX
- SYSCFG registers
- RTC and TAMP

For more details please refer to Section 4.6.6: Managing security in TrustZone®-aware peripherals.

TrustZone® illegal access controller (TZIC)

The TZIC block in GTZC gathers all illegal access events originated from sources either protected by GTZC or TrustZone®-aware, generating one global secure interrupt towards the NVIC.

TZIC is available only when the system is TrustZone® enabled (TZEN = 1). All accesses to TZIC registers must be secured.

For each illegal event source, a status flag and a clear bit exist. Each illegal event can be masked, not generating an interrupt toward the NVIC.

Note: By default all events are masked.

4.6.6 Managing security in TrustZone®-aware peripherals

This section gives more details on the way security is implemented in the TrustZone®-aware peripherals listed on Section 4.6.5.
Embedded Flash

When the TrustZone® security is enabled through option bytes (TZEN = 1), the whole Flash memory is secure after reset and the following protections, shown on Figure 7, are available to the application:

- Non-volatile user secure areas, defined with non-volatile secure user option bytes
  - Watermark-based secure only area (x2 in dual bank configuration)
  - Secure hide protection (HDP) area, stickily hidden after boot (x2 in dual bank configuration)
- Volatile user secure pages, defined with volatile secure registers (lost after reset)
  - Any page set as non-secure (example: outside watermark-based secure only area), can be set as secure on-the-fly using the block-based configuration registers

Note: All areas aligned on Flash memory page granularity.

Flash memory area can be configured as secure while they are tagged as non-secure in Cortex®-M33 IDAU/SAU. In this case non-secure accesses by the CPU to the Flash memory is denied.

Erase or program operation can be performed in secure or non-secure mode with associated configuration bits.

Figure 7. Flash memory TrustZone® protections

As shown above, when TrustZone® is activated (TZEN=1) the application code can use the HDP area that is part of the Flash watermark-based secure area. Indeed, when application sets HDPxACCDIS bit, data read, write and instruction fetch on this hide protection area are denied until next system reset. For example, the software code in the secure Flash hide protected area can be executed only once, with any further access to this area denied until next system reset. Additionally, any Flash memory page belonging to an active HDP area cannot be erased anymore.
When TrustZone® is disabled (TZEN=0) the volatile/non-volatile secure areas features are deactivated and all secure registers are RAZ/WI.

See Section 6: Embedded Flash memory (FLASH) for details.

**On-the-fly encryption/decryption (OTFDEC)**

When the TrustZone® security is activated (TZEN=1) the OTFDEC peripheral can only be initialized by secure applications. Each of the four encrypted regions, once the configuration is confirmed, can be write-locked until next power-on-reset.

*Note:* Any application (secure or non-secure) can verify the initialization context of each OTFDEC region (including CRC of the keys), by reading the peripheral registers.

*Key registers in OTFDEC are write-only.*

See Section 4.10.3 for more details on this cryptographic engine.

**DMA and DMAMUX**

When a DMA channel is defined as secure (SECM = 1 in DMA_CCRx registers), the source and destination transfers can be independently set as secure or non-secure by a secure application using SSEC and DSEC bits in DMA_CCRx registers. Table 13 summarizes these security options available in each DMA channel.

*Note:* Secure (resp. non-secure) DMA channel and associated DMAMUX is programmed by a secure (resp. secure or non-secure) application.

*This feature is not available when TrustZone® is disabled.*

<table>
<thead>
<tr>
<th>Table 12. DMA channel usage (security) (1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Secure DMA channel (SECM = 1)</td>
</tr>
<tr>
<td>Secure source</td>
</tr>
<tr>
<td>Secure destination</td>
</tr>
<tr>
<td>Non-secure destination</td>
</tr>
</tbody>
</table>

1. When a transfer is blocked, the transfer completes but the corresponding writes are ignored, and reads return zeros. Also an illegal access event to TZIC is automatically triggered by the memory/peripheral used as source or destination.
2. If the source is a memory the transfer is only possible if SSEC = 0, otherwise the transfer is blocked.
3. If the destination is a memory the transfer is only possible if DSEC = 0, otherwise the transfer is blocked.
4. If the transfer is memory-to-memory, the transfer is only possible if SSEC = 0 and DSEC = 0, otherwise the transfer is blocked.

Similarly, when a DMA channel is defined as privileged (PRIV = 1 in DMA_CCRx register), special rules apply when accessing privileged/unprivileged source or destination. Those rules are summarized on Table 13.

*Note:* A privileged (resp. unprivileged) DMA channel and associated DMAMUX is programmed by a privileged (resp. privileged or unprivileged) application.
Table 13. DMA channel usage (privilege) \(^{(1)}\)

<table>
<thead>
<tr>
<th>Privileged DMA channel (PRIV=1)</th>
<th>Non-privileged DMA channel (PRIV=0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Privileged source</td>
<td>Non-privileged source</td>

<td>OK</td>
</tr>
<tr>
<td>Non-privileged destination</td>
<td>OK</td>
</tr>
</tbody>
</table>

1. When a transfer is blocked, the transfer completes but the corresponding writes are ignored, and reads return zeros.

Note: When a DMA transfer error occurs during a DMA read or write access, the faulty channel \(x\) is automatically disabled, and TEIF\(x\) bit is set in DMA_ISR register.

See Section 14: Direct memory access controller (DMA) and Section 15: DMA request multiplexer (DMAMUX) for details.

Power control (PWR)

When the TrustZone® security is activated (TZEN = 1), the selected PWR registers can be secured through the PWR_SECCFGR register, protecting the following PWR features:

- Low-power mode setup
- Wakeup (WKUP) pins definition
- Voltage detection and monitoring
- VBAT mode setup

Other PWR configuration bits becomes secure when:

- the system clock selection is secure in RCC. In this case the voltage scaling (VOS) configuration becomes secure.
- a GPIO is configured as secure. In this case its corresponding bit for pull-up/pull-down configuration in Standby mode becomes secure.
- the TrustZone®-aware RTC is configured as secure. In this case the backup domain write protection bit (DBP) becomes secure.
- the USB Type-C™ / USB power delivery interface (UCPD) is configured as secure in TZSC. In this case UCPD bits in PWR becomes secure.

See Section 8: Power control (PWR) for details.

Secure clock and reset (RCC)

When the TrustZone® security is activated (TZEN = 1) and security is enabled in the RCC, the bits controlling the peripheral clocks and resets becomes TrustZone®-aware:

- If the peripheral is securable the peripheral clock and reset bits become secure if the peripheral is programmed as secure in the TZSC.
- If the peripheral is TrustZone®-aware, the peripheral clock and reset bits become secure as soon as at least one function is configured as secured inside the peripheral.

When a peripheral is defined as secure in the RCC, the bits Enable, Reset & LPEnable become secure, and in some case the selection of clock source as well. The RCC can also secure the system clock, the system configuration, the system multiplex and the reset flag.

Note: Refer to Table 10 and Table 11 in Section 4.6.5 for the list of securable and TrustZone®-aware peripherals.
See Section 9: Reset and clock control (RCC) for details.

Real time clock (RTC)

Like all TrustZone®-aware peripherals, a non-secure read/write access to a secured RTC register is RAZ/WI. It also generates an illegal access event that triggers a secure illegal access interrupt if the RTC illegal access event is enabled in the TZIC peripheral.

After a backup domain power-on reset, all RTC registers can be read or written in both secure and non-secure modes. Secure boot code can then change this security setup, making registers Alarm A, alarm B, wakeup Timer and timestamp secure or not as needed, using RTC_SMCR register.

Note: The RTC security configuration is not affected by a system reset.

See Section 41: Real-time clock (RTC) for details.

Tamper and backup registers (TAMP)

Like all TrustZone®-aware peripherals, a non-secure read/write access to a secured TAMP register is RAZ/WI. It also generates an illegal access event that triggers a secure illegal access interrupt if the TAMP illegal access event is enabled in the TZIC peripheral.

After a backup domain power-on reset, all TAMP registers can be read or written in both secure and non-secure modes. Secure boot code can change this security setup, making some registers secure or not as needed, using TAMP_SMCR register. More specifically:

• When TAMPDPROT=0 in the TAMP_SMCR register
  – Writing the TAMP registers is possible only in secure mode. Backup registers have their own write protection (see below).
  – Reading the TAMP registers (with the exception of TAMP_SMCR, TAMP_PRIVCR and TAMP_MISR) returns zero if the access is non-secure.
    Backup registers have their own read protection (see below).
• Backup registers in TAMP have three protection zones configured in BKPRWDPROT[7:0] and BKPWDPROT[7:0] registers:
  – Protection zone 1 is read non-secure, write non-secure
  – Protection zone 2 is read non-secure, write secure
  – Protection zone 3 is read secure, write secure

Note: The TAMP security configuration is not affected by a system reset.

See Section 42: Tamper and backup registers (TAMP) for details.

General-purpose I/Os (GPIO)

When TrustZone® security is activated (TZEN = 1), each I/O pin of GPIO port can be individually configured as secure through the GPIOx_SECCFGR registers. Only secure application can write to GPIOx_SECCFGR registers. After boot, each I/O pin of GPIO is set as secure.

When an I/O pin is configured as secure, its corresponding configuration bits for alternate function (AF), mode selection (MODE) and I/O data are RAZ/WI in case of non-secure access.

When digital alternate function is used (input/output mode), in order to protect the data transiting from/to the I/O managed by a secure peripheral, the STM32L552xx and
STM32L562xx add a secure alternate function gate on the path between the peripheral and its allocated I/Os:

- If the peripheral is secure, the I/O pin must also be secure to allow input/output of data
- If the peripheral is not secure, the connection is allowed regardless of the I/O pin state.

TrustZone®-aware logic around GPIO ports used as alternate function is summarized in Table 14.

### Table 14. Secure Alternate function between peripherals and allocated I/Os

</tbody>
</table>

1. To find the I/O corresponding to the signal/function on the package, refer to the product datasheet.

Finally, regarding GPIO and security, Table 16 summarizes the list of I/Os that do not have an hardware protection linked to TrustZone®. More specifically the listed signals (input and/or outputs) are not blocked when the I/O is set as secure and the associated peripheral is non secure.

For example, when secure application sets PA4 as secure to be used as LPTIM2\_OUT, if the DAC peripheral is non-secure it can be programmed to output data to PA4, potentially causing malfunction to the secure application.

Similarly, when secure application sets PA0 as secure to be used as UART4\_TX, if the TAMP peripheral is non-secure it can be programmed to capture the USART\_input traffic through the TAMP\_IN signal.

Hence it is important that for each case described in Table 16 secure application decides if a potential effect on data integrity or confidentiality is critical or not. For example, if the USART situation described above is not acceptable (data transiting on secure USART is confidential) then the secure application should configure the TAMP peripheral as secure even if it is not used by the secure application.
Note: How to make a peripheral secure is summarized on the last column.

1. To find the I/O corresponding to the signal/function on the package, refer to the product datasheet.

For more detailed information on the topic refer to Section 11: General-purpose I/Os (GPIO).

Extended interrupts and event controller (EXTI)

When the TrustZone® security is activated (TZEN = 1), the EXTI is able to protect event register bits from being modified by non-secure accesses. The protection can individually be activated per input event via the register bits in EXTI_SECCFGR registers. At EXTI level, the protection consists in preventing unauthorized write access to:

- the change of settings for the secure configurable events,
- the change of masking for the secure input events,
- the clearing of pending status for the secure input events.

The security configuration in registers EXTI_SECCFGR can be globally locked after reset in EXTI_LOCKR register.
See Section 17: Extended interrupts and event controller ( EXTI) for details.

System configuration controller (SYSCFG)

Like all TrustZone®-aware peripherals, a non-secure read/write access to a secured SYSCFG register is RAZ/WI. Such access also generates an illegal access event that triggers a secure illegal access interrupt if the SYSCFG illegal access event is not masked in the TZIC.

See Section 12: System configuration controller (SYSCFG) for details.

4.6.7 Activating TrustZone® security

TrustZone® is disabled by default in all STM32L552xx and STM32L562xx devices. It can be activated by setting the TZEN option bit in FLASH.OPTR when RDP level = 0. Once TZEN has changed from 0 to 1 the default security state after reset is always the following:

- **CPU subsystem**
  - Cortex®-M33 exits reset in secure state, hence the boot address must point toward a secure memory area
  - All interrupt sources are secure (in NVIC)
  - The memory mapped viewed by the CPU through IDAU/SAU is fully secure

- **Embedded Flash memory**
  - Flash memory non-volatile secure areas are defined with non-volatile registers SECWMxR (where x = 1 or 2).
  - Volatile block-based security attributions of the Flash memory are non-secure.

- **Embedded SRAM memories**
  - All SRAMs are secure, as defined in GTZC/MPCBB (see Section 4.6.5). Secure boot code can change this security setup, making blocks secure or not as needed.

- **External memories**
  - All memory devices connected to FSMC and OCTOSPIs are secure, as defined in GTZC/MPCWM (see Section 4.6.5). Secure boot code can change this security setup, making components secure or not as needed.

- **All GPIOs are secure**
- **All DMA channels are non-secure**
- **Backup registers are non-secure**

- **About peripherals and GTZC**
  - Securable peripherals are non-secure and unprivileged
  - TrustZone®-aware peripherals are non-secure, with their secure configuration registers being secure.
  - All illegal access interrupts in GTZC/TZIC are disabled

Note: Refer to Table 10 and Table 11 in Section 4.6.5 for the list of securable and TrustZone®-aware peripherals.

4.6.8 De-activating TrustZone® security

Once TrustZone® is activated on the device it can only be deactivated during a RDP regression to level 0 (example: RDP change from 1 to 0, or from 0.5 to 0).
Note: Such RDP regression triggers the erase of embedded memories (SRAM2, flash), and the reset of all peripherals, including the on-the-fly decryption and all the crypto engines.

After the TrustZone® deactivation, most features mentioned in Section 4.6 are no more available. More specifically:
- Non-volatile secure area of embedded Flash memory is deactivated, including the HDP area
- NVIC only manages non-secure interrupts
- All secure registers in TrustZone®-aware peripherals are RAZ/WI.

Note: When TrustZone® is disabled GTZC can still be used to configure the privilege access to securable peripherals.

For more information please refer to application AN5347 available at www.st.com.

4.7 Other resource isolations

These are hardware mechanisms offering an additional level of isolation on top of TrustZone® technology.

4.7.1 Temporal isolation using secure hide protection (HDP)

The STM32L552xx and STM32L562xx embedded Flash memory allows to define one hide protection (HDP) area per watermarked-secure area of each bank. The code executed in HDP area, with its related data and keys, can be hidden after boot until the next system reset. Hide protection principle is pictured on Figure 8.

The number of HDP area, and its granularity, depends on the DBANK mode:
- in single-bank mode (DBANK=0) two HDP area can be defined, with the granularity of a 4 Kbytes page.
- in dual-bank mode (DBANK=1) one HDP area per bank can be defined, with the granularity of a 2 Kbytes page.
When HDPxEN and HDPxACCDIS bits are set, data read, write and instruction fetch on the area defined by SECWMx_STRT and HDPx_PEND are denied until next device reset.

**Figure 8. Flash memory secure hide protection (HDP) area**

**Note:** Bank erase aborts when it contains a write-protected area (WRP or HDP area).

HDP area can be resized by secure application if the area is not hidden and if RDP level is different than 2.

## 4.8 Secure execution

### 4.8.1 Introduction

Through a mix of special software and hardware features, STM32L552xx and STM32L562xx devices ensure the correct operation of their functions against abnormal situations caused by programmer errors, software attacks through network access or local attempt for tampering code execution.

This section describes the hardware features specifically designed for secure execution.

### 4.8.2 Memory protection unit (MPU)

The Cortex®-M in STM32L552xx and STM32L562xx devices includes a memory protection unit (MPU) that can restrict the read and write accesses to memory regions (including regions mapped to peripherals), based on one or more of the following parameters:

- Cortex®-M operating mode (privileged, unprivileged)
- Data/instruction fetch

The memory map and the programming of the non-secure and secure MPUs split memory into regions (up to eight per MPU). Secure MPU is only available when TrustZone is activated.
4.8.3 Embedded Flash memory write protection

The embedded Flash memory write protection (WRP) prevents illegals or unwanted write/erase to special sections of the embedded Flash memory user area (system area is permanently write protected).

Write protected area is defined through the option bytes, writing the start and end addresses. More specifically, in STM32L552xx and STM32L562xx:

- In single-bank mode (DBANK = 0) four write-protected areas can be defined, with the granularity of a 4 Kbytes page.
- In dual-bank mode (DBANK = 1) two write-protected areas can be defined in each bank, with the granularity of a 2 Kbytes page.

WRP areas can be modified through option byte changes while RDP level is less than 2.

Note: Bank erase aborts when it contains a write-protected area (WRP or HDP area)

4.8.4 Tamper detection and response

Principle

STM32L552xx and STM32L562xx devices include active protection of critical security assets against temperature, voltage and frequency attacks. More specifically, it features:

- Erasure of device secrets upon tamper detection
- Improved guarantee of safe execution for the CPU and its associated security peripherals, including:
  - Out-of-range voltage (example: VBAT, VDDA), temperature and clocking (LSE) detection
  - Security watchdog IW DG clocked by the internal oscillator LSI
  - Possible selection of internal oscillator HSI as system clock
- Power supply protection
  - RTC/TAMP domain powered automatically with VDD or VBAT

See Section 42: Tamper and backup registers (TAMP) for details.

Tamper detection sources

The device features three active tamper inputs (TAMP_IN1,2,3) associated to one active output tamper pin (TAMP_OUT2), available in all power modes (including VBAT mode).

The device also has a number of internal tamper sources, as described in Table 17.

Note: Timestamps are automatically generated when a tamper event occurs.

Table 17. Internal tampers in TAMP

<table>
<thead>
<tr>
<th>Tamper input</th>
<th>NOER bit</th>
<th>Tamper source</th>
</tr>
</thead>
<tbody>

<td>-</td>
<td>not used</td>
</tr>
<tr>
<td>itamp5</td>
<td>TAMP_CR3[4]</td>
<td>RTC calendar overflow (rtc_calovf)</td>
</tr>
</tbody>
</table>
Response to tampers

Each source of tamper in the device can be configured to trigger the following events:

- Generate an interrupt, capable of waking up the device from Stop and Standby modes (see TAMPxMSK bits in TAMP_CR2 register)
- Generate a hardware trigger for the low-power timers
- Erase of device secrets if corresponding TAMPxNOER bit is cleared in TAMP_CR2 register (for tamper pins) or TAMP_CR3 register (for internal tamper). These erasable secrets are:
  - Symmetric keys stored in backup registers (x32), in AES, HASH and in OTFDEC (encrypted Flash memory regions are read as zero)
  - Asymmetric keys stored in PKA SRAM
  - Other secrets stored in SRAM2 and CPU instruction cache memory

Note: Device secrets erase are also triggered by setting the BKERASE bit in the TAMP_CR2 register, or by performing an RDP regression as defined in Section 4.11.2: Lifecycle management with readout protection (RDP).

Device secrets are not reset by system reset or when the device wakes up from Standby mode.

Tamper detection and low power modes

The effect of low power modes on tamper detection are summarized on Table 18.

### Table 18. Effect of low-power modes on TAMP

<table>

</tr>
</tbody>
</table>
4.9 Secure storage

4.9.1 Introduction

A critical feature of any security system is how root keys are stored, protected, and provisioned. Such keys are typically used for loading a boot image, or handling of critical user data.

*Figure 9* shows how key management service application can use the AES engine for example to compute external image decryption keys. Embedded non-volatile key can be stored in the secure HDP area (see *Section 4.7.1*), while volatile key storage consists in the battery-powered, tamper-protected SRAM or registers in TrustZone®-aware TAMP peripheral.

Details on tamper protection is found in *Section 4.8.4*, while TrustZone® features of TAMP is briefly described in *Section 4.6.6*.

![Figure 9. Key management principle](image_url)

4.9.2 Unique ID

The STM32L552xx and STM32L562xx store a 96-bit ID that is unique to each device. It is stored at the address 0x0BFA 0590.

Application services can use this unique identity key to identify the product in the cloud network, or make it difficult for counterfeit devices or clones to inject untrusted data into the network.

4.10 Crypto engines

4.10.1 Introduction

STM32L552xx and STM32L562xx devices implement state-of-the-art cryptographic algorithms featuring key sizes and computing protection as recommended by national security agencies such as NIST for the U.S.A, BSI for Germany or ANSSI for France. Those algorithms are used to support privacy, authentication, integrity, entropy and identity attestation.
The crypto engines embedded in STM32 reduces weaknesses on the implementation of critical cryptographic functions, preventing for example the use of weak cryptographic algorithms and key sizes. They also enable lower processing times and lower power consumption when performing cryptographic operations, offloading those computations from Cortex®-M33. This is especially true for asymmetric cryptography.

For product certification purpose, ST can provides certified device information on how these security functions are implemented and validated.

For more information on crypto engine processing times, refer to their respective sections in the reference manual.

### 4.10.2 Crypto engines features

*Table 19* lists the accelerated cryptographic operations available in the STM32L552xx and STM32L562xx devices.

**Note:** Additional operations can be added using firmware.

Public key accelerator can accelerate asymmetric crypto operations (like key pair generation, ECC scalar multiplication, point on curve check). See *Section 32: Public key accelerator (PKA)* for details.

4.10.3 On-the-fly decryption engine (OTFDEC)

OTFDEC TrustZone®-aware peripheral proposes on-the-fly decryption of encrypted images stored on external Flash memory, connected through OCTOSPI peripheral. This decryption process introduces almost no additional cycle overhead when standard NOR Flash memory is used. OTFDEC can also be used to encrypt Flash memory images on the device, for example to encrypt with a device unique secret key.

When a tamper event is confirmed in TAMP peripheral, all OTFDEC keys are erased and encrypted regions read as zero until OTFDEC is properly initialized again.

Typical usage of OTFDEC can be found in Section 4.13.3: Software intellectual property protection with OTFDEC. For more details on the programming of the peripheral please refer to Section 31: On-the-fly decryption engine (OTFDEC).

4.11 Product Lifecycle

4.11.1 Introduction

A typical IoT device lifecycle is summarized in Figure 10. For each step, STM32L552xx and STM32L562xx devices propose secure lifecycle management mechanisms embedded in the hardware.
More details on the various phases and associated transitions, found either at the vendor or end user premises, are summarized on Table 20.

<table>
<thead>
<tr>
<th>Transitions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device manufacturing</td>
<td>STMicroelectronics creates new STM32 devices, always checking for manufacturing defects. During this process STM32 is provisioned with ROM firmware, secure firmware install (SFI) unique key pair, and a public ID.</td>
</tr>
<tr>
<td>Vendor manufacturing</td>
<td>One (or more) vendor is responsible for the platform assembly, initialization, and provisioning before delivery to the end user. This end user can use the final product (&quot;productization&quot; transition) or he/she can use the platform for software development (&quot;user provisioning&quot; transition).</td>
</tr>
<tr>
<td>Productization</td>
<td>The end user gets a product ready for use. All security functions of the platform are enabled, the debugging/testing features are restricted/disabled, and unique boot entry to immutable code is enforced.</td>
</tr>
<tr>
<td>User provisioning</td>
<td>Platform vendor prepares an individual platform for development, not to be connected to a production cloud network.</td>
</tr>
<tr>
<td>Field return or decommissioning</td>
<td>Those are one way transitions, with devices kept in user premises or returned to the manufacturer. In both cases all data including user data are destroyed, therefore the device loses the ability to operate securely (e.g., connecting to a managed IoT network).</td>
</tr>
</tbody>
</table>

The features described hereafter contribute to securing the device lifecycle.
4.11.2 Lifecycle management with readout protection (RDP)

The readout protection mechanism (full hardware feature) controls the access to the STM32L552xx and STM32L562xx debug, test and provisioned secrets, as summarized on Table 21. The supported transitions, summarized on Figure 11, can be requested (when available) through the debug interface or via the system bootloader.

</tbody>
</table>

1. Debug is not available when executing RSS code.
2. Only applicable when TrustZone\(^{\circledR}\) security is activated in the product.
3. External Flash memory area decrypted on-the-fly with OTFDEC peripheral.

Figure 11. RDP level transition scheme

As shown on Figure 11, the user Flash memory is automatically erased, either partially or in totality, during a RDP regression. During the transition from RDP1 to RDP0.5 only non-secure embedded Flash memory is erased, keeping functional for example the secure boot and the secure firmware update. In all regressions OTP area in Flash memory is kept, and device secrets are erased, hence no secrets shall be stored in OTP as they are revealed after a regression to RDP0. Those secrets, erased as response to tamper, are defined in Section 4.8.4: Tamper detection and response.

Note: Enabling TrustZone\(^{\circledR}\) using option byte TZEN is only possible when RDP level is 0.
4.11.3 **Recommended option byte settings**

Most of the time, the user threat model focuses mainly on software attacks, in this case, it may be sufficient to keep the RDP level 1 as device protection.

For a more aggressive threat model, where user may fear physical attacks on the STM32 device, it is recommended to optimize the level of security by setting the RDP level 2. The recommended settings are detailed below:

If TrustZone® is disabled (TZEN=0) it is recommended to set the following option bytes:

- RDP = level 2
- Non-secure boot address option bytes set in user Flash memory

If TrustZone® is enabled (TZEN=1) it is recommended to set the following option bytes:

- RDP = level 2
- Boot_lock = 1
- Secure boot address option bytes set in user Flash memory

4.12 **Access controlled debug**

4.12.1 **Introduction**

The device restricts access to embedded debug features, in order to guarantee the confidentiality of customer assets against unauthorized usage of debug & trace features.

4.12.2 **Debug protection with readout protection (RDP)**

As described in *Section 4.11.2* the hardware readout protection (RDP) mechanism automatically controls the accesses to the device debug and tests. The protection of these debug features are defined in *Table 22*

<table>
<thead>
<tr>
<th>RDP protection level</th>

1. Including ST engineering test modes, used for field returns.
2. Only applicable when TrustZone® security is activated in the product.
3. External Flash memory area decrypted on-the-fly with OTFDEC peripheral.
4.13 Software intellectual property protection and collaborative development

4.13.1 Introduction

Thanks to software intellectual property protection and collaborative model the STM32L552xx and STM32L562xx devices allow to integrate and implement with third-party libraries innovative solutions.

Collaborative development is summarized on Figure 12. Starting from a personalized device sold by STMicroelectronics, a vendor A can integrate a portion of hardware and software on a platform A, that can then be used by a vendor B that will do the same before deploying a final product to the end users.

Note: Each platform vendor can provision individual platforms for development, not to be connected to a production cloud network (“Development Platform X”).

<table>
<thead>
<tr>
<th>Development platform B</th>

</tr>
<tr>
<td></td>
<td>Platform B</td>
</tr>
<tr>
<td>Decommissioned product</td>
<td></td>
</tr>
</tbody>
</table>

The features described hereafter contribute to securing the software intellectual property within such a collaborative development.

4.13.2 Software intellectual property protection with readout protection (RDP)

As described in Section 4.11.2 the hardware readout protection (RDP) mechanism automatically controls the accesses to secrets provisioned in the device. The protection of these secrets are defined in Table 23.
As described in Section 4.10.3 the OTFDEC peripheral associated with the OCTOSPI is able to decrypt on-the-fly encrypted images stored in external SPI Flash memory devices. Thanks to this feature STM32L562xx devices allow the installation of intellectual properties:

- over the air, with the image already encrypted with a key provisioned in the device, or
- through a provisioning host located in a trusted or non-trusted environment/facility.

Figure 13 illustrates this last case with the provisioning, in a non-trusted environment, of software intellectual properties both in embedded Flash memory and in external SPI Flash memory (encrypted).

**Note:** Since OTFDEC is using AES in counter mode (CTR) to achieve the lowest possible latency, each time the content of one encrypted region is changed the corresponding cryptographic context (key or initialization vector) must be changed. This constraint makes OTFDEC suitable to decrypt read-only data or code, stored in external NOR Flash memory.
Assuming the device is virgin, the first step is to provision both Flash memories, as detailed below:

1. User creates an SFI image, composed of:
   - Encrypted internal firmware and data (including external Flash memory drivers)
   - Encrypted external firmware and data AES key (up to 4)
   - Encrypted external firmware and data image

2. The secure bootloader stored in system memory loads the second part of the secure-bootloader in SRAM2 through the supported communication ports (USART, SPI, I2C, FDCAN, USB and JTAG). This second part runs in secure SRAM2 and is responsible for...
for executing the SFI process, applying the SFI protocol thanks to the commands received through the above mentioned supported communication ports.

3. Internal Flash memory is programmed with decrypted option bytes, internal firmware and data, and external firmware and data AES key(s). Alternatively, device unique external firmware AES keys could be used instead of such global keys.

4. OTFDEC is properly initialized with encrypted region(s) information, including the corresponding external firmware and data AES key.

5. Running the SFI process, chunks of encrypted external firmware and data image are decrypted in the device, then re-encrypted in OTFDEC.

6. After chunk OTFDEC re-encryption, user external Flash memory programmer is responsible for programming those last encrypted chunks to external SPI Flash memories through OCTOSPI peripheral.

Secure boot

After provisioning, each time the device initializes on trusted firmware, the following actions are required:

1. Secure boot firmware executes, programming the external firmware and data AES key(s) to OTFDEC write-only key registers, along with the other needed information.

2. Application reads or executes the encrypted external firmware and data through OCTOSPI memory mapped mode, unless a tamper event is detected. In this case all OTFDEC keys are erased and encrypted regions read as zero until OTFDEC is properly initialized again.

For more information on above secure firmware install (SFI) solutions for STM32L552xx and STM32L562xx devices please refer to AN4992 on STMicroelectronics website.

4.13.4 Other software intellectual property protections

STM32L552xx and STM32L562xx devices additional protections to software intellectual property is:

- Invasive attacks such as physical tampering or perturbation are countered by detection then decommissioning of the device before the detected attack succeeds.
5 Global TrustZone® controller (GTZC)

5.1 GTZC introduction
This section includes the description of the three following sub-blocks:

- **TZSC**: TrustZone® security controller
  This sub-block defines the secure/privilege state of slave/master peripherals. It also controls the non-secure area size for the watermark memory peripheral controller (MPCWM). The TZSC block informs some peripherals (such as RCC or GPIOs) about the secure status of each securable peripheral, by sharing with RCC and I/O logic.

- **MPCBB**: block-based memory protection controller
  This sub-block controls secure states of all blocks (256-byte pages) of the associated SRAM.

- **TZIC**: TrustZone illegal access controller
  This sub-block gathers all illegal access events in the system and generates a secure interrupt towards NVIC.

These sub-blocks are used to configure TrustZone system security in a product having bus agents with programmable-security and privileged attributes (securable) such as:

- on-chip RAM with programmable secure blocks (pages)
- AHB and APB peripherals with programmable security and/or privilege access
- AHB master granted as secure and/or privilege
- off-chip memories with secure areas

5.2 GTZC main features
GTZC main features are listed below:

- 3 independent 32-bit AHB interface for TZSC, MPCBB and TZIC
- MPCBB and TZIC accessible only with secure transactions
- Secure and non-secure access supported for priv/non-priv part of TZSC
- Set of registers to define product security settings:
  - Secure blocks for internal SRAM
  - Non-secure regions for external memories
  - Secure/privilege access mode for securable and TrustZone-aware peripherals
  - Secure/privilege access mode for securable masters

5.2.1 GTZC TrustZone system architecture
The Armv8-M supports security per TrustZone-M model with isolation between:

- a secure world, where usually security sensitive applications are run and critical resources are located; secure transactions are signaled with HNONSEC[1] = 0 on AHB bus
- a non-secure or public world (such as usual non secure and user space) where non-secure transactions are signaled with HNONSEC = 1 on AHB bus
The TrustZone architecture is extended beyond AHB and Armv8-M with:

- AHB/APB bridge used as secure gate to block or propagate secure/non-secure and privilege/non-privilege transaction towards APB agents
- Peripheral protection controller (PPC) used as secure gate to block or propagate secure/non-secure and privilege/non-privilege transaction towards AHB agents
- TrustZone block-based MPC firewalls used as secure gate to filter secure/non-secure access towards internal SRAMs
- Trustzone watermark MPC firewalls used as secure gate to filter secure/non-secure access towards external memories

AHB and APB peripherals can be categorized as:

- **privilege**: peripherals protected by AHB/APB firewall stub that is controlled from TZSC to define privilege properties
- **secure**: peripherals always protected by an AHB/APB firewall stub. These peripherals are always secure (TZIC).
- **securable**: peripherals protected by an AHB/APB firewall stub that is controlled from TZSC to define security properties (optional)
- **non-secure and non-privilege**: peripherals connected directly to AHB/APB interconnect without any secure gate
- **TrustZone-aware**: peripherals connected directly to AHB or APB bus and implementing a specific TrustZone behavior (such as a subset of registers being secure). TrustZone-aware AHB masters always drive HNONSEC signal according to their security mode (such as Armv8-M core or DMA).

AHB securable masters can be configured in the TZSC to be secure/non-secure and/or privilege/non-privilege.

**Application information**

The TZSC, MPCBB and TZIC sub-blocks can be used in one of the following ways:

- programmed during secure Boot only, locked and not changed afterwards
- dynamically re-programmed when using specific application code or secure kernel (microvisor). When not locked, MPC secure blocks or region size can be changed by secure software executing from the secure FLASH memory region or secure SRAM. Same remark applies to the GTZC_TZSC_SECCFRGx and GTZC_TZSC_PRIVCFGRx registers that define secure/privilege state of each peripheral.
The Armv8-M security architecture with secure, securable and TrustZone-aware peripherals is shown in Figure 14.

Figure 14. GTZC in Armv8-M subsystem block diagram

5.3 GTZC functional description

5.3.1 GTZC block diagram

Figure 15 describes the combined feature of TZSC, MPCBB and TZIC. Each sub-block is controlled by its own AHB configuration port. The TZSC defines which peripheral is secured and/or privileged.

The privilege configuration bit of a given peripheral can be modified by a secure-privilege transaction when the peripheral has been configured as secure, otherwise a privileged transaction (non-secure) is sufficient. The definition of these privilege attributes is possible even when TZEN = 0.
The secure configuration bit a given peripheral can be modified only with a secure-privilege transaction if the peripheral has been configured as privilege, otherwise a secure transaction (non-privileged) is sufficient.

Figure 15. GTZC block diagram

5.3.2 Illegal access definition

Three different types of illegal access exist:

- **Illegal non-secure access**
  
  Any non-secure transaction trying to write a secure resource is considered as illegal and thus the addressed resource generates an illegal access event for illegal write access, and a bus error for illegal fetch access. However some exceptions exist on transactions to secure and privilege configuration registers; these later ones authorized non-secure read access to secure registers (see GTZC_TZSC_SECCFGRx and GTZC_TZSC_PRIVCFGRx registers).

- **Illegal secure access**
  
  Any secure transaction trying to access a non-secure block in internal block-based SRAM or watermarked external memory, is considered as illegal.

  Correct settings of the TZIC allows the capture of the associated event and then generates the GTZC_IRQn interrupt to the NVIC. This applies for read, write and execute access.
Concerning the MPCBB controller, there is an option to ignore secure data read/write access on non-secure SRAM blocks, by setting the SRWILADIS configuration bit in the GTZC_MPCBBx_CR register. Secure read and write data transactions are then allowed on non-secure SRAM blocks, while secure execution access remains not allowed.

Any secure execute transaction trying to access a non-secure peripheral register or memory is considered as illegal and generates a bus error.

- **Illegal non-privilege access**
  Any non-privilege transaction trying to access a privilege resource is considered as illegal. There is no illegal access event generated for this type of illegal access. The addressed resource follows a silent-fail behavior, returning all zero data for read and ignoring any write. No bus error is generated.

### 5.3.3 TrustZone security controller (TZSC)

This block is composed of a configurable set of registers, providing the following features:

- Control of secure and privilege state for all peripherals, done through:
  - GTZC_TZSC_SECCFGRx registers to control AHB/APB firewall stubs for the securable peripherals and/or master
  - GTZC_TZSC_PRIVCFGRx registers to control AHB/APB firewall stubs for the privileged peripherals and/or master

- For watermark memory protection controller (external memories), two independent regions can be defined and the following fields are used to program:
  - start of the first non-secure area on external memory = NSWMxSTRT1[10:0]
  - length of the first non-secure area on external memory = NSWMxLGTH1[11:0]
  - start of the second non-secure area on external memory = NSWMxSTRT2[10:0]
  - length of the second non-secure area on external memory = NSWMxLGTH2[11:0]

**Note:**

- x represents the target external memory interface (such as FMC or OCTOSPI).
- The total area considered as non-secure is the sum of the two independent ones. An overlap of one section over the other one has no specific effect.
- Table 24 describes the characteristics of the available MPCWMx.

#### Table 24. MPCWMx

<table>
<thead>
<tr>
<th>MPC</th>
<th>Type</th>

</tr>
<tr>
<td>MPCWM3</td>
<td>Non secure watermark (region)</td>
<td>1</td>
<td>FMC_NAND bank</td>
</tr>
</tbody>
</table>

### 5.3.4 Memory protection controller - block based (MPCBB)

For block-based memory protection controller (internal SRAM), the below registers are available:

- GTZC_MPCBBx_VCTRy to program the vector defining 32 consecutive 256-byte block states, secure or non-secure (means y registers of 32 bits)
- GTZC_MPCBBx_LCKVTRy to program the lock of super block (32 blocks)
Note: \( y \) represents the number of super-blocks (super-block = 32 blocks of SRAM_BB_size). On the STM32L552xx and STM32L562xx devices, the SRAM size = 192 Kbytes and the block size = 256 bytes, then super-block size = 32 * 256 = 8 Kbytes and \( y = 192 / 8 = 24 \). It means 24 vector registers (32-bit) are needed to control the secure state of all the 256-byte blocks. Concerning the lock bit, only one 32-bit lock register is needed since a single lock bit applies on a super-block (32 * 256 bytes).

Table 25 describes the characteristics of the available MPCBBx.

<table>
<thead>
<tr>
<th>MPC</th>
<th>Type</th>
<th>Number of blocks</th>
<th>Target memory interface</th>
</tr>
</thead>
<tbody>
<tr>
<td>MPCBB1</td>
<td>Block based (block size = 256 bytes)</td>
<td>768</td>
<td>SRAM1</td>
</tr>
<tr>
<td>MPCBB2</td>
<td>Block based (block size = 256 bytes)</td>
<td>256</td>
<td>SRAM2</td>
</tr>
</tbody>
</table>

5.3.5 TrustZone illegal access controller (TZIC)

This block concentrates all illegal access source events. It is used only when the system is TrustZone enabled (TZEN = 1).

TZIC allows the trace of which event triggered the NVIC GTZC_IRQn. Register masks (GTZC_TZIC_IERx) are available to filter unwanted event. On unmasked illegal event, the TZIC generates the GTZC_IRQn signal to NVIC that corresponds to the GTZC_IRQn secure interrupt.

For each illegal event source, a status flag and a clear bit exist (respectively within GTZC_TZIC_SRx and GTZC_TZIC_FCRx registers). The reset value of mask registers (GTZC_TZIC_IERx) is such that all events are masked.

5.3.6 Power-on/reset state

The power-on and reset state of the TZSC clear all bits of GTZC_TZSC_SECCFGRx and GTZC_TZSC_PRIVCFGRx registers to 0, which respectively means non-secure and non-privilege. Concerning the internal SRAM, the reset values of the GTZC_MPCBBx_VCTRy registers are set to 0xFFFF FFFF, making all blocks of the block-based SRAM memory secure. This is valid only when TrustZone security is enabled at system level (TZEN = 1). In the other case (legacy mode, TZEN = 0), the reset values of the GTZC_MPCBBx_VCTRy registers are set to 0x0000 0000 so that all block-based SRAM memories are non-secure.

Same thing applies for external memories, all MPCWMx_NSWMyR registers must be set to 0xFFFF FFFF, making the whole external memory non-secure. Secure Boot code can then program the security settings, making components secure or not as needed.

5.3.7 DMA requests

TZSC does not support any DMA interface.

5.4 GTZC events

MPCBB and TZIC are secure peripherals, thus they both systematically generate an illegal access event when accessed by a non-secure access. The TZSC is a TrustZone-aware peripheral, meaning that secure and non-secure registers co-exist within the peripheral. An
exception exists for the GTZC_TZSC_SECCFGR and GTZC_TZSC_PRIVCFGR: any read access, secure or not, are supported.

5.5 GTZC_TZSC registers

All registers are accessed only by words (32-bit).

5.5.1 GTZC_TZSC control register (GTZC_TZSC_CR)

Address offset: 0x000

Reset value: 0x0000 0000

Write-secure access only.

Read accesses are authorized for any type of transactions, secure or not, privilege or not.

<table>
<thead>
<tr>

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **LCK**: lock the configuration of TZSC items until next reset

This bit is unset by default and once set, it can not be reset until global TZSC reset.

0: control register not locked

1: control register locked
5.5.2 GTZC_TZSC secure configuration register 1 (GTZC_TZSC_SECCFGR1)

Address offset: 0x010
Reset value: 0x0000 0000

Write-secure access only.

This register can be written only by privilege secure transaction when corresponding TZSC_PRIVCFGR register signal is set to 1. If a given PRIV bit is not set, the equivalent SEC bit can be written by non-privilege secure transaction.

Read accesses are authorized for any type of transactions, secure or not, privilege or not.

### 5.5.4 GTZC_TZSC privilege configuration register 1 (GTZC_TZSC_PRIVCFGR1)

Address offset: 0x020
Reset value: 0x0000 0000

Write-privileged access only.

This register can be read or written only by secure privilege transaction when corresponding TZSC_SECFCGR register signal is set to 1. If a given SEC bit is not set, the equivalent PRIV bit can be read/written by non-secure privileged transaction.

Read accesses are authorized for any type of transactions, secure or not, privilege or not.

</table>
5.5.6 GTZC_TZSC external memory x non-secure watermark register 1 (GTZC_TZSC_MPCWMxANSR)

Address offset: 0x030 + 0x008 * (x-1), (x = 1 to 3)

Reset value: 0x0000 0000

The given reset value is valid when TZEN = 1. The reset value is 0x0800 0000 when TZEN = 0.

Secure access only.

Caution: When NSWM1STRT + NSWM1LGTH is higher than the maximum size allowed for the memory, a saturation of NSWM1LGTH is applied automatically.

<table>
<thead>
<tr>
<th>Bit</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:28</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
<tr>
<td>27:16</td>
<td>NSWM1LGTH[11:0]: length of the first non-secure area (multiple of 128 Kbytes)</td>
</tr>
<tr>
<td>15:11</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
<tr>
<td>10:0</td>
<td>NSWM1STRT[10:0]: offset address for the first non-secure area (multiple of 128 Kbytes)</td>
</tr>
</tbody>
</table>

Note: If programmed NSWM1LGTH + NSWM1STRT is over 2048, the value stored in the register is truncated to (0x800 - NSWM1STRT). Any subsequent read returns this value.

5.5.7 GTZC_TZSC external memory x non-secure watermark register 2 (GTZC_TZSC_MPCWMxBNSR)

Address offset: 0x034 + 0x008 * (x-1), (x = 1 to 2)

Reset value: 0x0000 0000

The given reset value is valid when TZEN = 1. The reset value is 0x0800 0000 when TZEN = 0.

Secure access only.

Caution: When NSWM1STRT + NSWM1LGTH is higher than the maximum size allowed for the memory, a saturation of NSWM1LGTH is applied automatically.
Note: If NSWM1LGTH = 0, the region 1 is disabled and the only non-secure memory space is defined by NSWMPxWM2.

If both NSWMPxWM1 and NSWMPxWM2 have the reset value 0x0000 0000, all the memory space of the external memory x (FMC NOR/ SRAM or OCTOSPI) is secure.

If NSWM1LGTH = 0x800 and NSWM1STRT = 0, the whole 256-Mbyte memory space is non-secure (independent of NSWMPxWM2 value).

If NSWM1LGTH = 0x001 and NSWM1STRT = 0x7FF, only one 128-Kbyte block is defined as non-secure (at address offset = 0x0FE 0000, ending at 0x0FFF FFFF).

### 5.5.8 GTZC_TZSC register map and reset values

<table>
<thead>
<tr>
<th>Offset</th>
<th>Register</th>

<td>SPI1SEC TIM1SEC COMPSEC VARAFU1SEC UCP11SEC LTCH1SEC LFART1SEC LPTM1SEC LPTM2SEC DPAPISEC</td>
</tr>
</tbody>
</table>

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **NSWM2LGTH[11:0]**: length of the second non-secure area (multiple of 128 Kbytes)

- **Note:** If programmed NSWM2LGTH + NSWM2STRT is over 2048, the value stored in the register is truncated to (0x800 - NSWM2STRT). Any subsequent read returns this value.

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:0 **NSWM2STRT[10:0]**: offset address for the second non-secure area (multiple of 128 Kbytes)

- **Note:** External memories which are watermark controlled start fully non-secure at reset when TZEN = 0. When TZEN = 1, external memories start fully secure (inverted reset-value).

Refer to Section 2.3 on page 87 for the register boundary addresses.
5.6 **GTZC_MPCBB registers**

All registers are accessed only by words (32-bit).

5.6.1 **GTZC_MPCBBx control register (GTZC_MPCBBx_CR) (x = 1 to 2)**

Address offset: 0x800 + 0x400 * (x - 1)

Reset value: 0x0000 0000

Secure access only.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

Bit 31 **SRWILADIS**: secure read/write illegal access disable

This bit disables the detection of an illegal access when a secure read/write transaction access a non-secure blocks of the block-based SRAM (secure fetch on non-secure block is always considered illegal).

0: enabled, secure read/write access not allowed on non-secure SRAM block
1: disabled, secure read/write access allowed on non-secure SRAM block

Bit 30 **INVSECSTATE**: default security state

This bit is used to invert the MPCBB status information (secure or non-secure) connected to the RCC, in order to define the MPCBB clock control as secure or not.

0: default state (source clock secured if a secure area exists in the MPCBB and vice-versa)
1: invert the state, source clock remains secure even if no secure block is set in the MPCBB

Bits 29:1 **Reserved, must be kept at reset value**.

Bit 0 **LCK**: lock the control register of the MPCBB sub-block until next reset

This bit is unset by default and once set, it can not be reset until global TZSC reset.

0: control register not locked
1: control register locked
### 5.6.2 GTZC_MPCBB1 lock register 1 (GTZC_MPCBB1_LCKVTR1)

Address offset: 0x810  
Reset value: 0x0000 0000  
Secure access only.

</tbody>
</table>

Bits 31:8 Reserved, must be kept at reset value.  
Bits 7:0 **LCKSB[7:0]**: lock/unlock status of secure access mode for the super-blocks 0 to 7  
0x00: security configuration unlocked for all super-blocks  
...  
0xFF: security configuration locked for super-blocks 0 to 7
5.6.4 **GTZC_MPCBBx vector register y**  
(\textit{GTZC\_MPCBBx\_VCTRy}) (x = 1 to 2)

Address offset: \(0x900 + 0x04 \times y\) (y = 0 to 23)

Reset value: \(0xFFFF\ FFFF\)

The given reset value is valid when TZEN = 1. The reset value is \(0x0000\ 0000\) when TZEN = 0.

Secure access only.

Bits 31:0 \(B_{[31+ 32 \times y:32 \times y]}\): define secure access mode for the super-block \(y\)

- \(0x0000\ 0000\): all blocks of super-block \(y\) are non-secure.
- \(0x0000\ 00FF\): only blocks 0 to 7 of super-block \(y\) are secure.
- \(0x8000\ 0001\): only blocks 0 and 31 of super-block \(y\) are secure.
- \(0xFFFF\ FFFF\): all super-blocks are secure.

5.7 GTZC_TZIC registers

All registers are accessed only by words (32-bit).

5.7.1 GTZC_TZIC interrupt enable register 1 (GTZC_TZIC_IER1)

Address offset: 0x400
Reset value: 0x0000 0000
Secure access only.

This register is used to enable/disable generation of GTZC_IRQn interrupt towards NVIC on illegal access event for each source.

Refer to Section 2.3 on page 87 for the register boundary addresses.
6 Embedded Flash memory (FLASH)

6.1 Introduction

The Flash memory interface manages accesses to the Flash memory, maximizing throughput to the CPU, instruction cache and DMAs. It implements the Flash memory erase and program operations as well as the read and write protection mechanisms. It also implements the security and privilege access control features.

6.2 FLASH main features

- Up to 512 Kbytes of Flash memory with dual bank architecture supporting read-while-write capability (RWW).
- Flash memory read operations with two data width modes supported:
  - Single bank mode DBANK=0: read access of 128 bits
  - Dual bank mode DBANK=1: read access of 64 bits
- Page erase, bank erase and mass erase (both banks).
- Bank swapping: the address mapping of the user Flash memory of each bank can be swapped.
- Readout protection activated by option (RDP) byte.
- Four write protection areas (two per bank when DBANK=1 and four for full memory when DBANK=0).
- TrustZone support:
  - Two secure areas (1 per bank when DBANK=1, 2 for all memory when DBANK=0)
  - Two secure HDP (hide protection) areas part of the secure areas (one per bank when DBANK=1, two for all memory when DBANK=0).
- Error code correction ECC: 8 bits per 64-bit double-word:
  - DBANK=1: 8 + 64 = 72 bits, two bits detection, one bit correction
  - DBANK=0: (8+64) + (8+64) = 144 bits, two bits detection, one bit correction per 64-bit double-word.
- Option-byte loader.
- Low-power mode.
- Privileged and unprivileged support.
6.3 Flash memory functional description

6.3.1 Flash memory organization

The Flash memory has the following main features:

- Capacity up to 512 Kbytes, in single-bank mode (read width of 128 bits) or in dual-bank mode (read width of 64-bits).
- Dual-bank mode when DBANK bit is set:
  - 256 Kbytes organized in two banks for main memory.
  - Page size of 2 Kbytes.
  - 72 bits wide data read (64 bits plus 8 ECC bits).
  - Bank and mass erase.
- Single-bank mode when DBANK is reset:
  - 512 Kbytes organized in one single bank for main memory.
  - Page size of 4 Kbytes.
  - 144 bits wide data read (64 bits plus 2x 8 ECC bits).
  - Mass erase.

The Flash memory is organized as follows:

- A main memory block organized depending on the dual bank configuration bit:
  - When dual bank is enabled (DBANK bit set), the Flash is divided in two banks of 256 Kbytes, and each bank is organized as follows:
    The main memory block containing 128 pages of 2 Kbytes
  - When dual bank is disabled (DBANK bit reset), the main memory block is organized as one single bank of 512 Kbytes as follows:
    The main memory block containing 128 pages of 4 Kbytes.
- An Information block containing:
  - 32 Kbytes for system memory. The area is reserved for use by STMicroelectronics and contains the bootloader that is used to reprogram the Flash memory through one of the following interfaces: USART1, USART2, USART3, USB (DFU), I2C1, I2C2, I2C3, SPI1, SPI2, SPI3. It is programmed by STMicroelectronics when the device is manufactured, and protected against spurious write/erase operations. For further details, please refer to the application note STM32 microcontroller system memory boot mode (AN2606) available from www.st.com.
  - 10 Kbytes for root secure services (RSS).
  - 512 bytes OTP (one-time programmable) bytes for user data. The OTP data cannot be erased and can be written only once. If only one bit is at 0, the entire double word cannot be written anymore, even with the value 0x0000 0000 0000 0000.
  - 4 Kbytes of option bytes for user configuration. Unlike user Flash memory and system memory, it is not mapped to any memory address and can be accessed only through the Flash register interface.

The memory organization is based on a main area and an information block as shown in Table 30: Flash module - 512 KB dual bank organization (64 bits read width) and Table 31: Flash module - 512 KB single bank organization (128 bits read width).

1. When the TrustZone is enabled (TZEN = 1), the non-secure information block is accessible only with a non-secure access. This means that in order to be able to access any address in this region, it should be configured as non-secure through the SAU. This region is also accessible when booting from RSS.

**Note:** The secure information block is only available when TrustZone is active.

1. When the TrustZone is enabled (TZEN = 1), the non-secure information block is accessible only with a non-secure access. This means that in order to be able to access any address in this region, it should be configured as non-secure through the SAU. This region is also accessible when booting from RSS.
Note: The secure information block is only available when TrustZone is active.

6.3.2 Error code correction (ECC)

Dual bank mode (DBANK=1, 64-bits data width)

Data in Flash memory are 72-bits words: 8 bits are added per double word (64 bits). The ECC mechanism supports:

- One error detection and correction per 64 double words
- Two errors detection

When one error is detected and corrected, the flag ECCC (ECC correction) is set in Flash ECC register (FLASH_ECCR). If ECCCIE is set, an interrupt is generated.

When two errors are detected, a flag ECCD (ECC detection) is set in FLASH_ECCR register. In this case, a NMI is generated.

When an ECC error is detected, the address of the failing double word and its associated bank are saved in ADDR_ECC[17:0] and BK_ECC in the FLASH_ECCR register. ADDR_ECC[18] and ADDR_ECC[2:0] are always cleared.

When ECC or ECCD is set, ADDR_ECC and BK_ECC are not updated if a new ECC error occurs. FLASH_ECCR is updated only when ECC flags are cleared.

Note: For a virgin data: 0xFF FFFF FFFF FFFF FFF F, one error is detected and corrected but two errors detection is not supported.

When an ECC error is reported, a new read at the failing address may not generate an ECC error if the data is still present in the current buffer, even if ECCC and ECCD are cleared.

Single bank mode (DBANK=0, 128-bits data width)

Data in Flash memory are 144-bits words: 8 bits are added per each double word. The ECC mechanism supports:

- One error detection and correction
- Two errors detection per 64 double words

The user must first check the SYSF_ECC bit, and if it is set, the user must refer to the DBANK=1 programming model (because system Flash is always on two banks). If the bit is not set, the user must refer to the following programing model:

Each double word (bits 63:0 and bits 127:64) has ECC.

When one error is detected in 64 LSB bits (bits 63:0) and corrected, a flag ECCC (ECC correction) is set in the FLASH_ECCR register.

When one error is detected in 64 MSB bits (bits 127:64) and corrected, a flag ECCC2 (ECC2 correction) is set in the FLASH_ECCR register.

If the ECCCIE is set, an interrupt is generated. The user has to read ECCC and ECCC2 to see which part of the 128-bits data has been corrected (either 63:0, 127:64 or both).

When two errors are detected in 64 LSB bits, a flag ECCD (ECC detection) is set in the FLASH_ECCR register.

When two errors are detected in 64 MSB bits (bits 127:64), a flag ECCD2 (ECC2 detection) is set in the FLASH_ECCR register.
In this case, a NMI is generated. The user has to read ECCD and ECCD2 to see which part of the 128-bits data has error detection (either 63:0, 127:64 or both).

When an ECC error is detected, the address of the failing the two times double word is saved into ADDR_ECC[18:0] in FLASH_ECCR. ADDR_ECC[18:0] contains an address of a two times double word.

The ADDR_ECC[3:0] are always cleared. BK_ECC is not used in this mode.

When ECC/ECC2 or ECCD/ECCD2 is/are set, if a new ECC error occurs, the ADDR_ECC is not updated. The FLASH_ECCR is updated only if the ECC flags (ECCC/ECC2/ECCD/ECCD2) are cleared.

**Note:**

- For a virgin data: 0xFF FFFF FFFF FFFF FFF F, one error is detected and corrected but two errors detection is not supported.
- When an ECC error is reported, a new read at the failing address may not generate an ECC error if the data is still present in the current buffer, even if ECCC and ECCD are cleared.

### 6.3.3 Read access latency

To correctly read data from Flash memory, the number of wait states (LATENCY) must be correctly programmed in the FLASH registers according to the frequency of the CPU clock (HCLK) and the internal voltage range of the device VCORE. Refer to [Section 8.2.5: Dynamic voltage scaling management](#). Table 32 shows the correspondence between wait states and CPU clock frequency.

#### Table 32. Number of wait states according to CPU clock (HCLK) frequency

<table>
<thead>
<tr>
<th>Wait states (WS) (Latency)</th>
<th>HCLK (MHz)</th>
<th>VCORE Range 0</th>
<th>VCORE Range 1</th>
<th>VCORE Range 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 WS (1 CPU cycles)</td>
<td>≤20</td>
<td>≤20</td>
<td>≤8</td>
<td></td>
</tr>
<tr>
<td>1 WS (2 CPU cycles)</td>
<td>≤40</td>
<td>≤40</td>
<td>≤16</td>
<td></td>
</tr>
<tr>
<td>2 WS (3 CPU cycles)</td>
<td>≤60</td>
<td>≤60</td>
<td>≤26</td>
<td></td>
</tr>
<tr>
<td>3 WS (4 CPU cycles)</td>
<td>≤80</td>
<td>≤80</td>
<td>-</td>
<td></td>
</tr>
<tr>
<td>4 WS (5 CPU cycles)</td>
<td>≤100</td>
<td>-</td>
<td>-</td>
<td></td>
</tr>
<tr>
<td>5 WS (6 CPU cycles)</td>
<td>≤110</td>
<td>-</td>
<td>-</td>
<td></td>
</tr>
</tbody>
</table>

After reset, the CPU clock frequency is 4 MHz and 0 wait state (WS) is configured in the Flash_ACR register.

When changing the CPU frequency, the following software sequences must be applied in order to tune the number of wait states needed to access the Flash memory:
Increasing the CPU frequency:

1. Program the new number of wait states to the LATENCY bits in Section 6.9: FLASH registers.
2. Check that the new number of wait states is taken into account to access the Flash memory by reading the FLASH_ACR register.
3. Modify the CPU clock source by writing the SW bits in the RCC_CFGR register.
4. If needed, modify the CPU clock prescaler by writing the HPRE bits in RCC_CFGR.
5. Check that the new CPU clock source or/and the new CPU clock prescaler value is/are taken into account by reading the clock source status (SWS bits) or/and the AHB prescaler value (HPRE bits), respectively, in the RCC_CFGR register.

Decreasing the CPU frequency:

1. Modify the CPU clock source by writing the SW bits in the RCC_CFGR register.
2. If needed, modify the CPU clock prescaler by writing the HPRE bits in RCC_CFGR.
3. Check that the new CPU clock source or/and the new CPU clock prescaler value is/are taken into account by reading the clock source status (SWS bits) or/and the AHB prescaler value (HPRE bits), respectively, in the RCC_CFGR register.
4. Program the new number of wait states to the LATENCY bits in Section 6.9: FLASH registers.
5. Check that the new number of wait states is used to access the Flash memory by reading the FLASH_ACR register.

6.3.4 Low-voltage read

When the external SMPS option is used, the Flash must be programmed in low voltage read mode.

- Voltage scaling range must be in range 2.
- Unlock the LVEN bit by the following procedure:
  - Write LVEKEY1 = 0xF4F5F6F7 in the FLASH_LVEKEYR.
  - Write LVEKEY2 = 0x0A1B2C3D in the FLASH_LVEKEYR.
- Set the LVEN bit in the FLASH_ACR register.
- Check the LVEN bit is set.
- Read back the LVEN bit the FLASH_ACR register

6.3.5 Flash program and erase operations

The embedded Flash memory can be programmed using in-circuit programming or in-application programming.

The in-circuit programming (ICP) method is used to update the entire contents of the Flash memory, using the JTAG, SWD protocol or the bootloader to load the user application into the microcontroller. ICP offers quick and efficient design iterations and eliminates unnecessary package handling or socketing of devices.

In contrast to the ICP method, in-application programming (IAP) can use any communication interface supported by the microcontroller (I/Os, USB, CAN, UART, I2C, SPI, etc.) to download programming data into memory. IAP allows the user to re-program the
Flash memory while the application is running. Nevertheless, part of the application must have been previously programmed in the Flash memory using ICP.

The contents of the Flash memory are not guaranteed if a device reset occurs during a Flash memory program or erase operation.

In dual bank mode, an on-going Flash memory operation does not block the CPU as long as the CPU does not access the same Flash memory bank. Code or data fetches are possible on one bank while a write/erase operation is performed to the other bank (refer to Section 6.3.9: Read-while-write (RWW) available only in dual-bank mode (DBANK = 1)). The Flash erase and programming is only possible in the voltage scaling range 0 and 1.

**Note:** At power-on reset or a system reset, the main regulator voltage range 2 is selected by default. Consequently, the voltage scaling range must be programmed to range 0 or range 1 via VOS[1:0] bits in the PWR_CR1 register prior to any Flash erase and programming operation.

On the contrary, during a program/erase operation to the Flash memory, any attempt to read the same Flash memory bank stalls the bus. The read operation proceeds correctly once the program/erase operation has been completed.

The MCU supports Arm® TrustZone® which defines secure and non-secure areas in Flash. All program and erase operations can be performed in secure mode through the secure registers or in non-secure mode through the non-secure registers. For more information, refer to Section 6.5: Flash TrustZone security and privilege protections.

**Unlocking the secure/non-secure Flash control register**

After reset, write is not allowed in the secure/non-secure Flash control register `FLASH_NSCR/FLASH_SECCR` to protect the Flash memory against possible unwanted operations due, for example, to electric disturbances. The following sequence is used to unlock this register:

1. Write KEY1 = 0x45670123 in the Flash secure key register (`FLASH_SECKEYR`) or Flash non-secure key register (`FLASH_NSKEYR`).
2. Write KEY2 = 0xCDEF89AB in the Flash secure key register (`FLASH_SECKEYR`) or Flash non-secure key register (`FLASH_NSKEYR`).

Any wrong sequence locks up the `FLASH_NSCR/FLASH_SECCR` register until the next system reset. In the case of a wrong key sequence, a bus error is detected and a Hard Fault interrupt is generated.

The `FLASH_NSCR` and `FLASH_SECCR` registers can be locked again by software by setting the NSLOCK and SECLOCK bit in the `FLASH_NSCR` and `FLASH_SECCR` register respectively.

**Note:** The `FLASH_NSCR` and `FLASH_SECCR` registers cannot be written when the NSBSY or SECBSY bits are set. Any attempt to write to them with the NSBSY or SECBSY bit causes the AHB bus to stall until the NSBSY and SECBSY bits are cleared.
Flash secure and non-secure busy flags

The SECBSY and NSBSY flags are both set when a secure or non-secure Flash operation is started:

- Erase operation: setting the NSSTRT in the Flash non-secure control register (FLASH_NSCR) or setting the SECSTRT in the Flash secure control register (FLASH_SECCR).
- Write operation: setting the NSPG or SECPG bit in the FLASH_NSCR or FLASH_SECCR register respectively and writing a double-word in the Flash memory.
- Option bytes programming: setting the OPTSTRT in the FLASH_NSCR.

6.3.6 Flash main memory erase sequences

The Flash memory erase operation can be performed at page level, bank level or on the whole Flash memory (mass erase). Mass erase does not affect the information block (system Flash, OTP and option bytes). The erase operation is either secure or non-secure.

Non-secure page erase

To erase a non-secure page, follow the procedure below:

1. Check that no Flash memory operation is ongoing by checking the NSBSY bit in the Flash status register (FLASH_NSSR).
2. Check and clear all non-secure error programming flags due to a previous programming. If not, NSPGSERR is set.
3. In dual-bank mode (DBANK option bit is set), set the NSPER bit and select the non-secure page to erase (NSPNB) with the associated bank (NSBKER) in the FLASH_NSCR. In single-bank mode (DBANK option bit is reset), set the NSPER bit and select the page to erase (NSPNB). The NSBKER bit in the FLASH_NSCR must be kept cleared.
4. Set the NSSTRT bit in the FLASH_NSCR register.
5. Wait for the NSBSY bit to be cleared in the FLASH_NSSR register.

Secure page erase

To erase a secure page, follow the procedure below:

1. Check that no Flash memory operation is ongoing by checking the SECBSY bit in the Flash status register (FLASH_SECSR).
2. Check and clear all secure error programming flags due to a previous programming. If not, SECPGSERR is set.
3. In dual-bank mode (DBANK option bit is set), set the SECPER bit and select the secure page to erase (SECPNB) with the associated bank (SECBKER) in the FLASH_SECCR. In single-bank mode (DBANK option bit is reset), set the SECPER bit and select the page to erase (SECPNB). The SECBKER bit in the FLASH_SECCR must be kept cleared.
4. Set the SECSTRT bit in the FLASH_SECR register.
5. Wait for the SECBSY bit to be cleared in the FLASH_SECSR register.

Note: If the page erase is part of write-protected area (by WRP), NSWRPERR or SECWRPERR is set and the page erase request is aborted.
Non-secure bank 1, bank 2 mass erase (available only in dual-bank mode when DBANK=1)

To perform a non-secure bank mass erase, follow the procedure below:
1. Check that no Flash memory operation is ongoing by checking the NSBSY bit in the FLASH_NSSR register.
2. Check and clear all non-secure error programming flags due to a previous programming. If not, NSPGSERR is set.
3. Set the NSMER1 bit or NSMER2 (depending on the bank) in the FLASH_NSCR register. Both banks can be selected in the same operation, in that case it corresponds to a mass erase.
4. Set the NSSTRT bit in the FLASH_NSCR register.
5. Wait for the NSBSY bit to be cleared in the FLASH_NSSR register.
6. The NSMER1 or NSMER2 bits can be cleared if no more non-secure bank erase is requested.

Secure bank 1, bank 2 mass erase (available only in dual-bank mode when DBANK=1)

To perform a secure bank mass erase, follow the procedure below:
1. Check that no Flash memory operation is ongoing by checking the SECBSY bit in the FLASH_SECSR register.
2. Check and clear all secure error programming flags due to a previous programming. If not, SECPGSERR is set.
3. Set the SECMER1 bit or SECMER2 (depending on the bank) in the FLASH_SECCR register. Both banks can be selected in the same operation, in that case it corresponds to a mass erase.
4. Set the SECSTRT bit in the FLASH_SECCR register.
5. Wait for the SECBSY bit to be cleared in the FLASH_SECSR register.
6. The SECMER1 or SECMER2 bit can be cleared if no more secure bank erase is requested.

Non-secure mass erase

To perform a non-secure mass erase, follow the procedure below:
1. Check that no Flash memory operation is ongoing by checking the NSBSY bit in the FLASH_NSSR register.
2. Check and clear all non-secure error programming flags due to a previous programming. If not, NSPGSERR is set.
3. Set the NSMER1 bit and NSMER2 bits in the FLASH_NSCR register.
4. Set the NSSTRT bit in the FLASH_NSCR register.
5. Wait for the NSBSY bit to be cleared in the FLASH_NSSR.
6. The NSMER1 and NSMER2 bit can be cleared if no more non-secure mass erase is requested.
Note: When DBANK=0, if only the NSMERA or the NSMERB bit is set, NSPGSERR is set and no erase operation is performed.

If the bank to erase or if one of the banks to erase contains a write-protected area (by WRP), NSWRPERR is set and the mass erase request is aborted (for both banks if both are selected).

Secure mass erase

To perform a secure mass erase, follow the procedure below:

1. Check that no Flash memory operation is ongoing by checking the SECBSY bit in the FLASH_SECSR register.
2. Check and clear all error programming flags due to a previous programming. If not, SECPGSERR is set.
3. Set the SECMER1 bit and SECMER2 bits in FLASH_SECCR register.
4. Set the SECTRT bit in the FLACH_SECR register.
5. Wait for the SECBSY bit to be cleared in the FLASH_SECSR.
6. The SECMER1 and SECMER2 bit can be cleared if no more secure mass erase is requested.

Note: The internal oscillator HSI16 (16 MHz) is enabled automatically when SECSTRT bit is set, and disabled automatically when SECSTRT bit is cleared, except if the HSI16 is previously enabled with HSION in RCC_CR register.

When DBANK=0, if only the SECMERA or the SECMERB bit is set, SECPGSERR is set and no erase operation is performed.

If the bank to erase or if one of the banks to erase contains a write-protected area (by WRP), SECWRPERR is set and the mass erase request is aborted (for both banks if both are selected).
6.3.7 Flash main memory programming sequences

The Flash memory is programmed 72 bits at a time (64 bits + 8 bits ECC).

Programming in a previously programmed address is not allowed except if the data to write is full zero, and any attempt sets the NSPROGERR or SECPROGERR flag in the Flash.

It is only possible to program double word (2 x 32-bit data).

- Any attempt to write byte or half-word sets NSSIZERR or SECSIZERR flag in the FLASH_NSSR or FLASH_SECSR register.
- Any attempt to write a double word which is not aligned with a double word address sets NSPGAERR or SECPGAERR flag in the FLASH_NSSR or FLASH_SECSR register.

Non-secure programming

The Flash memory programming sequence is as follows:

1. Check that no Flash main memory operation is ongoing by checking the NSBSY bit in the FLASH_NSSR.
2. Check and clear all non-secure error programming flags due to a previous programming. If not, NSPGSERR is set.
3. Set the NSPG bit in the FLASH_NSCR register.
4. Perform the data write operation at the desired memory non-secure address, or in the OTP area. Only double word can be programmed.
   - Write a first word in an address aligned with double word
   - Write the second word in the same double-word.
5. Wait until the NSBSY bit is cleared in the FLASH_NSSR register.
6. Check that NSEOP flag is set in the FLASH_NSSR register (meaning that the programming operation has succeed), and clear it by software.
7. Clear the NSPG bit in the FLASH_NSSR register if there no more programming request anymore.

Secure programming

The Flash memory programming sequence is as follows:

1. Check that no Flash main memory operation is ongoing by checking the SECBSY bit in the FLASH_SECSR.
2. Check and clear all secure error programming flags due to a previous programming. If not, SECPGSERR is set.
3. Set the SECPG bit in the FLASH_SECCR register.
4. Perform the data write operation at the desired memory secure address. Only double word can be programmed.
   - Write a first word in an address aligned with double word
   - Write the second word in the same double-word.
5. Wait until the SECBSY bit is cleared in the FLASH_SECSR register.
6. Check that SECEOP flag is set in the FLASH_SECSR register (meaning that the programming operation has succeed), and clear it by software.
7. Clear the SECPG bit in the FLASH_SECSR register if there is no more programming request anymore.
Note: When the Flash interface has received a good sequence (a double word), programming is automatically launched and SECBSY/NSBSY bit is set. The internal oscillator HSI16 (16 MHz) is enabled automatically when SECPG/NSPG bit is set, and disabled automatically when SECPG/NSPG bit is cleared, except if the HSI16 is previously enabled with HSION in RCC_CR register.

If the user needs to program only one word, double word must be completed with the erase value 0xFFFF FFFF to launch automatically the programming.

ECC is calculated from the double word to program.

6.3.8 Flash errors flags

Flash programming errors

Several kind of errors can be detected during a secure and non-secure operations. In case of error, the Flash operation (programming or erasing) is aborted. The secure errors flags are only set during a secure operation and non-secure flags are only set during a non-secure access.

- **SECPROGERR, NSPROGERR**: secure/non-secure programming error.
  
  It is set when the double word to program is pointing to an address:
  
  - Not previously erased
  
  - Already fully programmed to “0”
  
  - Already partially programmed (contains “0” and “1”) and the new value to program is not full zero.
  
  - For OTP programming, the **SECPROGERR, NSPROGERR** flag is set when the address is already partially programmed (contains “0” and “1”).

- **SECSIZERR, NSSIZERR**: secure/non-secure size programming error.
  
  Only a double word can be programmed and only 32-bit data can be written. SECSIZERR or NSSIZERR flag is set if a byte or a half-word is written.

- **SECPGAERR, NSPGAERR**: secure/non-secure alignment programming error.
  
  It is set when the first word to be programmed is not aligned with a double word address, or the second word doesn’t belong to the same double word address.

- **SECPGSERR**: Secure programming sequence error.
  
  SECPGSERR is set if one of the following conditions occurs during a secure erase or program operation:
  
  - A data is written when SECPG is cleared.
  
  - A program operation is requested during erase: SECPG is set while SECMER1 or SECMER2 or SECPER is set.
  
  - In the erase sequence: SECPG is set while SECSTRT is set
  
  - If SECSTRT is set with SECMER1 and SECMER2 and SECPER are cleared.
  
  - If secure page and mass erase are requested at the same time: SECSTRT and SECPER are set and SECMER1 or SECMER2 is set.
  
  - In single-bank mode (DBANK=0), if SECSTRT is set and only SECMER1 or SECMER2 is set.
  
  - If SECPROGERR, SECSIZERR, SECPGAERR, SECWRPERR or SECPGSERR is already set due to a previous programming error.
- **NSPGSERR**: non-secure programming sequence error.
  NSPGSERR is set if one of the following conditions occurs during a non-secure erase or program operation:
  - A data is written when NSPG is cleared.
  - A program operation is during erase: NSPG is set while NSMER1 or NSMER2 or NSPER is set.
  - In the erase sequence: NSPG is set while NSSTRT is set.
  - If NSSTRT is set with NSMER1 and NSMER2 and NSPER are cleared.
  - If non-secure page and mass erase are requested at the same time: NSSTRT and NSPER are set and NSMER1 or NSMER2 is set.
  - In single-bank mode (DBANK=0), if NSSTRT is set and only NSMER1 or NSMER2 is set.
  - If NSPROGERR, NSSIZERR, NSPGEERR, NSWRPERR, NSPGSERR or OPTWERR is already set due to a previous programming error.
  - If NSSTRT is set by a secure access.
  - If NSSTRT and OPTSTRT are set at the same time.

- **SECWRPERR**: secure write protection error.
  SEWRPERR is set if one of the following conditions occurs:
  - A secure program or erase on a non-secure page or a write protected area (WRP).
  - A secure bank erase or mass erase when one page or more is protected by WRP or HDP area with access disabled.
  - Refer to Table 47 to Table 49 for all the conditions of SECWRPERR flag setting.

- **NSWRPERR**: non-secure write protection error.
  NSWRPERR is set if one of the following conditions occurs:
  - A non-secure program or erase in a non-secure write protected area (WRP) or in a secure area (Secure watermark-based, HDP, Secure block-based).
  - A non-secure bank erase or mass erase when one page or more is protected by WRP or a secure area (SECWM, HDP, SECBB).
  - Refer to Table 47 to Table 49 for all the conditions of NSWRPERR flag setting.

- **OPTWERR**: option bytes write error.
  OPTWERR is set if when user option bytes are modified with an invalid configuration. It set when attempt:
  - To program an invalid secure watermark-based area. Refer to Table 35: Secure watermark-based area.
  - To set or unset TZEN option bit without being in correct RDP level (refer to Rules for modifying specific option bytes).
  - To modify DBANK option bit while the Flash is secure (watermark or block-based).
  - To set SWAP_BANK option bit while DBANK is cleared.
  - To modify SWAP_BANK option bit while BOOT_LOCK and TZEN are set.
  - To modify SECBOOTADD0 option bit while BOOT_LOCK is set.
  - To modify DB256 option bit while BOOT_LOCK and TZEN are set.
  - Attempt to modify the option bytes, except the SWAP_BANK option bit, when the readout protection (RDP) is set to 2.
If an error occurs during a secure or non-secure program or erase operation, one of the following programming error flags is set:

- **Non-secure programming error flags:** NSPROGERR, NSSIZERR, NSPGAERR, NSPGSERR, OPTWRERR or NSWRPERR is set in the FLASH_NSSR register.
- If the non-secure error interrupt enable bit NSERRIE is set in the **Flash non-secure control register (FLASH_NSCR)**, an interrupt is generated and the operation error flag NSOPERR is set in the FLASH_NSSR register.

- **Secure programming error flags:** SECPROGERR, SECSIZERR, SECPGAERR, SECPGSERR or SECWRPERR is set in the FLASH_SECSR register.
- If the secure error interrupt enable bit SECERRIE is set in the **Flash secure control register (FLASH_SECCR)**, an interrupt is generated and the operation error flag SECOPERR is set in the FLASH_SECSR register.

**Note:** If several successive errors are detected (for example, in case of DMA transfer to the Flash memory), the error flags cannot be cleared until the end of the successive write requests.

### 6.3.9 Read-while-write (RWW) available only in dual-bank mode (DBANK = 1)

The dual-bank mode is available only when the DBANK option bit is reset, allowing read-while-write operations. This feature permits to perform a read operation from one bank while erase or program operation is performed to the other bank.

**Note:** Read-while-write operations are not allowed. As an example, it is not possible to perform an erase operation on one bank while programming the other one.

**Read from bank 1 while page erasing in bank 2 (or vice versa)**

While executing a program code from bank 1, it is possible to perform a page erase operation on bank 2 (and vice versa). Follow the procedure below:

1. Check that no Flash memory operation is ongoing by checking the NSBSY or SECBSY bit in the FLASH_NSSR or FLASH_SECSR register (NSBSY, SECBSY are set when erase/program operation is on going in bank 1 or bank 2).
2. Set NSPER or SECPER bit, NSPSB or SECPSB to select the non-secure or secure page and NSBKER or SECBER to select the bank following the security state non-secure or secure.
3. Set the NSSTRT or SECESTRT bit in the FLASH_NSCR/FLASH_SECCR register.
4. Wait for the NSBSY or SECBSY bit to be cleared (or use the NSEOP or SECEOP interrupt).
Read from bank 1 while mass erasing bank 2 (or vice versa)

While executing a program code from bank 1, it is possible to perform a mass erase operation on bank 2 (and vice versa). Follow the procedure below:

1. Check that no Flash memory operation is ongoing by checking the NSBSY/SECBSY bit in the FLASH_NSSR/FLASH_SECSR register (NSBSY, SECBSY are active when erase/program operation is on going in bank 1 or bank 2).
2. Non-secure bank erase, set the NSMER1 or NSMER2 in the FLASH_NSCR register. For secure bank erase, set the SECMER1 or SECMER2 in the FLASH_SECCR register.
3. Set the NSSTRT/SECESTR bit in the FLASH_NSCR/FLASH_SECCR register.
4. Wait for the NSBSY or SECBSY bit to be cleared (or use the NSEOP or SECEOP interrupt).

Read from bank 1 while programming bank 2 (or vice versa)

While executing a program code from bank 1, it is possible to perform a program operation on the bank 2. (and vice versa). Follow the procedure below:

1. Check that no Flash memory operation is ongoing by checking the NSBSY/SECBSY bit in the FLASH_NSSR/FLASH_SECSR register (NSBSY, SECBSY are active when erase/program operation is on going in bank 1 or bank 2).
2. Set the NSPG or SECPG bit in the FLASH_NSCR/FLASH_SECCR register.
3. Perform the data write operations at the desired address memory inside the main memory block or OTP area.
4. Wait for the NSBSY or SECBSY bit to be cleared (or use the NSEOP or SECEOP interrupt).

Note: Due to Cortex M33 unified C-Bus, user software must ensure to not stall C-Bus with multiple consecutive writes. It is recommended to wait the NSBSY/SECBSY flag to be cleared before programming the next double word.
6.4 Flash memory option bytes

6.4.1 Option bytes description

The option bytes are configured by the end user depending on the application requirements. As a configuration example, the watchdog may be selected in hardware or software mode (refer to Section 6.4.2: Option bytes programming). The user option bytes are accessible through the Flash interface registers interface.

Table 33 describes the organization of all user option bytes available in the Flash interface registers.

Table 33. User option byte organization mapping

6.4.2 Option bytes programming

After reset, the options related bits in the FLASH_OPTR are write-protected. To run any operation on the option bytes page, the option lock bit OPTLOCK in the Flash non-secure control register (FLASH_NSCR) must be cleared. The following sequence is used to unlock this register:

1. Unlock the FLASH_NSCR with the NSLOCK clearing sequence (refer to Unlocking the secure/non-secure Flash control register).
2. Write OPTKEY1 = 0x08192A3B in the FLASH_OPTKEYR register.
3. Write OPTKEY2 = 0x4C5D6E7F in the FLASH_OPTKEYR register.

The user options can be protected against unwanted erase/program operations by setting the OPTLOCK bit by software.

Note: If NSLOCK is set by software, OPTLOCK is automatically set too.

Option bytes modification sequence

To modify the user options value, follow the procedure below:

1. Check that no Flash memory operation is on going by checking the NSBSY bit in the FLASH_NSSR register.
2. Clear OPTLOCK option lock bit with the clearing sequence described above.
3. Write the desired options value in the options registers.
4. Set the options start bit OPTSTRT in the Flash non-secure control register (FLASH_NSCR).
5. Wait for the NSBSY bit to be cleared.
6. Set the OBL_LAUNCH option bit to start option bytes loading.

Note: If the OPTWERR or NSPGSERR error bit is set, the old option byte values are kept.

Option byte loading

After the NSBSY bit is cleared, all new options are updated into the Flash but they are not applied to the system. They affect the system when they are loaded. Option bytes loading (OBL) is performed in two cases:

- When OBL_LAUNCH bit is set in the Flash non-secure control register (FLASH_NSCR).
- After a power reset (BOR reset or exit from Standby/Shutdown modes).

On system reset rising, internal option registers are copied into option registers. These registers are also used to modify the option bytes. If these registers are not modified by
user, they reflect the options states of the system. See Section 6.4.2: Option bytes programming for more details.

**Activating dual-bank mode (switching from DBANK=0 to DBANK=1)**

When switching from one Flash mode to another (for example from single to dual bank) it is recommended to execute the code from the SRAM or use the bootloader. To avoid reading corrupted data from the Flash when the memory organization is changed, any access (either CPU or DMAs) to Flash memory should be avoided before reprogramming.

- If any secure Flash protection is enabled (watermark or block-based), all must be disabled.
- Disable the instruction cache if it is enabled
- Set the DBANK option bit and clear all the WRP write protection (follow user option modification and option bytes loader procedure).
  - Once OBL is done with DBANK=0, perform a mass erase.
  - Start a new programing of code in 64 bits mode with DBANK=1 memory mapping.
  - Set the new secure protection if needed.

The new software is ready to be run using the bank configuration.

**De-activating dual-bank mode (switching from DBANK=1 to DBANK=0)**

When switching from one Flash mode to another (for example from single to dual bank) it is recommended to execute the code from the SRAM or use the bootloader. To avoid reading corrupted data from the Flash when the memory organization is changed, any access (either CPU or DMAs) to Flash memory should be avoided before reprogramming.

- If any secure Flash protection is enabled (watermark or block-based), all must be disabled.
- Disable the instruction cache if it is enabled
- Clear the DBANK option bit and all WRP write protection (follow user option modification and option bytes loader procedure).
  - Once OBL is done with DBANK=0, perform a mass erase.
  - Start a new programing of code in 128 bits mode with DBANK=0 memory mapping.
  - Set the new secure protection if needed.

The new software is ready to be run using the bank configuration.
Rules for modifying specific option bytes

Some of the option byte field must respect specific rules before being updated with new values. These option bytes, as well as the associated constraints, are described below:

- **TZEN option bit**
  - TZEN can only be set on RDP level 0.
  - Deactivation of TZEN must be done at the same time as RDP regression to level 0 (from level 1 to level 0 or from level 0.5 to level 0).

- **BOOT_LOCK option bit**
  - BOOT_LOCK can be set without any constraint.
  - It is not possible to deactivate the BOOT_LOCK option bit.

- **SWAP_BANK option bit**
  - It is not possible to set the SWAP_BANK in single-bank mode (DBANK=0).
  - It can not be modified when BOOT_LOCK and TZEN option bit are set.

- **SECBOOTADD0 option bytes**
  - It can not be modified when BOOT_LOCK option bit is set.

- **DB256K option bit**
  - It is not possible to modify the DB256K when BOOT_LOCK and TZEN option bits are set.
  - In single-bank mode (DBANK=0).

- **DBANK option bit**
  - It can only be modified when all secure protections are disabled (secure watermark or block-based area).

- **SECWMx_PSTRT[6:0], SECWMxPEND[6:0], HDPx_PEND[6:0], HDPxEN option bytes**
  - It can only be modified when HDPxACCDIS bit is cleared. When it is set, options bytes listed in the table below are locked and can not be modified until next system reset. If the user options modification try to modify one of the those option bytes while HDPxACCDIS bit is set, the option bytes modification is discarded without error flag.

If the above user options modification tries to set or modify one of the listed option bytes without following their associated rules, the option bytes modification is discarded and the OPTWERR error flag is set.

Rules of RDP level regression

When TrustZone is active, in case of RDP level 0.5 or level 1, the RDP regression to level 0 or level 0.5 can only be done by the debug interface or by the system bootloader.

## 6.5 Flash TrustZone security and privilege protections

### 6.5.1 TrustZone security protection

The global TrustZone system security is activated by setting the TZEN option bit in the FLASH_OPTR register.
When the TrustZone is active (TZEN=1), additional security features are available:

- Secure watermark-based user options bytes defining secure, HDP areas.
- Secure or non-secure block-based areas can be configured on-the-fly after reset. This is a volatile secure area.
- An additional RDP protection: RDP level 0.5.
- Erase or program operation can be performed in secure or non-secure mode with associated configuration bit.

When the TrustZone is disabled (TZEN=0), the above features are deactivated and all secure registers are RAZ/WI.

All other option bytes not listed above, can be modified without any constraints.

**Activating TrustZone security**

On first TrustZone activation (TZEN is modified from 0 to 1), the secure watermark-based user options bytes are set to default secure state: All Flash is secure, no HDP area. Refer to Table 34: Default secure option bytes after TZEN activation.

**Deactivating TrustZone security**

Deactivation of TZEN (from 1 to 0) is only possible when the RDP is changing to level 0 (from level 1 to level 0 or from level 0.5 to level 0).

When the TrustZone is deactivated (TZEN is modified from 1 to 0) after option bytes loading, the following security features are deactivated:

- Watermark-based secure area
- Block-based secure area
- RDP level 0.5
- Secure interrupt
- All secure registers are RAZ/WI.

<td>Bank 1 is fully secure&lt;br&gt;Bank 2 is fully secure</td>
</tr>
<tr>
<td>0/1</td>
<td>HDPxEN = 0&lt;br&gt;HDPx_PEND = 0</td>
<td>No secure HDP area</td>
</tr>
</tbody>
</table>
6.5.2 Secure watermark-based area protection

When TrustZone security is active (TZEN=1), a part of the Flash memory can be protected against non-secure read and write access. Up to two different non-volatile secure areas can be defined by option bytes and can be read or written by a secure access only:

- In single-bank mode, two areas can be selected with a page granularity.
- In dual-bank mode, one area per bank can be selected with a page granularity.

The secure areas are defined by a start page offset and end page offset using the SECWMx_PSTRT and SECWMx_PEND (x=1,2 for area 1 and area 2) option bytes. These offsets are defined in the Secure watermark registers address registers Flash bank 1 secure watermak1 register (FLASH_SECM1R1), Flash secure watermak2 register (FLASH_SECM2R1).

The SECWMx_PSTRT and SECWMx_PEND option bytes can only be modified by secure firmware when the HDPxACCDIS bit is reset.

If the HDPxACCDIS bit is set, the SECWMx_PSTRT and SECWMx_PEND cannot be modified until next system reset.

Caution: Switching a Flash memory area from secure to non-secure does not erase its content. The user secure software must perform the needed operation to erase the secure area before switching an area to non-secure attribute whenever is needed. It is also recommended to flush the instruction cache.

6.5.3 Secure hide protection (HDP)

The secure HDP area is part of the Flash watermark-based secure area. Access to the hide protection area can be denied by setting the HDPxACCDIS bit in FLASH_SECHDPCR register.

When the HDPxACCDIS bit is set, data read, write and instruction fetch on this hide protection area are denied. For example, software code in the secure Flash hide protected area can be executed only once and deny any further access to this area until next system reset. The HDPxACCDIS bit can be only cleared by a system reset.

Up to two non-volatile secure hide protection (HDP) areas can be defined depending of the DBANK mode:

- In single-bank mode, two HDP areas can be selected with a page granularity.
- In dual-bank mode, one HDP area per bank can be selected with a page granularity.

<table>
<thead>
<tr>
<th>DBANK option bit</th>
<th>Secure watermark option bytes values (x = 1,2)</th>
<th>Secure watermark protection area</th>
</tr>
</thead>
<tbody>
<tr>
<td>0/1</td>
<td>SECWMx_PSTRT &gt; SECWMx_PEND</td>
<td>No secure area</td>
</tr>
<tr>
<td>0/1</td>
<td>SECWMx_PSTRT = SECWMx_PEND</td>
<td>One page defined by SECWMx_PSTRT is secure watermark-based protected</td>
</tr>
<tr>
<td>0/1</td>
<td>SECWMx_PSTRT &lt; SECWMx_PEND</td>
<td>The area between SECWMx_PSTRT and SECWMx_PEND is secure watermark-based protected</td>
</tr>
</tbody>
</table>

Caution: Switching a Flash memory area from secure to non-secure does not erase its content. The user secure software must perform the needed operation to erase the secure area before switching an area to non-secure attribute whenever is needed. It is also recommended to flush the instruction cache.
The secure HDP area is enabled by the HDPxEN (x=1,2 for area 1 and area 2). When the HDPxEN bit is reset, there is no HDP area. The HDPxEN bit can be set or reset by the secure firmware if the HDPx_ACCDIS bit is reset.

The secure HDP area size is defined by the end page offset using the HDPx_PEND option bytes while the start page offset is already defined by SECWMx_PSTRT option bytes. These offsets are defined in the Secure watermark registers address registers Flash bank 1 secure watermak1 register (FLASH_SECWM1R1), Flash secure watermak1 register 2 (FLASH_SECWM1R2), Flash secure watermak2 register (FLASH_SECWM2R1), Flash secure watermak2 register 2 (FLASH_SECWM2R2).

The HDPxEN and HDPx_PEND option bytes can only be modified by secure firmware when the HDPxACCDIS bit is reset.

If the HDPxACCDIS bit is set, the HDPxEN and HDPx_PEND cannot be modified until next system reset.

If an invalid secure HDP area is defined as described in Table 36: Secure, HDP protections summary, the OPTWERR flag error is set and option bytes modification is discarded.

<table>

</tr>
</tbody>
</table>

6.5.4 Secure block-based area (SECBB) protection

Any page, non-secure through secure Flash memory watermark option bytes, can be programmed on-the-fly as secure using the block-based configuration registers.

With SECBB, it is not possible to unsecure a secure page through secure watermark option bytes.

In dual-bank mode (DBANK=1):
- FLASH_SECBB1Rx registers are used to configure the security attribute for pages in bank1
- FLASH_SECBB2Rx registers are used to configure the security attribute for pages in bank2
In single-bank mode (DBANK=0):
- the FLASH_SECBB1Rx registers are used to configure the security attribute for pages in all Flash memory.

It is possible to temporary secure a non-secure watermark page by setting corresponding SECBB bit to 1. Setting SECBB bit to 1 on an already secure watermark page has no effect.

To modify a page block-based security attribution, it is recommended to:
- Check that no Flash operation is ongoing on the related page.
- Add ISB instruction after modifying the page security attribute SECBB1/2[i].

6.5.5 **Forcing boot from a secure memory address**

When TrustZone is enabled by setting the TZEN option bit, the boot space must be in secure area. The SECBOOTADD0[24:0] option bytes are used to select the boot secure memory address. To increase the security and establish a chain of trust, a unique boot entry option can be selected regardless the other boot options. This is done by setting the BOOT_LOCK option bit in the FLASH_SECBOOTADD0R register.

This bit can be set only by a secure access.

**Caution:** Once set, the BOOT_LOCK option bit cannot be cleared.

6.5.6 **Flash security attribute state**

The Flash is secure when at least one secure area is defined either by watermark-based option bytes or block-based security registers.

It is possible to override the Flash security state using the SECINV bit in the FLASH_SECCR register.

<table>
<thead>
<tr>
<th>Secure Area</th>
<th>SECINV bit</th>
<th>Flash security state</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>

</tr>
<tr>
<td>Yes</td>
<td>0</td>
<td>Secure</td>
</tr>
<tr>
<td></td>
<td>1</td>
<td>Non secure</td>
</tr>
</tbody>
</table>

- A non-secure access to a a secure Flash memory area is RAZ/WI and generates an illegal access event. An illegal access interrupt is generated if the FLASHIE illegal access interrupt is enabled in the GTZC_TZIC_IER2 register.
- A non-secure access to a secure Flash register generates an illegal access event. An illegal access interrupt is generated if the FLASH_REGIE illegal access interrupt is enabled in the GTZC_TZIC_IER2 register.
6.5.7 Flash registers privileged and unprivileged modes

The Flash registers can be read and written by privileged and unprivileged accesses depending on PRIV bit in FLASH_PRIVCFGR register.

- When the PRIV bit is reset, all Flash registers could be read and written by both privileged or unprivileged access.
- When the PRIV bit is set, all Flash registers could be read and written by privileged access only. Unprivileged access to a privileged registers is RAZ/WI.

6.6 Secure system memory

6.6.1 Introduction

Secure system memory stores RSS (root secure services) firmware that is programmed by ST during STM32L552xx and STM32L562xx production. The RSS provides secure services to the bootloader and the user firmware. These services are described hereafter in this section.

The RSS services are only available after the user enables the microcontroller TrustZone® feature thanks to TZEN bitfield set to 1 within FLASH_OPTR option byte register.

At boot time, the RSS firmware enables and jumps to bootloader; the RSS provides services to secure user firmware at runtime.

6.6.2 RSS allocates resource to bootloader

When the microcontroller is configured in TrustZone® enabled (option byte register FLASH_OPTR bitfield TZEN set to 1), then the microcontroller must boot on a secure address after reset. According to boot configuration, the boot can be done either from a secure address programmed through SECBOOT0ADDR bitfield of FLASH_SECBOOTADD0R option byte register or from RSS. In this last case, RSS firmware is the first firmware running after boot.

The RSS is then responsible for the microcontroller bootloader resource allocation. The RSS allocates SRAM, system Flash memory, peripherals (USART, I2C, SPI, ...), the respective Os and IRQs to non-secure. The bootloader uses these resources to enable communication ports as described in AN2606 – STM32 microcontroller system memory boot mode.

Once resource allocation is done, the RSS triggers a secure to non-secure transition jumping to the bootloader, that in turn enables all its communication ports. At this step, the user can connect to the microcontroller either using bootloader communication ports or debug ports (JTAG or SWD).

As a non-secure firmware, the bootloader never accesses to secure resources. However, in RDP level 0 only, the bootloader can access the secure option bytes.

For detailed boot modes, please refer to Section 3: Boot configuration.

Table 38 sums up user accesses via bootloader communications ports or JTAG according to RDP level value.
Non secure peripherals, IRQn and IOs allocated to non-secure for bootloader execution are described within Table 39.
Table 39. Non-secure peripherals, IRQn and IOs for bootloader execution

<table>
<thead>
<tr>
<th>HW resource type</th>
<th>Resource description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Peripherals</td>
<td>USART1, USART2, USART3, SPI1, SPI2, SPI3, I2C1, I2C2, I2C3, USBFS, FDCAN1, ICACHE, IWDG</td>
</tr>
<tr>
<td>IRQn</td>
<td>DMA1_Channel3_IRQn, DMA1_Channel5_IRQn, DMA2_Channel2_IRQn, USB_FS_IRQn</td>
</tr>
</tbody>
</table>

For IRQn and IO bootloader detailed usage, please refer to AN2606 – STM32 microcontroller system memory boot mode.

6.6.3 RSSLIB functions

The RSS provides runtime services thanks to RSS library. As other microcontroller peripherals features and mapping, the RSS library functions are exposed to user within the CMSIS device header file provided by the STM32CubeL5 firmware package. Please refer to UM2656 to get more details regarding STM32CubeL5 firmware package. RSS library functions are named RSSLIB functions hereafter.

The user firmware calls RSSLIB functions using RSSLIB_PFUNC C defined macro, that points to a location within non-secure system memory. Hence prior calling RSSLIB functions, the secure user firmware must define a non-secure region above this location within SAU of the Cortex®-M33. This non-secure region starts from RSSLIB_SYS_FLASH_NS_PFUNC_START up to RSSLIB_SYS_FLASH_NS_PFUNC_END. These last addresses are provided within the CMSIS device header file. The user can set this non-secure region either by using the CMSIS system partition header file or by implementing its own code for SAU setup. The CMSIS system partition header file is part of the STM32CubeL5 firmware package.

**Note:** Some RSSLIB functions are tied to bootloader version (bootloader ID); before calling any RSSLIB function, the user must check within the dedicated section in this document, if it depends or not on a bootloader ID. If the RSSLIB function is dependent on bootloader ID,
the user must read this ID using BL_ID C defined macro from the CMSIS device header file (BL_ID is one-byte long value). Then, the user firmware must call the right function according to bootloader ID value.

RSSLIB functions are split between non-secure callable and secure callable function. The RSS library functions are described within sections hereafter.

**CloseExitHDP_BL90**

Bootloader ID:

- CloseExitHDP_BL90 function is compliant for bootloader ID 0x90.

Secure attribute:

- Secure callable function.

Prototype:

```c
uint32_t CloseExitHDP_BL90(uint32_t HdpArea, uint32_t VectorTableAddr)
```

Arguments:

- **HdpArea**:
  - Input parameter, bitfield that identifies which HDP area to close. Values can be either: RSSLIB_HDP_AREA1_Msk, RSSLIB_HDP_AREA2_Msk or RSSLIB_HDP_AREA1_Msk | RSSLIB_HDP_AREA2_Msk.

- **VectorTableAddr**:
  - Input parameter, address of the next vector table to apply.
  - The vector table format is the one used by the Cortex®-M33 core.

Description:

- User calls CloseExitHDP_BL90 to close Flash HDP secure memory area and jump to the reset handler embedded within the vector table which address is passed as input parameter.

- CloseExitHDP_BL90 sets the SP provided by the passed vector table, however it is up to the caller to first set the new vector table. Then it clears all general-purpose Cortex®-M33 registers (r0, r1, …) before jumping to new vector table reset handler.

- On successful execution, the function does not return and does not push LR onto the stack.

- In case of failure (bad input parameter value), this function returns RSSLIB_ERROR.

Please refer to section Section 6.5.3: Secure hide protection (HDP) to get more details on Flash memory HDP protection.

**CloseExitHDP_BL91**

Bootloader ID:

- CloseExitHDP_BL91 function is compliant for bootloader ID 0x91 up to 0x9F.

Secure attribute:

- Secure callable function.

Prototype:

```c
uint32_t CloseExitHDP_BL91(uint32_t HdpArea, uint32_t VectorTableAddr)
```
Arguments:

- **HdpArea:**
  Input parameter, bitfield that identifies which HDP area to close. Values can be either: RSSLIB_HDP_AREA1_Msk, RSSLIB_HDP_AREA2_Msk or RSSLIB_HDP_AREA1_Msk | RSSLIB_HDP_AREA2_Msk.

- **VectorTableAddr:**
  Input parameter, address of the next vector table to apply.
  The vector table format is the one used by the Cortex®-M33 core.

Description:

The user calls CloseExitHDP_BL91 to close Flash HDP secure memory area and jump to the reset handler embedded within the vector table which address is passed as input parameter.

CloseExitHDP_BL91 sets the SP provided by the passed vector table, however it is up to the caller to first set the new vector table. Then it clears all general-purpose ACortex®-M33 registers (r0, r1, ...) before jumping to new vector table reset handler.

On successful execution, the function does not return and does not push LR onto the stack.

In case of failure (bad input parameter value), this function returns RSSLIB_ERROR.

Please refer to section Section 6.5.3: Secure hide protection (HDP) to get more details on Flash memory HDP protection.

### 6.7 FLASH memory protection

The Flash interface implements different protection mechanisms:

- **Write protection (WRP)**
- **Readout protection (RDP)**
- **Secure protection when TrustZone is active**
  - Up to two secure watermark-based non-volatile areas
  - Up to two secure block-based volatile areas
  - Up to two secure hide protection areas

#### 6.7.1 Write protection (WRP)

The user area in Flash memory can be protected against unwanted write operations.

Depending on the DBANK option bit configuration, it allows either to specify:

- In single-bank mode (DBANK=0): four write-protected (WRP) areas can be defined in each bank, with page size (4 Kbytes) granularity.
- In dual-bank mode (DBANK=1): two write-protected (WRP) areas can be defined in each bank, with page (2 Kbytes) granularity.

Each area is defined by a start page offset and an end page offset related to the physical Flash bank base address. These offsets are defined in the WRP address registers: Flash WPR1 area A address register (FLASH_WRP1AR), Flash WPR1 area B address register (FLASH_WRP1BR), Flash WPR2 area A address register (FLASH_WRP2AR), Flash WPR2 area B address register (FLASH_WRP2BR).
Dual bank mode (DBANK=1)

The bank “x” WRP “y” area (x=1,2 and y=A,B) is defined from the address: bank “x” base address + [WRPxy_STRT x 0x800] (included) to the address: bank “x” base address + [(WRPxy_END+1) x 0x800] (excluded).

Single bank mode (DBANK=0)

The WRPx “y” area (x=1,2 and y=A,B) is defined from the address: base address + [WRPy_STRT x 0x800] (included) to the address: base address + [(WRPy_END+1) x 0x1000] (excluded).

For example, to protect by WRP from the address 0x0806 2800 (included) to the address 0x0807 07FF (included):

- If boot in Flash is done in bank 1, FLASH_WRP1AR register must be programmed with:
  - WRP1A_STRT = 0xC5.
  - WRP1A_END = 0xE0.

WRP1B_STRT and WRP1B_END in FLASH_WRP1BR can be used instead (area “B” in bank 1).

- If the two banks are swapped, the protection must apply to bank 2, and FLASH_WRP2AR register must be programmed with:
  - WRP2A_STRT = 0xC5.
  - WRP2A_END = 0xE0.

WRP2B_STRT and WRP2B_END in FLASH_WRP2BR can be used instead (area “B” in bank 2).

When WRP is active, it cannot be erased or programmed. Consequently, a software mass erase cannot be performed if one area is write-protected.

If an erase/program operation to a write-protected part of the Flash memory is attempted, the secure or non-secure write protection error flag (NSWRPERR or SECWRPERR) is set in the FLASH_NSSR or FLASH_SECSR register. This flag is also set for any write access to:

- System Flash memory.
- OTP area.

Note: When the memory readout protection level is selected (RDP level = 1), it is not possible to program or erase Flash memory (secure or non-secure) if the CPU debug features are connected (JTAG or single wire) or boot code is being executed from RAM or system Flash, even if WRP is not activated.

Note: To validate the WRP options, the option bytes must be reloaded through the OBL_LAUNCH bit in Flash control register.

Note: When DBANK=0, it is the user’s responsibility to make sure that no overlapping occurs on the WRP zone.
6.7.2 Readout protection (RDP)

The readout protection is activated by setting the RDP option byte and then, by applying OBL launch or power-on reset to reload the new RDP option byte. The readout protection protects the Flash main memory, the option bytes, the backup registers and the SRAMs.

Readout protection levels when Trustzone is disabled

There are three levels of readout protection from no protection (level 0) to maximum protection or no debug (level 2).

The Flash memory is protected according to the RDP option byte value shown in the table below.

<table>
<thead>
<tr>
<th>RDP byte value</th>
<th>Readout protection level</th>
</tr>
</thead>
<tbody>
<tr>
<td>0xAA</td>
<td>Level 0</td>
</tr>
<tr>
<td>Any value except 0xAA or 0xCC</td>
<td>Level 1</td>
</tr>
<tr>
<td>0xCC</td>
<td>Level 2</td>
</tr>
</tbody>
</table>

Level 0: no protection

Read, program and erase operations into the Flash main memory area are possible. The option bytes, the SRAMs and the backup registers are also accessible by all operations.

Level 1: readout protection

- **User mode**: code executing in user mode (boot Flash) can access Flash main memory, option bytes, SRAMs and backup registers with all operations (read, erase, program).
- **Debug, boot RAM and bootloader modes**: in debug mode or when code is running from boot RAM or bootloader, the Flash main memory, the backup registers and the SRAM2 are totally inaccessible. In Debug and boot RAM modes an intrusion is detected and a read or write access to the Flash or backup SRAM generates a bus error and a hard fault interrupt. The on-the-fly decryption region (OTFDEC on OCTOSPI) is read as zero.
Level 2: no debug

- The protection level 1 is guaranteed.
- All debug features are disabled.
- The boot from SRAM (boot RAM mode) and the boot from system memory (bootloader mode) are no longer available.
- When booting from Flash, all operations are allowed on the Flash main memory. Read, erase and program accesses to Flash memory and SRAMs from user code are allowed.
- Option bytes cannot be programmed nor erased except the SWAP_BANK option bit. Thus, the level 2 cannot be removed: it is an irreversible operation. When attempting to modify the options bytes, the protection error flag OPTWERR is set in the FLASH_NSSR register and an interrupt can be generated.

Note: The debug feature is also disabled under reset.

Table 42. Access status versus protection level and execution modes when TZEN=0

<td>Yes</td>
</tr>
<tr>
<td></td>
<td>2</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

1. When the protection level 2 is active, the debug port and the bootloader mode are disabled.
2. The Flash main memory is erased when the RDP option byte regresses from level 1 to level 0.
3. The system memory is only read-accessible whatever the protection level (0, 1 or 2) and execution mode.
4. Option bytes are only accessible through the Flash registers interface and OPSTRT bit.
5. SWAP_BANK option, bit can be modified.
6. OTP can only be written once.
7. The backup registers are erased when RDP changes from level 1 to level 0.
8. All SRAMs are erased when RDP changes from level 1 to level 0.
9. The OTFDEC keys are erased when the RDP option byte changes from level 1 to level 0.
Readout protection levels when Trustzone is enabled

There are four levels of readout protection from no protection (level 0) to maximum protection or no debug (level 2).

The Flash memory is protected according to the RDP option byte value shown in the table below.

<table>
<thead>
<tr>
<th>RDP byte value</th>
<th>Readout protection level</th>
</tr>
</thead>
<tbody>
<tr>
<td>0xAA</td>
<td>Level 0</td>
</tr>
<tr>
<td>0x55</td>
<td>Level 0.5</td>
</tr>
<tr>
<td>Any value except 0xAA or 0x55 or 0xCC</td>
<td>Level 1</td>
</tr>
<tr>
<td>0xCC</td>
<td>Level 2</td>
</tr>
</tbody>
</table>

Table 43. Flash memory readout protection status (TZEN=1)

Level 0: no protection

Read, program and erase operations into the Flash main memory area are possible. The option bytes, the SRAMs and the backup registers are also accessible by all operations. When booting from RSS, the debug access is disabled while executing RSS code.

Level 0.5: non-secure debug only

All read and write operations (if no write protection is set) from/to the non-secure Flash memory are possible. The debug access to secure area is prohibited. Debug access to non-secure area remains possible.

- **User mode**: code executing in user mode (boot Flash) can access Flash main memory, option bytes, SRAMs and backup registers with all operations (read, erase, program).
- **Non-secure debug mode**: non-secure debug is possible when the CPU is in non-secure state. The secure Flash memory, the secure backup registers and SRAMs area are inaccessible; the non-secure Flash memory, the non-secure backup registers and the non-secure SRAMs area remain accessible for debug purpose.
- **RSS mode**: when booting from RSS, the debug access is disabled while executing RSS code.
- **Boot RAM mode**: boot from SRAM is not possible.

Level 1: readout protection

- **User mode**: code executing in user mode (boot Flash) can access Flash main memory, option bytes, SRAMs and backup registers with all operations (read, erase, program).
- **Non-secure debug mode**: non-secure debug is possible when the CPU is in non-secure state. However, an intrusion is detected in case of debug access: the Flash main memory, the backup registers and the SRAM2 are totally inaccessible; any read or write access to these memories generates a bus error and a hard fault interrupt. The on-the-fly decryption region (OTFDEC on OCTOSPI) is read as zero.
- **RSS mode**: when booting from RSS, the debug access is disabled while executing the RSS code.
- **Boot RAM mode**: boot from SRAM is no longer possible.
Level 2: no debug

When the readout protection level 2 is set:

- The protection level 1 is guaranteed.
- All debug features are disabled.
- The boot from SRAM (boot RAM mode) and the boot from system memory (bootloader mode) are no longer available.
- Boot from RSS is possible.
- When booting from Flash or RSS, all operations are allowed on the Flash main memory. Read, erase and program accesses to Flash memory and SRAMs from user code are allowed.
- Option bytes cannot be programmed nor erased except the SWAP_BANK option bit. Thus, the level 2 cannot be removed: it is an irreversible operation. When attempting to modify the options bytes, the protection error flag OPTWERR is set in the FLASH_NSSR register and an interrupt can be generated.

Note: The debug feature is also disabled under reset.

</tbody>
</table>
Device life cycle managed by readout protection (RDP) transitions

It is easy to move from level 0 or level 0.5 to level 1 by changing the value of the RDP byte to any value (except 0xCC). By programming the 0xCC value in the RDP byte, it is possible to go to level 2 either directly from level 0 or from level 0.5 or level 1. Once in level 2, it is no longer possible to modify the readout protection level.

When the RDP is reprogrammed to the value 0xAA to move from level 0.5 or from level 1 to level 0, a mass erase of the Flash main memory is performed. The backup registers, all SRAMs and the OTFDEC keys are also erased. The OTP area is not erased.

When the RDP is programmed to the value 0x55 to move from level 1 to level 0.5, a partial mass erase of Flash main memory is performed. Only non-secure watermark-based areas are erased (even if it is defined as secure by block-based). The backup registers, the OTFDEC keys and all SRAMs are mass erased. The OTP area is not erased. The RDP level 0.5 and partial non-secure erase are only available when TrustZone is active.

When TrustZone is active, in case of RDP level 0.5 or level 1, the RDP regression to level 0 or level 0.5 can only be done by debug interface or by system bootloader.

Note: Full mass erase is performed only when level 1 or level 0.5 is active and level 0 requested. When the protection level is increased (0->0.5, 0->1, 0.5->1, 1->2, 0->2, 0.5->2) there is no mass erase.

To validate the protection level change, the option bytes must be reloaded through the OBL_LAUNCH bit in Flash non-secure control register.

Note: Before launching a RDP regression, the software must invalidate the ICACHE and wait for the BUSYF bit to get cleared.

Table 44. Access status versus protection level and execution modes when TZEN=1

<table>
<thead>
<tr>
<th>Area</th>
<th>RDP level</th>
<th>User execution (boot from Flash)</th>
<th>Debug/ bootloader(1)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>Read</td>
<td>Write</td>
</tr>
<tr>
<td>OTFDEC regions (OCTOSPI)</td>

</tr>
<tr>
<td></td>
<td>1</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td></td>
<td>2</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

1. When the protection level 2 is active, the debug port and the bootloader mode are disabled.
2. Dependent on TrustZone security access rights.
3. The Flash main memory is erased when the RDP option byte regresses from level 1 to level 0.
4. The system memory is only read-accessible whatever the protection level (0, 1 or 2) and execution mode.
5. Option bytes are only accessible through the Flash registers interface and OPSTRT bit.
6. SWAP_BANK option bit can be modified.
7. All SRAMs are erased when RDP changes from level 1 to level 0.
8. The backup registers are erased when RDP changes from level 1 to level 0.
9. All SRAMs are erased when RDP changes from level 1 to level 0.
10. The OTFDEC keys are erased when the RDP option byte changes from level 1 to level 0.
Summary of Flash memory and Flash registers access control

*Table 45* to *Table 47* summarize all the Flash memory access versus RDP level, WPR and HDP protection when TrustZone is active and disabled.
Table 45. Flash access versus RDP level when TrustZone is active (TZEN=1)

<table>
<thead>
<tr>
<th>Access type</th>
<th>RDP level-0, RDP level-0.5, RDP level-1 no intrusion(^1) or RDP level-2</th>

<td>NSERRIE</td>
<td></td>
</tr>
<tr>
<td>ECC correction</td>
<td>ECCC</td>
<td>Write ECCC=1</td>
<td>ECCCIE</td>
<td></td>
</tr>
</tbody>
</table>

1. SECEOP or NSEOP are set only if SECEOPIE or NSEOPIE is set.
2. SECOERR is set only if SECERRIE is set.
3. SECEOP is set only if SECEOPIE is set.
4. NSOPERR is set only if NSERRIE is set.
6.9 FLASH registers

6.9.1 Flash access control register (FLASH_ACR)

This register is non-secure. It can be read and written by both secure and non-secure access. This register can be protected against non-privileged access when PRIV=1 in the FLASH_PRIVCFGR register.

Address offset: 0x00
Reset value: 0x0000 0000
Access: no wait state, word, half-word and byte access

<table>
<thead>
<tr>
<th>31</th>

</tr>
</tbody>
</table>

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **LVEN**: Flash low-voltage enable
This bit can only be written when it is unlocked by writing the FLASH_LVEKEYR register.
When set, this bit enable the flash low voltage and bypass the voltage range selected by PWR. This bit must be set when using the external SMPS.
When this bit is cleared, it is locked again.
0: Flash low voltage is disabled. Flash low voltage is managed by the power controller PWR.
1: Flash low voltage is enabled.

Bit 14 **SLEEP_PD**: Flash power-down mode during Sleep or Low-power sleep mode
This bit determines whether the Flash memory is in power-down mode or Idle mode when the device is in Sleep or Low-power sleep mode.
0: Flash in Idle mode during Sleep and Low-power sleep modes
1: Flash in power-down mode during Sleep and Low-power sleep modes

**Caution**: The Flash must not be put in power-down while a program or an erase operation is on-going.
6.9.2 Flash power-down key register (FLASH_PDKEYR)

This register is non-secure. It can be read and written by both secure and non-secure access.

This register can be protected against non-privileged access when PRIV=1 in the FLASH_PRIVCFGR register.

Address offset: 0x04

Reset value: 0x0000 0000

Access: no wait state, word access

<table>
<thead>
<tr>

</table>

Bits 31:0 PDKEYR[31:0]: Power-down in Run mode Flash key

The following values must be written consecutively to unlock the RUN_PD bit in FLASH_ACR:

PDKEY1: 0x0415 2637
PDKEY2: 0xFAFB FCFD

Caution: The Flash must not be put in power-down while a program or an erase operation is on-going.
6.9.3 Flash non-secure key register (FLASH_NSKEYR)

This register is non-secure. It can be read and written by both secure and non-secure access.

This register can be protected against non-privileged access when PRIV=1 in the FLASH_PRIVCFGR register.

Address offset: 0x08
Reset value: 0x0000 0000
Access: no wait state, word access

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **NSBSY**: Busy
This indicates that a Flash secure or non-secure operation is in progress. This is set on the beginning of a Flash operation and reset when the operation finishes or when an error occurs.

Bit 15 Reserved, must be kept at reset value.

Bit 14 Reserved, must be kept at reset value.

Bit 13 **OPTWERR**: Option write error
Set by hardware when the options bytes are written with an invalid configuration.
Cleared by writing 1.
Refer to Section 6.3.8: Flash errors flags for full conditions of error flag setting.

Bits 12:8 Reserved, must be kept at reset value.

Bit 7 **NSPGSERR**: Non-secure programming sequence error
This bit is set by hardware when programming sequence is not correct. It is cleared by writing 1.
Refer to Section 6.3.8: Flash errors flags for full conditions of error flag setting.

Bit 6 **NSSIZERR**: Non-secure size error
Set by hardware when the size of the access is a byte or half-word during a non-secure program sequence. Only double word programming is allowed (consequently: word access).
Cleared by writing 1.

Bit 5 **NSPGAERR**: Non-secure programming alignment error
Set by hardware when the first word to be programmed is not aligned with a double word address, or the second word does not belong to the same double word address.
Cleared by writing 1.
6.9.8 Flash status register (FLASH_SECSR)

This register is secure. It can be read and written only by secure access. A non-secure read/write access is RAZ/WI.

This register can be protected against non-privileged access when PRIV=1 in the FLASH_PRIVCFGR register.

Address offset: 0x24
Reset value: 0x0000 0000
Access: no wait state, word, half-word and byte access

</table>
Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **SECBSY**: Busy
This indicates that a Flash secure or non-secure operation is in progress. This is set on the beginning of a Flash operation and reset when the operation finishes or when an error occurs.

Bit 15 Reserved, must be kept at reset value.

Bits 14:8 Reserved, must be kept at reset value.

Bit 7 **SECPGSERR**: Secure programming sequence error
Set by hardware when a NSSTRT bit is set by a secure access. Set also by hardware when SECPROGERR, SECSIZERR, SECPGAERR, SECWRPERR or SECPGSER is set due to a previous programming error.
Cleared by writing 1.
Refer to *Section 6.3.8: Flash errors flags* for full conditions of error flag setting.

Bit 6 **SECSIZERR**: Secure size error
Set by hardware when the size of the access is a byte or half-word during a secure program sequence. Only double word programming is allowed (consequently: word access).
Cleared by writing 1.

Bit 5 **SECPGAERR**: Secure programming alignment error
Set by hardware when the first word to be programmed is not aligned with a double word address, or the second word does not belong to the same double word address.
Cleared by writing 1.

Bit 4 **SECWRPERR**: Secure write protection error
Set by hardware when an secure address to be erased/programmed belongs to a write-protected part (by WRP, HDP or RDP level 1) of the Flash memory.
Cleared by writing 1.
Refer to *Section 6.3.8: Flash errors flags* for full conditions of error flag setting.

Bit 3 **SECPROGERR**: Secure programming error
Set by hardware when a secure double-word address to be programmed contains a value different from ‘0xFFFF FFFF’ before programming, or already fully programmed to ‘0x0000 0000’.
Cleared by writing 1.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **SECOPERR**: Secure operation error
Set by hardware when a Flash memory secure operation (program / erase) completes unsuccessfully.
This bit is set only if secure error interrupts are enabled (SECERRIE = 1).
Cleared by writing ‘1’.

Bit 0 **SECEOP**: Secure end of operation
Set by hardware when one or more Flash memory secure operation (programming / erase) has been completed successfully.
This bit is set only if the secure end of operation interrupts are enabled (SECEOPIE = 1).
Cleared by writing 1.
6.9.9 Flash non-secure control register (FLASH_NSCR)

This register can only be written when the SECBSY, NSBSY or OBL_LAUNCH are reset. Otherwise, the write access is stalled till SECBSY and NSBSY are reset.

This register is non-secure. It can be read and written by both secure and non-secure access.

This register can be protected against non-privileged access when PRIV=1 in the FLASH_PRIVCFGR register.

Address offset: 0x28

Reset value: 0xC000 0000

Access: no wait state when no Flash memory operation is on going, word, half-word and byte access

<table>

<tr>
<td></td>
<td>1: NSOPERR error interrupt enabled</td>
</tr>
</tbody>
</table>
Bit 24 **NSEOPIE**: Non-secure End of operation interrupt enable
This bit enables the interrupt generation when the NSEOP bit in the FLASH_NSSR is set to 1.
0: NSEOP Interrupt disabled
1: NSEOP Interrupt enabled

Bits 23:18 Reserved, must be kept at reset value.

Bit 17 **OPTSTRT**: Options modification start
This bit triggers an options operation when set. It can not be written if OPTLOCK bit is set.
This bit is set only by software, and is cleared when the NSBSY bit is cleared in FLASH_NSSR.

Bit 16 **NSSTRT**: Non-secure start
This bit triggers a non-secure erase operation when set. If NSMER1, NSMER2 and NSPER bits are reset and the NSSTRT bit is set, the NSPGERR is set. This condition should be forbidden.
This bit is set only by software, and is cleared when the NSBSY bit is cleared in FLASH_NSSR.

Bit 15 **NSMER2**: Non-secure Bank 2 Mass erase
This bit triggers the bank 2 non-secure mass erase (all bank 2 user pages) when set.

Bits 14:12 Reserved, must be kept at reset value.

Bit 11 **NSBKER**: Non-secure page number MSB (bank selection)
This bit must be only set when DBANK=1.
0: Bank 1 is selected for non-secure page erase
1: Bank 2 is selected for non-secure page erase.

Bit 10 Reserved, must be kept at reset value.

Bits 9:3 **NSPNB[6:0]**: Non-secure page number selection
These bits select the page to erase:
00000000:page 0
00000001:page 1
...
11111111:page 127

Bit 2 **NSMER1**: Non-secure bank 1 mass erase
This bit triggers the bank 1 non-secure mass erase (all bank 1 user pages) when set.

Bit 1 **NSPER**: Non-secure page erase
0: Non-secure page erase disabled
1: Non-secure page erase enabled

Bit 0 **NSPG**: Non-secure programming
0: Non-secure Flash programming disabled
1: Non-secure Flash programming enabled
### 6.9.10 Flash secure control register (FLASH_SECCR)

This register can only be written when the SECBSY, NSBSY or OBL_LAUNCH are reset. Otherwise, the write access stalls till SECBSY and NSBSY are reset.

This register is secure. It can be read and written only by secure access. A non-secure read/write access is RAZ/WI.

This register can be protected against non-privileged access when PRIV=1 in the FLASH_PRIVCFGR register.

Address offset: 0x2C

Reset value: 0x8000 0000

Access: no wait state when no Flash memory operation is on going, word, half-word and byte access

#### Bit 31  SECLOCK: FLASH_SECCR Lock

This bit is set only. When set, the FLASH_SECCR register is locked. It is cleared by hardware after detecting the unlock sequence in FLASH_SECKEYR register.

In case of an unsuccessful unlock operation, this bit remains set until the next system reset.

#### Bit 30  Reserved, must be kept at reset value.

#### Bit 29  SECINV: Flash security state invert

This bit inverts the flash security state

#### Bits 28:26  Reserved, must be kept at reset value.

#### Bit 25  SECERRIE: Secure error interrupt enable

This bit enables the interrupt generation when the SECOPERR bit in the FLASH_SECSR is set to 1.

- 0: SECOPERR error interrupt disabled
- 1: SECOPERR error interrupt enabled

#### Bit 24  SECEOPIE: Secure End of operation interrupt enable

This bit enables the interrupt generation when the SECEOP bit in the FLASH_SECSR is set to 1.

- 0: SECEOP Interrupt disabled
- 1: SECEOP Interrupt enabled

#### Bits 23:17  Reserved, must be kept at reset value.

#### Bit 16  SECSTRT: Secure start

This bit triggers a non-secure erase operation when set. If SECMER1, SECMER2 and SECPER bits are reset and the SECSTRT bit is set, the SECPGERR is set. This condition should be forbidden.

This bit is set only by software, and is cleared when the SECBSY bit is cleared in FLASH_SECSR.
6.9.11 Flash ECC register (FLASH_ECCR)

This register is non-secure. It can be read and written by both secure and non-secure access.

This register can be protected against non-privileged access when PRIV=1 in the FLASH_PRIVCFGR register.

Address offset: 0x30

Reset value: 0x0000 0000

Access: no wait state when no Flash memory operation is on going, word, half-word and byte access

</tbody>
</table>
Bit 31  **ECCD**: ECC detection  
   DBANK=0  
   Set by hardware when two ECC errors have been detected (only if ECCC/ECC2/ECCD/ 
   ECCD2 are previously cleared). When this bit is set, a NMI is generated.  
   Cleared by writing 1.  
   DBANK=1  
   Set by hardware when two ECC errors have been detected on 64-bits LSB (bits 63:0) (only if 
   ECCC/ECC2/ECCD/ ECCD2 are previously cleared). When this bit is set, a NMI is 
   generated.  
   Cleared by writing 1.

Bit 30  **ECCC**: ECC correction  
   Set by hardware when one ECC error has been detected and corrected. An interrupt is 
   generated if ECCIE is set.  
   Cleared by writing 1.

Bit 29  **ECCD2**: ECC2 detection  
   DBANK=0  
   Set by hardware when two ECC errors have been detected on 64-bits MSB (bits127:64). This bit is set (only if ECCC/ECC2/ECCD/ECCD2 are previously cleared). When this bit is set, a NMI is generated.  
   Cleared by writing 1.  
   DBANK=1  
   Reserved, must be kept at reset value.

Bit 28  **ECC2**: ECC correction  
   DBANK=0  
   Set by hardware when one ECC error has been detected and corrected on 64-bits MSB 
   (bits127:64). This bit is set (only if ECCC/ECC2/ECCD/ECCD2 are previously cleared). An 
   interrupt is generated if ECCIE is set.  
   Cleared by writing 1.  
   DBANK=1  
   Reserved, must be kept at reset value.

Bits 27:25  Reserved, must be kept at reset value.

Bit 24  **ECCIE**: ECC correction interrupt enable  
   0: ECCC interrupt disabled  
   1: ECCC interrupt enabled.  
   DBANK=0  
   This bit enables the interrupt generation when the ECCC or ECC2 bits in the 
   FLASH_ECCR register are set.  
   DBANK=1  
   This bit enables the interrupt generation when the ECCC bit in the FLASH_ECCR register is 
   set.

Bit 23  Reserved, must be kept at reset value.

Bit 22  **SYSF_ECC**: System Flash ECC fail  
   This bit indicates that the ECC error correction or double ECC error detection is located in 
   the system Flash.
6.9.12 Flash option register (FLASH_OPTR)

This register is non-secure. It can be read and written by both secure and non-secure access.

This register can be protected against non-privileged access when PRIV=1 in the FLASH_PRIVCFGR register.

Address offset: 0x40

ST production value: 0x7FEFF8AA (Register bits 0 to 31 are loaded with values from Flash memory at OBL)

Access: no wait state when no option bytes modification is on going; word, half-word and byte access.

</tbody>
</table>
Bit 26  **nSWBOOT0**: Software BOOT0
       0: BOOT0 taken from the option bit nBOOT0
       1: BOOT0 taken from PH3/BOOT0 pin

Bit 25  **SRAM2_RST**: SRAM2 erase when system reset
       0: SRAM2 erased when a system reset occurs
       1: SRAM2 is not erased when a system reset occurs

Bit 24  **SRAM2_PE**: SRAM2 parity check enable
       0: SRAM2 parity check enable
       1: SRAM2 parity check disable

Bit 23  Reserved, must be kept at reset value.

Bit 22  **DBANK**: 
       0: Single bank mode with 128 bits data read width
       1: Dual bank mode with 64 bits data
       This bit can only be written when all protection (secure, HDP) are disabled.

Bit 21  **DB256K**: Dual-bank on 256 Kbytes Flash memory devices
       0: 256 Kbytes single Flash: contiguous address in bank1
       1: 256 Kbytes dual-bank Flash with contiguous addresses.

Bit 20  **SWAP_BANK**: Swap banks
       It must be only used in dual-bank mode (DBANK=1). It can only be written when all the Flash memory is non-secure. Otherwise the OPTWERR is set.
       0: Bank 1 and bank 2 address are not swapped.
       1: Bank 1 and bank 2 address are swapped.

Bit 19  **WWDG_SW**: Window watchdog selection
       0: Hardware window watchdog
       1: Software window watchdog

Bit 18  **IWDG_STDBY**: Independent watchdog counter freeze in Standby mode
       0: Independent watchdog counter is frozen in Standby mode
       1: Independent watchdog counter is running in Standby mode

Bit 17  **IWDG_STOP**: Independent watchdog counter freeze in Stop mode
       0: Independent watchdog counter is frozen in Stop mode
       1: Independent watchdog counter is running in Stop mode

Bit 16  **IWDG_SW**: Independent watchdog selection
       0: Hardware independent watchdog
       1: Software independent watchdog

Bit 15  Reserved, must be kept at reset value.

Bit 14  **nRST_SHDW**: 
       0: Reset generated when entering the Shutdown mode
       1: No reset generated when entering the Shutdown mode

Bit 13  **nRST_STDBY**: 
       0: Reset generated when entering the Standby mode
       1: No reset generated when entering the Standby mode

Bit 12  **nRST_STOP**: 
       0: Reset generated when entering the Stop mode
       1: No reset generated when entering the Stop mode
6.9.13 Flash non-secure boot address 0 register (FLASH_NSBOOTADD0R)

This register can not be written if OPTLOCK bit is set.

This register is non-secure. It can be read and written by both secure and non-secure access.

This register can be protected against non-privileged access when PRIV=1 in the FLASH_PRIVCFGR register.

Address offset: 0x44

ST production value: 0x0800007F (The option bytes are loaded with values from the Flash memory at reset release)

Access: no wait state when no option bytes modification is on going; word, half-word and byte access.

Bits 31:7 **NSBOOTADD0[24:0]**: Non-secure Boot base address 0

The non-secure boot memory address can be programmed to any address in the valid address range with a granularity of 128 bytes.

The NSBOOTADD0[24:0] correspond to address [31:7]. The NSBOOTADD0 option bytes are selected following the Boot pin or nSWBOOTO state.

Example:
NSBOOTADD0[24:0] = 0x01000000: Boot from non-secure Flash (0x0800 0000)
NSBOOTADD0[24:0] = 0x017F200: Boot from system memory bootloader (0x0BF9 0000)
NSBOOTADD0[24:0] = 0x0040000: Boot from non-secure SRAM1 on S-Bus(0x2000 0000)

Bits 6:0 Reserved, must be kept at reset value.
6.9.14  Flash non-secure boot address 1 register (FLASH_NSBOOTADD1R)

This register can not be written if OPTLOCK bit is set.
This register is non-secure. It can be read and written by both secure and non-secure access.
This register can be protected against non-privileged access when PRIV=1 in the FLASH_PRIVCFGR register.

Address offset: 0x48
ST production value: 0x0BF9007F (The option bytes are loaded with values from the Flash memory at reset release)
Access: no wait state when no option bytes modification is on going; word, half-word and byte access.

Bits 31:7  NSBOOTADD1[24:0]: Non-secure boot address 1
The non-secure boot memory address can be programmed to any address in the valid address range with a granularity of 128 bytes.
The NSBOOTADD1[24:0] correspond to address [31:7]. The NSBOOTADD0 option bytes are selected following the boot pin or nSWBOOT0 state.
Example:
NSBOOTADD1[24:0] = 0x0100000: Boot from non-secure Flash (0x0800 0000)
NSBOOTADD1[24:0] = 0x017F200: Boot from system memory bootloader (0x0BF9 0000)
NSBOOTADD1[24:0] = 0x0040000: Boot from non-secure SRAM1 on S-Bus(0x2000 0000)

Bits 6:0  Reserved, must be kept at reset value.

6.9.15  Flash secure boot address 0 register (FLASH_SECBOOTADD0R)

This register can not be written if OPTLOCK bit is set.
This register is secure. It can be read and written only by secure access. A non-secure read/write access is RAZ/WI.
This register can be protected against non-privileged access when PRIV=1 in the FLASH_PRIVCFGR register.

Address offset: 0x4C
ST production value: 0x0C00007C (The option bytes are loaded with values from the Flash memory at reset release)
Access: no wait state when no option bytes modification is on going; word, half-word and byte access.
6.9.16 Flash bank 1 secure watermak1 register (FLASH_SECWM1R1)

This register can not be written if OPTLOCK bit is set.

This register is secure. It can be read and written only by secure access. A non-secure read/write access is RAZ/WI.

This register can be protected against non-privileged access when PRIV=1 in the FLASH_PRIVCFGR register.

Address offset: 0x50

ST production value: 0xFFFFFFFF (Register bits are loaded with values from Flash memory at OBL. Reserved bits are read as “1”)

Access: no wait state when no option bytes modification is on going; word, half-word and byte access.

Bits 31:7 SECBOOTADD0[24:0]: Secure boot base address 0

The secure boot memory address can be programmed to any address in the valid address range with a granularity of 128 bytes.

The SECBOOTADD0[24:0] correspond to address [31:7] The SECBOOTADD0 option bytes are selected following the boot pin or nSWBOOT state.

Example:
SECBOOTADD0[24:0] = 0x018 0000: Boot from secure Flash (0x0C00 0000)
SECBOOTADD0[24:0] = 0x01F F000: Boot from RSS (0x0FF8 0000)
SECBOOTADD0[24:0] = 0x060 0000: Boot from secure SRAM1 on S-Bus (0x3000 0000)

Bits 6:1 Reserved, must be kept at reset value.

Bit 0 BOOT_LOCK: BOOT LOCK

When set, the boot is always forced to base address value programmed in SECBOOTADD0[24:0] option bytes whatever the boot selection option.

When set, it cannot be cleared.
6.9.17 Flash secure watermak1 register 2 (FLASH_SECWM1R2)

This register can not be written if OPTLOCK bit is set.

This register is secure. It can be read and written only by secure access. A non-secure read/write access is RAZ/WI.

This register can be protected against non-privileged access when PRIV=1 in the FLASH_PRIVCFGR register.

Address offset: 0x54

ST production value: 0x7F807F80 (Register bits are loaded with values from Flash memory at OBL)

Access: no wait state when no option bytes modification is on going; word, half-word and byte access

6.9.26  **FLASH secure HDP control register (FLASH_SECHDPCR)**

This register is secure. It can be read and written only by secure access. A non-secure read/write access is RAZ/WI.

This register can be protected against non-privileged access when PRIV=1 in the FLASH_PRIVCFGR register.

Address offset: 0xC0

Reset value: 0x0000 0000

Access: no wait state when no option bytes modification is on going; word, half-word and byte access

<table>
<thead>
<tr>
<th>Bit 31:20</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
</table>
| 31:0      | SECBB2[31:0]: page secure/non-secure attribution | 0: Page (32 * x+y) in bank 2 is non secure  
1: Page (32 * x+y) in bank 2 is secure |
| 19:15     | Reserved, must be kept at reset value.          |                              |
| 14:8      | Reserved, must be kept at reset value.          |                              |
| 7:0       | Reserved, must be kept at reset value.          |                              |

Bits 31:2  Reserved, must be kept at reset value.

Bit 1  **HDP2_ACCDIS**: HDP2 area access disable

- When set, this bit is only cleared by a system reset
- 0: Access to HDP2 area is granted
- 1: Access to HDP2 area is denied and options bytes modification listed in Table 34: Default secure option bytes after TZEN activation are denied

Bit 0  **HDP1_ACCDIS**: HDP1 area access disable

- When set, this bit is only cleared by a system reset
- 0: Access to HDP1 area is granted
- 1: Access to HDP1 area is denied and options bytes modification listed in Table 34: Default secure option bytes after TZEN activation are denied

6.9.27  **FLASH privilege configuration register (FLASH_PRIVCFGR)**

This register can be read by both privileged and unprivileged access.

When the system is secure (TZEN =1), this register can be read by secure and non-secure access. It is write-protected against non-secure write access when the Flash is secure. A non-secure write access is ignored and generates an illegal access event.

Address offset: 0xC4
Reset value: 0x0000 0000

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 PRIV: Privilege protection

This bit can be read by both privileged or unprivileged, secure and non-secure access. When set, it can only be cleared by a privileged access.

0: All Flash registers can be read and written by privileged or unprivileged access.
1: All Flash registers can be read and written by privileged access only.

If the Flash is not secure (no secure area defined), the PRIV bit can be written by a secure or non-secure privileged access.

If the Flash is secure, the PRIV bit can be written only by a secure privileged access:

- A non-secure write access is ignored and generates an illegal access event.
- A secure unprivileged write access on PRIV bit is ignored

7 Instruction cache (ICACHE)

7.1 Introduction

The instruction cache (ICACHE) is introduced on C-AHB code bus of Cortex-M33 processor to improve performance when fetching instruction and data from both internal and external memories.

Some specific features like dual master port, hit-under-miss and critical-word-first refill policy, allow close to zero wait states performance in most use cases.

7.2 ICACHE main features

The main features of ICACHE are described below:

- **Bus interface**
  - one 32-bit AHB slave port, the execution port (input from Cortex-M33 C-AHB code interface)
  - two 32-bit AHB master ports: master1 and master2 ports (outputs to Fast and Slow buses of main AHB busmatrix, respectively)
  - one 32-bit AHB slave port for control (input from AHB peripherals interconnect, for ICACHE registers access)

- **Cache access**
  - 0 wait-state on hits
  - Hit-under-miss capability: ability to serve processor requests (access to cached data) during an ongoing line refill due to a previous cache miss
  - Dual master access: feature used to decouple the traffic according to targeted memory. For example, ICACHE assigns fast traffic (addressing FLASH and SRAM memories) to the AHB master1 port, and slow traffic (addressing external memories sitting on OCTOSPI and FMC interfaces) to AHB master2 port, thus preventing processor stalls on lines refills from external memories. This allows ISR (interrupt service routine) fetching on internal FLASH memory to take place in parallel with a cache line refill from external memory.
    - Minimal impact on interrupt latency, thanks to dual master
  - Optimal cache line refill thanks to WRAP bursts of the size of the cache line (such as WRAP4 for 128-bit cache line)
  - 2-ways set-associative default configuration with possibility to configure as 1-way, means direct mapped cache, for applications needing very-low-power consumption profile

- **Memory address remap**
  - Possibility to remap input address falling into up to four memory regions (used to remap aliased code in external memories to the internal Code region, for execution)

- **Replacement and refill**
  - pLRU-t replacement policy (pseudo-least-recently-used, based on binary tree), algorithm with best complexity/performance balance
  - Critical-word-first refill policy, minimizing processor stalls
Possibility to configure burst type of AHB memory transaction for remapped regions: INCRw or WRAPw (size w aligned on cache line size)

- Performance counters
  ICACHE implements two performance counters:
  - Hit monitor counter (32-bit)
  - Miss monitor counter (16-bit)

- Error management
  - Possibility to detect an unexpected cacheable write access, to flag an error and optionally to raise an interrupt

- TrustZone® security support

- Maintenance operation
  - Cache invalidate: full cache invalidation, fast command, non interruptible

### 7.4 ICACHE functional description

The purpose of the instruction cache is to cache instruction fetches or instruction memories loads, coming from the processor. As such ICACHE only manages read transactions and does not manage write transactions.

For error management purpose, in case a write cacheable transaction is presented (this only happens in case of bad software programming), ICACHE sets an error flag and, if enabled, raises an interrupt to the processor.
7.4.1 ICACHE block diagram

Figure 18. ICACHE block diagram

7.4.2 ICACHE reset and clocks

ICACHE is clocked on Cortex-M33 C-AHB bus clock.

When the ICACHE reset signal is released, a cache invalidate procedure is automatically launched, making ICACHE busy (ICACHE_SR = 0x0000 0001).

When this procedure is finished:
- ICACHE is invalidated: “cold cache”, with all cache line valid bits = 0 (ICACHE must be filled up)
- ICACHE_SR = 0x0000 0002 (reflecting the cache is no more busy)
- ICACHE is disabled: the EN bit in ICACHE_CR holds its reset state (=0).

Note: When disabled, ICACHE is bypassed, except the remapping mechanism that is still functional: the slave input requests (remapped or not) are just forwarded to the master port(s).
7.4.3 ICACHE TAG memory

The ICACHE TAG memory contains:
- address tags, that indicate which data are contained in the cache data memories
- validity bits

There is one valid bit per cache line (per way).

The valid bit is set when a cache line is refilled (after a miss).

Valid bits are reset in any of the below cases:
- after ICACHE reset is released
- when cache is disabled, by setting the EN bit low in the ICACHE_CR register (by software)
- when executing ICACHE invalidate command, by setting the CACHEINV bit high in the ICACHE_CR register (by software)

When a cacheable transaction is received at input execution port, its AHB address (HADDR_in) is split into the following fields (see table below for definition of B and W):
- HADDR_in[B-1:0]: address byte offset, indicates which byte to select inside a cache line.
- HADDR_in[B+W-1:B]: address way index, indicates which cache line to select inside each way.
- HADDR_in[31:B+W]: tag address, to be compared to TAG memory address to check if the requested data is already available (meaning valid) inside the ICACHE.

The table below gives a summary of ICACHE main parameters for TAG memory dimensioning and Figure 19 shows the functional view of TAG and data memories, for a n-way set associative ICACHE.

<table>
<thead>
<tr>

</tr>
<tr>
<td>TAG address size</td>
</tr>
</tbody>
</table>
### 7.4.4 Direct mapped ICACHE (1-way cache)

Default configuration (at reset) is 2-way set associative cache (WAYSEL = 1 in ICACHE_CR), but the user can configure ICACHE as direct mapped by writing WAYSEL = 0 (only possible when cache is disabled, EN=0 in ICACHE_CR).

The table below gives a summary of ICACHE main parameters for TAG memory in case the direct mapped cache operating mode is selected.

**Table 54. TAG memory dimensioning parameters for direct mapped cache mode**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cache size</td>
<td>S Kbytes = s bytes (s = 1024 x S)</td>
<td>8 Kbytes = 8192 bytes</td>
</tr>
<tr>
<td>Cache number of ways</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>Cache line size</td>
<td>L-byte = l-bit (l = 8 x L)</td>
<td>16-byte=128-bit</td>
</tr>
<tr>
<td>Number of cache lines</td>
<td>LpW = s / L lines</td>
<td>512 lines</td>
</tr>
<tr>
<td>Address byte offset size</td>
<td>B = log2(L) bit</td>
<td>4-bit</td>
</tr>
<tr>
<td>Address way index size</td>
<td>W = log2(LpW) bit</td>
<td>9-bit</td>
</tr>
<tr>
<td>TAG address size</td>
<td>T = (32 - W - B) bit</td>
<td>19-bit</td>
</tr>
</tbody>
</table>
All cache operations (such as read, refill, remapping, invalidation) remain the same in direct mapped configuration; the only difference is the absence of a replacement algorithm in case of line eviction (as explained in Section 7.4.8), since only one way (the unique one) is possible for any data refill.

### 7.4.5 ICACHE enable

In order to activate the ICACHE functioning, the EN bit must be set in the ICACHE_CR register.

When ICACHE is disabled, it is bypassed and all transactions are copied from slave port to master ports in the same clock cycle.

It is recommended to initialize or to modify the main memory content (the region to be later cached) with ICACHE disabled, and to enable ICACHE only when this region remains unchanged (an enabled ICACHE detects cacheable write transactions as errors).

In order to insure performance determinism, it is recommended to wait for the end of a potential cache invalidate procedure before enabling the ICACHE. This invalidate procedure occurs when hardware reset signal is released, when ICACHE_CR.CACHEINV is set or when ICACHE_CR.EN is cleared. During the procedure, ICACHE_SR.BUSYF is set, and once finished, ICACHE_SR.BUSYF is cleared and ICACHE_SR.BSYENDF is set (raising the ICACHE interrupt if enabled on such a busy end condition).

Software must test BUSYF and/or BSYENDF values before enabling the ICACHE. Else, if ICACHE is enabled before the end of an invalidate procedure, any cache access (while BUSYF still at 1) is treated as non cacheable, and its performance depends on the main memory access time.

The address remapping is performed, whether ICACHE is enabled or not, if input transaction address falls into memory regions defined and enabled in ICACHE_CRRx (see Figure 20).

ICACHE is by default disabled at boot.

### 7.4.6 Cacheable and non-cacheable traffic

ICACHE is developed for Cortex-M33 core. It is placed on C-AHB bus, and thus caches the Code memory region, ranging from address 0x0000 0000 to 0x1FFF FFFF of the memory map.

In order to make some other memory regions cacheable, ICACHE supports a memory region remapping feature. It allows to define up to four external memory regions, which addresses have an alias in the Code region. Addressing these external memory regions through their Code alias address allows the memory request to be routed to the C-AHB bus and to be managed by ICACHE.

Typically, any external memory space physically mapped at an address somewhere in range [0x6000 0000:0x9FFF FFFF] can be aliased with an address in range [0x0000 0000:0x07FF FFFF] or [0x1000 0000:0x1FFF FFFF].

For a given memory request in the Code region, ICACHE implements the address remapping functionality first. If aliased, it is the remapped address which is then cached, and, if needed, provided to the master port to address the main AHB bus matrix. The destination physical address does not need further manipulation on the AHB bus.
The remapping functionality is available also for non-cacheable traffic and when cache is disabled.

Further details on address remapping are provided in Section 7.4.7.

An incoming memory request to ICACHE is defined as cacheable according to its AHB transaction memory lookup attribute, as shown in Table 55. This AHB attribute depends on the MPU programming for the addressed region.

**Table 55. ICACHE cacheability for AHB transaction**

<table>
<thead>
<tr>
<th>AHB Lookup attribute</th>
<th>Cacheability</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Cacheable</td>
</tr>
<tr>
<td>0</td>
<td>Non cacheable</td>
</tr>
</tbody>
</table>

In case of non cacheable access, ICACHE is bypassed, meaning that the AHB transaction is propagated unchanged to the master output port, except the transaction address which may be modified due to the address remapping feature (see Section 7.4.7).

The bypass, and eventual remap logic, does not increase the latency of the access to the targeted memory.

In case of cacheable access, the ICACHE behaves as explained in Section 7.4.8.

Cacheable memory regions are defined and programmed by the user in the memory protection unit (MPU), that is responsible for the generation of the AHB attribute signals for any transaction addressing a given region.

Table 56 summarizes product memories programmable configurations.

**Table 56. Configurations of product memories**

<td></td>
</tr>
</tbody>
</table>

### 7.4.7 Address remapping

ICACHE allows to define an alias address in Code region for up to four external memory regions.

The address remapping is applied on the Code alias address, transforming it into the destination external physical address.

The remapping operation is fully software configurable by programming ICACHE_CRRx register (x = 0 to 3, number of remapped regions). This programming can be done only when ICACHE is disabled.
Each region \( x \) can be individually enabled with the REN bit in ICACHE_CRRx. Once enabled, the remap operation occurs even if ICACHE is disabled or if the transaction is not cacheable.

Remap regions can have different size: each region size can be programmed in the RSIZE field of its ICACHE_CRRx register. The size of each region is a power of two multiple of range granularity (2 Mbytes), with a minimum region size of 2 Mbytes and a maximum region size of 128 Mbytes.

The address remapping mechanism is based on the matching of an incoming AHB address (HADDR\_in) with a given Code sub-region base address, and the modification of this address into its (remapped) external physical address, as follows:

- HADDR\_in belongs to region \( x \) if HADDR\_in[31:RI] = 000:BASEADDR[28:RI], where:
  - 000:BASEADDR is the code sub-region base address programmed in the BASEADDR field of ICACHE_CRRx.
  - RI defines the number of significant bits to consider. RI = log2(region size) with a minimum value of 21 (for a 2-Mbyte region) and a maximum value of 27 (for a 128-Mbyte region)

- If region \( x \) is enabled, the master port output AHB address (HADDR\_out) is then composed by concatenating the two below parts:
  - REMAPADDR[31:RI] field of ICACHE_CRRx as MSBs
  - HADDR\_in[RI-1:0] as LSBs.

The figure below describes the matching and the output address generation.

The table below summarizes all possible configurations of BASEADDR and REMAPADDR sizes (number of significant MSBs) in ICACHE_CRRx, depending on RSIZE.

<table>
<thead>
<tr>
<th>Region size (Mbytes)</th>
<th>Base address size (MSBs)</th>
<th>Remap address (MSBs)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>8</td>
<td>11</td>
</tr>
<tr>
<td>4</td>
<td>7</td>
<td>10</td>
</tr>
<tr>
<td>8</td>
<td>6</td>
<td>9</td>
</tr>
<tr>
<td>16</td>
<td>5</td>
<td>8</td>
</tr>
<tr>
<td>32</td>
<td>4</td>
<td>7</td>
</tr>
</tbody>
</table>
Care must be taken while programming BASEADDR and REMAPADDR fields in ICACHE_CRRx: if programmed value is bigger than expected (in terms of number of MSBs, see Table 57), the unnecessary extra LSBs are ignored.

Typical remapping example: a 128-Mbyte FMC region (NOR/SRAM) physically located in the external address range [0x6800 0000:0x6FFF FFFF], remapped in Code section range [0x1000 0000:0x17FF FFFF]:
- REMAPADDR[31:21] = 0x340
- BASEADDR[28:21] = 0x80
- HADDR_in[31:27] is compared to 000:BASEADDR[28:27], and HADDR_in/BASEADDR[26:21] are ignored for the comparison.

If the comparison matches:
- HADDR_out[31:27] gets REMAPADDR[31:27] (in place of HADDR_in[31:27])
- HADDR_out[26:0] gets HADDR_in[26:0]

The software can program the kind of AHB burst that is generated by ICACHE master ports on busmatrix (for cache line refill), by setting the HBURST bit in ICACHE_CRRx with:
- WRAP: for remapped external memories accessed through OCTOSPI interface that can support WRAP burst mode, providing the benefit of the critical-word-first feature performance:
  - WRAP burst size = cache line size
  - WRAP burst start address = word address of the first data requested by the core
- INCR: INCR burst mode for external memories accessed through FMC interface that does not support WRAP burst mode (losing the benefit of critical-word-first feature):
  - INCR burst size = cache line size
  - INCR burst start address = address aligned on the boundary of the cache line containing the requested word.

Note: Coherency is needed when programming SAU (secure attribution unit) and MPU (memory protection unit) attributes for both the external regions and their aliased Code sub-regions.

7.4.8 Cacheable accesses

When ICACHE receives a cacheable transaction from Cortex-M33, ICACHE checks if the address requested is present in its TAG memory and if the corresponding cache line is valid.

<table>
<thead>
<tr>
<th>Region size (Mbytes)</th>
<th>Base address size (MSBs)</th>
<th>Remap address (MSBs)</th>
</tr>
</thead>
<tbody>
<tr>
<td>64</td>
<td>3</td>
<td>6</td>
</tr>
<tr>
<td>128</td>
<td>2</td>
<td>5</td>
</tr>
</tbody>
</table>
There are then three alternatives:

- Address is present inside the TAG memory, cache line is valid: **cache hit**, the data is read from cache and provided to the processor in the same cycle.
- Address is not present in the TAG memory: **cache miss**, the data is read from main memory and provided to the processor, and a cache line refill is performed.

  The critical-word-first policy insures minimum wait cycles for the processor, since read data can be provided while cache is still performing cache line refill (associated latency is the latency of fetching one word from main memory).

  In case no address remap occurs, the burst generated on ICACHE master bus is WRAPw (w being the cache line width, in words); if an address remap occurs, the kind of burst depends on the HBURST bit programmed in the corresponding ICACHE_CRRx register.

  The AHB transaction attributes are also propagated to main AHB bus matrix on the master port selected for the line refill.
- Address is not present in TAG memory but belongs to the refill burst from main memory that is currently ongoing: **cache hit** (hit-under-miss feature).

  This happens during cache line refill, ICACHE is capable of providing the requested data as soon as the data is available at its master interface, thus avoiding a miss (fetching data from main memory).

In case of cache refill (due to cache miss), ICACHE selects which cache line is written with the refill data:

- In direct map (1-way) mode, only one line can be used to store the refill data, the line pointed by the index of the input address.
- In n-way set associative mode, one line among 2 can be used (the line pointed by the address index, in each of the 2 ways). The way selection is based on a pLRU-t replacement algorithm. This algorithm points, for each index, on the way candidate for the next refill.

If ever the cache line where the refill data must be written, is already valid, the targeted cache line must be invalidated first; this is true whatever the direct map or n-way set associative cache mode.

### 7.4.9 Dual master cache

ICACHE can implement a dual port AHB master on main AHB bus matrix: master1 and master2 ports. This allows to split the traffic going to different destination memories.

The non-remapped traffic goes systematically to master1 port. The re-mapped traffic to external memories must be routed on master2 port by programming the MSTSEL bit of ICACHE_CRRx (on a region basis).

Typically, code can be fetched as follows:

- internal FLASH memory and internal SRAM on master1 port (Fast bus)
- external FLASH/RAM (through OCTOSPI/FMC interfaces) on master2 port (Slow bus)

For systems not implementing external memories, it is also possible to decouple the traffic to the internal FLASH memory from the traffic to the internal SRAM (when remapped by the ICACHE). This feature allows to prevent further processor stalls on misses.

Alongside with hit-under-miss, this dual master feature allows the processor to have an alternative path in case of fetching from different memories.
7.4.10 ICACHE security

ICACHE implements a v8-M TrustZone as defined by Arm.
ICACHE configuration registers are protected at system level.

7.4.11 ICACHE maintenance

The software can invalidate the whole content of the ICACHE by programming the CACHEINV bit in the ICACHE_CR register.

When CACHEINV is set, the ICACHE control logic sets the BUSYF flag in ICACHE_SR and launches the invalidate cache operation, resetting each TAG valid bit to 0 (one valid bit per cache line). The CACHEINV bit of ICACHE_CR is also automatically cleared.

Once the invalidate operation is finished, ICACHE automatically clears the BUSYF flag and sets the BSYENDF flag in the ICACHE_SR register.

If enabled on this flag condition (BSYENDIE = 1 in ICACHE_IER), the ICACHE interrupt is raised.

Then, the (empty) cache is available again.

7.4.12 ICACHE performance monitoring

ICACHE provides two monitors for performance analysis: a 32-bit hit monitor and a 16-bit miss monitor.

- The hit monitor counts the AHB-transactions at the input of ICACHE (execution port) that do not generate a transaction on ICACHE output (master1 or master2 port).
  It also takes into account all accesses whose address is present in the TAG memory or in the refill buffer (due to a previous miss, and whose data is coming, or is soon to come, from cache master port) (see Section 7.4.8).
- The miss monitor counts the AHB-transactions at the input of the ICACHE (execution port) that generate a transaction on ICACHE output (master1 or master2 port).
  It also takes into account all accesses whose address is not present neither in the TAG memory nor in the refill buffer.

Upon reaching their maximum values, monitors do not wrap over.
Hit and miss monitors can be enabled and reset by software allowing the analysis of specific pieces of code.

The software can perform the following tasks:
- Enable/stop the hit monitor through the HITMEN bit in ICACHE_CR.
- Reset the hit monitor by setting the HITMRST bit in ICACHE_CR.
- Enable/stop the miss monitor through the MISSMEN bit in ICACHE_CR.
- Reset the miss monitor by setting the MISSMRST bit in ICACHE_CR.

To reduce power consumption, these monitors are disabled (stopped) by default.

7.4.13 ICACHE Boot

ICACHE is disabled (EN = 0 in ICACHE_CR) at Boot.

Code remapping at Boot is not needed for Cortex®-M33 since it implements the VTOR (vector tables) that allows a boot start address definition different than 0x0.
Once Boot is finished, ICACHE can be enabled (software setting the EN bit to 1 in ICACHE_CR).

### 7.5 ICACHE low-power modes

At product level, using ICACHE reduces the power consumption by fetching instructions from the internal ICACHE most of the time, rather than from the bigger and then more power consuming main memories. This reduction is even higher if the cached main memories are external.

Applications with a lower-performance profile (in terms of hit ratio) and stringent low-power consumption constraints, may benefit from the lower power consumption of an ICACHE configured as direct mapped. This single way cache configuration is obtained by programming WAYSEL = 0 in ICACHE_CR (see Figure 19). The power consumption is then reduced by accessing, for each request, only the necessary cut of TAG and data memories. Meanwhile, the cache effect still improves fetch performance; even if for most codes execution, it is a little less efficient than with an n-way set associative cache mode.

### 7.6 ICACHE error management and interrupts

In case an unsupported cacheable write request is detected (functional error), ICACHE generates an error by setting the ERRF flag in ICACHE_SR. In such a case, an interrupt is generated if the corresponding interrupt enable bit is set (ERRIE = 1 in ICACHE_IER).

The other possible interrupt generation is at the end of a cache invalidation operation. When the cache-busy state is finished, ICACHE sets the BSYENDF flag in ICACHE_SR. An interrupt is then generated if the corresponding interrupt enable bit is set (BSYENDIE = 1 in ICACHE_IER).

Both interrupts use the same ICACHE interrupt vector.

### Remark

For region x, \textit{REN} must be high to enable the region.
Bit 31  **HBURST**: output burst type for region x
   0: WRAP
   1: INCR

Bits 30:29  Reserved, must be kept at reset value.

Bit 28  **MSTSEL**: AHB cache master selection for region x
   0: no action (master1 selected by default)
   1: master2 selected

Bit 27  Reserved, must be kept at reset value.

Bits 26:16  **REMAPADDR[31:21]**: remapped address for region x
   This field replaces the alias address defined by BASEADDR field.
   The only useful bits are [31:RI], where 21 ≤ RI ≤ 27 is the number of bits of RSIZE (see Section 7.4.7). If the programmed value has more LSBs, the useless bits are ignored.

Bit 15  **REN**: enable for region x
   0: disabled
   1: enabled

Bits 14:12  Reserved, must be kept at reset value.

Bits 11:9  **RSIZE[2:0]**: size for region x
   000: reserved
   001: 2 Mbytes
   010: 4 Mbytes
   011: 8 Mbytes
   100: 16 Mbytes
   101: 32 Mbytes
   110: 64 Mbytes
   111: 128 Mbytes

Bit 8  Reserved, must be kept at reset value.

Bits 7:0  **BASEADDR[28:21]**: base address for region x
   This alias address is replaced by REMAPADDR field.
   The only useful bits are [28:RI], where 21 ≤ RI ≤ 27 is the number of bits of RSIZE (see Section 7.4.7). If the programmed value has more LSBs, the useless bits are ignored.

8 Power control (PWR)

The power controller (PWR) main features are:

- Power supplies and supply domains
  - Core domains (VCORE)
  - VDD domain
  - Backup domain (VBAT)
  - Analog domain (VDDA)
  - Supply for the SMPS power stage (available on SMPS packages)
  - VDDIO2 domain on Port G
  - VDDUSB for USB transceiver

- System supply voltage regulation
  - SMPS step down converter
  - Voltage regulator (LDO)
  - External SMPS mode

- Power supply supervision
  - POR/PDR monitor
  - BOR monitor
  - PVD monitor
  - PVM monitor (VDDA, VDDUSB, VDDIO2)
  - Temperature threshold monitor
  - Upper VDD voltage threshold monitor

- Power management
  - Operating modes
  - Voltage scaling control
  - Low-power modes

- VBAT battery charging

- TrustZone security

8.1 Power supplies and supply domains

The STM32L552xx and STM32L562xx devices require a 1.71 V to 3.6 V operating supply voltage (\(V_{\text{DD}}\)). Several peripherals are supplied through independent power domains: \(V_{\text{DDA}}\), \(V_{\text{DDIO2}}\), \(V_{\text{DDUSB}}\). Those supplies must not be provided without a valid operating supply on the \(V_{\text{DD}}\) pin.

- \(V_{\text{DD}} = 1.71\ \text{V to 3.6 V}\)
  \(V_{\text{DD}}\) is the external power supply for the I/Os, the internal regulator (or the SMPS step down converter depending on the device) and the system analog such as reset, power management and internal clocks. It is provided externally through VDD pins.

- \(V_{\text{DDA}} = 1.62\ \text{V (ADCs/COMPs) / 1.8 V (DACs/OPAMPs) / 2.4 V (VREFBUF)}\) to 3.6 V
  \(V_{\text{DDA}}\) is the external analog power supply for A/D converters, D/A converters, voltage reference buffer, operational amplifiers and comparators. The \(V_{\text{DDA}}\) voltage level is independent from the \(V_{\text{DD}}\) voltage. \(V_{\text{DDA}}\) should be preferably connected to \(V_{\text{DD}}\) when...
these peripherals are not used.

- **VDDSMPS = 2 V to 3.6 V**
  VDDSMPS is the external power supply for the SMPS step down converter. It is provided externally through VDDSMPS supply pin, and shall be connected to the same supply as VDD.

- **V_{LXSMP}** is the switched SMPS step down converter output.

- **V_{15SMPS}** are the power supply for the system regulator. It is provided externally through the SMPS step down converter V_{LXSMP} output.

**Note:** The SMPS power supply pins are available only on a specific package with SMPS step down converter option.

- **VDD12 = 1.05 to 1.32 V**
  VDD12 is the external power supply bypassing the internal regulator when connected to an external SMPS. It is provided externally through VDD12 pins and only available on packages with the external SMPS supply option. VDD12 does not require any external decoupling capacitance and cannot support any external load.

**Note:** The VDD12 power supply pins are available only on a specific package with external SMPS option.

- **VDDUSB = 3.0 V to 3.6 V**
  VDDUSB is the external independent power supply for USB transceivers. The VDDUSB voltage level is independent from the VDD voltage. VDDUSB should be preferably connected to VDD when the USB is not used.

  The VDDUSB power supply may not be present as a dedicated pin, but to be internally bonded to VDD. For such devices, VDD has to respect the VDDUSB supply range when the USB is used.

- **VDDIO2 = 1.08 V to 3.6 V**
  VDDIO2 is the external power supply for 14 I/Os (Port G[15:2]). The VDDIO2 voltage level is independent from the VDD voltage and should preferably be connected to VDD when PG[15:2] are not used.

- **VBAT = 1.55 V to 3.6 V**
  VBAT is the power supply for RTC, external clock 32 kHz oscillator and backup registers (through power switch) when VDD is not present. VBAT is internally bonded to VDD for small packages without dedicated pin.

- **VREF-, VREF+**
  VREF+ is the input reference voltage for ADCs and DACs. It is also the output of the internal voltage reference buffer when enabled.

  When VDDA < 2 V, VREF+ must be equal to VDDA.

  When VDDA > 2 V, VREF+ must be between 2 V and VDDA.

  VREF+ can be grounded when ADC and DAC are not active.

  The internal voltage reference buffer supports two output voltages, which are configured with VRS bit in the VREFBUF_CSR register:

  - VREF+ around 2.048 V. This requires VDDA equal to or higher than 2.4 V.
  - VREF+ around 2.5 V. This requires VDDA equal to or higher than 2.8 V.

  On some packages, VREF- and VREF+ pins are not available. When not available on the package, they are internally bonded to respectively VSSA and VDDA.
When the $V_{\text{REF}+}$ is double-bonded with $V_{\text{DDA}}$ in a package, the internal voltage reference buffer is not available and must be kept disable (refer to related device datasheet for packages pinout description).

$V_{\text{REF}-}$ must always be equal to $V_{\text{SSA}}$.

In the STM32L552xx and STM32L562xx devices, the I/Os, the embedded LDO regulator and the system analog peripherals (such as PLLs and reset block) are fed by $V_{\text{DD}}$ supply source. The embedded linear voltage regulator is used to supply the internal digital power $V_{\text{CORE}}$. $V_{\text{CORE}}$ is the power supply for digital peripherals and memories.

**Figure 21. STM32L552xx and STM32L562xx power supply overview**

1. $V_{\text{CORE}}$ is provided by either MR or LPR, depending on the operating power mode.
In the STM32L552xxxP and STM32L562xxxP devices, the I/Os and system analog peripherals (such as PLLs, and reset block) are fed by \( V_{DD} \) supply source. The \( V_{CORE} \), power supply for digital peripherals and memories is generated from external SMPS.

**Figure 22. STM32L552xxxP and STM32L562xxxP power supply overview**

1. If the selected package has the external SMPS option but no external SMPS is used by the application (the embedded LDO is used instead), the VDD12 pins are kept unconnected.

2. VDD12 is intended to be connected with external SMPS (switched-mode power supply) to generate the \( V_{CORE} \) logic supply in Run, Sleep and Stop 0 modes only.
In the STM32L552xxxQ and STM32L562xxxQ devices, the I/Os, the embedded SMPS step down converter and the system analog peripherals (such as PLLs and reset block) are fed by $V_{DD}$ supply source. The embedded linear main voltage regulator that provides the $V_{CORE}$ supply for digital peripherals and memories is fed by the SMSP step down converter output.

**Figure 23. STM32L552xxxQ and STM32L562xxxQ power supply overview**

1. Refer to Figure 24 for SMPS step down converter power supply scheme.

2. During Low-power sleep, Low-power run, Stop 1, Stop 2, Standby and Shutdown modes, the SMPS step down converter is switched to Open mode. In Low-power sleep, Low-power run, Stop 1, Stop 2 and Standby with SRAM2 retention modes, the low-power regulator is used to provide the $V_{CORE}$. The SMPS is used in Run, Sleep and Stop 0 modes. It supplies the main regulator which provides the $V_{CORE}$.

**Note:** If the selected package has the SMPS step down converter option but the SMPS is not used by the application (and the embedded LDO is used instead), it is recommended to set the SMPS power supply pins as follows:
- $VDDSMPS$ and $VLXSMPS$ connected to VSS
- $V15SMPS$ connected to VDD.
8.1.1 Independent analog peripherals supply

To improve ADC and DAC conversion accuracy and to extend the supply flexibility, the analog peripherals have an independent power supply which can be separately filtered and shielded from noise on the PCB.

- The analog peripherals voltage supply input is available on a separate VDDA pin.
- An isolated supply ground connection is provided on VSSA pin.

The VDDA supply voltage can be different from VDD. The presence of VDDA must be checked before enabling any of the analog peripherals supplied by VDDA (A/D converter, D/A converter, comparators, operational amplifiers, voltage reference buffer).

The VDDA supply can be monitored by the peripheral voltage monitoring (PVM), and compared with two thresholds (1.65 V for PVM3 or 1.8 V for PVM4), refer to Section 8.3.3: Peripheral voltage monitoring (PVM) for more details.

When a single supply is used, VDDA can be externally connected to VDD through the external filtering circuit in order to ensure a noise-free VDDA reference voltage.

ADC and DAC reference voltage

To ensure a better accuracy on low-voltage inputs and outputs, the user can connect to VREF+ a separate reference voltage lower than VDDA. VREF+ is the highest voltage, represented by the full scale value, for an analog input (ADC) or output (DAC) signal.

VREF+ can be provided either by an external reference or by an internal buffered voltage reference (VREFBUF).

The internal voltage reference is enabled by setting the ENVR bit in the Section 23.4.1: VREFBUF control and status register (VREFBUF_CSR). The voltage reference is set to 2.5 V when the VRS bit is set and to 2.048 V when the VRS bit is cleared. The internal voltage reference can also provide the voltage to external components through VREF+ pin. Refer to the device datasheet and to Section 23: Voltage reference buffer (VREFBUF) for further information.

8.1.2 Independent I/O supply rail

Some I/Os from port G (PG[15:2]) are supplied from a separate supply rail. The power supply for this rail can range from 1.08 V to 3.6 V and is provided externally through the VDDIO2 pin. The VDDIO2 voltage level is completely independent from VDD or VDDA. The VDDIO2 pin is available only for some packages. Refer to the pinout diagrams or tables in the related device datasheet(s) for I/O list(s).

After reset, the I/Os supplied by VDDIO2 are logically and electrically isolated and therefore are not available. The isolation must be removed before using any I/O from PG[15:2], by setting the IOSV bit in the PWR_CR2 register, once the VDDIO2 supply is present.

The VDDIO2 supply is monitored by the peripheral voltage monitoring (PVM2) and compared with the internal reference voltage (3/4 VREFINT, around 0.9V), refer to Section 8.3.3: Peripheral voltage monitoring (PVM) for more details.

8.1.3 Independent USB transceivers supply

The USB transceivers are supplied from a separate VDDUSB power supply pin. VDDUSB range is from 3.0 V to 3.6 V and is completely independent from VDD or VDDA.
After reset, the USB features supplied by VDDUSB are logically and electrically isolated and therefore are not available. The isolation must be removed before using the USB peripheral, by setting the USV bit in the PWR_CR2 register, once the VDDUSB supply is present.

The VDDUSB supply is monitored by the peripheral voltage monitoring (PVM1) and compared with the internal reference voltage (VREFINT, around 1.2 V), refer to Section 8.3.3: Peripheral voltage monitoring (PVM) for more details.

### 8.1.4 Battery backup domain

To retain the content of the backup registers and supply the RTC function when VDD is turned off, the VBAT pin can be connected to an optional backup voltage supplied by a battery or by another source.

The VBAT pin powers the RTC unit, the LSE oscillator and the PC13 to PC15 I/Os, allowing the RTC to operate even when the main power supply is turned off. The switch to the VBAT supply is controlled by the power-down reset embedded in the Reset block.

---

**Warning:** During tRSTTEMPO (temporization at VDD startup) or after a PDR has been detected, the power switch between VBAT and VDD remains connected to VBAT. During the startup phase, if VDD is established in less than tRSTTEMPO (refer to the datasheet for the value of tRSTTEMPO) and VDD > VBAT + 0.6 V, a current may be injected into VBAT through an internal diode connected between VDD and the power switch (VBAT).

If the power supply/battery connected to the VBAT pin cannot support this current injection, it is strongly recommended to connect an external low-drop diode between this power supply and the VBAT pin.

---

If no external battery is used in the application, it is recommended to connect VBAT externally to VDD with a 100 nF external ceramic decoupling capacitor.

When the backup domain is supplied by VDD (analog switch connected to VDD), the following pins are available:

- PC13, PC14 and PC15, which can be used as GPIO pins
- PC13, PC14 and PC15, which can be configured by RTC or LSE (refer to Section 41.3: RTC functional description on page 1402)
- PA0/TAMP_IN2/TAMP_OUT1 and PE6/TAMP_IN3/TAMP_OUT6 when they are configured by the tamper as tamper pins

**Note:** Due to the fact that the analog switch can transfer only a limited amount of current (3 mA), the use of GPIO PC13 to PC15 in Output mode is restricted: the speed has to be limited to 2 MHz with a maximum load of 30 pF and these I/Os must not be used as a current source (for example to drive a LED).

When the backup domain is supplied by VBAT (analog switch connected to VBAT because VDD is not present), the following functions are available:

- PC13, PC14 and PC15 can be controlled only by RTC or LSE (refer to Section 41.3:...
RTC functional description

• PA0/TAMP_IN2 and PE6/TAMP_IN3 when they are configured by the tamper as tamper pins

Backup domain access

After a system reset, the backup domain (RTC registers and backup registers) is protected against possible unwanted write accesses. To enable access to the backup domain, proceed as follows:

1. Enable the power interface clock by setting the PWREN bits in the Section 9.8.13: RCC APB1 peripheral reset register 1 (RCC_APB1RSTR1)
2. Set the DBP bit in the Power control register 1 (PWR_CR1) to enable access to the backup domain
3. Select the RTC clock source in the RCC Backup domain control register (RCC_BDCR).

VBAT battery charging

When VDD is present, it is possible to charge the external battery on VBAT through an internal resistance.

The VBAT charging is done either through a 5 kOhm resistor or through a 1.5 kOhm resistor depending on the VBRS bit value in the PWR_CR4 register.

The battery charging is enabled by setting VBE bit in the PWR_CR4 register. It is automatically disabled in VBAT mode.

8.2 System supply voltage regulation

8.2.1 Voltage regulator

Two embedded linear voltage regulators supply all the digital circuitries, except for the Standby circuitry and the backup domain. The main regulator output voltage (VCORE) can be programmed by software to three different power ranges (Range 0, Range 1 and Range 2) in order to optimize the consumption depending on the system’s maximum operating frequency (refer to Section 9.3.10: Clock source frequency versus voltage scaling and to Section 6.3.3: Read access latency).

At power-on reset or a system reset, the main regulator voltage Range 2 is selected by default.

The voltage regulators are always enabled after a reset. Depending on the application modes, the VCORE supply is provided either by the main regulator (MR) or by the low-power regulator (LPR).

• In Run, Sleep and Stop 0 modes, both regulators are enabled and the main regulator (MR) supplies full power to the VCORE domain (core, memories and digital peripherals).
• In Low-power run and Low-power sleep modes, the main regulator is off and the low-power regulator (LPR) supplies low power to the VCORE domain, preserving the contents of the registers, SRAM1 and SRAM2.
• In Stop 1 and Stop 2 modes, the main regulator is off and the low-power regulator (LPR) supplies low-power to the VCORE domain, preserving the contents of the
registers, SRAM1 and SRAM2.

- In Standby mode, the SRAM2 content can be fully or partially (only 4 Kbytes) preserved (depending on RRS[1:0] bits in the PWR_CR3 register), the main regulator (MR) is off and the low-power regulator (LPR) provides the supply to SRAM2 only. The core, digital peripherals (except Standby circuitry and backup domain) and SRAM1 are powered off.

- In Standby mode, both regulators are powered off. The contents of the registers, SRAM1 and SRAM2 is lost except for the Standby circuitry and the backup domain.

- In Shutdown mode, both regulators are powered off. When exiting from Shutdown mode, a power-on reset is generated. Consequently, the contents of the registers, all SRAMs is lost, except for the backup domain.

### 8.2.2 Embedded SMPS step down converter

The built-in SMPS step down converter is a power-efficient DC/DC non-linear switching regulator that improves low-power performance when the VDD voltage is high enough. The SMPS step down converter automatically enters in Bypass mode when the VDD voltage falls below a VDD minimum value following the selected voltage range and switched back to the selected operating mode when VDD rises above the minimum value.

When the SMPS step down converter is enabled, it can be configured in:

- **High-power mode (HPM):** achieving a high efficiency at high current load. SMPS high-power mode is used in all ranges (0, 1 and 2). It is the default selected mode after POR reset.

- **Low-power mode (LPM):** achieving a high efficiency at low current load. When enabled, the voltage scaling must not be modified. This mode shall be only selected in Range 2 and when power consumption does not exceed 30 mA.

- **Bypass mode:** When the Bypass mode is enabled, the SMPS step down converter is switched OFF and it is possible to change the voltage scaling. This mode can be forced by software by setting the SMPSBYP bit in PWR_CR4 register. The Bypass mode can be enabled or disabled on the fly at any time by the application software whatever the selected operation mode.

  In Range 0 and Range 1, the SMPS Bypass mode is selected automatically when VDD drops below 2.05 V.

  In Range 2, if VDD is less than 2.05 V, the SMPS Bypass mode must be forced by software. For this purpose, the PVD0 should monitor the VDD power supply and the software must force bypass mode by setting the SMPSBYP bit in PWR_CR4 register.

The following table summarizes the SMPS behavior depending on the main regulator range, VDD and consumption.
Refer to Table 61 for SMPS step down converter operating mode.

### Table 61. SMPS step down converter operating mode

<table>
<thead>
<tr>
<th>SMPSBYP bit</th>
<th>SMPSLPEN bit</th>
<th>SMPSHPRDY flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>1</td>
<td>High-power mode</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>0</td>
<td>Low-power mode</td>
</tr>
<tr>
<td>1</td>
<td>x</td>
<td>x</td>
<td>Bypass mode</td>
</tr>
</tbody>
</table>

The sequence to go from Low-power to High-power mode is:
1. Clearing the SMPSLPEN bit in the PWR_CR4 register
2. Check that the SMPSHPRDY flag is set in PWR_SR1 register

The sequence to go from High-power to Low-power mode is:
1. Configure the system frequency and voltage scaling
2. Set the SMPSLPEN bit in the PWR_CR4 register

Note: If the Bypass mode is active and the SMPSLPEN bit is set, the switch to SMPS Low-power mode is delayed until the SMPS step down converter exits the Bypass mode.

Note: The SMPS step down converter operating mode and Voltage scaling range selection shall be changed only in RUN mode.

### 8.2.3 SMPS step down converter power supply scheme

The SMPS step down converter requires an external coil with typical value of 4.7 µH to be connected between the dedicated $V_{LXSMP}$ pin to $V_{SSSMPS}$ via a capacitor of 4.7µF. It is switched OFF when:
- LPREG is used
- SMPS is configured in Bypass mode by software in RUN/SLEEP modes (SMPSBYP bit set in PWR_CR4).
Thus, only main regulator is used by the application.
Refer to Figure 24 below.

Figure 24. SMPS step down converter power supply scheme

If the selected package is with the SMPS step down converter option but it is never used by the application, it is recommended to set the SMPS power supply pins as follows:
- $V_{DDMSPS}$ and $V_{LXSMPS}$ connected to VSS
- $V_{15SMPS}$ connected to VDD

8.2.4 SMPS step down converter versus low-power mode

The SMPS step down converter operating mode depends on the selected operating and upon the system operating modes (LP)Run, (LP)Sleep, Stop 0, Stop 1, Stop 2, Standby, and Shutdown.

During Stop 1, Stop 2, Standby and Shutdown modes the SMPS step down converter is switched to Open mode (see Table 62). When exiting from low-power modes (except Shutdown) the SMPS step down converter is set by hardware to the mode selected prior to the low-power mode selection. The SMPS step down converter mode configuration bits in PWR CR4 (SMPSLEN or SMPSBYP) are retained in Standby mode.

After POR reset, the SMPS step down converter is in High-power mode.

Table 62. SMPS step down converter versus low-power modes

<table>
<thead>
<tr>
<th>System operating mode</th>
<th>SMPS step down converter state</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Run, Sleep</td>
<td>ON</td>
<td>SMPS in HPM or LPM mode and, in ranges 0/1 it switches to Bypass mode following VDD minimum value versus the selected voltage range</td>
</tr>
<tr>
<td>Stop 0</td>
<td>ON</td>
<td>SMPS in HPM or LPM mode</td>
</tr>
<tr>
<td>Stop 1, Stop 2, Low power run, Low power sleep, Standby with SRAM2 retention</td>
<td>Open</td>
<td>SMPS is bypassed, LPR regulator is used</td>
</tr>
<tr>
<td>Standby and Shutdown</td>
<td>Open</td>
<td>SMPS is bypassed</td>
</tr>
</tbody>
</table>

Note: It is recommended to enable the SMPS bypass mode prior entering Stop modes in order to reduce the wake up time.
Note: If the Bypass mode is requested, entering Stop 1 or Stop 2 or Low-power run or Low-power sleep modes shall be delayed until the SMPS BYPASS ready flag SMPSBYPRDY is set.

Note: In Low-power run mode, the following bits shall not be modified (PWR_CR4: SMPSLPEN, SMPSFSTEN, SMPSBYP).

SMPS step down converter fast startup

After POR reset, the SMPS step down converter starts in High-power mode and in Slow-startup mode. The low-startup feature is selected to limit the inrush current after power-on reset.

However, it is possible to configure a faster startup on the fly and it is applied for next SMPS startup (after a wakeup from low-power mode - except Shutdown and VBAT modes) or for next SMPS output voltage change (Bypass or VOS change). The fast startup is selected by setting the SMPSFSTEN bit in the PWR_CR4 register.

Note: Setting the SMPSFSTEN bit in the PWR_CR4 register allows also a faster switch to Bypass mode (i.e. \( V_{15\text{SMPS}} \)- reaching \( V_{DD} \)).

Note: The timing needed for Bypass mode to be effective (i.e. SMPSBYPDY flag is set) is counted starting from V15 already at target value (1.3V (Range 2); 1.5V (Range 1); 1.6V (Range 0)). This timing is determined by the parameter V15 slew rate, depending itself on the fact that fast startup is enabled or disabled. Refer to the device datasheet.

8.2.5 Dynamic voltage scaling management

The dynamic voltage scaling is a power management technique which consists in increasing or decreasing the voltage used for the digital peripherals (V\(_{CORE}\)), according to the application performance and power consumption needs.

Dynamic voltage scaling to increase V\(_{CORE}\) is known as overvolting. It allows the device to improve its performance.

Dynamic voltage scaling to decrease V\(_{CORE}\) is known as undervolting. It is performed to save power, particularly in laptop and other mobile devices where the energy comes from a battery and is thus limited.

The main regulator operates in the following ranges:

- **Main regulator Range 0**: high performance;
  - It provides a typical output voltage at 1.28 V. It is used when the system clock frequency is up to 110 MHz. The Flash access time for read access is minimum, write and erase operations are possible.

- **Main regulator Range 1**: medium performance;
  - It provides a typical output voltage at 1.2 V. It is used when the system clock frequency is up to 80 MHz. The Flash access time for read access is minimum, write and erase operations are possible.

- **Main regulator Range 2**: low-power range.
  - It provides a typical output voltage at 1.0 V. The system clock frequency can be up to 26 MHz. The Flash access time for a read access is increased as compared to Range 1; write and erase operations are not possible.

Voltage scaling is selected through the VOS[1:0] bits in the PWR_CR1 register. The main regulator voltage Range 2 is selected by default.

Note: In Low-power run mode, the VOS[1:0] must not be modified.
Voltage scaling and SMPS step down converter

When the SMPS step down converter is selected, the VOS[1:0] bits must not be modified when the SMPS is in a low-power mode.

When the voltage scaling is updated, the SMPS step down converter output voltage is scaled automatically following the selected voltage range.

The sequence to go from Range 0 /Range 1 to Range 2 is:

1. In case of switching from Range 0 to Range 2, the system clock must be divided by 2 using the AHB prescaler before switching to a lower system frequency for at least 1 us and then reconfigure the AHB prescaler.
2. Reduce the system frequency to a value lower than 26 MHz.
3. Adjust number of wait states according new frequency target in Range 2 (LATENCY bits in the FLASH_ACR).
4. Program the VOS[1:0] bits to “10” in the PWR_CR1 register.

The sequence to go from Range 2 to Range 1/Range 0 is:

1. Program the VOS[1:0] bits to “01” in the PWR_CR1 register.
2. Wait until the VOSF flag is cleared in the PWR_SR2 register.
3. Adjust number of wait states according new frequency target in Range 0 or Range 1 (LATENCY bits in the FLASH_ACR).
4. Increase the system frequency by following below procedure:
   - If the system frequency is 26 MHz < SYSCLK <= 80 MHz:
     - Configure and switch to PLL for a new system frequency.
   - If the system frequency is SYSCLK > 80 MHz:
     - The system clock must be divided by 2 using the AHB prescaler before switching to a higher system frequency.
     - Configure and switch to PLL for a new system frequency.
     - Wait for at least 1us and then reconfigure the AHB prescaler to get the needed HCLK clock frequency.

The sequence to switch from Range 1 to Range 0 is:

1. The system clock must be divided by 2 using the AHB prescaler before switching to a higher system frequency.
2. Adjust the number of wait states according to the new frequency target in range1
3. Configure and switch to new system frequency.
4. Wait for at least 1us and then reconfigure the AHB prescaler to get the needed HCLK clock frequency.

The sequence to switch from Range 0 boost mode to Range 1 mode is:

1. Adjust the number of wait states according to the new frequency target in Range 0 default mode
2. Configure and switch to new system frequency.

VDD12 domain and external SMPS

VDD12 is intended to be connected with external SMPS (switched-mode power supply) to generate the V\textsubscript{CORE} logic supply in Run, Sleep and Stop 0 modes only.
VDD12 pins correspond to the internal $V_{\text{CORE}}$ powering the digital part of Core, RAMs, FLASH and peripherals. This significantly improves the power consumption with a gain from 50% or more depending on the external SMPS performances.

The main benefit occurs in Run and Sleep modes whereas in Stop 0 mode, the gain is less significant.

The figure below shows a schematic to understand how the internal regulator stops supplying $V_{\text{CORE}}$ when an external voltage VDD12 is provided.

As VDD12 shares the same pin as output of the internal regulator, applying a slightly higher voltage (typically +50 mV) on the VDD12 blocks, the PMOS and the regulator consumption is negligible.

**Figure 25. Internal main regulator overview**

A switch, controlled by the chosen GPIO, is inserted between the external SMPS output and VDD12.

There are two possible states:
- Connected: Switch is closed so external SMPS powers VDD12
- Disconnected: Switch is open and VDD12 is disconnected from external SMPS output

Proper software management through GPIOs to enable/disable external SMPS and to connect/disconnect external SMPS through the switch, is required to conform with the rules described below. See also *Section 8.2.5: Dynamic voltage scaling management.*
It is mandatory to respect the following rules to avoid any damage or instability on either digital parts or internal regulators:

- In Run, Sleep and Stop 0 modes, VDD12 can be connected and should respect
  - $V_{DD12} < 1.32 \text{ V}$
  - $V_{DD12} \geq V_{CORE} + 50 \text{ mV}$ giving for main regulator
    - Range 0, $V_{CORE} = 1.28 \text{ V}$ so $V_{DD12}$ should be greater than $1.33 \text{ V}$, but this cannot match previous rule $V_{DD12} < 1.32 \text{ V}$, so it is not a functional use case with an external SMPS.
    - Range 1, $V_{CORE} = 1.2 \text{ V}$ so $V_{DD12}$ should be greater than $1.25 \text{ V}$.
    - Range 2, $V_{CORE} = 1.0 \text{ V}$ so $V_{DD12}$ should be greater than $1.05 \text{ V}$
  - $V_{DD12} \geq 1.08 \text{ V}$ in Range 1 when $80 \text{ MHz} \geq SYSCLK$ frequency $\geq 26 \text{ MHz}$
  - $V_{DD12} \geq 1.14 \text{ V}$ in Range 0 when SYSCLK frequency $> 80 \text{ MHz}$

- In all other modes, such as LPRun, LPSleep, Stop 1, Stop 2, Standby and Shutdown modes, VDD12 must be disconnected from external SMPS output. This means that the pin must be connected to a high impedance output:
  - $V_{DD12}$ connected to HiZ (voltage is provided by internal regulators)

- Transitions of $V_{DD12}$ from connected to disconnected is only allowed when SYSCLK frequency $\leq 26 \text{ MHz}$ to avoid big voltage drop on main regulator side.

**Note:** In case of asynchronous reset while having the $V_{DD12} \leq 1.25 \text{ V}$, $V_{DD12}$ should switch to HiZ in less than regulator switching time from Range 2 to Range 1 (~1 us).

**Note:** $V_{DD12}$ Range 2 is extended down to $1.00 \text{ V}$ for better efficiency, thus following formula applies when bit EXTSMPSEN in the Power control register 4 (PWR_CR4) is set:
  - Range 2, $V_{CORE} = 0.95 \text{ V}$ so $V_{DD12}$ should be greater than $1.00 \text{ V}$

**Note:** For more details on $V_{DD12}$ management, refer to AN4978 “Design recommendations for STM32L4xxxx with external SMPS, for ultra-low-power applications with high performance”.

### 8.3 Power supply supervision

#### 8.3.1 Power-on reset (POR) / power-down reset (PDR) / brown-out reset (BOR)

The device has an integrated power-on reset (POR) / power-down reset (PDR), coupled with a brown-out reset (BOR) circuitry. The BOR is active in all power modes except Shutdown mode, and cannot be disabled.

Five BOR thresholds can be selected through option bytes.

During power-on, the BOR keeps the device under reset until the supply voltage $V_{DD}$ reaches the specified $V_{BORx}$ threshold. When $V_{DD}$ drops below the selected threshold, a device reset is generated. When $V_{DD}$ is above the $V_{BORx}$ upper limit, the device reset is released and the system can start.

For more details on the brown-out reset thresholds, refer to the electrical characteristics section in the datasheet.

During Stop 2 and Standby modes, it is possible to set the BOR in Ultra-low-power mode to further reduce the current consumption by setting the ULPMEN bit in PWR_CR3 register.
For Stop 2 mode, the BOR Ultra-low-power mode can be set if the BORH is set, otherwise there is no power consumption optimization.

**Figure 26. Brown-out reset waveform**

1. The reset temporization \( t_{\text{RSTTEMPO}} \) is present only for the BOR lowest threshold \( V_{\text{BOR0}} \).

### 8.3.2 Programmable voltage detector (PVD)

The user can use the PVD to monitor the \( V_{\text{DD}} \) power supply by comparing it to a threshold selected by the \( \text{PLS}[2:0] \) bits in the *Power control register 2 (PWR_CR2)*.

The PVD is enabled by setting the PVDE bit.

A PVDO flag is available, in the *Power control register 2 (PWR_CR2)*, to indicate if \( V_{\text{DD}} \) is higher or lower than the PVD threshold. This event is internally connected to the EXTI line16 and can generate an interrupt if enabled through the EXTI registers.

The rising/falling edge sensitivity of the EXTI Line16 should be configured according to PVD output behavior. For example, if the EXTI line 16 is configured to rising edge sensitivity, the interrupt is generated when \( V_{\text{DD}} \) drops below the PVD threshold. As an example the service routine could perform emergency shutdown tasks.

During during Stop 2 and Standby modes, it is possible to set the PDV in Ultra-low-power mode to further reduce the current consumption by setting the ULPMEN bit in PWR_CR3 register.

For Stop 2 mode, the PVD Ultra-low-power mode can be set if the PVD is set, otherwise if PVD is disabled, there is no power consumption optimization.
8.3.3 Peripheral voltage monitoring (PVM)

Only V\textsubscript{DD} is monitored by default, as it is the only supply required for all system-related functions. The other supplies (V\textsubscript{DDA}, V\textsubscript{DDIO2} and V\textsubscript{DDUSB}) can be independent from V\textsubscript{DD} and can be monitored with four peripheral voltage monitoring (PVM).

Each of the four PVM\textsubscript{x} (x=1, 2, 3, 4) is a comparator between a fixed threshold V\textsubscript{PVM\textsubscript{x}} and the selected power supply. PVMO\textsubscript{x} flags indicate if the independent power supply is higher or lower than the PVM\textsubscript{x} threshold: PVMO\textsubscript{x} flag is cleared when the supply voltage is above the PVM\textsubscript{x} threshold, and is set when the supply voltage is below the PVM\textsubscript{x} threshold.

Each PVM output is connected to an EXTI line and can generate an interrupt if enabled through the EXTI registers. The PVM\textsubscript{x} output interrupt is generated when the independent power supply drops below the PVM\textsubscript{x} threshold and/or when it rises above the PVM\textsubscript{x} threshold, depending on EXTI line rising/falling edge configuration.

Each PVM can remain active in Stop 0, Stop 1 and Stop 2 modes, and the PVM interrupt can wake up from the Stop mode.

<table>
<thead>
<tr>
<th>PVM</th>
<th>Power supply</th>
<th>PVM threshold</th>
<th>EXTI line</th>
</tr>
</thead>
<tbody>
<tr>
<td>PVM1</td>
<td>V\textsubscript{DDUSB}</td>
<td>V\textsubscript{PVM1 (around 1.2 V)}</td>
<td>35</td>
</tr>
<tr>
<td>PVM2</td>
<td>V\textsubscript{DDIO2}</td>
<td>V\textsubscript{PVM2 (around 0.9 V)}</td>
<td>36</td>
</tr>
<tr>
<td>PVM3</td>
<td>V\textsubscript{DDA}</td>
<td>V\textsubscript{PVM3 (around 1.65 V)}</td>
<td>37</td>
</tr>
<tr>
<td>PVM4</td>
<td>V\textsubscript{DDA}</td>
<td>V\textsubscript{PVM4 (around 1.8 V)}</td>
<td>38</td>
</tr>
</tbody>
</table>

The independent supplies (V\textsubscript{DDA}, V\textsubscript{DDIO2} and V\textsubscript{DDUSB}) are not considered as present by default, and a logical and electrical isolation is applied to ignore any information coming from the peripherals supplied by these dedicated supplies.

- If these supplies are shorted externally to V\textsubscript{DD}, the application should assume they are available without enabling any peripheral voltage monitoring.
- If these supplies are independent from V\textsubscript{DD}, the peripheral voltage monitoring (PVM)
can be enabled to confirm whether the supply is present or not.

The following sequence must be done before using the USB peripheral:

1. If \( \text{V}_{\text{DDUSB}} \) is independent from \( \text{V}_{\text{DD}} \):
   a) Enable the PVM1 by setting PVME1 bit in the Power control register 2 (PWR_CR2).
   b) Wait for the PVM1 wakeup time.
   c) Wait until PVMO1 bit is cleared in the Power status register 2 (PWR_SR2).
   d) Optional: Disable the PVM1 for consumption saving.

2. Set the USV bit in the Power control register 2 (PWR_CR2) to remove the \( \text{V}_{\text{DDUSB}} \) power isolation.

The following sequence must be done before using any I/O from PG[15:2]:

1. If \( \text{V}_{\text{DDIO2}} \) is independent from \( \text{V}_{\text{DD}} \):
   a) Enable the PVM2 by setting PVME2 bit in the Power control register 2 (PWR_CR2).
   b) Wait for the PVM2 wakeup time.
   c) Wait until PVMO2 bit is cleared in the Power control register 2 (PWR_CR2).
   d) Optional: Disable the PVM2 for consumption saving.

2. Set the IOSV bit in the Power control register 2 (PWR_CR2) to remove the \( \text{V}_{\text{DDIO2}} \) power isolation.

The following sequence must be done before using any of these analog peripherals: analog to digital converters, digital to analog converters, comparators, operational amplifiers, voltage reference buffer:

1. If \( \text{V}_{\text{DDA}} \) is independent from \( \text{V}_{\text{DD}} \):
   a) Enable the PVM3 (or PVM4) by setting PVME3 (or PVME4) bit in the Power control register 2 (PWR_CR2).
   b) Wait for the PVM3 (or PVM4) wakeup time.
   c) Wait until PVMO3 (or PVMO4) bit is cleared in the Power status register 2 (PWR_SR2).
   d) Optional: Disable the PVM3 (or PVM4) for consumption saving.

Enable the analog peripheral, which automatically removes the \( \text{V}_{\text{DDA}} \) isolation.

### 8.3.4 Upper voltage threshold monitoring

The upper VDD voltage monitoring is enabled by setting the bit VMONEN in the TAMP_CFGR register.

If the upper VDD voltage monitoring internal tamper is enabled in the TAMP peripheral (ITAMP1E=1 in the TAMP_CR1 register), a tamper event is generated when the VDD domain voltage is above the specified threshold.

The upper VDD monitoring can be periodical. This feature is enabled by setting the bit WUTMONEN in the TAMP configuration register TAMP_CFGR.

In this case, the monitoring is controlled by the RTC wakeup timer PWM resulting from the WUTF flag automatic clear and depending on the bitsfield WUTOCLR in the RTC_WUTR register. For more details, refer to the RTC section.
The monitoring is enabled during the PWM high level and disabled during the PWM low level.

**Note:**  *For threshold value, refer to the product datasheet.*

**Note:**  *In case the VDD is below the functional range, a Brown-out reset is generated.*

### 8.3.5 Temperature threshold monitoring

The temperature monitoring is enabled by setting the bit TMONEN in the TAMP_CFG register.

If the temperature monitoring internal tamper is enabled in the TAMP peripheral (ITAMP2E=1 in the TAMP_CR1 register), a tamper event is generated when the temperature is above or below the specified thresholds.

The temperature monitoring can be periodical. This feature is enabled by setting the bit WUTMONENT in the TAMP configuration register TAMP_CFG.

In this case, the monitoring is controlled by the RTC wakeup timer PWM resulting from the WUTF flag automatic clear and depending on the bitfield WUTOCLR in the RTC_WUTR register. For more details, refer to the RTC section.

The monitoring is enabled during the PWM high level and disabled during the PWM low level.

**Note:**  *For thresholds values, refer to the product datasheet.*

---

### 8.4 Power management

#### 8.4.1 Power modes

By default, the microcontroller is in Run mode after a system or a power reset. Several low-power modes are available to save power when the CPU does not need to be kept running, for example when waiting for an external event. It is up to the user to select the mode that gives the best compromise between low-power consumption, short startup time and available wakeup sources.

The device features eight low-power modes:

- **Sleep mode:** CPU clock off, all peripherals including Cortex®-M33 core such as NVIC and SysTick can run and wake up the CPU when an interrupt or an event occurs. Refer to [Section 8.4.5: Sleep mode](#).

- **Low-power run mode:** This mode is achieved when the system clock frequency is reduced below 2 MHz. The code is executed from the SRAM or the Flash memory. The regulator is in Low-power mode to minimize the regulator's operating current. Refer to [Section 8.4.3: Low-power run mode (LP run)](#).

- **Low-power sleep mode:** This mode is entered from the Low-power run mode: Cortex®-M33 is off. Refer to [Section 8.4.6: Low-power sleep mode (LP sleep)](#).

- **Stop 0, Stop 1 and Stop 2 modes:** SRAM1, SRAM2 and all registers content are retained. All clocks in the VCORE domain are stopped, the PLL, the MSI, the HSI16 and the HSE are disabled. The LSI and the LSE can be kept running.

The RTC can remain active (Stop mode with RTC, Stop mode without RTC).

Some peripherals with the wakeup capability can enable the HSI16 RC during the Stop mode.
mode to detect their wakeup condition.

In Stop 2 mode, most of the $V_{\text{CORE}}$ domain is put in a lower leakage mode.

Stop 1 offers the largest number of active peripherals and wakeup sources, a smaller wakeup time but a higher consumption than Stop 2. In Stop 0 mode, the main regulator remains ON, which allows the fastest wakeup time but with much higher consumption. The active peripherals and wakeup sources are the same as in Stop 1 mode.

The system clock, when exiting from Stop 0, Stop 1 or Stop 2 mode, can be either MSI up to 48 MHz or HSI16, depending on the software configuration.

Refer to Section 8.4.7: Stop 0 mode and Section 8.4.9: Stop 2 mode.

- **Standby mode:** $V_{\text{CORE}}$ domain is powered off. However, it is possible to preserve the full SRAM2 content or only 4 Kbytes:
  - Standby mode with full or only the upper 4 Kbytes of SRAM2 retention when the RRS[1:0] bits are set to ‘01’ or ‘10’ respectively in the PWR_CR3 register. In this case, the SRAM2 is supplied by the low-power regulator.
  - Standby mode when the RRS[1:0] bits are cleared in PWR_CR3 register. In this case the main regulator and the low-power regulator are powered off.

All clocks in the $V_{\text{CORE}}$ domain are stopped, the PLL, the MSI, the HSI16 and the HSE are disabled. The LSI and the LSE can be kept running.

The RTC can remain active (Standby mode with RTC, Standby mode without RTC).

The system clock, when exiting Standby modes, is MSI from 1 MHz up to 8 MHz.

Refer to Section 8.4.10: Standby mode.

- **Shutdown mode:** $V_{\text{CORE}}$ domain is powered off. All clocks in the $V_{\text{CORE}}$ domain are stopped, the PLL, the MSI, the HSI16, the LSI and the HSE are disabled. The LSE can be kept running. The system clock, when exiting the Shutdown mode, is MSI at 4 MHz.

In this mode, the supply voltage monitoring is disabled and the product behavior is not guaranteed in case of a power voltage drop. Refer to Section 8.4.11: Shutdown mode.

In addition, the power consumption in Run mode can be reduced by one of the following means:

- Slowing down the system clocks
- Gating the clocks to the APB and AHB peripherals when they are unused.

</table>

1. Legend: Y = yes (enable). O = optional (disable by default, can be enabled by software). - = not available. Gray cells highlight the wakeup capability in each mode.
2. The Flash can be configured in Power-down mode. By default, it is not in Power-down mode.
3. The SRAM clock can be gated on or off.
4. 4 Kbytes or full SRAM2 content is preserved depending on RRS[1:0] bits configuration in PWR_CR3 register.
5. Some peripherals with wakeup from Stop capability can request HSI16 to be enabled. In this case, HSI16 is woken up by the peripheral, and only feeds the peripheral which requested it. HSI16 is automatically put off when the peripheral does not need it anymore.
6. UART and LPUART reception is functional in Stop mode, and generates a wakeup interrupt on Start, address match or received frame event.
7. I2C address detection is functional in Stop mode, and generates a wakeup interrupt in case of address match.
8. Voltage scaling range 1 only.
9. I/Os can be configured with internal pull-up, pull-down or floating in Standby mode.
10. The I/Os with wakeup from standby/shutdown capability are: PA0, PC13, PE6, PA2, PC5.
11. I/Os can be configured with internal pull-up, pull-down or floating in Shutdown mode but the configuration is lost when exiting the Shutdown mode.
Debug mode

By default, the debug connection is lost if the application puts the MCU in Stop 0, Stop 1, Stop 2, Standby or Shutdown mode while the debug features are used. This is due to the fact that the Cortex®-M33 core is no longer clocked.

However, by setting some configuration bits in the DBGMCU_CR register, the software can be debugged even when using the low-power modes extensively. For more details, refer to Section 52.2.5: Debug and low-power modes.

8.4.2 Run mode

Slowing down system clocks

In Run mode, the speed of the system clocks (SYSCLK, HCLK, PCLK) can be reduced by programming the prescaler registers. These prescalers can also be used to slow down the peripherals before entering the Sleep mode.

For more details, refer to Section 9.8.3: RCC clock configuration register (RCC_CFGR).

Peripheral clock gating

In Run mode, the HCLK and PCLK for individual peripherals and memories can be stopped at any time to reduce the power consumption.

To further reduce the power consumption in Sleep mode, the peripheral clocks can be disabled prior to executing the WFI or WFE instructions.

The peripheral clock gating is controlled by the RCC_AHBxENR and RCC_APBxENR registers.

Disabling the peripherals clocks in Sleep mode can be performed automatically by resetting the corresponding bit in the RCC_AHBxSMENR and RCC_APBxSMENR registers.

8.4.3 Low-power run mode (LP run)

To further reduce the consumption when the system is in Run mode, the regulator can be configured in low-power mode. In this mode, the system frequency should not exceed 2 MHz.

Refer to the product datasheet for more details on voltage regulator and peripherals operating conditions.

I/O states in Low-power run mode

In Low-power run mode, all I/O pins keep the same state as in Run mode.

Entering the Low-power run mode

To enter the Low-power run mode, proceed as follows:

1. Optional: Jump into the SRAM and power-down the Flash by setting the RUN_PD bit in the Flash access control register (FLASH_ACR).
2. Decrease the system clock frequency below 2 MHz.
3. Force the regulator in Low-power mode by setting the LPR bit in the PWR_CR1 register.

Refer to Table 66: Low-power run on how to enter the Low-power run mode.
8.4.4 Low-power modes

Entering into a low-power mode

Low-power modes are entered by the MCU by executing the WFI (wait for interrupt), or WFE (wait for event) instructions, or when the SLEEPONEXIT bit in the Cortex®-M33 system control register is set on Return from ISR.

Entering into a low-power mode through WFI or WFE is executed only if no interrupt is pending or no event is pending.

Exiting from a low-power mode

From Sleep mode and Stop mode the MCU exits the low-power mode depending on the way the low-power mode was entered:

- If the WFI instruction or return from ISR was used to enter the low-power mode, any peripheral interrupt acknowledged by the NVIC can wake up the device.
- If the WFE instruction is used to enter the low-power mode, the MCU exits the low-power mode as soon as an event occurs. The wakeup event can be generated either by:
  - NVIC IRQ interrupt.
  - When SEVONPEND = 0 in the Cortex®-M33 system control register. By enabling an interrupt in the peripheral control register and in the NVIC. When the MCU resumes from WFE, the peripheral interrupt pending bit and the NVIC peripheral IRQ channel pending bit (in the NVIC interrupt clear pending register) have to be cleared.

Only NVIC interrupts with sufficient priority wakeup and interrupt the MCU.
- When SEVONPEND = 1 in the Cortex®-M33 System Control register.

By enabling an interrupt in the peripheral control register and optionally in the NVIC. When the MCU resumes from WFE, the peripheral interrupt pending bit and
when enabled the NVIC peripheral IRQ channel pending bit (in the NVIC interrupt clear pending register) have to be cleared.

All NVIC interrupts wakes up the MCU, even the disabled ones. Only enabled NVIC interrupts with sufficient priority wake up and interrupt the MCU.

- Event

Configuring a EXTI line in Event mode. When the CPU resumes from WFE, it is not necessary to clear the EXTI peripheral interrupt pending bit or the NVIC IRQ channel pending bit as the pending bits corresponding to the event line is not set.

It may be necessary to clear the interrupt flag in the peripheral.

From Standby modes, and Shutdown modes the MCU exits the low-power mode through an external reset (NRST pin), an IWDG reset, a rising edge on one of the enabled WKUPx pins or a RTC event occurs (see Figure 395: RTC block diagram).

After waking up from Standby or Shutdown mode, program execution restarts in the same way as after a Reset (boot pin sampling, option bytes loading, reset vector is fetched, etc.).

8.4.5 Sleep mode

I/O states in Sleep mode

In Sleep mode, all I/O pins keep the same state as in Run mode.

Entering the Sleep mode

The Sleep mode is entered according Section : Entering into a low-power mode, when the SLEEPDEEP bit in the Cortex®-M33 System Control register is clear.

Refer to Table 67: Sleep mode for details on how to enter the Sleep mode.

Exiting the Sleep mode

The Sleep mode is exit according Section : Exiting from a low-power mode.

Refer to Table 67: Sleep mode for more details on how to exit the Sleep mode.

Table 67. Sleep mode

</tbody>
</table>
8.4.6 Low-power sleep mode (LP sleep)

Refer to the product datasheet for more details on voltage regulator and peripherals operating conditions.

I/O states in Low-power sleep mode

In Low-power sleep mode, all I/O pins keep the same state as in Run mode.

Entering the Low-power sleep mode

The Low-power sleep mode is entered from Low-power run mode according to Section: Entering into a low-power mode, when the SLEEPDEEP bit in the Cortex®-M33 system control register is clear.

Refer to Table 68: Low-power sleep for details on how to enter the Low-power sleep mode.

Exiting the Low-power sleep mode

The Low-power sleep mode is exit according to Section: Exiting from a low-power mode.

When exiting the Low-power sleep mode by issuing an interrupt or an event, the MCU is in Low-power run mode.

Refer to Table 68: Low-power sleep for details on how to exit the Low-power sleep mode.
8.4.7 Stop 0 mode

The Stop 0 mode is based on the Cortex®-M33 Deepsleep mode combined with the peripheral clock gating. The voltage regulator is configured in Main regulator mode. In Stop 0 mode, all clocks in the VCORE domain are stopped; the PLL, the MSI, the HSI16 and the HSE oscillators are disabled. Some peripherals with the wakeup capability (I2Cx (x=1,2,3), U(S)ARTx(x=1,2...5) and LPUART) can switch on the HSI16 to receive a frame, and switch off the HSI16 after receiving the frame if it is not a wakeup frame. In this case, the HSI16 clock is propagated only to the peripheral requesting it.

SRAM1, SRAM2 and register contents are preserved.

The BOR is always available in Stop 0 mode. The consumption is increased when thresholds higher than VBOR0 are used.

I/O states in Stop 0 mode

In the Stop 0 mode, all I/O pins keep the same state as in the Run mode.

Entering the Stop 0 mode

The Stop 0 mode is entered according to Section : Entering into a low-power mode, when the SLEEPDEEP bit in the Cortex®-M33 System Control register is set.

Interrupt: refer to Table 104: STM32L552xx and STM32L562xx vector table  
If WFE was used for entry and SEVONPEND = 0:  
Wakeup event: refer to Section 17.3: EXTI functional description  
If WFE was used for entry and SEVONPEND = 1:  
Interrupt even when disabled in NVIC: refer to Table 104: STM32L552xx and STM32L562xx vector table  
Wakeup event: refer to Section 17.3: EXTI functional description  
After exiting the Low-power sleep mode, the MCU is in Low-power run mode. |
| Wakeup latency           | None |
Refer to *Table 69: Stop 0 mode* for details on how to enter the Stop 0 mode.

If Flash memory programming is ongoing, the Stop 0 mode entry is delayed until the memory access is finished.

If an access to the APB domain is ongoing, The Stop 0 mode entry is delayed until the APB access is finished.

In Stop 0 mode, the following features can be selected by programming individual control bits:

- Independent watchdog (IWDG): the IWDG is started by writing to its key register or by hardware option. Once started, it cannot be stopped except by a reset. See *Section 39.3: IWDG functional description*.
- Real-time clock (RTC): this is configured by the RTCE bit in the *RCC Backup domain control register (RCC_BDCR)*.
- Internal RC oscillator (LSI): LSI clock or LSI clock divided by 128, this is configured by the LSION and LSIPRE bits in the *RCC control/status register (RCC_CSR)*.
- External 32.768 kHz oscillator (LSE): this is configured by the LSEON bit in the *RCC Backup domain control register (RCC_BDCR)*.

Several peripherals can be used in Stop 0 mode and can add consumption if they are enabled and clocked by LSI or LSE, or when they request the HSI16 clock: LPTIM1, LPTIM2, I2Cx (x=1,2,3,4) U(S)ARTx(x=1,2...5), LPUART.

The DACx (x=1,2), the OPAMPs and the comparators can be used in Stop 0 mode, the PVMx (x=1,2,3,4) and the PVD as well. If they are not needed, they must be disabled by software to save their power consumptions.

The ADCx (x=1,2,3), temperature sensor and VREFBUF buffer can consume power during the Stop 0 mode, unless they are disabled before entering this mode.

**Exiting the Stop 0 mode**

The Stop 0 mode is exit according *Section : Entering into a low-power mode*. Refer to *Table 69: Stop 0 mode* for details on how to exit Stop 0 mode.

When exiting Stop 0 mode by issuing an interrupt or a wakeup event, the HSI16 oscillator is selected as system clock if the bit STOPWUCK is set in *RCC clock configuration register (RCC_CFGR)*. The MSI oscillator is selected as system clock if the bit STOPWUCK is cleared. The wakeup time is shorter when HSI16 is selected as wakeup system clock. The MSI selection allows wakeup at higher frequency, up to 48 MHz.

When exiting the Stop 0 mode, the MCU is either in Run mode (Range 0, Range 1 or Range 2) or in Low-power run mode if the bit LPR is set in the PWR_CR1 register.
### 8.4.8 Stop 1 mode

The Stop 1 mode is the same as Stop 0 mode except that the main regulator is OFF, and only the low-power regulator is ON. Stop 1 mode can be entered from Run mode and from Low-power run mode.

Refer to *Table 70: Stop 1 mode* for details on how to enter and exit Stop 1 mode.

<table>
<thead>
<tr>

</tr>
</thead>
</table>
| Mode entry | WiFi (Wait for Interrupt) or WFE (Wait for Event) while:  
  - SLEEPDEEP bit is set in Cortex®-M33 System Control register  
  - No interrupt (for WiFi) or event (for WFE) is pending  
  - LPMS = "000" in PWR_CR1  
  
  On Return from ISR while:  
  - SLEEPDEEP bit is set in Cortex®-M33 System Control register  
  - SLEEPONEXIT = 1  
  - No interrupt is pending  
  - LPMS = "000" in PWR_CR1  
  
  Note: To enter Stop 0 mode, all EXTI Line pending bits (in EXTI rising edge pending register (EXTI_RPR2)), and the peripheral flags generating wakeup interrupts must be cleared. Otherwise, the Stop 0 mode entry procedure is ignored and program execution continues. |
| Mode exit | If WFI or Return from ISR was used for entry  
  Any EXTI Line configured in Interrupt mode (the corresponding EXTI Interrupt vector must be enabled in the NVIC). The interrupt source can be external interrupts or peripherals with wakeup capability. Refer to *Table 104: STM32L552xx and STM32L562xx vector table*.  
  
  If WFE was used for entry and SEVONPEND = 0:  
  Any EXTI Line configured in Event mode. Refer to *Section 17.3: EXTI functional description*.  
  
  If WFE was used for entry and SEVONPEND = 1:  
  Any EXTI Line configured in Interrupt mode (even if the corresponding EXTI Interrupt vector is disabled in the NVIC). The interrupt source can be external interrupts or peripherals with wakeup capability. Refer to *Table 104: STM32L552xx and STM32L562xx vector table*.  
  
  Wakeup event: refer to *Section 17.3: EXTI functional description* |
| Wakeup latency | Longest wakeup time between: MSI or HSI16 wakeup time and Flash wakeup time from Stop 0 mode. |
The Stop 2 mode is based on the Cortex®-M33 Deepsleep mode combined with peripheral clock gating. In Stop 2 mode, all clocks in the VCORE domain are stopped, the PLL, the MSI, the HSI16 and the HSE oscillators are disabled. Some peripherals with wakeup capability (I2C3 and LPUART) can switch on the HSI16 to receive a frame, and switch off the HSI16 after receiving the frame if it is not a wakeup frame. In this case the HSI16 clock is propagated only to the peripheral requesting it.

SRAM1, SRAM2 and register contents are preserved.

The BOR is always available in Stop 2 mode. The consumption is increased when thresholds higher than VBOR0 are used.

Note: The comparators outputs, the LPUART outputs and the LPTIM1 outputs are forced to low speed (OSPEEDy=00) during the Stop 2 mode.
I/O states in Stop 2 mode
In the Stop 2 mode, all I/O pins keep the same state as in the Run mode.

Entering Stop 2 mode
The Stop 2 mode is entered according to Section : Entering into a low-power mode, when the SLEEPDEEP bit in the Cortex®-M33 System Control register is set.

Refer to Table 71: Stop 2 mode for details on how to enter the Stop 2 mode.
Stop 2 mode can only be entered from Run mode. It is not possible to enter Stop 2 mode from the Low-power run mode.

If Flash memory programming is ongoing, the Stop 2 mode entry is delayed until the memory access is finished.

If an access to the APB domain is ongoing, the Stop 2 mode entry is delayed until the APB access is finished.

In Stop 2 mode, the following features can be selected by programming individual control bits:

- Independent watchdog (IWDG): the IWDG is started by writing to its key register or by hardware option. Once started it cannot be stopped except by a Reset. See Section 39.3: IWDG functional description in Section 39: Independent watchdog (IWDG).
- Real-time clock (RTC): this is configured by the RTCEN bit in the RCC Backup domain control register (RCC_BDCR).
- Internal RC oscillator (LSI): LSI clock or LSI clock divided by 128, this is configured by the LSION and LSIPRE bits in the RCC control/status register (RCC_CSR).
- External 32.768 kHz oscillator (LSE): this is configured by the LSEON bit in the RCC Backup domain control register (RCC_BDCR).

Several peripherals can be used in Stop 2 mode and can add consumption if they are enabled and clocked by LSI or LSE, or when they request the HSI16 clock: LPTIM1, I2C3, LPUART.

The comparators can be used in Stop 2 mode, the PVMx (x=1,2,3,4) and the PVD as well. If they are not needed, they must be disabled by software to save their power consumptions.

The ADCx, OPAMPx, DACx, temperature sensor and VREFBUF buffer can consume power during Stop 2 mode, unless they are disabled before entering this mode.

All the peripherals which cannot be enabled in Stop 2 mode must be either disabled by clearing the enable bit in the peripheral itself, or put under reset state by setting the corresponding bit in the RCC AHB1 peripheral reset register (RCC_AHB1RSTR), RCC AHB2 peripheral reset register (RCC_AHB2RSTR), RCC AHB3 peripheral reset register (RCC_AHB3RSTR), RCC APB1 peripheral reset register 1 (RCC_APB1RSTR1), RCC APB1 peripheral reset register 2 (RCC_APB1RSTR2), RCC APB2 peripheral reset register (RCC_APB2RSTR).

Exiting Stop 2 mode
The Stop 2 mode is exit according to Section : Exiting from a low-power mode.

Refer to Table 71: Stop 2 mode for details on how to exit Stop 2 mode.
When exiting Stop 2 mode by issuing an interrupt or a wakeup event, the HSI16 oscillator is selected as system clock if the bit STOPWUCK is set in RCC clock configuration register (RCC_CFGR). The MSI oscillator is selected as system clock if the bit STOPWUCK is cleared. The wakeup time is shorter when HSI16 is selected as wakeup system clock. The MSI selection allows wakeup at higher frequency, up to 48 MHz.

When exiting the Stop 2 mode, the MCU is in Run mode (Range 0, Range 1 or Range 2 depending on VOS bit in PWR_CR1).

| Wakeup latency | Longest wakeup time between: MSI or HSI16 wakeup time and regulator wakeup time from low-power mode + Flash wakeup time from Stop 2 mode. |

### 8.4.10 Standby mode

The Standby mode permits the achievement of the lowest power consumption with BOR. It is based on the Cortex®-M33 Deepsleep mode, with the voltage regulators disabled (except when SRAM2 content is preserved). The PLL, the HSI16, the MSI and the HSE oscillators are also switched off.
SRAM1 and register contents are lost except for registers in the Backup domain and Standby circuitry (see Figure 21). SRAM2 content can be partially or fully preserved depending on RRS[1:0] bits configuration in PWR_CR3. In this case the Low-power regulator is ON and provides the supply to SRAM2 only.

The BOR is always available in Standby mode. The consumption is increased when thresholds higher than $V_{BOR0}$ are used.

**I/O states in Standby mode**

In the Standby mode, the I/O’s are by default in floating state. If the APC bit of PWR_CR3 register has been set, the I/Os can be configured either with a pull-up (refer to PWR_PUCRx registers ($x=A,B,C,D,E,F,G,H$)), or with a pull-down (refer to PWR_PDCRx registers ($x=A,B,C,D,E,F,G,H$)), or can be kept in analog state if none of the PWR_PUCRx or PWR_PDCRx register has been set. The pull-down configuration has highest priority over pull-up configuration in case both PWR_PUCRx and PWR_PDCRx are set for the same IO.

Some I/Os (listed in Section 11.3.1: General-purpose I/O (GPIO)) are used for JTAG/SW debug and can only be configured to their respective reset pull-up or pull-down state during Standby mode setting their respective bit in the PWR_PUCRx or PWR_PDCRx registers to ‘1’, or to be configured to floating state if the bit is kept at ‘0’.

The RTC outputs on PC13 are functional in Standby mode. PC14 and PC15 used for LSE are also functional. 5 wakeup pins (WKUPx, x=1,2...5) and tamper inputs are available.

**Entering Standby mode**

The Standby mode is entered according Section : Entering into a low-power mode, when the SLEEPDEEP bit in the Cortex®-M33 System Control register is set.

Refer to Table 72: Standby mode for details on how to enter Standby mode.

In Standby mode, the following features can be selected by programming individual control bits:

- Independent watchdog (IWDG): the IWDG is started by writing to its Key register or by hardware option. Once started it cannot be stopped except by a reset. See Section 39.3: IWDG functional description in Section 39: Independent watchdog (IWDG).

- Real-time clock (RTC): this is configured by the RTCEN bit in the Backup domain control register (RCC_BDCR).

- Internal RC oscillator (LSI): LSI clock or LSI clock divided by 128, this is configured by the LSION and LSIPRE bits in the Control/status register (RCC_CSR).

- External 32.768 kHz oscillator (LSE): this is configured by the LSEON bit in the Backup domain control register (RCC_BDCR).

**Exiting Standby mode**

The Standby mode is exited according Section : Entering into a low-power mode. The SBF status flag in the Power control register 3 (PWR_CR3) indicates that the MCU was in Standby mode. All registers are reset after wakeup from Standby except for Power control register 3 (PWR_CR3).

Refer to Table 72: Standby mode for more details on how to exit Standby mode.
When exiting Standby mode, I/O’s that were configured with pull-up or pull-down during Standby through registers PWR_PUCRx or PWR_PDCRx keep this configuration upon exiting Standby mode until the bit APC of PWR_CR3 register has been cleared. Once the bit APC is cleared, they are either configured to their reset values or to the pull-up/pull-down state according the GPIOx_PUPDR registers. The content of the PWR_PUCRx or PWR_PDCRx registers however is not lost and can be re-used for a subsequent entering into Standby mode.

Some I/Os (listed in Section 11.3.1: General-purpose I/O (GPIO)) are used for JTAG/SW debug and have internal pull-up or pull-down activated after reset so is configured at this reset value as well when exiting Standby mode.

For IO’s, with a pull-up or pull-down pre-defined after reset (some JTAG/SW IO’s) or with GPIOx_PUPDR programming done after exiting from Standby, in case those programming is different from the PWR_PUCRx or PWR_PDCRx programmed value during Standby, both a pull-down and pull-up are applied until the bit APC is cleared, releasing the PWR_PUCRx or PWR_PDCRx programmed value.

</tbody>
</table>
8.4.11 Shutdown mode

The Shutdown mode allows to achieve the lowest power consumption. It is based on the Deepsleep mode, with the voltage regulator disabled. The VCore domain is consequently powered off. The PLL, the HSI16, the MSI, the LSI and the HSE oscillators are also switched off.

SRAM1, SRAM2 and register contents are lost except for registers in the Backup domain. The BOR is not available in Shutdown mode. No power voltage monitoring is possible in this mode, therefore the switch to Backup domain is not supported.

I/O states in Shutdown mode

In the Shutdown mode, all I/Os are by default in floating state. If the APC bit of PWR_CR3 register has been set, the I/Os can be configured either with a pull-up (refer to PWR_PUCRx registers (x=A,B,C,D,E,F,G,H), or with a pull-down (refer to PWR_PDCRx registers (x=A,B,C,D,E,F,G,H), or can be kept in analog state if none of the PWR_PUCRx or PWR_PDCRx register has been set. The pull-down configuration has highest priority over pull-up configuration in case both PWR_PUCRx and PWR_PDCRx are set for the same IO. However this configuration is lost when exiting the Shutdown mode due to the power-on reset.

Some I/Os (listed in Section 11.3.1: General-purpose I/O (GPIO)) are used for JTAG/SW debug and can only be configured to their respective reset pull-up or pull-down state during Standby mode setting their respective bit in the PWR_PUCRx or PWR_PDCRx registers to ‘1’, or to be configured to floating state if the bit is kept at ‘0’.

The RTC outputs on PC13 are functional in Shutdown mode. PC14 and PC15 used for LSE are also functional. Five wakeup pins (WKUPx, x=1,2...5) and the three RTC tampers are available.

Entering Shutdown mode

The Shutdown mode is entered according Entering into a low-power mode, when the SLEEPDEEP bit in the Cortex®-M33 System Control register is set.

Refer to Table 73: Shutdown mode for details on how to enter Shutdown mode.

In Shutdown mode, the following features can be selected by programming individual control bits:

- Real-time clock (RTC): this is configured by the RTCEN bit in the Backup domain control register (RCC_BDCR). Caution: in case of VDD power-down the RTC content is lost.
- External 32.768 kHz oscillator (LSE): this is configured by the LSEON bit in the Backup domain control register (RCC_BDCR).

Exiting Shutdown mode

The Shutdown mode is exit according Section : Exiting from a low-power mode. A power-on reset occurs when exiting from Shutdown mode. All registers (except for the ones in the Backup domain) are reset after wakeup from Shutdown.

Refer to Table 73: Shutdown mode for more details on how to exit Shutdown mode.

When exiting Shutdown mode, I/Os that were configured with pull-up or pull-down during Shutdown through registers PWR_PUCRx or PWR_PDCRx lose their configuration and are
configured in floating state or to their pull-up pull-down reset value (for some I/Os listed in Section 11.3.1: General-purpose I/O (GPIO)).

8.4.12 Auto-wakeup from a low-power mode

The RTC can be used to wakeup the MCU from a low-power mode without depending on an external interrupt (Auto-wakeup mode). The RTC provides a programmable time base for waking up from Stop (0, 1 or 2) or Standby mode at regular intervals. For this purpose, two of the three alternative RTC clock sources can be selected by programming the RTCSEL[1:0] bits in the RCC Backup domain control register (RCC_BDCR):

- Low-power 32.768 kHz external crystal oscillator (LSE OSC)
  This clock source provides a precise time base with very low-power consumption.
- Low-power internal RC Oscillator (LSI)
  This clock source has the advantage of saving the cost of the 32.768 kHz crystal. This internal RC Oscillator is designed to add minimum power consumption.

To wakeup from Stop mode with an RTC event (alarm, wake-up timer, timestamp), it is necessary to:

- Configure the EXTI Line 17 for non-secure interrupt and EXTI Line 18 for secure interrupts to be sensitive to rising edge
- Configure the RTC to generate the RTC event (alarm, wake-up timer, timestamp)

To wakeup from Standby mode, there is no need to configure the EXTI Line 17 or EXTI Line 18.

8.5 PWR TrustZone security

When the TrustZone security is activated by the TZEN option bit in the FLASH_OPTR register, some PWR register fields can be secured against non-secure access.
The PWR TrustZone security allows to secure the following features through the security configuration register PWR_SECCFGR:

- Low-power mode
- Wake-up (WKUP) pins
- Voltage detection and monitoring
- VBAT mode

Other PWR configuration bits are secure when:

- The system clock selection is secure in RCC, the voltage scaling (VOS) configuration is secure
- A GPIO is configured as secure, its corresponding bit for Pull-up/Pull-down configuration in Standby mode is secure
- The RTC is secure, the backup domain write protection DBP bit in PWR_CR1 register is secure.
- The UCPD is secure, the UCPD_DBDIS and UCPD_STDBY bits are secure in the PWR_CR3 register.

Table 74 gives a summary of the PWR secured bits following the security configuration bit in the PWR_SECCFGR register. When one security configuration bit is set, some configuration bits are secured. The PWR registers may contain secure and non-secure bits:

- Secured bits: read and write operations are only allowed by a secure access. Non-secure read or write accesses are RAZ/WI. There is no illegal access event generated.
- Non-secure bits: no restriction. Read and write operations are allowed by both secure and non-secure accesses.

A non-secure write access to PWR_SECCFGR register is WI and generates an illegal access event. An illegal access interrupt is generated if the PWR illegal access interrupt is enabled in the TZIC_IER2 register. There is no restriction for non-secure read access.

When the TrustZone security is disabled (TZEN = 0 in FLASH_OPTR register), all registers are non-secure. The PWR_SECCFGR secure register and security status registers are RAZ/WI.

</tr>
</tbody>
</table>
### 8.5.1 PWR Privileged and Unprivileged modes

The PWR registers can be read and written by privileged and unprivileged accesses depending on PRIV bit in PWR_PRIVCFGR register.

- When the PRIV bit is reset, all PWR registers could be read and written by both privileged or unprivileged access.
- When the PRIV bit is set, all PWR registers could be read and written by privileged access only (except PWR_SR1, PWR_SR2 and PWR_SECCFGFR registers). Unprivileged access to a privileged registers is RAZ/WI.

### 8.6 PWR registers

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

2. Illegal access event is generated only when the PWR_PRIVCFGR is secure.
8.6.1 Power control register 1 (PWR_CR1)

When the system is secure (TZEN = 1), some register fields are protected against non-secure access depending on PWR_SECCFGR and RCC_SECCFGR configuration registers. A non-secure read/write access on secured bits is RAZ/WI.

When the system is not secure (TZEN=0), there is no access restriction.

This register is protected against non-privileged access when PRIV=1 in the PWR_PRIVCFGR register.

This register is reset after wakeup from Standby mode.

Address offset: 0x00
Reset value: 0x0000 0400

</tr>
</tbody>
</table>

Note: Stop 2 mode cannot be entered when LPR bit is set. Stop 1 is entered instead.

Note: In Standby mode, SRAM2 can be preserved or not, depending on RRS bit configuration in PWR_CR3.
### 8.6.2 Power control register 2 (PWR_CR2)

When the system is secure (TZEN = 1), this register is protected against non-secure access when VDMSEC=1 in the PWR_SECCFG register. A non-secure read/write access is RAZ/WI and generates illegal access event.

When the system is not secure (TZEN=0), there is no access restriction.

This register is protected against non-privileged access when PRIV=1 in the PWR_PRIVCFG register.

Address offset: 0x04
Reset value: 0x0000 0000

This register is reset when exiting the Standby mode.

| Bits 31:11 | Reserved, must be kept at reset value. |

**Bit 10** USV: VDDUSB USB supply valid
This bit is used to validate the VDDUSB supply for electrical and logical isolation purpose.
Setting this bit is mandatory to use the USB peripheral. If VDDUSB is not always present in the application, the PVM can be used to determine whether this supply is ready or not.

- 0: VDDUSB is not present. Logical and electrical isolation is applied to ignore this supply.
- 1: VDDUSB is valid.

**Bit 9** IOSV: VDDIO2 Independent I/Os supply valid
This bit is used to validate the VDDIO2 supply for electrical and logical isolation purpose.
Setting this bit is mandatory to use PG[15:2]. If VDDIO2 is not always present in the application, the PVM can be used to determine whether this supply is ready or not.

- 0: VDDIO2 is not present. Logical and electrical isolation is applied to ignore this supply.
- 1: VDDIO2 is valid.

**Bit 8** Reserved, must be kept at reset value.

**Bit 7** PVME4: Peripheral voltage monitoring 4 enable: VDDA vs. 1.8 V

- 0: PVM4 (VDDA monitoring vs. 1.8 V threshold) disable.
- 1: PVM4 (VDDA monitoring vs. 1.8 V threshold) enable.

**Bit 6** PVME3: Peripheral voltage monitoring 3 enable: VDDA vs. 1.62V

- 0: PVM3 (VDDA monitoring vs. 1.62V threshold) disable.
- 1: PVM3 (VDDA monitoring vs. 1.62V threshold) enable.

**Bit 5** PVME2: Peripheral voltage monitoring 2 enable: VDDIO2 vs. 0.9V

- 0: PVM2 (VDDIO2 monitoring vs. 0.9V threshold) disable.
- 1: PVM2 (VDDIO2 monitoring vs. 0.9V threshold) enable.
Bit 4 **PVME1**: Peripheral voltage monitoring 1 enable: \( V_{DDUSB} \) vs. 1.2V
0: PVM1 (\( V_{DDUSB} \) monitoring vs. 1.2V threshold) disable.
1: PVM1 (\( V_{DDUSB} \) monitoring vs. 1.2V threshold) enable.

Bits 3:1 **PLS[2:0]**: Power voltage detector level selection.
These bits select the voltage threshold detected by the power voltage detector:
000: \( V_{PVDO} \) around 2.0 V
001: \( V_{PVDO} \) around 2.2 V
010: \( V_{PVDO} \) around 2.4 V
011: \( V_{PVDO} \) around 2.5 V
100: \( V_{PVDO} \) around 2.6 V
101: \( V_{PVDO} \) around 2.8 V
110: \( V_{PVDO} \) around 2.9 V
111: External input analog voltage \( PVD\_IN \) (compared internally to \( VREFINT \))

*Note: These bits are write-protected when the bit PVDL (PVD Lock) is set in the SYSCFG_CBR register.*
*These bits are reset only by a system reset.*

Bit 0 **PVDE**: Power voltage detector enable
0: Power voltage detector disable.
1: Power voltage detector enable.

*Note: This bit is write-protected when the bit PVDL (PVD Lock) is set in the SYSCFG_CBR register.*
*This bit is reset only by a system reset.*

### 8.6.3 Power control register 3 (PWR_CR3)

When the system is secure (TZEN=1), some register fields are protected against non-secure access depending on PWR_SECCFGR and TZSC_SECCFGR configuration. A non-secure read/write access on secured bits is RAZ/WI.

When the system is not secure (TZEN=0), there is no access restriction.

This register is protected against non-privileged access when PRIV=1 in the PWR_PRIVCFG register.

Access: Additional APB cycles are needed to access this register versus a standard APB access (3 for a write and 2 for a read).

This register is not reset when exiting Standby modes and with the PWRRST bit in the RCC_APB1RSTR1 register.

Address offset: 0x08
Reset value: 0x0000 0000

RM0438 Rev 7 305/2194
Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **UCPD_DBDIS**: USB Type-C and power delivery dead battery disable

After exiting reset, the USB Type-C “dead battery” behavior is enabled, which may have a pull-down effect on CC1 and CC2 pins. It is recommended to disable it in all cases, either to stop this pull-down or to hand over control to the UCPD (which should therefore be initialized before doing the disable).

0: enable USB Type-C dead battery pull-down behavior on UCPDx_CC1 and UCPDx_CC2 pins
1: disable USB Type-C dead battery pull-down behavior on UCPDx_CC1 and UCPDx_CC2 pins

Bit 13 **UCPD_STDBY**: USB Type-C and power delivery Standby mode

When set, this bit allows to memorize the UCPD configuration in Standby mode. This bit must be written to ‘1’ just before entering Standby mode when using UCPD, and it must be written to 0 after exiting the Standby mode and before writing any UCPD registers.

Bit 12 Reserved, must be kept at reset value.

Bit 11 **ULPMEN**: Ultra-low-power mode enable

When this bit is set, the BOR and PVD are in Ultra-low-power mode during Stop 2 and Standby mode in order to further reduce the current consumption.

0: BORL, BORH and PVD operating in Default mode.
1: Enable Ultra-low-power mode for BORL, BORH and PVD during Stop 2 and Standby mode.

In Stop 2 mode, ULPMEN can be set if BORH and PVD are enabled, otherwise there is no power consumption optimization.

Bit 10 **APC**: Apply pull-up and pull-down configuration

When this bit is set, the I/O pull-up and pull-down configurations defined in the PWR_PUCRx and PWR_PDCRx registers are applied. When this bit is cleared, the PWR_PUCRx and PWR_PDCRx registers are not applied to the I/Os, instead the I/Os are in Floating mode during Standby or configured according GPIO controller GPIOx_PUPDR register during Run mode.

Bits 9:8 **RRS[1:0]**: SRAM2 retention in Standby mode

00: SRAM2 is powered off in Standby mode (SRAM2 content is lost).
01: Full SRAM2 is powered by the low-power regulator in Standby mode (Full SRAM2 content is kept).
10: Only the upper 4 Kbytes of SRAM2 are powered by the low-power regulator in Standby mode (upper 4 Kbytes of SRAM2 content 0x2003 F000 - 0x2003 FFFF is kept).
11: Reserved

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **EWUP5**: Enable wakeup pin WKUP5

When this bit is set, the external wakeup pin WKUP5 is enabled and triggers a wakeup from Standby or Shutdown event when a rising or a falling edge occurs. The active edge is configured via the WUPP5 bit in the PWR_CR4 register.

Bit 3 **EWUP4**: Enable wakeup pin WKUP4

When this bit is set, the external wakeup pin WKUP4 is enabled and triggers a wakeup from Standby or Shutdown event when a rising or a falling edge occurs. The active edge is configured via the WUPP4 bit in the PWR_CR4 register.
8.6.4 Power control register 4 (PWR_CR4)

When the system is secure (TZEN =1), some register fields are protected against non-secure access depending on PWR_SECCFGFR configuration. A non-secure read/write access on secured bits is RAZ/WI.

When the system is not secure (TZEN=0), there is no access restriction.

This register is protected against non-privileged access when PRIV=1 in the PWR_PRIVCFGR register.

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

This register is not reset when exiting Standby modes and with the PWRRST bit in the RCC_APB1RSTR1 register.

Bits 31:16  Reserved, must be kept at reset value.

Bit 15 **SMPSHPRDY**: SMPS High-power mode ready
This bit is set when the SMPS step down converter is in High-power mode.

Bit 14 Reserved, must be kept at reset value.

Bit 13 **EXTSMPSRDY**: External SMPS mode ready
This bit is set when the main regulator is ready and can be switched in external SMPS mode. When set, the external SMPS switch can be closed.

Bit 12 **SMPSBYPRDY**: SMPS BYPASS ready
This bit is set when the SMPS step down converter is in Bypass mode. It is cleared when the SMPS exits the Bypass mode when it is switched to High-power or Low-power mode.

Bits 11:9  Reserved, must be kept at reset value.

Bit 8 **SBF**: Standby flag
This bit is set by hardware when the device enters the Standby mode and is cleared by setting the CSBF bit in the PWR_SCR register, or by a power-on reset. It is not cleared by the system reset.
0: The device did not enter the Standby mode
1: The device entered the Standby mode.

Bits 7:5  Reserved, must be kept at reset value.

Bit 4 **WUF5**: Wakeup flag 5
This bit is set when a wakeup event is detected on wakeup pin, WKUP5. It is cleared by writing ‘1’ in the CWUF5 bit of the PWR_SCR register.

Bit 3 **WUF4**: Wakeup flag 4
This bit is set when a wakeup event is detected on wakeup pin, WKUP4. It is cleared by writing ‘1’ in the CWUF4 bit of the PWR_SCR register.

Bit 2 **WUF3**: Wakeup flag 3
This bit is set when a wakeup event is detected on wakeup pin, WKUP3. It is cleared by writing ‘1’ in the CWUF3 bit of the PWR_SCR register.

Bit 1 **WUF2**: Wakeup flag 2
This bit is set when a wakeup event is detected on wakeup pin, WKUP2. It is cleared by writing ‘1’ in the CWUF2 bit of the PWR_SCR register.

Bit 0 **WUF1**: Wakeup flag 1
This bit is set when a wakeup event is detected on wakeup pin, WKUP1. It is cleared by writing ‘1’ in the CWUF1 bit of the PWR_SCR register.
### 8.6.6 Power status register 2 (PWR_SR2)

This register is protected against non-privileged access when PRIV=1 in the PWR_PRIVCFGR register.

This register is partially reset when exiting Standby/Shutdown modes.

Address offset: 0x14

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31:16</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
</table>

**Bit 15 PVMO4**: Peripheral voltage monitoring output: VDDA vs. 1.8 V

0: VDDA voltage is above PVM4 threshold (around 1.8 V).

1: VDDA voltage is below PVM4 threshold (around 1.8 V).

*Note: PVMO4 is cleared when PVM4 is disabled (PVME4 = 0). After enabling PVM4, the PVM4 output is valid after the PVM4 wakeup time.*

**Bit 14 PVMO3**: Peripheral voltage monitoring output: VDDA vs. 1.62 V

0: VDDA voltage is above PVM3 threshold (around 1.62 V).

1: VDDA voltage is below PVM3 threshold (around 1.62 V).

*Note: PVMO3 is cleared when PVM3 is disabled (PVME3 = 0). After enabling PVM3, the PVM3 output is valid after the PVM3 wakeup time.*

**Bit 13 PVMO2**: Peripheral voltage monitoring output: VDDIO2 vs. 0.9 V

0: VDDIO2 voltage is above PVM2 threshold (around 0.9 V).

1: VDDIO2 voltage is below PVM2 threshold (around 0.9 V).

*Note: PVMO2 is cleared when PVM2 is disabled (PVME2 = 0). After enabling PVM2, the PVM2 output is valid after the PVM2 wakeup time.*

**Bit 12 PVMO1**: Peripheral voltage monitoring output: VDDUSB vs. 1.2 V

0: VDDUSB voltage is above PVM1 threshold (around 1.2 V).

1: VDDUSB voltage is below PVM1 threshold (around 1.2 V).

*Note: PVMO1 is cleared when PVM1 is disabled (PVME1 = 0). After enabling PVM1, the PVM1 output is valid after the PVM1 wakeup time.*

**Bit 11 PVDO**: Power voltage detector output

0: VDD is above the selected PVD threshold

1: VDD is below the selected PVD threshold

**Bit 10 VOSF**: Voltage scaling flag

A delay is required for the internal regulator to be ready after the voltage scaling has been changed. VOSF indicates that the regulator reached the voltage level defined with VOS bits of the PWR_CR1 register.

0: The regulator is ready in the selected voltage range

1: The regulator output voltage is changing to the required voltage level
8.6.7 Power status clear register (PWR_SCR)

When the system is secure (TZEN = 1), this register is protected against non-secure access when LPMSEC = 1 in the PWR_SECCFGR register. A non-secure read/write access is RAZ/WI and generates an illegal access event.

When the system is not secure (TZEN = 0), there is no access restriction.

This register is protected against non-privileged access when PRIV = 1 in the PWR_PRIVCFGR register.

Access: 3 additional APB cycles are needed to write this register vs. a standard APB write.
Address offset: 0x18
Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 PU[15:0]: Port A pull-up bit y (y=0..15)

When set, this bit activates the pull-up on PA[y] when APC bit is set in PWR_CR3 register.

If the corresponding PDy bit is also set, the pull-up is not activated and the pull-down is activated instead with highest priority.

8.6.9 Power Port A pull-down control register (PWR_PDCRA)

When the system is secure (TZEN = 1), some register fields are protected against non-secure access depending on GPIO secure bit configuration. A non-secure read/write access on secured bits is RAZ/WI.

When the system is not secure (TZEN = 0), there is no access restriction.

This register is protected against non-privileged access when PRIV=1 in the PWR_PRIVCFGR register.

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).
This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register.
Address offset: 0x24.
Reset value: 0x0000 0000

### 8.6.10 Power Port B pull-up control register (PWR_PUCRB)

When the system is secure (TZEN = 1), some register fields are protected against non-secure access depending on GPIO secure bit configuration. A non-secure read/write access on secured bits is RAZ/WI.

When the system is not secure (TZEN=0), there is no access restriction.

This register is protected against non-privileged access when PRIV=1 in the PWR_PRIVCFGR register.

This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register.

Bits 31:14  Reserved, must be kept at reset value.

Bits 15:0  **PU[15:0]**: Port B pull-up bit \( y = 0 \ldots 15 \)

When set, this bit activates the pull-up on PB\( y \) when APC bit is set in PWR_CR3 register.

The pull-up is not activated if the corresponding PD\( y \) bit is also set.
8.6.11 Power Port B pull-down control register (PWR_PDCRB)

When the system is secure (TZEN = 1), some register fields are protected against non-secure access depending on GPIO secure bit configuration. A non-secure read/write access on secured bits is RAZ/WI.

When the system is not secure (TZEN=0), there is no access restriction.

This register is protected against non-privileged access when PRIV=1 in the PWR_PRIVCFGR register.

This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register.

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).
Address offset: 0x2C.
Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 PD[15:0]: Port B pull-down bit y (y=0..15)
When set, this bit activates the pull-down on PB[y] when APC bit is set in PWR_CR3 register.

8.6.12 Power Port C pull-up control register (PWR_PUCRC)

When the system is secure (TZEN = 1), some register fields are protected against non-secure access depending on GPIO secure bit configuration. A non-secure read/write access on secured bits is RAZ/WI.

When the system is not secure (TZEN=0), there is no access restriction.

This register is protected against non-privileged access when PRIV=1 in the PWR_PRIVCFGR register.

This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register.

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).
Address offset: 0x30.
Reset value: 0x0000 0000
8.6.13 Power Port C pull-down control register (PWR_PDCRC)

When the system is secure (TZEN = 1), some register fields are protected against non-secure access depending on GPIO secure bit configuration. A non-secure read/write access on secured bits is RAZ/WI.

When the system is not secure (TZEN = 0), there is no access restriction.

This register is protected against non-privileged access when PRIV = 1 in the PWR_PRIVCFGR register.

This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register.

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

Address offset: 0x34.

Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

 Bits 15:0 PD[15:0]: Port C pull-down bit y (y=0..15)
When set, this bit activates the pull-down on PC[y] when APC bit is set in PWR_CR3 register.
The pull-up is not activated if the corresponding PDy bit is also set.

8.6.14 Power Port D pull-up control register (PWR_PUCRD)

When the system is secure (TZEN = 1), some register fields are protected against non-secure access depending on GPIO secure bit configuration. A non-secure read/write access on secured bits is RAZ/WI.

When the system is not secure (TZEN = 0), there is no access restriction.
This register is protected against non-privileged access when PRIV=1 in the PWR_PRIVCFGR register.

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register.

Address offset: 0x38.
Reset value: 0x0000 0000

8.6.15 Power Port D pull-down control register (PWR_PDCRD)

When the system is secure (TZEN =1), some register fields are protected against non-secure access depending on GPIO secure bit configuration. A non-secure read/write access on secured bits is RAZ/WI.

When the system is not secure (TZEN=0), there is no access restriction.

This register is protected against non-privileged access when PRIV=1 in the PWR_PRIVCFGR register.

This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register.

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

Address offset: 0x3C.
Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **PU[15:0]**: Port D pull-up bit y (y=0..15)
When set, this bit activates the pull-up on PD[y] when APC bit is set in PWR_CR3 register.
The pull-up is not activated if the corresponding PDy bit is also set.

**8.6.15 Power Port D pull-down control register (PWR_PDCRD)**

When the system is secure (TZEN =1), some register fields are protected against non-secure access depending on GPIO secure bit configuration. A non-secure read/write access on secured bits is RAZ/WI.

When the system is not secure (TZEN=0), there is no access restriction.

This register is protected against non-privileged access when PRIV=1 in the PWR_PRIVCFGR register.

This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register.

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

Address offset: 0x3C.
Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **PD[15:0]**: Port D pull-down bit y (y=0..15)
When set, this bit activates the pull-down on PD[y] when APC bit is set in PWR_CR3 register.
8.6.16  **Power Port E pull-up control register (PWR_PUCRE)**

When the system is secure (TZEN = 1), some register fields are protected against non-secure access depending on GPIO secure bit configuration. A non-secure read/write access on secured bits is RAZ/WI.

When the system is not secure (TZEN=0), there is no access restriction.

This register is protected against non-privileged access when PRIV=1 in the PWR_PRIVCFGR register.

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register.

Address offset: 0x20.
Reset value: 0x0000 0000

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:0  PU[15:0]: Port E pull-up bit y (y=0..15)

  - When set, this bit activates the pull-up on PE[y] when APC bit is set in PWR_CR3 register.
  - The pull-up is not activated if the corresponding PDy bit is also set.

8.6.17  **Power Port E pull-down control register (PWR_PDCRE)**

When the system is secure (TZEN = 1), some register fields are protected against non-secure access depending on GPIO secure bit configuration. A non-secure read/write access on secured bits is RAZ/WI.

When the system is not secure (TZEN=0), there is no access restriction.

This register is protected against non-privileged access when PRIV=1 in the PWR_PRIVCFGR register.

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register.

Address offset: 0x44.
Reset value: 0x0000 0000
Power control (PWR) RM0438

When the system is secure (TZEN =1), some register fields are protected against non-secure access depending on GPIO secure bit configuration. A non-secure read/write access on secured bits is RAZ/WI.

When the system is not secure (TZEN=0), there is no access restriction.

This register is protected against non-privileged access when PRIV=1 in the PWR_PRIVCFGR register.

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register.

Address offset: 0x48.
Reset value: 0x0000 0000

8.6.18 Power Port F pull-up control register (PWR_PUCRF)

When the system is secure (TZEN =1), some register fields are protected against non-secure access depending on GPIO secure bit configuration. A non-secure read/write access on secured bits is RAZ/WI.

When the system is not secure (TZEN=0), there is no access restriction.

This register is protected against non-privileged access when PRIV=1 in the PWR_PRIVCFGR register.

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register.

Address offset: 0x48.
Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 PD[15:0]: Port E pull-down bit y (y=0..15)

When set, this bit activates the pull-down on PE[y] when APC bit is set in PWR_CR3 register.

8.6.19 Power Port F pull-down control register (PWR_PDCRF)

When the system is secure (TZEN =1), some register fields are protected against non-secure access depending on GPIO secure bit configuration. A non-secure read/write access on secured bits is RAZ/WI.

When the system is not secure (TZEN=0), there is no access restriction.

This register is protected against non-privileged access when PRIV=1 in the PWR_PRIVCFGR register.

Address offset: 0x48.
Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 PU[15:0]: Port F pull-up bit y (y=0..15)

When set, this bit activates the pull-up on PF[y] when APC bit is set in PWR_CR3 register.
The pull-up is not activated if the corresponding PFy bit is also set.
Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register.

Address offset: 0x4C.

Reset value: 0x0000 0000

8.6.20 Power Port G pull-up control register (PWR_PUCRG)

When the system is secure (TZEN = 1), some register fields are protected against non-secure access depending on GPIO secure bit configuration. A non-secure read/write access on secured bits is RAZ/WI.

When the system is not secure (TZEN=0), there is no access restriction.

This register is protected against non-privileged access when PRIV=1 in the PWR_PRIVCFGR register.

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register.

Address offset: 0x50.

Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 \( \text{PU}[15:0] \): Port G pull-up bit \( y = 0..15 \)

When set, this bit activates the pull-up on PG\( y \) when APC bit is set in PWR_CR3 register.
8.6.21 Power Port G pull-down control register (PWR_PDCRG)

When the system is secure (TZEN =1), some register fields are protected against non-secure access depending on GPIO secure bit configuration. A non-secure read/write access on secured bits is RAZ/WI.

When the system is not secure (TZEN=0), there is no access restriction.

This register is protected against non-privileged access when PRIV=1 in the PWR_PRIVCFGR register.

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register.

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 PD[15:0]: Port G pull-down bit y (y=0..15)
When set, this bit activates the pull-down on PG[y] when APC bit is set in PWR_CR3 register.

8.6.22 Power Port H pull-up control register (PWR_PUCRH)

When the system is secure (TZEN =1), some register fields are protected against non-secure access depending on GPIO secure bit configuration. A non-secure read/write access on secured bits is RAZ/WI.

When the system is not secure (TZEN=0), there is no access restriction.

This register is protected against non-privileged access when PRIV=1 in the PWR_PRIVCFGR register.

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register.

Address offset: 0x58.
Reset value: 0x0000 0000
8.6.23 Power Port H pull-down control register (PWR_PDCRH)

When the system is secure (TZEN =1), some register fields are protected against non-secure access depending on GPIO secure bit configuration. A non-secure read/write access on secured bits is RAZ/WI.

When the system is not secure (TZEN=0), there is no access restriction.

This register is protected against non-privileged access when PRIV=1 in the PWR_PRIVCFGR register.

Access: Additional APB cycles are needed to access this register vs. a standard APB access (3 for a write and 2 for a read).

This register is not reset when exiting Standby modes and with PWRRST bit in the RCC_APB1RSTR1 register.

Address offset: 0x5C.

Reset value: 0x0000 0000

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:0  PU[15:0]: Port H pull-up bit y (y=0..15)

When set, this bit activates the pull-up on PH[y] when APC bit is set in PWR_CR3 register. The pull-up is not activated if the corresponding PHy bit is also set.

8.6.24 Power secure configuration register (PWR_SECCFGR)

When the system is secure (TZEN =1), this register provides write access security and can be written only when the access is secure. A non-secure write access is WI and generates an illegal access event. There are no read restrictions

When the system is not secure (TZEN=0), this register is RAZ/WI.

This register can be protected against non-privileged access when PRIV=1 in the PWR_PRIVCFGR register.
Power control (PWR)

Address offset: 0x78.
Reset value: 0x0000 0000

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

Bits 31:12  Reserved, must be kept at reset value.

**Bit 11  APCSEC:** APC security
0: APC bit in PWR_CR3 can be read and written by secure or non-secure access.
1: APC bit in PWR_CR3 can be read and written by secure access only

**Bit 10  VBSEC:** Voltage battery security
0: VBRS and VBE bits in PWR_CR4 and DPB bit in PWR_CR1 can be read and written by secure or non-secure access.
1: VBRS and VBE bits in PWR_CR4 and DPB bit in PWR_CR1 can be read and written by secure access only.
Refer to Table 74 for full list of secured bits.

**Bit 9  VDMSEC:** Voltage detection and monitoring security
0: PWR_CR2 and some bit fields in PWR_CR3 and PWR_CR4 registers can be read and written by secure or non-secure access.
1: PWR_CR2 and some bit fields in PWR_CR3 and PWR_CR4 registers can be read and written by secure access only.
Refer to Table 74 for full list of secured bits.

**Bit 8  LPMSEC:** Low-power mode security
0: Low-power mode and WKUPx related bit field in PWR_CR1, PWR_CR3, PWR_CR4 and PWR_SCR can be read and written by secure or non-secure access.
1: Low-power mode and WKUPx related bit field in PWR_CR1, PWR_CR3, PWR_CR4 and PWR_SCR can be read and written by secure access only

*Note: This bit has a priority over WKUPxSEC bit.*

Bits 7:5  Reserved, must be kept at reset value.

**Bit 4  WUP5SEC:** WKUP5 pin security
0: The bits related to the WKUP5 wakeup pin in PWR_CR3 and PWR_CR4 can be read and written by secure or non-secure access.
1: The bits related to the WKUP5 wakeup pin in PWR_CR3 and PWR_CR4 can be read and written by secure access only

**Bit 3  WUP4SEC:** WKUP4 pin security
0: The bits related to the WKUP4 wakeup pin in PWR_CR3 and PWR_CR4 can be read and written by secure or non-secure access.
1: The bits related to the WKUP4 wakeup pin in PWR_CR3 and PWR_CR4 can be read and written by secure access only
Bit 2 **WUP3SEC**: WKUP3 pin security
- 0: The bits related to the WKUP3 wakeup pin in PWR_CR3 and PWR_CR4 can be read and written by secure or non-secure access.
- 1: The bits related to the WKUP3 wakeup pin in PWR_CR3 and PWR_CR4 can be read and written by secure access only

Bit 1 **WUP2SEC**: WKUP2 pin security
- 0: The bits related to the WKUP2 wakeup pin in PWR_CR3 and PWR_CR4 can be read and written by secure or non-secure access.
- 1: The bits related to the WKUP2 wakeup pin in PWR_CR3 and PWR_CR4 can be read and written by secure access only

Bit 0 **WUP1SEC**: WKUP1 pin security
- 0: The bits related to the WKUP1 wakeup pin in PWR_CR3 and PWR_CR4 can be read and written by secure or non-secure access.
- 1: The bits related to the WKUP1 wakeup pin in PWR_CR3 and PWR_CR4 can be read and written by secure access only

### 8.6.25 Power privilege configuration register (PWR_PRIVCFGR)

This register can be read by both privileged and unprivileged access.

When the system is secure (TZEN = 1), this register can be read by secure and non-secure access. It is write-protected against non-secure write access when at least one bit is set in the PWR_SECCFGR register.

Address offset: 0x80.
Reset value: 0x0000 0000

<table>

**Bits 31:1** Reserved, must be kept at reset value.

**Bit 0 PRIV**: Privilege protection

Set and reset by software.

This bit can be read by both privileged or unprivileged access. When set, it can only be cleared by a privileged access.

- 0: All PWR registers can be read and written with privileged or non-privileged access.
- 1: All PWR registers (except PWR_SR1, PWR_SR2 and PWR_SECFCGR registers) can be read and written only with privileged access. An unprivileged access to PWR registers is RAZ/WI.

If the PWR is not secure, the PRIV bit can be written by a secure or non-secure privileged access.

If TrustZone security is enabled (TZEN = 1), if the PWR is secure, the PRIV bit can be written only by a secure privileged access:
- A non-secure write access generates an illegal access event and write is ignored.
- A secure unprivileged write access on PRIV bit is ignored.

**Note:** The table continues with additional registers and their reset values in the document.
Refer to *Section 2.3 on page 87* for the register boundary addresses.
9 Reset and clock control (RCC)

9.1 Reset

There are three types of reset:
- a system reset
- a power reset
- a Backup domain reset

9.1.1 Power reset

A power reset is generated when one of the following events occurs:
- a Brownout reset (BOR)
- when exiting from Standby mode
- when exiting from Shutdown mode

A Brownout reset, including power-on or power-down reset (POR/PDR), sets all registers to their reset values except the ones in the Backup domain.

When exiting Standby mode, all registers in the V\text{CORE} domain are set to their reset value. Registers outside the V\text{CORE} domain (RTC, WKUP, IWDG, and Standby/Shutdown modes control) are not impacted.

When exiting Shutdown mode, a Brownout reset is generated, resetting all registers except those in the Backup domain.

9.1.2 System reset

A system reset sets all registers to their reset values except the reset flags in \textit{RCC control/status register (RCC\_CSR)} and the registers in the Backup domain.

A system reset is generated when one of the following events occurs:
- a low level on the NRST pin (external reset)
- a window watchdog event (WWWDG reset)
- an independent watchdog event (IWDG reset)
- a software reset (SW reset) (see \textit{Software reset})
- a low-power mode security reset (see \textit{Low-power mode security reset})
- an option byte loader reset (see \textit{Option byte loader reset})
- a Brownout reset

The reset source can be identified by checking the reset flags in \textit{RCC control/status register (RCC\_CSR)}.

These sources act on the NRST pin and this pin is always kept low during the delay phase. The reset service routine vector is selected via the Boot option bytes.

The system reset signal provided to the device is output on the NRST pin. The pulse generator guarantees a minimum reset pulse duration of 20 µs for each internal reset source. In case of an external reset, the reset pulse is generated while the NRST pin is asserted low.
In case on an internal reset, the internal pull-up $R_{PU}$ is deactivated in order to save the power consumption through the pull-up resistor.

**Figure 29. Simplified diagram of the reset circuit**

![Simplified diagram of the reset circuit](image)

**Software reset**

The SYSRESETREQ bit in Cortex®-M33 application interrupt and reset control register must be set to force a software reset on the device.

**Low-power mode security reset**

To avoid that critical applications mistakenly enter a low-power mode, two low-power mode security resets are available. If enabled in option bytes, the resets are generated in any of the following conditions:

- **Entering Standby mode**: this type of reset is enabled by resetting nRST_STDBY bit in user option bytes. In this case, whenever a Standby mode entry sequence is successfully executed, the device is reset instead of entering Standby mode.

- **Entering Stop mode**: this type of reset is enabled by resetting nRST_STOP bit in user option bytes. In this case, whenever a Stop mode entry sequence is successfully executed, the device is reset instead of entering Stop mode.

- **Entering Shutdown mode**: this type of reset is enabled by resetting nRST_SHDW bit in user option bytes. In this case, whenever a Shutdown mode entry sequence is successfully executed, the device is reset instead of entering Shutdown mode.

For further information on the user option bytes, refer to [Section 6.4.1: Option bytes description].

**Option byte loader reset**

The option byte loader reset is generated when the OBL_LAUNCH bit (#27) is set in the FLASH_CR register. This bit is used to launch the option byte loading by software.
9.1.3 Backup domain reset

The Backup domain has two specific resets.

A Backup domain reset is generated when one of the following events occurs:
- a software reset, triggered by setting the BDRST bit in the **RCC Backup domain control register (RCC_BDCR)**
- a V_DD or V_BAT power on, if both supplies have previously been powered off

A Backup domain reset only affects the LSE oscillator, the RTC, the backup registers, the SRAM2 and the RCC_BDCR register.

9.2 RCC pins and internal signals

9.3 Clocks

Four different clock sources can be used to drive the system clock (SYSCLK):
- HSI16 (high-speed internal) 16 MHz RC oscillator clock
- MSI (multispeed internal) RC oscillator clock
- HSE oscillator clock, from 4 to 48 MHz
- PLL clock

The devices have the following additional clock sources:
- 32 kHz low-speed internal RC (LSI RC) that drives the independent watchdog and optionally the RTC used for auto-wakeup from Stop and Standby modes
- 32.768 kHz low-speed external crystal (LSE crystal) that optionally drives the real-time clock (RTCCLOCK)
- RC 48 MHz internal clock sources (HSI48) to potentially drive the USB FS, the SDMMC and the RNG
Each clock source can be switched on or off independently when it is not used, to optimize power consumption.

Several prescalers can be used to configure the AHB frequency, the APB1 and APB2 domains. The maximum frequency of the AHB, APB1 and APB2 domains is 110 MHz.

All the peripheral clocks are derived from their bus clock (HCLK, PCLK1 or PCLK2) except the following ones:

- The 48 MHz clock used for USB FS, SDMMC and RNG, is derived from one of the following sources (selected by software):
  - main PLL VCO (PLL48M1CLK)
  - PLLSAI1 VCO (PLL48M2CLK)
  - MSI clock
  - HSI48 internal oscillator

  When the MSI clock is auto-trimmed with the LSE, it can be used by the USB FS device.

  When available, the HSI48 clock can be coupled to the clock recovery system (CRS) allowing adequate clock connection for the USB FS (crystal less solution).

- The ADCs clock is derived from one of the following sources (selected by software):
  - system clock (SYSCLK)
  - PLLSAI1 VCO (PLLADC1CLK)

- The U(S)ARTs clocks are derived from one of the following sources (selected by software):
  - system clock (SYSCLK)
  - HSI16 clock
  - LSE clock
  - APB1 or APB2 clock (PCLK1 or PCLK2, depending on which APB is mapped to the U(S)ART)

  The wakeup from Stop mode is supported only when the clock is HSI16 or LSE.

- The I2Cs clocks are derived from one of the following sources (selected by software):
  - system clock (SYSCLK)
  - HSI16 clock
  - APB1 clock (PCLK1)

  The wakeup from Stop mode is supported only when the clock is HSI16.

- The SAI1 and SAI2 clocks are derived from one of the following sources (selected by software):
  - an external clock mapped on SAI1_EXTCLK for SAI1 and SAI2_EXTCLK for SAI2
  - PLLSAI1 VCO (PLLSAI1CLK)
  - PLLSAI2 VCO (PLLSAI2CLK)
  - main PLL VCO (PLLSAI3CLK)
  - HSI16 clock

- The DFSDM audio clock which is derived from one of the following sources (selected by software):
  - SAI1 clock
  - HSI clock
The OCTOSPI kernel clock is derived from one of the following sources (selected by software):
- system clock
- PLL48M1CLK
- MSI clock

The FDCAN kernel clock is derived from one of the following sources (selected by software):
- PLL48M1CLK
- PLLSAI1CLK
- HSE clock

The low-power timers (LPTIMx) clocks are derived from one of the following sources (selected by software):
- LSI clock
- LSE clock
- HSI16 clock
- APB1 clock (PCLK1)
- external clock mapped on LPTIMx_IN1

The functionality in Stop mode (including wakeup) is supported only when the clock is LSI or LSE, or in external clock mode.

The RTC clock is derived from one of the following sources (selected by software):
- LSE clock
- LSI clock
- HSE clock divided by 32

The functionality in Stop mode (including wakeup) is supported only when the clock is LSI or LSE.

The IWDG clock which is always the LSI 32 kHz clock.

The UCPD kernel clock is derived from HSI16 clock. The HSI16 RC oscillator must be enabled prior enabling the UCPD.

The RCC feeds the Cortex® System Timer (SysTick) external clock with the AHB clock (HCLK) divided by 8. The SysTick can work either with this clock or directly with the Cortex® clock (HCLK), configurable in the SysTick control and status register.

FCLK acts as Cortex®-M33 free-running clock.
1. For full details about the internal and external clock source characteristics, refer to the Electrical characteristics section in the datasheet.

2. The ADC clock can be derived from the AHB clock of the ADC bus interface, divided by a programmable factor (1, 2 or 4). When the programmable factor is '1', the AHB prescaler must be equal to '1'.
9.3.1 HSE clock

The high-speed external clock signal (HSE) can be generated from two possible clock sources:

- HSE external crystal/ceramic resonator
- HSE user external clock

The resonator and the load capacitors have to be placed as close as possible to the oscillator pins in order to minimize output distortion and startup stabilization time. The loading capacitance values must be adjusted according to the selected oscillator.

Figure 31. HSE/ LSE clock sources

<table>

<tr>
<td>Crystal/Ceramic resonators</td>
<td><img src="image" alt="Diagram of crystal/ceramic resonators" /></td>
</tr>
</tbody>
</table>
External crystal/ceramic resonator (HSE crystal)

The 4 to 48 MHz external oscillator has the advantage of producing a very accurate rate on the main clock.

The associated hardware configuration is shown in Figure 31. Refer to the electrical characteristics section of the datasheet for more details.

The HSERDY flag in the RCC clock control register (RCC_CR) indicates if the HSE oscillator is stable or not. At startup, the clock is not released until this bit is set by hardware. An interrupt can be generated if enabled in the RCC clock interrupt enable register (RCC_CIER).

The HSE crystal can be switched on and off using the HSEON bit in the RCC clock control register (RCC_CR).

External source (HSE bypass)

In this mode, an external clock source must be provided. It can have a frequency of up to 48 MHz. This mode is selected by setting the HSEBYP and HSEON bits in the RCC clock control register (RCC_CR). The external clock signal (square, sinus or triangle) with ~40-60 % duty cycle depending on the frequency (refer to the datasheet) must drive the OSC_IN pin while the OSC_OUT pin can be used a GPIO (see Figure 31).

9.3.2 HSI16 clock

The HSI16 clock signal is generated from an internal 16 MHz RC oscillator.

The HSI16 RC oscillator has the advantage of providing a clock source at low cost (no external components). It also has a faster startup time than the HSE crystal oscillator. However, even with calibration, the frequency is less accurate than an external crystal oscillator or ceramic resonator.

The HSI16 clock can be selected as system clock after wakeup from Stop modes (Stop 0, Stop 1 or Stop 2). Refer to Section 9.4: Low-power modes. It can also be used as a backup clock source (auxiliary clock) if the HSE crystal oscillator fails. Refer to Section 9.3.11: Clock security system (CSS).

Calibration

The RC oscillator frequencies may vary from one chip to another due to manufacturing process variations, this is why each device is factory calibrated by ST for 1 % accuracy at TA = 25°C.

After reset, the factory calibration value is loaded in the HSICAL[7:0] bits in the RCC internal clock sources calibration register (RCC_ICSCR).

If the application is subject to voltage or temperature variations this may affect the RC oscillator speed. The HSI16 frequency can be trimmed in the application using the HSITRIM[6:0] in the RCC internal clock sources calibration register (RCC_ICSCR).

For more details on how to measure the HSI16 frequency variation, refer to Section 9.3.18: Internal/external clock measurement with TIM15/TIM16/TIM17.

The HSIRDY flag in the RCC clock control register (RCC_CR) indicates if the HSI16 RC is stable or not. At startup, the HSI16 RC output clock is not released until this bit is set by hardware.
The HSI16 RC can be switched on and off using the HSION bit in the RCC clock control register (RCC_CR).

The HSI16 signal can also be used as a backup source (Auxiliary clock) if the HSE crystal oscillator fails. Refer to Section 9.3.11: Clock security system (CSS) on page 339.

### 9.3.3 MSI clock

The MSI clock signal is generated from an internal RC oscillator. Its frequency range can be adjusted by software by using the MSIRANGE[3:0] bits in the RCC clock control register (RCC_CR). Twelve frequency ranges are available: 100 kHz, 200 kHz, 400 kHz, 800 kHz, 1 MHz, 2 MHz, 4 MHz (default value), 8 MHz, 16 MHz, 24 MHz, 32 MHz and 48 MHz.

The MSI clock is used as system clock after restart from Reset, wakeup from Standby and Shutdown low-power modes. After restart from Reset, the MSI frequency is set to its default value 4 MHz. Refer to Section 9.4: Low-power modes.

The MSI clock can be selected as system clock after a wakeup from Stop mode (Stop 0, Stop 1 or Stop 2). Refer to Section 9.4: Low-power modes. It can also be used as a backup clock source (auxiliary clock) if the HSE crystal oscillator fails. Refer to Section 9.3.11: Clock security system (CSS).

The MSI RC oscillator has the advantage of providing a low-cost (no external components) low-power clock source. In addition, when used in PLL-mode with the LSE, it provides a very accurate clock source that can be used by the USB FS device, and feed the main PLL to run the system at the maximum speed 110 MHz.

The MSIRDY flag in the RCC clock control register (RCC_CR) indicates whether the MSI RC is stable or not. At startup, the MSI RC output clock is not released until this bit is set by hardware. The MSI RC can be switched on and off by using the MSION bit in the RCC clock control register (RCC_CR).

#### Hardware auto calibration with LSE (PLL-mode)

When a 32.768 kHz external oscillator is present in the application, it is possible to configure the MSI in a PLL-mode by setting the MSIPLEN bit in the RCC clock control register (RCC_CR). When configured in PLL-mode, the MSI automatically calibrates itself thanks to the LSE. This mode is available for all MSI frequency ranges. At 48 MHz, the MSI in PLL-mode can be used for the USB FS device, saving the need of an external high-speed crystal.

#### Software calibration

The MSI RC oscillator frequency may vary from one chip to another due to manufacturing process variations, this is why each device is factory calibrated by ST for 1 % accuracy at an ambient temperature, $T_A = 25$ °C. After reset, the factory calibration value is loaded in the MSICAL[7:0] bits in the RCC internal clock sources calibration register (RCC_ICSCR). If the application is subject to voltage or temperature variations, this may affect the RC oscillator speed. You can trim the MSI frequency in the application by using the MSITRIM[7:0] bits in the RCC_ICSCR register. For more details on how to measure the MSI frequency variation please refer to Section 9.3.18: Internal/external clock measurement with TIM15/TIM16/TIM17.
9.3.4 HSI48 clock

The HSI48 clock signal is generated from an internal 48 MHz RC oscillator and can be used directly for USB and for random number generator (RNG) as well as SDMMC.

The internal 48 MHz RC oscillator is mainly dedicated to provide a high-precision clock to the USB peripheral by means of a special clock recovery system (CRS) circuitry. The CRS can use the USB SOF signal, the LSE or an external signal to automatically and quickly adjust the oscillator frequency on-fly. It is disabled as soon as the system enters Stop or Standby mode. When the CRS is not used, the HSI48 RC oscillator runs on its default frequency which is subject to manufacturing process variations.

For more details on how to configure and use the CRS peripheral please refer to Section 10: Clock recovery system (CRS).

The HSI48RDY flag in the RCC_CRRCR register indicates whether the HSI48 RC oscillator is stable or not. At startup, the HSI48 RC oscillator output clock is not released until this bit is set by hardware.

The HSI48 can be switched on and off using the HSI48ON bit in the RCC_CRRCR register.

9.3.5 PLL

The device embeds three PLLs: PLL, PLLSAI1 and PLLSAI2. Each PLL provides up to three independent outputs. The internal PLLs can be used to multiply the HSI16, HSE or MSI output clock frequency. The PLLs input frequency must be between 4 and 16 MHz. The selected clock source for each PLL is divided by a dedicated programmable factor PLLM, PLLSAI1M, PLLSAI2M, from 1 to 8 to provide a clock frequency in the requested input range. Refer to Figure 30: Clock tree, RCC PLL configuration register (RCC_PLLCFGR), RCC PLLSAI1 configuration register (RCC_PLLSAI1CFGR) and RCC PLLSAI2 configuration register (RCC_PLLSAI2CFGR).

The PLLs configuration (selection of the input clock and multiplication factor) must be done before enabling the PLL. Once the PLL is enabled, these parameters cannot be changed.

To modify the PLL configuration, proceed as follows:
1. Disable the PLL by clearing PLLON to 0 in RCC clock control register (RCC_CR).
2. Wait until PLLRDY bit is cleared. The PLL is now fully stopped.
3. Change the desired parameter.
4. Enable the PLL again by setting PLLON bit to 1.
5. Enable the desired PLL outputs by configuring PLLPEN, PLLQEN, PLLREN bits in RCC PLL configuration register (RCC_PLLCFGR).

An interrupt can be generated when the PLL is ready, if enabled in the RCC clock interrupt enable register (RCC_CIER).
The same procedure is applied for changing the configuration of PLLSAI1 or PLLSAI2:
1. Disable the PLLSAI1/PLLSAI2 by clearing PLLSAI1ON/PLLSAI2ON to 0 in **RCC clock control register (RCC_CR)**.
2. Wait until PLLSAI1RDY/PLLSAI2RDY bit is cleared. The PLLSAI1/PLLSAI2 is now fully stopped.
3. Change the desired parameter.
4. Enable the PLLSAI1/PLLSAI2 again by setting PLLSAI1ON/PLLSAI2ON bit to 1.
5. Enable the desired PLL outputs by configuring PLLSAI1PEN/PLLSAI2PEN, PLLSAI1QEN, PLLSAI1REN bits in **RCC PLLSAI1 configuration register (RCC_PLLSAI1CFGR)** or **RCC PLLSAI2 configuration register (RCC_PLLSAI2CFGR)**.

The PLL output frequency must not exceed 110 MHz.

The enable bit of each PLL output clock (PLLPEN, PLLQEN, PLLREN, PLLSAI1PEN, PLLSAI1QEN, PLLSAI1REN and PLLSAI2PEN) can be modified at any time without stopping the corresponding PLL.

The PLLREN bit cannot be cleared if PLLCLK is used as system clock.

### 9.3.6 LSE clock

The LSE crystal is a 32.768 kHz low-speed external crystal or ceramic resonator. It has the advantage of providing a low-power but highly accurate clock source to the real-time clock peripheral (RTC) for clock/calendar or other timing functions.

The LSE crystal is switched on and off using the LSEON bit in **RCC Backup domain control register (RCC_BDCR)**. The crystal oscillator driving strength can be changed at runtime using the LSEDRV[1:0] bits in the **RCC Backup domain control register (RCC_BDCR)** to obtain the best compromise between robustness and short start-up time on one side and low-power-consumption on the other side. The LSE drive can be decreased to the lower drive capability (LSEDRV = 00) when the LSE is ON. However, once LSEDRV is selected, the drive capability can not be increased if LSEON = 1.

The LSERDY flag in the **RCC Backup domain control register (RCC_BDCR)** indicates whether the LSE crystal is stable or not. At startup, the LSE crystal output clock signal is not released until this bit is set by hardware. An interrupt can be generated if enabled in the **RCC clock interrupt enable register (RCC_CIER)**.

#### External source (LSE bypass)

In this mode, an external clock source must be provided. It can have a frequency of up to 1 MHz. This mode is selected by setting the LSEBYP and LSEON bits in the **RCC AHB1 peripheral clocks enable in Sleep and Stop modes register (RCC_AHB1SMENR)**. The external clock signal (square, sinus or triangle) with ~50 % duty cycle has to drive the OSC32_IN pin while the OSC32_OUT pin can be used as GPIO. See Figure 31.

### 9.3.7 LSE system clock

The LSE system clock (LSESYS) is generated by RCC to:
- a peripheral when source clock is the LSE as LPTIM, USART, LPUART, TIMER, CRS
- the system in case of one of the LSCOSEL, MCO, MSI PLL mode or CSS on LSE functionality is enabled

By default the LSESYS clock is disabled. To enable the LSESYS clock, proceed as follows:
1. Wait the LSE clock is ready and set the LSEON and LSERDY bits in **RCC Backup domain control register (RCC_BDCR)**.

2. Set the LSESYSEN bit in RCC_BDCR.

3. Wait the LSESYS clock is ready and set the LSESYSRDY bit in RCC_BDCR.

**9.3.8 LSI clock**

The LSI RC acts as a low-power clock source that can be kept running in Stop and Standby mode for the independent watchdog (IWDG) and RTC. The clock frequency is either 32 kHz or 250 Hz depending on the LSIPRE bit in **RCC control/status register (RCC_CSR)**. When using the IWDG, only the 32 kHz LSI clock is selected and forced on. For more details, refer to the electrical characteristics section of the datasheet.

The LSI RC can be switched on and off using the LSION bit in the **RCC control/status register (RCC_CSR)**.

The LSI prescaler clock (LSIPRE bit in RCC_CSR) is only taken into account when the LSION bit is reset.

The LSIRDY flag in the **RCC control/status register (RCC_CSR)** indicates if the LSI oscillator is stable or not. At startup, the clock is not released until this bit is set by hardware. An interrupt can be generated if enabled in the **RCC clock interrupt enable register (RCC_CIER)**.

**9.3.9 System clock (SYSCLK) selection**

Four different clock sources can be used to drive the system clock (SYSCLK):

- MSI oscillator
- HSI16 oscillator
- HSE oscillator
- PLL

The system clock maximum frequency is 110 MHz. After a system reset, the MSI oscillator, at 4 MHz, is selected as system clock. When a clock source is used directly or through the PLL as a system clock, it is not possible to stop it.

A switch from one clock source to another occurs only if the target clock source is ready (clock stable after startup delay or PLL locked). If a clock source that is not yet ready is selected, the switch occurs when the clock source becomes ready. Status bits in the **RCC internal clock sources calibration register (RCC_ICSCR)** indicate which clock(s) is (are) ready and which clock is currently used as a system clock.

Clock source switching conditions:

- Switching from HSE or HSI or MSI to PLL with AHB frequency (HCLK) higher than 80 MHz
- Switching from PLL with HCLK higher than 80 MHz to HSE or HSI or MSI

Transition state:

- Set the AHB prescaler HPRE[3:0] bits in RCC_CFGR to divide the system frequency by 2.
- Switch system clock to PLL.
- Wait for at least 1 µs and then reconfigure AHB prescaler bits to the needed HCLK frequency.
9.3.10 Clock source frequency versus voltage scaling

Table 77 gives the different clock source frequencies depending on the product voltage range.

9.3.11 Clock security system (CSS)

CSS can be activated by software. In this case, the clock detector is enabled after the HSE oscillator startups delay, and disabled when this oscillator is stopped.

If a failure is detected on the HSE clock, the HSE oscillator is automatically disabled, a clock failure event is sent to the break input of the advanced-control timers (TIM1/TIM8 and TIM15/16/17) and an interrupt is generated to inform the software about the failure (clock security system interrupt CSSI), allowing the MCU to perform rescue operations. The CSSI is linked to the Cortex®-M33 NMI (non-maskable interrupt) exception vector.

Note: Once the CSS is enabled and if the HSE clock fails, the CSSI occurs and a NMI is automatically generated. The NMI is executed indefinitely unless the CSS pending bit is cleared. As a consequence, in the NMI ISR, the user must clear the CSSI by setting the CSSC bit in the RCC clock interrupt clear register (RCC_CICR).

If the HSE oscillator is used directly or indirectly as the system clock (indirectly means: it is used as PLL input clock and the PLL clock is used as system clock), a detected failure causes a switch of the system clock to the MSI or the HSI16 oscillator depending on the STOPWUCK configuration in the RCC clock configuration register (RCC_CFGR), and the disabling of the HSE oscillator. If the HSE clock (divided or not) is the clock entry of the PLL used as system clock when the failure occurs, the PLL is disabled too.

9.3.12 Clock security system on LSE

A clock security system on LSE can be activated by software writing the LSECSSON bit in the RCC Backup domain control register (RCC_BDCR). This bit can be disabled only by a hardware reset or RTC software reset, or after a failure detection on LSE. LSECSSON must be written after LSE and LSI are enabled (LSEON and LSION enabled) and ready (LSERDY and LSIRDY set by hardware, LSIPRE disabled), and after the RTC clock has been selected by RTCSEL.

The CSS on LSE is working in all modes except VBAT. It is working also under system reset (excluding power-on reset). If a failure is detected on the external 32 kHz oscillator, the LSE clock is no longer supplied to the RTC but no hardware action is made to the registers. If the MSI was in PLL-mode, this mode is disabled.

The CSS on LSE failure is detected by a tamper event.
In Standby mode a wakeup is generated. In other modes a TAMP interrupt can be sent to wake up the software (see Table 310: TAMP interconnection and Section 42.5: TAMP interrupts).

The software must then disable the LSECSSON bit, stop the defective 32 kHz oscillator (disabling LSEON), and change the RTC clock source (no clock or LSI or HSE, with RTCSEL), or take any required action to secure the application.

The frequency of LSE oscillator have to be higher than 30 kHz to avoid false positive CSS detection.

9.3.13 ADC clock

The ADC clock is derived from the system clock, or from the PLLSAI1 or the PLLSAI2 output. It can reach 110 MHz and can be divided by the following prescalers values: 1,2,4,6,8,10,12,16,32,64,128 or 256 by configuring the ADC1_CCR register. It is asynchronous to the AHB clock.

Alternatively, the ADC clock can be derived from the AHB clock of the ADC bus interface, divided by a programmable factor (1, 2 or 4). This programmable factor is configured using the CKMODE bit fields in the ADC123_CCR register.

If the programmed factor is 1, the AHB prescaler must be set to 1.

9.3.14 RTC clock

The RTCCLK clock source can be either the HSE / 32, LSE or LSI clock. It is selected by programming the RTCSEL[1:0] bits in the RCC Backup domain control register (RCC_BDCR). This selection cannot be modified without resetting the Backup domain. The system must always be configured so as to get a PCLK frequency greater then or equal to the RTCCLK frequency for a proper operation of the RTC.

The LSE clock is in the Backup domain, whereas the HSE and LSI clocks are not.

Consequently:
- If LSE is selected as RTC clock, the RTC continues to work even if the VDD supply is switched off, provided the VBAT supply is maintained.
- If LSI is selected as the RTC clock, the RTC state is not guaranteed if the VDD supply is powered off.
- If the HSE clock divided by a prescaler is used as the RTC clock, the RTC state is not guaranteed if the VDD supply is powered off or if the internal voltage regulator is powered off (removing power from the VCORE domain).

When the RTC clock is LSE or LSI, the RTC remains clocked and functional under system reset.

9.3.15 Timer clock

The timer clock frequencies are automatically defined by hardware.

There are two cases:
- If the APB prescaler equals 1, the timer clock frequencies are set to the APB domain frequency.
- Otherwise, they are set to twice (×2) the APB domain frequency.
9.3.16 Watchdog clock

If the independent watchdog (IWDG) is started by either hardware option or software access, the LSI oscillator is forced on and cannot be disabled. After the LSI oscillator temporization, the LSI 32 kHz clock is provided to the IWDG.

9.3.17 Clock-out capability

- **MCO**
  The microcontroller clock output (MCO) capability allows the clock to be output onto the external MCO pin. One of eight clock signals can be selected as MCO clock.
  - LSI
  - LSE
  - SYSCLK
  - HSI16
  - HSI48
  - HSE
  - PLLCLK
  - MSI
  The selection is controlled by the MCOSSEL[3:0] bits of the RCC clock configuration register (RCC_CFGR). The selected clock can be divided with the MCOPRE[2:0] field of the RCC clock configuration register (RCC_CFGR).

- **LSCO**
  Another output (LSCO) allows one of the low-speed clocks below to be output onto the external LSCO pin:
  - LSI
  - LSE
  This output remains available in Stop (Stop 0, Stop 1 and Stop 2) and Standby modes. The selection is controlled by the LSCOSEL bit and enabled with the LSCOEN in the RCC Backup domain control register (RCC_BDCR).

The MCO clock output requires the corresponding alternate function selected on the MCO pin. The LSCO pin must be left in default POR state.

9.3.18 Internal/external clock measurement with TIM15/TIM16/TIM17

It is possible to indirectly measure the frequency of all on-board clock sources by mean of the TIM15, TIM16 or TIM17 channel 1 input capture, as represented Figure 32, Figure 33 and Figure 34.
The input capture channel of the Timer 15 can be a GPIO line or an internal clock of the MCU. This selection is performed through the TI1_RMP bit in the TIM15_OR register. The possibilities are the following ones:

- TIM15 Channel1 is connected to the GPIO. Refer to the alternate function mapping in the device datasheets.
- TIM15 Channel1 is connected to the LSE.

The input capture channel of the Timer 16 can be a GPIO line or an internal clock of the MCU. This selection is performed through the TI1_RMP[1:0] bits in the TIM16_OR register. The possibilities are the following ones:

- TIM16 Channel1 is connected to the GPIO. Refer to the alternate function mapping in the device datasheets.
- TIM16 Channel1 is connected to the LSI clock.
- TIM16 Channel1 is connected to the LSE clock.
- TIM16 Channel1 is connected to the RTC wakeup interrupt signal. In this case the RTC interrupt should be enabled.
The input capture channel of the Timer 17 can be a GPIO line or an internal clock of the MCU. This selection is performed through the T11_RMP[1:0] bits in the TIM17_OR register. The possibilities are the following ones:

- TIM17 Channel1 is connected to the GPIO. Refer to the alternate function mapping in the device datasheets.
- TIM17 Channel1 is connected to the MSI Clock.
- TIM17 Channel1 is connected to the HSE/32 Clock.
- TIM17 Channel1 is connected to the microcontroller clock output (MCO), this selection is controlled by the MCOSEL[3:0] bits of the RCC_CFGR register.

Calibration of the HSI16 and the MSI

For TIM15 and TIM16, the primary purpose of connecting the LSE to the channel 1 input capture is to be able to precisely measure the HSI16 and MSI system clocks (for this, either HSI16 or MSI must be used as system clock source). The number of HSI16 (MSI, respectively) clock counts between consecutive edges of the LSE signal provides a measure of the internal clock period. Taking advantage of the high precision of LSE crystals (typically a few tens of ppms), it is possible to determine the internal clock frequency with the same resolution, and trim the source to compensate manufacturing, process, temperature and/or voltage related frequency deviations.

The MSI and HSI16 oscillator both have dedicated user-accessible calibration bits for this purpose.

The basic concept consists in providing a relative measurement (such as the HSI16/LSE ratio). The precision is therefore closely related to the ratio between the two clock sources. The higher the ratio is, the better the measurement is. If LSE is not available, HSE/32 is the better option in order to reach the most precise calibration possible.

It is however not possible to have a good enough resolution when the MSI clock is low (typically below 1 MHz). In this case, the following steps are needed:

1. Accumulate the results of several captures in a row.
2. Use the timer input capture prescaler (up to 1 capture every 8 periods).
3. Use the RTC wakeup interrupt signal (when the RTC is clocked by the LSE) as the input for the channel1 input capture. This improves the measurement precision. For this purpose the RTC wakeup interrupt must be enabled.
Calibration of the LSI

The calibration of the LSI follows the same pattern that for the HSI16, but changing the reference clock. It is necessary to connect LSI clock to the channel 1 input capture of the TIM16. Then defining the HSE as system clock source, the number of its clock counts between consecutive edges of the LSI signal provides a measure of the internal low-speed clock period.

The basic concept consists in providing a relative measurement (such as the HSE/LSI ratio). The precision is therefore closely related to the ratio between the two clock sources. The higher the ratio is, the better the measurement is.

9.3.19 Peripheral clock enable registers (RCC_AHBxENR, RCC_APBxENRx)

Each peripheral clock can be enabled by the corresponding EN bit in the RCC_AHBxENR and RCC_APBxENRx registers.

When the peripheral clock is not active, read or write accesses to the peripheral registers are not supported.

The enable bit has a synchronization mechanism to create a glitch-free clock for the peripheral. After the enable bit is set, there is a 2-clock-cycles delay before the clock is active.

Caution: Just after enabling the clock for a peripheral, the software must wait for a delay before accessing the peripheral registers.

9.4 Low-power modes

- AHB and APB peripheral clocks, including DMA clock, can be disabled by software.
- Sleep and Low-power sleep modes stop the CPU clock. The memory interface clocks (Flash memory, SRAM1 and SRAM2 interfaces) can be stopped by software during Sleep mode. The AHB to APB bridge clocks are disabled by hardware during Sleep mode when all the clocks of the peripherals connected to them are disabled.
- Stop modes (Stop 0, Stop 1 and Stop 2) stop all the clocks in the V_CORE domain and disable the three PLL, HSI16, MSI and HSE oscillators.
  All U(S)ARTs, LPUARTs and I2Cs have the capability to enable the HSI16 oscillator even when the MCU is in Stop mode (if HSI16 is selected as the clock source for that peripheral).
  All U(S)ARTs and LPUARTs can also be driven by the LSE oscillator when the system is in Stop mode (if LSE is selected as clock source for that peripheral) and the LSE oscillator is enabled (LSEON). In that case the LSE remains always ON in Stop mode (no capability to turn on the LSE oscillator).
- Standby and Shutdown modes stop all the clocks in the V_CORE domain and disable the PLLs, HSI16, MSI and HSE oscillators.

The CPU’s deepsleep mode can be overridden for debugging by setting the DBG_STOP or DBG_STANDBY bits in the DBGMCU_CR register.

When exiting Stop modes (Stop 0, Stop 1 or Stop 2), the system clock is either MSI or HSI16, depending on the software configuration of the STOPWUCK bit in the RCC_CFGR register. The frequency (range and user trim) of the MSI oscillator is the one configured
before entering Stop mode. The user trim of HSI16 is kept. If the MSI was in PLL-mode before entering Stop mode, the PLL-mode stabilization time must be waited for after wakeup even if the LSE was kept ON during the Stop mode.

When leaving the Standby and Shutdown modes, the system clock is MSI. The MSI frequency at wakeup from Standby mode is configured with the MSISRANGE is the RCC_CSR register, from 1 to 8 MHz. The MSI frequency at wakeup from Shutdown mode is 4 MHz. The user trim is lost.

If a Flash memory programming operation is on going, Stop, Standby and Shutdown modes entry is delayed until the Flash memory interface access is finished. If an access to the APB domain is ongoing, Stop, Standby and Shutdown modes entry is delayed until the APB access is finished.

### 9.5 RCC TrustZone® security

When the TrustZone security is activated by the TZEN option bit in the FLASH_OPTR register, the RCC is able to secure RCC configuration and status bits from being modified by non-secure accesses.

This is configured through the security configuration register RCC_SECCFGR to prevent non-secure access to read or modify the following features:

- HSE, HSE-CSS, HSI, MSI, LSI, LSE, LSE-CSS, HSI48 configuration and status bits
- main PLL, PLLSAI1, PLLSAI2, AHB prescaler configuration and status bits
- system clock SYSCLK and HSI48 source clock selection and status bits
- MCO clock output configuration and STOPWUCK bit
- reset flag RMVF configuration

When a peripheral is configured as secure, its related clock, reset, clock source selection and clock enable during low-power modes control bits are also secure in the RCC_AHBxENR, RCC_APBxENR, RCC_AHBxSMEN, RCC_APBxSMEN, RCC_CCIPR1 and RCC_CCIPR2 registers.

A peripheral is secure when:

- For securable peripherals by TZSC (TrustZone security controller), the SEC security bit corresponding to this peripheral is set in the TZSC_SECCFGRx register.
- For TrustZone-aware peripherals, a security feature of this peripheral is enabled through its dedicated bits.

Table 78 gives a summary of the RCC secured bits following the security configuration bit in the RCC_SECCFGR register.

When one security configuration bit is set, some configuration and status bits are secured. The RCC registers may contain secure and non-secure bits:

- Secured bits: read and write operations are only allowed by a secure access. Non-secure read or write accesses are RAZ/WI. There is no illegal access event generated.
- Non-secure bits: no restriction. Read and write operations are allowed by both secure and non-secure accesses.
- A non-secure read/write access to RCC_SECCFGR register is RAZ/WI and generates an illegal access event. An illegal access interrupt is generated if the RCC illegal access interrupt is enabled in the TZIC_IER2 register.
When the TrustZone security is disabled (TZEN = 0 in FLASH_OPTR register), all registers are non-secure. The RCC_SECCFGR secure register and security status registers are RAZ/WI.

</tbody>
</table>
9.6 RCC Privileged and Unprivileged mode

By default, after reset, all RCC registers can be read or written in both Privileged and Unprivileged modes except RCC privilege bit (PRIV bit in RCC_CR) that can be written in Privilege mode only.

When the PRIV bit is set in RCC_CR register:
- Writing the RCC registers is possible only in privileged mode.
- All RCC registers can be read only in privileged mode except RCC security status registers (RCC_AHBxSECSR, RCC_APBx_SECSR, RCC_SECSR) and PRIV bit in RCC_CR register.
- An unprivileged access to a privileged RCC register is discarded. RAZ/WI.

9.7 RCC interrupts

The RCC provides three interrupt lines:
- `rcc_it`: general interrupt line providing events when the PLLs are ready or when the oscillators are ready
- `rcc_hsecss_it`: interrupt line dedicated to the failure detection of the HSE CSS (clock security system)
- `rcc_lsecss_it`: interrupt line dedicated to the failure detection of the LSE CSS

The interrupt enable is controlled via `RCC clock interrupt enable register (RCC_CIER)`, except for the HSE CSS failure. When the HSE CSS feature is enabled, it is not possible to mask the interrupt generation.

The interrupt flags can be checked via `RCC clock interrupt flag register (RCC_CIFR)`, and those flags can be cleared via `RCC clock interrupt clear register (RCC_CICR)`.

Note: The interrupt flags are not relevant if the corresponding interrupt enable bit is not set.

Table 79 gives a summary of the interrupt sources and the way to control them.

Bit 26 **PLLSAI1ON**: SAI1 PLL enable
Set and cleared by software to enable PLLSAI1.
Cleared by hardware when entering Stop, Standby or Shutdown mode.
0: PLLSAI1 OFF
1: PLLSAI1 ON

Bit 25 **PLLRDY**: main PLL clock ready flag
Set by hardware to indicate that the main PLL is locked.
0: PLL unlocked
1: PLL locked

Bit 24 **PLLON**: main PLL enable
Set and cleared by software to enable the main PLL.
Cleared by hardware when entering Stop, Standby or Shutdown mode. This bit cannot be reset if the PLL clock is used as the system clock.
0: PLL OFF
1: PLL ON

Bits 23:20 Reserved, must be kept at reset value.

Bit 19 **CSSON**: clock security system enable
Set by software to enable the clock security system. When CSSON is set, the clock detector is enabled by hardware when the HSE oscillator is ready, and disabled by hardware if a HSE clock failure is detected. This bit is set only and is cleared by reset.
0: clock security system OFF (clock detector OFF)
1: clock security system ON (clock detector ON if the HSE oscillator is stable, OFF if not).

Bit 18 **HSEBYP**: HSE crystal oscillator bypass
Set and cleared by software to bypass the oscillator with an external clock. The external clock must be enabled with the HSEON bit set, to be used by the device. The HSEBYP bit can be written only if the HSE oscillator is disabled.
0: HSE crystal oscillator not bypassed
1: HSE crystal oscillator bypassed with external clock

Bit 17 **HSERDY**: HSE clock ready flag
Set by hardware to indicate that the HSE oscillator is stable.
0: HSE oscillator not ready
1: HSE oscillator ready

*Note:* Once the HSEON bit is cleared, HSERDY goes low after 6 HSE clock cycles.

Bit 16 **HSEON**: HSE clock enable
Set and cleared by software.
Cleared by hardware to stop the HSE oscillator when entering Stop, Standby or Shutdown mode. This bit cannot be reset if the HSE oscillator is used directly or indirectly as the system clock.
0: HSE oscillator OFF
1: HSE oscillator ON

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **HSIASFS**: HSI16 automatic start from Stop
Set and cleared by software. When the system wakeup clock is MSI, this bit is used to wakeup the HSI16 is parallel of the system wakeup.
0: HSI16 oscillator is not enabled by hardware when exiting Stop mode with MSI as wakeup clock.
1: HSI16 oscillator is enabled by hardware when exiting Stop mode with MSI as wakeup clock.
Bit 10 **HSIRDY**: HSI16 clock ready flag

Set by hardware to indicate that HSI16 oscillator is stable. This bit is set only when HSI16 is enabled by software by setting HSION.

0: HSI16 oscillator not ready
1: HSI16 oscillator ready

*Note:* Once the HSION bit is cleared, HSIRDY goes low after 6 HSI16 clock cycles.

Bit 9 **HSIKERON**: HSI16 always enable for peripheral kernels.

Set and cleared by software to force HSI16 ON even in Stop modes. The HSI16 can only feed USARTs and I²Cs peripherals configured with HSI16 as kernel clock. Keeping the HSI16 ON in Stop mode allows to avoid slowing down the communication speed because of the HSI16 startup time. This bit has no effect on HSION value.

0: No effect on HSI16 oscillator.
1: HSI16 oscillator is forced ON even in Stop mode.

Bit 8 **HSION**: HSI16 clock enable

Set and cleared by software.

Cleared by hardware to stop the HSI16 oscillator when entering Stop, Standby or Shutdown mode.

Set by hardware to force the HSI16 oscillator ON when STOPWUCK=1 or HSIASFS = 1 when leaving Stop modes, or in case of failure of the HSE crystal oscillator.

This bit is set by hardware if the HSI16 is used directly or indirectly as system clock.

0: HSI16 oscillator OFF
1: HSI16 oscillator ON

Bits 7:4 **MSIRANGE[3:0]**: MSI clock ranges

These bits are configured by software to choose the frequency range of MSI when MSIRGSEL is set. 12 frequency ranges are available:

0000: range 0 around 100 kHz
0001: range 1 around 200 kHz
0010: range 2 around 400 kHz
0011: range 3 around 800 kHz
0100: range 4 around 1M Hz
0101: range 5 around 2 MHz
0110: range 6 around 4 MHz (reset value)
0111: range 7 around 8 MHz
1000: range 8 around 16 MHz
1001: range 9 around 24 MHz
1010: range 10 around 32 MHz
1011: range 11 around 48 MHz
others: not allowed (hardware write protection)

*Note:* Warning: MSIRANGE can be modified when MSI is OFF (MSION=0) or when MSI is ready (MSIRDY=1). MSIRANGE must NOT be modified when MSI is ON and NOT ready (MSION=1 and MSIRDY=0)

Bit 3 **MSIRGSEL**: MSI clock range selection

Set by software to select the MSI clock range with MSIRANGE[3:0]. Write 0 has no effect.

After a standby or a reset MSIRGSEL is at 0 and the MSI range value is provided by MSISRANGE in CSR register.

0: MSI Range is provided by MSISRANGE[3:0] in RCC_CSR register
1: MSI Range is provided by MSISRANGE[3:0] in the RCC_CR register
9.8.2 RCC internal clock sources calibration register (RCC_ICSCR)

Address offset: 0x004
Reset value: 0x40XX 00XX
X is factory-programmed.

Access: no wait state, word, half-word and byte access

**Bit 31** Reserved, must be kept at reset value.

**Bits 30:24** HSiTRIM[6:0]: HSI16 clock trimming

These bits provide an additional user-programmable trimming value that is added to the HSICAL[7:0] bits. It can be programmed to adjust to variations in voltage and temperature that influence the frequency of the HSI16.
**9.8.3 RCC clock configuration register (RCC_CFGR)**

Address offset: 0x008

Reset value: 0x0000 0000

Access: 0 ≤ wait state ≤ 2, word, half-word and byte access

1 or 2 wait states are inserted only if the access occurs during clock source switch.

From 0 to 15 wait states are inserted if the access occurs when the APB or AHB prescalers values update is on going.

Bit 31 Reserved, must be kept at reset value.

**Bits 30:28** **MCOPRE[2:0]:** microcontroller clock output prescaler

These bits are set and cleared by software.

It is highly recommended to change this prescaler before MCO output is enabled.

000: MCO divided by 1
001: MCO divided by 2
010: MCO divided by 4
011: MCO divided by 8
100: MCO divided by 16
Others: not allowed

Bits 23:16 **HSICAL[7:0]:** HSI16 clock calibration

These bits are initialized at startup with the factory-programmed HSI16 calibration trim value. When HSITRIM is written, HSICAL is updated with the sum of HSITRIM and the factory trim value.

Bits 15:8 **MSITRIM[7:0]:** MSI clock trimming

These bits provide an additional user-programmable trimming value that is added to the MSICAL[7:0] bits. It can be programmed to adjust to variations in voltage and temperature that influence the frequency of the MSI.

Bits 7:0 **MSICAL[7:0]:** MSI clock calibration

These bits are initialized at startup with the factory-programmed MSI calibration trim value. When MSITRIM is written, MSICAL is updated with the sum of MSITRIM and the factory trim value.
Bits 27:24 **MCOSEL[3:0]**: microcontroller clock output

- Set and cleared by software.
- 0000: MCO output disabled, no clock on MCO
- 0001: SYSClk system clock selected
- 0010: MSI clock selected
- 0011: HSI16 clock selected
- 0100: HSE clock selected
- 0101: Main PLL clock selected
- 0110: LSI clock selected
- 0111: LSE clock selected
- 1000: Internal HSI48 clock selected
- Others: reserved

*Note:* This clock output may have some truncated cycles at startup or during MCO clock source switching.

Bits 23:16 Reserved, must be kept at reset value.

Bit 15 **STOPWUCK**: wakeup from Stop and CSS backup clock selection

- Set and cleared by software to select the system clock used when exiting Stop mode.
- The selected clock is also used as emergency clock for the clock security system on HSE.
- Warning: STOPWUCK must not be modified when the CSS is enabled by HSECSSON bit in the RCC_CR register and the system clock is HSE (SWS="10") or a switch on HSE is requested (SW="10").
- 0: MSI oscillator selected as wakeup from stop clock and CSS backup clock
- 1: HSI16 oscillator selected as wakeup from stop clock and CSS backup clock

Bit 14 Reserved, must be kept at reset value.

Bits 13:11 **PPRE2[2:0]**: APB high-speed prescaler (APB2)

- Set and cleared by software to control the division factor of the APB2 clock (PCLK2).
- 0xx: HCLK not divided
- 100: HCLK divided by 2
- 101: HCLK divided by 4
- 110: HCLK divided by 8
- 111: HCLK divided by 16

Bits 10:8 **PPRE1[2:0]**: APB low-speed prescaler (APB1)

- Set and cleared by software to control the division factor of the APB1 clock (PCLK1).
- 0xx: HCLK not divided
- 100: HCLK divided by 2
- 101: HCLK divided by 4
- 110: HCLK divided by 8
- 111: HCLK divided by 16
Bits 7:4 **HPRE[3:0]: AHB prescaler**  
Set and cleared by software to control the division factor of the AHB clock.  

**Caution:** Depending on the device voltage range, the software must set correctly these bits to ensure that the system frequency does not exceed the maximum allowed frequency (for more details, refer to Section 8.2.5: *Dynamic voltage scaling management*). After a write operation to these bits and before decreasing the voltage range, this register must be read to be sure that the new value has been taken into account.

0xxx: SYSCLK not divided  
1000: SYSCLK divided by 2  
1001: SYSCLK divided by 4  
1010: SYSCLK divided by 8  
1011: SYSCLK divided by 16  
1100: SYSCLK divided by 64  
1101: SYSCLK divided by 128  
1110: SYSCLK divided by 256  
1111: SYSCLK divided by 512

Bits 3:2 **SWS[1:0]: system clock switch status**  
Set and cleared by hardware to indicate which clock source is used as system clock.  
00: MSI oscillator used as system clock  
01: HSI16 oscillator used as system clock  
10: HSE used as system clock  
11: PLL used as system clock

Bits 1:0 **SW[1:0]: system clock switch**  
Set and cleared by software to select system clock source (SYSCLK).  
Configured by hardware to force MSI oscillator selection when exiting Standby or Shutdown mode. Configured by hardware to force MSI or HSI16 oscillator selection when exiting Stop mode or in case of failure of the HSE oscillator, depending on STOPWUCK value.  
00: MSI selected as system clock  
01: HSI16 selected as system clock  
10: HSE selected as system clock  
11: PLL selected as system clock
9.8.4 RCC PLL configuration register (RCC_PLLCFGR)

Address offset: 0x00C
Reset value: 0x0000 1000
Access: no wait state, word, half-word and byte access

This register is used to configure the PLL clock outputs according to the formulas:

- \( f(\text{VCO clock}) = f(\text{PLL clock input}) \times (\text{PLLN} / \text{PLLM}) \)
- \( f(\text{PLL}_P) = f(\text{VCO clock}) / \text{PLLP} \)
- \( f(\text{PLL}_Q) = f(\text{VCO clock}) / \text{PLLQ} \)
- \( f(\text{PLL}_R) = f(\text{VCO clock}) / \text{PLLR} \)

Bits 31:27 **PLLPDIV[4:0]**: Main PLL division factor for PLLSAI3CLK
Set and cleared by software to control the SAI1 or SAI2 clock frequency.
PLLSAI3CLK output clock frequency = VCO frequency / PLLPDIV.
00000: PLLSAI3CLK is controlled by the bit PLLP
00001: Reserved
00010: PLLSAI3CLK = VCO / 2
....
11111: PLLSAI3CLK = VCO / 31

Bits 26:25 **PLLR[1:0]**: Main PLL division factor for PLLCLK (system clock)
Set and cleared by software to control the frequency of the main PLL output clock PLLCLK.
This output can be selected as system clock. These bits can be written only if PLL is disabled.
PLLCLK output clock frequency = VCO frequency / PLLR with PLLR = 2, 4, 6, or 8
00: PLLR = 2
01: PLLR = 4
10: PLLR = 6
11: PLLR = 8

Caution: The software must set these bits correctly not to exceed 110 MHz on this domain.

Bit 24 **PLLEN**: Main PLL PLLCLK output enable
Set and reset by software to enable the PLLCLK output of the main PLL (used as system clock).
This bit cannot be written when PLLCLK output of the PLL is used as system clock.
In order to save power, when the PLLCLK output of the PLL is not used, the value of PLLREN must be 0.
0: PLLCLK output disabled
1: PLLCLK output enabled
Bit 23 Reserved, must be kept at reset value.

Bits 22:21 PLLQ[1:0]: Main PLL division factor for PLL48M1CLK (48 MHz clock)
Set and cleared by software to control the frequency of the main PLL output clock
PLL48M1CLK. This output can be selected for USB, RNG, SDMMC (48 MHz clock). These
bits can be written only if PLL is disabled.
PLL48M1CLK output clock frequency = VCO frequency / PLLQ with PLLQ = 2, 4, 6, or 8
00: PLLQ = 2
01: PLLQ = 4
10: PLLQ = 6
11: PLLQ = 8

Caution: The software must set these bits correctly not to exceed 80 MHz on this
domain.

Bit 20 PLLQEN: Main PLL PLL48M1CLK output enable
Set and reset by software to enable the PLL48M1CLK output of the main PLL.
In order to save power, when the PLL48M1CLK output of the PLL is not used, the value of
PLLQEN must be 0.
0: PLL48M1CLK output disabled
1: PLL48M1CLK output enabled

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 PLLP: Main PLL division factor for PLLSAI3CLK (SAI1 and SAI2 clock)
Set and cleared by software to control the frequency of the main PLL output clock
PLLSAI3CLK. This output can be selected for SAI1 or SAI2. These bits can be written only if
PLL is disabled.
When the PLLPDIV[4:0] is set to 0x0, PLLSAI3CLK output clock frequency = VCO
frequency / PLLP with PLLP =7, or 17.
0: PLLP = 7
1: PLLP = 17

Caution: The software must set these bits correctly not to exceed 80 MHz on this
domain.

Bit 16 PLLPEN: Main PLL PLLSAI3CLK output enable
Set and reset by software to enable the PLLSAI3CLK output of the main PLL.
In order to save power, when the PLLSAI3CLK output of the PLL is not used, the value of
PLLPEN must be 0.
0: PLLSAI3CLK output disabled
1: PLLSAI3CLK output enabled

Bit 15 Reserved, must be kept at reset value.
Bits 14:8  **PLLN[6:0]**: Main PLL multiplication factor for VCO

Set and cleared by software to control the multiplication factor of the VCO. These bits can be written only when the PLL is disabled.

VCO output frequency = VCO input frequency * PLLN with 8 ≤ PLLN ≤ 86

0000000: PLLN = 0 wrong configuration
0000001: PLLN = 1 wrong configuration
...
0000111: PLLN = 7 wrong configuration
0001000: PLLN = 8
0001001: PLLN = 9
...
1111111: PLLN = 127 wrong configuration

**Caution:** The software must set correctly these bits to secure that the VCO output frequency is between 64 and 344 MHz.

Bits 7:4  **PLLM[3:0]**: Division factor for the main PLL input clock

Set and cleared by software to divide the PLL input clock before the VCO. These bits can be written only when all PLLs are disabled.

VCO input frequency = PLL input clock frequency / PLLM with 1 ≤ PLLM ≤ 8

0000: PLLM = 1
0001: PLLM = 2
0010: PLLM = 3
0011: PLLM = 4
0100: PLLM = 5
0101: PLLM = 6
0110: PLLM = 7
0111: PLLM = 8
...
1111: PLLM = 16

**Caution:** The software must set these bits correctly to ensure that the VCO input frequency is between 4 to 16 MHz.

Bits 3:2  Reserved, must be kept at reset value.

Bits 1:0  **PLLSRC[1:0]**: Main PLL entry clock source

Set and cleared by software to select PLL clock source. These bits can be written only when the PLL is disabled.

In order to save power, when no PLL is used, the value of PLLSRC must be 00.

00: No clock sent to PLL
01: MSI clock selected as PLL clock entry
10: HSI16 clock selected as PLL clock entry
11: HSE clock selected as PLL clock entry
9.8.5 RCC PLLSAI1 configuration register (RCC_PLLSAI1CFGR)

Address offset: 0x010
Reset value: 0x0000 1000
Access: no wait state, word, half-word and byte access

This register is used to configure the PLLSAI1 clock outputs according to the formulas:

- \( f(\text{VCOSAI1 clock}) = f(\text{PLL clock input}) \times (\text{PLLSAI1N} / \text{PLL}\text{M}) \)
- \( f(\text{PLLSAI1_P}) = f(\text{VCOSAI1 clock}) / \text{PLLSAI1PDIV} \)
- \( f(\text{PLLSAI1_Q}) = f(\text{VCOSAI1 clock}) / \text{PLLSAI1Q} \)
- \( f(\text{PLLSAI1_R}) = f(\text{VCOSAI1 clock}) / \text{PLLSAI1R} \)

<table>

Bits 31:27 **PLLSAI1PDIV[4:0]**: PLLSAI1 division factor for PLLSAI1CLK
- Set and cleared by software to control the SAI1 or SAI2 clock frequency.
- PLLSAI1CLK output clock frequency = VCOSAI1 frequency / PLLSAI1PDIV.
  - 00000: PLLSAI1CLK controlled by PLLSAI1P bit
  - 00001: reserved
  - 00010: PLLSAI1CLK = VCOSAI1 / 2
  - ...
  - 11111: PLLSAI1CLK = VCOSAI1 / 31

*Note: This bit can be written only when the PLLSAI1 is disabled.*

Bits 26:25 **PLLSAI1R[1:0]**: PLLSAI1 division factor for PLLADC1CLK (ADC clock)
- Set and cleared by software to control the frequency of the PLLSAI1 output clock PLLADC1CLK. This output can be selected as ADC clock.
- These bits can be written only if PLLSAI1 is disabled.
- PLLADC1CLK output clock frequency = VCOSAI1 frequency / PLLSAI1R, with PLLSAI1R = 2, 4, 6, or 8.
  - 00: PLLSAI1R = 2
  - 01: PLLSAI1R = 4
  - 10: PLLSAI1R = 6
  - 11: PLLSAI1R = 8
Bit 24 **PLLSAI1REN**: PLLSAI1 PLLADC1CLK output enable
- Set and reset by software to enable the PLLADC1CLK output of the PLLSAI1 (used as clock for ADC).
- In order to save power, when the PLLADC1CLK output of the PLLSAI1 is not used, the value of PLLSAI1REN must be 0.
0: PLLADC1CLK output disabled
1: PLLADC1CLK output enabled

Bit 23 Reserved, must be kept at reset value.

Bits 22:21 **PLLSAI1Q[1:0]**: PLLSAI1 division factor for PLL48M2CLK (48 MHz clock)
- Set and cleared by software to control the frequency of the PLLSAI1 output clock PLL48M2CLK. This output can be selected for USB, RNG, SDMMC (48 MHz clock). These bits can be written only if PLLSAI1 is disabled.
- PLL48M2CLK output clock frequency = VCOSAI1 frequency / PLLSAI1Q with PLLSAI1Q = 2, 4, 6, or 8
  00: PLLSAI1Q = 2
  01: PLLSAI1Q = 4
  10: PLLSAI1Q = 6
  11: PLLSAI1Q = 8

**Caution:** The software must set these bits correctly not to exceed 110 MHz on this domain.

Bit 20 **PLLSAI1QEN**: PLLSAI1 PLL48M2CLK output enable
- Set and reset by software to enable the PLL48M2CLK output of the PLLSAI1.
- In order to save power, when the PLL48M2CLK output of the PLLSAI1 is not used, the value of PLLSAI1QEN must be 0.
0: PLL48M2CLK output disabled
1: PLL48M2CLK output enabled

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **PLLSAI1P**: PLLSAI1 division factor for PLLSAI1CLK (SAI1 or SAI2 clock).
- Set and cleared by software to control the frequency of the PLLSAI1 output clock PLLSAI1CLK. This output can be selected for SAI1 or SAI2. These bits can be written only if PLLSAI1 is disabled.
- When the PLLSAI1PDI[4:0] is set to 0x0, PLLSAI1CLK output clock frequency = VCOSAI1 frequency / PLLSAI1P with PLLSAI1P = 7, or 17
  0: PLLSAI1P = 7
  1: PLLSAI1P = 17

Bit 16 **PLLSAI1PEN**: PLLSAI1 PLLSAI1CLK output enable
- Set and reset by software to enable the PLLSAI1CLK output of the PLLSAI1.
- In order to save power, when the PLLSAI1CLK output of the PLLSAI1 is not used, the value of PLLSAI1PEN must be 0.
0: PLLSAI1CLK output disabled
1: PLLSAI1CLK output enabled

Bit 15 Reserved, must be kept at reset value.
Bits 14:8  **PLLSAI1N[6:0]**: PLLSAI1 multiplication factor for VCO  
Set and cleared by software to control the multiplication factor of the VCO.  
These bits can be written only when the PLLSAI1 is disabled.  
VCOSAI1 output frequency = VCOSAI1 input frequency x PLLSAI1N, with  
8 ≤ PLLSAI1N ≤ 86.  
0000000: PLLSAI1N = 0 wrong configuration  
0000001: PLLSAI1N = 1 wrong configuration  
...  
0000111: PLLSAI1N = 7 wrong configuration  
0001000: PLLSAI1N = 8  
0001001: PLLSAI1N = 9  
...  
1111111: PLLSAI1N = 127  
**Caution:** The software must set correctly these bits to ensure that the VCO output frequency is between 64 and 344 MHz.

Bits 7:4  **PLLSAI1M[3:0]**: Division factor for PLLSAI1 input clock  
Set and reset by software to divide the PLLSAI1 input clock before the VCO.  
These bits can be written only when PLLSAI1 is disabled.  
VCO input frequency = PLLSAI1 input clock frequency / PLLSAI1M with 1 ≤ PLLSAI1M ≤ 16.  
0000: PLLSAI1M = 1  
0001: PLLSAI1M = 2  
0010: PLLSAI1M = 3  
0011: PLLSAI1M = 4  
0100: PLLSAI1M = 5  
0101: PLLSAI1M = 6  
0110: PLLSAI1M = 7  
0111: PLLSAI1M = 8  
1000: PLLSAI1M = 9  
...  
1111: PLLSAI1M = 16  
**Caution:** The software must set these bits correctly to ensure that the VCO input frequency ranges from 2.66 to 8 MHz.

Bits 3:2  Reserved, must be kept at reset value.

Bits 1:0  **PLLSAI1SRC[1:0]**: Main PLLSAI1 entry clock source  
Set and cleared by software to select PLLSAI1 clock source.  
These bits can be written only when PLLSAI1 is disabled.  
In order to save power, when PLLSAI1 is not used, the value of PLLSAI1 must be 00.  
00: No clock sent to PLLSAI1  
01: MSI clock selected as PLLSAI1 clock entry  
10: HSI16 clock selected as PLLSAI1 clock entry  
11: HSE clock selected as PLLSAI1 clock entry
9.8.6  RCC PLLSAI2 configuration register (RCC_PLLSAI2CFGR)

Address offset: 0x014
Reset value: 0x0000 1000
Access: no wait state, word, half-word and byte access

This register is used to configure the PLLSAI2 clock outputs according to the formulas:

- \( f(\text{VCOSAI2 clock}) = f(\text{PLL clock input}) \times (\text{PLLSAI2N} / \text{PLLM}) \)
- \( f(\text{PLLSAI2}_P) = f(\text{VCOSAI2 clock}) / \text{PLLSAI2P} \)
- \( f(\text{PLLSAI2}_R) = f(\text{VCOSAI2 clock}) / \text{PLLSAI2R} \)

</tbody>
</table>

Bits 31:27  PLLSAI2PDIV[4:0]: PLLSAI2 division factor for PLLSAI2CLK
Set and cleared by software to control the SAI1 or SAI2 clock frequency.
PLLSAI2CLK output clock frequency = VCOSAI2 frequency / PLLSAI2PDIV.
00000: PLLSAI2CLK controlled by the bit PLLSAI2P
00001: reserved
00010: PLLSAI2CLK = VCOSAI2 / 2
....
11111: PLLSAI2CLK = VCOSAI2 / 31

Bits 26:18  Reserved, must be kept at reset value.

Bit 17  PLLSAI2P: PLLSAI2 division factor for PLLSAI2CLK (SAI1 or SAI2 clock).
Set and cleared by software to control the frequency of the PLLSAI2 output clock PLLSAI2CLK. This output can be selected for SAI1 or SAI2.
These bits can be written only if PLLSAI2 is disabled.
When the PLLSAI2PDIV[4:0] is set to 0x0, PLLSAI2CLK output clock frequency = VCOSAI2 frequency / PLLSAI2P with PLLSAI2P =7 or 17.
0: PLLSAI2P = 7
1: PLLSAI2P = 17

Bit 16  PLLSAI2PEN: PLLSAI2 PLLSAI2CLK output enable
Set and reset by software to enable the PLLSAI2CLK output of the PLLSAI2.
In order to save power, when the PLLSAI2CLK output of the PLLSAI2 is not used, the value of PLLSAI2PEN must be 0.
0: PLLSAI2CLK output disabled
1: PLLSAI2CLK output enabled

Bit 15  Reserved, must be kept at reset value.
Bits 14:8 **PLLSAI2N[6:0]**: PLLSAI2 multiplication factor for VCO
Set and cleared by software to control the multiplication factor of the VCO.
These bits can be written only when the PLLSAI2 is disabled.
VCOSAI2 output frequency = VCOSAI2 input frequency × PLLSAI2N, with
8 ≤ PLLSAI2N ≤ 86
0000000: PLLSAI2N = 0 wrong configuration
0000001: PLLSAI2N = 1 wrong configuration
... 0000111: PLLSAI2N = 7 wrong configuration
0001000: PLLSAI2N = 8
0001001: PLLSAI2N = 9
... 1111111: PLLSAI2N = 127 wrong configuration

**Caution:** The software must set correctly these bits to ensure that the VCO output
frequency is between 64 and 344 MHz.

Bits 7:4 **PLLSAI2M[3:0]**: Division factor for PLLSAI2 input clock
Set and reset by software to divide the PLLSAI2 input clock before the VCO.
These bits can be written only when PLLSAI2 is disabled.
VCO input frequency = PLLSAI2 input clock frequency / PLLM with 1 ≤ PLLSAI2N ≤ 16
0000: PLLSAI2M = 1
0001: PLLSAI2M = 2
0010: PLLSAI2M = 3
0011: PLLSAI2M = 4
0100: PLLSAI2M = 5
0101: PLLSAI2M = 6
0110: PLLSAI2M = 7
0111: PLLSAI2M = 8
1000: PLLSAI2M = 9
... 1111: PLLSAI2M = 16

**Caution:** The software must set these bits correctly to ensure that the VCO input
frequency is between 2.66 to 8 MHz.

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 **PLLSAI2SRC[1:0]**: Main PLLSAI2 entry clock source
Set and cleared by software to select PLLSAI2 clock source.
These bits can be written only when PLLSAI2 is disabled.
In order to save power, when PLLSAI2 is not used, the value of PLLSAI2 must be 00.
00: No clock sent to PLLSAI2
01: MSI clock selected as PLLSAI2 clock entry
10: HSI16 clock selected as PLLSAI2 clock entry
11: HSE clock selected as PLLSAI2 clock entry
### 9.8.7 RCC clock interrupt enable register (RCC_CIER)

Address offset: 0x018  
Reset value: 0x0000 0000  
Access: no wait state, word, half-word and byte access

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 15 | 14 | 13 | 12 | 11 | 10 |  9 |  8 |  7 |  6 |  5 |  4 |  3 |  2 |  1 |  0 | HSI48RDYIE | PLLSAI2RDYIE | PLLSAI1RDYIE | PLLRDYIE | HSERDYIE | HSIRDYIE | HSI16RDYIE | PLLRDYIE | MSIRDYIE | LSIRDYIE | LSIRDYIE |

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **HSI48RDYIE**: HSI48 ready interrupt enable  
Set and cleared by software to enable/disable interrupt caused by the internal HSI48 oscillator.  
0: HSI48 ready interrupt disabled  
1: HSI48 ready interrupt enabled

Bit 9 Reserved, must be kept at reset value.

Bit 8 Reserved, must be kept at reset value.

Bit 7 **PLLSAI2RDYIE**: PLLSAI2 ready interrupt enable  
Set and cleared by software to enable/disable interrupt caused by PLLSAI2 lock.  
0: PLLSAI2 lock interrupt disabled  
1: PLLSAI2 lock interrupt enabled

Bit 6 **PLLSAI1RDYIE**: PLLSAI1 ready interrupt enable  
Set and cleared by software to enable/disable interrupt caused by PLLSAI1 lock.  
0: PLLSAI1 lock interrupt disabled  
1: PLLSAI1 lock interrupt enabled

Bit 5 **PLLRDYIE**: PLL ready interrupt enable  
Set and cleared by software to enable/disable interrupt caused by PLL lock.  
0: PLL lock interrupt disabled  
1: PLL lock interrupt enabled

Bit 4 **HSERDYIE**: HSE ready interrupt enable  
Set and cleared by software to enable/disable interrupt caused by the HSE oscillator stabilization.  
0: HSE ready interrupt disabled  
1: HSE ready interrupt enabled

Bit 3 **HSIRDYIE**: HSI16 ready interrupt enable  
Set and cleared by software to enable/disable interrupt caused by the HSI16 oscillator stabilization.  
0: HSI16 ready interrupt disabled  
1: HSI16 ready interrupt enabled
Bit 2 **MSIRDYIE**: MSI ready interrupt enable
Set and cleared by software to enable/disable interrupt caused by the MSI oscillator stabilization.
- 0: MSI ready interrupt disabled
- 1: MSI ready interrupt enabled

Bit 1 **LSERDYIE**: LSE ready interrupt enable
Set and cleared by software to enable/disable interrupt caused by the LSE oscillator stabilization.
- 0: LSE ready interrupt disabled
- 1: LSE ready interrupt enabled

Bit 0 **LSIRDYIE**: LSI ready interrupt enable
Set and cleared by software to enable/disable interrupt caused by the LSI oscillator stabilization.
- 0: LSI ready interrupt disabled
- 1: LSI ready interrupt enabled

### 9.8.8 RCC clock interrupt flag register (RCC_CIFR)
Address offset: 0x01C
Reset value: 0x0000 0000
Access: no wait state, word, half-word and byte access

```

</tr>
</tbody>
</table>
```

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **HSI48RDYF**: HSI48 ready interrupt flag
Set by hardware when the HSI48 clock becomes stable and HSI48RDYIE is set in a response to setting the HSI48ON (refer to **RCC clock recovery RC register (RCC_CRRRCR)**).
Cleared by software setting the HSI48RDYC bit.
- 0: No clock ready interrupt caused by the HSI48 oscillator
- 1: Clock ready interrupt caused by the HSI48 oscillator

Bit 9 Reserved, must be kept at reset value.

Bit 8 **CSSF**: Clock security system interrupt flag
Set by hardware when a failure is detected in the HSE oscillator.
Cleared by software setting the CSSC bit.
- 0: No clock security interrupt caused by HSE clock failure
- 1: Clock security interrupt caused by HSE clock failure
Bit 7 **PLLSAI2RDYF**: PLLSAI2 ready interrupt flag
Set by hardware when the PLLSAI2 locks and PLLSAI2RDYDIE is set.
Cleared by software setting the PLLSAI2RDYC bit.
0: No clock ready interrupt caused by PLLSAI2 lock
1: Clock ready interrupt caused by PLLSAI2 lock

Bit 6 **PLLSAI1RDYF**: PLLSAI1 ready interrupt flag
Set by hardware when the PLLSAI1 locks and PLLSAI1RDYDIE is set.
Cleared by software setting the PLLSAI1RDYC bit.
0: No clock ready interrupt caused by PLLSAI1 lock
1: Clock ready interrupt caused by PLLSAI1 lock

Bit 5 **PLLRDYF**: PLL ready interrupt flag
Set by hardware when the PLL locks and PLLRDYDIE is set.
Cleared by software setting the PLLRDYC bit.
0: No clock ready interrupt caused by PLL lock
1: Clock ready interrupt caused by PLL lock

Bit 4 **HSERDYF**: HSE ready interrupt flag
Set by hardware when the HSE clock becomes stable and HSERDYDIE is set.
Cleared by software setting the HSERDYC bit.
0: No clock ready interrupt caused by the HSE oscillator
1: Clock ready interrupt caused by the HSE oscillator

Bit 3 **HSIRDYF**: HSI16 ready interrupt flag
Set by hardware when the HSI16 clock becomes stable and HSIRDYDIE is set in a response to setting the HSION (refer to **RCC clock control register (RCC_CR)**). When HSION is not set but the HSI16 oscillator is enabled by the peripheral through a clock request, this bit is not set and no interrupt is generated.
Cleared by software setting the HSIRDYC bit.
0: No clock ready interrupt caused by the HSI16 oscillator
1: Clock ready interrupt caused by the HSI16 oscillator

Bit 2 **MSIRDYF**: MSI ready interrupt flag
Set by hardware when the MSI clock becomes stable and MSIRDYDIE is set.
Cleared by software setting the MSIRDYC bit.
0: No clock ready interrupt caused by the MSI oscillator
1: Clock ready interrupt caused by the MSI oscillator

Bit 1 **LSERDYF**: LSE ready interrupt flag
Set by hardware when the LSE clock becomes stable and LSERDYDIE is set.
Cleared by software setting the LSERDYC bit.
0: No clock ready interrupt caused by the LSE oscillator
1: Clock ready interrupt caused by the LSE oscillator

Bit 0 **LSIRDYF**: LSI ready interrupt flag
Set by hardware when the LSI clock becomes stable and LSIRDYDIE is set.
Cleared by software setting the LSIRDYC bit.
0: No clock ready interrupt caused by the LSI oscillator
1: Clock ready interrupt caused by the LSI oscillator
### 9.8.9 RCC clock interrupt clear register (RCC_CICR)

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **ICACHESMEN**: Instruction cache ICACHE clocks enable during Sleep and Stop modes
Set and cleared by software.
0: ICACHE clocks disabled by the clock gating during Sleep and Stop modes
1: ICACHE clocks enabled by the clock gating during Sleep and Stop modes

Bit 22 **GTZCSMEN**: GTZC clocks enable during Sleep and Stop modes
Set and cleared by software
0: GTZC clocks disabled by the clock gating during Sleep and Stop modes
1: GTZC clocks enabled by the clock gating during Sleep and Stop modes

Bits 21:17 Reserved, must be kept at reset value.

Bit 16 **TSCSMEN**: Touch sensing controller clocks enable during Sleep and Stop modes
Set and cleared by software.
0: TSC clocks disabled by the clock gating during Sleep and Stop modes
1: TSC clocks enabled by the clock gating during Sleep and Stop modes

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **CRCSMEN**: CRC clocks enable during Sleep and Stop modes
Set and cleared by software.
0: CRC clocks disabled by the clock gating during Sleep and Stop modes
1: CRC clocks enabled by the clock gating during Sleep and Stop modes

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **SRAM1SMEN**: SRAM1 interface clocks enable during Sleep and Stop modes
Set and cleared by software.
0: SRAM1 interface clocks disabled by the clock gating during Sleep and Stop modes
1: SRAM1 interface clocks enabled by the clock gating during Sleep and Stop modes

Bit 8 **FLASHSMEN**: Flash memory interface clocks enable during Sleep and Stop modes
Set and cleared by software.
0: Flash memory interface clocks disabled by the clock gating during Sleep and Stop modes
1: Flash memory interface clocks enabled by the clock gating during Sleep and Stop modes

Bits 7:3 Reserved, must be kept at reset value.

Bit 2 **DMAMUX1SMEN**: DMAMUX1 clocks enable during Sleep and Stop modes.
Set and cleared by software.
0: DMAMUX1 clocks disabled by the clock gating during Sleep and Stop modes
1: DMAMUX1 clocks enabled by the clock gating during Sleep and Stop modes

Bit 1 **DMA2SMEN**: DMA2 clocks enable during Sleep and Stop modes
Set and cleared by software during Sleep mode.
0: DMA2 clocks disabled by the clock gating during Sleep and Stop modes
1: DMA2 clocks enabled by the clock gating during Sleep and Stop modes

Bit 0 **DMA1SMEN**: DMA1 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: DMA1 clocks disabled by the clock gating during Sleep and Stop modes
1: DMA1 clocks enabled by the clock gating during Sleep and Stop modes
9.8.23 RCC AHB2 peripheral clocks enable in Sleep and Stop modes register (RCC_AHB2SMENR)

Address offset: 0x06C
Reset value: 0x006F 22FF
Access: no wait state, word, half-word and byte access

This register only configures the clock gating, not the clock source itself. Most of the peripherals are clocked by a single clock (AHB or APB clock), which is always disabled in Stop mode. In this case setting the bit has no effect in Stop mode.

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **UCPD1SMEN**: UCPD1 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: UCPD1 clocks disabled by the clock gating during Sleep and Stop modes
1: UCPD1 clocks enabled by the clock gating during Sleep and Stop modes

Bit 22 Reserved, must be kept at reset value.

Bit 21 **USBFSSMEN**: USB FS clocks enable during Sleep and Stop modes
Set and cleared by software.
0: USB FS clocks disabled by the clock gating during Sleep and Stop modes
1: USB FS clocks enabled by the clock gating during Sleep and Stop modes

Bits 20:10 Reserved, must be kept at reset value.

Bit 9 **FDCAN1SMEN**: FDCAN1 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: FDCAN1 clocks disabled by the clock gating during Sleep and Stop modes
1: FDCAN1 clocks enabled by the clock gating during Sleep and Stop modes

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **LPTIM3SMEN**: Low-power timer 3 clocks enable during Sleep and Stop modes
Set and cleared by software.
0: LPTIM3 clocks disabled by the clock gating during Sleep and Stop modes
1: LPTIM3 clocks enabled by the clock gating during Sleep and Stop modes
Bit 5  **LPTIM2SMEN**: Low-power timer 2 clocks enable during Sleep and Stop modes  
Set and cleared by software.  
0: LPTIM2 clocks disabled by the clock gating during Sleep and Stop modes  
1: LPTIM2 clocks enabled by the clock gating during Sleep and Stop modes

Bits 4:2  Reserved, must be kept at reset value.

Bit 1  **I2C4SMEN**: I2C4 clocks enable during Sleep and Stop modes  
Set and cleared by software  
0: I2C4 clocks disabled by the clock gating during Sleep and Stop modes  
1: I2C4 clocks enabled by the clock gating during Sleep and Stop modes

Bit 0  **LPUART1SMEN**: Low-power UART 1 clocks enable during Sleep and Stop modes  
Set and cleared by software.  
0: LPUART1 clocks disabled by the clock gating during Sleep and Stop modes  
1: LPUART1 clocks enabled by the clock gating during Sleep and Stop modes

### 9.8.27 RCC APB2 peripheral clocks enable in Sleep and Stop modes register (RCC_APB2SMENR)

Address: 0x080  
Reset value: 0x0167 7801  
Access: word, half-word and byte access

This register only configures the clock gating, not the clock source itself. Most of the peripherals are clocked by a single clock (AHB or APB clock), which is always disabled in Stop mode. In this case setting the bit has no effect in Stop mode.

Bits 11:10  **LPUART1SEL[1:0]:** Low-power UART1 clock source selection  
These bits are set and cleared by software to select the LPUART1 clock source.  
00: PCLK1 selected  
01: System clock (SYSCLK) selected  
10: HSI16 clock selected  
11: LSE clock selected  

Bits 9:8  **UART5SEL[1:0]:** UART5 clock source selection  
These bits are set and cleared by software to select the UART5 clock source.  
00: PCLK1 selected  
01: System clock (SYSCLK) selected  
10: HSI16 clock selected  
11: LSE clock selected
Bits 7:6  **UART4SEL[1:0]: UART4 clock source selection**
   This bit is set and cleared by software to select the UART4 clock source.
   00: PCLK1 selected
   01: System clock (SYSCLK) selected
   10: HSI16 clock selected
   11: LSE clock selected

Bits 5:4  **USART3SEL[1:0]: USART3 clock source selection**
   This bit is set and cleared by software to select the USART3 clock source.
   00: PCLK1 selected
   01: System clock (SYSCLK) selected
   10: HSI16 clock selected
   11: LSE clock selected

Bits 3:2  **USART2SEL[1:0]: USART2 clock source selection**
   This bit is set and cleared by software to select the USART2 clock source.
   00: PCLK1 selected
   01: System clock (SYSCLK) selected
   10: HSI16 clock selected
   11: LSE clock selected

Bits 1:0  **USART1SEL[1:0]: USART1 clock source selection**
   This bit is set and cleared by software to select the USART1 clock source.
   00: PCLK2 selected
   01: System clock (SYSCLK) selected
   10: HSI16 clock selected
   11: LSE clock selected

### 9.8.29 RCC Backup domain control register (RCC_BDCR)

**Address offset:** 0x0090
**Reset value:** 0x0000 0000

Reset by Backup domain reset except LSCOSEL, LSCOEN and BDRST that are reset only by Backup domain power-on reset.

**Access:** 0 ≤ wait state ≤ 3, word, half-word and byte access

Wait states are inserted in case of successive accesses to this register.

**Note:** The bits of the RCC Backup domain control register (RCC_BDCR) are outside of the V_{CORE} domain. As a result, after reset, these bits are write-protected and the DBP bit in the Power control register 1 (PWR_CR1) must be set before these can be modified. Refer to Section 8.1.4: Battery backup domain for further information. These bits (except LSCOSEL,
**LSCOEN and BDRST** are only reset after a Backup domain reset (see Section 9.1.3: Backup domain reset). Any internal or external reset does not have any effect on these bits.

</table>

Bits 31:26  Reserved, must be kept at reset value.

Bit 25 **LSCOSEL**: Low-speed clock output selection
- Set and cleared by software.
  - 0: LSI clock selected
  - 1: LSE clock selected

Bit 24 **LSCOEN**: Low-speed clock output (LSCO) enable
- Set and cleared by software.
  - 0: LSCO disabled
  - 1: LSCO enabled

Bits 23:17  Reserved, must be kept at reset value.

Bit 16 **BDRST**: Backup domain software reset
- Set and cleared by software.
  - 0: Reset not activated
  - 1: Reset the entire Backup domain and SRAM2

Bit 15 **RTCEN**: RTC clock enable
- Set and cleared by software.
  - 0: RTC clock disabled
  - 1: RTC clock enabled

Bits 14:12  Reserved, must be kept at reset value.

Bit 11 **LSESYSDY**: LSE system clock (LSESYS) ready
- Set and cleared by hardware to indicate when the LSE system clock is stable. When the LSESYSEN bit is set, the LSESYSDY flag is set after two LSE clock cycles.
  - The LSE clock must be already enabled and stable (LSEON and LSERDY are set).
  - When the LSEON bit is cleared, LSERDY goes low after 6 external low-speed oscillator clock cycles.
  - 0: LSESYS clock not ready
  - 1: LSESYS clock ready

Bit 10  Reserved, must be kept at reset value.
Bits 9:8 \textbf{RTCSEL[1:0]}: RTC clock source selection

Set by software to select the clock source for the RTC. Once the RTC clock source has been selected, it cannot be changed anymore unless the Backup domain is reset, or unless a failure is detected on LSE (LSECSSD is set). The BDRST bit can be used to reset them.

- 00: No clock selected
- 01: LSE oscillator clock selected
- 10: LSI oscillator clock selected
- 11: HSE oscillator clock divided by 32 selected

Bit 7 \textbf{LSESYSEN}: LSE system clock (LSESYS) enable

Set by software to enable always the LSE system clock generated by RCC. This clock can be then used by any peripheral when its source clock is the LSE or at system level in case of one of the LSCOSEL, MCO, MSI PLL mode or CSS on LSE is needed.

The LSESYS clock can be generated even if LSESYSEN= 0 if the LSE clock is requested by the CSS on LSE, by a peripheral or any other source clock using LSE.

- 0: LSESYS only enabled when requested by a peripheral or system function
- 1: LSESYS enabled always generated by RCC

Bit 6 \textbf{LSECSSD}: CSS on LSE failure Detection

Set by hardware to indicate when a failure has been detected by the Clock Security System on the external 32 kHz oscillator (LSE).

- 0: No failure detected on LSE (32 kHz oscillator)
- 1: Failure detected on LSE (32 kHz oscillator)

Bit 5 \textbf{LSECSSON}: CSS on LSE enable

Set by software to enable the Clock Security System on LSE (32 kHz oscillator).

LSECSSON must be enabled after the LSE oscillator is enabled (LSEON bit enabled) and ready (LSERDY flag set by hardware), and after the RTCSEL bit is selected.

Once enabled this bit cannot be disabled, except after a LSE failure detection (LSECSSD =1). In that case the software MUST disable the LSECSSON bit.

- 0: CSS on LSE (32 kHz external oscillator) OFF
- 1: CSS on LSE (32 kHz external oscillator) ON

Bits 4:3 \textbf{LSEDRV[1:0]}: LSE oscillator drive capability

Set by software to modulate the LSE oscillator’s drive capability.

- 00: ‘Xtal mode’ lower driving capability
- 01: ‘Xtal mode’ medium low driving capability
- 10: ‘Xtal mode’ medium high driving capability
- 11: ‘Xtal mode’ higher driving capability

The oscillator is in Xtal mode when it is not in bypass mode.
**9.8.30 RCC control/status register (RCC_CSR)**

Address: 0x094
Reset value: 0x0C00 0600
Reset by system reset, except reset flags by power reset only.
Access: 0 ≤ wait state ≤ 3, word, half-word and byte access
Wait states are inserted in case of successive accesses to this register.

```

Bit 2 **LSEBYP**: LSE oscillator bypass
Set and cleared by software to bypass oscillator in debug mode. This bit can be written only when the external 32 kHz oscillator is disabled (LSEON=0 and LSERDY=0).
0: LSE oscillator not bypassed
1: LSE oscillator bypassed

Bit 1 **LSERDY**: LSE oscillator ready
Set and cleared by hardware to indicate when the external 32 kHz oscillator is stable. After the LSEON bit is cleared, LSERDY goes low after 6 external low-speed oscillator clock cycles.
0: LSE oscillator not ready
1: LSE oscillator ready

Bit 0 **LSEON**: LSE oscillator enable
Set and cleared by software.
0: LSE oscillator OFF
1: LSE oscillator ON
Bit 31 **LPWRSTF**: Low-power reset flag
Set by hardware when a reset occurs due to illegal Stop, Standby or Shutdown mode entry.
Cleared by writing to the RMVF bit.
0: No illegal mode reset occurred
1: Illegal mode reset occurred

Bit 30 **WWDGRSTF**: Window watchdog reset flag
Set by hardware when a window watchdog reset occurs.
Cleared by writing to the RMVF bit.
0: No window watchdog reset occurred
1: Window watchdog reset occurred

Bit 29 **IWWDGRSTF**: Independent window watchdog reset flag
Set by hardware when an independent watchdog reset domain occurs.
Cleared by writing to the RMVF bit.
0: No independent watchdog reset occurred
1: Independent watchdog reset occurred

Bit 28 **SFTRSTF**: Software reset flag
Set by hardware when a software reset occurs.
Cleared by writing to the RMVF bit.
0: No software reset occurred
1: Software reset occurred

Bit 27 **BORRSTF**: BOR flag
Set by hardware when a BOR occurs.
Cleared by writing to the RMVF bit.
0: No BOR occurred
1: BOR occurred

Bit 26 **PINRSTF**: Pin reset flag
Set by hardware when a reset from the NRST pin occurs.
Cleared by writing to the RMVF bit.
0: No reset from NRST pin occurred
1: Reset from NRST pin occurred

Bit 25 **OBLRSTF**: Option byte loader reset flag
Set by hardware when a reset from the option byte loading occurs.
Cleared by writing to the RMVF bit.
0: No reset from option byte loading occurred
1: Reset from option byte loading occurred

Bit 24 Reserved, must be kept at reset value.

Bit 23 **RMVF**: Remove reset flag
Set by software to clear the reset flags.
0: No effect
1: Clear the reset flags

Bits 22:12 Reserved, must be kept at reset value.
Bits 11:8 **MSISRANGE[3:0]**: MSI range after Standby mode
Set by software to chose the MSI frequency at startup. This range is used after exiting Standby mode until MSIRGSEL is set. After a pad or a power-on reset, the range is always 4 MHz. MSISRANGE can be written only when MSIRGSEL = 1.
- 0100: Range 4 around 1 MHz
- 0101: Range 5 around 2 MHz
- 0111: Range 6 around 4 MHz (reset value)
- others: reserved
*Note:* Changing the MSISRANGE does not change the current MSI frequency.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **LSIPRE**: LSI frequency prescaler (LSI /128) enable
Set and reset by software.
This bit is used to enable the internal clock prescaler (/128) of the LSI clock. The LSIPRE bit value is only taken into account when LSI is disabled (LSION and LSIRDY bits are reset)
- 0: LSI clock is not divided (LSI)
- 1: LSI clock is divided by 128 (LSI/128).

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **LSIRDY**: LSI oscillator ready
Set and cleared by hardware to indicate when the LSI oscillator is stable. After the LSION bit is cleared, LSIRDY goes low after 3 LSI oscillator clock cycles. This bit can be set even if LSION = 0 if the LSI is requested by the CSS on LSE, by the IWDG or by the RTC.
In case LSIPRE bit is set, the LSIRDY bit is set after 0.5 LSI clock cycle (~2ms) and when LSION bit is reset, LSIRDY bit is reset after 1.5 LSI clock cycles (~6ms).
- 0: LSI oscillator not ready
- 1: LSI oscillator ready

Bit 0 **LSION**: LSI oscillator enable
Set and cleared by software.
- 0: LSI oscillator OFF
- 1: LSI oscillator ON

### 9.8.31 RCC clock recovery RC register (RCC_CRRCCR)
Address: 0x098
Reset value: 0x0000 XXX
X is factory-programmed.

Access: no wait state, word, half-word and byte access

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:20 **OSPISEL[1:0]: OCTOSPI clock source selection**
Set and reset by software. This bit allows to select the OCTOSPI clock source
00: System clock selected
01: MSI clock selected
10: PLL48M1CLK clock selected
11: reserved

Bits 19:15 Reserved, must be kept at reset value.
Bit 14  **SDMCSEL**: SDMMC clock selection
Set and reset by software.
This bit allows to select the SDMMC kernel clock source between PLLP clock (PLLSAI3CLK) or clock from internal multiplexer.
It is recommended to change this bit only after reset and before enabling the SDMMC.
0: 48 MHz clock selected
1: PLLSAI3CLK selected, in case higher than 48 MHz is needed (for SDR50 mode)

Bits 13:11  Reserved, must be kept at reset value.

Bits 10:8  **SAI2SEL[2:0]**: SAI2 clock source selection
Set and reset by software.
If the selected clock is the external clock and this clock is stopped, it is not possible to switch to another clock. The user must switch to another clock before stopping the external clock.
000: PLLSAI1CLK clock selected
001: PLLSAI2CLK clock selected
010: PLLSAI3CLK clock selected
011: External clock SAI2_EXTCLK clock selected
100: HSI clock selected
Others: reserved

Bits 7:5  **SAI1SEL[2:0]**: SAI1 clock source selection
Set and reset by software.
If the selected clock is the external clock and this clock is stopped it is not possible to switch to another clock. The user must switch to another clock before stopping the external clock.
000: PLLSAI1CLK clock selected
001: PLLSAI2CLK clock selected
010: PLLSAI3CLK clock selected
011: External clock SAI1_EXTCLK selected
100: HSI clock selected
Others: reserved

Bits 4:3  **ADFSDMSEL[1:0]**: Digital filter for sigma-delta modulator audio clock source selection
Set and reset by software.
00: SAI1clock selected
01: HSI clock selected
10: MSI clock selected
11: reserved

Bit 2  **DFSDMSEL**: Digital filter for sigma-delta modulator kernel clock source selection
Set and reset by software.
0: APB2 clock (PCLK2) selected
1: System clock selected

Bits 1:0  **I2C4SEL[1:0]**: I2C4 clock source selection
These bits are set and cleared by software.
00: PCLK1 selected
01: System clock (SYSCLK) selected
10: HSI16 clock selected
11: reserved

**9.8.33 OCTOSPI delay configuration register (RCC_DLYCFGFR)**

Address: 0x0A4
Reset value: 0x0000 0000h
Access: no wait state, word, half-word and byte access

This register allows to configure OCTOSPI’s delay cell.

9.8.34 RCC secure configuration register (RCC_SECCFGR)

Address: 0x0B8

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access

When the system is secure (TZEN = 1), this register provides write access security and can be read and written only by a secure access. A non-secure read and write access generates an illegal access event and data is RAZ/WI.

When the system is not secure (TZEN = 0), this register is RAZ/WI.
Bits 31:13  Reserved, must be kept at reset value.

Bit 12  **RMVFSEC**: Remove reset flag security  
Set and reset by software.  
0: non secure  
1: secure

Bit 11  **HSI48SEC**: HSI48 clock configuration and status bits security  
Set and reset by software.  
0: non secure

9.8.35 RCC secure status register (RCC_SECSR)

Address: 0x0BC

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access

When the system is secure (TZEN = 1), this register provides security status of security configuration bits in RCC_SECCFG register. Both privileged and unprivileged, accesses are allowed.

When the system is not secure (TZEN = 0), this register is RAZ/WI.

9.8.36 RCC AHB1 security status register (RCC_AHB1SECSR)

Address: 0x0E8
Reset value: 0x0040 0300
Access: no wait state, word, half-word and byte access

When the system is secure (TZEN = 1), this register provides AHB1 peripheral clock security status. When a peripheral is configured as secure, its clock is also secure.

Both privileged and unprivileged, secure and non-secure accesses are allowed.

When the system is not secure (TZEN = 0), this register is RAZ.

| Bit 31:24 Reserved, must be kept at reset value. |

      1: secure
9.8.40 RCC APB1 security status register 2 (RCC_APB1SECSR2)

Address: 0x0FC
Reset value: 0x0000 0000
Access: no wait state, word, half-word and byte access

When the system is secure (TZEN = 1), this register provides APB1 peripheral clock security status. When a peripheral is configured as secure, its clock is also secure.

Both privileged and unprivileged, secure and non-secure accesses are allowed.

When the system is not secure (TZEN = 0), this register is RAZ.

Refer to Section 2.3 on page 87 for the register boundary addresses.
10 Clock recovery system (CRS)

10.1 Introduction

The clock recovery system (CRS) is an advanced digital controller acting on the internal fine-granularity trimmable RC oscillator HSI48. The CRS provides powerful means for oscillator output frequency evaluation, based on comparison with a selectable synchronization signal. It is capable of doing automatic adjustment of oscillator trimming based on the measured frequency error value, while keeping the possibility of a manual trimming.

The CRS is ideally suited to provide a precise clock to the USB peripheral. In such case, the synchronization signal can be derived from the start-of-frame (SOF) packet signalization on the USB bus, which is sent by a USB host at 1 ms intervals.

The synchronization signal can also be derived from the LSE oscillator output or it can be generated by user software.

10.2 CRS main features

- Selectable synchronization source with programmable prescaler and polarity:
  - External pin
  - LSE oscillator output
  - USB SOF packet reception
- Possibility to generate synchronization pulses by software
- Automatic oscillator trimming capability with no need of CPU action
- Manual control option for faster start-up convergence
- 16-bit frequency error counter with automatic error value capture and reload
- Programmable limit for automatic frequency error value evaluation and status reporting
- Maskable interrupts/events:
  - Expected synchronization (ESYNC)
  - Synchronization OK (SYNCOOK)
  - Synchronization warning (SYNCWARN)
  - Synchronization or trimming error (ERR)

10.3 CRS implementation

10.4 CRS functional description

10.4.1 CRS block diagram

Figure 35. CRS block diagram

10.4.2 Synchronization input

The CRS synchronization (SYNC) source, selectable through the CRS_CFGR register, can be the signal from the LSE clock or the USB SOF signal. For a better robustness of the SYNC input, a simple digital filter (2 out of 3 majority votes, sampled by the RC48 clock) is implemented to filter out any glitches. This source signal also has a configurable polarity and can then be divided by a programmable binary prescaler to obtain a synchronization signal in a suitable frequency range (usually around 1 kHz).

For more information on the CRS synchronization source configuration, refer to Section 10.7.2: CRS configuration register (CRS_CFGR).

It is also possible to generate a synchronization event by software, by setting the SWSYNC bit in the CRS_CR register.
10.4.3 Frequency error measurement

The frequency error counter is a 16-bit down/up counter which is reloaded with the RELOAD value on each SYNC event. It starts counting down till it reaches the zero value, where the ESYNC (expected synchronization) event is generated. Then it starts counting up to the OUTRANGE limit where it eventually stops (if no SYNC event is received) and generates a SYNCMISS event. The OUTRANGE limit is defined as the frequency error limit (FELIM field of the CRS_CFGR register) multiplied by 128.

When the SYNC event is detected, the actual value of the frequency error counter and its counting direction are stored in the FECAP (frequency error capture) field and in the FEDIR (frequency error direction) bit of the CRS_ISR register. When the SYNC event is detected during the downcounting phase (before reaching the zero value), it means that the actual frequency is lower than the target (and so, that the TRIM value must be incremented), while when it is detected during the upcounting phase it means that the actual frequency is higher (and that the TRIM value must be decremented).

Figure 36. CRS counter behavior
10.4.4 Frequency error evaluation and automatic trimming

The measured frequency error is evaluated by comparing its value with a set of limits:

- TOLERANCE LIMIT, given directly in the FELIM field of the CRS_CFGCR register
- WARNING LIMIT, defined as 3 * FELIM value
- OUTRANGE (error limit), defined as 128 * FELIM value

The result of this comparison is used to generate the status indication and also to control the automatic trimming which is enabled by setting the AUTOTRIMEN bit in the CRS_CR register:

- When the frequency error is below the tolerance limit, it means that the actual trimming value in the TRIM field is the optimal one, hence no trimming action is needed.
  - SYNCOK status indicated
  - TRIM value not changed in AUTOTRIM mode

- When the frequency error is below the warning limit but above or equal to the tolerance limit, it means that some trimming action is necessary but that adjustment by one trimming step is enough to reach the optimal TRIM value.
  - SYNCWARN status indicated
  - TRIM value adjusted by one trimming step in AUTOTRIM mode

- When the frequency error is above or equal to the warning limit but below the error limit, it means that a stronger trimming action is necessary, and there is a risk that the optimal TRIM value is not reached for the next period.
  - SYNCERR or SYNCMISS status indicated
  - TRIM value adjusted by two trimming steps in AUTOTRIM mode

- When the frequency error is above or equal to the error limit, it means that the frequency is out of the trimming range. This can also happen when the SYNC input is not clean or when some SYNC pulse is missing (for example when one USB SOF is corrupted).
  - SYNCERR or SYNCMISS status indicated
  - TRIM value not changed in AUTOTRIM mode

Note: If the actual value of the TRIM field is so close to its limits that the automatic trimming would force it to overflow or underflow, then the TRIM value is set just to the limit and the TRIMOVF status is indicated.

In AUTOTRIM mode (AUTOTRIMEN bit set in the CRS_CR register), the TRIM field of CRS_CR is adjusted by hardware and is read-only.

10.4.5 CRS initialization and configuration

RELOAD value

The RELOAD value must be selected according to the ratio between the target frequency and the frequency of the synchronization source after prescaling. It is then decreased by one to reach the expected synchronization on the zero value. The formula is the following:

\[
RELOAD = (f_{\text{TARGET}} / f_{\text{SYNC}}) - 1
\]

The reset value of the RELOAD field corresponds to a target frequency of 48 MHz and a synchronization signal frequency of 1 kHz (SOF signal from USB).
FELIM value

The selection of the FELIM value is closely coupled with the HSI48 oscillator characteristics and its typical trimming step size. The optimal value corresponds to half of the trimming step size, expressed as a number of HSI48 oscillator clock ticks. The following formula can be used:

\[ FELIM = \left( \frac{f_{TARGET}}{f_{SYNC}} \right) \times \frac{\text{STEP}[^\%]}{100[^\%]} / 2 \]

The result must be always rounded up to the nearest integer value to obtain the best trimming response. If frequent trimming actions are not needed in the application, the hysteresis can be increased by slightly increasing the FELIM value.

The reset value of the FELIM field corresponds to \( \left( \frac{f_{TARGET}}{f_{SYNC}} \right) = 48000 \) and to a typical trimming step size of 0.14%.

**Caution:** There is no hardware protection from a wrong configuration of the RELOAD and FELIM fields which can lead to an erratic trimming response. The expected operational mode requires proper setup of the RELOAD value (according to the synchronization source frequency), which is also greater than 128 * FELIM value (OUTRANGE limit).

### 10.5 CRS low-power modes

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect. CRS interrupts cause the device to exit the Sleep mode.</td>

10.7 CRS registers

Refer to Section 1.2 on page 76 for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed only by words (32-bit).

10.7.1 CRS control register (CRS_CR)

Address offset: 0x00

Reset value: 0x0000 X000 (X=4 for products supporting 7-bit TRIM width, otherwise X=2)

<table>
<thead>
<tr>
<th>No.</th>
<th>TRIM[6:0]</th>
<th>SW_SYNC</th>

<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rt_w1</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:8 TRIM[6:0]: HSI48 oscillator smooth trimming

For product supporting the 7-bit TRIM width (see Section 10.3), the default value of the HSI48 oscillator smooth trimming is 64, which corresponds to the middle of the trimming interval.

For products supporting the 6-bit TRIM width (see Section 10.3) this bit is reserved, must be kept at reset value.

Bit 7 SWSYNC: Generate software SYNC event

This bit is set by software in order to generate a software SYNC event. It is automatically cleared by hardware.

0: No action
1: A software SYNC event is generated.

Bit 6 AUTOTRIMEN: Automatic trimming enable

This bit enables the automatic hardware adjustment of TRIM bits according to the measured frequency error between two SYNC events. If this bit is set, the TRIM bits are read-only. The TRIM value can be adjusted by hardware by one or two steps at a time, depending on the measured frequency error value. Refer to Section 10.4.4 for more details.

0: Automatic trimming disabled, TRIM bits can be adjusted by the user.
1: Automatic trimming enabled, TRIM bits are read-only and under hardware control.

Bit 5 CEN: Frequency error counter enable

This bit enables the oscillator clock for the frequency error counter.

0: Frequency error counter disabled
1: Frequency error counter enabled

When this bit is set, the CRS_CFGR register is write-protected and cannot be modified.

Bit 4 Reserved, must be kept at reset value.

Bit 3 ESYNCIE: Expected SYNC interrupt enable

0: Expected SYNC (ESYNCF) interrupt disabled
1: Expected SYNC (ESYNCF) interrupt enabled
Bit 2 **ERRIE**: Synchronization or trimming error interrupt enable
0: Synchronization or trimming error (ERRF) interrupt disabled
1: Synchronization or trimming error (ERRF) interrupt enabled

Bit 1 **SYNCWARNIE**: SYNC warning interrupt enable
0: SYNC warning (SYNCWARNF) interrupt disabled
1: SYNC warning (SYNCWARNF) interrupt enabled

Bit 0 **SYNCOKIE**: SYNC event OK interrupt enable
0: SYNC event OK (SYNCOKF) interrupt disabled
1: SYNC event OK (SYNCOKF) interrupt enabled

### 10.7.2 CRS configuration register (CRS_CFGR)

This register can be written only when the frequency error counter is disabled (CEN bit is cleared in CRS_CR). When the counter is enabled, this register is write-protected.

**Address offset**: 0x04

**Reset value**: 0x2022 BB7F

**Bit 31** **SYNCPOL**: SYNC polarity selection
This bit is set and cleared by software to select the input polarity for the SYNC signal source.
0: SYNC active on rising edge (default)
1: SYNC active on falling edge

**Bit 30** Reserved, must be kept at reset value.

**Bits 29:28** **SYNCSRC[1:0]**: SYNC signal source selection
These bits are set and cleared by software to select the SYNC signal source.
00: GPIO selected as SYNC signal source
01: LSE selected as SYNC signal source
10: USB SOF selected as SYNC signal source (default).
11: Reserved

**Note**: When using USB LPM (Link Power Management) and the device is in Sleep mode, the periodic USB SOF is not generated by the host. No SYNC signal is therefore provided to the CRS to calibrate the HSI48 oscillator on the run. To guarantee the required clock precision after waking up from Sleep mode, the LSE or reference clock on the GPIOs should be used as SYNC signal.

**Bit 27** Reserved, must be kept at reset value.
Bits 26:24 **SYNCDIV[2:0]**: SYNC divider
These bits are set and cleared by software to control the division factor of the SYNC signal.
000: SYNC not divided (default)
001: SYNC divided by 2
010: SYNC divided by 4
011: SYNC divided by 8
100: SYNC divided by 16
101: SYNC divided by 32
110: SYNC divided by 64
111: SYNC divided by 128

Bits 23:16 **FELIM[7:0]**: Frequency error limit
FELIM contains the value to be used to evaluate the captured frequency error value latched in the FECAP[15:0] bits of the CRS_ISR register. Refer to Section 10.4.4 for more details about FECAP evaluation.

Bits 15:0 **RELOAD[15:0]**: Counter reload value
RELOAD is the value to be loaded in the frequency error counter with each SYNC event. Refer to Section 10.4.3 for more details about counter behavior.

### 10.7.3 CRS interrupt and status register (CRS_ISR)

Address offset: 0x08
Reset value: 0x0000 0000

</tbody>
</table>

| Bit 10 | **TRIMOVF**: Trimming overflow or underflow |
| 0: No trimming error signalized |
| 1: Trimming error signalized |
Bit 9  **SYNCMISS**: SYNC missed

This flag is set by hardware when the frequency error counter reached value FELIM * 128 and no SYNC was detected, meaning either that a SYNC pulse was missed or that the frequency error is too big (internal frequency too high) to be compensated by adjusting the TRIM value, and that some other action has to be taken. At this point, the frequency error counter is stopped (waiting for a next SYNC) and an interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.

0: No SYNC missed error signalized
1: SYNC missed error signalized

Bit 8  **SYNCERR**: SYNC error

This flag is set by hardware when the SYNC pulse arrives before the ESYNC event and the measured frequency error is greater than or equal to FELIM * 128. This means that the frequency error is too big (internal frequency too low) to be compensated by adjusting the TRIM value, and that some other action has to be taken. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.

0: No SYNC error signalized
1: SYNC error signalized

Bits 7:4  Reserved, must be kept at reset value.

Bit 3  **ESYNC**: Expected SYNC flag

This flag is set by hardware when the frequency error counter reached a zero value. An interrupt is generated if the ESYNCIE bit is set in the CRS_CR register. It is cleared by software by setting the ESYNCC bit in the CRS_ICR register.

0: No expected SYNC signalized
1: Expected SYNC signalized

Bit 2  **ERRF**: Error flag

This flag is set by hardware in case of any synchronization or trimming error. It is the logical OR of the TRIMOVF, SYNCMISS and SYNCERR bits. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software in reaction to setting the ERRC bit in the CRS_ICR register.

0: No synchronization or trimming error signalized
1: Synchronization or trimming error signalized

Bit 1  **SYNCWARNF**: SYNC warning flag

This flag is set by hardware when the measured frequency error is greater than or equal to FELIM * 3, but smaller than FELIM * 128. This means that to compensate the frequency error, the TRIM value must be adjusted by two steps or more. An interrupt is generated if the SYNCWARNIE bit is set in the CRS_CR register. It is cleared by software by setting the SYNCWARNC bit in the CRS_ICR register.

0: No SYNC warning signalized
1: SYNC warning signalized

Bit 0  **SYNCOKF**: SYNC event OK flag

This flag is set by hardware when the measured frequency error is smaller than FELIM * 3. This means that either no adjustment of the TRIM value is needed or that an adjustment by one trimming step is enough to compensate the frequency error. An interrupt is generated if the SYNCOKIE bit is set in the CRS_CR register. It is cleared by software by setting the SYNCOKFC bit in the CRS_ICR register.

0: No SYNC event OK signalized
1: SYNC event OK signalized
### 10.7.4 CRS interrupt flag clear register (CRS_ICR)

Address offset: 0x0C  
Reset value: 0x0000 0000

| 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
|     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
| rw  | rw  | rw  | rw  | rw  | rw  | rw  | rw  | rw  | rw  | rw  | rw  | rw  | rw  | rw  | rw  |

Bits 31:4 Reserved, must be kept at reset value.

- **Bit 3 ESYNCC**: Expected SYNC clear flag
  Writing 1 to this bit clears the ESYNCF flag in the CRS_ISR register.

- **Bit 2 ERRC**: Error clear flag
  Writing 1 to this bit clears TRIMOVF, SYNCMISS and SYNCCERR bits and consequently also the ERRF flag in the CRS_ISR register.

- **Bit 1 SYNCWARNC**: SYNC warning clear flag
  Writing 1 to this bit clears the SYNCWARNF flag in the CRS_ISR register.

- **Bit 0 SYNCOKC**: Sync event OK clear flag
  Writing 1 to this bit clears the SYNCOKF flag in the CRS_ISR register.
### 10.7.5 CRS register map

Refer to Section 2.3 on page 87 for the register boundary addresses.
11 General-purpose I/Os (GPIO)

11.1 Introduction

Each general-purpose I/O port has four 32-bit configuration registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR and GPIOx_PUPDR), two 32-bit data registers (GPIOx_IDR and GPIOx_ODR) and a 32-bit set/reset register (GPIOx_BSRR). In addition all GPIOs have a 32-bit locking register (GPIOx_LCKR) and two 32-bit alternate function selection registers (GPIOx_AFRH and GPIOx_AFRL) and a secure configuration register (GPIOx_SECCFGR).

11.2 GPIO main features

- Output states: push-pull or open drain + pull-up/down
- Output data from output data register (GPIOx_ODR) or peripheral (alternate function output)
- Speed selection for each I/O
- Input states: floating, pull-up/down, analog
- Input data to input data register (GPIOx_IDR) or peripheral (alternate function input)
- Bit set and reset register (GPIOx_BSRR) for bitwise write access to GPIOx_ODR
- Locking mechanism (GPIOx_LCKR) provided to freeze the I/O port configurations
- Analog function
- Alternate function selection registers
- Fast toggle capable of changing every two clock cycles
- Highly flexible pin multiplexing allows the use of I/O pins as GPIOs or as one of several peripheral functions
- TrustZone security support

11.3 GPIO functional description

Subject to the specific hardware characteristics of each I/O port listed in the datasheet, each port bit of the general-purpose I/O (GPIO) ports can be individually configured by software in several modes:

- Input floating
- Input pull-up
- Input-pull-down
- Analog
- Output open-drain with pull-up or pull-down capability
- Output push-pull with pull-up or pull-down capability
- Alternate function push-pull with pull-up or pull-down capability
- Alternate function open-drain with pull-up or pull-down capability

Each I/O port bit is freely programmable, however the I/O port registers have to be accessed as 32-bit words, half-words or bytes. The purpose of the GPIOx_BSRR register is
to allow atomic read/modify accesses to any of the GPIOx_ODR registers. In this way, there is no risk of an IRQ occurring between the read and the modify access.

*Figure 37* and *Figure 38* show the basic structures of a standard and a 5-Volt tolerant I/O port bit, respectively. *Table 85* gives the possible port bit configurations.

---

**Figure 37. Basic structure of an I/O port bit**

1. GP = general-purpose, PP = push-pull, PU = pull-up, PD = pull-down, OD = open-drain, AF = alternate function.
11.3.1 General-purpose I/O (GPIO)

During and just after reset, the alternate functions are not active and most of the I/O ports are configured in analog mode.

The debug pins are in AF pull-up/pull-down after reset:
- PA15: JTDI in pull-up
- PA14: JTCK/SWCLK in pull-down
- PA13: JTMS/SWDAT in pull-up
- PB4: NJTRST in pull-up
- PB3: JTDO in floating state no pull-up/pull-down

PH3/BOOT0 is in input mode during the reset until at least the end of the option byte loading phase. See Section 11.3.15: Using PH3 as GPIO.

When the pin is configured as output, the value written to the output data register (GPIOx_ODR) is output on the I/O pin. It is possible to use the output driver in push-pull mode or open-drain mode (only the low level is driven, high level is HI-Z).

The input data register (GPIOx_IDR) captures the data present on the I/O pin at every AHB clock cycle.

All GPIO pins have weak internal pull-up and pull-down resistors, which can be activated or not depending on the value in the GPIOx_PUPDR register.

11.3.2 I/O pin alternate function multiplexer and mapping

The device I/O pins are connected to on-board peripherals/modules through a multiplexer that allows only one peripheral alternate function (AF) connected to an I/O pin at a time. In this way, there can be no conflict between peripherals available on the same I/O pin.

Each I/O pin has a multiplexer with up to sixteen alternate function inputs (AF0 to AF15) that can be configured through the GPIOx_AFRL (for pin 0 to 7) and GPIOx_AFRH (for pin 8 to 15) registers:
- After reset the multiplexer selection is alternate function 0 (AF0). The I/Os are configured in alternate function mode through GPIOx_MODER register.
- The specific alternate function assignments for each pin are detailed in the device datasheet.

In addition to this flexible I/O multiplexing architecture, each peripheral has alternate functions mapped onto different I/O pins to optimize the number of peripherals available in smaller packages.

To use an I/O in a given configuration, the user has to proceed as follows:
- **Debug function**: after each device reset these pins are assigned as alternate function pins immediately usable by the debugger host
- **GPIO**: configure the desired I/O as output, input or analog in the GPIOx.MODER register.
- **Peripheral alternate function**:
  - Connect the I/O to the desired AFx in one of the GPIOx.AFRL or GPIOx.AFRH register.
  - Select the type, pull-up/pull-down and output speed via the GPIOx.OTYPER, GPIOx.PUPDR and GPIOx.OSPEEDER registers, respectively.
- Configure the desired I/O as an alternate function in the GPIOx_MODER register.

- **Additional functions:**
  - For the ADC, DAC and COMP, configure the desired I/O in analog mode in the GPIOx_MODER register and configure the required function in the ADC, DAC, OPAMP and COMP registers.
    
    As indicated above, for the additional functions (such as DAC or OPAMP), the output is controlled by the corresponding peripheral. Care must be taken to select the I/O port analog function before enabling the additional function output in the peripheral control register.
  
    - For the additional functions like RTC, WKUPx and oscillators, configure the required function in the related RTC, PWR and RCC registers. These functions have priority over the configuration in the standard GPIO registers.

Refer to the “Alternate function mapping” table in the device datasheet for the detailed mapping of the alternate function I/O pins.

### 11.3.3 I/O port control registers

Each of the GPIO ports has four 32-bit memory-mapped control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR) to configure up to 16 I/Os. The GPIOx_MODER register is used to select the I/O mode (input, output, AF, analog). The GPIOx_OTYPER and GPIOx_OSPEEDR registers are used to select the output type (push-pull or open-drain) and speed. The GPIOx_PUPDR register is used to select the pull-up/pull-down whatever the I/O direction.

### 11.3.4 I/O port data registers

Each GPIO has two 16-bit memory-mapped data registers: input and output data registers (GPIOx_IDR and GPIOx_ODR). GPIOx_ODR stores the data to be output, it is read/write accessible. The data input through the I/O are stored into the input data register (GPIOx_IDR), a read-only register.

See Section 11.6.5: GPIO port input data register (GPIOx_IDR) (x = A to H) and Section 11.6.6: GPIO port output data register (GPIOx_ODR) (x = A to H) for the register descriptions.

### 11.3.5 I/O data bitwise handling

The bit set reset register (GPIOx_BSRR) is a 32-bit register which allows the application to set and reset each individual bit in the output data register (GPIOx_ODR). The bit set reset register has twice the size of GPIOx_ODR.

To each bit in GPIOx_ODR, correspond two control bits in GPIOx_BSRR: BS(i) and BR(i). When written to 1, bit BS(i) sets the corresponding ODR(i) bit. When written to 1, bit BR(i) resets the ODR(i) corresponding bit.

Writing any bit to 0 in GPIOx_BSRR does not have any effect on the corresponding bit in GPIOx_ODR. If there is an attempt to both set and reset a bit in GPIOx_BSRR, the set action takes priority.

Using the GPIOx_BSRR register to change the values of individual bits in GPIOx_ODR is a "one-shot" effect that does not lock the GPIOx_ODR bits. The GPIOx_ODR bits can always be accessed directly. The GPIOx_BSRR register provides a way of performing atomic bitwise handling.
There is no need for the software to disable interrupts when programming the GPIOx_ODR at bit level: it is possible to modify one or more bits in a single atomic AHB write access.

### 11.3.6 GPIO locking mechanism

It is possible to freeze the GPIO control registers by applying a specific write sequence to the GPIOx_LCKR register. The frozen registers are GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL and GPIOx_AFRH.

To write the GPIOx_LCKR register, a specific write / read sequence has to be applied. When the right LOCK sequence is applied to bit 16 in this register, the value of LCKR[15:0] is used to lock the configuration of the I/Os (during the write sequence the LCKR[15:0] value must be the same). When the LOCK sequence has been applied to a port bit, the value of the port bit can no longer be modified until the next MCU reset or peripheral reset. Each GPIOx_LCKR bit freezes the corresponding bit in the control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL and GPIOx_AFRH).

The LOCK sequence (refer to Section 11.6.8: GPIO port configuration lock register (GPIOx_LCKR) (x = A to H)) can only be performed using a word (32-bit long) access to the GPIOx_LCKR register due to the fact that GPIOx_LCKR bit 16 has to be set at the same time as the [15:0] bits.

For more details refer to LCKR register description in Section 11.6.8: GPIO port configuration lock register (GPIOx_LCKR) (x = A to H).

### 11.3.7 I/O alternate function input/output

Two registers are provided to select one of the alternate function inputs/outputs available for each I/O. With these registers, the user can connect an alternate function to some other pin as required by the application.

This means that a number of possible peripheral functions are multiplexed on each GPIO using the GPIOx_AFRL and GPIOx_AFRH alternate function registers. The application can thus select any one of the possible functions for each I/O. The AF selection signal being common to the alternate function input and alternate function output, a single channel is selected for the alternate function input/output of a given I/O.

To know which functions are multiplexed on each GPIO pin, refer to the device datasheet.

### 11.3.8 External interrupt/wakeup lines

All ports have external interrupt capability. To use external interrupt lines, the port can be configured in input, output or alternate function mode (the port must not be configured in analog mode).

Refer to Section 17: Extended interrupts and event controller (EXTI).
11.3.9 Input configuration

When the I/O port is programmed as input:

- The output buffer is disabled
- The Schmitt trigger input is activated
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle
- A read access to the input data register provides the I/O state

*Figure 39* shows the input configuration of the I/O port bit.

![Figure 39. Input floating/pull up/pull down configurations](image)

11.3.10 Output configuration

When the I/O port is programmed as output:

- The output buffer is enabled:
  - Open drain mode: A “0” in the Output register activates the N-MOS whereas a “1” in the Output register leaves the port in Hi-Z (the P-MOS is never activated)
  - Push-pull mode: A “0” in the Output register activates the N-MOS whereas a “1” in the Output register activates the P-MOS
- The Schmitt trigger input is activated
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle
- A read access to the input data register gets the I/O state
- A read access to the output data register gets the last written value

*Figure 40* shows the output configuration of the I/O port bit.

![Figure 40](image)
11.3.11 Alternate function configuration

When the I/O port is programmed as alternate function:

- The output buffer can be configured in open-drain or push-pull mode
- The output buffer is driven by the signals coming from the peripheral (transmitter enable and data)
- The Schmitt trigger input is activated
- The weak pull-up and pull-down resistors are activated or not depending on the value
  in the GPIOx_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle
- A read access to the input data register gets the I/O state

*Figure 41* shows the Alternate function configuration of the I/O port bit.
11.3.12 Analog configuration

When the I/O port is programmed as analog configuration:

- The output buffer is disabled
- The Schmitt trigger input is deactivated, providing zero consumption for every analog value of the I/O pin. The output of the Schmitt trigger is forced to a constant value (0).
- The weak pull-up and pull-down resistors are disabled by hardware
- Read access to the input data register gets the value "0"

*Figure 42* shows the high-impedance, analog-input configuration of the I/O port bits.

![Figure 42. High impedance-analog configuration](image)

11.3.13 Using the HSE or LSE oscillator pins as GPIOs

When the HSE or LSE oscillator is switched OFF (default state after reset), the related oscillator pins can be used as normal GPIOs.

When the HSE or LSE oscillator is switched ON (by setting the HSEON or LSEON bit in the RCC_CSR register) the oscillator takes control of its associated pins and the GPIO configuration of these pins has no effect.

When the oscillator is configured in a user external clock mode, only the pin is reserved for clock input and the OSC_OUT or OSC32_OUT pin can still be used as normal GPIO.

11.3.14 Using the GPIO pins in the RTC supply domain

The PC13/PC14/PC15 GPIO functionality is lost when the core supply domain is powered off (when the device enters Standby mode). In this case, if their GPIO configuration is not bypassed by the RTC configuration, these pins are set in an analog input mode.

For details about I/O control by the RTC, refer to *Section 41.3: RTC functional description.*
11.3.15 Using PH3 as GPIO

PH3 may be used as boot pin (BOOT0) or as a GPIO. Depending on the nSWBOOT0 bit in the user option byte, it switches from the input mode to the analog input mode:

- After the option byte loading phase if nSWBOOT0 = 1.
- After reset if nSWBOOT0 = 0.

11.4 TrustZone security

The TrustZone security is activated by the TZEN option bit in the FLASH_OPTR. When the TrustZone is active (TZEN=1), each I/O pin of GPIO port can be individually configured as secure through the GPIOx_SECCFGR register.

When the selected I/O pin is configured as secure, its corresponding configuration bits for alternate function, mode selection, I/O data are secure against a non-secure access. In case of non-secure access, these bits are RAZ/WI.

The I/Os with peripherals functions are also conditioned by the peripheral security configuration:

- For peripherals for which the I/O pin selection is done through alternate functions registers: if the peripheral is configured as secure, it cannot be connected to a non-secure I/O pin. If this is not respected, the input data to the secure peripheral is forced to '0' (I/O input pin value is ignored) and the output pin value is forced to '0', thus avoiding any secure information leak through non-secure I/Os.
- For I/Os with analog switches, directly controlled by peripherals (such as ADC for instance): If the I/O is secure, the I/O analog switch cannot be controlled by a non-secure peripheral. If this is not respected, the switch would remain open. This prevent the redirection of secure data to a non-secure peripheral or I/O through analog path.
- Some of the paths between I/Os additional functions mainly and peripherals are not blocked if the I/O is secure and the peripheral is non-secure. Therefore it is recommended to configure those peripherals as secure even when not used by the application. When the path has a security control, it follows the same rule as I/O selection through alternate functions.
- Refer to the device pins definition table in datasheet for more information about peripherals alternate functions and additional functions mapping.

After reset, all GPIO ports are secure.

Table 86 gives a summary of the I/O port secured bits following the security configuration bit in the GPIOx_SECCFGR register. When the I/O bit port is configured as secure:

- Secured bits: read and write operations are only allowed by a secure access. Non-secure read or write accesses on secured bits are RAZ/WI. There is no illegal access event generated.
- Non-secure bits: no restriction. Read and write operations are allowed by both secure and non-secure accesses.

When the TrustZone security is disabled (TZEN = 0 in FLASH_OPTR register), all registers bits are non-secure. The GPIOx_SECCFGR register is RAZ/WI.
11.5 Privileged and Unprivileged modes

All GPIO registers can be read and written by privileged and unprivileged accesses, whatever the security state (secure or non-secure).

11.6 GPIO registers

This section gives a detailed description of the GPIO registers.

For a summary of register bits, register address offsets and reset values, refer to Table 87.

The peripheral registers can be written in word, half word or byte mode.

11.6.1 GPIO port mode register (GPIOx_MODER) (x =A to H)

Address offset: 0x00
Reset value: 0xABFF FFFF (for port A)
Reset value: 0xFFFF FEBF (for port B)
Reset value: 0xFFFF FFFF (for ports C..G)
Reset value: 0x0000 000F (for port H)

Bits 31:16 Reserved, must be kept at reset value.
Bits 15:0 OD[15:0]: Port output data I/O pin y (y = 15 to 0)
These bits can be read and written by software.
Note: For atomic bit set/reset, the OD bits can be individually set and/or reset by writing to the GPIOx_BSRR register (x = A to H).

11.6.7 GPIO port bit set/reset register (GPIOx_BSRR) (x = A to H)

Address offset: 0x18
### 11.6.8 GPIO port configuration lock register (GPIOx_LCKR) (x = A to H)

This register is used to lock the configuration of the port bits when a correct write sequence is applied to bit 16 (LCKK). The value of bits [15:0] is used to lock the configuration of the GPIO. During the write sequence, the value of LCKR[15:0] must not change. When the LOCK sequence has been applied on a port bit, the value of this port bit can no longer be modified until the next MCU reset or peripheral reset.

**Note:** A specific write sequence is used to write to the GPIOx_LCKR register. Only word access (32-bit long) is allowed during this locking sequence.

Each lock bit freezes a specific configuration register (control and alternate function registers).

**Address offset:** 0x1C

**Reset value:** 0x0000 0000

**Reset value:** 0x0000 0000
11.6.9  GPIO alternate function low register (GPIOx_AFRL)  
(x = A to H)

Address offset: 0x20
Reset value: 0x0000 0000

Bits 31:17  Reserved, must be kept at reset value.

Bit 16  LCKK: Lock key
This bit can be read any time. It can only be modified using the lock key write sequence.
0: Port configuration lock key not active
1: Port configuration lock key active. The GPIOx_LCKR register is locked until the next MCU reset or peripheral reset.

LOCK key write sequence:
WR LCKR[16] = ‘1’ + LCKR[15:0]
WR LCKR[16] = ‘0’ + LCKR[15:0]
WR LCKR[16] = ‘1’ + LCKR[15:0]
RD LCKR
RD LCKR[16] = ‘1’ (this read operation is optional but it confirms that the lock is active)

Note: During the LOCK key write sequence, the value of LCK[15:0] must not change.
Any error in the lock sequence aborts the lock.
After the first lock sequence on any bit of the port, any read access on the LCKK bit returns ‘1’ until the next MCU reset or peripheral reset.

Bits 15:0  LCK[15:0]: Port x lock I/O pin y (y = 15 to 0)
These bits are read/write but can only be written when the LCKK bit is ‘0’.
0: Port configuration not locked
1: Port configuration locked
Bits 31:0 **AFSEL[7:0][3:0]**: Alternate function selection for port x I/O pin y (y = 7 to 0)
These bits are written by software to configure alternate function I/Os.

Bits 15:0  **BR[x:0]**: Port x reset I/O pin (y = 15 to 0)

These bits are write-only. A read to these bits returns the value 0x0000.

0: No action on the corresponding ODx bit

1: Reset the corresponding ODx bit

11.6.12  GPIO secure configuration register (GPIOx_SECCFGR) (x = A to H)

When the system is secure (TZEN = 1), this register provides write access security and can be written only by a secure access. It is used to configure a selected I/O as secure. A non-secure write access to this register is discarded. A non-secure read is possible, and thus provides visibility on secured I/O pins on the GPIO port.

When the system is not secure (TZEN = 0), this register is WI and its content has no effect.

Address offset: 0x30
Reset value: 0x0000 FFFF (A to G) and 0x0000 000B (H)
### Bits are "rw" when TZEN = 1.

Refer to Section 2.3 on page 87 for the register boundary addresses.
12 System configuration controller (SYSCFG)

12.1 SYSCFG main features

The STM32L552xx and STM32L552xx devices feature a set of configuration registers. The main purposes of the system configuration controller are the following:

- Managing robustness feature
- Setting SRAM2 write protection and software erase
- Configuring FPU interrupts
- Enabling/disabling the I2C fast-mode plus driving capability on some I/Os and voltage booster for I/Os analog switches
- Configuring TrustZone security register access

12.2 SYSCFG TrustZone security and privilege

SYSCFG TrustZone security

When the TrustZone security is activated, the SYSCFG is able to secure registers from being modified by non-secure accesses.

The TrustZone security is activated by the TZEN option bit in the FLASH_OPTR register. A non-secure read/write access to a secured register is RAZ/WI and generates an illegal access event. An illegal access interrupt is generated if the SYSCFG illegal access event is enabled in the GTZC_TZIC_IER register.

Privileged/unprivileged mode

The SYSCFG registers can be read and written by privileged and unprivileged accesses except the SYSCFG registers for CPU configuration: SYSCFG_CSLCKR, SYSCFG_FPUIMR and SYSCFG_CNSLCKR registers.

An unprivileged access to a privileged register is RAZ/WI.

Table 88 shows the register security overview.

</tbody>
</table>

1. TrustZone security is activated by the TZEN option bit in the FLASH_OPTR register.
2. Refer to register description for register access.
12.3 SYSCFG registers

12.3.1 SYSCFG secure configuration register (SYSCFG_SECCFGR)

When the system is secure (TZEN =1), this register provides write access security and can be written only when the access is secure. It can be globally write-protected, or each bit of this register can be individually write-protected. A non-secure write access is WI and generates an illegal access event. There are no read restrictions.

When the system is not secure (TZEN=0), this register is RAZ/WI.

This register can be read and written by privileged and unprivileged access.

12.3.2 SYSCFG configuration register 1 (SYSCFG_CFGR1)

When the system is secure (TZEN =1), this register can be a mix of secure and non-secure bits depending on I2Cx, ADC security configuration bit in TZSC_SECCFGR register and GPIO security bits. A non-secure read/write access on secured bits is RAZ/WI.

When the system is not secure (TZEN=0), there is no access restriction.

This register can be read and written by privileged and unprivileged access.

Bits 31:24 Reserved, must be kept at reset value.

**Bit 23 I2C4_FMP:** I2C4 fast-mode plus (Fm+) driving capability activation.
This bit enables the Fm+ driving mode on I2C4 pins selected through AF selection bits.
- 0: Fm+ mode is not enabled on I2C4 pins selected through AF selection bits
- 1: Fm+ mode is enabled on I2C4 pins selected through AF selection bits

**Bit 22 I2C3_FMP:** I2C3 fast-mode plus driving capability activation.
This bit enables the Fm+ driving mode on I2C3 pins selected through AF selection bits.
- 0: Fm+ mode is not enabled on I2C3 pins selected through AF selection bits
- 1: Fm+ mode is enabled on I2C3 pins selected through AF selection bits

**Bit 21 I2C2_FMP:** I2C2 fast-mode plus driving capability activation.
This bit enables the Fm+ driving mode on I2C2 pins selected through AF selection bits.
- 0: Fm+ mode is not enabled on I2C2 pins selected through AF selection bits
- 1: Fm+ mode is enabled on I2C2 pins selected through AF selection bits

**Bit 20 I2C1_FMP:** I2C1 fast-mode plus driving capability activation.
This bit enables the Fm+ driving mode on I2C1 pins selected through AF selection bits.
- 0: Fm+ mode is not enabled on I2C1 pins selected through AF selection bits
- 1: Fm+ mode is enabled on I2C1 pins selected through AF selection bits

**Bit 19 I2C_PB9_FMP:** I2C1 fast-mode plus driving capability activation on PB9.
This bit enables the Fm+ driving mode for PB9.
- 0: PB9 pin operates in standard mode
- 1: Fm+ mode is enabled on PB9 pin, and the speed control is bypassed

**Bit 18 I2C_PB8_FMP:** I2C1 fast-mode plus driving capability activation on PB8.
This bit enables the Fm+ driving mode for PB8.
- 0: PB8 pin operates in standard mode
- 1: Fm+ mode is enabled on PB8 pin, and the speed control is bypassed

**Bit 17 I2C_PB7_FMP:** I2C1 fast-mode plus driving capability activation on PB7.
This bit enables the Fm+ driving mode for PB7.
- 0: PB7 pin operates in standard mode
- 1: Fm+ mode is enabled on PB7 pin, and the speed control is bypassed

**Bit 16 I2C_PB6_FMP:** I2C1 fast-mode plus driving capability activation on PB6.
This bit enables the Fm+ driving mode for PB6.
- 0: PB6 pin operates in standard mode
- 1: Fm+ mode is enabled on PB6 pin, and the speed control is bypassed

Bits 15:10 Reserved, must be kept at reset value.
Bit 9 **ANASWVDD**: GPIO analog switch control voltage selection.
0: I/O analog switches supplied by VDDA or booster when booster is ON
1: I/O analog switches supplied by VDD.

*Note: Refer to Table 89: BOOSTEN and ANASWVDD set/reset for bit 9 setting.*

Bit 8 **BOOSTEN**: I/O analog switch voltage booster enable.
0: I/O analog switches are supplied by VDDA voltage.
This is the recommended configuration when using the ADC in high VDDA voltage operation
1: I/O analog switches are supplied by a dedicated voltage booster (supplied by VDD).
This is the recommended configuration when using the ADC in low VDDA voltage operation.

*Note: Refer to Table 89: BOOSTEN and ANASWVDD set/reset for bit 8 setting.*

Bits 7:0 Reserved, must be kept at reset value.

Table describes when the bit 8 (BOOSTEN) and the bit 9 (ANASWVDD) should be set or reset depending on the voltage settings.

### Table 89. BOOSTEN and ANASWVDD set/reset

#### 12.3.3 FPU interrupt mask register (SYSCFG_FPUIMR)

When the system is secure (TZEN = 1), this register can be protected against non-secure access by setting the FPUSERC bit in the SYSCFG_SECCFG register. A non-secure read/write access is RAZ/WI and generates an illegal access event.

When the system is not secure (TZEN = 0), there is no access restriction.

This register can be read and written by privileged access only. Unprivileged access is RAZ/WI.

Address offset: 0x08

Reset value: 0x0000 001F
12.3.4 SYSCFG CPU non-secure lock register (SYSCFG_CNSLCKR)

This register is used to lock the configuration of non-secure MPU and VTOR_NS registers. This register can be read and written by privileged access only. Unprivileged access is RAZ/WI.

Address offset: 0x0C

Reset value: 0x0000 0000

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **FPU_IE[5:0]**: Floating point unit interrupts enable bits.
- **FPU_IE[5]**: Inexact interrupt enable (interrupt disable at reset)
- **FPU_IE[4]**: Input abnormal interrupt enable
- **FPU_IE[3]**: Overflow interrupt enable
- **FPU_IE[2]**: Underflow interrupt enable
- **FPU_IE[1]**: Divide-by-zero interrupt enable
- **FPU_IE[0]**: Invalid operation Interrupt enable

12.3.5 SYSCFG CPU secure lock register (SYSCFG_CSLOCKR)

This register is used to lock the configuration of PRIS and BFHFNMINS bits in the AIRCR register, SAU, secure MPU and VTOR_S registers.

When the system is secure (TZEN=1), this register can be written only when the access is secure. A non-secure read/write access is RAZ/WI and generates an illegal access event.

When the system is not secure (TZEN=0), this register is RAZ/WI

This register can be read and written by privileged access only. Unprivileged access is RAZ/WI.
Address offset: 0x10
Reset value: 0x0000 0000

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 LOCKSAU: SAU registers lock.
This bit is set by software and cleared only by a system reset. When set, it disables write access to SAU_CTRL, SAU_RNR, SAU_RBAR and SAU_RLAR registers.
0: SAU registers write is enabled
1: SAU registers write is disabled.

Bit 1 LOCKSMPU: Secure MPU registers lock.
This bit is set by software and cleared only by a system reset. When set, it disables write access to secure MPU_CTRL, MPU_RNR and MPU_RBAR registers.
0: Secure MPU registers writes is enabled
1: Secure MPU registers writes is disabled.

Bit 0 LOCKSVTAIRCR: VTOR_S register and AIRCR register bits lock.
This bit is set by software and cleared only by a system reset. When set, it disables write access to VTOR_S register, PRIS and BFHFNMINS bits in the AIRCR register.
0: VTOR_S register PRIS and BFHFNMINS bits in the AIRCR register write is enabled
1: VTOR_S register PRIS and BFHFNMINS bits in the AIRCR register write is disabled.

12.3.6 SYSCFG configuration register 2 (SYSCFG_CFGR2)

When the system is secure (TZEN=1), this register can be protected against non-secure access by setting the CLASSBSEC bit in the SYSCFG_SECCFGR register. When CLASSBSEC bit is set, only secure access is allowed. A non-secure read/write access is RAZ/WI and generates an illegal access event.

When the system is not secure (TZEN=0), there is no access restriction.

This register can be read and written by privileged and unprivileged access.

Address offset: 0x14
Reset value: 0x0000 0000
Bits 31:9  Reserved, must be kept at reset value.

Bit 8  SPF: SRAM2 parity error flag.
This bit is set by hardware when an SRAM2 parity error is detected. It is cleared by software by writing ‘1’.
0: No SRAM2 parity error detected
1: SRAM2 parity error detected.

Bits 7:4  Reserved, must be kept at reset value.

Bit 3  ECCL: ECC lock.
This bit is set by software and cleared only by a system reset. It can be used to enable and lock the Flash ECC error connection to TIM1/8/15/16/17 Break input.
0: ECC error disconnected from TIM1/8/15/16/17 Break input
1: ECC error connected to TIM1/8/15/16/17 Break input.

Bit 2  PVDL: PVD lock enable bit.
This bit is set by software and cleared only by a system reset. It can be used to enable and lock the PVD connection to TIM1/8/15/16/17 Break input, as well as the PVDE and PLS[2:0] in the PWR_CR2 register.
0: PVD interrupt disconnected from TIM1/8/15/16/17 Break input. PVDE and PLS[2:0] bits can be programmed by the application
1: PVD interrupt connected to TIM1/8/15/16/17 Break input, PVDE and PLS[2:0] bits are read only.

Bit 1  SPL: SRAM2 parity lock bit.
This bit is set by software and cleared only by a system reset. It can be used to enable and lock the SRAM2 parity error signal connection to TIM1/8/15/16/17 Break inputs.
0: SRAM2 parity error signal disconnected from TIM1/8/15/16/17 Break inputs
1: SRAM2 parity error signal connected to TIM1/8/15/16/17 Break inputs.

Bit 0  CLL: Cortex®-M33 LOCKUP (hardfault) output enable bit.
This bit is set by software and cleared only by a system reset. It can be used to enable and lock the connection of Cortex®-M33 LOCKUP (hardfault) output to TIM1/8/15/16/17 Break input.
0: Cortex®-M33 LOCKUP output disconnected from TIM1/8/15/16/17 Break inputs
1: Cortex®-M33 LOCKUP output connected to TIM1/8/15/16/17 Break inputs.

12.3.7  SYSCFG SRAM2 control and status register (SYSCFG_SCSR)

When the system is secure (TZEN =1), this register can be protected against non-secure access by setting the SRAM2SEC bit in the SYSCFG_SECCFGR register. When SRAM2SEC bit is set, only secure access is allowed. A non-secure read/write access is RAZ/WI and generates an illegal access event.

When the system is not secure (TZEN=0), there is no access restriction.

This register can be read and written by privileged and unprivileged access.

Address offset: 0x18

Reset value: 0x0000 0000
### 12.3.8 SYSCFG SRAM2 key register (SYSCFG_SKR)

When the system is secure (TZEN = 1), this register can be protected against non-secure access by setting the SRAM2SEC bit in the SYSCFG_SECCFGR register. When SRAM2SEC bit is set, only secure access is allowed. A non-secure read/write access is RAZ/WI and generates an illegal access event.

When the system is not secure (TZEN = 0), there is no access restriction.

This register can be read and written by privileged and unprivileged access.

Address offset: 0x1C

Reset value: 0x0000 0000

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **KEY[7:0]**: SRAM2 write protection key for software erase.

The following steps are required to unlock the write protection of the SRAM2ER bit in the SYSCFG_CFRG2 register.

0: Write "0xCA" into Key[7:0]
1: Write "0x53" into Key[7:0]

**Note:** Writing a wrong key reactivates the write protection.
### 12.3.9 SYSCFG SRAM2 write protection register (SYSCFG_SWPR)

When the system is secure (TZEN = 1), this register can be protected against non-secure access by setting the SRAM2SEC bit in the SYSCFG_SECCFGR register. When SRAM2SEC bit is set, only secure access is allowed. A non-secure read/write access is RAZ/WI and generates an illegal access event.

When the system is not secure (TZEN=0), there is no access restriction.

This register can be read and written by privileged and unprivileged access.

Bits 31:0 **PxWP (x = 0 to 31):** SRAM2 1 Kbyte page x write protection.

These bits are set by software and cleared only by a system reset.

0: Write protection of SRAM2 1 Kbyte page x is disabled
1: Write protection of SRAM2 1 Kbyte page x is enabled.

### 12.3.10 SYSCFG SRAM2 write protection register 2 (SYSCFG_SWPR2)

When the system is secure (TZEN = 1), this register can be protected against non-secure access by setting the SRAM2SEC bit in the SYSCFG_SECCFGR register. When SRAM2SEC bit is set, only secure access is allowed. A non-secure read/write access is RAZ/WI and generates an illegal access event.

When the system is not secure (TZEN=0), there is no access restriction.

This register can be read and written by privileged and unprivileged access.

Address offset: 0x24

Reset value: 0x0000 0000

Bits 31:0 **PxWP (x = 32 to 63):** SRAM2 1 Kbyte page x write protection.

These bits are set by software and cleared only by a system reset.

0: Write protection of SRAM2 1 Kbyte page x is disabled
1: Write protection of SRAM2 1 Kbyte page x is enabled.
12.3.11 SYSCFG RSS command register (SYSCFG_RSSCMDR)

When the system is secure (TZEN =1), this register can be read and written only when the APB access is secure. Otherwise it is RAZ/WI.

When the system is not secure (TZEN=0), this register is RAZ/WI.

This register can be read and written by privileged and unprivileged access.

Address offset: 0x2C

Power-on reset value: 0x0000 0000

System reset: not affected

13 Peripherals interconnect matrix

13.1 Introduction

Several peripherals have direct connections between them.

This allows autonomous communication and or synchronization between peripherals, saving CPU resources thus power supply consumption.

In addition, these hardware connections remove software latency and allow design of predictable system.

Depending on peripherals, these interconnections can operate in Run, Sleep, Low-power run and sleep, Stop 0, Stop 1 and Stop 2 modes.

13.2 Connection summary

Table 91. STM32L552xx and STM32L562xx peripherals interconnect matrix(1) (2)

13.3 Interconnection details

13.3.1 From timer (TIM1/TIM2/TIM3/TIM4/TIM5/TIM8/TIM15/TIM16/TIM17) to timer (TIM1/TIM2/TIM3/TIM4/TIM5/TIM8/TIM15)

**Purpose**

Some of the TIMx timers are linked together internally for timer synchronization or chaining.

When one timer is configured in Master Mode, it can reset, start, stop or clock the counter of another timer configured in Slave Mode.

A description of the feature is provided in: Section 34.3.19: Timer synchronization.

The modes of synchronization are detailed in:

- Section 33.3.26: Timer synchronization for advanced-control timers (TIM1/TIM8)
- Section 34.3.18: Timers and external trigger synchronization for general-purpose timers (TIM2/TIM3/TIM4/TIM5)
- Section 35.4.19: External trigger synchronization (TIM15 only) for general-purpose timer (TIM15)

1. Numbers in table are links to corresponding detailed sub-section in Section 13.3: Interconnection details.
2. The "-" symbol in grayed cells means no interconnect.
Triggering signals

The output (from Master) is on signal TIMx_TRGO (and TIMx_TRGO2 for TIM1/TIM8) following a configurable timer event.

The input (to slave) is on signals TIMx_ITR0/ITR1/ITR2/ITR3

The input and output signals for TIM1/TIM8 are shown in Figure 228: Advanced-control timer block diagram.

The possible master/slave connections are given in:
- Table 270: TIMx internal trigger connection
- Table 275: TIMx internal trigger connection
- Table 279: TIMx Internal trigger connection

Active power mode

Run, Sleep, Low-power run, Low-power sleep.

13.3.2 From timer (TIM1/TIM2/TIM3/TIM4/TIM6/TIM8/TIM15) and EXTI to ADC (ADC1/ADC2)

Purpose

General-purpose timers (TIM2/TIM3/TIM4), basic timer (TIM6), advanced-control timers (TIM1/TIM8), general-purpose timer (TIM15) and EXTI can be used to generate an ADC triggering event.

TIMx synchronization is described in: Section 33.3.27: ADC synchronization (TIM1/TIM8).

ADC synchronization is described in: Section 21.4.18: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN).

Triggering signals

The output (from timer) is on signal TIMx_TRGO, TIMx_TRGO2 or TIMx_CCx event.

The input (to ADC) is on signal EXT[15:0], JEXT[15:0].

The connection between timers and ADC is provided in:

Active power mode

Run, Sleep, Low-power run, Low-power sleep.

13.3.3 From ADC1/ADC2 to timer (TIM1/TIM8)

Purpose

ADC1/ADC2 can provide trigger event through watchdog signals to advanced-control timers (TIM1/TIM8).

A description of the ADC analog watchdog setting is provided in: .

Trigger settings on the timer are provided in: Section 33.3.4: External trigger input.
Triggering signals
The output (from ADC) is on signals ADCn_AWDx_OUT n = 1 (for ADC1,2) x = 1, 2, 3 (3 watchdog per ADC) and the input (to timer) on signal TIMx_ETR (external trigger).

Active power mode
Run, Sleep, Low-power run, Low-power sleep.

13.3.4 From timer (TIM2/TIM4/TIM5/TIM6/TIM7/TIM8) and EXTI to DAC (DAC1/DAC2)

Purpose
General-purpose timers (TIM2/TIM4/TIM5), basic timers (TIM6, TIM7), advanced-control timers (TIM8) and EXTI can be used as triggering event to start a DAC conversion.

Triggering signals
The output (from timer) is on signal TIMx_TRGO directly connected to corresponding DAC inputs.

Selection of input triggers on DAC is provided in Section 22.4.6: DAC trigger selection (single and dual mode).

Active power mode
Run, Sleep, Low-power run, Low-power sleep.

13.3.5 From timer (TIM1/TIM3/TIM4/TIM6/TIM7/TIM8/TIM16/LPTIM1) and EXTI to DFSDM1

Purpose
General-purpose timers (TIM3/TIM4), basic timers (TIM6/TIM7), advanced-control timers (TIM1/TIM8), general-purpose timer (TIM16), Low power timer (LPTIM1), EXTI11 and EXTI15 can be used to generate a triggering event on DFSDM1 module (on each possible data block DFSDM1_FLT0/DFSDM1_FLT1/DFSDM1_FLT2/DFSDM1_FLT3) and start an ADC conversion.

DFSDM triggered conversion feature is described in: Section 26.4.15: Launching conversions.

Triggering signals
The output (from timer) is on signal TIMx_TRGO/TIMx_TRGO2 or TIM16_OC1.

The input (on DFSDM1) is on signal DFSDM1_INTRG[0:8].

The connection between timers, EXTI and DFSDM1 is provided in Table 200: DFSDM triggers connection.

Active power mode
Run, Sleep, Low-power run, Low-power sleep.
13.3.6 From DFSDM1 to timer (TIM1/TIM8/TIM15/TIM16/TIM17)

Purpose
DFSDM1 can generate a timer break on advanced-control timers (TIM1/TIM8) and general-purpose timers (TIM15/TIM16/TIM17) when a watchdog is activated (minimum or maximum threshold value crossed by analog signal) or when a short-circuit detection is made.

DFSDM1 watchdog is described in Section 26.4.10: Analog watchdog.
DFSDM1 short-circuit detection is described in Section 26.4.11: Short-circuit detector.

Timer break is described in:
- Section 33.3.16: Using the break function (TIM1/TIM8)
- Section 35.4.13: Using the break function (TIM15/TIM16/TIM17)

Triggering signals
The output (from DFSDM1) is on signals dfsdm1_break[0:3] directly connected to timer and ‘Ored’ with other break input signals of the timer.

Active power mode
Run, Sleep, Low-power run, Low-power sleep.

13.3.7 From HSE, LSE, LSI, MSI, MCO, RTC to timer (TIM2/TIM15/TIM16/TIM17)

Purpose
External clocks (HSE, LSE), internal clocks (LSI, MSI), microcontroller output clock (MCO), GPIO and RTC wakeup interrupt can be used as input to general-purpose timer (TIM15/16/17) channel 1.

This allows to calibrate the HSI16/MSI system clocks (with TIM15/TIM16 and LSE) or LSI (with TIM16 and HSE). This is also used to precisely measure LSI (with TIM16 and HSI16) or MSI (with TIM17 and HSI16) oscillator frequency.

When Low Speed External (LSE) oscillator is used, no additional hardware connections are required.

This feature is described in Section 9.3.18: Internal/external clock measurement with TIM15/TIM16/TIM17.

External clock LSE can be used as input to general-purpose timers (TIM2) on TIM2_ETR pin, see Section 34.4.22: TIM2 option register 1 (TIM2_OR1).

Active power mode
Run, Sleep, Low-power run, Low-power sleep.
13.3.8 From RTC, COMP1, COMP2 to low-power timer (LPTIM1/LPTIM2/LPTIM3)

**Purpose**
RTC alarm A/B, RTC_TAMP1/2/3 input detection, COMP1/2_OUT can be used as trigger to start LPTIM counters (LPTIM1/2/3).

**Triggering signals**
This trigger feature is described in *Section 37.4.7: Trigger multiplexer* (and following sections).
The input selection is described in *Table 288: LPTIM1 external trigger connection*.

**Active power mode**
Run, Sleep, Low-power run, Low-power sleep, Stop 0, Stop 1, Stop 2 (LPTIM1 only).

13.3.9 From timer (TIM1/TIM2/TIM3/TIM8/TIM15) to comparators (COMP1/COMP2)

**Purpose**
Advanced-control timers (TIM1/TIM8), general-purpose timers (TIM2/TIM3) and general-purpose timer (TIM15) can be used as blanking window input to COMP1/COMP2.
The blanking function is described in *Section 24.3.7: Comparator output blanking function*.
The blanking sources are given in:
- *Section 24.6.1: Comparator 1 control and status register (COMP1_CSR)* bits 20:18 BLANKING[2:0]
- *Section 24.6.2: Comparator 2 control and status register (COMP2_CSR)* bits 20:18 BLANKING[2:0]

**Triggering signals**
Timer output signal TIMx_Ocx are the inputs to blanking source of COMP1/COMP2.

**Active power mode**
Run, Sleep, Low-power run, Low-power sleep.

13.3.10 From ADC (ADC1) to ADC (ADC2)

**Purpose**
ADC1 can be used as a “master” to trigger ADC2 “slave” start of conversion.
In dual ADC mode, the converted data of the master and slave ADCs can be read in parallel.

**Triggering signals**
Internal to the ADCs.
Active power mode
Run, Sleep, Low-power run, Low-power sleep.

13.3.11 From USB to timer (TIM2)

Purpose
USB (FS SOF) can generate a trigger to general-purpose timer (TIM2).
Connection of USB to TIM2 is described in Table 275: TIMx internal trigger connection.

Triggering signals
Internal signal generated by USB FS Start Of Frame.

Active power mode
Run, Sleep.

13.3.12 From internal analog source to ADC (ADC1/ADC2) and OPAMP (OPAMP1/OPAMP2)

Purpose
Internal temperature sensor (V_Ts) and V_BAT monitoring channel are connected to ADC1 input channels.
Internal reference voltage (V_REFINT) is connected to ADC1 input channels.
OPAMP1 and OPAMP2 outputs can be connected to ADC1 or ADC2 input channels through the GPIO.
DAC1_OUT1 can be connected to OPAMP1_VINP.
DAC1_OUT2 can be connected to OPAMP2_VINP.
This is according:
• Section 21.2: ADC main features
• Section 21.4.11: Channel selection (SQRx, JSQRx)
• Section Figure 93.: ADC1 connectivity
• Table 193: Operational amplifier possible connections

Active power mode
Run, Sleep, Low-power run, Low-power sleep.

13.3.13 From comparators (COMP1/COMP2) to timers (TIM1/TIM2/TIM3/TIM8/TIM15/TIM16/TIM17)

Purpose
Comparators (COMP1/COMP2) output values can be connected to timers (TIM1/TIM2/TIM3/TIM8/TIM15/TIM16/TIM17) input captures or TIMx_ETR signals.
The connection to ETR is described in Section 33.3.4: External trigger input.
Comparators (COMP1/COMP2) output values can also generate break input signals for timers (TIM1/TIM8) on input pins TIMx_BKIN or TIMx_BKIN2 through GPIO alternate function selection using open drain connection of IO, see Section 33.3.17: Bidirectional break inputs.

The possible connections are given in:
- Section 33.4.23: TIM1 option register 1 (TIM1_OR1)
- Section 33.4.24: TIM8 option register 1 (TIM8_OR1)
- Section 34.4.22: TIM2 option register 1 (TIM2_OR1)
- Section 34.4.23: TIM3 option register 1 (TIM3_OR1)
- Section 34.4.24: TIM2 option register 2 (TIM2_OR2)
- Section 34.4.25: TIM3 option register 2 (TIM3_OR2)
- Section 35.3: TIM16/TIM17 main features

Active power mode
Run, Sleep, Low-power run, Low-power sleep.

13.3.14 From system errors to timers (TIM1/TIM8/TIM15/TIM16/TIM17)

Purpose
CSS, CPU hardfault, RAM parity error, FLASH ECC double error detection, PVD can generate system errors in the form of timer break toward timers (TIM1/TIM8/TIM15/TIM16/TIM17).

The purpose of the break function is to protect power switches driven by PWM signals generated by the timers.

List of possible source of break are described in:
- Section 33.3.16: Using the break function (TIM1/TIM8)
- Section 35.4.13: Using the break function (TIM15/TIM16/TIM17)
- Figure 339: TIM15 block diagram
- Figure 340: TIM16/TIM17 block diagram

Active power mode
Run, Sleep, Low-power run, Low-power sleep.

13.3.15 From timers (TIM16/TIM17) to IRTIM

Purpose
General-purpose timer (TIM16/TIM17) output channel TIMx_OC1 are used to generate the waveform of infrared signal output.

The functionality is described in Section 38: Infrared interface (IRTIM).

Active power mode
Run, Sleep, Low-power run, Low-power sleep.
13.3.16 From ADC (ADC1/ADC2) to DFSDM

Purpose

Up to 3 internal ADC results can be directly connected through a parallel bus to DFSDM input in order to use DFSDM filtering capabilities.

The feature is described as part of DFSDM peripheral description in Section 26.4.6: Parallel data inputs - Input from internal ADC

The possible connections are given in:

- Section 26.7.1: DFSDM channel y configuration register (DFSDM_CHyCFGR1)
  - Bits 13:12 DATMPX[1:0]: Input data multiplexer for channel y
- Section 26.7.5: DFSDM channel y data input register (DFSDM_CHyDATINR)
  - Bits 31:16 INDAT0[15:0]: Input data for channel y or channel y+1
  - Bits 15:0 INDAT0[15:0]: Input data for channel y

Active power mode

Run, Sleep, Low-power run, Low-power sleep.
14 Direct memory access controller (DMA)

14.1 Introduction

The direct memory access (DMA) controller is a bus master and system peripheral. The DMA is used to perform programmable data transfers between memory-mapped peripherals and/or memories, upon the control of an off-loaded CPU.

The DMA controller features a single AHB master architecture.

There are two instances of DMA, DMA1 and DMA2.

Each channel is dedicated to managing memory access requests from one or more peripherals. Each DMA includes an arbiter for handling the priority between DMA requests.

14.2 DMA main features

- Single AHB master
- Peripheral-to-memory, memory-to-peripheral, memory-to-memory and peripheral-to-peripheral data transfers
- Access, as source and destination, to on-chip memory-mapped devices such as Flash memory, SRAM, and AHB and APB peripherals
- All DMA channels independently configurable:
  - Each channel is associated either with a DMA request signal coming from a peripheral, or with a software trigger in memory-to-memory transfers. This configuration is done by software.
  - Priority between the requests is programmable by software (4 levels per channel: very high, high, medium, low) and by hardware in case of equality (such as request to channel 1 has priority over request to channel 2).
  - Transfer size of source and destination are independent (byte, half-word, word), emulating packing and unpacking. Source and destination addresses must be aligned on the data size.
  - Support of transfers from/to peripherals to/from memory with circular buffer management
  - Programmable number of data to be transferred: 0 to $2^{18} - 1$
- Generation of an interrupt request per channel. Each interrupt request is caused from any of the three DMA events: transfer complete, half transfer, or transfer error.
- TrustZone support:
  - Support for AHB secure and non-secure DMA transfers, independently of a first channel level, and independently at a source and destination sub-level
  - TrustZone-aware AHB slave port, protecting any secure resource (register, register field) from a non-secure software access
- Privileged/unprivileged support:
  - Support for AHB privileged and unprivileged DMA transfers, independently of a channel level
  - Privileged-aware AHB slave port
14.3 DMA implementation

14.3.1 DMA1 and DMA2

DMA1 and DMA2 are implemented with the hardware configuration parameters shown in Table 92.

Table 92. DMA1 and DMA2 implementation

<table>

<td>1 (supported)</td>
</tr>
</tbody>
</table>

14.3.2 DMA request mapping

The DMA controller is connected to DMA requests from the AHB/APB peripherals through the DMAMUX peripheral.

For the mapping of the different requests, refer to the Section 15.3: DMAMUX implementation.
14.4 DMA functional description

14.4.1 DMA block diagram

The DMA block diagram is shown in Figure 43.

Figure 43. DMA block diagram
The DMA controller performs direct memory transfer by sharing the AHB system bus with other system masters. The bus matrix implements round-robin scheduling. DMA requests may stop the CPU access to the system bus for a number of bus cycles, when CPU and DMA target the same destination (memory or peripheral).

According to its configuration through the AHB slave interface, the DMA controller arbitrates between the DMA channels and their associated received requests. The DMA controller also schedules the DMA data transfers over the single AHB port master.

The DMA controller generates a secure bus and a privileged bus, to keep the DMAMUX peripheral informed of the secure or non-secure state, and the privileged or unprivileged state of each channel x.

The DMA controller generates an interrupt per channel to the interrupt controller.

The DMA controller also generates an illegal access event, as a pulse, to the TrustZone interrupt controller, when a non-secure software attempts to access a secure DMA register or register field.

### 14.4.2 DMA pins and internal signals

### 14.4.3 DMA transfers

The secure software configures the DMA controller at channel level, in order to perform a block transfer, composed of a sequence of AHB secure or non-secure, privileged or unprivileged bus transfers.

A DMA block transfer may be requested from a peripheral, or triggered by the software in case of memory-to-memory transfer.

After an event, the following steps of a single DMA transfer occur:

1. The peripheral sends a single DMA request signal to the DMA controller.
2. The DMA controller serves the request, depending on the priority of the channel associated to this peripheral request.
3. As soon as the DMA controller grants the peripheral, an acknowledge is sent to the peripheral by the DMA controller.
4. The peripheral releases its request as soon as it gets the acknowledge from the DMA controller.
5. Once the request is de-asserted by the peripheral, the DMA controller releases the acknowledge.

The peripheral may order a further single request and initiate another single DMA transfer.
The request/acknowledge protocol is used when a peripheral is either the source or the destination of the transfer. For example, in case of memory-to-peripheral transfer, the peripheral initiates the transfer by driving its single request signal to the DMA controller. The DMA controller reads then a single data in the memory and writes this data to the peripheral.

For a given channel $x$, a DMA block transfer consists of a repeated sequence of:

- a single DMA transfer, encapsulating two AHB transfers of a single data, over the DMA AHB bus master:
  - a single data read (byte, half-word or word) from the peripheral data register or a location in the memory, addressed through an internal current peripheral/memory address register. The start address used for the first single transfer is the base address of the peripheral or memory, and is programmed in the DMA_CPARx or DMA_CM0/1ARx register.
  - a single data write (byte, half-word or word) to the peripheral data register or a location in the memory, addressed through an internal current peripheral/memory address register. The start address used for the first transfer is the base address of the peripheral or memory, and is programmed in the DMA_CPARx or DMA_CM0/1ARx register.
- post-decrementing of the programmed DMA_CNDTRx register
  This register contains the remaining number of data items to transfer (number of AHB 'read followed by write' transfers).

This sequence is repeated until DMA_CNDTRx is null.

**Note:** The AHB master bus source/destination address must be aligned with the programmed size of the transferred single data to the source/destination.

### 14.4.4 DMA arbitration

The DMA arbiter manages the priority between the different channels.

When an active channel $x$ is granted by the arbiter (hardware requested or software triggered), a single DMA transfer is issued (such as a AHB 'read followed by write' transfer of a single data). Then, the arbiter considers again the set of active channels and selects the one with the highest priority.

The priorities are managed in two stages:

- software: priority of each channel is configured in the DMA_CCRx register, to one of the four different levels:
  - very high
  - high
  - medium
  - low
- hardware: if two requests have the same software priority level, the channel with the lowest index gets priority. For example, channel 2 gets priority over channel 4.

When a channel $x$ is programmed for a block transfer in memory-to-memory mode, re arbitration is considered between each single DMA transfer of this channel $x$. Whenever there is another concurrent active requested channel, the DMA arbiter automatically alternates and grants the other highest-priority requested channel, which may be of lower priority than the memory-to-memory channel.
14.4.5 DMA channels

Each channel may handle a DMA transfer between a peripheral register located at a fixed address, and a memory address. The amount of data items to transfer is programmable. The register that contains the amount of data items to transfer is decremented after each transfer.

Each channel is either secure or non-secure.

A DMA channel is programmed at block transfer level.

Programmable data sizes

The transfer sizes of a single data (byte, half-word, or word) to the peripheral and memory are programmable through, respectively, the PSIZE[1:0] and MSIZE[1:0] fields of the DMA_CCRx register.

Pointer incrementation

The peripheral and memory pointers may be automatically incremented after each transfer, depending on the PINC and MINC bits of the DMA_CCRx register.

If the **incremented mode** is enabled (PINC or MINC set to 1), the address of the next transfer is the address of the previous one incremented by 1, 2 or 4, depending on the data size defined in PSIZE[1:0] or MSIZE[1:0]. The first transfer address is the one programmed in the DMA_CPARx or DMA_CM0/1ARx register. During transfers, these registers keep the initially programmed value. The current transfer addresses (in the current internal peripheral/memory address register) are not accessible by software.

If the channel x is configured in **non-circular mode**, no DMA request is served after the last data transfer (once the number of single data to transfer reaches zero). The DMA channel must be disabled in order to reload a new number of data items into the DMA_CNDTRx register.

*Note:* If the channel x is disabled, the DMA registers are not reset. The DMA channel registers (DMA_CCRx, DMA_CPARx and DMA_CM0ARx) retain the initial values programmed during the channel configuration phase.

In **circular mode**, after the last data transfer, the DMA_CNDTRx register is automatically reloaded with the initially programmed value. The current internal address registers are reloaded with the base address values from the DMA_CPARx and DMA_CM0/1ARx registers.

Security

The DMA controller is compliant with the TrustZone-M hardware architecture, partitioning all its resources so that they exist in one of the two worlds: the secure world and the non-secure world, at any given time.

A secure software is able to access any resource/register, whatever secure or non-secure. A non-secure software is restricted to access any non-secure resource/register.

Any channel is in a secure or non-secure state, as securely configured by the DMA_CCRx.SECM secure register bit.
When a channel x is configured in secure mode, the following access controls rules are applied:

- A non-secure read access to a register field of this channel is forced to return 0, except for both the secure state and the privileged state of this channel x (SECM and PRIV bits of the DMA_CCRx register) which are readable by a non-secure software.
- A non-secure write access to a register field of this channel has no impact.

When a channel is configured in secure mode, a secure software can separately configure as secure or non-secure the AHB DMA master transfer from the source (by the DMA_CCRx.SSEC register bit), and as secure or non-secure the AHB DMA master transfer to the destination (by the DMA_CCRx.DSEC register bit).

The DMA controller generates a secure bus, dma_secm[7:0], reflecting the DMA_CCRx.SECM register, in order to keep the other hardware peripherals like the DMAMUX, informed of the secure/non-secure state of each DMA channel x.

The DMA controller also generates a security illegal access pulse event, dma_sec_ilac, on an illegal non-secure software access to a secure DMA register or register field. This event is routed to the TrustZone interrupt controller.

The dma_sec_ilac event is generated in the configurations described below:

- If the channel x is in secure state (SECM bit of the DMA_CCRx register set), the dma_sec_ilac is generated on one of the following accesses:
  - a non-secure write access to a dedicated register of this channel x (DMA_CCRx, DMA_CNDTRx, DMA_CPARx, DMA_CM0ARx and DMA_CM1ARx)
  - a non-secure read access to a dedicated register of this channel x, except the DMA_CxCR register (DMA_CNDTRx, DMA_CPARx, DMA_CM0ARx, and DMA_CM1ARx).

- If the channel x is in non-secure state (SECM bit of the DMA_CCRx register cleared), the dma_sec_ilac is generated on a non-secure write access to the DMA_CCRx register which attempts to write 1 into any of the secure configuration bits SECM, DSEC, SSEC.

When the software is switching from a secure state to a non-secure state (after the secure transfer is completed), the secure software must disable the channel by a 32-bit write at the DMA_CCRx address before switching. This operation is needed for the two below reasons:

- a non-secure software cannot do so
- the EN bit of the DMA_CCRx register must be cleared before the (non-secure) software can reprogram the DMA_CCRx for a next transfer.

Note: A trusted application may require that the secure software does not only disable the channel, but also reset the full DMA_CCRx word register to its reset value, as well as reset any other DMA register corresponding to this channel x.

Privileged / unprivileged mode

Any channel x is a privileged or unprivileged hardware resource, as configured by a privileged software via the PRIV bit of the DMA_CCRx register.

When a channel x is configured in privileged mode, the following access controls rules are applied:

- An unprivileged read access to a register field of this channel is forced to return 0, except for both the privileged state and the secure state of this channel x (PRIV and
SECM bits of the DMA_CCRx register) which are readable by an unprivileged software.

- An unprivileged write access to a register field of this channel has no impact.

When a channel is configured in a privileged (or unprivileged) mode, the AHB master transfers from the source and to the destination, are privileged (respectively unprivileged).

DMA generates a privileged bus, dma_priv[7:0], reflecting the PRIV bit of the DMA_CCRx register, in order to keep the other hardware peripherals, like DMAMUX, informed of the privileged / unprivileged state of each DMA channel x.

Channel configuration procedure

The following sequence is needed to configure a DMA channel x:

1. Set a channel x to secure or non-secure, by a secure write access to the secure SECM bit of the DMA_CCRx register. Set a channel x to privileged or unprivileged, by a privileged write access to the privileged PRIV bit of the DMA_CCRx register.

2. Set the peripheral register address in the DMA_CPARx register. The data is moved from/to this address to/from the memory after the peripheral event, or after the channel is enabled in memory-to-memory mode.

3. Set the memory address in the DMA_CM0ARx register. The data is written to/read from the memory after the peripheral event or after the channel is enabled in memory-to-memory mode.

4. Configure the total number of data to transfer in the DMA_CNDTRx register. After each data transfer, this value is decremented.

5. Configure the parameters listed below in the DMA_CCRx register:
   - the channel priority
   - the data transfer direction
   - the security level of the data transfers from source and to destination when the channel is secure
   - the circular mode
   - the double-buffer mode
   - the peripheral and memory incremented mode
   - the peripheral and memory data size
   - the interrupt enable at half and/or full transfer and/or transfer error

6. Activate the channel by setting the EN bit in the DMA_CCRx register.

A channel, as soon as enabled, may serve any DMA request from the peripheral connected to this channel, or may start a memory-to-memory block transfer.

Note: The two last steps of the channel configuration procedure may be merged into a single access to the DMA_CCRx register, to configure and enable the channel.

Channel state and disabling a channel

A channel x in active state is an enabled channel (read DMA_CCRx.EN = 1). An active channel x is a channel that must have been enabled by the software (DMA_CCRx.EN set to 1) and afterwards with no occurred transfer error (DMA_ISR.TEIFx = 0). In case there is a transfer error, the channel is automatically disabled by hardware (DMA_CCRx.EN = 0).
The three following use cases may happen:

- **Suspend and resume a channel**
  This corresponds to the two following actions:
  - An active channel is disabled by software (writing DMA_CCRx.EN = 0 whereas DMA_CCRx.EN = 1).
  - The software enables the channel again (DMA_CCRx.EN set to 1) without reconfiguring the other channel registers (such as DMA_CNDTRx, DMA_CPARx and DMA_CMARx).
  This case is not supported by the DMA hardware, that does not guarantee that the remaining data transfers are performed correctly.

- **Stop and abort a channel**
  If the application does not need any more the channel, this active channel can be disabled by software. The channel is stopped and aborted but the DMA_CNDTRx register content may not correctly reflect the remaining data transfers versus the aborted source and destination buffer/ register.

- **Abort and restart a channel**
  This corresponds to the software sequence: disable an active channel, then reconfigure the channel and enable it again.
  This is supported by the hardware if the following conditions are met:
  - The application guarantees that, when the software is disabling the channel, a DMA data transfer is not occurring at the same time over its master port. For example, the application can first disable the peripheral in DMA mode, in order to ensure that there is no pending hardware DMA request from this peripheral.
  - The software must operate separated write accesses to the same DMA_CCRx register: First disable the channel. Second reconfigure the channel for a next block transfer including the DMA_CCRx if a configuration change is needed. There are read-only DMA_CCRx register fields when DMA_CCRx.EN=1. Finally enable again the channel.

When a channel transfer error occurs, the EN bit of the DMA_CCRx register is cleared by hardware. This EN bit can not be set again by software to re-activate the channel x, until the TEIFx bit of the DMA_ISR register is set.

**Circular mode (in memory-to-peripheral/peripheral-to-memory transfers)**

The circular mode is available to handle circular buffers and continuous data flows (such as ADC scan mode). This feature is enabled using the CIRC bit in the DMA_CCRx register.

*Note:* The circular mode must not be used in memory-to-memory mode. Before enabling a channel in circular mode (CIRC = 1), the software must clear the MEM2MEM bit of the DMA_CCRx register. When the circular mode is activated, the amount of data to transfer is automatically reloaded with the initial value programmed during the channel configuration phase, and the DMA requests continue to be served.

In order to stop a circular transfer, the software needs to stop the peripheral from generating DMA requests (such as quit the ADC scan mode), before disabling the DMA channel.

The software must explicitly program the DMA_CNDTRx value before starting/enabling a transfer, and after having stopped a circular transfer.
Memory-to-memory mode

The DMA channels may operate without being triggered by a request from a peripheral. This mode is called memory-to-memory mode, and is initiated by software.

If the MEM2MEM bit in the DMA_CCRx register is set, the channel, if enabled, initiates transfers. The transfer stops once the DMA_CNDTRx register reaches zero.

Note: The memory-to-memory mode must not be used in circular mode. Before enabling a channel in memory-to-memory mode (MEM2MEM = 1), the software must clear the CIRC bit of the DMA_CCRx register.

Double-buffer mode (in memory-to-peripheral and peripheral-to-memory transfers)

The DMA channels can operate in double-buffer mode.

The difference compared to a regular operation is that the DMA controller toggles between two memory address pointers at the end of each DMA transfer, thus accessing two memory areas in an alternate way. This allows the software to access one of the two memory areas while the DMA controller accesses the other one. The double-buffer mode transfer operates in both directions, so the target memory can be either the source or the destination.

The double-buffer mode is configured by setting both the DBM and CIRC bits of the DMA_CCRx register.

Note: The double-buffer mode must not be used in memory-to-memory mode. Before enabling a channel in double-buffer mode (DBM = 1), the software has to configure appropriately the MEM2MEM bit (MEM2MEM = 0).

The steps described below allow the configuration of a DMA channel x in double-buffer mode:

- Set the DBM and CIRC bits and clear the MEM2MEM bit of the DMA_CCRx register. The circular mode is then activated for the swap mechanism to occur.
- Configure the second memory address register DMA_CM1ARx.
- Continue with the regular channel configuration procedure, and lastly, activate the channel by setting the EN bit of the DMA_CCRx register. The first DMA transfer target memory of the corresponding DMA channel x, is given by the CT bit of the DMA_CCRx register.

Note: Independently from the value of DBM bit of the DMA_CCRx register, if CT = 1, the memory address pointer for the DMA transfer is defined by DMA_CM1ARx, and not by DMA_CM0ARx.

Peripheral-to-peripheral mode

Any DMA channel can operate in peripheral-to-peripheral mode:

- when the hardware request from a peripheral is selected to trigger the DMA channel
  This peripheral is the DMA initiator and paces the data transfer from/to this peripheral to/from a register belonging to another memory-mapped peripheral (this one being not configured in DMA mode).
- when no peripheral request is selected and connected to the DMA channel
  The software configures a register-to-register transfer by setting the MEM2MEM bit of the DMA_CCRx register.
Programming transfer direction, assigning source/destination

The value of the DIR bit of the DMA_CCRx register sets the direction of the transfer, and consequently, it identifies the source and the destination, regardless the source/destination type (peripheral or memory):

- **DIR = 1** defines typically a memory-to-peripheral transfer. More generally, if DIR = 1:
  - The *source* attributes are defined by the DMA_MARx register, the MSIZE[1:0] field and MINC bit of the DMA_CCRx register. Regardless of their usual naming, these ‘memory’ register, field and bit are used to define the source peripheral in peripheral-to-peripheral mode.
  - The *destination* attributes are defined by the DMA_PARx register, the PSIZE[1:0] field and PINC bit of the DMA_CCRx register. Regardless of their usual naming, these ‘peripheral’ register, field and bit are used to define the destination memory in memory-to-memory mode.

- **DIR = 0** defines typically a peripheral-to-memory transfer. More generally, if DIR = 0:
  - The *source* attributes are defined by the DMA_PARx register, the PSIZE[1:0] field and PINC bit of the DMA_CCRx register. Regardless of their usual naming, these ‘peripheral’ register, field and bit are used to define the source memory in memory-to-memory mode.
  - The *destination* attributes are defined by the DMA_MARx register, the MSIZE[1:0] field and MINC bit of the DMA_CCRx register. Regardless of their usual naming, these ‘memory’ register, field and bit are used to define the destination peripheral in peripheral-to-peripheral mode.

14.4.6 DMA data width, alignment and endianness

When PSIZE[1:0] and MSIZE[1:0] are not equal, the DMA controller performs some data alignments as described in Table 94.

### Addressing AHB peripherals not supporting byte/half-word write transfers

When the DMA controller initiates an AHB byte or half-word write transfer, the data are duplicated on the unused lanes of the AHB master 32-bit data bus (HWDATA[31:0]).

When the AHB slave peripheral does not support byte or half-word writes and does not generate any error, the DMA controller writes the 32 HWDATA bits as shown in the two examples below:

- To write the half-word 0xABCD, the DMA controller sets the HWDATA bus to 0xABCDAABC with a half-word data size (HSIZE = HalfWord in AHB master bus).
- To write the byte 0xAB, the DMA controller sets the HWDATA bus to 0xABABABAB with a byte data size (HSIZE = Byte in the AHB master bus).

Assuming the AHB/APB bridge is an AHB 32-bit slave peripheral that does not take into account the HSIZE data, any AHB byte or half-word transfer is changed into a 32-bit APB transfer as described below:

- An AHB byte write transfer of 0xB0 to one of the 0x0, 0x1, 0x2 or 0x3 addresses, is converted to an APB word write transfer of 0xB0B0B0B0 to the 0x0 address.
- An AHB half-word write transfer of 0xB1B0 to the 0x0 or 0x2 addresses, is converted to an APB word write transfer of 0xB1B0B1B0 to the 0x0 address.

### 14.4.7 DMA error management

A DMA transfer error is generated when reading from or writing to a reserved address space. When a DMA transfer error occurs during a DMA read or write access, the faulty channel x is automatically disabled through a hardware clear of its EN bit in the corresponding DMA_CCRx register.
The TEIFx bit of the DMA_ISR register is set. An interrupt is then generated if the TEIE bit of the DMA_CCRx register is set.

The EN bit of the DMA_CCRx register can not be set again by software (channel x re-activated) until the TEIFx bit of the DMA_ISR register is cleared (by setting the CTEIFx bit of the DMA_IFCR register).

When the software is notified with a transfer error over a channel which involves a peripheral, the software has first to stop this peripheral in DMA mode, in order to disable any pending or future DMA request. Then software may normally reconfigure both DMA and the peripheral in DMA mode for a new transfer.

Additionally, a security illegal access pulse signal is generated on an illegal non-secure software access to a secure DMA register. This signal is routed to the TrustZone interrupt controller.

### 14.5 DMA interrupts

An interrupt can be generated on a half transfer, transfer complete or transfer error for each DMA channel x (whatever the channel is secure or non-secure). Separate interrupt enable bits are available for flexibility.

### 14.6 DMA registers

Refer to Section 1.2 for a list of abbreviations used in register descriptions.

The DMA registers have to be accessed by words (32-bit).

#### 14.6.1 DMA interrupt status register (DMA_ISR)

Address offset: 0x00

Reset value: 0x0000 0000

This register may mix secure and non secure information, depending on the secure mode of each channel (SECM bit of the DMA_CCRx register). A secure software can read the full interrupt status. A non-secure software is restricted to read the status of non-secure channel(s), other secure bit fields returning zero.

This register may mix privileged and unprivileged information, depending on the privileged mode of each channel (PRIV bit of the DMA_CCRx register). A privileged software can read
the full interrupt status. An unprivileged software is restricted to read the status of unprivileged channel(s), other privileged bit fields returning zero.

Every status / flag bit is set by hardware, independently of the privileged and the secure mode of the channel.

Every status bit is cleared by hardware when the software sets the corresponding clear bit or the corresponding global clear bit CGIFx, in the DMA_IFCR register, provided that, if the channel x is in privileged mode and/or in secure mode, then the software access to DMA_IFCR is also privileged and/or secure.

14.6.2 DMA interrupt flag clear register (DMA_IFCR)

Address offset: 0x04
Reset value: 0x0000 0000

This register may mix secure and non secure information, depending on the secure mode of each channel (SECM bit of the DMA_CCRx register).

A secure software is able to set any flag clear bit of the DMA_IFCR, and order DMA hardware to clear any corresponding flag(s) in the DMA_ISR register.

A non-secure software is restricted to order DMA hardware to clear the non-secure flag(s) in the DMA_ISR, by setting any non-secure corresponding flag clear bit(s) of the DMA_IFCR register.

This register may mix privileged and unprivileged information, depending on the privileged mode of each channel (PRIV bit of the DMA_CCRx register).

A privileged software is able to set any flag clear bit of the DMA_IFCR, and order DMA hardware to clear any corresponding flag(s) in the DMA_ISR register.

An unprivileged software is restricted to order DMA hardware to clear the unprivileged flag(s) in the DMA_ISR, by setting any unprivileged corresponding flag clear bit(s) of the DMA_IFCR register.

Setting the global clear bit CGIFx of the channel x in this DMA_IFCR register, causes the DMA hardware to clear the corresponding GIFx bit and any individual flag among TEIFx, HTIFx, TCFIFx, in the DMA_ISR register.

Setting any individual clear bit among CTEIFx, CHIFx, CTCIFx in this DMA_IFCR register, causes the DMA hardware to clear the corresponding individual flag and the global flag GIFx in the DMA_ISR register, provided that none of the two other individual flags is set.

Writing 0 into any flag clear bit has no effect.

14.6.3 DMA channel x configuration register (DMA_CCRx)

Address offset: 0x08 + 0x14 * (x - 1), (x = 1 to 8)

Reset value: 0x0000 0000

This register contains secure and privileged information: the secure state and the privileged state of the channel x (SECM and PRIV control bits).

Modifying the SECM bit must be performed by a secure write access to this register. Modifying the PRIV bit must be performed by a privileged write access to this register.
Setting any of the DSEC or SSEC bits must be performed by a secure write access to this register.

Except SECM and PRIV control bits, any other register field is non-readable by a non-secure software if the SECM bit is set, and non-readable by an unprivileged software if the PRIV bit is set.

The register fields/bits PRIV, DSEC, SSEC, SECM, CT, DBM, MEM2MEM, PL[1:0], MSIZE[1:0], PSIZE[1:0], MINC, PINC, and DIR are read-only when EN = 1.

The states of MEM2MEM and CIRC bits must not be both high at the same time.

Bits 31:21  Reserved, must be kept at reset value.

Bit 20 **PRIV**: privileged mode
- This bit can only be set and cleared by a privileged software.
  - 0: disabled
  - 1: enabled

  *This bit must not be written when the channel is enabled (EN = 1).*

  *It is read-only when the channel is enabled (EN = 1).*

Bit 19 **DSEC**: security of the DMA transfer to the destination
- This bit can only be read, set or cleared by a secure software. It must be a privileged software if the channel is in privileged mode.
- This bit is cleared by hardware when the securely written data bit 17 is cleared (on a secure reconfiguration of the channel as non-secure).
- A non-secure read to this secure configuration bit returns 0.
- A non-secure write of 1 to this secure configuration bit has no impact on the register setting and an illegal access pulse is asserted.
- Destination (peripheral or memory) of the DMA transfer is defined by the direction DIR configuration bit.
  - 0: non-secure DMA transfer to the destination
  - 1: secure DMA transfer to the destination

  *This bit must not be written when the channel is enabled (EN = 1).*

  *It is read-only when the channel is enabled (EN = 1).*
Bit 18 **SSEC**: security of the DMA transfer from the source
This bit can only be accessed - read, set or cleared - by a secure software. It must be a privileged software if the channel is in privileged mode.
This bit is cleared by hardware when the securely written data bit 17 is cleared (on a secure reconfiguration of the channel as non-secure).
A non-secure read to this secure configuration bit returns 0.
A non-secure write of 1 to this secure configuration bit has no impact on the register setting and an illegal access pulse is asserted.
Source (peripheral or memory) of the DMA transfer is defined by the direction DIR configuration bit.
0: non-secure DMA transfer from the source
1: secure DMA transfer from the source
*This bit must not be written when the channel is enabled (EN = 1).*
*It is read-only when the channel is enabled (EN = 1).*

Bit 17 **SEC**: secure mode
This bit can only be set or cleared by a secure software.
0: non-secure channel
1: secure channel
*This bit must not be written when the channel is enabled (EN = 1).*
*It is read-only when the channel is enabled (EN = 1).*

Bit 16 **CT**: current target memory of DMA transfer in double-buffer mode
This bit is toggled by hardware at the end of each channel transfer in double-buffer mode.
0: memory 0 (addressed by the DMA_CMOAR pointer)
1: memory 1 (addressed by the DMA_CM1AR pointer)
*Note:* This bit is set and cleared by software (privileged/secure software if the channel is in privileged/secure mode).
*It must not be written when the channel is enabled (EN = 1).*
*It is read-only when the channel is enabled (EN = 1).*

Bit 15 **DBM**: double-buffer mode
This bit must be set only in memory-to-peripheral and peripheral-to-memory transfers (MEM2MEM=0). The CIRC bit must also be set in double buffer mode.
0: disabled (no memory address switch at the end of the DMA transfer)
1: enabled (memory address switched at the end of the DMA transfer)
*Note:* This bit is set and cleared by software (privileged/secure software if the channel is in privileged/secure mode).
*It must not be written when the channel is enabled (EN = 1).*
*It is read-only when the channel is enabled (EN = 1).*

Bit 14 **MEM2MEM**: memory-to-memory mode
0: disabled
1: enabled
*Note:* This bit is set and cleared by software (privileged/secure software if the channel is in privileged/secure mode).
*It must not be written when the channel is enabled (EN = 1).*
*It is read-only when the channel is enabled (EN = 1).*
Bits 13:12 **PL[1:0]:** priority level
- 00: low
- 01: medium
- 10: high
- 11: very high

*Note:* This field is set and cleared by software (privileged/secure software if the channel is in privileged/secure mode).
- It must not be written when the channel is enabled (EN = 1).
- It is read-only when the channel is enabled (EN = 1).

Bits 11:10 **MSIZE[1:0]:** memory size
Defines the data size of each DMA transfer to the identified memory.
- In memory-to-memory mode, this field identifies the memory source if DIR = 1 and the memory destination if DIR = 0.
- In peripheral-to-peripheral mode, this field identifies the peripheral source if DIR = 1 and the peripheral destination if DIR = 0.
- 00: 8 bits
- 01: 16 bits
- 10: 32 bits
- 11: reserved

*Note:* This field is set and cleared by software (privileged/secure software if the channel is in privileged/secure mode).
- It must not be written when the channel is enabled (EN = 1).
- It is read-only when the channel is enabled (EN = 1).

Bits 9:8 **PSIZE[1:0]:** peripheral size
Defines the data size of each DMA transfer to the identified peripheral.
- In memory-to-memory mode, this field identifies the memory destination if DIR = 1 and the memory source if DIR = 0.
- In peripheral-to-peripheral mode, this field identifies the peripheral destination if DIR = 1 and the peripheral source if DIR = 0.
- 00: 8 bits
- 01: 16 bits
- 10: 32 bits
- 11: reserved

*Note:* This field is set and cleared by software (privileged/secure software if the channel is in privileged/secure mode).
- It must not be written when the channel is enabled (EN = 1).
- It is read-only when the channel is enabled (EN = 1).

Bit 7 **MINC:** memory increment mode
Defines the increment mode for each DMA transfer to the identified memory.
- In memory-to-memory mode, this field identifies the memory source if DIR = 1 and the memory destination if DIR = 0.
- In peripheral-to-peripheral mode, this field identifies the peripheral source if DIR = 1 and the peripheral destination if DIR = 0.
- 0: disabled
- 1: enabled

*Note:* This bit is set and cleared by software (privileged/secure software if the channel is in privileged/secure mode).
- It must not be written when the channel is enabled (EN = 1).
- It is read-only when the channel is enabled (EN = 1).
Bit 6  **PINC**: peripheral increment mode
- Defines the increment mode for each DMA transfer to the identified peripheral.
- In memory-to-memory mode, this field identifies the memory destination if DIR = 1 and the memory source if DIR = 0.
- In peripheral-to-peripheral mode, this field identifies the peripheral destination if DIR = 1 and the peripheral source if DIR = 0.
0: disabled
1: enabled

*Note:* This bit is set and cleared by software (privileged/secure software if the channel is in privileged/secure mode).
- It must not be written when the channel is enabled (EN = 1).
- It is read-only when the channel is enabled (EN = 1).

Bit 5  **CIRC**: circular mode
0: disabled
1: enabled

*Note:* This bit is set and cleared by software (privileged/secure software if the channel is in privileged/secure mode).
- It must not be written when the channel is enabled (EN = 1).
- It is read-only when the channel is enabled (EN = 1).

Bit 4  **DIR**: data transfer direction
- This bit must be set only in memory-to-peripheral and peripheral-to-memory modes.
0: read from peripheral
  - Source attributes are defined by PSIZE and PINC, plus the DMA_CPARx register.
  - This is still valid in a memory-to-memory mode.
  - Destination attributes are defined by MSIZE and MINC, plus the DMA_CM0/1ARx register. This is still valid in a peripheral-to-peripheral mode.
1: read from memory
  - Destination attributes are defined by PSIZE and PINC, plus the DMA_CPARx register. This is still valid in a memory-to-memory mode.
  - Source attributes are defined by MSIZE and MINC, plus the DMA_CM0/1ARx register. This is still valid in a peripheral-to-peripheral mode.

*Note:* This bit is set and cleared by software (privileged/secure software if the channel is in privileged/secure mode).
- It must not be written when the channel is enabled (EN = 1).
- It is read-only when the channel is enabled (EN = 1).

Bit 3  **TEIE**: transfer error interrupt enable
0: disabled
1: enabled

*Note:* This bit is set and cleared by software (privileged/secure software if the channel is in privileged/secure mode).
- It must not be written when the channel is enabled (EN = 1).
- It is not read-only when the channel is enabled (EN = 1).
Bit 2 **HTIE**: half transfer interrupt enable

- **0**: disabled
- **1**: enabled

*Note*: This bit is set and cleared by software (privileged/secure software if the channel is in privileged/secure mode).

- It must not be written when the channel is enabled (EN = 1).
- It is not read-only when the channel is enabled (EN = 1).

Bit 1 **TCIE**: transfer complete interrupt enable

- **0**: disabled
- **1**: enabled

*Note*: This bit is set and cleared by software (privileged/secure software if the channel is in privileged/secure mode).

- It must not be written when the channel is enabled (EN = 1).
- It is not read-only when the channel is enabled (EN = 1).

Bit 0 **EN**: channel enable

When a channel transfer error occurs, this bit is cleared by hardware. It can not be set again by software (channel x re-activated) until the TEIFx bit of the DMA_ISR register is cleared (by setting the CTEIFx bit of the DMA_IFCR register).

- **0**: disabled
- **1**: enabled

*Note*: This bit is set and cleared by software (privileged/secure software if the channel is in privileged/secure mode).

### 14.6.4 DMA channel x number of data to transfer register (DMA_CNDTRx)

Address offset: 0x0C + 0x14 * (x - 1), (x = 1 to 8)

Reset value: 0x0000 0000

</tbody>
</table>

Bits 31:18 Reserved, must be kept at reset value.

Bits 17:0 **NDT[17:0]**: number of data to transfer (0 to \(2^{18} - 1\))

This field is updated by hardware when the channel is enabled:

- It is decremented after each single DMA 'read followed by write' transfer, indicating the remaining amount of data items to transfer.
- It is kept at zero when the programmed amount of data to transfer is reached, if the channel is not in circular mode (CIRC = 0 in the DMA_CCRx register).
- It is reloaded automatically by the previously programmed value, when the transfer is complete, if the channel is in circular mode (CIRC = 1).

If this field is zero, no transfer can be served whatever the channel status (enabled or not).

*Note*: This field is set and cleared by software (privileged/secure software if the channel is in privileged/secure mode).

- It must not be written when the channel is enabled (EN = 1).
- It is read-only when the channel is enabled (EN = 1).
14.6.5 DMA channel x peripheral address register (DMA_CPARx)

Address offset: 0x10 + 0x14 * (x - 1), (x = 1 to 8)
Reset value: 0x0000 0000

Bits 31:0 PA[31:0]: peripheral address
- It contains the base address of the peripheral data register from/to which the data is read/written.
- When PSIZE[1:0] = 01 (16 bits), bit 0 of PA[31:0] is ignored. Access is automatically aligned to a half-word address.
- When PSIZE = 10 (32 bits), bits 1 and 0 of PA[31:0] are ignored. Access is automatically aligned to a word address.
- In memory-to-memory mode, this register identifies the memory destination address if DIR = 1 and the memory source address if DIR = 0.
- In peripheral-to-peripheral mode, this register identifies the peripheral destination address DIR = 1 and the peripheral source address if DIR = 0.

Note: This register is set and cleared by software (privileged/secure software if the channel is in privileged/secure mode).
It must not be written when the channel is enabled (EN = 1).
It is read-only when the channel is enabled (EN = 1).

14.6.6 DMA channel x memory 0 address register (DMA_CM0ARx)

Address offset: 0x14 + 0x14 * (x - 1), (x = 1 to 8)
Reset value: 0x0000 0000

Bits 31:0 MA[31:0]: memory address
- It contains the base address of the memory destination address in memory-to-memory mode.
- It contains the base address of the peripheral destination address in peripheral-to-peripheral mode.

Note: This register is set and cleared by software (privileged/secure software if the channel is in privileged/secure mode).
It must not be written when the channel is enabled (EN = 1).
It is read-only when the channel is enabled (EN = 1).
Bits 31:0 **MA[31:0]:** peripheral address

It contains the base address of the memory from/to which the data is read/written.

- When MSIZE[1:0] = 01 (16 bits), bit 0 of MA[31:0] is ignored. Access is automatically aligned to a half-word address.
- When MSIZE = 10 (32 bits), bits 1 and 0 of MA[31:0] are ignored. Access is automatically aligned to a word address.

In memory-to-memory mode, this register identifies the memory source address if DIR = 1 and the memory destination address if DIR = 0.
In peripheral-to-peripheral mode, this register identifies the peripheral source address DIR = 1 and the peripheral destination address if DIR = 0.

**Note:** This register is set and cleared by software (privileged/secure software if the channel is in privileged/secure mode).

It must not be written when the channel is enabled (EN = 1).
It is read-only when the channel is enabled (EN = 1).

### 14.6.7 DMA channel x memory 1 address register (DMA_CM1ARx)

Refer to Section 2.3 for the register boundary addresses.
15 DMA request multiplexer (DMAMUX)

15.1 Introduction

A peripheral indicates a request for DMA transfer by setting its DMA request signal. The DMA request is pending until it is served by the DMA controller that generates a DMA acknowledge signal, and the corresponding DMA request signal is deasserted.

In this document, the set of control signals required for the DMA request/acknowledge protocol is not explicitly shown or described, and it is referred to as DMA request line.

The DMAMUX request multiplexer enables routing a DMA request line between the peripherals and the DMA controllers of the product. The routing function is ensured by a programmable multi-channel DMA request line multiplexer. Each channel selects a unique DMA request line, unconditionally or synchronously with events from its DMAMUX synchronization inputs. The DMAMUX may also be used as a DMA request generator from programmable events on its input trigger signals.

The number of DMAMUX instances and their main characteristics are specified in Section 15.3.1.

The assignment of DMAMUX request multiplexer inputs to the DMA request lines from peripherals and to the DMAMUX request generator outputs, the assignment of DMAMUX request multiplexer outputs to DMA controller channels, and the assignment of DMAMUX synchronizations and trigger inputs to internal and external signals depend on the product implementation, and are detailed in Section 15.3.2.
15.2 DMAMUX main features

- 16-channel programmable DMA request line multiplexer output
- 4-channel DMA request generator
- 23 trigger inputs to DMA request generator
- 23 synchronization inputs
- Per DMA request generator channel:
  - DMA request trigger input selector
  - DMA request counter
  - Event overrun flag for selected DMA request trigger input
- Per DMA request line multiplexer channel output:
  - 90 input DMA request lines from peripherals
  - One DMA request line output
  - Synchronization input selector
  - DMA request counter
  - Event overrun flag for selected synchronization input
  - One event output, for DMA request chaining
- TrustZone support:
  - Support for AHB secure and non-secure DMA transfers, independently at a channel level.
  - TrustZone-aware AHB slave port, protecting any secure resource (register, register field) from a non-secure software access, with configurable interrupt event.
  - Two secure and non-secure interrupt requests, resulting from any of the respectively secure and non-secure channels. Each channel event being caused from any of the two DMAMUX input events: trigger or synchronization overrun, associated with a respectively secure and non-secure channels.
- Privileged / Unprivileged support:
  - Support for AHB privileged and unprivileged DMA transfers, independently, at a channel level.
  - Privileged-aware AHB slave port.

15.3 DMAMUX implementation

15.3.1 DMAMUX instantiation

DMAMUX is instantiated with the hardware configuration parameters listed in the following table.

<table>
<thead>
<tr>
<th>Feature</th>
<th>DMAMUX</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of DMAMUX output request channels</td>
<td>16</td>
</tr>
<tr>
<td>Number of DMAMUX request generator channels</td>
<td>4</td>
</tr>
<tr>
<td>Number of DMAMUX request trigger inputs</td>
<td>23</td>
</tr>
</tbody>
</table>
15.3.2 DMAMUX mapping

The mapping of resources to DMAMUX is hardwired.

DMAMUX is used with DMA1 and DMA2:
- DMAMUX channels 0 to 7 are connected to DMA1 channels 0 to 7
- DMAMUX channels 8 to 15 are connected to DMA2 channels 0 to 7

15.4 DMAMUX functional description

15.4.1 DMAMUX block diagram

Figure 44 shows the DMAMUX block diagram.

Figure 44. DMAMUX block diagram

DMAMUX features two main sub-blocks: the request line multiplexer and the request line generator.

The implementation assigns:

- DMAMUX request multiplexer sub-block inputs (dmamux_reqx) from peripherals (dmamux_req_inx) and from channels of the DMAMUX request generator sub-block (dmamux_req_genx)
- DMAMUX request outputs to channels of DMA controllers (dmamux_req_outx)
- Internal or external signals to DMA request trigger inputs (dmamux_trgx)
- Internal or external signals to synchronization inputs (dmamux_syncx)
15.4.2 DMAMUX signals

Table 101 lists the DMAMUX signals.

</tbody>
</table>

15.4.3 DMAMUX channels

A DMAMUX channel is a DMAMUX request multiplexer channel that may include, depending on the selected input of the request multiplexer, an additional DMAMUX request generator channel.

A DMAMUX request multiplexer channel is connected and dedicated to one single channel of DMA controller(s).

Channel configuration procedure

Follow the sequence below to configure both a DMAMUX x channel and the related DMA channel y:

1. Set to secure or non-secure the DMA channel y by a secure write access to the secure control bit of the DMA channel y configuration register, and set to privileged or unprivileged the DMA channel y by a privileged write access to the privileged control bit of the DMA channel y configuration register.
2. Set and configure completely the DMA channel y, except enabling the channel y.
3. Set and configure completely the related DMAMUX y channel.
4. Last, activate the DMA channel y by setting the EN bit in the DMA y channel register.
15.4.4 DMAMUX secure/non-secure channels

The DMAMUX is a security-aware peripheral compliant with the TrustZone hardware architecture, partitioning all its resources so that they exist in one of the two worlds: the secure world and the normal/non-secure world, at any given time. The DMAMUX security is controlled by software at channel level. Any DMAMUX channel is in secure or non-secure state, as configured by the secure register bit of the associated channel of the DMA controller(s).

**Note:** A DMA controller(s) channel must be first configured as secure or non-secure, before the configuration of the connected DMAMUX channel.

**Note:** A secure software is able to access any DMAMUX register, whatever secure or non-secure. A non-secure software is restricted to access only non-secure DMAMUX register or non-secure register fields.

A secure read/write access is a read/write transaction on AHB slave with the signal HNONSEC = 0 (at the clock cycle of the address sampling). On the contrary, a non-secure read/write access is a read/write transaction on AHB slave with the signal HNONSEC = 1. When a channel is configured in secure mode, its configuration register fields become secure resources, meaning that:

- A non-secure read access to a (secure register) field is forced to return 0.
- A non-secure write access to a (secure register) field has no impact.

Additionally, an illegal access signal is generated, as a pulse, to the TrustZone interrupt controller, when a non-secure software attempts to access a secure DMAMUX register:

- DMAMUX_CxCR if the request multiplexer channel x is secure.
- DMAMUX_RGxCR if the request generator channel x is secure.

**Note:** The secure illegal access signal is never asserted on a non-secure access to the global interrupt status and clear registers, even despite all the DMAMUX channels are set as secure.

15.4.5 DMAMUX privileged / unprivileged channels

The DMAMUX is aware of the privileged or unprivileged state of a given DMA connected channel, and manages consequently its DMAMUX requested channel.

**Note:** A DMA controller(s) channel must be first configured as privileged or unprivileged, before the configuration of the connected DMAMUX channel.

**Note:** A privileged software is able to access any DMAMUX register, privileged or unprivileged. An unprivileged software is restricted to access only unprivileged DMAMUX register or register fields.

When a privileged software configures a DMA channel x either as privileged, an unprivileged software is not able to access (write is ignored, read returns zero) the related DMAMUX channel registers or register fields.

15.4.6 DMAMUX request line multiplexer

The DMAMUX request multiplexer with its multiple channels ensures the actual routing of DMA request/acknowledge control signals, named DMA request lines.

Each DMA request line is connected in parallel to all the channels of the DMAMUX request line multiplexer.
A DMA request is sourced either from the peripherals or from the DMAMUX request generator.

The DMAMUX request line multiplexer channel x selects the DMA request line number as configured by the DMAREQ_ID field in the DMAMUX_CxCR register.

**Note:** The null value in the field DMAREQ_ID corresponds to no DMA request line selected.

**Caution:** A same non-null DMAREQ_ID can be assigned to two different channels only if the application ensures that these channels are not requested to be served at the same time. In other words, if two different channels receive a same asserted hardware request at the same time, an unpredictable DMA hardware behavior occurs.

On top of the DMA request selection, the synchronization mode and/or the event generation may be configured and enabled, if required.

**Synchronization mode and channel event generation**

Each DMAMUX request line multiplexer channel x can be individually synchronized by setting the synchronization enable (SE) bit in the DMAMUX_CxCR register.

DMAMUX has multiple synchronization inputs. The synchronization inputs are connected in parallel to all the channels of the request multiplexer.

The synchronization input is selected via the SYNC_ID field in the DMAMUX_CxCR register of a given channel x.

When a channel is in this synchronization mode, the selected input DMA request line is propagated to the multiplexer channel output, once is detected a programmable rising/falling edge on the selected input synchronization signal, via the SPOL[1:0] field of the DMAMUX_CxCR register.

Additionally, there is a programmable DMA request counter, internally to the DMAMUX request multiplexer, which may be used for the channel request output generation and also possibly for an event generation. An event generation on the channel x output is enabled through the EGE bit (event generation enable) of the DMAMUX_CxCR register.

As shown in Figure 46, upon the detected edge of the synchronization input, the pending selected input DMA request line is connected to the DMAMUX multiplexer channel x output. 

**Note:** If a synchronization event occurs while there is no pending selected input DMA request line, it is discarded. The following asserted input request lines is not connected to the DMAMUX multiplexer channel output until a synchronization event occurs again.

From this point on, each time the connected DMAMUX request is served by the DMA controller (a served request is deasserted), the DMAMUX request counter is decremented. At its underrun, the DMA request counter is automatically loaded with the value in NBREQ field of the DMAMUX_CxCR register and the input DMA request line is disconnected from the multiplexer channel x output.

Thus, the number of DMA requests transferred to the multiplexer channel x output following a detected synchronization event, is equal to the value in NBREQ field, plus one.

**Note:** The NBREQ field value shall only be written by software when both synchronization enable bit SE and event generation enable EGE bit of the corresponding multiplexer channel x are disabled.
If EGE is enabled, the multiplexer channel generates a channel event, as a pulse of one AHB clock cycle, when its DMA request counter is automatically reloaded with the value of the programmed NBREQ field, as shown in Figure 45 and Figure 46.
Note: If EGE is enabled and NBREQ = 0, an event is generated after each served DMA request.

Note: A synchronization event (edge) is detected if the state following the edge remains stable for more than two AHB clock cycles.

Upon writing into DMAMUX_CxCR register, the synchronization events are masked during three AHB clock cycles.

**Synchronization overrun and interrupt**

If a new synchronization event occurs before the request counter underrun (the internal request counter programmed via the NBREQ field of the DMAMUX_CxCR register), the synchronization overrun flag bit SOFx is set in the DMAMUX_CSR status register.

Note: The request multiplexer channel x synchronization must be disabled (DMAMUX_CxCR.SE = 0) at the completion of the use of the related channel of the DMA controller. Else, upon a new detected synchronization event, there is a synchronization overrun due to the absence of a DMA acknowledge (that is, no served request) received from the DMA controller.

The overrun flag SOFx is reset by setting the associated clear synchronization overrun flag bit CSOFx in the DMAMUX_CCFR register.

Setting the synchronization overrun flag generates an interrupt if the synchronization overrun interrupt enable bit SOIE is set in the DMAMUX_CxCR register.

**15.4.7 DMAMUX request generator**

The DMAMUX request generator produces DMA requests following trigger events on its DMA request trigger inputs.

The DMAMUX request generator has multiple channels. DMA request trigger inputs are connected in parallel to all channels.

The outputs of DMAMUX request generator channels are inputs to the DMAMUX request line multiplexer.

Each DMAMUX request generator channel x has an enable bit GE (generator enable) in the corresponding DMAMUX_RGxCR register.

The DMA request trigger input for the DMAMUX request generator channel x is selected through the SIG_ID (trigger signal ID) field in the corresponding DMAMUX_RGxCR register.

Trigger events on a DMA request trigger input can be rising edge, falling edge or either edge. The active edge is selected through the GPOL (generator polarity) field in the corresponding DMAMUX_RGxCR register.

Upon the trigger event, the corresponding generator channel starts generating DMA requests on its output. Each time the DMAMUX generated request is served by the connected DMA controller (a served request is deasserted), a built-in (inside the DMAMUX request generator) DMA request counter is decremented. At its underrun, the request generator channel stops generating DMA requests and the DMA request counter is automatically reloaded to its programmed value upon the next trigger event.

Thus, the number of DMA requests generated after the trigger event is GNBREQ + 1.
Note: The GNBREQ field value must be written by software only when the enable GE bit of the corresponding generator channel x is disabled.

A trigger event (edge) is detected if the state following the edge remains stable for more than two AHB clock cycles.

Upon writing into DMAMUX_RGxCR register, the trigger events are masked during three AHB clock cycles.

**Trigger overrun and interrupt**

If a new DMA request trigger event occurs before the DMAMUX request generator counter underrun (the internal counter programmed via the GNBREQ field of the DMAMUX_RGxCR register), and if the request generator channel x was enabled via GE, then the request trigger event overrun flag bit OFx is asserted by the hardware in the status DMAMUX_RGSR register.

Note: The request generator channel x must be disabled (DMAMUX_RGxCR.GE = 0) at the completion of the usage of the related channel of the DMA controller. Else, upon a new detected trigger event, there is a trigger overrun due to the absence of an acknowledge (that is, no served request) received from the DMA.

The overrun flag OFx is reset by setting the associated clear overrun flag bit COFx in the DMAMUX_RGCFR register.

Setting the DMAMUX request trigger overrun flag generates an interrupt if the DMA request trigger event overrun interrupt enable bit OIE is set in the DMAMUX_RGxCR register.

### 15.5 DMAMUX interrupts

An interrupt can be generated upon:
- a synchronization event overrun in each DMA request line multiplexer channel
- a trigger event overrun in each DMA request generator channel

For each case, per-channel individual interrupt enable, status and clear flag register bits are available. As a consequence, there are mixed secure and non-secure status and clear flag bit fields inside a same global status and clear flag interrupt register, depending on the security of the considered DMAMUX channel.

There are two different secure and non-secure interrupt signals that may be generated, depending on the security of the DMAMUX channel.

15.6 DMAMUX registers

Refer to the table containing register boundary addresses for the DMAMUX base address.

DMAMUX registers may be accessed per (8-bit) byte, (16-bit) half-word, or (32-bit) word.
The address must be aligned with the data size.

15.6.1 DMAMUX request line multiplexer channel x configuration register (DMAMUX_CxCR)

Address offset: 0x000 + 0x04 * x (x = 0 to 15)
Reset value: 0x0000 0000

This register shall be written by a non-secure or secure write, according to the secure mode of the considered DMAMUX request line multiplexer channel x, depending on the secure mode bit of the connected DMA controller channel y. This assumes that the DMAMUX x channel output is connected to the y channel of the DMA (refer to the DMAMUX mapping implementation section).

This register shall be accessed by a privileged or unprivileged read/write, according to the privileged mode of the considered DMAMUX request line multiplexer channel x, depending on the privileged control bit of the connected DMA controller channel y. This assumes that the DMAMUX x channel output is connected to the y channel of the DMA (refer to the DMAMUX mapping implementation section).

</table>

Bits 31:29  Reserved, must be kept at reset value.

Bits 28:24  **SYNC_ID[4:0]**: Synchronization identification
Selects the synchronization input (see Table 100: DMAMUX: assignment of synchronization inputs to resources).

Bits 23:19  **NBREQ[4:0]**: Number of DMA requests minus 1 to forward
Defines the number of DMA requests to forward to the DMA controller after a synchronization event, and/or the number of DMA requests before an output event is generated.
This field shall only be written when both SE and EGE bits are low.

Bits 18:17  **SPOL[1:0]**: Synchronization polarity
Defines the edge polarity of the selected synchronization input:
00: No event, i.e. no synchronization nor detection.
01: Rising edge
10: Falling edge
11: Rising and falling edges

Bit 16  **SE**: Synchronization enable
0: synchronization disabled
1: synchronization enabled

Bits 15:10  Reserved, must be kept at reset value.
15.6.2 DMAMUX request line multiplexer interrupt channel status register (DMAMUX_CSR)

Address offset: 0x080
Reset value: 0x0000 0000

This register must be accessed at bit level by a non-secure or secure read, according to the secure mode of the considered DMAMUX request line multiplexer channel x, depending on the secure mode bit of the connected DMA controller channel y, and considering that the DMAMUX x channel output is connected to the y channel of the DMA (refer to the DMAMUX mapping implementation section).

```
  31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
  15 14 13 12 11 10  9  8  7  6  5  4  3  2  1  0
SOF15 SOF14 SOF13 SOF12 SOF11 SOF10 SOF9 SOF8 SOF7 SOF6 SOF5 SOF4 SOF3 SOF2 SOF1 SOF0
```

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 SOF[15:0]: Synchronization overrun event flag
The flag is set when a synchronization event occurs on a DMA request line multiplexer channel x, while the DMA request counter value is lower than NBREQ.
The flag is cleared by writing 1 to the corresponding CSOFx bit in DMAMUX_CCFR register.

15.6.3 DMAMUX request line multiplexer interrupt channel clear flag register (DMAMUX_CCFR)

Address offset: 0x084
Reset value: 0x0000 0000

This register must be written at bit level by a non-secure or secure write, according to the secure mode of the considered DMAMUX request line multiplexer channel x, depending on the secure control bit of the connected DMA controller channel y, and considering that the DMAMUX x channel output is connected to the y channel of the DMA (refer to the DMAMUX mapping implementation section).

This register must be written at bit level by an unprivileged or privileged write, according to the privileged mode of the considered DMAMUX request line multiplexer channel x,
depending on the privileged control bit of the connected DMA controller channel y, and
considering that the DMAMUX x channel output is connected to the y channel of the DMA
(refer to the DMAMUX mapping implementation section).

</table>

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **CSOF[15:0]**: Clear synchronization overrun event flag
Writing 1 in each bit clears the corresponding overrun flag SOFx in the DMAMUX_CSR register.

### 15.6.4 DMAMUX request generator channel x configuration register (DMAMUX_RGxCR)

Address offset: 0x100 + 0x04 * x (x = 0 to 3)
Reset value: 0x0000 0000

This register shall be written by a non-secure or secure write, according to the secure mode
of the considered DMAMUX request line multiplexer channel y it is assigned to, and
considering that the DMAMUX request generator x channel output is selected by the y
channel of the DMAMUX request line channel (refer to DMAMUX_CyCR.DMAREQ_ID[7:0]
and to the DMAMUX mapping implementation section).

This register shall be written by an unprivileged or privileged write, according to the
privileged mode of the considered DMAMUX request line multiplexer channel y it is
assigned to, and considering that the DMAMUX request generator x channel output is
selected by the y channel of the DMAMUX request line channel (refer to
DMAMUX_CyCR.DMAREQ_ID[7:0] and to the DMAMUX mapping implementation section).

</table>

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:19 **GBNBREQ[4:0]**: Number of DMA requests to be generated (minus 1)
Defines the number of DMA requests to be generated after a trigger event. The actual
number of generated DMA requests is GNBREQ +1.

*Note: This field must be written only when GE bit is disabled.*
Bits 18:17 **GPOL[1:0]**: DMA request generator trigger polarity
- Defines the edge polarity of the selected trigger input
  - 00: No event, i.e. no trigger detection nor generation.
  - 01: Rising edge
  - 10: Falling edge
  - 11: Rising and falling edges

Bit 16 **GE**: DMA request generator channel x enable
- 0: DMA request generator channel x disabled
- 1: DMA request generator channel x enabled

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **OIE**: Trigger overrun interrupt enable
- 0: Interrupt on a trigger overrun event occurrence is disabled
- 1: Interrupt on a trigger overrun event occurrence is enabled

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **SIG_ID[4:0]**: Signal identification
- Selects the DMA request trigger input used for the channel x of the DMA request generator

---

15.6.5 **DMAMUX request generator interrupt status register (DMAMUX_RGSR)**

Address offset: 0x140
Reset value: 0x0000 0000

This register shall be accessed at bit level by a non-secure or secure read, according to the secure mode of the considered DMAMUX request line multiplexer channel x, depending on the secure mode bit of the connected DMA controller channel y, and considering that the DMAMUX x channel output is connected to the y channel of the DMA (refer to the DMAMUX mapping implementation section).

This register shall be accessed at bit level by an unprivileged or privileged read, according to the privileged mode of the considered DMAMUX request line multiplexer channel x, depending on the privileged control bit of the connected DMA controller channel y, and considering that the DMAMUX x channel output is connected to the y channel of the DMA (refer to the DMAMUX mapping implementation section).

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 **OF[3:0]**: Trigger overrun event flag
- The flag is set when a new trigger event occurs on DMA request generator channel x, before the request counter underrun (the internal request counter programmed via the GNBREQ field of the DMAMUX_RGxCR register).
- The flag is cleared by writing 1 to the corresponding COFx bit in the DMAMUX_RGCFR register.
15.6.6 DMAMUX request generator interrupt clear flag register (DMAMUX_RGCFR)

Address offset: 0x144
Reset value: 0x0000 0000

This register shall be written at bit level by a non-secure or secure write, according to the secure mode of the considered DMAMUX request line multiplexer channel y it is assigned to, and considering that the DMAMUX request generator x channel output is selected by the y channel of the DMAMUX request line channel (refer to DMAMUX_CyCR.DMAREQ_ID[7:0] and to the DMAMUX mapping implementation section).

This register shall be written at bit level by an unprivileged or privileged write, according to the privileged mode of the considered DMAMUX request line multiplexer channel y it is assigned to, and considering that the DMAMUX request generator x channel output is selected by the y channel of the DMAMUX request line channel (refer to DMAMUX_CyCR.DMAREQ_ID[7:0] and to the DMAMUX mapping implementation section).

Refer to Section 2.3 on page 87 for the register boundary addresses.
16 Nested vectored interrupt controller (NVIC)

16.1 NVIC main features

- 109 maskable interrupt channels (not including the 16 Cortex®-M33 with FPU interrupt lines)
- 8 programmable priority levels (3 bits of interrupt priority are used)
- Low-latency exception and interrupt handling
- Power management control
- Implementation of system control registers

The NVIC and the processor core interface are closely coupled, which enables low latency interrupt processing and efficient processing of late arriving interrupts.

The NVIC registers are banked across secure and non-secure states.

All interrupts including the core exceptions are managed by the NVIC.

16.2 SysTick calibration value register

The Cortex®-M33 with TrustZone mainline security extension embeds two SysTick timers.

When TrustZone is activated, two SysTick timer are available:

- SysTick, secure instance.
- SysTick, non-secure instance.

When TrustZone is disabled, only one SysTick timer is available.

The SysTick timer calibration value (STCALIB) is 0x3E8. It gives a reference time base of 1 ms based on a SysTick clock frequency of 1 MHz. In order to match the 1 ms time base for an application Running at a given frequency, the SysTick reload value must be programmed as follows in the SYST_RVR register:

- SysTick clock source is CPU clock HCLK: reload value = (HCLK x STCALIB)-1
- SysTick clock source is external clock (HCLK/8): reload value = ((HCLK/8) x STCALIB)-1

The HCLK refers to AHB frequency value in MHz.

Example: SysTick clock source is CPU clock HCLK of 100 MHz, to match a time base of 1 ms:

- SysTick reload value = (100 x STCALIB) -1 = 0x1869F
### 16.3 Interrupt and exception vectors

The grey rows in Table 104 describe the vectors without specific position.

17 Extended interrupts and event controller (EXTI)

The extended interrupts and event controller (EXTI) manages the individual CPU and system wakeup through configurable and direct event inputs. It provides wakeup requests to the power control, and generates an interrupt request to the CPU NVIC and events to the CPU event input. For the CPU an additional event generation block (EVG) is needed to generate the CPU event signal.

The EXTI wakeup requests allow the system to be woken up from Stop modes.

The interrupt request and event request generation can be used also in Run modes.

The EXTI also includes the EXTI mux IOport selection.

17.1 EXTI main features

The EXTI main features are the following:

- 43 input events supported.
- All event inputs allow the possibility to wake up the system.
- Events which do not have an associated wakeup flag in the peripheral, have a flag in the EXTI and generate an interrupt to the CPU from the EXTI.
- Events can be used to generate a CPU wakeup event.

The asynchronous event inputs are classified in two groups:

- Configurable events (signals from I/Os or peripherals able to generate a pulse).
  The configurable events have the following features:
  - Selectable active trigger edge
  - Interrupt pending status register bits independent for the rising and falling edge
  - Individual interrupt and event generation mask, used for conditioning the CPU wakeup, interrupt and event generation
  - SW trigger possibility

- Direct events (interrupt and wakeup sources from peripherals having an associated flag which requires to be cleared in the peripheral).
  The direct events have the following features:
  - Fixed rising edge active trigger
  - No interrupt pending status register bit in the EXTI. (The interrupt pending status flag is provided by the peripheral generating the event.)
  - Individual interrupt and event generation mask, used for conditioning the CPU wakeup and event generation
  - No SW trigger possibility

- Secure events
  - The access to control and configuration bits of secure input events can be made secure and or privilege.

- EXTI IO port selection.
17.2 EXTI block diagram

The EXTI consists of a register block accessed via an AHB interface, the event input trigger block, the masking block, and EXTI mux as shown in Figure 47.

The register block contains all the EXTI registers.

The event input trigger block provides event input edge trigger logic.

The masking block provides the event input distribution to the different wakeup, interrupt and event outputs, and their masking.

The EXTI mux provides the IO port selection on to the EXTI event signal.

17.2.1 EXTI connections between peripherals and CPU

The peripherals able to generate wakeup or interrupt events when the system is in Stop mode are connected to the EXTI.

- Peripheral wakeup signals which generate a pulse or which do not have an interrupt status bits in the peripheral, are connected to an EXTI configurable event input. For these events the EXTI provides a status pending bit which requires to be cleared. It is the EXTI interrupt associated with the status bit that will interrupt the CPU.

- Peripheral interrupt and wakeup signals that have a status bit in the peripheral which requires to be cleared in the peripheral, are connected to an EXTI direct event input. There is no status pending bit within the EXTI. The interrupt or wakeup is cleared by the CPU in the peripheral. It is the peripheral interrupt that interrupts the CPU directly.

- All GPIO ports input to the EXTI multiplexer, allowing the selection of a port pin to wake up the system via a configurable event.

The EXTI configurable event interrupts are connected to the NVIC of the CPU.

The dedicated EXTI/EVG CPU event is connected to the CPU rxev input.

The EXTI CPU wakeup signals are connected to the PWR block, and are used to wake up the system and CPU sub-system bus clocks.

17.2.2 EXTI interrupt/event mapping

The EXTI lines are connected as shown in Table 107: EXTI line connections.

17.3 EXTI functional description

Depending on the EXTI event input type and wakeup target(s), different logic implementations are used. The applicable features are controlled from register bits:

- Active trigger edge enable, by rising edge selection
  EXTI rising trigger selection register (EXTI_RTSR1), EXTI rising trigger selection register (EXTI_RTSR2), and falling edge selection
  EXTI falling trigger selection register (EXTI_FTSR1), EXTI falling trigger selection register (EXTI_FTSR2).

- Software trigger, by
  EXTI software interrupt event register (EXTI_SWIER1), EXTI software interrupt event register (EXTI_SWIER2).

- Interrupt pending flag, by
  EXTI rising edge pending register (EXTI_RPR1), EXTI falling edge pending register (EXTI_FPR1), EXTI rising edge pending register (EXTI_RPR2), EXTI falling edge pending register (EXTI_FPR2).

- CPU wakeup and interrupt enable, by
  EXTI CPU wakeup with interrupt mask register (EXTI_IMR1), EXTI CPU wakeup with interrupt mask register (EXTI_IMR2).

- CPU wakeup and event enable, by
  EXTI CPU wakeup with event mask register (EXTI_EMR2).

1. Only for input events with configuration “rxev generation” enabled.

17.3.1 EXTI configurable event input wakeup

Figure 48 is a detailed representation of the logic associated with configurable event inputs which wakeup the CPU sub-system bus clocks and generated an EXTI pending flag and interrupt to the CPU and or a CPU wakeup event.
1. Only for the input events that support CPU rxev generation c_event.

The software interrupt event register allows to trigger configurable events by software, writing the corresponding register bit, irrespective of the edge selection setting.

The rising edge and falling edge selection registers allow the enabling and selection of the configurable event active trigger edge or both edges.

The CPU has its dedicated wakeup (interrupt) mask register and a dedicated event mask registers. The enabled event make it possible to generate an event on the CPU. All events for a CPU are ordered together into a single CPU event signal. The event pending registers (EXTI_RPR and EXTI_FPR) is not set for an unmasked CPU event.

The configurable events have unique interrupt pending request registers, shared by the CPU. The pending register is only set for an unmasked interrupt. Each configurable event provides a common interrupt to the CPU. The configurable event interrupts need to be acknowledged by software in the EXTI_RPR and/or EXTI_FPR registers.

When a CPU wakeup (interrupt) or CPU event is enabled the asynchronous edge detection circuit is reset by the clocked delay and rising edge detect pulse generator. This guarantees that the EXTI hclk clock is woken up before the asynchronous edge detection circuit is reset.

**Note:** A detected configurable event interrupt pending request, may be cleared by any CPU with the correct access permission. The system is not able to enter into low-power modes as long as an interrupt pending request is active.
17.3.2 EXTI direct event input wakeup

Figure 49 is a detailed representation of the logic associated with direct event inputs waking up the system.

The direct events do not have an associated EXTI interrupt. The EXTI only wakes up the system and CPU sub-system clocks and may generate a CPU wakeup event. The peripheral synchronous interrupt, associated with the direct wakeup event wakes up the CPU.

The EXTI direct event is able to generate a CPU event. This CPU event wakes up the CPU. The CPU event may occur before the associated peripheral interrupt flag is set.

1. Only for the input events that support CPU rxev generation c_event.

17.3.3 EXTI mux selection

The EXTI mux allow the selection of GPIOs as interrupts and wakeup. The GPIOs are connected via 16 EXTI mux lines to the first 16 EXTI events as configurable event. The selection of GPIO port as EXTI mux output, is controlled by registers: EXTI external interrupt selection register (EXTI_EXTICRn).
The EXTI mux outputs are available as output signals from the EXTI to trigger other IPs. The EXTI mux outputs are available independent from any masking in EXTI_IMRx and EXTI_EMRx.

### 17.4 EXTI functional behavior

The direct event inputs are enabled in the respective peripheral generating the wakeup event. The configurable events are enabled by enabling at least one of the trigger edges. Once an event input is enabled, the generation of a CPU wakeup is conditioned by the CPU interrupt mask and CPU event mask.

Table 109. Masking functionality

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

1. The single exti(n) interrupt will go to the CPU. If no interrupt is required for CPU, the exti(n) interrupt shall be masked in the CPU NVIC.

2. Only if CPU interrupt is enabled in EXTI_IMR.IMn.

For configurable event inputs, when the enabled edge(s) occur on the event input, an event request is generated. When the associated CPU interrupt is unmasked the corresponding pending bit EXTI_RPR.RPIFn and/or EXTI_FPR.FPIFn is/are set and the CPU sub-system is woken up and CPU interrupt signal is activated. The EXTI_RPR.RPIFn and/or EXTI_FPR.FPIFn pending bit shall be cleared by software writing it to ‘1’. This action clears the CPU interrupt.

For direct event inputs, when enabled in the associated peripheral, an event request is generated on the rising edge only. There is no corresponding CPU pending bit in the EXTI.
When the associated CPU interrupt is unmasked, the corresponding CPU sub-system is woken up. The CPU is woken up (interrupted) by the peripheral synchronous interrupt.

The CPU event has to be unmasked to generate an event. When the enabled edge(s) occur on the event input a CPU event pulse is generated. There is no event pending bit.

For the configurable event inputs an event request can be generated by software when writing a ‘1’ in the software interrupt/event register EXTI_SWIER, allowing the generation of a rising edge on the event. The rising edge event pending bit is set in EXTI_RPR, irrespective of the setting in EXTI_RTSR.

### 17.5 EXTI event protection

The EXTI is able to protect event register bits from being modified by non-secure and unprivileged accesses. The protection can individually be activated per input event via the register bits in EXTI_SECCFGR and EXTI_PRIVCFGR. At EXTI level the protection consists in preventing unauthorized write access to:

- Change the settings of the secure and/or privileged configurable events.
- Change the masking of the secure and/or privileged input events.
- Clear pending status of the secure and/or privileged input events.

#### Table 110. Register protection overview

<td>RW</td>
<td></td>
</tr>
</tbody>
</table>

1. Security is enabled with the individual Input event. EXTI_SECCFG registers.
2. Privilege is enabled with the individual Input event EXTI_PRIVCFGRn registers.

#### 17.5.1 EXTI security protection

When security is enabled for an input event, the associated input event configuration and control bits can only be modified and read by a secure access, a non-secure write access is discarded and a read returns 0.
When input events are non-secure, the security is disabled. The associated input event configuration and control bits can be modified and read by a secure access and non-secure access.

The security configuration in registers EXTI_SECCFGR can be globally locked after reset by EXTI_LOCKR.LOCK.

### 17.5.2 EXTI privilege protection

When privilege is enabled for an input event, the associated input event configuration and control bits can only be modified and read by a privilege access, an unprivileged write access is discarded and a read returns 0.

When input events are unprivileged, the privilege is disabled. The associated input event configuration and control bits can be modified and read by a privilege access and unprivileged access.

The privilege configuration in registers EXTI_PRIVCFGRn can be globally locked after reset by EXTI_LOCKR.LOCK.
17.6 EXTI registers

The EXTI register map is divided in the following sections:

<table>
<thead>
<tr>
<th>Table 111. EXTI register map sections</th>

Bits 31:23 Reserved, must be kept at reset value.
Bits 22:21 **RT[22:21]**: Rising trigger event configuration bit of configurable event input x \(^{(1)}\) (where x = 18 to 22)

- When SECx is disabled, RTx can be accessed with non-secure and secure access.
- When SECx is enabled, RTx can only be accessed with secure access. Non-secure write to this bit x is discarded, non-secure read returns 0.
- When EXTI_PRIVCFGRn.PRIVx is disabled, RTx can be accessed with unprivileged and privilege access.
- When EXTI_PRIVCFGRn.PRIVx is enabled, RTx can only be accessed with privilege access. Unprivileged write to this bit x is discarded, unprivileged read returns 0.

0: Rising trigger disabled (for event and Interrupt) for input line
1: Rising trigger enabled (for event and Interrupt) for input line

Bits 20:17 Reserved, must be kept at reset value.

Bits 16:0 **RT[16:0]**: Rising trigger event configuration bit of configurable event input x \(^{(1)}\) (where x = 0 to 16)

- When EXTI_SECCFGR SECx is disabled, RTx can be accessed with non-secure and secure access.
- When EXTI_SECCFGR SECx is enabled, RTx can only be accessed with secure access. Non-secure write to this bit x is discarded, non-secure read returns 0.
- When EXTI_PRIVCFGR PRIVx is disabled, RTx can be accessed with unprivileged and privilege access.
- When EXTI_PRIVCFGR PRIVx is enabled, RTx can only be accessed with privilege access. Unprivileged write to this bit x is discarded, unprivileged read returns 0.

0: Rising trigger disabled (for event and Interrupt) for input line
1: Rising trigger enabled (for event and Interrupt) for input line

1. The configurable event inputs are edge triggered, no glitch must be generated on these inputs.
   If a rising edge on the configurable event input occurs during writing of the register, the associated pending bit is not set.
   Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.

### 17.6.2 EXTI falling trigger selection register (EXTI_FTSR1)

**Address offset**: 0x004

**Reset value**: 0x0000 0000

Contains only register bits for configurable events.

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:21 **FT[22:21]**: Falling trigger event configuration bit of configurable event input x \(^{(1)}\) (where x = 18 to 22).

- When EXTI_SECCFGR.SECx is disabled, FTx can be accessed with non-secure and secure access.
- When EXTI_SECCFGR.SECx is enabled, FTx can only be accessed with secure access. Non-secure write to this FTx is discarded, non-secure read returns 0.
- When EXTI_PRIVCFGR.PRIVx is disabled, FTx can be accessed with unprivileged and privilege access.
- When EXTI_PRIVCFGR.PRIVx is enabled, FTx can only be accessed with privilege access. Unprivileged write to this FTx is discarded, unprivileged read returns 0.

0: Falling trigger disabled (for event and Interrupt) for input line
1: Falling trigger enabled (for event and Interrupt) for input line.

Bit 20:17 Reserved, must be kept at reset value.

Bits 16:0 **FT[16:0]**: Falling trigger event configuration bit of configurable event input x \(^{(1)}\) (where x = 0 to 16).

- When EXTI_SECCFGR.SECx is disabled, FTx can be accessed with non-secure and secure access.
- When EXTI_SECCFGR.SECx is enabled, FTx can only be accessed with secure access. Non-secure write to this FTx is discarded, non-secure read returns 0.
- When EXTI_PRIVCFGR.PRIVx is disabled, FTx can be accessed with unprivileged and privilege access.
- When EXTI_PRIVCFGR.PRIVx is enabled, FTx can only be accessed with privilege access. Unprivileged write to this FTx is discarded, unprivileged read returns 0.

0: Falling trigger disabled (for event and Interrupt) for input line
1: Falling trigger enabled (for event and Interrupt) for input line.

---

1. The configurable event inputs are edge triggered, no glitch must be generated on these inputs. If a falling edge on the configurable event input occurs during writing of the register, the associated pending bit is not set. Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.
Bits 31:23 Reserved, must be kept at reset value.

Bits 22:21 **SWI[22:21]**: Software interrupt on event x (where x = 18 to 22)
- When EXTI_SECCFGR.SECx is disabled, SWIx can be accessed with non-secure and secure access.
- When EXTI_SECCFGR.SECx is enabled, SWIx can only be accessed with secure access.
- Non-secure write to this SWIx is discarded, non-secure read returns 0.
- When EXTI_PRIVCFGPR.PRIVx is disabled, SWIx can be accessed with unprivileged and privilege access.
- When EXTI_PRIVCFGPR.PRIVx is enabled, SWIx can only be accessed with privilege access.
- Unprivileged write to this SWIx is discarded, unprivileged read returns 0.
- A software interrupt is generated independent from the setting in EXTI_RTSR and EXTI_FTSR. It always returns 0 when read.
  - 0: Writing 0 has no effect.
  - 1: Writing a 1 to this bit triggers a rising edge event on event x. This bit is auto cleared by HW.

Bit 20:17 Reserved, must be kept at reset value.

Bits 16:0 **SWI[16:0]**: Software interrupt on event x (where x = 18 to 22)
- When EXTI_SECCFGR.SECx is disabled, SWIx can be accessed with non-secure and secure access.
- When EXTI_SECCFGR.SECx is enabled, SWIx can only be accessed with secure access.
- Non-secure write to this SWIx is discarded, non-secure read returns 0.
- When EXTI_PRIVCFGPR.PRIVx is disabled, SWIx can be accessed with unprivileged and privilege access.
- When EXTI_PRIVCFGPR.PRIVx is enabled, SWIx can only be accessed with privilege access.
- Unprivileged write to this SWIx is discarded, unprivileged read returns 0.
- A software interrupt is generated independent from the setting in EXTI_RTSR and EXTI_FTSR. It always returns 0 when read.
  - 0: Writing 0 has no effect.
  - 1: Writing a 1 to this bit triggers a rising edge event on event x. This bit is auto cleared by HW.

**17.6.4 EXT burst edge pending register (EXTI_RPR1)**

17.6.5 EXTI falling edge pending register (EXTI_FPR1)

Address offset: 0x010

Reset value: 0x0000 0000

Contains only register bits for configurable events.
Bits 31:23  Reserved, must be kept at reset value.

Bits 22:21  **FPiF[22:21]**: configurable event inputs x falling edge pending bit (where x = 22 to 18)
When EXTI_SECCFGR.SECx is disabled, FPIFx can be accessed with non-secure and secure access.
When EXTI_SECCFGR.SECx is enabled, FPIFx can only be accessed with secure access. Non-secure write to this FPIFx is discarded, non-secure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, FPIFx can be accessed with unprivileged and privilege access.
When EXTI_PRIVCFGR.PRIVx is enabled, FPIFx can only be accessed with privilege access. Unprivileged write to this FPIFx is discarded, unprivileged read returns 0.
0: No falling edge trigger request occurred
1: Rising edge trigger request occurred
This bit is set when the falling edge event arrives on the configurable event line. This bit is cleared by writing a 1 into the bit.

Bit 20:17  Reserved, must be kept at reset value.

Bits 16:0  **FPiF[16:0]**: configurable event inputs x falling edge pending bit (where x = 0 to 16)
When EXTI_SECCFGR.SECx is disabled, FPIFx can be accessed with non-secure and secure access.
When EXTI_SECCFGR.SECx is enabled, FPIFx can only be accessed with secure access. Non-secure write to this FPIFx is discarded, non-secure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, FPIFx can be accessed with unprivileged and privilege access.
When EXTI_PRIVCFGR.PRIVx is enabled, FPIFx can only be accessed with privilege access. Unprivileged write to this FPIFx is discarded, unprivileged read returns 0.
0: No falling edge trigger request occurred
1: Rising edge trigger request occurred
This bit is set when the falling edge event arrives on the configurable event line. This bit is cleared by writing a 1 into the bit.

### 17.6.6 EXTI security configuration register (EXTI_SECCFGR1)

Address offset: 0x014
Reset value: 0x0000 0000

This register provides write access security, a non-secure write access is ignored and causes the generation of an illegal access event. A non-secure read returns the register data.

Contains only register bits for security capable input events.
17.6.7 EXTI privilege configuration register (EXTI_PRIVCFGR1)

Address offset: 0x018
Reset value: 0x0000 0000

This register provides privileged write access protection. An unprivileged read returns the register data.

Contains only register bits for security capable input events.

17.6.8 EXTI rising trigger selection register (EXTI_RTSR2)

Address offset: 0x020
Reset value: 0x0000 0000

Contains only register bits for configurable events.
17.6.9 EXTI falling trigger selection register (EXTI_FTSR2)

Address offset: 0x024
Reset value: 0x0000 0000
Contains only register bits for configurable events.

</table>

Bits 31:7 Reserved, must be kept at reset value.

Bits 6:3 FT[38:35]: Falling trigger event configuration bit of configurable event input x\(^{(1)}\) (where x = 35 to 38)
When EXTI_SECCFGR.SECx is disabled, FTx can be accessed with non-secure and secure access.
When EXTI_SECCFGR.SECx is enabled, FTx can only be accessed with secure access. Non-secure write to this FTx is discarded, non-secure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, FTx can be accessed with unprivileged and privilege access.
When EXTI_PRIVCFGR.PRIVx is enabled, FTx can only be accessed with privilege access. Unprivileged write to this FTx is discarded, unprivileged read returns 0.
0: Falling trigger disabled (for event and interrupt) for input line
1: Falling trigger enabled (for event and interrupt) for input line

1. The configurable event inputs are edge triggered, no glitch must be generated on these inputs. If a falling edge on the configurable event input occurs during writing of the register, the associated pending bit is not set. Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.
1. The configurable event inputs are edge triggered, no glitch must be generated on these inputs. If a falling edge on the configurable event input occurs during writing of the register, the associated pending bit is not set. Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.

17.6.10 EXTI software interrupt event register (EXTI_SWIER2)

Address offset: 0x028
Reset value: 0x0000 0000
Contains only register bits for configurable events.

</tr>
</tbody>
</table>

Bits 31:7 Reserved, must be kept at reset value.

Bits 6:3 **SWI[38:35]**: Software interrupt on event x (where x = 35 to 38)
- When EXTI_SECCFGR.SECx is disabled, SWIx can be accessed with non-secure and secure access.
- When EXTI_SECCFGR.SECx is enabled, SWIx can only be accessed with secure access. Non-secure write to this SWIx is discarded, non-secure read returns 0.
- When EXTI_PRIVCFGR.PRIVx is disabled, SWIx can be accessed with unprivileged and privilege access.
- When EXTI_PRIVCFGR.PRIVx is enabled, SWIx can only be accessed with privilege access. Unprivileged write to this SWIx is discarded, unprivileged read returns 0.

A software interrupt is generated independent from the setting in EXTI_RTSR and EXTI_FTSR. It always return 0 when read.
- 0: Writing 0 has no effect.
- 1: Writing a 1 to this bit triggers a rising edge event on event x+32. This bit is auto cleared by HW.

Bits 2:0 Reserved, must be kept at reset value.

17.6.11 EXTI rising edge pending register (EXTI_RPR2)

Address offset: 0x02C
Reset value: 0x0000 0000
Contains only register bits for configurable events.
### EXTI falling edge pending register (EXTI_FPR2)

**Address offset:** 0x030  
**Reset value:** 0x0000 0000  
**Contains only register bits for configurable events.**

| Bits 2:0  | Reserved, must be kept at reset value. |

**0:** No rising edge trigger request occurred  
**1:** Rising edge trigger request occurred  

This bit is set when the rising edge event or an EXTI_SWIER software trigger arrives on the configurable event line. This bit is cleared by writing a 1 into the bit.
Bits 31:7 Reserved, must be kept at reset value.

Bits 6:3 **FPIF[38:35]:** configurable event inputs \( x \) pending bit (where \( x = 35 \) to 38).
- When EXTI_SECCFGR.SECx is disabled, FPIFx can be accessed with non-secure and secure access.
- When EXTI_SECCFGR.SECx is enabled, FPIFx can only be accessed with secure access.
- Non-secure write to this FPIFx is discarded, non-secure read returns 0.
- When EXTI_PRIVCFGR.PRIVx is disabled, FPIFx can be accessed with unprivileged and privilege access.
- When EXTI_PRIVCFGR.PRIVx is enabled, FPIFx can only be accessed with privilege access.
  - Non-secure write to this FPIFx is discarded, unprivileged read returns 0.
  - 0: No falling edge trigger request occurred
  - 1: Rising edge trigger request occurred
    - This bit is set when the falling edge event arrives on the configurable event line. This bit is cleared by writing a 1 into the bit.

Bits 2:0 Reserved, must be kept at reset value.

### 17.6.13 EXTI security enable register (EXTI_SECCFGR2)

Address offset: 0x034

Reset value: 0x0000 0000

This register provides write access security, a non-secure write access is ignored and causes the generation of an illegal access event. A non-secure read returns the register data.

Contains only register bits for security capable Input events.

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:0 **SEC[42:32]:** Security enable on event input \( x \) (where \( x = 32 \) to 42)
- When EXTI_PRIVCFGRn.PRIVx is disabled, SECx can be accessed with privilege and unprivileged access.
- When EXTI_PRIVCFGRn.PRIVx is enabled, SECx can only be written with privilege access.
  - Unprivileged write to this SECx is discarded
  - 0: Event security disabled (non-secure)
  - 1: Event security enabled (secure)

### 17.6.14 EXTI privilege enable register (EXTI_PRIVCFGR2)

Address offset: 0x038

Reset value: 0x0000 0000
This register provides privileged write access protection, an unprivileged write access is discarded and causes the generation of an illegal access event. An unprivileged read returns the register data.

Contains only register bits for security capable Input events.

### Bits 31:11
Reserved, must be kept at reset value.

### Bits 10:0
**PRIV[42:32]:** Privilege enable on event input x (where x = 32 to 42)
- When EXTI\_SECCFGR.SECx is disabled, PRIVx can be accessed with secure and non-secure access.
- When EXTI\_SECCFGR.SECx is enabled, PRIVx can only be accessed with secure access.
- Non-secure write to this PRIVx is discarded.
  - 0: Event privilege disabled (unprivileged)
  - 1: Event security enabled (privileged)

### 17.6.15 EXTI external interrupt selection register (EXTI\_EXTICRn)

Address offset: 0x060 (EXTI\_EXTICR1) EXTI mux 0, 1, 2, 3 (m =0)
Address offset: 0x064 (EXTI\_EXTICR2) EXTI mux 4, 5, 6, 7 (m = 4)
Address offset: 0x068 (EXTI\_EXTICR3) EXTI mux 8, 9, 10, 11 (m = 8)
Address offset: 0x06C (EXTI\_EXTICR4) EXTI mux 12, 13, 14, 15 (m = 12)

Reset value: 0x0000 0000

EXTIm fields contain only the number of bits in line with the nb\_ioport configuration.
Bits 31:24 \textbf{EXTI}m+3[7:0]: EXTI\textsubscript{m+3} GPIO port selection (where m = 0, 4, 8, or 12 for respectively EXTI\textsubscript{EXTICR}[1:4]).

These bits are written by software to select the source input for EXTI\textsubscript{m+3} external interrupt. When EXTI\textsubscript{SECCFG}R.SEC(m+3) is disabled, EXTI\textsubscript{m+3} can be accessed with non-secure and secure access. When EXTI\textsubscript{SECCFG}R.SEC(m+3) is enabled, EXTI\textsubscript{m+3} can only be accessed with secure access. Non-secure write is discarded, non-secure read returns 0. When EXTI\textsubscript{PRIVCFG}R.PRIV(m+3) is disabled, EXTI\textsubscript{m+3} can be accessed with privilege and unprivileged access. When EXTI\textsubscript{PRIVCFG}R.PRIV(m+3) is enabled, EXTI\textsubscript{m+3} can only be accessed with privilege access. Unprivileged write to this bit is discarded.

</table>

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:0  IM[42:40]: CPU wakeup with interrupt mask on event input x \(^1\) (where x = 40 to 42).
- When EXTI_SECCFGR.SECx is disabled, IMx can be accessed with non-secure and secure access.
- When EXTI_SECCFGR.SECx is enabled, IMx can only be accessed with secure access. Non-secure write to this bit is discarded, non-secure read returns 0.
- When EXTI_PRIVCFGR.PRIVx is disabled, IMx can be accessed with privilege and unprivileged access.
- When EXTI_PRIVCFGR.PRIVx is enabled, IMx can only be accessed with privilege access. Unprivileged write to this bit is discarded.
  0: Wakeup with interrupt request from input event x is masked
  1: Wakeup with interrupt request from input event x is unmasked

Bit 7  Reserved, must be kept at reset value.

Bits 6:0  IM[38:32]: CPU wakeup with interrupt mask on event input x \(^1\) (where x = 32 to 38).
- When EXTI_SECCFGR.SECx is disabled, IMx can be accessed with non-secure and secure access.
- When EXTI_SECCFGR.SECx is enabled, IMx can only be accessed with secure access. Non-secure write to this bit is discarded, non-secure read returns 0.
- When EXTI_PRIVCFGR.PRIVx is disabled, IMx can be accessed with privilege and unprivileged access.
- When EXTI_PRIVCFGR.PRIVx is enabled, IMx can only be accessed with privilege access. Unprivileged write to this bit is discarded.
  0: Wakeup with interrupt request from input event x is masked
  1: Wakeup with interrupt request from input event x is unmasked

The reset value for configurable event inputs is set to ‘0’ in order to disable the interrupt by default.

17.6.20  EXTI CPU wakeup with event mask register (EXTI_EMR2)

Address offset: 0x094
Reset value: 0x0000 0000
### 17.6.21 EXTI register map

The following table gives the EXTI register map and the reset values.

| Offset | Register | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|--------|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|    |
| 0x000  | EXTI_RTSR1 |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

**Reset value**: U U U U U U U U U U U U U U U U U U U U
Extended interrupts and event controller (EXTI)

Refer to Section 2.3 on page 87 for the register boundary addresses.
18  Cyclic redundancy check calculation unit (CRC)

18.1  Introduction

The CRC (cyclic redundancy check) calculation unit is used to get a CRC code from 8-, 16- or 32-bit data word and a generator polynomial.

Among other applications, CRC-based techniques are used to verify data transmission or storage integrity. In the scope of the functional safety standards, they offer a means of verifying the Flash memory integrity. The CRC calculation unit helps compute a signature of the software during runtime, to be compared with a reference signature generated at link time and stored at a given memory location.

18.2  CRC main features

- Uses CRC-32 (Ethernet) polynomial: 0x4C11DB7
  \[x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1\]
- Alternatively, uses fully programmable polynomial with programmable size (7, 8, 16, 32 bits)
- Handles 8-, 16-, 32-bit data size
- Programmable CRC initial value
- Single input/output 32-bit data register
- Input buffer to avoid bus stall during calculation
- CRC computation done in 4 AHB clock cycles (HCLK) for the 32-bit data size
- General-purpose 8-bit register (can be used for temporary storage)
- Reversibility option on I/O data

18.3.3 CRC operation

The CRC calculation unit has a single 32-bit read/write data register (CRC_DR). It is used to input new data (write access), and holds the result of the previous CRC calculation (read access).

Each write operation to the data register creates a combination of the previous CRC value (stored in CRC_DR) and the new one. CRC computation is done on the whole 32-bit data word or byte by byte depending on the format of the data being written.

The CRC_DR register can be accessed by word, right-aligned half-word and right-aligned byte. For the other registers only 32-bit access is allowed.

The duration of the computation depends on data width:
- 4 AHB clock cycles for 32-bit
- 2 AHB clock cycles for 16-bit
- 1 AHB clock cycles for 8-bit

An input buffer allows a second data to be immediately written without waiting for any wait states due to the previous CRC calculation.

The data size can be dynamically adjusted to minimize the number of write accesses for a given number of bytes. For instance, a CRC for 5 bytes can be computed with a word write followed by a byte write.
The input data can be reversed, to manage the various endianness schemes. The reversing operation can be performed on 8 bits, 16 bits and 32 bits depending on the REV_IN[1:0] bits in the CRC_CR register.

For example: input data 0x1A2B3C4D is used for CRC calculation as:
- 0x58D43CB2 with bit-reversal done by byte
- 0xD458B23C with bit-reversal done by half-word
- 0xB23CD458 with bit-reversal done on the full word

The output data can also be reversed by setting the REV_OUT bit in the CRC_CR register.

The operation is done at bit level: for example, output data 0x11223344 is converted into 0x22CC4488.

The CRC calculator can be initialized to a programmable value using the RESET control bit in the CRC_CR register (the default value is 0xFFFFFFFF).

The initial CRC value can be programmed with the CRC_INIT register. The CRC_DR register is automatically initialized upon CRC_INIT register write access.

The CRC_IDR register can be used to hold a temporary value related to CRC calculation. It is not affected by the RESET bit in the CRC_CR register.

**Polynomial programmability**

The polynomial coefficients are fully programmable through the CRC_POL register, and the polynomial size can be configured to be 7, 8, 16 or 32 bits by programming the POLYSIZE[1:0] bits in the CRC_CR register. Even polynomials are not supported.

If the CRC data is less than 32-bit, its value can be read from the least significant bits of the CRC_DR register.

To obtain a reliable CRC calculation, the change on-fly of the polynomial value or size cannot be performed during a CRC calculation. As a result, if a CRC calculation is ongoing, the application must either reset it or perform a CRC_DR read before changing the polynomial.

The default polynomial value is the CRC-32 (Ethernet) polynomial: 0x4C11DB7.
18.4 CRC registers

18.4.1 CRC data register (CRC_DR)

Address offset: 0x00
Reset value: 0xFFFF FFFF

Bits 31:8  Reserved, must be kept at reset value.

Bit 7  REV_OUT: Reverse output data
This bit controls the reversal of the bit order of the output data.
0: Bit order not affected
1: Bit-reversed output format

Bits 6:5  REV_IN[1:0]: Reverse input data
These bits control the reversal of the bit order of the input data
00: Bit order not affected
01: Bit reversal done by byte
10: Bit reversal done by half-word
11: Bit reversal done by word

Bits 4:3  POLYSIZE[1:0]: Polynomial size
These bits control the size of the polynomial.
00: 32 bit polynomial
01: 16 bit polynomial
10: 8 bit polynomial
11: 7 bit polynomial

Bits 2:1  Reserved, must be kept at reset value.

Bit 0  RESET: RESET bit
This bit is set by software to reset the CRC calculation unit and set the data register to the value stored in the CRC_INIT register. This bit can only be set, it is automatically cleared by hardware.
18.4.4 CRC initial value (CRC_INIT)

Address offset: 0x10
Reset value: 0xFFFF FFFF

**Bits 31:0** CRC_INIT[31:0]: Programmable initial CRC value
This register is used to write the CRC initial value.

18.4.5 CRC polynomial (CRC_POL)

Address offset: 0x14
Reset value: 0x04C1 1DB7

**Bits 31:0** POL[31:0]: Programmable polynomial
This register is used to write the coefficients of the polynomial to be used for CRC calculation.
If the polynomial size is less than 32 bits, the least significant bits have to be used to program the correct value.
## 18.4.6 CRC register map

Refer to Section 2.3 on page 87 for the register boundary addresses.
19  Flexible static memory controller (FSMC)

19.1  Introduction

The flexible static memory controller (FSMC) includes two memory controllers:

- The NOR/PSRAM memory controller
- The NAND memory controller

This memory controller is also named flexible memory controller (FMC).

19.2  FMC main features

The FMC functional block makes the interface with: synchronous and asynchronous static memories, and NAND Flash memory. Its main purposes are:

- to translate AHB transactions into the appropriate external device protocol
- to meet the access time requirements of the external memory devices

All external memories share the addresses, data and control signals with the controller. Each external device is accessed by means of a unique chip select. The FMC performs only one access at a time to an external device.

The main features of the FMC controller are the following:

- Interface with static-memory mapped devices including:
  - Static random access memory (SRAM)
  - NOR Flash memory/OneNAND Flash memory
  - PSRAM (4 memory banks)
  - Ferroelectric RAM (FRAM)
  - NAND Flash memory with ECC hardware to check up to 8 Kbytes of data
- Interface with parallel LCD modules, supporting Intel 8080 and Motorola 6800 modes.
- Burst mode support for faster access to synchronous devices such as NOR Flash memory, PSRAM)
- Programmable continuous clock output for asynchronous and synchronous accesses
- 8-, 16-bit wide data bus
- Independent chip select control for each memory bank
- Independent configuration for each memory bank
- Write enable and byte lane select outputs for use with PSRAM, SRAM devices
- External asynchronous wait control
- Write FIFO with 16 x32-bit depth

The Write FIFO is common to all memory controllers and consists of:

- a Write Data FIFO which stores the AHB data to be written to the memory (up to 32 bits) plus one bit for the AHB transfer (burst or not sequential mode)
- a Write Address FIFO which stores the AHB address (up to 28 bits) plus the AHB data size (up to 2 bits). When operating in burst mode, only the start address is stored except when crossing a page boundary (for PSRAM). In this case, the AHB burst is broken into two FIFO entries.
At startup the FMC pins must be configured by the user application. The FMC I/O pins which are not used by the application can be used for other purposes.

The FMC registers that define the external device type and associated characteristics are usually set at boot time and do not change until the next reset or power-up. However, the settings can be changed at any time.

19.3 FMC block diagram

The FMC consists of the following main blocks:
- The AHB interface (including the FMC configuration registers)
- The NOR Flash/PSRAM/SRAM controller

The block diagram is shown in the figure below.

![FMC block diagram](image)
19.4 AHB interface

The AHB slave interface allows internal CPUs and other bus master peripherals to access the external memories.

AHB transactions are translated into the external device protocol. In particular, if the selected external memory is 16- or 8-bit wide, 32-bit wide transactions on the AHB are split into consecutive 16- or 8-bit accesses. The FMC chip select (FMC_NEx) does not toggle between the consecutive accesses except in case of Access mode D when the Extended mode is enabled.

The FMC generates an AHB error in the following conditions:

- When reading or writing to an FMC bank (Bank 1 to 4) which is not enabled.
- When reading or writing to the NOR Flash bank while the FACCEN bit is reset in the FMC_BCRx register.

The effect of an AHB error depends on the AHB master which has attempted the R/W access:

- If the access has been attempted by the Cortex®-M33 CPU, a hard fault interrupt is generated.
- If the access has been performed by a DMA controller, a DMA transfer error is generated and the corresponding DMA channel is automatically disabled.

The AHB clock (HCLK) is the reference clock for the FMC.

19.4.1 Supported memories and transactions

General transaction rules

The requested AHB transaction data size can be 8-, 16- or 32-bit wide whereas the accessed external device has a fixed data width. This may lead to inconsistent transfers.

Therefore, some simple transaction rules must be followed:

- AHB transaction size and memory data size are equal
  There is no issue in this case.
- AHB transaction size is greater than the memory size:
  In this case, the FMC splits the AHB transaction into smaller consecutive memory accesses to meet the external data width. The FMC chip select (FMC_NEx) does not toggle between the consecutive accesses. If the bus turnaround timings is configured
to any other value than 0, the FMC chip select (FMC_NEx) toggles between the consecutive accesses. This feature is required when interfacing with FRAM memory.

- AHB transaction size is smaller than the memory size:
  - The transfer may or not be consistent depending on the type of external device:
    - Accesses to devices that have the byte select feature (SRAM, ROM, PSRAM)
      In this case, the FMC allows read/write transactions and accesses the right data through its byte lanes NBL[1:0].
      Bytes to be written are addressed by NBL[1:0].
      All memory bytes are read (NBL[1:0] are driven low during read transaction) and the useless ones are discarded.
    - Accesses to devices that do not have the byte select feature (NOR and NAND Flash memories)
      This situation occurs when a byte access is requested to a 16-bit wide Flash memory. Since the device cannot be accessed in Byte mode (only 16-bit words can be read/written from/to the Flash memory), Write transactions and Read transactions are allowed (the controller reads the entire 16-bit memory word and uses only the required byte).

Wrap support for NOR Flash/PSRAM

Wrap burst mode for synchronous memories is not supported. The memories must be configured in Linear burst mode of undefined length.

Configuration registers

The FMC can be configured through a set of registers. Refer to Section 19.6.6, for a detailed description of the NOR Flash/PSRAM controller registers. Refer to Section 19.7.7, for a detailed description of the NAND Flash registers.

19.5 External device address mapping

From the FMC point of view, the external memory is divided into fixed-size banks of 256 Mbytes each (see Figure 53):

- Bank 1 used to address up to 4 NOR Flash memory or PSRAM devices. This bank is split into 4 NOR/PSRAM subbanks with 4 dedicated chip selects, as follows:
  - Bank 1 - NOR/PSRAM 1
  - Bank 1 - NOR/PSRAM 2
  - Bank 1 - NOR/PSRAM 3
  - Bank 1 - NOR/PSRAM 4
- Bank 3 used to address NAND Flash memory devices. The MPU memory attribute for this space must be reconfigured by software to Device.

For each bank the type of memory to be used can be configured by the user application through the Configuration register.
19.5.1 NOR/PSRAM address mapping

HADDR[27:26] bits are used to select one of the four memory banks as shown in Table 115.

Table 115. NOR/PSRAM bank selection

<table>
<thead>
<tr>
<th>Address</th>
<th>Bank</th>
<th>Supported memory type</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x6000 0000</td>
<td>Bank 1</td>
<td>NOR/PSRAM/SRAM</td>
</tr>
<tr>
<td>0x6FFFF FFFF</td>
<td>4 x 64 Mbyte</td>
<td></td>
</tr>
<tr>
<td>0x7000 0000</td>
<td>Not used</td>
<td></td>
</tr>
<tr>
<td>0x7FFFF FFFF</td>
<td></td>
<td></td>
</tr>
<tr>
<td>0x8000 0000</td>
<td>Bank 3</td>
<td>NAND Flash memory</td>
</tr>
<tr>
<td>0x8FFFF FFFF</td>
<td>4 x 64 Mbyte</td>
<td></td>
</tr>
<tr>
<td>0x9000 0000</td>
<td>Not used</td>
<td></td>
</tr>
<tr>
<td>0x9FFFF FFFF</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

1. HADDR are internal AHB address lines that are translated to external memory.

The HADDR[25:0] bits contain the external memory address. Since HADDR is a byte address whereas the memory is addressed at word level, the address actually issued to the memory varies according to the memory data width, as shown in the following table.

Table 116. NOR/PSRAM External memory address

<table>
<thead>
<tr>
<th>Memory width(1)</th>
<th>Data address issued to the memory</th>
<th>Maximum memory capacity (bits)</th>
</tr>
</thead>
<tbody>
<tr>
<td>8-bit</td>
<td>HADDR[25:0]</td>
<td>64 Mbytes x 8 = 512 Mbit</td>
</tr>
<tr>
<td>16-bit</td>
<td>HADDR[25:1] &gt;&gt; 1</td>
<td>64 Mbytes/2 x 16 = 512 Mbit</td>
</tr>
</tbody>
</table>

1. In case of a 16-bit external memory width, the FMC internally uses HADDR[25:1] to generate the address for external memory FMC_A[24:0]. Whatever the external memory width, FMC_A[0] should be connected to external memory address A[0].
19.5.2 NAND Flash memory address mapping

The NAND bank is divided into memory areas as indicated in Table 117.

Table 117. NAND memory mapping and timing registers

</tr>
</tbody>
</table>

For NAND Flash memory, the common and attribute memory spaces are subdivided into three sections (see in Table 118 below) located in the lower 256 Kbytes:

- Data section (first 64 Kbytes in the common/attribute memory space)
- Command section (second 64 Kbytes in the common / attribute memory space)
- Address section (next 128 Kbytes in the common / attribute memory space)

</tr>
<tr>
<td>Data section</td>
<td>00</td>
<td>0x000000-0x0FFFF</td>
</tr>
</tbody>
</table>

The application software uses the 3 sections to access the NAND Flash memory:

- **To sending a command to NAND Flash memory**, the software must write the command value to any memory location in the command section.
- **To specify the NAND Flash address that must be read or written**, the software must write the address value to any memory location in the address section. Since an address can be 4 or 5 bytes long (depending on the actual memory size), several consecutive write operations to the address section are required to specify the full address.
- **To read or write data**, the software reads or writes the data from/to any memory location in the data section.

Since the NAND Flash memory automatically increments addresses, there is no need to increment the address of the data section to access consecutive memory locations.
19.6 NOR Flash/PSRAM controller

The FMC generates the appropriate signal timings to drive the following types of memories:

- Asynchronous SRAM, FRAM and ROM
  - 8 bits
  - 16 bits
- PSRAM (CellularRAM™)
  - Asynchronous mode
  - Burst mode for synchronous accesses
  - Multiplexed or non-multiplexed
- NOR Flash memory
  - Asynchronous mode
  - Burst mode for synchronous accesses
  - Multiplexed or non-multiplexed

The FMC outputs a unique chip select signal, NE[4:1], per bank. All the other signals (addresses, data and control) are shared.

The FMC supports a wide range of devices through a programmable timings among which:

- Programmable wait states (up to 15)
- Programmable bus turnaround cycles (up to 15)
- Programmable output enable and write enable delays (up to 15)
- Independent read and write timings and protocol to support the widest variety of memories and timings
- Programmable continuous clock (FMC_CLK) output.

The FMC Clock (FMC_CLK) is a submultiple of the HCLK clock. It can be delivered to the selected external device either during synchronous accesses only or during asynchronous and synchronous accesses depending on the CCKEN bit configuration in the FMC_BCR1 register:

- If the CCLKEN bit is reset, the FMC generates the clock (CLK) only during synchronous accesses (Read/write transactions).
- If the CCLKEN bit is set, the FMC generates a continuous clock during asynchronous and synchronous accesses. To generate the FMC_CLK continuous clock, Bank 1 must be configured in Synchronous mode (see Section 19.6.6: NOR/PSRAM controller registers). Since the same clock is used for all synchronous memories, when a continuous output clock is generated and synchronous accesses are performed, the AHB data size has to be the same as the memory data width (MWID) otherwise the FMC_CLK frequency is changed depending on AHB data transaction (refer to Section 19.6.5: Synchronous transactions for FMC_CLK divider ratio formula).

The size of each bank is fixed and equal to 64 Mbytes. Each bank is configured through dedicated registers (see Section 19.6.6: NOR/PSRAM controller registers).

The programmable memory parameters include access times (see Table 119) and support for wait management (for PSRAM and NOR Flash accessed in Burst mode).

19.6.3 General timing rules

Signals synchronization

- All controller output signals change on the rising edge of the internal clock (HCLK)
- In Synchronous mode (read or write), all output signals change on the rising edge of HCLK. Whatever the CLKDIV value, all outputs change as follows:
  - NOEL/NWEL/ NEL/NADV/L/ NADVH /NBLL/ Address valid outputs change on the falling edge of FMC_CLK clock.
  - NOEH/ NWEH / NEH/ NOEH/NBLH/ Address invalid outputs change on the rising edge of FMC_CLK clock.
19.6.4 NOR Flash/PSRAM controller asynchronous transactions

Asynchronous static memories (NOR Flash, PSRAM, SRAM, FRAM)

- Signals are synchronized by the internal clock HCLK. This clock is not issued to the memory.
- The FMC always samples the data before de-asserting the NOE signal. This guarantees that the memory data hold timing constraint is met (minimum Chip Enable high to data transition is usually 0 ns).
- If the Extended mode is enabled (EXTMOD bit is set in the FMC_BCRx register), up to four extended modes (A, B, C and D) are available. It is possible to mix A, B, C and D modes for read and write operations. For example, read operation can be performed in mode A and write in mode B.
- If the Extended mode is disabled (EXTMOD bit is reset in the FMC_BCRx register), the FMC can operate in mode 1 or mode 2 as follows:
  - Mode 1 is the default mode when SRAM/PSRAM memory type is selected (MTYP = 0x0 or 0x01 in the FMC_BCRx register).
  - Mode 2 is the default mode when NOR memory type is selected (MTYP = 0x10 in the FMC_BCRx register).

Mode 1 - SRAM/FRAM/PSRAM (CRAM)

The next figures show the read and write transactions for the supported modes followed by the required configuration of FMC_BCRx, and FMC_BTRx/FMC_BWTRx registers.

![Figure 54. Mode 1 read access waveforms](MSv41666V1)
The DATAHLD time at the end of the read and write transactions guarantee the address and data hold time after the NOE/NWE rising edge. The DATAST value must be greater than zero (DATAST > 0).

WAIT management in asynchronous accesses

If the asynchronous memory asserts the WAIT signal to indicate that it is not yet ready to accept or to provide data, the ASYNCEWAIT bit has to be set in FMC_BCRx register.

If the WAIT signal is active (high or low depending on the WAITPOL bit), the second access phase (Data setup phase), programmed by the DATAST bits, is extended until WAIT becomes inactive. Unlike the data setup phase, the first access phases (Address setup and Address hold phases), programmed by the ADDSET and ADDHLD bits, are not WAIT sensitive and so they are not prolonged.

The data setup phase must be programmed so that WAIT can be detected 4 HCLK cycles before the end of the memory transaction. The following cases must be considered:

<table>

</tr>
</tbody>
</table>
1. The memory asserts the WAIT signal aligned to NOE/NWE which toggles:
   \[ \text{DATAST} \geq (4 \times \text{HCLK}) + \text{max\_wait\_assertion\_time} \]

2. The memory asserts the WAIT signal aligned to NEx (or NOE/NWE not toggling):
   if
   \[ \text{max\_wait\_assertion\_time} > \text{address\_phase} + \text{hold\_phase} \]
   then:
   \[ \text{DATAST} \geq (4 \times \text{HCLK}) + (\text{max\_wait\_assertion\_time} - \text{address\_phase} - \text{hold\_phase}) \]
   otherwise
   \[ \text{DATAST} \geq 4 \times \text{HCLK} \]

   where max_wait Assertion time is the maximum time taken by the memory to assert
   the WAIT signal once NEx/NOE/NWE is low.

   Figure 67 and Figure 68 show the number of HCLK clock cycles that are added to
   the memory access phase after WAIT is released by the asynchronous memory
   (independently of the above cases).

Figure 67. Asynchronous wait during a read access waveforms

1. NWAIT polarity depends on WAITPOL bit setting in FMC_BCRx register.
1. NWAIT polarity depends on WAITPOL bit setting in FMC_BCRx register.

**CellularRAM™ (PSRAM) refresh management**

The CellularRAM™ does not allow maintaining the chip select signal (NE) low for longer than the \( t_{CEM} \) timing specified for the memory device. This timing can be programmed in the FMC_PCSCNTR register. It defines the maximum duration of the NE low pulse in HCLK cycles for asynchronous accesses and FMC_CLK cycles for synchronous accesses.

### 19.6.5 Synchronous transactions

The memory clock, FMC_CLK, is a submultiple of HCLK. It depends on the value of CLKDIV and the MWID/ AHB data size, following the formula given below:

Whatever MWID size: 16 or 8-bit, the FMC_CLK divider ratio is always defined by the programmed CLKDIV value.

Example:
- If CLKDIV=1, MWID = 16 bits, AHB data size=8 bits, FMC_CLK=HCLK/2.

NOR Flash memories specify a minimum time from NADV assertion to CLK high. To meet this constraint, the FMC does not issue the clock to the memory during the first internal clock cycle of the synchronous access (before NADV assertion). This guarantees that the rising edge of the memory clock occurs in the middle of the NADV low pulse.

### Data latency versus NOR memory latency

The data latency is the number of cycles to wait before sampling the data. The DATLAT value must be consistent with the latency value specified in the NOR Flash configuration.
register. The FMC does not include the clock cycle when NADV is low in the data latency count.

Caution: Some NOR Flash memories include the NADV Low cycle in the data latency count, so that the exact relation between the NOR Flash latency and the FMC DATLAT parameter can be either:

- NOR Flash latency = (DATLAT + 2) CLK clock cycles
- or NOR Flash latency = (DATLAT + 3) CLK clock cycles

Some recent memories assert NWAIT during the latency phase. In such cases DATLAT can be set to its minimum value. As a result, the FMC samples the data and waits long enough to evaluate if the data are valid. Thus the FMC detects when the memory exits latency and real data are processed.

Other memories do not assert NWAIT during latency. In this case the latency must be set correctly for both the FMC and the memory, otherwise invalid data are mistaken for good data, or valid data are lost in the initial phase of the memory access.

Single-burst transfer

When the selected bank is configured in Burst mode for synchronous accesses, if for example an AHB single-burst transaction is requested on 16-bit memories, the FMC performs a burst transaction of length 1 (if the AHB transfer is 16 bits), or length 2 (if the AHB transfer is 32 bits) and de-assert the chip select signal when the last data is strobed.

Such transfers are not the most efficient in terms of cycles compared to asynchronous read operations. Nevertheless, a random asynchronous access would first require to re-program the memory access mode, which would altogether last longer.

Cross boundary page for CellularRAM™ 1.5

CellularRAM™ 1.5 does not allow burst access to cross the page boundary. The FMC controller allows to split automatically the burst access when the memory page size is reached by configuring the CPSIZE bits in the FMC_BCR1 register following the memory page size.

Wait management

For synchronous NOR Flash memories, NWAIT is evaluated after the programmed latency period, which corresponds to (DATLAT+2) CLK clock cycles.

If NWAIT is active (low level when WAITPOL = 0, high level when WAITPOL = 1), wait states are inserted until NWAIT is inactive (high level when WAITPOL = 0, low level when WAITPOL = 1).

When NWAIT is inactive, the data is considered valid either immediately (bit WAITCFG = 1) or on the next clock edge (bit WAITCFG = 0).

During wait-state insertion via the NWAIT signal, the controller continues to send clock pulses to the memory, keeping the chip select and output enable signals valid. It does not consider the data as valid.

In Burst mode, there are two timing configurations for the NOR Flash NWAIT signal:

- The Flash memory asserts the NWAIT signal one data cycle before the wait state (default after reset).
- The Flash memory asserts the NWAIT signal during the wait state.
The FMC supports both NOR Flash wait state configurations, for each chip select, thanks to the WAITCFG bit in the FMC_BCRx registers ($x = 0..3$).

**Figure 69. Wait configuration waveforms**

[Waveform diagram showing memory transaction and wait states]
Figure 70. Synchronous multiplexed read mode waveforms - NOR, PSRAM (CRAM)

1. Byte lane outputs (NBL) are not shown; for NOR access, they are held high, and, for PSRAM (CRAM) access, they are held low.

19.6.6  NOR/PSRAM controller registers

SRAM/NOR-Flash chip-select control register for bank x (FMC_BCRx) (x = 1 to 4)

Address offset: 8 * (x – 1), (x = 1 to 4)
Reset value: Bank 1: 0x0000 30DB
Reset value: Bank 2: 0x0000 30D2
Reset value: Bank 3: 0x0000 30D2
Reset value: Bank 4: 0x0000 30D2

This register contains the control information of each memory bank, used for SRAMs, PSRAM, FRAM and NOR Flash memories.

</tr>
</tbody>
</table>
Bit 20 **CCLKEN**: Continuous clock enable
- This bit enables the FMC_CLK clock output to external memory devices.
  - 0: The FMC_CLK is only generated during the synchronous memory access (read/write transaction). The FMC_CLK clock ratio is specified by the programmed CLKDIV value in the FMC_BCRx register (default after reset).
  - 1: The FMC_CLK is generated continuously during asynchronous and synchronous access. The FMC_CLK clock is activated when the CCLKEN is set.

*Note:* The CCLKEN bit of the FMC_BCR2..4 registers is don't care. It is only enabled through the FMC_BCR1 register. Bank 1 must be configured in Synchronous mode to generate the FMC_CLK continuous clock.

*Note:* If CCLKEN bit is set, the FMC_CLK clock ratio is specified by CLKDIV value in the FMC_BTR1 register. CLKDIV in FMC_BWTR1 is don't care.

*Note:* If the Synchronous mode is used and CCLKEN bit is set, the synchronous memories connected to other banks than Bank 1 are clocked by the same clock (the CLKDIV value in the FMC_BTR2..4 and FMC_BWTR2..4 registers for other banks has no effect.)

Bit 19 **CBURSTRW**: Write burst enable
- For PSRAM (CRAM) operating in Burst mode, the bit enables synchronous accesses during write operations. The enable bit for synchronous read accesses is the BURSTEN bit in the FMC_BCRx register.
  - 0: Write operations are always performed in Asynchronous mode.
  - 1: Write operations are performed in Synchronous mode.

Bits 18:16 **CPSIZE[2:0]**: CRAM page size
- These are used for CellularRAM™ 1.5 which does not allow burst access to cross the address boundaries between pages. When these bits are configured, the FMC controller splits automatically the burst access when the memory page size is reached (refer to memory datasheet for page size).
  - 000: No burst split when crossing page boundary (default after reset)
  - 001: 128 bytes
  - 010: 256 bytes
  - 011: 512 bytes
  - 100: 1024 bytes
  - Others: reserved

Bit 15 **ASYNCWAIT**: Wait signal during asynchronous transfers
- This bit enables/disables the FMC to use the wait signal even during an asynchronous protocol.
  - 0: NWAIT signal is not taken in to account when running an asynchronous protocol (default after reset).
  - 1: NWAIT signal is taken in to account when running an asynchronous protocol.

Bit 14 **EXTMOD**: Extended mode enable
- This bit enables the FMC to program the write timings for non multiplexed asynchronous accesses inside the FMC_BWTR register, thus resulting in different timings for read and write operations.
  - 0: values inside FMC_BWTR register are not taken into account (default after reset)
  - 1: values inside FMC_BWTR register are taken into account

*Note:* When the Extended mode is disabled, the FMC can operate in mode 1 or mode 2 as follows:
- Mode 1 is the default mode when the SRAM/PSRAM memory type is selected (MTYP = 0x0 or 0x01)
- Mode 2 is the default mode when the NOR memory type is selected (MTYP = 0x10).
Bit 13  **WAITEN**: Wait enable bit
This bit enables/disables wait-state insertion via the NWAIT signal when accessing the memory in Synchronous mode.
0: NWAIT signal is disabled (its level not taken into account, no wait state inserted after the programmed Flash latency period).
1: NWAIT signal is enabled (its level is taken into account after the programmed latency period to insert wait states if asserted) (default after reset).

Bit 12  **WREN**: Write enable bit
This bit indicates whether write operations are enabled/disabled in the bank by the FMC.
0: Write operations are disabled in the bank by the FMC, an AHB error is reported.
1: Write operations are enabled for the bank by the FMC (default after reset).

Bit 11  **WAITCFG**: Wait timing configuration
The NWAIT signal indicates whether the data from the memory are valid or if a wait state must be inserted when accessing the memory in Synchronous mode. This configuration bit determines if NWAIT is asserted by the memory one clock cycle before the wait state or during the wait state:
0: NWAIT signal is active one data cycle before wait state (default after reset).
1: NWAIT signal is active during wait state (not used for PSRAM).

Bit 10 Reserved, must be kept at reset value.

Bit 9  **WAITPOL**: Wait signal polarity bit
Defines the polarity of the wait signal from memory used for either in Synchronous or Asynchronous mode.
0: NWAIT active low (default after reset)
1: NWAIT active high

Bit 8  **BURSTEN**: Burst enable bit
This bit enables/disables synchronous accesses during read operations. It is valid only for synchronous memories operating in Burst mode.
0: Burst mode disabled (default after reset). Read accesses are performed in Asynchronous mode.
1: Burst mode enable. Read accesses are performed in Synchronous mode.

Bit 7 Reserved, must be kept at reset value.

Bit 6  **FACCEN**: Flash access enable
Enables NOR Flash memory access operations.
0: Corresponding NOR Flash memory access is disabled.
1: Corresponding NOR Flash memory access is enabled (default after reset).

Bits 5:4  **MWID[1:0]**: Memory data bus width
Defines the external memory device width, valid for all type of memories.
00: 8 bits
01: 16 bits (default after reset)
10: reserved
11: reserved
Bits 3:2  **MTYP[1:0]: Memory type**
Defines the type of external memory attached to the corresponding memory bank.
00: SRAM/FRAM (default after reset for Bank 2...4)
01: PSRAM (CRAM) / FRAM
10: NOR Flash/OneNAND Flash (default after reset for Bank 1)
11: reserved

Bit 1  **MUXEN**: Address/data multiplexing enable bit
When this bit is set, the address and data values are multiplexed on the data bus, valid only with NOR and PSRAM memories:
0: Address/data non multiplexed
1: Address/data multiplexed on databus (default after reset)

Bit 0  **MBKEN**: Memory bank enable bit
Enables the memory bank. After reset Bank1 is enabled, all others are disabled. Accessing a disabled bank causes an ERROR on AHB bus.
0: Corresponding memory bank is disabled.
1: Corresponding memory bank is enabled.

**SRAM/NOR-Flash chip-select timing register for bank x (FMC_BTRx)**
Address offset: 0x04 + 8 * (x – 1), (x = 1 to 4)
Reset value: 0x0FFF FFFF

This register contains the control information of each memory bank, used for SRAMs, PSRAM and NOR Flash memories. If the EXTMOD bit is set in the FMC_BCRx register, then this register is partitioned for write and read access, that is, 2 registers are available: one to configure read accesses (this register) and one to configure write accesses (FMC_BWTRx registers).

</tbody>
</table>

Bits 31:30  **DATAHLD[1:0]: Data hold phase duration**
These bits are written by software to define the duration of the data hold phase in HCLK cycles (refer to Figure 54 to Figure 66), used in asynchronous accesses:
For read accesses
00: DATAHLD phase duration = 0 × HCLK clock cycle (default)
01: DATAHLD phase duration = 1 × HCLK clock cycle
10: DATAHLD phase duration = 2 × HCLK clock cycle
11: DATAHLD phase duration = 3 × HCLK clock cycle
For write accesses
00: DATAHLD phase duration = 1 × HCLK clock cycle (default)
01: DATAHLD phase duration = 2 × HCLK clock cycle
10: DATAHLD phase duration = 3 × HCLK clock cycle
11: DATAHLD phase duration = 4 × HCLK clock cycle
Bits 29:28 **ACCMOD[1:0]: Access mode**

Specifies the asynchronous access modes as shown in the timing diagrams. These bits are taken into account only when the EXTMOD bit in the FMC_BCRx register is 1.
- 00: Access mode A
- 01: Access mode B
- 10: Access mode C
- 11: Access mode D

Bits 27:24 **DATLAT[3:0]:** (see note below bit descriptions): Data latency for synchronous memory

For synchronous access with read/write Burst mode enabled (BURSTEN / CBURSTRW bits set), defines the number of memory clock cycles (+2) to issue to the memory before reading/writing the first data:

This timing parameter is not expressed in HCLK periods, but in FMC_CLK periods.

For asynchronous access, this value is don't care.

- 0000: Data latency of 2 CLK clock cycles for first burst access
- 1111: Data latency of 17 CLK clock cycles for first burst access (default value after reset)

Bits 23:20 **CLKDIV[3:0]:** Clock divide ratio (for FMC_CLK signal)

Defines the period of FMC_CLK clock output signal, expressed in number of HCLK cycles:

- 0000: FMC_CLK period = 1x HCLK period
- 0001: FMC_CLK period = 2 × HCLK periods
- 0010: FMC_CLK period = 3 × HCLK periods
- 1111: FMC_CLK period = 16 × HCLK periods (default value after reset)

In asynchronous NOR Flash, SRAM or PSRAM accesses, this value is don't care.

**Note:** Refer to Section 19.6.5: Synchronous transactions for FMC_CLK divider ratio formula

Bits 19:16 **BUSTURN[3:0]:** Bus turnaround phase duration

These bits are written by software to add a delay at the end of current read or write transaction to next transaction on the same bank.

This delay allows to match the minimum time between consecutive transactions (tEHEL from NEx high to NEx low) and the maximum time needed by the memory to free the data bus after a read access (tEHQZ, chip enable high to output Hi-Z). This delay is recommended for mode D and muxed mode. For non-muxed memory, the bus turnaround delay can be set to minimum value.

\[(BUSTURN + 1)\times HCLK \geq \max(t_{EHEL}, t_{EHQZ})\]

For FRAM memories, the bus turnaround delay should be configured to match the minimum tPC (precharge time) timings. The bus turnaround delay is inserted between any consecutive transactions on the same bank (read/read, write/write, read/write and write/read) to match the tPC memory timing. The chip select is toggling between any consecutive accesses.

\[(BUSTURN + 1)\times HCLK \geq t_{PC}\]

- 0000: BUSTURN phase duration = 1 HCLK clock cycle added
- 1111: BUSTURN phase duration = 16 x HCLK clock cycles added (default value after reset)
Bits 15:8 **DATAST[7:0]:** Data-phase duration
These bits are written by software to define the duration of the data phase (refer to Figure 54 to Figure 66), used in asynchronous accesses:
- 0000 0000: Reserved
- 0000 0001: DATAST phase duration = 1 × HCLK clock cycles
- 0000 0010: DATAST phase duration = 2 × HCLK clock cycles
- ... 
- 1111 1111: DATAST phase duration = 255 × HCLK clock cycles (default value after reset)

For each memory type and access mode data-phase duration, refer to the respective figure (Figure 54 to Figure 66).
Example: Mode 1, write access, DATAST=1: Data-phase duration= DATAST+1 = 2 HCLK clock cycles.

Note: In synchronous accesses, this value is don’t care.

Bits 7:4 **ADDHLD[3:0]:** Address-hold phase duration
These bits are written by software to define the duration of the address hold phase (refer to Figure 54 to Figure 66), used in mode D or multiplexed accesses:
- 0000: Reserved
- 0001: ADDHLD phase duration =1 × HCLK clock cycle
- 0010: ADDHLD phase duration = 2 × HCLK clock cycle
- ... 
- 1111: ADDHLD phase duration = 15 × HCLK clock cycles (default value after reset)

For each access mode address-hold phase duration, refer to the respective figure (Figure 54 to Figure 66).

Note: In synchronous accesses, this value is not used, the address hold phase is always 1 memory clock period duration.

Bits 3:0 **ADDSET[3:0]:** Address setup phase duration
These bits are written by software to define the duration of the address setup phase (refer to Figure 54 to Figure 66), used in SRAMs, ROMs, asynchronous NOR Flash and PSRAM:
- 0000: ADDSET phase duration = 0 × HCLK clock cycle
- ... 
- 1111: ADDSET phase duration = 15 × HCLK clock cycles (default value after reset)

For each access mode address setup phase duration, refer to the respective figure (Figure 54 to Figure 66).

Note: In synchronous accesses, this value is don’t care.

In Muxed mode or mode D, the minimum value for ADDSET is 1.

In mode 1 and PSRAM memory, the minimum value for ADDSET is 1.

Note: **PSRAMs (CRAMs)** have a variable latency due to internal refresh. Therefore these memories issue the NWAIT signal during the whole latency phase to prolong the latency as needed.

With PSRAMs (CRAMs) the filled DATLAT must be set to 0, so that the FMC exits its latency phase soon and starts sampling NWAIT from memory, then starts to read or write when the memory is ready.

This method can be used also with the latest generation of synchronous Flash memories that issue the NWAIT signal, unlike older Flash memories (check the datasheet of the specific Flash memory being used).
SRAM/NOR-Flash write timing registers x (FMC_BWTRx)

Address offset: 0x104 + 8 * (x – 1), (x = 1 to 4)

Reset value: 0xFFFF FFFF

This register contains the control information of each memory bank. It is used for SRAMs, PSRAMs and NOR Flash memories. When the EXTMOD bit is set in the FMC_BCRx register, then this register is active for write access.

</tbody>
</table>

For FRAM memories, the bus turnaround delay should be configured to match the minimum tPC (precharge time) timings. The bus turnaround delay is inserted between any consecutive transactions on the same bank (read/read, write/write, read/write and write/read). The chip select is toggling between any consecutive accesses. 

(BUSTURN + 1)HCLK period ≥ tPC min

0000: BUSTURN phase duration = 1 HCLK clock cycle added

...
Bits 15:8 **DATAST[7:0]**: Data-phase duration.

These bits are written by software to define the duration of the data phase (refer to Figure 54 to Figure 66), used in asynchronous SRAM, PSRAM and NOR Flash memory accesses:

- 0000 0000: Reserved
- 0000 0001: DATAST phase duration = 1 × HCLK clock cycles
- 0000 0010: DATAST phase duration = 2 × HCLK clock cycles
- ... 
- 1111 1111: DATAST phase duration = 255 × HCLK clock cycles (default value after reset)

Bits 7:4 **ADDHLD[3:0]**: Address-hold phase duration.

These bits are written by software to define the duration of the address hold phase (refer to Figure 63 to Figure 66), used in asynchronous multiplexed accesses:

- 0000: Reserved
- 0001: ADDHLD phase duration = 1 × HCLK clock cycle
- 0010: ADDHLD phase duration = 2 × HCLK clock cycle
- ... 
- 1111: ADDHLD phase duration = 15 × HCLK clock cycles (default value after reset)

**Note:** In synchronous NOR Flash accesses, this value is not used, the address hold phase is always 1 Flash clock period duration.

Bits 3:0 **ADDSET[3:0]**: Address setup phase duration.

These bits are written by software to define the duration of the address setup phase in HCLK cycles (refer to Figure 54 to Figure 66), used in asynchronous accesses:

- 0000: ADDSET phase duration = 0 × HCLK clock cycle
- ... 
- 1111: ADDSET phase duration = 15 × HCLK clock cycles (default value after reset)

**Note:** In synchronous accesses, this value is not used, the address setup phase is always 1 Flash clock period duration. In muxed mode, the minimum ADDSET value is 1.

**PSRAM chip select counter register (FMC_PCSCNTR)**

Address offset: 0x20

Reset value: 0x0000 0000

This register contains the PSRAM chip select counter value for Synchronous and Asynchronous modes. The chip select counter is common to all banks and can be enabled separately on each bank. During PSRAM read or write accesses, this value is loaded into a timer which is decremented while the NE signal is held low. When the timer reaches 0, the PSRAM controller splits the current access, toggles NE to allow PSRAM device refresh, and restarts a new access. The programmed counter value guarantees a maximum NE pulse width (tCEM) as specified for PSRAM devices. The counter is reloaded and starts decrementing each time a new access is started by a transition of NE from high to low.
Bits 31:20  Reserved, must be kept at reset value.

Bit 19  **CNTB4EN**: Counter Bank 4 enable
       This bit enables the chip select counter for PSRAM/NOR Bank 4.
       0: Counter disabled for Bank 4
       1: Counter enabled for Bank 4

Bit 18  **CNTB3EN**: Counter Bank 3 enable
       This bit enables the chip select counter for PSRAM/NOR Bank 3.
       0: Counter disabled for Bank 3.
       1: Counter enabled for Bank 3

Bit 17  **CNTB2EN**: Counter Bank 2 enable
       This bit enables the chip select counter for PSRAM/NOR Bank 2.
       0: Counter disabled for Bank 2.
       1: Counter enabled for Bank 2

Bit 16  **CNTB1EN**: Counter Bank 1 enable
       This bit enables the chip select counter for PSRAM/NOR Bank 1.
       0: Counter disabled for Bank 1.
       1: Counter enabled for Bank 1

Bits 15:0  **CSCOUNT[15:0]**: Chip select counter.
       These bits are written by software to define the maximum chip select low pulse duration. It is expressed in FMC_CLK cycles for synchronous accesses and in HCLK cycles for asynchronous accesses.
       The counter is disabled if the programmed value is 0.

### 19.7 NAND Flash controller

The FMC generates the appropriate signal timings to drive the following types of device:

- 8- and 16-bit NAND Flash memories

The NAND bank is configured through dedicated registers (Section 19.7.7). The programmable memory parameters include access timings (shown in Table 145) and ECC configuration.

#### Table 145. Programmable NAND Flash access parameters

19.7.3 Timing diagrams for NAND Flash memory

The NAND Flash memory bank is managed through a set of registers:
- Control register: FMC_PCR
- Interrupt status register: FMC_SR
- ECC register: FMC_ECCR
- Timing register for Common memory space: FMC_PMEM
- Timing register for Attribute memory space: FMC_PATT

Each timing configuration register contains three parameters used to define number of HCLK cycles for the three phases of any NAND Flash access, plus one parameter that defines the timing for starting driving the data bus when a write access is performed. Figure 72 shows the timing parameter definitions for common memory accesses, knowing that Attribute memory space access timings are similar.
19.7.4 NAND Flash operations

The command latch enable (CLE) and address latch enable (ALE) signals of the NAND Flash memory device are driven by address signals from the FMC controller. This means that to send a command or an address to the NAND Flash memory, the CPU has to perform a write to a specific address in its memory space.

A typical page read operation from the NAND Flash device requires the following steps:

1. Program and enable the corresponding memory bank by configuring the FMC_PCR and FMC_PMEM (and for some devices, FMC_PATT, see Section 19.7.5: NAND Flash prewait functionality) registers according to the characteristics of the NAND Flash memory (PWID bits for the data bus width of the NAND Flash, PTYP = 1, PWAITEN = 0 or 1 as needed, see Section 19.5.2: NAND Flash memory address mapping for timing configuration).

2. The CPU performs a byte write to the common memory space, with data byte equal to one Flash command byte (for example 0x00 for Samsung NAND Flash devices). The LE input of the NAND Flash memory is active during the write strobe (low pulse on NWE), thus the written byte is interpreted as a command by the NAND Flash memory. Once the command is latched by the memory device, it does not need to be written again for the following page read operations.

3. The CPU can send the start address (STARTAD) for a read operation by writing four bytes (or three for smaller capacity devices), STARTAD[7:0], STARTAD[16:9], STARTAD[24:17] and finally STARTAD[25] (for 64 Mb x 8 bit NAND Flash memories) in the common memory or attribute space. The ALE input of the NAND Flash device is active during the write strobe (low pulse on NWE), thus the written bytes are interpreted as the start address for read operations. Using the attribute memory space makes it possible to use a different timing configuration of the FMC, which can be used.
to implement the prewait functionality needed by some NAND Flash memories (see details in Section 19.7.5: NAND Flash prewait functionality).

4. The controller waits for the NAND Flash memory to be ready (R/NB signal high), before starting a new access to the same or another memory bank. While waiting, the controller holds the NCE signal active (low).

5. The CPU can then perform byte read operations from the common memory space to read the NAND Flash page (data field + Spare field) byte by byte.

6. The next NAND Flash page can be read without any CPU command or address write operation. This can be done in three different ways:
   – by simply performing the operation described in step 5
   – a new random address can be accessed by restarting the operation at step 3
   – a new command can be sent to the NAND Flash device by restarting at step 2

19.7.5 NAND Flash prewait functionality

Some NAND Flash devices require that, after writing the last part of the address, the controller waits for the R/NB signal to go low. (see Figure 73).

Figure 73. Access to non ‘CE don’t care’ NAND-Flash

1. CPU wrote byte 0x00 at address 0x7001 0000.
2. CPU wrote byte A7~A0 at address 0x7002 0000.
3. CPU wrote byte A16~A9 at address 0x7002 0000.
4. CPU wrote byte A24~A17 at address 0x7002 0000.
5. CPU wrote byte A25 at address 0x7002 0000: FMC performs a write access using FMC_PATT timing definition, where ATTHOLD = 7 (providing that (7+1) × HCLK = 112 ns > tWB max). This guarantees that NCE remains low until R/NB goes low and high again (only requested for NAND Flash memories where NCE is not don’t care).
When this functionality is required, it can be ensured by programming the MEMHOLD value to meet the \( t_{WB} \) timing. However any CPU read access to the NAND Flash memory has a hold delay of \((\text{MEMHOLD} + 2) \cdot \text{HCLK}\) cycles and CPU write access has a hold delay of \((\text{MEMHOLD}) \cdot \text{HCLK}\) cycles inserted between the rising edge of the NWE signal and the next access.

To cope with this timing constraint, the attribute memory space can be used by programming its timing register with an ATTHOLD value that meets the \( t_{WB} \) timing, and by keeping the MEMHOLD value at its minimum value. The CPU must then use the common memory space for all NAND Flash read and write accesses, except when writing the last address byte to the NAND Flash device, where the CPU must write to the attribute memory space.

19.7.6 Computation of the error correction code (ECC) in NAND Flash memory

The FMC NAND Card controller includes two error correction code computation hardware blocks, one per memory bank. They reduce the host CPU workload when processing the ECC by software.

These two ECC blocks are identical and associated with Bank 2 and Bank 3. As a consequence, no hardware ECC computation is available for memories connected to Bank 4.

The ECC algorithm implemented in the FMC can perform 1-bit error correction and 2-bit error detection per 256, 512, 1 024, 2 048, 4 096 or 8 192 bytes read or written from/to the NAND Flash memory. It is based on the Hamming coding algorithm and consists in calculating the row and column parity.

The ECC modules monitor the NAND Flash data bus and read/write signals (NCE and NWE) each time the NAND Flash memory bank is active.

The ECC operates as follows:

- When accessing NAND Flash memory bank 2 or bank 3, the data present on the \( \text{D}[15:0] \) bus is latched and used for ECC computation.
- When accessing any other address in NAND Flash memory, the ECC logic is idle, and does not perform any operation. As a result, write operations to define commands or addresses to the NAND Flash memory are not taken into account for ECC computation.

Once the desired number of bytes has been read/written from/to the NAND Flash memory by the host CPU, the FMC_ECCR registers must be read to retrieve the computed value. Once read, they should be cleared by resetting the ECCEN bit to ‘0’. To compute a new data block, the ECCEN bit must be set to one in the FMC_PCR registers.
To perform an ECC computation:

1. Enable the ECCEN bit in the FMC_PCR register.
2. Write data to the NAND Flash memory page. While the NAND page is written, the ECC block computes the ECC value.
3. Read the ECC value available in the FMC_ECCR register and store it in a variable.
4. Clear the ECCEN bit and then enable it in the FMC_PCR register before reading back the written data from the NAND page. While the NAND page is read, the ECC block computes the ECC value.
5. Read the new ECC value available in the FMC_ECCR register.
6. If the two ECC values are the same, no correction is required, otherwise there is an ECC error and the software correction routine returns information on whether the error can be corrected or not.

### 19.7.7 NAND Flash controller registers

**NAND Flash control registers (FMC_PCR)**

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:17 **ECCPS[2:0]: ECC page size**

Defines the page size for the extended ECC:

- 000: 256 bytes
- 001: 512 bytes
- 010: 1024 bytes
- 011: 2048 bytes
- 100: 4096 bytes
- 101: 8192 bytes

Bits 16:13 **TAR[3:0]: ALE to RE delay**

Sets time from ALE low to RE low in number of AHB clock cycles (HCLK).

Time is: \( t_{ar} = (TAR + SET + 2) \times THCLK \) where \( THCLK \) is the HCLK clock period

- 0000: 1 HCLK cycle (default)
- 1111: 16 HCLK cycles

**Note:** \( SET \) is MEMSET or ATTSET according to the addressed space.
Bits 12:9  **TCLR[3:0]**: CLE to RE delay
Sets time from CLE low to RE low in number of AHB clock cycles (HCLK).
Time is $t_{clr} = (\text{TCLR} + \text{SET} + 2) \times \text{THCLK}$ where THCLK is the HCLK clock period
0000: 1 HCLK cycle (default)
1111: 16 HCLK cycles
Note: SET is MEMSET or ATTSET according to the addressed space.

Bits 8:7  Reserved, must be kept at reset value.

Bit 6  **ECCEN**: ECC computation logic enable bit
0: ECC logic is disabled and reset (default after reset),
1: ECC logic is enabled.

Bits 5:4  **PWID[1:0]**: Data bus width
Defines the external memory device width.
00: 8 bits
01: 16 bits (default after reset).
10: reserved.
11: reserved.

Bit 3  **PTYP**: Memory type
Defines the type of device attached to the corresponding memory bank:
0: Reserved, must be kept at reset value
1: NAND Flash (default after reset)

Bit 2  **PBKEN**: NAND Flash memory bank enable bit
Enables the memory bank. Accessing a disabled memory bank causes an ERROR on AHB bus
0: Corresponding memory bank is disabled (default after reset)
1: Corresponding memory bank is enabled

Bit 1  **PWAITEN**: Wait feature enable bit
Enables the Wait feature for the NAND Flash memory bank:
0: disabled
1: enabled

Bit 0  Reserved, must be kept at reset value.
FIFO status and interrupt register (FMC_SR)

Address offset: 0x84

Reset value: 0x0000 0040

This register contains information about the FIFO status and interrupt. The FMC features a FIFO that is used when writing to memories to transfer up to 16 words of data from the AHB.

This is used to quickly write to the FIFO and free the AHB for transactions to peripherals other than the FMC, while the FMC is draining its FIFO into the memory. One of these register bits indicates the status of the FIFO, for ECC purposes.

The ECC is calculated while the data are written to the memory. To read the correct ECC, the software must consequently wait until the FIFO is empty.

Bits 0 IRS: Interrupt rising edge status
The flag is set by hardware and reset by software.
0: No interrupt rising edge occurred
1: Interrupt rising edge occurred
Note: If this bit is written by software to 1 it is set.

Common memory space timing register (FMC_PMEM)
Address offset: Address: 0x88
Reset value: 0xFCFC FCFC
The FMC_PMEM read/write register contains the timing information for NAND Flash memory bank. This information is used to access either the common memory space of the NAND Flash for command, address write access and data read/write access.

Bits 7:0 **MEMSET[7:0]**: Common memory x setup time

Defines the number of HCLK (+1) clock cycles to set up the address before the command assertion (NWE, NOE), for NAND Flash read or write access to common memory space on socket x:

- 0000 0000: 1 HCLK cycle
- 1111 1110: 255 HCLK cycles
- 1111 1111: reserved

**Attribute memory space timing register (FMC_PATT)**

Address offset: 0x8C
Reset value: 0xFCFC FCFC

The FMC_PATT read/write register contains the timing information for NAND Flash memory bank. It is used for 8-bit accesses to the attribute memory space of the NAND Flash for the last address write access if the timing must differ from that of previous accesses (for Ready/Busy management, refer to *Section 19.7.5: NAND Flash prewait functionality*).

Bits 31:24 **ATTHIZ[7:0]**: Attribute memory data bus Hi-Z time

Defines the number of HCLK clock cycles during which the data bus is kept in Hi-Z after the start of a NAND Flash write access to attribute memory space on socket. Only valid for write transaction:

- 0000 0000: 0 HCLK cycle
- 1111 1110: 255 HCLK cycles
- 1111 1111: reserved.

Bits 23:16 **ATTHOLD[7:0]**: Attribute memory hold time

Defines the number of HCLK clock cycles for write access and HCLK (+2) clock cycles for read access during which the address is held (and data for write access) after the command deassertion (NWE, NOE), for NAND Flash read or write access to attribute memory space on socket:

- 0000 0000: reserved
- 0000 0001: 1 HCLK cycle for write access / 3 HCLK cycles for read access
- 1111 1110: 254 HCLK cycles for write access / 256 HCLK cycles for read access
- 1111 1111: reserved.

Bits 15:8 **ATTWAIT[7:0]**: Attribute memory wait time

Defines the minimum number of HCLK (+1) clock cycles to assert the command (NWE, NOE), for NAND Flash read or write access to attribute memory space on socket x. The duration for command assertion is extended if the wait signal (NWAIT) is active (low) at the end of the programmed value of HCLK:

- 0000 0000: reserved
- 0000 0001: 2 HCLK cycles (+ wait cycle introduced by deassertion of NWAIT)
- 1111 1110: 255 HCLK cycles (+ wait cycle introduced by deassertion of NWAIT)
- 1111 1111: reserved.
Bits 7:0 ATTSET[7:0]: Attribute memory setup time

Defines the number of HCLK (+1) clock cycles to set up address before the command assertion (NWE, NOE), for NAND Flash read or write access to attribute memory space on socket:

0000 0000: 1 HCLK cycle
1111 1110: 255 HCLK cycles
1111 1111: reserved.

**ECC result registers (FMC_ECCR)**

Address offset: 0x94
Reset value: 0x0000 0000

This register contain the current error correction code value computed by the ECC computation modules of the FMC NAND controller. When the CPU reads the data from a NAND Flash memory page at the correct address (refer to Section 19.7.6: Computation of the error correction code (ECC) in NAND Flash memory), the data read/written from/to the NAND Flash memory are processed automatically by the ECC computation module. When X bytes have been read (according to the ECCPS field in the FMC_PCR registers), the CPU must read the computed ECC value from the FMC_ECC registers. It then verifies if these computed parity data are the same as the parity value recorded in the spare area, to determine whether a page is valid, and, to correct it otherwise. The FMC_ECCR register should be cleared after being read by setting the ECCEN bit to 0. To compute a new data block, the ECCEN bit must be set to 1.

**Notes:**
- **NBL** (Number of Burst Length): Indicates how many bursts of data are sent before the controller waits for the next transfer.
- **CBURST** (Control Burst): Specifies the type of burst mode.
- **CPSIZE** (Control Burst Size): Determines the size of the burst.
- **ASYNCWAIT** (Asynchronous Wait): Enables or disables asynchronous waiting.
- **EXTMOD** (External Mode): Enables or disables external mode operation.
- **WAITEN** (Wait Enable): Enables or disables wait states.
- **WREN** (Wait Enable): Enables or disables wait states.
- **WAITCFG** (Wait Configuration): Configures the wait states.
- **WAITPOL** (Wait Polarity): Determines the polarity of the wait signals.
- **BURSTEN** (Burst Enable): Enables or disables bursting.
- **FACCEN** (Fast Access Enable): Enables or disables fast access.
- **MWID** (Memory Width): Specifies the width of the memory.
- **MTYP** (Memory Type): Indicates the type of memory used.
- **MUXEN** (Multiplexer Enable): Enables or disables the multiplexer.
- **MBKEN** (Multiplexer Bank Enable): Enables or disables the multiplexer bank.
- **DATAHLD** (Data Hold): Indicates the duration of data hold.
- **ACCMOD** (Address Mode): Determines the addressing mode.
- **DATLAT** (Data Latency): Specifies the latency of data transfer.
- **CLKDIV** (Clock Divide): Divides the clock frequency.
- **BUSTURN** (Burst Turn): Enables or disables burst turn.
- **ADDHLD** (Address Hold): Indicates the duration of address hold.
- **ADDSET** (Address Set): Specifies the address set.
- **DATAST** (Data Strobe): Indicates the data strobe.

**Reset Values:**
- **0x00** for **FMC_BCR1**
- **0x08** for **FMC_BCR2**
- **0x10** for **FMC_BCR3**
- **0x18** for **FMC_BCR4**
- **0x04** for **FMC_BTR1**
- **0x0C** for **FMC_BTR2**
- **0x14** for **FMC_BTR3**
- **0x1C** for **FMC_BTR4**
- **0x20** for **FMC_PSCCNTR**
- **0x28** for **FMC_BWTR1**
Refer to Section 2.3 on page 87 for the register boundary addresses.
20 Octo-SPI interface (OCTOSPI)

20.1 Introduction

The OCTOSPI supports most external serial memories such as serial PSRAMs, serial NAND and serial NOR Flash memories, HyperRAM™ and HyperFlash™ memories, with the following functional modes:

- Indirect mode: all the operations are performed using the OCTOSPI registers to preset commands, addresses, data and transfer parameters.
- Automatic status-polling mode: the external memory status register is periodically read and an interrupt can be generated in case of flag setting.
- Memory-mapped mode: the external memory is memory mapped and it is seen by the system as if it was an internal memory, supporting both read and write operations.

The OCTOSPI supports the following protocols with associated frame formats:

- the Regular-command frame format with the command, address, alternate byte, dummy cycles and data phase
- the HyperBus™ frame format

20.2 OCTOSPI main features

- Functional modes: Indirect, Automatic status-polling, and Memory-mapped
- Read and write support in Memory-mapped mode
- External (P)SRAM memory support
- Support for single, dual, quad and octal communication
- Dual-quad configuration, where eight bits can be sent/received simultaneously by accessing two quad memories in parallel
- SDR (single-data rate) and DTR (double-transfer rate) support
- Data strobe support
- Fully programmable opcode
- Fully programmable frame format
- Support wrapped-type access to memory in read direction
- HyperBus support
- Integrated FIFO for reception and transmission
- Asynchronous bus clock versus kernel clock support
- 8-, 16-, and 32-bit data accesses allowed
- DMA channel for Indirect mode operations
- Interrupt generation on FIFO threshold, timeout, operation complete, and access error
- AHB interface with transaction acceptance limited to one: the interface accepts the next transfer on AHB bus only once the previous is completed on memory side.

20.4 OCTOSPI functional description

20.4.1 OCTOSPI block diagram

Figure 74. OCTOSPI block diagram in octal configuration

Figure 75. OCTOSPI block diagram in quad configuration
20.4.2 OCTOSPI interface to memory modes

The OCTOSPI supports the following protocols:
- Regular-command protocol
- HyperBus protocol

The OCTOSPI uses from 6 to 12 signals to interface with a memory, depending on the functional mode:
- NCS: chip-select
- CLK: communication clock
- NCLK: inverted clock used only in the 1.8 V HyperBus protocol
- DQS: data strobe used only in Regular-command protocol as input only
- IO[3:0]: data bus LSB
- IO[7:4]: data bus MSB used in dual-quad and octal configurations

20.4.3 OCTOSPI Regular-command protocol

When in Regular-command protocol, the OCTOSPI communicates with the external device using commands. Each command can include the following phases:
- Instruction phase
- Address phase
- Alternate-byte phase
- Dummy-cycle phase
- Data phase

Any of these phases can be configured to be skipped, but at least one of the instruction, address, alternate byte, or data phases must be present.
The NCS falls before the start of each command and rises again after each command finishes.

In Memory-mapped mode, both read and write operations are supported; as a consequence, some of the configuration registers are duplicated to specify write operations (read operations are configured using regular registers).

**Instruction phase**

During this phase, a 1- to 4-byte instruction is sent to the external device specifying the type of operation to be performed. The size of the instruction to be sent is configured in ISIZE[1:0] of OCTOSPI_CCR and the instruction is programmed in INSTRUCTION[31:0] of OCTOSPI_IR.

The instruction phase can optionally send:
- 1 bit at a time from the IO0/SO signal (Single-SPI mode)
- 2 bits at a time (over IO0/IO1 in Dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in Quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in Octal-SPI mode).

This can be configured using IMODE[2:0] of OCTOSPI_CCR.

The instruction can be sent in DTR (double-transfer rate) mode on each rising and falling edge of the clock, by setting IDTR in OCTOSPI_CCR.

When IMODE[2:0] = 000 in OCTOSPI_CCR, the instruction phase is skipped, and the command sequence starts with the address phase, if present.

In Memory-mapped mode, the instruction used for the write operation is specified in OCTOSPI_WIR and the instruction format is specified in OCTOSPI_WCCR. The instruction used for the read operation and the instruction format are specified in OCTOSPI_IR and OCTOSPI_CCR.

**Address phase**

In the address phase, 1 to 4 bytes are sent to the external device, to indicate the address of the operation. The number of address bytes to be sent is configured in ADSIZE[1:0] of OCTOSPI_CCR.

In Indirect and Automatic status-polling modes, the address bytes to be sent are specified in ADDRESS[31:0] of OCTOSPI_AR. In Memory-mapped mode, the address is given directly via the AHB (from any master in the system).
The address phase can send:
- 1 bit at a time (over SOI in Single-SPI mode)
- 2 bits at a time (over IO0/IO1 in Dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in Quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in Octal-SPI mode)

This can be configured using ADMODE[2:0] of OCTOSPI_CCR.

The address can be sent in DTR mode (on each rising and falling edge of the clock) setting ADDTR of OCTOSPI_CCR.

When ADMODE[2:0] = 000, the address phase is skipped and the command sequence proceeds directly to the next phase, if any.

In Memory-mapped mode, the address format for the write operation is specified in OCTOSPI_WCCR. The address format for the read operation is specified in OCTOSPI_CCR.

Alternate-bytes phase

In the alternate-bytes phase, 1 to 4 bytes are sent to the external device, generally to control the mode of operation. The number of alternate bytes to be sent is configured in ABSIZE[1:0] of OCTOSPI_CCR. The bytes to be sent are specified in OCTOSPI_ABR.

The alternate-byte phase can send:
- 1 bit at a time (over SOI in Single-SPI mode)
- 2 bits at a time (over IO0/IO1 in Dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in Quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in Octal-SPI mode)

This can be configured using ABMODE[2:0] of OCTOSPI_CCR.

The alternate bytes can be sent in DTR mode (on each rising and falling edge of the clock) setting ABDTR of OCTOSPI_CCR.

When ABMODE[2:0] = 000, the alternate-bytes phase is skipped and the command sequence proceeds directly to the next phase, if any.

There may be times when only a single nibble needs to be sent during the alternate-byte phase rather than a full byte, such as when the Dual-SPI mode is used and only two cycles are used for the alternate bytes.

In this case, the firmware can use the Quad-SPI mode (ABMODE[2:0] = 011) and send a byte with bits 7 and 3 of ALTERNATE[31:0] set to 1 (keeping the IO3 line high), and bits 6 and 2 set to 0 (keeping the IO2 line low), in OCTOSPI_IR.

The upper two bits of the nibble to be sent are then placed in bits 4:3 of ALTERNATE[31:0] while the lower two bits are placed in bits 1:0. For example, if the nibble 2 (0010) is to be sent over IO0/IO1, then ALTERNATE[31:0] must be set to 0x8A (1000_1010).

In Memory-mapped mode, the alternate bytes used for the write operation are specified in OCTOSPI_WABR and the alternate byte format is specified in OCTOSPI_WCCR. The alternate bytes used for read operation and the alternate byte format are specified in OCTOSPI_ABR and OCTOSPI_CCR.
**Dummy-cycle phase**

In the dummy-cycle phase, 1 to 31 cycles are given without any data being sent or received, in order to give the external device, the time to prepare for the data phase when the higher clock frequencies are used. The number of cycles given during this phase is specified in DCYC[4:0] of OCTOSPI_TCR. In both SDR and DTR modes, the duration is specified as a number of full CLK cycles.

When DCYC[4:0] = 00000, the dummy-cycle phase is skipped, and the command sequence proceeds directly to the data phase, if present.

In order to assure enough “turn-around” time for changing the data signals from the output mode to the input mode, there must be at least one dummy cycle when using the Dual-SPI, the Quad-SPI or the Octal-SPI mode, to receive data from the external device.

In Memory-mapped mode, the dummy cycles for the write operations are specified in OCTOSPI_WTCR. The dummy cycles for the read operation are specified in OCTOSPI_TCR.

**Data phase**

During the data phase, any number of bytes can be sent to or received from the external device.

In Indirect mode, the number of bytes to be sent/received is specified in OCTOSPI_DLR. In this mode, the data to be sent to the external device must be written to OCTOSPI_DR, while in Indirect-read mode the data received from the external device is obtained by reading OCTOSPI_DR.

In Automatic status-polling mode, the number of bytes to be received is specified in OCTOSPI_DLR and the data received from the external device can be obtained by reading OCTOSPI_DR.

In Memory-mapped mode, the data read or written, is sent or received directly over the AHB to the Cortex core or to a DMA.

The data phase can send/receive:
- 1 bit at a time (over SO/SI in Single-SPI mode)
- 2 bits at a time (over IO0/IO1 in Dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in Quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in Octal-SPI mode)

This can be configured using DMODE[2:0] of OCTOSPI_CCR.

The data can be sent or received in DTR mode (on each rising and falling edge of the clock) setting DDTR of OCTOSPI_CCR.

When DMODE[2:0] = 000, the data phase is skipped, and the command sequence finishes immediately by raising the NCS. This configuration must be used only in Indirect-write mode.

In Memory-mapped mode, the data format for the write operation is specified in OCTOSPI_WCCR. The data format for the read operation is specified in OCTOSPI_CCR.

**DQS usage**

The DQS signal can be used for data strobing during the read transactions when the device toggles the DQS aligned with the data.
20.4.4 OCTOSPI Regular-command protocol signal interface

Single-SPI mode

The legacy SPI mode allows just a single bit to be sent/received serially. In this mode, the data is sent to the external device over the SO signal (whose I/Os are shared with IO0). The data received from the external device arrives via SI (whose I/Os are shared with IO1).

The different phases can each be configured separately to use this Single-bit mode by setting to 001 the IMODE, ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase configured in Single-SPI mode:
- IO0 (SO) is in output mode.
- IO1 (SI) is in input mode (high impedance).
- IO2 is in output mode and forced to 0 (to deactivate the “write protect” function).
- IO3 is in output mode and forced to 1 (to deactivate the “hold” function).
- IO4 to IO7 are in output mode and forced to 0.

This is the case even for the dummy phase if DMODE[2:0] = 001.

Dual-SPI mode

In Dual-SPI mode, two bits are sent/received simultaneously over the IO0/IO1 signals.

The different phases can each be configured separately to use Dual-SPI mode by setting to 010 the IMODE, ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase configured in Dual-SPI mode:
- IO0/IO1 are at high-impedance (input) during the data phase for the read operations, and outputs in all other cases.
- IO2 is in output mode and forced to 0.
- IO3 is in output mode and forced to 1.
- IO4 to IO7 are in output mode and forced to 0.
In the dummy phase when DMODE[2:0] = 010, IO0/IO1 are always high-impedance.

**Quad-SPI mode**

In Quad-SPI mode, four bits are sent/received simultaneously over the IO0/IO1/IO2/IO3 signals.

The different phases can each be configured separately to use the Quad-SPI mode by setting to 011 the IMODE, ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase configured in Quad-SPI mode:
- IO0 to IO3 are all at high-impedance (inputs) during the data phase for the read operations, and outputs in all other cases.
- IO4 to IO7 are in output mode and forced to 0.

In the dummy phase when DMODE[2:0] = 011, IO0 to IO3 are all high-impedance.

IO2 and IO3 are used only in Quad-SPI mode. If none of the phases are configured to use the Quad-SPI mode, then the pins corresponding to IO2 and IO3 can be used for other functions even while the OCTOSPI is active.

**Octal-SPI mode**

In regular Octal-SPI mode, the eight bits are sent/received simultaneously over the IO[0:7] signals.

The different phases can each be configured separately to use the Octal-SPI mode by setting to 100 the IMODE, ADMODE, ABMODE, and DMODE fields in OCTOSPI_CCR and OCTOSPI_WCCR.

In each phase that is configured in Octal-SPI mode, IO[0:7] are all at high-impedance (input) during the data phase for read operations, and outputs in all other cases.

In the dummy phase when DMODE[2:0] = 100, IO[0:7] are all high-impedance.

IO[4:7] are used only in Octal-SPI mode. If none of the phases are configured to use Octal-SPI mode, then the pins corresponding to IO[4:7] can be used for other functions even while the OCTOSPI is active.

**Single-data rate (SDR) mode**

By default, all the phases operate in Single-data rate (SDR) mode.

In SDR mode, when the OCTOSPI drives the IO0/SO, IO1 to IO7 signals, these signals transition only with the falling edge of CLK.

When receiving data in SDR mode, the OCTOSPI assumes that the external devices also send the data using CLK falling edge. By default (when SSHIFT = 0 in OCTOSPI_TCR), the signals are sampled using the following (rising) edge of CLK.
Double-transfer rate (DTR) mode

Each of the instruction, address, alternate-byte and data phases can be configured to operate in DTR mode setting IDTR, ADDTR, ABDTR, and DDTR in OCTOSPI_CCR.

In Memory-mapped mode, the DTR mode for each phase of the write operations is specified in OCTOSPI_WCCR. The DTR mode for each phase of the read operations is specified in OCTOSPI_CCR.

In DTR mode, when the OCTOSPI drives the IO0/SO and IO1 to IO7 signals in the instruction, address, and alternate-byte phases, a bit is sent or received on each of the falling and rising edges of CLK.

When receiving data in DTR mode, the OCTOSPI assumes that the external devices also send the data using both CLK rising and falling edges. When DDTR = 1 in OCTOSPI_CCR, the software must clear SSHIFT in OCTOSPI_TCR. Thus, the signals are sampled one half of a CLK cycle later (on the following, opposite edge).

In DTR mode, it is recommended to set DHQC of OCTOSPI_TCR, to shift the outputs by a quarter of cycle and avoid to hold issues on the memory side.

Note: DHQC must not be set when the prescaler value is 0, as this action leads to unpredictable behavior.

Dual-quad configuration

When DMM = 1 in OCTOSPI_CR, the OCTOSPI is in dual-memory configuration: if DMODE = 100, two external Quad-SPI devices (device A and device B) are used in order to send/receive eight bits (or 16 bits in DTR mode) every cycle, effectively doubling the throughput.

Each device (A or B) uses the same CLK and NCS signals, but each has separate IO0 to IO3 signals.
The dual-quad configuration can be used in conjunction with the Single-SPI, Dual-SPI, and Quad-SPI modes, as well as with either the SDR or DTR mode.

The device size, as specified in DEVSIZE[4:0] of OCTOSPI_DCR1, must reflect the total external device capacity, that is the double of the size of one individual component.

If address X is even, then the byte that the OCTOSPI gives for address X is the byte at the address X/2 of device A, and the byte that the OCTOSPI gives for address X + 1 is the byte at the address X/2 of device B. In other words, the bytes at even addresses are all stored in device A and the bytes at odd addresses are all stored in device B.

When reading the status registers of the devices in dual-quad configuration, twice as many bytes must be read compared to the same read in Regular-command protocol: if each device gives eight valid bits after the instruction for fetching the status register, then the OCTOSPI must be configured with a data length of 2 bytes (16 bits), and the OCTOSPI receives one byte from each device.

If each device gives a status of 16 bits, then the OCTOSPI must be configured to read 4 bytes to get all the status bits of both devices in dual-quad configuration. The least-significant byte of the result (in the data register) is the least-significant byte of device A status register. The next byte is the least-significant byte of device B status register. Then, the third byte of the data register is the device A second byte. The forth byte is the device B second byte (if devices have 16-bit status registers).

An even number of bytes must always be accessed in dual-quad configuration. For this reason, bit 0 of DL[31:0] in OCTOSPI_DLR is stuck at 1 when DMM = 1.

In dual-quad configuration, the behavior of device A interface signals is basically the same as in normal mode. Device B interface signals have exactly the same waveforms as device A ones during the instruction, address, alternate-byte, and dummy-cycle phases. In other words, each device always receives the same instruction and the same address.

Then, during the data phase, the AIOx and the BIOx buses both transfer data in parallel, but the data that is sent to (or received from) device A is distinct than the one from device B.

20.4.5 HyperBus protocol

The OCTOSPI can communicate with the external device using the HyperBus protocol.

The HyperBus uses 11 to 12 pins depending on the operating voltage:
- IO[7:0] as bidirectional data bus
- RWDS for read and write data strobe and latency insertion (mapped on DQS pin)
- NCS
- CLK
- NCLK for 1.8 V operations

The HyperBus does not require any command specification nor any alternate bytes. As a consequence, a separate register set is used to define the timing of the transaction.

The HyperBus frame is composed of the following phases:
- Command/address phase
- Data phase

The NCS falls before the start of a transaction and rises again after each transaction finishes.
The specific HyperBus features are configured through the registers in the 0x0200-0x02FC offset range.

**Command/address phase**

During this initial phase, the OCTOSPI sends 48 bits over IO[7:0] to specify the operations to be performed with the external device.

<table>
<thead>

<td>Selects the starting 16-bit word within the half page.</td>
</tr>
</tbody>
</table>

The address space is configured through the memory type MTYP[2:0] of OCTOSPI_DCR1.

The total size of the device is configured in DEVSIZE[4:0] of OCTOSPI_DCR1. In case of multi-chip product (MCP), the device size is the sum of all the sizes of all the MCP dies.

**Read/write operation with initial latency**

The HyperBus read and write operations need to respect two timings:

- \( t_{\text{RWR}} \): minimal read/write recovery time for the device (defined in TRWR[7:0] of OCTOSPI_HLCR)
- \( t_{\text{ACC}} \): access time for the device (defined in TAC[7:0] of OCTOSPI_HLCR)
During the read operation, the RWDS is used by the device, in two ways (see Figure 81):
- during the command/address phase, to request an additional latency
- during the data phase, for data strobing

During the write operation the RWDS is used:
- by the device, during the command/address phase, to request an additional latency.
- by the OCTOSPI, during the data phase, for write data masking.

**Figure 82. HyperBus write operation with initial latency**

Read/write operation with additional latency

If the device needs an additional latency (during refresh period of a SDRAM for example), RWDS must be tied to one during one of the RWDS signals, during the command/address phase.

An additional $t_{ACC}$ duration is added by the OCTOSPI to meet the device request.

**Figure 83. HyperBus read operation with additional latency**
Fixed-latency mode

Some devices or some applications may not want to operate with a variable latency time as described above.

The latency can be forced to 2 x t\textsubscript{ACC} by setting LM of OCTOSPI_HLCR.

In this OCTOSPI latency mode, the state of the RWDS signal is not taken into account by the OCTOSPI and an additional latency is always added, leading to a fixed 2 x t\textsubscript{ACC} latency time.

Write operation with no latency

Some devices can also require a zero latency for the write operations. This write-zero latency can be forced by setting WZL in OCTOSPI_HLCR.
Latency on page-crossing during the read operations

An additional latency can be needed by some devices for the read operation when crossing pages.

The initial latency must be respected for any page access, as a consequence, when the first access is close to the page boundary, a latency is automatically added at the page crossing to respect the $t_{ACC}$ time.

Figure 86. HyperBus read operation page crossing with latency

20.4.6 Specific features

The OCTOSPI supports some specific features, such as:

- Wrap support
- NCS boundary and refresh

Wrap support

The OCTOSPI supports an hybrid wrap as defined by the HyperBus protocol. An hybrid wrap is also supported in the Regular-command protocol.

In hybrid wrap, the transaction can continue after the initial wrap with an incremental access.

The wrap size supported by the target memory is configured by WRAPSIZE in OCTOSPI_DCR2.

Wrap is supported only in memory-read direction and only for data size = 4 bytes. Wrapped reads are supported for both HyperBus and Regular-command protocols. To enable wrapped-read accesses, the dedicated registers OCTOSPI_WPxxx must be programmed according to the wrapped-read access characteristics. The dedicated OCTOSPI_WPxxx registers apply for both HyperBus and Regular-command protocols.

If the target memory is not supporting the hybrid wrap, WRAPSIZE must be set to 0.

NCS boundary and refresh

Two processes can be activated to regulate the OCTOSPI transactions:

- NCS boundary
- Refresh

The NCS boundary feature limits a transaction to a boundary of aligned addresses. The size of the address to be aligned with, is configured in CSBOUND[4:0] of OCTOSPI_DCR3 and it is equal to $2^{CSBOUND}$. 
As an example, if CSBOUND(4:0] = 0x4, the boundary is set to $2^4 = 16$ bytes. As a consequence, the NCS is released each time that the LSB address is equal to 0xF and each time that a new transaction is issued to address the next data.

If CSBOUND[4:0] = 0, the feature is disabled and a minimum value of 3 is recommended.

The NCS boundary feature cannot be used for Flash memory devices in write mode since a command is necessary to program another page of the Flash memory.

The refresh feature limits the duration of the transactions to the value programmed in REFRESH[31:0] of OCTOSPI_DCR4. The duration is expressed in number of cycles. This allows an external RAM to perform its internal refresh operation regularly.

The refresh value must be greater than the minimal transaction size in terms of number of cycles including the command/address/alternate/dummy phases.

If NCS boundary and refresh are enabled at the same time, the NCS is released on the first condition met.

**Re-starting after an interrupted transfer**

When a read or write operation is interrupted by a timeout or communication regulation feature, the Octo-SPI interface, as soon as possible after getting back the port ownership, re-issues the initial command sequence together with the address following the last address actually accessed before interruption. The transfer initially set goes on and ends seamlessly.

20.4.7 OCTOSPI operating modes introduction

The OCTOSPI has the following operating modes regardless of the low-level protocol used (either Regular-command or HyperBus):

- Indirect mode (read or write)
- Automatic status-polling mode
- Memory-mapped mode

20.4.8 OCTOSPI Indirect mode

In Indirect mode, the commands are started by writing to the OCTOSPI registers and the data is transferred by writing or reading the data register, in a similar way to other communication peripherals.

When FMODE[1:0] = 0 in OCTOSPI_CR, the OCTOSPI is in Indirect-write mode: bytes are sent to the external device during the data phase. Data is provided by writing to OCTOSPI_DR.

When FMODE[1:0] = 01, the OCTOSPI is in Indirect-read mode: bytes are received from the external device during the data phase. Data is recovered by reading OCTOSPI_DR.

In Indirect mode, when the OCTOSPI is configured in DTR mode over eight lanes with DQS disabled, the given starting address and the data length must be even.

*Note:* The OCTOSPI_AR register must be updated even if the start address is the same as the start address of the previous indirect access.
The number of bytes to be read/written is specified in OCTOSPI_DLR:

- If DL[31:0] = 0xFFFF FFFF, the data length is considered undefined and the OCTOSPI simply continues to transfer data until it reaches the end of the external device (as defined by DEVSIZE). If no bytes are to be transferred, DMODE[2:0] must be set to 0 in OCTOSPI_CCR.
- If DL[31:0] = 0xFFFF FFFFF and DEVSIZE[4:0] = 0x1F (its maximum value indicating at 4-Gbyte device), the transfers continue indefinitely, stopping only after an abort request or after the OCTOSPI is disabled. After the last memory address is read (at address 0xFFFF FFFF), reading continues with address = 0x0000 0000.

When the programmed number of bytes to be transmitted or received is reached, TCF bit is set in OCTOSPI_SR and an interrupt is generated if TCIE = 1 in OCTOSPI_CR. In the case of an undefined number of data, TCF is set when the limit of the external SPI memory is reached, according to the device size defined in OCTOSPI_DCR1.

**Triggering the start of a transfer in Regular-command protocol**

Depending on the OCTOSPI configuration, there are three different ways to trigger the start of a transfer in Indirect mode when using Regular-command protocol. In general, the start of transfer is triggered as soon as the software gives the last information that is necessary for the command. More specifically in Indirect mode, a transfer starts when one of the following sequence of events occurs:

- if no address is necessary (ADMODE[2:0] = 000) and if no data needs to be provided by the software (FMODE[1:0] = 01 or DMODE[2:0] = 000), and at the moment when a write is performed to INSTRUCTION[31:0] in OCTOSPI_IR
- if an address is necessary (when ADMODE[2:0] ≠ 000) and if no data needs to be provided by the software (when FMODE[1:0] = 01 or DMODE[2:0] = 000), and at the moment when a write is performed to ADDRESS[31:0] in OCTOSPI_AR
- if an address is necessary (when ADMODE[2:0] ≠ 000) and if data needs to be provided by the software (when FMODE[1:0] = 00 and DMODE[2:0] ≠ 000), and at the moment when a write is performed to DATA[31:0] in OCTOSPI_DR

A write to OCTOSPI_ABR never triggers the communication start. If alternate bytes are required, they must have been programmed before.

As soon as a command is started, the BUSY bit is automatically set in OCTOSPI_SR.

**Triggering the start of a transfer in HyperBus protocol**

Depending on the OCTOSPI configuration, there are different ways to trigger the start of a command in Indirect mode. In general, it is triggered as soon as the firmware gives the last information that is necessary for the transfer to start, and more specifically, a communication in Indirect mode is triggered by one of the following register settings, when it is the last one to be executed:

- when a write is performed to ADDRESS[31:0] (OCTOSPI_AR) in Indirect-read mode (when FMODE = 01).
- when a write is performed to DATA[31:0] (OCTOSPI_DR) in Indirect-write mode (when FMODE = 00).
- when a write is performed to INSTRUCTION[31:0] (OCTOSPI_IR) for both Indirect read and write modes

**Note:** In case of HyperBus, a (dummy) write to OCTOSPI_IR is required to trigger the transfer, as for Regular-command protocol.
As soon as a transfer is started, the BUSY bit (OCTOSPI_SR[5]) is automatically set.

**FIFO and data management**

Data in Indirect mode passes through a 32-byte FIFO that is internal to the OCTOSPI. FLEVEL in OCTOSPI_SR indicates how many bytes are currently being held in the FIFO.

AHB burst transactions are supported. Data of the burst are successively written in OCTOSPI_DR and immediately transferred in the internal FIFO.

In Indirect-write mode (FMODE[1:0] = 00), the software adds data to the FIFO when it writes in OCTOSPI_DR. A word write adds 4 bytes to the FIFO, an half-word write adds 2 bytes, and a byte write adds only 1 byte. If the software adds too many bytes to the FIFO (more than indicated in DL[31:0]), the extra bytes are flushed from the FIFO at the end of the write operation (when TCF is set).

The byte/half-word accesses to OCTOSPI_DR must be done only to the least significant byte/halfword of the 32-bit register.

FTHRES is used to define a FIFO threshold after which point the FIFO threshold flag, FTF, gets set. In Indirect-read mode, FTF is set when the number of valid bytes to be read from the FIFO is above the threshold. FTF is also set if there is any data left in the FIFO after the last byte is read from the external device, regardless of FTHRES setting. In Indirect-write mode, the FTF is set when the number of empty bytes in the FIFO is above the threshold.

If FTIE = 1, there is an interrupt when the FTF is set. If DMAEN = 1, a DMA transfer is initiated when the FTF is set. The FTF is cleared by hardware as soon as the threshold condition is no longer true (after enough data has been transferred by the CPU or DMA).

The last data read in RX FIFO remains valid as long as there is no request for the next line. This means that, when the application reads several times in a row at the same location, the data is provided from the RX FIFO and not read again from the distant memory.

20.4.9 OCTOSPI Automatic status-polling mode

In Automatic status-polling mode, the OCTOSPI periodically starts a command to read a defined number of status bytes (up to four). The received bytes can be masked to isolate some status bits and an interrupt can be generated when the selected bits have a defined value.

The access to the device begins in the same manner as in Indirect-read mode. BUSY in OCTOSPI_SR goes high at this point and stays high even between the periodic accesses.

The content of MASK[31:0] in OCTOSPI_PSMAR is used to mask the data from the external device in Automatic status-polling mode:

- If the MASK[n] = 0, then bit n of the result is masked and not considered.
- If MASK[n] = 1, and the content of bit[n] is the same as MATCH[n] in OCTOSPI_PSMAR, then there is a match for bit n.

If PMM = 0 in OCTOSPI_CR, the AND-match mode is activated: SMF is set in OCTOSPI_SR only when there is a match on all of the unmasked bits.

If PMM = 1 in OCTOSPI_CR, the OR-match mode is activated: SMF gets set if there is a match on any of the unmasked bits.

An interrupt is called when SMF = 1 if SMIE = 1.
If APMS is set in OCTOSPI_CR, the operation stops and BUSY goes to 0 as soon as a match is detected. Otherwise, BUSY stays at 1 and the periodic accesses continue until there is an abort or until the OCTOSPI is disabled (EN = 0).

OCTOSPI_DR contains the latest received status bytes (FIFO deactivated). The content of this register is not affected by the masking used in the matching logic. FTF in OCTOSPI_SR is set as soon as a new reading of the status is complete. FTF is cleared as soon as the data is read.

In Automatic status-polling mode, variable latency is not supported. As a consequence, the memory must be configured in fixed latency.

### 20.4.10 OCTOSPI Memory-mapped mode

When configured in Memory-mapped mode, the external SPI device is seen as an internal memory.

**Note:** More than 256 Mbytes can be addressed even if the external device capacity is larger.

If an access is made to an address outside of the range defined by DEVSIZE[4:0] but still within the 256 Mbytes range, then an AHB error is given. The effect of this error depends on the AHB master that attempted the access:

- If it is the Cortex CPU, a hard-fault interrupt is generated.
- If it is a DMA, a DMA transfer error is generated and the corresponding DMA channel is automatically disabled.

Byte, half-word, and word access types are all supported.

A support for execute in place (XIP) operation is implemented, where the OCTOSPI continues to load the bytes to the addresses following the most recent access. If subsequent accesses are continuous to the bytes that follow, then these operations ends up quickly since their results were pre-fetched.

By default, the OCTOSPI never stops its prefetch operation, it either keeps the previous read operation active with the NCS maintained low or it relaunches a new transfer, even if no access to the external device occurs for a long time.

Since external devices tend to consume more when the NCS is held low, the application may want to activate the timeout counter (TCEN = 1 in OCTOSPI_CR): the NCS is released after a period defined by TIMEOUT[15:0] in OCTOSPI_LPTR, when x cycles have elapsed without an access since the clock is inactive.

BUSY goes high as soon as the first memory-mapped access occurs. Because of the prefetch operations, BUSY does not fall until there is an abort, or the peripheral is disabled.

### 20.4.11 OCTOSPI configuration introduction

The OCTOSPI configuration is done in three steps:

1. OCTOSPI system configuration
2. OCTOSPI device configuration
3. OCTOSPI mode configuration
20.4.12 OCTOSPI system configuration

The OCTOSPI is configured using OCTOSPI_CR. The user must program:

- Functional mode with FMODE[1:0]
- Automatic status-polling mode behavior if needed with PMM and APMS
- FIFO level with FTHRES
- DMA usage with DMAEN
- Timeout counter usage with TCEN
- Dual-quad configuration, if needed, with DMM (only for Quad-SPI mode)

In case of an interrupt usage, the respective enable bit can also be set during this phase.

If the timeout counter is used, the timeout value is programmed in OCTOSPI_LPTR.

The DMA channel must not be enabled during the OCTOSPI configuration: it must be enabled only when the operation is fully configured, to avoid any unexpected request generation.

The DMA and OCTOSPI must be configured in a coherent manner regarding data length: FTHRES value must reflect the DMA burst size.

20.4.13 OCTOSPI device configuration

The parameters related to the external device targeted are configured through OCTOSPI_DCR1 and OCTOSPI_DCR2. The user must program:

- Device size with DEVSIZE[4:0]
- Chip-select minimum high time with CSHT[2:0]
- Clock mode with FRCK and CKMODE
- Device frequency with PRESCALER[7:0]

MTYP[2:0] defines the memory type to be used for 8-line modes:

- Micron mode with D0/D1 ordering in 8-data-bit mode (DMODE[2:0] = 100)
- Macronix mode with D1/D0 ordering in 8-data-bit mode (DMODE[2:0] = 100)
- HyperBus memory mode: the protocol follows the HyperBus specification, and an 8-data-bit DTR mode must be selected.
- HyperBus register mode, addressing register space: the memory-mapped accesses in this mode must be non-cacheable, or the Indirect read/write modes must be used.

DEVSIZE[4:0] defines the size of external memory using the following formula:

\[
\text{Number of bytes in the device} = 2^{\text{DEVSIZE}+1}
\]

where DEVSIZE+1 is the number of address bits required to address the external device. The external device capacity can go up to 4 Gbytes (addressed using 32 bits) in Indirect mode, but the addressable space in Memory-mapped mode is limited to 256 Mbytes.

If DMM = 1, DEVSIZE[4:0] indicates the total capacity of the two devices together.

When the OCTOSPI executes two commands, one immediately after the other, it raises the chip-select signal (NCS) high between the two commands for only one CLK cycle by default.

If the external device requires more time between commands, the chip-select high time CSHT[2:0] can be used to specify the minimum number of CLK cycles for which the NCS must remain high.
CKMODE indicates the level that the CLK takes between commands (when NCS = 1).
In HyperBus protocol, the device timing (tACC and tRWR) and the Latency mode must be configured in OCTOSPI_HLCR.

### 20.4.14 OCTOSPI Regular-command mode configuration

#### Indirect mode configuration

When FMODE[1:0] = 00, the Indirect-write mode is selected and data can be sent to the external device. When FMODE[1:0] = 01, the Indirect-read mode is selected and data can be read from the external device.

When the OCTOSPI is used in Indirect mode, the frames are constructed in the following way:

1. Specify a number of data bytes to read or write in OCTOSPI_DLR.
2. Specify the frame timing in OCTOSPI_TCR.
3. Specify the frame format in OCTOSPI_CCR.
4. Specify the instruction in OCTOSPI_IR.
5. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_ABR.
6. Specify the targeted address in OCTOSPI_AR.
7. Enable the DMA channel if needed.
8. Read/write the data from/to the FIFO through OCTOSPI_DR (if no DMA usage).

If neither the address register (OCTOSPI_AR) nor the data register (OCTOSPI_DR) need to be updated for a particular command, then the command sequence starts as soon as OCTOSPI_IR is written. This is the case when both ADMODE[2:0] and DMODE[2:0] equal 000, or if just ADMODE[2:0] = 000 when in Indirect-read mode (FMODE[1:0] = 01).

When an address is required (ADMODE[2:0] ≠ 000) and the data register does not need to be written (FMODE[1:0] = 01 or DMODE[2:0] = 000), the command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.

In case of data transmission (FMODE[1:0] = 00 and DMODE[2:0] ≠ 000), the communication start is triggered by a write in the FIFO through OCTOSPI_DR.

#### Automatic status-polling mode configuration

The Automatic status-polling mode is enabled by setting FMODE[1:0] = 10. In this mode, the programmed frame is sent and the data is retrieved periodically.

The maximum amount of data read in each frame is 4 bytes. If more data is requested in OCTOSPI_DLR, it is ignored and only 4 bytes are read. The periodicity is specified in OCTOSPI_PIR.

Once the status data has been retrieved, the following can be processed:
- Set SMF (an interrupt is generated if enabled).
- Stop automatically the periodic retrieving of the status bytes.

The received value can be masked with the value stored in OCTOSPI_PSMKR, and can be ORed or ANDed with the value stored in OCTOSPI_PSMAR.
In case of a match, SMF is set and an interrupt is generated if enabled; The OCTOSPI can be automatically stopped if AMPS is set. In any case, the latest retrieved value is available in OCTOSPI_DR.

When the OCTOSPI is used in Automatic status-polling mode, the frames are constructed in the following way:

1. Specify the input mask in OCTOSPI_PSMKR.
2. Specify the comparison value in OCTOSPI_PSMAR.
3. Specify the read period in OCTOSPI_PIR.
4. Specify a number of data bytes to read in OCTOSPI_DLR.
5. Specify the frame timing in OCTOSPI_TCR.
6. Specify the frame format in OCTOSPI_CCR.
7. Specify the instruction in OCTOSPI_IR.
8. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_ABR.
9. Specify the optional targeted address in OCTOSPI_AR.

If the address register (OCTOSPI_AR) does not need to be updated for a particular command, then the command sequence starts as soon as OCTOSPI_CCR is written. This is the case when ADMODE[2:0] = 000.

When an address is required (ADMODE[2:0] ≠ 000), the command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.

**Memory-mapped mode configuration**

In Memory-mapped mode, the external device is seen as an internal memory but with some latency during accesses. Read and write operations are allowed to the external device in this mode.

It is not recommended to program the Flash memory using memory-mapped writes, as the internal flags for erase or programming status have to be polled.

Memory-mapped mode is entered by setting FMODE[1:0] = 11 in OCTOSPI_CR.

The programmed instruction and frame are sent when an AHB master accesses the memory mapped space.

The FIFO is used as a prefetch buffer to anticipate any linear reads. Any access to OCTOSPI_DR in this mode returns zero.

The data length register (OCTOSPI_DLR) has no meaning in Memory-mapped mode.

When the OCTOSPI is used in Memory-mapped mode, the frames are constructed in the following way:
1. Specify the frame timing in OCTOSPI_TCR for read operation.
2. Specify the frame format in OCTOSPI_CCR for read operation.
3. Specify the instruction in OCTOSPI_IR.
4. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_ABR for read operation.
5. Specify the frame timing in OCTOSPI_WTCR for write operation.
6. Specify the frame format in OCTOSPI_WCCR for write operation.
7. Specify the instruction in OCTOSPI_WIR.
8. Specify the optional alternate byte to be sent right after the address phase in OCTOSPI_WABR for read operation.

All the configuration operations must be completed before the first access to the memory area. On the first access, the OCTOSPI becomes busy, and no further configuration is allowed.

**OCTOSPI delayed data sampling when no DQS is used**

By default, when no DQS is used, the OCTOSPI samples the data driven by the external device one half of a CLK cycle after the external device drives the signal.

In case of any external signal delays, it may be useful to sample the data later. Using SSHIFT in OCTOSPI_TCR, the sampling of the data can be shifted by half of a CLK cycle.

The firmware must clear SSHIFT when the data phase is configured in DTR mode (DDTR = 1).

**OCTOSPI delayed data sampling when DQS is used**

When external DQS is used as a sampling clock, it can be shifted in time to compensate the data propagation delay. This shift is performed by an external delay block located outside the OCTOSPI. The control of this feature depends on the device implementation (see the product reference manual for more details).

In certain configuration cases, this external delay block is implemented but is not useful, so it can be bypassed by setting DLYBYP in OCTOSPI_DCR1.

**Sending the instruction only once (SIOO)**

A Flash memory can provide a mode where an instruction must be sent only with the first command sequence, while subsequent commands start directly with the address. The user can take advantage of this type of features using SIOO in OCTOSPI_CCR.

SIOO is valid for Memory-mapped mode only. If this bit is set, the instruction is sent only for the first command following a write to OCTOSPI_CCR.

Subsequent command sequences skip the instruction phase, until there is a write to OCTOSPI_CCR. SIOO has no effect when IMODE[1:0] = 00 (no instruction).

SIOO mode is not supported when any of the communication regulation, NCS boundary or refresh features are used.
20.4.15 OCTOSPI HyperBus protocol configuration

Indirect mode configuration
When FMODE[1:0] = 00, the Indirect-write mode is selected and data can be sent to the external device. When FMODE[1:0] = 01, the Indirect-read mode is selected where data can be read from the external device.

When the OCTOSPI is used in Indirect mode, the frames are constructed in the following way:
1. Specify a number of data bytes to read or write in OCTOSPI_DLR.
2. Specify the targeted address in OCTOSPI_AR.
3. Make a write operation in OCTOSPI_IR and enable the DMA channel if needed.
4. Read/write the data from/to the FIFO through OCTOSPI_DR (if no DMA usage).

In Indirect-read mode, the command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.
In Indirect-write mode, the communication start is triggered by a write in the FIFO through OCTOSPI_DR.

Automatic status-polling mode configuration
The Automatic status-polling mode is enabled setting FMODE[1:0] = 10. In this mode, the programmed frame is sent and the data is retrieved periodically.

The maximum amount of data read in each frame is 4 bytes. If more data is requested in OCTOSPI_DLR, it is ignored and only 4 bytes are read. The periodicity is specified in OCTOSPI_PIR.

Once the status data has been retrieved, it can be internally processed to:
- Set SMF (an interrupt is generated if enabled).
- Stop automatically the periodic retrieving of the status bytes.

The received value can be masked with the value stored in OCTOSPI_PSMKR and can be ORed or ANDed with the value stored in OCTOSPI_PSMAR.

In case of a match, SMF is set and an interrupt is generated if enabled. The OCTOSPI can be automatically stopped if AMPS is set.

In any case, the latest retrieved value is available in OCTOSPI_DR.

When the OCTOSPI is used in Automatic status-polling mode, the frames are constructed in the following way:
1. Specify the input mask in OCTOSPI_PSMKR.
2. Specify the comparison value in OCTOSPI_PSMAR.
3. Specify the read period in OCTOSPI_PIR.
4. Specify a number of data bytes to read in OCTOSPI_DLR.
5. Specify the targeted address in OCTOSPI_AR.

The command sequence starts as soon as the address is updated with a write to OCTOSPI_AR.
Memory-mapped mode configuration

In Memory-mapped mode, the external device is seen as an internal memory but with some latency during the accesses. Read and write operations are allowed to the external device in this mode.

The Memory-mapped mode is entered by setting FMODE[1:0] = 11. The programmed instruction and frame is sent when an AHB master accesses the memory mapped space.

The FIFO is used as a prefetch buffer to anticipate any linear reads. Any access to OCTOSPI_DR in this mode returns zero.

The data length register (OCTOSPI_DLR) has no meaning in Memory-mapped mode.

All the configuration operation must be completed prior to the first access to the memory area. On the first access, the OCTOSPI becomes busy, and no configuration is allowed.

20.4.16 OCTOSPI error management

A error can be generated in the following cases:

- in Indirect or Automatic status-polling mode, when a wrong address has been programmed in OCTOSPI_AR (according to the device size defined by DEVSIZE[4:0]). This sets TEF and an interrupt is generated if enabled.
- in Indirect mode, if the address plus the data length exceed the device size. TEF is set as soon as the access is triggered.
- in Memory-mapped mode when an out-of-range access is done by an AHB master. This generates an AHB error as a response to the faulty AHB request.
- when the Memory-mapped mode is disabled. An access to the memory-mapped area generates an AHB error as a response to the faulty AHB request.

The OCTOSPI generates an AHB slave error in the following situations:

- Memory-mapped mode is disabled and an AHB read request occurs.
- Read or write address exceeds the size of the external memory.
- Abort is received while a read or write burst is ongoing.
- OCTOSPI is disabled while a read or write burst is ongoing.
- Write wrap burst is received.
- Write request is received while DQSE = 0 in OCTOSPI_WCCR, which means that the DQS output is disabled.
- Write request is received while DMODE[2:0] = 000 (no data phase), except when MTYP[2:0] is HyperBus.
- Illegal access size when wrap read burst. This means the HSIZE is different from 4 bytes (only for Memory-mapped mode).
- Illegal wrap size when receiving read wrap burst with size different from 4 bytes (only for Memory-mapped mode).

20.4.17 OCTOSPI BUSY and ABORT

Once the OCTOSPI starts an operation with the external device, BUSY is automatically set in OCTOSPI_SR.

In Indirect mode, BUSY is reset once the OCTOSPI has completed the requested command sequence and the FIFO is empty.
In Automatic status-polling mode, BUSY goes low only after the last periodic access is complete, due to a match when APMS = 1 or due to an abort.

After the first access in Memory-mapped mode, BUSY goes low only on an abort.

Any operation can be aborted by setting ABORT in OCTOSPI_CR. Once the abort is completed, BUSY and ABORT are automatically reset, and the FIFO is flushed.

Before setting ABORT, the software must ensure that all the current transactions are finished using the synchronization barriers.

Note: Some devices may misbehave if a write operation to a status register is aborted.

20.4.18 OCTOSPI reconfiguration or deactivation

Prior to any OCTOSPI reconfiguration, the software must ensure that all the transactions are completed:

- After a Memory-mapped write, the software must perform a dummy read followed by a synchronization barrier, then an abort.
- After a Memory-mapped read, the software must perform a synchronization barrier then an abort.

20.4.19 NCS behavior

By default, NCS is high, deselecting the external device. NCS falls before an operation begins and rises as soon as it finishes.

When CKMODE = 0 (Mode 0: CLK stays low when no operation is in progress), NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final rising CLK edge (see the figure below).

Figure 87. NCS when CKMODE = 0 (T = CLK period)
When CKMODE = 1 (Mode 3: CLK goes high when no operation is in progress) and when in SDR mode, NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final rising CLK edge (see the figure below).

Figure 88. NCS when CKMODE = 1 in SDR mode (T = CLK period)

When the CKMODE = 1 (Mode 3) and DDTR = 1 (data DTR mode), NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final active rising CLK edge (see the figure below). Because the DTR operations must finish with a falling edge, CLK is low when NCS rises, and CLK rises back up one half of a CLK cycle afterwards.

Figure 89. NCS when CKMODE = 1 in DTR mode (T = CLK period)

When the FIFO stays full during a read operation, or if the FIFO stays empty during a write operation, the operation stalls and CLK stays low until the software services the FIFO. If an abort occurs when an operation is stalled, NCS rises just after the abort is requested and then CLK rises one half of a CLK cycle later (see the figure below).

Figure 90. NCS when CKMODE = 1 with an abort (T = CLK period)

When not in dual-quad configuration (DMM = 0), only device A is accessed and thus the BNCS stays high. In dual-quad configuration, the BNCS behaves exactly the same as the ANCS. Thus, if there is a device B and if the application always stays in dual-quad
configuration, then the device B may use the ANCS and the pin outputting BNCS can be used for other functions.

20.5 Address alignment and data number

The following table summarizes the effect of the address alignment and programmed data number depending on the use case.

<table>

</table>

1. To be respected by the software.
2. IND = Indirect mode.
3. MM = Memory-mapped mode
4. RDS = read data strobe, WDM = write data mask.
20.6 OCTOSPI interrupts

An interrupt can be produced on the following events:

- Timeout
- Status match
- FIFO threshold
- Transfer complete
- Transfer error

Separate interrupt enable bits are available to provide more flexibility.

<table>

20.7 OCTOSPI registers

20.7.1 OCTOSPI control register (OCTOSPI_CR)

Address offset: 0x0000
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

Bits 31:30 Reserved, must be kept at reset value.
Bits 29:28 **FMODE[1:0]** Functional mode
This field defines the OCTOSPI functional mode of operation.
00: Indirect-write mode
01: Indirect-read mode
10: Automatic status-polling mode
11: Memory-mapped mode
If DMAEN = 1 already, then the DMA controller for the corresponding channel must be disabled before changing the FMODE[1:0] value. If FMODE[1:0] and FTHRES[4:0] are wrongly updated while DMAEN = 1, the DMA request signal automatically goes to inactive state.

Bits 27:24 Reserved, must be kept at reset value.

Bit 23 **PMM**: Polling match mode
This bit indicates which method must be used to determine a match during the Automatic status-polling mode.
0: AND-match mode, SMF is set if all the unmasked bits received from the device match the corresponding bits in the match register.
1: OR-match mode, SMF is set if any of the unmasked bits received from the device matches its corresponding bit in the match register.

Bit 22 **APMS**: Automatic status-polling mode stop
This bit determines if the Automatic status-polling mode is stopped after a match.
0: Automatic status-polling mode is stopped only by abort or by disabling the OCTOSPI.
1: Automatic status-polling mode stops as soon as there is a match.

Bit 21 Reserved, must be kept at reset value.

Bit 20 **TOIE**: Timeout interrupt enable
This bit enables the timeout interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 19 **SMIE**: Status match interrupt enable
This bit enables the status match interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 18 **FTIE**: FIFO threshold interrupt enable
This bit enables the FIFO threshold interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 17 **TCIE**: Transfer complete interrupt enable
This bit enables the transfer complete interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 16 **TEIE**: Transfer error interrupt enable
This bit enables the transfer error interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bits 15:13 Reserved, must be kept at reset value.
Bits 12:8  **FTHRES[4:0]:** FIFO threshold level

This field defines, in Indirect mode, the threshold number of bytes in the FIFO that causes the FIFO threshold flag FTF in OCTOSPI_SR, to be set.

- **00000:** FTF is set if there are one or more free bytes available to be written to in the FIFO in Indirect-write mode, or if there are one or more valid bytes can be read from the FIFO in Indirect-read mode.
- **00001:** FTF is set if there are two or more free bytes available to be written to in the FIFO in Indirect-write mode, or if there are two or more valid bytes can be read from the FIFO in Indirect-read mode.
- ...  
- **11111:** FTF is set if there are 32 free bytes available to be written to in the FIFO in Indirect-write mode, or if there are 32 valid bytes can be read from the FIFO in Indirect-read mode.

**Note:** If **DMAEN = 1,** the DMA controller for the corresponding channel must be disabled before changing the FTHRES[4:0] value.

Bit 7  **MSEL:** Flash select

This bit selects the Flash memory to be addressed in Single-, Dual-, Quad-SPI mode in single-memory configuration (when DMM = 0).

- **0:** FLASH 1 selected (data exchanged over IO[3:0])
- **1:** FLASH 2 selected (data exchanged over IO[7:4])

This bit is ignored when DMM = 1 or when Octal-SPI mode is selected.

Bit 6  **DMM:** Dual-memory configuration

This bit activates the dual-memory configuration, where two external devices are used simultaneously to double the throughput and the capacity

- **0:** Dual-quad configuration disabled
- **1:** Dual-quad configuration enabled

Bits 5:4  Reserved, must be kept at reset value.

Bit 3  **TCEN:** Timeout counter enable

This bit is valid only when the Memory-mapped mode (FMODE[1:0] = 11) is selected. This bit enables the timeout counter.

- **0:** Timeout counter is disabled, and thus the chip-select (NCS) remains active indefinitely after an access in Memory-mapped mode.
- **1:** Timeout counter is enabled, and thus the chip-select is released in the Memory-mapped mode after TIMEOUT[15:0] cycles of external device inactivity.

Bit 2  **DMAEN:** DMA enable

In Indirect mode, the DMA can be used to input or output data via OCTOSPI_DR. DMA transfers are initiated when FTF is set.

- **0:** DMA disabled for Indirect mode
- **1:** DMA enabled for Indirect mode

**Note:**  *Resetting the DMAEN bit while a DMA transfer is ongoing, breaks the handshake with the DMA. Do not write this bit during DMA operation.*

Bit 1  **ABORT:** Abort request

This bit aborts the on-going command sequence. It is automatically reset once the abort is completed. This bit stops the current transfer.

- **0:** No abort requested
- **1:** Abort requested

**Note:**  *This bit is always read as 0.*
20.7.2 OCTOSPI device configuration register 1 (OCTOSPI_DCR1)

Address offset: 0x0008
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

| Bit 31:27 | Reserved, must be kept at reset value. |
| Bit 26:24 | MTYP[2:0]: Memory type |
|          | This bit indicates the type of memory to be supported. |
|          | 000: Micron mode, D0/D1 ordering in DTR 8-data-bit mode. Regular-command protocol in Single-, Dual-, Quad- and Octal-SPI modes. |
|          | Note: In this mode, DQS signal polarity is inverted with respect to the memory clock signal. This is the default value and care must be taken to change MTYP[2:0] for memories different from Micron. |
|          | 010: Standard mode |
|          | 100: HyperBus memory mode, the protocol follows the HyperBus specification. 8-data-bit DTR mode must be selected. |
|          | 101: HyperBus register mode, addressing register space. The memory-mapped accesses in this mode must be non-cacheable, or Indirect read/write modes must be used. |
|          | Others: Reserved |

| Bit 23:21 | Reserved, must be kept at reset value. |
20.7.3 OCTOSPI device configuration register 2 (OCTOSPI_DCR2)

Address offset: 0x000C
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

| Bit 32  | Bit 31  | Bit 30  | Bit 29  | Bit 28  | Bit 27  | Bit 26  | Bit 25  | Bit 24  | Bit 23  | Bit 22  | Bit 21  | Bit 20  | Bit 19  | Bit 18  | Bit 17  | Bit 16  | Bit 15  | Bit 14  | Bit 13  | Bit 12  | Bit 11  | Bit 10  | Bit 9   | Bit 8   | Bit 7   | Bit 6   | Bit 5   | Bit 4   | Bit 3   | Bit 2   | Bit 1   | Bit 0   |
|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|
|         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         | WRAPSIZE[2:0] | rw | rw | rw |
|         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |
|         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         | PRESCALER[7:0] | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bits 20:16 **DEVSIZE[4:0]: Device size**

This field defines the size of the external device using the following formula:

Number of bytes in device = \(2^{(\text{DEVSIZE}+1)}\).

DEVSIZE+1 is effectively the number of address bits required to address the external device.

The device capacity can be up to 4 Gbytes (addressed using 32-bits) in Indirect mode, but the addressable space in Memory-mapped mode is limited to 256 Mbytes.

In Regular-command protocol, if DMM = 1, DEVSIZE[4:0] indicates the total capacity of the two devices together.

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:8 **CSHT[2:0]: Chip-select high time**

CSHT + 1 defines the minimum number of CLK cycles where the chip-select (NCS) must remain high between commands issued to the external device.

000: NCS stays high for at least 1 cycle between external device commands.

001: NCS stays high for at least 2 cycles between external device commands.

... 111: NCS stays high for at least 8 cycles between external device commands.

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **DLYBYP: Delay block bypass**

0: The internal sampling clock (called feedback clock) or the DQS data strobe external signal is delayed by the delay block (for more details on this block, refer to the dedicated section of the reference manual as it is not part of the OCTOSPI peripheral).

1: The delay block is bypassed, so the internal sampling clock or the DQS data strobe external signal is not affected by the delay block. The delay is shorter than when the delay block is not bypassed, even with the delay value set to minimum value in delay block.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **FRCK: Free running clock**

This bit configures the free running clock.

0: CLK is not free running.

1: CLK is free running (always provided).

Bit 0 **CKMODE: Mode 0/Mode 3**

This bit indicates the level taken by the CLK between commands (when NCS = 1).

0: CLK must stay low while NCS is high (chip-select released). This is referred to as Mode 0.

1: CLK must stay high while NCS is high (chip-select released). This is referred to as Mode 3.
Bits 31:19  Reserved, must be kept at reset value.

Bits 18:16  **WRAPSIZE[2:0]**: Wrap size

This field indicates the wrap size to which the memory is configured. For memories which have a separate command for wrapped instructions, this field indicates the wrap-size associated with the command held in the OCTOSPI1_WPIR register.

- 000: Wrapped reads are not supported by the memory.
- 001: Reserved
- 010: External memory supports wrap size of 16 bytes.
- 011: External memory supports wrap size of 32 bytes.
- 100: External memory supports wrap size of 64 bytes.
- 101: External memory supports wrap size of 128 bytes.
- 110-111: Reserved

Bits 15:8  Reserved, must be kept at reset value.

Bits 7:0  **PRESCALER[7:0]**: Clock prescaler

This field defines the scaler factor for generating the CLK based on the kernel clock (value + 1).

- 0: \( F_{CLK} = F_{KERNEL} \), kernel clock used directly as OCTOSPI CLK (prescaler bypassed). In this case, if the DTR mode is used, it is mandatory to provide to the OCTOSPI a kernel clock that has 50% duty-cycle.
- 1: \( F_{CLK} = F_{KERNEL}/2 \)
- 2: \( F_{CLK} = F_{KERNEL}/3 \)
- ...
- 255: \( F_{CLK} = F_{KERNEL}/256 \)

For odd clock division factors, the CLK duty cycle is not 50%. The clock signal remains low one cycle longer than it stays high.

### 20.7.4  OCTOSPI device configuration register 3 (OCTOSPI_DCR3)

Address offset: 0x0010

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.
**20.7.5 OCTOSPI device configuration register 4 (OCTOSPI_DCR4)**

Address offset: 0x0014  
Reset value: 0x0000 0000  
This register can be modified only when BUSY = 0.

**Bits 31:21** Reserved, must be kept at reset value.

**Bits 20:16** **CSBOUND[4:0]: NCS boundary**
This field enables the transaction boundary feature. When active, a minimum value of 3 is recommended.
The NCS is released on each boundary of $2^{CSBOUND}$ bytes.
- 0: NCS boundary disabled
- others: NCS boundary set to $2^{CSBOUND}$ bytes

**Bits 15:0** Reserved, must be kept at reset value.

**Bits 31:0** **REFRESH[31:0]: Refresh rate**
This field enables the refresh rate feature.
The NCS is released every REFRESH + 1 clock cycles for writes, and REFRESH + 4 clock cycles for reads.

*Note:* These two values can be extended with few clock cycles when refresh occurs during a byte transmission in Single-, Dual- or Quad-SPI mode, because the byte transmission must be completed.
- 0: Refresh disabled
- others: Maximum communication length is set to REFRESH + 1 clock cycles.
Bits 31:14  Reserved, must be kept at reset value.

Bits 13:8  **FLEVEL[5:0]:** FIFO level
   This field gives the number of valid bytes that are being held in the FIFO. FLEVEL = 0 when
   the FIFO is empty, and 32 when it is full.
   In Automatic status-polling mode, FLEVEL is zero.

Bits 7:6  Reserved, must be kept at reset value.

Bit 5  **BUSY:** Busy
   This bit is set when an operation is ongoing. It is cleared automatically when the operation
   with the external device is finished and the FIFO is empty.

Bit 4  **TOF:** Timeout flag
   This bit is set when timeout occurs. It is cleared by writing 1 to CTOF.

Bit 3  **SMF:** Status match flag
   This bit is set in Automatic status-polling mode when the unmasked received data matches
   the corresponding bits in the match register (OCTOSPI_PSMAR).
   It is cleared by writing 1 to CSMF.

Bit 2  **FTF:** FIFO threshold flag
   In Indirect mode, this bit is set when the FIFO threshold has been reached, or if there is any
   data left in the FIFO after the reads from the external device are complete.
   It is cleared automatically as soon as the threshold condition is no longer true.
   In Automatic status-polling mode, this bit is set every time the status register is read, and the
   bit is cleared when the data register is read.

Bit 1  **TCF:** Transfer complete flag
   This bit is set in Indirect mode when the programmed number of data has been transferred or
   in any mode when the transfer has been aborted. It is cleared by writing 1 to CTCF.

Bit 0  **TEF:** Transfer error flag
   This bit is set in Indirect mode when an invalid address is being accessed in Indirect mode.
   It is cleared by writing 1 to CTEF.

20.7.8 OCTOSPI data length register (OCTOSPI_DLR)

Address offset: 0x0040
Reset value: 0x0000_0000

This register can be modified only when BUSY = 0.

Bits 31:0 DL[31:0]: Data length
Number of data to be retrieved (value+1) in Indirect and Automatic status-polling modes. A value not greater than three (indicating 4 bytes) must be used for Automatic status-polling mode.
All 1’s in Indirect mode means undefined length, where OCTOSPI continues until the end of the memory, as defined by DEVSIZE.
0x0000_0000: 1 byte is to be transferred.
0x0000_0001: 2 bytes are to be transferred.
0x0000_0002: 3 bytes are to be transferred.
0x0000_0003: 4 bytes are to be transferred.
...
0xFFFF_FFFD: 4,294,967,294 (4G-2) bytes are to be transferred.
0xFFFF_FFFE: 4,294,967,295 (4G-1) bytes are to be transferred.
0xFFFF_FFFF: undefined length; all bytes, until the end of the external device, (as defined by DEVSIZE) are to be transferred. Continue reading indefinitely if DEVSIZE = 0x1F.
DL[0] is stuck at 1 in dual-memory configuration (DMM = 1) even when 0 is written to this bit, thus assuring that each access transfers an even number of bytes.
This field has no effect in Memory-mapped mode.
20.7.9 OCTOSPI address register (OCTOSPI_AR)

Address offset: 0x0048
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bits 31:0 ADDRESS[31:0]: Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Address to be sent to the external device. In HyperBus protocol, this field must be even as this protocol is 16-bit word oriented. In dual-memory configuration, AR[0] is forced to 1. Writes to this field are ignored when BUSY = 1 or when FMODE = 11 (Memory-mapped mode).</td>
</tr>
</tbody>
</table>

20.7.10 OCTOSPI data register (OCTOSPI_DR)

Address offset: 0x0050
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bits 31:0 DATA[31:0]: Data</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data to be sent/received to/from the external SPI device</td>
</tr>
<tr>
<td>In Indirect-write mode, data written to this register is stored on the FIFO before it is sent to the external device during the data phase. If the FIFO is too full, a write operation is stalled until the FIFO has enough space to accept the amount of data being written.</td>
</tr>
<tr>
<td>In Indirect-read mode, reading this register gives (via the FIFO) the data that was received from the external device. If the FIFO does not have as many bytes as requested by the read operation and if BUSY = 1, the read operation is stalled until enough data is present or until the transfer is complete, whichever happens first.</td>
</tr>
<tr>
<td>In Automatic status-polling mode, this register contains the last data read from the external device (without masking).</td>
</tr>
<tr>
<td>Word, half-word, and byte accesses to this register are supported. In Indirect-write mode, a byte write adds 1 byte to the FIFO, a half-word write 2 bytes, and a word write 4 bytes. Similarly, in Indirect-read mode, a byte read removes 1 byte from the FIFO, a halfword read 2 bytes, and a word read 4 bytes. Accesses in Indirect mode must be aligned to the bottom of this register: A byte read must read DATA[7:0] and a half-word read must read DATA[15:0].</td>
</tr>
</tbody>
</table>
20.7.11 OCTOSPI polling status mask register (OCTOSPI_PSMKR)

Address offset: 0x0080
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

</tbody>
</table>

Bits 31:0 MASK[31:0]: Status mask
Mask to be applied to the status bytes received in Automatic status-polling mode
For bit n:
0: Bit n of the data received in Automatic status-polling mode is masked and its value is not considered in the matching logic.
1: Bit n of the data received in Automatic status-polling mode is unmasked and its value is considered in the matching logic.

20.7.12 OCTOSPI polling status match register (OCTOSPI_PSMAR)

Address offset: 0x0088
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

**Bit 31 SIIO**: Send instruction only once mode  
This bit has no effect when IMODE = 00 (see *Sending the instruction only once (SIIO)*).  
0: Send instruction on every transaction  
1: Send instruction only for the first command

**Bit 30** Reserved, must be kept at reset value.

**Bit 29 DQSE**: DQS enable  
This bit enables the data strobe management.  
0: DQS disabled  
1: DQS enabled

**Bit 28** Reserved, must be kept at reset value.
Bit 27  **DDTR**: Data double transfer rate
This bit sets the DTR mode for the data phase.
0: DTR mode disabled for data phase
1: DTR mode enabled for data phase

Bits 26:24  **DMODE[2:0]**: Data mode
This field defines the data phase mode of operation.
000: No data
001: Data on a single line
010: Data on two lines
011: Data on four lines
100: Data on eight lines
101-111: Reserved

Bits 23:22  Reserved, must be kept at reset value.

Bits 21:20  **ABSIZE[1:0]**: Alternate bytes size
This bit defines alternate bytes size.
00: 8-bit alternate bytes
01: 16-bit alternate bytes
10: 24-bit alternate bytes
11: 32-bit alternate bytes

Bit 19  **ABDTR**: Alternate bytes double transfer rate
This bit sets the DTR mode for the alternate bytes phase.
0: DTR mode disabled for alternate bytes phase
1: DTR mode enabled for alternate bytes phase
This field can be written only when BUSY = 0.

Bits 18:16  **ABMODE[2:0]**: Alternate-byte mode
This field defines the alternate-byte phase mode of operation.
000: No alternate bytes
001: Alternate bytes on a single line
010: Alternate bytes on two lines
011: Alternate bytes on four lines
100: Alternate bytes on eight lines
101-111: Reserved

Bits 15:14  Reserved, must be kept at reset value.

Bits 13:12  **ADSIZE[1:0]**: Address size
This field defines address size.
00: 8-bit address
01: 16-bit address
10: 24-bit address
11: 32-bit address

Bit 11  **ADDTR**: Address double transfer rate
This bit sets the DTR mode for the address phase.
0: DTR mode disabled for address phase
1: DTR mode enabled for address phase
Bits 10:8 **ADMODE[2:0]**: Address mode
This field defines the address phase mode of operation.
- 000: No address
- 001: Address on a single line
- 010: Address on two lines
- 011: Address on four lines
- 100: Address on eight lines
- 101-111: Reserved

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **ISIZE[1:0]**: Instruction size
This bit defines instruction size.
- 00: 8-bit instruction
- 01: 16-bit instruction
- 10: 24-bit instruction
- 11: 32-bit instruction

Bit 3 **IDTR**: Instruction double transfer rate
This bit sets the DTR mode for the instruction phase.
- 0: DTR mode disabled for instruction phase
- 1: DTR mode enabled for instruction phase

Bits 2:0 **IMODE[2:0]**: Instruction mode
This field defines the instruction phase mode of operation.
- 000: No instruction
- 001: Instruction on a single line
- 010: Instruction on two lines
- 011: Instruction on four lines
- 100: Instruction on eight lines
- 101-111: Reserved

### 20.7.15 OCTOSPI timing configuration register (OCTOSPI_TCR)

Address offset: 0x0108
Reset value: 0x0000 0000
This register can be modified only when BUSY = 0.
Octo-SPI interface (OCTOSPI)

20.7.16 OCTOSPI instruction register (OCTOSPI_IR)

Address offset: 0x0110
Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 TIMEOUT[15:0]: Timeout period
After each access in Memory-mapped mode, the OCTOSPI prefetches the subsequent bytes and hold them in the FIFO.
This field indicates how many CLK cycles the OCTOSPI waits after the clock becomes inactive and until it raises the NCS, putting the external device in a lower-consumption state.
### OCTOSPI wrap communication configuration register (OCTOSPI_WPCCR)

Address offset: 0x0140

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

</table>

**Bit 31** Reserved, must be kept at reset value.

**Bit 30** **SSHIFT**: Sample shift
By default, the OCTOSPI samples data 1/2 of a CLK cycle after the data is driven by the external device.
This bit allows the data to be sampled later in order to consider the external signal delays.
0: No shift
1: 1/2 cycle shift
The firmware must assure that SSHIFT=0 when the data phase is configured in DTR mode (when DDTR = 1).

**Bit 29** Reserved, must be kept at reset value.

**Bit 28** **DHQC**: Delay hold quarter cycle
Add a quarter cycle delay on the outputs in DTR communication to match hold requirement.
0: No quarter cycle delay
1: Quarter cycle delay inserted

**Bits 27:5** Reserved, must be kept at reset value.

**Bits 4:0** **DCYC[4:0]**: Number of dummy cycles
This field defines the duration of the dummy phase.
In both SDR and DTR modes, it specifies a number of CLK cycles (0-31). It is recommended to have at least 5 dummy cycles when using memories with DQS activated.
20.7.21 OCTOSPI wrap instruction register (OCTOSPI_WPIR)

Address offset: 0x0150
Reset value: 0x0000 0000
This register can be modified only when BUSY = 0.

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 TRWR[7:0]: Read write recovery time
Device read write recovery time expressed in number of communication clock cycles

Bits 15:8 TACC[7:0]: Access time
Device access time expressed in number of communication clock cycles
Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **WZL**: Write zero latency
This bit enables zero latency on write operations.
0: Latency on write accesses
1: No latency on write accesses

Bit 0 **LM**: Latency mode
This bit selects the Latency mode.
0: Variable initial latency
1: Fixed latency

21 Analog-to-digital converters (ADC)

21.1 Introduction

This section describes the implementation of up to 2 ADCs:

- ADC1 and ADC2 are tightly coupled and can operate in dual mode (ADC1 is master).

Each ADC consists of a 12-bit successive approximation analog-to-digital converter.

Each ADC has up to 20 multiplexed channels. A/D conversion of the various channels can be performed in single, continuous, scan or discontinuous mode. The result of the ADC is stored in a left-aligned or right-aligned 16-bit data register.

The ADCs are mapped on the AHB bus to allow fast data handling.

The analog watchdog features allow the application to detect if the input voltage goes outside the user-defined high or low thresholds.

A built-in hardware oversampler allows to improve analog performance while off-loading the related computational burden from the CPU.

An efficient low-power mode is implemented to allow very low consumption at low frequency.
21.2 ADC main features

- High-performance features
  - Up to 2 ADCs which can operate in dual mode:
    - ADC1 is connected to 16 external channels + 3 internal channels
    - ADC2 is connected to 16 external channels
  - 12, 10, 8 or 6-bit configurable resolution
  - ADC conversion time is independent from the AHB bus clock frequency
  - Faster conversion time by lowering resolution
  - Manage single-ended or differential inputs
  - AHB slave bus interface to allow fast data handling
  - Self-calibration
  - Channel-wise programmable sampling time
  - Up to four injected channels (analog inputs assignment to regular or injected channels is fully configurable)
  - Hardware assistant to prepare the context of the injected channels to allow fast context switching
  - Data alignment with in-built data coherency
  - Data can be managed by DMA for regular channel conversions
  - Data can be routed to DFSDM for post processing
  - 4 dedicated data registers for the injected channels

- Oversampler
  - 16-bit data register
  - Oversampling ratio adjustable from 2 to 256
  - Programmable data shift up to 8-bit

- Low-power features
  - Speed adaptive low-power mode to reduce ADC consumption when operating at low frequency
  - Allows slow bus frequency application while keeping optimum ADC performance
  - Provides automatic control to avoid ADC overrun in low AHB bus clock frequency application (auto-delayed mode)

- Number of external analog input channels per ADC
  - Up to 5 fast channels from GPIO pads
  - Up to 11 slow channels from GPIO pads

- In addition, there are several internal dedicated channels
  - The internal reference voltage (VREFINT), connected to ADC1
  - The internal temperature sensor (VTs), connected to ADC1
  - The VBAT monitoring channel (VBAT/3), connected to ADC1
  - DAC1 and DAC2 internal channels, connected to ADC2

- Start-of-conversion can be initiated:
  - By software for both regular and injected conversions
  - By hardware triggers with configurable polarity (internal timers events or GPIO input events) for both regular and injected conversions
• Conversion modes
  – Each ADC can convert a single channel or can scan a sequence of channels
  – Single mode converts selected inputs once per trigger
  – Continuous mode converts selected inputs continuously
  – Discontinuous mode
• Dual ADC mode for ADC1 and 2
• Interrupt generation at ADC ready, the end of sampling, the end of conversion (regular or injected), end of sequence conversion (regular or injected), analog watchdog 1, 2 or 3 or overrun events
• 3 analog watchdogs per ADC
• ADC input range: \( \text{V}_{\text{REF}-} \leq \text{V}_{\text{IN}} \leq \text{V}_{\text{REF}+} \)

*Figure 91* shows the block diagram of one ADC.

21.4.3 ADC clocks

Dual clock domain architecture

The dual clock-domain architecture means that the ADC clock is independent from the AHB bus clock.

The input clock is the same for all ADCs and can be selected between two different clock sources (see Figure 92: ADC clock scheme):

1. The ADC clock can be a specific clock source, derived from the following clock sources:
   - The system clock
   - PLLSAI1 (single ADC implementation)
   Refer to RCC Section for more information on how to generate ADC dedicated clock. To select this scheme, bits CKMODE[1:0] of the ADCx_CCR register must be reset.

2. The ADC clock can be derived from the AHB clock of the ADC bus interface, divided by a programmable factor (1, 2 or 4). In this mode, a programmable divider factor can be selected (/1, 2 or 4 according to bits CKMODE[1:0]). To select this scheme, bits CKMODE[1:0] of the ADCx_CCR register must be different from “00”.

Note: For option 2), a prescaling factor of 1 (CKMODE[1:0]=01) can be used only if the AHB prescaler is set to 1 (HPRE[3:0] = 0xxx in RCC_CFGR register).

Option 1) has the advantage of reaching the maximum ADC clock frequency whatever the AHB clock scheme selected. The ADC clock can eventually be divided by the following ratio: 1, 2, 4, 6, 8, 12, 16, 32, 64, 128, 256; using the prescaler configured with bits PRESC[3:0] in the ADCx_CCR register.

Option 2) has the advantage of bypassing the clock domain resynchronizations. This can be useful when the ADC is triggered by a timer and if the application requires that the ADC is precisely triggered without any uncertainty (otherwise, an uncertainty of the trigger instant time is added by the resynchronizations between the two clock domains).
Clock ratio constraint between ADC clock and AHB clock

There are generally no constraints to be respected for the ratio between the ADC clock and the AHB clock except if some injected channels are programmed. In this case, it is mandatory to respect the following ratio:

- \( F_{\text{HCLK}} \geq F_{\text{ADC}} / 4 \) if the resolution of all channels are 12-bit or 10-bit
- \( F_{\text{HCLK}} \geq F_{\text{ADC}} / 3 \) if there are some channels with resolutions equal to 8-bit (and none with lower resolution)
- \( F_{\text{HCLK}} \geq F_{\text{ADC}} / 2 \) if there are some channels with resolutions equal to 6-bit
21.4.4 ADC1/2 connectivity

ADC1 and ADC2 are tightly coupled and share some external channels as described in the below figures.

Figure 93. ADC1 connectivity
Figure 94. ADC2 connectivity
21.4.5 Slave AHB interface

The ADCs implement an AHB slave port for control/status register and data access. The features of the AHB interface are listed below:

- Word (32-bit) accesses
- Single cycle response
- Response to all read/write accesses to the registers with zero wait states.

The AHB slave interface does not support split/retry requests, and never generates AHB errors.

21.4.6 ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)

By default, the ADC is in Deep-power-down mode where its supply is internally switched off to reduce the leakage currents (the reset state of bit DEEPPWD is 1 in the ADC_CR register).

To start ADC operations, it is first needed to exit Deep-power-down mode by setting bit DEEPPWD=0.

When ADC operations are complete, the ADC can be disabled (ADEN=0). It is possible to save power by also disabling the ADC voltage regulator. This is done by writing bit ADVREGEN=0.

Then, to save more power by reducing the leakage currents, it is also possible to re-enter in ADC Deep-power-down mode by setting bit DEEPPWD=1 into ADC_CR register. This is particularly interesting before entering Stop mode.

Note: Writing DEEPPWD=1 automatically disables the ADC voltage regulator and bit ADVREGEN is automatically cleared.

When the internal voltage regulator is disabled (ADVREGEN=0), the internal analog calibration is kept.

In ADC Deep-power-down mode (DEEPPWD=1), the internal analog calibration is lost and it is necessary to either relaunch a calibration or re-apply the calibration factor which was previously saved (refer to Section 21.4.8: Calibration (ADCAL, ADCALDIF, ADC_CALFACT)).

21.4.7 Single-ended and differential input channels

Channels can be configured to be either single-ended input or differential input by programming DIFSEL[i] bits in the ADC_DIFSEL register. This configuration must be written while the ADC is disabled (ADEN=0). Note that the DIFSEL[i] bits corresponding to single-ended channels are always programmed at 0.

In single-ended input mode, the analog voltage to be converted for channel “i” is the difference between the ADCy_INPx external voltage equal to VINP[i] (positive input) and VREF− (negative input).

In differential input mode, the analog voltage to be converted for channel “i” is the difference between the ADCy_INPx external voltage positive input equal to VINP[i], and the ADCy_INNx negative input equal to VINN[i].

The input voltage in differential mode ranges from VREF− to VREF+, which makes a full scale range of 2xVREF+. When VINP[i] equals VREF−, VINN[i] equals VREF+, and the maximum
negative input differential voltage ($V_{REF-}$) corresponds to 0x000 ADC output. When $V_{INP[i]}$ equals $V_{REF+}$, $V_{INN[i]}$ equals $V_{REF-}$, and the maximum positive input differential voltage ($V_{REF+}$) corresponds to 0xFFF ADC output. When $V_{INP[i]}$ and $V_{INN[i]}$ are connected together, the zero input differential voltage corresponds to 0x800 ADC output.

The ADC sensitivity in differential mode is twice smaller than in single-ended mode.

When ADC is configured as differential mode, both inputs should be biased at ($V_{REF+}$) / 2 voltage. Refer to the device datasheet for the allowed common mode input voltage $V_{CMIN}$.

The input signals are supposed to be differential (common mode voltage should be fixed).

Internal channels (such as $V_{TS}$ and $V_{REFINT}$) are used in single-ended mode only.

For a complete description of how the input channels are connected for each ADC, refer to Section 21.4.4: ADC1/2 connectivity.

Caution: When configuring the channel "i" in differential input mode, its negative input voltage $V_{INN[i]}$ is connected to another channel. As a consequence, this channel is no longer usable in single-ended mode or in differential mode and must never be configured to be converted. Some channels are shared between ADC1/ADC2: this can make the channel on the other ADC unusable. Only exception is interleaved mode for ADC master and the slave.

### 21.4.8 Calibration (ADCAL, ADCALDIF, ADC_CALFACT)

Each ADC provides an automatic calibration procedure which drives all the calibration sequence including the power-on/off sequence of the ADC. During the procedure, the ADC calculates a calibration factor which is 7-bit wide and which is applied internally to the ADC until the next ADC power-off. During the calibration procedure, the application must not use the ADC and must wait until calibration is complete.

Calibration is preliminary to any ADC operation. It removes the offset error which may vary from chip to chip due to process or bandgap variation.

The calibration factor to be applied for single-ended input conversions is different from the factor to be applied for differential input conversions:

- Write ADCALDIF=0 before launching a calibration which will be applied for single-ended input conversions.
- Write ADCALDIF=1 before launching a calibration which will be applied for differential input conversions.

The calibration is then initiated by software by setting bit ADCAL=1. Calibration can only be initiated when the ADC is disabled (when ADEN=0). ADCAL bit stays at 1 during all the calibration sequence. It is then cleared by hardware as soon the calibration completes. At this time, the associated calibration factor is stored internally in the analog ADC and also in the bits CALFACT_S[6:0] or CALFACT_D[6:0] of ADC_CALFACT register (depending on single-ended or differential input calibration).

The internal analog calibration is kept if the ADC is disabled (ADEN=0). However, if the ADC is disabled for extended periods, then it is recommended that a new calibration cycle is run before re-enabling the ADC.

The internal analog calibration is lost each time the power of the ADC is removed (example, when the product enters in Standby or VBAT mode). In this case, to avoid spending time recalibrating the ADC, it is possible to re-write the calibration factor into the ADC_CALFACT register without recalibrating, supposing that the software has previously saved the calibration factor delivered during the previous calibration.
The calibration factor can be written if the ADC is enabled but not converting (ADEN=1 and ADSTART=0 and JADSTART=0). Then, at the next start of conversion, the calibration factor will automatically be injected into the analog ADC. This loading is transparent and does not add any cycle latency to the start of the conversion. It is recommended to recalibrate when $V_{REF+}$ voltage changed more than 10%.

**Software procedure to calibrate the ADC**

1. Ensure DEEPPWD=0, ADVREGEN=1 and that ADC voltage regulator startup time has elapsed.
2. Ensure that ADEN=0.
3. Select the input mode for this calibration by setting ADCALDIF=0 (single-ended input) or ADCALDIF=1 (differential input).
4. Set ADCAL=1.
5. Wait until ADCAL=0.
6. The calibration factor can be read from ADC_CALFACT register.

**Figure 95. ADC calibration**

<table>
<thead>
<tr>

<td>OFF</td>
<td>Calibrate</td>
</tr>
<tr>
<td>CALFACT_x[6:0]</td>
<td>0x00</td>
<td>Calibration factor</td>
</tr>
</tbody>
</table>

**Software procedure to re-inject a calibration factor into the ADC**

1. Ensure ADEN=1 and ADSTART=0 and JADSTART=0 (ADC enabled and no conversion is ongoing).
2. Write CALFACT_S and CALFACT_D with the new calibration factors.
3. When a conversion is launched, the calibration factor will be injected into the analog ADC only if the internal analog calibration factor differs from the one stored in bits CALFACT_S for single-ended input channel or bits CALFACT_D for differential input channel.
Converting single-ended and differential analog inputs with a single ADC

If the ADC is supposed to convert both differential and single-ended inputs, two calibrations must be performed, one with ADCALDIF=0 and one with ADCALDIF=1. The procedure is the following:

1. Disable the ADC.
2. Calibrate the ADC in single-ended input mode (with ADCALDIF=0). This updates the register CALFACT_S[6:0].
3. Calibrate the ADC in differential input modes (with ADCALDIF=1). This updates the register CALFACT_D[6:0].
4. Enable the ADC, configure the channels and launch the conversions. Each time there is a switch from a single-ended to a differential inputs channel (and vice-versa), the calibration will automatically be injected into the analog ADC.
21.4.9 ADC on-off control (ADEN, ADDIS, ADRDY)

First of all, follow the procedure explained in Section 21.4.6: ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN).

Once DEEPPWD=0 and ADVREGEN=1, the ADC can be enabled and the ADC needs a stabilization time of $t_{STAB}$ before it starts converting accurately, as shown in Figure 98. Two control bits enable or disable the ADC:

- ADEN=1 enables the ADC. The flag ADRDY will be set once the ADC is ready for operation.
- ADDIS=1 disables the ADC. ADEN and ADDIS are then automatically cleared by hardware as soon as the analog ADC is effectively disabled.

Regular conversion can then start either by setting ADSTART=1 (refer to Section 21.4.18: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN)) or when an external trigger event occurs, if triggers are enabled.

Injected conversions start by setting JADSTART=1 or when an external injected trigger event occurs, if injected triggers are enabled.

Software procedure to enable the ADC

1. Clear the ADRDY bit in the ADC_ISR register by writing ‘1’.
2. Set ADEN=1.
3. Wait until ADRDY=1 (ADRDY is set after the ADC startup time). This can be done using the associated interrupt (setting ADRDYIE=1).
4. Clear the ADRDY bit in the ADC_ISR register by writing ‘1’ (optional).

Caution: ADEN bit cannot be set when ADCAL is set and during four ADC clock cycles after the ADCAL bit is cleared by hardware (end of the calibration).

Software procedure to disable the ADC

1. Check that both ADSTART=0 and JADSTART=0 to ensure that no conversion is ongoing. If required, stop any regular and injected conversion ongoing by setting ADSTP=1 and JADSTP=1 and then wait until ADSTP=0 and JADSTP=0.
2. Set ADDIS=1.
3. If required by the application, wait until ADEN=0, until the analog ADC is effectively disabled (ADDIS will automatically be reset once ADEN=0).
21.4.10 Constraints when writing the ADC control bits

The software is allowed to write the RCC control bits to configure and enable the ADC clock (refer to RCC Section), the DIFSEL[i] control bits in the ADC_DIFSEL register and the control bits ADCAL and ADEN in the ADC_CR register, only if the ADC is disabled (ADEN must be equal to 0).

The software is then allowed to write the control bits ADSTART, JADSTART and ADDIS of the ADC_CR register only if the ADC is enabled and there is no pending request to disable the ADC (ADEN must be equal to 1 and ADDIS to 0).

For all the other control bits of the ADC_CFGR, ADC_SMPRx, ADC_SQRy, ADC_JDRy, ADC_OFRy, ADC_OFCHRy and ADC_IER registers:

- For control bits related to configuration of regular conversions, the software is allowed to write them only if the ADC is enabled (ADEN=1) and if there is no regular conversion ongoing (ADSTART must be equal to 0).
- For control bits related to configuration of injected conversions, the software is allowed to write them only if the ADC is enabled (ADEN=1) and if there is no injected conversion ongoing (JADSTART must be equal to 0).

The software is allowed to write the ADSTP or JADSTP control bits of the ADC_CR register only if the ADC is enabled, possibly converting, and if there is no pending request to disable the ADC (ADSTART or JADSTART must be equal to 1 and ADDIS to 0).

The software can write the register ADC_JSQR at any time, when the ADC is enabled (ADEN=1). Refer to Section 21.6.16: ADC injected sequence register (ADC_JSQR) for additional details.

**Note:** There is no hardware protection to prevent these forbidden write accesses and ADC behavior may become in an unknown state. To recover from this situation, the ADC must be disabled (clear ADEN=0 as well as all the bits of ADC_CR register).
21.4.11 Channel selection (SQRx, JSQRx)

There are up to 20 multiplexed channels per ADC:

- Up to 11 slow analog inputs coming from GPIO pads (ADCx_INP/INN[6:16])
  Depending on the products, not all of them are available on GPIO pads.
- The ADCs are connected to the following internal analog inputs:
  - The internal reference voltage (VREFINT) is connected to ADC1_INP0/INN0.
  - The internal temperature sensor (VTS) is connected to ADC1_INP17/INN17.
  - The VBAT monitoring channel (VBAT/3) is connected to ADC1_INP18/INN18.
  - The DAC1 internal channel 1 is connected to ADC2_INP/INN17.
  - The DAC1 internal channel 2 is connected to ADC2_INP/INN18.

Note: To convert one of the internal analog channels, the corresponding analog sources must first be enabled by programming bits VREFEN, CH17SEL or CH18SEL in the ADCx_CCR registers.

It is possible to organize the conversions in two groups: regular and injected. A group consists of a sequence of conversions that can be done on any channel and in any order. For instance, it is possible to implement the conversion sequence in the following order: ADCx_INP/INN3, ADCx_INP/INN8, ADCx_INP/INN2, ADCx_INN/INP2, ADCx_INP/INN0, ADCx_INP/INN2, ADCx_INP/INN2, ADCx_INP/INN15.

- A **regular group** is composed of up to 16 conversions. The regular channels and their order in the conversion sequence must be selected in the ADC_SQRy registers. The total number of conversions in the regular group must be written in the L[3:0] bits in the ADC_SQR1 register.
- An **injected group** is composed of up to 4 conversions. The injected channels and their order in the conversion sequence must be selected in the ADC_JSQR register. The total number of conversions in the injected group must be written in the L[1:0] bits in the ADC_JSQR register.

ADC_SQRy registers must not be modified while regular conversions can occur. For this, the ADC regular conversions must be first stopped by writing ADSTP=1 (refer to Section 21.4.17: Stopping an ongoing conversion (ADSTP, JADSTP)).

The software is allowed to modify on-the-fly the ADC_JSQR register when JADSTART is set to 1 (injected conversions ongoing) only when the context queue is enabled (JQDIS=0 in ADC_CFGIR register). Refer to Section 21.4.21: Queue of context for injected conversions.
### 21.4.12 Channel-wise programmable sampling time (SMPR1, SMPR2)

Before starting a conversion, the ADC must establish a direct connection between the voltage source under measurement and the embedded sampling capacitor of the ADC. This sampling time must be enough for the input voltage source to charge the embedded capacitor to the input voltage level.

Each channel can be sampled with a different sampling time which is programmable using the SMP[2:0] bits in the ADC_SMPR1 and ADC registers. It is therefore possible to select among the following sampling time values:

- SMP = 000: 2.5 ADC clock cycles
- SMP = 001: 6.5 ADC clock cycles
- SMP = 010: 12.5 ADC clock cycles
- SMP = 011: 24.5 ADC clock cycles
- SMP = 100: 47.5 ADC clock cycles
- SMP = 101: 92.5 ADC clock cycles
- SMP = 110: 247.5 ADC clock cycles
- SMP = 111: 640.5 ADC clock cycles

The total conversion time is calculated as follows:

\[ T_{CONV} = \text{Sampling time} + 12.5 \text{ ADC clock cycles} \]

Example:

With \( F_{ADC\_CLK} = 30 \text{ MHz} \) and a sampling time of 2.5 ADC clock cycles:

\[ T_{CONV} = (2.5 + 12.5) \text{ ADC clock cycles} = 15 \text{ ADC clock cycles} = 500 \text{ ns} \]

The ADC notifies the end of the sampling phase by setting the status bit EOSMP (only for regular conversion).

#### Constraints on the sampling time

For each channel, SMP[2:0] bits must be programmed to respect a minimum sampling time as specified in the ADC characteristics section of the datasheets.

#### I/O analog switches voltage booster

The I/O analog switches resistance increases when the \( V_{DDA} \) voltage is too low. This requires to have the sampling time adapted accordingly (cf datasheet for electrical characteristics). This resistance can be minimized at low \( V_{DDA} \) by enabling an internal voltage booster with BOOSTEN bit in the SYSCFG_CFGR1 register.

### 21.4.13 Single conversion mode (CONT=0)

In Single conversion mode, the ADC performs once all the conversions of the channels. This mode is started with the CONT bit at 0 by either:

- Setting the ADSTART bit in the ADC_CR register (for a regular channel)
- Setting the JADSTART bit in the ADC_CR register (for an injected channel)
- External hardware trigger event (for a regular or injected channel)
Inside the regular sequence, after each conversion is complete:
- The converted data are stored into the 16-bit ADC_DR register
- The EOC (end of regular conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

Inside the injected sequence, after each conversion is complete:
- The converted data are stored into one of the four 16-bit ADC_JDRy registers
- The JEOC (end of injected conversion) flag is set
- An interrupt is generated if the JEOCIE bit is set

After the regular sequence is complete:
- The EOS (end of regular sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

After the injected sequence is complete:
- The JEOS (end of injected sequence) flag is set
- An interrupt is generated if the JEOSIE bit is set

Then the ADC stops until a new external regular or injected trigger occurs or until bit ADSTART or JADSTART is set again.

Note: To convert a single channel, program a sequence with a length of 1.

### 21.4.14 Continuous conversion mode (CONT=1)

This mode applies to regular channels only.

In continuous conversion mode, when a software or hardware regular trigger event occurs, the ADC performs once all the regular conversions of the channels and then automatically restarts and continuously converts each conversions of the sequence. This mode is started with the CONT bit at 1 either by external trigger or by setting the ADSTART bit in the ADC_CR register.

Inside the regular sequence, after each conversion is complete:
- The converted data are stored into the 16-bit ADC_DR register
- The EOC (end of conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

After the sequence of conversions is complete:
- The EOS (end of sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

Then, a new sequence restarts immediately and the ADC continuously repeats the conversion sequence.

Note: To convert a single channel, program a sequence with a length of 1.

It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN=1 and CONT=1.

Injected channels cannot be converted continuously. The only exception is when an injected channel is configured to be converted automatically after regular channels in continuous mode (using JAUTO bit), refer to Auto-injection mode section).
21.4.15 Starting conversions (ADSTART, JADSTART)

Software starts ADC regular conversions by setting ADSTART=1.

When ADSTART is set, the conversion starts:
- Immediately: if EXTEN[1:0] = 00 (software trigger)
- At the next active edge of the selected regular hardware trigger: if EXTEN[1:0] is not equal to 00

Software starts ADC injected conversions by setting JADSTART=1.

When JADSTART is set, the conversion starts:
- Immediately, if JEXTEN[1:0] = 00 (software trigger)
- At the next active edge of the selected injected hardware trigger: if JEXTEN[1:0] is not equal to 00

Note: In auto-injection mode (JAUTO=1), use ADSTART bit to start the regular conversions followed by the auto-injected conversions (JADSTART must be kept cleared).

ADSTART and JADSTART also provide information on whether any ADC operation is currently ongoing. It is possible to re-configure the ADC while ADSTART=0 and JADSTART=0 are both true, indicating that the ADC is idle.

ADSTART is cleared by hardware:
- In single mode with software regular trigger (CONT=0, EXTSEL=0x0)
  - At any end of regular conversion sequence (EOS assertion) or at any end of subgroup processing if DISCEN = 1
- In all cases (CONT=x, EXTSEL=x)
  - After execution of the ADSTP procedure asserted by the software.

Note: In continuous mode (CONT=1), ADSTART is not cleared by hardware with the assertion of EOS because the sequence is automatically relaunched.

When a hardware trigger is selected in single mode (CONT=0 and EXTSEL≠0x00), ADSTART is not cleared by hardware with the assertion of EOS to help the software which does not need to reset ADSTART again for the next hardware trigger event. This ensures that no further hardware triggers are missed.

JADSTART is cleared by hardware:
- In single mode with software injected trigger (JEXTSEL = 0x0)
  - At any end of injected conversion sequence (JEOS assertion) or at any end of subgroup processing if JDISCEN = 1
- In all cases (JEXTSEL=x)
  - After execution of the JADSTP procedure asserted by the software.

Note: When the software trigger is selected, ADSTART bit should not be set if the EOC flag is still high.
21.4.16 **ADC timing**

The elapsed time between the start of a conversion and the end of conversion is the sum of the configured sampling time plus the successive approximation time depending on data resolution:

\[
T_{\text{CONV}} = T_{\text{SMPL}} + T_{\text{SAR}} = [2.5 \text{ min} + 12.5 \text{ 12bit}] \times T_{\text{ADC_CLK}}
\]

\[
T_{\text{CONV}} = T_{\text{SMPL}} + T_{\text{SAR}} = 83.33 \text{ ns 1min} + 416.67 \text{ ns 12bit} = 500.0 \text{ ns (for } F_{\text{ADC_CLK}} = 30 \text{ MHz)}
\]

**Figure 99. Analog to digital conversion time**

1. \(T_{\text{SMPL}}\) depends on \(\text{SMP}[2:0]\).
2. \(T_{\text{SAR}}\) depends on \(\text{RES}[2:0]\).

21.4.17 **Stopping an ongoing conversion (ADSTP, JADSTP)**

The software can decide to stop regular conversions ongoing by setting ADSTP=1 and injected conversions ongoing by setting JADSTP=1.

Stopping conversions will reset the ongoing ADC operation. Then the ADC can be reconfigured (ex: changing the channel selection or the trigger) ready for a new operation.

Note that it is possible to stop injected conversions while regular conversions are still operating and vice-versa. This allows, for instance, re-configuration of the injected conversion sequence and triggers while regular conversions are still operating (and vice-versa).

When the ADSTP bit is set by software, any ongoing regular conversion is aborted with partial result discarded (ADC_DR register is not updated with the current conversion).

When the JADSTP bit is set by software, any ongoing injected conversion is aborted with partial result discarded (ADC_JDRy register is not updated with the current conversion). The scan sequence is also aborted and reset (meaning that relaunching the ADC would restart a new sequence).

Once this procedure is complete, bits ADSTP/ADSTART (in case of regular conversion), or JADSTP/JADSTART (in case of injected conversion) are cleared by hardware and the software must poll ADSTART (or JADSTART) until the bit is reset before assuming the ADC is completely stopped.
Note: In auto-injection mode (JAUTO=1), setting ADSTP bit aborts both regular and injected conversions (JADSTP must not be used).

MSv30533V2

MS30534V1
21.4.18 Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN)

A conversion or a sequence of conversions can be triggered either by software or by an external event (e.g. timer capture, input pins). If the EXTEN[1:0] control bits (for a regular conversion) or JEXTEN[1:0] bits (for an injected conversion) are different from 0b00, then external events are able to trigger a conversion with the selected polarity.

When the Injected Queue is enabled (bit JQDIS=0), injected software triggers are not possible.

The regular trigger selection is effective once software has set bit ADSTART=1 and the injected trigger selection is effective once software has set bit JADSTART=1.

Any hardware triggers which occur while a conversion is ongoing are ignored.
- If bit ADSTART=0, any regular hardware triggers which occur are ignored.
- If bit JADSTART=0, any injected hardware triggers which occur are ignored.

Table 159 provides the correspondence between the EXTEN[1:0] and JEXTEN[1:0] values and the trigger polarity.

**Table 159. Configuring the trigger polarity for regular external triggers**

<table>
<thead>

</tr>
</tbody>
</table>

**Note:** The polarity of the injected trigger can be anticipated and changed on-the-fly when the queue is enabled (JQDIS=0). Refer to Section 21.4.21: Queue of context for injected conversions.

The EXTSEL and JEXTSEL control bits select which out of 16 possible events can trigger conversion for the regular and injected groups.

A regular group conversion can be interrupted by an injected trigger.
Note: The regular trigger selection cannot be changed on-the-fly. The injected trigger selection can be anticipated and changed on-the-fly. Refer to Section 21.4.21: Queue of context for injected conversions on page 710.

Each ADC master shares the same input triggers with its ADC slave as described in Figure 102.

**Figure 102. Triggers sharing between ADC master and ADC slave**

Triggered injection mode

To use triggered injection, the JAUTO bit in the ADC_CFGR register must be cleared.

1. Start the conversion of a group of regular channels either by an external trigger or by setting the ADSTART bit in the ADC_CR register.
2. If an external injected trigger occurs, or if the JADSTART bit in the ADC_CR register is set during the conversion of a regular group of channels, the current conversion is
reset and the injected channel sequence switches are launched (all the injected channels are converted once).

3. Then, the regular conversion of the regular group of channels is resumed from the last interrupted regular conversion.

4. If a regular event occurs during an injected conversion, the injected conversion is not interrupted but the regular sequence is executed at the end of the injected sequence. Figure 103 shows the corresponding timing diagram.

Note: When using triggered injection, one must ensure that the interval between trigger events is longer than the injection sequence. For instance, if the sequence length is 30 ADC clock cycles (that is two conversions with a sampling time of 2.5 clock periods), the minimum interval between triggers must be 31 ADC clock cycles.

Auto-injection mode

If the JAUTO bit in the ADC_CFGR register is set, then the channels in the injected group are automatically converted after the regular group of channels. This can be used to convert a sequence of up to 20 conversions programmed in the ADC_SQRy and ADC_JSQR registers.

In this mode, the ADSTART bit in the ADC_CR register must be set to start regular conversions, followed by injected conversions (JADSTART must be kept cleared). Setting the ADSTP bit aborts both regular and injected conversions (JADSTP bit must not be used).

In this mode, external trigger on injected channels must be disabled.

If the CONT bit is also set in addition to the JAUTO bit, regular channels followed by injected channels are continuously converted.

Note: It is not possible to use both the auto-injected and discontinuous modes simultaneously.

When the DMA is used for exporting regular sequencer’s data in JAUTO mode, it is necessary to program it in circular mode (CIRC bit set in DMA_CCRx register). If the CIRC bit is reset (single-shot mode), the JAUTO sequence will be stopped upon DMA Transfer Complete event.
21.4.20 Discontinuous mode (DISCEN, DISCNUM, JDISCEN)

Regular group mode

This mode is enabled by setting the DISCEN bit in the ADC_CFGR register.

It is used to convert a short sequence (subgroup) of \( n \) conversions \((n \leq 8)\) that is part of the sequence of conversions selected in the ADC_SQRy registers. The value of \( n \) is specified by writing to the DISCNUM[2:0] bits in the ADC_CFGR register.

When an external trigger occurs, it starts the next \( n \) conversions selected in the ADC_SQRy registers until all the conversions in the sequence are done. The total sequence length is defined by the L[3:0] bits in the ADC_SQR1 register.

Example:
- **DISCEN=1, \( n=3 \), channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10, 11**
  - 1st trigger: channels converted are 1, 2, 3 (an EOC event is generated at each conversion).
  - 2nd trigger: channels converted are 6, 7, 8 (an EOC event is generated at each conversion).
  - 3rd trigger: channels converted are 9, 10, 11 (an EOC event is generated at each conversion) and an EOS event is generated after the conversion of channel 11.
  - 4th trigger: channels converted are 1, 2, 3 (an EOC event is generated at each conversion).
  - ...
- **DISCEN=0, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10,11**
  - 1st trigger: the complete sequence is converted: channel 1, then 2, 3, 6, 7, 8, 9, 10 and 11. Each conversion generates an EOC event and the last one also generates an EOS event.
  - All the next trigger events will relaunch the complete sequence.
Analog-to-digital converters (ADC) RM0438

Note: The channel numbers referred to in the above example might not be available on all microcontrollers.

When a regular group is converted in discontinuous mode, no rollover occurs (the last subgroup of the sequence can have less than n conversions).

When all subgroups are converted, the next trigger starts the conversion of the first subgroup. In the example above, the 4th trigger reconverts the channels 1, 2 and 3 in the 1st subgroup.

It is not possible to have both discontinuous mode and continuous mode enabled. In this case (if DISCEN=1, CONT=1), the ADC behaves as if continuous mode was disabled.

Injected group mode

This mode is enabled by setting the JDISCEN bit in the ADC_CFGR register. It converts the sequence selected in the ADC_JSQR register, channel by channel, after an external injected trigger event. This is equivalent to discontinuous mode for regular channels where ‘n’ is fixed to 1.

When an external trigger occurs, it starts the next channel conversions selected in the ADC_JSQR registers until all the conversions in the sequence are done. The total sequence length is defined by the JL[1:0] bits in the ADC_JSQR register.

Example:
- JDISCEN=1, channels to be converted = 1, 2, 3
  - 1st trigger: channel 1 converted (a JEOC event is generated)
  - 2nd trigger: channel 2 converted (a JEOC event is generated)
  - 3rd trigger: channel 3 converted and a JEOC event + a JEOS event are generated
  - ...

Note: The channel numbers referred to in the above example might not be available on all microcontrollers.

When all injected channels have been converted, the next trigger starts the conversion of the first injected channel. In the example above, the 4th trigger reconverts the 1st injected channel 1.

It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

21.4.21 Queue of context for injected conversions

A queue of context is implemented to anticipate up to 2 contexts for the next injected sequence of conversions. JQDIS bit of ADC_CFGR register must be reset to enable this feature. Only hardware-triggered conversions are possible when the context queue is enabled.

This context consists of:
- Configuration of the injected triggers (bits JEXTEN[1:0] and JEXTSEL bits in ADC_JSQR register)
- Definition of the injected sequence (bits JSQx[4:0] and JL[1:0] in ADC_JSQR register)
All the parameters of the context are defined into a single register ADC_JSQR and this
register implements a queue of 2 buffers, allowing the bufferization of up to 2 sets of
parameters:

- The JSQR register can be written at any moment even when injected conversions are
  ongoing.
- Each data written into the JSQR register is stored into the Queue of context.
- At the beginning, the Queue is empty and the first write access into the JSQR register
  immediately changes the context and the ADC is ready to receive injected triggers.
- Once an injected sequence is complete, the Queue is consumed and the context
  changes according to the next JSQR parameters stored in the Queue. This new
  context is applied for the next injected sequence of conversions.
- A Queue overflow occurs when writing into register JSQR while the Queue is full. This
  overflow is signaled by the assertion of the flag JQOVF. When an overflow occurs, the
  write access of JSQR register which has created the overflow is ignored and the queue
  of context is unchanged. An interrupt can be generated if bit JQOVFIE is set.
- Two possible behaviors are possible when the Queue becomes empty, depending on
  the value of the control bit JQM of register ADC_CFGR:
  - If JQM=0, the Queue is empty just after enabling the ADC, but then it can never be
    empty during run operations: the Queue always maintains the last active context
    and any further valid start of injected sequence will be served according to the last
    active context.
  - If JQM=1, the Queue can be empty after the end of an injected sequence or if the
    Queue is flushed. When this occurs, there is no more context in the queue and
    hardware triggers are disabled. Therefore, any further hardware injected triggers
    are ignored until the software re-writes a new injected context into JSQR register.
- Reading JSQR register returns the current JSQR context which is active at that
  moment. When the JSQR context is empty, JSQR is read as 0x0000.
- The Queue is flushed when stopping injected conversions by setting JADSTP=1 or
  when disabling the ADC by setting ADDIS=1:
  - If JQM=0, the Queue is maintained with the last active context.
  - If JQM=1, the Queue becomes empty and triggers are ignored.

Note: When configured in discontinuous mode (bit JDISCEN=1), only the last trigger of the
injected sequence changes the context and consumes the Queue. The 1st trigger only
consumes the queue but others are still valid triggers as shown by the discontinuous mode
example below (length = 3 for both contexts):

- 1st trigger, discontinuous. Sequence 1: context 1 consumed, 1st conversion carried out
- 2nd trigger, disc. Sequence 1: 2nd conversion.
- 3rd trigger, discontinuous. Sequence 1: 3rd conversion.
- 4th trigger, discontinuous. Sequence 2: context 2 consumed, 1st conversion carried out.
- 5th trigger, discontinuous. Sequence 2: 2nd conversion.
- 6th trigger, discontinuous. Sequence 2: 3rd conversion.
Behavior when changing the trigger or sequence context

The Figure 104 and Figure 105 show the behavior of the context Queue when changing the sequence or the triggers.

**Figure 104. Example of JSQR queue of context (sequence change)**

<td>Conversion1</td>
<td>Conversion2</td>
</tr>
</tbody>
</table>

1. Parameters:
   - P1: sequence of 2 conversions, hardware trigger 1
   - P2: sequence of 1 conversion, hardware trigger 2
   - P3: sequence of 4 conversions, hardware trigger 1
Queue of context: Behavior when a queue overflow occurs

The Figure 106 and Figure 107 show the behavior of the context Queue if an overflow occurs before or during a conversion.

Figure 106. Example of JSQR queue of context with overflow before conversion

1. Parameters:
P1: sequence of 2 conversions, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 2
P3: sequence of 3 conversions, hardware trigger 1
P4: sequence of 4 conversions, hardware trigger 1

Figure 107. Example of JSQR queue of context with overflow during conversion

1. Parameters:
P1: sequence of 2 conversions, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 2
P3: sequence of 3 conversions, hardware trigger 1
P4: sequence of 4 conversions, hardware trigger 1
It is recommended to manage the queue overflows as described below:

- After each P context write into JSQR register, flag JQOVF shows if the write has been ignored or not (an interrupt can be generated).
- Avoid Queue overflows by writing the third context (P3) only once the flag JEOS of the previous context P2 has been set. This ensures that the previous context has been consumed and that the queue is not full.

**Queue of context: Behavior when the queue becomes empty**

*Figure 108* and *Figure 109* show the behavior of the context Queue when the Queue becomes empty in both cases JQM=0 or 1.

*Figure 108. Example of JSQR queue of context with empty queue (case JQM=0)*

1. Parameters:
   - P1: sequence of 1 conversion, hardware trigger 1
   - P2: sequence of 1 conversion, hardware trigger 1
   - P3: sequence of 1 conversion, hardware trigger 1

*Note:* When writing P3, the context changes immediately. However, because of internal resynchronization, there is a latency and if a trigger occurs just after or before writing P3, it can happen that the conversion is launched considering the context P2. To avoid this situation, the user must ensure that there is no ADC trigger happening when writing a new context that applies immediately.
1. Parameters:
P1: sequence of 1 conversion, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 1
P3: sequence of 1 conversion, hardware trigger 1

**Flushing the queue of context**

The figures below show the behavior of the context Queue in various situations when the queue is flushed.

**Figure 109. Example of JSQR queue of context with empty queue (case JQM=1)**

![Diagram of JSQR queue with empty queue]

**Figure 110. Flushing JSQR queue of context by setting JADSTP=1 (JQM=0). Case when JADSTP occurs during an ongoing conversion.**

![Diagram of JSQR queue with flushing]

1. Parameters:
P1: sequence of 1 conversion, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 1
P3: sequence of 1 conversion, hardware trigger 1
Figure 111. Flushing JSQR queue of context by setting JADSTP=1 (JQM=0). Case when JADSTP occurs during an ongoing conversion and a new trigger occurs.

1. Parameters:
P1: sequence of 1 conversion, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 1
P3: sequence of 1 conversion, hardware trigger 1

Figure 112. Flushing JSQR queue of context by setting JADSTP=1 (JQM=0). Case when JADSTP occurs outside an ongoing conversion

1. Parameters:
P1: sequence of 1 conversion, hardware trigger 1
P2: sequence of 1 conversion, hardware trigger 1
P3: sequence of 1 conversion, hardware trigger 1
Figure 113. Flushing JSQR queue of context by setting JADSTP=1 (JQM=1)

1. Parameters:
   - P1: sequence of 1 conversion, hardware trigger 1
   - P2: sequence of 1 conversion, hardware trigger 1
   - P3: sequence of 1 conversion, hardware trigger 1

Figure 114. Flushing JSQR queue of context by setting ADDIS=1 (JQM=0)

1. Parameters:
   - P1: sequence of 1 conversion, hardware trigger 1
   - P2: sequence of 1 conversion, hardware trigger 1
   - P3: sequence of 1 conversion, hardware trigger 1
Queue of context: Starting the ADC with an empty queue

The following procedure must be followed to start ADC operation with an empty queue, in case the first context is not known at the time the ADC is initialized. This procedure is only applicable when JQM bit is reset:

5. Write a dummy JSQR with JEXTEN[1:0] not equal to 00 (otherwise triggering a software conversion)
6. Set JADSTART
7. Set JADSTP
8. Wait until JADSTART is reset
9. Set JADSTART.

Disabling the queue

It is possible to disable the queue by setting bit JQDIS=1 into the ADC_CFGR register.

21.4.22 Programmable resolution (RES) - Fast conversion mode

It is possible to perform faster conversion by reducing the ADC resolution.

The resolution can be configured to be either 12, 10, 8, or 6 bits by programming the control bits RES[1:0]. Figure 120, Figure 121, Figure 122 and Figure 123 show the conversion result format with respect to the resolution as well as to the data alignment.

Lower resolution allows faster conversion time for applications where high-data precision is not required. It reduces the conversion time spent by the successive approximation steps according to Table 163.
### 21.4.23 End of conversion, end of sampling phase (EOC, JEOC, EOSMP)

The ADC notifies the application for each end of regular conversion (EOC) event and each injected conversion (JEOC) event.

The ADC sets the EOC flag as soon as a new regular conversion data is available in the ADC_DR register. An interrupt can be generated if bit EOCIE is set. EOC flag is cleared by the software either by writing 1 to it or by reading ADC_DR.

The ADC sets the JEOC flag as soon as a new injected conversion data is available in one of the ADC_JDRy register. An interrupt can be generated if bit JEOCIE is set. JEOC flag is cleared by the software either by writing 1 to it or by reading the corresponding ADC_JDRy register.

The ADC also notifies the end of Sampling phase by setting the status bit EOSMP (for regular conversions only). EOSMP flag is cleared by software by writing 1 to it. An interrupt can be generated if bit EOSMPIE is set.

### 21.4.24 End of conversion sequence (EOS, JEOS)

The ADC notifies the application for each end of regular sequence (EOS) and for each end of injected sequence (JEOS) event.

The ADC sets the EOS flag as soon as the last data of the regular conversion sequence is available in the ADC_DR register. An interrupt can be generated if bit EOSIE is set. EOS flag is cleared by the software either by writing 1 to it.

The ADC sets the JEOS flag as soon as the last data of the injected conversion sequence is complete. An interrupt can be generated if bit JEOSIE is set. JEOS flag is cleared by the software either by writing 1 to it.

21.4.26 Data management

Data register, data alignment and offset (ADC_DR, OFFSETy, OFFSETy_CH, ALIGN)

Data and alignment

At the end of each regular conversion channel (when EOC event occurs), the result of the converted data is stored into the ADC_DR data register which is 16 bits wide.

At the end of each injected conversion channel (when JEOC event occurs), the result of the converted data is stored into the corresponding ADC_JDRy data register which is 16 bits wide.

The ALIGN bit in the ADC_CFGR register selects the alignment of the data stored after conversion. Data can be right- or left-aligned as shown in Figure 120, Figure 121, Figure 122 and Figure 123.

Special case: when left-aligned, the data are aligned on a half-word basis except when the resolution is set to 6-bit. In that case, the data are aligned on a byte basis as shown in Figure 122 and Figure 123.

Note: Left-alignment is not supported in oversampling mode. When ROVSE and/or JOVSE bit is set, the ALIGN bit value is ignored and the ADC only provides right-aligned data.

Offset

An offset \( y (y=1,2,3,4) \) can be applied to a channel by setting the bit OFFSETy_EN=1 into ADC_OFRy register. The channel to which the offset will be applied is programmed into the bits OFFSETy_CH[4:0] of ADC_OFRy register. In this case, the converted value is decreased by the user-defined offset written in the bits OFFSETy[11:0]. The result may be a negative value so the read data is signed and the SEXT bit represents the extended sign value.

Note: Offset correction is not supported in oversampling mode. When ROVSE and/or JOVSE bit is set, the value of the OFFSETy_EN bit in ADC_OFRy register is ignored (considered as reset).

Table 166 describes how the comparison is performed for all the possible resolutions for analog watchdog 1.

ADC overrun (OVR, OVRMOD)

The overrun flag (OSR) notifies of that a buffer overrun event occurred when the regular converted data has not been read (by the CPU or the DMA) before new converted data became available.

The OVR flag is set if the EOC flag is still 1 at the time when a new conversion completes. An interrupt can be generated if bit OVRIE=1.

When an overrun condition occurs, the ADC is still operating and can continue converting unless the software decides to stop and reset the sequence by setting bit ADSTP=1.

OVR flag is cleared by software by writing 1 to it.

It is possible to configure if data is preserved or overwritten when an overrun event occurs by programming the control bit OVRMOD:

- OVRMOD=0: The overrun event preserves the data register from being overrun: the old data is maintained and the new conversion is discarded and lost. If OVR remains at 1, any further conversions will occur but the result data will be also discarded.
- OVRMOD=1: The data register is overwritten with the last conversion result and the previous unread data is lost. If OVR remains at 1, any further conversions will operate normally and the ADC_DR register will always contain the latest converted data.
Analog-to-digital converters (ADC)

Managing a sequence of conversions without using the DMA

If the conversions are slow enough, the conversion sequence can be handled by the software. In this case the software must use the EOC flag and its associated interrupt to handle each data. Each time a conversion is complete, EOC is set and the ADC_DR register can be read. OVRMOD should be configured to 0 to manage overrun events as an error.

Managing conversions without using the DMA and without overrun

It may be useful to let the ADC convert one or more channels without reading the data each time (if there is an analog watchdog for instance). In this case, the OVRMOD bit must be configured to 1 and OVR flag should be ignored by the software. An overrun event will not prevent the ADC from continuing to convert and the ADC_DR register will always contain the latest conversion.

Managing conversions using the DMA

Since converted channel values are stored into a unique data register, it is useful to use DMA for conversion of more than one channel. This avoids the loss of the data already stored in the ADC_DR register.

When the DMA mode is enabled (DMAEN bit set to 1 in the ADC_CFGR register in single ADC mode or MDMA different from 0b00 in dual ADC mode), a DMA request is generated after each conversion of a channel. This allows the transfer of the converted data from the ADC_DR register to the destination location selected by the software.
Despite this, if an overrun occurs (OVR=1) because the DMA could not serve the DMA transfer request in time, the ADC stops generating DMA requests and the data corresponding to the new conversion is not transferred by the DMA. Which means that all the data transferred to the RAM can be considered as valid.

Depending on the configuration of OVRMOD bit, the data is either preserved or overwritten (refer to Section : ADC overrun (OVR, OVRMOD)).

The DMA transfer requests are blocked until the software clears the OVR bit.

Two different DMA modes are proposed depending on the application use and are configured with bit DMACFG of the ADC_CFGR register in single ADC mode, or with bit DMACFG of the ADC_CCR register in dual ADC mode:

- **DMA one shot mode (DMACFG=0)**
  This mode is suitable when the DMA is programmed to transfer a fixed number of data.

- **DMA circular mode (DMACFG=1)**
  This mode is suitable when programming the DMA in circular mode.

**DMA one shot mode (DMACFG=0)**

In this mode, the ADC generates a DMA transfer request each time a new conversion data is available and stops generating DMA requests once the DMA has reached the last DMA transfer (when DMA_EOT interrupt occurs - refer to DMA paragraph) even if a conversion has been started again.

When the DMA transfer is complete (all the transfers configured in the DMA controller have been done):

- The content of the ADC data register is frozen.
- Any ongoing conversion is aborted with partial result discarded.
- No new DMA request is issued to the DMA controller. This avoids generating an overrun error if there are still conversions which are started.
- Scan sequence is stopped and reset.
- The DMA is stopped.

**DMA circular mode (DMACFG=1)**

In this mode, the ADC generates a DMA transfer request each time a new conversion data is available in the data register, even if the DMA has reached the last DMA transfer. This allows configuring the DMA in circular mode to handle a continuous analog input data stream.

**21.4.27 Managing conversions using the DFSDM**

The ADC conversion results can be transferred directly to the Digital filter for sigma delta modulators (DFSDM).

In this case, the DFSDMCFG bit must be set to 1 and DMAEN bit must be cleared to 0.

The ADC transfers all the 16 bits of the regular data register to the DFSDM and resets the EOC flag once the transfer is complete.
The data format must be 16-bit signed:

\[
\text{ADC\_DR}[15:12] = \text{sign extended} \\
\text{ADC\_DR}[11] = \text{sign} \\
\text{ADC\_DR}[11:0] = \text{data}
\]

To obtain 16-bit signed format in 12-bit ADC mode, the software needs to configure the \( \text{OFFSETy}[11:0] \) to 0x800 after having set \( \text{OFFSETy\_EN} \) to 1.

Only right aligned data format is available for the DFSDM interface (see Figure 121: Right alignment (offset enabled, signed value)).

21.4.28 Dynamic low-power features

Auto-delayed conversion mode (AUTDLY)

The ADC implements an auto-delayed conversion mode controlled by the AUTDLY configuration bit. Auto-delayed conversions are useful to simplify the software as well as to optimize performance of an application clocked at low frequency where there would be risk of encountering an ADC overrun.

When AUTDLY=1, a new conversion can start only if all the previous data of the same group has been treated:

- For a regular conversion: once the ADC\_DR register has been read or if the EOC bit has been cleared (see Figure 125).
- For an injected conversion: when the JEOS bit has been cleared (see Figure 126).

This is a way to automatically adapt the speed of the ADC to the speed of the system which will read the data.

The delay is inserted after each regular conversion (whatever DISCEN=0 or 1) and after each sequence of injected conversions (whatever JDISCEN=0 or 1).

Note: There is no delay inserted between each conversions of the injected sequence, except after the last one.

During a conversion, a hardware trigger event (for the same group of conversions) occurring during this delay is ignored.

Note: This is not true for software triggers where it remains possible during this delay to set the bits ADSTART or JADSTART to restart a conversion: it is up to the software to read the data before launching a new conversion.

No delay is inserted between conversions of different groups (a regular conversion followed by an injected conversion or conversely):

- If an injected trigger occurs during the automatic delay of a regular conversion, the injected conversion starts immediately (see Figure 126).
- Once the injected sequence is complete, the ADC waits for the delay (if not ended) of the previous regular conversion before launching a new regular conversion (see Figure 128).

The behavior is slightly different in auto-injected mode (JAUTO=1) where a new regular conversion can start only when the automatic delay of the previous injected sequence of conversion has ended (when JEOS has been cleared). This is to ensure that the software can read all the data of a given sequence before starting a new sequence (see Figure 129).
To stop a conversion in continuous auto-injection mode combined with autodelay mode (JAUTO=1, CONT=1 and AUTDLY=1), follow the following procedure:

1. Wait until JEOS=1 (no more conversions are restarted)
2. Clear JEOS,
3. Set ADSTP=1
4. Read the regular data.

If this procedure is not respected, a new regular sequence can restart if JEOS is cleared after ADSTP has been set.

In AUTDLY mode, a hardware regular trigger event is ignored if it occurs during an already ongoing regular sequence or during the delay that follows the last regular conversion of the sequence. It is however considered pending if it occurs after this delay, even if it occurs during an injected sequence of the delay that follows it. The conversion then starts at the end of the delay of the injected sequence.

In AUTDLY mode, a hardware injected trigger event is ignored if it occurs during an already ongoing injected sequence or during the delay that follows the last injected conversion of the sequence.

21.4.29  Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)

The three AWD analog watchdogs monitor whether some channels remain within a configured voltage range (window).

![Analog watchdog guarded area](MS45396V1)

**AWDx flag and interrupt**

An interrupt can be enabled for each of the 3 analog watchdogs by setting AWDxIE in the ADC_IER register (x=1,2,3).

AWDx (x=1,2,3) flag is cleared by software by writing 1 to it.

The ADC conversion result is compared to the lower and higher thresholds before alignment.

**Description of analog watchdog 1**

The AWD analog watchdog 1 is enabled by setting the AWD1EN bit in the ADC_CFGR register. This watchdog monitors whether either one selected channel or all enabled channels(1) remain within a configured voltage range (window).

*Table 165* shows how the ADC_CFGR registers should be configured to enable the analog watchdog on one or more channels.

1. Selected by the AWD1CH[4:0] bits. The channels must also be programmed to be converted in the appropriate regular or injected sequence.

The AWD1 analog watchdog status bit is set if the analog voltage converted by the ADC is below a lower threshold or above a higher threshold.
These thresholds are programmed in bits HT1[11:0] and LT1[11:0] of the ADC_TR1 register for the analog watchdog 1. When converting data with a resolution of less than 12 bits (according to bits RES[1:0]), the LSB of the programmed thresholds must be kept cleared because the internal comparison is always performed on the full 12-bit raw converted data (left aligned).

*Table 166* describes how the comparison is performed for all the possible resolutions for analog watchdog 1.

**Description of analog watchdog 2 and 3**

The second and third analog watchdogs are more flexible and can guard several selected channels by programming the corresponding bits in AWDxCH[18:0] (x=2,3).

The corresponding watchdog is enabled when any bit of AWDxCH[18:0] (x=2,3) is set.

They are limited to a resolution of 8 bits and only the 8 MSBs of the thresholds can be programmed into HTx[7:0] and LTx[7:0]. *Table 167* describes how the comparison is performed for all the possible resolutions.

ADC\textsubscript{y} AWD\textsubscript{x} OUT signal output generation

Each analog watchdog is associated to an internal hardware signal ADC\textsubscript{y} AWD\textsubscript{x} OUT (y=ADC number, x=watchdog number) which is directly connected to the ETR input (external trigger) of some on-chip timers. Refer to the on-chip timers section to understand how to select the ADC\textsubscript{y} AWD\textsubscript{x} OUT signal as ETR.

ADC\textsubscript{y} AWD\textsubscript{x} OUT is activated when the associated analog watchdog is enabled:

- ADC\textsubscript{y} AWD\textsubscript{x} OUT is set when a guarded conversion is outside the programmed thresholds.
- ADC\textsubscript{y} AWD\textsubscript{x} OUT is reset after the end of the next guarded conversion which is inside the programmed thresholds (It remains at 1 if the next guarded conversions are still outside the programmed thresholds).
- ADC\textsubscript{y} AWD\textsubscript{x} OUT is also reset when disabling the ADC (when setting ADDIS=1). Note that stopping regular or injected conversions (setting ADSTP=1 or JADSTP=1) has no influence on the generation of ADC\textsubscript{y} AWD\textsubscript{x} OUT.

\textbf{Note:} AWD\textsubscript{x} flag is set by hardware and reset by software: AWD\textsubscript{x} flag has no influence on the generation of ADC\textsubscript{y} AWD\textsubscript{x} OUT (ex: ADC\textsubscript{y} AWD\textsubscript{x} OUT can toggle while AWD\textsubscript{x} flag remains at 1 if the software did not clear the flag).

21.4.30 Oversampler

The oversampling unit performs data pre-processing to offload the CPU. It is able to handle multiple conversions and average them into a single data with increased data width, up to 16-bit.

It provides a result with the following form, where N and M can be adjusted:

\[
\text{Result} = \frac{1}{M} \sum_{n=0}^{n-N-1} \text{Conversion}(t_n)
\]

It allows to perform by hardware the following functions: averaging, data rate reduction, SNR improvement, basic filtering.

The oversampling ratio N is defined using the OVFS[2:0] bits in the ADC_CFGR2 register, and can range from 2x to 256x. The division coefficient M consists of a right bit shift up to 8 bits, and is defined using the OVSS[3:0] bits in the ADC_CFGR2 register.

The summation unit can yield a result up to 20 bits (256x 12-bit results), which is first shifted right. It is then truncated to the 16 least significant bits, rounded to the nearest value using the least significant bits left apart by the shifting, before being finally transferred into the ADC_DR data register.

Note: If the intermediary result after the shifting exceeds 16-bit, the result is truncated as is, without saturation.

Figure 135. 20-bit to 16-bit result truncation

Figure 136 gives a numerical example of the processing, from a raw 20-bit accumulated data to the final 16-bit result.

Figure 136. Numerical example with 5-bit shift and rounding

Table 168 gives the data format for the various N and M combinations, for a raw conversion data equal to 0xFFF.
There are no changes for conversion timings in oversampled mode: the sample time is maintained equal during the whole oversampling sequence. A new data is provided every N conversions, with an equivalent delay equal to N x T_{CONV} = N x (t_{SMPL} + t_{SAR}). The flags are set as follows:

- The end of the sampling phase (EOSMP) is set after each sampling phase
- The end of conversion (EOC) occurs once every N conversions, when the oversampled result is available
- The end of sequence (EOS) occurs once the sequence of oversampled data is completed (i.e. after N x sequence length conversions total)

**ADC operating modes supported when oversampling (single ADC mode)**

In oversampling mode, most of the ADC operating modes are maintained:

- Single or continuous mode conversions
- ADC conversions start either by software or with triggers
- ADC stop during a conversion (abort)
- Data read via CPU or DMA with overrun detection
- Low-power modes (AUTDLY)
- Programmable resolution: in this case, the reduced conversion values (as per RES[1:0] bits in ADC_CFGR1 register) are accumulated, truncated, rounded and shifted in the same way as 12-bit conversions are

**Note:** The alignment mode is not available when working with oversampled data. The ALIGN bit in ADC_CFGR1 is ignored and the data are always provided right-aligned.

Offset correction is not supported in oversampling mode. When ROVSE and/or JOVSE bit is set, the value of the OFFSETy_EN bit in ADC_OFRy register is ignored (considered as reset).

</table>
Analog watchdog

The analog watchdog functionality is maintained (AWDSGL and AWDEN bits), with the following difference:

- The RES[1:0] bits are ignored, comparison is always done using the full 12-bit values HT[11:0] and LT[11:0]
- The comparison is performed on the most significant 12-bit of the 16-bit oversampled results ADC_DR[15:4]

Note: Care must be taken when using high shifting values, this will reduce the comparison range. For instance, if the oversampled result is shifted by 4 bits, thus yielding a 12-bit data right-aligned, the effective analog watchdog comparison can only be performed on 8 bits. The comparison is done between ADC_DR[11:4] and HT[0:7] / LT[0:7], and HT[11:8] / LT[11:8] must be kept reset.

Triggered mode

The averager can also be used for basic filtering purpose. Although not a very powerful filter (slow roll-off and limited stop band attenuation), it can be used as a notch filter to reject constant parasitic frequencies (typically coming from the mains or from a switched mode power supply). For this purpose, a specific discontinuous mode can be enabled with TROVS bit in ADC_CFGR2, to be able to have an oversampling frequency defined by a user and independent from the conversion time itself.

Figure 137 below shows how conversions are started in response to triggers during discontinuous mode.

If the TROVS bit is set, the content of the DISCEN bit is ignored and considered as 1.

Figure 137. Triggered regular oversampling mode (TROVS bit = 1)

Injected and regular sequencer management when oversampling

In oversampling mode, it is possible to have differentiated behavior for injected and regular sequencers. The oversampling can be enabled for both sequencers with some limitations if they have to be used simultaneously (this is related to a unique accumulation unit).
Oversampling regular channels only

The regular oversampling mode bit ROVSM defines how the regular oversampling sequence is resumed if it is interrupted by injected conversion:

- In continued mode, the accumulation restarts from the last valid data (prior to the conversion abort request due to the injected trigger). This ensures that oversampling will be complete whatever the injection frequency (providing at least one regular conversion can be complete between triggers);
- In resumed mode, the accumulation restarts from 0 (previous conversion results are ignored). This mode allows to guarantee that all data used for oversampling were converted back-to-back within a single timeslot. Care must be taken to have a injection trigger period above the oversampling period length. If this condition is not respected, the oversampling cannot be complete and the regular sequencer will be blocked.

*Figure 138* gives examples for a 4x oversampling ratio.

**Figure 138. Regular oversampling modes (4x ratio)**

![Diagram showing regular oversampling modes](MS34456V1)

Oversampling Injected channels only

The Injected oversampling mode bit JOVSE enables oversampling solely for conversions in the injected sequencer.
Oversampling regular and injected channels

It is possible to have both ROVSE and JOVSE bits set. In this case, the regular oversampling mode is forced to resumed mode (ROVSM bit ignored), as represented on Figure 139 below.

Figure 139. Regular and injected oversampling modes used simultaneously

Triggered regular oversampling with injected conversions

It is possible to have triggered regular mode with injected conversions. In this case, the injected mode oversampling mode must be disabled, and the ROVSM bit is ignored (resumed mode is forced). The JOVSE bit must be reset. The behavior is represented on Figure 140 below.

Figure 140. Triggered regular oversampling with injection
Auto-injected mode

It is possible to oversample auto-injected sequences and have all conversions results stored in registers to save a DMA resource. This mode is available only with both regular and injected oversampling active: JAUTO = 1, ROVSE = 1 and JOVSE = 1, other combinations are not supported. The ROVSM bit is ignored in auto-injected mode. The *Figure 141* below shows how the conversions are sequenced.

*Figure 141. Oversampling in auto-injected mode*

It is possible to have also the triggered mode enabled, using the TROVS bit. In this case, the ADC must be configured as following: JAUTO = 1, DISCEN = 0, JDISCEN = 0, ROVSE = 1, JOVSE = 1 and TROVSE = 1.

Dual ADC modes supported when oversampling

It is possible to have oversampling enabled when working in dual ADC configuration, for the injected simultaneous mode and regular simultaneous mode. In this case, the two ADCs must be programmed with the very same settings (including oversampling).

All other dual ADC modes are not supported when either regular or injected oversampling is enabled (ROVSE = 1 or JOVSE = 1).

Combined modes summary

The *Table 169* below summarizes all combinations, including modes not supported.

21.4.31 Dual ADC modes

Dual ADC modes can be used in devices with two ADCs or more (see Figure 142).

In dual ADC mode the start of conversion is triggered alternately or simultaneously by the ADCx master to the ADC slave, depending on the mode selected by the bits DUAL[4:0] in the ADCx_CCR register.

Four possible modes are implemented:

- Injected simultaneous mode
- Regular simultaneous mode
- Interleaved mode
- Alternate trigger mode

It is also possible to use these modes combined in the following ways:

- Injected simultaneous mode + Regular simultaneous mode
- Regular simultaneous mode + Alternate trigger mode
- Injected simultaneous mode + Interleaved mode

In dual ADC mode (when bits DUAL[4:0] in ADCx_CCR register are not equal to zero), the bits CONT, AUTDLY, DISCEN, DISCNUM[2:0], JDIISCEN, JQM, JAUTO of the ADC_CFGR register are shared between the master and slave ADC: the bits in the slave ADC are always equal to the corresponding bits of the master ADC.

To start a conversion in dual mode, the user must program the bits EXTEN[1:0], EXTSEL, JEXTEN[1:0], JEXTSEL of the master ADC only, to configure a software or hardware trigger, and a regular or injected trigger. (the bits EXTEN[1:0] and JEXTEN[1:0] of the slave ADC are don’t care).

In regular simultaneous or interleaved modes: once the user sets bit ADSTART or bit ADSTP of the master ADC, the corresponding bit of the slave ADC is also automatically set. However, bit ADSTART or bit ADSTP of the slave ADC is not necessary cleared at the same time as the master ADC bit.

In injected simultaneous or alternate trigger modes: once the user sets bit JADSTART or bit JADSTP of the master ADC, the corresponding bit of the slave ADC is also automatically set. However, bit JADSTART or bit JADSTP of the slave ADC is not necessary cleared at the same time as the master ADC bit.

In dual ADC mode, the converted data of the master and slave ADC can be read in parallel, by reading the ADC common data register (ADCx_CDR). The status bits can be also read in parallel by reading the dual-mode status register (ADCx_CSR).
1. External triggers also exist on slave ADC but are not shown for the purposes of this diagram.
2. The ADC common data register (ADCx_CDR) contains both the master and slave ADC regular converted data.
**Injected simultaneous mode**

This mode is selected by programming bits DUAL[4:0]=00101

This mode converts an injected group of channels. The external trigger source comes from the injected group multiplexer of the master ADC (selected by the JEXTSEL bits in the ADC_JSQR register).

**Note:** Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).

In simultaneous mode, one must convert sequences with the same length or ensure that the interval between triggers is longer than the longer of the 2 sequences. Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

Regular conversions can be performed on one or all ADCs. In that case, they are independent of each other and are interrupted when an injected event occurs. They are resumed at the end of the injected conversion group.

- At the end of injected sequence of conversion event (JEOS) on the master ADC, the converted data is stored into the master ADC_JDRy registers and a JEOS interrupt is generated (if enabled)
- At the end of injected sequence of conversion event (JEOS) on the slave ADC, the converted data is stored into the slave ADC_JDRy registers and a JEOS interrupt is generated (if enabled)
- If the duration of the master injected sequence is equal to the duration of the slave injected one (like in Figure 143), it is possible for the software to enable only one of the two JEOS interrupt (ex: master JEOS) and read both converted data (from master ADC_JDRy and slave ADC_JDRy registers).

**Figure 143. Injected simultaneous mode on 4 channels: dual ADC mode**

If JDISCEN=1, each simultaneous conversion of the injected sequence requires an injected trigger event to occur.

This mode can be combined with AUTDLY mode:

- Once a simultaneous injected sequence of conversions has ended, a new injected trigger event is accepted only if both JEOS bits of the master and the slave ADC have been cleared (delay phase). Any new injected trigger events occurring during the ongoing injected sequence and the associated delay phase are ignored.
- Once a regular sequence of conversions of the master ADC has ended, a new regular trigger event of the master ADC is accepted only if the master data register (ADC_DR) has been read. Any new regular trigger events occurring for the master ADC during the
ongoing regular sequence and the associated delay phases are ignored.
There is the same behavior for regular sequences occurring on the slave ADC.

**Regular simultaneous mode with independent injected**

This mode is selected by programming bits DUAL[4:0] = 00110.

This mode is performed on a regular group of channels. The external trigger source comes from the regular group multiplexer of the master ADC (selected by the EXTSEL bits in the ADC_CFGR register). A simultaneous trigger is provided to the slave ADC.

In this mode, independent injected conversions are supported. An injection request (either on master or on the slave) will abort the current simultaneous conversions, which are restarted once the injected conversion is completed.

*Note:* Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).

In regular simultaneous mode, one must convert sequences with the same length or ensure that the interval between triggers is longer than the longer conversion time of the 2 sequences. Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

Software is notified by interrupts when it can read the data:

- At the end of each conversion event (EOC) on the master ADC, a master EOC interrupt is generated (if EOCIE is enabled) and software can read the ADC_DR of the master ADC.
- At the end of each conversion event (EOC) on the slave ADC, a slave EOC interrupt is generated (if EOCIE is enabled) and software can read the ADC_DR of the slave ADC.
- If the duration of the master regular sequence is equal to the duration of the slave one (like in *Figure 144*), it is possible for the software to enable only one of the two EOC interrupt (ex: master EOC) and read both converted data from the Common Data register (ADCx_CDR).

It is also possible to read the regular data using the DMA. Two methods are possible:

- Using two DMA channels (one for the master and one for the slave). In this case bits MDMA[1:0] must be kept cleared.
  - Configure the DMA master ADC channel to read ADC_DR from the master. DMA requests are generated at each EOC event of the master ADC.
  - Configure the DMA slave ADC channel to read ADC_DR from the slave. DMA requests are generated at each EOC event of the slave ADC.

- Using MDMA mode, which leaves one DMA channel free for other uses:
  - Configure MDMA[1:0]=0b10 or 0b11 (depending on resolution).
  - A single DMA channel is used (the one of the master). Configure the DMA master ADC channel to read the common ADC register (ADCx_CDR)
  - A single DMA request is generated each time both master and slave EOC events have occurred. At that time, the slave ADC converted data is available in the upper half-word of the ADCx_CDR 32-bit register and the master ADC converted data is available in the lower half-word of ADCx_CCR register.
  - Both EOC flags are cleared when the DMA reads the ADCx_CCR register.

*Note:* In MDMA mode (MDMA[1:0]=0b10 or 0b11), the user must program the same number of conversions in the master’s sequence as in the slave’s sequence. Otherwise, the remaining conversions will not generate a DMA request.
If DISCEN=1 then each “n” simultaneous conversions of the regular sequence require a regular trigger event to occur (“n” is defined by DISCNUM).

This mode can be combined with AUTDLY mode:

- Once a simultaneous conversion of the sequence has ended, the next conversion in the sequence is started only if the common data register, ADCx_CDR (or the regular data register of the master ADC) has been read (delay phase).
- Once a simultaneous regular sequence of conversions has ended, a new regular trigger event is accepted only if the common data register (ADCx_CDR) has been read (delay phase). Any new regular trigger events occurring during the ongoing regular sequence and the associated delay phases are ignored.

It is possible to use the DMA to handle data in regular simultaneous mode combined with AUTDLY mode, assuming that multi-DMA mode is used: bits MDMA must be set to 0b10 or 0b11.

When regular simultaneous mode is combined with AUTDLY mode, it is mandatory for the user to ensure that:

- The number of conversions in the master’s sequence is equal to the number of conversions in the slave’s.
- For each simultaneous conversions of the sequence, the length of the conversion of the slave ADC is inferior to the length of the conversion of the master ADC. Note that the length of the sequence depends on the number of channels to convert and the sampling time and the resolution of each channels.

**Note:** This combination of regular simultaneous mode and AUTDLY mode is restricted to the use case when only regular channels are programmed: it is forbidden to program injected channels in this combined mode.

**Interleaved mode with independent injected**

This mode is selected by programming bits DUAL[4:0] = 00111.

This mode can be started only on a regular group (usually one channel). The external trigger source comes from the regular channel multiplexer of the master ADC.

After an external trigger occurs:

- The master ADC starts immediately.
- The slave ADC starts after a delay of several-ADC clock cycles after the sampling phase of the master ADC has complete.

The minimum delay which separates two conversions in interleaved mode is configured in the DELAY bits in the ADCx_CCR register. This delay starts counting one half cycle after the end of the sampling phase of the master conversion. This way, an ADC cannot start a
conversion if the complementary ADC is still sampling its input (only one ADC can sample
the input signal at a given time).

- The minimum possible DELAY is 1 to ensure that there is at least one cycle time
  between the opening of the analog switch of the master ADC sampling phase and the
  closing of the analog switch of the slave ADC sampling phase.

- The maximum DELAY is equal to the number of cycles corresponding to the selected
  resolution. However the user must properly calculate this delay to ensure that an ADC
does not start a conversion while the other ADC is still sampling its input.

If the CONT bit is set on both master and slave ADCs, the selected regular channels of both
ADCs are continuously converted.

The software is notified by interrupts when it can read the data at the end of each
conversion event (EOC) on the slave ADC. A slave and master EOC interrupts are
generated (if EOCIE is enabled) and the software can read the ADC_DR of the slave/master
ADC.

**Note:** It is possible to enable only the EOC interrupt of the slave and read the common data
register (ADCx_CDR). But in this case, the user must ensure that the duration of the
conversions are compatible to ensure that inside the sequence, a master conversion is
always followed by a slave conversion before a new master conversion restarts. It is
recommended to use the MDMA mode.

It is also possible to have the regular data transferred by DMA. In this case, individual DMA
requests on each ADC cannot be used and it is mandatory to use the MDMA mode, as
following:

- Configure MDMA[1:0]=0b10 or 0b11 (depending on resolution).
- A single DMA channel is used (the one of the master). Configure the DMA master ADC
  channel to read the common ADC register (ADCx_CDR).
- A single DMA request is generated each time both master and slave EOC events have
  occurred. At that time, the slave ADC converted data is available in the upper half-word
  of the ADCx_CDR 32-bit register and the master ADC converted data is available in
  the lower half-word of ADCx_CCR register.
- Both EOC flags are cleared when the DMA reads the ADCx_CCR register.

**Figure 145. Interleaved mode on 1 channel in continuous conversion mode: dual ADC
mode**
If DISCEN=1, each “n” simultaneous conversions (“n” is defined by DISCNUM) of the regular sequence require a regular trigger event to occur.

In this mode, injected conversions are supported. When injection is done (either on master or on slave), both the master and the slave regular conversions are aborted and the sequence is restarted from the master (see Figure 147 below).

**Alternate trigger mode**

This mode is selected by programming bits DUAL[4:0] = 01001.

This mode can be started only on an injected group. The source of external trigger comes from the injected group multiplexer of the master ADC.

This mode is only possible when selecting hardware triggers: JEXTEN[1:0] must not be 00.

**Injected discontinuous mode disabled** (JDISCEN=0 for both ADC)
1. When the 1st trigger occurs, all injected master ADC channels in the group are converted.
2. When the 2nd trigger occurs, all injected slave ADC channels in the group are converted.
3. And so on.

A JEOS interrupt, if enabled, is generated after all injected channels of the master ADC in the group have been converted.

A JEOS interrupt, if enabled, is generated after all injected channels of the slave ADC in the group have been converted.

JEOC interrupts, if enabled, can also be generated after each injected conversion.

If another external trigger occurs after all injected channels in the group have been converted then the alternate trigger process restarts by converting the injected channels of the master ADC in the group.

**Figure 148. Alternate trigger: injected group of each ADC**

---

**Note:**

Regular conversions can be enabled on one or all ADCs. In this case the regular conversions are independent of each other. A regular conversion is interrupted when the ADC has to perform an injected conversion. It is resumed when the injected conversion is finished.

The time interval between 2 trigger events must be greater than or equal to 1 ADC clock period. The minimum time interval between 2 trigger events that start conversions on the same ADC is the same as in the single ADC mode.

**Injected discontinuous mode enabled (JDISCEN=1 for both ADC)**
If the injected discontinuous mode is enabled for both master and slave ADCs:

- When the 1st trigger occurs, the first injected channel of the master ADC is converted.
- When the 2nd trigger occurs, the first injected channel of the slave ADC is converted.
- And so on.

A JEOS interrupt, if enabled, is generated after all injected channels of the master ADC in the group have been converted.

A JEOS interrupt, if enabled, is generated after all injected channels of the slave ADC in the group have been converted.

JEOC interrupts, if enabled, can also be generated after each injected conversions.

If another external trigger occurs after all injected channels in the group have been converted then the alternate trigger process restarts.

**Figure 149. Alternate trigger: 4 injected channels (each ADC) in discontinuous mode**

**Combined regular/injected simultaneous mode**

This mode is selected by programming bits DUAL[4:0] = 00001.

It is possible to interrupt the simultaneous conversion of a regular group to start the simultaneous conversion of an injected group.

*Note:* In combined regular/injected simultaneous mode, one must convert sequences with the same length or ensure that the interval between triggers is longer than the long conversion time of the 2 sequences. Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

**Combined regular simultaneous + alternate trigger mode**

This mode is selected by programming bits DUAL[4:0]=00010.

It is possible to interrupt the simultaneous conversion of a regular group to start the alternate trigger conversion of an injected group. **Figure 150** shows the behavior of an alternate trigger interrupting a simultaneous regular conversion.

The injected alternate conversion is immediately started after the injected event. If a regular conversion is already running, in order to ensure synchronization after the injected conversion, the regular conversion of all (master/slave) ADCs is stopped and resumed synchronously at the end of the injected conversion.
Note: In combined regular simultaneous + alternate trigger mode, one must convert sequences with the same length or ensure that the interval between triggers is longer than the long conversion time of the 2 sequences. Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

Figure 150. Alternate + regular simultaneous

If a trigger occurs during an injected conversion that has interrupted a regular conversion, the alternate trigger is served. Figure 151 shows the behavior in this case (note that the 6th trigger is ignored because the associated alternate conversion is not complete).

Figure 151. Case of trigger occurring during injected conversion

Combined injected simultaneous plus interleaved

This mode is selected by programming bits DUAL[4:0]=00011.

It is possible to interrupt an interleaved conversion with a simultaneous injected event.

In this case the interleaved conversion is interrupted immediately and the simultaneous injected conversion starts. At the end of the injected sequence the interleaved conversion is resumed. When the interleaved regular conversion resumes, the first regular conversion which is performed is always the master’s one. Figure 152, Figure 153 and Figure 154 show the behavior using an example.

Caution: In this mode, it is mandatory to use the Common Data Register to read the regular data with a single read access. On the contrary, master-slave data coherency is not guaranteed.
Figure 152. Interleaved single channel CH0 with injected sequence CH11, CH12

Figure 153. Two Interleaved channels (CH1, CH2) with injected sequence CH11, CH12
- case 1: Master interrupted first

Figure 154. Two Interleaved channels (CH1, CH2) with injected sequence CH11, CH12
- case 2: Slave interrupted first
DMA requests in dual ADC mode

In all dual ADC modes, it is possible to use two DMA channels (one for the master, one for the slave) to transfer the data, like in single mode (refer to Figure 155: DMA Requests in regular simultaneous mode when MDMA=0b00).

Figure 155. DMA Requests in regular simultaneous mode when MDMA=0b00

</tr>
<tr>
<td>ADC_DR</td>
<td></td>
</tr>
</tbody>
</table>

In simultaneous regular and interleaved modes, it is also possible to save one DMA channel and transfer both data using a single DMA channel. For this MDMA bits must be configured in the ADCx_CCR register:

- **MDMA=0b10**: A single DMA request is generated each time both master and slave EOC events have occurred. At that time, two data items are available and the 32-bit register ADCx_CDR contains the two half-words representing two ADC-converted data items. The slave ADC data take the upper half-word and the master ADC data take the lower half-word.

  This mode is used in interleaved mode and in regular simultaneous mode when resolution is 10-bit or 12-bit.

**Example:**

Interleaved dual mode: a DMA request is generated each time 2 data items are available:

1st DMA request: ADCx_CDR[31:0] = SLV_ADC_DR[15:0] | MST_ADC_DR[15:0]
2nd DMA request: ADCx_CDR[31:0] = SLV_ADC_DR[15:0] | MST_ADC_DR[15:0]
Figure 156. DMA requests in regular simultaneous mode when MDMA=0b10

Figure 157. DMA requests in interleaved mode when MDMA=0b10
Note: When using MDMA mode, the user must take care to configure properly the duration of the master and slave conversions so that a DMA request is generated and served for reading both data (master + slave) before a new conversion is available.

- **MDMA=0b11**: This mode is similar to the MDMA=0b10. The only differences are that on each DMA request (two data items are available), two bytes representing two ADC converted data items are transferred as a half-word.
  
  This mode is used in interleaved and regular simultaneous mode when resolution is 6-bit or when resolution is 8-bit and data is not signed (offsets must be disabled for all the involved channels).

  **Example:**

  Interleaved dual mode: a DMA request is generated each time 2 data items are available:

  1st DMA request: ADCx_CDR[15:0] = SLV_ADC_DR[7:0] | MST_ADC_DR[7:0]
  2nd DMA request: ADCx_CDR[15:0] = SLV_ADC_DR[7:0] | MST_ADC_DR[7:0]

**Overrun detection**

In dual ADC mode (when DUAL[4:0] is not equal to b00000), if an overrun is detected on one of the ADCs, the DMA requests are no longer issued to ensure that all the data transferred to the RAM are valid (this behavior occurs whatever the MDMA configuration). It may happen that the EOC bit corresponding to one ADC remains set because the data register of this ADC contains valid data.

**DMA one shot mode/ DMA circular mode when MDMA mode is selected**

When MDMA mode is selected (0b10 or 0b11), bit DMACFG of the ADCx_CCR register must also be configured to select between DMA one shot mode and circular mode, as explained in section Section 21.3 Managing conversions using the DMA (bits DMACFG of master and slave ADC_CFGR are not relevant).

**Stopping the conversions in dual ADC modes**

The user must set the control bits ADSTP/JADSTP of the master ADC to stop the conversions of both ADC in dual ADC mode. The other ADSTP control bit of the slave ADC has no effect in dual ADC mode.

Once both ADC are effectively stopped, the bits ADSTART/JADSTART of the master and slave ADCs are both cleared by hardware.

**21.4.32 Temperature sensor**

The temperature sensor can be used to measure the junction temperature (Tj) of the device. The temperature sensor is internally connected to the ADC input channels which are used to convert the sensor output voltage to a digital value. When not in use, the sensor can be put in power down mode. It support the temperature range -40 to 125 °C.

*Figure 158* shows the block diagram of connections between the temperature sensor and the ADC.

The temperature sensor output voltage changes linearly with temperature. The offset of this line varies from chip to chip due to process variation (up to 45 °C from one chip to another).
The uncalibrated internal temperature sensor is more suited for applications that detect temperature variations instead of absolute temperatures. To improve the accuracy of the temperature sensor measurement, calibration values are stored in system memory for each device by ST during production.

During the manufacturing process, the calibration data of the temperature sensor and the internal voltage reference are stored in the system memory area. The user application can then read them and use them to improve the accuracy of the temperature sensor or the internal reference (refer to the datasheet for additional information).

The temperature sensor is internally connected to the ADC input channel which is used to convert the sensor’s output voltage to a digital value. Refer to the electrical characteristics section of the device datasheet for the sampling time value to be applied when converting the internal temperature sensor.

When not in use, the sensor can be put in power-down mode.

*Figure 158* shows the block diagram of the temperature sensor.

**Figure 158. Temperature sensor channel block diagram**

---

### Reading the temperature

To use the sensor:

1. Select the ADC input channels that is connected to $V_{TS}$.
2. Program with the appropriate sampling time (refer to electrical characteristics section of the device datasheet).
3. Set the CH17SEL bit in the ADCx_CCR register to wake up the temperature sensor from power-down mode.
4. Start the ADC conversion.
5. Read the resulting $V_{TS}$ data in the ADC data register.
6. Calculate the actual temperature using the following formula:

$$
\text{Temperature (in °C)} = \frac{\text{TS\_CAL2\_TEMP} - \text{TS\_CAL1\_TEMP}}{\text{TS\_CAL2} - \text{TS\_CAL1}} \times (\text{TS\_DATA} - \text{TS\_CAL1}) + 30 \ ^\circ \text{C}
$$
Where:
- TS_CAL2 is the temperature sensor calibration value acquired at TS_CAL2_TEMP.
- TS_CAL1 is the temperature sensor calibration value acquired at TS_CAL1_TEMP.
- TS_DATA is the actual temperature sensor output value converted by ADC.

Refer to the device datasheet for more information about TS_CAL1 and TS_CAL2 calibration points.

Note: The sensor has a startup time after waking from power-down mode before it can output \( V_{TS} \) at the correct level. The ADC also has a startup time after power-on, so to minimize the delay, the ADEN and CH17SEL bits should be set at the same time.

The above formula is given for TS_DATA measurement done with the same \( V_{REF} \) voltage as TS_CAL1/TS_CAL2 values. If \( V_{REF} \) is different, the formula must be adapted. For example if \( V_{REF} = 3.3 \text{ V} \) and TS_CAL data are acquired at \( V_{REF} = 3.0 \text{ V} \), TS_DATA must be replaced by TS_DATA x \( (3.3/3.0) \).

21.4.33 \( V_{BAT} \) supply monitoring

The CH18SEL bit in the ADCx_CCR register is used to switch to the battery voltage. As the \( V_{BAT} \) voltage could be higher than \( V_{DDA} \), to ensure the correct operation of the ADC, the \( V_{BAT} \) pin is internally connected to a bridge divider by 3. This bridge is automatically enabled when CH18SEL is set, to connect \( V_{BAT}/3 \) to the ADC input channels. As a consequence, the converted digital value is one third of the \( V_{BAT} \) voltage. To prevent any unwanted consumption on the battery, it is recommended to enable the bridge divider only when needed, for ADC conversion.

Refer to the electrical characteristics of the device datasheet for the sampling time value to be applied when converting the \( V_{BAT}/3 \) voltage.

The figure below shows the block diagram of the \( V_{BAT} \) sensing feature.

![Figure 159. \( V_{BAT} \) channel block diagram](MSv37245V1)

1. The CH18SEL bit must be set to enable the conversion of internal channel for \( V_{BAT}/3 \).
21.4.34 Monitoring the internal voltage reference

It is possible to monitor the internal voltage reference \(V_{\text{REFINT}}\) to have a reference point for evaluating the ADC \(V_{\text{REF+}}\) voltage level.

The internal voltage reference is internally connected to the input channel 0 of the ADC1 (ADC1_INP0).

Refer to the electrical characteristics section of the product datasheet for the sampling time value to be applied when converting the internal voltage reference voltage.

*Figure 160* shows the block diagram of the \(V_{\text{REFINT}}\) sensing feature.

*Figure 160. \(V_{\text{REFINT}}\) channel block diagram*

1. The VREFEN bit into ADCx_CCR register must be set to enable the conversion of internal channels \(V_{\text{REFINT}}\).

Calculating the actual \(V_{\text{REF+}}\) voltage using the internal reference voltage

The power supply voltage applied to the device may be subject to variations or not precisely known. When \(V_{\text{DDA}}\) is connected to \(V_{\text{REF+}}\), it is possible to compute the actual \(V_{\text{DDA}}\) voltage using the embedded internal reference voltage \(V_{\text{REFINT}}\). \(V_{\text{REFINT}}\) and its calibration data, acquired by the ADC during the manufacturing process at \(V_{\text{DDA, Charac}}\), can be used to evaluate the actual \(V_{\text{DDA}}\) voltage level.

The following formula gives the actual \(V_{\text{REF+}}\) voltage supplying the device:

\[
V_{\text{REF+}} = V_{\text{REF+ Charac}} \times \frac{V_{\text{REFINT CAL}}}{V_{\text{REFINT DATA}}}
\]

Where:

- \(V_{\text{REF+ Charac}}\) is the value of \(V_{\text{REF+}}\) voltage characterized at \(V_{\text{REFINT}}\) during the manufacturing process. It is specified in the device datasheet.
- \(V_{\text{REFINT CAL}}\) is the \(V_{\text{REFINT}}\) calibration value
- \(V_{\text{REFINT DATA}}\) is the actual \(V_{\text{REFINT}}\) output value converted by ADC

Converting a supply-relative ADC measurement to an absolute voltage value

The ADC is designed to deliver a digital value corresponding to the ratio between \(V_{\text{REF+}}\) and the voltage applied on the converted channel.

For most applications \(V_{\text{DDA}}\) value is unknown and ADC converted values are right-aligned. In this case, it is necessary to convert this ratio into a voltage independent from \(V_{\text{DDA}}\):
By replacing $V_{REF+}$ by the formula provided above, the absolute voltage value is given by the following formula:

$$V_{\text{CHANNEL}x} = V_{\text{REF+ Charac}} \times V_{\text{REFINT_CAL}} \times \frac{ADC_{\text{DATA}}}{V_{\text{REFINT_DATA}} \times \text{FULL\_SCALE}}$$

For applications where $V_{REF+}$ is known and ADC converted values are right-aligned, the absolute voltage value can be obtained by using the following formula:

$$V_{\text{CHANNEL}x} = \frac{V_{\text{REF+}}}{\text{FULL\_SCALE}} \times \text{ADC\_DATA}$$

Where:
- $V_{\text{REF+ Charac}}$ is the value of $V_{REF+}$ voltage characterized at $V_{\text{REFINT}}$ during the manufacturing process.
- $V_{\text{REFINT_CAL}}$ is the $V_{\text{REFINT}}$ calibration value
- $\text{ADC\_DATA}$ is the value measured by the ADC on channel $x$ (right-aligned)
- $V_{\text{REFINT\_DATA}}$ is the actual $V_{\text{REFINT}}$ output value converted by the ADC
- $\text{FULL\_SCALE}$ is the maximum digital value of the ADC output. For example with 12-bit resolution, it will be $2^{12} - 1 = 4095$ or with 8-bit resolution, $2^8 - 1 = 255$.

Note: If ADC measurements are done using an output format other than 16-bit right-aligned, all the parameters must first be converted to a compatible format before the calculation is done.

21.5 ADC interrupts

For each ADC, an interrupt can be generated:
- After ADC power-up, when the ADC is ready (flag ADRDY)
- On the end of any conversion for regular groups (flag EOC)
- On the end of a sequence of conversion for regular groups (flag EOS)
- On the end of any conversion for injected groups (flag JEOC)
- On the end of a sequence of conversion for injected groups (flag JEOS)
- When an analog watchdog detection occurs (flag AWD1, AWD2 and AWD3)
- When the end of sampling phase occurs (flag EOSMP)
- When the data overrun occurs (flag OVR)
- When the injected sequence context queue overflows (flag JQOVF)

Separate interrupt enable bits are available for flexibility.

Bits 31:11  Reserved, must be kept at reset value.

**Bit 10**  JQOVF: Injected context queue overflow

This bit is set by hardware when an Overflow of the Injected Queue of Context occurs. It is cleared by software writing 1 to it. Refer to Section 21.4.21: Queue of context for injected conversions for more information.

0: No injected context queue overflow occurred (or the flag event was already acknowledged and cleared by software)
1: Injected context queue overflow has occurred

**Bit 9**  AWD3: Analog watchdog 3 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT3[7:0] and HT3[7:0] of ADC_TR3 register. It is cleared by software writing 1 to it.

0: No analog watchdog 3 event occurred (or the flag event was already acknowledged and cleared by software)
1: Analog watchdog 3 event occurred

**Bit 8**  AWD2: Analog watchdog 2 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT2[7:0] and HT2[7:0] of ADC_TR2 register. It is cleared by software writing 1 to it.

0: No analog watchdog 2 event occurred (or the flag event was already acknowledged and cleared by software)
1: Analog watchdog 2 event occurred

**Bit 7**  AWD1: Analog watchdog 1 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LT1[11:0] and HT1[11:0] of ADC_TR1 register. It is cleared by software, writing 1 to it.

0: No analog watchdog 1 event occurred (or the flag event was already acknowledged and cleared by software)
1: Analog watchdog 1 event occurred

**Bit 6**  JEOS: Injected channel end of sequence flag

This bit is set by hardware at the end of the conversions of all injected channels in the group. It is cleared by software writing 1 to it.

0: Injected conversion sequence not complete (or the flag event was already acknowledged and cleared by software)
1: Injected conversions complete
Bit 5  **JEOC**: Injected channel end of conversion flag
This bit is set by hardware at the end of each injected conversion of a channel when a new data is available in the corresponding ADC_JDRy register. It is cleared by software writing 1 to it or by reading the corresponding ADC_JDRy register.
0: Injected channel conversion not complete (or the flag event was already acknowledged and cleared by software)
1: Injected channel conversion complete

Bit 4  **OVR**: ADC overrun
This bit is set by hardware when an overrun occurs on a regular channel, meaning that a new conversion has completed while the EOC flag was already set. It is cleared by software writing 1 to it.
0: No overrun occurred (or the flag event was already acknowledged and cleared by software)
1: Overrun has occurred

Bit 3  **EOS**: End of regular sequence flag
This bit is set by hardware at the end of the conversions of a regular sequence of channels. It is cleared by software writing 1 to it.
0: Regular Conversions sequence not complete (or the flag event was already acknowledged and cleared by software)
1: Regular Conversions sequence complete

Bit 2  **EOC**: End of conversion flag
This bit is set by hardware at the end of each regular conversion of a channel when a new data is available in the ADC_DR register. It is cleared by software writing 1 to it or by reading the ADC_DR register.
0: Regular channel conversion not complete (or the flag event was already acknowledged and cleared by software)
1: Regular channel conversion complete

Bit 1  **EOSMP**: End of sampling flag
This bit is set by hardware during the conversion of any channel (only for regular channels), at the end of the sampling phase.
0: not at the end of the sampling phase (or the flag event was already acknowledged and cleared by software)
1: End of sampling phase reached

Bit 0  **ADRDY**: ADC ready
This bit is set by hardware after the ADC has been enabled (bit ADEN=1) and when the ADC reaches a state where it is ready to accept conversion requests. It is cleared by software writing 1 to it.
0: ADC not yet ready to start conversion (or the flag event was already acknowledged and cleared by software)
1: ADC is ready to start conversion
### 21.6.2 ADC interrupt enable register (ADC_IER)

Address offset: 0x04  
Reset value: 0x0000 0000

| Bit 10    | JQOVFIE | Injected context queue overflow interrupt enable  
This bit is set and cleared by software to enable/disable the Injected Context Queue Overflow interrupt.  
0: Injected Context Queue Overflow interrupt disabled  
1: Injected Context Queue Overflow interrupt enabled. An interrupt is generated when the JQOVF bit is set.  
*Note: The software is allowed to write this bit only when JADSTART=0 (which ensures that no injected conversion is ongoing).*
|          |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| Bit 9    | AWD3IE | Analog watchdog 3 interrupt enable  
This bit is set and cleared by software to enable/disable the analog watchdog 2 interrupt.  
0: Analog watchdog 3 interrupt disabled  
1: Analog watchdog 3 interrupt enabled  
*Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*
|          |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| Bit 8    | AWD2IE | Analog watchdog 2 interrupt enable  
This bit is set and cleared by software to enable/disable the analog watchdog 2 interrupt.  
0: Analog watchdog 2 interrupt disabled  
1: Analog watchdog 2 interrupt enabled  
*Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*
|          |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| Bit 7    | AWD1IE | Analog watchdog 1 interrupt enable  
This bit is set and cleared by software to enable/disable the analog watchdog 1 interrupt.  
0: Analog watchdog 1 interrupt disabled  
1: Analog watchdog 1 interrupt enabled  
*Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*
|          |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| Bit 6    | JEOSIE | End of injected sequence of conversions interrupt enable  
This bit is set and cleared by software to enable/disable the end of injected sequence of conversions interrupt.  
0: JEOS interrupt disabled  
1: JEOS interrupt enabled. An interrupt is generated when the JEOS bit is set.  
*Note: The software is allowed to write this bit only when JADSTART=0 (which ensures that no injected conversion is ongoing).*

Bits 31:11 Reserved, must be kept at reset value.
Bit 5  **JEOCIE:** End of injected conversion interrupt enable

This bit is set and cleared by software to enable/disable the end of an injected conversion interrupt.

0: JEOC interrupt disabled.
1: JEOC interrupt enabled. An interrupt is generated when the JEOC bit is set.

*Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).*

Bit 4  **OVRIE:** Overrun interrupt enable

This bit is set and cleared by software to enable/disable the Overrun interrupt of a regular conversion.

0: Overrun interrupt disabled
1: Overrun interrupt enabled. An interrupt is generated when the OVR bit is set.

*Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bit 3  **EOSIE:** End of regular sequence of conversions interrupt enable

This bit is set and cleared by software to enable/disable the end of regular sequence of conversions interrupt.

0: EOS interrupt disabled
1: EOS interrupt enabled. An interrupt is generated when the EOS bit is set.

*Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bit 2  **EOCIE:** End of regular conversion interrupt enable

This bit is set and cleared by software to enable/disable the end of a regular conversion interrupt.

0: EOC interrupt disabled.
1: EOC interrupt enabled. An interrupt is generated when the EOC bit is set.

*Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bit 1  **EOSMPIE:** End of sampling flag interrupt enable for regular conversions

This bit is set and cleared by software to enable/disable the end of the sampling phase interrupt for regular conversions.

0: EOSMP interrupt disabled.
1: EOSMP interrupt enabled. An interrupt is generated when the EOSMP bit is set.

*Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bit 0  **ADRDYIE:** ADC ready interrupt enable

This bit is set and cleared by software to enable/disable the ADC Ready interrupt.

0: ADRDY interrupt disabled
1: ADRDY interrupt enabled. An interrupt is generated when the ADRDY bit is set.

*Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

<tr>
<td>0</td>
<td>ADC Voltage regulator disabled</td>
</tr>
<tr>
<td>1</td>
<td>ADC Voltage regulator enabled</td>
</tr>
</tbody>
</table>

For more details about the ADC voltage regulator enable and disable sequences, refer to Section 21.4.6: ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN). The software can program this bit field only when the ADC is disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).
Bits 27:6  Reserved, must be kept at reset value.

Bit 5 **JADSTP**: ADC stop of injected conversion command

This bit is set by software to stop and discard an ongoing injected conversion (JADSTP Command).

It is cleared by hardware when the conversion is effectively discarded and the ADC injected sequence and triggers can be re-configured. The ADC is then ready to accept a new start of injected conversions (JADSTART command).

0: No ADC stop injected conversion command ongoing
1: Write 1 to stop injected conversions ongoing. Read 1 means that an ADSTP command is in progress.

*Note:* The software is allowed to set JADSTP only when JADSTART=1 and ADDIS=0 (ADC is enabled and eventually converting an injected conversion and there is no pending request to disable the ADC)

In Auto-injection mode (JAUTO=1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP)

Bit 4 **ADSTP**: ADC stop of regular conversion command

This bit is set by software to stop and discard an ongoing regular conversion (ADSTP Command).

It is cleared by hardware when the conversion is effectively discarded and the ADC regular sequence and triggers can be re-configured. The ADC is then ready to accept a new start of regular conversions (ADSTART command).

0: No ADC stop regular conversion command ongoing
1: Write 1 to stop regular conversions ongoing. Read 1 means that an ADSTP command is in progress.

*Note:* The software is allowed to set ADSTP only when ADSTART=1 and ADDIS=0 (ADC is enabled and eventually converting a regular conversion and there is no pending request to disable the ADC).

In auto-injection mode (JAUTO=1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP).

Bit 3 **JADSTART**: ADC start of injected conversion

This bit is set by software to start ADC conversion of injected channels. Depending on the configuration bits JEXten[1:0], a conversion will start immediately (software trigger configuration) or once an injected hardware trigger event occurs (hardware trigger configuration).

It is cleared by hardware:

– in single conversion mode when software trigger is selected (JEXTSEL=0x0): at the assertion of the End of Injected Conversion Sequence (JEOS) flag.
– in all cases: after the execution of the JADSTP command, at the same time that JADSTP is cleared by hardware.

0: No ADC injected conversion is ongoing.
1: Write 1 to start injected conversions. Read 1 means that the ADC is operating and eventually converting an injected channel.

*Note:* The software is allowed to set JADSTART only when ADEN=1 and ADDIS=0 (ADC is enabled and there is no pending request to disable the ADC).

In auto-injection mode (JAUTO=1), regular and auto-injected conversions are started by setting bit ADSTART (JADSTART must be kept cleared)
Bit 2  **ADSTART**: ADC start of regular conversion

This bit is set by software to start ADC conversion of regular channels. Depending on the configuration bits EXTEN[1:0], a conversion will start immediately (software trigger configuration) or once a regular hardware trigger event occurs (hardware trigger configuration).

It is cleared by hardware:

- in single conversion mode when software trigger is selected (EXTSEL=0x0): at the assertion of the End of Regular Conversion Sequence (EOS) flag.
- in all cases: after the execution of the ADSTP command, at the same time that ADSTP is cleared by hardware.

0: No ADC regular conversion is ongoing.
1: Write 1 to start regular conversions. Read 1 means that the ADC is operating and eventually converting a regular channel.

**Note:** The software is allowed to set ADSTART only when ADEN=1 and ADDIS=0 (ADC is enabled and there is no pending request to disable the ADC)

In auto-injection mode (JAUTO=1), regular and auto-injected conversions are started by setting bit ADSTART (JADSTART must be kept cleared)

Bit 1  **ADDIS**: ADC disable command

This bit is set by software to disable the ADC (ADDIS command) and put it into power-down state (OFF state).

It is cleared by hardware once the ADC is effectively disabled (ADEN is also cleared by hardware at this time).

0: no ADDIS command ongoing
1: Write 1 to disable the ADC. Read 1 means that an ADDIS command is in progress.

**Note:** The software is allowed to set ADDIS only when ADEN=1 and both ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing)

Bit 0  **ADEN**: ADC enable control

This bit is set by software to enable the ADC. The ADC will be effectively ready to operate once the flag ADRDY has been set.

It is cleared by hardware when the ADC is disabled, after the execution of the ADDIS command.

0: ADC is disabled (OFF state)
1: Write 1 to enable the ADC.

**Note:** The software is allowed to set ADEN only when all bits of ADC_CR registers are 0 (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0) except for bit ADVREGEN which must be 1 (and the software must have wait for the startup time of the voltage regulator)

Bit 31 **JQDIS**: Injected Queue disable
These bits are set and cleared by software to disable the Injected Queue mechanism:

0: Injected Queue enabled
1: Injected Queue disabled

Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no regular nor injected conversion is ongoing).
A set or reset of JQDIS bit causes the injected queue to be flushed and the JSQR register is cleared.

Bits 30:26 **AWD1CH[4:0]**: Analog watchdog 1 channel selection
These bits are set and cleared by software. They select the input channel to be guarded by the analog watchdog.
00000: ADC analog input channel 0 monitored by AWD1 (available on ADC1 only)
00001: ADC analog input channel 1 monitored by AWD1
....
10010: ADC analog input channel 18 monitored by AWD1
others: reserved, must not be used

Note: Some channels are not connected physically. Keep the corresponding AWD1CH[4:0] setting to the reset value.
The channel selected by AWD1CH must be also selected into the SQRi or JSQRi registers.
The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

Bit 25 **JAUTO**: Automatic injected group conversion
This bit is set and cleared by software to enable/disable automatic injected group conversion after regular group conversion.
0: Automatic injected group conversion disabled
1: Automatic injected group conversion enabled

Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no regular nor injected conversion is ongoing).
When dual mode is enabled (DUAL bits in ADCx_CCR register are not equal to zero), the bit JAUTO of the slave ADC is no more writable and its content is equal to the bit JAUTO of the master ADC.
Bit 24  **JAWD1EN**: Analog watchdog 1 enable on injected channels
This bit is set and cleared by software.
0: Analog watchdog 1 disabled on injected channels
1: Analog watchdog 1 enabled on injected channels

*Note: The software is allowed to write this bit only when JADSTART=0 (which ensures that no injected conversion is ongoing).*

Bit 23  **AWD1EN**: Analog watchdog 1 enable on regular channels
This bit is set and cleared by software.
0: Analog watchdog 1 disabled on regular channels
1: Analog watchdog 1 enabled on regular channels

*Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bit 22  **AWD1SGL**: Enable the watchdog 1 on a single channel or on all channels
This bit is set and cleared by software to enable the analog watchdog on the channel identified by the AWD1CH[4:0] bits or on all the channels.
0: Analog watchdog 1 enabled on all channels
1: Analog watchdog 1 enabled on a single channel

*Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

Bit 21  **JQM**: JSQR queue mode
This bit is set and cleared by software.
It defines how an empty Queue is managed.
0: JSQR mode 0: The Queue is never empty and maintains the last written configuration into JSQR.
1: JSQR mode 1: The Queue can be empty and when this occurs, the software and hardware triggers of the injected sequence are both internally disabled just after the completion of the last valid injected sequence.
Refer to Section 21.4.21: Queue of context for injected conversions for more information.

*Note: The software is allowed to write this bit only when JADSTART=0 (which ensures that no injected conversion is ongoing).*

When dual mode is enabled (DUAL bits in ADCx_CCR register are not equal to zero), the bit JQM of the slave ADC is no more writable and its content is equal to the bit JQM of the master ADC.

Bit 20  **JDISCEN**: Discontinuous mode on injected channels
This bit is set and cleared by software to enable/disable discontinuous mode on the injected channels of a group.
0: Discontinuous mode on injected channels disabled
1: Discontinuous mode on injected channels enabled

*Note: The software is allowed to write this bit only when JADSTART=0 (which ensures that no injected conversion is ongoing).*

It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

When dual mode is enabled (bits DUAL of ADCx_CCR register are not equal to zero), the bit JDISCEN of the slave ADC is no more writable and its content is equal to the bit JDISCEN of the master ADC.
Bits 19:17 **DISCNUM[2:0]**: Discontinuous mode channel count

These bits are written by software to define the number of regular channels to be converted in discontinuous mode, after receiving an external trigger.

000: 1 channel  
001: 2 channels  
...  
111: 8 channels

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

When dual mode is enabled (DUAL bits in ADCx_CCR register are not equal to zero), the bits DISCNUM[2:0] of the slave ADC are no more writable and their content is equal to the bits DISCNUM[2:0] of the master ADC.

Bit 16 **DISCEN**: Discontinuous mode for regular channels

This bit is set and cleared by software to enable/disable Discontinuous mode for regular channels.

0: Discontinuous mode for regular channels disabled  
1: Discontinuous mode for regular channels enabled

*Note:* It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN=1 and CONT=1.  
It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.  
The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).  
When dual mode is enabled (DUAL bits in ADCx_CCR register are not equal to zero), the bit DISCEN of the slave ADC is no more writable and its content is equal to the bit DISCEN of the master ADC.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **AUTDLY**: Delayed conversion mode

This bit is set and cleared by software to enable/disable the Auto Delayed Conversion mode.

0: Auto-delayed conversion mode off  
1: Auto-delayed conversion mode on

*Note:* The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).  
When dual mode is enabled (DUAL bits in ADCx_CCR register are not equal to zero), the bit AUTDLY of the slave ADC is no more writable and its content is equal to the bit AUTDLY of the master ADC.

Bit 13 **CONT**: Single / continuous conversion mode for regular conversions

This bit is set and cleared by software. If it is set, regular conversion takes place continuously until it is cleared.

0: Single conversion mode  
1: Continuous conversion mode

*Note:* It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN=1 and CONT=1.  
The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).  
When dual mode is enabled (DUAL bits in ADCx_CCR register are not equal to zero), the bit CONT of the slave ADC is no more writable and its content is equal to the bit CONT of the master ADC.
Bit 12 **OVRMOD**: Overrun mode
This bit is set and cleared by software and configure the way data overrun is managed.
0: ADC_DR register is preserved with the old data when an overrun is detected.
1: ADC_DR register is overwritten with the last conversion result when an overrun is detected.
*Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bits 11:10 **EXTEN[1:0]**: External trigger enable and polarity selection for regular channels
These bits are set and cleared by software to select the external trigger polarity and enable the trigger of a regular group.
00: Hardware trigger detection disabled (conversions can be launched by software)
01: Hardware trigger detection on the rising edge
10: Hardware trigger detection on the falling edge
11: Hardware trigger detection on both the rising and falling edges
*Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bits 9:6 **EXTSEL[3:0]**: External trigger selection for regular group
These bits select the external event used to trigger the start of conversion of a regular group:
0000: Event 0
0001: Event 1
0010: Event 2
0011: Event 3
0100: Event 4
0101: Event 5
0110: Event 6
0111: Event 7
... 1111: Event 15
*Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).*

Bit 5 **ALIGN**: Data alignment
This bit is set and cleared by software to select right or left alignment. Refer to Section : Data register, data alignment and offset (ADC_DR, OFFSETy, OFFSETy_CH, ALIGN)
0: Right alignment
1: Left alignment
*Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*

Bits 4:3 **RES[1:0]**: Data resolution
These bits are written by software to select the resolution of the conversion.
00: 12-bit
01: 10-bit
10: 8-bit
11: 6-bit
*Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).*
Bit 2 DFSDMCFG: DFSDM mode configuration
This bit is set and cleared by software to enable the DFSDM mode. It is effective only when DMAEN=0.
0: DFSDM mode disabled
1: DFSDM mode enabled
Note: To make sure no conversion is ongoing, the software is allowed to write this bit only when ADSTART= 0 and JADSTART= 0.

Bit 1 DMACFG: Direct memory access configuration
This bit is set and cleared by software to select between two DMA modes of operation and is effective only when DMAEN=1.
0: DMA One Shot mode selected
1: DMA Circular mode selected
For more details, refer to Section : Managing conversions using the DMA
Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).
In dual-ADC modes, this bit is not relevant and replaced by control bit DMACFG of the ADCx_CCR register.

Bit 0 DMAEN: Direct memory access enable
This bit is set and cleared by software to enable the generation of DMA requests. This allows to use the DMA to manage automatically the converted data. For more details, refer to Section : Managing conversions using the DMA.
0: DMA disabled
1: DMA enabled
Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).
In dual-ADC modes, this bit is not relevant and replaced by control bits MDMA[1:0] of the ADCx_CCR register.

Bits 31:28 Reserved, must be kept at reset value.
Bits 27:17 Reserved, must be kept at reset value.
Bits 16:11 Reserved, must be kept at reset value.
**Bit 10 ROVSM: Regular Oversampling mode**

This bit is set and cleared by software to select the regular oversampling mode.

0: Continued mode: When injected conversions are triggered, the oversampling is temporary stopped and continued after the injection sequence (oversampling buffer is maintained during injected sequence)

1: Resumed mode: When injected conversions are triggered, the current oversampling is aborted and resumed from start after the injection sequence (oversampling buffer is zeroed by injected sequence start)

*Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no conversion is ongoing).*

**Bit 9 TROVS: Triggered Regular Oversampling**

This bit is set and cleared by software to enable triggered oversampling

0: All oversampled conversions for a channel are done consecutively following a trigger

1: Each oversampled conversion for a channel needs a new trigger

*Note: The software is allowed to write this bit only when ADSTART=0 (which ensures that no conversion is ongoing).*

**Bits 8:5 OVSS[3:0]: Oversampling shift**

This bitfield is set and cleared by software to define the right shifting applied to the raw oversampling result.

0000: No shift
0001: Shift 1-bit
0010: Shift 2-bits
0011: Shift 3-bits
0100: Shift 4-bits
0101: Shift 5-bits
0110: Shift 6-bits

*Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no conversion is ongoing).*
21.6.6 ADC sample time register 1 (ADC_SMPR1)

Address offset: 0x14
Reset value: 0x0000 0000

### Bits 4:2 OVSR[2:0]: Oversampling ratio
This bitfield is set and cleared by software to define the oversampling ratio.
- 000: 2x
- 001: 4x
- 010: 8x
- 011: 16x
- 100: 32x
- 101: 64x
- 110: 128x
- 111: 256x

*Note: The software is allowed to write these bits only when ADSTART=0 (which ensures that no conversion is ongoing).*

### Bit 1 JOVSE: Injected Oversampling Enable
This bit is set and cleared by software to enable injected oversampling.
- 0: Injected Oversampling disabled
- 1: Injected Oversampling enabled

*Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing)*

### Bit 0 ROVSE: Regular Oversampling Enable
This bit is set and cleared by software to enable regular oversampling.
- 0: Regular Oversampling disabled
- 1: Regular Oversampling enabled

*Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing)*
21.6.7 ADC sample time register 2 (ADC_SMPR2)

Address offset: 0x18
Reset value: 0x0000 0000

Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

Some channels are not connected physically. Keep the corresponding SMPx[2:0] setting to the reset value.

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:0 SMP[9:0][2:0]: Channel x sampling time selection

These bits are written by software to select the sampling time individually for each channel. During sample cycles, the channel selection bits must remain unchanged.

000: 2.5 ADC clock cycles
001: 6.5 ADC clock cycles
010: 12.5 ADC clock cycles
011: 24.5 ADC clock cycles
100: 47.5 ADC clock cycles
101: 92.5 ADC clock cycles
110: 247.5 ADC clock cycles
111: 640.5 ADC clock cycles

Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).
Some channels are not connected physically. Keep the corresponding SMPx[2:0] setting to the reset value.

Bits 26:0 SMP[18:10][2:0]: Channel x sampling time selection

These bits are written by software to select the sampling time individually for each channel. During sample cycles, the channel selection bits must remain unchanged.

000: 2.5 ADC clock cycles
001: 6.5 ADC clock cycles
010: 12.5 ADC clock cycles
011: 24.5 ADC clock cycles
100: 47.5 ADC clock cycles
101: 92.5 ADC clock cycles
110: 247.5 ADC clock cycles
111: 640.5 ADC clock cycles

Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).
Some channels are not connected physically. Keep the corresponding SMPx[2:0] setting to the reset value.

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **HT1[11:0]:** Analog watchdog 1 higher threshold
- These bits are written by software to define the higher threshold for the analog watchdog 1.
- Refer to Section 21.4.29: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)
- Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **LT1[11:0]:** Analog watchdog 1 lower threshold
- These bits are written by software to define the lower threshold for the analog watchdog 1.
- Refer to Section 21.4.29: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)
- Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **HT3[7:0]**: Analog watchdog 3 higher threshold

These bits are written by software to define the higher threshold for the analog watchdog 3.

Refer to Section 21.4.29: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)

Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **LT3[7:0]**: Analog watchdog 3 lower threshold

These bits are written by software to define the lower threshold for the analog watchdog 3.

Refer to Section 21.4.29: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)

Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).
### 21.6.11 ADC regular sequence register 1 (ADC_SQR1)

Address offset: 0x30  
Reset value: 0x0000 0000

| Bit 31:29  | Reserved, must be kept at reset value. |
| Bit 28:24  | SQ4[4:0]: 4th conversion in regular sequence  
            | These bits are written by software with the channel number (0 to 18) assigned as the 4th in the regular conversion sequence.  
            | **Note:** The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing). |
| Bit 23     | Reserved, must be kept at reset value. |
| Bit 22:18  | SQ3[4:0]: 3rd conversion in regular sequence  
            | These bits are written by software with the channel number (0 to 18) assigned as the 3rd in the regular conversion sequence.  
            | **Note:** The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing). |
| Bit 17     | Reserved, must be kept at reset value. |
| Bit 16:12  | SQ2[4:0]: 2nd conversion in regular sequence  
            | These bits are written by software with the channel number (0 to 18) assigned as the 2nd in the regular conversion sequence.  
            | **Note:** The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing). |
| Bit 11     | Reserved, must be kept at reset value. |
| Bit 10:6   | SQ1[4:0]: 1st conversion in regular sequence  
            | These bits are written by software with the channel number (0 to 18) assigned as the 1st in the regular conversion sequence.  
            | **Note:** The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing). |
| Bit 5:4    | Reserved, must be kept at reset value. |
| Bit 3:0    | L[3:0]: Regular channel sequence length  
            | These bits are written by software to define the total number of conversions in the regular channel conversion sequence.  
            | 0000: 1 conversion  
            | 0001: 2 conversions  
            | ...  
            | 1111: 16 conversions  
            | **Note:** The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing). |

**Note:** Some channels are not connected physically and must not be selected for conversion.

</table>

Bit 31  Reserved, must be kept at reset value.

Bits 30:26  **JSQ4[4:0]**: 4th conversion in the injected sequence

These bits are written by software with the channel number (0 to 18) assigned as the 4th in the injected conversion sequence.

*Note:* The software is allowed to write these bits only when JADSTART=0 (which ensures that no injected conversion is ongoing).

Bit 25  Reserved, must be kept at reset value.

Bits 24:20  **JSQ3[4:0]**: 3rd conversion in the injected sequence

These bits are written by software with the channel number (0 to 18) assigned as the 3rd in the injected conversion sequence.

*Note:* The software is allowed to write these bits only when JADSTART=0 (which ensures that no injected conversion is ongoing).

Bit 19  Reserved, must be kept at reset value.

Bits 18:14  **JSQ2[4:0]**: 2nd conversion in the injected sequence

These bits are written by software with the channel number (0 to 18) assigned as the 2nd in the injected conversion sequence.

*Note:* The software is allowed to write these bits only when JADSTART=0 (which ensures that no injected conversion is ongoing).

Bit 13  Reserved, must be kept at reset value.

Bits 12:8  **JSQ1[4:0]**: 1st conversion in the injected sequence

These bits are written by software with the channel number (0 to 18) assigned as the 1st in the injected conversion sequence.

*Note:* The software is allowed to write these bits only when JADSTART=0 (which ensures that no injected conversion is ongoing).
Bits 7:6  **JEXTEN[1:0]**: External Trigger Enable and Polarity Selection for injected channels
These bits are set and cleared by software to select the external trigger polarity and enable the trigger of an injected group.
- 00: If JQDIS=0 (queue enabled), Hardware and software trigger detection disabled
- 00: If JQDIS=1 (queue disabled), Hardware trigger detection disabled (conversions can be launched by software)
- 01: Hardware trigger detection on the rising edge
- 10: Hardware trigger detection on the falling edge
- 11: Hardware trigger detection on both the rising and falling edges

*Note:* The software is allowed to write these bits only when JADSTART=0 (which ensures that no injected conversion is ongoing).

If JQM=1 and if the Queue of Context becomes empty, the software and hardware triggers of the injected sequence are both internally disabled (refer to Section 21.4.21: Queue of context for injected conversions)

Bits 5:2  **JEXTSEL[3:0]**: External Trigger Selection for injected group
These bits select the external event used to trigger the start of conversion of an injected group:
- 0000: Event 0
- 0001: Event 1
- 0010: Event 2
- 0011: Event 3
- 0100: Event 4
- 0101: Event 5
- 0110: Event 6
- 0111: Event 7
- ...
- 1111: Event 15

*Note:* The software is allowed to write these bits only when JADSTART=0 (which ensures that no injected conversion is ongoing).

Bits 1:0  **JL[1:0]**: Injected channel sequence length
These bits are written by software to define the total number of conversions in the injected channel conversion sequence.
- 00: 1 conversion
- 01: 2 conversions
- 10: 3 conversions
- 11: 4 conversions

*Note:* The software is allowed to write these bits only when JADSTART=0 (which ensures that no injected conversion is ongoing).

*Note:* Some channels are not connected physically and must not be selected for conversion.
21.6.17 ADC offset y register (ADC_OFRy)

Address offset: 0x60 + 0x04 * (y -1), (y= 1 to 4)
Reset value: 0x0000 0000

</table>

Bit 31 OFFSETy_EN: Offset y enable
This bit is written by software to enable or disable the offset programmed into bits OFFSETy[11:0].

Note: The software is allowed to write this bit only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

Bits 30:26 OFFSETy_CH[4:0]: Channel selection for the data offset y
These bits are written by software to define the channel to which the offset programmed into bits OFFSETy[11:0] will apply.

Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

Some channels are not connected physically and must not be selected for the data offset y.

Bits 25:12 Reserved, must be kept at reset value.

Bits 11:0 OFFSETy[11:0]: Data offset y for the channel programmed into bits OFFSETy_CH[4:0]
These bits are written by software to define the offset y to be subtracted from the raw converted data when converting a channel (can be regular or injected). The channel to which applies the data offset y must be programmed in the bits OFFSETy_CH[4:0]. The conversion result can be read from in the ADC_DR (regular conversion) or from in the ADC_JDRyi registers (injected conversion).

Note: The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

If several offset (OFFSETy) point to the same channel, only the offset with the lowest x value is considered for the subtraction.

Ex: if OFFSET1_CH[4:0]=4 and OFFSET2_CH[4:0]=4, this is OFFSET1[11:0] which is subtracted when converting channel 4.
21.6.18  ADC injected channel y data register (ADC_JDRy)

Address offset: 0x80 + 0x04 * (y - 1), (y = 1 to 4)
Reset value: 0x0000 0000

**AWD2CH[15:0]**

Bits 31:19  Reserved, must be kept at reset value.

Bits 18:0  **AWD2CH[18:0]: Analog watchdog 2 channel selection**

These bits are set and cleared by software. They enable and select the input channels to be guarded by the analog watchdog 2.

- AWD2CH[i] = 0: ADC analog input channel i is not monitored by AWD2
- AWD2CH[i] = 1: ADC analog input channel i is monitored by AWD2

When AWD2CH[18:0] = 000..0, the analog watchdog 2 is disabled

**Note:** The channels selected by AWD2CH must be also selected into the SQRI or JSQRi registers. The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).

Some channels are not connected physically and must not be selected for the analog watchdog.
21.6.20 ADC analog watchdog 3 configuration register (ADC_AWD3CR)

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:0 AWD3CH[18:0]: Analog watchdog 3 channel selection

These bits are set and cleared by software. They enable and select the input channels to be guarded by the analog watchdog 3.

AWD3CH[i] = 0: ADC analog input channel i is not monitored by AWD3
AWD3CH[i] = 1: ADC analog input channel i is monitored by AWD3

When AWD3CH[18:0] = 000..0, the analog watchdog 3 is disabled

Note: The channels selected by AWD3CH must be also selected into the SQRi or JSQRi registers.
The software is allowed to write these bits only when ADSTART=0 and JADSTART=0 (which ensures that no conversion is ongoing).
Some channels are not connected physically and must not be selected for the analog watchdog.

21.6.21 ADC differential mode selection register (ADC_DIFSEL)

Address offset: 0xB0
Reset value: 0x0000 0000

<td>0</td>
</tr>
</tbody>
</table>

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:0 DIFSEL[18:0]: Differential mode for channels 18 to 0.

These bits are set and cleared by software. They allow to select if a channel is configured as single-ended or differential mode.

DIFSEL[i] = 0: ADC analog input channel is configured in single ended mode
DIFSEL[i] = 1: ADC analog input channel i is configured in differential mode

Note: The DIFSEL bits corresponding to channels that are either connected to a single-ended I/O port or to an internal channel must be kept their reset value (single-ended input mode).
The software is allowed to write these bits only when the ADC is disabled (ADCAL=0, JADSTART=0, JADSTP=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).
21.6.22  ADC calibration factors (ADC_CALFACT)

Address offset: 0xB4
Reset value: 0x0000 0000

Bits 31:23  Reserved, must be kept at reset value.

Bits 22:16  CALFACT_D[6:0]: Calibration Factors in differential mode
These bits are written by hardware or by software.
Once a differential inputs calibration is complete, they are updated by hardware with the calibration factors.
Software can write these bits with a new calibration factor. If the new calibration factor is different from the current one stored into the analog ADC, it will then be applied once a new differential calibration is launched.

Note:  The software is allowed to write these bits only when ADEN=1, ADSTART=0 and
JADSTART=0 (ADC is enabled and no calibration is ongoing and no conversion is ongoing).

Bits 15:7  Reserved, must be kept at reset value.

Bits 6:0  CALFACT_S[6:0]: Calibration Factors in single-ended mode
These bits are written by hardware or by software.
Once a single-ended inputs calibration is complete, they are updated by hardware with the calibration factors.
Software can write these bits with a new calibration factor. If the new calibration factor is different from the current one stored into the analog ADC, it will then be applied once a new single-ended calibration is launched.

Note:  The software is allowed to write these bits only when ADEN=1, ADSTART=0 and
JADSTART=0 (ADC is enabled and no calibration is ongoing and no conversion is ongoing).

21.7  ADC common registers

These registers define the control and status registers common to master and slave ADCs:

21.7.1  ADC common status register (ADC_CSR)

Address offset: 0x00 (this offset address is relative to the master ADC base address + 0x300)
Reset value: 0x0000 0000

This register provides an image of the status bits of the different ADCs. Nevertheless it is read-only and does not allow to clear the different status bits. Instead each status bit must be cleared by writing 0 to it in the corresponding ADC_ISR register.

Bits 31:27 Reserved, must be kept at reset value.

- **Bit 26 JQOVF_SLV:** Injected Context Queue Overflow flag of the slave ADC
  - This bit is a copy of the JQOVF bit in the corresponding ADC_ISR register.

- **Bit 25 AWD3_SLV:** Analog watchdog 3 flag of the slave ADC
  - This bit is a copy of the AWD3 bit in the corresponding ADC_ISR register.

- **Bit 24 AWD2_SLV:** Analog watchdog 2 flag of the slave ADC
  - This bit is a copy of the AWD2 bit in the corresponding ADC_ISR register.

- **Bit 23 AWD1_SLV:** Analog watchdog 1 flag of the slave ADC
  - This bit is a copy of the AWD1 bit in the corresponding ADC_ISR register.

- **Bit 22 JEOS_SLV:** End of injected sequence flag of the slave ADC
  - This bit is a copy of the JEOS bit in the corresponding ADC_ISR register.

- **Bit 21 JEOC_SLV:** End of injected conversion flag of the slave ADC
  - This bit is a copy of the JEOC bit in the corresponding ADC_ISR register.

- **Bit 20 OVR_SLV:** Overrun flag of the slave ADC
  - This bit is a copy of the OVR bit in the corresponding ADC_ISR register.

- **Bit 19 EOS_SLV:** End of regular sequence flag of the slave ADC. This bit is a copy of the EOS bit in the corresponding ADC_ISR register.

- **Bit 18 EOC_SLV:** End of regular conversion of the slave ADC
  - This bit is a copy of the EOC bit in the corresponding ADC_ISR register.

- **Bit 17 EOSMP_SLV:** End of Sampling phase flag of the slave ADC
  - This bit is a copy of the EOSMP2 bit in the corresponding ADC_ISR register.

- **Bit 16 ADRDY_SLV:** Slave ADC ready
  - This bit is a copy of the ADRDY bit in the corresponding ADC_ISR register.

Bits 15:11 Reserved, must be kept at reset value.

- **Bit 10 JQOVF_MST:** Injected Context Queue Overflow flag of the master ADC
  - This bit is a copy of the JQOVF bit in the corresponding ADC_ISR register.

- **Bit 9 AWD3_MST:** Analog watchdog 3 flag of the master ADC
  - This bit is a copy of the AWD3 bit in the corresponding ADC_ISR register.

- **Bit 8 AWD2_MST:** Analog watchdog 2 flag of the master ADC
  - This bit is a copy of the AWD2 bit in the corresponding ADC_ISR register.

- **Bit 7 AWD1_MST:** Analog watchdog 1 flag of the master ADC
  - This bit is a copy of the AWD1 bit in the corresponding ADC_ISR register.

- **Bit 6 JEOS_MST:** End of injected sequence flag of the master ADC
  - This bit is a copy of the JEOS bit in the corresponding ADC_ISR register.
Bit 5  **JEOC_MST**: End of injected conversion flag of the master ADC  
This bit is a copy of the JEOC bit in the corresponding ADC_ISR register.

Bit 4  **OVR_MST**: Overrun flag of the master ADC  
This bit is a copy of the OVR bit in the corresponding ADC_ISR register.

Bit 3  **EOS_MST**: End of regular sequence flag of the master ADC  
This bit is a copy of the EOS bit in the corresponding ADC_ISR register.

Bit 2  **EOC_MST**: End of regular conversion of the master ADC  
This bit is a copy of the EOC bit in the corresponding ADC_ISR register.

Bit 1  **EOSMP_MST**: End of Sampling phase flag of the master ADC  
This bit is a copy of the EOSMP bit in the corresponding ADC_ISR register.

Bit 0  **ADRDY_MST**: Master ADC ready  
This bit is a copy of the ADRDY bit in the corresponding ADC_ISR register.

### 21.7.2 ADC common control register (ADC_CCR)

Address offset: 0x08 (this offset address is relative to the master ADC base address + 0x300)

Reset value: 0x0000 0000

Bits 31:25 Reserved, must be kept at reset value.

Bit 24  **CH18SEL**: CH18 selection  
This bit is set and cleared by software to control channel 18.  
0: VBAT channel disabled.  
1: VBAT channel enabled

Bit 23  **CH17SEL**: CH17 selection  
This bit is set and cleared by software to control channel 17.  
0: Temperature sensor channel disabled  
1: Temperature sensor channel enabled

Bit 22  **VREFEN**: VREFINT enable  
This bit is set and cleared by software to enable/disable the VREFINT channel.  
0: VREFINT channel disabled  
1: VREFINT channel enabled
Bits 21:18 **PRESC[3:0]**: ADC prescaler
These bits are set and cleared by software to select the frequency of the clock to the ADC. The clock is common for all the ADCs.

- 0000: input ADC clock not divided
- 0001: input ADC clock divided by 2
- 0010: input ADC clock divided by 4
- 0011: input ADC clock divided by 6
- 0100: input ADC clock divided by 8
- 0101: input ADC clock divided by 10
- 0110: input ADC clock divided by 12
- 0111: input ADC clock divided by 16
- 1000: input ADC clock divided by 32
- 1001: input ADC clock divided by 64
- 1010: input ADC clock divided by 128
- 1011: input ADC clock divided by 256
- other: reserved

*Note:* The software is allowed to write these bits only when the ADC is disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0). The ADC prescaler value is applied only when CKMODE[1:0] = 0b00.

Bits 17:16 **CKMODE[1:0]**: ADC clock mode
These bits are set and cleared by software to define the ADC clock scheme (which is common to both master and slave ADCs):

- 00: CK_ADCx (x=123) (Asynchronous clock mode), generated at product level (refer to Section 6: Reset and clock control (RCC))
- 01: HCLK/1 (Synchronous clock mode). This configuration must be enabled only if the AHB clock prescaler is set to 1 (HPRE[3:0] = 0xxx in RCC_CFRGR register) and if the system clock has a 50% duty cycle.
- 10: HCLK/2 (Synchronous clock mode)
- 11: HCLK/4 (Synchronous clock mode)

In all synchronous clock modes, there is no jitter in the delay from a timer trigger to the start of a conversion.

*Note:* The software is allowed to write these bits only when the ADCs are disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

Bits 15:14 **MDMA[1:0]**: Direct memory access mode for dual ADC mode
This bitfield is set and cleared by software. Refer to the DMA controller section for more details.

- 00: MDMA mode disabled
- 01: Enable dual interleaved mode to output to the master channel of DFSDM interface both Master and the Slave result (16-bit data width)
- 10: MDMA mode enabled for 12 and 10-bit resolution
- 11: MDMA mode enabled for 8 and 6-bit resolution

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).

Bit 13 **DMACFG**: DMA configuration (for dual ADC mode)
This bit is set and cleared by software to select between two DMA modes of operation and is effective only when DMAEN=1.

- 0: DMA One Shot mode selected
- 1: DMA Circular mode selected

For more details, refer to Section : Managing conversions using the DMA

*Note:* The software is allowed to write these bits only when ADSTART=0 (which ensures that no regular conversion is ongoing).
Bit 12  Reserved, must be kept at reset value.

Bits 11:8  **DELAY**: Delay between 2 sampling phases
These bits are set and cleared by software. These bits are used in dual interleaved modes. Refer to Table 171 for the value of ADC resolution versus DELAY bits values.

*Note: The software is allowed to write these bits only when the ADCs are disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).*

Bits 7:5  Reserved, must be kept at reset value.

Bits 4:0  **DUAL[4:0]**: Dual ADC mode selection
These bits are written by software to select the operating mode.
All the ADCs independent:
00000: Independent mode

00001 to 01001: Dual mode, master and slave ADCs working together
00001: Combined regular simultaneous + injected simultaneous mode
00010: Combined regular simultaneous + alternate trigger mode
00011: Combined Interleaved mode + injected simultaneous mode
00100: Reserved
00101: Injected simultaneous mode only
00110: Regular simultaneous mode only
00111: Interleaved mode only
01001: Alternate trigger mode only

All other combinations are reserved and must not be programmed

*Note: The software is allowed to write these bits only when the ADCs are disabled (ADCAL=0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).*

Bits 31:16 **RDATA_SLV[15:0]**: Regular data of the slave ADC.

In dual mode, these bits contain the regular data of the slave ADC. Refer to Section 21.4.31: Dual ADC modes.

The data alignment is applied as described in Section: Data register, data alignment and offset (ADC_DR, OFFSETy, OFFSETy_CH, ALIGN).

Bits 15:0 **RDATA_MST[15:0]**: Regular data of the master ADC.

In dual mode, these bits contain the regular data of the master ADC. Refer to Section 21.4.31: Dual ADC modes.

The data alignment is applied as described in Section: Data register, data alignment and offset (ADC_DR, OFFSETy, OFFSETy_CH, ALIGN).

In MDMA=0b11 mode, bits 15:8 contains SLV_ADC_DR[7:0], bits 7:0 contains MST_ADC_DR[7:0].

Refer to Section 2.3 on page 87 for the register boundary addresses.
22  Digital-to-analog converter (DAC)

22.1  Introduction

The DAC module is a 12-bit, voltage output digital-to-analog converter. The DAC can be configured in 8- or 12-bit mode and may be used in conjunction with the DMA controller. In 12-bit mode, the data could be left- or right-aligned. The DAC features two output channels, each with its own converter. In dual DAC channel mode, conversions could be done independently or simultaneously when both channels are grouped together for synchronous update operations. An input reference pin, \( V_{\text{REF+}} \) (shared with others analog peripherals) is available for better resolution. An internal reference can also be set on the same input. Refer to voltage reference buffer (VREFBUF) section.

The DACx\_OUTy pin can be used as general purpose input/output (GPIO) when the DAC output is disconnected from output pad and connected to on chip peripheral. The DAC output buffer can be optionally enabled to allow a high drive output current. An individual calibration can be applied on each DAC output channel. The DAC output channels support a low power mode, the Sample and hold mode.

22.2  DAC main features

The DAC main features are the following (see Figure 161: Dual-channel DAC block diagram)

- One DAC interface, maximum two output channels
- Left or right data alignment in 12-bit mode
- Synchronized update capability
- Noise-wave and Triangular-wave generation
- Dual DAC channel for independent or simultaneous conversions
- DMA capability for each channel including DMA underrun error detection
- External triggers for conversion
- DAC output channel buffered/unbuffered modes
- Buffer offset calibration
- Each DAC output can be disconnected from the DACx\_OUTy output pin
- DAC output connection to on chip peripherals
- Sample and hold mode for low power operation in Stop mode
- Input voltage reference, \( V_{\text{REF+}} \)

Figure 161 shows the block diagram of a DAC channel and Table 176 gives the pin description.

22.4  DAC functional description

22.4.1  DAC block diagram

Figure 161. Dual-channel DAC block diagram

1. MODEx bits in the DAC_MCR control the output mode and allow switching between the Normal mode in buffer/unbuffered configuration and the Sample and hold mode.

2. Refer to Section 22.3: DAC implementation for channel2 availability.
The DAC includes:
- Up to two output channels
- The DACx_OUTy can be disconnected from the output pin and used as an ordinary GPIO
- The DAC_OUTx can use an internal pin connection to on-chip peripherals such as comparator, operational amplifier and ADC (if available).
- DAC output channel buffered or non buffered
- Sample and hold block and registers operational in Stop mode, using the LSI clock source for static conversion.

The DAC includes up to two separate output channels. Each output channel can be connected to on-chip peripherals such as comparator, operational amplifier and ADC (if available). In this case, the DAC output channel can be disconnected from the DACx_OUTy output pin and the corresponding GPIO can be used for another purpose.

The DAC output can be buffered or not. The Sample and hold block and its associated registers can run in Stop mode using the LSI clock source.

**22.4.2 DAC channel enable**

Each DAC channel can be powered on by setting its corresponding ENx bit in the DAC_CR register. The DAC channel is then enabled after a tWAKEUP startup time.

*Note:* The ENx bit enables the analog DAC channel x only. The DAC channel x digital interface is enabled even if the ENx bit is reset.

**22.4.3 DAC data format**

Depending on the selected configuration mode, the data have to be written into the specified register as described below:
- Single DAC channel
  - There are three possibilities:
    - 8-bit right alignment: the software has to load data into the DAC_DHR8Rx[7:0] bits (stored into the DHRx[11:4] bits)
    - 12-bit left alignment: the software has to load data into the DAC_DHR12Lx[15:4] bits (stored into the DHRx[11:0] bits)
    - 12-bit right alignment: the software has to load data into the DAC_DHR12Rx[11:0] bits (stored into the DHRx[11:0] bits)

Depending on the loaded DAC_DHRyyyyx register, the data written by the user is shifted and stored into the corresponding DHRx (data holding register x, which are internal non-memory-
mapped registers). The DHR\textsubscript{x}x register is then loaded into the DOR\textsubscript{x}x register either automatically, by software trigger or by an external event trigger.

**Figure 162. Data registers in single DAC channel mode**

</tbody>
</table>

- **Dual DAC channels (when available)**
  
  There are three possibilities:
  
  - 8-bit right alignment: data for DAC channel1 to be loaded into the DAC\_DHR8RD [7:0] bits (stored into the DHR1[11:4] bits) and data for DAC channel2 to be loaded into the DAC\_DHR8RD [15:8] bits (stored into the DHR2[11:4] bits)
  
  - 12-bit left alignment: data for DAC channel1 to be loaded into the DAC\_DHR12LD [15:4] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC\_DHR12LD [31:20] bits (stored into the DHR2[11:0] bits)
  
  - 12-bit right alignment: data for DAC channel1 to be loaded into the DAC\_DHR12RD [11:0] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC\_DHR12RD [27:16] bits (stored into the DHR2[11:0] bits)

Depending on the loaded DAC\_DHR\textsubscript{yyy}D register, the data written by the user is shifted and stored into DHR1 and DHR2 (data holding registers, which are internal non-memory-mapped registers). The DHR1 and DHR2 registers are then loaded into the DAC\_DOR1 and DOR2 registers, respectively, either automatically, by software trigger or by an external event trigger.

22.4.4 DAC conversion

The DAC_DORx cannot be written directly and any data transfer to the DAC channel must be performed by loading the DAC_DHRx register (write operation to DAC_DHR8Rx, DAC_DHR12Lx, DAC_DHR12Rx, DAC_DHR8RD, DAC_DHR12RD or DAC_DHR12LD).

Data stored in the DAC_DHRx register are automatically transferred to the DAC_DORx register after one APB1 clock cycle, if no hardware trigger is selected (TENx bit in DAC_CR register is reset). However, when a hardware trigger is selected (TENx bit in DAC_CR register is set) and a trigger occurs, the transfer is performed three APB1 clock cycles after the trigger signal.

When DAC_DORx is loaded with the DAC_DHRx contents, the analog output voltage becomes available after a time \( t_{SETTLING} \) that depends on the power supply voltage and the analog output load.

HFSEL bit of DAC_CR must be set when APB1 clock speed is faster than 80 MHz. It adds an extra delay of three APB1 clock cycles to the transfer from DAC_DHRx register to DAC_DORx register (\( t_{SETTLING} \)).

The DAC_DORx update rate is limited to 1/3 of APB1 clock frequency. When HFSEL bit is set, this rate is limited to 1/8 of the APB1 clock frequency.

When HFSEL is set, it is not allowed to write the DHRx register during a period of eight clock cycles after the ENx bit is set. During this period, making software/hardware triggering is not allowed either.

![Figure 164. Timing diagram for conversion with trigger disabled TEN = 0](image)

22.4.5 DAC output voltage

Digital inputs are converted to output voltages on a linear conversion between 0 and \( V_{REF+} \).

The analog output voltages on each DAC channel pin are determined by the following equation:

\[
DAC_{output} = V_{REF} \times \frac{DOR}{4096}
\]
22.4.6 DAC trigger selection

If the TENx control bit is set, the conversion can then be triggered by an external event (timer counter, external interrupt line). The TSELx[3:0] control bits determine which out of 16 possible events triggers the conversion as shown in TSELx[3:0] bits of the DAC_CR register. These events can be either the software trigger or hardware triggers. Refer to Table 177: DAC trigger selection.

Each time a DAC interface detects a rising edge on the selected trigger source (refer to the table below), the last data stored into the DAC_DHRx register are transferred into the DAC_DORx register. The DAC_DORx register is updated three APB1 cycles after the trigger occurs.

If the software trigger is selected, the conversion starts once the SWTRIG bit is set. SWTRIG is reset by hardware once the DAC_DORx register has been loaded with the DAC_DHRx register contents.

Note: TSELx[3:0] bit cannot be changed when the ENx bit is set.

When software trigger is selected, the transfer from the DAC_DHRx register to the DAC_DORx register takes only one APB1 clock cycle.

22.4.7 DMA requests

Each DAC channel has a DMA capability. Two DMA channels are used to service DAC channel DMA requests.

When an external trigger (but not a software trigger) occurs while the DMAENx bit is set, the value of the DAC_DHRx register is transferred into the DAC_DORx register when the transfer is complete, and a DMA request is generated.

In dual mode, if both DMAENx bits are set, two DMA requests are generated. If only one DMA request is needed, only the corresponding DMAENx bit must be set. In this way, the application can manage both DAC channels in dual mode by using one DMA request and a unique DMA channel.

As DAC_DHRx to DAC_DORx data transfer occurred before the DMA request, the very first data has to be written to the DAC_DHRx before the first trigger event occurs.

DMA underrun

The DAC DMA request is not queued so that if a second external trigger arrives before the acknowledgment for the first external trigger is received (first request), then no new request is issued and the DMA channelx underrun flag DMAUDRx in the DAC_SR register is set, reporting the error condition. The DAC channelx continues to convert old data.

The software must clear the DMAUDRx flag by writing 1, clear the DMAEN bit of the used DMA stream and re-initialize both DMA and DAC channelx to restart the transfer correctly. The software must modify the DAC trigger conversion frequency or lighten the DMA workload to avoid a new DMA underrun. Finally, the DAC conversion could be resumed by enabling both DMA data transfer and conversion trigger.

For each DAC channelx, an interrupt is also generated if its corresponding DMAUDRIEx bit in the DAC_CR register is enabled.

22.4.8 Noise generation

In order to generate a variable-amplitude pseudonoise, an LFSR (linear feedback shift register) is available. DAC noise generation is selected by setting WAVEx[1:0] to 01. The preloaded value in LFSR is 0xAAA. This register is updated three APB1 clock cycles after each trigger event, following a specific calculation algorithm.
The LFSR value, that may be masked partially or totally by means of the MAMPx[3:0] bits in the DAC_CR register, is added up to the DAC_DHRx contents without overflow and this value is then transferred into the DAC_DORx register.

If LFSR is 0x0000, a ‘1’ is injected into it (antilock-up mechanism).

It is possible to reset LFSR wave generation by resetting the WAVEx[1:0] bits.

**Figure 166. DAC conversion (SW trigger enabled) with LFSR wave generation**

---

**Note:** The DAC trigger must be enabled for noise generation by setting the TENx bit in the DAC_CR register.
22.4.9 Triangle-wave generation

It is possible to add a small-amplitude triangular waveform on a DC or slowly varying signal. DAC triangle-wave generation is selected by setting WAVEx[1:0] to 10. The amplitude is configured through the MAMPx[3:0] bits in the DAC_CR register. An internal triangle counter is incremented three APB1 clock cycles after each trigger event. The value of this counter is then added to the DAC_DHRx register without overflow and the sum is transferred into the DAC_DORx register. The triangle counter is incremented as long as it is less than the maximum amplitude defined by the MAMPx[3:0] bits. Once the configured amplitude is reached, the counter is decremented down to 0, then incremented again and so on.

It is possible to reset triangle wave generation by resetting the WAVEx[1:0] bits.

**Figure 167. DAC triangle wave generation**

**Figure 168. DAC conversion (SW trigger enabled) with triangle wave generation**

*Note: The DAC trigger must be enabled for triangle wave generation by setting the TENx bit in the DAC_CR register.*

*The MAMPx[3:0] bits must be configured before enabling the DAC, otherwise they cannot be changed.*
22.4.10 DAC channel modes

Each DAC channel can be configured in Normal mode or Sample and hold mode. The output buffer can be enabled to allow a high drive capability. Before enabling output buffer, the voltage offset needs to be calibrated. This calibration is performed at the factory (loaded after reset) and can be adjusted by software during application operation.

Normal mode

In Normal mode, there are four combinations, by changing the buffer state and by changing the DACx_OUTy pin interconnections.

To enable the output buffer, the MODEx[2:0] bits in DAC_MCR register must be:
- 000: DAC is connected to the external pin
- 001: DAC is connected to external pin and to on-chip peripherals

To disable the output buffer, the MODEx[2:0] bits in DAC_MCR register must be:
- 010: DAC is connected to the external pin
- 011: DAC is connected to on-chip peripherals

Sample and hold mode

In Sample and hold mode, the DAC core converts data on a triggered conversion, and then holds the converted voltage on a capacitor. When not converting, the DAC cores and buffer are completely turned off between samples and the DAC output is tri-stated, therefore reducing the overall power consumption. A stabilization period, which value depends on the buffer state, is required before each new conversion.

In this mode, the DAC core and all corresponding logic and registers are driven by the LSI low-speed clock in addition to the APB1 clock, allowing to use the DAC channels in deep low power modes such as Stop mode.

The LSI low-speed clock must not be stopped when the Sample and hold mode is enabled.

The sample/hold mode operations can be divided into 3 phases:

1. Sample phase: the sample/hold element is charged to the desired voltage. The charging time depends on capacitor value (internal or external, selected by the user). The sampling time is configured with the TSAMPLEx[9:0] bits in DAC_SHSRx register. During the write of the TSAMPLEx[9:0] bits, the BWSTx bit in DAC_SR register is set to 1 to synchronize between both clock domains (APB and low speed clock) and allowing the software to change the value of sample phase during the DAC channel operation

2. Hold phase: the DAC output channel is tri-stated, the DAC core and the buffer are turned off, to reduce the current consumption. The hold time is configured with the THOLDx[9:0] bits in DAC_SHHR register

3. Refresh phase: the refresh time is configured with the TREFRESHx[7:0] bits in DAC_SHRR register

The timings for the three phases above are in units of LSI clock periods. As an example, to configure a sample time of 350 µs, a hold time of 2 ms and a refresh time of 100 µs assuming LSI ~32 KHz is selected:

12 cycles are required for sample phase: TSAMPLEx[9:0] = 11,
62 cycles are required for hold phase: THOLDx[9:0] = 62,
and 4 cycles are required for refresh period: TREFRESHx[7:0] = 4.
In this example, the power consumption is reduced by almost a factor of 15 versus Normal modes.

The formulas to compute the right sample and refresh timings are described in the table below, the Hold time depends on the leakage current.

### Table 178. Sample and refresh timings

<table>
<thead>
<tr>
<th>Buffer State</th>
<th>$t_{\text{SAMP}}^{(1,2)}$</th>
<th>$t_{\text{REFRESH}}^{(2,3)}$</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable</td>
<td>$7 \mu s + (10 \times R_{\text{BON}} \times C_{\text{SH}})$</td>
<td>$7 \mu s + (R_{\text{BON}} \times C_{\text{SH}}) \times \ln(2 \times N_{\text{LSB}})$</td>
</tr>
<tr>
<td>Disable</td>
<td>$3 \mu s + (10 \times R_{\text{BOFF}} \times C_{\text{SH}})$</td>
<td>$3 \mu s + (R_{\text{BOFF}} \times C_{\text{SH}}) \times \ln(2 \times N_{\text{LSB}})$</td>
</tr>
</tbody>
</table>

1. In the above formula the settling to the desired code value with $\frac{1}{2}$ LSB or accuracy requires 10 constant time for 12 bits resolution. For 8 bits resolution, the settling time is 7 constant time.
2. $C_{\text{SH}}$ is the capacitor in Sample and hold mode.
3. The tolerated voltage drop during the hold phase “$V_d$” is represented by the number of LSBs after the capacitor discharging with the output leakage current. The settling back to the desired value with $\frac{1}{2}$ LSB error accuracy requires $\ln(2 \times N_{\text{LSB}})$ constant time of the DAC.

### Example of the sample and refresh time calculation with output buffer on

The values used in the example below are provided as indication only. Please refer to the product datasheet for product data.

$C_{\text{SH}} = 100 \ \text{nF}$

$V_{\text{DDA}} = 3.0 \ \text{V}$

**Sampling phase:**

$t_{\text{SAMP}} = 7 \mu s + (10 \times 2000 \times 100 \times 10^{-9}) = 2.007 \ \text{ms}$

(where $R_{\text{BON}} = 2 \ \text{k}\Omega$)

**Refresh phase:**

$t_{\text{REFRESH}} = 7 \mu s + (2000 \times 100 \times 10^{-9}) \times \ln(2 \times 10) = 606.1 \ \mu\text{s}$

(where $N_{\text{LSB}} = 10$ (10 LSB drop during the hold phase))

**Hold phase:**

$D_v = i_{\text{leak}} \times t_{\text{hold}} / C_{\text{SH}} = 0.0073 \ \text{V}$ (10 LSB of 12bit at 3 V)

$i_{\text{leak}} = 150 \ \text{nA}$ (worst case on the IO leakage on all the temperature range)

$t_{\text{hold}} = 0.0073 \times 100 \times 10^{-9} / (150 \times 10^{-9}) = 4.867 \ \text{ms}$
Like in Normal mode, the Sample and hold mode has different configurations.

To enable the output buffer, MODEx[2:0] bits in DAC_MCR register must be set to:
- 100: DAC is connected to the external pin
- 101: DAC is connected to external pin and to on chip peripherals

To disabled the output buffer, MODEx[2:0] bits in DAC_MCR register must be set to:
- 110: DAC is connected to external pin and to on chip peripherals
- 111: DAC is connected to on chip peripherals

When MODEx[2:0] bits are equal to 111, an internal capacitor, C_{Int}, holds the voltage output of the DAC core and then drive it to on-chip peripherals.

All Sample and hold phases are interruptible, and any change in DAC_DHRx immediately triggers a new sample phase.

22.4.11 DAC channel buffer calibration

The transfer function for an N-bit digital-to-analog converter (DAC) is:

\[ V_{\text{out}} = \left( \frac{D}{2^N - 1} \times G \times V_{\text{ref}} \right) + V_{\text{OS}} \]

Where \( V_{\text{OUT}} \) is the analog output, \( D \) is the digital input, \( G \) is the gain, \( V_{\text{ref}} \) is the nominal full-scale voltage, and \( V_{\text{OS}} \) is the offset voltage. For an ideal DAC channel, \( G = 1 \) and \( V_{\text{OS}} = 0 \).

Due to output buffer characteristics, the voltage offset may differ from part-to-part and introduce an absolute offset error on the analog output. To compensate the \( V_{\text{OS}} \), a calibration is required by a trimming technique.

The calibration is only valid when the DAC channel is operating with buffer enabled (MODEx[2:0] = 000b or 001b or 100b or 101b). If applied in other modes when the buffer is off, it has no effect. During the calibration:

- The buffer output is disconnected from the pin internal/external connections and put in tristate mode (HiZ).
- The buffer acts as a comparator to sense the middle-code value 0x800 and compare it to \( V_{\text{REF}}/2 \) signal through an internal bridge, then toggle its output signal to 0 or 1 depending on the comparison result (CAL_FLAGx bit).

Two calibration techniques are provided:

- Factory trimming (default setting)
  The DAC buffer offset is factory trimmed. The default value of OTRIMx[4:0] bits in DAC_CCR register is the factory trimming value and it is loaded once DAC digital interface is reset.

- User trimming
  The user trimming can be done when the operating conditions differ from nominal factory trimming conditions and in particular when \( V_{\text{DDA}} \) voltage, temperature, \( V_{\text{REF}}+ \) values change and can be done at any point during application by software.

**Note:** Refer to the datasheet for more details of the Nominal factory trimming conditions

In addition, when \( V_{\text{DD}} \) is removed (example the device enters in STANDBY or VBAT modes) the calibration is required.

The steps to perform a user trimming calibration are as below:

---

<table>
<thead>
<tr>
<th>MODEx[2:0]</th>
<th>Mode</th>
<th>Buffer</th>
<th>Output connections</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 0 0</td>
<td>Sample and hold mode</td>
<td>Enabled</td>
<td>Connected to external pin</td>
</tr>
<tr>
<td>1 0 1</td>
<td>Sample and hold mode</td>
<td>Enabled</td>
<td>Connected to external pin and to on chip peripherals (such as comparators)</td>
</tr>
<tr>
<td>1 1 0</td>
<td>Disabled</td>
<td></td>
<td>Connected to external pin and to on chip peripherals (such as comparators)</td>
</tr>
<tr>
<td>1 1 1</td>
<td>Disabled</td>
<td></td>
<td>Connected to on chip peripherals (such as comparators)</td>
</tr>
</tbody>
</table>
1. If the DAC channel is active, write 0 to ENx bit in DAC_CR to disable the channel.
2. Select a mode where the buffer is enabled, by writing to DAC_MCR register, MODEx[2:0] = 000b or 001b or 100b or 101b.
3. Start the DAC channelx calibration, by setting the CENx bit in DAC_CR register to 1.
4. Apply a trimming algorithm:
   a) Write a code into OTRIMx[4:0] bits, starting by 00000b.
   b) Wait for tTRIM delay.
   c) Check if CAL_FLAGx bit in DAC_SR is set to 1.
   d) If CAL_FLAGx is set to 1, the OTRIMx[4:0] trimming code is found and can be used during device operation to compensate the output value, else increment OTRIMx[4:0] and repeat sub-steps from (a) to (d) again.

The software algorithm may use either a successive approximation or dichotomy techniques to compute and set the content of OTRIMx[4:0] bits in a faster way.

The commutation/toggle of CAL_FLAGx bit indicates that the offset is correctly compensated and the corresponding trim code must be kept in the OTRIMx[4:0] bits in DAC_CCR register.

**Note:** A tTRIM delay must be respected between the write to the OTRIMx[4:0] bits and the read of the CAL_FLAGx bit in DAC_SR register in order to get a correct value. This parameter is specified into datasheet electrical characteristics section.

If VDDA, VREF+ and temperature conditions do not change during device operation while it enters more often in standby and VBAT mode, the software may store the OTRIMx[4:0] bits found in the first user calibration in the flash or in back-up registers. then to load/write them directly when the device power is back again thus avoiding to wait for a new calibration time.
When CENx bit is set, it is not allowed to set ENx bit.

### 22.4.12 Dual DAC channel conversion modes (if dual channels are available)

To efficiently use the bus bandwidth in applications that require the two DAC channels at the same time, three dual registers are implemented: DHR8RD, DHR12RD and DHR12LD. A unique register access is then required to drive both DAC channels at the same time. For the wave generation, no accesses to DHRxxxD registers are required. As a result, two output channels can be used either independently or simultaneously.

11 conversion modes are possible using the two DAC channels and these dual registers. All the conversion modes can nevertheless be obtained using separate DHRx registers if needed.

All modes are described in the paragraphs below.

**Independent trigger without wave generation**

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).
When a DAC channel1 trigger arrives, the DHR1 register is transferred into DAC_DOR1 (three APB1 clock cycles later).

When a DAC channel2 trigger arrives, the DHR2 register is transferred into DAC_DOR2 (three APB1 clock cycles later).

Independent trigger with single LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and the same LFSR mask value in the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD). 

When a DAC channel1 trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three APB1 clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel2 trigger arrives, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three APB1 clock cycles later). Then the LFSR2 counter is updated.

Independent trigger with different LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and set different LFSR masks values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three APB1 clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel2 trigger arrives, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three APB1 clock cycles later). Then the LFSR2 counter is updated.
Independent trigger with single triangle generation

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and the same maximum amplitude value in the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the DAC channel1 triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three APB1 clock cycles later). The DAC channel1 triangle counter is then updated.

When a DAC channel2 trigger arrives, the DAC channel2 triangle counter, with the same triangle amplitude, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three APB1 clock cycles later). The DAC channel2 triangle counter is then updated.

Independent trigger with different triangle generation

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure different trigger sources by setting different values in the TSEL1 and TSEL2 bits.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and set different maximum amplitude values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a DAC channel1 trigger arrives, the DAC channel1 triangle counter, with a triangle amplitude configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three APB1 clock cycles later). The DAC channel1 triangle counter is then updated.

When a DAC channel2 trigger arrives, the DAC channel2 triangle counter, with a triangle amplitude configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three APB1 clock cycles later). The DAC channel2 triangle counter is then updated.

Simultaneous software start

To configure the DAC in this conversion mode, the following sequence is required:
• Load the dual DAC channel data to the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

In this configuration, one APB1 clock cycle later, the DHR1 and DHR2 registers are transferred into DAC_DOR1 and DAC_DOR2, respectively.

Simultaneous trigger without wave generation

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2.
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Load the dual DAC channel data to the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DHR1 and DHR2 registers are transferred into DAC_DOR1 and DAC_DOR2, respectively (after three APB1 clock cycles).

**Simultaneous trigger with single LFSR generation**

1. To configure the DAC in this conversion mode, the following sequence is required:
2. Set the two DAC channel trigger enable bits TEN1 and TEN2.
3. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
4. Configure the two DAC channel WAVEx[1:0] bits as 01 and the same LFSR mask value in the MAMPx[3:0] bits.
5. Load the dual DAC channel data to the desired DHR register (DHR12RD, DHR12LD or DHR8RD).

When a trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three APB1 clock cycles later). The LFSR1 counter is then updated. At the same time, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three APB1 clock cycles later). The LFSR2 counter is then updated.

**Simultaneous trigger with different LFSR generation**

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 01 and set different LFSR mask values using the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three APB1 clock cycles later). The LFSR1 counter is then updated. At the same time, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three APB1 clock cycles later). The LFSR2 counter is then updated.

**Simultaneous trigger with single triangle generation**

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and the same maximum amplitude value using the MAMPx[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DAC channel1 triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three APB1 clock cycles later). The DAC channel1 triangle counter is then updated.

At the same time, the DAC channel2 triangle counter, with the same triangle amplitude, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three APB1 clock cycles later). The DAC channel2 triangle counter is then updated.

**Simultaneous trigger with different triangle generation**

To configure the DAC in this conversion mode, the following sequence is required:
1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1 and TSEL2 bitfields.
3. Configure the two DAC channel WAVEx[1:0] bits as 1x and set different maximum amplitude values in the MAMP1[3:0] and MAMP2[3:0] bits.
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD).

When a trigger arrives, the DAC channel1 triangle counter, with a triangle amplitude configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three APB clock cycles later). Then the DAC channel1 triangle counter is updated.

At the same time, the DAC channel2 triangle counter, with a triangle amplitude configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three APB1 clock cycles later). Then the DAC channel2 triangle counter is updated.

### 22.5 DAC low-power modes

**Table 180. Effect of low-power modes on DAC**

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect, DAC used with DMA</td>

<td>This bit is set and cleared by software. 0: DAC channel2 DMA mode disabled 1: DAC channel2 DMA mode enabled</td>
</tr>
</tbody>
</table>

Note: This bit is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.
Bits 27:24 **MAMP2[3:0]**: DAC channel2 mask/amplitude selector

These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.

0000: Unmask bit0 of LFSR/ triangle amplitude equal to 1
0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3
0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7
0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15
0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31
0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63
0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127
0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255
1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511
1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023
1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047
≥ 1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095

*Note:* These bits are available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Bits 23:22 **WAVE2[1:0]**: DAC channel2 noise/triangle wave generation enable

These bits are set/reset by software.
00: wave generation disabled
01: Noise wave generation enabled
1x: Triangle wave generation enabled

*Note:* Only used if bit TEN2 = 1 (DAC channel2 trigger enabled) These bits are available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Bits 21:18 **TSEL2[3:0]**: DAC channel2 trigger selection

These bits select the external event used to trigger DAC channel2
0000: SWTRIG2
0001: dac_ch2_trg1
0010: dac_ch2_trg2
...
1111: dac_ch2_trg15

Refer to the trigger selection tables in Section 22.4.6: DAC trigger selection for details on trigger configuration and mapping.

*Note:* Only used if bit TEN2 = 1 (DAC channel2 trigger enabled). These bits are available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Bit 17 **TEN2**: DAC channel2 trigger enable

This bit is set and cleared by software to enable/disable DAC channel2 trigger
0: DAC channel2 trigger disabled and data written into the DAC_DHR2 register are transferred one APB1 clock cycle later to the DAC_DOR2 register
1: DAC channel2 trigger enabled and data from the DAC_DHR2 register are transferred three APB1 clock cycles later to the DAC_DOR2 register

*Note:* When software trigger is selected, the transfer from the DAC_DHR2 register to the DAC_DOR2 register takes only one APB1 clock cycle.

These bits are available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.
Bit 16 **EN2**: DAC channel2 enable
This bit is set and cleared by software to enable/disable DAC channel2.
0: DAC channel2 disabled
1: DAC channel2 enabled

*Note: These bits are available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.*

Bit 15 **HFSEL**: High frequency interface mode enable
This bit is set and cleared by software to enable/disable DAC interface high speed mode. This bit need to be set when APB1 clock frequency is higher than 80 MHz.
0: High frequency interface mode disabled
1: High frequency interface mode enabled

Bit 14 **CEN1**: DAC channel1 calibration enable
This bit is set and cleared by software to enable/disable DAC channel1 calibration, it can be written only if bit EN1=0 into DAC_CR (the calibration mode can be entered/exit only when the DAC channel is disabled) Otherwise, the write operation is ignored.
0: DAC channel1 in Normal operating mode
1: DAC channel1 in calibration mode

Bit 13 **DMAUDRIE1**: DAC channel1 DMA Underrun Interrupt enable
This bit is set and cleared by software.
0: DAC channel1 DMA Underrun Interrupt disabled
1: DAC channel1 DMA Underrun Interrupt enabled

Bit 12 **DMAEN1**: DAC channel1 DMA enable
This bit is set and cleared by software.
0: DAC channel1 DMA mode disabled
1: DAC channel1 DMA mode enabled

Bits 11:8 **MAMP1[3:0]**: DAC channel1 mask/amplitude selector
These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.
0000: Unmask bit0 of LFSR/ triangle amplitude equal to 1
0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3
0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7
0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15
0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31
0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63
0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127
0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255
1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511
1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023
1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047
≥ 1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095

Bits 7:6 **WAVE1[1:0]**: DAC channel1 noise/triangle wave generation enable
These bits are set and cleared by software.
00: wave generation disabled
01: Noise wave generation enabled
1x: Triangle wave generation enabled
Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).
Bits 5:2 **TSEL[3:0]:** DAC channel1 trigger selection
These bits select the external event used to trigger DAC channel1
0000: SWTRIG1
0001: dac_ch1_trg1
0010: dac_ch1_trg2
...
1111: dac_ch1_trg15
Refer to the trigger selection tables in Section 22.4.6: DAC trigger selection for details on trigger configuration and mapping.
*Note:* Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).

Bit 1 **TEN1:** DAC channel1 trigger enable
This bit is set and cleared by software to enable/disable DAC channel1 trigger.
0: DAC channel1 trigger disabled and data written into the DAC_DHR1 register are transferred one APB1 clock cycle later to the DAC_DOR1 register
1: DAC channel1 trigger enabled and data from the DAC_DHR1 register are transferred three APB1 clock cycles later to the DAC_DOR1 register
*Note:* When software trigger is selected, the transfer from the DAC_DHR1 register to the DAC_DOR1 register takes only one APB1 clock cycle.

Bit 0 **EN1:** DAC channel1 enable
This bit is set and cleared by software to enable/disable DAC channel1.
0: DAC channel1 disabled
1: DAC channel1 enabled

### 22.7.2 DAC software trigger register (DAC_SWTRGR)

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **SWTRIG2**: DAC channel2 software trigger
This bit is set by software to trigger the DAC in software trigger mode.
0: No trigger
1: Trigger

*Note:* This bit is cleared by hardware (one APB1 clock cycle later) once the DAC_DHR2 register value has been loaded into the DAC_DOR2 register.

This bit is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Bit 0 **SWTRIG1**: DAC channel1 software trigger
This bit is set by software to trigger the DAC in software trigger mode.
0: No trigger
1: Trigger

*Note:* This bit is cleared by hardware (one APB1 clock cycle later) once the DAC_DHR1 register value has been loaded into the DAC_DOR1 register.

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **DACC1DOR[11:0]**: DAC channel1 data output
These bits are read-only, they contain data output for DAC channel1.
### 22.7.13 DAC channel2 data output register (DAC_DOR2)

This register is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Address offset: 0x30

Reset value: 0x0000 0000

![DAC DOR2 Register](image)

**Bits 31:12** Reserved, must be kept at reset value.

**Bits 11:0** DAC2DOR[11:0]: DAC channel2 data output

These bits are read-only, they contain data output for DAC channel2.

### 22.7.14 DAC status register (DAC_SR)

Address offset: 0x34

Reset value: 0x0000 0000

![DAC SR Register](image)
**Bit 31**  **BWST2**: DAC channel2 busy writing sample time flag

This bit is systematically set just after Sample and hold mode enable. It is set each time the software writes the register DAC_SHSR2. It is cleared by hardware when the write operation of DAC_SHSR2 is complete. (It takes about 3 LSI periods of synchronization).

0: There is no write operation of DAC_SHSR2 ongoing: DAC_SHSR2 can be written
1: There is a write operation of DAC_SHSR2 ongoing: DAC_SHSR2 cannot be written

*Note:* This bit is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

**Bit 30**  **CAL_FLAG2**: DAC channel2 calibration offset status

This bit is set and cleared by hardware

0: Calibration trimming value is lower than the offset correction value
1: Calibration trimming value is equal or greater than the offset correction value

*Note:* This bit is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

**Bit 29**  **DMAUDR2**: DAC channel2 DMA underrun flag

This bit is set by hardware and cleared by software (by writing it to 1).

0: No DMA underrun error condition occurred for DAC channel2
1: DMA underrun error condition occurred for DAC channel2 (the currently selected trigger is driving DAC channel2 conversion at a frequency higher than the DMA service capability rate).

*Note:* This bit is available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

**Bit 28**  Reserved, must be kept at reset value.

**Bit 27**  Reserved, must be kept at reset value.

**Bits 26:16**  Reserved, must be kept at reset value.

**Bit 15**  **BWST1**: DAC channel1 busy writing sample time flag

This bit is systematically set just after Sample and hold mode enable and is set each time the software writes the register DAC_SHSR1. It is cleared by hardware when the write operation of DAC_SHSR1 is complete. (It takes about 3 LSI periods of synchronization).

0: There is no write operation of DAC_SHSR1 ongoing: DAC_SHSR1 can be written
1: There is a write operation of DAC_SHSR1 ongoing: DAC_SHSR1 cannot be written

**Bit 14**  **CAL_FLAG1**: DAC channel1 calibration offset status

This bit is set and cleared by hardware

0: Calibration trimming value is lower than the offset correction value
1: Calibration trimming value is equal or greater than the offset correction value

**Bit 13**  **DMAUDR1**: DAC channel1 DMA underrun flag

This bit is set by hardware and cleared by software (by writing it to 1).

0: No DMA underrun error condition occurred for DAC channel1
1: DMA underrun error condition occurred for DAC channel1 (the currently selected trigger is driving DAC channel1 conversion at a frequency higher than the DMA service capability rate)

**Bit 12**  Reserved, must be kept at reset value.

**Bit 11**  Reserved, must be kept at reset value.

**Bits 10:0**  Reserved, must be kept at reset value.
### 22.7.15 DAC calibration control register (DAC_CCR)

Bits 31:26  Reserved, must be kept at reset value.

Bit 25  Reserved, must be kept at reset value.

Bit 24  Reserved, must be kept at reset value.

Bits 23:19  Reserved, must be kept at reset value.
Bits 18:16 **MODE2[2:0]**: DAC channel2 mode

These bits can be written only when the DAC is disabled and not in the calibration mode (when bit EN2=0 and bit CEN2 =0 in the DAC_CR register). If EN2=1 or CEN2 =1 the write operation is ignored.

They can be set and cleared by software to select the DAC channel2 mode:

- DAC channel2 in Normal mode
  - 000: DAC channel2 is connected to external pin with Buffer enabled
  - 001: DAC channel2 is connected to external pin and to on chip peripherals with buffer enabled
  - 010: DAC channel2 is connected to external pin with buffer disabled
  - 011: DAC channel2 is connected to on chip peripherals with Buffer disabled

- DAC channel2 in Sample and hold mode
  - 100: DAC channel2 is connected to external pin with Buffer enabled
  - 101: DAC channel2 is connected to external pin and to on chip peripherals with Buffer enabled
  - 110: DAC channel2 is connected to external pin and to on chip peripherals with Buffer disabled
  - 111: DAC channel2 is connected to on chip peripherals with Buffer disabled

*Note: This register can be modified only when EN2=0.*

Refer to Section 22.3: DAC implementation for the availability of DAC channel2.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:10 Reserved, must be kept at reset value.

Bit 9 Reserved, must be kept at reset value.

Bit 8 Reserved, must be kept at reset value.

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **MODE1[2:0]**: DAC channel1 mode

These bits can be written only when the DAC is disabled and not in the calibration mode (when bit EN1=0 and bit CEN1 =0 in the DAC_CR register). If EN1=1 or CEN1 =1 the write operation is ignored.

They can be set and cleared by software to select the DAC channel1 mode:

- DAC channel1 in Normal mode
  - 000: DAC channel1 is connected to external pin with Buffer enabled
  - 001: DAC channel1 is connected to external pin and to on chip peripherals with Buffer enabled
  - 010: DAC channel1 is connected to external pin with buffer disabled
  - 011: DAC channel1 is connected to on chip peripherals with Buffer disabled

- DAC channel1 in sample & hold mode
  - 100: DAC channel1 is connected to external pin with Buffer enabled
  - 101: DAC channel1 is connected to external pin and to on chip peripherals with Buffer enabled
  - 110: DAC channel1 is connected to external pin and to on chip peripherals with Buffer disabled
  - 111: DAC channel1 is connected to on chip peripherals with Buffer disabled

*Note: This register can be modified only when EN1=0.*
### 22.7.17 DAC channel1 sample and hold sample time register (DAC_SHSR1)

Address offset: 0x40

Bits 31:10  Reserved, must be kept at reset value.  
Bits 9:0  **TSAMPLE1[9:0]:** DAC channel1 sample time (only valid in Sample and hold mode)  
These bits can be written when the DAC channel1 is disabled or also during normal operation. In the latter case, the write can be done only when BWST1 of DAC_SR register is low. If BWST1=1, the write operation is ignored.

**Note:**  
It represents the number of LSI clocks to perform a sample phase. Sampling time = (TSAMPLE1[9:0] + 1) x LSI clock period.

### 22.7.18 DAC channel2 sample and hold sample time register (DAC_SHSR2)

This register is available only on dual-channel DACs. Refer to **Section 22.3: DAC implementation.**

Address offset: 0x44  
Reset value: 0x0000 0000

Bits 31:10  Reserved, must be kept at reset value.  
Bits 9:0  **TSAMPLE2[9:0]:** DAC channel2 sample time (only valid in Sample and hold mode)  
These bits can be written when the DAC channel2 is disabled or also during normal operation. In the latter case, the write can be done only when BWST2 of DAC_SR register is low. If BWST2=1, the write operation is ignored.

**Note:**  
It represents the number of LSI clocks to perform a sample phase. Sampling time = (TSAMPLE1[9:0] + 1) x LSI clock period.
22.7.19 DAC sample and hold time register (DAC_SHHR)

Address offset: 0x48
Reset value: 0x0001 0001

| Bits 31:26 | Reserved, must be kept at reset value. |
| Bits 25:16 | THOLD2[9:0]: DAC channel2 hold time (only valid in Sample and hold mode). Hold time= (THOLD[9:0]) x LSI clock period. *Note: This register can be modified only when EN2=0.* |
| Bits 15:10 | Reserved, must be kept at reset value. |
| Bits 9:0  | THOLD1[9:0]: DAC channel1 hold time (only valid in Sample and hold mode) Hold time= (THOLD[9:0]) x LSI clock period. *Note: This register can be modified only when EN1=0.* |

*Note: These bits can be written only when the DAC channel is disabled and in Normal operating mode (when bit ENx=0 and bit CENx=0 in the DAC_CR register). If ENx=1 or CENx=1 the write operation is ignored.*

22.7.20 DAC sample and hold refresh time register (DAC_SHRR)

Address offset: 0x4C
Reset value: 0x0001 0001

| Bits 31:26 | Reserved, must be kept at reset value. |
| Bits 25:16 | TREFRESH2[7:0]: DAC channel2 refresh time (only valid in Sample and hold mode). |
| Bits 15:10 | Reserved, must be kept at reset value. |
| Bits 9:0  | TREFRESH1[7:0]: DAC channel1 refresh time (only valid in Sample and hold mode). |
Bits 31:24  Reserved, must be kept at reset value.

Bits 23:16  TREFRESH2[7:0]: DAC channel2 refresh time (only valid in Sample and hold mode)
            Refresh time= (TREFRESH[7:0]) x LSI clock period
            Note: This register can be modified only when EN2=0.
            These bits are available only on dual-channel DACs. Refer to Section 22.3: DAC implementation.

Bits 15:8  Reserved, must be kept at reset value.

Bits 7:0  TREFRESH1[7:0]: DAC channel1 refresh time (only valid in Sample and hold mode)
            Refresh time= (TREFRESH[7:0]) x LSI clock period
            Note: This register can be modified only when EN1=0.

Note: These bits can be written only when the DAC channel is disabled and in Normal operating mode (when bit ENx=0 and bit CENx=0 in the DAC_CR register). If ENx=1 or CENx=1 the write operation is ignored.
22.7.21  DAC register map

Digital-to-analog converter (DAC)  
RM0438

Refer to Section 2.3 on page 87 for the register boundary addresses.
23 Voltage reference buffer (VREFBUF)

23.1 Introduction
The devices embed a voltage reference buffer which can be used as voltage reference for ADCs, DACs and also as voltage reference for external components through the VREF+ pin. When the VREF+ pin is double-bonded with VDDA pin in a package, the voltage reference buffer is not available and must be kept disabled (refer to datasheet for packages pinout description).

23.2 VREFBUF functional description
The internal voltage reference buffer supports two voltages\(^{(a)}\), which are configured with VRS bits in the VREFBUF_CSR register:
- VRS = 0: \(V_{\text{REF\_OUT1}}\) around 2.048 V.
- VRS = 1: \(V_{\text{REF\_OUT2}}\) around 2.5 V.

The internal voltage reference can be configured in four different modes depending on ENVR and HIZ bits configuration. These modes are provided in the table below:

<table>
<thead>
<tr>
<th>ENVR</th>
<th>HIZ</th>
<th>VREF buffer configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>VREFBUF buffer off mode:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– (V_{\text{REF+}}) pin pulled-down to (V_{\text{SSA}})</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>External voltage reference mode (default value):</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VREFBUF buffer off</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– (V_{\text{REF+}}) pin input mode</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>Internal voltage reference mode:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VREFBUF buffer on</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– (V_{\text{REF+}}) pin connected to VREFBUF buffer output</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Hold mode:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VREFBUF buffer off</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– (V_{\text{REF+}}) pin floating. The voltage is held with the external capacitor</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– VRR detection disabled and VRR bit keeps last state</td>
</tr>
</tbody>
</table>

After enabling the VREFBUF by setting ENVR bit and clearing HIZ bit in the VREFBUF_CSR register, the user must wait until VRR bit is set, meaning that the voltage reference output has reached its expected value.

23.3 VREFBUF trimming
The VREFBUF output voltage is factory-calibrated by ST. For the VRS = 1 setting, the calibration data is automatically loaded to the TRIM register at reset. For the VRS = 0

\(^{(a)}\) The minimum \(V_{\text{DDA}}\) voltage depends on VRS setting, refer to the product datasheet.
setting, the software must take care of copying the calibration data from the read-only system memory area (Flash memory) to the TRIM register.

Optionally user can trim the output voltage by changing the TRIM register bits.

Table 184. VREFBUF trimming data

<table>
<thead>

<td>2</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 VRR: Voltage reference buffer ready
- 0: the voltage reference buffer output is not ready.
- 1: the voltage reference buffer output reached the requested level.

Bit 2 VRS: Voltage reference scale
This bit selects the value generated by the voltage reference buffer.
- 0: Voltage reference set to VREF_OUT1 (around 2.048 V).
- 1: Voltage reference set to VREF_OUT2 (around 2.5 V).

Bit 1 HIZ: High impedance mode
This bit controls the analog switch to connect or not the VREF+ pin.
- 0: VREF+ pin is internally connected to the voltage reference buffer output.
- 1: VREF+ pin is high impedance.

Refer to Table 183: VREF buffer modes for the mode descriptions depending on ENVR bit configuration.

Bit 0 ENVR: Voltage reference buffer mode enable
This bit is used to enable the voltage reference buffer mode.
- 0: Internal voltage reference mode disable (external voltage reference mode).
- 1: Internal voltage reference mode (reference buffer enable or hold mode) enable.
23.4.2 VREFBUF calibration control register (VREFBUF_CCR)

Address offset: 0x04
Reset value: 0x0000 00XX

| Bit 31:6 | Reserved, must be kept at reset value. |
| Bit 5:0 | TRIM[5:0]: Trimming code

For VRS = 1 (2.5 V), these bits are automatically initialized after reset with the trimming value stored in the Flash memory during the production test.

For VRS = 0 (2.048V), the software must take care of copying the calibration data from the read-only system memory area (Flash memory) to the TRIM[5:0] bitfield. Writing into these bits allows the tuning of the internal reference buffer voltage.

Note: If the user application performs the trimming, the trimming code should start from 000000 to 111111 in ascending order.

23.4.3 VREFBUF register map

The following table gives the VREFBUF register map and the reset values.

Table 185. VREFBUF register map and reset values

| Offset | Register name | 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|--------|---------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| 0x00   | VREFBUF_CSR   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        | Reset value   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| 0x04   | VREFBUF_CCR   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|        | Reset value   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |

Refer to Section 2.3 on page 87 for the register boundary addresses.
24 Comparator (COMP)

24.1 Introduction

The device embeds two ultra-low-power comparators COMP1, and COMP2

The comparators can be used for a variety of functions including:
- Wakeup from low-power mode triggered by an analog signal,
- Analog signal conditioning,
- Cycle-by-cycle current control loop when combined with a PWM output from a timer.

24.2 COMP main features

- Each comparator has configurable plus and minus inputs used for flexible voltage selection:
  - Multiplexed I/O pins
  - DAC Channel1 and Channel2
  - Internal reference voltage and three submultiple values (1/4, 1/2, 3/4) provided by scaler (buffered voltage divider)
- Programmable hysteresis
- Programmable speed / consumption
- The outputs can be redirected to an I/O or to timer inputs for triggering:
  - Break events for fast PWM shutdowns
- Comparator outputs with blanking source
- The two comparators can be combined in a window comparator
- Each comparator has interrupt generation capability with wakeup from Sleep and Stop modes (through the EXTI controller)
24.3 COMP functional description

24.3.1 COMP block diagram

The block diagram of the comparators is shown in Figure 170.

**Figure 170. Comparator block diagram**

24.3.2 COMP pins and internal signals

The I/Os used as comparators inputs must be configured in analog mode in the GPIOs registers.

The comparator output can be connected to the I/Os using the alternate function channel given in “Alternate function mapping” table in the datasheet.

The output can also be internally redirected to a variety of timer input for the following purposes:
- Emergency shut-down of PWM signals, using BKin and BKin2 inputs
- Cycle-by-cycle current control, using OREF_CLR inputs
- Input capture for timing measures

It is possible to have the comparator output simultaneously redirected internally and externally.

### COMP reset and clocks

The COMP clock provided by the clock controller is synchronous with the APB2 clock. There is no clock enable control bit provided in the RCC controller. Reset and clock enable bits are common for COMP and SYSCFG.

**Important:** The polarity selection logic and the output redirection to the port works independently from the APB2 clock. This allows the comparator to work even in Stop mode.

### Comparator LOCK mechanism

The comparators can be used for safety purposes, such as over-current or thermal protection. For applications having specific functional safety requirements, it is necessary to

</tbody>
</table>
insure that the comparator programming cannot be altered in case of spurious register access or program counter corruption.

For this purpose, the comparator control and status registers can be write-protected (read-only).

Once the programming is completed, the COMPx LOCK bit can be set to 1. This causes the whole register to become read-only, including the COMPx LOCK bit.

The write protection can only be reset by a MCU reset.

24.3.5 Window comparator

The purpose of window comparator is to monitor the analog voltage if it is within specified voltage range defined by lower and upper threshold.

Two embedded comparators can be utilized to create window comparator. The monitored analog voltage is connected to the non-inverting (plus) inputs of comparators connected together and the upper and lower threshold voltages are connected to the inverting (minus) inputs of the comparators. Two non-inverting inputs can be connected internally together by enabling WINMODE bit to save one IO for other purposes.

Figure 171. Window mode

24.3.6 Hysteresis

The comparator includes a programmable hysteresis to avoid spurious output transitions in case of noisy signals. The hysteresis can be disabled if it is not needed (for instance when exiting from low-power mode) to be able to force the hysteresis value using external components.
24.3.7 Comparator output blanking function

The purpose of the blanking function is to prevent the current regulation to trip upon short current spikes at the beginning of the PWM period (typically the recovery current in power switches anti parallel diodes). It consists of a selection of a blanking window which is a timer output compare signal. The selection is done by software (refer to the comparator register description for possible blanking signals). Then, the complementary of the blanking signal is ANDed with the comparator output to provide the wanted comparator output. See the example provided in the figure below.
24.3.8 **COMP power and speed modes**

COMP1 and COMP2 power consumption versus propagation delay can be adjusted to have the optimum trade-off for a given application.

The bits PWRMODE[1:0] in COMPx_CSR registers can be programmed as follows:

- 00: High speed / full power
- 01 or 10: Medium speed / medium power
- 11: Low speed / ultra-low-power

24.4 **COMP low-power modes**

### Table 190. Comparator behavior in the low power modes

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect on the comparators. Comparator interrupts cause the device to exit the Sleep mode.</td>
</tr>
<tr>

<tr>
<td>Standby</td>
<td>The COMP registers are powered down and must be reinitialized after exiting Standby or Shutdown mode.</td>
</tr>
<tr>
<td>Shutdown</td>
<td>No effect on the comparators. Comparator interrupts cause the device to exit the Shutdown mode.</td>
</tr>
</tbody>
</table>

24.5 **COMP interrupts**

The comparator outputs are internally connected to the Extended interrupts and events controller. Each comparator has its own EXTI line and can generate either interrupts or events. The same mechanism is used to exit from low-power modes.

Refer to Interrupt and events section for more details.

To enable COMPx interrupt, it is required to follow this sequence:

1. Configure and enable the EXTI line corresponding to the COMPx output event in interrupt mode and select the rising, falling or both edges sensitivity
2. Configure and enable the NVIC IRQ channel mapped to the corresponding EXTI lines
3. Enable COMPx.
### COMP registers

#### 24.6.1 Comparator 1 control and status register (COMP1_CSR)

The COMP1_CSR is the Comparator 1 control/status register. It contains all the bits/flags related to comparator1.

Address offset: 0x00

System reset value: 0x0000 0000

<table>
<thead>

</tbody>
</table>

Bit 31 **LOCK**: COMP1_CSR register lock bit

This bit is set by software and cleared by a hardware system reset. It locks the whole content of the comparator 1 control register, COMP1_CSR[31:0].

0: COMP1_CSR[31:0] for comparator 1 are read/write
1: COMP1_CSR[31:0] for comparator 1 are read-only

Bit 30 **VALUE**: Comparator 1 output status bit

This bit is read-only. It reflects the current comparator 1 output taking into account POLARITY bit effect.

Bits 29: Reserved, must be kept at reset value.

Bit 23 **SCALEN**: Voltage scaler enable bit

This bit is set and cleared by software. This bit enable the outputs of the VREFINT divider available on the minus input of the Comparator 1.

0: Bandgap scaler disable (if SCALEN bit of COMP2_CSR register is also reset)
1: Bandgap scaler enable
Bit 22 **BRGEN**: Scaler bridge enable

- This bit is set and cleared by software (only if LOCK not set). This bit enable the bridge of the scaler.
- 0: Scaler resistor bridge disable (if BRGEN bit of COMP2_CSR register is also reset)
- 1: Scaler resistor bridge enable

If SCALEN is set and BRGEN is reset, BG voltage reference is available but not 1/4 BGAP, 1/2 BGAP, 3/4 BGAP. BGAP value is sent instead of 1/4 BGAP, 1/2 BGAP, 3/4 BGAP.

If SCALEN and BRGEN are set, 1/4 BGAP 1/2 BGAP 3/4 BGAP and BGAP voltage references are available.

Bit 21 Reserved, must be kept at reset value

Bits 20:18 **BLANKING[2:0]**: Comparator 1 blanking source selection bits

- These bits select which timer output controls the comparator 1 output blanking.
- 000: No blanking
- 001: TIM1 OC5 selected as blanking source
- 010: TIM2 OC3 selected as blanking source
- 100: TIM3 OC3 selected as blanking source
- All other values: reserved

Bits 17:16 **HYST[1:0]**: Comparator 1 hysteresis selection bits

- These bits are set and cleared by software (only if LOCK not set). They select the hysteresis voltage of the comparator 1.
- 00: No hysteresis
- 01: Low hysteresis
- 10: Medium hysteresis
- 11: High hysteresis

Bit 15 **POLARITY**: Comparator 1 polarity selection bit

- This bit is set and cleared by software (only if LOCK not set). It inverts Comparator 1 polarity.
- 0: Comparator 1 output value not inverted
- 1: Comparator 1 output value inverted

Bits 14:9 Reserved, must be kept at reset value.

Bits 8:7 **INPSEL**: Comparator 1 input plus selection bit

- This bit is set and cleared by software (only if LOCK not set).
- 00: PC5
- 01: PB2
- 10: PA2
- 11: Reserved

Bits 6:4 **INMSEL**: Comparator 1 input minus selection bits

- These bits are set and cleared by software (only if LOCK not set). They select which input is connected to the input minus of comparator 1.
- 000 = 1/4 VREFINT
- 001 = 1/2 VREFINT
- 010 = 3/4 VREFINT
- 011 = VREFINT
- 100 = DAC Channel1
- 101 = DAC Channel2
- 110 = PB1111 = PC4
**24.6.2 Comparator 2 control and status register (COMP2_CSR)**

The COMP2_CSR is the Comparator 2 control/status register. It contains all the bits /flags related to comparator 2.

Address offset: 0x04

System reset value: 0x0000 0000

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

**Bits 3:2** **PWRMODE[1:0]**: Power Mode of the comparator 1

These bits are set and cleared by software (only if LOCK not set). They control the power/speed of the Comparator 1.

00: High speed
01 or 10: Medium speed
11: Ultra low power

Bit 1 Reserved, must be kept cleared.

Bit 0 **EN**: Comparator 1 enable bit

This bit is set and cleared by software (only if LOCK not set). It switches on Comparator 1.
0: Comparator 1 switched OFF
1: Comparator 1 switched ON
Bit 22 **BRGEN**: Scaler bridge enable
This bit is set and cleared by software (only if LOCK not set). This bit enable the bridge of
the scaler.
0: Scaler resistor bridge disable (if BRGEN bit of COMP1_CSR register is also reset)
1: Scaler resistor bridge enable
If SCALEN is set and BRGEN is reset, BG voltage reference is available but not 1/4 BGAP,
1/2 BGAP, 3/4 BGAP. BGAP value is sent instead of 1/4 BGAP, 1/2 BGAP, 3/4 BGAP.
If SCALEN and BRGEN are set, 1/4 BGAP 1/2 BGAP 3/4 BGAP and BGAP voltage
references are available.

Bit 21 Reserved, must be kept at reset value

Bits 20:18 **BLANKING[2:0]**: Comparator 2 blanking source selection bits
These bits select which timer output controls the comparator 2 output blanking.
000: No blanking
001: TIM3 OC4 selected as blanking source
010: TIM8 OC5 selected as blanking source
100: TIM15 OC1 selected as blanking source
All other values: reserved

Bits 17:16 **HYST[1:0]**: Comparator 2 hysteresis selection bits
These bits are set and cleared by software (only if LOCK not set). Select the hysteresis
voltage of the comparator 2.
00: No hysteresis
01: Low hysteresis
10: Medium hysteresis
11: High hysteresis

Bit 15 **POLARITY**: Comparator 2 polarity selection bit
This bit is set and cleared by software (only if LOCK not set). It inverts Comparator 2
polarity.
0: Comparator 2 output value not inverted
1: Comparator 2 output value inverted

Bits 14:10 Reserved, must be kept at reset value.

Bit 9 **WINMODE**: Windows mode selection bit
This bit is set and cleared by software (only if LOCK not set). This bit selects the window
mode of the comparators. If set, both positive inputs of comparators will be connected
together.
0: Input plus of Comparator 2 is not connected to Comparator 1
1: Input plus of Comparator 2 is connected with input plus of Comparator 1

Bit 8 Reserved, must be kept at reset value.

Bit 7 **INPSEL**: Comparator 1 input plus selection bit
This bit is set and cleared by software (only if LOCK not set).
0: PB4
1: PB6
Bits 6:4 **INMSEL**: Comparator 2 input minus selection bits
These bits are set and cleared by software (only if LOCK not set). They select which input is connected to the input minus of comparator 2.
- 000 = 1/4 V\text{REFINT}
- 001 = 1/2 V\text{REFINT}
- 010 = 3/4 V\text{REFINT}
- 011 = V\text{REFINT}
- 100 = DAC Channel1
- 101 = DAC Channel2
- 110 = PB3
- 111 = PB7

Bits 3:2 **PWRMODE[1:0]**: Power Mode of the comparator 2
These bits are set and cleared by software (only if LOCK not set). They control the power/speed of the Comparator 2.
- 00: High speed
- 01 or 10: Medium speed
- 11: Ultra low power

Bit 1 Reserved, must be kept cleared.

Bit 0 **EN**: Comparator 2 enable bit
This bit is set and cleared by software (only if LOCK not set). It switches on comparator 2.
- 0: Comparator 2 switched OFF
- 1: Comparator 2 switched ON
24.6.3 COMP register map

The following table summarizes the comparator registers.

Table 192. COMP register map and reset values

| Offset | Register | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

Refer to Section 2.3 on page 87 for the register boundary addresses.
25 Operational amplifiers (OPAMP)

25.1 Introduction
The device embeds two operational amplifiers with two inputs and one output each. The three I/Os can be connected to the external pins, this enables any type of external interconnections. The operational amplifier can be configured internally as a follower or as an amplifier with a non-inverting gain ranging from 2 to 16.

The positive input can be connected to the internal DAC.

The output can be connected to the internal ADC.

25.2 OPAMP main features
- Rail-to-rail input and output voltage range
- Low input bias current (down to 1 nA)
- Low input offset voltage (1.5 mV after calibration, 3 mV with factory calibration)
- Low-power mode (current consumption reduced to 30 µA instead of 100 µA)
- Fast wakeup time (10 µs in normal mode, 30 µs in low-power mode)
- Gain bandwidth of 1.6 MHz

25.3 OPAMP functional description
The OPAMP has several modes.

Each OPAMP can be individually enabled, when disabled the output is high-impedance.

When enabled, it can be in calibration mode, all input and output of the OPAMP are then disconnected, or in functional mode.

There are two functional modes, the low-power mode or the normal mode. In functional mode the inputs and output of the OPAMP are connected as described in the Section 25.3.3: Signal routing.

25.3.1 OPAMP reset and clocks
The operational amplifier clock is necessary for accessing the registers. When the application does not need to have read or write access to those registers, the clock can be switched off using the peripheral clock enable register (see OPAMPEN bit in Section 9.8.19: RCC APB1 peripheral clock enable register 1 (RCC_APB1ENR1)).

The bit OPAEN enables and disables the OPAMP operation. The OPAMP registers configurations should be changed before enabling the OPAEN bit in order to avoid spurious effects on the output.

When the output of the operational amplifier is no more needed the operational amplifier can be disabled to save power. All the configurations previously set (including the calibration) are maintained while OPAMP is disabled.
25.3.2 Initial configuration

The default configuration of the operational amplifier is a functional mode where the three IOs are connected to external pins. In the default mode the operational amplifier uses the factory trimming values. See electrical characteristics section of the datasheet for factory trimming conditions, usually the temperature is 30 °C and the voltage is 3 V. The trimming values can be adjusted, see Section 25.3.5: Calibration for changing the trimming values. The default configuration uses the normal mode, which provides the highest performance. Bit OPALPM can be set in order to switch the operational amplifier to low-power mode and reduced performance. Both normal and low-power mode characteristics are defined in the section “electrical characteristics” of the datasheet. Before utilization, the bit OPA_RANGE of OPAMP_CMR must be set to 1 if VDDA is above 2.4V, or kept at 0 otherwise.

As soon as the OPAEN bit in OPAMP_CSR register is set, the operational amplifier is functional. The two input pins and the output pin are connected as defined in Section 25.3.3: Signal routing and the default connection settings can be changed.

Note: The inputs and output pins must be configured in analog mode (default state) in the corresponding GPIOx_MODER register.

25.3.3 Signal routing

The routing for the operational amplifier pins is determined by OPAMP_CSR register.

The connections of the two operational amplifiers (OPAMP1 and OPAMP2) are described in the table below.

<table>
<thead>
<tr>
<th>Signal</th>
<th>Pin</th>
<th>Internal</th>
<th>comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>OPAMP1_VINM</td>
<td>PA1 or dedicated pin(1)</td>
<td>OPAMP1_OUT or PGA</td>
<td>Controlled by bits OPAMODE and VM_SEL.</td>
</tr>
<tr>
<td>OPAMP1_VINP</td>
<td>PA0</td>
<td>DAC1_OUT1</td>
<td>Controlled by bit VP_SEL.</td>
</tr>
<tr>
<td>OPAMP1_VOUT</td>
<td>PA3</td>
<td>ADC1_IN8</td>
<td>The pin is connected when the OPAMP is enabled. The ADC input is controlled by ADC.</td>
</tr>
<tr>
<td>OPAMP2_VINM</td>
<td>PA7 or dedicated pinChapter 1.</td>
<td>OPAMP2_OUT or PGA</td>
<td>Controlled by bits OPAMODE and VM_SEL.</td>
</tr>
<tr>
<td>OPAMP2_VINP</td>

<td>DAC1_OUT2</td>
<td>Controlled by bit VP_SEL.</td>
</tr>
<tr>
<td>OPAMP2_VOUT</td>
<td>PB0</td>
<td>ADC1_IN15</td>
<td>The pin is connected when the OPAMP is enabled. The ADC input is controlled by ADC.</td>
</tr>
</tbody>
</table>

1. The dedicated pin is only available on BGA132 and BGA169 package. This configuration provides the lowest input bias current (see datasheet).
25.3.4 OPAMP modes

The operational amplifier inputs and outputs are all accessible on terminals. The amplifiers can be used in multiple configuration environments:

- Standalone mode (external gain setting mode)
- Follower configuration mode
- PGA modes

Note: The amplifier output pin is directly connected to the output pad to minimize the output impedance. It cannot be used as a general purpose I/O, even if the amplifier is configured as a PGA and only connected to the ADC channel.

Note: The impedance of the signal must be maintained below a level which avoids the input leakage to create significant artifacts (due to a resistive drop in the source). Please refer to the electrical characteristics section in the datasheet for further details.

Standalone mode (external gain setting mode)

The procedure to use the OPAMP in standalone mode is presented hereafter.

Starting from the default value of OPAMP_CSR, and the default state of GPIOx_MODE, configure bit OPA_RANGE according the VDDA voltage. As soon as the OPAEN bit is set, the two input pins and the output pin are connected to the operational amplifier.

This default configuration uses the factory trimming values and operates in normal mode (highest performance). The behavior of the OPAMP can be changed as follows:

- OPALPM can be set to “operational amplifier low-power” mode in order to save power.
- USERTRIM can be set to modify the trimming values for the input offset.

Figure 174. Standalone mode: external gain setting mode
Follower configuration mode

The procedure to use the OPAMP in follower mode is presented hereafter.
- configure OPAMODE bits as “internal follower”
- configure VP_SEL bits as “GPIO connected to VINP”.
- As soon as the OPAEN bit is set, the signal on pin OPAMP_VINP is copied to pin OPAMP_VOUT.

**Note:** The pin corresponding to OPAMP_VINM is free for another usage.

**Note:** The signal on the operational amplifier output is also seen as an ADC input. As a consequence, the OPAMP configured in follower mode can be used to perform impedance adaptation on input signals before feeding them to the ADC input, assuming the input signal frequency is compatible with the operational amplifier gain bandwidth specification.

![Figure 175. Follower configuration](MS35325V1)
Programmable Gain Amplifier mode

The procedure to use the OPAMP to amplify the amplitude of an input signal is presented hereafter.

- configure OPAMODE bits as "internal PGA enabled",
- configure PGA_GAIN bits as "internal PGA Gain 2, 4, 8 or 16",
- configure VM_SEL bits as "inverting not externally connected",
- configure VP_SEL bits as "GPIO connected to VINP".

As soon as the OPAEN bit is set, the signal on pin OPAMP_VINP is amplified by the selected gain and visible on pin OPAMP_VOUT.

Note: To avoid saturation, the input voltage should stay below \( V_{DDA} \) divided by the selected gain.

Figure 176. PGA mode, internal gain setting (x2/x4/x8/x16), inverting input not used
Programmable Gain Amplifier mode with external filtering

The procedure to use the OPAMP to amplify the amplitude of an input signal, with an external filtering, is presented hereafter.

- configure OPAMODE bits as “internal PGA enabled”,
- configure PGA_GAIN bits as “internal PGA Gain 2, 4, 8 or 16”,
- configure VM_SEL bits as “GPIO connected to VINM”,
- configure VP_SEL bits as “GPIO connected to VINP”.

Any external connection on VINP can be used in parallel with the internal PGA, for example a capacitor can be connected between VOUT and VINM for filtering purpose (see datasheet for the value of resistors used in the PGA resistor network).

25.3.5 Calibration

At startup, the trimming values are initialized with the preset ‘factory’ trimming value.

Each operational amplifier offset can be trimmed by the user. Specific registers allow to have different trimming values for normal mode and for low-power mode.

The aim of the calibration is to cancel as much as possible the OPAMP inputs offset voltage. The calibration circuitry allows to reduce the inputs offset voltage to less than +/-1.5 mV within stable voltage and temperature conditions.

For each operational amplifier and each mode two trimming values need to be trimmed, one for N differential pair and one for P differential pair.

There are two registers for trimming the offsets for each operational amplifiers, one for normal mode (OPAMP_OTR) and one low-power mode (OPAMP_LPOTR). Each register is composed of five bits for P differential pair trimming and five bits for N differential pair trimming. These are the ‘user’ values.

1. The gain depends on the cut-off frequency.
The user is able to switch from ‘factory’ values to ‘user’ trimmed values using the USERTRIM bit in the OPAMP_CSR register. This bit is reset at startup and so the ‘factory’ value are applied by default to the OPAMP trimming registers.

User is liable to change the trimming values in calibration or in functional mode.

The offset trimming registers are typically configured after the calibration operation is initialized by setting bit CALON to 1. When CALON = 1 the inputs of the operational amplifier are disconnected from the functional environment.

- Setting CALSEL to 1 initializes the offset calibration for the P differential pair (low voltage reference used).
- Resetting CALSEL to 0 initializes the offset calibration for the N differential pair (high voltage reference used).

When CALON = 1, the bit CALOUT will reflect the influence of the trimming value selected by CALSEL and OPALPM. When the value of CALOUT switches between two consecutive trimming values, this means that those two values are the best trimming values. The CALOUT flag needs up to 1 ms after the trimming value is changed to become steady (see $t_{\text{OFFTRIM} \text{max}}$ delay specification in the electrical characteristics section of the datasheet).

Note: The closer the trimming value is to the optimum trimming value, the longer it takes to stabilize (with a maximum stabilization time remaining below 1 ms in any case).

</tbody>
</table>
Calibration procedure

Here are the steps to perform a full calibration of either one of the operational amplifiers:

1. Select correct OPA_RANGE in OPAMP_CSR, then set the OPAEN bit in OPAMP_CSR to 1 to enable the operational amplifier.
2. Set the USERTRIM bit in the OPAMP_CSR register to 1.
3. Choose a calibration mode (refer to Table 194: Operating modes and calibration). The steps 3 to 4 will have to be repeated 4 times. For the first iteration select
   - Normal mode, offset cal high (N differential pair)
   - The above calibration mode correspond to OPALPM=0 and CALSEL=0 in the OPAMP_CSR register.
4. Increment TRIMOFFSETN[4:0] in OPAMP_OTR starting from 00000b until CALOUT changes to 1 in OPAMP_CSR.

Note: CALOUT will switch from 0 to 1 for offset cal high and from 1 to 0 for offset cal low.

Note: Between the write to the OPAMP_OTR register and the read of the CALOUT value, make sure to wait for the $t_{OFFTRIM}$max delay specified in the electrical characteristics section of the datasheet, to get the correct CALOUT value.

The commutation means that the offset is correctly compensated and that the corresponding trim code must be saved in the OPAMP_OTR register.

Repeat steps 3 to 4 for:
   - Normal mode and offset cal low
   - Low power mode and offset cal high
   - Low power mode and offset cal low

If a mode is not used it is not necessary to perform the corresponding calibration.

All operational amplifier can be calibrated at the same time.

Note: During the whole calibration phase the external connection of the operational amplifier output must not pull up or down currents higher than 500 $\mu$A.

During the calibration procedure, it is necessary to set up OPAMODE bits as 00 or 01 (PGA disable) or 11 (internal follower).

25.4 OPAMP low-power modes

26 Digital filter for sigma delta modulators (DFSDM)

26.1 Introduction

Digital filter for sigma delta modulators (DFSDM) is a high-performance module dedicated to interface external ΣΔ modulators. It is featuring up to 4 external digital serial interfaces (channels) and up to 4 digital filters with flexible Sigma Delta stream digital processing options to offer up to 24-bit final ADC resolution. DFSDM also features optional parallel data stream input from internal ADC peripherals or from device memory.

An external ΣΔ modulator provides digital data stream of converted analog values from the external ΣΔ modulator analog input. This digital data stream is sent into a DFSDM input channel through a serial interface. DFSDM supports several standards to connect various ΣΔ modulator outputs: SPI interface and Manchester coded 1-wire interface (both with adjustable parameters). DFSDM module supports the connection of up to 4 multiplexed input digital serial channels which are shared with up to 4 DFSDM modules. DFSDM module also supports alternative parallel data inputs from up to 4 internal 16-bit data channels (from internal ADCs or from device memory).

DFSDM is converting an input data stream into a final digital data word which represents an analog input value on a ΣΔ modulator analog input. The conversion is based on a configurable digital process: the digital filtering and decimation of the input serial data stream.

The conversion speed and resolution are adjustable according to configurable parameters for digital processing: filter type, filter order, length of filter, integrator length. The maximum output data resolution is up to 24 bits. There are two conversion modes: single conversion mode and continuous mode. The data can be automatically stored in a system RAM buffer through DMA, thus reducing the software overhead.

A flexible timer triggering system can be used to control the start of conversion of DFSDM. This timing control is capable of triggering simultaneous conversions or inserting a programmable delay between conversions.

DFSDM features an analog watchdog function. Analog watchdog can be assigned to any of the input channel data stream or to final output data. Analog watchdog has its own digital filtering of input data stream to reach the required speed and resolution of watched data.

To detect short-circuit in control applications, there is a short-circuit detector. This block watches each input channel data stream for occurrence of stable data for a defined time duration (several 0’s or 1’s in an input data stream).

An extremes detector block watches final output data and stores maximum and minimum values from the output data values. The extremes values stored can be restarted by software.

Two power modes are supported: normal mode and stop mode.
26.2 DFSDM main features

- Up to 4 multiplexed input digital serial channels:
  - configurable SPI interface to connect various ΣΔ modulators
  - configurable Manchester coded 1 wire interface support
  - clock output for ΣΔ modulator(s)
- Alternative inputs from up to 4 internal digital parallel channels:
  - inputs with up to 16 bit resolution
  - internal sources: ADCs data or memory (CPU/DMA write) data streams
- Adjustable digital signal processing:
  - Sinc\(x\) filter: filter order/type (1..5), oversampling ratio (up to 1..1024)
  - integrator: oversampling ratio (1..256)
- Up to 24-bit output data resolution:
  - right bit-shifter on final data (0..31 bits)
- Signed output data format
- Automatic data offset correction (offset stored in register by user)
- Continuous or single conversion
- Start-of-conversion synchronization with:
  - software trigger
  - internal timers
  - external events
  - start-of-conversion synchronously with first DFSDM filter (DFSDM_FLT0)
- Analog watchdog feature:
  - low value and high value data threshold registers
  - own configurable Sinc\(x\) digital filter (order = 1..3, oversampling ratio = 1..32)
  - input from output data register or from one or more input digital serial channels
  - continuous monitoring independently from standard conversion
- Short-circuit detector to detect saturated analog input values (bottom and top ranges):
  - up to 8-bit counter to detect 1..256 consecutive 0’s or 1’s on input data stream
  - monitoring continuously each channel (4 serial channel transceiver outputs)
- Break generation on analog watchdog event or short-circuit detector event
- Extremes detector:
  - store minimum and maximum values of output data values
  - refreshed by software
- Pulse skipper feature to support beamforming applications (delay line like behavior)
- DMA may be used to read the conversion data
- Interrupts: end of conversion, overrun, analog watchdog, short-circuit, channel clock absence
- “regular” or “injected” conversions:
  - “regular” conversions can be requested at any time or even in continuous mode without having any impact on the timing of “injected” conversions
  - “injected” conversions for precise timing and with high conversion priority
26.3 DFSDM implementation

26.4.3 DFSDM reset and clocks

**DFSDM on-off control**

The DFSDM interface is globally enabled by setting DFSDMEN=1 in the DFSDM_CH0CFGR1 register. Once DFSDM is globally enabled, all input channels (y=0..3) and digital filters DFSDM_FLTx (x=0..3) start to work if their enable bits are set (channel enable bit CHEN in DFSDM_CHyCFGR1 and DFSDM_FLTx enable bit DFEN in DFSDM_FLTxCR1).

Digital filter x DFSDM_FLTx (x=0..3) is enabled by setting DFEN=1 in the DFSDM_FLTxCR1 register. Once DFSDM_FLTx is enabled (DFEN=1), both Sincx digital filter unit and integrator unit are reinitialized.

By clearing DFEN, any conversion which may be in progress is immediately stopped and DFSDM_FLTx is put into stop mode. All register settings remain unchanged except DFSDM_FLTxAWSR and DFSDM_FLTxISR (which are reset).

Channel y (y=0..3) is enabled by setting CHEN=1 in the DFSDM_CHyCFGR1 register. Once the channel is enabled, it receives serial data from the external Σ∆ modulator or parallel internal data sources (ADCs or CPU/DMA wire from memory).

DFSDM must be globally disabled (by DFSDMEN=0 in DFSDM_CH0CFGR1) before stopping the system clock to enter in the STOP mode of the device.

**DFSDM clocks**

The internal DFSDM clock fDFSDMCLK, which is used to drive the channel transceivers, digital processing blocks (digital filter, integrator) and next additional blocks (analog watchdog, short-circuit detector, extremes detector, control block) is generated by the RCC block and is derived from the system clock SYSCLK or peripheral clock PCLK2 (see Section 9.8.32: RCC peripherals independent clock configuration register 2 (RCC_CCIPR2)). The DFSDM clock is automatically stopped in stop mode (if DFEN = 0 for all DFSDM_FLTx, x=0..3).

The DFSDM serial channel transceivers can receive an external serial clock to sample an external serial data stream. The internal DFSDM clock must be at least 4 times faster than the external serial clock if standard SPI coding is used, and 6 times faster than the external serial clock if Manchester coding is used.

DFSDM can provide one external output clock signal to drive external Σ∆ modulator(s) clock input(s). It is provided on CKOUT pin. This output clock signal must be in the range specified in given device datasheet and is derived from DFSDM clock or from audio clock (see CKOUTSRC bit in DFSDM_CH0CFGR1 register) by programmable divider in the range 2 - 256 (CKOUTDIV in DFSDM_CH0CFGR1 register). Audio clock source is SAI1 clock selected by SAI1SEL[1:0] field in RCC configuration (see ).

26.4.4 Serial channel transceivers

There are 4 multiplexed serial data channels which can be selected for conversion by each filter or Analog watchdog or Short-circuit detector. Those serial transceivers receive data stream from external ΣΔ modulator. Data stream can be sent in SPI format or Manchester coded format (see SITP[1:0] bits in DFSDM_CHyCFGR1 register). The channel is enabled for operation by setting CHEN=1 in DFSDM_CHyCFGR1 register.

Channel inputs selection

Serial inputs (data and clock signals) from DATINy and CKINy pins can be redirected from the following channel pins. This serial input channel redirection is set by CHINSEL bit in DFSDM_CHyCFGR1 register.

Channel redirection can be used to collect audio data from PDM (pulse density modulation) stereo microphone type. PDM stereo microphone has one data and one clock signal. Data signal provides information for both left and right audio channel (rising clock edge samples for left channel and falling clock edge samples for right channel).

Configuration of serial channels for PDM microphone input:

- PDM microphone signals (data, clock) will be connected to DFSDM input serial channel y (DATINy, CKOUT) pins.
- Channel y will be configured: CHINSEL = 0 (input from given channel pins: DATINy, CKINy).
- Channel (y-1) (modulo 4) will be configured: CHINSEL = 1 (input from the following channel ((y-1)+1) pins: DATINy, CKINy).
- Channel y: SITP[1:0] = 0 (rising edge to strobe data) => left audio channel on channel y.
- Channel (y-1): SITP[1:0] = 1 (falling edge to strobe data) => right audio channel on channel y-1.
- Two DFSDM filters will be assigned to channel y and channel (y-1) (to filter left and right channels from PDM microphone).
Figure 179. Input channel pins redirection

Output clock generation

A clock signal can be provided on CKOUT pin to drive external ΣΔ modulator clock inputs. The frequency of this CKOUT signal is derived from DFSDM clock or from audio clock (see CKOUTSRC bit in DFSDM_CH0CFG1 register) divided by a prescaler (see CKOUTDIV bits in DFSDM_CH0CFG1 register). If the output clock is stopped, then CKOUT signal is set to low state (output clock can be stopped by CKOUTDIV=0 in DFSDM_CH0CFG1 register or by DFSMEN=0 in DFSDM_CH0CFG1 register). The output clock stopping is performed:

- 4 system clocks after DFSMEN is cleared (if CKOUTSRC=0)
- 1 system clock and 3 audio clocks after DFSMEN is cleared (if CKOUTSRC=1)

Before changing CKOUTSRC the software has to wait for CKOUT being stopped to avoid glitch on CKOUT pin. The output clock signal frequency must be in the range 0 - 20 MHz.
SPI data input format operation

In SPI format, the data stream is sent in serial format through data and clock signals. Data signal is always provided from DATINy pin. A clock signal can be provided externally from CKINy pin or internally from a signal derived from the CKOUT signal source.

In case of external clock source selection (SPICKSEL[1:0]=0) data signal (on DATINy pin) is sampled on rising or falling clock edge (of CKINy pin) according SITP[1:0] bits setting (in DFSDM_CHyCFGR1 register).

Internal clock sources - see SPICKSEL[1:0] in DFSDM_CHyCFGR1 register:

- **CKOUT signal:**
  - For connection to external Σ∆ modulator which uses directly its clock input (from CKOUT) to generate its output serial communication clock.
  - Sampling point: on rising/falling edge according SITP[1:0] setting.

- **CKOUT/2 signal (generated on CKOUT rising edge):**
  - For connection to external Σ∆ modulator which divides its clock input (from CKOUT) by 2 to generate its output serial communication clock (and this output clock change is active on each clock input rising edge).
  - Sampling point: on each second CKOUT falling edge.

- **CKOUT/2 signal (generated on CKOUT falling edge):**
  - For connection to external Σ∆ modulator which divides its clock input (from CKOUT) by 2 to generate its output serial communication clock (and this output clock change is active on each clock input falling edge).
  - Sampling point: on each second CKOUT rising edge.

Note: An internal clock source can only be used when the external Σ∆ modulator uses CKOUT signal as a clock input (to have synchronous clock and data operation).

Internal clock source usage can save CKINy pin connection (CKINy pins can be used for other purpose).

The clock source signal frequency must be in the range 0 - 20 MHz for SPI coding and less than fDFSDMCLK/4.

Manchester coded data input format operation

In Manchester coded format, the data stream is sent in serial format through DATINy pin only. Decoded data and clock signal are recovered from serial stream after Manchester decoding. There are two possible settings of Manchester codings (see SITP[1:0] bits in DFSDM_CHyCFGR1 register):

- signal rising edge = log 0; signal falling edge = log 1
- signal rising edge = log 1; signal falling edge = log 0

The recovered clock signal frequency for Manchester coding must be in the range 0 - 10 MHz and less than fDFSDMCLK/6.

To correctly receive Manchester coded data, the CKOUTDIV divider (in DFSDM_CH0CFGR1 register) must be set with respect to expected Manchester data rate according formula:

\[(CKOUTDIV + 1) \times T_{SYSCLK} < T_{\text{Manchester clock}} < (2 \times CKOUTDIV \times T_{SYSCLK})\]

Clock absence detection

Channels serial clock inputs can be checked for clock absence/presence to ensure the correct operation of conversion and error reporting. Clock absence detection can be enabled or disabled on each input channel \( y \) by bit CKABEN in DFSDM_CHyCFGR1 register. If enabled, then this clock absence detection is performed continuously on a given channel. A clock absence flag is set (\( \text{CKABF}[y] = 1 \)) and an interrupt can be invoked (if \( \text{CKABIE}=1 \)) in case of an input clock error (see \( \text{CKABF}[3:0] \) in DFSDM_FLT0ISR register and CKABEN in DFSDM_CHyCFGR1). After a clock absence flag clearing (by CLRCKABF in DFSDM_FLT0ICR register), the clock absence flag is refreshed. Clock absence status bit \( \text{CKABF}[y] \) is set also by hardware when corresponding channel \( y \) is disabled (if \( \text{CHEN}[y] = 0 \) then \( \text{CKABF}[y] \) is held in set state).

When a clock absence event has occurred, the data conversion (and/or analog watchdog and short-circuit detector) provides incorrect data. The user should manage this event and discard given data while a clock absence is reported.

The clock absence feature is available only when the system clock is used for the CKOUT signal (CKOUTSRC=0 in DFSDM_CH0CFGR1 register).

When the transceiver is not yet synchronized, the clock absence flag is set and cannot be cleared by CLRCKABF[y] bit (in DFSDM_FLT0ICR register). The software sequence concerning clock absence detection feature should be:

- Enable given channel by \( \text{CHEN} = 1 \)
- Try to clear the clock absence flag (by CLRCKABF = 1) until the clock absence flag is really cleared (\( \text{CKABF} = 0 \)). At this time, the transceiver is synchronized (signal clock is valid) and is able to receive data.
- Enable the clock absence feature \( \text{CKABEN} = 1 \) and the associated interrupt \( \text{CKABIE} = 1 \) to detect if the SPI clock is lost or Manchester data edges are missing.

If SPI data format is used, then the clock absence detection is based on the comparison of an external input clock with an output clock generation (CKOUT signal). The external input clock signal into the input channel must be changed at least once per 8 signal periods of CKOUT signal (which is controlled by CKOUTDIV field in DFSDM_CH0CFGR1 register).

**Figure 181. Clock absence timing diagram for SPI**

If Manchester data format is used, then the clock absence means that the clock recovery is unable to perform from Manchester coded signal. For a correct clock recovery, it is first necessary to receive data with 1 to 0 or 0 to 1 transition (see Figure 183 for Manchester synchronization).
The detection of a clock absence in Manchester coding (after a first successful synchronization) is based on changes comparison of coded serial data input signal with output clock generation (CKOUT signal). There must be a voltage level change on DAT1Ny pin during 2 periods of CKOUT signal (which is controlled by CKOUTDIV bits in DFSDM_CH0CFGR1 register). This condition also defines the minimum data rate to be able to correctly recover the Manchester coded data and clock signals.

The maximum data rate of Manchester coded data must be less than the CKOUT signal. So to correctly receive Manchester coded data, the CKOUTDIV divider must be set according the formula:

\[(\text{CKOUTDIV} + 1) \times \frac{T_{\text{SYCLK}}}{2} < T_{\text{Manchester clock}} < (2 \times \text{CKOUTDIV} \times \frac{T_{\text{SYCLK}}}{2})\]

A clock absence flag is set (CKABF[y] = 1) and an interrupt can be invoked (if CKABIE=1) in case of an input clock recovery error (see CKABF[3:0] in DFSDM_FLT0ISR register and CKABEN in DFSDM_CHyCFGR1). After a clock absence flag clearing (by CLRCKABF in DFSDM_FLT0ICR register), the clock absence flag is refreshed.

Figure 182. Clock absence timing diagram for Manchester coding
Manchester/SPI code synchronization

The Manchester coded stream must be synchronized the first time after enabling the channel (CHEN=1 in DFSDM.CHyCFG1 register). The synchronization ends when a data transition from 0 to 1 or from 1 to 0 (to be able to detect valid data edge) is received. The end of the synchronization can be checked by polling CKABF[y]=0 for a given channel after it has been cleared by CLRCKABF[y] in DFSDM_FLT0ICR, following the software sequence detailed hereafter:

CKABF[y] flag is cleared by setting CLRCKABF[y] bit. If channel y is not yet synchronized the hardware immediately set the CKABF[y] flag. Software is then reading back the CKABF[y] flag and if it is set then perform again clearing of this flag by setting CLRCKABF[y] bit. This software sequence (polling of CKABF[y] flag) continues until CKABF[y] flag is set (signalizing that Manchester stream is synchronized). To be able to synchronize/receive Manchester coded data the CKOUTDIV divider (in DFSDM.CH0CFG1 register) must be set with respect to expected Manchester data rate according the formula below.

\[ ((\text{CKOUTDIV} + 1) \times T_{\text{SYSCLK}}) < T_{\text{Manchester clock}} < (2 \times \text{CKOUTDIV} \times T_{\text{SYSCLK}}) \]

SPI coded stream is synchronized after first detection of clock input signal (valid rising/falling edge).

**Note:** When the transceiver is not yet synchronized, the clock absence flag is set and cannot be cleared by CLRCKABF[y] bit (in DFSDM_FLT0ICR register).
External serial clock frequency measurement

The measuring of a channel serial clock input frequency provides a real data rate from an external Σ∆ modulator, which is important for application purposes.

An external serial clock input frequency can be measured by a timer counting DFSDM clocks (fDFSDMCLK) during one conversion duration. The counting starts at the first input data clock after a conversion trigger (regular or injected) and finishes by last input data clock before conversion ends (end of conversion flag is set). Each conversion duration (time between first serial sample and last serial sample) is updated in counter CNVCNT[27:0] in register DFSDM_FLTxCNVTIMR when the conversion finishes (JEOCF=1 or REOCF=1). The user can then compute the data rate according to the digital filter settings (FORD, FOSR, IOSR, FAST). The external serial frequency measurement is stopped only if the filter is bypassed (FOSR=0, only integrator is active, CNVCNT[27:0]=0 in DFSDM_FLTxCNVTIMR register).

In case of parallel data input (Section 26.4.6: Parallel data inputs) the measured frequency is the average input data rate during one conversion.
Note: When conversion is interrupted (e.g. by disabling/enabling the selected channel) the interruption time is also counted in CNVCNT[27:0]. Therefore it is recommended to not interrupt the conversion for correct conversion duration result.

Conversion times:

Injected conversion or regular conversion with FAST = 0 (or first conversion if FAST=1):

for Sinc\(^x\) filters (x=1..5):
\[ t = \frac{\text{CNVCNT}}{f_{DFSDMCLK}} = \frac{[\text{FOSR} \cdot (\text{IOSR}-1 + \text{FORD}) + \text{FORD}]}{f_{CKIN}} \]
for FastSinc filter:
\[ t = \frac{\text{CNVCNT}}{f_{DFSDMCLK}} = \frac{[\text{FOSR} \cdot (\text{IOSR}-1 + 4) + 2]}{f_{CKIN}} \]

Regular conversion with FAST = 1 (except first conversion):

for Sinc\(^x\) and FastSinc filters:
\[ t = \frac{\text{CNVCNT}}{f_{DFSDMCLK}} = \frac{[\text{FOSR} \cdot \text{IOSR}]}{f_{CKIN}} \]
in case if F\(_{OSR}\) = FOSR[9:0]+1 = 1 (filter bypassed, active only integrator):
\[ t = \frac{\text{IOSR}}{f_{CKIN}} \ldots \text{but CNVCNT}=0 \]

where:
- \( f_{CKIN} \) is the channel input clock frequency (on given channel CKIN\(y\) pin) or input data rate (in case of parallel data input)
- \( \text{FOSR} \) is the filter oversampling ratio: \( \text{FOSR} = \text{FOSR}[9:0]+1 \) (see DFSDM_FLTxFCR register)
- \( \text{IOSR} \) is the integrator oversampling ratio: \( \text{IOSR} = \text{IOSR}[7:0]+1 \) (see DFSDM_FLTxFCR register)
- \( \text{FORD} \) is the filter order: \( \text{FORD} = \text{FORD}[2:0] \) (see DFSDM_FLTxFCR register)

Channel offset setting

Each channel has its own offset setting (in register) which is finally subtracted from each conversion result (injected or regular) from a given channel. Offset correction is performed after the data right bit shift. The offset is stored as a 24-bit signed value in OFFSET[23:0] field in DFSDM_CHyCFGR2 register.

Data right bit shift

To have the result aligned to a 24-bit value, each channel defines a number of right bit shifts which will be applied on each conversion result (injected or regular) from a given channel. The data bit shift number is stored in DTRBS[4:0] bits in DFSDM_CHyCFGR2 register.

The right bit-shift is rounding the result to nearest integer value. The sign of shifted result is maintained, in order to have valid 24-bit signed format of result data.

Pulses skipper

Purpose of the pulses skipper is to implement delay line like behavior for given input channel(s). Given number of samples from input serial data stream (serial stream only) can be discarded before they enter into the filter. This data discarding is performed by skipping given number of sampling input clock pulses (given serial data samples are then not sampled by filter). The sampling clock is gated by pulses skipper function for given number of clock pulses. When given clock pulses are skipped then the filtering continues for following input data. With comparison to non skipped data stream this operation causes that
the final output sample (and next samples) from filter will be calculated from later input data. This final sample then looks a bit in forward - because it is calculated from newer input samples than the “non-skipped” sample. The final “skipped sample” is converted later because the skipped input data samples must be replaced by followed input data samples. The final data buffers behavior (skipped and non-skipped output data buffers comparison) looks like the non-skipped data stream is a bit delayed - both data buffers will be phase shifted.

Number of clock pulses to be skipped should be written into PLSSKP[5:0] field in DFSDM_CHyDLYR register. Once PLSSKP[5:0] field is written the execution of pulses skipping is started on given channel. PLSSKP[5:0] field can be read in order to check the progress of pulses skipper. When PLSSKP[5:0]=0 means that pulses skipping has been executed.

Up to 63 clock pulses can be skip with a single write operation into PLSSKP[5:0]. If more pulses need to be skipped, then user has to write several times into the PLSSKP[5:0] field. The application software should handle cumulative skipped clock number per each filter.

### 26.4.5 Configuring the input serial interface

The following parameters must be configured for the input serial interface:

- **Output clock predivider.** There is a programmable predivider to generate the output clock from DFSDM clock (2 - 256). It is defined by CKOUTDIV[7:0] bits in DFSDM_CH0CFGR1 register.

- **Serial interface type and input clock phase.** Selection of SPI or Manchester coding and sampling edge of input clock. It is defined by SITP [1:0] bits in DFSDM_CHyCFGR1 register.

- **Input clock source.** External source from CKINy pin or internal from CKOUT pin. It is defined by SPICKSEL[1:0] field in DFSDM_CHyCFGR1 register.

- **Final data right bit-shift.** Defines the final data right bit shift to have the result aligned to a 24-bit value. It is defined by DTRBS[4:0] in DFSDM_CHyCFGR2 register.

- **Channel offset per channel.** Defines the analog offset of a given serial channel (offset of connected external Σ∆ modulator). It is defined by OFFSET[23:0] bits in DFSDM_CHyCFGR2 register.

- **short-circuit detector and clock absence per channel enable.** To enable or disable the short-circuit detector (by SCDEN bit) and the clock absence monitoring (by CKABEN bit) on a given serial channel in register DFSDM_CHyCFGR1.

- **Analog watchdog filter and short-circuit detector threshold settings.** To configure channel analog watchdog filter parameters and channel short-circuit detector parameters. Configurations are defined in DFSDM_CHyAWSCDR register.

### 26.4.6 Parallel data inputs

Each input channel provides a register for 16-bit parallel data input (besides serial data input). Each 16-bit parallel input can be sourced from internal data sources only:

- internal ADC results
- direct CPU/DMA writing.

The selection for using serial or parallel data input for a given channel is done by field DATMPX[1:0] of DFSDM_CHyCFGR1 register. In DATMPX[1:0] is also defined the parallel data source: internal ADC or direct write by CPU/DMA.
Each channel contains a 32-bit data input register DFSDM_CHyDATINR in which it can be written a 16-bit data. Data are in 16-bit signed format. Those data can be used as input to the digital filter which is accepting 16-bit parallel data.

If serial data input is selected (DATMPX[1:0] = 0), the DFSDM_CHyDATINR register is write protected.

**Input from internal ADC**

In case of ADC data parallel input (DATMPX[1:0]=1) the ADC[y+1] result is assigned to channel y input (ADC1 is filling DFSDM_CHDATIN0R register, ADC2 is filling DFSDM_CHDATIN1R register, ... , ADC8 is filling DFSDM_CHDATIN7R register). End of conversion event from ADC[y+1] causes update of channel y data (parallel data from ADC[y+1] are put as next sample to digital filter). Data from ADC[y+1] is written into DFSDM_CHyDATINR register (field INDAT0[15:0]) when end of conversion event occurred.

The setting of data packing mode (DATPACK[1:0] in the DFSDM_CHyCFGR1 register) has no effect in case of ADC data input.

*Note: Extension of ADC specification: in case the internal ADC is configured in interleaved mode (e.g. ADC1 together with ADC2 - see ADC specification) then each result from ADC1 or from ADC2 will come to the same 16-bit bus - to the bus of ADC1 - which is coming into DFSDM channel 0 (fixed connection). So there will be double input data rate into DFSDM channel 0 (even samples come from ADC1 and odd samples from ADC2). Channel 1 associated with ADC2 will be free.*

**Input from memory (direct CPU/DMA write)**

The direct data write into DFSDM_CHyDATINR register by CPU or DMA (DATMPX[1:0]=2) can be used as data input in order to process digital data streams from memory or peripherals.

Data can be written by CPU or DMA into DFSDM_CHyDATINR register:

1. **CPU data write:**
   Input data are written directly by CPU into DFSDM_CHyDATINR register.

2. **DMA data write:**
   The DMA should be configured in memory-to-memory transfer mode to transfer data from memory buffer into DFSDM_CHyDATINR register. The destination memory address is the address of DFSDM_CHyDATINR register. Data are transferred at DMA transfer speed from memory to DFSDM parallel input.
   This DMA transfer is different from DMA used to read DFSDM conversion results. Both DMA can be used at the same time - first DMA (configured as memory-to-memory transfer) for input data writings and second DMA (configured as peripheral-to-memory transfer) for data results reading.

The accesses to DFSDM_CHyDATINR can be either 16-bit or 32-bit wide, allowing to load respectively one or two samples in one write operation. 32-bit input data register (DFSDM_CHyDATINR) can be filled with one or two 16-bit data samples, depending on the data packing operation mode defined in field DATPACK[1:0] of DFSDM_CHyCFGR1 register:

1. **Standard mode (DATPACK[1:0]=0):**
   Only one sample is stored in field INDAT0[15:0] of DFSDM_CHyDATINR register which is used as input data for channel y. The upper 16 bits (INDAT1[15:0]) are ignored and write protected. The digital filter must perform one input sampling (from INDAT0[15:0])
to empty data register after it has been filled by CPU/DMA. This mode is used together with 16-bit CPU/DMA access to DFSDM_CHyDATINR register to load one sample per write operation.

2. **Interleaved mode (DATPACK[1:0]=1):**

DFSDM_CHyDATINR register is used as a two sample buffer. The first sample is stored in INDAT0[15:0] and the second sample is stored in INDAT1[15:0]. The digital filter must perform two input samplings from channel y to empty DFSDM_CHyDATINR register. This mode is used together with 32-bit CPU/DMA access to DFSDM_CHyDATINR register to load two samples per write operation.

3. **Dual mode (DATPACK[1:0]=2):**

Two samples are written into DFSDM_CHyDATINR register. The data INDAT0[15:0] is for channel y, the data in INDAT1[15:0] is for channel y+1. The data in INDAT1[15:0] is automatically copied INDAT0[15:0] of the following (y+1) channel data register DFSDM_CH[y+1]DATINR. The digital filters must perform two samplings - one from channel y and one from channel (y+1) - in order to empty DFSDM_CHyDATINR registers.

Dual mode setting (DATPACK[1:0]=2) is available only on even channel numbers (y = 0, 2). If odd channel (y = 1, 3) is set to Dual mode then both INDAT0[15:0] and INDAT1[15:0] parts are write protected for this channel. If even channel is set to Dual mode then the following odd channel must be set into Standard mode (DATPACK[1:0]=0) for correct cooperation with even channels.

See **Figure 184** for DFSDM_CHyDATINR registers data modes and assignments of data samples to channels.

**Figure 184. DFSDM_CHyDATINR registers operation modes and assignment**

</table>

The write into DFSDM_CHyDATINR register to load one or two samples must be performed after the selected input channel (channel y) is enabled for data collection (starting conversion for channel y). Otherwise written data are lost for next processing.

For example: for single conversion and interleaved mode, do not start writing pair of data samples into DFSDM_CHyDATINR before the single conversion is started (any data present in the DFSDM_CHyDATINR before starting a conversion is discarded).

### 26.4.7 Channel selection

There are 4 multiplexed channels which can be selected for conversion using the injected channel group and/or using the regular channel.

The **injected channel group** is a selection of any or all of the 4 channels. JCHG[3:0] in the DFSDM_FLTxJCHGR register selects the channels of the injected group, where JCHG[y]=1 means that channel y is selected.
Injected conversions can operate in scan mode (JSCAN=1) or single mode (JSCAN=0). In scan mode, each of the selected channels is converted, one after another. The lowest channel (channel 0, if selected) is converted first, followed immediately by the next higher channel until all the channels selected by JCHG[3:0] have been converted. In single mode (JSCAN=0), only one channel from the selected channels is converted, and the channel selection is moved to the next channel. Writing to JCHG[3:0] if JSCAN=0 resets the channel selection to the lowest selected channel.

Injected conversions can be launched by software or by a trigger. They are never interrupted by regular conversions.

The **regular channel** is a selection of just one of the 4 channels. RCH[1:0] in the DFSDM_FLTxCR1 register indicates the selected channel.

Regular conversions can be launched only by software (not by a trigger). A sequence of continuous regular conversions is temporarily interrupted when an injected conversion is requested.

Performing a conversion on a disabled channel (CHEN=0 in DFSDM_CHyCFGR1 register) causes that the conversion will never end - because no input data is provided (with no clock signal). In this case, it is necessary to enable a given channel (CHEN=1 in DFSDM_CHyCFGR1 register) or to stop the conversion by DFEN=0 in DFSDM_FLTxCR1 register.

### 26.4.8 Digital filter configuration

DFSDM contains a Sincx type digital filter implementation. This Sincx filter performs an input digital data stream filtering, which results in decreasing the output data rate (decimation) and increasing the output data resolution. The Sincx digital filter is configurable in order to reach the required output data rates and required output data resolution. The configurable parameters are:

- **Filter order/type**: (see FORD[2:0] bits in DFSDM_FLTxFCR register):
  - FastSinc
  - Sinc 1
  - Sinc 2
  - Sinc 3
  - Sinc 4
  - Sinc 5
- **Filter oversampling/decimation ratio** (see FOSR[9:0] bits in DFSDM_FLTxFCR register):
  - FOSR = 1-1024 - for FastSinc filter and Sincx filter $x = F_{ORD} = 1..3$
  - FOSR = 1-215 - for Sincx filter $x = F_{ORD} = 4$
  - FOSR = 1-73 - for Sincx filter $x = F_{ORD} = 5$

The filter has the following transfer function (impulse response in H domain):

- **Sincx filter type**: $H(z) = \left(\frac{1-z^{-FOSR}}{1-z^{-1}}\right)^x$
- **FastSinc filter type**: $H(z) = \left(\frac{1-z^{-FOSR}}{1-z^{-1}}\right)^2 \cdot (1 + z^{-2 \cdot FOSR})$
For more information about Sinc filter type properties and usage, it is recommended to study the theory about digital filters (more resources can be downloaded from internet).

### 26.4.9 Integrator unit

The integrator performs additional decimation and a resolution increase of data coming from the digital filter. The integrator simply performs the sum of data from a digital filter for a given number of data samples from a filter.

The integrator oversampling ratio parameter defines how many data counts will be summed to one data output from the integrator. IOSR can be set in the range 1-256 (see IOSR[7:0] bits description in DFSDM_FLTxFCR register).
The analog watchdog purpose is to trigger an external signal (break or interrupt) when an analog signal reaches or crosses given maximum and minimum threshold values. An interrupt/event/break generation can then be invoked.

Each analog watchdog will supervise serial data receiver outputs (after the analog watchdog filter on each channel) or data output register (current injected or regular conversion result) according to AWFSEL bit setting (in DFSDM_FLTxCR1 register). The input channels to be monitored or not by the analog watchdog x will be selected by AWDCH[3:0] in DFSDM_FLTxCR2 register.

Analog watchdog conversions on input channels are independent from standard conversions. In this case, the analog watchdog uses its own filters and signal processing on each input channel independently from the main injected or regular conversions. Analog watchdog conversions are performed in a continuous mode on the selected input channels in order to watch channels also when main injected or regular conversions are paused (RCIP = 0, JCIP = 0).

There are high and low threshold registers which are compared with given data values (set by AWHT[23:0] bits in DFSDM_FLTxAWHTR register and by AWLT[23:0] bits in DFSDM_FLTxAWLTR register).

Table 203. Integrator maximum output resolution (peak data values from integrator output) for some IOSR values and FOSR = 256 and Sinc⁵ filter type (largest data)
There are 2 options for comparing the threshold registers with the data values

- **Option1:** in this case, the input data are taken from final output data register (AWFSEL=0). This option is characterized by:
  - high input data resolution (up to 24-bits)
  - slow response time - inappropriate for fast response applications like overcurrent detection
  - for the comparison the final data are taken after bit shifting and offset data correction
  - final data are available only after main regular or injected conversions are performed
  - can be used in case of parallel input data source (DATMPX[1:0] ≠ 0 in DFSDM_CHyCFGR1 register)

- **Option2:** in this case, the input data are taken from any serial data receivers output (AWFSEL=1). This option is characterized by:
  - input serial data are processed by dedicated analog watchdog Sinc^x channel filters with configurable oversampling ratio (1..32) and filter order (1..3) (see AWFOSR[4:0] and AWFORD[1:0] bits setting in DFSDM_CHyAWSCDR register)
  - lower resolution (up to 16-bit)
  - fast response time - appropriate for applications which require a fast response like overcurrent/overvoltage detection
  - data are available in continuous mode independently from main regular or injected conversions activity

In case of input channels monitoring (AWFSEL=1), the data for comparison to threshold is taken from channels selected by AWDCH[3:0] field (DFSDM_FLTxCR2 register). Each of the selected channels filter result is compared to one threshold value pair (AWHT[23:0] / AWLT[23:0]). In this case, only higher 16 bits (AWHT[23:8] / AWLT[23:8]) define the 16-bit threshold compared with the analog watchdog filter output because data coming from the analog watchdog filter is up to a 16-bit resolution. Bits AWHT[7:0] / AWLT[7:0] are not taken into comparison in this case (AWFSEL=1).

Parameters of the analog watchdog filter configuration for each input channel are set in DFSDM_CHyAWSCDR register (filter order AWFORD[1:0] and filter oversampling ratio AWFOSR[4:0]).

Each input channel has its own comparator which compares the analog watchdog data (from analog watchdog filter) with analog watchdog threshold values (AWHT/AWLT). When several channels are selected (field AWDC[3:0] field of DFSDM_FLTxCR2 register), several comparison requests may be received simultaneously. In this case, the channel request with the lowest number is managed first and then continuing to higher selected channels. For each channel, the result can be recorded in a separate flag (fields AWHFT[3:0], AWLFT[3:0] of DFSDM_FLTxAWSR register). Each channel request is executed in 8 DFSDM clock cycles. So, the bandwidth from each channel is limited to 8 DFSDM clock cycles (if AWDC[3:0] = 0x0F). Because the maximum input channel sampling clock frequency is the DFSDM clock frequency divided by 4, the configuration AWFOSR = 0 (analog watchdog filter is bypassed) cannot be used for analog watchdog feature at this input clock speed. Therefore user must properly configure the number of watched channels and analog watchdog filter parameters with respect to input sampling clock speed and DFSDM frequency.
Analog watchdog filter data for given channel y is available for reading by firmware on field WDATA[15:0] in DFSDM_CHyWDATR register. That analog watchdog filter data is converted continuously (if CHEN=1 in DFSDM_CHyCFGR1 register) with the data rate given by the analog watchdog filter setting and the channel input clock frequency.

The analog watchdog filter conversion works like a regular Fast Continuous Conversion without the integrator. The number of serial samples needed for one result from analog watchdog filter output (at channel input clock frequency f_{CKIN}):

- **first conversion:**
  - for Sinc^x filters (x=1..5): number of samples = \[ F_{OSR} \cdot F_{ORD} + F_{ORD} + 1 \]
  - for FastSinc filter: number of samples = \[ F_{OSR} \cdot 4 + 2 + 1 \]
- **next conversions:**
  - for Sinc^x and FastSinc filters: number of samples = \[ F_{OSR} \cdot IOSR \]

where:
- \( F_{OSR} \) ...... filter oversampling ratio: \( F_{OSR} = AWF_{OSR}[4:0]+1 \) (see DFSDM_CHyAWSCDR register)
- \( F_{ORD} \) ...... the filter order: \( F_{ORD} = AWF_{ORD}[1:0] \) (see DFSDM_CHyAWSCDR register)

In case of output data register monitoring (AWFSEL=0), the comparison is done after a right bit shift and an offset correction of final data (see OFFSET[23:0] and DTRBS[4:0] fields in DFSDM_CHyCFGR2 register). A comparison is performed after each injected or regular end of conversion for the channels selected by AWDCH[3:0] field (in DFSDM_FLTxCBxCR2 register).

The status of an analog watchdog event is signalized in DFSDM_FLTxAWSR register where a given event is latched. AWHTF[y]=1 flag signalizes crossing AWHT[23:0] value on channel y. AWLTF[y]=1 flag signalizes crossing AWLT[23:0] value on channel y. Latched events in DFSDM_FLTxAWSR register are cleared by writing ‘1’ into the corresponding clearing bit CLRAWHTF[y] or CLRAWLTF[y] in DFSDM_FLTxCBxCFR register.

The global status of an analog watchdog is signalized by the AWDF flag bit in DFSDM_FLTxCBxISR register (it is used for the fast detection of an interrupt source). AWDF=1 signals that at least one watchdog occurred (AWHTF[y]=1 or AWLTF[y]=1 for at least one channel). AWDF bit is cleared when all AWHTF[3:0] and AWLTF[3:0] are cleared.

An analog watchdog event can be assigned to break output signal. There are four break outputs to be assigned to a high or low threshold crossing event (dbsd_break[3:0]). The break signal assignment to a given analog watchdog event is done by BKAWH[3:0] and BKAWL[3:0] fields in DFSDM_FLTxCBxAWHTR and DFSDM_FLTxCBxAWLTR register.

### 26.4.11 Short-circuit detector

The purpose of a short-circuit detector is to signalize with a very fast response time if an analog signal reached saturated values (out of full scale ranges) and remained on this value given time. This behavior can detect short-circuit or open circuit errors (e.g. overcurrent or overvoltage). An interrupt/event/break generation can be invoked.

Input data into a short-circuit detector is taken from channel transceiver outputs.

There is an upcounting counter on each input channel which is counting consecutive 0’s or 1’s on serial data receiver outputs. A counter is restarted if there is a change in the data stream received - 1 to 0 or 0 to 1 change of data signal. If this counter reaches a short-circuit threshold register value (SCDT[7:0] bits in DFSDM_CHyAWSCDR register), then a short-
circuit event is invoked. Each input channel has its short-circuit detector. Any channel can be selected to be continuously monitored by setting the SCDEN bit (in DFSDM_CHyCFGR1 register) and it has its own short-circuit detector settings (threshold value in SCDT[7:0] bits, status bit SCDF[3:0], status clearing bits CLRSCDF[3:0]). Status flag SCDF[y] is cleared also by hardware when corresponding channel y is disabled (CHEN[y] = 0).

On each channel, a short-circuit detector event can be assigned to break output signal dfsdm_break[3:0]. There are four break outputs to be assigned to a short-circuit detector event. The break signal assignment to a given channel short-circuit detector event is done by BKSCD[3:0] field in DFSDM_CHyAWSCDR register.

Short circuit detector cannot be used in case of parallel input data channel selection (DATMPX[1:0] ≠ 0 in DFSDM_CHyCFGR1 register).

Four break outputs are totally available (shared with the analog watchdog function).

26.4.12 Extreme detector

The purpose of an extremes detector is to collect the minimum and maximum values of final output data words (peak to peak values).

If the output data word is higher than the value stored in the extremes detector maximum register (EXMAX[23:0] bits in DFSDM_FLTxEXMAX register), then this register is updated with the current output data word value and the channel from which the data is stored is in EXMAXCH[1:0] bits (in DFSDM_FLTxEXMAX register).

If the output data word is lower than the value stored in the extremes detector minimum register (EXMIN[23:0] bits in DFSDM_FLTxEXMIN register), then this register is updated with the current output data word value and the channel from which the data is stored is in EXMINCH[1:0] bits (in DFSDM_FLTxEXMIN register).

The minimum and maximum register values can be refreshed by software (by reading given DFSDM_FLTxEXMAX or DFSDM_FLTxEXMIN register). After refresh, the extremes detector minimum data register DFSDM_FLTxEXMIN is filled with 0x7FFFFFFF (maximum positive value) and the extremes detector maximum register DFSDM_FLTxEXMAX is filled with 0x80000000 (minimum negative value).

The extremes detector performs a comparison after a right bit shift and an offset data correction. For each extremes detector, the input channels to be considered into computing the extremes value are selected in EXCH[3:0] bits (in DFSDM_FLTxCR2 register).

26.4.13 Data unit block

The data unit block is the last block of the whole processing path: External ΣΔ modulators - Serial transceivers - Sinc filter - Integrator - Data unit block.

The output data rate depends on the serial data stream rate, and filter and integrator settings. The maximum output data rate is:

\[
\text{Datarate [samples / s]} = \frac{f_{\text{CKIN}}}{F_{\text{OSR}} \cdot (I_{\text{OSR}} - 1 + F_{\text{ORD}}) + (F_{\text{ORD}} + 1)} \quad \text{...FAST = 0, Sinc filter}
\]

\[
\text{Datarate [samples / s]} = \frac{f_{\text{CKIN}}}{F_{\text{OSR}} \cdot (I_{\text{OSR}} - 1 + 4) + (2 + 1)} \quad \text{...FAST = 0, FastSinc filter}
\]
or

\[ \text{Datarate } \frac{\text{[samples / s]}}{\text{[FOSR]}} = \frac{f_{\text{CKIN}}}{F_{\text{OSR}}} \quad \text{FAST} = 1 \]

Maximum output data rate in case of parallel data input:

\[ \text{Datarate } \frac{\text{[samples / s]}}{\text{[FOSR]}} = \frac{f_{\text{DATAIN RATE}}}{F_{\text{OSR}}} \frac{1}{(1 + F_{\text{ORD}} + (F_{\text{ORD}} + 1))} \quad \text{FAST} = 0, \text{ Sinc}^x \text{ filter} \]

or

\[ \text{Datarate } \frac{\text{[samples / s]}}{\text{[FOSR]}} = \frac{f_{\text{DATAIN RATE}}}{F_{\text{OSR}}} \frac{1}{(1 + 4) + (2 + 1)} \quad \text{FAST} = 0, \text{ FastSinc filter} \]

or

\[ \text{Datarate } \frac{\text{[samples / s]}}{\text{[FOSR]}} = \frac{f_{\text{DATAIN RATE}}}{F_{\text{OSR}}} \frac{1}{(1 + 4) + (2 + 1)} \quad \text{FAST} = 1 \text{ or any filter bypass case } (F_{\text{OSR}} = 1) \]

where: \( f_{\text{DATAIN RATE}} \) ...input data rate from ADC or from CPU/DMA

The right bit-shift of final data is performed in this module because the final data width is 24-bit and data coming from the processing path can be up to 32 bits. This right bit-shift is configurable in the range 0-31 bits for each selected input channel (see DTRBS[4:0] bits in DFSDM_CHyCFGR2 register). The right bit-shift is rounding the result to nearest integer value. The sign of shifted result is maintained - to have valid 24-bit signed format of result data.

In the next step, an offset correction of the result is performed. The offset correction value (OFFSET[23:0] stored in register DFSDM_CHyCFGR2) is subtracted from the output data for a given channel. Data in the OFFSET[23:0] field is set by software by the appropriate calibration routine.

Due to the fact that all operations in digital processing are performed on 32-bit signed registers, the following conditions must be fulfilled not to overflow the result:

\[ \text{FOSR } F_{\text{ORD}} \cdot \text{IOSR} \leq 2^{31} \quad \text{for Sinc}^x \text{ filters, } x = 1 \ldots 5 \]
\[ 2 \cdot \text{FOSR } F_{\text{ORD}} \cdot \text{IOSR} \leq 2^{31} \quad \text{for FastSinc filter} \]

Note: In case of filter and integrator bypass \((\text{IOSR}[7:0]=0, \text{FOSR}[9:0]=0)\), the input data rate \( f_{\text{DATAIN RATE}} \) must be limited to be able to read all output data:

\[ f_{\text{DATAIN RATE}} \leq f_{\text{APB}} \]

where \( f_{\text{APB}} \) is the bus frequency to which the DFSDM peripheral is connected.

### 26.4.14 Signed data format

Each DFSDM input serial channel can be connected to one external \( \Sigma \Delta \) modulator. An external \( \Sigma \Delta \) modulator can have 2 differential inputs (positive and negative) which can be used for a differential or single-ended signal measurement.

A \( \Sigma \Delta \) modulator output is always assumed in a signed format (a data stream of zeros and ones from a \( \Sigma \Delta \) modulator represents values -1 and +1).
**Signed data format in registers:** Data is in a signed format in registers for final output data, analog watchdog, extremes detector, offset correction. The msb of output data word represents the sign of value (two’s complement format).

### 26.4.15 Launching conversions

**Injected conversions** can be launched using the following methods:

- **Software:** writing ‘1’ to JSWSTART in the DFSDM_FLTxCR1 register.
- **Trigger:** JEXTSEL[4:0] selects the trigger signal while JEXTEN activates the trigger and selects the active edge at the same time (see the DFSDM_FLTxCR1 register).
- **Synchronous with DFSDM_FLT0 if JSYNC=1:** for DFSDM_FLTx (x>0), an injected conversion is automatically launched when in DFSDM_FLT0; the injected conversion is started by software (JSWSTART=1 in DFSDM_FLT0CR2 register). Each injected conversion in DFSDM_FLTx (x>0) is always executed according to its local configuration settings (JSCAN, JCHG, etc.).

If the scan conversion is enabled (bit JSCAN=1) then, each time an injected conversion is triggered, all of the selected channels in the injected group (JCHG[3:0] bits in DFSDM_FLTxJCHGR register) are converted sequentially, starting with the lowest channel (channel 0, if selected).

If the scan conversion is disabled (bit JSCAN=0) then, each time an injected conversion is triggered, only one of the selected channels in the injected group (JCHG[3:0] bits in DFSDM_FLTxJCHGR register) is converted and the channel selection is then moved to the next selected channel. Writing to the JCHG[3:0] bits when JSCAN=0 sets the channel selection to the lowest selected injected channel.

Only one injected conversion can be ongoing at a given time. Thus, any request to launch an injected conversion is ignored if another request for an injected conversion has already been issued but not yet completed.

**Regular conversions** can be launched using the following methods:

- **Software:** by writing ‘1’ to RSWSTART in the DFSDM_FLTxCR1 register.
- **Synchronous with DFSDM_FLT0 if RSYNC=1:** for DFSDM_FLTx (x>0), a regular conversion is automatically launched when in DFSDM_FLT0; a regular conversion is started by software (RSWSTART=1 in DFSDM_FLT0CR2 register). Each regular conversion in DFSDM_FLTx (x>0) is always executed according to its local configuration settings (RCONT, RCH, etc.).

Only one regular conversion can be pending or ongoing at a given time. Thus, any request to launch a regular conversion is ignored if another request for a regular conversion has already been issued but not yet completed. A regular conversion can be pending if it was interrupted by an injected conversion or if it was started while an injected conversion was in progress. This pending regular conversion is then delayed and is performed when all injected conversion are finished. Any delayed regular conversion is signalized by RPEND bit in DFSDM_FLTxRDATAR register.

### 26.4.16 Continuous and fast continuous modes

Setting RCONT in the DFSDM_FLTxCR1 register causes regular conversions to execute in continuous mode. RCONT=1 means that the channel selected by RCH[1:0] is converted repeatedly after ‘1’ is written to RSWSTART.
The regular conversions executing in continuous mode can be stopped by writing ‘0’ to RCONT. After clearing RCONT, the on-going conversion is stopped immediately.

In continuous mode, the data rate can be increased by setting the FAST bit in the DFSDM_FLTxCR1 register. In this case, the filter does not need to be refilled by new fresh data if converting continuously from one channel because data inside the filter is valid from previously sampled continuous data. The speed increase depends on the chosen filter order. The first conversion in fast mode (FAST=1) after starting a continuous conversion by RSWSTART=1 takes still full time (as when FAST=0), then each subsequent conversion is finished in shorter intervals.

Conversion time in continuous mode:
- if FAST = 0 (or first conversion if FAST=1):
  - for Sinc filters:
    \[ t = \frac{CNVCNT}{f_{DFSDMCLK}} = \frac{[FOSR \times (IOSR-1 + FORD) + FORD]}{f_{CKIN}} \]
  - for FastSinc filter:
    \[ t = \frac{CNVCNT}{f_{DFSDMCLK}} = \frac{[FOSR \times (IOSR-1 + 4) + 2]}{f_{CKIN}} \]
- if FAST = 1 (except first conversion):
  - for Sinc and FastSinc filters:
    \[ t = \frac{CNVCNT}{f_{DFSDMCLK}} = \frac{[FOSR \times IOSR]}{f_{CKIN}} \]
  - in case \( FOSR = FOSR[9:0]+1 = 1 \) (filter bypassed, only integrator active):
    \[ t = \frac{IOSR}{f_{CKIN}} \]

Continuous mode is not available for injected conversions. Injected conversions can be started by timer trigger to emulate the continuous mode with precise timing.

If a regular continuous conversion is in progress (RCONT=1) and if a write access to DFSDM_FLTxCR1 register requesting regular continuous conversion (RCONT=1) is performed, then regular continuous conversion is restarted from the next conversion cycle (like new regular continuous conversion is applied for new channel selection - even if there is no change in DFSDM_FLTxCR1 register).

### 26.4.17 Request precedence

An injected conversion has a higher precedence than a regular conversion. A regular conversion which is already in progress is immediately interrupted by the request of an injected conversion; this regular conversion is restarted after the injected conversion finishes.

An injected conversion cannot be launched if another injected conversion is pending or already in progress: any request to launch an injected conversion (either by JSWSTART or by a trigger) is ignored as long as bit JCIP is ‘1’ (in the DFSDM_FLTxISR register).

Similarly, a regular conversion cannot be launched if another regular conversion is pending or already in progress: any request to launch a regular conversion (using RSWSTART) is ignored as long as bit RCIP is ‘1’ (in the DFSDM_FLTxISR register).

However, if an injected conversion is requested while a regular conversion is already in progress, the regular conversion is immediately stopped and an injected conversion is launched. The regular conversion is then restarted and this delayed restart is signalized in bit RPEND.

Injected conversions have precedence over regular conversions in that a injected conversion can temporarily interrupt a sequence of continuous regular conversions. When
the sequence of injected conversions finishes, the continuous regular conversions start again if RCONT is still set (and RPEND bit will signalize the delayed start on the first regular conversion result).

Precedence also matters when actions are initiated by the same write to DFSDM, or if multiple actions are pending at the end of another action. For example, suppose that, while an injected conversion is in process (JCIP=1), a single write operation to DFSDMFLTxCR1 writes ‘1’ to RSWSTART, requesting a regular conversion. When the injected sequence finishes, the precedence dictates that the regular conversion is performed next and its delayed start is signalized in RPEND bit.

26.4.18 Power optimization in run mode

In order to reduce the consumption, the DFSDM filter and integrator are automatically put into idle when not used by conversions (RCIP=0, JCIP=0).

26.5 DFSDM interrupts

In order to increase the CPU performance, a set of interrupts related to the CPU event occurrence has been implemented:

- **End of injected conversion interrupt:**
  - enabled by JEOCIE bit in DFSDMFLTxCR2 register
  - indicated in JEOCF bit in DFSDMFLTxISR register
  - cleared by reading DFSDMFLTxJDATAR register (injected data)
  - indication of which channel end of conversion occurred, reported in JDATACH[1:0] bits in DFSDMFLTxJDATAR register

- **End of regular conversion interrupt:**
  - enabled by REOCIE bit in DFSDMFLTxCR2 register
  - indicated in REOCF bit in DFSDMFLTxISR register
  - cleared by reading DFSDMFLTxRDATAR register (regular data)
  - indication of which channel end of conversion occurred, reported in RDATACH[1:0] bits in DFSDMFLTxRDATAR register

- **Data overrun interrupt for injected conversions:**
  - occurred when injected converted data were not read from DFSDMFLTxJDATAR register (by CPU or DMA) and were overwritten by a new injected conversion
  - enabled by JOVRIE bit in DFSDMFLTxCR2 register
  - indicated in JOVRF bit in DFSDMFLTxISR register
  - cleared by writing ‘1’ into CLRJOVRF bit in DFSDMFLTxICR register

- **Data overrun interrupt for regular conversions:**
  - occurred when regular converted data were not read from DFSDMFLTxRDATAR register (by CPU or DMA) and were overwritten by a new regular conversion
  - enabled by ROVRIE bit in DFSDMFLTxCR2 register
  - indicated in ROVRF bit in DFSDMFLTxISR register
  - cleared by writing ‘1’ into CLRROVRF bit in DFSDMFLTxICR register

- **Analog watchdog interrupt:**
– occurred when converted data (output data or data from analog watchdog filter - according to AWFSSEL bit setting in DFSDM_FLTxCR1 register) crosses over/under high/low thresholds in DFSDM_FLTxAWHTR / DFSDM_FLTxAWLTR registers
– enabled by AWDIE bit in DFSDM_FLTxCR2 register (on selected channels AWDCH[3:0])
– indicated in AWDF bit in DFSDM_FLTxISR register
– separate indication of high or low analog watchdog threshold error by AWHTF[3:0] and AWLTF[3:0] fields in DFSDM_FLTxAWSR register
– cleared by writing ‘1’ into corresponding CLRAWHTF[3:0] or CLRAWLTF[3:0] bits in DFSDM_FLTxAWCFR register

• Short-circuit detector interrupt:
  – occurred when the number of stable data crosses over thresholds in DFSDM_Ch-yAWSCDR register
  – enabled by SCDIE bit in DFSDM_FLTxCR2 register (on channel selected by SCDEN bit in DFSDM_Ch-yCFGR1 register)
  – indicated in SCDF[3:0] bits in DFSDM_FLTxISR register (which also reports the channel on which the short-circuit detector event occurred)
  – cleared by writing ‘1’ into the corresponding CLRSCDF[3:0] bit in DFSDM_FLTxICR register

• Channel clock absence interrupt:
  – occurred when there is clock absence on CKINy pin (see Clock absence detection in Section 26.4.4: Serial channel transceivers)
  – enabled by CKABIE bit in DFSDM_FLTxCR2 register (on channels selected by CKABEN bit in DFSDM_Ch-yCFGR1 register)
  – indicated in CKABF[y] bit in DFSDM_FLTxISR register
  – cleared by writing ‘1’ into CLRCKABF[y] bit in DFSDM_FLTxICR register

26.6 DFSDM DMA transfer

To decrease the CPU intervention, conversions can be transferred into memory using a DMA transfer. A DMA transfer for injected conversions is enabled by setting bit JDMAEN=1 in DFSDM_FLTxCR1 register. A DMA transfer for regular conversions is enabled by setting bit RDMAEN=1 in DFSDM_FLTxCR1 register.

Note: With a DMA transfer, the interrupt flag is automatically cleared at the end of the injected or regular conversion (JEOCF or REOCF bit in DFSDM_FLTxEISR register) because DMA is reading DFSDM_FLTxJDATAR or DFSDM_FLTxRDATAR register.

26.7 DFSDM channel y registers (y=0..3)

Word access (32-bit) must be used for registers write access except DFSDM_CHyDATINR register. Write access to DFSDM_CHyDATINR register can be either word access (32-bit) or half-word access (16-bit).

26.7.1 DFSDM channel y configuration register (DFSDM_CHyCFGR1)

This register specifies the parameters used by channel y.

Address offset: 0x00 + 0x20 * y, (y = 0 to 3)

Reset value: 0x0000 0000

<td>Note: CKOUTSRC is present only in DFSDM_CH0CFGR1 register (channel y=0)</td>
</tr>
</tbody>
</table>

Bits 29:24 Reserved, must be kept at reset value.
Bits 23:16 **CKOUTDIV[7:0]**: Output serial clock divider

0: Output clock generation is disabled (CKOUT signal is set to low state)
1-255: Defines the division of system clock for the serial clock output for CKOUT signal in range 2 - 256 (Divider = CKOUTDIV+1).

CKOUTDIV also defines the threshold for a clock absence detection.
This value can only be modified when DFSDMEN=0 (in DFSDM_CH0CFG1 register).
If DFSDMEN=0 (in DFSDM_CH0CFG1 register) then CKOUT signal is set to low state (setting is performed one DFSDM clock cycle after DFSDMEN=0).

*Note: CKOUTDIV is present only in DFSDM_CH0CFG1 register (channel y=0)*

Bits 15:14 **DATPACK[1:0]**: Data packing mode in DFSDM_CHyDATINR register.

0: Standard: input data in DFSDM_CHyDATINR register are stored only in INDAT0[15:0]. To empty DFSDM_CHyDATINR register one sample must be read by the DFSDM filter from channel y.
1: Interleaved: input data in DFSDM_CHyDATINR register are stored as two samples:
--first sample in INDAT0[15:0] (assigned to channel y)
--second sample INDAT1[15:0] (assigned to channel y)

To empty DFSDM_CHyDATINR register, two samples must be read by the digital filter from channel y (INDAT0[15:0] part is read as first sample and then INDAT1[15:0] part is read as next sample).
2: Dual: input data in DFSDM_CHyDATINR register are stored as two samples:
--first sample INDAT0[15:0] (assigned to channel y)
--second sample INDAT1[15:0] (assigned to channel y+1)

To empty DFSDM_CHyDATINR register first sample must be read by the digital filter from channel y and second sample must be read by another digital filter from channel y+1. Dual mode is available only on even channel numbers (y = 0, 2), for odd channel numbers (y = 1, 3) DFSDM_CHyDATINR is write protected. If an even channel is set to dual mode then the following odd channel must be set into standard mode (DATPACK[1:0]=0) for correct cooperation with even channel.
3: Reserved
This value can be modified only when CHEN=0 (in DFSDM_CHyCFG1 register).

Bits 13:12 **DATMPX[1:0]**: Input data multiplexer for channel y

0: Data to channel y are taken from external serial inputs as 1-bit values. DFSDM_CHyDATINR register is write protected.
1: Data to channel y are taken from internal analog to digital converter ADCy+1 output register update as 16-bit values (if ADCy+1 is available). Data from ADCs are written into INDAT0[15:0] part of DFSDM_CHyDATINR register.
2: Data to channel y are taken from internal DFSDM_CHyDATINR register by direct CPU/DMA write.
   There can be written one or two 16-bit data samples according DATPACK[1:0] bit field setting.
3: Reserved
This value can be modified only when CHEN=0 (in DFSDM_CHyCFG1 register).

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **CHINSEL**: Channel inputs selection
0: Channel inputs are taken from pins of the same channel y.
1: Channel inputs are taken from pins of the following channel (channel (y+1) modulo 8).
This value can be modified only when CHEN=0 (in DFSDM_CHyCFG1 register).

Bit 7 **CHEN**: Channel y enable
0: Channel y disabled
1: Channel y enabled
If channel y is enabled, then serial data receiving is started according to the given channel setting.
Bit 6 **CKABEN**: Clock absence detector enable on channel y
0: Clock absence detector disabled on channel y
1: Clock absence detector enabled on channel y

Bit 5 **SCDEN**: Short-circuit detector enable on channel y
0: Input channel y will not be guarded by the short-circuit detector
1: Input channel y will be continuously guarded by the short-circuit detector

Bit 4 Reserved, must be kept at reset value.

Bits 3:2 **SPICSEL[1:0]**: SPI clock select for channel y
0: Clock coming from external CKINy input - sampling point according SITP[1:0]
1: Clock coming from internal CKOUT output - sampling point according SITP[1:0]
2: Clock coming from internal CKOUT - sampling point on each second CKOUT falling edge.
   For connection to external ΣΔ modulator which divides its clock input (from CKOUT) by 2 to
generate its output serial communication clock (and this output clock change is active on each
clock input rising edge).
3: Clock coming from internal CKOUT output - sampling point on each second CKOUT rising edge.
   For connection to external ΣΔ modulator which divides its clock input (from CKOUT) by 2 to
generate its output serial communication clock (and this output clock change is active on each
clock input falling edge).
This value can be modified only when CHEN=0 (in DFSDM_CHyCFGR1 register).

Bits 1:0 **SITP[1:0]**: Serial interface type for channel y
00: SPI with rising edge to strobe data
01: SPI with falling edge to strobe data
10: Manchester coded input on DATINy pin: rising edge = logic 0, falling edge = logic 1
11: Manchester coded input on DATINy pin: rising edge = logic 1, falling edge = logic 0
This value can only be modified when CHEN=0 (in DFSDM_CHyCFGR1 register).

### 26.7.2 DFSDM channel y configuration register (DFSDM_CHyCFGR2)

This register specifies the parameters used by channel y.

Address offset: 0x04 + 0x20 * y, (y = 0 to 3)

Reset value: 0x0000 0000
26.7.3 DFSDM channel y analog watchdog and short-circuit detector register (DFSDM_CHyAWSCDR)

Short-circuit detector and analog watchdog settings for channel y.

Address offset: 0x08 + 0x20 * y, (y = 0 to 3)

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits 31:8 <strong>OFFSET[23:0]</strong>: 24-bit calibration offset for channel y</td>
</tr>
<tr>
<td>For channel y, OFFSET is applied to the results of each conversion from this channel. This value is set by software.</td>
</tr>
</tbody>
</table>

| Bits 7:3 **DTRBS[4:0]**: Data right bit-shift for channel y |
| 0-31: Defines the shift of the data result coming from the integrator - how many bit shifts to the right will be performed to have final results. Bit-shift is performed before offset correction. The data shift is rounding the result to nearest integer value. The sign of shifted result is maintained (to have valid 24-bit signed format of result data). |
| This value can be modified only when CHEN=0 (in DFSDM_CHyCFGR1 register). |

| Bits 2:0 Reserved, must be kept at reset value. |

**AWFORD[1:0]**: Analog watchdog Sinc filter order on channel y

0: FastSinc filter type
1: Sinc\(^1\) filter type
2: Sinc\(^2\) filter type
3: Sinc\(^3\) filter type

Sinc\(^x\) filter type transfer function:

\[
H(z) = \left(\frac{1 - Z^{-FOSR}}{1 - Z^{-1}}\right)^x
\]

FastSinc filter type transfer function:

\[
H(z) = \left(\frac{1 - Z^{-FOSR}}{1 - Z^{-1}}\right)^2 \cdot (1 + Z^{-2 \cdot FOSR})
\]

This bit can be modified only when CHEN=0 (in DFSDM_CHyCFGR1 register).

**AWFOSR[4:0]**: Analog watchdog filter oversampling ratio (decimation rate) on channel y

0 - 31: Defines the length of the Sinc type filter in the range 1 - 32 (AWFOSR + 1). This number is also the decimation ratio of the analog data rate.

This bit can be modified only when CHEN=0 (in DFSDM_CHyCFGR1 register).

*Note: If AWFOSR = 0 then the filter has no effect (filter bypass).*
26.7.4 DFSDM channel y watchdog filter data register
(DFSDM_CHANWDATR)

This register contains the data resulting from the analog watchdog filter associated to the input channel y.

Address offset: 0x0C + 0x20 * y, (y = 0 to 3)
Reset value: 0x0000 0000

Bits 15:12 BKSCD[3:0]: Break signal assignment for short-circuit detector on channel y
BKSCD[i] = 0: Break i signal not assigned to short-circuit detector on channel y
BKSCD[i] = 1: Break i signal assigned to short-circuit detector on channel y

Bits 11:8 Reserved, must be kept at reset value.

Bits 7:0 SCDT[7:0]: short-circuit detector threshold for channel y
These bits are written by software to define the threshold counter for the short-circuit detector. If this value is reached, then a short-circuit detector event occurs on a given channel.

26.7.5 DFSDM channel y data input register (DFSDM_CHANDATINR)

This register contains 16-bit input data to be processed by DFSDM filter module. Write access can be either word access (32-bit) or half-word access (16-bit).

Address offset: 0x10 + 0x20 * y, (y = 0 to 3)

Bits 31:16 **INDAT1[15:0]**: Input data for channel y or channel y+1

Input parallel channel data to be processed by the digital filter if DATMPX[1:0]=1 or DATMPX[1:0]=2. Data can be written by CPU/DMA (if DATMPX[1:0]=2) or directly by internal ADC (if DATMPX[1:0]=1).

If DATPACK[1:0]=0 (standard mode)

- INDAT0[15:0] is write protected (not used for input sample).

If DATPACK[1:0]=1 (interleaved mode)

- Second channel y data sample is stored into INDAT1[15:0]. First channel y data sample is stored into INDAT0[15:0]. Both samples are read sequentially by DFSDM_FLTx filter as two channel y data samples.

- INDAT0[15:0] is in the 16-bit signed format.

If DATPACK[1:0]=2 (dual mode).

- For even y channels: sample in INDAT1[15:0] is automatically copied into INDAT0[15:0] of channel (y+1).
- For odd y channels: INDAT1[15:0] is write protected.

See Section 26.4.6: Parallel data inputs for more details.

Bit 15:0 **INDAT0[15:0]**: Input data for channel y

Input parallel channel data to be processed by the digital filter if DATMPX[1:0]=1 or DATMPX[1:0]=2. Data can be written by CPU/DMA (if DATMPX[1:0]=2) or directly by internal ADC (if DATMPX[1:0]=1).

If DATPACK[1:0]=0 (standard mode)

- Channel y data sample is stored into INDAT0[15:0].

If DATPACK[1:0]=1 (interleaved mode)

- First channel y data sample is stored into INDAT0[15:0]. Second channel y data sample is stored into INDAT1[15:0]. Both samples are read sequentially by DFSDM_FLTx filter as two channel y data samples.

- INDAT0[15:0] is in the 16-bit signed format.

If DATPACK[1:0]=2 (dual mode).

- For even y channels: Channel y data sample is stored into INDAT0[15:0].
- For odd y channels: INDAT0[15:0] is write protected.

See Section 26.4.6: Parallel data inputs for more details.

| rw  | rw  | rw  | rw  | rw  | rw  | rw  | rw  | rw  | rw  | rw  | rt_w | rw  |

Bit 31  Reserved, must be kept at reset value.

Bit 30  AWFSEL: Analog watchdog fast mode select

0: Analog watchdog on data output value (after the digital filter). The comparison is done after offset correction and shift
1: Analog watchdog on channel transceivers value (after watchdog filter)

Bit 29  FAST: Fast conversion mode selection for regular conversions

0: Fast conversion mode disabled
1: Fast conversion mode enabled

When converting a regular conversion in continuous mode, having enabled the fast mode causes each conversion (except the first) to execute faster than in standard mode. This bit has no effect on conversions which are not continuous.

This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).

if FAST=0 (or first conversion in continuous mode if FAST=1):

\[
t = \left[ F_{\text{OSR}} \cdot (I_{\text{OSR}} - 1 + F_{\text{ORD}}) + F_{\text{ORD}} \right] / f_{\text{CKIN}} \quad \text{for Sinc}^x \text{ filters}
\]

\[
t = \left[ F_{\text{OSR}} \cdot (I_{\text{OSR}} - 1 + 4) + 2 \right] / f_{\text{CKIN}} \quad \text{for FastSinc filter}
\]

if FAST=1 in continuous mode (except first conversion):

\[
t = \left[ F_{\text{OSR}} \cdot I_{\text{OSR}} \right] / f_{\text{CKIN}}
\]

in case if \( F_{\text{OSR}} = F_{\text{OSR}}[9:0] + 1 = 1 \) (filter bypassed, active only integrator):

\[
t = I_{\text{OSR}} / f_{\text{CKIN}} \quad \text{(... but CNVCNT=0)}
\]

where: \( f_{\text{CKIN}} \) is the channel input clock frequency (on given channel CKINy pin) or input data rate in case of parallel data input.

Bits 28:26  Reserved, must be kept at reset value.
Bits 25:24 **RCH[1:0]**: Regular channel selection

0: Channel 0 is selected as the regular channel
1: Channel 1 is selected as the regular channel
...
3: Channel 3 is selected as the regular channel

Writing this bit when RCIP=1 takes effect when the next regular conversion begins. This is especially useful in continuous mode (when RCONT=1). It also affects regular conversions which are pending (due to ongoing injected conversion).

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **RDMAEN**: DMA channel enabled to read data for the regular conversion

0: The DMA channel is not enabled to read regular data
1: The DMA channel is enabled to read regular data

This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).

Bit 20 Reserved, must be kept at reset value.

Bit 19 **RSYNC**: Launch regular conversion synchronously with DFSDM_FLT0

0: Do not launch a regular conversion synchronously with DFSDM_FLT0
1: Launch a regular conversion in this DFSDM_FLTx at the very moment when a regular conversion is launched in DFSDM_FLT0

This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).

Bit 18 **RCONT**: Continuous mode selection for regular conversions

0: The regular channel is converted just once for each conversion request
1: The regular channel is converted repeatedly after each conversion request

Writing ‘0’ to this bit while a continuous regular conversion is already in progress stops the continuous mode immediately.

Bit 17 **RSWSTART**: Software start of a conversion on the regular channel

0: Writing ‘0’ has no effect
1: Writing ‘1’ makes a request to start a conversion on the regular channel and causes RCIP to become ‘1’. If RCIP=1 already, writing to RSWSTART has no effect. Writing ‘1’ has no effect if RSYNC=1.

This bit is always read as ‘0’.

Bits 16:15 Reserved, must be kept at reset value.

Bits 14:13 **JEXTEN[1:0]**: Trigger enable and trigger edge selection for injected conversions

00: Trigger detection is disabled
01: Each rising edge on the selected trigger makes a request to launch an injected conversion
10: Each falling edge on the selected trigger makes a request to launch an injected conversion
11: Both rising edges and falling edges on the selected trigger make requests to launch injected conversions

This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).
Bits 12:8 JEXTSEL[4:0]: Trigger signal selection for launching injected conversions

0x0-0x1F: Trigger inputs selected by the following table (internal or external trigger).

This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).

Note: synchronous trigger has latency up to one $f_{DFSDMCLK}$ clock cycle (with deterministic jitter), asynchronous trigger has latency 2-3 $f_{DFSDMCLK}$ clock cycles (with jitter up to 1 cycle).

DFSDM_FLTx
0x00 dfsdm_jtrg0
0x01 dfsdm_jtrg1
...
0x1E dfsdm_jtrg30
0x1F dfsdm_jtrg31
Refer to Table 200: DFSDM triggers connection.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 JDMAEN: DMA channel enabled to read data for the injected channel group

0: The DMA channel is not enabled to read injected data
1: The DMA channel is enabled to read injected data

This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).

Bit 4 JSCAN: Scanning conversion mode for injected conversions

0: One channel conversion is performed from the injected channel group and next the selected channel from this group is selected.
1: The series of conversions for the injected group channels is executed, starting over with the lowest selected channel.

This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).

Writing JCHG if JSCAN=0 resets the channel selection to the lowest selected channel.

Bit 3 JSYNC: Launch an injected conversion synchronously with the DFSDM_FLT0 JSWSTART trigger

0: Do not launch an injected conversion synchronously with DFSDM_FLT0
1: Launch an injected conversion in this DFSDM_FLTx at the very moment when an injected conversion is launched in DFSDM_FLT0 by its JSWSTART trigger

This bit can be modified only when DFEN=0 (DFSDM_FLTxCR1).

Bit 2 Reserved, must be kept at reset value.

Bit 1 JSWSTART: Start a conversion of the injected group of channels

0: Writing ‘0’ has no effect.
1: Writing ‘1’ makes a request to convert the channels in the injected conversion group, causing JCIP to become ‘1’ at the same time. If JCIP=1 already, then writing to JSWSTART has no effect. Writing ‘1’ has no effect if JSYNC=1.

This bit is always read as ‘0’.

Bit 0 DFEN: DFSDM_FLTx enable

0: DFSDM_FLTx is disabled. All conversions of given DFSDM_FLTx are stopped immediately and all DFSDM_FLTx functions are stopped.
1: DFSDM_FLTx is enabled. If DFSDM_FLTx is enabled, then DFSDM_FLTx starts operating according to its setting.

Data which are cleared by setting DFEN=0:
–register DFSDM_FLTxISR is set to the reset state
–register DFSDM_FLTxAWSR is set to the reset state
**DFSDM filter x control register 2 (DFSDM_FLTxCR2)**

Address offset: $0x104 + 0x80 \times x$, ($x = 0$ to 3)

Reset value: $0x0000\ 0000$

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:16 **AWDCH[3:0]**: Analog watchdog channel selection

These bits select the input channel to be guarded continuously by the analog watchdog.

$AWDCH[y] = 0$: Analog watchdog is disabled on channel $y$

$AWDCH[y] = 1$: Analog watchdog is enabled on channel $y$

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **EXCH[3:0]**: Extremes detector channel selection

These bits select the input channels to be taken by the Extremes detector.

$EXCH[y] = 0$: Extremes detector does not accept data from channel $y$

$EXCH[y] = 1$: Extremes detector accepts data from channel $y$

Bit 7 Reserved, must be kept at reset value.

Bit 6 **CKABIE**: Clock absence interrupt enable

0: Detection of channel input clock absence interrupt is disabled
1: Detection of channel input clock absence interrupt is enabled

Please see the explanation of **CKABF[3:0]** in DFSDM_FLTxISR.

**Note**: **CKABIE is present only in DFSDM_FLT0CR2 register (filter $x=0$)**

Bit 5 **SCDIE**: Short-circuit detector interrupt enable

0: short-circuit detector interrupt is disabled
1: short-circuit detector interrupt is enabled

Please see the explanation of **SCDF[3:0]** in DFSDM_FLTxISR.

**Note**: **SCDIE is present only in DFSDM_FLT0CR2 register (filter $x=0$)**

Bit 4 **AWDIE**: Analog watchdog interrupt enable

0: Analog watchdog interrupt is disabled
1: Analog watchdog interrupt is enabled

Please see the explanation of **AWDF** in DFSDM_FLTxISR.

Bit 3 **ROVRIE**: Regular data overrun interrupt enable

0: Regular data overrun interrupt is disabled
1: Regular data overrun interrupt is enabled

Please see the explanation of **ROVRF** in DFSDM_FLTxISR.
Bit 2 **JOVRIE**: Injected data overrun interrupt enable
- 0: Injected data overrun interrupt is disabled
- 1: Injected data overrun interrupt is enabled

Please see the explanation of JOVRF in DFSDM_FLT0ISR.

Bit 1 **REOCIE**: Regular end of conversion interrupt enable
- 0: Regular end of conversion interrupt is disabled
- 1: Regular end of conversion interrupt is enabled

Please see the explanation of REOCF in DFSDM_FLT0ISR.

Bit 0 **JEOCIE**: Injected end of conversion interrupt enable
- 0: Injected end of conversion interrupt is disabled
- 1: Injected end of conversion interrupt is enabled

Please see the explanation of JEOCF in DFSDM_FLT0ISR.

### 26.8.3 DFSDM filter x interrupt and status register (DFSDM_FLTxISR)

Address offset: 0x108 + 0x80 * x, (x = 0 to 3)

Reset value: 0x00FF 0000

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:24 **SCDF[3:0]**: short-circuit detector flag
- SCDF[y]=0: No short-circuit detector event occurred on channel y
- SCDF[y]=1: The short-circuit detector counter reaches, on channel y, the value programmed in the DFSDM_CHyAWSCDR registers

This bit is set by hardware. It can be cleared by software using the corresponding CLRSCDF[y] bit in the DFSDM_FLT0ISR register. SCDF[y] is cleared also by hardware when CHEN[y] = 0 (given channel is disabled).

*Note: SCDF[3:0] is present only in DFSDM_FLT0ISR register (filter x=0)*

Bits 23:20 Reserved, must be kept at reset value.

Bits 19:16 **CKABF[3:0]**: Clock absence flag
- CKABF[y]=0: Clock signal on channel y is present.
- CKABF[y]=1: Clock signal on channel y is not present.

Given y bit is set by hardware when clock absence is detected on channel y. It is held at CKABF[y]=1 state by hardware when CHEN=0 (see DFSDM_CHyCFGR1 register). It is held at CKABF[y]=1 state by hardware when the transceiver is not yet synchronized. It can be cleared by software using the corresponding CLRCKABF[y] bit in the DFSDM_FLT0ISR register.

*Note: CKABF[3:0] is present only in DFSDM_FLT0ISR register (filter x=0)*

Bit 15 Reserved, must be kept at reset value.
Bit 14 **RCIP**: Regular conversion in progress status
0: No request to convert the regular channel has been issued
1: The conversion of the regular channel is in progress or a request for a regular conversion is pending
A request to start a regular conversion is ignored when RCIP=1.

Bit 13 **JCIP**: Injected conversion in progress status
0: No request to convert the injected channel group (neither by software nor by trigger) has been issued
1: The conversion of the injected channel group is in progress or a request for an injected conversion is pending, due either to ‘1’ being written to JSWSTART or to a trigger detection
A request to start an injected conversion is ignored when JCIP=1.

Bits 12:5 Reserved, must be kept at reset value.

Bit 4 **AWDF**: Analog watchdog
0: No Analog watchdog event occurred
1: The analog watchdog block detected voltage which crosses the value programmed in the DFSDM_FLTxAWLTR or DFSDM_FLTxAWHTR registers.
This bit is set by hardware. It is cleared by software by clearing all source flag bits AWHTF[3:0] and AWLTF[3:0] in DFSDM_FLTxAWSR register (by writing ‘1’ into the clear bits in DFSDM_FLTxAWCFR register).

Bit 3 **ROVRF**: Regular conversion overrun flag
0: No regular conversion overrun has occurred
1: A regular conversion overrun has occurred, which means that a regular conversion finished while REOCF was already ‘1’. RDATAR is not affected by overruns
This bit is set by hardware. It can be cleared by software using the CLRROVRF bit in the DFSDM_FLTxCICR register.

Bit 2 **JOVRF**: Injected conversion overrun flag
0: No injected conversion overrun has occurred
1: An injected conversion overrun has occurred, which means that an injected conversion finished while JEOCF was already ‘1’. JDATAR is not affected by overruns
This bit is set by hardware. It can be cleared by software using the CLRJOVRF bit in the DFSDM_FLTxCICR register.

Bit 1 **REOCF**: End of regular conversion flag
0: No regular conversion has completed
1: A regular conversion has completed and its data may be read
This bit is set by hardware. It is cleared when the software or DMA reads DFSDM_FLTxDATAR.

Bit 0 **JEOCF**: End of injected conversion flag
0: No injected conversion has completed
1: An injected conversion has completed and its data may be read
This bit is set by hardware. It is cleared when the software or DMA reads DFSDM_FLTxJDATAR.

**Note:** For each of the flag bits, an interrupt can be enabled by setting the corresponding bit in DFSDM_FLTxCIR2. If an interrupt is called, the flag must be cleared before exiting the interrupt service routine.

All the bits of DFSDM_FLTxISR are automatically reset when DFEN=0.
26.8.4  DFSDM filter x interrupt flag clear register (DFSDM_FLT0ICR)

Address offset: 0x10C + 0x80 * x, (x = 0 to 3)
Reset value: 0x0000 0000

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:24 CLRSCDF[3:0]: Clear the short-circuit detector flag
CLRSCDF[y]=0: Writing '0' has no effect
CLRSCDF[y]=1: Writing '1' to position y clears the corresponding SCDF[y] bit in the DFSDM_FLT0ISR register

Note: CLRSCDF[3:0] is present only in DFSDM_FLT0ICR register (filter x=0)

Bits 23:20 Reserved, must be kept at reset value.

Bits 19:16 CLRCKABF[3:0]: Clear the clock absence flag
CLRCKABF[y]=0: Writing '0' has no effect
CLRCKABF[y]=1: Writing '1' to position y clears the corresponding CKABF[y] bit in the DFSDM_FLT0ISR register. When the transceiver is not yet synchronized, the clock absence flag is set and cannot be cleared by CLRCKABF[y].

Note: CLRCKABF[3:0] is present only in DFSDM_FLT0ICR register (filter x=0)

Bits 15:4 Reserved, must be kept at reset value.

Bit 3 CLRROVRF: Clear the regular conversion overrun flag
0: Writing '0' has no effect
1: Writing '1' clears the ROVRF bit in the DFSDM_FLT0ISR register

Bit 2 CLRJOVRF: Clear the injected conversion overrun flag
0: Writing '0' has no effect
1: Writing '1' clears the JOVRF bit in the DFSDM_FLT0ISR register

Bits 1:0 Reserved, must be kept at reset value.

Note: The bits of DFSDM_FLT0ICR are always read as '0'.
### 26.8.5 DFSDM filter x injected channel group selection register (DFSDM_FLTxJCHGR)

Address offset: 0x110 + 0x80 * x, (x = 0 to 3)

Reset value: 0x0000 0001

<table>
<thead>
<tr>

</tbody>
</table>

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 JCHG[3:0]: Injected channel group selection
- JCHG[y]=0: channel y is not part of the injected group
- JCHG[y]=1: channel y is part of the injected group

If JSCAN=1, each of the selected channels is converted, one after another. The lowest channel (channel 0, if selected) is converted first and the sequence ends at the highest selected channel.

If JSCAN=0, then only one channel is converted from the selected channels, and the channel selection is moved to the next channel. Writing JCHG, if JSCAN=0, resets the channel selection to the lowest selected channel.

At least one channel must always be selected for the injected group. Writes causing all JCHG bits to be zero are ignored.

### 26.8.6 DFSDM filter x control register (DFSDM_FLTxFCR)

Bits 31:29 **FORD[2:0]**: Sinc filter order
- 0: FastSinc filter type
- 1: Sinc1 filter type
- 2: Sinc2 filter type
- 3: Sinc3 filter type
- 4: Sinc4 filter type
- 5: Sinc5 filter type
- 6-7: Reserved

Sinc\(x\) filter type transfer function:

\[ H(z) = \left( 1 - z^{-FOSR} \right)^x \]

FastSinc filter type transfer function:

\[ H(z) = \left( 1 - z^{-FOSR} \right)^2 \cdot (1 + z^{-2 \cdot FOSR}) \]

This bit can only be modified when DFEN=0 (DFSDM_FLTxCR1).

Bits 28:26 Reserved, must be kept at reset value.

Bits 25:16 **FOSR[9:0]**: Sinc filter oversampling ratio (decimation rate)
- 0 - 1023: Defines the length of the Sinc type filter in the range 1 - 1024 (\(FOSR = FOSR[9:0] + 1\)). This number is also the decimation ratio of the output data rate from filter.
- This bit can only be modified when DFEN=0 (DFSDM_FLTxCR1)

*Note: If FOSR = 0, then the filter has no effect (filter bypass).*

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **IOSR[7:0]**: Integrator oversampling ratio (averaging length)
- 0 - 255: The length of the Integrator in the range 1 - 256 (\(IOSR + 1\)). Defines how many samples from Sinc filter will be summed into one output data sample from the integrator. The output data rate from the integrator will be decreased by this number (additional data decimation ratio).
- This bit can only be modified when DFEN=0 (DFSDM_FLTxCR1)

*Note: If IOSR = 0, then the Integrator has no effect (Integrator bypass).*

Bits 31:8 RDATA[23:0]: Regular channel conversion data
When each regular conversion finishes, its data is stored in this register. The data is valid when REOCF=1. Reading this register clears the corresponding REOCF.

Bits 3:2 Reserved, must be kept at reset value.

Bit 4 RPEND: Regular channel pending data
Regular data in RDATA[23:0] was delayed due to an injected channel trigger during the conversion

Bits 1:0 RDATA[1:0]: Regular channel most recently converted
When each regular conversion finishes, RDATA[1:0] is updated to indicate which channel was converted (because regular channel selection RCH[1:0] in DFSDM_FLTxCR1 register can be updated during regular conversion). Thus RDATA[23:0] holds the data that corresponds to the channel indicated by RDATA[1:0].

Note: Half-word accesses may be used to read only the MSBs of conversion data.
Reading this register also clears REOCF in DFSDM_FLTxISR.

Note: DMA may be used to read the data from this register. Half-word accesses may be used to read only the MSBs of conversion data.
Reading this register also clears JEOCF in DFSDM_FLTxISR. Thus, the firmware must not read this register if DMA is activated to read data from this register.
26.8.9  DFSDM filter x analog watchdog high threshold register
(DFSDM_FLTxAWHTR)

Address offset: 0x120 + 0x80 * x, (x = 0 to 3)
Reset value: 0x0000 0000

Bits 31:8  **AWHT[23:0]**: Analog watchdog high threshold

These bits are written by software to define the high threshold for the analog watchdog.

*Note*: In case channel transceivers monitor (AWFSEL=1), the higher 16 bits (AWHT[23:8]) define the 16-bit threshold as compared with the analog watchdog filter output (because data coming from the analog watchdog filter are up to a 16-bit resolution). Bits AWHT[7:0] are not taken into comparison in this case.

Bits 7:4  Reserved, must be kept at reset value.

Bits 3:0  **BKAWH[3:0]**: Break signal assignment to analog watchdog high threshold event

- **BKAWH[i]** = 0: Break i signal is not assigned to an analog watchdog high threshold event
- **BKAWH[i]** = 1: Break i signal is assigned to an analog watchdog high threshold event

26.8.10  DFSDM filter x analog watchdog low threshold register
(DFSDM_FLTxAWLTR)

Address offset: 0x124 + 0x80 * x, (x = 0 to 3)
Reset value: 0x0000 0000

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:8 \textbf{AWHTF}[3:0]: Analog watchdog high threshold flag
\textbf{AWHTF}[y]=1 indicates a high threshold error on channel y. It is set by hardware. It can be cleared by software using the corresponding CLR\textbf{AWHTF}[y] bit in the DFSDM_FLTxAWCFR register.

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 \textbf{AWLTF}[3:0]: Analog watchdog low threshold flag
\textbf{AWLTF}[y]=1 indicates a low threshold error on channel y. It is set by hardware. It can be cleared by software using the corresponding CLR\textbf{AWLTF}[y] bit in the DFSDM_FLTxAWCFR register.

\textbf{Note:} All the bits of \textbf{DFSDM}_FLTxAWSR are automatically reset when \textbf{DFEN}=0.
26.8.12 **DFSDM filter x analog watchdog clear flag register (DFSDM_FLTxAWCFR)**

Address offset: 0x12C + 0x80 * x, (x = 0 to 3)

Reset value: 0x0000 0000

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:8 **CLRAWHTF[3:0]**: Clear the analog watchdog high threshold flag
- CLRAWHTF[y]=0: Writing ‘0’ has no effect
- CLRAWHTF[y]=1: Writing ‘1’ to position y clears the corresponding AWHTF[y] bit in the DFSDM_FLTxAWSR register

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **CLRAWLTF[3:0]**: Clear the analog watchdog low threshold flag
- CLRAWLTF[y]=0: Writing ‘0’ has no effect
- CLRAWLTF[y]=1: Writing ‘1’ to position y clears the corresponding AWLTF[y] bit in the DFSDM_FLTxAWSR register

26.8.13 **DFSDM filter x extremes detector maximum register (DFSDM_FLTxEEXMAX)**

Address offset: 0x130 + 0x80 * x, (x = 0 to 3)

Reset value: 0x8000 0000

Bits 31:8 **EXMAX[23:8]**: Extremes detector maximum value
These bits are set by hardware and indicate the highest value converted by DFSDM_FLTx. EXMAX[23:0] bits are reset to value (0x800000) by reading of this register.

Bits 7:2 Reserved, must be kept at reset value.

Bits 1:0 **EXMAXCH[1:0]**: Extremes detector maximum data channel.
These bits contains information about the channel on which the data is stored into EXMAX[23:0]. Bits are cleared by reading of this register.
26.8.14 DFSDM filter x extremes detector minimum register (DFSDM_FLTxEXMIN)

Address offset: 0x134 + 0x80 * x, (x = 0 to 3)
Reset value: 0x7FFF FF00

Bits 31:8 EXMIN[23:0]: Extremes detector minimum value
These bits are set by hardware and indicate the lowest value converted by DFSDM_FLTx. EXMIN[23:0] bits are reset to value (0x7FFFFF) by reading of this register.

Bits 7:2 Reserved, must be kept at reset value.

Bits 1:0 EXMINCH[1:0]: Extremes detector minimum data channel
These bits contain information about the channel on which the data is stored into EXMIN[23:0]. Bits are cleared by reading of this register.

26.8.15 DFSDM filter x conversion timer register (DFSDM_FLTxCNVTIMR)

Address offset: 0x138 + 0x80 * x, (x = 0 to 3)
Reset value: 0x0000 0000
**26.8.16 DFSDM register map**

Note: When conversion is interrupted (e.g. by disable/enable selected channel) the timer counts also this interruption time.

**Bits 31:4 CNVCNT[27:0]:** 28-bit timer counting conversion time \( t = \text{CNVCNT}[27:0] / f_{\text{DFSDMCLK}} \)

The timer has an input clock from DFSDM clock (system clock \( f_{\text{DFSDMCLK}} \)). Conversion time measurement is started on each conversion start and stopped when conversion finishes (interval between first and last serial sample). Only in case of filter bypass (FOSR[9:0] = 0) is the conversion time measurement stopped and CNVCNT[27:0] = 0. The counted time is:

- if FAST=0 (or first conversion in continuous mode if FAST=1):
  \[ t = \left( F_{\text{OSR}} \times (I_{\text{OSR}} - 1 + F_{\text{ORD}}) + F_{\text{ORD}} \right) / f_{\text{CKIN}} \]  for Sinc^c filters
  \[ t = \left( F_{\text{OSR}} \times (I_{\text{OSR}} - 1 + 4) + 2 \right) / f_{\text{CKIN}} \]  for FastSinc filter
- if FAST=1 in continuous mode (except first conversion):
  \[ t = \left( F_{\text{OSR}} \times I_{\text{OSR}} \right) / f_{\text{CKIN}} \]
- in case if FOSR = FOSR[9:0] + 1 = 1 (filter bypassed, active only integrator):
  \[ \text{CNVCNT} = 0 \] (counting is stopped, conversion time: \( t = I_{\text{OSR}} / f_{\text{CKIN}} \))

where: \( f_{\text{CKIN}} \) is the channel input clock frequency (on given channel CKINy pin) or input data rate in case of parallel data input (from internal ADC or from CPU/DMA write)

Refer to Section 2.3 on page 87 for the register boundary addresses.
27 Touch sensing controller (TSC)

27.1 Introduction
The touch sensing controller provides a simple solution for adding capacitive sensing functionality to any application. Capacitive sensing technology is able to detect finger presence near an electrode that is protected from direct touch by a dielectric (for example glass, plastic). The capacitive variation introduced by the finger (or any conductive object) is measured using a proven implementation based on a surface charge transfer acquisition principle.

The touch sensing controller is fully supported by the STMTouch touch sensing firmware library, which is free to use and allows touch sensing functionality to be implemented reliably in the end application.

27.2 TSC main features
The touch sensing controller has the following main features:

- Proven and robust surface charge transfer acquisition principle
- Supports up to 24 capacitive sensing channels
- Up to 8 capacitive sensing channels can be acquired in parallel offering a very good response time
- Spread spectrum feature to improve system robustness in noisy environments
- Full hardware management of the charge transfer acquisition sequence
- Programmable charge transfer frequency
- Programmable sampling capacitor I/O pin
- Programmable channel I/O pin
- Programmable max count value to avoid long acquisition when a channel is faulty
- Dedicated end of acquisition and max count error flags with interrupt capability
- One sampling capacitor for up to 3 capacitive sensing channels to reduce the system components
- Compatible with proximity, touchkey, linear and rotary touch sensor implementation
- Designed to operate with STMTouch touch sensing firmware library

Note: The number of capacitive sensing channels is dependent on the size of the packages and subject to IO availability.
27.3 TSC functional description

27.3.1 TSC block diagram

The block diagram of the touch sensing controller is shown in Figure 186.

27.3.2 Surface charge transfer acquisition overview

The surface charge transfer acquisition is a proven, robust and efficient way to measure a capacitance. It uses a minimum number of external components to operate with a single ended electrode type. This acquisition is designed around an analog I/O group composed of up to four GPIOs (see Figure 187). Several analog I/O groups are available to allow the acquisition of several capacitive sensing channels simultaneously and to support a larger number of capacitive sensing channels. Within a same analog I/O group, the acquisition of the capacitive sensing channels is sequential.

One of the GPIOs is dedicated to the sampling capacitor \( C_S \). Only one sampling capacitor I/O per analog I/O group must be enabled at a time.

The remaining GPIOs are dedicated to the electrodes and are commonly called channels. For some specific needs (such as proximity detection), it is possible to simultaneously enable more than one channel per analog I/O group.
The surface charge transfer acquisition principle consists of charging an electrode capacitance \( (C_X) \) and transferring a part of the accumulated charge into a sampling capacitor \( (C_S) \). This sequence is repeated until the voltage across \( C_S \) reaches a given threshold \( (V_{IH} \text{ in our case}) \). The number of charge transfers required to reach the threshold is a direct representation of the size of the electrode capacitance.

*Table 206* details the charge transfer acquisition sequence of the capacitive sensing channel 1. States 3 to 7 are repeated until the voltage across \( C_S \) reaches the given threshold. The same sequence applies to the acquisition of the other channels. The electrode serial resistor \( R_S \) improves the ESD immunity of the solution.

*Note:* \( G_x \_I/O_y \) where \( x \) is the analog I/O group number and \( y \) the GPIO number within the selected group.
The voltage variation over the time on the sampling capacitor C_S is detailed below:

Figure 188. Sampling capacitor voltage variation

27.3.3 Reset and clocks

The TSC clock source is the AHB clock (HCLK). Two programmable prescalers are used to generate the pulse generator and the spread spectrum internal clocks:

- The pulse generator clock (PGCLK) is defined using the PGPSC[2:0] bits of the TSC_CR register
- The spread spectrum clock (SSCLK) is defined using the SSPSC bit of the TSC_CR register

The Reset and Clock Controller (RCC) provides dedicated bits to enable the touch sensing controller clock and to reset this peripheral. For more information, refer to Section 9: Reset and clock control (RCC).
27.3.4 Charge transfer acquisition sequence

An example of a charge transfer acquisition sequence is detailed in Figure 189.

Figure 189. Charge transfer acquisition sequence

For higher flexibility, the charge transfer frequency is fully configurable. Both the pulse high state (charge of \( C_X \)) and the pulse low state (transfer of charge from \( C_X \) to \( C_S \)) duration can be defined using the CTPH[3:0] and CTPL[3:0] bits in the TSC_CR register. The standard range for the pulse high and low states duration is 500 ns to 2 µs. To ensure a correct measurement of the electrode capacitance, the pulse high state duration must be set to ensure that \( C_X \) is always fully charged.

A dead time where both the sampling capacitor I/O and the channel I/O are in input floating state is inserted between the pulse high and low states to ensure an optimum charge transfer acquisition sequence. This state duration is 1 periods of HCLK.

At the end of the pulse high state and if the spread spectrum feature is enabled, a variable number of periods of the SSCLK clock are added.

The reading of the sampling capacitor I/O, to determine if the voltage across \( C_S \) has reached the given threshold, is performed at the end of the pulse low state.

**Note:** The following TSC control register configurations are forbidden:
- bits PGPSC are set to ‘000’ and bits CTPL are set to ‘0000’
- bits PGPSC are set to ‘000’ and bits CTPL are set to ‘0001’
- bits PGPSC are set to ‘001’ and bits CTPL are set to ‘0000’
27.3.5 Spread spectrum feature

The spread spectrum feature allows to generate a variation of the charge transfer frequency. This is done to improve the robustness of the charge transfer acquisition in noisy environments and also to reduce the induced emission. The maximum frequency variation is in the range of 10% to 50% of the nominal charge transfer period. For instance, for a nominal charge transfer frequency of 250 kHz (4 µs), the typical spread spectrum deviation is 10% (400 ns) which leads to a minimum charge transfer frequency of ~227 kHz.

In practice, the spread spectrum consists of adding a variable number of SSCLK periods to the pulse high state using the principle shown below:

![Figure 190. Spread spectrum variation principle](image)

The table below details the maximum frequency deviation with different HCLK settings:

<table>
<thead>
<tr>
<th>f_HCLK</th>
<th>Spread spectrum step</th>
<th>Maximum spread spectrum deviation</th>
</tr>
</thead>
<tbody>
<tr>
<td>24 MHz</td>
<td>41.6 ns</td>
<td>10666.6 ns</td>
</tr>
<tr>
<td>48 MHz</td>
<td>20.8 ns</td>
<td>5333.3 ns</td>
</tr>
<tr>
<td>80 MHz</td>
<td>12.5 ns</td>
<td>3205.1 ns</td>
</tr>
<tr>
<td>110 MHz</td>
<td>9.09 ns</td>
<td>2327.3 ns</td>
</tr>
</tbody>
</table>

The spread spectrum feature can be disabled/enabled using the SSE bit in the TSC_CR register. The frequency deviation is also configurable to accommodate the device HCLK clock frequency and the selected charge transfer frequency through the SSPSC and SSD[6:0] bits in the TSC_CR register.

27.3.6 Max count error

The max count error prevents long acquisition times resulting from a faulty capacitive sensing channel. It consists of specifying a maximum count value for the analog I/O group counters. This maximum count value is specified using the MCV[2:0] bits in the TSC_CR register. As soon as an acquisition group counter reaches this maximum value, the ongoing acquisition is stopped and the end of acquisition (EOAF bit) and max count error (MCEF bit) flags are both set. An interrupt can also be generated if the corresponding end of acquisition (EOAIE bit) or max count error (MCEIE bit) interrupt enable bits are set.
27.3.7 **Sampling capacitor I/O and channel I/O mode selection**

To allow the GPIOs to be controlled by the touch sensing controller, the corresponding alternate function must be enabled through the standard GPIO registers and the GPIOxAFR registers.

The GPIOs modes controlled by the TSC are defined using the TSC_IOSCR and TSC_IOCCR register.

When there is no ongoing acquisition, all the I/Os controlled by the touch sensing controller are in default state. While an acquisition is ongoing, only unused I/Os (neither defined as sampling capacitor I/O nor as channel I/O) are in default state. The IODEF bit in the TSC_CR register defines the configuration of the I/Os which are in default state. The table below summarizes the configuration of the I/O depending on its mode.

<table>
<thead>
<tr>
<th>IODEF bit</th>
<th>Acquisition status</th>
<th>Unused I/O mode</th>
<th>Channel I/O mode</th>
<th>Sampling capacitor I/O mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 (output push-pull low)</td>
<td>No</td>
<td>Output push-pull low</td>
<td>Output push-pull low</td>
<td>Output push-pull low</td>
</tr>
<tr>
<td>0 (output push-pull low)</td>
<td>Ongoing</td>
<td>Output push-pull low</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>1 (input floating)</td>
<td>No</td>
<td>Input floating</td>
<td>Input floating</td>
<td>Input floating</td>
</tr>
<tr>
<td>1 (input floating)</td>
<td>Ongoing</td>
<td>Input floating</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>

**Unused I/O mode**

An unused I/O corresponds to a GPIO controlled by the TSC peripheral but not defined as an electrode I/O nor as a sampling capacitor I/O.

**Sampling capacitor I/O mode**

To allow the control of the sampling capacitor I/O by the TSC peripheral, the corresponding GPIO must be first set to alternate output open drain mode and then the corresponding Gx_IOy bit in the TSC_IOSCR register must be set.

Only one sampling capacitor per analog I/O group must be enabled at a time.

**Channel I/O mode**

To allow the control of the channel I/O by the TSC peripheral, the corresponding GPIO must be first set to alternate output push-pull mode and the corresponding Gx_IOy bit in the TSC_IOCCR register must be set.

For proximity detection where a higher equivalent electrode surface is required or to speed-up the acquisition process, it is possible to enable and simultaneously acquire several channels belonging to the same analog I/O group.

**Note:** *During the acquisition phase and even if the TSC peripheral alternate function is not enabled, as soon as the TSC_IOSCR or TSC_IOCCR bit is set, the corresponding GPIO analog switch is automatically controlled by the touch sensing controller.*
27.3.8 Acquisition mode

The touch sensing controller offers two acquisition modes:

- Normal acquisition mode: the acquisition starts as soon as the START bit in the TSC_CR register is set.
- Synchronized acquisition mode: the acquisition is enabled by setting the START bit in the TSC_CR register but only starts upon the detection of a falling edge or a rising edge and high level on the SYNC input pin. This mode is useful for synchronizing the capacitive sensing channels acquisition with an external signal without additional CPU load.

The GxE bits in the TSC_IOGCSR registers specify which analog I/O groups are enabled (corresponding counter is counting). The Cs voltage of a disabled analog I/O group is not monitored and this group does not participate in the triggering of the end of acquisition flag. However, if the disabled analog I/O group contains some channels, they are pulsed.

When the Cs voltage of an enabled analog I/O group reaches the given threshold, the corresponding GxS bit of the TSC_IOGCSR register is set. When the acquisition of all enabled analog I/O groups is complete (all GxS bits of all enabled analog I/O groups are set), the EOAF flag in the TSC_ISR register is set. An interrupt request is generated if the EOAIE bit in the TSC_IER register is set.

In the case that a max count error is detected, the ongoing acquisition is stopped and both the EOAF and MCEF flags in the TSC_ISR register are set. Interrupt requests can be generated for both events if the corresponding bits (EOAIE and MCEIE bits of the TSCIER register) are set. Note that when the max count error is detected the remaining GxS bits in the enabled analog I/O groups are not set.

To clear the interrupt flags, the corresponding EOAIC and MCEIC bits in the TSC_ICR register must be set.

The analog I/O group counters are cleared when a new acquisition is started. They are updated with the number of charge transfer cycles generated on the corresponding channel(s) upon the completion of the acquisition.

27.3.9 I/O hysteresis and analog switch control

In order to offer a higher flexibility, the touch sensing controller also allows to take the control of the Schmitt trigger hysteresis and analog switch of each Gx_IOy. This control is available whatever the I/O control mode is (controlled by standard GPIO registers or other peripherals) assuming that the touch sensing controller is enabled. This may be useful to perform a different acquisition sequence or for other purposes.

In order to improve the system immunity, the Schmitt trigger hysteresis of the GPIOs controlled by the TSC must be disabled by resetting the corresponding Gx_IOy bit in the TSC_IOHCR register.
27.4 TSC low-power modes

Table 209. Effect of low-power modes on TSC

<table>

<td></td>
</tr>
<tr>
<td>11111111</td>
<td>128x $t_{SSCLK}$</td>
</tr>
</tbody>
</table>

**Note:** These bits must not be modified when an acquisition is ongoing.
Bit 16 **SSE**: Spread spectrum enable
This bit is set and cleared by software to enable/disable the spread spectrum feature.
0: Spread spectrum disabled
1: Spread spectrum enabled
*Note: This bit must not be modified when an acquisition is ongoing.*

Bit 15 **SSPSC**: Spread spectrum prescaler
This bit is set and cleared by software. It selects the AHB clock divider used to generate the spread spectrum clock (SSCLK).
0: \( f_{HCLK} \)
1: \( f_{HCLK} /2 \)
*Note: This bit must not be modified when an acquisition is ongoing.*

Bits 14:12 **PGPSC[2:0]**: Pulse generator prescaler
These bits are set and cleared by software. They select the AHB clock divider used to generate the pulse generator clock (PGCLK).
000: \( f_{HCLK} \)
001: \( f_{HCLK} /2 \)
010: \( f_{HCLK} /4 \)
011: \( f_{HCLK} /8 \)
100: \( f_{HCLK} /16 \)
101: \( f_{HCLK} /32 \)
110: \( f_{HCLK} /64 \)
111: \( f_{HCLK} /128 \)
*Note: These bits must not be modified when an acquisition is ongoing.*
*Note: Some configurations are forbidden. Refer to the Section 27.3.4: Charge transfer acquisition sequence for details.*

Bits 11:8 Reserved, must be kept at reset value.

Bits 7:5 **MCV[2:0]**: Max count value
These bits are set and cleared by software. They define the maximum number of charge transfer pulses that can be generated before a max count error is generated.
000: 255
001: 511
010: 1023
011: 2047
100: 4095
101: 8191
110: 16383
111: reserved
*Note: These bits must not be modified when an acquisition is ongoing.*

Bit 4 **IODEF**: I/O Default mode
This bit is set and cleared by software. It defines the configuration of all the TSC I/Os when there is no ongoing acquisition. When there is an ongoing acquisition, it defines the configuration of all unused I/Os (not defined as sampling capacitor I/O or as channel I/O).
0: I/Os are forced to output push-pull low
1: I/Os are in input floating
*Note: This bit must not be modified when an acquisition is ongoing.*

Bit 3 **SYNCPOL**: Synchronization pin polarity
This bit is set and cleared by software to select the polarity of the synchronization input pin.
0: Falling edge only
1: Rising edge and high level
Bit 2 **AM**: Acquisition mode
   This bit is set and cleared by software to select the acquisition mode.
   0: Normal acquisition mode (acquisition starts as soon as START bit is set)
   1: Synchronized acquisition mode (acquisition starts if START bit is set and when the selected signal is detected on the SYNC input pin)
   
   **Note:** This bit must not be modified when an acquisition is ongoing.

Bit 1 **START**: Start a new acquisition
   This bit is set by software to start a new acquisition. It is cleared by hardware as soon as the acquisition is complete or by software to cancel the ongoing acquisition.
   0: Acquisition not started
   1: Start a new acquisition

Bit 0 **TSCE**: Touch sensing controller enable
   This bit is set and cleared by software to enable/disable the touch sensing controller.
   0: Touch sensing controller disabled
   1: Touch sensing controller enabled
   
   **Note:** When the touch sensing controller is disabled, TSC registers settings have no effect.

</table>

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **MCEF**: Max count error flag
This bit is set by hardware as soon as an analog I/O group counter reaches the max count value specified. It is cleared by software writing 1 to the bit MCEIC of the TSC_ICR register.
0: No max count error (MCE) detected
1: Max count error (MCE) detected

Bit 0 **EOAF**: End of acquisition flag
This bit is set by hardware when the acquisition of all enabled group is complete (all GxS bits of all enabled analog I/O groups are set or when a max count error is detected). It is cleared by software writing 1 to the bit EOAIC of the TSC_ICR register.
0: Acquisition is ongoing or not started
1: Acquisition is complete

Bits 31:0 **Gx_IOy**: Gx_IOy channel mode  
These bits are set and cleared by software to configure the Gx_IOy as a channel I/O.  
0: Gx_IOy unused  
1: Gx_IOy used as channel  
 noted: These bits must not be modified when an acquisition is ongoing.  
During the acquisition phase and even if the TSC peripheral alternate function is not enabled, as soon as the TSC_IOCCR bit is set, the corresponding GPIO analog switch is automatically controlled by the touch sensing controller.

## 27.6.9 TSC I/O group control status register (TSC_IOGCSR)

Address offset: 0x30  
Reset value: 0x0000 0000

Bits 31:24 Reserved, must be kept at reset value.  
Bits 23:16 **GxS**: Analog I/O group x status  
These bits are set by hardware when the acquisition on the corresponding enabled analog I/O group x is complete. They are cleared by hardware when a new acquisition is started.  
0: Acquisition on analog I/O group x is ongoing or not started  
1: Acquisition on analog I/O group x is complete  
 noted: When a max count error is detected the remaining GxS bits of the enabled analog I/O groups are not set.  

Bits 15:8 Reserved, must be kept at reset value.  
Bits 7:0 **GxE**: Analog I/O group x enable  
These bits are set and cleared by software to enable/disable the acquisition (counter is counting) on the corresponding analog I/O group x.  
0: Acquisition on analog I/O group x disabled  
1: Acquisition on analog I/O group x enabled
27.6.10  TSC I/O group x counter register (TSC_IOGxCr)

x represents the analog I/O group number.

Address offset: 0x30 + 0x04 * x, (x = 1..8)

Reset value: 0x0000 0000

Bits 31:14  Reserved, must be kept at reset value.

Bits 13:0  **CNT[13:0]:** Counter value

These bits represent the number of charge transfer cycles generated on the analog I/O group x to complete its acquisition (voltage across CS has reached the threshold).
## 27.6.11 TSC register map

### Table 211. TSC register map and reset values

| Offset   | Register | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

Refer to Section 2.3 on page 87 for the register boundary addresses.
28 True random number generator (RNG)

28.1 Introduction

The RNG is a true random number generator that provides full entropy outputs to the application as 32-bit samples. It is composed of a live entropy source (analog) and an internal conditioning component.

The RNG is a NIST SP 800-90B compliant entropy source that can be used to construct a non-deterministic random bit generator (NDRBG).

The RNG true random number generator has been pre-certified NIST SP800-90B. It has also been tested using German BSI statistical tests of AIS-31 (T0 to T8).

28.2 RNG main features

- The RNG delivers 32-bit true random numbers, produced by an analog entropy source conditioned by a NIST SP800-90B approved conditioning stage.
- It can be used as entropy source to construct a non-deterministic random bit generator (NDRBG).
- It produces four 32-bit random samples every 412 AHB clock cycles if \( f_{\text{AHB}} < 77 \text{ MHz} \) (256 RNG clock cycles otherwise).
- It embeds start-up and NIST SP800-90B approved continuous health tests (repetition count and adaptive proportion tests), associated with specific error management.
- It can be disabled to reduce power consumption, or enabled with an automatic low power mode (default configuration).
- It has an AMBA AHB slave peripheral, accessible through 32-bit word single accesses only (else an AHB bus error is generated, and the write accesses are ignored).
28.3 RNG functional description

28.3.1 RNG block diagram

*Figure 191* shows the RNG block diagram.

![RNG block diagram](image-url)

28.3.2 RNG internal signals

*Table 212* describes a list of useful-to-know internal signals available at the RNG level, not at the STM32 product level (on pads).

28.3.3 Random number generation

The true random number generator (RNG) delivers truly random data through its AHB interface at deterministic intervals.

Within its boundary RNG integrates all the required NIST components depicted on Figure 192. Those components are an analog noise source, a digitization stage, a conditioning algorithm, a health monitoring block and two interfaces that are used to interact with the entropy source: GetEntropy and HealthTest.

![Figure 192. NIST SP800-90B entropy source model](image)

The components pictured above are detailed hereafter:

**Noise source**

The noise source is the component that contains the non-deterministic, entropy-providing activity that is ultimately responsible for the uncertainty associated with the bitstring output by the entropy source. This noise source provides 1-bit samples. It is composed of:

- Multiple analog noise sources (x6), each based on three XORed free-running ring oscillator outputs. It is possible to disable those analog oscillators to save power, as described in Section 28.3.8: RNG low-power usage.
- The XORing of the 6 noise sources into a single analog output.
- A sampling stage of this output clocked by a dedicated clock input (rng_clk with integrated divider), delivering a 1-bit raw data output.

This noise source sampling is independent to the AHB interface clock frequency (rng_hclk), with a possibility for the software to decrease the sampling frequency by using the integrated divider.

**Note:** In Section 28.6: RNG entropy source validation recommended RNG clock frequencies and associated divider value are given.
Post processing

In NIST configuration no post-processing is applied to sampled noise source. In non-NIST configuration B (as defined in Section 28.6.2) a normalization debiasing is applied, i.e. half of the bits are taken from the sampled noise source, half of the bits are taken from inverted sampled noise source.

Conditioning

The conditioning component in the RNG is a deterministic function that increases the entropy rate of the resulting fixed-length bitstrings output (128-bit). The NIST SP800-90B target is full entropy on the output (i.e. 128-bit).

The times required between two random number generations, and between the RNG initialization and availability of first sample are described in Section 28.5: RNG processing time.

Output buffer

A data output buffer can store up to four 32-bit words that have been output from the conditioning component. When four words have been read from the output FIFO through the RNG_DR register, the content of the 128-bit conditioning output register is pushed into the output FIFO, and a new conditioning round is automatically started. Four new words are added to the conditioning output register after a number of clock cycles specified in Section 28.5: RNG processing time.

Whenever a random number is available through the RNG_DR register the DRDY flag transitions from “0” to “1”. This flag remains high until output buffer becomes empty after reading four words from the RNG_DR register.

Note: When interrupts are enabled an interrupt is generated when this data ready flag transitions from “0” to “1”. Interrupt is then cleared automatically by the RNG as explained above.
Health checks

This component ensures that the entire entropy source (with its noise source) starts then operates as expected, obtaining assurance that failures are caught quickly and with a high probability and reliability.

The RNG implements the following health check features in accordance with NIST SP800-90B. The described thresholds correspond to the value recommended for register RNG_HTCR (in Section 28.6.2).

1. **Start-up health tests, performed after reset and before the first use of the RNG as entropy source**
   - Adaptive proportion test running on one 1024 bit windows: the RNG verifies that the first bit on the outputs of the noise source is not repeated more than 691 times.
   - Known-answer tests, to verify the conditioning stage.
   - Repetition count test, flagging an error when the noise source has provided more than 40 consecutive bits at a constant value ("0" or "1")

2. **Continuous health tests, running indefinitely on the outputs of the noise source**
   - Repetition count test, similar to the one running in start-up tests
   - Adaptive proportion test running on 1024 consecutive samples, like during start-up health tests.

3. **Vendor specific continuous tests**
   - Transition count test, flagging an error when the noise source has delivered more than 32 consecutive occurrence of two bits patterns ("01" or "10").
   - Real-time "too slow" sampling clock detector, flagging an error when one RNG clock cycle (before divider) is smaller than AHB clock cycle divided by 32.

4. **On-demand test of digitized noise source (raw data)**
   - Supported by restarting the entropy source and re-running the startup tests (see software reset sequence in Section 28.3.4: RNG initialization). Other kinds of on-demand testing (software based) are not supported.

The CECS and SECS status bits in the RNG_SR register indicate when an error condition is detected, as detailed in Section 28.3.7: Error management.

**Note:** An interrupt can be generated when an error is detected.

Above health test thresholds are modified by changing value in RNG_HTCR register. See Section 28.6: RNG entropy source validation for details.
28.3.4 RNG initialization

The RNG simplified state machine is pictured on Figure 193.

After enabling the RNG (RNGEN=1 in RNG_CR) the following chain of events occurs:

1. The analog noise source is enabled, and by default the RNG waits 16 cycles of RNG clock cycles (before divider) before starting to sample analog output and filling 128-bit conditioning shift register.
2. The conditioning hardware initializes, automatically triggering start-up behavior test on the raw data samples and known-answer tests.
3. When start-up health tests are completed. During this time three 128-bit noise source samples are used.
4. The conditioning stage internal input data buffer is filled again with 128-bit and a number of conditioning rounds defined by the RNG configuration (NIST or non-NIST) is performed. The output buffer is then filled with the post processing result.
5. The output buffer is refilled automatically according to the RNG usage.

The associated initialization time can be found in Section 28.5: RNG processing time.

Figure 193. RNG initialization overview
Figure 193 also highlights a possible software reset sequence, implemented by:

a) Writing bits RNGEN=0 and CONDRST=1 in the RNG_CR register with the same RNG configuration and a new CLKDIV if needed.

b) Then writing RNGEN=1 and CONDRST=0 in the RNG_CR register.

c) Wait for random number to be ready, after initialization completes.

Note: When RNG peripheral is reset through RCC (hardware reset) the RNG configuration for optimal randomness is lost in RNG registers. Software reset with CONFIGLOCK set preserves the RNG configuration.

28.3.5 RNG operation

Normal operations

To run the RNG using interrupts the following steps are recommended:

1. Consult the Section 28.6: RNG entropy source validation on page 949 and verify if a specific RNG configuration is required for your application.
   – If it is the case, write in the RNG_CR register the bit CONDRST=“1” together with the correct RNG configuration. Then perform a second write to the RNG_CR register with the bit CONDRST=“0”, the interrupt enable bit IE=“1” and the RNG enable bit RNGEN=“1”.
   – If it is not the case perform a write to the RNG_CR register with the interrupt enable bit IE=“1” and the RNG enable bit RNGEN=“1”.

2. An interrupt is now generated when a random number is ready or when an error occurs. Therefore at each interrupt, check that:
   – No error occurred. The SEIS and CEIS bits should be set to 0 in the RNG_SR register.
   – A random number is ready. The DRDY bit must be set to 1 in the RNG_SR register.
   – If above two conditions are true the content of the RNG_DR register can be read up to four consecutive times. If valid data is available in the conditioning output buffer, four additional words can be read by the application (in this case the DRDY bit is still high). If one or both of above conditions are false, the RNG_DR register must not be read. If an error occurred error recovery sequence described in Section 28.3.7 must be used.

To run the RNG in polling mode following steps are recommended:

1. Consult the Section 28.6: RNG entropy source validation on page 949 and verify if a specific RNG configuration is required for your application.
   – If it is the case write in the RNG_CR register the bit CONDRST=“1” together with the correct RNG configuration. Then perform a second write to the RNG_CR register with the bit CONDRST=“0” and the RNG enable bit RNGEN=“1”.
   – If it is not the case only enable the RNG by setting the RNGEN bit to “1” in the RNG_CR register.

2. Read the RNG_SR register and check that:
   – No error occurred (the SEIS and CEIS bits should be set to 0)
   – A random number is ready (the DRDY bit should be set to 1)

3. If above conditions are true read the content of the RNG_DR register up to four consecutive times. If valid data is available in the conditioning output buffer four
additional words can be read by the application (in this case the DRDY bit is still high).
If one or both of above conditions are false, the RNG_DR register must not be read. If an error occurred error recovery sequence described in Section 28.3.7 must be used.

Note: When data is not ready (DRDY="0") RNG_DR returns zero.
It is recommended to always verify that RNG_DR is different from zero. Because when it is the case a seed error occurred between RNG_SR polling and RND_DR output reading (rare event).

If the random number generation period is a concern to the application and if NIST compliance is not required it is possible to select a faster RNG configuration by using the RNG configuration “B”, described in Section 28.6: RNG entropy source validation. The gain in random number generation speed is summarized in Section 28.5: RNG processing time.

Low-power operations
