Introduction

This document is addressed to application developers. It provides complete information on how to use the STM32F0x1/STM32F0x2/STM32F0x8 microcontroller memory and peripherals.

It applies to the STM32F031x4/x6, STM32F051x4/x6/x8, STM32F071x8/xB, STM32F091xB/xC, STM32F042x4/x6, STM32F072x8/xB, STM32F038x6, STM32F048x6, STM32F058x8, STM32F078xB and STM32F098xC devices.

For the purpose of this manual, STM32F0x1/STM32F0x2/STM32F0x8 microcontrollers are referred to as “STM32F0xx”.

The STM32F0xx is a family of microcontrollers with different memory sizes, packages and peripherals.

For ordering information, mechanical and electrical device characteristics, refer to the corresponding datasheet.

For information on the Arm® Cortex®-M0 core, refer to the Cortex®-M0 technical reference manual.

1 Documentation conventions

1.1 General information

The STM32F0xx devices have an Arm®(a) Cortex®-M0 core.

1.2 List of abbreviations for registers

The following abbreviations(b) are used in register descriptions:

- **read/write (rw)**: Software can read and write to this bit.
- **read-only (r)**: Software can only read this bit.
- **write-only (w)**: Software can only write to this bit. Reading this bit returns the reset value.
- **read/clear write0 (rc_w0)**: Software can read as well as clear this bit by writing 0. Writing 1 has no effect on the bit value.
- **read/clear write1 (rc_w1)**: Software can read as well as clear this bit by writing 1. Writing 0 has no effect on the bit value.
- **read/clear write (rc_w)**: Software can read as well as clear this bit by writing to the register. The value written to this bit is not important.
- **read/clear by read (rc_r)**: Software can read this bit. Reading this bit automatically clears it to 0. Writing this bit has no effect on the bit value.
- **read/set by read (rs_r)**: Software can read this bit. Reading this bit automatically sets it to 1. Writing this bit has no effect on the bit value.
- **read/set (rs)**: Software can read as well as set this bit. Writing 0 has no effect on the bit value.
- **read/write once (rwo)**: Software can only write once to this bit and can also read it at any time. Only a reset can return the bit to its reset value.
- **toggle (t)**: The software can toggle this bit by writing 1. Writing 0 has no effect.
- **read-only write trigger (rt_w1)**: Software can read this bit. Writing 1 triggers an event but has no effect on the bit value.
- **Reserved (Res.)**: Reserved bit, must be kept at reset value.

---

a. Arm is a registered trademark of Arm Limited (or its subsidiaries) in the US and/or elsewhere.

b. This is an exhaustive list of all abbreviations applicable to STMicroelectronics microcontrollers, some of them may not be used in the current document.
1.3 **Glossary**

This section gives a brief definition of acronyms and abbreviations used in this document:

- **Word**: data of 32-bit length.
- **Half-word**: data of 16-bit length.
- **Byte**: data of 8-bit length.
- **SWD-DP (SWD DEBUG PORT)**: SWD-DP provides a 2-pin (clock and data) interface based on the Serial Wire Debug (SWD) protocol. Please refer to the Cortex®-M0 technical reference manual.
- **IAP (in-application programming)**: IAP is the ability to re-program the flash memory of a microcontroller while the user program is running.
- **ICP (in-circuit programming)**: ICP is the ability to program the flash memory of a microcontroller using the JTAG protocol, the SWD protocol or the bootloader while the device is mounted on the user application board.
- **Option bytes**: product configuration bits stored in the flash memory.
- **OBL**: option byte loader.
- **AHB**: advanced high-performance bus.
- **APB**: advanced peripheral bus.

1.4 **Availability of peripherals**

For availability of peripherals and their number across all sales types, refer to the particular device datasheet.
2 System and memory overview

2.1 System architecture

The main system consists of:
- Up to three masters:
  - Cortex®-M0 core
  - General-purpose DMA1
  - General purpose DMA2 (available on STM32F09x devices only)
- Four slaves:
  - Internal SRAM
  - Internal flash memory
  - AHB1 with AHB to APB bridge, which connects all the APB peripherals
  - AHB2 dedicated to GPIO ports

These are interconnected using a multilayer AHB bus architecture, as shown in Figure 1:

Figure 1. System architecture

System bus
This bus connects the system bus of the Cortex®-M0 core (peripherals bus) to a BusMatrix which manages the arbitration between the core and the DMA.
DMA bus

This bus connects the AHB master interface of the DMA to the BusMatrix which manages the access of CPU and DMA to SRAM, flash memory and peripherals.

BusMatrix

The BusMatrix manages the access arbitration between the core system bus and the DMA master bus. The arbitration uses a Round Robin algorithm. The BusMatrix is composed of up to three masters (CPU, DMA1, DMA2) and four slaves (FLITF, SRAM, AHB1 with AHB to APB bridge and AHB2).

AHB peripherals are connected on system bus through a BusMatrix to allow DMA access.

AHB to APB bridge (APB)

The AHB to APB bridge provides full synchronous connections between the AHB and the APB bus.

Refer to Section 2.2.2: Memory map and register boundary addresses for the address mapping of the peripherals connected to this bridge.

After each device reset, all peripheral clocks are disabled (except for the SRAM and flash). Before using a peripheral you have to enable its clock in the RCC_AHBENR, RCC_APB2ENR or RCC_APB1ENR register.

Note: When a 16- or 8-bit access is performed on an APB register, the access is transformed into a 32-bit access: the bridge duplicates the 16- or 8-bit data to feed the 32-bit vector.
2.2 Memory organization

2.2.1 Introduction

Program memory, data memory, registers and I/O ports are organized within the same linear 4-Gbyte address space.

The bytes are coded in memory in Little Endian format. The lowest numbered byte in a word is considered the word’s least significant byte and the highest numbered byte the most significant.

The addressable memory space is divided into eight main blocks, of 512 Mbytes each.
2.2.2 Memory map and register boundary addresses

Figure 2. Memory map

All the memory map areas not allocated to on-chip memories and peripherals are considered “Reserved”. For the detailed mapping of available memory and register areas, refer to the following table, which gives the boundary addresses of the available peripherals.

Table 1. STM32F0xx peripheral register boundary addresses

2.3 Embedded SRAM

STM32F03x devices feature 4 Kbytes of static SRAM. STM32F04x devices feature 6 Kbytes of static SRAM. STM32F05x devices feature 8 Kbytes of static SRAM. STM32F07xS devices feature 16 Kbytes of static SRAM. STM32F09x devices feature 32 Kbytes of static SRAM.

This RAM can be accessed as bytes, half-words (16 bits) or full words (32 bits). This memory can be addressed at maximum system clock frequency without wait state and thus by both CPU and DMA.

Parity check

The user can enable the parity check using the option bit RAM_PARITY_CHECK in the user option byte (refer to Section 4: Option bytes).

The data bus width is 36 bits because 4 bits are available for parity check (1 bit per byte) in order to increase memory robustness, as required for instance by Class B or SIL norms.

The parity bits are computed and stored when writing into the SRAM. Then, they are automatically checked when reading. If one bit fails, an NMI is generated. The same error can also be linked to the BRK_IN Break input of TIM1/15/16/17, with the
SRAM_PARITY_LOCK control bit in the SYSCFG configuration register 2 (SYSCFG_CFRG2). The SRAM Parity Error flag (SRAM_PEF) is available in the SYSCFG configuration register 2 (SYSCFG_CFRG2).

Note: When enabling the RAM parity check, it is advised to initialize by software the whole RAM memory at the beginning of the code, to avoid getting parity errors when reading non-initialized locations.

2.4 Flash memory overview

The flash memory is composed of two distinct physical areas:

- The main flash memory block. It contains the application program and user data if necessary.
- The information block. It is composed of two parts:
  - option bytes for hardware and memory protection user configuration
  - system memory which contains the proprietary boot loader code (refer to Section 3: Embedded flash memory for more details.)

The flash interface implements instruction access and data access based on the AHB protocol. It implements the prefetch buffer that speeds up CPU code execution. It also implements the logic necessary to carry out the flash memory operations (Program/Erase) controlled through the flash registers.
2.5 Boot configuration

In the STM32F0xx, three different boot modes can be selected through the BOOT0 pin and boot configuration bits nBOOT1, BOOT_SEL and nBOOT0 in the User option byte, as shown in the following table.

Table 3. Boot modes

</tbody>
</table>

1. Grey options are available on STM32F04x and STM32F09x devices only.
2. For STM32F04x and STM32F09x devices, see also Empty check description.

The boot mode configuration is latched on the 4th rising edge of SYSCLK after a reset. It is up to the user to set boot mode configuration related to the required boot mode.

The boot mode configuration is also re-sampled when exiting from Standby mode. Consequently they must be kept in the required Boot mode configuration in Standby mode. After this startup delay has elapsed, the CPU fetches the top-of-stack value from address 0x0000 0000, then starts code execution from the boot memory at 0x0000 0004.

Depending on the selected boot mode, main flash memory, system memory or SRAM is accessible as follows:

- Boot from main flash memory: the main flash memory is aliased in the boot memory space (0x0000 0000), but still accessible from its original memory space (0x0800 0000). In other words, the flash memory contents can be accessed starting from address 0x0000 0000 or 0x0800 0000.
- Boot from system memory: the system memory is aliased in the boot memory space (0x0000 0000), but still accessible from its original memory space (0x1FFF EC00 on STM32F03x and STM32F05x devices, 0x1FFF C400 on STM32F04x devices, 0x1FFF C800 on STM32F07x and 0x1FFF D800 on STM32F09x devices).
- Boot from the embedded SRAM: the SRAM is aliased in the boot memory space (0x0000 0000), but it is still accessible from its original memory space (0x2000 0000).

Empty check

On STM32F04x and STM32F09x devices only, internal empty check flag is implemented to allow easy programming of virgin devices by the boot loader. This flag is used when BOOT0 pin is defining Main flash memory as the target boot area. When the flag is set, the device is considered as empty and System memory (boot loader) is selected instead of the main flash as a boot area to allow user to program the flash memory.
This flag is updated only during the loading of option bytes: it is set when the content of the address 0x08000 0000 is read as 0xFFFF FFFF, otherwise it is cleared. It means a power reset or setting of OBL_LAUNCH bit in FLASH_CR register is needed to clear this flag after programming of a virgin device to execute user code after System reset.

**Note:** If the device is programmed for a first time but the option bytes are not reloaded, the device still selects System memory as a boot area after a System reset. In the STM32F04x, the boot loader code is able to detect this situation. It then changes the boot memory mapping to main flash and performs a jump to user code programmed there. In the STM32F09x, a POR must be performed or the Option bytes reloaded before applying the system reset.

**Physical remap**

Once the boot mode is selected, the application software can modify the memory accessible in the code area. This modification is performed by programming the MEM_MODE bits in the **SYSCFG configuration register 1 (SYSCFG_CFGR1)**. Unlike Cortex® M3 and M4, the M0 CPU does not support the vector table relocation. For application code which is located in a different address than 0x0800 0000, some additional code must be added in order to be able to serve the application interrupts. A solution is to relocate by software the vector table to the internal SRAM:

- Copy the vector table from the flash (mapped at the base of the application load address) to the base address of the SRAM at 0x2000 0000.
- Remap SRAM at address 0x0000 0000, using SYSCFG configuration register 1.
- Then once an interrupt occurs, the Cortex®-M0 processor fetches the interrupt handler start address from the relocated vector table in SRAM, then it jumps to execute the interrupt handler located in the flash.

This operation should be done at the initialization phase of the application. Please refer to AN4065 and attached IAP code from [www.st.com](http://www.st.com) for more details.

**Embedded boot loader**

The embedded boot loader is located in the System memory, programmed by ST during production. It is used to reprogram the flash memory using one of the following serial interfaces:

- **USART** on pins PA9/PA10, PA14/PA15 or PA2/PA3
- **I2C** on pins PB6/PB7 (STM32F04xxx, STM32F07xxx and STM32F09xxx devices only)
- **USB DFU interface** (STM32F04xxx and STM32F07xxx devices only)

For further details, refer to the application note AN2606.
3 Embedded flash memory

3.1 Flash main features

- Up to 256 Kbyte of flash memory
- Memory organization:
  - Main flash memory block: Up to 64 Kword (64 K × 32 bits)
  - Information block: Up to 3 Kword (3 K × 32 bits) for the system memory
  - Up to 2 x 8 byte for the option byte

Flash memory interface features:
- Read interface with prefetch buffer
- Option byte loader
- Flash program / erase operation
- Read / write protection
- Low-power mode

3.2 Flash memory functional description

3.2.1 Flash memory organization

The flash memory is organized as 32-bit wide memory cells that can be used for storing both code and data constants.

The memory organization of STM32F03x, STM32F04x and STM32F05x devices is based on a main flash memory block containing up to 64 pages of 1 Kbyte or up to 16 sectors of 4 Kbytes (4 pages). The sector is the granularity of the write protection (see Section 3.3).

The memory organization of STM32F07x and STM32F09x devices is based on a main flash memory block containing up to 128 pages of 2 Kbytes or up to 64 sectors of 4 Kbytes (2 pages). The sector is the granularity of the write protection (see Section 3.3).

The information block is divided into two parts:

1. System memory: used to boot the device in System memory boot mode. The area is reserved for use by STMicroelectronics and contains the boot loader, which is used to reprogram the flash memory through the selected communication interface. It is programmed by ST when the device is manufactured, and protected against spurious write/erase operations. For further details refer to AN2606.

2. Option byte

</tbody>
</table>

1. Main flash memory space of STM32F03x and STM32F04x devices is limited to sector 7.
2. STM32F03x and STM32F05x devices.
3. STM32F04x devices.
Read operations

The embedded flash module can be addressed directly, as a common memory space. Any data read operation accesses the content of the flash module through dedicated read senses and provides the requested data.

The instruction fetch and the data access are both done through the same AHB bus. Read accesses can be performed with the following options managed through the flash access control register (FLASH_ACR):

- Instruction fetch: Prefetch buffer enabled for a faster CPU execution
- Latency: number of wait states for a correct read operation (from 0 to 1)

Instruction fetch

The Cortex®-M0 fetches the instruction over the AHB bus. The prefetch block aims at increasing the efficiency of instruction fetching.

Prefetch buffer

The prefetch buffer is 3-block wide where each block consists of 4 bytes. The prefetch blocks are direct-mapped. A block can be completely replaced on a single read to the flash memory as the size of the block matches the bandwidth of the flash memory.

The implementation of this prefetch buffer makes a faster CPU execution possible as the CPU fetches one word at a time with the next word readily available in the prefetch buffer. This implies that the acceleration ratio is of the order of 2, assuming that the code is aligned at a 32-bit boundary for the jumps.

</table>

1. The main flash memory space of STM32F07x is limited to sector 31.
2. STM32F07x devices only.
3. STM32F09x devices only.
However the prefetch buffer has an impact on the performance only when the wait state number is 1. In the other case (no wait state) the performance remains the same whatever the prefetch buffer status. There could be some impacts on the power consumption but this is strongly dependent from the actual application code.

**Prefetch controller**

The prefetch controller decides to access the flash memory depending on the available space in the prefetch buffer. The Controller initiates a read request when there is at least one block free in the prefetch buffer.

The prefetch buffer is usually switched on/off during the initialization routine, while the microcontroller is running on the internal 8 MHz RC (HSI) oscillator.

**Access latency**

In order to maintain the control signals to read the flash memory, the ratio of the prefetch controller clock period to the access time of the flash memory has to be programmed in the flash access control register with the LATENCY[2:0] bits. This value gives the number of cycles needed to maintain the control signals of the flash memory and correctly read the required data. After reset, the value is zero and only one cycle without additional wait states is required to access the flash memory.

### 3.2.2 Flash program and erase operations

The STM32F0xx embedded flash memory can be programmed using in-circuit programming or in-application programming.

The in-circuit programming (ICP) method is used to update the entire contents of the flash memory, using the SWD protocol or the boot loader to load the user application into the microcontroller. ICP offers quick and efficient design iterations and eliminates unnecessary package handling or socketing of devices.

In contrast to the ICP method, in-application programming (IAP) can use any communication interface supported by the microcontroller (I/Os, USB, CAN, USART, \(^2\text{C}, \text{SPI}\), etc.) to download programming data into memory. IAP allows the user to re-program the flash memory while the application is running. Nevertheless, part of the application has to have been previously programmed in the flash memory using ICP.

The program and erase operations can be performed over the whole product voltage range. They are managed through the following seven flash registers:

- Key register (FLASH_KEYR)
- Option byte key register (FLASH_OPTKEYR)
- Flash control register (FLASH_CR)
- Flash status register (FLASH_SR)
- Flash address register (FLASH_AR)
- Option byte register (FLASH_OBR)
- Write protection register (FLASH_WPR)

An ongoing flash memory operation does not block the CPU as long as the CPU does not access the flash memory.

On the contrary, during a program/erase operation to the flash memory, any attempt to read the flash memory stalls the bus. The read operation proceeds correctly once the
program/erase operation has completed. This means that code or data fetches cannot be made while a program/erase operation is ongoing.

For program and erase operations on the flash memory (write/erase), the internal RC oscillator (HSI) must be ON.

Unlocking the flash memory

After reset, the flash memory is protected against unwanted write or erase operations. The FLASH_CR register is not accessible in write mode, except for the OBL_LAUNCH bit, used to reload the option bits. An unlocking sequence should be written to the FLASH_KEYR register to open the access to the FLASH_CR register. This sequence consists of two write operations:

- Write KEY1 = 0x45670123
- Write KEY2 = 0xCDEF89AB

Any wrong sequence locks up the FLASH_CR register until the next reset.

In the case of a wrong key sequence, a bus error is detected and a Hard Fault interrupt is generated. This is done after the first write cycle if KEY1 does not match, or during the second write cycle if KEY1 has been correctly written but KEY2 does not match.

The FLASH_CR register can be locked again by user software by writing the LOCK bit in the FLASH_CR register to 1.

For code example refer to the Appendix section A.2.1: Flash memory unlocking sequence.

Main flash memory programming

The main flash memory can be programmed 16 bits at a time. The program operation is started when the CPU writes a half-word into a main flash memory address with the PG bit of the FLASH_CR register set. Any attempt to write data that are not half-word long results in a bus error generating a Hard Fault interrupt.
The flash memory interface preliminarily reads the value at the addressed main flash memory location and checks that it has been erased. If not, the program operation is skipped and a warning is issued by the PGERR bit in FLASH_SR register. The only exception to this is when 0x0000 is programmed. In this case, the location is correctly programmed to 0x0000 and the PGERR bit is not set.

If the addressed main flash memory location is write-protected by the FLASH_WRPR register, the program operation is skipped and a warning is issued by the WRPRTERR bit in the FLASH_SR register. The end of the program operation is indicated by the EOP bit in the FLASH_SR register.
The main flash memory programming sequence in standard mode is as follows:

1. Check that no main flash memory operation is ongoing by checking the BSY bit in the \texttt{FLASH\_SR} register.
2. Set the PG bit in the \texttt{FLASH\_CR} register.
3. Perform the data write (half-word) at the desired address.
4. Wait until the BSY bit is reset in the \texttt{FLASH\_SR} register.
5. Check the EOP flag in the \texttt{FLASH\_SR} register (it is set when the programming operation has succeeded), and then clear it by software.

\textit{Note:} \textit{The registers are not accessible in write mode when the BSY bit of the \texttt{FLASH\_SR} register is set.}

For code example refer to the Appendix section \texttt{A.2.2: Main Flash programming sequence}.

**Flash memory erase**

The flash memory can be erased page by page or completely (mass erase).

**Page erase**

To erase a page, the procedure below should be followed:

1. Check that no flash memory operation is ongoing by checking the BSY bit in the \texttt{FLASH\_CR} register.
2. Set the PER bit in the \texttt{FLASH\_CR} register.
3. Program the \texttt{FLASH\_AR} register to select a page to erase.
4. Set the STRT bit in the \texttt{FLASH\_CR} register (see note below).
5. Wait for the BSY bit to be reset.
6. Check the EOP flag in the \texttt{FLASH\_SR} register (it is set when the erase operation has succeeded).
7. Clear the EOP flag.

\textit{Note:} \textit{The software should start checking if the BSY bit equals “0” at least one CPU cycle after setting the STRT bit.}

For code example refer to the Appendix section \texttt{A.2.3: Page erase sequence}. 
Figure 4. Flash memory Page erase procedure

- Read LOCK bit in FLASH_CR
- If LOCK bit in FLASH_CR = 1, then Perform unlock sequence.
- If LOCK bit in FLASH_CR = 0, then Write PER bit in FLASH_CR.
- Write into FAR an address within the page to erase.
- Write STRT bit in FLASH_CR to 1.
- If BSY bit in FLASH_SR = 1, then Check the page is erased by reading all the addresses in the page.
- If BSY bit in FLASH_SR = 0, then No.
Mass erase

The mass erase command can be used to completely erase the pages of the main flash memory. The information block is unaffected by this procedure. The following sequence is recommended:

1. Check that no flash memory operation is ongoing by checking the BSY bit in the FLASH_SR register.
2. Set the MER bit in the FLASH_CR register.
3. Set the STRT bit in the FLASH_CR register.
4. Wait until the BSY bit is reset in the FLASH_SR register.
5. Check the EOP flag in the FLASH_SR register (it is set when the programming operation has succeeded).
6. Clear the EOP flag.

*Note:* The software should start checking if the BSY bit equals “0” at least one CPU cycle after setting the STRT bit.

For code example refer to the Appendix section A.2.4: Mass erase sequence.

**Figure 5. Flash memory mass erase procedure**
Option byte programming

The option byte are programmed differently from normal user addresses. The number of option byte is limited to 8 (1, 2 or 4 for write protection, 1 for read protection, 1 for hardware configuration and 2 free byte for user data). After unlocking the flash access, the user has to authorize the programming of the option byte by writing the same set of KEYS (KEY1 and KEY2) to the FLASH_OPTKEYR register to set the OPTWRE bit in the FLASH_CR register (refer to Unlocking the flash memory for key values). Then the user has to set the OPTPG bit in the FLASH_CR register and perform a half-word write operation at the desired flash address.

The value of the addressed option byte is first read to check it is really erased. If not, the program operation is skipped and a warning is issued by the WRPRTERR bit in the FLASH_SR register. The end of the program operation is indicated by the EOP bit in the FLASH_SR register.

The option byte is automatically complemented into the next flash memory address before the programming operation starts. This guarantees that the option byte and its complement are always correct.

The sequence is as follows:
1. Check that no flash memory operation is ongoing by checking the BSY bit in the FLASH_SR register.
2. Unlock the OPTWRE bit in the FLASH_CR register.
3. Set the OPTPG bit in the FLASH_CR register.
4. Write the data (half-word) to the desired address.
5. Wait for the BSY bit to be reset.
6. Read the programmed value and verify.

For code example refer to the Appendix section A.2.6: Option byte programming sequence.

When the flash memory read protection option is changed from protected to unprotected, a mass erase of the main flash memory is performed before reprogramming the read protection option. If the user wants to change an option other than the read protection option, then the mass erase is not performed. The erased state of the read protection option byte protects the flash memory.

Erase procedure

The option byte erase sequence is as follows:
1. Check that no flash memory operation is ongoing by reading the BSY bit in the FLASH_SR register
2. Unlock the OPTWRE bit in the FLASH_CR register
3. Set the OPTER bit in the FLASH_CR register
4. Set the STRT bit in the FLASH_CR register
5. Wait for the BSY bit to be reset
6. Read the erased option byte and verify

For code example refer to the Appendix section A.2.7: Option byte erasing sequence.
3.3 Memory protection

The user area of the flash memory can be protected against read by untrusted code. The pages of the flash memory can also be protected against unwanted write due to loss of program counter contexts. The write-protection granularity is one sector (four pages).

3.3.1 Read protection

The read protection is activated by setting the RDP option byte and then, by applying a system reset to reload the new RDP option byte.

Note: If the read protection is set while the debugger is still connected through SWD, apply a POR (power-on reset) instead of a system reset.

There are three levels of read protection from no protection (level 0) to maximum protection or no debug (level 2). Refer to Table 7: Access status versus protection level and execution modes.

The flash memory is protected when the RDP option byte and its complement contain the pair of values shown in Table 6.

<table>
<thead>
<tr>
<th>RDP byte value</th>
<th>RDP complement value</th>
<th>Read protection level</th>
</tr>
</thead>
<tbody>
<tr>
<td>0xAA</td>
<td>0x55</td>
<td>Level 0 (ST production configuration)</td>
</tr>
<tr>
<td>Any value except 0xAA or 0xCC</td>
<td>Any value except 0x55 and 0x33</td>
<td>Level 1</td>
</tr>
<tr>
<td>0xCC</td>
<td>0x33</td>
<td>Level 2</td>
</tr>
</tbody>
</table>

The System memory area is read accessible whatever the protection level. It is never accessible for program/erase operation.

**Level 0: no protection**

Read, program and erase operations into the main flash memory area are possible.

The option byte are as well accessible by all operations.

**Level 1: read protection**

This is the default protection level when RDP option byte is erased. It is defined as well when RDP value is at any value different from 0xAA and 0xCC, or even if the complement is not correct.

- **User mode**: Code executing in user mode can access main flash memory and option byte with all operations.
- **Debug, boot RAM and boot loader modes**: In debug mode (with SWD) or when code is running from boot RAM or boot loader, the main flash memory and the backup registers (RTC_BKPxR in the RTC) are totally inaccessible.
  In these modes, even a simple read access generates a bus error and a Hard Fault interrupt. The main flash memory is program/erase protected to prevent malicious or unauthorized users from reprogramming any of the user code with a dump routine. Any
attempted program/erase operation sets the PGERR flag of flash status register (FLASH_SR).

When the RPD is reprogrammed to the value 0xAA to move back to Level 0, a mass erase of the main flash memory is performed and the backup registers (RTC_BKPxR in the RTC) are reset.

**Level 2: no debug**

In this level, the protection level 1 is guaranteed. In addition, the CortexM0 debug capabilities are disabled. Consequently, the debug port (SWD), the boot from RAM (boot RAM mode) and the boot from System memory (boot loader mode) are no more available.

In user execution mode, all operations are allowed on the main flash memory. On the contrary, only read and program operations can be performed on the option byte. Option byte are not accessible for erase operations.

Moreover, the RDP byte cannot be programmed. Thus, the level 2 cannot be removed at all: it is an irreversible operation. When attempting to program the RDP byte, the protection error flag WRPRTRERR is set in the flash_SR register and an interrupt can be generated.

*Note:* The debug feature is also disabled under reset.

**STMicroelectronics is not able to perform analysis on defective parts on which the level 2 protection has been set.**

</table>

1. When the protection level 2 is active, the Debug port, the boot from RAM and the boot from System memory are disabled.
2. The system memory is only read-accessible, whatever the protection level (0, 1 or 2) and execution mode.
3. Under RDP level 1 and level 2, the bootloader can be accessed by a jump to it. However it does not execute any command other than GetCmd/GetDl/GetVersion.
4. The main flash memory is erased when the RDP option byte is changed from level 1 to level 0 (0xAA).
5. When the RDP level 1 is active, the embedded boot loader does not allow to read or write the Option byte, except to remove the RDP protection (move from level 1 to level 0).
6. All option byte can be programmed, except the RDP byte.
7. These registers are reset when moving from RDP level 1 to level 0.
Changing read protection level

It is easy to move from level 0 to level 1 by changing the value of the RDP byte to any value (except 0xCC).

By programming the 0xCC value in the RDP byte, it is possible to go to level 2 either directly from level 0 or from level 1.

On the contrary, the change to level 0 (no protection) is not possible without a main flash memory Mass erase operation. This Mass erase is generated as soon as 0xAA is programmed in the RDP byte.

Note: When the mass erase command is used, the backup registers (RTC_BKPxR in the RTC) are also reset.

To validate the protection level change, the option bytes must be reloaded through the “OBL_LAUNCH” bit in flash control register.

3.3.2 Write protection

The write protection is implemented with a granularity of one sector. It is activated by configuring the WRPx option byte, and then by reloading them by setting the OBL_LAUNCH bit in the FLASH_CR register.

If a program or an erase operation is performed on a protected sector, the flash memory returns a WRPRTERR protection error flag in the flash memory Status Register (FLASH_SR).

Write unprotection

To disable the write protection, two application cases are provided:

- **Case 1: Read protection disabled after the write unprotection:**
  - Erase the entire option byte area by using the OPTER bit in the flash memory control register (FLASH_CR).
  - Program the code 0xAA in the RDP byte to unprotect the memory. This operation forces a mass erase of the main flash memory.
  - Set the OBL_LAUNCH bit in the flash control register (FLASH_CR) to reload the option byte (and the new WRP[1:0] byte), and to disable the write protection.

- **Case 2: Read protection maintained active after the write unprotection, useful for in-application programming with a user boot loader:**
  - Erase the entire option byte area by using the OPTER bit in the flash memory control register (FLASH_CR).
  - Set the OBL_LAUNCH bit in the flash control register (FLASH_CR) to reload the option byte (and the new WRP[1:0] byte), and to disable the write protection.

3.3.3 Option byte write protection

The option byte are always read-accessible and write-protected by default. To gain write access (Program/Erase) to the option byte, a sequence of keys (same as for lock) has to be written into the OPTKEYR. A correct sequence of keys gives write access to the option byte and this is indicated by OPTWRE in the FLASH_CR register being set. Write access can be disabled by resetting the bit through software.
3.4 Flash interrupts

Bits 31:6  Reserved, must be kept at reset value.

Bit 5 **PRFTBS**: Prefetch buffer status
This bit provides the status of the prefetch buffer.
0: Prefetch buffer is disabled
1: Prefetch buffer is enabled

*Note: The prefetch status is set to 1 as soon a first fetch request is done*

Bit 4 **PRFTBE**: Prefetch buffer enable
0: Prefetch is disabled
1: Prefetch is enabled

Bit 3  Reserved, must be kept at reset value.

Bits 2:0 **LATENCY[2:0]**: Latency
These bits represent the ratio of the SYSCLK (system clock) period to the flash access time.
000: Zero wait state, if SYSCLK ≤ 24 MHz
001: One wait state, if 24 MHz < SYSCLK ≤ 48 MHz
3.5.2 Flash key register (FLASH_KEYR)

Address offset: 0x04
Reset value: 0xXXXX XXXX

All these register bits are write-only and return a 0 when read.

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 EOP: End of operation
Set by hardware when a flash operation (programming / erase) is completed.
Reset by writing 1.

Note: EOP is asserted at the end of each successful program or erase operation

Bit 4 WRPRTERR: Write protection error
Set by hardware when programming a write-protected address of the flash memory.
Reset by writing 1.

Bit 3 Reserved, must be kept at reset value.

Bit 2 PGERR: Programming error
Set by hardware when an address to be programmed contains a value different from "0xFFFF" before programming.
Reset by writing 1.

Note: The STRT bit in the FLASH_CR register should be reset before starting a programming operation.

Bit 1 Reserved, must be kept at reset value.

Bit 0 BSY: Busy
This indicates that a flash operation is in progress. This is set on the beginning of a flash operation and reset when the operation finishes or when an error occurs.

3.5.5 Flash control register (FLASH_CR)

Address offset: 0x10
Reset value: 0x0000 0080

<table>
<thead>
<tr>

</tbody>
</table>

Bits 31:14 Reserved, must be kept at reset value.
Bit 13 **OBL_LAUNCH**: Force option byte loading
   When set to 1, this bit forces the option byte reloading. This operation generates a system reset.
   0: Inactive
   1: Active

Bit 12 **EOPIE**: End of operation interrupt enable
   This bit enables the interrupt generation when the EOP bit in the FLASH_SR register goes to 1.
   0: Interrupt generation disabled
   1: Interrupt generation enabled

Bit 11 Reserved, must be kept at reset value

Bit 10 **ERRIE**: Error interrupt enable
   This bit enables the interrupt generation on an error when PGERR / WRPRTERR are set in the FLASH_SR register.
   0: Interrupt generation disabled
   1: Interrupt generation enabled

Bit 9 **OPTWRE**: Option byte write enable
   When set, the option byte can be programmed. This bit is set on writing the correct key sequence to the FLASH_OPTKEYR register.
   This bit can be reset by software

Bit 8 Reserved, must be kept at reset value.

Bit 7 **LOCK**: Lock
   Write to 1 only. When it is set, it indicates that the flash is locked. This bit is reset by hardware after detecting the unlock sequence.
   In the event of unsuccessful unlock operation, this bit remains set until the next reset.

Bit 6 **STRT**: Start
   This bit triggers an ERASE operation when set. This bit is set only by software and reset when the BSY bit is reset.

Bit 5 **OPTER**: Option byte erase
   Option byte erase chosen.

Bit 4 **OPTPG**: Option byte programming
   Option byte programming chosen.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **MER**: Mass erase
   Erase of all user pages chosen.

Bit 1 **PER**: Page erase
   Page erase chosen.

Bit 0 **PG**: Programming
   Flash programming chosen.
3.5.6  Flash address register (FLASH_AR)

Address offset: 0x14
Reset value: 0x0000 0000

This register is updated by hardware with the currently/last used address. For Page erase operations, this should be updated by software to indicate the chosen page.

</tbody>
</table>

Refer to Section 2.2 on page 46 for the register boundary addresses.
4 Option bytes

There are up to 8 option bytes. They are configured by the end user depending on the application requirements. As a configuration example, the watchdog may be selected in hardware or software mode.

A 32-bit word is split up as follows in the option byte.

<table>
<thead>
<tr>
<th>31-24</th>
<th>23-16</th>
<th>15-8</th>
<th>7-0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Complemented option byte 1</td>
<td>Option byte 1</td>
<td>Complemented option byte 0</td>
<td>Option byte 0</td>
</tr>
</tbody>
</table>

The organization of these bytes inside the information block is as shown in Table 11.

The option byte can be read from the memory locations listed in Table 11 or from the Option byte register (FLASH_OBR).

Note: The new programmed option byte (user, read/write protection) are not loaded after a system reset. To reload them, either a POR or setting to ‘1’ the OBL_LAUNCH bit is necessary.

<table>

<td>WRP2</td>
</tr>
</tbody>
</table>

On every power-on reset, the option byte loader (OBL) reads the information block and stores the data into the option byte register (FLASH_OBR) and the write protection register (FLASH_WRPR). During option byte loading, the bit-wise complementarity of the option byte and its corresponding complemented option byte is verified. In case of failure, an option byte error (OPTERR) is generated and the corresponding option byte is considered as 0xFF. If the option byte and its complemented option byte are both equal to 0xFF (Electrical Erase state) the option byte error is not generated.

</tbody>
</table>

Bits 31:24 **nUSER**: User option byte complement
Option bytes

Bits 23:16 USER: User option byte (stored in FLASH_OBR[15:8])
Bit 23: **BOOT_SEL**
0: BOOT0 signal is defined by nBOOT0 option bit
1: BOOT0 signal is defined by BO0T0 pin value (legacy mode)
Available on STM32F04x and STM32F09x devices only. Considered as "1" on other devices.
Bit 22: **RAM_PARITY_CHECK**
0: RAM parity check enabled
1: RAM parity check disabled
Bit 21: **VDDA_MONITOR**
0: VDDA power supply supervisor disabled
1: VDDA power supply supervisor enabled
Bit 20: **nBOOT1**
Together with the BOOT0 signal, it selects the device boot mode. Refer to Section 2.5: Boot configuration for more details.
Bit 19: **nBOOT0**
When BOOT_SEL is cleared, nBOOT0 bit defines BOOT0 signal value used to select the device boot mode. Refer to Section 2.5: Boot configuration for more details.
Available on STM32F04x and STM32F09x devices only.
Bit 18: **nRST_STDBY**
0: Reset generated when entering Standby mode.
1: No reset generated.
Bit 17: **nRST_STOP**
0: Reset generated when entering Stop mode
1: No reset generated
Bit 16: **WDG_SW**
0: Hardware watchdog
1: Software watchdog

Bits 15:8 **nRDP**: Read protection option byte complement

Bits 7:0 **RDP**: Read protection option byte
The value of this byte defines the flash memory protection level
0xAA: level 0 (ST production configuration)
0XX (except 0xAA & 0xCC): Level 1
0xCC: Level 2
Note: Read protection level status is stored in bits RDPRT[1:0] of the Flash Option byte register (FLASH_OBR). For more details about read protection, refer to Section 3.3.1: Read protection.

### 4.1.2 User data option byte

Flash memory address: 0x1FFF F804
ST production value: 0x00FF 00FF

4.1.3 Write protection option byte

This set of registers is used to write-protect the flash memory. Clearing a bit in WRPx field (and at the same time setting a corresponding bit in nWRPx field) write-protects the given memory sector.

For STM32F03x, STM32F04x, STM32F05x and STM32F07x devices, WRP bits from 0 to 31 are protecting the flash memory by sector of 4 kB.

For STM32F09x devices, WRP bits from 0 to 30 are protecting the first 124 kB by sector of 4 kB and the bit 31 is protecting the last 132 kB.

Refer to Section 3.3.2: Write protection for more details.

Flash memory address: 0x1FFF F808
ST production value: 0x00FF 00FF

<table>
<thead>
<tr>

</tbody>
</table>
5 Power control (PWR)

5.1 Power supplies

The STM32F0x1/F0x2 subfamily embeds a voltage regulator in order to supply the internal 1.8 V digital power domain, unlike the STM32F0x8 subfamily where the stable 1.8 V must be delivered by the application.

- The STM32F0x1/F0x2 devices require a 2.0 V - 3.6 V operating supply voltage ($V_{DD}$) and a 2.0 V - 3.6 V analog supply voltage ($V_{DDA}$).
- The STM32F0x8 devices require a 1.8 V ± 8% operating supply voltage ($V_{DD}$), and a 1.65 V - 3.6 V analog supply voltage ($V_{DDA}$).

The real-time clock (RTC) and backup registers can be powered from the $V_{BAT}$ voltage when the main $V_{DD}$ supply is powered off.

Figure 6. Power supply overview

1. Available only on STM32F04x, STM32F07x and STM32F09x devices.
5.1.1 Independent A/D and D/A converter supply and reference voltage

To improve conversion accuracy and to extend the supply flexibility, the ADC and the DAC have an independent power supply that can be separately filtered and shielded from noise on the PCB.

- The ADC and DAC voltage supply input is available on a separate V\textsubscript{DDA} pin.
- An isolated supply ground connection is provided on pin V\textsubscript{SSA}.

The V\textsubscript{DDA} supply/reference voltage must be equal or higher than V\textsubscript{DD}.

When a single supply is used, V\textsubscript{DDA} can be externally connected to V\textsubscript{DD}, through the external filtering circuit in order to ensure a noise free V\textsubscript{DDA} reference voltage.

When V\textsubscript{DDA} is different from V\textsubscript{DD}, V\textsubscript{DDA} must always be higher or equal to V\textsubscript{DD}. To keep safe potential difference in between V\textsubscript{DDA} and V\textsubscript{DD} during power-up/power-down, an external Shottky diode may be used between V\textsubscript{DD} and V\textsubscript{DDA}. Refer to the datasheet for the maximum allowed difference.

5.1.2 Independent I/O supply rail

For better supply flexibility on STM32F04x, STM32F07x and STM32F09x devices, portions of the I/Os are supplied from a separate supply rail. Power supply for this rail can range from 1.65 to 3.6 V and is provided externally through the VDDIO2 pin. The V\textsubscript{DDIO2} voltage level is completely independent from V\textsubscript{DD} or V\textsubscript{DDA}, but it must not be provided without a valid operating supply on the V\textsubscript{DD} pin. Refer to the pinout diagrams or tables in related device datasheets for concerned I/Os list.

The V\textsubscript{DDIO2} supply is monitored and compared with the internal reference voltage (V\textsubscript{REFINT}). When the V\textsubscript{DDIO2} is below this threshold, all the I/Os supplied from this rail are disabled by hardware. The output of this comparator is connected to EXTI line 31 and it can be used to generate an interrupt.

5.1.3 Battery backup domain

To retain the content of the Backup registers and supply the whole RTC domain when V\textsubscript{DD} is turned off, V\textsubscript{BAT} pin can be connected to an optional standby voltage supplied by a battery or by another source.

The V\textsubscript{BAT} pin powers the RTC unit, the LSE oscillator and the PC13 to PC15 IOs, allowing the RTC to operate even when the main power supply is turned off. The switch to the V\textsubscript{BAT} supply is controlled by the Power Down Reset embedded in the Reset block or (on STM32F0x8 devices) by the external NPOR signal.

---

**Warning:** During t\textsubscript{RSTTEMPO} (temporization at V\textsubscript{DD} startup) or after a PDR is detected, the power switch between V\textsubscript{BAT} and V\textsubscript{DD} remains connected to V\textsubscript{BAT}.

During the startup phase, if V\textsubscript{DD} is established in less than t\textsubscript{RSTTEMPO} (Refer to the datasheet for the value of t\textsubscript{RSTTEMPO}) and V\textsubscript{DD} > V\textsubscript{BAT} + 0.6 V, a current may be injected into V\textsubscript{BAT} through an internal diode connected between V\textsubscript{DD} and the power switch (V\textsubscript{BAT}). If the power supply/battery connected to the V\textsubscript{BAT} pin cannot support
this current injection, it is strongly recommended to connect an external low-drop diode between this power supply and the \( V_{BAT} \) pin.

If no external battery is used in the application, it is recommended to connect \( V_{BAT} \) externally to \( V_{DD} \) with a 100 nF external ceramic decoupling capacitor (for more details refer to AN4080).

When the RTC domain is supplied by \( V_{DD} \) (analog switch connected to \( V_{DD} \)), the following functions are available:
- PC13, PC14 and PC15 can be used as GPIO pins
- PC13, PC14 and PC15 can be configured by RTC or LSE (refer to Section 25.4: RTC functional description on page 591)

**Note:** Due to the fact that the analog switch can transfer only a limited amount of current (3 mA), the use of GPIOs PC13 to PC15 in output mode is restricted: the speed has to be limited to 2 MHz with a maximum load of 30 pF and these IOs must not be used as a current source (e.g. to drive an LED).

When the RTC domain is supplied by \( V_{BAT} \) (analog switch connected to \( V_{BAT} \) because \( V_{DD} \) is not present), the following functions are available:
- PC13, PC14 and PC15 can be controlled only by RTC or LSE (refer to Section 25.4: RTC functional description on page 591)

### 5.1.4 Voltage regulator

The voltage regulator is always enabled after Reset. It works in three different modes depending on the application modes.
- In Run mode, the regulator supplies full power to the 1.8 V domain (core, memories and digital peripherals).
- In Stop mode the regulator supplies low-power to the 1.8 V domain, preserving contents of registers and SRAM
- In Standby Mode, the regulator is powered off. The contents of the registers and SRAM are lost except for the Standby circuitry and the RTC domain.

**Note:** In STM32F0x8 devices, the voltage regulator is bypassed and the microcontroller must be powered from a nominal \( V_{DD} = 1.8 \) V \( \pm 8\% \) supply.

### 5.2 Power supply supervisor

#### 5.2.1 Power on reset (POR) / power down reset (PDR)

STM32F0x1xx and STM32F0x2xx devices feature integrated power-on reset (POR) and power-down reset (PDR) circuits, which are always active and ensure proper operation above a threshold of 2 V.
The devices remain in Reset mode when the monitored supply voltage is below a specified threshold, $V_{POR/PDR}$, without the need for an external reset circuit.

- The POR monitors only the $V_{DD}$ supply voltage. During the startup phase $V_{DDA}$ must arrive first and be greater than or equal to $V_{DD}$.
- The PDR monitors both the $V_{DD}$ and $V_{DDA}$ supply voltages. However, the $V_{DDA}$ power supply supervisor can be disabled (by programming a dedicated option bit $V_{DDA\_MONITOR}$) to reduce the power consumption if the application is designed to make sure that $V_{DDA}$ is higher than or equal to $V_{DD}$.

For more details on the power on / power down reset threshold, refer to the electrical characteristics section in the datasheet.

![Figure 7. Power on reset/power down reset waveform](image)

**External NPOR signal**

In STM32F0x8 devices, the PB2 I/O (or PB1 on small packages) is not available and is replaced by the NPOR functionality used for power on reset.

To guarantee a proper power on and power down reset to the device, the NPOR pin must be held low until $V_{DD}$ is stable or before turning off the supply. When $V_{DD}$ is stable, the reset state can be exited by putting the NPOR pin in high impedance. The NPOR pin has an internal pull-up connected to $V_{DDA}$.

### 5.2.2 Programmable voltage detector (PVD)

STM32F0x1xx and STM32F0x2xx can use the PVD to monitor the $V_{DD}$ power supply by comparing it to a threshold selected by the PLS[2:0] bits in the **Power control register (PWR_CR)**.

The PVD is enabled by setting the PVDE bit.

A PVDO flag is available, in the **Power control/status register (PWR_CSR)**, to indicate if $V_{DD}$ is higher or lower than the PVD threshold. This event is internally connected to the EXTI line16 and can generate an interrupt if enabled through the EXTI registers. The PVD output interrupt can be generated when $V_{DD}$ drops below the PVD threshold and/or when $V_{DD}$...
rises above the PVD threshold depending on EXTI line16 rising/falling edge configuration. As an example the service routine could perform emergency shutdown tasks.

Figure 8. PVD thresholds

5.3 Low-power modes

By default, the microcontroller is in Run mode after a system or a power Reset. Several low-power modes are available to save power when the CPU does not need to be kept running, for example when waiting for an external event. It is up to the user to select the mode that gives the best compromise between low-power consumption, short startup time and available wake-up sources.

The device features three low-power modes:

- Sleep mode (CPU clock off, all peripherals including Cortex®-M0 core peripherals like NVIC, SysTick, etc. are kept running)
- Stop mode (all clocks are stopped)
- Standby mode (1.8V domain powered-off)

In addition, the power consumption in Run mode can be reduced by one of the following means:

- Slowing down the system clocks
- Gating the clocks to the APB and AHB peripherals when they are unused.
Caution: On STM32F0x8 devices, the Stop mode is available, but it is meaningless to distinguish between voltage regulator in low-power mode and voltage regulator in Run mode because the regulator is not used and the core is supplied directly from an external source. Consequently, the Standby mode is not available on those devices.

5.3.1 Slowing down system clocks

In Run mode the speed of the system clocks (SYSCLK, HCLK, PCLK) can be reduced by programming the prescaler registers. These prescalers can also be used to slow down peripherals before entering Sleep mode.

For more details refer to Section 6.4.2: Clock configuration register (RCC_CFR).
5.3.2 Peripheral clock gating

In Run mode, the AHB clock (HCLK) and the APB clock (PCLK) for individual peripherals and memories can be stopped at any time to reduce power consumption.

To further reduce power consumption in Sleep mode the peripheral clocks can be disabled prior to executing the WFI or WFE instructions.

Peripheral clock gating is controlled by the **AHB peripheral clock enable register (RCC_AHBENR)**, the **APB peripheral clock enable register 2 (RCC_APB2ENR)** and the **APB peripheral clock enable register 1 (RCC_APB1ENR)**.

5.3.3 Sleep mode

**Entering Sleep mode**

The Sleep mode is entered by executing the WFI (Wait For Interrupt) or WFE (Wait for Event) instructions. Two options are available to select the Sleep mode entry mechanism, depending on the SLEEPONEXIT bit in the Cortex®-M0 System Control register:

- **Sleep-now**: if the SLEEPONEXIT bit is cleared, the MCU enters Sleep mode as soon as WFI or WFE instruction is executed.
- **Sleep-on-exit**: if the SLEEPONEXIT bit is set, the MCU enters Sleep mode as soon as it exits the lowest priority ISR.

In the Sleep mode, all I/O pins keep the same state as in the Run mode.

Refer to **Table 14** and **Table 15** for details on how to enter Sleep mode.

**Exiting Sleep mode**

If the WFI instruction is used to enter Sleep mode, any peripheral interrupt acknowledged by the nested vectored interrupt controller (NVIC) can wake up the device from Sleep mode.

If the WFE instruction is used to enter Sleep mode, the MCU exits Sleep mode as soon as an event occurs. The wake-up event can be generated either by:

- enabling an interrupt in the peripheral control register but not in the NVIC, and enabling the SEVONPEND bit in the Cortex®-M0 System Control register. When the MCU resumes from WFE, the peripheral interrupt pending bit and the peripheral NVIC IRQ channel pending bit (in the NVIC interrupt clear pending register) must be cleared.
- or configuring an external or internal EXTI line in event mode. When the CPU resumes from WFE, it is not necessary to clear the peripheral interrupt pending bit or the NVIC IRQ channel pending bit as the pending bit corresponding to the event line is not set.

This mode offers the lowest wake-up time as no time is wasted in interrupt entry/exit.

Refer to **Table 14** and **Table 15** for more details on how to exit Sleep mode.
5.3.4 Stop mode

The Stop mode is based on the Cortex®-M0 deep sleep mode combined with peripheral clock gating. The voltage regulator can be configured either in normal or low-power mode. In Stop mode, all clocks in the 1.8 V domain are stopped, the PLL, the HSI and the HSE oscillators are disabled. SRAM and register contents are preserved.

In the Stop mode, all I/O pins keep the same state as in the Run mode.

Entering Stop mode

Refer to Table 16 for details on how to enter the Stop mode.

To further reduce power consumption in Stop mode, the internal voltage regulator can be put in low-power mode. This is configured by the LPDS bit of the Power control register (PWR_CR).

If Flash memory programming is ongoing, the Stop mode entry is delayed until the memory access is finished.

If an access to the APB domain is ongoing, The Stop mode entry is delayed until the APB access is finished.

In Stop mode, the following features can be selected by programming individual control bits:

- Independent watchdog (IWDG): the IWDG is started by writing to its Key register or by hardware option. Once started it cannot be stopped except by a Reset. See Section 23.3: IWDG functional description.

### Table 14. Sleep-now

<table>
<thead>
<tr>
<th>Sleep-now mode</th>
<th>Description</th>
</tr>
</thead>
</table>
| Mode entry     | WFI (Wait for Interrupt) or WFE (Wait for Event) while:  
- SLEEPDEEP = 0 and  
- SLEEPONEXIT = 0  
Refer to the Cortex®-M0 System Control register. |
| Mode exit      | If WFI was used for entry:  
Interrupt: Refer to Table 36: Vector table  
If WFE was used for entry  
Wake-up event: Refer to Section 11.2.3: Event management |
| Wake-up latency| None |

### Table 15. Sleep-on-exit

<table>
<thead>
<tr>
<th>Sleep-on-exit</th>
<th>Description</th>
</tr>
</thead>
</table>
| Mode entry    | WFI (wait for interrupt) while:  
- SLEEPDEEP = 0 and  
- SLEEPONEXIT = 1  
Refer to the Cortex®-M0 System Control register. |
| Mode exit     | Interrupt: Refer to Table 36: Vector table. |
| Wake-up latency| None |

5.3.4 Stop mode

The Stop mode is based on the Cortex®-M0 deep sleep mode combined with peripheral clock gating. The voltage regulator can be configured either in normal or low-power mode. In Stop mode, all clocks in the 1.8 V domain are stopped, the PLL, the HSI and the HSE oscillators are disabled. SRAM and register contents are preserved.

In the Stop mode, all I/O pins keep the same state as in the Run mode.

Entering Stop mode

Refer to Table 16 for details on how to enter the Stop mode.

To further reduce power consumption in Stop mode, the internal voltage regulator can be put in low-power mode. This is configured by the LPDS bit of the Power control register (PWR_CR).

If Flash memory programming is ongoing, the Stop mode entry is delayed until the memory access is finished.

If an access to the APB domain is ongoing, The Stop mode entry is delayed until the APB access is finished.

In Stop mode, the following features can be selected by programming individual control bits:

- Independent watchdog (IWDG): the IWDG is started by writing to its Key register or by hardware option. Once started it cannot be stopped except by a Reset. See Section 23.3: IWDG functional description.
• real-time clock (RTC): this is configured by the RTCEN bit in the **RTC domain control register (RCC_BDCR)**.

• Internal RC oscillator (LSI): this is configured by the LSION bit in the **Control/status register (RCC_CSR)**.

• External 32.768 kHz oscillator (LSE): this is configured by the LSEON bit in the **RTC domain control register (RCC_BDCR)**.

The ADC or DAC can also consume power during Stop mode, unless they are disabled before entering this mode. Refer to **ADC control register (ADC_CR)** and **DAC control register (DAC_CR)** for details on how to disable them.

### Exiting Stop mode

Refer to **Table 16** for more details on how to exit Stop mode.

When exiting Stop mode by issuing an interrupt or a wake-up event, the HSI oscillator is selected as system clock.

When the voltage regulator operates in low-power mode, an additional startup delay is incurred when waking up from Stop mode. By keeping the internal regulator ON during Stop mode, the consumption is higher although the startup time is reduced.

#### Table 16. Stop mode

<table>
<thead>
<tr>
<th>Stop mode</th>
<th>Description</th>
</tr>
</thead>
</table>
| Mode entry | WFI (Wait for Interrupt) or WFE (Wait for Event) while:  
– Set SLEEPDEEP bit in Cortex®-M0 System Control register  
– Clear PDDS bit in Power Control register (PWR_CR)  
– Select the voltage regulator mode by configuring LPDS bit in PWR_CR  

**Note:** To enter Stop mode, all EXTI line pending bits (in Pending register (EXTI_PR)), all peripherals interrupt pending bits and RTC Alarm flag must be reset. Otherwise, the Stop mode entry procedure is ignored and program execution continues.  
If the application needs to disable the external oscillator (external clock) before entering Stop mode, the system clock source must be first switched to HSI and then clear the HSEON bit.  
Otherwise, if before entering Stop mode the HSEON bit is kept at 1, the security system (CSS) feature must be enabled to detect any external oscillator (external clock) failure and avoid a malfunction when entering Stop mode. |
| Mode exit | If WFI was used for entry:  
– Any EXTI line configured in Interrupt mode (the corresponding EXTI Interrupt vector must be enabled in the NVIC).  
– Some specific communication peripherals (CEC, USART, I2C) interrupts, when programmed in wake-up mode (the peripheral must be programmed in wake-up mode and the corresponding interrupt vector must be enabled in the NVIC).  
Refer to **Table 36: Vector table**.  
If WFE was used for entry:  
Any EXTI line configured in event mode. Refer to **Section 11.2.3: Event management on page 218** |
| Wake-up latency | HSI wake-up time + regulator wake-up time from Low-power mode |
5.3.5 Standby mode

The Standby mode allows to achieve the lowest power consumption. It is based on the Cortex®-M0 deepsleep mode, with the voltage regulator disabled. The 1.8 V domain is consequently powered off. The PLL, the HSI oscillator and the HSE oscillator are also switched off. SRAM and register contents are lost except for registers in the RTC domain and Standby circuitry (see Figure 6).

Caution: The Standby mode is not available on STM32F0x8 devices.

Entering Standby mode

Refer to Table 17 for more details on how to enter Standby mode.

In Standby mode, the following features can be selected by programming individual control bits:

- Independent watchdog (IWDG): the IWDG is started by writing to its Key register or by hardware option. Once started it cannot be stopped except by a reset. See Section 23.3: IWDG functional description.
- Real-time clock (RTC): this is configured by the RTCEN bit in the RTC domain control register (RCC_BDCR).
- Internal RC oscillator (LSI): this is configured by the LSION bit in the Control/status register (RCC_CSR).
- External 32.768 kHz oscillator (LSE): this is configured by the LSEON bit in the RTC domain control register (RCC_BDCR).

Exiting Standby mode

The microcontroller exits the Standby mode when an external reset (NRST pin), an IWDG reset, a rising edge on one of the enabled WKUPx pins or an RTC event occurs. All registers are reset after wake-up from Standby except for Power control/status register (PWR_CSR).

After waking up from Standby mode, program execution restarts in the same way as after a Reset (boot pin sampling, option bytes loading, reset vector is fetched, etc.). The SBF status flag in the Power control/status register (PWR_CSR) indicates that the MCU was in Standby mode.

Refer to Table 17 for more details on how to exit Standby mode.

</tbody>
</table>

Table 17. Standby mode
I/O states in Standby mode

In Standby mode, all I/O pins are high impedance except:

- Reset pad (still available)
- PC13, PC14 and PC15 if configured by RTC or LSE
- WKUPx pins

Debug mode

By default, the debug connection is lost if the application puts the MCU in Stop or Standby mode while the debug features are used. This is due to the fact that the Cortex®-M0 core is no longer clocked.

However, by setting some configuration bits in the DBGMCU_CR register, the software can be debugged even when using the low-power modes extensively.

5.3.6 Auto-wake-up from low-power mode

The RTC can be used to wake-up the MCU from low-power mode by means of the RTC alarm from low-power mode without depending on an external interrupt (Auto-wake-up mode). The RTC provides a programmable time base for waking up from Stop or Standby mode at regular intervals. For this purpose, two of the three alternative RTC clock sources can be selected by programming the RTCSEL[1:0] bits in the RTC domain control register (RCC_BDCR):

- Low-power 32.768 kHz external crystal oscillator (LSE OSC)
  This clock source provides a precise time base with very low-power consumption (less than 1 µA added consumption in typical conditions)
- Low-power internal RC oscillator (LSI)
  This clock source has the advantage of saving the cost of the 32.768 kHz crystal. This internal RC oscillator is designed to add minimum power consumption.

To wake-up from Stop mode with an RTC alarm event, it is necessary to:

- Configure the EXTI Line 17 to be sensitive to rising edge
- Configure the RTC to generate the RTC alarm

To wake-up from Standby mode, there is no need to configure the EXTI Line 17.
5.4 **Power control registers**

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

5.4.1 **Power control register (PWR_CR)**

Address offset: 0x00  
Reset value: 0x0000 0000 (reset by wake-up from Standby mode)

  101: PVD threshold 5  
  110: PVD threshold 6  
  111: PVD threshold 7  
  Refer to the electrical characteristics of the datasheet for more details.
- **Bit 4** **PVDE**: Power voltage detector enable.  
  This bit is set and cleared by software. Once the PVD_LOCK is enabled in the **SYSCFG configuration register 2 (SYSCFG_CFGR2)** register, the PVDE bit cannot be programmed anymore.  
  0: PVD disabled  
  1: PVD enabled  
- **Bit 3** **CSBF**: Clear standby flag.  
  This bit is always read as 0.  
  0: No effect  
  1: Clear the SBF standby flag (write).
5.4.2 Power control/status register (PWR_CSR)

Address offset: 0x04

Reset value: 0x0000 000X (not reset by wake-up from Standby mode)

Additional APB cycles are needed to read this register versus a standard APB read.

<td></td>
</tr>
</tbody>
</table>

Refer to Section 2.2 on page 46 for the register boundary addresses.
6 Reset and clock control (RCC)

6.1 Reset

There are three types of reset, defined as system reset, power reset and RTC domain reset.

6.1.1 Power reset

A power reset is generated when one of the following events occurs:

1. Power-on/power-down reset (POR/PDR reset)
2. When exiting Standby mode

A power reset sets all registers to their reset values except the RTC domain (Figure 6: Power supply overview).

In STM32F0x8 devices, the POR/PDR reset is not functional and the Standby mode is not available. Power reset must be provided from an external NPOR pin (active low and released by the application when all supply voltages are stabilized).

6.1.2 System reset

A system reset sets all registers to their reset values except the reset flags in the clock controller CSR register and the registers in the RTC domain (see Figure 6: Power supply overview).

A system reset is generated when one of the following events occurs:

1. A low level on the NRST pin (external reset)
2. Window watchdog event (WWDG reset)
3. Independent watchdog event (IWDG reset)
4. A software reset (SW reset) (see Software reset)
5. Low-power management reset (see Low-power management reset)
6. Option byte loader reset (see Option byte loader reset)
7. A power reset

The reset source can be identified by checking the reset flags in the Control/Status register, RCC_CSR (see Section 6.4.10: Control/status register (RCC_CSR)).

These sources act on the NRST pin and it is always kept low during the delay phase. The RESET service routine vector is fixed at address 0x0000_0004 in the memory map.

The system reset signal provided to the device is output on the NRST pin. The pulse generator guarantees a minimum reset pulse duration of 20 µs for each internal reset source. In case of an external reset, the reset pulse is generated while the NRST pin is asserted low.
Software reset

The SYSRESETREQ bit in Cortex®-M0 Application Interrupt and Reset Control Register must be set to force a software reset on the device. Refer to the Cortex™-M0 technical reference manual for more details.

Low-power management reset

There are two ways to generate a low-power management reset:
1. Reset generated when entering Standby mode:
   This type of reset is enabled by resetting nRST_STDBY bit in User Option Bytes. In this case, whenever a Standby mode entry sequence is successfully executed, the device is reset instead of entering Standby mode.
2. Reset when entering Stop mode:
   This type of reset is enabled by resetting nRST_STOP bit in User Option Bytes. In this case, whenever a Stop mode entry sequence is successfully executed, the device is reset instead of entering Stop mode.

For further information on the User Option Bytes, refer to Section 4: Option bytes.

Option byte loader reset

The option byte loader reset is generated when the OBL_LAUNCH bit (bit 13) is set in the FLASH_CR register. This bit is used to launch the option byte loading by software.

6.1.3 RTC domain reset

The RTC domain has two specific resets that affect only the RTC domain (Figure 6: Power supply overview).

An RTC domain reset only affects the LSE oscillator, the RTC, the Backup registers and the RCC RTC domain control register (RCC_BDCR). It is generated when one of the following events occurs.
1. Software reset, triggered by setting the BDRST bit in the RTC domain control register (RCC_BDCR).
2. $V_{DD}$ power-up if $V_{BAT}$ has been disconnected when it was low.
The Backup registers are also reset when one of the following events occurs:
1. RTC tamper detection event.
2. Change of the read out protection from level 1 to level 0.

6.2 Clocks

Various clock sources can be used to drive the system clock (SYSCLK):
- HSI 8 MHz RC oscillator clock
- HSE oscillator clock
- PLL clock
- HSI48 48 MHz RC oscillator clock (available on STM32F04x, STM32F07x and STM32F09x devices only)

The devices have the following additional clock sources:
- 40 kHz low speed internal RC (LSI RC) which drives the independent watchdog and optionally the RTC used for Auto-wake-up from Stop/Standby mode.
- 32.768 kHz low speed external crystal (LSE crystal) which optionally drives the real-time clock (RTCLK)
- 14 MHz high speed internal RC (HSI14) dedicated for ADC.

Each clock source can be switched on or off independently when it is not used, to optimize power consumption.

Several prescalers can be used to configure the frequency of the AHB and the APB domains. The AHB and the APB domains maximum frequency is 48 MHz.
All the peripheral clocks are derived from their bus clock (HCLK for AHB or PCLK for APB) except:

- The Flash memory programming interface clock (FLITFCLK) which is always the HSI clock.
- The option byte loader clock which is always the HSI clock
- The ADC clock which is derived (selected by software) from one of the two following sources:
  - dedicated HSI14 clock, to run always at the maximum sampling rate
  - APB clock (PCLK) divided by 2 or 4
- The USART1 clock, USART2 clock (on STM32F07x and STM32F09x devices only) and USART3 clock (on STM32F09x devices only) which is derived (selected by software) from one of the four following sources:
  - system clock
  - HSI clock
  - LSE clock
  - APB clock (PCLK)
- The I2C1 clock which is derived (selected by software) from one of the two following sources:
  - system clock
  - HSI clock
- The USB clock which is derived (selected by software) from one of the two following sources:
  - PLL clock
  - HSI48 clock
- The CEC clock which is derived from the HSI clock divided by 244 or from the LSE clock.
- The I2S1 and I2S2 clock which is always the system clock.
- The RTC clock which is derived from the LSE, LSI or from the HSE clock divided by 32.
- The timer clock frequencies are automatically fixed by hardware. There are two cases:
  - if the APB prescaler is 1, the timer clock frequencies are set to the same frequency as that of the APB domain;
  - otherwise, they are set to twice (x2) the frequency of the APB domain.
- The IWDG clock which is always the LSI clock.

The RCC feeds the Cortex System Timer (SysTick) external clock with the AHB clock (HCLK) divided by 8. The SysTick can work either with this clock or directly with the Cortex clock (HCLK), configurable in the SysTick Control and Status Register.
Figure 10. Clock tree (STM32F03x and STM32F05x devices)

1. Not available on STM32F05x devices.
Figure 11. Clock tree (STM32F04x, STM32F07x and STM32F09x devices)

1. Not available on STM32F04x devices.
2. Not available on STM32F04x and STM32F07x devices

FCLK acts as Cortex®-M0’s free-running clock. For more details refer to the Arm Cortex-M0 r0p0 technical reference manual (TRM).
6.2.1 HSE clock

The high speed external clock signal (HSE) can be generated from two possible clock sources:

- HSE external crystal/ceramic resonator
- HSE user external clock

The resonator and the load capacitors have to be placed as close as possible to the oscillator pins in order to minimize output distortion and startup stabilization time. The loading capacitance values must be adjusted according to the selected oscillator.

![Figure 12. HSE/ LSE clock sources](MSv31915V1)

</tr>
</tbody>
</table>

**Figure 12. HSE/ LSE clock sources**
External crystal/ceramic resonator (HSE crystal)

The 4 to 32 MHz external oscillator has the advantage of producing a very accurate rate on the main clock.

The associated hardware configuration is shown in Figure 12. Refer to the electrical characteristics section of the datasheet for more details.

The HSERDY flag in the Clock control register (RCC_CR) indicates if the HSE oscillator is stable or not. At startup, the clock is not released until this bit is set by hardware. An interrupt can be generated if enabled in the Clock interrupt register (RCC_CIR).

The HSE Crystal can be switched on and off using the HSEON bit in the Clock control register (RCC_CR).

For code example refer to the Appendix section A.3.1: HSE start sequence code example.

Caution: To switch ON the HSE oscillator, 512 HSE clock pulses need to be seen by an internal stabilization counter after the HSEON bit is set. Even in the case that no crystal or resonator is connected to the device, excessive external noise on the OSC_IN pin may still lead the oscillator to start. Once the oscillator is started, it needs another 6 HSE clock pulses to complete a switching OFF sequence. If for any reason the oscillations are no more present on the OSC_IN pin, the oscillator cannot be switched OFF, locking the OSC pins from any other use and introducing unwanted power consumption. To avoid such situation, it is strongly recommended to always enable the Clock Security System (CSS) which is able to switch OFF the oscillator even in this case.

External source (HSE bypass)

In this mode, an external clock source must be provided. It can have a frequency of up to 32 MHz. You select this mode by setting the HSEBYP and HSEON bits in the Clock control register (RCC_CR). The external clock signal (square, sinus or triangle) with ~40-60% duty cycle depending on the frequency (refer to the datasheet) has to drive the OSC_IN pin while the OSC_OUT pin can be used a GPIO. See Figure 12.

6.2.2 HSI clock

The HSI clock signal is generated from an internal 8 MHz RC oscillator and can be used directly as a system clock or for PLL input.

The HSI RC oscillator has the advantage of providing a clock source at low cost (no external components). It also has a faster startup time than the HSE crystal oscillator however, even with calibration the frequency is less accurate than an external crystal oscillator or ceramic resonator.

Calibration

RC oscillator frequencies can vary from one chip to another due to manufacturing process variations, this is why each device is factory calibrated by ST for 1% accuracy at $T_A=25^\circ C$.

After reset, the factory calibration value is loaded in the HSICAL[7:0] bits in the Clock control register (RCC_CR).

If the application is subject to voltage or temperature variations this may affect the RC oscillator speed. You can trim the HSI frequency in the application using the HSITRIM[4:0] bits in the Clock control register (RCC_CR).
For more details on how to measure the HSI frequency variation refer to Section 6.2.13: Internal/external clock measurement with TIM14 on page 107.

The HSIRDY flag in the Clock control register (RCC_CR) indicates if the HSI RC is stable or not. At startup, the HSI RC output clock is not released until this bit is set by hardware.

The HSI RC can be switched on and off using the HSION bit in the Clock control register (RCC_CR).

The HSI signal can also be used as a backup source (Auxiliary clock) if the HSE crystal oscillator fails. Refer to Section 6.2.8: Clock security system (CSS) on page 105.

Furthermore it is possible to drive the HSI clock to the MCO multiplexer. Then the clock could be driven to the Timer 14 giving the ability to the user to calibrate the oscillator.

### 6.2.3 HSI48 clock

On STM32F04x, STM32F07x and STM32F09x devices only, the HSI48 clock signal is generated from an internal 48 MHz RC oscillator and can be used directly as a system clock or divided and be used as PLL input.

The internal 48MHz RC oscillator is mainly dedicated to provide a high precision clock to the USB peripheral by means of a special Clock recovery system (CRS) circuitry, which could use the USB SOF signal or the LSE or an external signal to automatically adjust the oscillator frequency on-fly, in a very small steps. This oscillator can also be used as a system clock source when the system is in run mode; it is disabled as soon as the system enters in Stop or Standby mode. When the CRS is not used, the HSI48 RC oscillator runs on its default frequency which is subject to manufacturing process variations, this is why each device is factory calibrated by ST for ~3% accuracy at $T_A = 25 \, ^\circ C$.

For more details on how to configure and use the CRS peripheral refer to Section 7.

The HSI48RDY flag in the Clock control register (RCC_CR) indicates if the HSI48 RC is stable or not. At startup, the HSI48 RC output clock is not released until this bit is set by hardware.

The HSI48 RC can be switched on and off using the HSI48ON bit in the Clock control register (RCC_CR). This oscillator is also automatically enabled (by hardware forcing HSI48ON bit to one) as soon as it is chosen as a clock source for the USB and the peripheral is enabled.

Furthermore it is possible to drive the HSI48 clock to the MCO multiplexer and use it as a clock source for other application components.

### 6.2.4 PLL

The internal PLL can be used to multiply the HSI, a divided HSI48 or the HSE output clock frequency. Refer to Figure 9: Simplified diagram of the reset circuit, Figure 12: HSE/ LSE clock sources and Clock control register (RCC_CR).

The PLL configuration (selection of the input clock, predivider and multiplication factor) must be done before enabling the PLL. Once the PLL is enabled, these parameters cannot be changed.
To modify the PLL configuration, proceed as follows:
1. Disable the PLL by setting PLLON to 0.
2. Wait until PLLRDY is cleared. The PLL is now fully stopped.
3. Change the desired parameter.
4. Enable the PLL again by setting PLLON to 1.
5. Wait until PLLRDY is set.

An interrupt can be generated when the PLL is ready, if enabled in the Clock interrupt register (RCC_CIR).

The PLL output frequency must be set in the range 16-48 MHz.

For code example refer to the Appendix section A.3.2: PLL configuration modification code example.

6.2.5 LSE clock

The LSE crystal is a 32.768 kHz Low Speed External crystal or ceramic resonator. It has the advantage of providing a low-power but highly accurate clock source to the real-time clock peripheral (RTC) for clock/calendar or other timing functions.

The LSE crystal is switched on and off using the LSEON bit in RTC domain control register (RCC_BDCR). The crystal oscillator driving strength can be changed at runtime using the LSEDRV[1:0] bits in the RTC domain control register (RCC_BDCR) to obtain the best compromise between robustness and short start-up time on one side and low-power consumption on the other.

The LSERDY flag in the RTC domain control register (RCC_BDCR) indicates whether the LSE crystal is stable or not. At startup, the LSE crystal output clock signal is not released until this bit is set by hardware. An interrupt can be generated if enabled in the Clock interrupt register (RCC_CIR).

Caution: To switch ON the LSE oscillator, 4096 LSE clock pulses need to be seen by an internal stabilization counter after the LSEON bit is set. Even in the case that no crystal or resonator is connected to the device, excessive external noise on the OSC32_IN pin may still lead the oscillator to start. Once the oscillator is started, it needs another 6 LSE clock pulses to complete a switching OFF sequence. If for any reason the oscillations are no more present on the OSC_IN pin, the oscillator cannot be switched OFF, locking the OSC32 pins from any other use and introducing unwanted power consumption. The only way to recover such situation is to perform the RTC domain reset by software.

External source (LSE bypass)

In this mode, an external clock source must be provided. It can have a frequency of up to 1 MHz. You select this mode by setting the LSEBYP and LSEON bits in the RTC domain control register (RCC_BDCR). The external clock signal (square, sinus or triangle) with ~50% duty cycle has to drive the OSC32_IN pin while the OSC32_OUT pin can be used as GPIO. See Figure 12.

6.2.6 LSI clock

The LSI RC acts as a low-power clock source that can be kept running in Stop and Standby mode for the independent watchdog (IWDG) and RTC. The clock frequency is around 40 kHz. For more details, refer to the electrical characteristics section of the datasheets.
The LSI RC can be switched on and off using the LSION bit in the Control/status register (RCC_CSR).

The LSIRDY flag in the Control/status register (RCC_CSR) indicates if the LSI oscillator is stable or not. At startup, the clock is not released until this bit is set by hardware. An interrupt can be generated if enabled in the Clock interrupt register (RCC_CIR).

6.2.7 System clock (SYSCLK) selection

Various clock sources can be used to drive the system clock (SYSCLK):
- HSI oscillator
- HSE oscillator
- PLL
- HSI48 oscillator (available only on STM32F04x, STM32F07x and STM32F09x devices)

After a system reset, the HSI oscillator is selected as system clock. When a clock source is used directly or through the PLL as a system clock, it is not possible to stop it.

A switch from one clock source to another occurs only if the target clock source is ready (clock stable after startup delay or PLL locked). If a clock source which is not yet ready is selected, the switch will occur when the clock source becomes ready. Status bits in the Clock control register (RCC_CR) indicate which clock(s) is (are) ready and which clock is currently used as a system clock.

6.2.8 Clock security system (CSS)

Clock security system can be activated by software. In this case, the clock detector is enabled after the HSE oscillator startup delay, and disabled when this oscillator is stopped.

If a failure is detected on the HSE clock, the HSE oscillator is automatically disabled, a clock failure event is sent to the break input of the advanced-control timers (TIM1) and general-purpose timers (TIM15, TIM16 and TIM17) and an interrupt is generated to inform the software about the failure (clock security system interrupt, or CSSI), allowing the MCU to perform rescue operations. The CSSI is linked to the Cortex®-M0 NMI (Non-Maskable Interrupt) exception vector.

Note: Once the CSS is enabled and if the HSE clock fails, the CSS interrupt occurs and an NMI is automatically generated. The NMI is executed indefinitely unless the CSS interrupt pending bit is cleared. As a consequence, in the NMI ISR user must clear the CSS interrupt by setting the CSSC bit in the Clock interrupt register (RCC_CIR).

If the HSE oscillator is used directly or indirectly as the system clock (indirectly means: it is used as PLL input clock, and the PLL clock is used as system clock), a detected failure causes a switch of the system clock to the HSI oscillator and the disabling of the HSE oscillator. If the HSE clock (divided or not) is the clock entry of the PLL used as system clock when the failure occurs, the PLL is disabled too.

6.2.9 ADC clock

The ADC clock selection is done inside the ADC_CFGR2 (refer to Section 13.11.5: ADC configuration register 2 (ADC_CFGR2) on page 271). It can be either the dedicated 14 MHz RC oscillator (HSI14) connected on the ADC asynchronous clock input or PCLK divided by 2 or 4. The 14 MHz RC oscillator can be configured by software either to be turned on/off (“auto-off mode”) by the ADC interface or to be always enabled. The HSI 14 MHz RC
oscillator cannot be turned on by ADC interface when the APB clock is selected as an ADC kernel clock.

6.2.10 RTC clock

The RTCCCLK clock source can be either the HSE/32, LSE or LSI clocks. This is selected by programming the RTCSEL[1:0] bits in the RTC domain control register (RCC_BDCR). This selection cannot be modified without resetting the RTC domain. The system must be always configured in a way that the PCLK frequency is greater then or equal to the RTCCCLK frequency for proper operation of the RTC.

The LSE clock is in the RTC domain, whereas the HSE and LSI clocks are not. Consequently:

- If LSE is selected as RTC clock:
  - The RTC continues to work even if the V_DD supply is switched off, provided the V_BAT supply is maintained.
  - The RTC remains clocked and functional under system reset
- If LSI is selected as the RTC clock:
  - The RTC state is not guaranteed if the V_DD supply is powered off. Refer to Section 6.2.6: LSI clock on page 104 for more details on LSI calibration.
- If the HSE clock divided by 32 is used as the RTC clock:
  - The RTC state is not guaranteed if the V_DD supply is powered off or if the internal voltage regulator is powered off (removing power from the 1.8 V domain).

When the RTC clock is LSE, the RTC remains clocked and functional under system reset.

6.2.11 Independent watchdog clock

If the Independent watchdog (IWDG) is started by either hardware option or software access, the LSI oscillator is forced ON and cannot be disabled. After the LSI oscillator temporization, the clock is provided to the IWDG.

6.2.12 Clock-out capability

The microcontroller clock output (MCO) capability allows the clock to be output onto the external MCO pin. The configuration registers of the corresponding GPIO port must be programmed in alternate function mode. One of the following clock signals can be selected as the MCO clock:

- HSI14
- SYSCLK
- HSI
- HSE
- PLL clock divided by 2 or direct (direct connection is not available on STM32F05x devices)
- LSE
- LSI
- HSI48 (on STM32F04x, STM32F07x and STM32F09x devices only)

The selection is controlled by the MCO[3:0] bits of the Clock configuration register (RCC_CFR).
For code example refer to the Appendix section A.3.3: MCO selection code example.

On STM32F03x, STM32F04x, STM32F07x and STM32F09x devices, the additional bit PLLNODIV of this register controls the divider bypass for a PLL clock input to MCO. The MCO frequency can be reduced by a configurable binary divider, controlled by the MCOPRE[2..0] bits of the Clock configuration register (RCC_CFGR).

6.2.13 Internal/external clock measurement with TIM14

It is possible to indirectly measure the frequency of all on-board clock sources by mean of the TIM14 channel 1 input capture. As represented on Figure 13.

Figure 13. Frequency measurement with TIM14 in capture mode

The input capture channel of the Timer 14 can be a GPIO line or an internal clock of the MCU. This selection is performed through the TI1_RMP [1:0] bits in the TIM14_OR register. The possibilities available are the following ones.

- TIM14 Channel1 is connected to the GPIO. Refer to the alternate function mapping in the device datasheets.
- TIM14 Channel1 is connected to the RTCCLK.
- TIM14 Channel1 is connected to the HSE/32 Clock.
- TIM14 Channel1 is connected to the microcontroller clock output (MCO). Refer to Section 6.2.12: Clock-out capability for MCO clock configuration.

For code example refer to the Appendix section A.3.4: Clock measurement configuration with TIM14 code example.

Calibration of the HSI

The primary purpose of connecting the LSE, through the MCO multiplexer, to the channel 1 input capture is to be able to precisely measure the HSI system clocks (for this, the HSI should be used as the system clock source). The number of HSI clock counts between consecutive edges of the LSE signal provides a measure of the internal clock period. Taking advantage of the high precision of LSE crystals (typically a few tens of ppm), it is possible to determine the internal clock frequency with the same resolution, and trim the source to compensate for manufacturing-process- and/or temperature- and voltage-related frequency deviations.

The HSI oscillator has dedicated user-accessible calibration bits for this purpose.

The basic concept consists in providing a relative measurement (e.g. the HSI/LSE ratio): the precision is therefore closely related to the ratio between the two clock sources. The higher the ratio is, the better the measurement is.
If LSE is not available, HSE/32 is the better option in order to reach the most precise calibration possible.

**Calibration of the LSI**

The calibration of the LSI will follow the same pattern that for the HSI, but changing the reference clock. It is necessary to connect LSI clock to the channel 1 input capture of the TIM14. Then define the HSE as system clock source, the number of its clock counts between consecutive edges of the LSI signal provides a measure of the internal low speed clock period.

The basic concept consists in providing a relative measurement (e.g. the HSE/LSI ratio): the precision is therefore closely related to the ratio between the two clock sources. The higher the ratio is, the better the measurement is.

**Calibration of the HSI14**

For the HSI14, because of its high frequency, it is not possible to have a precise resolution. However a solution could be to clock Timer 14 with HSE through PLL to reach 48 MHz, and to use the input capture line with the HSI14 and the capture prescaler defined to the higher value. In that configuration, we got a ratio of 27 events. It is still a bit low to have an accurate calibration. In order to increase the measure accuracy, it is advised to count the HSI periods after multiple cycles of Timer 14. Using polling to treat the capture event is necessary in this case.

### 6.3 Low-power modes

APB peripheral clocks and DMA clock can be disabled by software.

Sleep mode stops the CPU clock. The memory interface clocks (Flash and RAM interfaces) can be stopped by software during sleep mode. The AHB to APB bridge clocks are disabled by hardware during Sleep mode when all the clocks of the peripherals connected to them are disabled.

Stop mode stops all the clocks in the core supply domain and disables the PLL and the HSI, HSI48, HSI14 and HSE oscillators.

HDMI CEC, USART1, USART2 (only on STM32F07x and STM32F09x devices), USART3 (only on STM32F09x devices) and I2C1 have the capability to enable the HSI oscillator even when the MCU is in Stop mode (if HSI is selected as the clock source for that peripheral). When the system is in Stop mode, with the regulator in LP mode, the clock request coming from any of those three peripherals moves the regulator to MR mode in order to have the proper current drive capability for the core logic. The regulator moves back to LP mode once this request is removed without waking up the MCU.

HDMI CEC, USART1, USART2 (only on STM32F07x and STM32F09x devices) and USART3 (only on STM32F09x devices) can also be driven by the LSE oscillator when the system is in Stop mode (if LSE is selected as clock source for that peripheral) and the LSE oscillator is enabled (LSEON) but they do not have the capability to turn on the LSE oscillator.

Standby mode stops all the clocks in the core supply domain and disables the PLL and the HSI, HSI48, HSI14 and HSE oscillators.

The CPU's deepsleep mode can be overridden for debugging by setting the DBG_STOP or DBG_STANDBY bits in the DBGMCU_CR register.
When waking up from deepsleep after an interrupt (Stop mode) or reset (Standby mode),
the HSI oscillator is selected as system clock.

If a Flash programming operation is on going, deepsleep mode entry is delayed until the
Flash interface access is finished. If an access to the APB domain is ongoing, deepsleep
mode entry is delayed until the APB access is finished.
6.4 RCC registers

Refer to Section 1.2 on page 42 for a list of abbreviations used in register descriptions.

6.4.1 Clock control register (RCC_CR)

Address offset: 0x00

Reset value: 0x0000 XX83 where X is undefined.

Access: no wait state, word, half-word and byte access

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **PLLRDY**: PLL clock ready flag

Set by hardware to indicate that the PLL is locked.

0: PLL unlocked
1: PLL locked

Bit 24 **PLLON**: PLL enable

Set and cleared by software to enable PLL.

Cleared by hardware when entering Stop or Standby mode. This bit can not be reset if the PLL clock is used as system clock or is selected to become the system clock.

0: PLL OFF
1: PLL ON

Bits 23:20 Reserved, must be kept at reset value.

Bit 19 **CSSON**: Clock security system enable

Set and cleared by software to enable the clock security system. When CSSON is set, the clock detector is enabled by hardware when the HSE oscillator is ready, and disabled by hardware if a HSE clock failure is detected.

0: Clock security system disabled (clock detector OFF).
1: Clock security system enabled (clock detector ON if the HSE is ready, OFF if not).

Bit 18 **HSEBYP**: HSE crystal oscillator bypass

Set and cleared by software to bypass the oscillator with an external clock. The external clock must be enabled with the HSEON bit set, to be used by the device. The HSEBYP bit can be written only if the HSE oscillator is disabled.

0: HSE crystal oscillator not bypassed
1: HSE crystal oscillator bypassed with external clock
6.4.2 Clock configuration register (RCC_CFGR)

Address offset: 0x04
Reset value: 0x0000 0000
Access: 0 ≤ wait state ≤ 2, word, half-word and byte access
1 or 2 wait states inserted only if the access occurs during clock source switch.

Bit 17  **HSERDY**: HSE clock ready flag
Set by hardware to indicate that the HSE oscillator is stable. This bit needs 6 cycles of the HSE oscillator clock to fall down after HSEON reset.
0: HSE oscillator not ready
1: HSE oscillator ready

Bit 16  **HSEON**: HSE clock enable
Set and cleared by software.
Cleared by hardware to stop the HSE oscillator when entering Stop or Standby mode. This bit cannot be reset if the HSE oscillator is used directly or indirectly as the system clock.
0: HSE oscillator OFF
1: HSE oscillator ON

Bits 15:8  **HSICAL[7:0]**: HSI clock calibration
These bits are initialized automatically at startup. They are adjusted by SW through the HSITRIM setting.

Bits 7:3  **HSITRIM[4:0]**: HSI clock trimming
These bits provide an additional user-programmable trimming value that is added to the HSICAL[7:0] bits. It can be programmed to adjust to variations in voltage and temperature that influence the frequency of the HSI.
The default value is 16, which, when added to the HSICAL value, should trim the HSI to 8 MHz ± 1%. The trimming step is around 40 kHz between two consecutive HSICAL steps.
*Note: Increased value in the register results to higher clock frequency.*

Bit 2  Reserved, must be kept at reset value.

Bit 1  **HSIRDY**: HSI clock ready flag
Set by hardware to indicate that HSI oscillator is stable. After the HSION bit is cleared, HSIRDY goes low after 6 HSI oscillator clock cycles.
0: HSI oscillator not ready
1: HSI oscillator ready

Bit 0  **HSION**: HSI clock enable
Set and cleared by software.
Set by hardware to force the HSI oscillator ON when leaving Stop or Standby mode or in case of failure of the HSE crystal oscillator used directly or indirectly as system clock. This bit cannot be reset if the HSI is used directly or indirectly as system clock or is selected to become the system clock.
0: HSI oscillator OFF
1: HSI oscillator ON
### Bit 31 PLLNODIV: PLL clock not divided for MCO (not available on STM32F05x devices)

This bit is set and cleared by software. It switches off divider by 2 for PLL connection to MCO.

- **0**: PLL is divided by 2 for MCO
- **1**: PLL is not divided for MCO

### Bits 30:28 MCOPRE[2:0]: Microcontroller clock output prescaler (not available on STM32F05x devices)

These bits are set and cleared by software to select the MCO prescaler division factor. To avoid glitches, it is highly recommended to change this prescaler only when the MCO output is disabled.

- **000**: MCO is divided by 1
- **001**: MCO is divided by 2
- **010**: MCO is divided by 4
- **...**: **111**: MCO is divided by 128

### Bits 27:24 MCO[3:0]: Microcontroller clock output

Set and cleared by software.

- **0000**: MCO output disabled, no clock on MCO
- **0001**: Internal RC 14 MHz (HSI14) oscillator clock selected
- **0010**: Internal low speed (LSI) oscillator clock selected
- **0011**: External low speed (LSE) oscillator clock selected
- **0100**: System clock selected
- **0101**: Internal RC 8 MHz (HSI) oscillator clock selected
- **0110**: External 4-32 MHz (HSE) oscillator clock selected
- **0111**: PLL clock selected (divided by 1 or 2, depending on PLLNODIV)
- **1000**: Internal RC 48 MHz (HSI48) oscillator clock selected

**Note:** This clock output may have some truncated cycles at startup or during MCO clock source switching.

### Bits 23:22 Reserved, must be kept at reset value.
Bits 21:18 **PLLMUL[3:0]**: PLL multiplication factor  
These bits are written by software to define the PLL multiplication factor. These bits can be written only when PLL is disabled.  
Caution: The PLL output frequency must not exceed 48 MHz.  
0000: PLL input clock x 2  
0001: PLL input clock x 3  
0010: PLL input clock x 4  
0011: PLL input clock x 5  
0100: PLL input clock x 6  
0101: PLL input clock x 7  
0110: PLL input clock x 8  
0111: PLL input clock x 9  
1000: PLL input clock x 10  
1001: PLL input clock x 11  
1010: PLL input clock x 12  
1011: PLL input clock x 13  
1100: PLL input clock x 14  
1101: PLL input clock x 15  
1110: PLL input clock x 16  
1111: PLL input clock x 16  

Bit 17 **PLLXTPRE**: HSE divider for PLL input clock  
This bit is the same bit as bit PREDIV[0] from RCC_CFGR2. Refer to RCC_CFGR2 PREDIV bits description for its meaning.  

Bits 16:15 **PLLSRC[1:0]**: PLL input clock source  
Set and cleared by software to select PLL or PREDIV clock source. These bits can be written only when PLL is disabled.  
00: HSI/2 selected as PLL input clock (PREDIV forced to divide by 2 on STM32F04x, STM32F07x and STM32F09x devices)  
01: HSI/PREDIV selected as PLL input clock  
10: HSE/PREDIV selected as PLL input clock  
11: HSI48/PREDIV selected as PLL input clock  
Bit PLLSRC[0] is available only on STM32F04x, STM32F07x and STM32F09x devices, otherwise it is reserved (with value zero).  

Bit 14 **ADCPRE**: ADC prescaler  
Obsolete setting. Proper ADC clock selection is done inside the ADC_CFGR2 (refer to Section 13.11.5: ADC configuration register 2 (ADC_CFGR2) on page 271).  

Bits 13:11 Reserved, must be kept at reset value.  

Bits 10:8 **PPRE[2:0]**: PCLK prescaler  
Set and cleared by software to control the division factor of the APB clock (PCLK).  
0xx: HCLK not divided  
100: HCLK divided by 2  
101: HCLK divided by 4  
110: HCLK divided by 8  
111: HCLK divided by 16
6.4.3 Clock interrupt register (RCC_CIR)

Address offset: 0x08

Reset value: 0x0000 0000

Access: no wait state, word, half-word and byte access

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 CSSC: Clock security system interrupt clear
This bit is set by software to clear the CSSF flag.
0: No effect
1: Clear CSSF flag
Bit 22 **HSI48RDYC**: HSI48 Ready Interrupt Clear  
This bit is set by software to clear the HSI48RDYF flag.  
0: No effect  
1: Clear HSI48RDYF flag

Bit 21 **HSI14RDYC**: HSI14 ready interrupt clear  
This bit is set by software to clear the HSI14RDYF flag.  
0: No effect  
1: Clear HSI14RDYF flag

Bit 20 **PLLRDYC**: PLL ready interrupt clear  
This bit is set by software to clear the PLLRDYF flag.  
0: No effect  
1: Clear PLLRDYF flag

Bit 19 **HSERDYC**: HSE ready interrupt clear  
This bit is set by software to clear the HSERDYF flag.  
0: No effect  
1: Clear HSERDYF flag

Bit 18 **HSIRDYC**: HSI ready interrupt clear  
This bit is set by software to clear the HSIRDYF flag.  
0: No effect  
1: Clear HSIRDYF flag

Bit 17 **LSERDYC**: LSE ready interrupt clear  
This bit is set by software to clear the LSERDYF flag.  
0: No effect  
1: LSERDYF cleared

Bit 16 **LSIRDYC**: LSI ready interrupt clear  
This bit is set by software to clear the LSIRDYF flag.  
0: No effect  
1: LSIRDYF cleared

Bit 15 Reserved, must be kept at reset value.

Bit 14 **HSI48RDYIE**: HSI48 ready interrupt enable  
Set and cleared by software to enable/disable interrupt caused by the HSI48 oscillator stabilization.  
0: HSI48 ready interrupt disabled  
1: HSI48 ready interrupt enabled

Bit 13 **HSI14RDYIE**: HSI14 ready interrupt enable  
Set and cleared by software to enable/disable interrupt caused by the HSI14 oscillator stabilization.  
0: HSI14 ready interrupt disabled  
1: HSI14 ready interrupt enabled

Bit 12 **PLLRDYIE**: PLL ready interrupt enable  
Set and cleared by software to enable/disable interrupt caused by PLL lock.  
0: PLL lock interrupt disabled  
1: PLL lock interrupt enabled
Bit 11 **HSERDYIE**: HSE ready interrupt enable
Set and cleared by software to enable/disable interrupt caused by the HSE oscillator stabilization.
- 0: HSE ready interrupt disabled
- 1: HSE ready interrupt enabled

Bit 10 **HSIRDYIE**: HSI ready interrupt enable
Set and cleared by software to enable/disable interrupt caused by the HSI oscillator stabilization.
- 0: HSI ready interrupt disabled
- 1: HSI ready interrupt enabled

Bit 9 **LSERDYIE**: LSE ready interrupt enable
Set and cleared by software to enable/disable interrupt caused by the LSE oscillator stabilization.
- 0: LSE ready interrupt disabled
- 1: LSE ready interrupt enabled

Bit 8 **LSIRDYIE**: LSI ready interrupt enable
Set and cleared by software to enable/disable interrupt caused by the LSI oscillator stabilization.
- 0: LSI ready interrupt disabled
- 1: LSI ready interrupt enabled

Bit 7 **CSSF**: Clock security system interrupt flag
Set by hardware when a failure is detected in the HSE oscillator.
Cleared by software setting the CSSC bit.
- 0: No clock security interrupt caused by HSE clock failure
- 1: Clock security interrupt caused by HSE clock failure

Bit 6 **HSI48RDYF**: HSI48 ready interrupt flag
Set by hardware when the HSI48 becomes stable and HSI48RDYDIE is set in a response to setting the HSI48ON bit in Clock control register 2 (RCC_CR2). When HSI48ON is not set but the HSI48 oscillator is enabled by the peripheral through a clock request, this bit is not set and no interrupt is generated.
Cleared by software setting the HSI48RDYC bit.
- 0: No clock ready interrupt caused by the HSI48 oscillator
- 1: Clock ready interrupt caused by the HSI48 oscillator

Bit 5 **HSI14RDYF**: HSI14 ready interrupt flag
Set by hardware when the HSI14 becomes stable and HSI14RDYDIE is set in a response to setting the HSI14ON bit in Clock control register 2 (RCC_CR2). When HSI14ON is not set but the HSI14 oscillator is enabled by the peripheral through a clock request, this bit is not set and no interrupt is generated.
Cleared by software setting the HSI14RDYC bit.
- 0: No clock ready interrupt caused by the HSI14 oscillator
- 1: Clock ready interrupt caused by the HSI14 oscillator

Bit 4 **PLLRDYF**: PLL ready interrupt flag
Set by hardware when the PLL locks and PLLRDYDIE is set.
Cleared by software setting the PLLRDYC bit.
- 0: No clock ready interrupt caused by PLL lock
- 1: Clock ready interrupt caused by PLL lock
Bit 3 **HSERDYF**: HSE ready interrupt flag
Set by hardware when the HSE clock becomes stable and HSERDYDIE is set.
Cleared by software setting the HSERDYC bit.
- 0: No clock ready interrupt caused by the HSE oscillator
- 1: Clock ready interrupt caused by the HSE oscillator

Bit 2 **HSIRDYF**: HSI ready interrupt flag
Set by hardware when the HSI clock becomes stable and HSIRDYDIE is set in a response to setting the HSION (refer to Clock control register (RCC_CR)). When HSION is not set but the HSI oscillator is enabled by the peripheral through a clock request, this bit is not set and no interrupt is generated.
Cleared by software setting the HSIRDYC bit.
- 0: No clock ready interrupt caused by the HSI oscillator
- 1: Clock ready interrupt caused by the HSI oscillator

Bit 1 **LSERDYF**: LSE ready interrupt flag
Set by hardware when the LSE clock becomes stable and LSERDYDIE is set.
Cleared by software setting the LSERDYC bit.
- 0: No clock ready interrupt caused by the LSE oscillator
- 1: Clock ready interrupt caused by the LSE oscillator

Bit 0 **LSIRDYF**: LSI ready interrupt flag
Set by hardware when the LSI clock becomes stable and LSIRDYDIE is set.
Cleared by software setting the LSIRDYC bit.
- 0: No clock ready interrupt caused by the LSI oscillator
- 1: Clock ready interrupt caused by the LSI oscillator

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 TSCEN: Touch sensing controller clock enable
Set and cleared by software.
0: TSC clock disabled
1: TSC clock enabled

Bit 23 Reserved, must be kept at reset value.

Bit 22 IOFFEN: I/O port F clock enable
Set and cleared by software.
0: I/O port F clock disabled
1: I/O port F clock enabled
Bit 21  **IOPEEN**: I/O port E clock enable  
Set and cleared by software.  
0: I/O port E clock disabled  
1: I/O port E clock enabled

Bit 20  **IOPDEN**: I/O port D clock enable  
Set and cleared by software.  
0: I/O port D clock disabled  
1: I/O port D clock enabled

Bit 19  **IOPCEN**: I/O port C clock enable  
Set and cleared by software.  
0: I/O port C clock disabled  
1: I/O port C clock enabled

Bit 18  **IOPBEN**: I/O port B clock enable  
Set and cleared by software.  
0: I/O port B clock disabled  
1: I/O port B clock enabled

Bit 17  **IOPAEN**: I/O port A clock enable  
Set and cleared by software.  
0: I/O port A clock disabled  
1: I/O port A clock enabled

Bits 16:7 Reserved, must be kept at reset value.

Bit 6  **CRCEN**: CRC clock enable  
Set and cleared by software.  
0: CRC clock disabled  
1: CRC clock enabled

Bit 5 Reserved, must be kept at reset value.

Bit 4  **FLITFEN**: FLITF clock enable  
Set and cleared by software to disable/enable FLITF clock during Sleep mode.  
0: FLITF clock disabled during Sleep mode  
1: FLITF clock enabled during Sleep mode

Bit 3 Reserved, must be kept at reset value.

Bit 2  **SRAMEN**: SRAM interface clock enable  
Set and cleared by software to disable/enable SRAM interface clock during Sleep mode.  
0: SRAM interface clock disabled during Sleep mode  
1: SRAM interface clock enabled during Sleep mode

Bit 1  **DMA2EN**: DMA2 clock enable  
Set and cleared by software.  
0: DMA2 clock disabled  
1: DMA2 clock enabled

Bit 0  **DMAEN**: DMA clock enable  
Set and cleared by software.  
0: DMA clock disabled  
1: DMA clock enabled
6.4.7 APB peripheral clock enable register 2 (RCC_APB2ENR)

Address: 0x18
Reset value: 0x0000 0000
Access: word, half-word and byte access

No wait states, except if the access occurs while an access to a peripheral in the APB domain is on going. In this case, wait states are inserted until the access to APB peripheral is finished.

Note: When the peripheral clock is not active, the peripheral register values may not be readable by software and the returned value is always 0x0.

- 1: TIM15 timer clock enabled

Bit 15 Reserved, must be kept at reset value.

Bit 14 USART1EN: USART1 clock enable
Set and cleared by software.
- 0: USART1 clock disabled
- 1: USART1 clock enabled

Bit 13 Reserved, must be kept at reset value.
6.4.8 **APB peripheral clock enable register 1 (RCC_APB1ENR)**

Address: 0x1C

Reset value: 0x0000 0000

Access: word, half-word and byte access

No wait state, except if the access occurs while an access to a peripheral on APB domain is on going. In this case, wait states are inserted until this access to APB peripheral is finished.

*Note:* *When the peripheral clock is not active, the peripheral register values may not be readable by software and the returned value is always 0x0.*

### 6.4.9 RTC domain control register (RCC_BDCR)

Address offset: 0x20  
Reset value: 0x0000 0018, reset by RTC domain reset.  
Access: 0 ≤ wait state ≤ 3, word, half-word and byte access  
Wait states are inserted in case of successive accesses to this register.  

**Note:** The LSEON, LSEBYP, RTCSEL and RTCEN bits of the RTC domain control register (RCC_BDCR) are in the RTC domain. As a result, after reset, these bits are write-protected and the DBP bit in the Power control register (PWR_CR) has to be set before they can be modified. Refer to Section 5.1.3: Battery backup domain for further information. These bits are only reset after a RTC domain reset (see Section 6.1.3: RTC domain reset). Any internal or external reset does not have any effect on these bits.

Bits 31:17 Reserved, must be kept at reset value.
6.4.10 Control/status register (RCC_CSR)

Address: 0x24

Reset value: 0xXXX0 0000, reset by system Reset, except reset flags by power Reset only.

Access: 0 ≤ wait state ≤ 3, word, half-word and byte access

Wait states are inserted in case of successive accesses to this register.
Bit 31 **LPWRRSTF**: Low-power reset flag
Set by hardware when a Low-power management reset occurs.
Cleared by writing to the RMVF bit.
0: No Low-power management reset occurred
1: Low-power management reset occurred
For further information refer to **Low-power management reset**.

Bit 30 **WWDGRSTF**: Window watchdog reset flag
Set by hardware when a window watchdog reset occurs.
Cleared by writing to the RMVF bit.
0: No window watchdog reset occurred
1: Window watchdog reset occurred

Bit 29 **IWDGRSTF**: Independent watchdog reset flag
Set by hardware when an independent watchdog reset from VDD domain occurs.
Cleared by writing to the RMVF bit.
0: No watchdog reset occurred
1: Watchdog reset occurred

Bit 28 **SFRSTF**: Software reset flag
Set by hardware when a software reset occurs.
Cleared by writing to the RMVF bit.
0: No software reset occurred
1: Software reset occurred

Bit 27 **PORRSTF**: POR/PDR reset flag
Set by hardware when a POR/PDR reset occurs.
Cleared by writing to the RMVF bit.
0: No POR/PDR reset occurred
1: POR/PDR reset occurred

Bit 26 **PINRSTF**: PIN reset flag
Set by hardware when a reset from the NRST pin occurs.
Cleared by writing to the RMVF bit.
0: No reset from NRST pin occurred
1: Reset from NRST pin occurred

Bit 25 **OBLRSTF**: Option byte loader reset flag
Set by hardware when a reset from the OBL occurs.
Cleared by writing to the RMVF bit.
0: No reset from OBL occurred
1: Reset from OBL occurred

Bit 24 **RMVF**: Remove reset flag
Set by software to clear the reset flags including RMVF.
0: No effect
1: Clear the reset flags

Bit 23 **V18PWRRSTF**: Reset flag of the 1.8 V domain.
Set by hardware when a POR/PDR of the 1.8 V domain occurred.
Cleared by writing to the RMVF bit.
0: No POR/PDR reset of the 1.8 V domain occurred
1: POR/PDR reset of the 1.8 V domain occurred

**Caution**: On the STM32F0x8 family, this flag must be read as reserved.
6.4.11 AHB peripheral reset register (RCC_AHBRSTR)

Address: 0x28
Reset value: 0x0000 0000
Access: no wait states, word, half-word and byte access

Set and cleared by software.
0: No effect
1: Reset I/O port D

Bits 22:2 Reserved, must be kept at reset value.

Bit 1 **LSIRDY**: LSI oscillator ready
Set and cleared by hardware to indicate when the LSI oscillator is stable. After the LSION bit is cleared, LSIRDY goes low after 3 LSI oscillator clock cycles.
0: LSI oscillator not ready
1: LSI oscillator ready

Bit 0 **LSION**: LSI oscillator enable
Set and cleared by software.
0: LSI oscillator OFF
1: LSI oscillator ON
6.4.12 Clock configuration register 2 (RCC_CFGR2)

Address: 0x2C

Reset value: 0x0000 0000

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:18 **USART3SW[1:0]**: USART3 clock source selection (available only on STM32F09x devices)
This bit is set and cleared by software to select the USART3 clock source.

00: PCLK selected as USART3 clock source (default)
01: System clock (SYSCLK) selected as USART3 clock
10: LSE clock selected as USART3 clock
11: HSI clock selected as USART3 clock
Bits 17:16 **USART2SW[1:0]**: USART2 clock source selection (available only on STM32F07x and STM32F09x devices)

This bit is set and cleared by software to select the USART2 clock source.
- 00: PCLK selected as USART2 clock source (default)
- 01: System clock (SYSCLK) selected as USART2 clock
- 10: LSE clock selected as USART2 clock
- 11: HSI clock selected as USART2 clock

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **ADCSW**: ADC clock source selection

Obsolete setting. To be kept at reset value, connecting the HSI14 clock to the ADC asynchronous clock input. Proper ADC clock selection is done inside the ADC_CFGR2 (refer to Section 13.11.5: ADC configuration register 2 (ADC_CFGR2) on page 271).

Bit 7 **USBSW**: USB clock source selection

This bit is set and cleared by software to select the USB clock source.
- 0: HSI48 clock selected as USB clock source (default)
- 1: PLL clock (PLLCLK) selected as USB clock

Bit 6 **CECSW**: HDMI CEC clock source selection

This bit is set and cleared by software to select the CEC clock source.
- 0: HSI clock, divided by 244, selected as CEC clock (default)
- 1: LSE clock selected as CEC clock

Bit 5 Reserved, must be kept at reset value.

Bit 4 **I2C1SW**: I2C1 clock source selection

This bit is set and cleared by software to select the I2C1 clock source.
- 0: HSI clock selected as I2C1 clock source (default)
- 1: System clock (SYSCLK) selected as I2C1 clock

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 **USART1SW[1:0]**: USART1 clock source selection

This bit is set and cleared by software to select the USART1 clock source.
- 00: PCLK selected as USART1 clock source (default)
- 01: System clock (SYSCLK) selected as USART1 clock
- 10: LSE clock selected as USART1 clock
- 11: HSI clock selected as USART1 clock

### 6.4.14 Clock control register 2 (RCC_CR2)

Address: 0x34

Reset value: 0xXX00 XX80, where X is undefined.

Access: no wait states, word, half-word and byte access
Bits 31:24 **HSI48CAL[7:0]**: HSI48 factory clock calibration
These bits are initialized automatically at startup and are read-only.

Bits 23:18 Reserved, must be kept at reset value.

**Bit 17 HSI48RDY**: HSI48 clock ready flag
Set by hardware to indicate that HSI48 oscillator is stable. After the HSI48ON bit is cleared, HSI48RDY goes low after 6 HSI48 oscillator clock cycles.
0: HSI48 oscillator not ready
1: HSI48 oscillator ready

**Bit 16 HSI48ON**: HSI48 clock enable
Set and cleared either by software or by hardware. Set by hardware when the USB peripheral is enabled and switched on this source; reset by hardware to stop the oscillator when entering in Stop or Standby mode. This bit cannot be reset if the HSI48 is used directly or indirectly as system clock or is selected to become the system clock.
0: HSI48 oscillator OFF
1: HSI48 oscillator ON

Bits 15:8 **HSI14CAL[7:0]**: HSI14 clock calibration
These bits are initialized automatically at startup.

**Bits 7:3 HSI14TRIM[4:0]**: HSI14 clock trimming
These bits provide an additional user-programmable trimming value that is added to the HSI14CAL[7:0] bits. It can be programmed to adjust to variations in voltage and temperature that influence the frequency of the HSI14.
The default value is 16, which, when added to the HSI14CAL value, should trim the HSI14 to 14 MHz ± 1%. The trimming step is around 50 kHz between two consecutive HSI14CAL steps.

**Bit 2 HSI14DIS**: HSI14 clock request from ADC disable
Set and cleared by software.
When set this bit prevents the ADC interface from enabling the HSI14 oscillator.
0: ADC interface can turn on the HSI14 oscillator
1: ADC interface can not turn on the HSI14 oscillator

**Bit 1 HSI14RDY**: HSI14 clock ready flag
Set by hardware to indicate that HSI14 oscillator is stable. After the HSI14ON bit is cleared, HSI14RDY goes low after 6 HSI14 oscillator clock cycles. When HSI14ON is not set but the HSI14 oscillator is enabled by the peripheral through a clock request, this bit is not set.
0: HSI14 oscillator not ready
1: HSI14 oscillator ready
Bit 0  **HSI14ON**: HSI14 clock enable

Set and cleared by software. When the HSI14 oscillator is enabled by the peripheral through a clock request, this bit is not set and resetting it does not stop the HSI14 oscillator.

0: HSI14 oscillator OFF
1: HSI14 oscillator ON
### 6.4.15 RCC register map

The following table gives the RCC register map and the reset values.

| Offset | Register | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|--------|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 0x00   | RCC_CR   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | 0  | 0  | 0  | 0  | 0  |
|        |          |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

**Table 19. RCC register map and reset values**

- **Offset**: The offset of the register in memory.
- **Register**: The name of the register.
- **31-0**: The hexadecimal value of the register. The reset value is indicated by an underscore `_`. The default value is `0x00`.

### RCC register map details

- **RCC_CR**: Reset and clock control register (RCC CR)
- **RCC_CFG**: RCC configuration register (RCC CFG)
- **RCC_CIR**: RCC clock interrupt register (RCC CIR)
- **RCC_APB2RSTR**: RCC APB2 reset control register (RCC_APB2RSTR)
- **RCC_APB1RSTR**: RCC APB1 reset control register (RCC_APB1RSTR)
- **RCC_AHBENR**: RCC AHB enable register (RCC_AHBENR)
- **RCC_CSR**: RCC control and status register (RCC_CSR)

The table provides the reset values for each register, with values indicated by `0x00` or hexadecimal values in the register fields.
Refer to Section 2.2 on page 46 for the register boundary addresses.
7 Clock recovery system (CRS)

This section applies to STM32F04x, STM32F07x and STM32F09x devices only.

7.1 Introduction

The clock recovery system (CRS) is an advanced digital controller acting on the internal fine-granularity trimmable RC oscillator HSI48. The CRS provides powerful means for oscillator output frequency evaluation, based on comparison with a selectable synchronization signal. It is capable of doing automatic adjustment of oscillator trimming based on the measured frequency error value, while keeping the possibility of a manual trimming.

The CRS is ideally suited to provide a precise clock to the USB peripheral. In such case, the synchronization signal can be derived from the start-of-frame (SOF) packet signalization on the USB bus, which is sent by a USB host at 1 ms intervals.

The synchronization signal can also be derived from the LSE oscillator output, from an external pin, or it can be generated by user software.

7.2 CRS main features

- Selectable synchronization source with programmable prescaler and polarity:
  - External pin
  - LSE oscillator output
  - USB SOF packet reception
- Possibility to generate synchronization pulses by software
- Automatic oscillator trimming capability with no need of CPU action
- Manual control option for faster start-up convergence
- 16-bit frequency error counter with automatic error value capture and reload
- Programmable limit for automatic frequency error value evaluation and status reporting
- Maskable interrupts/events:
  - Expected synchronization (ESYNC)
  - Synchronization OK (SYNCKOK)
  - Synchronization warning (SYNCWARN)
  - Synchronization or trimming error (ERR)

7.3 CRS implementation

7.4 CRS functional description

7.4.1 CRS block diagram

The CRS synchronization (SYNC) source, selectable through the CRS_CFGR register, can be the signal from the external CRS_SYNC pin, the LSE clock or the USB SOF signal. For a better robustness of the SYNC input, a simple digital filter (2 out of 3 majority votes, sampled by the RC48 clock) is implemented to filter out any glitches. This source signal also has a configurable polarity and can then be divided by a programmable binary prescaler to obtain a synchronization signal in a suitable frequency range (usually around 1 kHz).

For more information on the CRS synchronization source configuration, refer to Section 7.7.2: CRS configuration register (CRS_CFGR).

It is also possible to generate a synchronization event by software, by setting the SWSYNC bit in the CRS_CR register.
7.4.3 Frequency error measurement

The frequency error counter is a 16-bit down/up counter which is reloaded with the RELOAD value on each SYNC event. It starts counting down till it reaches the zero value, where the ESYNC (expected synchronization) event is generated. Then it starts counting up to the OUTRANGE limit where it eventually stops (if no SYNC event is received) and generates a SYNCMISS event. The OUTRANGE limit is defined as the frequency error limit (FELIM field of the CRS_CFGR register) multiplied by 128.

When the SYNC event is detected, the actual value of the frequency error counter and its counting direction are stored in the FECAP (frequency error capture) field and in the FEDIR (frequency error direction) bit of the CRS_ISR register. When the SYNC event is detected during the downcounting phase (before reaching the zero value), it means that the actual frequency is lower than the target (and so, that the TRIM value must be incremented), while when it is detected during the upcounting phase it means that the actual frequency is higher (and that the TRIM value must be decremented).

![Figure 15. CRS counter behavior](image)

7.4.4 Frequency error evaluation and automatic trimming

The measured frequency error is evaluated by comparing its value with a set of limits:
- TOLERANCE LIMIT, given directly in the FELIM field of the CRS_CFGR register
- WARNING LIMIT, defined as 3 \times FELIM value
- OUTRANGE (error limit), defined as 128 \times FELIM value
The result of this comparison is used to generate the status indication and also to control the automatic trimming which is enabled by setting the AUTOTRIMEN bit in the CRS_CR register:

- When the frequency error is below the tolerance limit, it means that the actual trimming value in the TRIM field is the optimal one, hence no trimming action is needed.
  - SYNCOK status indicated
  - TRIM value not changed in AUTOTRIM mode

- When the frequency error is below the warning limit but above or equal to the tolerance limit, it means that some trimming action is necessary but that adjustment by one trimming step is enough to reach the optimal TRIM value.
  - SYNCOK status indicated
  - TRIM value adjusted by one trimming step in AUTOTRIM mode

- When the frequency error is above or equal to the warning limit but below the error limit, it means that a stronger trimming action is necessary, and there is a risk that the optimal TRIM value is not reached for the next period.
  - SYNCWARN status indicated
  - TRIM value adjusted by two trimming steps in AUTOTRIM mode

- When the frequency error is above or equal to the error limit, it means that the frequency is out of the trimming range. This can also happen when the SYNC input is not clean or when some SYNC pulse is missing (for example when one USB SOF is corrupted).
  - SYNCERR or SYNCMISS status indicated
  - TRIM value not changed in AUTOTRIM mode

Note: If the actual value of the TRIM field is so close to its limits that the automatic trimming would force it to overflow or underflow, then the TRIM value is set just to the limit and the TRIMOVF status is indicated.

In AUTOTRIM mode (AUTOTRIMEN bit set in the CRS_CR register), the TRIM field of CRS_CR is adjusted by hardware and is read-only.

7.4.5 CRS initialization and configuration

**RELOAD value**

The RELOAD value must be selected according to the ratio between the target frequency and the frequency of the synchronization source after prescaling. It is then decreased by one to reach the expected synchronization on the zero value. The formula is the following:

\[
\text{RELOAD} = \left(\frac{f_{\text{TARGET}}}{f_{\text{SYNC}}} \right) - 1
\]

The reset value of the RELOAD field corresponds to a target frequency of 48 MHz and a synchronization signal frequency of 1 kHz (SOF signal from USB).

**FELIM value**

The selection of the FELIM value is closely coupled with the HSI48 oscillator characteristics and its typical trimming step size. The optimal value corresponds to half of the trimming step size, expressed as a number of HSI48 oscillator clock ticks. The following formula can be used:

\[
\text{FELIM} = \left(\frac{f_{\text{TARGET}}}{f_{\text{SYNC}}} \right) \times \text{STEP} \% / 100 \% / 2
\]
The result must be always rounded up to the nearest integer value to obtain the best trimming response. If frequent trimming actions are not needed in the application, the hysteresis can be increased by slightly increasing the FELIM value.

The reset value of the FELIM field corresponds to \( \frac{f_{\text{TARGET}}}{f_{\text{SYNC}}} \approx 48000 \) and to a typical trimming step size of 0.14%.

**Note:** The trimming step size depends upon the product, check the datasheet for accurate setting.

**Caution:** There is no hardware protection from a wrong configuration of the RELOAD and FELIM fields which can lead to an erratic trimming response. The expected operational mode requires proper setup of the RELOAD value (according to the synchronization source frequency), which is also greater than 128 * FELIM value (OUTRANGE limit).

### 7.5 CRS low-power modes

Table 21. Effect of low-power modes on CRS

<table>

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:8 **TRIM[5:0]**: HSI48 oscillator smooth trimming  
These bits provide a user-programmable trimming value to the HSI48 oscillator. They can be programmed to adjust to variations in voltage and temperature that influence the frequency of the HSI48 oscillator.  
The default value is 32, which corresponds to the middle of the trimming interval. The trimming step is specified in the product datasheet. A higher TRIM value corresponds to a higher output frequency.  
When the AUTOTRIMEN bit is set, this field is controlled by hardware and is read-only.

Bit 7 **SWSYNC**: Generate software SYNC event  
This bit is set by software in order to generate a software SYNC event. It is automatically cleared by hardware.  
0: No action  
1: A software SYNC event is generated.

Bit 6 **AUTOTRIMEN**: Automatic trimming enable  
This bit enables the automatic hardware adjustment of TRIM bits according to the measured frequency error between two SYNC events. If this bit is set, the TRIM bits are read-only. The TRIM value can be adjusted by hardware by one or two steps at a time, depending on the measured frequency error value. Refer to *Section 7.4.4* for more details.  
0: Automatic trimming disabled, TRIM bits can be adjusted by the user.  
1: Automatic trimming enabled, TRIM bits are read-only and under hardware control.

Bit 5 **CEN**: Frequency error counter enable  
This bit enables the oscillator clock for the frequency error counter.  
0: Frequency error counter disabled  
1: Frequency error counter enabled  
When this bit is set, the CRS_CFGR register is write-protected and cannot be modified.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **ESYNCE**: Expected SYNC interrupt enable  
0: Expected SYNC (ESYNCF) interrupt disabled  
1: Expected SYNC (ESYNCF) interrupt enabled
Bit 2 **ERRIE**: Synchronization or trimming error interrupt enable
0: Synchronization or trimming error (ERRF) interrupt disabled
1: Synchronization or trimming error (ERRF) interrupt enabled

Bit 1 **SYNCWARNIE**: SYNC warning interrupt enable
0: SYNC warning (SYNCWARNF) interrupt disabled
1: SYNC warning (SYNCWARNF) interrupt enabled

Bit 0 **SYNCOKIE**: SYNC event OK interrupt enable
0: SYNC event OK (SYNCOKF) interrupt disabled
1: SYNC event OK (SYNCOKF) interrupt enabled

### 7.7.2 CRS configuration register (CRS_CFRG)

This register can be written only when the frequency error counter is disabled (CEN bit is cleared in CRS_CR). When the counter is enabled, this register is write-protected.

Address offset: 0x04

Reset value: 0x2022 BB7F

Bit 31 **SYNCPOL**: SYNC polarity selection
This bit is set and cleared by software to select the input polarity for the SYNC signal source.
0: SYNC active on rising edge (default)
1: SYNC active on falling edge

Bit 30 Reserved, must be kept at reset value.

Bits 29:28 **SYNCSRC[1:0]**: SYNC signal source selection
These bits are set and cleared by software to select the SYNC signal source.
00: GPIO selected as SYNC signal source
01: LSE selected as SYNC signal source
10: USB SOF selected as SYNC signal source (default).
11: Reserved

*Note: When using USB LPM (Link Power Management) and the device is in Sleep mode, the periodic USB SOF is not generated by the host. No SYNC signal is therefore provided to the CRS to calibrate the HSI48 oscillator on the run. To guarantee the required clock precision after waking up from Sleep mode, the LSE or reference clock on the GPIOs should be used as SYNC signal.*

Bit 27 Reserved, must be kept at reset value.
Bits 26:24 SYNCDIV[2:0]: SYNC divider
These bits are set and cleared by software to control the division factor of the SYNC signal.
000: SYNC not divided (default)
001: SYNC divided by 2
010: SYNC divided by 4
011: SYNC divided by 8
100: SYNC divided by 16
101: SYNC divided by 32
110: SYNC divided by 64
111: SYNC divided by 128

Bits 23:16 FELIM[7:0]: Frequency error limit
FELIM contains the value to be used to evaluate the captured frequency error value latched in the FECAP[15:0] bits of the CRS_ISR register. Refer to Section 7.4.4 for more details about FECAP evaluation.

Bits 15:0 RELOAD[15:0]: Counter reload value
RELOAD is the value to be loaded in the frequency error counter with each SYNC event. Refer to Section 7.4.3 for more details about counter behavior.

</table>

Bits 31:16 FECAP[15:0]: Frequency error capture
FECAP is the frequency error counter value latched in the time of the last SYNC event. Refer to Section 7.4.4 for more details about FECAP usage.

Bit 15 FEDIR: Frequency error direction
FEDIR is the counting direction of the frequency error counter latched in the time of the last SYNC event. It shows whether the actual frequency is below or above the target.
0: Upcounting direction, the actual frequency is above the target.
1: Downcounting direction, the actual frequency is below the target.

Bits 14:11 Reserved, must be kept at reset value.

Bit 10 TRIMOVF: Trimming overflow or underflow
This flag is set by hardware when the automatic trimming tries to over- or under-flow the TRIM value. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.
0: No trimming error signalized
1: Trimming error signalized
Clock recovery system (CRS) RM0091

Bit 9 **SYNCMISS**: SYNC missed
This flag is set by hardware when the frequency error counter reached value FELIM * 128 and no SYNC was detected, meaning either that a SYNC pulse was missed or that the frequency error is too big (internal frequency too high) to be compensated by adjusting the TRIM value, and that some other action has to be taken. At this point, the frequency error counter is stopped (waiting for a next SYNC) and an interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.

0: No SYNC missed error signalized
1: SYNC missed error signalized

Bit 8 **SYNCERR**: SYNC error
This flag is set by hardware when the SYNC pulse arrives before the ESYNC event and the measured frequency error is greater than or equal to FELIM * 128. This means that the frequency error is too big (internal frequency too low) to be compensated by adjusting the TRIM value, and that some other action has to be taken. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.

0: No SYNC error signalized
1: SYNC error signalized

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **ESYNC**: Expected SYNC flag
This flag is set by hardware when the frequency error counter reached a zero value. An interrupt is generated if the ESYNCIE bit is set in the CRS_CR register. It is cleared by software by setting the ESYNCC bit in the CRS_ICR register.

0: No expected SYNC signalized
1: Expected SYNC signalized

Bit 2 **ERRF**: Error flag
This flag is set by hardware in case of any synchronization or trimming error. It is the logical OR of the TRIMOVF, SYNCMISS and SYNCERR bits. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software in reaction to setting the ERRC bit in the CRS_ICR register.

0: No synchronization or trimming error signalized
1: Synchronization or trimming error signalized

Bit 1 **SYNCTWRF**: SYNC warning flag
This flag is set by hardware when the measured frequency error is greater than or equal to FELIM * 3, but smaller than FELIM * 128. This means that to compensate the frequency error, the TRIM value must be adjusted by two steps or more. An interrupt is generated if the SYNCWARNIE bit is set in the CRS_CR register. It is cleared by software by setting the SYNCWARNC bit in the CRS_ICR register.

0: No SYNC warning signalized
1: SYNC warning signalized

Bit 0 **SYNCOKEF**: SYNC event OK flag
This flag is set by hardware when the measured frequency error is smaller than FELIM * 3. This means that either no adjustment of the TRIM value is needed or that an adjustment by one trimming step is enough to compensate the frequency error. An interrupt is generated if the SYNCOKIE bit is set in the CRS_CR register. It is cleared by software by setting the SYNCOKC bit in the CRS_ICR register.

0: No SYNC event OK signalized
1: SYNC event OK signalized
7.7.4 CRS interrupt flag clear register (CRS_ICR)

Address offset: 0x0C
Reset value: 0x0000 0000

| Bits 31:4 | Reserved, must be kept at reset value. |
| Bit 3    | ESYNCC: Expected SYNC clear flag |
| Writing 1 to this bit clears the ESYNCF flag in the CRS_ISR register. |
| Bit 2    | ERRC: Error clear flag |
| Writing 1 to this bit clears TRIMOVF, SYNCMISS and SYNCERR bits and consequently also the ERRF flag in the CRS_ISR register. |
| Bit 1    | SYNCWARNC: SYNC warning clear flag |
| Writing 1 to this bit clears the SYNCWARNF flag in the CRS_ISR register. |
| Bit 0    | SYNCOKC: SYNC event OK clear flag |
| Writing 1 to this bit clears the SYNCOKF flag in the CRS_ISR register. |

7.7.5 CRS register map

Table 23. CRS register map and reset values
Refer to *Section 2.2 on page 46* for the register boundary addresses.
8 General-purpose I/Os (GPIO)

8.1 Introduction

Each general-purpose I/O port has four 32-bit configuration registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR and GPIOx_PUPDR), two 32-bit data registers (GPIOx_IDR and GPIOx_ODR) and a 32-bit set/reset register (GPIOx_BSSR). Ports A and B also have a 32-bit locking register (GPIOx_LCKR) and two 32-bit alternate function selection registers (GPIOx_AFRH and GPIOx_AFRL).

On STM32F07x and STM32F09x devices, also ports C, D, E, and F have two 32-bit alternate function selection registers (GPIOx_AFRH and GPIOx_AFRL).

Port E is available on STM32F07x and STM32F09x devices only.

8.2 GPIO main features

- Output states: push-pull or open drain + pull-up/down
- Output data from output data register (GPIOx_ODR) or peripheral (alternate function output)
- Speed selection for each I/O
- Input states: floating, pull-up/down, analog
- Input data to input data register (GPIOx_IDR) or peripheral (alternate function input)
- Bit set and reset register (GPIOx_BSRR) for bitwise write access to GPIOx_ODR
- Locking mechanism (GPIOx_LCKR) provided to freeze the port A or B I/O port configuration.
- Analog function
- Alternate function selection registers (at most 16 AFs possible per I/O)
- Fast toggle capable of changing every two clock cycles
- Highly flexible pin multiplexing allows the use of I/O pins as GPIOs or as one of several peripheral functions

8.3 GPIO functional description

Subject to the specific hardware characteristics of each I/O port listed in the datasheet, each port bit of the general-purpose I/O (GPIO) ports can be individually configured by software in several modes:

- Input floating
- Input pull-up
- Input-pull-down
- Analog
- Output open-drain with pull-up or pull-down capability
- Output push-pull with pull-up or pull-down capability
- Alternate function push-pull with pull-up or pull-down capability
- Alternate function open-drain with pull-up or pull-down capability
Each I/O port bit is freely programmable, however the I/O port registers have to be accessed as 32-bit words, half-words or bytes. The purpose of the GPIOx_BSRR register is to allow atomic read/modify accesses to any of the GPIOx_ODR registers. In this way, there is no risk of an IRQ occurring between the read and the modify access.

*Figure 16* shows the basic structures of a standard I/O port bit. *Table 24* gives the possible port bit configurations.

8.3.1 General-purpose I/O (GPIO)

During and just after reset, the alternate functions are not active and most of the I/O ports are configured in input floating mode.

The debug pins are in AF pull-up/pull-down after reset:
- PA14: SWCLK in pull-down
- PA13: SWDIO in pull-up

When the pin is configured as output, the value written to the output data register (GPIOx_ODR) is output on the I/O pin. It is possible to use the output driver in push-pull mode or open-drain mode (only the low level is driven, high level is HI-Z).

The input data register (GPIOx_IDR) captures the data present on the I/O pin at every AHB clock cycle.

All GPIO pins have weak internal pull-up and pull-down resistors, which can be activated or not depending on the value in the GPIOx_PUPDR register.

8.3.2 I/O pin alternate function multiplexer and mapping

The device I/O pins are connected to on-board peripherals/modules through a multiplexer that allows only one peripheral alternate function (AF) connected to an I/O pin at a time. In this way, there can be no conflict between peripherals available on the same I/O pin.

Each I/O pin has a multiplexer with up to eight alternate function inputs (AF0 to AF7) that can be configured through the GPIOx_AFRL (for pin 0 to 7) and GPIOx_AFRH (for pin 8 to 15) registers:
- After reset the multiplexer selection is alternate function 0 (AF0). The I/Os are configured in alternate function mode through GPIOx_MODER register.
- The specific alternate function assignments for each pin are detailed in the device datasheet.

In addition to this flexible I/O multiplexing architecture, each peripheral has alternate functions mapped onto different I/O pins to optimize the number of peripherals available in smaller packages.
To use an I/O in a given configuration, the user has to proceed as follows:

- **Debug function:** after each device reset these pins are assigned as alternate function pins immediately usable by the debugger host

- **GPIO:** configure the desired I/O as output, input or analog in the GPIOx_MODER register.

- **Peripheral alternate function:**
  - Connect the I/O to the desired AFx in one of the GPIOx_AFRL or GPIOx_AFRH register.
  - Select the type, pull-up/pull-down and output speed via the GPIOx_OTYPER, GPIOx_PUPDR and GPIOx_OSPEEDER registers, respectively.
  - Configure the desired I/O as an alternate function in the GPIOx_MODER register.

- **Additional functions:**
  - ADC and DAC connection can be enabled in ADC or DAC registers regardless the configured GPIO mode. When ADC or DAC uses a GPIO, it is recommended to configure the GPIO in analog mode, through the GPIOx_MODER register.
  - For the additional functions like RTC, WKUPx and oscillators, configure the required function in the related RTC, PWR and RCC registers. These functions have priority over the configuration in the standard GPIO registers.

Refer to the “Alternate function mapping” table in the device datasheet for the detailed mapping of the alternate function I/O pins.

### 8.3.3 I/O port control registers

Each of the GPIO ports has four 32-bit memory-mapped control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR) to configure up to 16 I/Os. The GPIOx_MODER register is used to select the I/O mode (input, output, AF, analog). The GPIOx_OTYPER and GPIOx_OSPEEDR registers are used to select the output type (push-pull or open-drain) and speed. The GPIOx_PUPDR register is used to select the pull-up/pull-down whatever the I/O direction.

### 8.3.4 I/O port data registers

Each GPIO has two 16-bit memory-mapped data registers: input and output data registers (GPIOx_IDR and GPIOx_ODR). GPIOx_ODR stores the data to be output, it is read/write accessible. The data input through the I/O are stored into the input data register (GPIOx_IDR), a read-only register.

See Section 8.4.5: GPIO port input data register (GPIOx_IDR) (x = A to F) and Section 8.4.6: GPIO port output data register (GPIOx_ODR) (x = A to F) for the register descriptions.

### 8.3.5 I/O data bitwise handling

The bit set reset register (GPIOx_BSRR) is a 32-bit register which allows the application to set and reset each individual bit in the output data register (GPIOx_ODR). The bit set reset register has twice the size of GPIOx_ODR.

To each bit in GPIOx_ODR, correspond two control bits in GPIOx_BSRR: BS(i) and BR(i). When written to 1, bit BS(i) sets the corresponding ODR(i) bit. When written to 1, bit BR(i) resets the ODR(i) corresponding bit.
Writing any bit to 0 in GPIOx_BSRR does not have any effect on the corresponding bit in GPIOx_ODR. If there is an attempt to both set and reset a bit in GPIOx_BSRR, the set action takes priority.

Using the GPIOx_BSRR register to change the values of individual bits in GPIOx_ODR is a “one-shot” effect that does not lock the GPIOx_ODR bits. The GPIOx_ODR bits can always be accessed directly. The GPIOx_BSRR register provides a way of performing atomic bitwise handling.

There is no need for the software to disable interrupts when programming the GPIOx_ODR at bit level: it is possible to modify one or more bits in a single atomic AHB write access.

8.3.6 GPIO locking mechanism

It is possible to freeze the port A and B GPIO control registers by applying a specific write sequence to the GPIOx_LCKR register. The frozen registers are GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL and GPIOx_AFRH.

To write the GPIOx_LCKR register, a specific write / read sequence has to be applied. When the right LOCK sequence is applied to bit 16 in this register, the value of LCKR[15:0] is used to lock the configuration of the I/Os (during the write sequence the LCKR[15:0] value must be the same). When the LOCK sequence has been applied to a port bit, the value of the port bit can no longer be modified until the next MCU reset or peripheral reset. Each GPIOx_LCKR bit freezes the corresponding bit in the control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL and GPIOx_AFRH.

The LOCK sequence (refer to Section 8.4.8: GPIO port configuration lock register (GPIOx_LCKR) (x = A to B)) can only be performed using a word (32-bit long) access to the GPIOx_LCKR register due to the fact that GPIOx_LCKR bit 16 has to be set at the same time as the [15:0] bits.

For more details refer to LCKR register description in Section 8.4.8: GPIO port configuration lock register (GPIOx_LCKR) (x = A to B).

8.3.7 I/O alternate function input/output

Two registers are provided to select one of the alternate function inputs/outputs available for each I/O. With these registers, the user can connect an alternate function to some other pin as required by the application.

This means that a number of possible peripheral functions are multiplexed on each GPIO using the GPIOx_AFRL and GPIOx_AFRH alternate function registers. The application can thus select any one of the possible functions for each I/O. The AF selection signal being common to the alternate function input and alternate function output, a single channel is selected for the alternate function input/output of a given I/O.

For code example refer to Section A.4.2: Alternate function selection sequence code example on page 945.

To know which functions are multiplexed on each GPIO pin refer to the device datasheet.

8.3.8 External interrupt/wake-up lines

All ports have external interrupt capability. To use external interrupt lines, the given pin must not be configured in analog mode or being used as oscillator pin, so the input trigger is kept enabled.
Refer to Section 11.2: Extended interrupts and events controller (EXTI) and to Section 11.2.3: Event management.

8.3.9 Input configuration

When the I/O port is programmed as input:
- The output buffer is disabled
- The Schmitt trigger input is activated
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle
- A read access to the input data register provides the I/O state

Figure 17 shows the input configuration of the I/O port bit.

8.3.10 Output configuration

When the I/O port is programmed as output:
- The output buffer is enabled:
  - Open drain mode: a “0” in the output register activates the N-MOS whereas a “1” in the output register leaves the port in Hi-Z (the P-MOS is never activated)
  - Push-pull mode: a “0” in the output register activates the N-MOS whereas a “1” in the output register activates the P-MOS
- The Schmitt trigger input is activated
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle
- A read access to the input data register gets the I/O state
- A read access to the output data register gets the last written value
Figure 18 shows the output configuration of the I/O port bit.

Figure 18. Output configuration

8.3.11 Alternate function configuration

When the I/O port is programmed as alternate function:

- The output buffer can be configured in open-drain or push-pull mode
- The output buffer is driven by the signals coming from the peripheral (transmitter enable and data)
- The Schmitt trigger input is activated
- The weak pull-up and pull-down resistors are activated or not depending on the value in the GPIOx_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle
- A read access to the input data register gets the I/O state
Figure 19 shows the alternate function configuration of the I/O port bit.

**Figure 19. Alternate function configuration**

8.3.12 Analog configuration

When the I/O port is programmed as analog configuration:
- The output buffer is disabled
- The Schmitt trigger input is deactivated, providing zero consumption for every analog value of the I/O pin. The output of the Schmitt trigger is forced to a constant value (0).
- The weak pull-up and pull-down resistors are disabled by hardware
- Read access to the input data register gets the value “0”

For code example refer to Section A.4.3: Analog GPIO configuration code example on page 946.

Figure 20 shows the high-impedance, analog-input configuration of the I/O port bits.

**Figure 20. High impedance-analog configuration**
8.3.13 Using the HSE or LSE oscillator pins as GPIOs

When the HSE or LSE oscillator is switched OFF (default state after reset), the related oscillator pins can be used as normal GPIOs.

When the HSE or LSE oscillator is switched ON (by setting the HSEON or LSEON bit in the RCC_CSR register) the oscillator takes control of its associated pins and the GPIO configuration of these pins has no effect.

When the oscillator is configured in a user external clock mode, only the pin is reserved for clock input and the OSC_OUT or OSC32_OUT pin can still be used as normal GPIO.

8.3.14 Using the GPIO pins in the RTC supply domain

The PC13/PC14/PC15 GPIO functionality is lost when the core supply domain is powered off (when the device enters Standby mode). In this case, if their GPIO configuration is not bypassed by the RTC configuration, these pins are set in an analog input mode.

For details about I/O control by the RTC, refer to Section 25.4: RTC functional description.
8.4 GPIO registers

For a summary of register bits, register address offsets and reset values, refer to Table 25. The peripheral registers can be written in word, half word or byte mode.

8.4.1 GPIO port mode register (GPIOx_MODER) (x = A to F)

Address offset: 0x00
Reset value: 0x2800 0000 for port A
Reset value: 0x0000 0000 for other ports

Bits 15:0 **BS[15:0]**: Port x set I/O pin y (y = 15 to 0)  
These bits are write-only. A read to these bits returns the value 0x0000.  
0: No action on the corresponding ODRx bit  
1: Sets the corresponding ODRx bit

8.4.8 GPIO port configuration lock register (GPIOx_LCKR)  
(x = A to B)

This register is used to lock the configuration of the port bits when a correct write sequence is applied to bit 16 (LCKK). The value of bits [15:0] is used to lock the configuration of the GPIO. During the write sequence, the value of LCKR[15:0] must not change. When the LOCK sequence has been applied on a port bit, the value of this port bit can no longer be modified until the next MCU reset or peripheral reset.

*Note: A specific write sequence is used to write to the GPIOx_LCKR register. Only word access (32-bit long) is allowed during this locking sequence.*

Each lock bit freezes a specific configuration register (control and alternate function registers).

Address offset: 0x1C
Reset value: 0x0000 0000

Bits 31:7 Reserved, must be kept at reset value.

Bit 16 **LCKK**: Lock key

This bit can be read any time. It can only be modified using the lock key write sequence.

0: Port configuration lock key not active
1: Port configuration lock key active. The GPIOx_LCKR register is locked until the next MCU reset or peripheral reset.

LOCK key write sequence:
- WR LCKR[16] = 1 + LCKR[15:0]
- WR LCKR[16] = 0 + LCKR[15:0]
- WR LCKR[16] = 1 + LCKR[15:0]

RD LCKR
RD LCKR[16] = 1 (this read operation is optional but it confirms that the lock is active)

*Note:* During the LOCK key write sequence, the value of LCK[15:0] must not change.

Any error in the lock sequence aborts the lock.
After the first lock sequence on any bit of the port, any read access on the LCKK bit returns 1 until the next MCU reset or peripheral reset. For code example refer to Section A.4.1: Lock sequence code example on page 945.

Bits 15:0 **LCK[15:0]**: Port x lock I/O pin y (y = 15 to 0)
These bits are read/write but can only be written when the LCKK bit is 0.
0: Port configuration not locked
1: Port configuration locked

Bits 31:0 **AFSELy[3:0]**: Alternate function selection for port x pin y (y = 0..7)
These bits are written by software to configure alternate function I/Os

Refer to Section 2.2 on page 46 for the register boundary addresses.
9 System configuration controller (SYSCFG)

The devices feature a set of configuration registers. The main purposes of the system configuration controller are the following:

- Enabling/disabling I²C Fast Mode Plus on some IO ports
- Remapping some DMA trigger sources to different DMA channels
- Remapping the memory located at the beginning of the code area
- Pending interrupt status registers for each interrupt line on STM32F09x devices
- Managing the external interrupt line connection to the GPIOs
- Managing robustness feature

9.1 SYSCFG registers

9.1.1 SYSCFG configuration register 1 (SYSCFG_CFGR1)

This register is used for specific configurations of memory and DMA requests remap and to control special I/O features.

Two bits are used to configure the type of memory accessible at address 0x0000 0000. These bits are used to select the physical remap by software and so, bypass the hardware BOOT selection.

After reset these bits take the value selected by the actual boot mode configuration.

Address offset: 0x00
Reset value: 0x0000 000X (X is the memory mode selected by the actual boot mode configuration)

Bit 31 Reserved, must be kept at reset value.

Bit 30 **TIM3_DMA_RMP**: TIM3 DMA request remapping bit. Available on STM32F07x devices only.
This bit is set and cleared by software. It controls the remapping of TIM3 DMA requests.

0: No remap (TIM3_CH1 and TIM3_TRIG DMA requests mapped on DMA channel 4)
1: Remap (TIM3_CH1 and TIM3_TRIG DMA requests mapped on DMA channel 6)
Bit 29 **TIM2_DMA_RMP**: TIM2 DMA request remapping bit. Available on STM32F07x devices only. This bit is set and cleared by software. It controls the remapping of TIM2 DMA requests.
- 0: No remap (TIM2_CH2 and TIM2_CH4 DMA requests mapped on DMA channel 3 and 4 respectively)
- 1: Remap (TIM2_CH2 and TIM2_CH4 DMA requests mapped on DMA channel 7)

Bit 28 **TIM1_DMA_RMP**: TIM1 DMA request remapping bit. Available on STM32F07x devices only. This bit is set and cleared by software. It controls the remapping of TIM1 DMA requests.
- 0: No remap (TIM1_CH1, TIM1_CH2 and TIM1_CH3 DMA requests mapped on DMA channel 2, 3 and 4 respectively)
- 1: Remap (TIM1_CH1, TIM1_CH2 and TIM1_CH3 DMA requests mapped on DMA channel 6)

Bit 27 **I2C1_DMA_RMP**: I2C1 DMA request remapping bit. Available on STM32F07x devices only. This bit is set and cleared by software. It controls the remapping of I2C1 DMA requests.
- 0: No remap (I2C1_RX and I2C1_TX DMA requests mapped on DMA channel 3 and 2 respectively)
- 1: Remap (I2C1_RX and I2C1_TX DMA requests mapped on DMA channel 7 and 6 respectively)

Bit 26 **USART3_DMA_RMP**: USART3 DMA request remapping bit. Available on STM32F07x devices only. This bit is set and cleared by software. It controls the remapping of USART3 DMA requests.
- 0: (USART3_RX and USART3_TX DMA requests mapped on DMA channel 6 and 7 respectively)
- 1: Remap (USART3_RX and USART3_TX DMA requests mapped on DMA channel 3 and 2 respectively)

Bit 25 **USART2_DMA_RMP**: USART2 DMA request remapping bit. Available on STM32F07x devices only. This bit is set and cleared by software. It controls the remapping of USART2 DMA requests.
- 0: No remap (USART2_RX and USART2_TX DMA requests mapped on DMA channel 5 and 4 respectively)
- 1: Remap (USART2_RX and USART2_TX DMA requests mapped on DMA channel 6 and 7 respectively)

Bit 24 **SPI2_DMA_RMP**: SPI2 DMA request remapping bit. Available on STM32F07x devices only. This bit is set and cleared by software. It controls the remapping of SPI2 DMA requests.
- 0: No remap (SPI2_RX and SPI2_TX DMA requests mapped on DMA channel 4 and 5 respectively)
- 1: Remap (SPI2_RX and SPI2_TX DMA requests mapped on DMA channel 6 and 7 respectively)

Bits 23:22 **I2C_PAx_FMP**: Fast Mode Plus (FM+) driving capability activation bits. Available on STM32F03x, STM32F04x and STM32F09x devices only. These bits are set and cleared by software. Each bit enables I2C FM+ mode for PA10 and PA9 I/Os.
- 0: PAx pin operates in standard mode.
- 1: I2C FM+ mode enabled on PAx pin and the Speed control is bypassed.
Bit 21 **I2C2_FMP**: FM+ driving capability activation for I2C2. Available on STM32F07x and STM32F09x devices only.

This bit is set and cleared by software. This bit is OR-ed with I2C_Pxx_FM+ bits.

0: FM+ mode is controlled by I2C_Pxx_FM+ bits only.
1: FM+ mode is enabled on all I2C2 pins selected through selection bits in GPIOx_AFR registers. This is the only way to enable the FM+ mode for pads without a dedicated I2C_Pxx_FM+ control bit.

Bit 20 **I2C1_FMP**: FM+ driving capability activation for I2C1. Not available on STM32F05x devices. This bit is set and cleared by software. This bit is OR-ed with I2C_Pxx_FM+ bits.

0: FM+ mode is controlled by I2C_Pxx_FM+ bits only.
1: FM+ mode is enabled on all I2C1 pins selected through selection bits in GPIOx_AFR registers. This is the only way to enable the FM+ mode for pads without a dedicated I2C_Pxx_FM+ control bit.

Bits 19:16 **I2C_PBx_FMP**: Fast Mode Plus (FM+) driving capability activation bits. These bits are set and cleared by software. Each bit enables I²C FM+ mode for PB6, PB7, PB8, and PB9 I/Os.

0: PBx pin operates in standard mode.
1: I²C FM+ mode enabled on PBx pin and the Speed control is bypassed.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TIM17_DMA_RMP2**: TIM17 alternate DMA request remapping bit. Available on STM32F07x devices only.

This bit is set and cleared by software. It controls the alternate remapping of TIM17 DMA requests.

0: No alternate remap (TIM17 DMA requests mapped according to TIM17_DMA_RMP bit)
1: Alternate remap (TIM17_CH1 and TIM17_UP DMA requests mapped on DMA channel 7)

Bit 13 **TIM16_DMA_RMP2**: TIM16 alternate DMA request remapping bit. Available on STM32F07x devices only.

This bit is set and cleared by software. It controls the alternate remapping of TIM16 DMA requests.

0: No alternate remap (TIM16 DMA requests mapped according to TIM16_DMA_RMP bit)
1: Alternate remap (TIM16_CH1 and TIM16_UP DMA requests mapped on DMA channel 6)

Bit 12 **TIM17_DMA_RMP**: TIM17 DMA request remapping bit. Available on STM32F03x, STM32F04x, STM32F05x and STM32F07x devices only.

This bit is set and cleared by software. It controls the remapping of TIM17 DMA requests.

0: No remap (TIM17_CH1 and TIM17_UP DMA requests mapped on DMA channel 1)
1: Remap (TIM17_CH1 and TIM17_UP DMA requests mapped on DMA channel 2)

Bit 11 **TIM16_DMA_RMP**: TIM16 DMA request remapping bit. Available on STM32F03x, STM32F04x, STM32F05x and STM32F07x devices only.

This bit is set and cleared by software. It controls the remapping of TIM16 DMA requests.

0: No remap (TIM16_CH1 and TIM16_UP DMA requests mapped on DMA channel 3)
1: Remap (TIM16_CH1 and TIM16_UP DMA requests mapped on DMA channel 4)

Bit 10 **USART1_RX_DMA_RMP**: USART1_RX DMA request remapping bit. Available on STM32F03x, STM32F04x, STM32F05x and STM32F07x devices only.

This bit is set and cleared by software. It controls the remapping of USART1_RX DMA requests.

0: No remap (USART1_RX DMA request mapped on DMA channel 3)
1: Remap (USART1_RX DMA request mapped on DMA channel 5)
9.1.2 SYSCFG external interrupt configuration register 1

</tbody>
</table>

- **Bits 31:9** Reserved, must be kept at reset value
- **Bit 8** SRAM_PEF: SRAM parity error flag
  - This bit is set by hardware when an SRAM parity error is detected. It is cleared by software by writing ‘1’.
  - 0: No SRAM parity error detected
  - 1: SRAM parity error detected

- **Bits 7:3** Reserved, must be kept at reset value
- **Bit 2** PVD_LOCK: PVD lock enable bit
  - This bit is set by software and cleared by a system reset. It can be used to enable and lock the PVD connection to TIM1/15/16/17 Break input, as well as the PVDE and PLS[2:0] in the PWR_CR register.
  - 0: PVD interrupt disconnected from TIM1/15/16/17 Break input. PVDE and PLS[2:0] bits can be programmed by the application.
  - 1: PVD interrupt connected to TIM1/15/16/17 Break input, PVDE and PLS[2:0] bits are read only.

- **Bit 1** SRAM_PARITY_LOCK: SRAM parity lock bit
  - This bit is set by software and cleared by a system reset. It can be used to enable and lock the SRAM parity error signal connection to TIM1/15/16/17 Break input.
  - 0: SRAM parity error disconnected from TIM1/15/16/17 Break input
  - 1: SRAM parity error connected to TIM1/15/16/17 Break input

- **Bit 0** LOCKUP_LOCK: Cortex-M0 LOCKUP bit enable bit
  - This bit is set by software and cleared by a system reset. It can be use to enable and lock the connection of Cortex-M0 LOCKUP (Hardfault) output to TIM1/15/16/17 Break input.
  - 0: Cortex-M0 LOCKUP output disconnected from TIM1/15/16/17 Break input
  - 1: Cortex-M0 LOCKUP output connected to TIM1/15/16/17 Break input

9.1.7 SYSCFG interrupt line 0 status register (SYSCFG_ITLINE0)

A dedicated set of registers is implemented on STM32F09x to collect all pending interrupt sources associated with each interrupt line into a single register. This allows users to check by single read which peripheral requires service in case more than one source is associated to the interrupt line.

All bits in those registers are read only, set by hardware when there is corresponding interrupt request pending and cleared by resetting the interrupt source flags in the peripheral registers.

Refer to Section 2.2 on page 46 for the register boundary addresses.
10 Direct memory access controller (DMA)

10.1 Introduction
The direct memory access (DMA) controller is a bus master and system peripheral.
The DMA is used to perform programmable data transfers between memory-mapped
peripherals and/or memories, upon the control of an off-loaded CPU.
The DMA controller features a single AHB master architecture.
There is one instance of DMA with up to 7 channels, except for the STM32F09x devices that
also include a DMA2 with 5 channels.
Each channel is dedicated to managing memory access requests from one or more
peripherals. Each DMA includes an arbiter for handling the priority between DMA requests.

10.2 DMA main features
• Single AHB master
• Peripheral-to-memory, memory-to-peripheral, memory-to-memory and peripheral-to-
  peripheral data transfers
• Access, as source and destination, to on-chip memory-mapped devices such as Flash
  memory, SRAM, and AHB and APB peripherals
• All DMA channels independently configurable:
  – Each channel is associated either with a DMA request signal coming from a
    peripheral, or with a software trigger in memory-to-memory transfers. This
    configuration is done by software.
  – Priority between the requests is programmable by software (4 levels per channel:
    very high, high, medium, low) and by hardware in case of equality (such as
    request to channel 1 has priority over request to channel 2).
  – Transfer size of source and destination are independent (byte, half-word, word),
    emulating packing and unpacking. Source and destination addresses must be
    aligned on the data size.
  – Support of transfers from/to peripherals to/from memory with circular buffer
    management
  – Programmable number of data to be transferred: 0 to $2^{16} - 1$
• Generation of an interrupt request per channel. Each interrupt request is caused from
  any of the three DMA events: transfer complete, half transfer, or transfer error.
10.3 DMA implementation

10.3.1 DMA1 and DMA2

DMA1 and DMA2 are implemented with the hardware configuration parameters shown in the table below.

<table>
<thead>
<tr>
<th>Feature</th>
<th>DMA1</th>
<th>DMA2 (only for STM32F09x devices)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of channels</td>
<td>Up to 7(1)</td>
<td>5</td>
</tr>
</tbody>
</table>

1. 5 channels for STM32F03x/04x/05x and 7 channels for STM32F07x.

10.3.2 DMA request mapping

DMA controller on STM32F03x/04x/05x/07x

The hardware requests from the peripherals (TIMx, ADC, DAC, SPI, I2C, and USARTx) are simply logically ORed before entering the DMA. This means that on one channel, only one request must be enabled at a time.

The peripheral DMA requests can be independently activated/de-activated by programming the DMA control bit in the registers of the corresponding peripheral.

Caution: A same peripheral request can be assigned to two different channels only if the application ensures that these channels are not requested to be served at the same time. In other words, if two different channels receive a same asserted peripheral request at the same time, an unpredictable DMA hardware behavior occurs.

Table 29 and Table 30 list the DMA requests for each channel.

</table>
DMA1 and DMA2 controllers on STM32F09x devices

The hardware requests from the peripherals are mapped to the DMA channels through the DMA_CSELR channel selection register. On one channel, only one request must be enabled at a time. Refer to Figure 21.

The peripheral DMA requests can be independently activated/de-activated by programming the DMA control bit in the registers of the corresponding peripheral.

Caution: A same peripheral request can be assigned to two different channels only if the application ensures that these channels are not requested to be served at the same time. In other words, if two different channels receive a same asserted peripheral request at the same time, an unpredictable DMA hardware behavior occurs.

The default mapping position 0 ensures the compatibility with the DMA mapping used on other STM32F0xx products. The hardware requests from the peripherals (TIMx, ADC, DAC, SPI, I2C, and USARTx) are simply logically ORed before entering the DMA. This means that on one channel, only one request must be enabled at a time.

Alternate mapping positions 1 to 15 brings higher flexibility to map hardware requests on DMA channels. When alternate mapping position is used for some peripheral, the same request is removed from the default mapping position to avoid conflicts. 

Table 31 and Table 32 list the DMA requests for each channel and alternate position.
1. Channels 6 and 7 are not available on DMA2.

2. Once a DMA request is selected on position 1 to 15, it disappears from the default location on position 0.

Table 32. DMA2 requests for each channel on STM32F09x devices
The DMA block diagram is shown in the figure below.

![Figure 22. DMA block diagram](image)

The DMA controller performs direct memory transfer by sharing the AHB system bus with other system masters. The bus matrix implements round-robin scheduling. DMA requests may stop the CPU access to the system bus for a number of bus cycles, when CPU and DMA target the same destination (memory or peripheral).

According to its configuration through the AHB slave interface, the DMA controller arbitrates between the DMA channels and their associated received requests. The DMA controller also schedules the DMA data transfers over the single AHB port master.

The DMA controller generates an interrupt per channel to the interrupt controller.

### 10.4.2 DMA transfers

The software configures the DMA controller at channel level, in order to perform a block transfer, composed of a sequence of AHB bus transfers.

A DMA block transfer may be requested from a peripheral, or triggered by the software in case of memory-to-memory transfer.
After an event, the following steps of a single DMA transfer occur:

1. The peripheral sends a single DMA request signal to the DMA controller.
2. The DMA controller serves the request, depending on the priority of the channel associated to this peripheral request.
3. As soon as the DMA controller grants the peripheral, an acknowledge is sent to the peripheral by the DMA controller.
4. The peripheral releases its request as soon as it gets the acknowledge from the DMA controller.
5. Once the request is de-asserted by the peripheral, the DMA controller releases the acknowledge.

The peripheral may order a further single request and initiate another single DMA transfer.

The request/acknowledge protocol is used when a peripheral is either the source or the destination of the transfer. For example, in case of memory-to-peripheral transfer, the peripheral initiates the transfer by driving its single request signal to the DMA controller. The DMA controller reads then a single data in the memory and writes this data to the peripheral.

For a given channel x, a DMA block transfer consists of a repeated sequence of:
   • a single DMA transfer, encapsulating two AHB transfers of a single data, over the DMA AHB bus master:
     – a single data read (byte, half-word or word) from the peripheral data register or a location in the memory, addressed through an internal current peripheral/memory address register. The start address used for the first single transfer is the base address of the peripheral or memory, and is programmed in the DMA_CPARx or DMA_CMARx register.
     – a single data write (byte, half-word or word) to the peripheral data register or a location in the memory, addressed through an internal current peripheral/memory address register. The start address used for the first transfer is the base address of the peripheral or memory, and is programmed in the DMA_CPARx or DMA_CMARx register.
   • post-decrementing of the programmed DMA_CNDTRx register
     This register contains the remaining number of data items to transfer (number of AHB ‘read followed by write’ transfers).

This sequence is repeated until DMA_CNDTRx is null.

Note: The AHB master bus source/destination address must be aligned with the programmed size of the transferred single data to the source/destination.

10.4.3 DMA arbitration

The DMA arbiter manages the priority between the different channels.

When an active channel x is granted by the arbiter (hardware requested or software triggered), a single DMA transfer is issued (such as a AHB ‘read followed by write’ transfer of a single data). Then, the arbiter considers again the set of active channels and selects the one with the highest priority.
The priorities are managed in two stages:

- **software**: priority of each channel is configured in the DMA_CCRx register, to one of the four different levels:
  - very high
  - high
  - medium
  - low

- **hardware**: if two requests have the same software priority level, the channel with the lowest index gets priority. For example, channel 2 gets priority over channel 4.

When a channel x is programmed for a block transfer in memory-to-memory mode, arbitration is considered between each single DMA transfer of this channel x. Whenever there is another concurrent active requested channel, the DMA arbiter automatically alternates and grants the other highest-priority requested channel, which may be of lower priority than the memory-to-memory channel.

### 10.4.4 DMA channels

Each channel may handle a DMA transfer between a peripheral register located at a fixed address, and a memory address. The amount of data items to transfer is programmable. The register that contains the amount of data items to transfer is decremented after each transfer.

A DMA channel is programmed at block transfer level.

**Programmable data sizes**

The transfer sizes of a single data (byte, half-word, or word) to the peripheral and memory are programmable through, respectively, the PSIZE[1:0] and MSIZE[1:0] fields of the DMA_CCRx register.

**Pointer incrementation**

The peripheral and memory pointers may be automatically incremented after each transfer, depending on the PINC and MINC bits of the DMA_CCRx register.

If the **incremented mode** is enabled (PINC or MINC set to 1), the address of the next transfer is the address of the previous one incremented by 1, 2 or 4, depending on the data size defined in PSIZE[1:0] or MSIZE[1:0]. The first transfer address is the one programmed in the DMA_CPARx or DMA_CMARx register. During transfers, these registers keep the initially programmed value. The current transfer addresses (in the current internal peripheral/memory address register) are not accessible by software.

If the channel x is configured in **non-circular mode**, no DMA request is served after the last data transfer (once the number of single data to transfer reaches zero). The DMA channel must be disabled in order to reload a new number of data items into the DMA_CNDTRx register.

**Note:** If the channel x is disabled, the DMA registers are not reset. The DMA channel registers (DMA_CCRx, DMA_CPARx and DMA_CMARx) retain the initial values programmed during the channel configuration phase.

In **circular mode**, after the last data transfer, the DMA_CNDTRx register is automatically reloaded with the initially programmed value. The current internal address registers are reloaded with the base address values from the DMA_CPARx and DMA_CMARx registers.
Channel configuration procedure

The following sequence is needed to configure a DMA channel x:

1. Set the peripheral register address in the DMA_CPARx register.  
The data is moved from/to this address to/from the memory after the peripheral event, 
or after the channel is enabled in memory-to-memory mode.

2. Set the memory address in the DMA_CMARx register.  
The data is written to/read from the memory after the peripheral event or after the 
channel is enabled in memory-to-memory mode.

3. Configure the total number of data to transfer in the DMA_CNDTRx register.  
After each data transfer, this value is decremented.

4. Configure the parameters listed below in the DMA_CCRx register:
   – the channel priority
   – the data transfer direction
   – the circular mode
   – the peripheral and memory incremented mode
   – the peripheral and memory data size
   – the interrupt enable at half and/or full transfer and/or transfer error

5. Activate the channel by setting the EN bit in the DMA_CCRx register.

For code example refer to the Appendix Section A.5.1: DMA channel configuration 
sequence code example.

A channel, as soon as enabled, may serve any DMA request from the peripheral connected 
to this channel, or may start a memory-to-memory block transfer.

Note: The two last steps of the channel configuration procedure may be merged into a single 
access to the DMA_CCRx register, to configure and enable the channel.

Channel state and disabling a channel

A channel x in active state is an enabled channel (read DMA_CCRx.EN = 1). An active 
channel x is a channel that must have been enabled by the software (DMA_CCRx.EN set 
to 1) and afterwards with no occurred transfer error (DMA_ISR.TEIFx = 0). In case there is a 
transfer error, the channel is automatically disabled by hardware (DMA_CCRx.EN = 0).

The three following use cases may happen:

- Suspend and resume a channel
  This corresponds to the two following actions:
  – An active channel is disabled by software (writing DMA_CCRx.EN = 0 whereas 
    DMA_CCRx.EN = 1).
  – The software enables the channel again (DMA_CCRx.EN set to 1) without 
    reconfiguring the other channel registers (such as DMA_CNDTRx, DMA_CPARx 
    and DMA_CMARx).
  
  This case is not supported by the DMA hardware, that does not guarantee that the 
  remaining data transfers are performed correctly.

- Stop and abort a channel
  If the application does not need any more the channel, this active channel can be 
  disabled by software. The channel is stopped and aborted but the DMA_CNDTRx
register content may not correctly reflect the remaining data transfers versus the aborted source and destination buffer/register.

- Abort and restart a channel
  This corresponds to the software sequence: disable an active channel, then reconfigure the channel and enable it again.
  This is supported by the hardware if the following conditions are met:
  - The application guarantees that, when the software is disabling the channel, a DMA data transfer is not occurring at the same time over its master port. For example, the application can first disable the peripheral in DMA mode, in order to ensure that there is no pending hardware DMA request from this peripheral.
  - The software must operate separated write accesses to the same DMA_CCRx register: First disable the channel. Second reconfigure the channel for a next block transfer including the DMA_CCRx if a configuration change is needed. There are read-only DMA_CCRx register fields when DMA_CCRx.EN=1. Finally enable again the channel.

When a channel transfer error occurs, the EN bit of the DMA_CCRx register is cleared by hardware. This EN bit can not be set again by software to re-activate the channel x, until the TEIFx bit of the DMA_ISR register is set.

Circular mode (in memory-to-peripheral/peripheral-to-memory transfers)

The circular mode is available to handle circular buffers and continuous data flows (such as ADC scan mode). This feature is enabled using the CIRC bit in the DMA_CCRx register.

Note: The circular mode must not be used in memory-to-memory mode. Before enabling a channel in circular mode (CIRC = 1), the software must clear the MEM2MEM bit of the DMA_CCRx register. When the circular mode is activated, the amount of data to transfer is automatically reloaded with the initial value programmed during the channel configuration phase, and the DMA requests continue to be served.

In order to stop a circular transfer, the software needs to stop the peripheral from generating DMA requests (such as quit the ADC scan mode), before disabling the DMA channel. The software must explicitly program the DMA_CNDTRx value before starting/enabling a transfer, and after having stopped a circular transfer.

Memory-to-memory mode

The DMA channels may operate without being triggered by a request from a peripheral. This mode is called memory-to-memory mode, and is initiated by software.

If the MEM2MEM bit in the DMA_CCRx register is set, the channel, if enabled, initiates transfers. The transfer stops once the DMA_CNDTRx register reaches zero.

Note: The memory-to-memory mode must not be used in circular mode. Before enabling a channel in memory-to-memory mode (MEM2MEM = 1), the software must clear the CIRC bit of the DMA_CCRx register.
Peripheral-to-peripheral mode
Any DMA channel can operate in peripheral-to-peripheral mode:
- when the hardware request from a peripheral is selected to trigger the DMA channel
  This peripheral is the DMA initiator and paces the data transfer from/to this peripheral
to/from a register belonging to another memory-mapped peripheral (this one being not
configured in DMA mode).
- when no peripheral request is selected and connected to the DMA channel
  The software configures a register-to-register transfer by setting the MEM2MEM bit of
  the DMA_CCRx register.

Programming transfer direction, assigning source/destination
The value of the DIR bit of the DMA_CCRx register sets the direction of the transfer, and
consequently, it identifies the source and the destination, regardless the source/destination
type (peripheral or memory):
- **DIR = 1** defines typically a memory-to-peripheral transfer. More generally, if DIR = 1:
  - The **source** attributes are defined by the DMA_MARx register, the MSIZE[1:0]
    field and MINC bit of the DMA_CCRx register.
    Regardless of their usual naming, these ‘memory’ register, field and bit are used to
define the source peripheral in peripheral-to-peripheral mode.
  - The **destination** attributes are defined by the DMA_PARx register, the PSIZE[1:0]
    field and PINC bit of the DMA_CCRx register.
    Regardless of their usual naming, these ‘peripheral’ register, field and bit are used
to define the destination memory in memory-to-memory mode.
- **DIR = 0** defines typically a peripheral-to-memory transfer. More generally, if DIR = 0:
  - The **source** attributes are defined by the DMA_PARx register, the PSIZE[1:0] field
    and PINC bit of the DMA_CCRx register.
    Regardless of their usual naming, these ‘peripheral’ register, field and bit are used
to define the source memory in memory-to-memory mode.
  - The **destination** attributes are defined by the DMA_MARx register, the
    MSIZE[1:0] field and MINC bit of the DMA_CCRx register.
    Regardless of their usual naming, these ‘memory’ register, field and bit are used to
define the destination peripheral in peripheral-to-peripheral mode.

10.4.5 DMA data width, alignment and endianness
When PSIZE[1:0] and MSIZE[1:0] are not equal, the DMA controller performs some data
alignments as described in the table below.
Addressing AHB peripherals not supporting byte/half-word write transfers

When the DMA controller initiates an AHB byte or half-word write transfer, the data are duplicated on the unused lanes of the AHB master 32-bit data bus (HWDATA[31:0]).

When the AHB slave peripheral does not support byte or half-word writes and does not generate any error, the DMA controller writes the 32 HWDATA bits as shown in the two examples below:

- To write the half-word 0xABCD, the DMA controller sets the HWDATA bus to 0xABCDABCD with a half-word data size (HSIZE = HalfWord in AHB master bus).
- To write the byte 0xAB, the DMA controller sets the HWDATA bus to 0xABABABAB with a byte data size (HSIZE = Byte in the AHB master bus).
Assuming the AHB/APB bridge is an AHB 32-bit slave peripheral that does not take into account the HSIZE data, any AHB byte or half-word transfer is changed into a 32-bit APB transfer as described below:

- An AHB byte write transfer of 0xB0 to one of the 0x0, 0x1, 0x2 or 0x3 addresses, is converted to an APB word write transfer of 0xB0B0B0B0 to the 0x0 address.
- An AHB half-word write transfer of 0xB1B0 to the 0x0 or 0x2 addresses, is converted to an APB word write transfer of 0xB1B0B1B0 to the 0x0 address.

10.4.6 DMA error management

A DMA transfer error is generated when reading from or writing to a reserved address space. When a DMA transfer error occurs during a DMA read or write access, the faulty channel x is automatically disabled through a hardware clear of its EN bit in the corresponding DMA_CCRx register.

The TEIFx bit of the DMA_ISR register is set. An interrupt is then generated if the TEIE bit of the DMA_CCRx register is set.

The EN bit of the DMA_CCRx register can not be set again by software (channel x re-activated) until the TEIFx bit of the DMA_ISR register is cleared (by setting the CTEIFx bit of the DMA_IFCR register).

When the software is notified with a transfer error over a channel which involves a peripheral, the software has first to stop this peripheral in DMA mode, in order to disable any pending or future DMA request. Then software may normally reconfigure both DMA and the peripheral in DMA mode for a new transfer.

10.5 DMA interrupts

An interrupt can be generated on a half transfer, transfer complete or transfer error for each DMA channel x. Separate interrupt enable bits are available for flexibility.

10.6 DMA registers

Refer to Section 1.2 for a list of abbreviations used in register descriptions.

The DMA registers have to be accessed by words (32-bit).
10.6.1 DMA interrupt status register (DMA_ISR)

Address offset: 0x00

Reset value: 0x0000 0000

The content of this register is linked to the DMA channels availability. See Section 10.3: DMA implementation for more details.

Every status bit is cleared by hardware when the software sets the corresponding clear bit or the corresponding global clear bit CGIFx, in the DMA_IFCR register.

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **TEIF7**: transfer error (TE) flag for channel 7
- 0: no TE event
- 1: a TE event occurred

Bit 26 **HTIF7**: half transfer (HT) flag for channel 7
- 0: no HT event
- 1: a HT event occurred

Bit 25 **TCIF7**: transfer complete (TC) flag for channel 7
- 0: no TC event
- 1: a TC event occurred

Bit 24 **GIF7**: global interrupt flag for channel 7
- 0: no TE, HT or TC event
- 1: a TE, HT or TC event occurred

Bit 23 **TEIF6**: transfer error (TE) flag for channel 6
- 0: no TE event
- 1: a TE event occurred

Bit 22 **HTIF6**: half transfer (HT) flag for channel 6
- 0: no HT event
- 1: a HT event occurred

Bit 21 **TCIF6**: transfer complete (TC) flag for channel 6
- 0: no TC event
- 1: a TC event occurred

Bit 20 **GIF6**: global interrupt flag for channel 6
- 0: no TE, HT or TC event
- 1: a TE, HT or TC event occurred

Bit 19 **TEIF5**: transfer error (TE) flag for channel 5
- 0: no TE event
- 1: a TE event occurred
Bit 18  **HTIF5**: half transfer (HT) flag for channel 5
        0: no HT event
        1: a HT event occurred

Bit 17  **TCIF5**: transfer complete (TC) flag for channel 5
        0: no TC event
        1: a TC event occurred

Bit 16  **GIF5**: global interrupt flag for channel 5
        0: no TE, HT or TC event
        1: a TE, HT or TC event occurred

Bit 15  **TEIF4**: transfer error (TE) flag for channel 4
        0: no TE event
        1: a TE event occurred

Bit 14  **HTIF4**: half transfer (HT) flag for channel 4
        0: no HT event
        1: a HT event occurred

Bit 13  **TCIF4**: transfer complete (TC) flag for channel 4
        0: no TC event
        1: a TC event occurred

Bit 12  **GIF4**: global interrupt flag for channel 4
        0: no TE, HT or TC event
        1: a TE, HT or TC event occurred

Bit 11  **TEIF3**: transfer error (TE) flag for channel 3
        0: no TE event
        1: a TE event occurred

Bit 10  **HTIF3**: half transfer (HT) flag for channel 3
        0: no HT event
        1: a HT event occurred

Bit 9   **TCIF3**: transfer complete (TC) flag for channel 3
        0: no TC event
        1: a TC event occurred

Bit 8   **GIF3**: global interrupt flag for channel 3
        0: no TE, HT or TC event
        1: a TE, HT or TC event occurred

Bit 7   **TEIF2**: transfer error (TE) flag for channel 2
        0: no TE event
        1: a TE event occurred

Bit 6   **HTIF2**: half transfer (HT) flag for channel 2
        0: no HT event
        1: a HT event occurred

Bit 5   **TCIF2**: transfer complete (TC) flag for channel 2
        0: no TC event
        1: a TC event occurred

Bit 4   **GIF2**: global interrupt flag for channel 2
        0: no TE, HT or TC event
        1: a TE, HT or TC event occurred
Bit 3 **TEIF1**: transfer error (TE) flag for channel 1  
0: no TE event  
1: a TE event occurred

Bit 2 **HTIF1**: half transfer (HT) flag for channel 1  
0: no HT event  
1: a HT event occurred

Bit 1 **TCIF1**: transfer complete (TC) flag for channel 1  
0: no TC event  
1: a TC event occurred

Bit 0 **GIF1**: global interrupt flag for channel 1  
0: no TE, HT or TC event  
1: a TE, HT or TC event occurred

10.6.2 DMA interrupt flag clear register (DMA_IFCR)

Address offset: 0x04  
Reset value: 0x0000 0000 0000

The content of this register is linked to the DMA channels availability. See Section 10.3: DMA implementation for more details.

Setting the global clear bit CGIFx of the channel x in this DMA_IFCR register, causes the DMA hardware to clear the corresponding GIFx bit and any individual flag among TEIFx, HTIFx, TCIFx, in the DMA_ISR register.

Setting any individual clear bit among CTEIFx, CHTIFx, CTCIFx in this DMA_IFCR register, causes the DMA hardware to clear the corresponding individual flag and the global flag GIFx in the DMA_ISR register, provided that none of the two other individual flags is set.

Writing 0 into any flag clear bit has no effect.

10.6.3 DMA channel x configuration register (DMA_CCRx)

Address offset: 0x08 + 0x14 * (x - 1), (x = 1 to 7)
Reset value: 0x0000 0000

The address offsets of these registers are linked to the DMA channels availability. See Section 10.3: DMA implementation for more details.

The register fields/bits MEM2MEM, PL[1:0], MSIZE[1:0], PSIZE[1:0], MINC, PINC, and DIR are read-only when EN = 1.

The states of MEM2MEM and CIRC bits must not be both high at the same time.
Bits 31:15  Reserved, must be kept at reset value.

Bit 14  **MEM2MEM**: memory-to-memory mode
- 0: disabled
- 1: enabled

*Note: this bit is set and cleared by software.*
- *It must not be written when the channel is enabled (EN = 1).*
- *It is read-only when the channel is enabled (EN = 1).*

Bits 13:12  **PL[1:0]**: priority level
- 00: low
- 01: medium
- 10: high
- 11: very high

*Note: this field is set and cleared by software.*
- *It must not be written when the channel is enabled (EN = 1).*
- *It is read-only when the channel is enabled (EN = 1).*

Bits 11:10  **MSIZE[1:0]**: memory size
Defines the data size of each DMA transfer to the identified memory.
In memory-to-memory mode, this field identifies the memory source if DIR = 1 and the memory destination if DIR = 0.
In peripheral-to-peripheral mode, this field identifies the peripheral source if DIR = 1 and the peripheral destination if DIR = 0.
- 00: 8 bits
- 01: 16 bits
- 10: 32 bits
- 11: reserved

*Note: this field is set and cleared by software.*
- *It must not be written when the channel is enabled (EN = 1).*
- *It is read-only when the channel is enabled (EN = 1).*

Bits 9:8  **PSIZE[1:0]**: peripheral size
Defines the data size of each DMA transfer to the identified peripheral.
In memory-to-memory mode, this field identifies the memory destination if DIR = 1 and the memory source if DIR = 0.
In peripheral-to-peripheral mode, this field identifies the peripheral destination if DIR = 1 and the peripheral source if DIR = 0.
- 00: 8 bits
- 01: 16 bits
- 10: 32 bits
- 11: reserved

*Note: this field is set and cleared by software.*
- *It must not be written when the channel is enabled (EN = 1).*
- *It is read-only when the channel is enabled (EN = 1).*
Bit 7 **MINC**: memory increment mode
Defines the increment mode for each DMA transfer to the identified memory.
In memory-to-memory mode, this field identifies the memory source if DIR = 1 and the memory destination if DIR = 0.
In peripheral-to-peripheral mode, this field identifies the peripheral source if DIR = 1 and the peripheral destination if DIR = 0.
0: disabled
1: enabled
Note: this bit is set and cleared by software.
It must not be written when the channel is enabled (EN = 1).
It is read-only when the channel is enabled (EN = 1).

Bit 6 **PINC**: peripheral increment mode
Defines the increment mode for each DMA transfer to the identified peripheral.
In memory-to-memory mode, this field identifies the memory destination if DIR = 1 and the memory source if DIR = 0.
In peripheral-to-peripheral mode, this field identifies the peripheral destination if DIR = 1 and the peripheral source if DIR = 0.
0: disabled
1: enabled
Note: this bit is set and cleared by software.
It must not be written when the channel is enabled (EN = 1).
It is read-only when the channel is enabled (EN = 1).

Bit 5 **CIRC**: circular mode
0: disabled
1: enabled
Note: this bit is set and cleared by software.
It must not be written when the channel is enabled (EN = 1).
It is not read-only when the channel is enabled (EN = 1).

Bit 4 **DIR**: data transfer direction
This bit must be set only in memory-to-peripheral and peripheral-to-memory modes.
0: read from peripheral
   – Source attributes are defined by PSIZE and PINC, plus the DMA_CPARx register. This is still valid in a memory-to-memory mode.
   – Destination attributes are defined by MSIZE and MINC, plus the DMA_CMARx register. This is still valid in a peripheral-to-peripheral mode.
1: read from memory
   – Destination attributes are defined by PSIZE and PINC, plus the DMA_CPARx register. This is still valid in a memory-to-memory mode.
   – Source attributes are defined by MSIZE and MINC, plus the DMA_CMARx register. This is still valid in a peripheral-to-peripheral mode.
Note: this bit is set and cleared by software.
It must not be written when the channel is enabled (EN = 1).
It is read-only when the channel is enabled (EN = 1).

Bit 3 **TEIE**: transfer error interrupt enable
0: disabled
1: enabled
Note: this bit is set and cleared by software.
It must not be written when the channel is enabled (EN = 1).
It is not read-only when the channel is enabled (EN = 1).
Bit 2 **HTIE**: half transfer interrupt enable
- 0: disabled
- 1: enabled

*Note: this bit is set and cleared by software.

*It must not be written when the channel is enabled (EN = 1).*

*It is not read-only when the channel is enabled (EN = 1).*

Bit 1 **TCIE**: transfer complete interrupt enable
- 0: disabled
- 1: enabled

*Note: this bit is set and cleared by software.

*It must not be written when the channel is enabled (EN = 1).*

*It is not read-only when the channel is enabled (EN = 1).*

Bit 0 **EN**: channel enable
When a channel transfer error occurs, this bit is cleared by hardware. It can not be set again by software (channel x re-activated) until the TEIFx bit of the DMA_ISR register is cleared (by setting the CTEIFx bit of the DMA_IFCR register).
- 0: disabled
- 1: enabled

*Note: this bit is set and cleared by software.*

### 10.6.4 DMA channel x number of data to transfer register (DMA_CNDTRx)

**Address offset**: 0x0C + 0x14 * (x - 1), (x = 1 to 7)

**Reset value**: 0x0000 0000

The address offsets of these registers are linked to the DMA channels availability. See *Section 10.3: DMA implementation* for more details.

```
31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16
15 14 13 12 11 10  9  8  7  6  5  4  3  2  1  0

NDT[15:0]
```

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **NDT[15:0]**: number of data to transfer (0 to 2^{16} - 1)

This field is updated by hardware when the channel is enabled:
- It is decremented after each single DMA `read followed by write` transfer, indicating the remaining amount of data items to transfer.
- It is kept at zero when the programmed amount of data to transfer is reached, if the channel is not in circular mode (CIRC = 0 in the DMA_CCRx register).
- It is reloaded automatically by the previously programmed value, when the transfer is complete, if the channel is in circular mode (CIRC = 1).

If this field is zero, no transfer can be served whatever the channel status (enabled or not).

*Note: this field is set and cleared by software.

*It must not be written when the channel is enabled (EN = 1).*

*It is read-only when the channel is enabled (EN = 1).*
10.6.5 DMA channel x peripheral address register (DMA_CPARx)

Address offset: 0x10 + 0x14 \times (x - 1), (x = 1 to 7)
Reset value: 0x0000 0000

The address offsets of these registers are linked to the DMA channels availability. See Section 10.3: DMA implementation for more details.

</tr>
</tbody>
</table>

Bits 31:0 PA[31:0]: peripheral address
- It contains the base address of the peripheral data register from/to which the data is read/written.
- When PSIZE[1:0] = 01 (16 bits), bit 0 of PA[31:0] is ignored. Access is automatically aligned to a half-word address.
- When PSIZE = 10 (32 bits), bits 1 and 0 of PA[31:0] are ignored. Access is automatically aligned to a word address.
- In memory-to-memory mode, this register identifies the memory destination address if DIR = 1 and the memory source address if DIR = 0.
- In peripheral-to-peripheral mode, this register identifies the peripheral destination address if DIR = 1 and the peripheral source address if DIR = 0.
- Note: this register is set and cleared by software.
  - It must not be written when the channel is enabled (EN = 1).
  - It is not read-only when the channel is enabled (EN = 1).

10.6.6 DMA channel x memory address register (DMA_CMARx)

Address offset: 0x14 + 0x14 \times (x - 1), (x = 1 to 7)
Reset value: 0x0000 0000

The address offsets of these registers are linked to the DMA channels availability. See Section 10.3: DMA implementation for more details.

Bits 31:0  \textbf{MA}[31:0]: peripheral address

It contains the base address of the memory from/to which the data is read/written.

When MSIZE[1:0] = 01 (16 bits), bit 0 of MA[31:0] is ignored. Access is automatically aligned to a half-word address.

When MSIZE = 10 (32 bits), bits 1 and 0 of MA[31:0] are ignored. Access is automatically aligned to a word address.

In memory-to-memory mode, this register identifies the memory source address if DIR = 1 and the memory destination address if DIR = 0.

In peripheral-to-peripheral mode, this register identifies the peripheral source address if DIR = 1 and the peripheral destination address if DIR = 0.

\textit{Note: this register is set and cleared by software.}

\textit{It must not be written when the channel is enabled (EN = 1).}

\textit{It is not read-only when the channel is enabled (EN = 1).}
10.6.7 DMA channel selection register (DMA_CSELR)

Address offset: 0xA8
Reset value: 0x0000 0000

This register is present only on STM32F09xx devices.

This register is used to manage the mapping of DMA channels as detailed in Section 10.3.2: DMA request mapping.

Bits 31:28 Reserved, must be kept at reset value.
Bits 27:24 \textbf{C7S}[3:0]: DMA channel 7 selection
Details available in Section 10.3.2: DMA request mapping
Bits 23:20 \textbf{C6S}[3:0]: DMA channel 6 selection

Table 35. DMA register map and reset values (continued)
Refer to Section 2.2 for the register boundary addresses.
11 Interrupts and events

11.1 Nested vectored interrupt controller (NVIC)

11.1.1 NVIC main features

- 32 maskable interrupt channels (not including the sixteen Cortex®-M0 interrupt lines)
- 4 programmable priority levels (2 bits of interrupt priority are used)
- Low-latency exception and interrupt handling
- Power management control
- Implementation of System control registers

The NVIC and the processor core interface are closely coupled, which enables low latency interrupt processing and efficient processing of late arriving interrupts.

All interrupts including the core exceptions are managed by the NVIC. For more information on exceptions and NVIC programming, refer to the PM0215 programming manual.

For code example refer to the Appendix section A.6.1: NVIC initialization example.

11.1.2 SysTick calibration value register

The SysTick calibration value is set to 6000, which gives a reference time base of 1 ms with the SysTick clock set to 6 MHz (max \( f_{\text{HCLK}} / 8 \)).

11.1.3 Interrupt and exception vectors

Table 36 is the vector table for STM32F0xx devices. Consider peripheral availability on your device.

11.2 Extended interrupts and events controller (EXTI)

The extended interrupts and events controller (EXTI) manages the external and internal asynchronous events/interrupts and generates the event request to the CPU/Interrupt controller and a wake-up request to the Power manager.

The EXTI allows the management of up to 32 external/internal event line (23 external event lines and 9 internal event lines).

The active edge of each external interrupt line can be chosen independently, whilst for internal interrupt the active edge is always the rising one. An interrupt could be left pending: in case of an external one, a status register is instantiated and indicates the source of the interrupt; an event is always a simple pulse and it’s used for triggering the core Wake-up (e.g. Cortex-M0 RXEV pin). For internal interrupts, the pending status is assured by the generating IP, so no need for a specific flag. Each input line can be masked independently for interrupt or event generation, in addition the internal lines are sampled only in STOP mode. This controller allows also to emulate the (only) external events by software, multiplexed with the corresponding hardware event line, by writing to a dedicated register.

11.2.1 Main features

The EXTI main features are the following:

- Supports generation of up to 32 event/interrupt requests
- Independent mask on each event/interrupt line
- Automatic disable of internal lines when system is not in STOP mode
- Independent trigger for external event/interrupt line
- Dedicated status bit for external interrupt line
- Emulation for all the external event requests
11.2.2 Block diagram

The extended interrupt/event block diagram is shown in Figure 23.

**Figure 23. Extended interrupts and events controller (EXTI) block diagram**

![Block diagram of EXTI](image)

11.2.3 Event management

The STM32F0xx is able to handle external or internal events in order to wake up the core (WFE). The wake-up event can be generated either by:

- enabling an interrupt in the peripheral control register but not in the NVIC, and enabling the SEVONPEND bit in the Cortex-M0 System control register. When the MCU resumes from WFE, the EXTI peripheral interrupt pending bit and the peripheral NVIC IRQ channel pending bit (in the NVIC interrupt clear pending register) have to be cleared.
- or by configuring an external or internal EXTI line in event mode. When the CPU resumes from WFE, it is not necessary to clear the peripheral interrupt pending bit or the NVIC IRQ channel pending bit as the pending bit corresponding to the event line is not set.

11.2.4 Functional description

For the external interrupt lines, to generate the interrupt, the interrupt line should be configured and enabled. This is done by programming the two trigger registers with the desired edge detection and by enabling the interrupt request by writing a ‘1’ to the corresponding bit in the interrupt mask register. When the selected edge occurs on the external interrupt line, an interrupt request is generated. The pending bit corresponding to the interrupt line is also set. This request is reset by writing a ‘1’ in the pending register.
For the internal interrupt lines, the active edge is always the rising edge, the interrupt is enabled by default in the interrupt mask register and there is no corresponding pending bit in the pending register.

To generate the event, the event line should be configured and enabled. This is done by programming the two trigger registers with the desired edge detection and by enabling the event request by writing a ‘1’ to the corresponding bit in the event mask register. When the selected edge occurs on the event line, an event pulse is generated. The pending bit corresponding to the event line is not set.

For the external lines, an interrupt/event request can also be generated by software by writing a ‘1’ in the software interrupt/event register.

**Note:** The interrupts or events associated to the internal lines can be triggered only when the system is in STOP mode. If the system is still running, no interrupt/event is generated.

For code example refer to the Appendix section A.6.2: External interrupt selection code example.

**Hardware interrupt selection**

To configure a line as interrupt source, use the following procedure:
- Configure the corresponding mask bit in the EXTI_IMR register.
- Configure the trigger selection bits of the interrupt line (EXTI_RTSR and EXTI_FTSR)
- Configure the enable and mask bits that control the NVIC IRQ channel mapped to the EXTI so that an interrupt coming from one of the EXTI line can be correctly acknowledged.

**Hardware event selection**

To configure a line as event source, use the following procedure:
- Configure the corresponding mask bit in the EXTI_EMR register.
- Configure the Trigger Selection bits of the Event line (EXTI_RTSR and EXTI_FTSR)

**Software interrupt/event selection**

Any of the external lines can be configured as software interrupt/event lines. The following is the procedure to generate a software interrupt.
- Configure the corresponding mask bit (EXTI_IMR, EXTI_EMR)
- Set the required bit of the software interrupt register (EXTI_SWIER)
11.2.5 External and internal interrupt/event line mapping

The GPIOs are connected to the 16 external interrupt/event lines in the following manner:

**Figure 24. External interrupt/event GPIO mapping**

![Diagram showing GPIO connections to EXTI0, EXTI1, EXTI15]
The remaining lines are connected as follow:

- EXTI line 16 is connected to the PVD output
- EXTI line 17 is connected to the RTC Alarm event
- EXTI line 18 is connected to the internal USB wake-up event
- EXTI line 19 is connected to the RTC Tamper and TimeStamp events
- EXTI line 20 is connected to the RTC Wake-up event (available only on STM32F07x and STM32F09x devices)
- EXTI line 21 is connected to the Comparator 1 output
- EXTI line 22 is connected to the Comparator 2 output
- EXTI line 23 is connected to the internal I2C1 wake-up event
- EXTI line 24 is reserved (internally held low)
- EXTI line 25 is connected to the internal USART1 wake-up event
- EXTI line 26 is connected to the internal USART2 wake-up event (available only on STM32F07x and STM32F09x devices)
- EXTI line 27 is connected to the internal CEC wake-up event
- EXTI line 28 is connected to the internal USART3 wake-up event (available only on STM32F09x devices)
- EXTI line 29 is reserved (internally held low)
- EXTI line 30 is reserved (internally held low)
- EXTI line 31 is connected to the $V_{DDIO2}$ supply comparator output (available only on STM32F04x, STM32F07x and STM32F09x devices)

Note: EXTI lines which are reserved or not used on some devices are considered as internal.

11.3 EXTI registers

Refer to Section 1.2 on page 42 for a list of abbreviations used in register descriptions.

The peripheral registers have to be accessed by words (32-bit).

11.3.1 Interrupt mask register (EXTI_IMR)

Address offset: 0x00

Reset value: 0xFF4 0000 (STM32F03x devices)
0x7FF4 0000 (STM32F04x devices)
0x0F94 0000 (STM32F05x devices)
0x7F84 0000 (STM32F07x and STM32F09x devices)

Note: The reset value for the internal lines is set to ‘1’ in order to enable the interrupt by default.
11.3.2 Event mask register (EXTI_EMR)

Address offset: 0x04
Reset value: 0x0000 0000

Bits 31:0 EMx: Event mask on line x (x = 31 to 0)
0: Event request from Line x is masked
1: Event request from Line x is not masked

Bit 31 RT31: Rising trigger event configuration bit of line 31
0: Rising trigger disabled (for Event and Interrupt) for input line
1: Rising trigger enabled (for Event and Interrupt) for input line.

Bits 30:23 Reserved, must be kept at reset value.

Bits 22:19 RTx: Rising trigger event configuration bit of line x (x = 22 to 19)
0: Rising trigger disabled (for Event and Interrupt) for input line
1: Rising trigger enabled (for Event and Interrupt) for input line.

Bit 18 Reserved, must be kept at reset value.

Bits 17:0 RTx: Rising trigger event configuration bit of line x (x = 17 to 0)
0: Rising trigger disabled (for Event and Interrupt) for input line
1: Rising trigger enabled (for Event and Interrupt) for input line.
Note: The external wake-up lines are edge triggered. No glitches must be generated on these lines. If a rising edge on an external interrupt line occurs during a write operation to the EXTI_RTSR register, the pending bit is not set. Rising and falling edge triggers can be set for the same interrupt line. In this case, both generate a trigger condition.

### 11.3.4 Falling trigger selection register (EXTI_FTSR)

Address offset: 0x0C  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit</th>

Refer to Section 2.2 on page 46 for the register boundary addresses.
12 Cyclic redundancy check calculation unit (CRC)

12.1 Introduction

The CRC (cyclic redundancy check) calculation unit is used to get a CRC code from 8-, 16-
or 32-bit data word and a generator polynomial.

Among other applications, CRC-based techniques are used to verify data transmission or
storage integrity. In the scope of the functional safety standards, they offer a means of
verifying the flash memory integrity. The CRC calculation unit helps compute a signature of
the software during runtime, to be compared with a reference signature generated at link
time and stored at a given memory location.

12.2 CRC main features

- Uses CRC-32 (Ethernet) polynomial: 0x4C11DB7
  \[X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1\]
- Alternatively, uses fully programmable polynomial with programmable size (7, 8, 16, 32
  bits)
- Handles 8-, 16-, 32-bit data size
- Programmable CRC initial value
- Single input/output 32-bit data register
- Input buffer to avoid bus stall during calculation
- CRC computation done in 4 AHB clock cycles (HCLK) for the 32-bit data size
- General-purpose 8-bit register (can be used for temporary storage)
- Reversibility option on I/O data
- Accessed through AHB slave peripheral by 32-bit words only, with the exception of
  CRC_DR register that can be accessed by words, right-aligned half-words and right-
  aligned bytes

12.4.3 **CRC operation**

The CRC calculation unit has a single 32-bit read/write data register (CRC_DR). It is used to input new data (write access), and holds the result of the previous CRC calculation (read access).

Each write operation to the data register creates a combination of the previous CRC value (stored in CRC_DR) and the new one. CRC computation is done on the whole 32-bit data word or byte by byte depending on the format of the data being written.

The CRC_DR register can be accessed by word, right-aligned half-word and right-aligned byte. For the other registers only 32-bit accesses are allowed.

The duration of the computation depends on data width:
- 4 AHB clock cycles for 32 bits
- 2 AHB clock cycles for 16 bits
- 1 AHB clock cycles for 8 bits

An input buffer allows a second data to be immediately written without waiting for any wait states due to the previous CRC calculation.
The data size can be dynamically adjusted to minimize the number of write accesses for a
given number of bytes. For instance, a CRC for 5 bytes can be computed with a word write
followed by a byte write.

The input data can be reversed to manage the various endianness schemes. The reversing
operation can be performed on 8 bits, 16 bits and 32 bits depending on the REV_IN[1:0] bits
in the CRC_CR register.

For example, 0x1A2B3C4D input data are used for CRC calculation as:
• 0x58D43CB2 with bit-reversal done by byte
• 0xD458B23C with bit-reversal done by half-word
• 0xB23CD458 with bit-reversal done on the full word

The output data can also be reversed by setting the REV_OUT bit in the CRC_CR register.
The operation is done at bit level. For example, 0x11223344 output data are converted to
0x22CC4488.

The CRC calculator can be initialized to a programmable value using the RESET control bit
in the CRC_CR register (the default value is 0xFFFFFFFF).

The initial CRC value can be programmed with the CRC_INIT register. The CRC_DR
register is automatically initialized upon CRC_INIT register write access.

The CRC_IDR register can be used to hold a temporary value related to CRC calculation. It
is not affected by the RESET bit in the CRC_CR register.

**Polynomial programmability**

The polynomial coefficients are fully programmable through the CRC_POL register, and the
polynomial size can be configured to be 7, 8, 16 or 32 bits by programming the
POLYSIZE[1:0] bits in the CRC_CR register. Even polynomials are not supported.

*Note:* The type of an even polynomial is \(X+X^2+..+X^n\), while the type of an odd polynomial is
\(1+X+X^2+..+X^n\).

If the CRC data is less than 32-bit, its value can be read from the least significant bits of the
CRC_DR register.

To obtain a reliable CRC calculation, the change on-fly of the polynomial value or size can
not be performed during a CRC calculation. As a result, if a CRC calculation is ongoing, the
application must either reset it or perform a CRC_DR read before changing the polynomial.

The default polynomial value is the CRC-32 (Ethernet) polynomial: 0x4C11DB7.
12.5 CRC registers

The CRC_DR register can be accessed by words, right-aligned half-words and right-aligned bytes. For the other registers only 32-bit accesses are allowed.

12.5.1 CRC data register (CRC_DR)

Address offset: 0x00
Reset value: 0xFFFF FFFF

<table>

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 REV_OUT: Reverse output data
   This bit controls the reversal of the bit order of the output data.
   0: Bit order not affected
   1: Bit-reversed output format

Bits 6:5 REV_IN[1:0]: Reverse input data
   This bitfield controls the reversal of the bit order of the input data
   00: Bit order not affected
   01: Bit reversal done by byte
   10: Bit reversal done by half-word
   11: Bit reversal done by word

Bits 4:3 POLYSIZE[1:0]: Polynomial size
   These bits control the size of the polynomial. This bitfield is reserved if the fully
   programmable polynomial is not available (refer to Section 12.3: CRC implementation).
   00: 32 bit polynomial
   01: 16 bit polynomial
   10: 8 bit polynomial
   11: 7 bit polynomial

Bits 2:1 Reserved, must be kept at reset value.

Bit 0 RESET: RESET bit
   This bit is set by software to reset the CRC calculation unit and set the data register to the
   value stored in the CRC_INIT register. This bit can only be set, it is automatically cleared by
   hardware
12.5.4 CRC initial value (CRC_INIT)

Refer to Section 2.2 on page 46 for the register boundary addresses.
13 Analog-to-digital converter (ADC)

13.1 Introduction

The 12-bit ADC is a successive approximation analog-to-digital converter. It has up to 19 multiplexed channels allowing it to measure signals from 16 external and 3 internal sources. A/D conversion of the various channels can be performed in single, continuous, scan or discontinuous mode. The result of the ADC is stored in a left-aligned or right-aligned 16-bit data register.

The analog watchdog feature allows the application to detect if the input voltage goes outside the user-defined higher or lower thresholds.

An efficient low-power mode is implemented to allow very low consumption at low frequency.
13.2 ADC main features

- High performance
  - 12-bit, 10-bit, 8-bit or 6-bit configurable resolution
  - ADC conversion time: 1.0 µs for 12-bit resolution (1 MHz), 0.93 µs conversion time for 10-bit resolution, faster conversion times can be obtained by lowering resolution.
  - Self-calibration
  - Programmable sampling time
  - Data alignment with built-in data coherency
  - DMA support

- Low-power
  - The application can reduce PCLK frequency for low-power operation while still keeping optimum ADC performance. For example, 1.0 µs conversion time is kept, whatever the PCLK frequency
  - Wait mode: prevents ADC overrun in applications with low PCLK frequency
  - Auto off mode: ADC is automatically powered off except during the active conversion phase. This dramatically reduces the power consumption of the ADC.

- Analog input channels
  - 16 external analog inputs
  - 1 channel for internal temperature sensor (VSENSE)
  - 1 channel for internal reference voltage (VREFINT)
  - 1 channel for monitoring external VBAT power supply pin

- Start-of-conversion can be initiated:
  - By software
  - By hardware triggers with configurable polarity (timer events)

- Conversion modes
  - Can convert a single channel or can scan a sequence of channels.
  - Single mode converts selected inputs once per trigger
  - Continuous mode converts selected inputs continuously
  - Discontinuous mode

- Interrupt generation at the end of sampling, end of conversion, end of sequence conversion, and in case of analog watchdog or overrun events

- Analog watchdog

- ADC input range: $V_{SSA} \leq V_{IN} \leq V_{DDA}$
13.3  ADC functional description

Figure 26 shows the ADC block diagram and Table 41 gives the ADC pin description.

The ADC has a calibration feature. During the calibration phase, the ADC calculates a calibration factor which is internally applied to the ADC until the next ADC power-off. The application must not use the ADC during calibration and must wait until it is complete.

Calibration should be performed before starting A/D conversion. It removes the offset error which may vary from chip to chip due to process variation.

The calibration is initiated by software by setting ADCAL bit to 1. It can only be initiated when the ADC is disabled (when ADEN = 0). ADCAL bit stays at 1 during the whole calibration sequence. It is then cleared by hardware as soon the calibration completes. After this, the calibration factor can be read from the ADC_DR register (from bits 6 to 0).

The internal analog calibration is kept if the ADC is disabled (ADEN = 0). When the ADC operating conditions change (VDDA changes are the main contributor to ADC offset variations and temperature change to a lesser extend), it is recommended to re-run a calibration cycle.

The calibration factor is lost each time power is removed from the ADC (for example when the product enters Standby mode).
Calibration software procedure
1. Ensure that ADEN = 0 and DMAEN = 0.
2. Set ADCAL = 1.
3. Wait until ADCAL = 0.
4. The calibration factor can be read from bits 6:0 of ADC_DR.
For code example refer to the Appendix section A.7.1: ADC calibration code example.

Figure 27. ADC calibration

13.3.3 ADC on-off control (ADEN, ADDIS, ADRDY)
At power-up, the ADC is disabled and put in power-down mode (ADEN = 0).
As shown in Figure 28, the ADC needs a stabilization time of t_{STAB} before it starts converting accurately.

Two control bits are used to enable or disable the ADC:
- Set ADEN = 1 to enable the ADC. The ADRDY flag is set as soon as the ADC is ready for operation.
- Set ADDIS = 1 to disable the ADC and put the ADC in power down mode. The ADEN and ADDIS bits are then automatically cleared by hardware as soon as the ADC is fully disabled.

Conversion can then start either by setting ADSTART to 1 (refer to Section 13.4: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN) on page 244) or when an external trigger event occurs if triggers are enabled.

Follow this procedure to enable the ADC:
1. Clear the ADRDY bit in ADC_ISR register by programming this bit to 1.
2. Set ADEN = 1 in the ADC_CR register.
3. Wait until ADRDY = 1 in the ADC_ISR register and continue to write ADEN = 1 (ADRDY is set after the ADC startup time). This can be handled by interrupt if the interrupt is enabled by setting the ADRDYIE bit in the ADC_IER register.
For code example refer to the Appendix section A.7.2: ADC enable sequence code example.
Follow this procedure to disable the ADC:

1. Check that ADSTART = 0 in the ADC_CR register to ensure that no conversion is ongoing. If required, stop any ongoing conversion by writing 1 to the ADSTP bit in the ADC_CR register and waiting until this bit is read at 0.

2. Set ADDIS = 1 in the ADC_CR register.

3. If required by the application, wait until ADEN = 0 in the ADC_CR register, indicating that the ADC is fully disabled (ADDIS is automatically reset once ADEN = 0).

4. Clear the ADRDY bit in ADC_ISR register by programming this bit to 1 (optional).

For code example refer to the Appendix section A.7.3: ADC disable sequence code example.

**Caution:** ADEN bit cannot be set when ADCAL = 1 and during four ADC clock cycles after the ADCAL bit is cleared by hardware (end of calibration).

---

**Figure 28. Enabling/disabling the ADC**

Note: In Auto-off mode (AUTOFF = 1) the power-on/off phases are performed automatically, by hardware and the ADRDY flag is not set.
13.3.4 ADC clock (CKMODE)

The ADC has a dual clock-domain architecture, so that the ADC can be fed with a clock (ADC asynchronous clock) independent from the APB clock (PCLK).

**Figure 29. ADC clock scheme**

The input clock of the analog ADC can be selected between two different clock sources (see Figure 29: ADC clock scheme to see how the PCLK clock and the ADC asynchronous clock are enabled):

a) The ADC clock can be a specific clock source, named “ADC asynchronous clock” which is independent and asynchronous with the APB clock.
   Refer to RCC Section for more information on generating this clock source.
   To select this scheme, bits CKMODE[1:0] of the ADC_CFGR2 register must be reset.
   For code example refer to the Appendix section A.7.4: ADC clock selection code example.

b) The ADC clock can be derived from the APB clock of the ADC bus interface, divided by a programmable factor (1, 2 or 4) according to bits CKMODE[1:0].
   To select this scheme, bits CKMODE[1:0] of the ADC_CFGR2 register must be different from “00”.

Option a) has the advantage of reaching the maximum ADC clock frequency whatever the APB clock scheme selected.

Option b) has the advantage of bypassing the clock domain resynchronizations. This can be useful when the ADC is triggered by a timer and if the application requires that the ADC is precisely triggered without any uncertainty (otherwise, an uncertainty of the trigger instant is added by the resynchronizations between the two clock domains).
13.3.5 Configuring the ADC

The software must write the ADCAL and ADEN bits in the ADC_CR register only when the ADC is disabled (ADEN cleared).

The software must only write to the ADSTART and ADDIS bits in the ADC_CR register only if the ADC is enabled and there is no pending request to disable the ADC (ADEN = 1 and ADDIS = 0).

For all the other control bits in the ADC_IER, ADC_CFGRi, ADC_SMPR, ADC_TR, ADC_CHSELR and ADC_CCR registers, refer to the description of the corresponding control bit in Section 13.11: ADC registers.

The software must only write to the ADSTP bit in the ADC_CR register if the ADC is enabled (and possibly converting) and there is no pending request to disable the ADC (ADSTART = 1 and ADDIS = 0).

Note: There is no hardware protection preventing software from making write operations forbidden by the above rules. If such a forbidden write access occurs, the ADC may enter an undefined state. To recover correct operation in this case, the ADC must be disabled (clear ADEN = 0 and all the bits in the ADC_CR register).

13.3.6 Channel selection (CHSEL, SCANDIR)

There are up to 19 multiplexed channels:

- 16 analog inputs from GPIO pins (ADC_INx)
- 3 internal analog inputs (temperature sensor, internal reference voltage, VBAT channel)

It is possible to convert a single channel or a sequence of channels.

The sequence of the channels to be converted can be programmed in the ADC_CHSELR channel selection register: each analog input channel has a dedicated selection bit (CHSELx).

The order in which the channels is scanned can be configured by programming the bit SCANDIR in the ADC_CFGR1 register:

- SCANDIR = 0: forward scan Channel 0 to Channel 18
- SCANDIR = 1: backward scan Channel 18 to Channel 0

Temperature sensor, VREFINT and VBAT internal channels

The temperature sensor is connected to channel ADC VIN[16].

---

**Table 44. Latency between trigger and start of conversion**

<table>

</tr>
</tbody>
</table>

1. Refer to the device datasheet for the maximum ADC_CLK frequency.
The internal voltage reference $V_{\text{REFINT}}$ is connected to channel ADC $V_{\text{IN}[17]}$. $V_{\text{BAT}}$ channel is connected to ADC $V_{\text{IN}[18]}$ channel.

13.3.7 Programmable sampling time (SMP)

Before starting a conversion, the ADC needs to establish a direct connection between the voltage source to be measured and the embedded sampling capacitor of the ADC. This sampling time must be enough for the input voltage source to charge the sample and hold capacitor to the input voltage level.

Having a programmable sampling time allows the conversion speed to be trimmed according to the input resistance of the input voltage source.

The ADC samples the input voltage for a number of ADC clock cycles that can be modified using the SMP[2:0] bits in the ADC_SMPR register.

This programmable sampling time is common to all channels. If required by the application, the software can change and adapt this sampling time between each conversions.

The total conversion time is calculated as follows:

$$ t_{\text{CONV}} = \text{Sampling time} + 12.5 \times \text{ADC clock cycles} $$

Example:

With $\text{ADC}_{\text{CLK}} = 14 \text{ MHz}$ and a sampling time of $1.5$ ADC clock cycles:

$$ t_{\text{CONV}} = 1.5 + 12.5 = 14 \text{ ADC clock cycles} = 1 \text{ } \mu\text{s} $$

The ADC indicates the end of the sampling phase by setting the EOSMP flag.

13.3.8 Single conversion mode (CONT = 0)

In Single conversion mode, the ADC performs a single sequence of conversions, converting all the channels once. This mode is selected when $\text{CONT} = 0$ in the ADC_CFRG1 register. Conversion is started by either:

- Setting the ADSTART bit in the ADC_CR register
- Hardware trigger event

Inside the sequence, after each conversion is complete:

- The converted data are stored in the 16-bit ADC_DR register
- The EOC (end of conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

After the sequence of conversions is complete:

- The EOS (end of sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

Then the ADC stops until a new external trigger event occurs or the ADSTART bit is set again.

Note: To convert a single channel, program a sequence with a length of 1.
13.3.9 Continuous conversion mode (CONT = 1)

In continuous conversion mode, when a software or hardware trigger event occurs, the ADC performs a sequence of conversions, converting all the channels once and then automatically re-starts and continuously performs the same sequence of conversions. This mode is selected when CONT = 1 in the ADC_CFGR1 register. Conversion is started by either:

- Setting the ADSTART bit in the ADC_CR register
- Hardware trigger event

Inside the sequence, after each conversion is complete:

- The converted data are stored in the 16-bit ADC_DR register
- The EOC (end of conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

After the sequence of conversions is complete:

- The EOS (end of sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

Then, a new sequence restarts immediately and the ADC continuously repeats the conversion sequence.

Note: To convert a single channel, program a sequence with a length of 1.
It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both bits DISCEN = 1 and CONT = 1.

13.3.10 Starting conversions (ADSTART)

Software starts ADC conversions by setting ADSTART = 1.

When ADSTART is set, the conversion:

- Starts immediately if EXTEN = 00 (software trigger)
- At the next active edge of the selected hardware trigger if EXTEN ≠ 00

The ADSTART bit is also used to indicate whether an ADC operation is currently ongoing. It is possible to re-configure the ADC while ADSTART = 0, indicating that the ADC is idle.

The ADSTART bit is cleared by hardware:

- In single mode with software trigger (CONT = 0, EXTEN = 00)
  - At any end of conversion sequence (EOS = 1)
- In discontinuous mode with software trigger (CONT = 0, DISCEN = 1, EXTEN = 00)
  - At end of conversion (EOC = 1)
- In all cases (CONT = x, EXTEN = xx)
  - After execution of the ADSTP procedure invoked by software (see Section 13.3.12: Stopping an ongoing conversion (ADSTP) on page 244)

Note: In continuous mode (CONT = 1), the ADSTART bit is not cleared by hardware when the EOS flag is set because the sequence is automatically relaunched.

When hardware trigger is selected in single mode (CONT = 0 and EXTEN = 01), ADSTART is not cleared by hardware when the EOS flag is set (except if DMAEN = 1 and DMACFG = 0 in which case ADSTART is cleared at end of the DMA transfer). This avoids
the need for software having to set the ADSTART bit again and ensures the next trigger event is not missed.

13.3.11 Timings

The elapsed time between the start of a conversion and the end of conversion is the sum of the configured sampling time plus the successive approximation time depending on data resolution:

\[
t_{\text{CONV}} = t_{\text{SMPL}} + t_{\text{SAR}} = [1.5 \text{ min} + 12.5 \text{ 12bit}] \times f_{\text{ADC_CLK}}
\]
\[
t_{\text{CONV}} = t_{\text{SMPL}} + t_{\text{SAR}} = 107.1 \text{ ns} \text{ min} + 892.8 \text{ ns} \text{ 12bit} = 1 \mu\text{s} \text{ min} \text{ (for } f_{\text{ADC_CLK}} = 14 \text{ MHz)}
\]

Figure 30. Analog to digital conversion time

Figure 31. ADC conversion timings

1. EXTEN = 00 or EXTEN ≠ 00
2. Trigger latency (refer to datasheet for more details)
3. ADC_DR register write latency (refer to datasheet for more details)
13.3.12 Stopping an ongoing conversion (ADSTP)

The software can decide to stop any ongoing conversions by setting ADSTP = 1 in the ADC_CR register.

This resets the ADC operation and the ADC is idle, ready for a new operation.

When the ADSTP bit is set by software, any ongoing conversion is aborted and the result is discarded (ADC_DR register is not updated with the current conversion).

The scan sequence is also aborted and reset (meaning that restarting the ADC would re-start a new sequence).

Once this procedure is complete, the ADSTP and ADSTART bits are both cleared by hardware and the software must wait until ADSTART=0 before starting new conversions.

Figure 32. Stopping an ongoing conversion

13.4 Conversion on external trigger and trigger polarity (EXTSEL, EXTEN)

A conversion or a sequence of conversion can be triggered either by software or by an external event (for example timer capture). If the EXTEN[1:0] control bits are not equal to “0b00”, then external events are able to trigger a conversion with the selected polarity. The trigger selection is effective once software has set bit ADSTART = 1.

Any hardware triggers which occur while a conversion is ongoing are ignored.

If bit ADSTART = 0, any hardware triggers which occur are ignored.

Table 45 provides the correspondence between the EXTEN[1:0] values and the trigger polarity.

Table 45. Configuring the trigger polarity

<table>
<thead>
<tr>
<th>Source</th>
<th>EXTEN[1:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Trigger detection disabled</td>
<td>00</td>
</tr>
<tr>
<td>Detection on rising edge</td>
<td>01</td>
</tr>
<tr>
<td>Detection on falling edge</td>
<td>10</td>
</tr>
<tr>
<td>Detection on both rising and falling edges</td>
<td>11</td>
</tr>
</tbody>
</table>

Note: The polarity of the external trigger can be changed only when the ADC is not converting (ADSTART = 0).

The EXTSEL[2:0] control bits are used to select which of 8 possible events can trigger conversions.
Refer to Table 43: External triggers in Section 13.3.1: ADC pins and internal signals for the list of all the external triggers that can be used for regular conversion.

The software source trigger events can be generated by setting the ADSTART bit in the ADC_CR register.

Note: The trigger selection can be changed only when the ADC is not converting (ADSTART = 0).

13.4.1 Discontinuous mode (DISCEN)

This mode is enabled by setting the DISCEN bit in the ADC_CFGR1 register.

In this mode (DISCEN = 1), a hardware or software trigger event is required to start each conversion defined in the sequence. On the contrary, if DISCEN = 0, a single hardware or software trigger event successively starts all the conversions defined in the sequence.

Example:
- DISCEN = 1, channels to be converted = 0, 3, 7, 10
  - 1st trigger: channel 0 is converted and an EOC event is generated
  - 2nd trigger: channel 3 is converted and an EOC event is generated
  - 3rd trigger: channel 7 is converted and an EOC event is generated
  - 4th trigger: channel 10 is converted and both EOC and EOS events are generated.
  - 5th trigger: channel 0 is converted an EOC event is generated
  - 6th trigger: channel 3 is converted and an EOC event is generated
  - ...
- DISCEN = 0, channels to be converted = 0, 3, 7, 10
  - 1st trigger: the complete sequence is converted: channel 0, then 3, 7 and 10. Each conversion generates an EOC event and the last one also generates an EOS event.
  - Any subsequent trigger events restarts the complete sequence.

Note: It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both bits DISCEN = 1 and CONT = 1.

13.4.2 Programmable resolution (RES) - Fast conversion mode

It is possible to obtain faster conversion times ($t_{SAR}$) by reducing the ADC resolution.

The resolution can be configured to be either 12, 10, 8, or 6 bits by programming the RES[1:0] bits in the ADC_CFGR1 register. Lower resolution allows faster conversion times for applications where high data precision is not required.

Note: The RES[1:0] bit must only be changed when the ADEN bit is reset.

The result of the conversion is always 12 bits wide and any unused LSB bits are read as zeros.

Lower resolution reduces the conversion time needed for the successive approximation steps as shown in Table 46.
13.4.3 End of conversion, end of sampling phase (EOC, EOSMP flags)

The ADC indicates each end of conversion (EOC) event. The ADC sets the EOC flag in the ADC_ISR register as soon as a new conversion data result is available in the ADC_DR register. An interrupt can be generated if the EOCIE bit is set in the ADC_IER register. The EOC flag is cleared by software either by writing 1 to it, or by reading the ADC_DR register.

The ADC also indicates the end of sampling phase by setting the EOSMP flag in the ADC_ISR register. The EOSMP flag is cleared by software by writing 1 to it. An interrupt can be generated if the EOSMPIE bit is set in the ADC_IER register.

The aim of this interrupt is to allow the processing to be synchronized with the conversions. Typically, an analog multiplexer can be accessed in hidden time during the conversion phase, so that the multiplexer is positioned when the next sampling starts.

Note: As there is only a very short time left between the end of the sampling and the end of the conversion, it is recommended to use polling or a WFE instruction rather than an interrupt and a WFI instruction.

13.4.4 End of conversion sequence (EOS flag)

The ADC notifies the application of each end of sequence (EOS) event. The ADC sets the EOS flag in the ADC_ISR register as soon as the last data result of a conversion sequence is available in the ADC_DR register. An interrupt can be generated if the EOSIE bit is set in the ADC_IER register. The EOS flag is cleared by software by writing 1 to it.

For code example refer to the Appendix section A.7.8: Continuous conversion sequence code example - Hardware trigger.
13.5 Data management

13.5.1 Data register and data alignment (ADC_DR, ALIGN)

At the end of each conversion (when an EOC event occurs), the result of the converted data is stored in the ADC_DR data register which is 16-bit wide.

The format of the ADC_DR depends on the configured data alignment and resolution. The ALIGN bit in the ADC_CFGR1 register selects the alignment of the data stored after conversion. Data can be right-aligned (ALIGN = 0) or left-aligned (ALIGN = 1) as shown in Figure 37.

Figure 37. Data alignment and resolution

| ALIGN | RES | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|-------|-----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|---|
| 0     | 0x0 | 0x0 | DR[11:0] |
| 0x1   | 0x0 | DR[9:0] |
| 0x2   | 0x0 | DR[7:0] |
| 0x3   | 0x0 | DR[5:0] |
| 1     | 0x0 | DR[11:0] | 0x0 |
| 0x1   | DR[9:0] | 0x0 |
| 0x2   | DR[7:0] | 0x0 |
| 0x3   | 0x0 | DR[5:0] | 0x0 |

13.5.2 ADC overrun (OVR, OVRMOD)

The overrun flag (OVR) indicates a data overrun event, when the converted data was not read in time by the CPU or the DMA, before the data from a new conversion is available.

The OVR flag is set in the ADC_ISR register if the EOC flag is still at ‘1’ at the time when a new conversion completes. An interrupt can be generated if the OVRIE bit is set in the ADC_IER register.

When an overrun condition occurs, the ADC keeps operating and can continue to convert unless the software decides to stop and reset the sequence by setting the ADSTP bit in the ADC_CR register.

The OVR flag is cleared by software by writing 1 to it.

It is possible to configure if the data is preserved or overwritten when an overrun event occurs by programming the OVRMOD bit in the ADC_CFGR1 register:

- OVRMOD = 0
  - An overrun event preserves the data register from being overwritten: the old data is maintained and the new conversion is discarded. If OVR remains at 1, further conversions can be performed but the resulting data is discarded.

- OVRMOD = 1
  - The data register is overwritten with the last conversion result and the previous unread data is lost. If OVR remains at 1, further conversions can be performed and the ADC_DR register always contains the data from the latest conversion.
13.5.3 Managing a sequence of data converted without using the DMA

If the conversions are slow enough, the conversion sequence can be handled by software. In this case the software must use the EOC flag and its associated interrupt to handle each data result. Each time a conversion is complete, the EOC bit is set in the ADC_ISR register and the ADC_DR register can be read. The OVRMOD bit in the ADC_CFGR1 register should be configured to 0 to manage overrun events as an error.

13.5.4 Managing converted data without using the DMA without overrun

It may be useful to let the ADC convert one or more channels without reading the data after each conversion. In this case, the OVRMOD bit must be configured at 1 and the OVR flag should be ignored by the software. When OVRMOD = 1, an overrun event does not prevent the ADC from continuing to convert and the ADC_DR register always contains the latest conversion data.

13.5.5 Managing converted data using the DMA

Since all converted channel values are stored in a single data register, it is efficient to use DMA when converting more than one channel. This avoids losing the conversion data results stored in the ADC_DR register.
When DMA mode is enabled (DMAEN bit set in the ADC_CFRG1 register), a DMA request is generated after the conversion of each channel. This allows the transfer of the converted data from the ADC_DR register to the destination location selected by the software.

**Note:** The DMAEN bit in the ADC_CFRG1 register must be set after the ADC calibration phase.

Despite this, if an overrun occurs (OVR = 1) because the DMA could not serve the DMA transfer request in time, the ADC stops generating DMA requests and the data corresponding to the new conversion is not transferred by the DMA. Which means that all the data transferred to the RAM can be considered as valid.

Depending on the configuration of OVRMOD bit, the data is either preserved or overwritten (refer to Section 13.5.2: ADC overrun (OVR, OVRMOD) on page 249).

The DMA transfer requests are blocked until the software clears the OVR bit.

Two different DMA modes are proposed depending on the application use and are configured with bit DMACFG in the ADC_CFRG1 register:

- **DMA one shot mode (DMACFG = 0)**
  This mode should be selected when the DMA is programmed to transfer a fixed number of data words.

- **DMA circular mode (DMACFG = 1)**
  This mode should be selected when programming the DMA in circular mode or double buffer mode.

**DMA one shot mode (DMACFG = 0)**

In this mode, the ADC generates a DMA transfer request each time a new conversion data word is available and stops generating DMA requests once the DMA has reached the last DMA transfer (when a transfer complete interrupt occurs, see Section 10: Direct memory access controller (DMA) on page 188) even if a conversion has been started again.

For code example refer to the Appendix section A.7.9: DMA one shot mode sequence code example.

When the DMA transfer is complete (all the transfers configured in the DMA controller have been done):

- The content of the ADC data register is frozen.
- Any ongoing conversion is aborted and its partial result discarded.
- No new DMA request is issued to the DMA controller. This avoids generating an overrun error if there are still conversions which are started.
- The scan sequence is stopped and reset.
- The DMA is stopped.

**DMA circular mode (DMACFG = 1)**

In this mode, the ADC generates a DMA transfer request each time a new conversion data word is available in the data register, even if the DMA has reached the last DMA transfer. This allows the DMA to be configured in circular mode to handle a continuous analog input data stream.

For code example refer to the Appendix section A.7.10: DMA circular mode sequence code example.
13.6 Low-power features

13.6.1 Wait mode conversion

Wait mode conversion can be used to simplify the software as well as optimizing the performance of applications clocked at low frequency where there might be a risk of ADC overrun occurring.

When the WAIT bit is set in the ADC_CFGR1 register, a new conversion can start only if the previous data has been treated, once the ADC_DR register has been read or if the EOC bit has been cleared.

This is a way to automatically adapt the speed of the ADC to the speed of the system that reads the data.

*Note:* Any hardware triggers which occur while a conversion is ongoing or during the wait time preceding the read access are ignored.

**Figure 39. Wait mode conversion (continuous mode, software trigger)**

1. EXTEN = 00, CONT = 1
2. CHSEL = 0x3, SCANDIR = 0, WAIT = 1, AUTOFF = 0

For code example refer to the Appendix section A.7.11: Wait mode sequence code example.
13.6.2 Auto-off mode (AUTOFF)

The ADC has an automatic power management feature which is called auto-off mode, and is enabled by setting AUTOFF = 1 in the ADC_CFGR1 register.

When AUTOFF = 1, the ADC is always powered off when not converting and automatically wakes-up when a conversion is started (by software or hardware trigger). A startup-time is automatically inserted between the trigger event which starts the conversion and the sampling time of the ADC. The ADC is then automatically disabled once the sequence of conversions is complete.

Auto-off mode can cause a dramatic reduction in the power consumption of applications which need relatively few conversions or when conversion requests are timed far enough apart (for example with a low frequency hardware trigger) to justify the extra power and extra time used for switching the ADC on and off.

Auto-off mode can be combined with the wait mode conversion (WAIT = 1) for applications clocked at low frequency. This combination can provide significant power savings if the ADC is automatically powered-off during the wait phase and restarted as soon as the ADC_DR register is read by the application (see Figure 41: Behavior with WAIT = 1, AUTOFF = 1).

Figure 40. Behavior with WAIT = 0, AUTOFF = 1

For code example refer to the Appendix section A.7.12: Auto Off and no wait mode sequence code example.
1. EXTSEL = TRGx, EXTEN = 01 (rising edge), CONT = x, ADSTART = 1, CHSEL = 0xF, SCANDIR = 0, WAIT = 1, AUTOFF = 1

For code example refer to the Appendix section A.7.13: Auto Off and wait mode sequence code example.

### 13.7 Analog window watchdog

#### 13.7.1 Description of the analog watchdog

The AWD analog watchdog is enabled by setting the AWDEN bit in the ADC_CFRG1 register. It is used to monitor that either one selected channel or all enabled channels (see Table 48: Analog watchdog channel selection) remain within a configured voltage range (window) as shown in Figure 42.

The AWD analog watchdog status bit is set if the analog voltage converted by the ADC is below a lower threshold or above a higher threshold. These thresholds are programmed in HT[11:0] and LT[11:0] bit of ADC_TR register. An interrupt can be enabled by setting the AWDIE bit in the ADC_IER register.

The AWD flag is cleared by software by programming it to it.

When converting data with a resolution of less than 12-bit (according to bits RES[1:0]), the LSB of the programmed thresholds must be kept cleared because the internal comparison is always performed on the full 12-bit raw converted data (left aligned).

For code example refer to the Appendix section A.7.14: Analog watchdog code example. Table 47 describes how the comparison is performed for all the possible resolutions.
### Table 47. Analog watchdog comparison

<table>
<thead>

### 13.7.2 ADC_AWD1_OUT output signal generation

The analog watchdog is associated to an internal hardware signal, ADC_AWD1_OUT that is directly connected to the ETR input (external trigger) of some on-chip timers (refer to the timers section for details on how to select the ADC_AWD1_OUT signal as ETR).
ADC_AWD1_OUT is activated when the analog watchdog is enabled:

- ADC_AWD1_OUT is set when a guarded conversion is outside the programmed thresholds.
- ADC_AWD1_OUT is reset after the end of the next guarded conversion which is inside the programmed thresholds. It remains at 1 if the next guarded conversions are still outside the programmed thresholds.
- ADC_AWD1_OUT is also reset when disabling the ADC (when setting ADDIS to 1). Note that stopping conversions (ADSTP set), might clear the ADC_AWD1_OUT state.
- ADC_AWD1_OUT state does not change when the ADC converts the none-guarded channel (see Figure 43).

AWD flag is set by hardware and reset by software: AWD flag has no influence on the generation of ADC_AWD1_OUT (as an example, ADC_AWD1_OUT can toggle while AWD flag remains at 1 if the software has not cleared the flag).

The ADC_AWD1_OUT signal is generated by the ADC_CLK domain. This signal can be generated even the APB clock is stopped.

The AWD comparison is performed at the end of each ADC conversion. The ADC_AWD1_OUT rising edge and falling edge occurs two ADC_CLK clock cycles after the comparison.

As ADC_AWD1_OUT is generated by the ADC_CLK domain and AWD flag is generated by the APB clock domain, the rising edges of these signals are not synchronized.

**Figure 43. ADC_AWD1_OUT signal generation**

Figure 44. ADC_AWD1_OUT signal generation (AWD flag not cleared by software)

Figure 45. ADC1_AWD_OUT signal generation (on a single channel)

13.7.3 Analog watchdog threshold control

LT[11:0] and HT[11:0] can be changed during an analog-to-digital conversion (that is between the start of the conversion and the end of conversion of the ADC internal state). If LT and HT bits are programmed during the ADC guarded channel conversion, the watchdog function is masked for this conversion. This mask is cleared when starting a new conversion, and the resulting new AWD threshold is applied starting the next ADC conversion result. AWD comparison is performed at each end of conversion. If the current ADC data are out of the new threshold interval, this does not generated any interrupt or an ADC_AWD1_OUT signal. The Interrupt and the ADC_AWD1_OUT generation only occurs at the end of the ADC conversion that started after the threshold update. If ADC_AWD1_OUT is already asserted, programming the new threshold does not deassert the ADC_AWD1_OUT signal.
### 13.8 Temperature sensor and internal reference voltage

The temperature sensor can be used to measure the junction temperature \( T_J \) of the device. The temperature sensor is internally connected to the ADC \( V_{IN}[16] \) input channel which is used to convert the sensor’s output voltage to a digital value. The sampling time for the temperature sensor analog pin must be greater than the minimum \( T_{S_{temp}} \) value specified in the datasheet. When not in use, the sensor can be put in power down mode.

The temperature sensor output voltage changes linearly with temperature, however its characteristics may vary significantly from chip to chip due to the process variations. To improve the accuracy of the temperature sensor (especially for absolute temperature measurement), calibration values are individually measured for each part by ST during production test and stored in the system memory area. Refer to the specific device datasheet for additional information.

The internal voltage reference (\( V_{REFINT} \)) provides a stable (bandgap) voltage output for the ADC and comparators. \( V_{REFINT} \) is internally connected to the ADC \( V_{IN}[17] \) input channel. The precise voltage of \( V_{REFINT} \) is individually measured for each part by ST during production test and stored in the system memory area.

*Figure 47* shows the block diagram of connections between the temperature sensor, the internal voltage reference and the ADC.

The TSEN bit must be set to enable the conversion of ADC \( V_{IN}[16] \) (temperature sensor) and the VREFEN bit must be set to enable the conversion of ADC \( V_{IN}[17] \) (\( V_{REFINT} \)).
Reading the temperature

1. Select the ADC V\textsubscript{IN}[16] input channel.
2. Select an appropriate sampling time specified in the device datasheet (T\textsubscript{S\_temp}).
3. Set the TSEN bit in the ADC\_CCR register to wake up the temperature sensor from power down mode and wait for its stabilization time (t\textsubscript{START}).
   For code example refer to the Appendix section A.7.15: Temperature configuration code example.
4. Start the ADC conversion by setting the ADSTART bit in the ADC\_CR register (or by external trigger).
5. Read the resulting V\textsubscript{SENSE} data in the ADC\_DR register.
6. Calculate the temperature using the following formula

   \[
   \text{Temperature (in °C)} = \frac{\text{TS\_CAL2\_TEMP} - \text{TS\_CAL1\_TEMP}}{\text{TS\_CAL2} - \text{TS\_CAL1}} \times \left(\frac{\text{TS\_DATA} - \text{TS\_CAL1}}{\text{TS\_CAL1\_TEMP}}\right)
   \]

   Where:
   - TS\_CAL2 is the temperature sensor calibration value acquired at TS\_CAL2\_TEMP (refer to the datasheet for TS\_CAL2 value)
   - TS\_CAL1 is the temperature sensor calibration value acquired at TS\_CAL1\_TEMP (refer to the datasheet for TS\_CAL1 value)
   - TS\_DATA is the actual temperature sensor output value converted by ADC
   - Refer to the specific device datasheet for more information about TS\_CAL1 and TS\_CAL2 calibration points.

   For code example refer to the A.7.16: Temperature computation code example.

**Note:** The sensor has a startup time after waking from power down mode before it can output V\textsubscript{SENSE} at the correct level. The ADC also has a startup time after power-on, so to minimize the delay, the ADEN and TSEN bits should be set at the same time.
Calculating the actual $V_{DDA}$ voltage using the internal reference voltage

The $V_{DDA}$ power supply voltage applied to the device may be subject to variation or not precisely known. The embedded internal voltage reference ($V_{REFINT}$) and its calibration data, acquired by the ADC during the manufacturing process at $V_{DDA, Charac}$, can be used to evaluate the actual $V_{DDA}$ voltage level.

The following formula gives the actual $V_{DDA}$ voltage supplying the device:

$$V_{DDA} = \frac{V_{DDA, Charac} \times V_{REFINT, CAL}}{V_{REFINT, DATA}}$$

Where:

- $V_{DDA, Charac}$ is the value of $V_{DDA}$ voltage characterized at $V_{REFINT}$ during the manufacturing process. It is specified in the device datasheet.
- $V_{REFINT, CAL}$ is the $V_{REFINT}$ calibration value
- $V_{REFINT, DATA}$ is the actual $V_{REFINT}$ output value converted by ADC

Converting a supply-relative ADC measurement to an absolute voltage value

The ADC is designed to deliver a digital value corresponding to the ratio between the analog power supply and the voltage applied on the converted channel. For most application use cases, it is necessary to convert this ratio into a voltage independent of $V_{DDA}$. For applications where $V_{DDA}$ is known and ADC converted values are right-aligned you can use the following formula to get this absolute value:

$$V_{CHANNELx} = \left(\frac{V_{DDA}}{\text{FULL\_SCALE}}\right) \times \frac{\text{ADC\_DATA}_x}{V_{REFINT, DATA}}$$

For applications where $V_{DDA}$ value is not known, you must use the internal voltage reference and $V_{DDA}$ can be replaced by the expression provided in Section: Calculating the actual $V_{DDA}$ voltage using the internal reference voltage, resulting in the following formula:

$$V_{CHANNELx} = \left(\frac{V_{DDA, Charac} \times V_{REFINT, CAL} \times \text{ADC\_DATA}_x}{V_{REFINT, DATA} \times \text{FULL\_SCALE}}\right)$$

Where:

- $V_{DDA, Charac}$ is the value of $V_{DDA}$ voltage characterized at $V_{REFINT}$ during the manufacturing process. It is specified in the device datasheet.
- $V_{REFINT, CAL}$ is the $V_{REFINT}$ calibration value
- $\text{ADC\_DATA}_x$ is the value measured by the ADC on channelx (right-aligned)
- $V_{REFINT, DATA}$ is the actual $V_{REFINT}$ output value converted by the ADC
- $\text{full\_SCALE}$ is the maximum digital value of the ADC output. For example with 12-bit resolution, it is $2^{12} - 1 = 4095$ or with 8-bit resolution, $2^8 - 1 = 255$.

Note: If ADC measurements are done using an output format other than 12 bit right-aligned, all the parameters must first be converted to a compatible format before the calculation is done.

13.9 Battery voltage monitoring

The VBATEN bit in the ADC_CCR register allows the application to measure the backup battery voltage on the VBAT pin. As the $V_{BAT}$ voltage could be higher than $V_{DDA}$, to ensure the correct operation of the ADC, the VBAT pin is internally connected to a bridge divider. This bridge is automatically enabled when VBATEN is set, to connect $V_{BAT}$ to the ADC $V_{IN}[18]$ input channel. As a consequence, the converted digital value is $V_{BAT}/2$. To prevent
any unwanted consumption on the battery, it is recommended to enable the bridge divider only when needed for ADC conversion.

13.10 **ADC interrupts**

An interrupt can be generated by any of the following events:

- ADC power-up, when the ADC is ready (ADRDY flag)
- End of any conversion (EOC flag)
- End of a sequence of conversions (EOS flag)
- When an analog watchdog detection occurs (AWD flag)
- When the end of sampling phase occurs (EOSMP flag)
- when a data overrun occurs (OVR flag)

Separate interrupt enable bits are available for flexibility.

Bits 31:13  Reserved, must be kept at reset value.

Bits 12:10  Reserved, must be kept at reset value.

Bits 9:8    Reserved, must be kept at reset value.

Bit 7  **AWD**: Analog watchdog flag
This bit is set by hardware when the converted voltage crosses the values programmed in ADC_TR register. It is cleared by software by programming it to 1.
0: No analog watchdog event occurred (or the flag event was already acknowledged and cleared by software)
1: Analog watchdog event occurred

Bits 6:5    Reserved, must be kept at reset value.

Bit 4  **OVR**: ADC overrun
This bit is set by hardware when an overrun occurs, meaning that a new conversion has complete while the EOC flag was already set. It is cleared by software writing 1 to it.
0: No overrun occurred (or the flag event was already acknowledged and cleared by software)
1: Overrun has occurred

Bit 3  **EOS**: End of sequence flag
This bit is set by hardware at the end of the conversion of a sequence of channels selected by the CHSEL bits. It is cleared by software writing 1 to it.
0: Conversion sequence not complete (or the flag event was already acknowledged and cleared by software)
1: Conversion sequence complete
Bit 2 **EOC**: End of conversion flag
This bit is set by hardware at the end of each conversion of a channel when a new data result is available in the ADC_DR register. It is cleared by software writing 1 to it or by reading the ADC_DR register.
0: Channel conversion not complete (or the flag event was already acknowledged and cleared by software)
1: Channel conversion complete

Bit 1 **EOSMP**: End of sampling flag
This bit is set by hardware during the conversion, at the end of the sampling phase. It is cleared by software by programming it to ‘1’.
0: Not at the end of the sampling phase (or the flag event was already acknowledged and cleared by software)
1: End of sampling phase reached

Bit 0 **ADRDY**: ADC ready
This bit is set by hardware after the ADC has been enabled (ADEN = 1) and when the ADC reaches a state where it is ready to accept conversion requests.
It is cleared by software writing 1 to it.
0: ADC not yet ready to start conversion (or the flag event was already acknowledged and cleared by software)
1: ADC is ready to start conversion

Note: In auto-off mode (AUTOFF = 1) the power-on/off phases are performed automatically, by hardware and the ADRDY flag is not set.

Bits 31:13 Reserved, must be kept at reset value.

Bits 12:10 Reserved, must be kept at reset value.

Bits 9:8 Reserved, must be kept at reset value.

Bit 7 **AWDIE**: Analog watchdog interrupt enable
This bit is set and cleared by software to enable/disable the analog watchdog interrupt.
0: Analog watchdog interrupt disabled
1: Analog watchdog interrupt enabled

Note: The Software is allowed to write this bit only when ADSTART bit is cleared (this ensures that no conversion is ongoing).

Bits 6:5 Reserved, must be kept at reset value.
Bit 4 **OVRIE**: Overrun interrupt enable
- This bit is set and cleared by software to enable/disable the overrun interrupt.
  - 0: Overrun interrupt disabled
  - 1: Overrun interrupt enabled. An interrupt is generated when the OVR bit is set.

*Note: The software is allowed to write this bit only when ADSTART bit is cleared (this ensures that no conversion is ongoing).*

Bit 3 **EOSIE**: End of conversion sequence interrupt enable
- This bit is set and cleared by software to enable/disable the end of sequence of conversions interrupt.
  - 0: EOS interrupt disabled
  - 1: EOS interrupt enabled. An interrupt is generated when the EOS bit is set.

*Note: The software is allowed to write this bit only when ADSTART bit is cleared (this ensures that no conversion is ongoing).*

Bit 2 **EOCIE**: End of conversion interrupt enable
- This bit is set and cleared by software to enable/disable the end of conversion interrupt.
  - 0: EOC interrupt disabled
  - 1: EOC interrupt enabled. An interrupt is generated when the EOC bit is set.

*Note: The software is allowed to write this bit only when ADSTART bit is cleared (this ensures that no conversion is ongoing).*

Bit 1 **EOSMPIE**: End of sampling flag interrupt enable
- This bit is set and cleared by software to enable/disable the end of the sampling phase interrupt.
  - 0: EOSMP interrupt disabled
  - 1: EOSMP interrupt enabled. An interrupt is generated when the EOSMP bit is set.

*Note: The software is allowed to write this bit only when ADSTART bit is cleared (this ensures that no conversion is ongoing).*

Bit 0 **ADRDYIE**: ADC ready interrupt enable
- This bit is set and cleared by software to enable/disable the ADC Ready interrupt.
  - 0: ADRDY interrupt disabled
  - 1: ADRDY interrupt enabled. An interrupt is generated when the ADRDY bit is set.

*Note: The software is allowed to write this bit only when ADSTART bit is cleared (this ensures that no conversion is ongoing).*

**Bit 31 ADCAL**: ADC calibration  
This bit is set by software to start the calibration of the ADC. It is cleared by hardware after calibration is complete.  
0: Calibration complete  
1: Write 1 to calibrate the ADC. Read at 1 means that a calibration is in progress.  
*Note: The software is allowed to set ADCAL only when the ADC is disabled (ADCAL = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0, AUTOFF = 0, and ADEN = 0).*  
*is allowed to*

**Bits 30:28** Reserved, must be kept at reset value.

**Bits 27:5** Reserved, must be kept at reset value.

**Bit 4 ADSTP**: ADC stop conversion command  
This bit is set by software to stop and discard an ongoing conversion (ADSTP Command). It is cleared by hardware when the conversion is effectively discarded and the ADC is ready to accept a new start conversion command.  
0: No ADC stop conversion command ongoing  
1: Write 1 to stop the ADC. Read 1 means that an ADSTP command is in progress.  
*Note: Setting ADSTP to ‘1’ is only effective when ADSTART = 1 and ADDIS = 0 (ADC is enabled and may be converting and there is no pending request to disable the ADC)*

**Bit 3** Reserved, must be kept at reset value.
Bit 2 **ADSTART**: ADC start conversion command

This bit is set by software to start ADC conversion. Depending on the EXTEN [1:0] configuration bits, a conversion either starts immediately (software trigger configuration) or once a hardware trigger event occurs (hardware trigger configuration).

It is cleared by hardware:
- In single conversion mode (CONT = 0, DISCEN = 0), when software trigger is selected (EXTEN = 00): at the assertion of the end of Conversion Sequence (EOS) flag.
- In discontinuous conversion mode (CONT = 0, DISCEN = 1), when the software trigger is selected (EXTEN = 00): at the assertion of the end of Conversion (EOC) flag.
- In all other cases: after the execution of the ADSTP command, at the same time as the ADSTP bit is cleared by hardware.

0: No ADC conversion is ongoing.
1: Write 1 to start the ADC. Read 1 means that the ADC is operating and may be converting.

*Note:* The software is allowed to set ADSTART only when ADEN = 1 and ADDIS = 0 (ADC is enabled and there is no pending request to disable the ADC).

Bit 1 **ADDIS**: ADC disable command

This bit is set by software to disable the ADC (ADDIS command) and put it into power-down state (OFF state).

It is cleared by hardware once the ADC is effectively disabled (ADEN is also cleared by hardware at this time).

0: No ADDIS command ongoing
1: Write 1 to disable the ADC. Read 1 means that an ADDIS command is in progress.

*Note:* Setting ADDIS to ‘1’ is only effective when ADEN = 1 and ADSTART = 0 (which ensures that no conversion is ongoing)

Bit 0 **ADEN**: ADC enable command

This bit is set by software to enable the ADC. The ADC is effectively ready to operate once the ADRDY flag has been set.

It is cleared by hardware when the ADC is disabled, after the execution of the ADDIS command.

0: ADC is disabled (OFF state)
1: Write 1 to enable the ADC.

*Note:* The software is allowed to set ADEN only when all bits of ADC_CR registers are 0 (ADCAL = 0, ADSTP = 0, ADSTART = 0, ADDIS = 0 and ADEN = 0)

Bit 31 Reserved, must be kept at reset value.

Bits 30:26 **AWDCH[4:0]:** Analog watchdog channel selection

These bits are set and cleared by software. They select the input channel to be guarded by the analog watchdog.

- 00000: ADC analog input Channel 0 monitored by AWD
- 00001: ADC analog input Channel 1 monitored by AWD
- ....
- 10001: ADC analog input Channel 17 monitored by AWD
- 10010: ADC analog input Channel 18 monitored by AWD
- Others: Reserved

**Note:** The channel selected by the AWDCH[4:0] bits must be also set into the CHSELR register.

The software is allowed to write this bit only when ADSTART bit is cleared (this ensures that no conversion is ongoing).

Bits 25:24 Reserved, must be kept at reset value.

Bit 23 **AWDEN:** Analog watchdog enable

This bit is set and cleared by software.

- 0: Analog watchdog disabled
- 1: Analog watchdog enabled

**Note:** The software is allowed to write this bit only when ADSTART bit is cleared (this ensures that no conversion is ongoing).

Bit 22 **AWDSGL:** Enable the watchdog on a single channel or on all channels

This bit is set and cleared by software to enable the analog watchdog on the channel identified by the AWDCH[4:0] bits or on all the channels

- 0: Analog watchdog enabled on all channels
- 1: Analog watchdog enabled on a single channel

**Note:** The software is allowed to write this bit only when ADSTART bit is cleared (this ensures that no conversion is ongoing).

Bits 21:17 Reserved, must be kept at reset value.
Bit 16  **DISCEN**: Discontinuous mode
This bit is set and cleared by software to enable/disable discontinuous mode.
0: Discontinuous mode disabled
1: Discontinuous mode enabled

*Note:* It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both bits DISCEN = 1 and CONT = 1.
The software is allowed to write this bit only when ADSTART bit is cleared (this ensures that no conversion is ongoing).

Bit 15  **AUTOFF**: Auto-off mode
This bit is set and cleared by software to enable/disable auto-off mode.
0: Auto-off mode disabled
1: Auto-off mode enabled

*Note:* The software is allowed to write this bit only when ADSTART bit is cleared (this ensures that no conversion is ongoing).

Bit 14  **WAIT**: Wait conversion mode
This bit is set and cleared by software to enable/disable wait conversion mode.
0: Wait conversion mode off
1: Wait conversion mode on

*Note:* The software is allowed to write this bit only when ADSTART bit is cleared (this ensures that no conversion is ongoing).

Bit 13  **CONT**: Single / continuous conversion mode
This bit is set and cleared by software. If it is set, conversion takes place continuously until it is cleared.
0: Single conversion mode
1: Continuous conversion mode

*Note:* It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both bits DISCEN = 1 and CONT = 1.
The software is allowed to write this bit only when ADSTART bit is cleared (this ensures that no conversion is ongoing).

Bit 12  **OVRMOD**: Overrun management mode
This bit is set and cleared by software and configure the way data overruns are managed.
0: ADC_DR register is preserved with the old data when an overrun is detected.
1: ADC_DR register is overwritten with the last conversion result when an overrun is detected.

*Note:* The software is allowed to write this bit only when ADSTART bit is cleared (this ensures that no conversion is ongoing).

Bits 11:10  **EXTEN[1:0]**: External trigger enable and polarity selection
These bits are set and cleared by software to select the external trigger polarity and enable the trigger.
00: Hardware trigger detection disabled (conversions can be started by software)
01: Hardware trigger detection on the rising edge
10: Hardware trigger detection on the falling edge
11: Hardware trigger detection on both the rising and falling edges

*Note:* The software is allowed to write this bit only when ADSTART bit is cleared (this ensures that no conversion is ongoing).

Bit 9  Reserved, must be kept at reset value.
Bits 8:6 **EXTSEL[2:0]**: External trigger selection

These bits select the external event used to trigger the start of conversion (refer to Table 43: *External triggers* for details):

- 000: TRG0
- 001: TRG1
- 010: TRG2
- 011: TRG3
- 100: TRG4
- 101: TRG5
- 110: TRG6
- 111: TRG7

*Note:* The software is allowed to write this bit only when ADSTART bit is cleared (this ensures that no conversion is ongoing).

Bit 5 **ALIGN**: Data alignment

This bit is set and cleared by software to select right or left alignment. Refer to Figure 37: *Data alignment and resolution* on page 249

- 0: Right alignment
- 1: Left alignment

*Note:* The software is allowed to write this bit only when ADSTART bit is cleared (this ensures that no conversion is ongoing).

Bits 4:3 **RES[1:0]**: Data resolution

These bits are written by software to select the resolution of the conversion.

- 00: 12 bits
- 01: 10 bits
- 10: 8 bits
- 11: 6 bits

*Note:* The software is allowed to write these bits only when ADEN is cleared.
Bit 2 **SCANDIR**: Scan sequence direction
This bit is set and cleared by software to select the direction in which the channels is scanned in the sequence.
0: Upward scan (from CHSEL0 to CHSEL18)
1: Backward scan (from CHSEL18 to CHSEL0)
*Note*: The software is allowed to write this bit only when ADSTART bit is cleared (this ensures that no conversion is ongoing).

Bit 1 **DMACFG**: Direct memory access configuration
This bit is set and cleared by software to select between two DMA modes of operation and is effective only when DMAEN = 1.
0: DMA one shot mode selected
1: DMA circular mode selected
For more details, refer to *Section 13.5.5: Managing converted data using the DMA on page 250*
*Note*: The software is allowed to write this bit only when ADSTART bit is cleared (this ensures that no conversion is ongoing).

Bit 0 **DMAEN**: Direct memory access enable
This bit is set and cleared by software to enable the generation of DMA requests. This allows the DMA controller to be used to manage automatically the converted data. For more details, refer to *Section 13.5.5: Managing converted data using the DMA on page 250*.
0: DMA disabled
1: DMA enabled
*Note*: The software is allowed to write this bit only when ADSTART bit is cleared (this ensures that no conversion is ongoing).

Bits 31:30 CKMODE[1:0]: ADC clock mode
These bits are set and cleared by software to define how the analog ADC is clocked:
00: ADCCLK (Asynchronous clock mode), generated at product level (refer to RCC section)
01: PCLK/2 (Synchronous clock mode)
10: PCLK/4 (Synchronous clock mode)
11: Reserved
In all synchronous clock modes, there is no jitter in the delay from a timer trigger to the start of a conversion.

Note: The software is allowed to write these bits only when the ADC is disabled (ADCAL = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bits 29:10 Reserved, must be kept at reset value.
Bits 9:0 Reserved, must be kept at reset value.

Refer to Section 2.2 on page 46 for the register boundary addresses.
14 Digital-to-analog converter (DAC)

This section applies to STM32F05x, STM32F07x and STM32F09x devices only. The second DAC channel (DAC_OUT2) and some other features are available only on STM32F07x and STM32F09x devices.

14.1 Introduction

The DAC module is a 12-bit, voltage output digital-to-analog converter. The DAC can be configured in 8- or 12-bit mode and may be used in conjunction with the DMA controller. In 12-bit mode, the data could be left- or right-aligned. An input reference voltage, $V_{DDA}$ (shared with ADC), is available. The output can optionally be buffered for higher current drive.

14.2 DAC main features

The devices integrate one 12-bit DAC channel DAC_OUT1. A second channel DAC_OUT2 is available on STM32F07x and STM32F09x devices.

DAC main features are the following:

- Left or right data alignment in 12-bit mode
- Synchronized update capability
- Noise-wave generation (STM32F07x and STM32F09x devices)
- Triangular-wave generation (STM32F07x and STM32F09x devices)
- Independent or simultaneous conversions (dual mode only)
- DMA capability
- DMA underrun error detection
- External triggers for conversion
- Programmable internal buffer
- Input voltage reference, $V_{DDA}$

*Figure 48* shows the block diagram of a DAC channel and *Table 51* gives the pin description.
Figure 48. DAC block diagram

Table 51. DAC pins

<table>
<thead>
<tr>
<th>Name</th>
<th>Signal type</th>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>VDDA</td>
<td>Input, analog supply</td>
<td>Analog power supply</td>

<tr>
<td>VSSA</td>
<td>Input, analog supply ground</td>
<td>Ground for analog power supply</td>
</tr>
<tr>
<td>DAC_OUT</td>
<td>Analog output signal</td>
<td>DAC channelx analog output</td>
</tr>
</tbody>
</table>

Note: Once DAC_Channelx is enabled, the corresponding GPIO pin (PA4 or PA5) is automatically connected to the analog converter output (DAC_OUTx). In order to avoid parasitic consumption, the PA4 or PA5 pin should first be configured to analog (AIN).

14.3 DAC output buffer enable

The DAC integrates one output buffer that can be used to reduce the output impedance and to drive external loads directly without having to add an external operational amplifier.

The DAC channel output buffers can be enabled and disabled through the corresponding BOFFx bit in the DAC_CR register.
14.4 DAC channel enable

Each DAC channel can be powered on by setting the corresponding ENx bit in the DAC_CR register. Each DAC channel is then enabled after a startup time $t_{\text{WAKEUP}}$.

*Note:* The ENx bit enables the analog DAC Channelx macrocell only. The DAC Channelx digital interface is enabled even if the ENx bit is reset.

14.5 Single mode functional description

14.5.1 DAC data format

There are three possibilities:

- 8-bit right alignment: the software has to load data into the DAC_DHR8Rx [7:0] bits (stored into the DHRx[11:4] bits)
- 12-bit left alignment: the software has to load data into the DAC_DHR12Lx [15:4] bits (stored into the DHRx[11:0] bits)
- 12-bit right alignment: the software has to load data into the DAC_DHR12Rx [11:0] bits (stored into the DHRx[11:0] bits)

Depending on the loaded DAC_DHRyyyx register, the data written by the user is shifted and stored into the corresponding DHRx (data holding registerx, which are internal non-memory-mapped registers). The DHRx register is then loaded into the DORx register either automatically, by software trigger or by an external event trigger.

![Figure 49. Data registers in single DAC channel mode](ai14710b)

14.5.2 DAC channel conversion

The DAC_DORx cannot be written directly and any data transfer to the DAC channelx must be performed by loading the DAC_DHRx register (write to DAC_DHR8Rx, DAC_DHR12Lx, DAC_DHR12Rx).

Data stored in the DAC_DHRx register are automatically transferred to the DAC_DORx register after one APB clock cycle, if no hardware trigger is selected (TENx bit in DAC_CR register is reset). However, when a hardware trigger is selected (TENx bit in DAC_CR register is set) and a trigger occurs, the transfer is performed three PCLK clock cycles later.

When DAC_DORx is loaded with the DAC_DHRx contents, the analog output voltage becomes available after a time $t_{\text{SETTLING}}$ that depends on the power supply voltage and the analog output load.
Independent trigger with single LFSR generation

To configure the DAC in this conversion mode (see Section 14.7: Noise generation (STM32F07x and STM32F09x devices)), the following sequence is required:

1. Set the DAC channel trigger enable bit TENx.
2. Configure the trigger source by setting TSELx[2:0] bits.
3. Configure the DAC channel WAVEx[1:0] bits as “01” and the same LFSR mask value in the MAMPx[3:0] bits.
4. Load the DAC channel data into the desired DAC_DHRx register (DHR12RD, DHR12LD or DHR8RD).

When a DAC channelx trigger arrives, the LFSRx counter, with the same mask, is added to the DHRx register and the sum is transferred into DAC_DORx (three APB clock cycles later). Then the LFSRx counter is updated.

Independent trigger with single triangle generation

To configure the DAC in this conversion mode (see Section 14.8: Triangle-wave generation (STM32F07x and STM32F09x devices)), the following sequence is required:

1. Set the DAC channelx trigger enable bit TENx.
2. Configure the trigger source by setting TSELx[2:0] bits.
3. Configure the DAC channelx WAVEx[1:0] bits as “1x” and the same maximum amplitude value in the MAMPx[3:0] bits.
4. Load the DAC channelx data into the desired DAC_DHRx register. (DHR12RD, DHR12LD or DHR8RD).

When a DAC channelx trigger arrives, the DAC channelx triangle counter, with the same triangle amplitude, is added to the DHRx register and the sum is transferred into DAC_DORx (three APB clock cycles later). The DAC channelx triangle counter is then updated.

14.5.3 DAC output voltage

Digital inputs are converted to output voltages on a linear conversion between 0 and $V_{DDA}$.

The analog output voltages on each DAC channel pin are determined by the following equation:

$$DAC_{output} = V_{DDA} \times \frac{DOR}{4096}$$
14.5.4 DAC trigger selection

If the TENx control bit is set, conversion can then be triggered by an external event (timer counter, external interrupt line). The TSELx[2:0] control bits determine which possible events will trigger conversion as shown in Table 52.

![Table 52. External triggers](image)

Each time a DAC interface detects a rising edge on the selected timer TRGO output, or on the selected external interrupt line 9, the last data stored into the DAC_DHRx register are transferred into the DAC_DORx register. The DAC_DORx register is updated three APB cycles after the trigger occurs.

If the software trigger is selected, the conversion starts once the SWTRIG bit is set. SWTRIG is reset by hardware once the DAC_DORx register has been loaded with the DAC_DHRx register contents.

![Note](image)

14.6 Dual-mode functional description (STM32F07x and STM32F09x devices)

14.6.1 DAC data format

In Dual DAC channel mode, there are three possibilities:

- 8-bit right alignment: data for DAC channel1 to be loaded in the DAC_DHR8RD [7:0] bits (stored in the DHR1[11:4] bits) and data for DAC channel2 to be loaded in the DAC_DHR8RD [15:8] bits (stored in the DHR2[11:4] bits)
- 12-bit left alignment: data for DAC channel1 to be loaded into the DAC_DHR12LD [15:4] bits (stored into the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC_DHR12LD [31:20] bits (stored in the DHR2[11:0] bits)
- 12-bit right alignment: data for DAC channel1 to be loaded into the DAC_DHR12RD [11:0] bits (stored in the DHR1[11:0] bits) and data for DAC channel2 to be loaded into the DAC_DHR12LD [27:16] bits (stored in the DHR2[11:0] bits)
Depending on the loaded DAC_DHRyyyD register, the data written by the user is shifted and stored in DHR1 and DHR2 (data holding registers, which are internal non-memory-mapped registers). The DHR1 and DHR2 registers are then loaded into the DOR1 and DOR2 registers, respectively, either automatically, by software trigger or by an external event trigger.

#### 14.6.2 DAC channel conversion in dual mode

The DAC channel conversion in dual mode is performed in the same way as in single mode (refer to Section 14.5.2) except that the data have to be loaded by writing to DAC_DHR8Rx, DAC_DHR12Lx, DAC_DHR12Rx, DAC_DHR8RD, DAC_DHR12LD or DAC_DHR12RD.

#### 14.6.3 Description of dual conversion modes

To efficiently use the bus bandwidth in applications that require the two DAC channels at the same time, three dual registers are implemented: DHR8RD, DHR12RD and DHR12LD. A unique register access is then required to drive both DAC channels at the same time.

Eleven conversion modes are possible using the two DAC channels and these dual registers. All the conversion modes can nevertheless be obtained using separate DHRx registers if needed.

All modes are described in the paragraphs below.

Refer to Section 14.5.2: DAC channel conversion for details on the APB bus (APB or APB1) that clocks the DAC conversions.

**Independent trigger without wave generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure different trigger sources by setting different values in the TSEL1[2:0] and TSEL2[2:0] bits
3. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD)

When a DAC channel1 trigger arrives, the DHR1 register is transferred into DAC_DOR1 (three APB clock cycles later).

When a DAC channel2 trigger arrives, the DHR2 register is transferred into DAC_DOR2 (three APB clock cycles later).

For code example refer to the Appendix section A.8.1: Independent trigger without wave generation code example
Independent trigger with single LFSR generation

To configure the DAC in this conversion mode (refer to Section 14.7: Noise generation (STM32F07x and STM32F09x devices)), the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure different trigger sources by setting different values in the TSEL1[2:0] and TSEL2[2:0] bits
3. Configure the two DAC channel WAVEx[1:0] bits as “01” and the same LFSR mask value in the MAMPx[3:0] bits
4. Load the dual DAC channel data into the desired DHR register (DHR12RD, DHR12LD or DHR8RD)

For code example refer to the Appendix section A.8.2: Independent trigger with single LFSR generation code example.

When a DAC channel1 trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three APB clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel2 trigger arrives, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three APB clock cycles later). Then the LFSR2 counter is updated.

Independent trigger with different LFSR generation

To configure the DAC in this conversion mode (refer to Section 14.7: Noise generation (STM32F07x and STM32F09x devices)), the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure different trigger sources by setting different values in the TSEL1[2:0] and TSEL2[2:0] bits
3. Configure the two DAC channel WAVEx[1:0] bits as “01” and set different LFSR masks values in the MAMP1[3:0] and MAMP2[3:0] bits
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD)

For code example refer to the Appendix section A.8.3: Independent trigger with different LFSR generation code example.

When a DAC channel1 trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three APB clock cycles later). Then the LFSR1 counter is updated.

When a DAC channel2 trigger arrives, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three APB clock cycles later). Then the LFSR2 counter is updated.

Independent trigger with single triangle generation

To configure the DAC in this conversion mode (refer to Section 14.8: Triangle-wave generation (STM32F07x and STM32F09x devices)), the following sequence is required:
1. Set the DAC channelx trigger enable TENx bits.
2. Configure different trigger sources by setting different values in the TSELx[2:0] bits
3. Configure the DAC channelx WAVEx[1:0] bits as “1x” and the same maximum amplitude value in the MAMPx[3:0] bits
4. Load the DAC channelx data into the desired DAC_DHRx register.

For code example refer to the Appendix section A.8.4: Independent trigger with single triangle generation code example.

Refer to Section 14.5.2: DAC channel conversion for details on the APB bus (APB or APB1) that clocks the DAC conversions.

When a DAC channelx trigger arrives, the DAC channelx triangle counter, with the same triangle amplitude, is added to the DHRx register and the sum is transferred into DAC_DORx (three APB clock cycles later). The DAC channelx triangle counter is then updated.

**Independent trigger with different triangle generation**

To configure the DAC in this conversion mode (refer to Section 14.8: Triangle-wave generation (STM32F07x and STM32F09x devices)), the following sequence is required:

1. Set the DAC channelx trigger enable TENx bits.
2. Configure different trigger sources by setting different values in the TSELx[2:0] bits
3. Configure the DAC channelx WAVEx[1:0] bits as “1x” and set different maximum amplitude values in the MAMPx[3:0] bits
4. Load the DAC channelx data into the desired DAC_DHRx register.

For code example refer to the Appendix section A.8.5: Independent trigger with different triangle generation code example.

When a DAC channelx trigger arrives, the DAC channelx triangle counter, with a triangle amplitude configured by MAMPx[3:0], is added to the DHRx register and the sum is transferred into DAC_DORx (three APB clock cycles later). The DAC channelx triangle counter is then updated.

**Simultaneous software start**

To configure the DAC in this conversion mode, the following sequence is required:

1. Load the dual DAC channel data to the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD)

In this configuration, one APB clock cycles).

For code example refer to the Appendix section A.8.6: Simultaneous software start code example.

**Simultaneous trigger without wave generation**

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1[2:0] and TSEL2[2:0] bits
3. Load the dual DAC channel data to the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD)
When a trigger arrives, the DHR1 and DHR2 registers are transferred into DAC_DOR1 and DAC_DOR2, respectively (after three APB clock cycles).

For code example refer to the Appendix section **A.8.7: Simultaneous trigger without wave generation code example**.

**Simultaneous trigger with single LFSR generation**

To configure the DAC in this conversion mode (refer to **Section 14.7: Noise generation(STM32F07x and STM32F09x devices)**), the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1[2:0] and TSEL2[2:0] bits
3. Configure the two DAC channel WAVEx[1:0] bits as “01” and the same LFSR mask value in the MAMPx[3:0] bits
4. Load the dual DAC channel data to the desired DHR register (DHR12RD, DHR12LD or DHR8RD)

For code example refer to the Appendix section **A.8.8: Simultaneous trigger with single LFSR generation code example**.

When a trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three APB clock cycles later). The LFSR1 counter is then updated. At the same time, the LFSR2 counter, with the same mask, is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three APB clock cycles later). The LFSR2 counter is then updated.

**Simultaneous trigger with different LFSR generation**

To configure the DAC in this conversion mode (refer to **Section 14.7: Noise generation(STM32F07x and STM32F09x devices)**), the following sequence is required:

1. Set the two DAC channel trigger enable bits TEN1 and TEN2
2. Configure the same trigger source for both DAC channels by setting the same value in the TSEL1[2:0] and TSEL2[2:0] bits
3. Configure the two DAC channel WAVEx[1:0] bits as “01” and set different LFSR mask values using the MAMP1[3:0] and MAMP2[3:0] bits
4. Load the dual DAC channel data into the desired DHR register (DAC_DHR12RD, DAC_DHR12LD or DAC_DHR8RD)

For code example refer to the Appendix section **A.8.9: Simultaneous trigger with different LFSR generation code example**.

When a trigger arrives, the LFSR1 counter, with the mask configured by MAMP1[3:0], is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three APB clock cycles later). The LFSR1 counter is then updated.

At the same time, the LFSR2 counter, with the mask configured by MAMP2[3:0], is added to the DHR2 register and the sum is transferred into DAC_DOR2 (three APB clock cycles later). The LFSR2 counter is then updated.

**Simultaneous trigger with single triangle generation**

To configure the DAC in this conversion mode (refer to **Section 14.8: Triangle-wave generation (STM32F07x and STM32F09x devices)**), the following sequence is required:
1. Set the DAC channelx trigger enable TEN1x bits.
2. Configure the same trigger source for both DAC channels by setting the same value in the TSELx[2:0] bits.
3. Configure the DAC channelx WAVEx[1:0] bits as “1x” and the same maximum amplitude value using the MAMPx[3:0] bits.
4. Load the DAC channelx data into the desired DAC_DHRx registers.

For code example refer to the Appendix section A.8.10: Simultaneous trigger with single triangle generation code example.

When a trigger arrives, the DAC channelx triangle counter, with the same triangle amplitude, is added to the DHRx register and the sum is transferred into DAC_DORx (three APB clock cycles later). The DAC channelx triangle counter is then updated.

**Simultaneous trigger with different triangle generation**

To configure the DAC in this conversion mode refer to Section 14.8: Triangle-wave generation (STM32F07x and STM32F09x devices), the following sequence is required:

1. Set the DAC channelx trigger enable TENx bits.
2. Configure the same trigger source for DAC channelx by setting the same value in the TSELx[2:0] bits.
3. Configure the DAC channelx WAVEx[1:0] bits as “1x” and set different maximum amplitude values in the MAMPx[3:0] bits.
4. Load the DAC channelx data into the desired DAC_DHRx registers.

For code example refer to the Appendix section A.8.11: Simultaneous trigger with different triangle generation code example.

When a trigger arrives, the DAC channelx triangle counter, with a triangle amplitude configured by MAMPx[3:0], is added to the DHRx register and the sum is transferred into DAC_DORx (three APB clock cycles later). Then the DAC channelx triangle counter is updated.

### 14.6.4 DAC output voltage

Refer to Section 14.5.3: DAC output voltage.
14.6.5 DAC trigger selection

Refer to Section 14.5.4: DAC trigger selection

14.7 Noise generation (STM32F07x and STM32F09x devices)

In order to generate a variable-amplitude pseudonoise, an LFSR (linear feedback shift register) is available. DAC noise generation is selected by setting WAVEx[1:0] to "01". The preloaded value in LFSR is 0xAAA. This register is updated three APB clock cycles after each trigger event, following a specific calculation algorithm.

The LFSR value, that may be masked partially or totally by means of the MAMPx[3:0] bits in the DAC_CR register, is added up to the DAC_DHRx contents without overflow and this value is then stored into the DAC_DORx register.

If LFSR is 0x0000, a '1 is injected into it (antilock-up mechanism).

It is possible to reset LFSR wave generation by resetting the WAVEx[1:0] bits.

Note: The DAC trigger must be enabled for noise generation by setting the TENx bit in the DAC_CR register.
14.8 Triangle-wave generation (STM32F07x and STM32F09x devices)

It is possible to add a small-amplitude triangular waveform on a DC or slowly varying signal. DAC triangle-wave generation is selected by setting WAVEx[1:0] to “10”. The amplitude is configured through the MAMPx[3:0] bits in the DAC_CR register. An internal triangle counter is incremented three APB clock cycles after each trigger event. The value of this counter is then added to the DAC_DHRx register without overflow and the sum is stored into the DAC_DORx register. The triangle counter is incremented as long as it is less than the maximum amplitude defined by the MAMPx[3:0] bits. Once the configured amplitude is reached, the counter is decremented down to 0, then incremented again and so on.

It is possible to reset triangle wave generation by resetting the WAVEx[1:0] bits.

Figure 54. DAC triangle wave generation

Figure 55. DAC conversion (SW trigger enabled) with triangle wave generation

Note: The DAC trigger must be enabled for triangle generation by setting the TENx bit in the DAC_CR register.
The MAMPx[3:0] bits must be configured before enabling the DAC, otherwise they cannot be changed.
14.9  **DMA request**

Each DAC channel has a DMA capability. Two DMA channels are used to service DAC channel DMA requests.

A DAC DMA request is generated when an external trigger (but not a software trigger) occurs while the DMAENx bit is set. The value of the DAC_DHRx register is then transferred to the DAC_DORx register.

In dual mode, if both DMAENx bits are set, two DMA requests are generated. If only one DMA request is needed, user should set only the corresponding DMAENx bit. In this way, the application can manage both DAC channels in dual mode by using one DMA request and a unique DMA channel.

For code example refer to the Appendix section **A.8.12: DMA initialization code example**.

**DMA underrun**

The DAC DMA request is not queued so that if a second external trigger arrives before the acknowledgment for the first external trigger is received (first request), then no new request is issued and the DMA channelx underrun flag DMAUDRx in the DAC_SR register is set, reporting the error condition. DMA data transfers are then disabled and no further DMA request is treated. The DAC channelx continues to convert old data.

The software should clear the DMAUDRx flag by writing “1”, clear the DMAEN bit of the used DMA stream and re-initialize both DMA and DAC channelx to restart the transfer correctly. The software should modify the DAC trigger conversion frequency or lighten the DMA workload to avoid a new DMA. Finally, the DAC conversion can be resumed by enabling both DMA data transfer and conversion trigger.

For each DAC channel, an interrupt is also generated if the corresponding DMAUDRIEx bit in the DAC_CR register is enabled.
14.10 DAC registers

Refer to Section 1.2 on page 42 for a list of abbreviations used in register descriptions.

The peripheral registers have to be accessed by words (32-bit).

14.10.1 DAC control register (DAC_CR)

Address offset: 0x00

Reset value: 0x0000 0000

|      | Note: These bits are available only in dual mode when wave generation is supported. Otherwise, they are reserved and must be kept at reset value. |
Bits 23:22 **WAVE2[1:0]**: DAC channel2 noise/triangle wave generation enable
These bits are set/reset by software.
- 00: wave generation disabled
- 01: Noise wave generation enabled
- 1x: Triangle wave generation enabled
*Note:* Only used if bit TEN2 = 1 (DAC channel2 trigger enabled)
These bits are available only in dual mode when wave generation is supported. Otherwise, they are reserved and must be kept at reset value.

Bits 21:19 **TSEL2[2:0]**: DAC channel2 trigger selection
These bits select the external event used to trigger DAC channel2
- 000: Timer 6 TRGO event
- 001: Timer 3 TRGO event
- 010: Timer 7 TRGO event
- 011: Timer 15 TRGO event
- 100: Timer 2 TRGO event
- 101: Reserved
- 110: EXTI line9
- 111: Software trigger
*Note:* Only used if bit TEN2 = 1 (DAC channel2 trigger enabled).
These bits are available in dual mode only. They are reserved in single mode.

Bit 18 **TEN2**: DAC channel2 trigger enable
This bit is set and cleared by software to enable/disable DAC channel2 trigger
- 0: DAC channel2 trigger disabled and data written into the DAC_DHRx register are transferred one APBclock cycle later to the DAC_DOR2 register
- 1: DAC channel2 trigger enabled and data from the DAC_DHRx register are transferred three APB clock cycles later to the DAC_DOR2 register
*Note:* When software trigger is selected, the transfer from the DAC_DHRx register to the DAC_DOR2 register takes only one APB clock cycle.
*Note:* This bit is available in dual mode only. It is reserved in single mode.

Bit 17 **BOFF2**: DAC channel2 output buffer disable
This bit is set and cleared by software to enable/disable DAC channel2 output buffer.
- 0: DAC channel2 output buffer enabled
- 1: DAC channel2 output buffer disabled
*Note:* This bit is available in dual mode only. It is reserved in single mode.

Bit 16 **EN2**: DAC channel2 enable
This bit is set and cleared by software to enable/disable DAC channel2.
- 0: DAC channel2 disabled
- 1: DAC channel2 enabled
*Note:* This bit is available in dual mode only. It is reserved in single mode.

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **DMAUDRIE1**: DAC channel1 DMA Underrun Interrupt enable
This bit is set and cleared by software.
- 0: DAC channel1 DMA Underrun Interrupt disabled
- 1: DAC channel1 DMA Underrun Interrupt enabled
Bit 12 **DMAEN1**: DAC channel1 DMA enable
This bit is set and cleared by software.
0: DAC channel1 DMA mode disabled
1: DAC channel1 DMA mode enabled

Bits 11:8 **MAMP1[3:0]**: DAC channel1 mask/amplitude selector
These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.

- 0000: Unmask bit0 of LFSR/ triangle amplitude equal to 1
- 0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3
- 0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7
- 0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15
- 0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31
- 0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63
- 0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127
- 0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255
- 1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511
- 1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023
- 1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047
- ≥ 1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095

Bits 7:6 **WAVE1[1:0]**: DAC channel1 noise/triangle wave generation enable
These bits are set and cleared by software.
00: Wave generation disabled
01: Noise wave generation enabled
1x: Triangle wave generation enabled

*Note: Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).*

Bits 5:3 **TSEL1[2:0]**: DAC channel1 trigger selection
These bits select the external event used to trigger DAC channel1.
000: Timer 6 TRGO event
001: Timer 3 TRGO event
010: Timer 7 TRGO event
011: Timer 15 TRGO event
100: Timer 2 TRGO event
101: Reserved
110: EXTI line9
111: Software trigger

*Note: Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).*
Bit 2  **TEN1**: DAC channel1 trigger enable
This bit is set and cleared by software to enable/disable DAC channel1 trigger.
0: DAC channel1 trigger disabled and data written into the DAC_DHRx register are transferred one APB clock cycle later to the DAC_DOR1 register
1: DAC channel1 trigger enabled and data from the DAC_DHRx register are transferred three APB clock cycles later to the DAC_DOR1 register
**Note:** When software trigger is selected, the transfer from the DAC_DHRx register to the DAC_DOR1 register takes only one APB clock cycle.

Bit 1  **BOFF1**: DAC channel1 output buffer disable
This bit is set and cleared by software to enable/disable DAC channel1 output buffer.
0: DAC channel1 output buffer enabled
1: DAC channel1 output buffer disabled

Bit 0  **EN1**: DAC channel1 enable
This bit is set and cleared by software to enable/disable DAC channel1.
0: DAC channel1 disabled
1: DAC channel1 enabled
### 14.10.2 DAC software trigger register (DAC_SWTRIGR)

**Address offset**: 0x04

**Bits 31:2**: Reserved, must be kept at reset value.

**Bit 1** **SWTRIG2**: DAC channel2 software trigger  
This bit is set and cleared by software to enable/disable the software trigger.  
0: Software trigger disabled  
1: Software trigger enabled  
*Note*: This bit is cleared by hardware (one APB clock cycle later) once the DAC_DHR2 register value has been loaded into the DAC_DOR2 register.  
This bit is available in dual mode only. It is reserved in single mode.

**Bit 0** **SWTRIG1**: DAC channel1 software trigger  
This bit is set and cleared by software to enable/disable the software trigger.  
0: Software trigger disabled  
1: Software trigger enabled  
*Note*: This bit is cleared by hardware (one APB clock cycle later) once the DAC_DHR1 register value has been loaded into the DAC_DOR1 register.

**Table 53. DAC register map and reset values**

*Offset* represents the address of the register. *Register name* lists the name of the register. *Reset value* shows the default value of the register when powered on.
Refer to *Section 2.2 on page 46* for the register boundary addresses.
15 Comparator (COMP)

This section applies to STM32F05x and STM32F07x and STM32F09x devices only.

15.1 Introduction

STM32F05x and STM32F07x and STM32F09x devices embed two general purpose comparators COMP1 and COMP2, that can be used either as standalone devices (all terminal are available on I/Os) or combined with the timers.

The comparators can be used for a variety of functions including:
- Wake-up from low-power mode triggered by an analog signal,
- Analog signal conditioning,
- Cycle-by-cycle current control loop when combined with the DAC and a PWM output from a timer.

15.2 COMP main features

- Rail-to-rail comparators
- Each comparator has positive and configurable negative inputs used for flexible voltage selection:
  - 3 I/O pins
  - DAC
  - Internal reference voltage and three submultiple values (1/4, 1/2, 3/4) provided by scaler (buffered voltage divider)
- Programmable hysteresis
- Programmable speed / consumption
- The outputs can be redirected to an I/O or to timer inputs for triggering:
  - OCREF_CLR events (for cycle-by-cycle current control)
  - Break events for fast PWM shutdowns
- COMP1 and COMP2 comparators can be combined in a window comparator.
- Each comparator has interrupt generation capability with wake-up from Sleep and Stop modes (through the EXTI controller)
15.3 **COMP functional description**

15.3.1 **COMP block diagram**

The block diagram of the comparators is shown in **Figure 56: Comparator 1 and 2 block diagrams**.

**Figure 56. Comparator 1 and 2 block diagrams**

15.3.2 **COMP pins and internal signals**

The I/Os used as comparators inputs must be configured in analog mode in the GPIOs registers.

The comparator output can be connected to the I/Os using the alternate function channel given in “Alternate function mapping” table in the datasheet.

The output can also be internally redirected to a variety of timer input for the following purposes:

- Emergency shut-down of PWM signals, using BKIN
- Cycle-by-cycle current control, using OCREF_CLR inputs
- Input capture for timing measures

It is possible to have the comparator output simultaneously redirected internally and externally.
15.3.3 COMP reset and clocks

The COMP clock provided by the clock controller is synchronous with the PCLK (APB clock).

There is no clock enable control bit provided in the RCC controller. Reset and clock enable bits are common for COMP and SYSCFG.

**Important:** The polarity selection logic and the output redirection to the port works independently from the PCLK clock. This allows the comparator to work even in Stop mode.

15.3.4 Comparator LOCK mechanism

The comparators can be used for safety purposes, such as over-current or thermal protection. For applications having specific functional safety requirements, it is necessary to insure that the comparator programming cannot be altered in case of spurious register access or program counter corruption.

For this purpose, the comparator control and status registers can be write-protected (read-only).

Once the programming is completed, using bits 30:16 and 15:0 of COMP_CSR, the COMPx LOCK bit can be set to 1. This causes the whole COMP_CSR register to become read-only, including the COMPx LOCK bit.

The write protection can only be reset by a MCU reset.

15.3.5 Hysteresis

The comparator includes a programmable hysteresis to avoid spurious output transitions in case of noisy signals. The hysteresis can be disabled if it is not needed (for instance when exiting from low-power mode) to be able to force the hysteresis value using external components.

![Figure 57. Comparator hysteresis](MS19984V1)
### 15.3.6 Power mode

The comparator power consumption versus propagation delay can be adjusted to have the optimum trade-off for a given application. The bits COMPxMODE[1:0] in COMP_CSR register can be programmed as follows:

- **00**: High speed / full power
- **01**: Medium speed / medium power
- **10**: Low speed / low-power
- **11**: Very-low speed / ultra-low-power

### 15.4 COMP interrupts

The comparator outputs are internally connected to the Extended interrupts and events controller. Each comparator has its own EXTI line and can generate either interrupts or events. The same mechanism is used to exit from low-power modes.

Refer to Interrupt and events section for more details.

### 15.5 COMP registers

#### 15.5.1 COMP control and status register (COMP_CSR)

Address offset: 0x1C
Reset value: 0x0000 0000

</table>
Bit 31 **COMP2LOCK**: Comparator 2 lock
This bit is write-once. It is set by software. It can only be cleared by a system reset.
It allows to have all control bits of comparator 2 as read-only.
0: COMP_CSR[31:16] bits are read-write.
1: COMP_CSR[31:16] bits are read-only.

Bit 30 **COMP2OUT**: Comparator 2 output
This read-only bit is a copy of comparator 2 output state.
0: Output is low (non-inverting input below inverting input).
1: Output is high (non-inverting input above inverting input).

Bits 29:28 **COMP2HYST[1:0]** Comparator 2 hysteresis
These bits control the hysteresis level.
00: No hysteresis
01: Low hysteresis
10: Medium hysteresis
11: High hysteresis
Please refer to the electrical characteristics for the hysteresis values.

Bit 27 **COMP2POL**: Comparator 2 output polarity
This bit is used to invert the comparator 2 output.
0: Output is not inverted
1: Output is inverted

Bits 26:24 **COMP2OUTSEL[2:0]**: Comparator 2 output selection
These bits select the destination of the comparator output.
000: No selection
001: Timer 1 break input
010: Timer 1 Input capture 1
011: Timer 1 OCrefclear input
100: Timer 2 input capture 4
101: Timer 2 OCrefclear input
110: Timer 3 input capture 1
111: Timer 3 OCrefclear input

Bit 23 **WNDWEN**: Window mode enable
This bit connects the non-inverting input of COMP2 to COMP1’s non-inverting input, which is simultaneously disconnected from PA3.
0: Window mode disabled
1: Window mode enabled

Bits 22:20 **COMP2INSEL[2:0]**: Comparator 2 inverting input selection
These bits allows to select the source connected to the inverting input of the comparator 2.
000: 1/4 of VREFINT
001: 1/2 of VREFINT
010: 3/4 of VREFINT
011: VREFINT
100: COMP2_INM4 (PA4 with DAC_OUT1 if enabled)
101: COMP2_INM5 (PA5 with DAC_OUT2 if present and enabled)
110: COMP2_INM6 (PA2)
111: Reserved
Bits 19:18 **COMP2MODE[1:0]**: Comparator 2 mode
These bits control the operating mode of the comparator 2 and allows to adjust the speed/consumption.
- 00: High speed / full power
- 01: Medium speed / medium power
- 10: Low speed / low-power
- 11: Very-low speed / ultra-low power

Bit 17 Reserved, must be kept at reset value.

Bit 16 **COMP2EN**: Comparator 2 enable
This bit switches ON/OFF the comparator 2.
- 0: Comparator 2 disabled
- 1: Comparator 2 enabled

Bit 15 **COMP1LOCK**: Comparator 1 lock
This bit is write-once. It is set by software. It can only be cleared by a system reset.
It allows to have all control bits of comparator 1 as read-only.
- 0: COMP_CSR[15:0] bits are read-write.
- 1: COMP_CSR[15:0] bits are read-only.

Bits 13:12 **COMP1HYST[1:0]** Comparator 1 hysteresis
These bits are controlling the hysteresis level.
- 00: No hysteresis
- 01: Low hysteresis
- 10: Medium hysteresis
- 11: High hysteresis
Please refer to the electrical characteristics for the hysteresis values.

Bit 11 **COMP1POL**: Comparator 1 output polarity
This bit is used to invert the comparator 1 output.
- 0: Output is not inverted
- 1: Output is inverted

Bits 10:8 **COMP1OUTSEL[2:0]**: Comparator 1 output selection
These bits selects the destination of the comparator 1 output.
- 000: no selection
- 001: Timer 1 break input
- 010: Timer 1 Input capture 1
- 011: Timer 1 OCrefclear input
- 100: Timer 2 input capture 4
- 101: Timer 2 OCrefclear input
- 110: Timer 3 input capture 1
- 111: Timer 3 OCrefclear input

Bit 7 Reserved, must be kept at reset value.
Bits 6:4  **COMP1INSEL[2:0]**: Comparator 1 inverting input selection
These bits select the source connected to the inverting input of the comparator 1.
- 000: 1/4 of V_REFINT
- 001: 1/2 of V_REFINT
- 010: 3/4 of V_REFINT
- 011: V_REFINT
- 100: COMP1_INM4 (PA4 with DAC_OUT1 if enabled)
- 101: COMP1_INM5 (PA5 with DAC_OUT2 if present and enabled)
- 110: COMP1_INM6 (PA0)
- 111: Reserved

Bits 3:2  **COMP1MODE[1:0]**: Comparator 1 mode
These bits control the operating mode of the comparator 1 and allows to adjust the speed/consumption.
- 00: High speed / full power
- 01: Medium speed / medium power
- 10: Low speed / low-power
- 11: Very-low speed / ultra-low power

Bit 1  **COMP1SW1**: Comparator 1 non inverting input DAC switch
This bit closes a switch between comparator 1 non-inverting input on PA1 and PA4 (DAC) I/O.
- 0: Switch open
- 1: Switch closed

*Note: This switch is solely intended to redirect signals onto high impedance input, such as COMP1 non-inverting input (highly resistive switch).*

Bit 0  **COMP1EN**: Comparator 1 enable
This bit switches COMP1 ON/OFF.
- 0: Comparator 1 disabled
- 1: Comparator 1 enabled

16 Touch sensing controller (TSC)

This section applies to STM32F05x, STM32F04x, STM32F07x and STM32F09x devices only.

16.1 Introduction

The touch sensing controller provides a simple solution for adding capacitive sensing functionality to any application. Capacitive sensing technology is able to detect finger presence near an electrode that is protected from direct touch by a dielectric (for example glass, plastic). The capacitive variation introduced by the finger (or any conductive object) is measured using a proven implementation based on a surface charge transfer acquisition principle.

The touch sensing controller is fully supported by the STMTouch touch sensing firmware library, which is free to use and allows touch sensing functionality to be implemented reliably in the end application.

16.2 TSC main features

The touch sensing controller has the following main features:

- Proven and robust surface charge transfer acquisition principle
- Supports up to 24 capacitive sensing channels
- Up to 8 capacitive sensing channels can be acquired in parallel offering a very good response time
- Spread spectrum feature to improve system robustness in noisy environments
- Full hardware management of the charge transfer acquisition sequence
- Programmable charge transfer frequency
- Programmable sampling capacitor I/O pin
- Programmable channel I/O pin
- Programmable max count value to avoid long acquisition when a channel is faulty
- Dedicated end of acquisition and max count error flags with interrupt capability
- One sampling capacitor for up to 3 capacitive sensing channels to reduce the system components
- Compatible with proximity, touchkey, linear and rotary touch sensor implementation
- Designed to operate with STMTouch touch sensing firmware library

*Note:* The number of capacitive sensing channels is dependent on the size of the packages and subject to IO availability.
16.3 TSC functional description

16.3.1 TSC block diagram

The block diagram of the touch sensing controller is shown in Figure 58.

![Figure 58. TSC block diagram](image)

16.3.2 Surface charge transfer acquisition overview

The surface charge transfer acquisition is a proven, robust and efficient way to measure a capacitance. It uses a minimum number of external components to operate with a single ended electrode type. This acquisition is designed around an analog I/O group composed of up to four GPIOs (see Figure 59). Several analog I/O groups are available to allow the acquisition of several capacitive sensing channels simultaneously and to support a larger number of capacitive sensing channels. Within a same analog I/O group, the acquisition of the capacitive sensing channels is sequential.

One of the GPIOs is dedicated to the sampling capacitor $C_S$. Only one sampling capacitor I/O per analog I/O group must be enabled at a time.

The remaining GPIOs are dedicated to the electrodes and are commonly called channels. For some specific needs (such as proximity detection), it is possible to simultaneously enable more than one channel per analog I/O group.
Figure 59. Surface charge transfer analog I/O group structure

Note: $G_{x\_I/Oy}$ where $x$ is the analog I/O group number and $y$ the GPIO number within the selected group.

The surface charge transfer acquisition principle consists of charging an electrode capacitance ($C_X$) and transferring a part of the accumulated charge into a sampling capacitor ($C_S$). This sequence is repeated until the voltage across $C_S$ reaches a given threshold ($V_{IH}$ in our case). The number of charge transfers required to reach the threshold is a direct representation of the size of the electrode capacitance.

Table 55 details the charge transfer acquisition sequence of the capacitive sensing channel 1. States 3 to 7 are repeated until the voltage across $C_S$ reaches the given threshold. The same sequence applies to the acquisition of the other channels. The electrode serial resistor $R_S$ improves the ESD immunity of the solution.

**Note:** $Gx_{IOy}$ where $x$ is the analog I/O group number and $y$ the GPIO number within the selected group.

The voltage variation over the time on the sampling capacitor $C_s$ is detailed below:

**Figure 60. Sampling capacitor voltage variation**

16.3.3 Reset and clocks

The TSC clock source is the AHB clock (HCLK). Two programmable prescalers are used to generate the pulse generator and the spread spectrum internal clocks:

- The pulse generator clock (PGCLK) is defined using the PGPSC[2:0] bits of the TSC_CR register
- The spread spectrum clock (SSCLK) is defined using the SSPSC bit of the TSC_CR register
The Reset and Clock Controller (RCC) provides dedicated bits to enable the touch sensing controller clock and to reset this peripheral. For more information, refer to Section 6: Reset and clock control (RCC).

16.3.4 Charge transfer acquisition sequence

An example of a charge transfer acquisition sequence is detailed in Figure 61.

Figure 61. Charge transfer acquisition sequence

For higher flexibility, the charge transfer frequency is fully configurable. Both the pulse high state (charge of C_X) and the pulse low state (transfer of charge from C_X to C_S) duration can be defined using the CTPH[3:0] and CTPL[3:0] bits in the TSC_CR register. The standard range for the pulse high and low states duration is 500 ns to 2 µs. To ensure a correct measurement of the electrode capacitance, the pulse high state duration must be set to ensure that C_X is always fully charged.

A dead time where both the sampling capacitor I/O and the channel I/O are in input floating state is inserted between the pulse high and low states to ensure an optimum charge transfer acquisition sequence. This state duration is 2 periods of HCLK.

At the end of the pulse high state and if the spread spectrum feature is enabled, a variable number of periods of the SSCLK clock are added.

The reading of the sampling capacitor I/O, to determine if the voltage across C_S has reached the given threshold, is performed at the end of the pulse low state.

Note: The following TSC control register configurations are forbidden:
- bits PGPSC are set to ‘000’ and bits CTPL are set to ‘0000’
- bits PGPSC are set to ‘000’ and bits CTPL are set to ‘0001’
- bits PGPSC are set to ‘001’ and bits CTPL are set to ‘0000’
16.3.5 Spread spectrum feature

The spread spectrum feature generates a variation of the charge transfer frequency. This is done to improve the robustness of the charge transfer acquisition in noisy environments and also to reduce the induced emission. The maximum frequency variation is in the range of 10% to 50% of the nominal charge transfer period. For instance, for a nominal charge transfer frequency of 250 kHz (4 µs), the typical spread spectrum deviation is 10% (400 ns) which leads to a minimum charge transfer frequency of ~227 kHz.

In practice, the spread spectrum consists of adding a variable number of SSCLK periods to the pulse high state using the principle shown below:

![Figure 62. Spread spectrum variation principle](image)

The table below details the maximum frequency deviation with different HCLK settings:

<table>
<thead>
<tr>
<th>f_{HCLK}</th>
<th>Spread spectrum step</th>
<th>Maximum spread spectrum deviation</th>
</tr>
</thead>
<tbody>
<tr>
<td>24 MHz</td>
<td>41.6 ns</td>
<td>10666.6 ns</td>
</tr>
<tr>
<td>48 MHz</td>
<td>20.8 ns</td>
<td>5333.3 ns</td>
</tr>
</tbody>
</table>

The spread spectrum feature can be disabled/enabled using the SSE bit in the TSC_CR register. The frequency deviation is also configurable to accommodate the device HCLK clock frequency and the selected charge transfer frequency through the SSPSC and SSD[6:0] bits in the TSC_CR register.

16.3.6 Max count error

The max count error prevents long acquisition times resulting from a faulty capacitive sensing channel. It consists of specifying a maximum count value for the analog I/O group counters. This maximum count value is specified using the MCV[2:0] bits in the TSC_CR register. As soon as an acquisition group counter reaches this maximum value, the ongoing acquisition is stopped and the end of acquisition (EOAF bit) and max count error (MCEF bit) flags are both set. An interrupt can also be generated if the corresponding end of acquisition (EOAIE bit) or/and max count error (MCEIE bit) interrupt enable bits are set.
16.3.7 Sampling capacitor I/O and channel I/O mode selection

To allow the GPIOs to be controlled by the touch sensing controller, the corresponding alternate function must be enabled through the standard GPIO registers and the GPIOxAFR registers.

The GPIOs modes controlled by the TSC are defined using the TSC_IOSCR and TSC_IOCCR register.

When there is no ongoing acquisition, all the I/Os controlled by the touch sensing controller are in default state. While an acquisition is ongoing, only unused I/Os (neither defined as sampling capacitor I/O nor as channel I/O) are in default state. The IODEF bit in the TSC_CR register defines the configuration of the I/Os which are in default state. The table below summarizes the configuration of the I/O depending on its mode.

<table>

<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>

Unused I/O mode

An unused I/O corresponds to a GPIO controlled by the TSC peripheral but not defined as an electrode I/O nor as a sampling capacitor I/O.

Sampling capacitor I/O mode

To allow the control of the sampling capacitor I/O by the TSC peripheral, the corresponding GPIO must be first set to alternate output open drain mode and then the corresponding Gx_IOy bit in the TSC_IOSCR register must be set.

Only one sampling capacitor per analog I/O group must be enabled at a time.

Channel I/O mode

To allow the control of the channel I/O by the TSC peripheral, the corresponding GPIO must be first set to alternate output push-pull mode and the corresponding Gx_IOy bit in the TSC_IOCCR register must be set.

For proximity detection where a higher equivalent electrode surface is required or to speed-up the acquisition process, it is possible to enable and simultaneously acquire several channels belonging to the same analog I/O group.

Note: During the acquisition phase and even if the TSC peripheral alternate function is not enabled, as soon as the TSC_IOSCR or TSC_IOCCR bit is set, the corresponding GPIO analog switch is automatically controlled by the touch sensing controller.
16.3.8 Acquisition mode

The touch sensing controller offers two acquisition modes:

- Normal acquisition mode: the acquisition starts as soon as the START bit in the TSC_CR register is set.
- Synchronized acquisition mode: the acquisition is enabled by setting the START bit in the TSC_CR register but only starts upon the detection of a falling edge or a rising edge and high level on the SYNC input pin. This mode is useful for synchronizing the capacitive sensing channels acquisition with an external signal without additional CPU load.

The GxE bits in the TSC_IOGCSR registers specify which analog I/O groups are enabled (corresponding counter is counting). The CS voltage of a disabled analog I/O group is not monitored and this group does not participate in the triggering of the end of acquisition flag. However, if the disabled analog I/O group contains some channels, they are pulsed.

When the CS voltage of an enabled analog I/O group reaches the given threshold, the corresponding GxS bit of the TSC_IOGCSR register is set. When the acquisition of all enabled analog I/O groups is complete (all GxS bits of all enabled analog I/O groups are set), the EOAF flag in the TSC_ISR register is set. An interrupt request is generated if the EOAIE bit in the TSC_IER register is set.

In the case that a max count error is detected, the ongoing acquisition is stopped and both the EOAF and MCEF flags in the TSC_ISR register are set. Interrupt requests can be generated for both events if the corresponding bits (EOAIE and MCEIE bits of the TSCIER register) are set. Note that when the max count error is detected the remaining GxS bits in the enabled analog I/O groups are not set.

To clear the interrupt flags, the corresponding EOAIC and MCEIC bits in the TSC_ICR register must be set.

The analog I/O group counters are cleared when a new acquisition is started. They are updated with the number of charge transfer cycles generated on the corresponding channel(s) upon the completion of the acquisition.

For code example refer to the Appendix section A.18.1: TSC configuration code example.

16.3.9 I/O hysteresis and analog switch control

In order to offer a higher flexibility, the touch sensing controller is able to take the control of the Schmitt trigger hysteresis and analog switch of each Gx_IOy. This control is available whatever the I/O control mode is (controlled by standard GPIO registers or other peripherals) assuming that the touch sensing controller is enabled. This may be useful to perform a different acquisition sequence or for other purposes.

In order to improve the system immunity, the Schmitt trigger hysteresis of the GPIOs controlled by the TSC must be disabled by resetting the corresponding Gx_IOy bit in the TSC_IOHCR register.

**Bits 31:28 CTPH[3:0]:** Charge transfer pulse high

These bits are set and cleared by software. They define the duration of the high state of the charge transfer pulse (charge of CX).

- 0000: 1x tPGCLK
- 0001: 2x tPGCLK
- ...
- 1111: 16x tPGCLK

*Note: These bits must not be modified when an acquisition is ongoing.*

**Bits 27:24 CTPL[3:0]:** Charge transfer pulse low

These bits are set and cleared by software. They define the duration of the low state of the charge transfer pulse (transfer of charge from CX to CS).

- 0000: 1x tPGCLK
- 0001: 2x tPGCLK
- ...
- 1111: 16x tPGCLK

*Note: These bits must not be modified when an acquisition is ongoing.*

*Note: Some configurations are forbidden. Refer to the Section 16.3.4: Charge transfer acquisition sequence for details.*

**Bits 23:17 SSD[6:0]:** Spread spectrum deviation

These bits are set and cleared by software. They define the spread spectrum deviation which consists in adding a variable number of periods of the SSCLK clock to the charge transfer pulse high state.

- 0000000: 1x tSSCLK
- 0000001: 2x tSSCLK
- ...
- 1111111: 128x tSSCLK

*Note: These bits must not be modified when an acquisition is ongoing.*
Bit 16  **SSE**: Spread spectrum enable
This bit is set and cleared by software to enable/disable the spread spectrum feature.
0: Spread spectrum disabled
1: Spread spectrum enabled
*Note:* This bit must not be modified when an acquisition is ongoing.

Bit 15  **SSPSC**: Spread spectrum prescaler
This bit is set and cleared by software. It selects the AHB clock divider used to generate the spread spectrum clock (SSCLK).
0: $f_{HCLK}$
1: $f_{HCLK}/2$
*Note:* This bit must not be modified when an acquisition is ongoing.

Bits 14:12  **PGPSC[2:0]**: Pulse generator prescaler
These bits are set and cleared by software. They select the AHB clock divider used to generate the pulse generator clock (PGCLK).
000: $f_{HCLK}$
001: $f_{HCLK}/2$
010: $f_{HCLK}/4$
011: $f_{HCLK}/8$
100: $f_{HCLK}/16$
101: $f_{HCLK}/32$
110: $f_{HCLK}/64$
111: $f_{HCLK}/128$
*Note:* These bits must not be modified when an acquisition is ongoing.
*Note:* Some configurations are forbidden. Refer to the Section 16.3.4: Charge transfer acquisition sequence for details.

Bits 11:8  Reserved, must be kept at reset value.

Bits 7:5  **MCV[2:0]**: Max count value
These bits are set and cleared by software. They define the maximum number of charge transfer pulses that can be generated before a max count error is generated.
000: 255
001: 511
010: 1023
011: 2047
100: 4095
101: 8191
110: 16383
111: reserved
*Note:* These bits must not be modified when an acquisition is ongoing.

Bit 4  **IODEF**: I/O Default mode
This bit is set and cleared by software. It defines the configuration of all the TSC I/Os when there is no ongoing acquisition. When there is an ongoing acquisition, it defines the configuration of all unused I/Os (not defined as sampling capacitor I/O or as channel I/O).
0: I/Os are forced to output push-pull low
1: I/Os are in input floating
*Note:* This bit must not be modified when an acquisition is ongoing.

Bit 3  **SYNCPOL**: Synchronization pin polarity
This bit is set and cleared by software to select the polarity of the synchronization input pin.
0: Falling edge only
1: Rising edge and high level
Bit 2 **AM**: Acquisition mode
This bit is set and cleared by software to select the acquisition mode.
0: Normal acquisition mode (acquisition starts as soon as START bit is set)
1: Synchronized acquisition mode (acquisition starts if START bit is set and when the selected signal is detected on the SYNC input pin)

*Note: This bit must not be modified when an acquisition is ongoing.*

Bit 1 **START**: Start a new acquisition
This bit is set by software to start a new acquisition. It is cleared by hardware as soon as the acquisition is complete or by software to cancel the ongoing acquisition.
0: Acquisition not started
1: Start a new acquisition

Bit 0 **TSCE**: Touch sensing controller enable
This bit is set and cleared by software to enable/disable the touch sensing controller.
0: Touch sensing controller disabled
1: Touch sensing controller enabled

*Note: When the touch sensing controller is disabled, TSC registers settings have no effect.*

Bits 31:2 Reserved, must be kept at reset value.

- **Bit 1 MCEIC**: Max count error interrupt clear  
  This bit is set by software to clear the max count error flag and it is cleared by hardware when the flag is reset. Writing a '0' has no effect.  
  0: No effect  
  1: Clears the corresponding MCEF of the TSC_ISR register

- **Bit 0 EOAIC**: End of acquisition interrupt clear  
  This bit is set by software to clear the end of acquisition flag and it is cleared by hardware when the flag is reset. Writing a '0' has no effect.  
  0: No effect  
  1: Clears the corresponding EOAF of the TSC_ISR register
### 16.6.4 TSC interrupt status register (TSC_ISR)

**Bits 31:2** Reserved, must be kept at reset value.

**Bit 1 MCEF:** Max count error flag  
This bit is set by hardware as soon as an analog I/O group counter reaches the max count value specified. It is cleared by software writing 1 to the bit MCEIC of the TSC_ICR register.

- 0: No max count error (MCE) detected  
- 1: Max count error (MCE) detected

**Bit 0 EOAF:** End of acquisition flag  
This bit is set by hardware when the acquisition of all enabled group is complete (all GxS bits of all enabled analog I/O groups are set or when a max count error is detected). It is cleared by software writing 1 to the bit EOAIC of the TSC_ICR register.

- 0: Acquisition is ongoing or not started  
- 1: Acquisition is complete

**Bits 31:0 Gx_IOy:** Gx_IOy Schmitt trigger hysteresis mode, x = 8 to 1, y = 4 to 1.  
These bits are set and cleared by software to enable/disable the Gx_IOy Schmitt trigger hysteresis.

- 0: Gx_IOy Schmitt trigger hysteresis disabled  
- 1: Gx_IOy Schmitt trigger hysteresis enabled

**Note:** These bits control the I/O Schmitt trigger hysteresis whatever the I/O control mode is (even if controlled by standard GPIO registers).

Bits 31:0  **Gx_IOy**: Gx_IOy analog switch enable

These bits are set and cleared by software to enable/disable the Gx_IOy analog switch.

0: Gx_IOy analog switch disabled (opened)
1: Gx_IOy analog switch enabled (closed)

*Note: These bits control the I/O analog switch whatever the I/O control mode is (even if controlled by standard GPIO registers).*

Bits 31:0  **Gx_IOy**: Gx_IOy sampling mode

These bits are set and cleared by software to configure the Gx_IOy as a sampling capacitor I/O. Only one I/O per analog I/O group must be defined as sampling capacitor.

0: Gx_IOy unused
1: Gx_IOy used as sampling capacitor

*Note: These bits must not be modified when an acquisition is ongoing.*

During the acquisition phase and even if the TSC peripheral alternate function is not enabled, as soon as the TSC_IOSCR bit is set, the corresponding GPIO analog switch is automatically controlled by the touch sensing controller.
16.6.8  TSC I/O channel control register (TSC_IOCCR)

16.6.9  TSC I/O group control status register (TSC_IOGCSR)

Address offset: 0x30
Reset value: 0x0000 0000

| Bits 31:24 | Reserved, must be kept at reset value. |
| Bits 23:16 | GxS: Analog I/O group x status |
|           | These bits are set by hardware when the acquisition on the corresponding enabled analog I/O group x is complete. They are cleared by hardware when a new acquisition is started. |
|           | 0: Acquisition on analog I/O group x is ongoing or not started |
|           | 1: Acquisition on analog I/O group x is complete |
|           | Note: When a max count error is detected the remaining GxS bits of the enabled analog I/O groups are not set. |
| Bits 15:8 | Reserved, must be kept at reset value. |
| Bits 7:0 | GxE: Analog I/O group x enable |
|          | These bits are set and cleared by software to enable/disable the acquisition (counter is counting) on the corresponding analog I/O group x. |
|          | 0: Acquisition on analog I/O group x disabled |
|          | 1: Acquisition on analog I/O group x enabled |
16.6.10 TSC I/O group x counter register (TSC_IOGxCR)

x represents the analog I/O group number. 
Address offset: 0x30 + 0x04 * x, (x = 1 to 8)
Reset value: 0x0000 0000

<table>

</tbody>
</table>

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:0 **CNT[13:0]**: Counter value

These bits represent the number of charge transfer cycles generated on the analog I/O group x to complete its acquisition (voltage across CS has reached the threshold).
### 16.6.11 TSC register map

Refer to Section 2.2 on page 46 for the register boundary addresses.
17 Advanced-control timers (TIM1)

17.1 TIM1 introduction

The advanced-control timers (TIM1) consist of a 16-bit auto-reload counter driven by a programmable prescaler.

It may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM, complementary PWM with dead-time insertion).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The advanced-control (TIM1) and general-purpose (TIMx) timers are completely independent, and do not share any resources. They can be synchronized together as described in Section 17.3.20.

17.2 TIM1 main features

TIM1 timer features include:

- 16-bit up, down, up/down auto-reload counter.
- 16-bit programmable prescaler allowing dividing (also “on the fly”) the counter clock frequency either by any factor between 1 and 65535.
- Up to 4 independent channels for:
  - Input Capture
  - Output Compare
  - PWM generation (Edge- and Center-aligned modes)
  - One-pulse mode output
- Complementary outputs with programmable dead-time
- Synchronization circuit to control the timer with external signals and to interconnect several timers together.
- Repetition counter to update the timer registers only after a given number of cycles of the counter.
- Break input to put the timer’s output signals in reset state or in a known state.
- Interrupt/DMA generation on the following events:
  - Update: counter overflow/underflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
  - Break input
- Supports incremental (quadrature) encoder and hall-sensor circuitry for positioning purposes
- Trigger input for external clock or cycle-by-cycle current management

- Interrupt & DMA output
17.3 TIM1 functional description

17.3.1 Time-base unit

The main block of the programmable advanced-control timer is a 16-bit counter with its related auto-reload register. The counter can count up, down or both up and down. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:
- Counter register (TIMx_CNT)
- Prescaler register (TIMx_PSC)
- Auto-reload register (TIMx_ARR)
- Repetition counter register (TIMx_RCR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow (or underflow when downcounting) and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detailed for each configuration.

The counter is clocked by the prescaler output CK_CNT, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the counter starts counting 1 clock cycle after setting the CEN bit in the TIMx_CR1 register.

Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 65* and *Figure 66* give some examples of the counter behavior when the prescaler ratio is changed on the fly:
Figure 64. Counter timing diagram with prescaler division change from 1 to 2

Figure 65. Counter timing diagram with prescaler division change from 1 to 4
17.3.2 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

If the repetition counter is used, the update event (UEV) is generated after upcounting is repeated for the number of times programmed in the repetition counter register (TIMx_RCR). Else the update event is generated at each counter overflow.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register,
- The auto-reload shadow register is updated with the preload value (TIMx_ARR),
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.
Figure 66. Counter timing diagram, internal clock divided by 1

Figure 68. Counter timing diagram, internal clock divided by 4

Figure 69. Counter timing diagram, internal clock divided by N
Figure 70. Counter timing diagram, update event when ARPE=0
(TIMx_ARR not preloaded)

Figure 71. Counter timing diagram, update event when ARPE=1
(TIMx_ARR preloaded)
Downcounting mode

In downcounting mode, the counter counts from the auto-reload value (content of the TIMx_ARR register) down to 0, then restarts from the auto-reload value and generates a counter underflow event.

If the repetition counter is used, the update event (UEV) is generated after downcounting is repeated for the number of times programmed in the repetition counter register (TIMx_RCR). Else the update event is generated at each counter underflow.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV update event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter restarts from the current auto-reload value, whereas the counter of the prescaler restarts from 0 (but the prescale rate doesn’t change).

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register)
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that the auto-reload is updated before the counter is reloaded, so that the next period is the expected one.

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

Figure 72. Counter timing diagram, internal clock divided by 1
Figure 73. Counter timing diagram, internal clock divided by 2

Figure 74. Counter timing diagram, internal clock divided by 4

Figure 75. Counter timing diagram, internal clock divided by N
Center-aligned mode (up/down counting)

In center-aligned mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register) – 1, generates a counter overflow event, then counts from the auto-reload value down to 1 and generates a counter underflow event. Then it restarts counting from 0.

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are not equal to '00'. The Output compare interrupt flag of channels configured in output is set when: the counter counts down (Center aligned mode 1, CMS = "01"), the counter counts up (Center aligned mode 2, CMS = "10") the counter counts up and down (Center aligned mode 3, CMS = "11").

In this mode, the DIR direction bit in the TIMx_CR1 register cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event. In this case, the counter restarts counting from 0, as well as the counter of the prescaler.

The UEV update event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter continues counting up and down, based on the current auto-reload value.

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an UEV update event but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.
When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register)
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that if the update source is a counter overflow, the auto-reload is updated before the counter is reloaded, so that the next period is the expected one (the counter is loaded with the new value).

The following figures show some examples of the counter behavior for different clock frequencies.

**Figure 77. Counter timing diagram, internal clock divided by 1, TIMx_ARR = 0x6**

1. Here, center-aligned mode 1 is used (for more details refer to *Section 17.4: TIM1 registers on page 375*).
1. Center-aligned mode 2 or 3 is used with an UIF on overflow.
Figure 80. Counter timing diagram, internal clock divided by N

Figure 81. Counter timing diagram, update event with ARPE=1 (counter underflow)
17.3.3 Repetition counter

Section 17.3.1: Time-base unit describes how the update event (UEV) is generated with respect to the counter overflows/underflows. It is actually generated only when the repetition counter has reached zero. This can be useful when generating PWM signals.

This means that data are transferred from the preload registers to the shadow registers (TIMx_ARR auto-reload register, TIMx_PSC prescaler register, but also TIMx_CCRx capture/compare registers in compare mode) every N counter overflows or underflows, where N is the value in the TIMx_RCR repetition counter register.

The repetition counter is decremented:
- At each counter overflow in upcounting mode,
- At each counter underflow in downcounting mode,
- At each counter overflow and at each counter underflow in center-aligned mode.

Although this limits the maximum number of repetition to 128 PWM cycles, it makes it possible to update the duty cycle twice per PWM period. When refreshing compare registers only once per PWM period in center-aligned mode, maximum resolution is 2xTck, due to the symmetry of the pattern.

The repetition counter is an auto-reload type; the repetition rate is maintained as defined by the TIMx_RCR register value (refer to Figure 83). When the update event is generated by software (by setting the UG bit in TIMx_EGR register) or by hardware through the slave mode controller, it occurs immediately whatever the value of the repetition counter is and the repetition counter is reloaded with the content of the TIMx_RCR register.
In center-aligned mode, for odd values of RCR, the update event occurs either on the overflow or on the underflow depending on when the RCR register was written and when the counter was started. If the RCR was written before starting the counter, the UEV occurs on the overflow. If the RCR was written after starting the counter, the UEV occurs on the underflow. For example for RCR = 3, the UEV is generated on each 4th overflow or underflow event depending on when RCR was written.

**Figure 83. Update rate examples depending on mode and TIMx_RCR register settings**

- **Counter-aligned mode**
  - TIMx_RCR = 0
  - TIMx_RCR = 1
  - TIMx_RCR = 2
  - TIMx_RCR = 3
  - TIMx_RCR = 3 and re-synchronization

- **Edge-aligned mode**
  - Upcounting (by SW)
  - Downcounting (by SW)

**UEV**: Update event: Preload registers transferred to active registers and update interrupt generated
17.3.4 Clock sources

The counter clock can be provided by the following clock sources:

- Internal clock (CK_INT)
- External clock mode1: external input pin
- External clock mode2: external trigger input ETR
- Internal trigger inputs (ITRx): using one timer as prescaler for another timer, for example, Timer 1 can be configured to act as a prescaler for Timer 2. Refer to Using one timer as prescaler for another on page 440 for more details.

**Internal clock source (CK_INT)**

If the slave mode controller is disabled (SMS=000), then the CEN, DIR (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK_INT.

*Figure 84* shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

*Figure 84. Control circuit in normal mode, internal clock divided by 1*
External clock source mode 1

This mode is selected when SMS=111 in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

Figure 85. TI2 external clock connection example

For example, to configure the upcounter to count in response to a rising edge on the TI2 input, use the following procedure:

1. Configure channel 2 to detect rising edges on the TI2 input by writing CC2S = '01' in the TIMx_CCMR1 register.
2. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx_CCMR1 register (if no filter is needed, keep IC2F=0000).
3. Select rising edge polarity by writing CC2P=0 in the TIMx_CCER register.
4. Configure the timer in external clock mode 1 by writing SMS=111 in the TIMx_SMCR register.
5. Select TI2 as the trigger input source by writing TS=110 in the TIMx_SMCR register.
6. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

Note: The capture prescaler is not used for triggering, so it does not need to be configured.

For code examples refer to the Appendix section A.9.1: Upcounter on TI2 rising edge code example.

When a rising edge occurs on TI2, the counter counts once and the TIF flag is set. The delay between the rising edge on TI2 and the actual clock of the counter is due to the resynchronization circuit on TI2 input.
External clock source mode 2

This mode is selected by writing ECE=1 in the TIMx_SMCR register.

The counter can count at each rising or falling edge on the external trigger input ETR.

The Figure 87 gives an overview of the external trigger input block.

For example, to configure the upcounter to count each 2 rising edges on ETR, use the following procedure:
1. As no filter is needed in this example, write ETF[3:0]=0000 in the TIMx_SMCR register.
2. Set the prescaler by writing ETPS[1:0]=01 in the TIMx_SMCR register.
3. Select rising edge detection on the ETR pin by writing ETP=0 in the TIMx_SMCR register.
4. Enable external clock mode 2 by writing ECE=1 in the TIMx_SMCR register.
5. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

The counter counts once each 2 ETR rising edges.

For code example refer to the Appendix section A.9.2: Up counter on each 2 ETR rising edges code example.

The delay between the rising edge on ETR and the actual clock of the counter is due to the resynchronization circuit on the ETRP signal.

**Figure 88. Control circuit in external clock mode 2**

17.3.5 **Capture/compare channels**

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

*Figure 89 to Figure 92* give an overview of one Capture/Compare channel.

The input stage samples the corresponding TIx input to generate a filtered signal TIxF. Then, an edge detector with polarity selection generates a signal (TIxFPx) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).
The output stage generates an intermediate waveform which is then used for reference: OCxRef (active high). The polarity acts at the end of the chain.

**Figure 89. Capture/compare channel (example: channel 1 input stage)**

**Figure 90. Capture/compare channel 1 main circuit**
The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.
17.3.6 Input capture mode

In input capture mode, the Capture/Compare Registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCxIF flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to ‘0’ or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx_CCR1 when TI1 input rises. To do this, use the following procedure:

- Select the active input: TIMx_CCR1 must be linked to the TI1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx_CCR1 register becomes read-only.
- Program the appropriate input filter duration in relation with the signal connected to the timer (when the input is one of the TIx (ICxF bits in the TIMx_CCMRx register). Let’s imagine that, when toggling, the input signal is not stable during at most 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on TI1 when 8 consecutive samples with the new level have been detected (sampled at f_DTS frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.
- Select the edge of the active transition on the TI1 channel by writing CC1P and CC1NP bits to 0 in the TIMx_CCER register (rising edge in this case).
- Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to ‘00’ in the TIMx_CCMR1 register).
- Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.
- If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx_DIER register.

For code example refer to the Appendix section A.9.3: Input capture configuration code example.

When an input capture occurs:

- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag), CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

For code example refer to the Appendix section A.9.4: Input capture data management code example.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

Note: IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.
17.3.7 **PWM input mode**

This mode is a particular case of input capture mode. The procedure is the same except:

- Two ICx signals are mapped on the same TIx input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two TIxFP signals is selected as trigger input and the slave mode controller is configured in reset mode.

For example, one can measure the period (in TIMx_CCR1 register) and the duty cycle (in TIMx_CCR2 register) of the PWM applied on TI1 using the following procedure (depending on CK_INT frequency and prescaler value):

- Select the active input for TIMx_CCR1: write the CC1S bits to 01 in the TIMx_CCMR1 register (TI1 selected).
- Select the active polarity for TI1FP1 (used both for capture in TIMx_CCR1 and counter clear): write the CC1P and CC1NP bits to '0' (active on rising edge).
- Select the active input for TIMx_CCR2: write the CC2S bits to 10 in the TIMx_CCMR1 register (TI1 selected).
- Select the active polarity for TI1FP2 (used for capture in TIMx_CCR2): write the CC2P bit to '1' and the CC2NP bit to '0' (active on falling edge).
- Select the valid trigger input: write the TS bits to 101 in the TIMx_SMCR register (TI1FP1 selected).
- Configure the slave mode controller in reset mode: write the SMS bits to 100 in the TIMx_SMCR register.
- Enable the captures: write the CC1E and CC2E bits to '1' in the TIMx_CCER register.

For code example refer to the Appendix section [A.9.5: PWM input configuration code example](#).

![Figure 93. PWM input mode timing](image-url)
17.3.8 Forced output mode

In output mode (CCxS bits = 00 in the TIMx_CCMRx register), each output compare signal (OCxREF and then OCx/OCxN) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (OCXREF/OCx) to its active level, one just needs to write 101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus OCXREF is forced high (OCxREF is always active high) and OCx get opposite value to CCxP polarity bit.

For example: CCxP=0 (OCx active high) => OCx is forced to high level.

The OCxREF signal can be forced low by writing the OCxM bits to 100 in the TIMx_CCMRx register.

Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the output compare mode section below.

17.3.9 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

• Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP bit in the TIMx_CCER register). The output pin can keep its level (OCxM=000), be set active (OCxM=001), be set inactive (OCxM=010) or can toggle (OCxM=011) on match.
• Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
• Generates an interrupt if the corresponding interrupt mask is set (CCXIE bit in the TIMx_DIER register).
• Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx_DIER register, CCDS bit in the TIMx_CR2 register for the DMA request selection).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on OCxREF and OCx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One Pulse mode).
Procedure:
1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
   - Write OCxM = 011 to toggle OCx output pin when CNT matches CCRx
   - Write OCxPE = 0 to disable preload register
   - Write CCxP = 0 to select active high polarity
   - Write CCxE = 1 to enable the output
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

For code example refer to the Appendix section A.9.7: Output compare configuration code example.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE='0', else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in Figure 94.

Figure 94. Output compare mode, toggle on OC1

17.3.10 PWM mode

Pulse Width Modulation mode allows to generate a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per OCx output) by writing ‘110’ (PWM mode 1) or ‘111’ (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the
OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

OCx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. OCx output is enabled by a combination of the CCxE, CCxNE, MOE, OSSI and OSSR bits (TIMx_CCER and TIMx_BDTR registers). Refer to the TIMx_CCER register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CCRx ≤ TIMx_CNT or TIMx_CNT ≤ TIMx_CCRx (depending on the direction of the counter).

The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIMx_CR1 register.

**PWM edge-aligned mode**

- **Upcounting configuration**
  Upcounting is active when the DIR bit in the TIMx_CR1 register is low. Refer to the *Upcounting mode on page 332*.

  In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is high as long as TIMx_CNT < TIMx_CCRx else it becomes low. If the compare value in TIMx_CCRx is greater than the auto-reload value (in TIMx_ARR) then OCxREF is held at ‘1’. If the compare value is 0 then OCxRef is held at ‘0’.

  *Figure 95* shows some edge-aligned PWM waveforms in an example where TIMx_ARR=8.
**Figure 95. Edge-aligned PWM waveforms (ARR=8)**

- **Downcounting configuration**
  
  Downcounting is active when DIR bit in TIMx_CR1 register is high. Refer to the Downcounting mode on page 336.

  In PWM mode 1, the reference signal OCxRef is low as long as TIMx_CNT > TIMx_CCRx else it becomes high. If the compare value in TIMx_CCRx is greater than the auto-reload value in TIMx_ARR, then OCxREF is held at ‘1’. 0% PWM is not possible in this mode.

For code example refer to the Appendix section A.9.8: Edge-aligned PWM configuration example.
PWM center-aligned mode

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are different from ‘00’ (all the remaining configurations having the same effect on the OCxRef/OCx signals). The compare flag is set when the counter counts up, when it counts down or both when it counts up and down depending on the CMS bits configuration. The direction bit (DIR) in the TIMx_CR1 register is updated by hardware and must not be changed by software. Refer to the Center-aligned mode (up/down counting) on page 338.

Figure 96 shows some center-aligned PWM waveforms in an example where:
- TIMx_ARR=8,
- PWM mode is the PWM mode 1,
- The flag is set when the counter counts down corresponding to the center-aligned mode 1 selected for CMS=01 in TIMx_CR1 register.

For code example refer to the Appendix section A.9.9: Center-aligned PWM configuration example.
Hints on using center-aligned mode:

- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit in the TIMx_CR1 register. Moreover, the DIR and CMS bits must not be changed at the same time by the software.
- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:
  - The direction is not updated if a value greater than the auto-reload value is written in the counter (TIMx_CNT > TIMx_ARR). For example, if the counter was counting up, it continues to count up.
  - The direction is updated if 0 or the TIMx_ARR value is written in the counter but no Update Event UEV is generated.
- The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIMx_EGR register) just before starting the counter and not to write the counter while it is running.

17.3.11 Complementary outputs and dead-time insertion

The advanced-control timers (TIM1) can output two complementary signals and manage the switching-off and the switching-on instants of the outputs.

This time is generally known as dead-time and it has to be adjusted depending on the devices that are connected to the outputs and their characteristics (intrinsic delays of level-shifters, delays due to power switches...)

The polarity of the outputs (main output OCx or complementary OCxN) can be selected independently for each output. This is done by writing to the CCxP and CCxNP bits in the TIMx_CCER register.

The complementary signals OCx and OCxN are activated by a combination of several control bits: the CCxE and CCxNE bits in the TIMx_CCER register and the MOE, OISx, OISxN, OSSI and OSSR bits in the TIMx_BDTR and TIMx_CR2 registers. Refer to Table 63: Output control bits for complementary OCx and OCxN channels with break feature on page 393 for more details. In particular, the dead-time is activated when switching to the IDLE state (MOE falling down to 0).

Dead-time insertion is enabled by setting both CCxE and CCxNE bits, and the MOE bit if the break circuit is present. There is one 10-bit dead-time generator for each channel. From a reference waveform OCxREF, it generates 2 outputs OCx and OCxN. If OCx and OCxN are active high:

- The OCx output signal is the same as the reference signal except for the rising edge, which is delayed relative to the reference rising edge.
- The OCxN output signal is the opposite of the reference signal except for the rising edge, which is delayed relative to the reference falling edge.

If the delay is greater than the width of the active output (OCx or OCxN) then the corresponding pulse is not generated.

The following figures show the relationships between the output signals of the dead-time generator and the reference signal OCxREF. (we suppose CCxP=0, CCxNP=0, MOE=1, CCxE=1 and CCxNE=1 in these examples)
The dead-time delay is the same for each of the channels and is programmable with the DTG bits in the TIMx_BDTR register. Refer to Section 17.4.18: TIM1 break and dead-time register (TIM1_BDTR) on page 398 for delay calculation.
Re-directing OCxREF to OCx or OCxN

In output mode (forced, output compare or PWM), OCxREF can be re-directed to the OCx output or to OCxN output by configuring the CCxE and CCxNE bits in the TIMx_CCER register.

This allows to send a specific waveform (such as PWM or static active level) on one output while the complementary remains at its inactive level. Other alternative possibilities are to have both outputs at inactive level or both outputs active and complementary with dead-time.

**Note:** When only OCxN is enabled (CCxE=0, CCxNE=1), it is not complemented and becomes active as soon as OCxREF is high. For example, if CCxNP=0 then OCxN=OCxRef. On the other hand, when both OCx and OCxN are enabled (CCxE=CCxNE=1) OCx becomes active when OCxREF is high whereas OCxN is complemented and becomes active when OCxREF is low.

17.3.12 Using the break function

When using the break function, the output enable signals and inactive levels are modified according to additional control bits (MOE, OSSI and OSSR bits in the TIMx_BDTR register, OISx and OISxN bits in the TIMx_CR2 register). In any case, the OCx and OCxN outputs cannot be set both to active level at a given time. Refer to Table 63: Output control bits for complementary OCx and OCxN channels with break feature on page 393 for more details.

The source for break (BRK) channel can be an external source connected to the BKin pin or one of the following internal sources:

- the core LOCKUP output
- the PVD output
- the SRAM parity error signal
- a clock failure event generated by the CSS detector
- the output from a comparator

When exiting from reset, the break circuit is disabled and the MOE bit is low. The break function can be enabled by setting the BKE bit in the TIMx_BDTR register. The break input polarity can be selected by configuring the BKP bit in the same register. BKE and BKP can be modified at the same time. When the BKE and BKP bits are written, a delay of 1 APB clock cycle is applied before the writing is effective. Consequently, it is necessary to wait 1 APB clock period to correctly read back the bit after the write operation.

Because MOE falling edge can be asynchronous, a resynchronization circuit has been inserted between the actual signal (acting on the outputs) and the synchronous control bit (accessed in the TIMx_BDTR register). It results in some delays between the asynchronous and the synchronous signals. In particular, if MOE is set to 1 whereas it was low, a delay must be inserted (dummy instruction) before reading it correctly. This is because the write acts on the asynchronous signal whereas the read reflects the synchronous signal.
When a break occurs (selected level on the break input):

- The MOE bit is cleared asynchronously, putting the outputs in inactive state, idle state or in reset state (selected by the OSSI bit). This feature functions even if the MCU oscillator is off.
- Each output channel is driven with the level programmed in the OISx bit in the TIMx_CR2 register as soon as MOE=0. If OSSI=0 then the timer releases the enable output else the enable output remains high.
- When complementary outputs are used:
  - The outputs are first put in reset state inactive state (depending on the polarity). This is done asynchronously so that it works even if no clock is provided to the timer.
  - If the timer clock is still present, then the dead-time generator is reactivated in order to drive the outputs with the level programmed in the OISx and OISxN bits after a dead-time. Even in this case, OCx and OCxN cannot be driven to their active level together. Note that because of the resynchronization on MOE, the dead-time duration is a bit longer than usual (around 2 ck_tim clock cycles).
  - If OSSI=0 then the timer releases the enable outputs else the enable outputs remain or become high as soon as one of the CCxE or CCxNE bits is high.
- The break status flag (BIF bit in the TIMx_SR register) is set. An interrupt can be generated if the BIE bit in the TIMx_DIER register is set.
- If the AOE bit in the TIMx_BDTR register is set, the MOE bit is automatically set again at the next update event UEV. This can be used to perform a regulation, for instance. Else, MOE remains low until it is written with 1 again. In this case, it can be used for security and the break input can be connected to an alarm from power drivers, thermal sensors or any security components.

**Note:** The break inputs is acting on level. Thus, the MOE cannot be set while the break input is active (neither automatically nor by software). In the meantime, the status flag BIF cannot be cleared.

The break can be generated by the BRK input which has a programmable polarity and an enable bit BKE in the TIMx_BDTR Register.

In addition to the break input and the output management, a write protection has been implemented inside the break circuit to safeguard the application. It allows to freeze the configuration of several parameters (dead-time duration, OCx/OCxN polarities and state when disabled, OCxM configurations, break enable and polarity). The protection can be selected among 3 levels with the LOCK bits in the TIMx_BDTR register. Refer to Section 17.4.18: TIM1 break and dead-time register (TIM1_BDTR) on page 398. The LOCK bits can be written only once after an MCU reset.

The Figure 100 shows an example of behavior of the outputs in response to a break.

17.3.13 Clearing the OCxREF signal on an external event

The OCxREF signal of a given channel can be cleared when a high level is applied on the OCREF_CLR_INPUT (OCxCE enable bit in the corresponding TIMx_CCMRx register set to 1). OCxREF remains low until the next update event (UEV) occurs. This function can only be used in Output compare and PWM modes. It does not work in Forced mode.

OCREF_CLR_INPUT can be selected between the OCREF_CLR input and ETRF (ETR after the filter) by configuring the OCCS bit in the TIMx_SMCR register.

When ETRF is chosen, ETR must be configured as follows:

The OCxREF signal for a given channel can be driven Low by applying a High level to the ETRF input (OCxCE enable bit of the corresponding TIMx_CCMRx register set to '1'). The OCxREF signal remains Low until the next update event, UEV, occurs.

This function can only be used in output compare and PWM modes, and does not work in forced mode.

For example, the OCxREF signal can be connected to the output of a comparator to be used for current handling. In this case, the ETR must be configured as follow:

1. The External Trigger Prescaler should be kept off: bits ETPS[1:0] of the TIMx_SMCR register set to '00'.
2. The external clock mode 2 must be disabled: bit ECE of the TIMx_SMCR register set to '0'.
3. The External Trigger Polarity (ETP) and the External Trigger Filter (ETF) can be configured according to the user needs.

For code example refer to the Appendix section A.9.10: ETR configuration to clear OCxREF code example.

Figure 101 shows the behavior of the OCxREF signal when the ETRF Input becomes High, for both values of the enable bit OCxCE. In this example, the timer TIMx is programmed in PWM mode.
Figure 101. Clearing TIMx OCxREF

Note: In case of a PWM with a 100% duty cycle (if CCRx>ARR), then OCxREF is enabled again at the next counter overflow.
17.3.14 6-step PWM generation

When complementary outputs are used on a channel, preload bits are available on the OCxM, CCxE and CCxNE bits. The preload bits are transferred to the shadow bits at the COM commutation event. Thus one can program in advance the configuration for the next step and change the configuration of all the channels at the same time. COM can be generated by software by setting the COM bit in the TIMx_EGR register or by hardware (on TRGI rising edge).

A flag is set when the COM event occurs (COMIF bit in the TIMx_SR register), which can generate an interrupt (if the COMIE bit is set in the TIMx_DIER register) or a DMA request (if the COMDE bit is set in the TIMx_DIER register).

The Figure 102 describes the behavior of the OCx and OCxN outputs when a COM event occurs, in 3 different examples of programmed configurations.

Figure 102. 6-step generation, COM example (OSSR=1)
17.3.15 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- In upcounting: CNT < CCRx ≤ ARR (in particular, 0 < CCRx)
- In downcounting: CNT > CCRx

**Figure 103. Example of one pulse mode**

For example one may want to generate a positive pulse on OC1 with a length of \( t_{\text{PULSE}} \) and after a delay of \( t_{\text{DELAY}} \) as soon as a positive edge is detected on the TI2 input pin.

Let’s use TI2FP2 as trigger 1:

- Map TI2FP2 to TI2 by writing CC2S='01' in the TIMx_CCMR1 register.
- TI2FP2 must detect a rising edge, write CC2P='0' and CC2NP='0' in the TIMx_CCER register.
- Configure TI2FP2 as trigger for the slave mode controller (TRGI) by writing TS='110' in the TIMx_SMCR register.
- TI2FP2 is used to start the counter by writing SMS to ‘110’ in the TIMx_SMCR register (trigger mode).
The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The $t_{\text{DELAY}}$ is defined by the value written in the TIMx_CCR1 register.
- The $t_{\text{PULSE}}$ is defined by the difference between the auto-reload value and the compare value ($\text{TIMx_ARR} - \text{TIMx_CCR1+1}$).
- Let’s say one wants to build a waveform with a transition from ‘0’ to ‘1’ when a compare match occurs and a transition from ‘1’ to ‘0’ when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing OC1M=111 in the TIMx_CCMR1 register. Optionally the preload registers can be enabled by writing OC1PE=’1’ in the TIMx_CCMR1 register and ARPE in the TIMx_CR1 register. In this case one has to write the compare value in the TIMx_CCR1 register, the auto-reload value in the TIMx_ARR register, generate an update by setting the UG bit and wait for external trigger event on TI2. CC1P is written to ‘0’ in this example.

In our example, the DIR and CMS bits in the TIMx_CR1 register should be low.

For code example refer to the Appendix section A.9.16: One-Pulse mode code example.

Since only 1 pulse (Single mode) is needed, a 1 must be written in the OPM bit in the TIMx_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0). When OPM bit in the TIMx_CR1 register is set to ‘0’, so the Repetitive Mode is selected.

**Particular case: OCx fast enable**

In One-pulse mode, the edge detection on TIx input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay $t_{\text{DELAY}}\text{ min}$ we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx_CCMRx register. Then OCxRef (and OCx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

For code example refer to the part of code, conditioned by PULSE_WITHOUT_DELAY > 0 in the Appendix section A.9.16: One-Pulse mode code example.

### Encoder interface mode

To select Encoder Interface mode write SMS='001' in the TIMx_SMCR register if the counter is counting on TI2 edges only, SMS='010' if it is counting on TI1 edges only and SMS='011' if it is counting on both TI1 and TI2 edges.

Select the TI1 and TI2 polarity by programming the CC1P and CC2P bits in the TIMx_CCER register. When needed, the input filter can be programmed as well. CC1NP and CC2NP must be kept low.

The two inputs TI1 and TI2 are used to interface to an incremental encoder. Refer to Table 61. The counter is clocked by each valid transition on TI1FP1 or TI2FP2 (TI1 and TI2 after input filter and polarity selection, TI1FP1=T11 if not filtered and not inverted, TI2FP2=T12 if not filtered and not inverted) assuming that it is enabled (CEN bit in TIMx_CR1 register written to ‘1’). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the TIMx_CR1 register is modified by hardware.
accordingly. The DIR bit is calculated at each transition on any input (TI1 or TI2), whatever the counter is counting on TI1 only, TI2 only or both TI1 and TI2.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value in the TIMx_ARR register (0 to ARR or ARR down to 0 depending on the direction). So the TIMx_ARR must be configured before starting. In the same way, the capture, compare, prescaler, repetition counter, trigger output features continue to work as normal. Encoder mode and External clock mode 2 are not compatible and must not be selected together.

In this mode, the counter is modified automatically following the speed and the direction of the incremental encoder and its content, therefore, always represents the encoder's position. The count direction correspond to the rotation direction of the connected sensor. The table summarizes the possible combinations, assuming TI1 and TI2 do not switch at the same time.

An external incremental encoder can be connected directly to the MCU without external interface logic. However, comparators are normally be used to convert the encoder’s differential outputs to digital signals. This greatly increases noise immunity. The third encoder output which indicate the mechanical zero position, may be connected to an external interrupt input and trigger a counter reset.

*Figure 104* gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points. For this example we assume that the configuration is the following:

- CC1S='01' (TIMx_CCMR1 register, TI1FP1 mapped on TI1).
- CC2S='01' (TIMx_CCMR2 register, TI1FP2 mapped on TI2).
- CC1P='0' (TIMx_CCER register, TI1FP1 non-inverted, TI1FP1=TI1).
- CC2P='0' (TIMx_CCER register, TI1FP2 non-inverted, TI1FP2=TI2).
- SMS='011' (TIMx_SMCR register, both inputs are active on both rising and falling edges).
- CEN='1' (TIMx_CR1 register, Counter enabled).

For code example refer to the Appendix section *A.9.11: Encoder interface code example*.

The timer, when configured in Encoder Interface mode provides information on the sensor’s current position. Dynamic information can be obtained (speed, acceleration, deceleration) by measuring the period between two encoder events using a second timer configured in capture mode. The output of the encoder which indicates the mechanical zero can be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. This can be done by latching the counter value into a third input capture register if available (then the capture signal must be periodic and can be generated by another timer). When available, it is also possible to read its value through a DMA request generated by a real-time clock.
17.3.17 Timer input XOR function

The TI1S bit in the TIMx_CR2 register, allows the input filter of channel 1 to be connected to the output of a XOR gate, combining the three input pins TIMx_CH1, TIMx_CH2 and TIMx_CH3.

The XOR output can be used with all the timer input functions such as trigger or input capture. An example of this feature used to interface Hall sensors is given in Section 17.3.18 below.

17.3.18 Interfacing with Hall sensors

This is done using the advanced-control timers (TIM1) to generate PWM signals to drive the motor and another timer TIMx (TIM2 or TIM3) referred to as “interfacing timer” in Figure 106.

The “interfacing timer” captures the 3 timer input pins (CC1, CC2, CC3) connected through a XOR to the TI1 input channel (selected by setting the TI1S bit in the TIMx_CR2 register).

The slave mode controller is configured in reset mode; the slave input is T1F_ED. Thus, each time one of the 3 inputs toggles, the counter restarts counting from 0. This creates a time base triggered by any change on the Hall inputs.

On the “interfacing timer”, capture/compare channel 1 is configured in capture mode, capture signal is TRC (See Figure 89: Capture/compare channel (example: channel 1 input stage) on page 348). The captured value, which corresponds to the time elapsed between 2 changes on the inputs, gives information about motor speed.

The “interfacing timer” can be used in output mode to generate a pulse which changes the configuration of the channels of the advanced-control timer (TIM1) (by triggering a COM event). The TIM1 timer is used to generate PWM signals to drive the motor. To do this, the interfacing timer channel must be programmed so that a positive pulse is generated after a programmed delay (in output compare or PWM mode). This pulse is sent to the advanced-control timer (TIM1) through the TRGO output.

Example: one wants to change the PWM configuration of the advanced-control timer TIM1 after a programmed delay each time a change occurs on the Hall inputs connected to one of the TIMx timers.

- Configure 3 timer inputs XORed to the TI1 input channel by writing the TI1S bit in the TIMx_CR2 register to ‘1’,
- Program the time base: write the TIMx_ARR to the max value (the counter must be cleared by the TI1 change. Set the prescaler to get a maximum counter period longer than the time between 2 changes on the sensors,
- Program channel 1 in capture mode (TRC selected): write the CC1S bits in the TIMx_CCMR1 register to ‘01’. The digital filter can also be programmed if needed,
- Program channel 2 in PWM 2 mode with the desired delay: write the OC2M bits to ‘111’ and the CC2S bits to ‘00’ in the TIMx_CCMR1 register,
- Select OC2REF as trigger output on TRGO: write the MMS bits in the TIMx_CR2 register to ‘101’.

In the advanced-control timer TIM1, the right ITR input must be selected as trigger input, the timer is programmed to generate PWM signals, the capture/compare control signals are preloaded (CCPC=1 in the TIMx_CR2 register) and the COM event is controlled by the trigger input (CCUS=1 in the TIMx_CR2 register). The PWM control bits (CCxE, OCxM) are written after a COM event for the next step (this can be done in an interrupt subroutine generated by the rising edge of OC2REF).
Figure 106 describes this example.

Figure 106. Example of hall sensor interface

Write CCxE, CCxNE and OCxM for next step
17.3.19 TIMx and external trigger synchronization

The TIMx timer can be synchronized with an external trigger in several modes: Reset mode, Gated mode and Trigger mode.

Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on TI1 input:

- Configure the channel 1 to detect rising edges on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx_CCMR1 register. Write CC1P=0 and CC1NP='0' in TIMx_CCRER register to validate the polarity (and detect rising edges only).
- Configure the timer in reset mode by writing SMS=100 in TIMx_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx_SMCR register.
- Start the counter by writing CEN=1 in the TIMx_CR1 register.

For code example refer to the Appendix section A.9.12: Reset mode code example.

The counter starts counting on the internal clock, then behaves normally until TI1 rising edge. When TI1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx_DIER register).

The following figure shows this behavior when the auto-reload register TIMx_ARR=0x36. The delay between the rising edge on TI1 and the actual reset of the counter is due to the resynchronization circuit on TI1 input.

Figure 107. Control circuit in reset mode
Slave mode: Gated mode

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when T11 input is low:

- Configure the channel 1 to detect low levels on T11. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S=01 in TIMx_CCMR1 register. Write CC1P=1 and CC1NP='0' in TIMx_CCER register to validate the polarity (and detect low level only).

- Configure the timer in gated mode by writing SMS=101 in TIMx_SMCR register. Select T11 as the input source by writing TS=101 in TIMx_SMCR register.

- Enable the counter by writing CEN=1 in the TIMx_CR1 register (in gated mode, the counter doesn’t start if CEN=0, whatever is the trigger input level).

For code example refer to the Appendix section A.9.13: Gated mode code example.

The counter starts counting on the internal clock as long as T11 is low and stops as soon as T11 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on T11 and the actual stop of the counter is due to the resynchronization circuit on T11 input.
Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on TI2 input:

- Configure the channel 2 to detect rising edges on TI2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC2S bits are configured to select the input capture source only, CC2S=01 in TIMx_CCMR1 register. Write CC2P=1 and CC2NP=0 in TIMx_CCRER register to validate the polarity (and detect low level only).
- Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select TI2 as the input source by writing TS=110 in TIMx_SMCR register.

For code example refer to the Appendix section A.9.14: Trigger mode code example.

When a rising edge occurs on TI2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on TI2 and the actual start of the counter is due to the resynchronization circuit on TI2 input.

Slave mode: external clock mode 2 + trigger mode

The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the ETR signal is used as external clock input, and another input can be selected as trigger input (in reset mode, gated mode or trigger mode). It is recommended not to select ETR as TRGI through the TS bits of TIMx_SMCR register.

In the following example, the upcounter is incremented at each rising edge of the ETR signal as soon as a rising edge of TI1 occurs:

1. Configure the external trigger input circuit by programming the TIMx_SMCR register as follows:
   - ETF = 0000: no filter
   - ETPS=00: prescaler disabled
   - ETP=0: detection of rising edges on ETR and ECE=1 to enable the external clock mode 2.
2. Configure the channel 1 as follows, to detect rising edges on TI:
   – IC1F=0000: no filter.
   – The capture prescaler is not used for triggering and does not need to be configured.
   – CC1S=01 in TIMx_CCMR1 register to select only the input capture source
   – CC1P=0 and CC1NP='0' in TIMx_CCER register to validate the polarity (and detect rising edge only).

3. Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx_SMCR register.

For code example refer to the Appendix section A.9.15: External clock mode 2 + trigger mode code example.

A rising edge on TI1 enables the counter and sets the TIF flag. The counter then counts on ETR rising edges.

The delay between the rising edge of the ETR signal and the actual reset of the counter is due to the resynchronization circuit on ETRP input.

**Figure 110. Control circuit in external clock mode 2 + trigger mode**

17.3.20 Timer synchronization

The TIM timers are linked together internally for timer synchronization or chaining. Refer to Section 18.3.15: Timer synchronization on page 439 for details.

17.3.21 Debug mode

When the microcontroller enters debug mode (Cortex™-M0 core halted), the TIMx counter either continues to work normally or stops, depending on DBG_TIMx_STOP configuration bit in DBG module.
17.4 TIM1 registers

Refer to Section 1.2 on page 42 for a list of abbreviations used in register descriptions.

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:8 CKD[1:0]: Clock division
This bit-field indicates the division ratio between the timer clock (CK_INT) frequency and the
dead-time and sampling clock (tDTS) used by the dead-time generators and the digital filters
(ETR, Tlx),

00: tDTS = tCK_INT
01: tDTS = 2tCK_INT
10: tDTS = 4tCK_INT
11: Reserved, do not program this value

Bit 7 ARPE: Auto-reload preload enable
0: TIMx_ARR register is not buffered
1: TIMx_ARR register is buffered

Bits 6:5 CMS[1:0]: Center-aligned mode selection
00: Edge-aligned mode. The counter counts up or down depending on the direction bit
(DIR).
01: Center-aligned mode 1. The counter counts up and down alternatively. Output compare
interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set
only when the counter is counting down.
10: Center-aligned mode 2. The counter counts up and down alternatively. Output compare
interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set
only when the counter is counting up.
11: Center-aligned mode 3. The counter counts up and down alternatively. Output compare
interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set
both when the counter is counting up or down.

Note: It is not allowed to switch from edge-aligned mode to center-aligned mode as long as
the counter is enabled (CEN=1).

Bit 4 DIR: Direction
0: Counter used as upcounter
1: Counter used as downcounter

Note: This bit is read only when the timer is configured in Center-aligned mode or Encoder
mode.

Bit 3 OPM: One pulse mode
0: Counter is not stopped at update event
1: Counter stops counting at the next update event (clearing the bit CEN)
17.4.2 TIM1 control register 2 (TIM1_CR2)

Address offset: 0x04
Reset value: 0x0000

| Bit 15 Reserved, must be kept at reset value. |
| Bit 14 OIS4: Output Idle state 4 (OC4 output) refer to OIS1 bit |
| Bit 13 OIS3N: Output Idle state 3 (OC3N output) refer to OIS1N bit |
| Bit 12 OIS3: Output Idle state 3 (OC3 output) refer to OIS1 bit |
| Bit 11 OIS2N: Output Idle state 2 (OC2N output) refer to OIS1N bit |
| Bit 10 OIS2: Output Idle state 2 (OC2 output) refer to OIS1 bit |
Bit 9 **OIS1N**: Output Idle state 1 (OC1N output)
0: OC1N=0 after a dead-time when MOE=0
1: OC1N=1 after a dead-time when MOE=0

*Note:* This bit cannot be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 8 **OIS1**: Output Idle state 1 (OC1 output)
0: OC1=0 (after a dead-time if OC1N is implemented) when MOE=0
1: OC1=1 (after a dead-time if OC1N is implemented) when MOE=0

*Note:* This bit cannot be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 7 **TI1S**: TI1 selection
0: The TIMx_CH1 pin is connected to TI1 input
1: The TIMx_CH1, CH2 and CH3 pins are connected to the TI1 input (XOR combination)

Bits 6:4 **MMS[2:0]**: Master mode selection
These bits allow to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows:

- 000: **Reset** - the UG bit from the TIMx_EGR register is used as trigger output (TRGO). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on TRGO is delayed compared to the actual reset.
- 001: **Enable** - the Counter Enable signal CNT_EN is used as trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic OR between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO, except if the master/slave mode is selected (see the MSM bit description in TIMx_SMCR register).
- 010: **Update** - The update event is selected as trigger output (TRGO). For instance a master timer can then be used as a prescaler for a slave timer.
- 011: **Compare Pulse** - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred.
- 100: **Compare** - OC1REF signal is used as trigger output (TRGO)
- 101: **Compare** - OC2REF signal is used as trigger output (TRGO)
- 110: **Compare** - OC3REF signal is used as trigger output (TRGO)
- 111: **Compare** - OC4REF signal is used as trigger output (TRGO)

Bit 3 **CCDS**: Capture/compare DMA selection
0: CCx DMA request sent when CCx event occurs
1: CCx DMA requests sent when update event occurs

Bit 2 **CCUS**: Capture/compare control update selection
0: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit only
1: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit or when an rising edge occurs on TRGI

*Note:* This bit acts only on channels that have a complementary output.

Bit 1 Reserved, must be kept at reset value.

Bit 0 **CCPC**: Capture/compare preloaded control
0: CCxE, CCxNE and OCxM bits are not preloaded
1: CCxE, CCxNE and OCxM bits are preloaded, after having been written, they are updated only when a communication event (COM) occurs (COMG bit set or rising edge detected on TRGI, depending on the CCUS bit).

*Note:* This bit acts only on channels that have a complementary output.
17.4.3  TIM1 slave mode control register (TIM1_SMCR)

Address offset: 0x08

Bit 15  **ETP**: External trigger polarity
This bit selects whether ETR or ETR is used for trigger operations
0: ETR is non-inverted, active at high level or rising edge.
1: ETR is inverted, active at low level or falling edge.

Bit 14  **ECE**: External clock enable
This bit enables External clock mode 2.
0: External clock mode 2 disabled
1: External clock mode 2 enabled. The counter is clocked by any active edge on the ETRF signal.

*Note:* 1. Setting the ECE bit has the same effect as selecting external clock mode 1 with TRGI connected to ETRF (SMS=111 and TS=111).
2. It is possible to simultaneously use external clock mode 2 with the following slave modes: reset mode, gated mode and trigger mode. Nevertheless, TRGI must not be connected to ETRF in this case (TS bits must not be 111).
3. If external clock mode 1 and external clock mode 2 are enabled at the same time, the external clock input is ETRF.

Bits 13:12  **ETPS[1:0]**: External trigger prescaler
External trigger signal ETRP frequency must be at most 1/4 of TIMxCLK frequency. A prescaler can be enabled to reduce ETRP frequency. It is useful when inputting fast external clocks.
00: Prescaler OFF
01: ETRP frequency divided by 2
10: ETRP frequency divided by 4
11: ETRP frequency divided by 8
Bits 11:8 **ETF[3:0]**: External trigger filter

This bit-field then defines the frequency used to sample ETRP signal and the length of the digital filter applied to ETRP. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

- 0000: No filter, sampling is done at f_{DTS}
- 0001: f_{SAMPLING} = f_{CK\_INT}, N = 2
- 0010: f_{SAMPLING} = f_{CK\_INT}, N = 4
- 0011: f_{SAMPLING} = f_{CK\_INT}, N = 8
- 0100: f_{SAMPLING} = f_{DTS} / 2, N = 6
- 0101: f_{SAMPLING} = f_{DTS} / 2, N = 8
- 0110: f_{SAMPLING} = f_{DTS} / 4, N = 6
- 0111: f_{SAMPLING} = f_{DTS} / 4, N = 8
- 1000: f_{SAMPLING} = f_{DTS} / 8, N = 6
- 1001: f_{SAMPLING} = f_{DTS} / 8, N = 8
- 1010: f_{SAMPLING} = f_{DTS} / 16, N = 5
- 1011: f_{SAMPLING} = f_{DTS} / 16, N = 6
- 1100: f_{SAMPLING} = f_{DTS} / 16, N = 8
- 1101: f_{SAMPLING} = f_{DTS} / 32, N = 5
- 1110: f_{SAMPLING} = f_{DTS} / 32, N = 6
- 1111: f_{SAMPLING} = f_{DTS} / 32, N = 8

*Note:* Care must be taken that f_{DTS} is replaced in the formula by f_{CK\_INT} when ETF[3:0] = 1, 2 or 3.

Bit 7 **MSM**: Master/slave mode

- 0: No action
- 1: The effect of an event on the trigger input (TRGI) is delayed to allow a perfect synchronization between the current timer and its slaves (through TRGO). It is useful if we want to synchronize several timers on a single external event.
Bits 6:4 **TS[2:0]:** Trigger selection

This bit-field selects the trigger input to be used to synchronize the counter.

- 000: Internal Trigger 0 (ITR0)
- 001: Internal Trigger 1 (ITR1)
- 010: Internal Trigger 2 (ITR2)
- 011: Internal Trigger 3 (ITR3)
- 100: TI1 Edge Detector (TI1F_ED)
- 101: Filtered Timer Input 1 (TI1FP1)
- 110: Filtered Timer Input 2 (TI2FP2)
- 111: External Trigger input (ETRF)

See Table 62: TIMx Internal trigger connection on page 380 for more details on ITRx meaning for each Timer.

**Note:** These bits must be changed only when they are not used (e.g. when SMS=000) to avoid wrong edge detections at the transition.

Bit 3 **OCCS: OCREF clear selection.**

This bit is used to select the OCREF clear source.

- 0: OCREF_CLR_INT is connected to the OCREF_CLR input
- 1: OCREF_CLR_INT is connected to ETRF

Bits 2:0 **SMS[2:0]:** Slave mode selection

When external signals are selected the active edge of the trigger signal (TRGI) is linked to the polarity selected on the external input (see Input Control register and Control Register description).

- 000: Slave mode disabled - if CEN = '1' then the prescaler is clocked directly by the internal clock.
- 001: Encoder mode 1 - Counter counts up/down on TI1FP1 edge depending on TI2FP2 level.
- 010: Encoder mode 2 - Counter counts up/down on TI2FP2 edge depending on TI1FP1 level.
- 011: Encoder mode 3 - Counter counts up/down on both TI1FP1 and TI2FP2 edges depending on the level of the other input.
- 100: Reset Mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter and generates an update of the registers.
- 101: Gated Mode - The counter clock is enabled when the trigger input (TRGI) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.
- 110: Trigger Mode - The counter starts at a rising edge of the trigger TRGI (but it is not reset). Only the start of the counter is controlled.
- 111: External Clock Mode 1 - Rising edges of the selected trigger (TRGI) clock the counter.

**Note:** The gated mode must not be used if TI1F_ED is selected as the trigger input (TS='100'). Indeed, TI1F_ED outputs 1 pulse for each transition on TI1F, whereas the gated mode checks the level of the trigger signal.

**Note:** The clock of the slave timer must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

            refer to CC1OF description |
| Bit 9     | **CC1OF**: Capture/Compare 1 overcapture flag  
            This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to '0'.  
            0: No overcapture has been detected.  
            1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set |
| Bit 8     | Reserved, must be kept at reset value. |
| Bit 7     | **BIF**: Break interrupt flag  
            This flag is set by hardware as soon as the break input goes active. It can be cleared by software if the break input is not active.  
            0: No break event occurred.  
            1: An active level has been detected on the break input. |
| Bit 6     | **TIF**: Trigger interrupt flag  
            This flag is set by hardware on trigger event (active edge detected on TRGI input when the slave mode controller is enabled in all modes but gated mode). It is cleared by software.  
            0: No trigger event occurred.  
            1: Trigger interrupt pending. |
| Bit 5     | **COMIF**: COM interrupt flag  
            This flag is set by hardware on COM event (when Capture/compare Control bits - CCxEx, CCxNE, OCxM - have been updated). It is cleared by software by writing it to '0'.  
            0: No COM event occurred.  
            1: COM interrupt pending. |
| Bit 4     | **CC4IF**: Capture/Compare 4 interrupt flag  
            refer to CC1IF description |
| Bit 3     | **CC3IF**: Capture/Compare 3 interrupt flag  
            refer to CC1IF description |

- **Bit 2** CC2IF: Capture/Compare 2 interrupt flag
  - refer to CC1IF description

- **Bit 1** CC1IF: Capture/Compare 1 interrupt flag
  - **If channel CC1 is configured as output:**
    - This flag is set by hardware when the counter matches the compare value, with some exception in center-aligned mode (refer to the CMS bits in the TIMx_CR1 register description).
    - It is cleared by software.
    - 0: No match.
    - 1: The content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register.
      - When the contents of TIMx_CCR1 are greater than the contents of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in upcounting and up/down-counting modes) or underflow (in downcounting mode)
  - **If channel CC1 is configured as input:**
    - This bit is set by hardware on a capture. It is cleared by software or by reading the TIMx_CCR1 register.
    - 0: No input capture occurred
    - 1: The counter value has been captured in TIMx_CCR1 register (An edge has been detected on IC1 which matches the selected polarity)

- **Bit 0** UIF: Update interrupt flag
  - This bit is set by hardware on an update event. It is cleared by software.
  - 0: No update occurred.
  - 1: Update interrupt pending. This bit is set by hardware when the registers are updated:
    - At overflow or underflow regarding the repetition counter value (update if repetition counter = 0) and if the UDIS=0 in the TIMx_CR1 register.
    - When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if URS=0 and UDIS=0 in the TIMx_CR1 register.
    - When CNT is reinitialized by a trigger event (refer to Section 7.4.3: TIM1 slave mode control register (TIM1_SMCR)), if URS=0 and UDIS=0 in the TIMx_CR1 register.
Bits 15:8  Reserved, must be kept at reset value.

Bit 7  **BG:** Break generation
- This bit is set by software in order to generate an event, it is automatically cleared by hardware.
  - 0: No action
  - 1: A break event is generated. MOE bit is cleared and BIF flag is set. Related interrupt or DMA transfer can occur if enabled.

Bit 6  **TG:** Trigger generation
- This bit is set by software in order to generate an event, it is automatically cleared by hardware.
  - 0: No action
  - 1: The TIF flag is set in TIMx_SR register. Related interrupt or DMA transfer can occur if enabled.

Bit 5  **COMG:** Capture/Compare control update generation
- This bit can be set by software, it is automatically cleared by hardware.
  - 0: No action
  - 1: When CCPC bit is set, it allows to update CCxE, CCxNE and OCxM bits
  
  *Note:* This bit acts only on channels having a complementary output.

Bit 4  **CC4G:** Capture/Compare 4 generation
- Refer to CC1G description

Bit 3  **CC3G:** Capture/Compare 3 generation
- Refer to CC1G description

Bit 2  **CC2G:** Capture/Compare 2 generation
- Refer to CC1G description

Bit 1  **CC1G:** Capture/Compare 1 generation
- This bit is set by software in order to generate an event, it is automatically cleared by hardware.
  - 0: No action
  - 1: A capture/compare event is generated on channel 1:

  **If channel CC1 is configured as output:**
  CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled.

  **If channel CC1 is configured as input:**
  The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0  **UG:** Update generation
- This bit can be set by software, it is automatically cleared by hardware.
  - 0: No action
  - 1: Reinitialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected). The counter is cleared if the center-aligned mode is selected or if DIR=0 (upcounting), else it takes the auto-reload value (TIMx_ARR) if DIR=1 (downcounting).
17.4.7 TIM1 capture/compare mode register 1 (TIM1_CCMR1)

Address offset: 0x18

Reset value: 0x0000

The channels can be used in input (capture mode) or in output (compare mode). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode. For a given bit, OCxx describes its function when the channel is configured in output, ICxx describes its function when the channel is configured in input. So one must take care that the same bit can have a different meaning for the input stage and for the output stage.

Output compare mode

Bit 15 OC2CE: Output Compare 2 clear enable
Bits 14:12 OC2M[2:0]: Output Compare 2 mode
Bit 11 OC2PE: Output Compare 2 preload enable
Bit 10 OC2FE: Output Compare 2 fast enable

Bits 9:8 CC2S[1:0]: Capture/Compare 2 selection
This bit-field defines the direction of the channel (input/output) as well as the used input.
00: CC2 channel is configured as output
01: CC2 channel is configured as input, IC2 is mapped on TI2
10: CC2 channel is configured as input, IC2 is mapped on TI1
11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through the TS bit (TIMx_SMCR register)

Note: CC2S bits are writable only when the channel is OFF (CC2E = ‘0’ in TIMx_CCER).

Bit 7 OC1CE: Output Compare 1 clear enable
OC1CE: Output Compare 1 Clear Enable
0: OC1Ref is not affected by the ETRF Input
1: OC1Ref is cleared as soon as a High level is detected on ETRF input
Bits 6:4 **OC1M**: Output Compare 1 mode

These bits define the behavior of the output reference signal OC1REF from which OC1 and OC1N are derived. OC1REF is active high whereas OC1 and OC1N active level depends on CC1P and CC1NP bits.

000: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs (this mode is used to generate a timing base).
001: Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).
010: Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).
011: Toggle - OC1REF toggles when TIMx_CNT=TIMx_CCR1.
100: Force inactive level - OC1REF is forced low.
101: Force active level - OC1REF is forced high.
110: PWM mode 1 - In upcounting, channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else inactive. In downcounting, channel 1 is inactive (OC1REF='0') as long as TIMx_CNT>TIMx_CCR1 else active (OC1REF='1').
111: PWM mode 2 - In upcounting, channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else active. In downcounting, channel 1 is active as long as TIMx_CNT>TIMx_CCR1 else inactive.

Note:
1: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S='00' (the channel is configured in output).
2: In PWM mode 1 or 2, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.
3: On channels having a complementary output, this bit field is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the OC1M active bits take the new value from the preloaded bits only when a COM event is generated.
Bit 3 **OC1PE**: Output Compare 1 preload enable

0: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken in account immediately.
1: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded in the active register at each update event.

*Note*: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S='00'(the channel is configured in output).

Bit 2 **OC1FE**: Output Compare 1 fast enable

This bit is used to accelerate the effect of an event on the trigger in input on the CC output.

0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.
1: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output
01: CC1 channel is configured as input, IC1 is mapped on TI1
10: CC1 channel is configured as input, IC1 is mapped on TI2
11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

*Note*: CC1S bits are writable only when the channel is OFF (CC1E = ’0’ in TIMx_CCER).

**Input capture mode**

Bits 15:12 **IC2F**: Input capture 2 filter

Bits 11:10 **IC2PSC[1:0]**: Input capture 2 prescaler

Bits 9:8 **CC2S**: Capture/Compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output
01: CC2 channel is configured as input, IC2 is mapped on TI2
10: CC2 channel is configured as input, IC2 is mapped on TI1
11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

*Note*: CC2S bits are writable only when the channel is OFF (CC2E = ’0’ in TIMx_CCER).
Bits 7:4 IC1F[3:0]: Input capture 1 filter
This bit-field defines the frequency used to sample TI1 input and the length of the digital filter applied to TI1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at fDTS
0001: fSAMPLING = fCK_INT, N = 2
0010: fSAMPLING = fCK_INT, N = 4
0011: fSAMPLING = fCK_INT, N = 8
0100: fSAMPLING = fDTS / 2, N = 6
0101: fSAMPLING = fDTS / 2, N = 8
0110: fSAMPLING = fDTS / 4, N = 6
0111: fSAMPLING = fDTS / 4, N = 8
1000: fSAMPLING = fDTS / 8, N = 6
1001: fSAMPLING = fDTS / 8, N = 8
1010: fSAMPLING = fDTS / 16, N = 5
1011: fSAMPLING = fDTS / 16, N = 6
1100: fSAMPLING = fDTS / 4, N = 6
1101: fSAMPLING = fDTS / 4, N = 8
1110: fSAMPLING = fDTS / 8, N = 6
1111: fSAMPLING = fDTS / 8, N = 8

Note: Care must be taken that fDTS is replaced in the formula by fCK_INT when ICxF[3:0] = 1, 2 or 3.

Bits 3:2 IC1PSC: Input capture 1 prescaler
This bit-field defines the ratio of the prescaler acting on CC1 input (IC1). The prescaler is reset as soon as CC1E='0' (TIMx_CCER register).

00: no prescaler, capture is done each time an edge is detected on the capture input
01: capture is done once every 2 events
10: capture is done once every 4 events
11: capture is done once every 8 events

Bits 1:0 CC1S: Capture/Compare 1 Selection
This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output
01: CC1 channel is configured as input, IC1 is mapped on TI1
10: CC1 channel is configured as input, IC1 is mapped on TI2
11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

Note: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIMx_CCER).

17.4.8 TIM1 capture/compare mode register 2 (TIM1_CCMR2)
Address offset: 0x1C
Reset value: 0x0000

Refer to the above CCMR1 register description.
Output compare mode

- Bit 15 **OC4CE**: Output compare 4 clear enable
- Bits 14:12 **OC4M**: Output compare 4 mode
  - Bit 11 **OC4PE**: Output compare 4 preload enable
  - Bit 10 **OC4FE**: Output compare 4 fast enable
- Bits 9:8 **CC4S**: Capture/Compare 4 selection
  - This bit-field defines the direction of the channel (input/output) as well as the used input.
    - 00: CC4 channel is configured as output
    - 01: CC4 channel is configured as input, IC4 is mapped on TI4
    - 10: CC4 channel is configured as input, IC4 is mapped on TI3
    - 11: CC4 channel is configured as input, IC4 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)
  - Note: **CC4S bits are writable only when the channel is OFF (CC4E = ‘0’ in TIMx_CCER).**
- Bit 7 **OC3CE**: Output compare 3 clear enable
- Bits 6:4 **OC3M**: Output compare 3 mode
  - Bit 3 **OC3PE**: Output compare 3 preload enable
  - Bit 2 **OC3FE**: Output compare 3 fast enable
- Bits 1:0 **CC3S**: Capture/Compare 3 selection
  - This bit-field defines the direction of the channel (input/output) as well as the used input.
    - 00: CC3 channel is configured as output
    - 01: CC3 channel is configured as input, IC3 is mapped on TI3
    - 10: CC3 channel is configured as input, IC3 is mapped on TI4
    - 11: CC3 channel is configured as input, IC3 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)
  - Note: **CC3S bits are writable only when the channel is OFF (CC3E = ‘0’ in TIMx_CCER).**

Input capture mode

- Bits 15:12 **IC4F**: Input capture 4 filter
- Bits 11:10 **IC4PSC**: Input capture 4 prescaler
- Bits 9:8 **CC4S**: Capture/Compare 4 selection
  - This bit-field defines the direction of the channel (input/output) as well as the used input.
    - 00: CC4 channel is configured as output
    - 01: CC4 channel is configured as input, IC4 is mapped on TI4
    - 10: CC4 channel is configured as input, IC4 is mapped on TI3
    - 11: CC4 channel is configured as input, IC4 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)
  - Note: **CC4S bits are writable only when the channel is OFF (CC4E = ‘0’ in TIMx_CCER).**
Bits 7:4 **IC3F**: Input capture 3 filter

Bits 3:2 **IC3PSC**: Input capture 3 prescaler

Bits 1:0 **CC3S**: Capture/compare 3 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC3 channel is configured as output
01: CC3 channel is configured as input, IC3 is mapped on TI3
10: CC3 channel is configured as input, IC3 is mapped on TI4
11: CC3 channel is configured as input, IC3 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

**Note**: CC3S bits are writable only when the channel is OFF (CC3E = ‘0’ in TIMx_CCER).

- Bit 7  **CC2NP**: Capture/Compare 2 complementary output polarity
  refer to CC1NP description

- Bit 6  **CC2NE**: Capture/Compare 2 complementary output enable
  refer to CC1NE description

- Bit 5  **CC2P**: Capture/Compare 2 output polarity
  refer to CC1P description

- Bit 4  **CC2E**: Capture/Compare 2 output enable
  refer to CC1E description
Bit 3 **CC1NP**: Capture/Compare 1 complementary output polarity

**CC1 channel configuration as output:**
0: OC1N active high.
1: OC1N active low.

**CC1 channel configuration as input:**
This bit is used in conjunction with CC1P to define the polarity of TI1FP1 and TI2FP1. Refer to CC1P description.

*Note:* On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1NP active bit takes the new value from the preloaded bits only when a Commutation event is generated.

*Note:* This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S="00" (the channel is configured in output).

Bit 2 **CC1NE**: Capture/Compare 1 complementary output enable
0: Off - OC1N is not active. OC1N level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.
1: On - OC1N signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.

*Note:* On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1NE active bit takes the new value from the preloaded bits only when a Commutation event is generated.

Bit 1 **CC1P**: Capture/Compare 1 output polarity

**CC1 channel configured as output:**
0: OC1 active high
1: OC1 active low

**CC1 channel configured as input:**
CC1NP/CC1P bits select the active polarity of TI1FP1 and TI2FP1 for trigger or capture operations.

00: non-inverted/rising edge
The circuit is sensitive to Ti1FP1 rising edge (capture or trigger operations in reset, external clock or trigger mode), Ti1FP1 is not inverted (trigger operation in gated mode or encoder mode).

01: inverted/falling edge
The circuit is sensitive to Ti1FP1 falling edge (capture or trigger operations in reset, external clock or trigger mode), Ti1FP1 is inverted (trigger operation in gated mode or encoder mode).

10: reserved, do not use this configuration.

11: non-inverted/both edges
The circuit is sensitive to both Ti1FP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), Ti1FP1 is not inverted (trigger operation in gated mode). This configuration must not be used in encoder mode.

*Note:* On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1P active bit takes the new value from the preloaded bits only when a Commutation event is generated.

*Note:* This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).
Bit 0  **CC1E**: Capture/Compare 1 output enable

**CC1 channel configured as output:**
0: Off - OC1 is not active. OC1 level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and CC1NE bits.
1: On - OC1 signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and CC1NE bits.

**CC1 channel configured as input:**
This bit determines if a capture of the counter value can actually be done into the input capture/compare register 1 (TIMx_CCR1) or not.
0: Capture disabled.
1: Capture enabled.

*Note:* On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1E active bit takes the new value from the preloaded bits only when a Commutation event is generated.

### Table 63. Output control bits for complementary OCx and OCxN channels with break feature

</tr>
<tr>
<td>1</td>
<td></td>
<td></td>
<td>1</td>
<td>1</td>
<td>Then if the clock is present: OCx=OISx and OCxN=OISxN after a dead-time, assuming that OISx and OISxN do not correspond to OCX and OCxN both in active state.</td>
<td></td>
</tr>
</tbody>
</table>

1. When both outputs of a channel are not used (CCxE = CCxNE = 0), the OISx, OISxN, CCxP and CCxNP bits must be kept cleared.

The state of the external I/O pins connected to the complementary OCx and OCxN channels depends on the OCx and OCxN channel state and the GPIO registers.
17.4.11 TIM1 prescaler (TIM1_PSC)

Address offset: 0x28
Reset value: 0x0000

<table>
<thead>
<tr>
<th>PSC[15:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw</td>
</tr>
</tbody>
</table>

Bits 15:0 **PSC[15:0]**: Prescaler value
The counter clock frequency (CK_CNT) is equal to f_{CK_PSC} / (PSC[15:0] + 1).
PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in “reset mode”).

17.4.12 TIM1 auto-reload register (TIM1_ARR)

Address offset: 0x2C
Reset value: 0xFFFF

<table>
<thead>
<tr>
<th>ARR[15:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw</td>
</tr>
</tbody>
</table>

Bits 15:0 **ARR[15:0]**: Auto-reload value
ARR is the value to be loaded in the actual auto-reload register.
Refer to the Section 17.3.1: Time-base unit on page 330 for more details about ARR update and behavior.
The counter is blocked while the auto-reload value is null.

17.4.13 TIM1 repetition counter register (TIM1_RCR)

Address offset: 0x30
Reset value: 0x0000

<table>
<thead>
<tr>
<th>REP[7:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw rw rw rw rw rw rw rw</td>
</tr>
</tbody>
</table>

Bits 7:0 **REP[7:0]**: Repetition counter value
The counter is blocked while the repetition counter value is null.
Bits 15:8  Reserved, must be kept at reset value.

Bits 7:0  **REP[7:0]**: Repetition counter value

These bits allow the user to set-up the update rate of the compare registers (i.e. periodic transfers from preload to active registers) when preload registers are enable, as well as the update interrupt generation rate, if this interrupt is enable.

Each time the REP_CNT related downcounter reaches zero, an update event is generated and it restarts counting from REP value. As REP_CNT is reloaded with REP value only at the repetition update event U_RC, any write to the TIMx_RCR register is not taken in account until the next repetition update event.

It means in PWM mode (REP+1) corresponds to:
- the number of PWM periods in edge-aligned mode
- the number of half PWM period in center-aligned mode.

### 17.4.14 TIM1 capture/compare register 1 (TIM1_CCR1)

**Address offset**: 0x34

**Reset value**: 0x0000

<table>
<thead>
<tr>
<th>Bit 15</th>
<th>Bit 14</th>
<th>Bit 13</th>
<th>Bit 12</th>
<th>Bit 11</th>
<th>Bit 10</th>
<th>Bit 9</th>
<th>Bit 8</th>
<th>Bit 7</th>
<th>Bit 6</th>
<th>Bit 5</th>
<th>Bit 4</th>
<th>Bit 3</th>
<th>Bit 2</th>
<th>Bit 1</th>
<th>Bit 0</th>

<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

**Bits 15:0 CCR1[15:0]**: Capture/Compare 1 value

If channel CC1 is configured as output:

CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).

If loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on OC1 output.

If channel CC1 is configured as input:

CCR1 is the counter value transferred by the last input capture 1 event (IC1).

### 17.4.15 TIM1 capture/compare register 2 (TIM1_CCR2)

**Address offset**: 0x38

**Reset value**: 0x0000

<table>
<thead>
<tr>
<th>Bit 15</th>
<th>Bit 14</th>
<th>Bit 13</th>
<th>Bit 12</th>
<th>Bit 11</th>
<th>Bit 10</th>
<th>Bit 9</th>
<th>Bit 8</th>
<th>Bit 7</th>
<th>Bit 6</th>
<th>Bit 5</th>
<th>Bit 4</th>
<th>Bit 3</th>
<th>Bit 2</th>
<th>Bit 1</th>
<th>Bit 0</th>

<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>
Bits 15:0 **CCR2[15:0]**: Capture/Compare 2 value

**If channel CC2 is configured as output:**
CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIMx_CCMR2 register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signalled on OC2 output.

**If channel CC2 is configured as input:**
CCR2 is the counter value transferred by the last input capture 2 event (IC2).

---

17.4.16 **TIM1 capture/compare register 3 (TIM1_CCR3)**

Address offset: 0x3C
Reset value: 0x0000

<table>
<thead>
<tr>
<th>CCR3[15:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw</td>
</tr>
</tbody>
</table>

Bits 15:0 **CCR3[15:0]**: Capture/Compare value

**If channel CC3 is configured as output:**
CCR3 is the value to be loaded in the actual capture/compare 3 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIMx_CCMR3 register (bit OC3PE). Else the preload value is copied in the active capture/compare 3 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signalled on OC3 output.

**If channel CC3 is configured as input:**
CCR3 is the counter value transferred by the last input capture 3 event (IC3).
17.4.17 TIM1 capture/compare register 4 (TIM1_CCR4)

Address offset: 0x40
Reset value: 0x0000

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>15</td>
<td>MOE: Main output enable</td>
</tr>
<tr>
<td>14</td>
<td>AOE: Automatic output enable</td>
</tr>
<tr>
<td>13</td>
<td>BKP: Break pin enable</td>
</tr>
<tr>
<td>12</td>
<td>BKE: Break pin enable</td>
</tr>
<tr>
<td>11</td>
<td>OSSR: Output compare pins reselect</td>
</tr>
<tr>
<td>10</td>
<td>OSSI: Output compare pins select</td>
</tr>
<tr>
<td>9</td>
<td>LOCK[1:0]: Lock configuration</td>
</tr>
<tr>
<td>8</td>
<td>DTG[7:0]: Dead-time control register</td>
</tr>
</tbody>
</table>

Note: As the bits AOE, BKP, BKE, OSSI, OSSR and DTG[7:0] can be write-locked depending on the LOCK configuration, it can be necessary to configure all of them during the first write access to the TIMx_BDTR register.

Bit 15 MOE: Main output enable
This bit is cleared asynchronously by hardware as soon as the break input is active. It is set by software or automatically depending on the AOE bit. It is acting only on the channels which are configured in output.
0: OC and OCN outputs are disabled or forced to idle state.
1: OC and OCN outputs are enabled if their respective enable bits are set (CCxE, CCxNE in TIMx_CCER register).
See OC/OCN enable description for more details (Section 17.4.9: TIM1 capture/compare enable register (TIM1_CCER) on page 391).

Bit 14 AOE: Automatic output enable
0: MOE can be set only by software
1: MOE can be set by software or automatically at the next update event (if the break input is not active)

Note: This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

17.4.18 TIM1 break and dead-time register (TIM1_BDTR)

Address offset: 0x44
Reset value: 0x0000

Bits 15:0 CCR4[15:0]: Capture/Compare value
If channel CC4 is configured as output:
CC4 is the value to be loaded in the actual capture/compare 4 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIMx_CCMR4 register (bit OC4PE). Else the preload value is copied in the active capture/compare 4 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signalled on OC4 output.
If channel CC4 is configured as input:
CCR4 is the counter value transferred by the last input capture 4 event (IC4).
Bit 13  **BKP**: Break polarity

0: Break input BRK is active low
1: Break input BRK is active high

*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

*Note:* Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 12  **BKE**: Break enable

0: Break inputs (BRK and CCS clock failure event) disabled
1: Break inputs (BRK and CCS clock failure event) enabled

*Note:* This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

*Note:* Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 11  **OSSR**: Off-state selection for Run mode

This bit is used when MOE=1 on channels having a complementary output which are configured as outputs. OSSR is not implemented if no complementary output is implemented in the timer.

See OC/OCN enable description for more details (Section 17.4.9: TIM1 capture/compare enable register (TIM1_CCER) on page 391).

0: When inactive, OC/OCN outputs are disabled (OC/OCN enable output signal=0).
1: When inactive, OC/OCN outputs are enabled with their inactive level as soon as CCxE=1 or CCxNE=1. Then, OC/OCN enable output signal=1

*Note:* This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 10  **OSSI**: Off-state selection for Idle mode

This bit is used when MOE=0 on channels configured as outputs.

See OC/OCN enable description for more details (Section 17.4.9: TIM1 capture/compare enable register (TIM1_CCER) on page 391).

0: When inactive, OC/OCN outputs are disabled (OC/OCN enable output signal=0).
1: When inactive, OC/OCN outputs are forced first with their idle level as soon as CCxE=1 or CCxNE=1. OC/OCN enable output signal=1

*Note:* This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 9:8  **LOCK[1:0]**: Lock configuration

These bits offer a write protection against software errors.

00: LOCK OFF - No bit is write protected.
01: LOCK Level 1 = DTG bits in TIMx_BDTR register, OISx and OISxN bits in TIMx_CR2 register and BKE/BKP/AOE bits in TIMx_BDTR register can no longer be written.
10: LOCK Level 2 = LOCK Level 1 + CC Polarity bits (CCxP/CCxNP bits in TIMx_CCER register, as long as the related channel is configured in output through the CCxS bits) as well as OSSR and OSSI bits can no longer be written.
11: LOCK Level 3 = LOCK Level 2 + CC Control bits (OCxM and OCxPE bits in TIMx_CCMRx registers, as long as the related channel is configured in output through the CCxS bits) can no longer be written.

*Note:* The LOCK bits can be written only once after the reset. Once the TIMx_BDTR register has been written, their content is frozen until the next reset.
### 17.4.19 TIM1 DMA control register (TIM1_DCR)

Address offset: 0x48  
Reset value: 0x0000

<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>
<th>10</th>
<th>9</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>

<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

**Bits 15:13**  Reserved, must be kept at reset value.

**Bits 12:8** **DBL[4:0]: DMA burst length**  
This 5-bit vector defines the number of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address)  
- 00000: 1 transfer  
- 00001: 2 transfers  
- 00010: 3 transfers  
- ...  
- 10001: 18 transfers

**Bits 7:5**  Reserved, must be kept at reset value.

**Bits 4:0** **DBA[4:0]: DMA base address**  
This 5-bit vector defines the base-address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register. **Example:**  
- 00000: TIMx_CR1,  
- 00001: TIMx_CR2,  
- 00010: TIMx_SMCR,  
- ...

**Example:** Let us consider the following transfer: DBL = 7 transfers and DBA = TIMx_CR1. In this case the transfer is done to/from 7 registers starting from the TIMx_CR1 address.
17.4.20  TIM1 DMA address for full transfer (TIM1_DMAR)

Address offset: 0x4C
Reset value: 0x0000

Example of how to use the DMA burst feature

In this example the timer DMA burst feature is used to update the contents of the CCRx registers (x = 2, 3, 4) with the DMA transferring half words into the CCRx registers.

This is done in the following steps:

1. Configure the corresponding DMA channel as follows:
   - DMA channel peripheral address is the DMAR register address
   - DMA channel memory address is the address of the buffer in the RAM containing the data to be transferred by DMA into CCRx registers.
   - Number of data to transfer = 3 (See note below).
   - Circular mode disabled.
2. Configure the DCR register by configuring the DBA and DBL bit fields as follows:
   - DBL = 3 transfers, DBA = 0xE.
3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).
4. Enable TIMx
5. Enable the DMA channel

Note: This example is for the case where every CCRx register to be updated once. If every CCRx register is to be updated twice for example, the number of data to transfer should be 6. Let’s take the example of a buffer in the RAM containing data1, data2, data3, data4, data5 and data6. The data is transferred to the CCRx registers as follows: on the first update DMA request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is transferred to CCR3 and data6 is transferred to CCR4.
# TIM1 register map

TIM1 registers are mapped as 16-bit addressable registers as described in the table below:

18 General-purpose timers (TIM2 and TIM3)

18.1 TIM2 and TIM3 introduction

The general-purpose timers consist of a 16-bit or 32-bit auto-reload counter driven by a programmable prescaler.

They may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare and PWM).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The timers are completely independent, and do not share any resources. They can be synchronized together as described in Section 18.3.15.

18.2 TIM2 and TIM3 main features

General-purpose TIMx timer features include:

- 16-bit (TIM3) or 32-bit (TIM2) up, down, up/down auto-reload counter.
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535.
- Up to 4 independent channels for:
  - Input capture
  - Output compare
  - PWM generation (Edge- and Center-aligned modes)
  - One-pulse mode output
- Synchronization circuit to control the timer with external signals and to interconnect several timers.
- Interrupt/DMA generation on the following events:
  - Update: counter overflow/underflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
- Supports incremental (quadrature) encoder and hall-sensor circuitry for positioning purposes
- Trigger input for external clock or cycle-by-cycle current management
18.3 TIM2 and TIM3 functional description

18.3.1 Time-base unit

The main block of the programmable timer is a 16-bit/32-bit counter with its related auto-reload register. The counter can count up but also down or both up and down. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.
The time-base unit includes:

- Counter Register (TIMx_CNT)
- Prescaler Register (TIMx_PSC)
- Auto-Reload Register (TIMx_ARR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow (or underflow when downcounting) and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detail for each configuration.

The counter is clocked by the prescaler output CK_CNT, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the actual counter enable signal CNT_EN is set 1 clock cycle after CEN.

**Prescaler description**

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit/32-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 112* and *Figure 113* give some examples of the counter behavior when the prescaler ratio is changed on the fly:

*Figure 112. Counter timing diagram with prescaler division change from 1 to 2*
18.3.2 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

An Update event can be generated at each counter overflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller).

The UEV event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register)
- The auto-reload shadow register is updated with the preload value (TIMx_ARR)

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.
Figure 114. Counter timing diagram, internal clock divided by 1

Figure 116. Counter timing diagram, internal clock divided by 4

Figure 117. Counter timing diagram, internal clock divided by N
Figure 118. Counter timing diagram, Update event when ARPE=0
(TIMx_ARR not preloaded)

Figure 119. Counter timing diagram, Update event when ARPE=1
(TIMx_ARR preloaded)
Downcounting mode

In downcounting mode, the counter counts from the auto-reload value (content of the TIMx_ARR register) down to 0, then restarts from the auto-reload value and generates a counter underflow event.

An Update event can be generate at each counter underflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller).

The UEV update event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter restarts from the current auto-reload value, whereas the counter of the prescaler restarts from 0 (but the prescale rate doesn’t change).

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that the auto-reload is updated before the counter is reloaded, so that the next period is the expected one.

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

**Figure 120. Counter timing diagram, internal clock divided by 1**

![Counter timing diagram](image-url)
Figure 121. Counter timing diagram, internal clock divided by 2

Figure 122. Counter timing diagram, internal clock divided by 4
Figure 123. Counter timing diagram, internal clock divided by N

Figure 124. Counter timing diagram, Update event when repetition counter is not used
Center-aligned mode (up/down counting)

In center-aligned mode, the counter counts from 0 to the auto-reload value (content of the TIMx_ARR register) – 1, generates a counter overflow event, then counts from the auto-reload value down to 1 and generates a counter underflow event. Then it restarts counting from 0.

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are not equal to '00'. The Output compare interrupt flag of channels configured in output is set when: the counter counts down (Center aligned mode 1, CMS = "01"), the counter counts up (Center aligned mode 2, CMS = "10") the counter counts up and down (Center aligned mode 3, CMS = "11").

In this mode, the direction bit (DIR from TIMx_CR1 register) cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event. In this case, the counter restarts counting from 0, as well as the counter of the prescaler.

The UEV update event can be disabled by software by setting the UDIS bit in TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter continues counting up and down, based on the current auto-reload value.

In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupt when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).
- The auto-reload active register is updated with the preload value (content of the TIMx_ARR register). Note that if the update source is a counter overflow, the auto-reload is updated before the counter is reloaded, so that the next period is the expected one (the counter is loaded with the new value).

The following figures show some examples of the counter behavior for different clock frequencies.
1. Here, center-aligned mode 1 is used (for more details refer to Section 18.4.1: TIM2 and TIM3 control register 1 (TIM2_CR1 and TIM3_CR1) on page 446).

18.3.3 Clock sources

The counter clock can be provided by the following clock sources:

- Internal clock (CK_INT)
- External clock mode1: external input pin (TIx)
- External clock mode2: external trigger input (ETR)
- Internal trigger inputs (ITRx): using one timer as prescaler for another timer, for example, Timer 1 can be configured to act as a prescaler for Timer 2. Refer to : Using one timer as prescaler for another on page 440 for more details.

Internal clock source (CK_INT)

If the slave mode controller is disabled (SMS=000 in the TIMx_SMCR register), then the CEN, DIR (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK_INT.

*Figure 131* shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

**Figure 131. Control circuit in normal mode, internal clock divided by 1**

---

External clock source mode 1

This mode is selected when SMS=111 in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.
For example, to configure the upcounter to count in response to a rising edge on the TI2 input, use the following procedure:

1. Configure channel 2 to detect rising edges on the TI2 input by writing CC2S=’01 in the TIMx_CCMR1 register.

2. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx_CCMR1 register (if no filter is needed, keep IC2F=0000).

3. Select rising edge polarity by writing CC2P=0 and CC2NP=0 in the TIMx_CCER register.

4. Configure the timer in external clock mode 1 by writing SMS=111 in the TIMx_SMCR register.

5. Select TI2 as the input source by writing TS=110 in the TIMx_SMCR register.

6. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

For code example refer to the Appendix section A.9.2: Up counter on each 2 ETR rising edges code example.

When a rising edge occurs on TI2, the counter counts once and the TIF flag is set.

The delay between the rising edge on TI2 and the actual clock of the counter is due to the resynchronization circuit on TI2 input.
External clock source mode 2

This mode is selected by writing ECE=1 in the TIMx_SMCR register.
The counter can count at each rising or falling edge on the external trigger input ETR.
The Figure 134 gives an overview of the external trigger input block.

For example, to configure the upcounter to count each 2 rising edges on ETR, use the following procedure:
1. As no filter is needed in this example, write ETF[3:0]=0000 in the TIMx_SMCR register.
2. Set the prescaler by writing ETPS[1:0]=01 in the TIMx_SMCR register.
3. Select rising edge detection on the ETR pin by writing ETP=0 in the TIMx_SMCR register.
4. Enable external clock mode 2 by writing ECE=1 in the TIMx_SMCR register.
5. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

The counter counts once each 2 ETR rising edges.

The delay between the rising edge on ETR and the actual clock of the counter is due to the resynchronization circuit on the ETRP signal.

18.3.4 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

The following figure gives an overview of one Capture/Compare channel.

The input stage samples the corresponding TIx input to generate a filtered signal TIxF. Then, an edge detector with polarity selection generates a signal (TIxFPx) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).
The output stage generates an intermediate waveform which is then used for reference: OCxRef (active high). The polarity acts at the end of the chain.

**Figure 136. Capture/compare channel (example: channel 1 input stage)**

**Figure 137. Capture/compare channel 1 main circuit**
The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 18.3.5 Input capture mode

In input capture mode, the Capture/Compare Registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCXIF flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to 0 or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx_CCR1 when TI1 input rises. To do this, use the following procedure:

- Select the active input: TIMx_CCR1 must be linked to the TI1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx_CCR1 register becomes read-only.
- Program the appropriate input filter duration in relation with the signal connected to the timer (when the input is one of the TIx (ICxF bits in the TIMx_CCMRx register). Let’s imagine that, when toggling, the input signal is not stable during at most 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on TI1 when 8 consecutive samples with the new level have been
detected (sampled at \( f_{\text{DTS}} \) frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.

- Select the edge of the active transition on the TI1 channel by writing the CC1P and CC1NP bits to 0 in the TIMx_CCER register (rising edge in this case).
- Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to 00 in the TIMx_CCMR1 register).
- Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.
- If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx_DIER register.

For code example refer to the Appendix section **A.9.3: Input capture configuration code example**.

When an input capture occurs:
- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1F flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

For code example refer to the Appendix section **A.9.4: Input capture data management code example**.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

**Note:** *IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.*
18.3.6 PWM input mode

This mode is a particular case of input capture mode. The procedure is the same except:

- Two ICx signals are mapped on the same TIx input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two TIxFP signals is selected as trigger input and the slave mode controller is configured in reset mode.

For example, one can measure the period (in TIMx_CCR1 register) and the duty cycle (in TIMx_CCR2 register) of the PWM applied on TI1 using the following procedure (depending on CK_INT frequency and prescaler value):

- Select the active input for TIMx_CCR1: write the CC1S bits to 01 in the TIMx_CCMR1 register (TI1 selected).
- Select the active polarity for TI1FP1 (used both for capture in TIMx_CCR1 and counter clear): write the CC1P to ‘0’ and the CC1NP bit to ‘0’ (active on rising edge).
- Select the active input for TIMx_CCR2: write the CC2S bits to 10 in the TIMx_CCMR1 register (TI1 selected).
- Select the active polarity for TI1FP2 (used for capture in TIMx_CCR2): write the CC2P bit to ‘1’ and the CC2NP bit to ‘0’ (active on falling edge).
- Select the valid trigger input: write the TS bits to 101 in the TIMx_SMCR register (TI1FP1 selected).
- Configure the slave mode controller in reset mode: write the SMS bits to 100 in the TIMx_SMCR register.
- Enable the captures: write the CC1E and CC2E bits to ‘1’ in the TIMx_CCER register.

For code example refer to the Appendix section A.9.5: PWM input configuration code example.

![Figure 139. PWM input mode timing](image-url)
18.3.7 Forced output mode

In output mode (CCxS bits = 00 in the TIMx_CCMRx register), each output compare signal (OCxREF and then OCx) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (ocxref/OCx) to its active level, one just needs to write 101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus ocxref is forced high (OCxREF is always active high) and OCx get opposite value to CCxP polarity bit.

e.g.: CCxP=0 (OCx active high) => OCx is forced to high level.

ocxref signal can be forced low by writing the OCxM bits to 100 in the TIMx_CCMRx register.

Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the Output Compare Mode section.

18.3.8 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP bit in the TIMx_CCER register). The output pin can keep its level (OCXM=000), be set active (OCXM=001), be set inactive (OCXM=010) or can toggle (OCXM=011) on match.
- Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCxIE bit in the TIMx_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx_DIER register, CCDS bit in the TIMx_CR2 register for the DMA request selection).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on ocxref and OCx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

Procedure:
1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE and/or CCxDE bits if an interrupt and/or a DMA request is to be generated.
4. Select the output mode. For example, one must write OCxM=011, OCxPE=0, CCxP=0 and CCxE=1 to toggle OCx output pin when CNT matchesCCRx, CCRx preload is not used, OCx is enabled and active high.
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.
For code example refer to the Appendix section A.9.7: Output compare configuration code example.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE=0, else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in Figure 140.

**Figure 140. Output compare mode, toggle on OC1**

![Diagram showing output compare mode, toggle on OC1](MSv67583V1)

### 18.3.9 PWM mode

Pulse width modulation mode allows to generate a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per OCx output) by writing 110 (PWM mode 1) or ‘111 (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

OCx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. OCx output is enabled by the CCxE bit in the TIMx_CCER register. Refer to the TIMx_CCERx register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CCRx ≤ TIMx_CNT or TIMx_CNT ≤ TIMx_CCRx (depending on the direction of the counter). However, to comply with the OCREF_CLR functionality (OCREF can be...
cleared by an external event through the ETR signal until the next PWM period), the OCREF signal is asserted only:

- When the result of the comparison changes, or
- When the output compare mode (OCxM bits in TIMx_CCMRx register) switches from the “frozen” configuration (no comparison, OCxM=’000) to one of the PWM modes (OCxM=’110 or ‘111).

This forces the PWM by software while the timer is running.

The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIMx_CR1 register.

**PWM edge-aligned mode**

Upcounting configuration

Upcounting is active when the DIR bit in the TIMx_CR1 register is low. Refer to the Section : Upcounting mode on page 407.

In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is high as long as TIMx_CNT < TIMx_CCRx else it becomes low. If the compare value in TIMx_CCRx is greater than the auto-reload value (in TIMx_ARR) then OCxREF is held at ‘1’. If the compare value is 0 then OCxREF is held at ‘0’. Figure 141 shows some edge-aligned PWM waveforms in an example where TIMx_ARR=8.

For code example refer to the Appendix section A.9.9: Center-aligned PWM configuration example.

**Downcounting configuration**

Downcounting is active when DIR bit in TIMx_CR1 register is high. Refer to *Downcounting mode on page 411*

In PWM mode 1, the reference signal ocxref is low as long as TIMx_CNT>TIMx_CCRx else it becomes high. If the compare value in TIMx_CCRx is greater than the auto-reload value in TIMx_ARR, then ocxref is held at ‘1. 0% PWM is not possible in this mode.

**PWM center-aligned mode**

Center-aligned mode is active when the CMS bits in TIMx_CR1 register are different from ‘00 (all the remaining configurations having the same effect on the ocxref/OCx signals). The compare flag is set when the counter counts up, when it counts down or both when it counts up and down depending on the CMS bits configuration. The direction bit (DIR) in the TIMx_CR1 register is updated by hardware and must not be changed by software. Refer to the *Center-aligned mode (up/down counting) on page 414.*

*Figure 142* shows some center-aligned PWM waveforms in an example where:

- TIMx_ARR=8,
- PWM mode is the PWM mode 1,
- The flag is set when the counter counts down corresponding to the center-aligned mode 1 selected for CMS=01 in TIMx_CR1 register.
Hints on using center-aligned mode:

- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit in the TIMx_CR1 register. Moreover, the DIR and CMS bits must not be changed at the same time by the software.

- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:
  - The direction is not updated if a value greater than the auto-reload value is written in the counter (TIMx_CNT>TIMx_ARR). For example, if the counter was counting up, it continues to count up.
  - The direction is updated if 0 or the TIMx_ARR value is written in the counter but no Update Event UEV is generated.

- The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIMx_EGR register) just before starting the counter and not to write the counter while it is running.
18.3.10 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:
- In upcounting: $CNT<CCRx \leq ARR$ (in particular, $0<CCRx$),
- In downcounting: $CNT>CCRx$.

Figure 143. Example of one-pulse mode

For example one may want to generate a positive pulse on OC1 with a length of $t_{PULSE}$ and after a delay of $t_{DELAY}$ as soon as a positive edge is detected on the TI2 input pin.

Use TI2FP2 as trigger 1:
- Map TI2FP2 on TI2 by writing CC2S=01 in the TIMx_CCMR1 register.
- TI2FP2 must detect a rising edge, write CC2P=0 and CC2NP='0' in the TIMx_CCER register.
- Configure TI2FP2 as trigger for the slave mode controller (TRGI) by writing TS=110 in the TIMx_SMCR register.
- TI2FP2 is used to start the counter by writing SMS to ‘110 in the TIMx_SMCR register (trigger mode).
The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The \( t_{\text{DELAY}} \) is defined by the value written in the TIMx_CCR1 register.
- The \( t_{\text{PULSE}} \) is defined by the difference between the auto-reload value and the compare value (\( \text{TIMx\_ARR} - \text{TIMx\_CCR1} + 1 \)).
- Let's say one wants to build a waveform with a transition from '0 to '1 when a compare match occurs and a transition from '1 to '0 when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing OC1M=111 in the TIMx_CCMR1 register. Optionally the preload registers can be enabled by writing OC1PE=1 in the TIMx_CCMR1 register and ARPE in the TIMx_CR1 register. In this case one has to write the compare value in the TIMx_CCR1 register, the auto-reload value in the TIMx_ARR register, generate an update by setting the UG bit and wait for external trigger event on TI2. CC1P is written to '0 in this example.

In our example, the DIR and CMS bits in the TIMx_CR1 register should be low.

For code example refer to the Appendix section A.9.16: One-Pulse mode code example.

Since only 1 pulse (Single mode) is needed, a 1 must be written in the OPM bit in the TIMx_CCMR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0). When OPM bit in the TIMx_CR1 register is set to '0', so the Repetitive Mode is selected.

**Particular case: OCx fast enable**

In One-pulse mode, the edge detection on TiRx input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay \( t_{\text{DELAY}} \) min we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx_CCMRx register. Then OCxRef (and OCx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

For code example refer to the part of code, conditioned by PULSE_WITHOUT_DELAY > 0 in the Appendix section A.9.16: One-Pulse mode code example.

### 18.3.11 Clearing the OCxREF signal on an external event

1. The external trigger prescaler should be kept off: bits ETPS[1:0] in the TIMx_SMCR register are cleared to 00.
2. The external clock mode 2 must be disabled: bit ECE in the TIM1_SMCR register is cleared to 0.
3. The external trigger polarity (ETP) and the external trigger filter (ETF) can be configured according to the application's needs.

For code example refer to the Appendix section A.9.10: ETR configuration to clear OCxREF code example.

*Figure 144* shows the behavior of the OCxREF signal when the ETRF input becomes high, for both values of the OCxCE enable bit. In this example, the timer TIMx is programmed in PWM mode.
18.3.12 Encoder interface mode

To select Encoder Interface mode write SMS='001 in the TIMx_SMCR register if the counter is counting on T12 edges only, SMS=010 if it is counting on T11 edges only and SMS=011 if it is counting on both T11 and T12 edges.

Select the T11 and T12 polarity by programming the CC1P and CC2P bits in the TIMx_CCER register. CC1NP and CC2NP must be kept cleared. When needed, the input filter can be programmed as well.

The two inputs T11 and T12 are used to interface to an incremental encoder. Refer to Table 65. The counter is clocked by each valid transition on T11FP1 or T12FP2 (T11 and T12 after input filter and polarity selection, T11FP1=T11 if not filtered and not inverted, T12FP2=T12 if not filtered and not inverted) assuming that it is enabled (CEN bit in TIMx_CR1 register written to ‘1). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the TIMx_CR1 register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (T11 or T12), whatever the counter is counting on T11 only, T12 only or both T11 and T12.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value in the TIMx_ARR register (0 to ARR or ARR down to 0 depending on the direction). So the TIMx_ARR must be configured before starting. In the same way, the capture, compare, prescaler, trigger output features continue to work as normal.

In this mode, the counter is modified automatically following the speed and the direction of the incremental encoder and its content, therefore, always represents the encoder’s
position. The count direction correspond to the rotation direction of the connected sensor. The table summarizes the possible combinations, assuming TI1 and TI2 do not switch at the same time.

<table>

</tbody>
</table>

An external incremental encoder can be connected directly to the MCU without external interface logic. However, comparators are normally be used to convert the encoder’s differential outputs to digital signals. This greatly increases noise immunity. The third encoder output which indicate the mechanical zero position, may be connected to an external interrupt input and trigger a counter reset.

Figure 145 gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points. For this example we assume that the configuration is the following:

- CC1S= 01 (TIMx_CCMR1 register, TI1FP1 mapped on TI1)
- CC2S= 01 (TIMx_CCMR2 register, TI2FP2 mapped on TI2)
- CC1P=0, CC1NP = ‘0’ (TIMx_CCER register, TI1FP1 noninverted, TI1FP1=TI1)
- CC2P=0, CC2NP = ‘0’ (TIMx_CCER register, TI2FP2 noninverted, TI2FP2=TI2)
- SMS= 011 (TIMx_SMCR register, both inputs are active on both rising and falling edges)
- CEN= 1 (TIMx_CR1 register, Counter is enabled)

For code example refer to the Appendix section A.9.10: ETR configuration to clear OCxREF code example.
The timer, when configured in Encoder Interface mode provides information on the sensor’s current position. Dynamic information can be obtained (speed, acceleration, deceleration) by measuring the period between two encoder events using a second timer configured in capture mode. The output of the encoder which indicates the mechanical zero can be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. This can be done by latching the counter value into a third input capture register if available (then the capture signal must be periodic and can be generated by another timer). When available, it is also possible to read its value through a DMA request generated by a Real-Time clock.

18.3.13 Timer input XOR function

The TI1S bit in the TIM1_CR2 register, allows the input filter of channel 1 to be connected to the output of a XOR gate, combining the three input pins TIMx_CH1 to TIMx_CH3.

The XOR output can be used with all the timer input functions such as trigger or input capture.
An example of this feature used to interface Hall sensors is given in Section 17.3.18 on page 369.

18.3.14 Timers and external trigger synchronization

The TIMx Timers can be synchronized with an external trigger in several modes: Reset mode, Gated mode and Trigger mode.

Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on TI1 input:

- Configure the channel 1 to detect rising edges on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the TIMx_CCMR1 register. Write CC1P=0 and CC1NP=0 in TIMx_CCRER register to validate the polarity (and detect rising edges only).

- Configure the timer in reset mode by writing SMS=100 in TIMx_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx_SMCR register.

- Start the counter by writing CEN=1 in the TIMx_CR1 register.

For code example refer to the Appendix section A.9.12: Reset mode code example.

The counter starts counting on the internal clock, then behaves normally until TI1 rising edge. When TI1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIMx_DIER register).

The following figure shows this behavior when the auto-reload register TIMx_ARR=0x36. The delay between the rising edge on TI1 and the actual reset of the counter is due to the resynchronization circuit on TI1 input.

![Figure 147. Control circuit in reset mode](image_url)
Slave mode: Gated mode

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when TI1 input is low:

- Configure the channel 1 to detect low levels on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S=01 in TIMx_CCMR1 register. Write CC1P=1 and CC1NP=0 in TIMx_CCER register to validate the polarity (and detect low level only).
- Configure the timer in gated mode by writing SMS=101 in TIMx_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx_SMCR register.
- Enable the counter by writing CEN=1 in the TIMx_CR1 register (in gated mode, the counter doesn’t start if CEN=0, whatever is the trigger input level).

For code example refer to the Appendix section A.9.13: Gated mode code example.

The counter starts counting on the internal clock as long as TI1 is low and stops as soon as TI1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on TI1 and the actual stop of the counter is due to the resynchronization circuit on TI1 input.

For code example refer to the Appendix section A.9.13: Gated mode code example.

Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on TI2 input:

- Configure the channel 2 to detect rising edges on TI2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. CC2S bits are selecting the input capture source only, CC2S=01 in TIMx_CCMR1 register. Write
CC2P=1 and CC2NP=0 in TIMx_CCER register to validate the polarity (and detect low level only).

- Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select TI2 as the input source by writing TS=110 in TIMx_SMCR register.

For code example refer to the Appendix section A.9.14: Trigger mode code example.

When a rising edge occurs on TI2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on TI2 and the actual start of the counter is due to the resynchronization circuit on TI2 input.

**Figure 149. Control circuit in trigger mode**

Slave mode: External Clock mode 2 + trigger mode

The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the ETR signal is used as external clock input, and another input can be selected as trigger input when operating in reset mode, gated mode or trigger mode. It is recommended not to select ETR as TRGI through the TS bits of TIMx_SMCR register.

In the following example, the upcounter is incremented at each rising edge of the ETR signal as soon as a rising edge of TI1 occurs:
1. Configure the external trigger input circuit by programming the TIMx_SMCR register as follows:
   - ETF = 0000: no filter
   - ETPS=00: prescaler disabled
   - ETP=0: detection of rising edges on ETR and ECE=1 to enable the external clock mode 2.
2. Configure the channel 1 as follows, to detect rising edges on TI:
   - IC1F=0000: no filter.
   - The capture prescaler is not used for triggering and does not need to be configured.
   - CC1S=01 in TIMx_CCMR1 register to select only the input capture source
   - CC1P=0 and CC1NP=0 in TIMx_CCER register to validate the polarity (and detect rising edge only).
3. Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx_SMCR register.

For code example refer to the Appendix section A.9.15: External clock mode 2 + trigger mode code example.

A rising edge on TI1 enables the counter and sets the TIF flag. The counter then counts on ETR rising edges.

The delay between the rising edge of the ETR signal and the actual reset of the counter is due to the resynchronization circuit on ETRP input.

Figure 150. Control circuit in external clock mode 2 + trigger mode

18.3.15 Timer synchronization

The TIMx timers are linked together internally for timer synchronization or chaining. When one Timer is configured in Master Mode, it can reset, start, stop or clock the counter of another Timer configured in Slave Mode.
Figure 151: Master/Slave timer example presents an overview of the trigger selection and the master mode selection blocks.

Using one timer as prescaler for another

**Figure 151. Master/Slave timer example**

For example, Timer 1 can be configured to act as a prescaler for Timer 2. Refer to Figure 151. To do this:

- Configure Timer 1 in master mode so that it outputs a periodic trigger signal on each update event UEV. If MMS=010 is written in the TIM1_CR2 register, a rising edge is output on TRGO1 each time an update event is generated.
- To connect the TRGO1 output of Timer 1 to Timer 2, Timer 2 must be configured in slave mode using ITR1 as internal trigger. This is selected through the TS bits in the TIM2_SMCR register (writing TS=000).
- Then the Timer2's slave mode controller should be configured in external clock mode 1 (write SMS=111 in the TIM2_SMCR register). This causes Timer 2 to be clocked by the rising edge of the periodic Timer 1 trigger signal (which correspond to the timer 1 counter overflow).
- Finally both timers must be enabled by setting their respective CEN bits within their respective TIMx_CR1 registers. Make sure to enable Timer2 before enabling Timer1.

For code example refer to the Appendix section A.9.17: Timer prescaling another timer code example.

Note: If OCx is selected on Timer 1 as trigger output (MMS=1xx), its rising edge is used to clock the counter of timer 2.
Using one timer to enable another timer

In this example, we control the enable of Timer 2 with the output compare 1 of Timer 1. Refer to Figure 151 for connections. Timer 2 counts on the divided internal clock only when OC1REF of Timer 1 is high. Both counter clock frequencies are divided by 3 by the prescaler compared to CK_INT (f_{CK_CNT} = f_{CK_INT}/3).

- Configure Timer 1 master mode to enable the slave timer (MMS=001 in the TIM1_CR2 register).
- Configure the Timer 1 OC1REF waveform (TIM1_CCMR1 register).
- Configure Timer 2 to get the input trigger from Timer 1 (TS=000 in the TIM2_SMCR register).
- Configure Timer 2 in gated mode (SMS=101 in TIM2_SMCR register).
- Enable Timer 2 by writing '1 in the CEN bit (TIM2_CR1 register).
- Start Timer 1 by writing '1 in the CEN bit (TIM1_CR1 register).

For code example refer to the Appendix section A.9.18: Timer enabling another timer code example.

Note: The counter 2 clock is not synchronized with counter 1, this mode only affects the Timer 2 counter enable signal.

Figure 152. Gating timer 2 with OC1REF of timer 1

In the example in Figure 152, the Timer 2 counter and prescaler are not initialized before being started. So they start counting from their current value. It is possible to start from a given value by resetting both timers before starting Timer 1. Then any value can be written in the timer counters. The timers can easily be reset by software using the UG bit in the TIMx_EGR registers.

In the next example, we synchronize Timer 1 and Timer 2. Timer 1 is the master and starts from 0. Timer 2 is the slave and starts from 0xE7. The prescaler ratio is the same for both
General-purpose timers (TIM2 and TIM3)

Timers. Timer 2 stops when Timer 1 is disabled by writing ‘0’ to the CEN bit in the TIM1_CR1 register:

- Configure Timer 1 master mode to send its Counter Enable signal (CNT_EN) as a trigger output (MMS=001 in the TIM1_CR2 register).
- Configure the Timer 1 OC1REF waveform (TIM1_CCMR1 register).
- Configure Timer 2 to get the input trigger from Timer 1 (TS=000 in the TIM2_SMCR register).
- Configure Timer 2 in gated mode (SMS=101 in TIM2_SMCR register).
- Reset Timer 1 by writing ‘1’ in UG bit (TIM1_EGR register).
- Reset Timer 2 by writing ‘1’ in UG bit (TIM2_EGR register).
- Initialize Timer 2 to 0xE7 by writing ‘0xE7’ in the timer 2 counter (TIM2_CNT).
- Enable Timer 2 by writing ‘1’ in the CEN bit (TIM2_CR1 register).
- Start Timer 1 by writing ‘1’ in the CEN bit (TIM1_CR1 register).
- Stop Timer 1 by writing ‘0’ in the CEN bit (TIM1_CR1 register).

For code example refer to the Appendix section A.9.19: Master and slave synchronization code example.

Figure 153. Gating timer 2 with Enable of timer 1
Using one timer to start another timer

In this example, we set the enable of Timer 2 with the update event of Timer 1. Refer to Figure 151 for connections. Timer 2 starts counting from its current value (which can be nonzero) on the divided internal clock as soon as the update event is generated by Timer 1. When Timer 2 receives the trigger signal its CEN bit is automatically set and the counter counts until we write ‘0 to the CEN bit in the TIM2_CR1 register. Both counter clock frequencies are divided by 3 by the prescaler compared to CK_INT (f_{CK_CNT} = f_{CK_INT}/3).

- Configure Timer 1 master mode to send its Update Event (UEV) as trigger output (MMS=010 in the TIM1_CR2 register).
- Configure the Timer 1 period (TIM1_ARR registers).
- Configure Timer 2 to get the input trigger from Timer 1 (TS=000 in the TIM2_SMCR register).
- Configure Timer 2 in trigger mode (SMS=110 in TIM2_SMCR register).
- Start Timer 1 by writing ‘1 in the CEN bit (TIM1_CR1 register).

Figure 154. Triggering timer 2 with update of timer 1

As in the previous example, both counters can be initialized before starting counting. Figure 155 shows the behavior with the same configuration as in Figure 154 but in trigger mode instead of gated mode (SMS=110 in the TIM2_SMCR register).
Starting 2 timers synchronously in response to an external trigger

In this example, we set the enable of timer 1 when its TI1 input rises, and the enable of Timer 2 with the enable of Timer 1. Refer to Figure 151 for connections. To ensure the counters are aligned, Timer 1 must be configured in Master/Slave mode (slave with respect to TI1, master with respect to Timer 2):

- Configure Timer 1 master mode to send its Enable as trigger output (MMS=001 in the TIM1_CR2 register).
- Configure Timer 1 slave mode to get the input trigger from TI1 (TS=100 in the TIM1_SMCR register).
- Configure Timer 1 in trigger mode (SMS=110 in the TIM1_SMCR register).
- Configure the Timer 1 in Master/Slave mode by writing MSM=1 (TIM1_SMCR register).
- Configure Timer 2 to get the input trigger from Timer 1 (TS=000 in the TIM2_SMCR register).
- Configure Timer 2 in trigger mode (SMS=110 in the TIM2_SMCR register).

For code example refer to the Appendix section A.9.20: Two timers synchronized by an external trigger code example.

When a rising edge occurs on TI1 (Timer 1), both counters starts counting synchronously on the internal clock and both TIF flags are set.

Note: In this example both timers are initialized before starting (by setting their respective UG bits). Both counters starts from 0, but an offset can easily be inserted between them by writing any of the counter registers (TIMx_CNT). One can see that the master/slave mode insert a delay between CNT_EN and CK_PSC on timer 1.
18.3.16 Debug mode

When the microcontroller enters debug mode (Arm® Cortex®-M0 core - halted), the TIMx counter either continues to work normally or stops, depending on DBG_TIMx_STOP configuration bit in DBGMCU module.
18.4 TIM2 and TIM3 registers

Refer to Section 1.2 on page 42 for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

18.4.1 TIM2 and TIM3 control register 1 (TIM2_CR1 and TIM3_CR1)

Address offset: 0x00

Reset value: 0x0000

| Bit 15-10 | Reserved, must be kept at reset value. |
| Bit 9-8   | CKD: Clock division |
|           | This bit-field indicates the division ratio between the timer clock (CK_INT) frequency and sampling clock used by the digital filters (ETR, TIx), |
|           | 00: tDTS = tCK_INT |
|           | 01: tDTS = 2 × tCK_INT |
|           | 10: tDTS = 4 × tCK_INT |
|           | 11: Reserved |
| Bit 7     | ARPE: Auto-reload preload enable |
|           | 0: TIMx_ARR register is not buffered |
|           | 1: TIMx_ARR register is buffered |
| Bits 6-5  | CMS[1:0]: Center-aligned mode selection |
| 00: Edge-aligned mode. The counter counts up or down depending on the direction bit (DIR). |
| 01: Center-aligned mode 1. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set only when the counter is counting down. |
| 10: Center-aligned mode 2. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set only when the counter is counting up. |
| 11: Center-aligned mode 3. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS=00 in TIMx_CCMRx register) are set both when the counter is counting up or down. |
| Note: It is not allowed to switch from edge-aligned mode to center-aligned mode as long as the counter is enabled (CEN=1) |
| Bit 4     | DIR: Direction |
| 0: Counter used as upcounter |
| 1: Counter used as downcounter |
| Note: This bit is read only when the timer is configured in Center-aligned mode or Encoder mode. |
| Bit 3     | OPM: One-pulse mode |
| 0: Counter is not stopped at update event |
| 1: Counter stops counting at the next update event (clearing the bit CEN) |
Bit 2 **URS:** Update request source

This bit is set and cleared by software to select the UEV event sources.

- 0: Any of the following events generate an update interrupt or DMA request if enabled. These events can be:
  - Counter overflow/underflow
  - Setting the UG bit
  - Update generation through the slave mode controller
- 1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1 **UDIS:** Update disable

This bit is set and cleared by software to enable/disable UEV event generation.

- 0: UEV enabled. The Update (UEV) event is generated by one of the following events:
  - Counter overflow/underflow
  - Setting the UG bit
  - Update generation through the slave mode controller

Buffered registers are then loaded with their preload values.

- 1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN:** Counter enable

- 0: Counter disabled
- 1: Counter enabled

*Note:* External clock, gated mode and encoder mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.

CEN is cleared automatically in one-pulse mode, when an update event occurs.
18.4.2 TIM2 and TIM3 control register 2 (TIM2_CR2 and TIM3_CR2)

Address offset: 0x04
Reset value: 0x0000

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **TI1S**: TI1 selection

0: The TIMx_CH1 pin is connected to TI1 input
1: The TIMx_CH1, CH2 and CH3 pins are connected to the TI1 input (XOR combination)

See also Section 17.3.18: Interfacing with Hall sensors on page 369

Bits 6:4 **MMS**: Master mode selection

These bits allow to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows:

000: **Reset** - the UG bit from the TIMx_EGR register is used as trigger output (TRGO). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on TRGO is delayed compared to the actual reset.

001: **Enable** - the Counter enable signal, CNT_EN, is used as trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic OR between CEN control bit and the trigger input when configured in gated mode.

When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO, except if the master/slave mode is selected (see the MSM bit description in TIMx_SMCR register).

010: **Update** - The update event is selected as trigger output (TRGO). For instance a master timer can then be used as a prescaler for a slave timer.

011: **Compare Pulse** - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred. (TRGO)

100: **Compare** - OC1REF signal is used as trigger output (TRGO)

101: **Compare** - OC2REF signal is used as trigger output (TRGO)

110: **Compare** - OC3REF signal is used as trigger output (TRGO)

111: **Compare** - OC4REF signal is used as trigger output (TRGO)

Bit 3 **CCDS**: Capture/compare DMA selection

0: CCx DMA request sent when CCx event occurs
1: CCx DMA requests sent when update event occurs

Bits 2:0 Reserved, must be kept at reset value.
18.4.3 TIM2 and TIM3 slave mode control register (TIM2_SMCR and TIM3_SMCR)

</table>
Bits 11:8 **ETF[3:0]:** External trigger filter

This bit-field defines the frequency used to sample ETRP signal and the length of the digital filter applied to ETRP. The digital filter is made of an event counter in which \( N \) consecutive events are needed to validate a transition on the output:

- 0000: No filter, sampling is done at \( f_{\text{DTS}} \)
- 0001: \( f_{\text{SAMPLING}} = f_{\text{ CK_INT}}, \; N = 2 \)
- 0010: \( f_{\text{SAMPLING}} = f_{\text{ CK_INT}}, \; N = 4 \)
- 0011: \( f_{\text{SAMPLING}} = f_{\text{ CK_INT}}, \; N = 8 \)
- 0100: \( f_{\text{SAMPLING}} = f_{\text{ DTS}} / 2, \; N = 6 \)
- 0101: \( f_{\text{SAMPLING}} = f_{\text{ DTS}} / 2, \; N = 8 \)
- 0110: \( f_{\text{SAMPLING}} = f_{\text{ DTS}} / 4, \; N = 6 \)
- 0111: \( f_{\text{SAMPLING}} = f_{\text{ DTS}} / 4, \; N = 8 \)
- 1000: \( f_{\text{SAMPLING}} = f_{\text{ DTS}} / 8, \; N = 6 \)
- 1001: \( f_{\text{SAMPLING}} = f_{\text{ DTS}} / 8, \; N = 8 \)
- 1010: \( f_{\text{SAMPLING}} = f_{\text{ DTS}} / 16, \; N = 5 \)
- 1011: \( f_{\text{SAMPLING}} = f_{\text{ DTS}} / 16, \; N = 6 \)
- 1100: \( f_{\text{SAMPLING}} = f_{\text{ DTS}} / 32, \; N = 5 \)
- 1101: \( f_{\text{SAMPLING}} = f_{\text{ DTS}} / 32, \; N = 6 \)
- 1110: \( f_{\text{SAMPLING}} = f_{\text{ DTS}} / 32, \; N = 8 \)

*Note:* Care must be taken that \( f_{\text{ DTS}} \) is replaced in the formula by \( f_{\text{ CK_INT}} \) when ETF[3:0] = 1, 2 or 3.

Bit 7 **MSM:** Master/Slave mode

- 0: No action
- 1: The effect of an event on the trigger input (TRGI) is delayed to allow a perfect synchronization between the current timer and its slaves (through TRGO). It is useful if we want to synchronize several timers on a single external event.

Bits 6:4 **TS:** Trigger selection

This bit-field selects the trigger input to be used to synchronize the counter.

- 000: Internal Trigger 0 (ITR0).
- 001: Internal Trigger 1 (ITR1).
- 010: Internal Trigger 2 (ITR2).
- 011: Internal Trigger 3 (ITR3).
- 100: TI1 Edge Detector (TI1F_ED)
- 101: Filtered Timer Input 1 (TI1FP1)
- 110: Filtered Timer Input 2 (TI2FP2)
- 111: External Trigger input (ETRF)

See Table 66: TIM2 and TIM3 internal trigger connection on page 451 for more details on ITRx meaning for each Timer.

*Note:* These bits must be changed only when they are not used (e.g. when SMS=000) to avoid wrong edge detections at the transition.

Bit 3 **OCCS:** OCREF clear selection.

This bit is used to select the OCREF clear source.

- 0: OCREF CLR_INT is connected to the OCREF CLR input
- 1: OCREF CLR_INT is connected to ETRF
Bits 2:0  **SMS**: Slave mode selection

When external signals are selected the active edge of the trigger signal (TRGI) is linked to the polarity selected on the external input (see Input Control register and Control Register description.

000: Slave mode disabled - if CEN = ‘1 then the prescaler is clocked directly by the internal clock.
001: Encoder mode 1 - Counter counts up/down on TI1FP1 edge depending on TI2FP2 level.
010: Encoder mode 2 - Counter counts up/down on TI2FP2 edge depending on TI1FP1 level.
011: Encoder mode 3 - Counter counts up/down on both TI1FP1 and TI2FP2 edges depending on the level of the other input.
100: Reset Mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter and generates an update of the registers.
101: Gated Mode - The counter clock is enabled when the trigger input (TRGI) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.
110: Trigger Mode - The counter starts at a rising edge of the trigger TRGI (but it is not reset). Only the start of the counter is controlled.
111: External Clock Mode 1 - Rising edges of the selected trigger (TRGI) clock the counter.

*Note:* The gated mode must not be used if TI1F_ED is selected as the trigger input (TS = 100). Indeed, TI1F_ED outputs 1 pulse for each transition on TI1F, whereas the gated mode checks the level of the trigger signal.

*Note:* The clock of the slave timer must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **CC4OF**: Capture/Compare 4 overcapture flag
 Refer to CC1OF description

Bit 11 **CC3OF**: Capture/Compare 3 overcapture flag
 Refer to CC1OF description

Bit 10 **CC2OF**: Capture/compare 2 overcapture flag
 Refer to CC1OF description

Bit 9 **CC1OF**: Capture/Compare 1 overcapture flag
 This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to ‘0’.
 0: No overcapture has been detected
 1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **TIF**: Trigger interrupt flag
 This flag is set by hardware on trigger event (active edge detected on TRGI input when the slave mode controller is enabled in all modes but gated mode. It is set when the counter starts or stops when gated mode is selected. It is cleared by software.
 0: No trigger event occurred
 1: Trigger interrupt pending

Bit 5 Reserved, must be kept at reset value.

Bit 4 **CC4IF**: Capture/Compare 4 interrupt flag
 Refer to CC1IF description

Bit 3 **CC3IF**: Capture/Compare 3 interrupt flag
 Refer to CC1IF description
Bit 2  **CC2IF**: Capture/Compare 2 interrupt flag  
Refer to CC1IF description

Bit 1  **CC1IF**: Capture/compare 1 interrupt flag

If channel **CC1** is configured as output:
This flag is set by hardware when the counter matches the compare value, with some exception in center-aligned mode (refer to the CMS bits in the TIMx_CR1 register description).
It is cleared by software.
0: No match  
1: The content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register.  
When the contents of TIMx_CCR1 are greater than the contents of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in upcounting and up/down-counting modes) or underflow (in downcounting mode)

If channel **CC1** is configured as input:
This bit is set by hardware on a capture. It is cleared by software or by reading the TIMx_CCR1 register.
0: No input capture occurred  
1: The counter value has been captured in TIMx_CCR1 register (An edge has been detected on IC1 which matches the selected polarity)

Bit 0  **UIF**: Update interrupt flag
This bit is set by hardware on an update event. It is cleared by software.
0: No update occurred.  
1: Update interrupt pending.
This bit is set by hardware when the registers are updated:  
At overflow or underflow and if UDIS=0 in the TIMx_CR1 register.  
When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if URS=0 and UDIS=0 in the TIMx_CR1 register.  
When CNT is reinitialized by a trigger event (refer to the synchro control register description), if URS=0 and UDIS=0 in the TIMx_CR1 register.

Bit 2 CC2G: Capture/compare 2 generation
Refer to CC1G description

Bit 1 CC1G: Capture/compare 1 generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action
1: A capture/compare event is generated on channel 1:
   if channel CC1 is configured as output:
   CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled.
   if channel CC1 is configured as input:
   The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 UG: Update generation
This bit can be set by software, it is automatically cleared by hardware.

0: No action
1: Re-initialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected). The counter is cleared if the center-aligned mode is selected or if DIR=0 (upcounting), else it takes the auto-reload value (TIMx_ARR) if DIR=1 (downcounting).
18.4.7 TIM2 and TIM3 capture/compare mode register 1 (TIM2_CCMR1 and TIM3_CCMR1)

Address offset: 0x18
Reset value: 0x0000

The channels can be used in input (capture mode) or in output (compare mode). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode. For a given bit, OCxx describes its function when the channel is configured in output, ICxx describes its function when the channel is configured in input. So one must take care that the same bit can have a different meaning for the input stage and for the output stage.

```
| Bit 15  | OC2CE: Output compare 2 clear enable |
| Bit 14:12 | OC2M[2:0]: Output compare 2 mode     |
| Bit 11   | OC2PE: Output compare 2 preload enable|
| Bit 10   | OC2FE: Output compare 2 fast enable  |
| Bits 9:8 | CC2S[1:0]: Capture/Compare 2 selection|
|          | This bit-field defines the direction of the channel (input/output) as well as the used input. |
|          | 00: CC2 channel is configured as output  |
|          | 01: CC2 channel is configured as input, IC2 is mapped on TI2 |
|          | 10: CC2 channel is configured as input, IC2 is mapped on TI1 |
|          | 11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if |
|          | an internal trigger input is selected through the TS bit (TIMx_SMCR register) |
|          | Note: CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCR). |
| Bit 7   | OC1CE: Output compare 1 clear enable  |
| OC1CE: Output Compare 1 Clear Enable |
| 0: OC1Ref is not affected by the ETRF input |
| 1: OC1Ref is cleared as soon as a High level is detected on ETRF input |
```
Bits 6:4 **OC1M**: Output compare 1 mode

These bits define the behavior of the output reference signal OC1REF from which OC1 and OC1N are derived. OC1REF is active high whereas OC1 and OC1N active level depends on CC1P and CC1NP bits.

- 000: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs (this mode is used to generate a timing base).
- 001: Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).
- 010: Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).
- 011: Toggle - OC1REF toggles when TIMx_CNT=TIMx_CCR1.
- 100: Force inactive level - OC1REF is forced low.
- 101: Force active level - OC1REF is forced high.
- 110: PWM mode 1 - In upcounting, channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else inactive. In downcounting, channel 1 is inactive (OC1REF='0) as long as TIMx_CNT>TIMx_CCR1 else active (OC1REF=1).
- 111: PWM mode 2 - In upcounting, channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else active. In downcounting, channel 1 is active as long as TIMx_CNT>TIMx_CCR1 else inactive.

**Note:**
1: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S=00 (the channel is configured in output).
2: In PWM mode 1 or 2, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.

Bit 3 **OC1PE**: Output compare 1 preload enable

- 0: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken in account immediately.
- 1: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded in the active register at each update event.

**Note:** These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S=00 (the channel is configured in output).

Bit 2 **OC1FE**: Output compare 1 fast enable

This bit is used to accelerate the effect of an event on the trigger in input on the CC output.

- 0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.
- 1: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

- 00: CC1 channel is configured as output.
- 01: CC1 channel is configured as input, IC1 is mapped on TI1.
- 10: CC1 channel is configured as input, IC1 is mapped on TI2.
- 11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

**Note:** CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx_CCER).

Input capture mode
Bits 15:12 **IC2F**: Input capture 2 filter

Bits 11:10 **IC2PSC[1:0]**: Input capture 2 prescaler

**Bits 9:8** **CC2S**: Capture/compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.
- 00: CC2 channel is configured as output.
- 01: CC2 channel is configured as input, IC2 is mapped on TI2.
- 10: CC2 channel is configured as input, IC2 is mapped on TI1.
- 11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register).

**Note:** **CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIMx_CCER).**

**Bits 7:4** **IC1F**: Input capture 1 filter

This bit-field defines the frequency used to sample TI1 input and the length of the digital filter applied to TI1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

- 0000: No filter, sampling is done at f_{DTS}
- 0001: f_{SAMPLING} = f_{CK_INT}, N = 2
- 0010: f_{SAMPLING} = f_{CK_INT}, N = 4
- 0011: f_{SAMPLING} = f_{CK_INT}, N = 8
- 0100: f_{SAMPLING} = f_{DTS} / 2, N = 6
- 0101: f_{SAMPLING} = f_{DTS} / 2, N = 8
- 0110: f_{SAMPLING} = f_{DTS} / 4, N = 6
- 0111: f_{SAMPLING} = f_{DTS} / 4, N = 8
- 1000: f_{SAMPLING} = f_{DTS} / 8, N = 6
- 1001: f_{SAMPLING} = f_{DTS} / 8, N = 8
- 1010: f_{SAMPLING} = f_{DTS} / 16, N = 5
- 1011: f_{SAMPLING} = f_{DTS} / 16, N = 6
- 1100: f_{SAMPLING} = f_{DTS} / 16, N = 8
- 1101: f_{SAMPLING} = f_{DTS} / 32, N = 5
- 1110: f_{SAMPLING} = f_{DTS} / 32, N = 6
- 1111: f_{SAMPLING} = f_{DTS} / 32, N = 8

**Note:** Care must be taken that f_{DTS} is replaced in the formula by CK_INT when ICxF[3:0] = 1, 2 or 3.

**Bits 3:2** **IC1PSC**: Input capture 1 prescaler

This bit-field defines the ratio of the prescaler acting on CC1 input (IC1).
The prescaler is reset as soon as CC1E=0 (TIMx_CCER register).
- 00: no prescaler, capture is done each time an edge is detected on the capture input
- 01: capture is done once every 2 events
- 10: capture is done once every 4 events
- 11: capture is done once every 8 events

**Bits 1:0** **CC1S**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.
- 00: CC1 channel is configured as output
- 01: CC1 channel is configured as input, IC1 is mapped on TI1
- 10: CC1 channel is configured as input, IC1 is mapped on TI2
- 11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

**Note:** **CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx_CCER).**
18.4.8 TIM2 and TIM3 capture/compare mode register 2 (TIM2_CCMR2 and TIM3_CCMR2)

Address offset: 0x1C
Reset value: 0x0000

Refer to the above CCMR1 register description.

**Output compare mode**

- **Bit 15 OC4CE**: Output compare 4 clear enable
- **Bits 14:12 OC4M**: Output compare 4 mode
  - Bit 11 **OC4PE**: Output compare 4 preload enable
  - Bit 10 **OC4FE**: Output compare 4 fast enable
- **Bits 9:8 CC4S**: Capture/Compare 4 selection
  - This bit-field defines the direction of the channel (input/output) as well as the used input.
  - 00: CC4 channel is configured as output
  - 01: CC4 channel is configured as input, IC4 is mapped on TI4
  - 10: CC4 channel is configured as input, IC4 is mapped on TI3
  - 11: CC4 channel is configured as input, IC4 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register).
  - **Note**: CC4S bits are writable only when the channel is OFF (CC4E = 0 in TIMx_CCR).  

- **Bit 7 OC3CE**: Output compare 3 clear enable
- **Bits 6:4 OC3M**: Output compare 3 mode
  - Bit 3 **OC3PE**: Output compare 3 preload enable
  - Bit 2 **OC3FE**: Output compare 3 fast enable
- **Bits 1:0 CC3S**: Capture/Compare 3 selection
  - This bit-field defines the direction of the channel (input/output) as well as the used input.
  - 00: CC3 channel is configured as output
  - 01: CC3 channel is configured as input, IC3 is mapped on TI3
  - 10: CC3 channel is configured as input, IC3 is mapped on TI4
  - 11: CC3 channel is configured as input, IC3 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register).
  - **Note**: CC3S bits are writable only when the channel is OFF (CC3E = 0 in TIMx_CCR).
Input capture mode

Bits 15:12  **IC4F**: Input capture 4 filter

Bits 11:10  **IC4PSC**: Input capture 4 prescaler

Bits 9:8  **CC4S**: Capture/Compare 4 selection
This bit-field defines the direction of the channel (input/output) as well as the used input.
00: CC4 channel is configured as output
01: CC4 channel is configured as input, IC4 is mapped on TI4
10: CC4 channel is configured as input, IC4 is mapped on TI3
11: CC4 channel is configured as input, IC4 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

*Note: CC4S bits are writable only when the channel is OFF (CC4E = 0 in TIMx_CCER).*

Bits 7:4  **IC3F**: Input capture 3 filter

Bits 3:2  **IC3PSC**: Input capture 3 prescaler

Bits 1:0  **CC3S**: Capture/Compare 3 selection
This bit-field defines the direction of the channel (input/output) as well as the used input.
00: CC3 channel is configured as output
01: CC3 channel is configured as input, IC3 is mapped on TI3
10: CC3 channel is configured as input, IC3 is mapped on TI4
11: CC3 channel is configured as input, IC3 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

*Note: CC3S bits are writable only when the channel is OFF (CC3E = 0 in TIMx_CCER).*

### 18.4.9 TIM2 and TIM3 capture/compare enable register (TIM2_CCER and TIM3_CCER)

Address offset: 0x20
Reset value: 0x0000

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| rw | rw | rw | rw | rw | rw | rw | rw |

Bit 15  **CC4NP**: Capture/Compare 4 output Polarity.
Refer to CC1NP description

Bit 14  Reserved, must be kept at reset value.

Bit 13  **CC4P**: Capture/Compare 4 output Polarity.
Refer to CC1P description

Bit 12  **CC4E**: Capture/Compare 4 output enable.
Refer to CC1P description

Bit 11  **CC3NP**: Capture/Compare 3 output Polarity.
Refer to CC1NP description

Bit 10  Reserved, must be kept at reset value.

Bit 9  **CC3P**: Capture/Compare 3 output Polarity.
Refer to CC1P description
Bit 8  **CC3E:** Capture/Compare 3 output enable.  
Refer to CC1E description

Bit 7  **CC2NP:** Capture/Compare 2 output Polarity.  
Refer to CC1NP description

Bit 6  Reserved, must be kept at reset value.

Bit 5  **CC2P:** Capture/Compare 2 output Polarity.  
Refer to CC1P description

Bit 4  **CC2E:** Capture/Compare 2 output enable.  
Refer to CC1E description

Bit 3  **CC1NP:** Capture/Compare 1 output Polarity.  
**CC1 channel configured as output:**  
CC1NP must be kept cleared in this case.  
**CC1 channel configured as input:**  
This bit is used in conjunction with CC1P to define TI1FP1/TI2FP1 polarity. refer to CC1P description.

Bit 2  Reserved, must be kept at reset value.

Bit 1  **CC1P:** Capture/Compare 1 output Polarity.  
**CC1 channel configured as output:**  
0: OC1 active high  
1: OC1 active low  
**CC1 channel configured as input:**  
CC1NP/CC1P bits select TI1FP1 and TI2FP1 polarity for trigger or capture operations.  
00: noninverted/rising edge  
Circuit is sensitive to TIxFP1 rising edge (capture, trigger in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger in gated mode, encoder mode).  
01: inverted/falling edge  
Circuit is sensitive to TIxFP1 falling edge (capture, trigger in reset, external clock or trigger mode), TIxFP1 is inverted (trigger in gated mode, encoder mode).  
10: reserved, do not use this configuration.  
11: noninverted/both edges  
Circuit is sensitive to both TIxFP1 rising and falling edges (capture, trigger in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger in gated mode). This configuration must not be used for encoder mode.

Bit 0  **CC1E:** Capture/Compare 1 output enable.  
**CC1 channel configured as output:**  
0: Off - OC1 is not active  
1: On - OC1 signal is output on the corresponding output pin  
**CC1 channel configured as input:**  
This bit determines if a capture of the counter value can actually be done into the input capture/compare register 1 (TIMx_CCR1) or not.  
0: Capture disabled  
1: Capture enabled
Table 67. Output control bit for standard OCx channels

CCR2[15:0]

Bits 31:16 **CCR2[31:16]**: High Capture/Compare 2 value (on TIM2).

Bits 15:0 **CCR2[15:0]**: Low Capture/Compare 2 value

If channel CC2 is configured as output:

CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx_CCMR2 register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on OC2 output.

If channel CC2 is configured as input:

CCR2 is the counter value transferred by the last input capture 2 event (IC2).

Bits 15:13 Reserved, must be kept at reset value.
18.4.18 TIM2 and TIM3 DMA address for full transfer (TIM2_DMAR and TIM3_DMAR)

Address offset: 0x4C
Reset value: 0x0000

<table>
<thead>
<tr>
<th>Bits 15:0 DMAB[15:0]: DMA register for burst accesses</th>
</tr>
</thead>
<tbody>
<tr>
<td>A read or write operation to the DMAR register accesses the register located at the address (TIMx_CR1 address) + (DBA + DMA index) x 4</td>
</tr>
<tr>
<td>where TIMx_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIMx_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIMx_DCR).</td>
</tr>
</tbody>
</table>
**Example of how to use the DMA burst feature**

In this example the timer DMA burst feature is used to update the contents of the CCRx registers \((x = 2, 3, 4)\) with the DMA transferring half words into the CCRx registers.

This is done in the following steps:

1. Configure the corresponding DMA channel as follows:
   - DMA channel peripheral address is the DMAR register address
   - DMA channel memory address is the address of the buffer in the RAM containing the data to be transferred by DMA into CCRx registers.
   - Number of data to transfer = 3 (See note below).
   - Circular mode disabled.
2. Configure the DCR register by configuring the DBA and DBL bit fields as follows: DBL = 3 transfers, DBA = 0xE.
3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).
4. Enable TIMx
5. Enable the DMA channel

For code example refer to the Appendix section A.9.20: Two timers synchronized by an external trigger code example.

**Note:** This example is for the case where every CCRx register to be updated once. If every CCRx register is to be updated twice for example, the number of data to transfer should be 6. Let us take the example of a buffer in the RAM containing data1, data2, data3, data4, data5 and data6. The data is transferred to the CCRx registers as follows: on the first update DMA request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is transferred to CCR3 and data6 is transferred to CCR4.
### 18.4.19 TIM2 and TIM3 register map

TIM2 and TIM3 registers are mapped as described in the table below:

Refer to Section 2.2 on page 46 for the register boundary addresses.
19 General-purpose timer (TIM14)

19.1 TIM14 introduction

The TIM14 general-purpose timer consists of a 16-bit auto-reload counter driven by a programmable prescaler.

It may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The TIM14 timer is completely independent, and does not share any resources. It can be synchronized together as described in Section 18.3.15.

19.2 TIM14 main features

• 16-bit auto-reload upcounter
• 16-bit programmable prescaler used to divide the counter clock frequency by any factor between 1 and 65535 (can be changed “on the fly”)
• independent channel for:
  – Input capture
  – Output compare
  – PWM generation (edge-aligned mode)
• Interrupt generation on the following events:
  – Update: counter overflow, counter initialization (by software)
  – Input capture
  – Output compare
19.3 TIM14 functional description

19.3.1 Time-base unit

The main block of the programmable general-purpose timer is a 16-bit upcounter with its related auto-reload register. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:
- Counter register (TIMx_CNT)
- Prescaler register (TIMx_PSC)
- Auto-reload register (TIMx_ARR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detailed for each configuration.

The counter is clocked by the prescaler output CK_CNT, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the counter starts counting 1 clock cycle after setting the CEN bit in the TIMx_CR1 register.
Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 159* and *Figure 160* give some examples of the counter behavior when the prescaler ratio is changed on the fly.

**Figure 158. Counter timing diagram with prescaler division change from 1 to 2**

**Figure 159. Counter timing diagram with prescaler division change from 1 to 4**

19.3.2 Counter operation

The counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.
Setting the UG bit in the TIMx_EGR register also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The auto-reload shadow register is updated with the preload value (TIMx_ARR),
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

**Figure 160. Counter timing diagram, internal clock divided by 1**

**Figure 161. Counter timing diagram, internal clock divided by 2**
Figure 162. Counter timing diagram, internal clock divided by 4

Figure 163. Counter timing diagram, internal clock divided by N

Figure 164. Counter timing diagram, update event when ARPE=0
(TIMx_ARR not preloaded)
19.3.3 Clock source

The counter clock is provided by the Internal clock (CK_INT) source.

The CEN (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except for UG that remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK_INT.

*Figure 166* shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

19.3.4 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).
Figure 167 to Figure 169 give an overview of one capture/compare channel.

The input stage samples the corresponding TIx input to generate a filtered signal TIxF. Then, an edge detector with polarity selection generates a signal (TIxFPx) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

The output stage generates an intermediate waveform which is then used for reference: OCxRef (active high). The polarity acts at the end of the chain.
The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

### 19.3.5 Input capture mode

In input capture mode, the Capture/Compare Registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCXIF flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to ‘0’ or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx_CCR1 when TI1 input rises. To do this, use the following procedure:

1. Select the active input: TIMx_CCR1 must be linked to the TI1 input, so write the CC1S bits to ‘01’ in the TIMx_CCMR1 register. As soon as CC1S becomes different from ‘00’, the channel is configured in input mode and the TIMx_CCR1 register becomes read-only.

2. Program the appropriate input filter duration in relation with the signal connected to the timer (when the input is one of the TIx (ICxF bits in the TIMx_CCMRx register). Let us imagine that, when toggling, the input signal is not stable during at most 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on TI1 when 8 consecutive samples with the new level have been
detected (sampled at f\textsubscript{DTS} frequency). Then write IC1F bits to ‘0011’ in the TIMx\_CCMR1 register.

3. Select the edge of the active transition on the TI1 channel by programming CC1P and CC1NP bits to ‘00’ in the TIMx\_CCER register (rising edge in this case).

4. Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to ‘00’ in the TIMx\_CCMR1 register).

5. Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx\_CCER register.

6. If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx\_DIER register.

For code example refer to the Appendix section A.9.3: Input capture configuration code example.

When an input capture occurs:

- The TIMx\_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.

For code example refer to the Appendix section A.9.4: Input capture data management code example.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

Note: IC interrupt requests can be generated by software by setting the corresponding CCxG bit in the TIMx\_EGR register.

19.3.6 Forced output mode

In output mode (CCxS bits = ‘00’ in the TIMx\_CCMRx register), each output compare signal (OCxREF and then OCx) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (OCXREF/OCx) to its active level, one just needs to write ‘101’ in the OCxM bits in the corresponding TIMx\_CCMRx register. Thus OCXREF is forced high (OCxREF is always active high) and OCx get opposite value to CCxP polarity bit.

For example: CCxP=’0’ (OCx active high) => OCx is forced to high level.

The OCxREF signal can be forced low by writing the OCxM bits to ‘100’ in the TIMx\_CCMRx register.

The comparison between the TIMx\_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt requests can be sent accordingly. This is described in the output compare mode section below.

19.3.7 Output compare mode

This function is used to control an output waveform or to indicate when a period of time has elapsed.
When a match is found between the capture/compare register and the counter, the output compare function:

1. Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP bit in the TIMx_CCMRx register). The output pin can keep its level (OCxM='000'), be set active (OCxM='001'), be set inactive (OCxM='010') or can toggle (OCxM='011') on match.
2. Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
3. Generates an interrupt if the corresponding interrupt mask is set (CCXIE bit in the TIMx_DIER register).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on OCxREF and OCx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

Procedure:

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
   - Write OCxM = '011' to toggle OCx output pin when CNT matches CCRx
   - Write OCxPE = '0' to disable preload register
   - Write CCxP = '0' to select active high polarity
   - Write CCxE = '1' to enable the output
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

For code example refer to the Appendix section A.9.7: Output compare configuration code example.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE='0', else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in Figure 170.
19.3.8 PWM mode

Pulse Width Modulation mode allows to generate a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per OCx output) by writing ‘110’ (PWM mode 1) or ‘111’ (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register by setting the ARPE bit in the TIMx_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

The OCx polarity is software programmable using the CCxP bit in the TIMx_CCER register. It can be programmed as active high or active low. The OCx output is enabled by the CCxE bit in the TIMx_CCER register. Refer to the TIMx_CCERx register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CNT ≤ TIMx_CCRx.

The timer is able to generate PWM in edge-aligned mode only since the counter is upcounting.

**PWM edge-aligned mode**

In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is high as long as TIMx_CNT < TIMx_CCRx else it becomes low. If the compare value in TIMx_CCRx is greater than the auto-reload value (in TIMx_ARR) then OCxREF is held at ‘1’. If the compare value is 0 then OCxRef is held at ‘0’. Figure 171 shows some edge-aligned PWM waveforms in an example where TIMx_ARR=8.
19.3.9 Debug mode

When the microcontroller enters debug mode (Cortex™-M0 core halted), the TIMx counter either continues to work normally or stops, depending on DBG_TIMx_STOP configuration bit in DBG module.

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **CC1OF**: Capture/Compare 1 overcapture flag

This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to ‘0’.

0: No overcapture has been detected.
1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set.

Bits 8:2 Reserved, must be kept at reset value.

Bit 1 **CC1IF**: Capture/compare 1 interrupt flag

**Condition: channel CC1 is configured as output**

This flag is set by hardware when the counter matches the compare value. It is cleared by software.

0: No match.
1: The content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the contents of TIMx_CCR1 are greater than the contents of TIMx_ARR, the CC1IF bit goes high on the counter overflow.

**Condition: channel CC1 is configured as input**

This bit is set by hardware on a capture. It is cleared by software or by reading the TIMx_CCR1 register.

0: No input capture occurred.
1: The counter value has been captured in TIMx_CCR1 register (an edge has been detected on IC1 which matches the selected polarity).

Bit 0 **UIF**: Update interrupt flag

This bit is set by hardware on an update event. It is cleared by software.

0: No update occurred.
1: Update interrupt pending. This bit is set by hardware when the registers are updated:

– At overflow and if UDIS='0’ in the TIMx_CR1 register.
– When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if URS='0’ and UDIS='0’ in the TIMx_CR1 register.

</tr>
</tbody>
</table>
Bits 15:2  Reserved, must be kept at reset value.

Bit 1  CC1G: Capture/compare 1 generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: A capture/compare event is generated on channel 1:

**Condition: channel CC1 is configured as output**

CC1IF flag is set, Corresponding interrupt or is sent if enabled.

**Condition: channel CC1 is configured as input**

The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0  UG: Update generation

This bit can be set by software, it is automatically cleared by hardware.
0: No action
1: Re-initialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected). The counter is cleared.

19.4.5  TIM14 capture/compare mode register 1 [alternate] (TIM14_CCMR1)

Address offset: 0x18

Reset value: 0x0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode. For a given bit, OCxx describes its function when the channel is configured in output, ICxx describes its function when the channel is configured in input. So one must take care that the same bit can have a different meaning for the input stage and for the output stage.

Bits 15:8  Reserved, must be kept at reset value.
19.4.6 TIM14 capture/compare mode register 1 [alternate] (TIM14_CCMR1)

Address offset: 0x18

Reset value: 0x0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode. For a given bit, OCxx describes its function when the channel is configured in output, ICxx describes its function when the channel is configured in input. So one must take care that the same bit can have a different meaning for the input stage and for the output stage.
19.4.7 TIM14 capture/compare enable register (TIM14_CCER)

Address offset: 0x20
Reset value: 0x0000

- **Bits 15:7**: Reserved, must be kept at reset value.
- **Bits 6:4**: **OC1M[2:0]**: Output compare 1 mode
  - These bits define the behavior of the output reference signal OC1REF from which OC1 is derived. OC1REF is active high whereas OC1 active level depends on CC1P bit.
  - 000: Frozen. The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs.
  - 001: Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).
  - 010: Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).
  - 011: Toggle - OC1REF toggles when TIMx_CNT = TIMx_CCR1.
  - 100: Force inactive level - OC1REF is forced low.
  - 101: Force active level - OC1REF is forced high.
  - 110: PWM mode 1 - Channel 1 is active as long as TIMx_CNT < TIMx_CCR1 else inactive.
  - 111: PWM mode 2 - Channel 1 is inactive as long as TIMx_CNT < TIMx_CCR1 else active.
  - **Note**: In PWM mode 1 or 2, the OCREF level changes when the result of the comparison changes or when the output compare mode switches from frozen to PWM mode.
- **Bit 3**: **OC1PE**: Output compare 1 preload enable
  - 0: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken in account immediately.
  - 1: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded in the active register at each update event.
  - **Note**: The PWM mode can be used without validating the preload register only in one pulse mode (OPM bit set in TIMx_CR1 register). Else the behavior is not guaranteed.
- **Bit 2**: **OC1FE**: Output compare 1 fast enable
  - This bit is used to accelerate the effect of an event on the trigger in input on the CC output.
  - 0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.
  - 1: An active edge on the trigger input acts like a compare match on CC1 output. OC is then set to the compare level independently of the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OC1FE acts only if the channel is configured in PWM1 or PWM2 mode.
- **Bits 1:0**: **CC1S[1:0]**: Capture/Compare 1 selection
  - This bit-field defines the direction of the channel (input/output) as well as the used input.
  - 00: CC1 channel is configured as output.
  - 01: CC1 channel is configured as input, IC1 is mapped on TI1.
  - 10: Reserved
  - 11: Reserved
  - **Note**: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIMx_CCRER).
General-purpose timer (TIM14) RM0091

Bits 15:4  Reserved, must be kept at reset value.

Bit 3  CC1NP: Capture/Compare 1 complementary output Polarity.
CC1 channel configured as output: CC1NP must be kept cleared.
CC1 channel configured as input: CC1NP bit is used in conjunction with CC1P to define TI1FP1 polarity (refer to CC1P description).

Bit 2  Reserved, must be kept at reset value.

Bit 1  CC1P: Capture/Compare 1 output Polarity.

Condition: CC1 channel configured as output
0: OC1 active high
1: OC1 active low

Condition: CC1 channel configured as input
The CC1P bit selects TI1FP1 and TI2FP1 polarity for trigger or capture operations.
00: noninverted/rising edge
   Circuit is sensitive to TI1FP1 rising edge (capture mode), TI1FP1 is not inverted.
01: inverted/falling edge
   Circuit is sensitive to TI1FP1 falling edge (capture mode), TI1FP1 is inverted.
10: reserved, do not use this configuration.
11: noninverted/both edges
   Circuit is sensitive to both TI1FP1 rising and falling edges (capture mode), TI1FP1 is not inverted.

Bit 0  CC1E: Capture/Compare 1 output enable.

Condition: CC1 channel configured as output:
0: Off - OC1 is not active
1: On - OC1 signal is output on the corresponding output pin

Condition: CC1 channel configured as input:
This bit determines if a capture of the counter value can actually be done into the input capture/compare register 1 (TIMx_CCR1) or not.
0: Capture disabled
1: Capture enabled

Table 69. Output control bit for standard OCx channels

<table>
<thead>
<tr>
<th>CCxE bit</th>
<th>OCx output state</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Output Disabled (OCx='0', OCx_EN='0')</td>
</tr>
<tr>
<td>1</td>
<td>OCx=OCxREF + Polarity, OCx_EN='1'</td>
</tr>
</tbody>
</table>

Note: The state of the external I/O pins connected to the standard OCx channels depends on the OCx channel state and the GPIO registers.

19.4.8  TIM14 counter (TIM14_CNT)

Address offset: 0x24

Reset value: 0x00000

Bits 15:0  CNT[15:0]: Counter value
19.4.9 TIM14 prescaler (TIM14_PSC)
Address offset: 0x28
Reset value: 0x0000

<table>
<thead>
<tr>
<th>PSC[15:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw</td>
</tr>
</tbody>
</table>

Bits 15:0 **PSC[15:0]**: Prescaler value
The counter clock frequency $f_{CK\_CNT}$ is equal to $f_{CK\_PSC} / (PSC[15:0] + 1)$.
PSC contains the value to be loaded in the active prescaler register at each update event.

19.4.10 TIM14 auto-reload register (TIM14_ARR)
Address offset: 0x2C
Reset value: 0xFFFF

<table>
<thead>
<tr>
<th>A R R[15:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw</td>
</tr>
</tbody>
</table>

Bits 15:0 **ARR[15:0]**: Auto-reload value
ARR is the value to be loaded in the actual auto-reload register.
Refer to the Section 19.3.1: Time-base unit on page 472 for more details about ARR update and behavior.
The counter is blocked while the auto-reload value is null.

19.4.11 TIM14 capture/compare register 1 (TIM14_CCR1)
Address offset: 0x34
Reset value: 0x0000

<table>
<thead>
<tr>
<th>C C R1[15:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw</td>
</tr>
</tbody>
</table>

Bits 15:0 **CCR1[15:0]**: Capture/Compare 1 value
**Condition: channel CC1 is configured as output**
CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on OC1 output.

**Condition: channel CC1 is configured as input**
CCR1 is the counter value transferred by the last input capture 1 event (IC1).
19.4.12 TIM14 option register (TIM14_OR)
Address offset: 0x50
Reset value: 0x0000

Refer to Section 2.2 on page 46 for the register boundary addresses.
20 General-purpose timers (TIM15/16/17)

TIM15 is not available on STM32F03x devices.

20.1 TIM15/16/17 introduction

The TIM15/16/17 timers consist of a 16-bit auto-reload counter driven by a programmable prescaler.

They may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM, complementary PWM with dead-time insertion).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The TIM15/16/17 timers are completely independent, and do not share any resources. The TIM15 can be synchronized with other timers.

20.2 TIM15 main features

TIM15 includes the following features:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535
- Up to 2 independent channels for:
  - Input capture
  - Output compare
  - PWM generation (Edge-aligned mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time (for channel 1 only)
- Synchronization circuit to control the timer with external signals and to interconnect several timers together
- Repetition counter to update the timer registers only after a given number of cycles of the counter
- Break input to put the timer’s output signals in the reset state or a known state
- Interrupt/DMA generation on the following events:
  - Update: counter overflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization or count by internal/external trigger)
  - Input capture
  - Output compare
  - Break input (interrupt request)

20.3 TIM16 and TIM17 main features

The TIM16 and TIM17 timers include the following features:

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide (also "on the fly") the counter clock frequency by any factor between 1 and 65535
- One channel for:
  - Input capture
  - Output compare
  - PWM generation (Edge-aligned mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time
- Repetition counter to update the timer registers only after a given number of cycles of the counter
- Break input to put the timer’s output signals in the reset state or a known state
- Interrupt/DMA generation on the following events:
  - Update: counter overflow
  - Input capture
  - Output compare
  - Break input
20.4 TIM15/16/17 functional description

20.4.1 Time-base unit

The main block of the programmable general purpose timer is a 16-bit upcounter with its related auto-reload register. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:

- Counter register (TIMx_CNT)
- Prescaler register (TIMx_PSC)
- Auto-reload register (TIMx_ARR)
- Repetition counter register (TIMx_RCR)

The auto-reload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the auto-reload preload enable bit (ARPE) in TIMx_CR1 register. The update event is sent when the counter reaches the overflow (or underflow when downcounting) and if the UDIS bit equals 0 in the
TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detail for each configuration.

The counter is clocked by the prescaler output CK_CNT, which is enabled only when the counter enable bit (CEN) in TIMx_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note that the counter starts counting 1 clock cycle after setting the CEN bit in the TIMx_CR1 register.

**Prescaler description**

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 159* and *Figure 160* give some examples of the counter behavior when the prescaler ratio is changed on the fly:

**Figure 174. Counter timing diagram with prescaler division change from 1 to 2**
20.4.2 Counter operation

The counter counts from 0 to the auto-reload value (content of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

If the repetition counter is used, the update event (UEV) is generated after upcounting is repeated for the number of times programmed in the repetition counter register (TIMx_RCR). Else the update event is generated at each counter overflow.

Setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIMx_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIMx_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIMx_RCR register,
- The auto-reload shadow register is updated with the preload value (TIMx_ARR),
- The buffer of the prescaler is reloaded with the preload value (content of the TIMx_PSC register).

Figure 175. Counter timing diagram with prescaler division change from 1 to 4
The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR=0x36.

**Figure 176. Counter timing diagram, internal clock divided by 1**

Figure 180. Counter timing diagram, update event when ARPE=0
(TIMx.ARR not preloaded)
20.4.3 Repetition counter

Section 19.3.1: Time-base unit describes how the update event (UEV) is generated with respect to the counter overflows/underflows. It is actually generated only when the repetition counter has reached zero. This can be useful when generating PWM signals.

This means that data are transferred from the preload registers to the shadow registers (TIMx_ARR auto-reload register, TIMx_PSC prescaler register, but also TIMx_CCRx capture/compare registers in compare mode) every N counter overflows or underflows, where N is the value in the TIMx_RCR repetition counter register.

The repetition counter is decremented at each counter overflow in upcounting mode.

The repetition counter is an auto-reload type; the repetition rate is maintained as defined by the TIMx_RCR register value (refer to Figure 182). When the update event is generated by software (by setting the UG bit in TIMx_EGR register) or by hardware through the slave mode controller, it occurs immediately whatever the value of the repetition counter is and the repetition counter is reloaded with the content of the TIMx_RCR register.
20.4.4 Clock sources

The counter clock can be provided by the following clock sources:

- Internal clock (CK_INT)
- External clock mode1: external input pin (only for TIM15)
- Internal trigger inputs (ITRx) (only for TIM15): using one timer as the prescaler for another timer, for example, TIM1 can be configured to act as a prescaler for TIM15. Refer to Using one timer as prescaler for another for more details.

Internal clock source (CK_INT)

For TIM15 if the slave mode controller is disabled (SMS=000), then the CEN and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK_INT.
Figure 19.3.4 shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

**Figure 183. Control circuit in normal mode, internal clock divided by 1**

- **Internal clock**
- **CEN=CNT_EN**

- **CNT_INIT**

Counter clock = CK_CNT = CK_PSC

Counter register

| 31 | 32 | 33 | 34 | 35 | 36 | 00 | 01 | 02 | 03 | 04 | 05 | 06 | 07 |

**External clock source mode 1**

This mode is selected when SMS=111 in the TIMx_SMCR register. The counter can count at each rising or falling edge on a selected input.

**Figure 184. TI2 external clock connection example**

For example, to configure the upcounter to count in response to a rising edge on the TI2 input, use the following procedure:
1. Configure channel 2 to detect rising edges on the TI2 input by writing CC2S = ‘01’ in 
the TIMx_CCMR1 register.
2. Configure the input filter duration by writing the IC2F[3:0] bits in the TIMx_CCMR1 
register (if no filter is needed, keep IC2F=0000).
3. Select rising edge polarity by writing CC2P=0 in the TIMx_CCER register.
4. Configure the timer in external clock mode 1 by writing SMS=111 in the TIMx_SMCR 
register.
5. Select TI2 as the trigger input source by writing TS=110 in the TIMx_SMCR register.
6. Enable the counter by writing CEN=1 in the TIMx_CR1 register.

Note: The capture prescaler is not used for triggering, so it does not need to be configured.
For code example refer to the Appendix section A.9.1: Upcounter on TI2 rising edge code example.

When a rising edge occurs on TI2, the counter counts once and the TIF flag is set.
The delay between the rising edge on TI2 and the actual clock of the counter is due to the 
resynchronization circuit on TI2 input.

**Figure 185. Control circuit in external clock mode 1**

---

### 20.4.5 Capture/compare channels

Each Capture/Compare channel is built around a capture/compare register (including a 
shadow register), a input stage for capture (with digital filter, multiplexing and prescaler) and 
an output stage (with comparator and output control).

*Figure 167 to Figure 189* give an overview of one Capture/Compare channel.

The input stage samples the corresponding TIx input to generate a filtered signal TIxF. 
Then, an edge detector with polarity selection generates a signal (TIxFPx) which can be 
used as trigger input by the slave mode controller or as the capture command. It is 
prescaled before the capture register (ICxPS).
The output stage generates an intermediate waveform which is then used for reference: OCxRef (active high). The polarity acts at the end of the chain.
The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.
20.4.6 Input capture mode

In Input capture mode, the Capture/Compare Registers (TIMx_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCXIF flag (TIMx_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the over-capture flag CCxOF (TIMx_SR register) is set. CCxIF can be cleared by software by writing it to ‘0’ or by reading the captured data stored in the TIMx_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIMx_CCR1 when TI1 input rises. To do this, use the following procedure:

- Select the active input: TIMx_CCR1 must be linked to the TI1 input, so write the CC1S bits to 01 in the TIMx_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIMx_CCR1 register becomes read-only.

- Program the appropriate input filter duration in relation with the signal connected to the timer (when the input is one of the TIx (ICxF bits in the TIMx_CCMRx register). Let’s imagine that, when toggling, the input signal is not stable during at most 5 internal clock cycles. We must program a filter duration longer than these 5 clock cycles. We can validate a transition on TI1 when 8 consecutive samples with the new level have been detected (sampled at fDTS frequency). Then write IC1F bits to 0011 in the TIMx_CCMR1 register.

- Select the edge of the active transition on the TI1 channel by writing CC1P bit to 0 in the TIMx_CCER register (rising edge in this case).

- Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to ‘00’ in the TIMx_CCMR1 register).

- Enable capture from the counter into the capture register by setting the CC1E bit in the TIMx_CCER register.

- If needed, enable the related interrupt request by setting the CC1IE bit in the TIMx_DIER register, and/or the DMA request by setting the CC1DE bit in the TIMx_DIER register.

For code example refer to the Appendix section A.9.3: Input capture configuration code example.

When an input capture occurs:

- The TIMx_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

For code example refer to the Appendix section A.9.4: Input capture data management code example.

In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which could happen after reading the flag and before reading the data.

Note: IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIMx_EGR register.
20.4.7 PWM input mode (only for TIM15)

This mode is a particular case of input capture mode. The procedure is the same except:

- Two ICx signals are mapped on the same TIx input.
- These 2 ICx signals are active on edges with opposite polarity.
- One of the two TIxFP signals is selected as trigger input and the slave mode controller is configured in reset mode.

For example, one can measure the period (in TIMx_CCR1 register) and the duty cycle (in TIMx_CCR2 register) of the PWM applied on TI1 using the following procedure (depending on CK_INT frequency and prescaler value):

- Select the active input for TIMx_CCR1: write the CC1S bits to 01 in the TIMx_CCMR1 register (TI1 selected).
- Select the active polarity for TI1FP1 (used both for capture in TIMx_CCR1 and counter clear): write the CC1P bit to ‘0’ (active on rising edge).
- Select the active input for TIMx_CCR2: write the CC2S bits to 10 in the TIMx_CCMR1 register (TI1 selected).
- Select the active polarity for TI1FP2 (used for capture in TIMx_CCR2): write the CC2P bit to ‘1’ and the CC2NP bit to ‘0’ (active on falling edge).
- Select the valid trigger input: write the TS bits to 101 in the TIMx_SMCR register (TI1FP1 selected).
- Configure the slave mode controller in reset mode: write the SMS bits to 100 in the TIMx_SMCR register.
- Enable the captures: write the CC1E and CC2E bits to ‘1’ in the TIMx_CCRER register.

For code example refer to the Appendix section A.9.5: PWM input configuration code example.

Figure 190. PWM input mode timing

1. The PWM input mode can be used only with the TIMx_CH1/TIMx_CH2 signals due to the fact that only TI1FP1 and TI2FP2 are connected to the slave mode controller.
20.4.8 Forced output mode

In output mode (CCxS bits = 00 in the TIMx_CCMRx register), each output compare signal (OCxREF and then OCx/OCxN) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (OCXREF/OCx) to its active level, one just needs to write 101 in the OCxM bits in the corresponding TIMx_CCMRx register. Thus OCXREF is forced high (OCxREF is always active high) and OCx get opposite value to CCxP polarity bit.

For example: CCxP=0 (OCx active high) => OCx is forced to high level.

The OCxREF signal can be forced low by writing the OCxM bits to 100 in the TIMx_CCMRx register.

Anyway, the comparison between the TIMx_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the output compare mode section below.

20.4.9 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIMx_CCMRx register) and the output polarity (CCxP bit in the TIMx_CCER register). The output pin can keep its level (OCxM=000), be set active (OCxM=001), be set inactive (OCxM=010) or can toggle (OCxM=011) on match.
- Sets a flag in the interrupt status register (CCxIF bit in the TIMx_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCXIE bit in the TIMx_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIMx_DIER register, CCDS bit in the TIMx_CR2 register for the DMA request selection).

The TIMx_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIMx_CCMRx register.

In output compare mode, the update event UEV has no effect on OCxREF and OCx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).
Procedure:
1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIMx_ARR and TIMx_CCRx registers.
3. Set the CCxIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
   - Write OCxM = 011 to toggle OCx output pin when CNT matches CCRx
   - Write OCxPE = 0 to disable preload register
   - Write CCxP = 0 to select active high polarity
   - Write CCxE = 1 to enable the output
5. Enable the counter by setting the CEN bit in the TIMx_CR1 register.

For code example refer to the Appendix section A.9.2: Up counter on each 2 ETR rising edges code example.

The TIMx_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE='0', else TIMx_CCRx shadow register is updated only at the next update event UEV). An example is given in Figure 170.

**Figure 191. Output compare mode, toggle on OC1**

20.4.10 PWM mode

Pulse Width Modulation mode allows to generate a signal with a frequency determined by the value of the TIMx_ARR register and a duty cycle determined by the value of the TIMx_CCRx register.

The PWM mode can be selected independently on each channel (one PWM per OCx output) by writing ‘110’ (PWM mode 1) or ‘111’ (PWM mode 2) in the OCxM bits in the TIMx_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIMx_CCMRx register, and eventually the auto-reload preload register by setting the ARPE bit in the TIMx_CR1 register.
As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIMx_EGR register.

OCx polarity is software programmable using the CCxE bit in the TIMx_CCER register. It can be programmed as active high or active low. OCx output is enabled by a combination of the CCxE, CCxNE, MOE, OSSI and OSSR bits (TIMx_CCER and TIMx_BDTR registers). Refer to the TIMx_CCER register description for more details.

In PWM mode (1 or 2), TIMx_CNT and TIMx_CCRx are always compared to determine whether TIMx_CCRx ≤ TIMx_CNT.

In the following example, we consider PWM mode 1. The reference PWM signal OCxREF is high as long as TIMx_CNT < TIMx_CCRx else it becomes low. If the compare value in TIMx_CCRx is greater than the auto-reload value (in TIMx_ARR) then OCxREF is held at ‘1’. If the compare value is 0 then OCxRef is held at ‘0’. Figure 171 shows some edge-aligned PWM waveforms in an example where TIMx_ARR=8.

**Figure 192. Edge-aligned PWM waveforms (ARR=8)**

![Waveform Diagram](image)

### 20.4.11 Complementary outputs and dead-time insertion

The TIM15/16/17 general-purpose timers can output one complementary signal and manage the switching-off and switching-on of the outputs.

This time is generally known as dead-time and it has to be adjusted depending on the devices that are connected to the outputs and their characteristics (intrinsic delays of level-shifters, delays due to power switches...)

---

**Figure 171**

![Waveform Diagram](image)
The polarity of the outputs (main output OCx or complementary OCxN) can be selected independently for each output. This is done by writing to the CCxP and CCxNP bits in the TIMx_CCER register.

The complementary signals OCx and OCxN are activated by a combination of several control bits: the CCxE and CCxNE bits in the TIMx_CCER register and the MOE, OISx, OISxN, OSSi and OSSR bits in the TIMx_BDTR and TIMx_CR2 registers. Refer to Table 72: Output control bits for complementary OCx and OCxN channels with break feature on page 535 for more details. In particular, the dead-time is activated when switching to the IDLE state (MOE falling down to 0).

Dead-time insertion is enabled by setting both CCxE and CCxNE bits, and the MOE bit if the break circuit is present. There is one 10-bit dead-time generator for each channel. From a reference waveform OCxREF, it generates 2 outputs OCx and OCxN. If OCx and OCxN are active high:

- The OCx output signal is the same as the reference signal except for the rising edge, which is delayed relative to the reference rising edge.
- The OCxN output signal is the opposite of the reference signal except for the rising edge, which is delayed relative to the reference falling edge.

If the delay is greater than the width of the active output (OCx or OCxN) then the corresponding pulse is not generated.

The following figures show the relationships between the output signals of the dead-time generator and the reference signal OCxREF. (we suppose CCxP=0, CCxNP=0, MOE=1, CCxE=1 and CCxNE=1 in these examples)

**Figure 193. Complementary output with dead-time insertion**

**Figure 193. Complementary output with dead-time insertion**

MS31095V1
The dead-time delay is the same for each of the channels and is programmable with the DTG bits in the TIMx_BDTR register. Refer to Section 20.5.16: TIM15 break and dead-time register (TIM15_BDTR) on page 538 for delay calculation.

**Re-directing OCxREF to OCx or OCxN**

In output mode (forced, output compare or PWM), OCxREF can be re-directed to the OCx output or to OCxN output by configuring the CCxE and CCxNE bits in the TIMx_CCER register.

This allows to send a specific waveform (such as PWM or static active level) on one output while the complementary remains at its inactive level. Other alternative possibilities are to have both outputs at inactive level or both outputs active and complementary with dead-time.

**Note:** When only OCxN is enabled (CCxE=0, CCxNE=1), it is not complemented and becomes active as soon as OCxREF is high. For example, if CCxNP=0 then OCxN=OCxRef. On the other hand, when both OCx and OCxN are enabled (CCxE=CCxNE=1) OCx becomes active when OCxREF is high whereas OCxN is complemented and becomes active when OCxREF is low.
20.4.12 Using the break function

When using the break function, the output enable signals and inactive levels are modified according to additional control bits (MOE, OSSI and OSSR bits in the TIMx_BDTR register, OISx and OISxN bits in the TIMx_CR2 register). In any case, the OCx and OCxN outputs cannot be set both to active level at a given time. Refer to Table 72: Output control bits for complementary OCx and OCxN channels with break feature on page 535 for more details.

The source for break (BRK) channel can be an external source connected to the BKIN pin or one of the following internal sources:

- the core LOCKUP output
- the PVD output
- the SRAM parity error signal
- a clock failure event generated by the CSS detector

When exiting from reset, the break circuit is disabled and the MOE bit is low. The break function can be enabled by setting the BKE bit in the TIMx_BDTR register. The break input polarity can be selected by configuring the BKP bit in the same register. BKE and BKP can be modified at the same time. When the BKE and BKP bits are written, a delay of 1 APB clock cycle is applied before the writing is effective. Consequently, it is necessary to wait 1 APB clock period to correctly read back the bit after the write operation.

Because MOE falling edge can be asynchronous, a resynchronization circuit has been inserted between the actual signal (acting on the outputs) and the synchronous control bit (accessed in the TIMx_BDTR register). It results in some delays between the asynchronous and the synchronous signals. In particular, if MOE is set to 1 whereas it was low, a delay must be inserted (dummy instruction) before reading it correctly. This is because the write acts on the asynchronous signal whereas the read reflects the synchronous signal.

When a break occurs (selected level on the break input):

- The MOE bit is cleared asynchronously, putting the outputs in inactive state, idle state or in reset state (selected by the OSSI bit). This feature functions even if the MCU oscillator is off.
- Each output channel is driven with the level programmed in the OISx bit in the TIMx_CR2 register as soon as MOE=0. If OSSI=0 then the timer releases the enable output else the enable output remains high.
- When complementary outputs are used:
  - The outputs are first put in reset state inactive state (depending on the polarity). This is done asynchronously so that it works even if no clock is provided to the timer.
  - If the timer clock is still present, then the dead-time generator is reactivated in order to drive the outputs with the level programmed in the OISx and OISxN bits after a dead-time. Even in this case, OCx and OCxN cannot be driven to their active level together. Note that because of the resynchronization on MOE, the dead-time duration is a bit longer than usual (around 2 ck_tim clock cycles).
  - If OSSI=0 then the timer releases the enable outputs else the enable outputs remain or become high as soon as one of the CCxEX or CCxNE bits is high.
- The break status flag (BIF bit in the TIMx_SR register) is set. An interrupt can be generated if the BIE bit in the TIMx_DIER register is set.
- If the AOE bit in the TIMx_BDTR register is set, the MOE bit is automatically set again at the next update event UEV. This can be used to perform a regulation, for instance.
Else, MOE remains low until it is written with 1 again. In this case, it can be used for security and the break input can be connected to an alarm from power drivers, thermal sensors or any security components.

**Note:** The break inputs is acting on level. Thus, the MOE cannot be set while the break input is active (neither automatically nor by software). In the meantime, the status flag BIF cannot be cleared.

The break can be generated by the BRK input which has a programmable polarity and an enable bit BKE in the TIMx_BDTR Register.

In addition to the break input and the output management, a write protection has been implemented inside the break circuit to safeguard the application. It allows to freeze the configuration of several parameters (dead-time duration, OCx/OCxN polarities and state when disabled, OCxM configurations, break enable and polarity). The protection can be selected among 3 levels with the LOCK bits in the TIMx_BDTR register. Refer to Section 20.5.16: TIM15 break and dead-time register (TIM15_BDTR) on page 538. The LOCK bits can be written only once after an MCU reset.

The **Figure 196** shows an example of behavior of the outputs in response to a break.

20.4.13 One-pulse mode

One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIMx_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- In upcounting: CNT < CCRx ≤ ARR (in particular, 0 < CCRx)
- In downcounting: CNT > CCRx

For example one may want to generate a positive pulse on OC1 with a length of tPULSE and after a delay of tDELAY as soon as a positive edge is detected on the TI2 input pin.

Let’s use TI2FP2 as trigger 1:

- Map TI2FP2 to TI2 by writing CC2S='01' in the TIMx_CCMR1 register.
- TI2FP2 must detect a rising edge, write CC2P='0' in the TIMx_CCER register.
- Configure TI2FP2 as trigger for the slave mode controller (TRGI) by writing TS='110' in the TIMx_SMCR register.
- TI2FP2 is used to start the counter by writing SMS to ‘110’ in the TIMx_SMCR register (trigger mode).

For code example refer to the Appendix section A.9.16: One-Pulse mode code example.
The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The \( t_{\text{DELAY}} \) is defined by the value written in the TIMx_CCR1 register.
- The \( t_{\text{PULSE}} \) is defined by the difference between the auto-reload value and the compare value (TIMx_ARR - TIMx_CCR1).
- Let’s say one want to build a waveform with a transition from ‘0’ to ‘1’ when a compare match occurs and a transition from ‘1’ to ‘0’ when the counter reaches the auto-reload value. To do this PWM mode 2 must be enabled by writing OC1M=111 in the TIMx_CCMR1 register. Optionally the preload registers can be enabled by writing OC1PE=’1’ in the TIMx_CCMR1 register and ARPE in the TIMx_CR1 register. In this case one has to write the compare value in the TIMx_CCR1 register, the auto-reload value in the TIMx_ARR register, generate an update by setting the UG bit and wait for external trigger event on TI2. CC1P is written to ‘0’ in this example.

Since only 1 pulse is needed, a 1 must be written in the OPM bit in the TIMx_CR1 register to stop the counter at the next update event (when the counter rolls over from the auto-reload value back to 0).

**Particular case: OCx fast enable**

In One-pulse mode, the edge detection on TiX input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay \( t_{\text{DELAY}} \) min we can get.

If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIMx_CCMRx register. Then OCxRef (and OCx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

For code example refer to the part of code conditioned by PULSE_WITHOUT_DELAY > 0 in the Appendix section A.9.16: One-Pulse mode code example.

### 20.4.14 TIM15 external trigger synchronization

This section applies to STM32F05x, STM32F07x and STM32F09x devices only.

The TIM15 timer can be synchronized with an external trigger in several modes: Reset mode, Gated mode and Trigger mode.

**Slave mode: Reset mode**

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIMx_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIMx_ARR, TIMx_CCRx) are updated.

In the following example, the upcounter is cleared in response to a rising edge on TI1 input:

- Configure the channel 1 to detect rising edges on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits
select the input capture source only, CC1S = 01 in the TIMx_CCMR1 register. Write
CC1P=0 in TIMx_CCER register to validate the polarity (and detect rising edges only).

- Configure the timer in reset mode by writing SMS=100 in TIMx_SMCR register. Select
TI1 as the input source by writing TS=101 in TIMx_SMCR register.
- Start the counter by writing CEN=1 in the TIMx_CR1 register.

For code example refer to the Appendix section A.9.12: Reset mode code example.

The counter starts counting on the internal clock, then behaves normally until TI1 rising
edge. When TI1 rises, the counter is cleared and restarts from 0. In the meantime, the
trigger flag is set (TIF bit in the TIMx_SR register) and an interrupt request, or a DMA
request can be sent if enabled (depending on the TIE and TDE bits in TIMx_DIER register).

The following figure shows this behavior when the auto-reload register TIMx_ARR=0x36.
The delay between the rising edge on TI1 and the actual reset of the counter is due to the
resynchronization circuit on TI1 input.

**Figure 198. Control circuit in reset mode**
Slave mode: Gated mode

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when TI1 input is low:

- Configure the channel 1 to detect low levels on TI1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S=01 in TIMx_CCMR1 register. Write CC1P=1 in TIMx_CCRER register to validate the polarity (and detect low level only).
- Configure the timer in gated mode by writing SMS=101 in TIMx_SMCR register. Select TI1 as the input source by writing TS=101 in TIMx_SMCR register.
- Enable the counter by writing CEN=1 in the TIMx_CR1 register (in gated mode, the counter doesn’t start if CEN=0, whatever is the trigger input level).

For code example refer to the Appendix section A.9.13: Gated mode code example.

The counter starts counting on the internal clock as long as TI1 is low and stops as soon as TI1 becomes high. The TIF flag in the TIMx_SR register is set both when the counter starts or stops.

The delay between the rising edge on TI1 and the actual stop of the counter is due to the resynchronization circuit on TI1 input.

Slave mode: Trigger mode

The counter can start in response to an event on a selected input.

In the following example, the upcounter starts in response to a rising edge on TI2 input:

- Configure the channel 2 to detect rising edges on TI2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F=0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC2S bits are configured to select the input capture source only, CC2S=01 in TIMx_CCMR1
Configure the timer in trigger mode by writing SMS=110 in TIMx_SMCR register. Select TI2 as the input source by writing TS=110 in TIMx_SMCR register.

For code example refer to the Appendix section A.9.14: Trigger mode code example.

When a rising edge occurs on TI2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on TI2 and the actual start of the counter is due to the resynchronization circuit on TI2 input.

**Figure 200. Control circuit in trigger mode**

The TIM timers are linked together internally for timer synchronization or chaining. Refer to Section 18.3.15: Timer synchronization on page 439 for details.

### 20.4.15 Timer synchronization (TIM15)

This section applies to STM32F05x, STM32F07x and STM32F09x devices only.

The TIM timers are linked together internally for timer synchronization or chaining. Refer to Section 18.3.15: Timer synchronization on page 439 for details.

### 20.4.16 Debug mode

When the microcontroller enters debug mode (Cortex™-M0 core halted), the TIMx counter either continues to work normally or stops, depending on DBG_TIMx_STOP configuration bit in DBG module.
20.5 TIM15 registers

Refer to Section 1.2 on page 42 for a list of abbreviations used in register descriptions.

20.5.1 TIM15 control register 1 (TIM15_CR1)

Address offset: 0x00
Reset value: 0x0000

<table>
<thead>
<tr>
<th>Bit 15:10</th>
<th>Bit 9:8</th>
<th>Bit 7</th>
<th>Bit 6:4</th>
<th>Bit 3</th>
<th>Bit 2</th>
</tr>
</thead>
</table>

**CKD[1:0]: Clock division**

This bit field indicates the division ratio between the timer clock (CK_INT) frequency and the dead-time and sampling clock (t_DTS) used by the dead-time generators and the digital filters (TIx).

- 00: t_DTS = t_{CK_INT}
- 01: t_DTS = 2\times t_{CK_INT}
- 10: t_DTS = 4\times t_{CK_INT}
- 11: Reserved, do not program this value

**ARPE: Auto-reload preload enable**

- 0: TIMx_ARR register is not buffered
- 1: TIMx_ARR register is buffered

**OPM: One-pulse mode**

- 0: Counter is not stopped at update event
- 1: Counter stops counting at the next update event (clearing the bit CEN)

**URS: Update request source**

This bit is set and cleared by software to select the UEV event sources.

- 0: Any of the following events generate an update interrupt if enabled. These events can be:
  - Counter overflow/underflow
  - Setting the UG bit
  - Update generation through the slave mode controller
- 1: Only counter overflow/underflow generates an update interrupt if enabled
Bit 1 **UDIS**: Update disable

This bit is set and cleared by software to enable/disable UEV event generation.

- 0: UEV enabled. The Update (UEV) event is generated by one of the following events:
  - Counter overflow/underflow
  - Setting the UG bit
  - Update generation through the slave mode controller

Buffered registers are then loaded with their preload values.

- 1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable

- 0: Counter disabled
- 1: Counter enabled

*Note: External clock and gated mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.*

### 20.5.2 TIM15 control register 2 (TIM15_CR2)

Address offset: 0x04

Reset value: 0x0000

<table>
<thead>

<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 15:11 Reserved, must be kept at reset value.

- Bit 10 **OIS2**: Output idle state 2 (OC2 output)
  - 0: OC2=0 when MOE=0
  - 1: OC2=1 when MOE=0

*Note: This bit cannot be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BKR register).*

- Bit 9 **OIS1N**: Output Idle state 1 (OC1N output)
  - 0: OC1N=0 after a dead-time when MOE=0
  - 1: OC1N=1 after a dead-time when MOE=0

*Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BKR register).*

- Bit 8 **OIS1**: Output Idle state 1 (OC1 output)
  - 0: OC1=0 (after a dead-time if OC1N is implemented) when MOE=0
  - 1: OC1=1 (after a dead-time if OC1N is implemented) when MOE=0

*Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BKR register).*

Bit 7 Reserved, must be kept at reset value.
20.5.3 TIM15 slave mode control register (TIM15_SMCR)

Address offset: 0x08
Reset value: 0x0000
Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **MSM**: Master/slave mode

0: No action
1: The effect of an event on the trigger input (TRGI) is delayed to allow a perfect synchronization between the current timer and its slaves (through TRGO). It is useful if we want to synchronize several timers on a single external event.

Bits 6:4 **TS[2:0]**: Trigger selection

This bit field selects the trigger input to be used to synchronize the counter.

- 000: Internal Trigger 0 (ITR0)
- 001: Internal Trigger 1 (ITR1)
- 010: Internal Trigger 2 (ITR2)
- 011: Internal Trigger 3 (ITR3)
- 100: TI1 Edge Detector (TI1F_ED)
- 101: Filtered Timer Input 1 (TI1FP1)
- 110: Filtered Timer Input 2 (TI2FP2)

See Table 71: TIMx Internal trigger connection on page 525 for more details on ITRx meaning for each Timer.

Note: These bits must be changed only when they are not used (e.g. when SMS=000) to avoid wrong edge detections at the transition.

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **SMS[2:0]**: Slave mode selection

When external signals are selected the active edge of the trigger signal (TRGI) is linked to the polarity selected on the external input (see Input Control register and Control Register description).

- 000: Slave mode disabled - if CEN = '1' then the prescaler is clocked directly by the internal clock.
- 100: Reset Mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter and generates an update of the registers.
- 101: Gated Mode - The counter clock is enabled when the trigger input (TRGI) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.
- 110: Trigger Mode - The counter starts at a rising edge of the trigger TRGI (but it is not reset). Only the start of the counter is controlled.
- 111: External Clock Mode 1 - Rising edges of the selected trigger (TRGI) clock the counter.

Note: The gated mode must not be used if TI1F_ED is selected as the trigger input (TS='100'). Indeed, TI1F_ED outputs 1 pulse for each transition on TI1F, whereas the gated mode checks the level of the trigger signal.

## TIM15 status register (TIM15_SR)

Address offset: 0x10  
Reset value: 0x0000

### Field Descriptions

| Bit 15:11 | Reserved, must be kept at reset value. |
| Bit 10   | **CC2OF**: Capture/Compare 2 overcapture flag  
Refer to CC1OF description. |
| Bit 9    | **CC1OF**: Capture/Compare 1 overcapture flag  
This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to ‘0’.
  0: No overcapture has been detected  
  1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set |
| Bit 8    | Reserved, must be kept at reset value. |
| Bit 7    | **BIF**: Break interrupt flag  
This flag is set by hardware as soon as the break input goes active. It can be cleared by software if the break input is not active.  
  0: No break event occurred  
  1: An active level has been detected on the break input |
| Bit 6    | **TIF**: Trigger interrupt flag  
This flag is set by hardware on trigger event (active edge detected on TRGI input when the slave mode controller is enabled in all modes but gated mode, both edges in case gated mode is selected). It is cleared by software.  
  0: No trigger event occurred  
  1: Trigger interrupt pending |
| Bit 5    | **COMIF**: COM interrupt flag  
This flag is set by hardware on a COM event (once the capture/compare control bits –CCxE, CCxNE, OCxM– have been updated). It is cleared by software by writing it to ‘0’.
  0: No COM event occurred  
  1: COM interrupt pending |
| Bits 4:3 | Reserved, must be kept at reset value. |
Bit 2 **CC2IF**: Capture/Compare 2 interrupt flag  
refer to CC1IF description

Bit 1 **CC1IF**: Capture/Compare 1 interrupt flag  
**Condition: channel CC1 is configured as output**  
This flag is set by hardware when the counter matches the compare value, it is cleared by software.  
0: No match.  
1: The content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register.  
When the contents of TIMx_CCR1 are greater than the contents of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in upcounting and up/down-counting modes) or underflow (in downcounting mode)  
**Condition: If channel CC1 is configured as input**  
This bit is set by hardware on a capture. It is cleared by software or by reading the TIMx_CCR1 register.  
0: No input capture occurred  
1: The counter value has been captured in TIMx_CCR1 register (An edge has been detected on IC1 which matches the selected polarity)

Bit 0 **UIF**: Update interrupt flag  
This bit is set by hardware on an update event. It is cleared by software.  
0: No update occurred.  
1: Update interrupt pending. This bit is set by hardware when the registers are updated:  
– At overflow regarding the repetition counter value (update if repetition counter = 0) and if the UDIS=0 in the TIMx_CR1 register.  
– When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if URS=0 and UDIS=0 in the TIMx_CR1 register.  
– When CNT is reinitialized by a trigger event (refer to [Section 20.5.3: TIM15 slave mode control register (TIM15_SMCR)](http://infocenter.arm.com/help/index.jsp?topic=%2Fcom.arm.doc.d165962%2Fpdfs%2Fm042826.pdf), if URS=0 and UDIS=0 in the TIMx_CR1 register.)

20.5.7 TIM15 capture/compare mode register 1 [alternate] (TIM15_CCMR1)

Address offset: 0x18
Reset value: 0x0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode. For a given bit, OCxx describes its function when the channel is configured in output, ICxx describes its function when the channel is configured in input. So one must take care that the same bit can have a different meaning for the input stage and for the output stage.

Bits 15:12 **IC2F[3:0]**: Input capture 2 filter

Bits 11:10 **IC2PSC[1:0]**: Input capture 2 prescaler

Bits 9:8 **CC2S[1:0]**: Capture/Compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output
01: CC2 channel is configured as input, IC2 is mapped on TI2
10: CC2 channel is configured as input, IC2 is mapped on TI1
11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

*Note: CC2S bits are writable only when the channel is OFF (CC2E = '0' in TIMx_CCER).*
Bits 7:4 **IC1F[3:0]**: Input capture 1 filter
This bit-field defines the frequency used to sample TI1 input and the length of the digital filter applied to TI1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

- 0000: No filter, sampling is done at f_{DTS}
- 0001: f_{SAMPLING} = f_{CK_INT}, N = 2
- 0010: f_{SAMPLING} = f_{CK_INT}, N = 4
- 0011: f_{SAMPLING} = f_{CK_INT}, N = 8
- 0100: f_{SAMPLING} = f_{DTS} / 2, N = 6
- 0101: f_{SAMPLING} = f_{DTS} / 2, N = 8
- 0110: f_{SAMPLING} = f_{DTS} / 4, N = 6
- 0111: f_{SAMPLING} = f_{DTS} / 4, N = 8
- 1000: f_{SAMPLING} = f_{DTS} / 8, N = 6
- 1001: f_{SAMPLING} = f_{DTS} / 8, N = 8
- 1010: f_{SAMPLING} = f_{DTS} / 16, N = 5
- 1011: f_{SAMPLING} = f_{DTS} / 16, N = 6
- 1100: f_{SAMPLING} = f_{DTS} / 32, N = 5
- 1101: f_{SAMPLING} = f_{DTS} / 32, N = 6
- 1110: f_{SAMPLING} = f_{DTS} / 32, N = 8
- 1111: f_{SAMPLING} = f_{DTS} / 32, N = 8

*Note: Care must be taken that f_{DTS} is replaced in the formula by f_{CK_INT} when ICxF[3:0] = 1, 2 or 3.*

Bits 3:2 **IC1PSC[1:0]**: Input capture 1 prescaler
This bit-field defines the ratio of the prescaler acting on CC1 input (IC1). The prescaler is reset as soon as CC1E='0' (TIMx_CCER register).

- 00: no prescaler, capture is done each time an edge is detected on the capture input
- 01: capture is done once every 2 events
- 10: capture is done once every 4 events
- 11: capture is done once every 8 events

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 Selection
This bit-field defines the direction of the channel (input/output) as well as the used input.

- 00: CC1 channel is configured as output
- 01: CC1 channel is configured as input, IC1 is mapped on TI1
- 10: CC1 channel is configured as input, IC1 is mapped on TI2
- 11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

*Note: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIMx_CCER).*

**20.5.8 TIM15 capture/compare mode register 1 [alternate] (TIM15_CCMR1)**

Address offset: 0x18
Reset value: 0x0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode. For a given bit, OCxx describes its function when the channel is configured in output, ICxx describes its function when the channel is configured in input. So one must take care that the same bit can have a different meaning for the input stage and for the output stage.
Bit 15  Reserved, must be kept at reset value.

Bits 14:12  **OC2M[2:0]**: Output Compare 2 mode

Bit 11  **OC2PE**: Output Compare 2 preload enable

Bit 10  **OC2FE**: Output Compare 2 fast enable

Bits 9:8  **CC2S[1:0]**: Capture/Compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output.
01: CC2 channel is configured as input, IC2 is mapped on TI2.
10: CC2 channel is configured as input, IC2 is mapped on TI1.
11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through the TS bit (TIMx_SMCR register)

*Note:* **CC2S** bits are writable only when the channel is OFF (CC2E = '0' in TIMx_CCER).

Bit 7  Reserved, must be kept at reset value.

Bits 6:4  **OC1M[2:0]**: Output Compare 1 mode

These bits define the behavior of the output reference signal OC1REF from which OC1 and OC1N are derived. OC1REF is active high whereas OC1 and OC1N active level depends on CC1P and CC1NP bits.

000: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs.
001: Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).
010: Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).
011: Toggle - OC1REF toggles when TIMx_CNT=TIMx_CCR1.
100: Force inactive level - OC1REF is forced low.
101: Force active level - OC1REF is forced high.
110: PWM mode 1 - In upcounting, channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else inactive. In downcounting, channel 1 is inactive (OC1REF='0') as long as TIMx_CNT> TIMx_CCR1 else active (OC1REF='1').
111: PWM mode 2 - In upcounting, channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else active. In downcounting, channel 1 is active as long as TIMx_CNT> TIMx_CCR1 else inactive.

*Note:* These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S='00' (the channel is configured in output).

*Note:* In PWM mode 1 or 2, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.
Bit 3 **OC1PE**: Output Compare 1 preload enable

0: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken in account immediately.

1: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded in the active register at each update event.

*Note: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S='00' (the channel is configured in output).*

Bit 2 **OC1FE**: Output Compare 1 fast enable

This bit is used to accelerate the effect of an event on the trigger in input on the CC output.

0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.

1: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently of the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output.

01: CC1 channel is configured as input, IC1 is mapped on TI1.

10: CC1 channel is configured as input, IC1 is mapped on TI2.

11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

*Note: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIMx_CCER).*

### 20.5.9 TIM15 capture/compare enable register (TIM15_CCER)

Address offset: 0x20

Reset value: 0x0000

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **CC2NP**: Capture/Compare 2 complementary output polarity

Refer to CC1NP description.

Bit 6 Reserved, must be kept at reset value.

Bit 5 **CC2P**: Capture/Compare 2 output polarity

Refer to CC1P description.

Bit 4 **CC2E**: Capture/Compare 2 output enable

Refer to CC1E description.
Bit 3 **CC1NP**: Capture/Compare 1 complementary output polarity

0: OC1N active high
1: OC1N active low

*Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S="00" (the channel is configured in output).*

Bit 2 **CC1NE**: Capture/Compare 1 complementary output enable

0: Off - OC1N is not active. OC1N level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.
1: On - OC1N signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.

Bit 1 **CC1P**: Capture/Compare 1 output polarity

**Condition: CC1 channel configured as output**

0: OC1 active high
1: OC1 active low

**Condition: CC1 channel configured as input**
The CC1NP/CC1P bits select the polarity of TI1FP1 and TI2FP1 for trigger or capture operations.

00: Noninverted/rising edge: circuit is sensitive to TIxFP1’s rising edge (capture, trigger in reset or trigger mode), TIxFP1 is not inverted (trigger in gated mode).
01: Inverted/falling edge: circuit is sensitive to TIxFP1’s falling edge (capture, trigger in reset, or trigger mode), TIxFP1 is inverted (trigger in gated mode).
10: Reserved, do not use this configuration.
11: Noninverted/both edges: circuit is sensitive to both the rising and falling edges of TIxFP1 (capture, trigger in reset or trigger mode), TIxFP1 is not inverted (trigger in gated mode).

*Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).*

Bit 0 **CC1E**: Capture/Compare 1 output enable

**Condition: CC1 channel configured as output**

0: Off - OC1 is not active. OC1 level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and CC1NE bits.
1: On - OC1 signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and CC1NE bits.

**Condition: CC1 channel configured as input**

This bit determines if a capture of the counter value can actually be done into the input capture/compare register 1 (TIMx_CCR1) or not.

0: Capture disabled
1: Capture enabled
### Table 72. Output control bits for complementary OCx and OCxN channels with break feature

<table>
<thead>
<tr>

<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 15:0 **PSC[15:0]**: Prescaler value

The counter clock frequency (CK_CNT) is equal to \( f_{CK_PSC} / (PSC[15:0] + 1) \).

PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in “reset mode”).

20.5.12 TIM15 auto-reload register (TIM15_ARR)

Address offset: 0x2C
Reset value: 0xFFFF

<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>
<th>10</th>

<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 15:0 **ARR[15:0]**: Auto-reload value

ARR is the value to be loaded in the actual auto-reload register.

Refer to the Section 19.3.1: Time-base unit on page 472 for more details about ARR update and behavior.

The counter is blocked while the auto-reload value is null.
20.5.13 TIM15 repetition counter register (TIM15_RCR)

Address offset: 0x30
Reset value: 0x0000

<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>
<th>10</th>
<th>9</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 REP[7:0]: Repetition counter value

These bits allow the user to set-up the update rate of the compare registers (i.e. periodic transfers from preload to active registers) when preload registers are enable, as well as the update interrupt generation rate, if this interrupt is enable.

Each time the REP_CNT related downcounter reaches zero, an update event is generated and it restarts counting from REP value. As REP_CNT is reloaded with REP value only at the repetition update event U_RC, any write to the TIMx_RCR register is not taken in account until the next repetition update event.

It means in PWM mode (REP+1) corresponds to the number of PWM periods in edge-aligned mode.

20.5.14 TIM15 capture/compare register 1 (TIM15_CCR1)

Address offset: 0x34
Reset value: 0x0000

<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>
<th>10</th>
<th>9</th>
<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

Bits 15:0 CCR1[15:0]: Capture/Compare 1 value

**Condition: if channel CC1 is configured as output**

CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on OC1 output.

**Condition: if channel CC1 is configured as input**

CCR1 is the counter value transferred by the last input capture 1 event (IC1).

20.5.15 TIM15 capture/compare register 2 (TIM15_CCR2)

Address offset: 0x38
Reset value: 0x0000

<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>
<th>11</th>

</table>
20.5.16 TIM15 break and dead-time register (TIM15_BDTR)

Address offset: 0x44
Reset value: 0x0000

<table>
<thead>
<tr>
<th></th>
<th>MOE</th>
<th>AOE</th>
<th>BKP</th>
<th>BKE</th>
<th>OSSR</th>
<th>OSSI</th>
<th>LOCK[1:0]</th>
<th>DTG[7:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Note: As the bits AOE, BKP, BKE, OSSR, OSSI and DTG[7:0] can be write-locked depending on the LOCK configuration, it can be necessary to configure all of them during the first write access to the TIMx_BDTR register.

Bit 15 MOE: Main output enable
- This bit is cleared asynchronously by hardware as soon as the break input is active. It is set by software or automatically depending on the AOE bit. It is acting only on the channels which are configured in output.
- 0: OC and OCN outputs are disabled or forced to idle state
- 1: OC and OCN outputs are enabled if their respective enable bits are set (CCxE, CCxNE in TIMx_CCER register)

See OC/OCN enable description for more details (Section 20.5.9: TIM15 capture/compare enable register (TIM15_CCER) on page 533).

Bit 14 AOE: Automatic output enable
- 0: MOE can be set only by software
- 1: MOE can be set by software or automatically at the next update event (if the break input is not be active)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 13 BKP: Break polarity
- 0: Break input BRK is active low
- 1: Break input BRK is active high

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Note: Any write operation to this bits takes a delay of 1 APB clock cycle to become effective.
Bit 12 **BKE**: Break enable

- 0: Break inputs (BRK and CCS clock failure event) disabled
- 1: Break inputs (BRK and CCS clock failure event) enabled

*Note:* This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

*Note:* Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 11 **OSSR**: Off-state selection for Run mode

This bit is used when MOE=1 on channels having a complementary output which are configured as outputs. OSSR is not implemented if no complementary output is implemented in the timer.

See OC/OCN enable description for more details (Section 20.5.9: TIM15 capture/compare enable register (TIM15_CCER) on page 533).

- 0: When inactive, OC/OCN outputs are disabled (OC/OCN enable output signal=0)
- 1: When inactive, OC/OCN outputs are enabled with their inactive level as soon as CCxE=1 or CCxNE=1. Then, OC/OCN enable output signal=1

*Note:* This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 10 **OSSI**: Off-state selection for Idle mode

This bit is used when MOE=0 on channels configured as outputs.

See OC/OCN enable description for more details (Section 20.5.9: TIM15 capture/compare enable register (TIM15_CCER) on page 533).

- 0: When inactive, OC/OCN outputs are disabled (OC/OCN enable output signal=0)
- 1: When inactive, OC/OCN outputs are forced first with their idle level as soon as CCxE=1 or CCxNE=1. OC/OCN enable output signal=1

*Note:* This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 9:8 **LOCK[1:0]**: Lock configuration

These bits offer a write protection against software errors.

- 00: LOCK OFF - No bit is write protected
- 01: LOCK Level 1 = DTG bits in TIMx_BDTR register, OISx and OISxN bits in TIMx_CR2 register and BKE/BKP/AOE bits in TIMx_BDTR register can no longer be written
- 10: LOCK Level 2 = LOCK Level 1 + CC Polarity bits (CCxP/CCxNP bits in TIMx_CCER register, as long as the related channel is configured in output through the CCxS bits) as well as OSSR and OSSI bits can no longer be written.
- 11: LOCK Level 3 = LOCK Level 2 + CC Control bits (OCxM and OCxPE bits in TIMx_CCMRx registers, as long as the related channel is configured in output through the CCxS bits) can no longer be written.

*Note:* The LOCK bits can be written only once after the reset. Once the TIMx_BDTR register has been written, their content is frozen until the next reset.
20.5.17 TIM15 DMA control register (TIM15_DCR)

Address offset: 0x48
Reset value: 0x0000

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **DBL[4:0]**: DMA burst length
This 5-bit vector defines the length of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address).
- 00000: 1 transfer
- 00001: 2 transfers
- 00010: 3 transfers
... 10001: 18 transfers

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DBA[4:0]**: DMA base address
This 5-bits vector defines the base-address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register.
Example:
- 00000: TIMx_CR1
- 00001: TIMx_CR2
- 00010: TIMx_SMCR
...
### 20.5.18 TIM15 DMA address for full transfer (TIM15_DMAR)

Address offset: 0x4C

Reset value: 0x0000

<table>
<thead>

<th>rw</th>
<th>rw</th>
<th>rw</th>
<th>rw</th>
</tr>
</thead>
</table>

Bits 15:0 **DMAB[15:0]**: DMA register for burst accesses

A read or write operation to the DMAR register accesses the register located at the address 

(TIMx_CR1 address) + (DBA + DMA index) x 4

where TIMx_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIMx_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIMx_DCR).

### 20.5.19 TIM15 register map

TIM15 registers are mapped as 16-bit addressable registers as described in the table below:

Table 73. TIM15 register map and reset values

</tbody>
</table>
Bits 15:10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]:** Clock division
This bit-field indicates the division ratio between the timer clock (CK_INT) frequency and the dead-time and sampling clock (tDTS) used by the dead-time generators and the digital filters (Tl(x)),
- 00: tDTS = tCK_INT
- 01: tDTS = 2*tCK_INT
- 10: tDTS = 4*tCK_INT
- 11: Reserved, do not program this value

Bit 7 **ARPE:** Auto-reload preload enable
0: TIMx_ARR register is not buffered
1: TIMx_ARR register is buffered

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM:** One pulse mode
0: Counter is not stopped at update event
1: Counter stops counting at the next update event (clearing the bit CEN)

Bit 2 **URS:** Update request source
This bit is set and cleared by software to select the UEV event sources.
0: Any of the following events generate an update interrupt or DMA request if enabled.
   These events can be:
   - Counter overflow/underflow
   - Setting the UG bit
   - Update generation through the slave mode controller
1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1 **UDIS:** Update disable
This bit is set and cleared by software to enable/disable UEV event generation.
0: UEV enabled. The Update (UEV) event is generated by one of the following events:
   - Counter overflow/underflow
   - Setting the UG bit
   - Update generation through the slave mode controller
   Buffered registers are then loaded with their preload values.
1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN:** Counter enable
0: Counter disabled
1: Counter enabled
### 20.6.2 TIMx control register 2 (TIMx_CR2)(x = 16 to 17)

Bits 15:10 Reserved, must be kept at reset value.

- **Bit 9 OIS1N**: Output Idle state 1 (OC1N output)
  - 0: OC1N=0 after a dead-time when MOE=0
  - 1: OC1N=1 after a dead-time when MOE=0
  
  *Note*: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BKR register).

- **Bit 8 OIS1**: Output Idle state 1 (OC1 output)
  - 0: OC1=0 (after a dead-time if OC1N is implemented) when MOE=0
  - 1: OC1=1 (after a dead-time if OC1N is implemented) when MOE=0
  
  *Note*: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BKR register).

Bits 7:4 Reserved, must be kept at reset value.

- **Bit 3 CCDS**: Capture/compare DMA selection
  - 0: CCx DMA request sent when CCx event occurs
  - 1: CCx DMA requests sent when update event occurs

- **Bit 2 CCUS**: Capture/compare control update selection
  - 0: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit only.
  - 1: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit or when an rising edge occurs on TRGI.
  
  *Note*: This bit acts only on channels that have a complementary output.

- **Bit 1** Reserved, must be kept at reset value.

- **Bit 0 CCPC**: Capture/compare preloaded control
  - 0: CCxE, CCxNE and OCxM bits are not preloaded
  - 1: CCxE, CCxNE and OCxM bits are preloaded, after having been written, they are updated only when COM bit is set.
  
  *Note*: This bit acts only on channels that have a complementary output.

### 20.6.3 TIMx DMA/interrupt enable register (TIMx_DIER)(x = 16 to 17)

544/1017  
RM0091 Rev 10
20.6.4 TIMx status register (TIMx_SR)(x = 16 to 17)

Address offset: 0x10
Reset value: 0x0000

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 CC1DE: Capture/Compare 1 DMA request enable
0: CC1 DMA request disabled
1: CC1 DMA request enabled

Bit 8 UDE: Update DMA request enable
0: Update DMA request disabled
1: Update DMA request enabled

Bit 7 BIE: Break interrupt enable
0: Break interrupt disabled
1: Break interrupt enabled

Bit 6 Reserved, must be kept at reset value.

Bit 5 COMIE: COM interrupt enable
0: COM interrupt disabled
1: COM interrupt enabled

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 CC1IE: Capture/Compare 1 interrupt enable
0: CC1 interrupt disabled
1: CC1 interrupt enabled

Bit 0 UIE: Update interrupt enable
0: Update interrupt disabled
1: Update interrupt enabled

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 CC1OF: Capture/Compare 1 overcapture flag
This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to '0'.
0: No overcapture has been detected
1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set

Bit 8 Reserved, must be kept at reset value.

Bit 7 BIF: Break interrupt flag
This flag is set by hardware as soon as the break input goes active. It can be cleared by software if the break input is not active.
0: No break event occurred
1: An active level has been detected on the break input
Bit 6  Reserved, must be kept at reset value.

Bit 5  **COMIF**: COM interrupt flag

This flag is set by hardware on a COM event (once the capture/compare control bits –CCxE, CCxNE, OCxM– have been updated). It is cleared by software by writing it to ‘0’.

0: No COM event occurred
1: COM interrupt pending

Bits 4:2  Reserved, must be kept at reset value.

Bit 1  **CC1IF**: Capture/Compare 1 interrupt flag

**Condition: channel CC1 is configured as output:**

This flag is set by hardware when the counter matches the compare value, it is cleared by software.

0: No match.
1: The content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the contents of TIMx_CCR1 are greater than the contents of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in upcounting and up/down-counting modes) or underflow (in downcounting mode)

**Condition: channel CC1 is configured as input:**

This bit is set by hardware on a capture. It is cleared by software or by reading the TIMx_CCR1 register.

0: No input capture occurred
1: The counter value has been captured in TIMx_CCR1 register (An edge has been detected on IC1 which matches the selected polarity)

Bit 0  **UIF**: Update interrupt flag

This bit is set by hardware on an update event. It is cleared by software.

0: No update occurred.
1: Update interrupt pending. This bit is set by hardware when the registers are updated:

– At overflow regarding the repetition counter value (update if repetition counter = 0) and if the UDIS=0 in the TIMx_CR1 register.
– When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if URS=0 and UDIS=0 in the TIMx_CR1 register.

### 20.6.5  TIMx event generation register (TIMx_EGR)(x = 16 to 17)

**Address offset**: 0x14

**Reset value**: 0x0000

</tbody>
</table>
Bits 15:8  Reserved, must be kept at reset value.

Bit 7  **BG**: Break generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action.
1: A break event is generated. MOE bit is cleared and BIF flag is set. Related interrupt or DMA transfer can occur if enabled.

Bit 6  Reserved, must be kept at reset value.

Bit 5  **COMG**: Capture/Compare control update generation
This bit can be set by software, it is automatically cleared by hardware.
0: No action
1: When the CCPC bit is set, it is possible to update the CCxE, CCxNE and OCxM bits
Note:  *This bit acts only on channels that have a complementary output.*

Bits 4:2  Reserved, must be kept at reset value.

Bit 1  **CC1G**: Capture/Compare 1 generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action.
1: A capture/compare event is generated on channel 1:

**Condition: channel CC1 is configured as output:**
CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled.

**Condition: channel CC1 is configured as input:**
The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0  **UG**: Update generation
This bit can be set by software, it is automatically cleared by hardware.
0: No action.
1: Reinitialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected).

### 20.6.6  TIMx capture/compare mode register 1 [alternate]
*(TIMx_CCMR1)(x = 16 to 17)*

Address offset: 0x18
Reset value: 0x0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode. For a given bit, OCxx describes its function when the channel is configured in output, ICxx describes its function when the channel is configured in input. So one must take care that the same bit can have a different meaning for the input stage and for the output stage.

<td></td>
</tr>
</tbody>
</table>
20.6.7 TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1)(x = 16 to 17)

Address offset: 0x18

Reset value: 0x0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and output mode. For a given bit, OCxx describes its function when the channel is configured in output, ICxx describes its function when the channel is configured in input. So
one must take care that the same bit can have a different meaning for the input stage and for the output stage.

Bits 15:7  Reserved, must be kept at reset value.

Bits 6:4  **OC1M[2:0]:** Output Compare 1 mode

These bits define the behavior of the output reference signal OC1REF from which OC1 and OC1N are derived. OC1REF is active high whereas OC1 and OC1N active level depends on CC1P and CC1NP bits.

- **000:** Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs.
- **001:** Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).
- **010:** Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).
- **011:** Toggle - OC1REF toggles when TIMx_CNT=TIMx_CCR1.
- **100:** Force inactive level - OC1REF is forced low.
- **101:** Force active level - OC1REF is forced high.
- **110:** PWM mode 1 - In upcounting, channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else inactive. In downcounting, channel 1 is inactive (OC1REF='0') as long as TIMx_CNT>TIMx_CCR1 else active (OC1REF='1').
- **111:** PWM mode 2 - In upcounting, channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else active. In downcounting, channel 1 is active as long as TIMx_CNT>TIMx_CCR1 else inactive.

**Note:** These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S='00' (the channel is configured in output).

**Note:** In PWM mode 1 or 2, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.

Bit 3  **OC1PE:** Output Compare 1 preload enable

- **0:** Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken in account immediately.
- **1:** Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded in the active register at each update event.

**Note:** These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S='00' (the channel is configured in output).

Bit 2  **OC1FE:** Output Compare 1 fast enable

This bit is used to accelerate the effect of an event on the trigger in input on the CC output.

- **0:** CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.
- **1:** An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently of the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OC1FE acts only if the channel is configured in PWM1 or PWM2 mode.
Bits 1:0  **CC1S[1:0]: Capture/Compare 1 selection**  
This bit-field defines the direction of the channel (input/output) as well as the used input.  
00: CC1 channel is configured as output  
01: CC1 channel is configured as input, IC1 is mapped on TI1  
10: CC1 channel is configured as input, IC1 is mapped on TI2  
11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)  
*Note: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIMx_CCER).*

**20.6.8 TIMx capture/compare enable register (TIMx_CCER)(x = 16 to 17)**

Address offset: 0x20  
Reset value: 0x0000

<table>
<thead>
<tr>
<th>15</th>

<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 15:4  Reserved, must be kept at reset value.

Bit 3  **CC1NP**: Capture/Compare 1 complementary output polarity

0: OC1N active high  
1: OC1N active low  
*Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S="00" (the channel is configured in output).*

Bit 2  **CC1NE**: Capture/Compare 1 complementary output enable

0: Off - OC1N is not active. OC1N level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.
1: On - OC1N signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.

Bit 1  **CC1P**: Capture/Compare 1 output polarity

**Condition: CC1 channel configured as output**

0: OC1 active high  
1: OC1 active low  

**Condition: CC1 channel configured as input**

The CC1NP/CC1P bits select the polarity of TI1FP1 and TI2FP1 for capture operation.

00: Non-inverted/rising edge: circuit is sensitive to TIxFP1’s rising edge TIxFP1 is not inverted.
01: Inverted/falling edge: circuit is sensitive to TIxFP1’s falling edge, TIxFP1 is inverted.
10: Reserved, do not use this configuration.
11: Non-inverted/both edges: circuit is sensitive to both the rising and falling edges of TIxFP1, TIxFP1 is not inverted.

*Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register)*
Bit 0  **CC1E**: Capture/Compare 1 output enable

**Condition: CC1 channel configured as output**

0: Off - OC1 is not active. OC1 level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and CC1NE bits.

1: On - OC1 signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and CC1NE bits.

**Condition: CC1 channel configured as input**

This bit determines if a capture of the counter value can actually be done into the input capture/compare register 1 (TIMx_CCR1) or not.

0: Capture disabled
1: Capture enabled

</tbody>
</table>

Bits 15:0 PSC[15:0]: Prescaler value

The counter clock frequency (CK_CNT) is equal to fCK_PSC / (PSC[15:0] + 1).

PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in “reset mode”).

20.6.11 TIMx auto-reload register (TIMx_ARR)(x = 16 to 17)

Bits 15:0 ARR[15:0]: Auto-reload value

ARR is the value to be loaded in the actual auto-reload register.

Refer to the Section 19.3.1: Time-base unit on page 472 for more details about ARR update and behavior.

The counter is blocked while the auto-reload value is null.
20.6.12  TIMx repetition counter register (TIMx_RCR)(x = 16 to 17)

Address offset: 0x30
Reset value: 0x0000

<th>0</th>
</tr>
</thead>
</table>

Bits 15:8  Reserved, must be kept at reset value.

Bits 7:0  REP[7:0]: Repetition counter value

These bits allow the user to set-up the update rate of the compare registers (i.e. periodic transfers from preload to active registers) when preload registers are enable, as well as the update interrupt generation rate, if this interrupt is enable.

Each time the REP_CNT related downcounter reaches zero, an update event is generated and it restarts counting from REP value. As REP_CNT is reloaded with REP value only at the repetition update event U_RC, any write to the TIMx_RCR register is not taken in account until the next repetition update event.

It means in PWM mode (REP+1) corresponds to the number of PWM periods in edge-aligned mode.

20.6.13  TIMx capture/compare register 1 (TIMx_CCR1)(x = 16 to 17)

Address offset: 0x34
Reset value: 0x0000

</tbody>
</table>

Bits 15:0  CCR1[15:0]: Capture/Compare 1 value

**Condition: channel CC1 is configured as output**

CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on OC1 output.

**Condition: channel CC1 is configured as input**

CCR1 is the counter value transferred by the last input capture 1 event (IC1).

20.6.14  TIMx break and dead-time register (TIMx_BDTR)(x = 16 to 17)

Address offset: 0x44
Reset value: 0x0000

</table>
Note: As the bits AOE, BKP, BKE, OSSI, OSSR and DTG[7:0] can be write-locked depending on the LOCK configuration, it can be necessary to configure all of them during the first write access to the TIMx_BDTR register.

Bit 15 MOE: Main output enable
This bit is cleared asynchronously by hardware as soon as the break input is active. It is set by software or automatically depending on the AOE bit. It is acting only on the channels which are configured in output.
0: OC and OCN outputs are disabled or forced to idle state
1: OC and OCN outputs are enabled if their respective enable bits are set (CCxE, CCxNE in TIMx_CCER register)
See OC/OCN enable description for more details (Section 20.5.9: TIM15 capture/compare enable register (TIM15_CCER) on page 533).

Bit 14 AOE: Automatic output enable
0: MOE can be set only by software
1: MOE can be set by software or automatically at the next update event (if the break input is not be active)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 13 BKP: Break polarity
0: Break input BRK is active low
1: Break input BRK is active high

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 12 BKE: Break enable
0: Break inputs (BRK and CCS clock failure event) disabled
1: Break inputs (BRK and CCS clock failure event) enabled

Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 11 OSSR: Off-state selection for Run mode
This bit is used when MOE=1 on channels having a complementary output which are configured as outputs. OSSR is not implemented if no complementary output is implemented in the timer.
See OC/OCN enable description for more details (Section 20.5.9: TIM15 capture/compare enable register (TIM15_CCER) on page 533).
0: When inactive, OC/OCN outputs are disabled (OC/OCN enable output signal=0)
1: When inactive, OC/OCN outputs are enabled with their inactive level as soon as CCxE=1 or CCxNE=1. Then, OC/OCN enable output signal=1

Note: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).
Bit 10 **OSSI**: Off-state selection for Idle mode

This bit is used when MOE=0 on channels configured as outputs. See OC/OCN enable description for more details (Section 20.5.9: TIM15 capture/compare enable register (TIM15_CCER) on page 533).

- **0**: When inactive, OC/OCN outputs are disabled (OC/OCN enable output signal=0)
- **1**: When inactive, OC/OCN outputs are forced first with their idle level as soon as CCxE=1 or CCxNE=1. OC/OCN enable output signal=1)

**Note**: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 9:8 **LOCK[1:0]**: Lock configuration

These bits offer a write protection against software errors.

- **00**: LOCK OFF - No bit is write protected
- **01**: LOCK Level 1 = DTG bits in TIMx_BDTR register, OISx and OISxN bits in TIMx_CR2 register and BKE/BKP/AOE bits in TIMx_BDTR register can no longer be written.
- **10**: LOCK Level 2 = LOCK Level 1 + CC Polarity bits (CCxP/CCxNP bits in TIMx_CCER register, as long as the related channel is configured in output through the CCxS bits) as well as OSSR and OSSI bits can no longer be written.
- **11**: LOCK Level 3 = LOCK Level 2 + CC Control bits (OCxM and OCxPE bits in TIMx_CCMRx registers, as long as the related channel is configured in output through the CCxS bits) can no longer be written.

**Note**: The LOCK bits can be written only once after the reset. Once the TIMx_BDTR register has been written, their content is frozen until the next reset.

Bits 7:0 **DTG[7:0]**: Dead-time generator setup

This bit-field defines the duration of the dead-time inserted between the complementary outputs. DT correspond to this duration.

- **DTG[7:5]=0xx**: DT=DTG[7:0]x t\(_{\text{DTS}}\) with t\(_{\text{DTS}}\)=t\(_{\text{DTS}}\)
- **DTG[7:5]=10x**: DT=(64+DTG[5:0])x t\(_{\text{DTS}}\) with T\(_{\text{DTS}}\)=2x\(_{\text{DTS}}\)
- **DTG[7:5]=110**: DT=(32+DTG[4:0])x t\(_{\text{DTS}}\) with T\(_{\text{DTS}}\)=8x\(_{\text{DTS}}\)
- **DTG[7:5]=111**: DT=(32+DTG[4:0])x t\(_{\text{DTS}}\) with T\(_{\text{DTS}}\)=16x\(_{\text{DTS}}\)

Example if T\(_{\text{DTS}}\)=125ns (8MHz), dead-time possible values are:
- 0 to 15875 ns by 125 ns steps,
- 16 µs to 31750 ns by 250 ns steps,
- 32 µs to 63 µs by 1 µs steps,
- 64 µs to 126 µs by 2 µs steps

**Note**: This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

### 20.6.15 TIMx DMA control register (TIMx_DCR)(x = 16 to 17)

**Address offset**: 0x48

**Reset value**: 0x0000

<table>

</tbody>
</table>

**Bits 15:13**: Reserved, must be kept at reset value.
Bits 12:8 **DBL[4:0]**: DMA burst length

This 5-bit vector defines the length of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address, i.e. the number of transfers. Transfers can be in half-words or in bytes (see example below).

00000: 1 transfer  
00001: 2 transfers  
00010: 3 transfers  
...  
10001: 18 transfers.

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DBA[4:0]**: DMA base address

This 5-bits vector defines the base-address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register.

Example:

00000: TIMx_CR1  
00001: TIMx_CR2  
00010: TIMx_SMCR  
...  

**Example:** Let us consider the following transfer: DBL = 7 transfers and DBA = TIMx_CR1. In this case the transfer is done to/from 7 registers starting from the TIMx_CR1 address.

### 20.6.16 TIMx DMA address for full transfer (TIMx_DMAR)(x = 16 to 17)

Address offset: 0x4C  
Reset value: 0x0000

<table>
<thead>
<tr>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**DMAB[15:0]**

Bits 15:0 **DMAB[15:0]**: DMA register for burst accesses

A read or write access to the DMAR register accesses the register located at the address: "(TIMx_CR1 address) + DBA + (DMA index)" in which:

TIMx_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIMx_DCR register, DMA index is the offset automatically controlled by the DMA transfer, depending on the length of the transfer DBL in the TIMx_DCR register.

**Example of how to use the DMA burst feature**

In this example the timer DMA burst feature is used to update the contents of the CCRx registers (x = 2, 3, 4) with the DMA transferring half words into the CCRx registers.

This is done in the following steps:
1. Configure the corresponding DMA channel as follows:
   – DMA channel peripheral address is the DMAR register address
   – DMA channel memory address is the address of the buffer in the RAM containing
     the data to be transferred by DMA into CCRx registers.
   – Number of data to transfer = 3 (See note below).
   – Circular mode disabled.

2. Configure the DCR register by configuring the DBA and DBL bit fields as follows:
   DBL = 3 transfers, DBA = 0xE.

3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).

4. Enable TIMx

5. Enable the DMA channel

Note: This example is for the case where every CCRx register to be updated once. If every CCRx
register is to be updated twice for example, the number of data to transfer should be 6. Let
us take the example of a buffer in the RAM containing data1, data2, data3, data4, data5 and
data6. The data is transferred to the CCRx registers as follows: on the first update DMA
request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to
CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is
transferred to CCR3 and data6 is transferred to CCR4.

20.6.17 TIM16/TIM17 register map

TIM16 and TIM17 registers are mapped as 16-bit addressable registers as described in the
table below:

| Offset | Register                  | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

Refer to Section 2.2 on page 46 for the register boundary addresses.
21 Basic timer (TIM6/TIM7)

This section applies to STM32F05x, STM32F07x and STM32F09x devices only. TIM7 is available only on STM32F07x and STM32F09x devices.

21.1 TIM6/TIM7 introduction

The basic timer TIM6 consists of a 16-bit auto-reload counter driven by a programmable prescaler.

It may be used as a generic timer for time-base generation but it is also specifically used to drive the digital-to-analog converter (DAC). In fact, TIM6 is internally connected to the DAC and is able to drive it through its trigger outputs.

21.2 TIM6/TIM7 main features

- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535
- Synchronization circuit to trigger the DAC
- Interrupt/DMA generation on the update event: counter overflow

![Figure 201. Basic timer block diagram](image)
21.3  **TIM6/TIM7 functional description**

21.3.1  **Time-base unit**

The main block of the programmable timer is a 16-bit upcounter with its related auto-reload register. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:

- Counter Register (TIMx_CNT)
- Prescaler Register (TIMx_PSC)
- Auto-Reload Register (TIMx_ARR)

The auto-reload register is preloaded. The preload register is accessed each time an attempt is made to write or read the auto-reload register. The contents of the preload register are transferred into the shadow register permanently or at each update event UEV, depending on the auto-reload preload enable bit (ARPE) in the TIMx_CR1 register. The update event is sent when the counter reaches the overflow value and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detail for each configuration.

The counter is clocked by the prescaler output CK_CNT, which is enabled only when the counter enable bit (CEN) in the TIMx_CR1 register is set.

Note that the actual counter enable signal CNT_EN is set 1 clock cycle after CEN.

**Prescaler description**

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as the TIMx_PSC control register is buffered. The new prescaler ratio is taken into account at the next update event.

*Figure 202* and *Figure 203* give some examples of the counter behavior when the prescaler ratio is changed on the fly.
Figure 202. Counter timing diagram with prescaler division change from 1 to 2

Figure 203. Counter timing diagram with prescaler division change from 1 to 4
21.3.2 Counter modes

The counter counts from 0 to the auto-reload value (contents of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

An update event can be generate at each counter overflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller).

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This avoids updating the shadow registers while writing new values into the preload registers. In this way, no update event occurs until the UDIS bit has been written to 0, however, the counter and the prescaler counter both restart from 0 (but the prescale rate does not change). In addition, if the URS (update request selection) bit in the TIMx_CR1 register is set, setting the UG bit generates an update event UEV, but the UIF flag is not set (so no interrupt or DMA request is sent).

When an update event occurs, all the registers are updated and the update flag (UIF bit in the TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (contents of the TIMx_PSC register)
- The auto-reload shadow register is updated with the preload value (TIMx_ARR)

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR = 0x36.

Write a new value in TIMx_ARR
21.3.3 Clock source

The counter clock is provided by the Internal clock (CK_INT) source.

The CEN (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except for UG that remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK_INT.

Figure 210 shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

![Figure 210. Control circuit in normal mode, internal clock divided by 1](image)

21.3.4 Debug mode

When the microcontroller enters the debug mode (Cortex™-M0 core - halted), the TIMx counter either continues to work normally or stops, depending on the DBG_TIMx_STOP configuration bit in the DBG module.
### 21.4 TIM6/TIM7 registers

Refer to [Section 1.2 on page 42](#) for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

#### 21.4.1 TIM6/TIM7 control register 1 (TIMx_CR1)

Address offset: 0x00

Reset value: 0x0000

<table>
<thead>

</tbody>
</table>

Bits 15:8  Reserved, always read as 0.

Bit 7 **ARPE**: Auto-reload preload enable

0: TIMx_ARR register is not buffered.
1: TIMx_ARR register is buffered.

Bits 6:4  Reserved, always read as 0.

Bit 3 **OPM**: One-pulse mode

0: Counter is not stopped at update event
1: Counter stops counting at the next update event (clearing the CEN bit).

Bit 2 **URS**: Update request source

This bit is set and cleared by software to select the UEV event sources.

0: Any of the following events generates an update interrupt or DMA request if enabled.

These events can be:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1 **UDIS**: Update disable

This bit is set and cleared by software to enable/disable UEV event generation.

0: UEV enabled. The Update (UEV) event is generated by one of the following events:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

Buffered registers are then loaded with their preload values.

1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable

0: Counter disabled
1: Counter enabled

*Note: Gated mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.*

CEN is cleared automatically in one-pulse mode, when an update event occurs.
21.4.2 TIM6/TIM7 control register 2 (TIMx_CR2)

Address offset: 0x04
Reset value: 0x0000

<table>
<thead>
<tr>
<th>15</th>

<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:4 **MMS**: Master mode selection

These bits are used to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows:

- **000**: *Reset* - the UG bit from the TIMx_EGR register is used as a trigger output (TRGO). If reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on TRGO is delayed compared to the actual reset.
- **001**: *Enable* - the Counter enable signal, CNT_EN, is used as a trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic OR between CEN control bit and the trigger input when configured in gated mode.
- **010**: *Update* - The update event is selected as a trigger output (TRGO). For instance a master timer can then be used as a prescaler for a slave timer.

Bits 3:0 Reserved, always read as 0.

21.4.3 TIM6/TIM7 DMA/Interrupt enable register (TIMx_DIER)

Address offset: 0x0C
Reset value: 0x0000

<table>
<thead>
<tr>
<th>15</th>

<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **UDE**: Update DMA request enable

- 0: Update DMA request disabled.
- 1: Update DMA request enabled.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **UIE**: Update interrupt enable

- 0: Update interrupt disabled.
- 1: Update interrupt enabled.
### 21.4.4 TIM6/TIM7 status register (TIMx_SR)

Address offset: 0x10  
Reset value: 0x0000

<table>
<thead>
<tr>
<th>15</th>
<th>14</th>

<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **UIF**: Update interrupt flag  
This bit is set by hardware on an update event. It is cleared by software.

- 0: No update occurred.
- 1: Update interrupt pending. This bit is set by hardware when the registers are updated:
  - At overflow or underflow regarding the repetition counter value and if UDIS = 0 in the TIMx_CR1 register.
  - When CNT is reinitialized by software using the UG bit in the TIMx_EGR register, if URS = 0 and UDIS = 0 in the TIMx_CR1 register.

### 21.4.5 TIM6/TIM7 event generation register (TIMx_EGR)

Address offset: 0x14  
Reset value: 0x0000

<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>

<th>8</th>
<th>7</th>
<th>6</th>
<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **UG**: Update generation  
This bit can be set by software, it is automatically cleared by hardware.

- 0: No action.
- 1: Re-initializes the timer counter and generates an update of the registers. Note that the prescaler counter is cleared too (but the prescaler ratio is not affected).

### 21.4.6 TIM6/TIM7 counter (TIMx_CNT)

Address offset: 0x24  
Reset value: 0x0000

<td>rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw</td>
</tr>
</tbody>
</table>

Bits 15:0 **PSC[15:0]**: Prescaler value
The counter clock frequency \( f_{CK\_CNT} \) is equal to \( f_{CK\_PSC} / (PSC[15:0] + 1) \).
PSC contains the value to be loaded into the active prescaler register at each update event.

21.4.8 TIM6/TIM7 auto-reload register (TIMx_ARR)

Address offset: 0x2C
Reset value: 0xFFFF

<table>
<thead>
<tr>
<th>ARR[15:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw</td>
</tr>
</tbody>
</table>

Bits 15:0 **ARR[15:0]**: Auto-reload value
ARR is the value to be loaded into the actual auto-reload register.
Refer to Section 21.3.1: Time-base unit on page 561 for more details about ARR update and behavior.
The counter is blocked while the auto-reload value is null.
### 21.4.9 TIM6/TIM7 register map

TIMx registers are mapped as 16-bit addressable registers as described in the table below:

#### Table 76. TIM6/TIM7 register map and reset values

| Offset | Register   | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0   |
|--------|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 0x00   | TIMx_CR1   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | Reset value| 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| 0x04   | TIMx_CR2   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | Reset value| 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| 0x0C   | TIMx_DIER  |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | Reset value| 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| 0x10   | TIMx_SR    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | Reset value| 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| 0x14   | TIMx_EGR   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | Reset value| 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| 0x24   | TIMx_CNT   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | Reset value| 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| 0x28   | TIMx_PSC   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | Reset value| 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| 0x2C   | TIMx_ARR   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|        | Reset value| 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  |

Refer to Section 2.2 on page 46 for the register boundary addresses.
22 Infrared interface (IRTIM)

An infrared interface (IRTIM) for remote control is available on the device. It can be used with an infrared LED to perform remote control functions.

It uses internal connections with USART1, USART4 (on STM32F03x and STM32F05x) or USART2 (STM32F07x), TIM16 and TIM17 as shown in Figure 211.

To generate the infrared remote control signals, the IR interface must be enabled and TIM16 channel 1 (TIM16_OC1) and TIM17 channel 1 (TIM17_OC1) must be properly configured to generate correct waveforms.

The infrared receiver can be implemented easily through a basic input capture mode.

![Figure 211. IRTIM internal hardware connections with TIM16 and TIM17](image)

1. USART1 and USART4 can be linked to IRTIM on STM32F09x devices only.

All standard IR pulse modulation modes can be obtained by programming the two timer output compare channels.

TIM17 is used to generate the high frequency carrier signal, while TIM16 generates the modulation envelope.

On STM32F09x devices, the modulation envelope can also be created from USART1 or USART4 transmitter line, upon setting appropriately the IR_MOD[1:0] bits in SYSCFG_CFRG1 register.

The infrared function is output on the IR_OUT pin. The activation of this function is done through the GPIOx_AFRx register by enabling the related alternate function bit.

The high sink LED driver capability (only available on the PB9 pin) can be activated through the I2C_PB9_FMP bit in the SYSCFG_CFGR1 register and used to sink the high current needed to directly control an infrared LED.

For code example refer to the Appendix section A.10.1: TIM16 and TIM17 configuration code example.
23 Independent watchdog (IWDG)

23.1 Introduction

The devices feature an embedded watchdog peripheral that offers a combination of high safety level, timing accuracy and flexibility of use. The Independent watchdog peripheral detects and solves malfunctions due to software failure, and triggers system reset when the counter reaches a given timeout value.

The independent watchdog (IWDG) is clocked by its own dedicated low-speed clock (LSI) and thus stays active even if the main clock fails.

The IWDG is best suited for applications that require the watchdog to run as a totally independent process outside the main application, but have lower timing accuracy constraints. For further information on the window watchdog, refer to Section 24 on page 583.

23.2 IWDG main features

- Free-running downcounter
- Clocked from an independent RC oscillator (can operate in Standby and Stop modes)
- Conditional reset
  - Reset (if watchdog activated) when the downcounter value becomes lower than 0x000
  - Reset (if watchdog activated) if the downcounter is reloaded outside the window

23.3 IWDG functional description

23.3.1 IWDG block diagram

Figure 212 shows the functional blocks of the independent watchdog module.

![Figure 212. Independent watchdog block diagram](MS19944V2)

1. The register interface is located in the CORE voltage domain. The watchdog function is located in the VDD voltage domain, still functional in Stop and Standby modes.
When the independent watchdog is started by writing the value 0x0000 CCCC in the IWDG key register (IWDG_KR), the counter starts counting down from the reset value of 0xFFF. When it reaches the end of count value (0x000) a reset signal is generated (IWDG reset).

Whenever the key value 0x0000 AAAA is written in the IWDG key register (IWDG_KR), the IWDG_RLR value is reloaded in the counter and the watchdog reset is prevented.

Once running, the IWDG cannot be stopped.

23.3.2 Window option

The IWDG can also work as a window watchdog by setting the appropriate window in the IWDG window register (IWDG_WINR).

If the reload operation is performed while the counter is greater than the value stored in the IWDG window register (IWDG_WINR), then a reset is provided.

The default value of the IWDG window register (IWDG_WINR) is 0x0000 0xFFF, so if it is not updated, the window option is disabled.

As soon as the window value is changed, a reload operation is performed in order to reset the downcounter to the IWDG reload register (IWDG_RLR) value and ease the cycle number calculation to generate the next reload.

Configuring the IWDG when the window option is enabled

1. Enable the IWDG by writing 0x0000 CCCC in the IWDG key register (IWDG_KR).
2. Enable register access by writing 0x0000 5555 in the IWDG key register (IWDG_KR).
3. Write the IWDG prescaler by programming IWDG prescaler register (IWDG_PR) from 0 to 7.
4. Write the IWDG reload register (IWDG_RLR).
5. Wait for the registers to be updated (IWDG_SR = 0x0000 0000).
6. Write to the IWDG window register (IWDG_WINR). This automatically refreshes the counter value in the IWDG reload register (IWDG_RLR).

Note: Writing the window value allows the counter value to be refreshed by the RLR when IWDG status register (IWDG_SR) is set to 0x0000 0000.

For code example refer to the Appendix section A.15.2: IWDG configuration with window code example.

Configuring the IWDG when the window option is disabled

When the window option it is not used, the IWDG can be configured as follows:

1. Enable the IWDG by writing 0x0000 CCCC in the IWDG key register (IWDG_KR).
2. Enable register access by writing 0x0000 5555 in the IWDG key register (IWDG_KR).
3. Write the prescaler by programming the IWDG prescaler register (IWDG_PR) from 0 to 7.
4. Write the IWDG reload register (IWDG_RLR).
5. Wait for the registers to be updated (IWDG_SR = 0x0000 0000).
6. Refresh the counter value with IWDG_RLR (IWDG_KR = 0x0000 AAAA).

For code example refer to the Appendix section A.15.1: IWDG configuration code example.
23.3.3 Hardware watchdog

If the “Hardware watchdog” feature is enabled through the device option bits, the watchdog is automatically enabled at power-on, and generates a reset unless the IWDG key register (IWDG_KR) is written by the software before the counter reaches end of count or if the downcounter is reloaded inside the window.

23.3.4 Register access protection

Write access to IWDG prescaler register (IWDG_PR), IWDG reload register (IWDG_RLR) and IWDG window register (IWDG_WINR) is protected. To modify them, the user must first write the code 0x0000 5555 in the IWDG key register (IWDG_KR). A write access to this register with a different value breaks the sequence and register access is protected again. This is the case of the reload operation (writing 0x0000 AAAAA).

A status register is available to indicate that an update of the prescaler or of the downcounter reload value or of the window value is ongoing.

For code example refer to the Appendix section A.15.1: IWDG configuration code example.

23.3.5 Debug mode

When the device enters Debug mode (core halted), the IWDG counter either continues to work normally or stops, depending on the configuration of the corresponding bit in DBGMCU freeze register.
23.4 IWDG registers

Refer to Section 1.2 on page 42 for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

23.4.1 IWDG key register (IWDG_KR)

Address offset: 0x00

Reset value: 0x0000 0000 (reset by Standby mode)

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:0  **KEY[15:0]:** Key value (write only, read 0x0000)

These bits must be written by software at regular intervals with the key value 0xAAAA, otherwise the watchdog generates a reset when the counter reaches 0.

Writing the key value 0x5555 to enable access to the IWDG_PR, IWDG_RLR and IWDG_WINR registers (see Section 23.3.4: Register access protection)

Writing the key value 0xCCCC starts the watchdog (except if the hardware watchdog option is selected)
23.4.2  IWDG prescaler register (IWDG_PR)

Address offset: 0x04
Reset value: 0x0000 0000

<table>
<thead>
<tr>

</tr>
</thead>
</table>

Bits 31:3  Reserved, must be kept at reset value.

Bits 2:0  PR[2:0]: Prescaler divider

These bits are write access protected see Section 23.3.4: Register access protection. They are written by software to select the prescaler divider feeding the counter clock. PVU bit of the IWDG status register (IWDG_SR) must be reset in order to be able to change the prescaler divider.

- 000: divider /4
- 001: divider /8
- 010: divider /16
- 011: divider /32
- 100: divider /64
- 101: divider /128
- 110: divider /256
- 111: divider /256

Note: Reading this register returns the prescaler value from the VDD voltage domain. This value may not be up to date/valid if a write operation to this register is ongoing. For this reason the value read from this register is valid only when the PVU bit in the IWDG status register (IWDG_SR) is reset.
23.4.3  IWDG reload register (IWDG_RLR)

Address offset: 0x08
Reset value: 0x0000 0FFF (reset by Standby mode)

</tbody>
</table>

Bits 31:12  Reserved, must be kept at reset value.

Bits 11:0  RL[11:0]: Watchdog counter reload value

These bits are write access protected see Register access protection. They are written by software to define the value to be loaded in the watchdog counter each time the value 0xAAAA is written in the IWDG key register (IWDG_KR). The watchdog counter counts down from this value. The timeout period is a function of this value and the clock prescaler. Refer to the datasheet for the timeout information.

The RVU bit in the IWDG status register (IWDG_SR) must be reset to be able to change the reload value.

Note: Reading this register returns the reload value from the VDD voltage domain. This value may not be up to date/valid if a write operation to this register is ongoing on it. For this reason the value read from this register is valid only when the RVU bit in the IWDG status register (IWDG_SR) is reset.
23.4.4 IWDG status register (IWDG_SR)

Address offset: 0x0C
Reset value: 0x0000 0000 (not reset by Standby mode)

</table>

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **WVU**: Watchdog counter window value update

- This bit is set by hardware to indicate that an update of the window value is ongoing. It is reset by hardware when the reload value update operation is completed in the V\textsubscript{DD} voltage domain (takes up to five RC 40 kHz cycles).
- Window value can be updated only when WVU bit is reset.

Bit 1 **RVU**: Watchdog counter reload value update

- This bit is set by hardware to indicate that an update of the reload value is ongoing. It is reset by hardware when the reload value update operation is completed in the V\textsubscript{DD} voltage domain (takes up to five RC 40 kHz cycles).
- Reload value can be updated only when RVU bit is reset.

Bit 0 **PVU**: Watchdog prescaler value update

- This bit is set by hardware to indicate that an update of the prescaler value is ongoing. It is reset by hardware when the prescaler update operation is completed in the V\textsubscript{DD} voltage domain (takes up to five RC 40 kHz cycles).
- Prescaler value can be updated only when PVU bit is reset.

**Note:** If several reload, prescaler, or window values are used by the application, it is mandatory to wait until RVU bit is reset before changing the reload value, to wait until PVU bit is reset before changing the prescaler value, and to wait until WVU bit is reset before changing the window value. However, after updating the prescaler and/or the reload/window value it is not necessary to wait until RVU or PVU or WVU is reset before continuing code execution except in case of low-power mode entry.
23.4.5 IWDG window register (IWDG_WINR)

</tbody>
</table>

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **WIN[11:0]**: Watchdog counter window value

These bits are write access protected, see Section 23.3.4, they contain the high limit of the window value to be compared with the downcounter.

To prevent a reset, the downcounter must be reloaded when its value is lower than the window register value and greater than 0x0.

The WVU bit in the **IWDG status register (IWDG_SR)** must be reset in order to be able to change the reload value.

**Note:** Reading this register returns the reload value from the VDD voltage domain. This value may not be valid if a write operation to this register is ongoing. For this reason the value read from this register is valid only when the WVU bit in the **IWDG status register (IWDG_SR)** is reset.
23.4.6  IWDG register map

Refer to Section 2.2 on page 46 for the register boundary addresses.
24 System window watchdog (WWDG)

24.1 Introduction

The system window watchdog (WWDG) is used to detect the occurrence of a software fault, usually generated by external interference or by unforeseen logical conditions, which causes the application program to abandon its normal sequence. The watchdog circuit generates an MCU reset on expiry of a programmed time period, unless the program refreshes the contents of the down-counter before the T6 bit becomes cleared. An MCU reset is also generated if the 7-bit down-counter value (in the control register) is refreshed before the down-counter has reached the window register value. This implies that the counter must be refreshed in a limited window.

The WWDG clock is prescaled from the APB clock and has a configurable time-window that can be programmed to detect abnormally late or early application behavior.

The WWDG is best suited for applications which require the watchdog to react within an accurate timing window.

24.2 WWDG main features

- Programmable free-running down-counter
- Conditional reset
  - Reset (if watchdog activated) when the down-counter value becomes lower than 0x40
  - Reset (if watchdog activated) if the down-counter is reloaded outside the window (see Figure 214)
- Early wake-up interrupt (EWI): triggered (if enabled and the watchdog activated) when the down-counter is equal to 0x40.

24.3 WWDG functional description

If the watchdog is activated (the WDGA bit is set in the WWDG_CR register) and when the 7-bit down-counter (T[6:0] bits) is decremented from 0x40 to 0x3F (T6 becomes cleared), it initiates a reset. If the software reloads the counter while the counter is greater than the value stored in the window register, then a reset is generated.

The application program must write in the WWDG_CR register at regular intervals during normal operation to prevent an MCU reset. This operation must occur only when the counter value is lower than the window register value and higher than 0x3F. The value to be stored in the WWDG_CR register must be between 0xFF and 0xC0.

Refer to Figure 213 for the WWDG block diagram.
24.3.1 WWDG block diagram

Figure 213. Watchdog block diagram

24.3.2 Enabling the watchdog

The watchdog is always disabled after a reset. It is enabled by setting the WDGA bit in the WWDG_CR register, then it cannot be disabled again except by a reset.

24.3.3 Controlling the down-counter

This down-counter is free-running, counting down even if the watchdog is disabled. When the watchdog is enabled, the T6 bit must be set to prevent generating an immediate reset.

The T[5:0] bits contain the number of increments that represent the time delay before the watchdog produces a reset. The timing varies between a minimum and a maximum value due to the unknown status of the prescaler when writing to the WWDG_CR register (see Figure 214). The WWDG configuration register (WWDG_CFR) contains the high limit of the window: to prevent a reset, the down-counter must be reloaded when its value is lower than the window register value and greater than 0x3F. Figure 214 describes the window watchdog process.

Note: The T6 bit can be used to generate a software reset (the WDGA bit is set and the T6 bit is cleared).

24.3.4 How to program the watchdog timeout

Use the formula in Figure 214 to calculate the WWDG timeout.

Warning: When writing to the WWDG_CR register, always write 1 in the T6 bit to avoid generating an immediate reset.
The formula to calculate the timeout value is given by:

\[ t_{\text{WWDG}} = t_{\text{PCLK}} \times 4096 \times 2^{\text{WDGTB}[1:0]} \times (T[5:0] + 1) \] (ms)

where:
- \( t_{\text{WWDG}} \): WWDG timeout
- \( t_{\text{PCLK}} \): APB clock period measured in ms
- 4096: value corresponding to internal divider

As an example, if APB frequency is 48 MHz, WDGTB1:0 is set to 3 and T[5:0] is set to 63:

\[ t_{\text{WWDG}} = \frac{1}{48000} \times 4096 \times 2^3 \times (63 + 1) = 43.69 \text{ms} \]

Refer to the datasheet for the minimum and maximum values of \( t_{\text{WWDG}} \).

### 24.3.5 Debug mode

When the device enters debug mode (processor halted), the WWDG counter either continues to work normally or stops, depending on the configuration bit in DBG module. For more details refer to Section 32.9.2: Debug support for timers, watchdog and I²C.
24.4 WWDG interrupts

The early wake-up interrupt (EWI) can be used if specific safety operations or data logging must be performed before the actual reset is generated. The EWI interrupt is enabled by setting the EWI bit in the WWDG_CFR register. When the down-counter reaches the value 0x40, an EWI interrupt is generated and the corresponding interrupt service routine (ISR) can be used to trigger specific actions (such as communications or data logging) before resetting the device.

In some applications the EWI interrupt can be used to manage a software system check and/or system recovery/graceful degradation, without generating a WWDG reset. In this case the corresponding ISR has to reload the WWDG counter to avoid the WWDG reset, then trigger the required actions.

The EWI interrupt is cleared by writing '0' to the EWIF bit in the WWDG_SR register.

Note: When the EWI interrupt cannot be served (for example due to a system lock in a higher priority task) the WWDG reset is eventually generated.

24.5 WWDG registers

Refer to Section 1.2 on page 42 for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by halfwords (16-bit) or words (32-bit).

24.5.1 WWDG control register (WWDG_CR)

Address offset: 0x000
Reset value: 0x0000 007F

<table>

</tbody>
</table>

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 WDGA: Activation bit
This bit is set by software and only cleared by hardware after a reset. When WDGA = 1, the watchdog can generate a reset.
0: Watchdog disabled
1: Watchdog enabled

Bits 6:0 T[6:0]: 7-bit counter (MSB to LSB)
These bits contain the value of the watchdog counter, decremented every \((4096 \times 2^{WDGTB1:0})\) PCLK cycles. A reset is produced when it is decremented from 0x40 to 0x3F (T6 becomes cleared).

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **EWI**: Early wake-up interrupt
When set, an interrupt occurs whenever the counter reaches the value 0x40. This interrupt is only cleared by hardware after a reset.

Bits 8:7 **WDGTB[1:0]**: Timer base
The time base of the prescaler can be modified as follows:
00: CK counter clock (PCLK div 4096) div 1
01: CK counter clock (PCLK div 4096) div 2
10: CK counter clock (PCLK div 4096) div 4
11: CK counter clock (PCLK div 4096) div 8

Bits 6:0 **W[6:0]**: 7-bit window value
These bits contain the window value to be compared with the down-counter.

25 Real-time clock (RTC)

25.1 Introduction

The RTC provides an automatic wake-up to manage all low-power modes.

The real-time clock (RTC) is an independent BCD timer/counter. The RTC provides a time-of-day clock/calendar with programmable alarm interrupt.

The RTC includes also a periodic programmable wake-up flag with interrupt capability.

Two 32-bit registers contain the seconds, minutes, hours (12- or 24-hour format), day (day of week), date (day of month), month, and year, expressed in binary coded decimal format (BCD). The sub-seconds value is also available in binary format.

Compensations for 28-, 29- (leap year), 30-, and 31-day months are performed automatically. Daylight saving time compensation can also be performed.

Additional 32-bit registers contain the programmable alarm subseconds, seconds, minutes, hours, day, and date.

A digital calibration feature is available to compensate for any deviation in crystal oscillator accuracy.

After RTC domain reset, all RTC registers are protected against possible parasitic write accesses.

As long as the supply voltage remains in the operating range, the RTC never stops, regardless of the device status (Run mode, low-power mode or under reset).
25.2 **RTC main features**

The RTC unit main features are the following (see Figure 215: RTC block diagram in STM32F03x, STM32F04x and STM32F05x devices and Figure 216: RTC block diagram for STM32F07x and STM32F09x devices):

- Calendar with subseconds, seconds, minutes, hours (12 or 24 format), day (day of week), date (day of month), month, and year.
- Daylight saving compensation programmable by software.
- Programmable alarm with interrupt function. The alarm can be triggered by any combination of the calendar fields.
- Automatic wake-up unit generating a periodic flag that triggers an automatic wake-up interrupt.
- Reference clock detection: a more precise second source clock (50 or 60 Hz) can be used to enhance the calendar precision.
- Accurate synchronization with an external clock using the subsecond shift feature.
- Digital calibration circuit (periodic counter correction): 0.95 ppm accuracy, obtained in a calibration window of several seconds
- Time-stamp function for event saving
- Tamper detection event with configurable filter and internal pull-up
- Maskable interrupts/events:
  - Alarm A
  - Wake-up interrupt
  - Time-stamp
  - Tamper detection
- 5 backup registers.

25.3 **RTC implementation**

25.4 RTC functional description

25.4.1 RTC block diagram

Figure 215. RTC block diagram in STM32F03x, STM32F04x and STM32F05x devices
Figure 216. RTC block diagram for STM32F07x and STM32F09x devices
The RTC includes:

- One alarm
- Up to three tamper events from I/Os
  - Tamper detection erases the backup registers.
- One timestamp event from I/O
- Tamper event detection can generate a timestamp event
- 5 32-bit backup registers
  - The backup registers (RTC_BKPxR) are implemented in the RTC domain that remains powered-on by VBAT when the VDD power is switched off.
- Output functions: RTC_OUT which selects one of the following two outputs:
  - RTC_CALIB: 512 Hz or 1Hz clock output (with an LSE frequency of 32.768 kHz). This output is enabled by setting the COE bit in the RTC_CR register.
  - RTC_ALARM: Alarm A. This output is selected by configuring the OSEL[1:0] bits in the RTC_CR register.
- Input functions:
  - RTC_TS: timestamp event
  - RTC_TAMP1: tamper1 event detection
  - RTC_TAMP2: tamper2 event detection
  - RTC_TAMP3: tamper3 event detection
  - RTC_REFIN: 50 or 60 Hz reference clock input

25.4.2 GPIOs controlled by the RTC

RTC_OUT, RTC_TS and RTC_TAMP1 are mapped on the same pin (PC13). PC13 pin configuration is controlled by the RTC, whatever the PC13 GPIO configuration, except for the RTC_ALARM output open-drain mode. In this particular case, the GPIO must be configured as input. The RTC functions mapped on PC13 are available in all low-power modes and in VBAT mode.

The selection of the RTC_ALARM output is performed through the RTC_TAFCR register as follows: the PC13VALUE bit is used to select whether the RTC_ALARM output is configured in push-pull or open drain mode.

When PC13 is not used as RTC function, it can be forced in output push-pull mode by setting the PC13MODE bit in the RTC_TAFCR. The output data value is then given by the PC13VALUE bit. In this case, PC13 output push-pull state and data are preserved in Standby mode.

The output mechanism follows the priority order shown in Table 80.

When PC14 and PC15 are not used as LSE oscillator, they can be forced in output push-pull mode by setting the PC14MODE and PC15MODE bits in the RTC_TAFCR register respectively. The output data values are then given by PC14VALUE and PC15VALUE. In this case, the PC14 and PC15 output push-pull states and data values are preserved in Standby mode.

The output mechanism follows the priority order shown in Table 81 and Table 82.

25.4.3 Clock and prescalers

The RTC clock source (RTCCCLK) is selected through the clock controller among the LSE clock, the LSI oscillator clock, and the HSE clock. For more information on the RTC clock source configuration, refer to Section 6: Reset and clock control (RCC).

A programmable prescaler stage generates a 1 Hz clock which is used to update the calendar. To minimize power consumption, the prescaler is split into 2 programmable prescalers (see Figure 215: RTC block diagram in STM32F03x, STM32F04x and STM32F05x devices and Figure 216: RTC block diagram for STM32F07x and STM32F09x devices):

- A 7-bit asynchronous prescaler configured through the PREDIV_A bits of the RTC_PRER register.
- A 15-bit synchronous prescaler configured through the PREDIV_S bits of the RTC_PRER register.

Note: When both prescalers are used, it is recommended to configure the asynchronous prescaler to a high value to minimize consumption.

The asynchronous prescaler division factor is set to 128, and the synchronous division factor to 256, to obtain an internal clock frequency of 1 Hz (ck_spre) with an LSE frequency of 32.768 kHz.

The minimum division factor is 1 and the maximum division factor is $2^{22}$.

This corresponds to a maximum input frequency of around 4 MHz.

$f_{ck\_apre}$ is given by the following formula:

$$ f_{CK\_APRE} = \frac{f_{RTCCCLK}}{PREDIV\_A + 1} $$

The $ck\_apre$ clock is used to clock the binary RTC_SSR subseconds downcounter. When it reaches 0, RTC_SSR is reloaded with the content of PREDIV_S.

$f_{ck\_spre}$ is given by the following formula:

$$ f_{CK\_SPRE} = \frac{f_{RTCCCLK}}{(PREDIV\_S + 1) \times (PREDIV\_A + 1)} $$

The $ck\_spre$ clock can be used either to update the calendar or as timebase for the 16-bit wake-up auto-reload timer. To obtain short timeout periods, the 16-bit wake-up auto-reload timer can also run with the RTCCCLK divided by the programmable 4-bit asynchronous prescaler (see Section 25.4.6: Periodic auto-wake-up for details).

25.4.4 Real-time clock and calendar

The RTC calendar time and date registers are accessed through shadow registers which are synchronized with PCLK (APB clock). They can also be accessed directly in order to avoid waiting for the synchronization duration.

- RTC_SSR for the subseconds
- RTC_TR for the time
- RTC_DR for the date
Every RTCCLK period, the current calendar value is copied into the shadow registers, and the RSF bit of RTC_ISR register is set (see Section 25.7.4: RTC initialization and status register (RTC_ISR)). The copy is not performed in Stop and Standby mode. When exiting these modes, the shadow registers are updated after up to 1 RTCCLK period.

When the application reads the calendar registers, it accesses the content of the shadow registers. It is possible to make a direct access to the calendar registers by setting the BYPSHAD control bit in the RTC_CR register. By default, this bit is cleared, and the user accesses the shadow registers.

When reading the RTC_SSR, RTC_TR or RTC_DR registers in BYPSHAD=0 mode, the frequency of the APB clock ($f_{APB}$) must be at least 7 times the frequency of the RTC clock ($f_{RTCCLK}$).

The shadow registers are reset by system reset.

### 25.4.5 Programmable alarm

The RTC unit provides programmable alarm: Alarm A.

The programmable alarm function is enabled through the ALRAE bit in the RTC_CR register. The ALRAF is set to 1 if the calendar subseconds, seconds, minutes, hours, date or day match the values programmed in the alarm registers RTC_ALRMASSR and RTC_ALRMAR. Each calendar field can be independently selected through the MSKx bits of the RTC_ALRMAR register, and through the MASKSSx bits of the RTC_ALRMASSR register. The alarm interrupt is enabled through the ALRAIE bit in the RTC_CR register.

**Caution:** If the seconds field is selected (MSK1 bit reset in RTC_ALRMAR), the synchronous prescaler division factor set in the RTC_PRER register must be at least 3 to ensure correct behavior.

Alarm A (if enabled by bits OSEL[1:0] in RTC_CR register) can be routed to the RTC_ALARM output. RTC_ALARM output polarity can be configured through bit POL the RTC_CR register.

### 25.4.6 Periodic auto-wake-up

The periodic wake-up flag is generated by a 16-bit programmable auto-reload down-counter. The wake-up timer range can be extended to 17 bits.

The wake-up function is enabled through the WUTE bit in the RTC_CR register.

The wake-up timer clock input can be:

- RTC clock (RTCCLK) divided by 2, 4, 8, or 16.
  - When RTCCLK is LSE(32.768 kHz), this allows to configure the wake-up interrupt period from 122 µs to 32 s, with a resolution down to 61 µs.
  - ck_spre (usually 1 Hz internal clock)
    - When ck_spre frequency is 1Hz, this allows to achieve a wake-up time from 1 s to around 36 hours with one-second resolution. This large programmable time range is divided in 2 parts:
      - from 1s to 18 hours when WUCKSEL [2:1] = 10
      - and from around 18h to 36h when WUCKSEL[2:1] = 11. In this last case $2^{16}$ is added to the 16-bit counter current value. When the initialization sequence is complete (see Programming the wake-up timer on page 598), the timer starts counting down. When the wake-up function is enabled, the down-counting remains
active in low-power modes. In addition, when it reaches 0, the WUTF flag is set in the RTC_ISR register, and the wake-up counter is automatically reloaded with its reload value (RTC_WUTR register value).

The WUTF flag must then be cleared by software.

When the periodic wake-up interrupt is enabled by setting the WUTIE bit in the RTC_CR register, it can exit the device from low-power modes.

The periodic wake-up flag can be routed to the RTC_ALARM output provided it has been enabled through bits OSEL[1:0] of RTC_CR register. RTC_ALARM output polarity can be configured through the POL bit in the RTC_CR register.

System reset, as well as low-power modes (Sleep, Stop and Standby) have no influence on the wake-up timer.

25.4.7 RTC initialization and configuration

RTC register access

The RTC registers are 32-bit registers. The APB interface introduces 2 wait-states in RTC register accesses except on read accesses to calendar shadow registers when BYPSHAD=0.

RTC register write protection

After system reset, the RTC registers are protected against parasitic write access by clearing the DBP bit in the PWR_CR register (refer to the power control section). DBP bit must be set in order to enable RTC registers write access.

After RTC domain reset, all the RTC registers are write-protected. Writing to the RTC registers is enabled by writing a key into the Write Protection register, RTC_WPR.

The following steps are required to unlock the write protection on all the RTC registers except for RTC_TAFCR, RTC_BKPxR and RTC_ISR[13:8].
1. Write '0xCA' into the RTC_WPR register.
2. Write '0x53' into the RTC_WPR register.

Writing a wrong key reactivates the write protection.

The protection mechanism is not affected by system reset.

Calendar initialization and configuration

To program the initial time and date calendar values, including the time format and the prescaler configuration, the following sequence is required:
1. Set INIT bit to 1 in the RTC_ISR register to enter initialization mode. In this mode, the calendar counter is stopped and its value can be updated.
2. Poll INITF bit of in the RTC_ISR register. The initialization phase mode is entered when INITF is set to 1. It takes around 2 RTCCLK clock cycles (due to clock synchronization).
3. To generate a 1 Hz clock for the calendar counter, program both the prescaler factors in RTC_PRER register.
4. Load the initial time and date values in the shadow registers (RTC_TR and RTC_DR), and configure the time format (12 or 24 hours) through the FMT bit in the RTC_CR register.
5. Exit the initialization mode by clearing the INIT bit. The actual calendar counter value is then automatically loaded and the counting restarts after 4 RTCCLK clock cycles.

When the initialization sequence is complete, the calendar starts counting.

Note: After a system reset, the application can read the INITS flag in the RTC_ISR register to check if the calendar has been initialized or not. If this flag equals 0, the calendar has not been initialized since the year field is set at its RTC domain reset default value (0x00).

To read the calendar after initialization, the software must first check that the RSF flag is set in the RTC_ISR register.

For code example refer to the Appendix section A.16.1: RTC calendar configuration code example.

Daylight saving time

The daylight saving time management is performed through bits SUB1H, ADD1H, and BKP of the RTC_CR register.

Using SUB1H or ADD1H, the software can subtract or add one hour to the calendar in one single operation without going through the initialization procedure.

In addition, the software can use the BKP bit to memorize this operation.

Programming the alarm

A similar procedure must be followed to program or update the programmable alarms.

1. Clear ALRAE in RTC_CR to disable Alarm A.
2. Program the Alarm A registers (RTC_ALRMASSR/RTC_ALRMAR).
3. Set ALRAE in the RTC_CR register to enable Alarm A again.

Note: Each change of the RTC_CR register is taken into account after around 2 RTCCLK clock cycles due to clock synchronization.

For code example refer to the Appendix section A.16.2: RTC alarm configuration code example.

Programming the wake-up timer

The following sequence is required to configure or change the wake-up timer auto-reload value (WUT[15:0] in RTC_WUTR):

1. Clear WUTE in RTC_CR to disable the wake-up timer.
2. Poll WUTWF until it is set in RTC_ISR to make sure the access to wake-up auto-reload counter and to WUCKSEL[2:0] bits is allowed. It takes around 2 RTCCLK clock cycles (due to clock synchronization).
3. Program the wake-up auto-reload value WUT[15:0], and the wake-up clock selection (WUCKSEL[2:0] bits in RTC_CR). Set WUTE in RTC_CR to enable the timer again. The wake-up timer restarts down-counting. The WUTWF bit is cleared up to 2 RTCCLK clock cycles after WUTE is cleared, due to clock synchronization.

For code example refer to the Appendix section A.16.3: RTC WUT configuration code example.
25.4.8 Reading the calendar

When BYPSHAD control bit is cleared in the RTC_CR register

To read the RTC calendar registers (RTC_SSR, RTC_TR and RTC_DR) properly, the APB clock frequency \( f_{PCLK} \) must be equal to or greater than seven times the RTC clock frequency \( f_{RTCCLK} \). This ensures a secure behavior of the synchronization mechanism.

If the APB clock frequency is less than seven times the RTC clock frequency, the software must read the calendar time and date registers twice. If the second read of the RTC_TR gives the same result as the first read, this ensures that the data is correct. Otherwise a third read access must be done. In any case the APB clock frequency must never be lower than the RTC clock frequency.

The RSF bit is set in RTC_ISR register each time the calendar registers are copied into the RTC_SSR, RTC_TR and RTC_DR shadow registers. The copy is performed every RTCCLK cycle. To ensure consistency between the 3 values, reading either RTC_SSR or RTC_TR locks the values in the higher-order calendar shadow registers until RTC_DR is read. In case the software makes read accesses to the calendar in a time interval smaller than 1 RTCCLK period: RSF must be cleared by software after the first calendar read, and then the software must wait until RSF is set before reading again the RTC_SSR, RTC_TR and RTC_DR registers.

After waking up from low-power mode (Stop or Standby), RSF must be cleared by software. The software must then wait until it is set again before reading the RTC_SSR, RTC_TR and RTC_DR registers.

The RSF bit must be cleared after wake-up and not before entering low-power mode.

After a system reset, the software must wait until RSF is set before reading the RTC_SSR, RTC_TR and RTC_DR registers. Indeed, a system reset resets the shadow registers to their default values.

After an initialization (refer to Calendar initialization and configuration on page 597): the software must wait until RSF is set before reading the RTC_SSR, RTC_TR and RTC_DR registers.

After synchronization (refer to Section 25.4.10: RTC synchronization): the software must wait until RSF is set before reading the RTC_SSR, RTC_TR and RTC_DR registers.

For code example refer to the Appendix section A.16.4: RTC read calendar code example.

When the BYPSHAD control bit is set in the RTC_CR register (bypass shadow registers)

Reading the calendar registers gives the values from the calendar counters directly, thus eliminating the need to wait for the RSF bit to be set. This is especially useful after exiting from low-power modes (STOP or Standby), since the shadow registers are not updated during these modes.

When the BYPSHAD bit is set to 1, the results of the different registers might not be coherent with each other if an RTCCLK edge occurs between two read accesses to the registers. Additionally, the value of one of the registers may be incorrect if an RTCCLK edge occurs during the read operation. The software must read all the registers twice, and then compare the results to confirm that the data is coherent and correct. Alternatively, the software can just compare the two results of the least-significant calendar register.
25.4.9 Resetting the RTC

The calendar shadow registers (RTC_SSR, RTC_TR and RTC_DR) and some bits of the RTC status register (RTC_ISR) are reset to their default values by all available system reset sources.

On the contrary, the following registers are reset to their default values by a RTC domain reset and are not affected by a system reset: the RTC current calendar registers, the RTC control register (RTC_CR), the prescaler register (RTC_PRER), the RTC calibration register (RTC_CALR), the RTC shift register (RTC_SHIFTR), the RTC timestamp registers (RTC_TSSSR, RTC_TSTR and RTC_TSDR), the RTC tamper and alternate function configuration register (RTC_TAFCR), the RTC backup registers (RTC_BKPxR), the wake-up timer register (RTC_WUTR), the Alarm A registers (RTC_ALRMASSR/RTC_ALRMAR).

In addition, when it is clocked by the LSE, the RTC keeps on running under system reset if the reset source is different from the RTC domain reset one (refer to the RTC clock section of the Reset and clock controller for details on the list of RTC clock sources not affected by system reset). When a RTC domain reset occurs, the RTC is stopped and all the RTC registers are set to their reset values.

25.4.10 RTC synchronization

The RTC can be synchronized to a remote clock with a high degree of precision. After reading the sub-second field (RTC_SSR or RTC_TSSSR), a calculation can be made of the precise offset between the times being maintained by the remote clock and the RTC. The RTC can then be adjusted to eliminate this offset by “shifting” its clock by a fraction of a second using RTC_SHIFTR.

RTC_SSR contains the value of the synchronous prescaler counter. This allows one to calculate the exact time being maintained by the RTC down to a resolution of $1 / (\text{PREDIV}_S + 1)$ seconds. As a consequence, the resolution can be improved by increasing the synchronous prescaler value ($\text{PREDIV}_S[14:0]$). The maximum resolution allowed (30.52 $\mu$s with a 32768 Hz clock) is obtained with $\text{PREDIV}_S$ set to 0x7FFF.

However, increasing $\text{PREDIV}_S$ means that $\text{PREDIV}_A$ must be decreased in order to maintain the synchronous prescaler output at 1 Hz. In this way, the frequency of the asynchronous prescaler output increases, which may increase the RTC dynamic consumption.

The RTC can be finely adjusted using the RTC shift control register (RTC_SHIFTR). Writing to RTC_SHIFTR can shift (either delay or advance) the clock by up to a second with a resolution of $1 / (\text{PREDIV}_S + 1)$ seconds. The shift operation consists of adding the $\text{SUBFS}[14:0]$ value to the synchronous prescaler counter $\text{SS}[15:0]$; this will delay the clock. If at the same time the $\text{ADD1S}$ bit is set, this results in adding one second and at the same time subtracting a fraction of second, so this will advance the clock.

Caution: Before initiating a shift operation, the user must check that $\text{SS}[15] = 0$ in order to ensure that no overflow will occur.

As soon as a shift operation is initiated by a write to the RTC_SHIFTR register, the SHPF flag is set by hardware to indicate that a shift operation is pending. This bit is cleared by hardware as soon as the shift operation has completed.
Caution: This synchronization feature is not compatible with the reference clock detection feature: firmware must not write to RTC_SHIFTR when REFCKON=1.

25.4.11 RTC reference clock detection

The update of the RTC calendar can be synchronized to a reference clock, RTC_REFIN, which is usually the mains frequency (50 or 60 Hz). The precision of the RTC_REFIN reference clock should be higher than the 32.768 kHz LSE clock. When the RTC_REFIN detection is enabled (REFCKON bit of RTC_CR set to 1), the calendar is still clocked by the LSE, and RTC_REFIN is used to compensate for the imprecision of the calendar update frequency (1 Hz).

Each 1 Hz clock edge is compared to the nearest RTC_REFIN clock edge (if one is found within a given time window). In most cases, the two clock edges are properly aligned. When the 1 Hz clock becomes misaligned due to the imprecision of the LSE clock, the RTC shifts the 1 Hz clock a bit so that future 1 Hz clock edges are aligned. Thanks to this mechanism, the calendar becomes as precise as the reference clock.

The RTC detects if the reference clock source is present by using the 256 Hz clock (ck_apre) generated from the 32.768 kHz quartz. The detection is performed during a time window around each of the calendar updates (every 1 s). The window equals 7 ck_apre periods when detecting the first reference clock edge. A smaller window of 3 ck_apre periods is used for subsequent calendar updates.

Each time the reference clock is detected in the window, the synchronous prescaler which outputs the ck_spre clock is forced to reload. This has no effect when the reference clock and the 1 Hz clock are aligned because the prescaler is being reloaded at the same moment. When the clocks are not aligned, the reload shifts future 1 Hz clock edges a little for them to be aligned with the reference clock.

If the reference clock halts (no reference clock edge occurred during the 3 ck_apre window), the calendar is updated continuously based solely on the LSE clock. The RTC then waits for the reference clock using a large 7 ck_apre period detection window centered on the ck_spre edge.

When the RTC_REFIN detection is enabled, PREDIV_A and PREDIV_S must be set to their default values:

- PREDIV_A = 0x007F
- PREVID_S = 0x00FF

Note: RTC_REFIN clock detection is not available in Standby mode.

25.4.12 RTC smooth digital calibration

The RTC frequency can be digitally calibrated with a resolution of about 0.954 ppm with a range from -487.1 ppm to +488.5 ppm. The correction of the frequency is performed using series of small adjustments (adding and/or subtracting individual RTCCLK pulses). These adjustments are fairly well distributed so that the RTC is well calibrated even when observed over short durations of time.

The smooth digital calibration is performed during a cycle of about $2^{20}$ RTCCLK pulses, or 32 seconds when the input frequency is 32768 Hz. This cycle is maintained by a 20-bit counter, cal_cnt[19:0], clocked by RTCCLK.
The smooth calibration register (RTC_CALR) specifies the number of RTCCCLK clock cycles to be masked during the 32-second cycle:

- Setting the bit CALM[0] to 1 causes exactly one pulse to be masked during the 32-second cycle.
- Setting CALM[1] to 1 causes two additional cycles to be masked
- Setting CALM[2] to 1 causes four additional cycles to be masked
- and so on up to CALM[8] set to 1 which causes 256 clocks to be masked.

**Note:** CALM[8:0] (RTC_CALR) specifies the number of RTCCCLK pulses to be masked during the 32-second cycle. Setting the bit CALM[0] to ‘1’ causes exactly one pulse to be masked during the 32-second cycle at the moment when cal_cnt[19:0] is 0x80000; CALM[1]=1 causes two other cycles to be masked (when cal_cnt is 0x40000 and 0xC0000); CALM[2]=1 causes four other cycles to be masked (cal_cnt = 0x20000/0x60000/0xA0000/0xE0000); and so on up to CALM[8]=1 which causes 256 clocks to be masked (cal_cnt = 0xXX800).

While CALM allows the RTC frequency to be reduced by up to 487.1 ppm with fine resolution, the bit CALP can be used to increase the frequency by 488.5 ppm. Setting CALP to ‘1’ effectively inserts an extra RTCCCLK pulse every $2^{11}$ RTCCCLK cycles, which means that 512 clocks are added during every 32-second cycle.

Using CALM together with CALP, an offset ranging from -511 to +512 RTCCCLK cycles can be added during the 32-second cycle, which translates to a calibration range of -487.1 ppm to +488.5 ppm with a resolution of about 0.954 ppm.

The formula to calculate the effective calibrated frequency ($F_{CAL}$) given the input frequency ($F_{RTCCLK})$ is as follows:

$$F_{CAL} = F_{RTCCLK} \times \left[1 + \left(\frac{CALP \times 512 - CALM}{2^{20} + CALM - CALP \times 512}\right)\right]$$

**Calibration when PREDIV_A < 3**

The CALP bit can not be set to 1 when the asynchronous prescaler value (PREDIV_A bits in RTC_PRER register) is less than 3. If CALP was already set to 1 and PREDIV_A bits are set to a value less than 3, CALP is ignored and the calibration operates as if CALP was equal to 0.

To perform a calibration with PREDIV_A less than 3, the synchronous prescaler value (PREDIV_S) should be reduced so that each second is accelerated by 8 RTCCCLK clock cycles, which is equivalent to adding 256 clock cycles every 32 seconds. As a result, between 255 and 256 clock pulses (corresponding to a calibration range from 243.3 to 244.1 ppm) can effectively be added during each 32-second cycle using only the CALM bits.

With a nominal RTCCCLK frequency of 32768 Hz, when PREDIV_A equals 1 (division factor of 2), PREDIV_S should be set to 16379 rather than 16383 (4 less). The only other interesting case is when PREDIV_A equals 0, PREDIV_S should be set to 32759 rather than 32767 (8 less).

If PREDIV_S is reduced in this way, the formula given the effective frequency of the calibrated input clock is as follows:

$$F_{CAL} = F_{RTCCLK} \times \left[1 + \left(\frac{256 - CALM}{2^{20} + CALM - 256}\right)\right]$$

In this case, CALM[7:0] equals 0x100 (the midpoint of the CALM range) is the correct setting if RTCCCLK is exactly 32768.00 Hz.
Verifying the RTC calibration

RTC precision is ensured by measuring the precise frequency of RTCCCLK and calculating the correct CALM value and CALP values. An optional 1 Hz output is provided to allow applications to measure and verify the RTC precision.

Measuring the precise frequency of the RTC over a limited interval can result in a measurement error of up to 2 RTCCCLK clock cycles over the measurement period, depending on how the digital calibration cycle is aligned with the measurement period.

However, this measurement error can be eliminated if the measurement period is the same length as the calibration cycle period. In this case, the only error observed is the error due to the resolution of the digital calibration.

- By default, the calibration cycle period is 32 seconds.

Using this mode and measuring the accuracy of the 1 Hz output over exactly 32 seconds guarantees that the measure is within 0.477 ppm (0.5 RTCCCLK cycles over 32 seconds, due to the limitation of the calibration resolution).

- CALW16 bit of the RTC_CALR register can be set to 1 to force a 16-second calibration cycle period.

In this case, the RTC precision can be measured during 16 seconds with a maximum error of 0.954 ppm (0.5 RTCCCLK cycles over 16 seconds). However, since the calibration resolution is reduced, the long term RTC precision is also reduced to 0.954 ppm: CALM[0] bit is stuck at 0 when CALW16 is set to 1.

- CALW8 bit of the RTC_CALR register can be set to 1 to force a 8-second calibration cycle period.

In this case, the RTC precision can be measured during 8 seconds with a maximum error of 1.907 ppm (0.5 RTCCCLK cycles over 8s). The long term RTC precision is also reduced to 1.907 ppm: CALM[1:0] bits are stuck at 00 when CALW8 is set to 1.

Re-calibration on-the-fly

The calibration register (RTC_CALR) can be updated on-the-fly while RTC_ISR/INITF=0, by using the follow process:

1. Poll the RTC_ISR/RECALPF (re-calibration pending flag).
2. If it is set to 0, write a new value to RTC_CALR, if necessary. RECALPF is then automatically set to 1
3. Within three ck_apre cycles after the write operation to RTC_CALR, the new calibration settings take effect.

For code example refer to the Appendix section A.16.5: RTC calibration code example.

25.4.13 Time-stamp function

Time-stamp is enabled by setting the TSE bit of RTC_CR register to 1.

The calendar is saved in the time-stamp registers (RTC_TSSSR, RTC_TSTR, RTC_TSDR) when a time-stamp event is detected on the RTC_TS pin.

When a time-stamp event occurs, the time-stamp flag bit (TSF) in RTC_ISR register is set.

By setting the TSIE bit in the RTC_CR register, an interrupt is generated when a time-stamp event occurs.
If a new time-stamp event is detected while the time-stamp flag (TSF) is already set, the time-stamp overflow flag (TSOVF) flag is set and the time-stamp registers (RTC_TSTR and RTC_TSDR) maintain the results of the previous event.

Note: TSF is set 2 ck_apre cycles after the time-stamp event occurs due to synchronization process.

There is no delay in the setting of TSOVF. This means that if two time-stamp events are close together, TSOVF can be seen as ‘1’ while TSF is still ‘0’. As a consequence, it is recommended to poll TSOVF only after TSF has been set.

Caution: If a time-stamp event occurs immediately after the TSF bit is supposed to be cleared, then both TSF and TSOVF bits are set. To avoid masking a time-stamp event occurring at the same moment, the application must not write ‘0’ into TSF bit unless it has already read it to ‘1’.

Optionally, a tamper event can cause a time-stamp to be recorded. See the description of the TAMPTS control bit in Section 25.7.15: RTC tamper and alternate function configuration register (RTC_TAFCR).

25.4.14 Tamper detection

The RTC_TAMPx input events can be configured either for edge detection, or for level detection with filtering.

The tamper detection can be configured for the following purposes:
- erase the RTC backup registers
- generate an interrupt, capable to wake-up from Stop and Standby modes

RTC backup registers

The backup registers (RTC_BKPxR) are not reset by system reset or when the device wakes up from Standby mode.

The backup registers are reset when a tamper detection event occurs (see Section 25.7.17: RTC backup registers (RTC_BKPxR) and Tamper detection initialization on page 604).

Tamper detection initialization

Each input can be enabled by setting the corresponding TAMPxE bits to 1 in the RTC_TAFCR register.

Each RTC_TAMPx tamper detection input is associated with a flag TAMPxF in the RTC_ISR register.

The TAMPxF flag is asserted after the tamper event on the pin, with the latency provided below:
- 3 ck_apre cycles when TAMPFLT differs from 0x0 (Level detection with filtering)
- 3 ck_apre cycles when TAMPTS=1 (Timestamp on tamper event)
- No latency when TAMPFLT=0x0 (Edge detection) and TAMPTS=0

A new tamper occurring on the same pin during this period and as long as TAMPxF is set cannot be detected.

By setting the TAMPIE bit in the RTC_TAFCR register, an interrupt is generated when a tamper detection event occurs.
**Timestamp on tamper event**

With TAMPTS set to ‘1’, any tamper event causes a timestamp to occur. In this case, either the TSF bit or the TSOVF bit are set in RTC_ISR, in the same manner as if a normal timestamp event occurs. The affected tamper flag register TAMPxF is set at the same time that TSF or TSOVF is set.

**Edge detection on tamper inputs**

If the TAMPFLT bits are “00”, the RTC_TAMPx pins generate tamper detection events when either a rising edge or a falling edge is observed depending on the corresponding TAMPxTRG bit. The internal pull-up resistors on the RTC_TAMPx inputs are deactivated when edge detection is selected.

**Caution:** To avoid losing tamper detection events, the signal used for edge detection is logically ANDed with the corresponding TAMPxE bit in order to detect a tamper detection event in case it occurs before the RTC_TAMPx pin is enabled.

- When TAMPxTRG = 0: if the RTC_TAMPx is already high before tamper detection is enabled (TAMPxE bit set to 1), a tamper event is detected as soon as the RTC_TAMPx input is enabled, even if there was no rising edge on the RTC_TAMPx input after TAMPxE was set.
- When TAMPxTRG = 1: if the RTC_TAMPx is already low before tamper detection is enabled, a tamper event is detected as soon as the RTC_TAMPx input is enabled (even if there was no falling edge on the RTC_TAMPx input after TAMPxE was set).

After a tamper event has been detected and cleared, the RTC_TAMPx should be disabled and then re-enabled (TAMPxE set to 1) before re-programming the backup registers (RTC_BKPxR). This prevents the application from writing to the backup registers while the RTC_TAMPx input value still indicates a tamper detection. This is equivalent to a level detection on the RTC_TAMPx input.

**Note:** Tamper detection is still active when $V_{DD}$ power is switched off. To avoid unwanted resetting of the backup registers, the pin to which the RTC_TAMPx is mapped should be externally tied to the correct level.

**Level detection with filtering on RTC_TAMPx inputs**

Level detection with filtering is performed by setting TAMPFLT to a non-zero value. A tamper detection event is generated when either 2, 4, or 8 (depending on TAMPFLT) consecutive samples are observed at the level designated by the TAMPxTRG bits.

The RTC_TAMPx inputs are precharged through the I/O internal pull-up resistance before its state is sampled, unless disabled by setting TAMPPUDIS to 1. The duration of the precharge is determined by the TAMPPRCH bits, allowing for larger capacitances on the RTC_TAMPx inputs.

The trade-off between tamper detection latency and power consumption through the pull-up can be optimized by using TAMPFREQ to determine the frequency of the sampling for level detection.

**Note:** Refer to the datasheets for the electrical characteristics of the pull-up resistors.

For code example refer to the Appendix sections: A.16.6: RTC tamper and time stamp configuration code example and A.16.7: RTC tamper and time stamp code example.
25.4.15 Calibration clock output

When the COE bit is set to 1 in the RTC_CR register, a reference clock is provided on the RTC_CALIB device output.

If the COSEL bit in the RTC_CR register is reset and PREDIV_A = 0x7F, the RTC_CALIB frequency is \( \frac{f_{RTCCLK}}{64} \). This corresponds to a calibration output at 512 Hz for an RTCCLOCK frequency at 32.768 kHz. The RTC_CALIB duty cycle is irregular: there is a light jitter on falling edges. It is therefore recommended to use rising edges.

When COSEL is set and “PREDIV_S+1” is a non-zero multiple of 256 (i.e: PREDIV_S[7:0] = 0xFF), the RTC_CALIB frequency is \( \frac{f_{RTCCLK}}{256 \times (PREDIV_A+1)} \). This corresponds to a calibration output at 1 Hz for prescaler default values (PREDIV_A = 0x7F, PREDIV_S = 0xFF), with an RTCCLOCK frequency at 32.768 kHz. The 1 Hz output is affected when a shift operation is on going and may toggle during the shift operation (SHPF=1).

Note: When COSEL bit is cleared, the RTC_CALIB output is the output of the 6th stage of the asynchronous prescaler.

When COSEL bit is set, the RTC_CALIB output is the output of the 8th stage of the synchronous prescaler.

For code example refer to the Appendix section A.16.8: RTC clock output code example.

25.4.16 Alarm output

The OSEL[1:0] control bits in the RTC_CR register are used to activate the alarm output RTC_ALARM, and to select the function which is output. These functions reflect the contents of the corresponding flags in the RTC_ISR register.

The polarity of the output is determined by the POL control bit in RTC_CR so that the opposite of the selected flag bit is output when POL is set to 1.

Alarm output

The RTC_ALARM pin can be configured in output open drain or output push-pull using RTC_TAFCR register.

Note: Once the RTC_ALARM output is enabled, it has priority over RTC_CALIB (COE bit is don’t care and must be kept cleared).

25.5 RTC low-power modes

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect. RTC interrupts cause the device to exit the Sleep mode.</td>
</tr>
<tr>
<td>Stop</td>
<td>The RTC remains active when the RTC clock source is LSE or LSI. RTC tamper event, RTC timestamp event, and RTC wake-up cause the device to exit the Stop mode.</td>
</tr>
<tr>
<td>Standby</td>
<td>The RTC remains active when the RTC clock source is LSE or LSI. RTC tamper event, RTC timestamp event, and RTC wake-up cause the device to exit the Standby mode.</td>
</tr>
</tbody>
</table>
25.6 RTC interrupts

All RTC interrupts are connected to the EXTI controller. Refer to Section 11.2: Extended interrupts and events controller (EXTI).

To enable RTC interrupt(s), the following sequence is required:
1. Configure and enable the NVIC line(s) corresponding to the RTC event(s) in interrupt mode and select the rising edge sensitivity.
2. Configure and enable the RTC IRQ channel in the NVIC.
3. Configure the RTC to generate RTC interrupt(s).

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

1. Wake-up from STOP and Standby modes is possible only when the RTC clock source is LSE or LSI.
2. On STM32F07x and STM32F09x devices.

25.7 RTC registers

Refer to Section 1.2 on page 42 of the reference manual for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by words (32-bit).

25.7.1 RTC time register (RTC_TR)

The RTC_TR is the calendar time shadow register. This register must be written in initialization mode only. Refer to Calendar initialization and configuration on page 597 and Reading the calendar on page 599.

This register is write protected. The write access procedure is described in RTC register write protection on page 597.

Address offset: 0x00

RTC domain reset value: 0x0000 0000

System reset: 0x0000 0000 when BYPSHAD = 0. Not affected when BYPSHAD = 1.
The RTC_DR is the calendar date shadow register. This register must be written in initialization mode only. Refer to Calendar initialization and configuration on page 597 and Reading the calendar on page 599.

This register is write protected. The write access procedure is described in RTC register write protection on page 597.

Address offset: 0x04

RTC domain reset value: 0x0000 2101

System reset: 0x0000 2101 when BYPSHAD = 0. Not affected when BYPSHAD = 1.

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **PM**: AM/PM notation
  0: AM or 24-hour format
  1: PM

Bits 21:20 **HT[1:0]**: Hour tens in BCD format

Bits 19:16 **HU[3:0]**: Hour units in BCD format

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **MNT[2:0]**: Minute tens in BCD format

Bits 11:8 **MNU[3:0]**: Minute units in BCD format

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **ST[2:0]**: Second tens in BCD format

Bits 3:0 **SU[3:0]**: Second units in BCD format

### 25.7.2 RTC date register (RTC_DR)

The RTC_DR is the calendar date shadow register. This register must be written in initialization mode only. Refer to Calendar initialization and configuration on page 597 and Reading the calendar on page 599.

This register is write protected. The write access procedure is described in RTC register write protection on page 597.

Address offset: 0x04

RTC domain reset value: 0x0000 2101

System reset: 0x0000 2101 when BYPSHAD = 0. Not affected when BYPSHAD = 1.

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:20 **YT[3:0]**: Year tens in BCD format

Bits 19:16 **YU[3:0]**: Year units in BCD format

Bits 15:13 **WDU[2:0]**: Week day units
  000: forbidden
  001: Monday
  ...
  111: Sunday
Bit 12  **MT**: Month tens in BCD format

Bits 11:8  **MU[3:0]**: Month units in BCD format

Bits 7:6  Reserved, must be kept at reset value.

Bits 5:4  **DT[1:0]**: Date tens in BCD format

Bits 3:0  **DU[3:0]**: Date units in BCD format
25.7.3 RTC control register (RTC_CR)

Address offset: 0x08

RTC domain reset value: 0x0000 0000

System reset: not affected

Bits 31:24  Reserved, must be kept at reset value.

Bit 23  **COE**: Calibration output enable
   This bit enables the RTC_CALIB output
   0: Calibration output disabled
   1: Calibration output enabled

Bits 22:21  **OSEL[1:0]**: Output selection
   These bits are used to select the flag to be routed to RTC_ALARM output
   00: Output disabled
   01: Alarm A output enabled
   10: Reserved
   11: Wake-up output enabled

Bit 20  **POL**: Output polarity
   This bit is used to configure the polarity of RTC_ALARM output
   0: The pin is high when ALRAF/WUTF is asserted (depending on OSEL[1:0])
   1: The pin is low when ALRAF/WUTF is asserted (depending on OSEL[1:0]).

Bit 19  **COSEL**: Calibration output selection
   When COE=1, this bit selects which signal is output on RTC_CALIB.
   0: Calibration output is 512 Hz (with default prescaler setting)
   1: Calibration output is 1 Hz (with default prescaler setting)
   These frequencies are valid for RTCCLK at 32.768 kHz and prescalers at their default values (PREDIV_A=127 and PREDIV_S=255). Refer to Section 25.4.15: Calibration clock output

Bit 18  **BKP**: Backup
   This bit can be written by the user to memorize whether the daylight saving time change has been performed or not.

Bit 17  **SUB1H**: Subtract 1 hour (winter time change)
   When this bit is set, 1 hour is subtracted to the calendar time if the current hour is not 0. This bit is always read as 0.
   Setting this bit has no effect when current hour is 0.
   0: No effect
   1: Subtracts 1 hour to the current time. This can be used for winter time change outside initialization mode.
Bit 16  **ADD1H**: Add 1 hour (summer time change)
When this bit is set, 1 hour is added to the calendar time. This bit is always read as 0.
0: No effect
1: Adds 1 hour to the current time. This can be used for summer time change outside
initialization mode.

Bit 15  **TSIE**: Time-stamp interrupt enable
0: Time-stamp Interrupt disable
1: Time-stamp Interrupt enable

Bit 14  **WUTIE**: Wake-up timer interrupt enable
0: Wake-up timer interrupt disabled
1: Wake-up timer interrupt enabled

Bit 13  Reserved, must be kept at reset value.

Bit 12  **ALRAIE**: Alarm A interrupt enable
0: Alarm A interrupt disabled
1: Alarm A interrupt enabled

Bit 11  **TSE**: timestamp enable
0: timestamp disable
1: timestamp enable

Bit 10  **WUTE**: Wake-up timer enable
0: Wake-up timer disabled
1: Wake-up timer enabled

*Note: When the wake-up timer is disabled, wait for WUTWF=1 before enabling it again.*

Bit 9  Reserved, must be kept at reset value.

Bit 8  **ALRAE**: Alarm A enable
0: Alarm A disabled
1: Alarm A enabled

Bit 7  Reserved, must be kept at reset value.

Bit 6  **FMT**: Hour format
0: 24 hour/day format
1: AM/PM hour format

Bit 5  **BYPSSHAD**: Bypass the shadow registers
0: Calendar values (when reading from RTC_SSR, RTC_TR, and RTC_DR) are taken from
the shadow registers, which are updated once every two RTCCCLK cycles.
1: Calendar values (when reading from RTC_SSR, RTC_TR, and RTC_DR) are taken
directly from the calendar counters.

*Note: If the frequency of the APB clock is less than seven times the frequency of RTCCLK,
BYPSSHAD must be set to ‘1’.*
Bit 4  **REFCKON**: RTC_REFIN reference clock detection enable (50 or 60 Hz)
   0: RTC_REFIN detection disabled
   1: RTC_REFIN detection enabled
   
   **Note**: PREDIV_S must be 0x00FF.

Bit 3  **TSEDGE**: Time-stamp event active edge
   0: RTC_TS input rising edge generates a time-stamp event
   1: RTC_TS input falling edge generates a time-stamp event
   
   TSE must be reset when TSEDGE is changed to avoid unwanted TSF setting.

Bits 2:0  **WUCKSEL[2:0]**: Wake-up clock selection
   000: RTC/16 clock is selected
   001: RTC/8 clock is selected
   010: RTC/4 clock is selected
   011: RTC/2 clock is selected
   10x: ck_spre (usually 1 Hz) clock is selected
   11x: ck_spre (usually 1 Hz) clock is selected and $2^{16}$ is added to the WUT counter value
   (see note below)

**Note**: Bits 7, 6 and 4 of this register can be written in initialization mode only (RTC_ISR/INITF = 1).

WUT = Wake-up unit counter value. WUT = (0x0000 to 0xFFFF) + 0x10000 added when WUCKSEL[2:1 = 11].

Bits 2 to 0 of this register can be written only when RTC_CR WUTE bit = 0 and RTC_ISR WUTWF bit = 1.

It is recommended not to change the hour during the calendar hour increment as it could mask the incrementation of the calendar hour.

ADD1H and SUB1H changes are effective in the next second.

This register is write protected. The write access procedure is described in RTC register write protection on page 597.

**Caution**: TSE must be reset when TSEDGE is changed to avoid spuriously setting of TSF.
### 25.7.4 RTC initialization and status register (RTC_ISR)

This register is write protected (except for RTC_ISR[13:8] bits). The write access procedure is described in [RTC register write protection on page 597](#).

Address offset: 0x0C

RTC domain reset value: 0x0000 0007

System reset: not affected except INIT, INITF, and RSF bits which are cleared to ‘0’

Bits 31:17 Reserved, must be kept at reset value.

- **Bit 16 RECALPF**: Recalibration pending Flag
  - The RECALPF status flag is automatically set to ‘1’ when software writes to the RTC_CALR register, indicating that the RTC_CALR register is blocked. When the new calibration settings are taken into account, this bit returns to ‘0’. Refer to [Re-calibration on-the-fly](#).

- **Bit 15 TAMP3F**: RTC_TAMP3 detection flag
  - This flag is set by hardware when a tamper detection event is detected on the RTC_TAMP3 input.
  - It is cleared by software writing 0

- **Bit 14 TAMP2F**: RTC_TAMP2 detection flag
  - This flag is set by hardware when a tamper detection event is detected on the RTC_TAMP2 input.
  - It is cleared by software writing 0

- **Bit 13 TAMP1F**: RTC_TAMP1 detection flag
  - This flag is set by hardware when a tamper detection event is detected on the RTC_TAMP1 input.
  - It is cleared by software writing 0

- **Bit 12 TSOVF**: Time-stamp overflow flag
  - This flag is set by hardware when a time-stamp event occurs while TSF is already set.
  - This flag is cleared by software by writing 0. It is recommended to check and then clear TSOVF only after clearing the TSF bit. Otherwise, an overflow might not be noticed if a time-stamp event occurs immediately before the TSF bit is cleared.

- **Bit 11 TSF**: Time-stamp flag
  - This flag is set by hardware when a time-stamp event occurs.
  - This flag is cleared by software by writing 0.

- **Bit 10 WUTF**: Wake-up timer flag
  - This flag is set by hardware when the wake-up auto-reload counter reaches 0.
  - This flag is cleared by software by writing 0.
  - This flag must be cleared by software at least 1.5 RTCCLOCK periods before WUTF is set to 1 again.

- **Bit 9 Reserved, must be kept at reset value.**
Real-time clock (RTC)

Bit 8 **ALRAF**: Alarm A flag
This flag is set by hardware when the time/date registers (RTC_TR and RTC_DR) match the Alarm A register (RTC_ALRMAR).
This flag is cleared by software by writing 0.

Bit 7 **INIT**: Initialization mode
0: Free running mode
1: Initialization mode used to program time and date register (RTC_TR and RTC_DR), and prescaler register (RTC_PRER). Counters are stopped and start counting from the new value when INIT is reset.

Bit 6 **INITF**: Initialization flag
When this bit is set to 1, the RTC is in initialization state, and the time, date and prescaler registers can be updated.
0: Calendar registers update is not allowed
1: Calendar registers update is allowed

Bit 5 **RSF**: Registers synchronization flag
This bit is set by hardware each time the calendar registers are copied into the shadow registers (RTC_SSR, RTC_TR and RTC_DR). This bit is cleared by hardware in initialization mode, while a shift operation is pending (SHPF=1), or when in bypass shadow register mode (BYPSSHAD=1). This bit can also be cleared by software.
It is cleared either by software or by hardware in initialization mode.
0: Calendar shadow registers not yet synchronized
1: Calendar shadow registers synchronized

Bit 4 **INITS**: Initialization status flag
This bit is set by hardware when the calendar year field is different from 0 (RTC domain reset state).
0: Calendar has not been initialized
1: Calendar has been initialized

Bit 3 **SHPF**: Shift operation pending
0: No shift operation is pending
1: A shift operation is pending
This flag is set by hardware as soon as a shift operation is initiated by a write to the RTC_SHIFTR register. It is cleared by hardware when the corresponding shift operation has been executed. Writing to the SHPF bit has no effect.

Bit 2 **WUTWF**: Wake-up timer write flag
This bit is set by hardware up to 2 RTCCLK cycles after the WUTE bit has been set to 0 in RTC_CR, and is cleared up to 2 RTCCLK cycles after the WUTE bit has been set to 1. The wake-up timer values can be changed when WUTE bit is cleared and WUTWF is set.
0: Wake-up timer configuration update not allowed
1: Wake-up timer configuration update allowed

Bit 1 **ALRAWF**: Alarm A write flag
This bit is set by hardware when Alarm A values can be changed, after the ALRAE bit has been set to 0 in RTC_CR.
It is cleared by hardware in initialization mode.
0: Alarm A update not allowed
1: Alarm A update allowed

**Note:** The bits ALRAF, WUTF and TSF are cleared 2 APB clock cycles after programming them to 0.
25.7.5RTC prescaler register (RTC_PRER)

This register must be written in initialization mode only. The initialization must be performed in two separate write accesses. Refer to Calendar initialization and configuration on page 597.

This register is write protected. The write access procedure is described in RTC register write protection on page 597.

Address offset: 0x10

RTC domain reset value: 0x007F 00FF

System reset: not affected

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:16 **PREDIV_A[6:0]**: Asynchronous prescaler factor
This is the asynchronous division factor:
\[ \text{ck\_apre frequency} = \frac{\text{RTCCLK frequency}}{\text{PREDIV\_A+1}} \]

Bit 15 Reserved, must be kept at reset value.

Bits 14:0 **PREDIV_S[14:0]**: Synchronous prescaler factor
This is the synchronous division factor:
\[ \text{ck\_spre frequency} = \frac{\text{ck\_apre frequency}}{\text{PREDIV\_S+1}} \]
25.7.6 RTC wake-up timer register (RTC_WUTR)

This register can be written only when WUTF is set to 1 in RTC_ISR.
This register is write protected. The write access procedure is described in RTC register write protection on page 597.

WUT[15:0]

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **WUT[15:0]:** Wake-up auto-reload value bits
- When the wake-up timer is enabled (WUTE set to 1), the WUTF flag is set every (WUT[15:0] + 1) ck_wut cycles. The ck_wut period is selected through WUCKSEL[2:0] bits of the RTC_CR register.
- When WUCKSEL[2] = 1, the wake-up timer becomes 17-bits and WUCKSEL[1] effectively becomes WUT[16] the most-significant bit to be reloaded into the timer.
- The first assertion of WUTF occurs (WUT+1) ck_wut cycles after WUTE is set. Setting WUT[15:0] to 0x0000 with WUCKSEL[2:0] =011 (RTCCLK/2) is forbidden.

25.7.7 RTC alarm A register (RTC_ALRMAR)

This register can be written only when ALRAWF is set to 1 in RTC_ISR, or in initialization mode.

This register is write protected. The write access procedure is described in RTC register write protection on page 597.

Address offset: 0x1C

RTC domain reset value: 0x0000 0000

</table>

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **SS[15:0]**: Sub second value
SS[15:0] is the value in the synchronous prescaler counter. The fraction of a second is given by the formula below:
Second fraction = \((\text{PREDIV}_S - \text{SS}) / (\text{PREDIV}_S + 1)\)
*Note: SS can be larger than PREDIV_S only after a shift operation. In that case, the correct time/date is one second less than as indicated by RTC_TR/RTC_DR.*
25.7.10 RTC shift control register (RTC_SHIFTR)

This register is write protected. The write access procedure is described in RTC register write protection on page 597.

Address offset: 0x2C

RTC domain reset value: 0x0000 0000

System reset: not affected

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| SUBFS[14:0] | w | w | w | w | w | w | w | w | w | w | w | w | w | w |

Bit 31 **ADD1S**: Add one second
0: No effect
1: Add one second to the clock/calendar
This bit is write only and is always read as zero. Writing to this bit has no effect when a shift operation is pending (when SHPF=1, in RTC_ISR).
This function is intended to be used with SUBFS (see description below) in order to effectively add a fraction of a second to the clock in an atomic operation.

Bits 30:15 Reserved, must be kept at reset value.

Bits 14:0 **SUBFS[14:0]**: Subtract a fraction of a second
These bits are write only and is always read as zero. Writing to this bit has no effect when a shift operation is pending (when SHPF=1, in RTC_ISR).
The value which is written to SUBFS is added to the synchronous prescaler counter. Since this counter counts down, this operation effectively subtracts from (delays) the clock by:
Delay (seconds) = SUBFS / (PREDIV_S + 1)
A fraction of a second can effectively be added to the clock (advancing the clock) when the ADD1S function is used in conjunction with SUBFS, effectively advancing the clock by:
Advance (seconds) = (1 - (SUBFS / (PREDIV_S + 1)))).

*Note*: Writing to SUBFS causes RSF to be cleared. Software can then wait until RSF=1 to be sure that the shadow registers have been updated with the shifted time.
25.7.11 RTC timestamp time register (RTC_TSTR)

The content of this register is valid only when TSF is set to 1 in RTC_ISR. It is cleared when TSF bit is reset.

Address offset: 0x30

<td>Reserved</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>Reserved</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 31:16  Reserved, must be kept at reset value.

Bit 15  **CALP**: Increase frequency of RTC by 488.5 ppm

0: No RTCCCLK pulses are added.

1: One RTCCCLK pulse is effectively inserted every $2^{11}$ pulses (frequency increased by 488.5 ppm).

This feature is intended to be used in conjunction with CALM, which lowers the frequency of the calendar with a fine resolution. If the input frequency is 32768 Hz, the number of RTCCCLK pulses added during a 32-second window is calculated as follows: $(512 \times \text{CALP}) - \text{CALM}$.

Refer to *Section 25.4.12: RTC smooth digital calibration*.

Bit 14  **CALW8**: Use an 8-second calibration cycle period

When CALW8 is set to ‘1’, the 8-second calibration cycle period is selected.

*Note*: CALM[1:0] are stuck at “00” when CALW8=’1’. Refer to *Section 25.4.12: RTC smooth digital calibration*.

Bit 13  **CALW16**: Use a 16-second calibration cycle period

When CALW16 is set to ‘1’, the 16-second calibration cycle period is selected. This bit must not be set to ‘1’ if CALW8=1.

*Note*: CALM[0] is stuck at ‘0’ when CALW16=’1’. Refer to *Section 25.4.12: RTC smooth digital calibration*.

Bits 12:9  Reserved, must be kept at reset value.

Bits 8:0  **CALM[8:0]**: Calibration minus

The frequency of the calendar is reduced by masking CALM out of $2^{20}$ RTCCCLK pulses (32 seconds if the input frequency is 32768 Hz). This decreases the frequency of the calendar with a resolution of 0.9537 ppm.

To increase the frequency of the calendar, this feature should be used in conjunction with CALP. See *Section 25.4.12: RTC smooth digital calibration on page 601*. 
25.7.15 RTC tamper and alternate function configuration register (RTC_TAFCR)

Address offset: 0x40

RTC domain reset value: 0x0000 0000

</tbody>
</table>

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **PC15MODE**: PC15 mode
0: PC15 is controlled by the GPIO configuration registers. Consequently PC15 is floating in Standby mode.
1: PC15 is forced to push-pull output if LSE is disabled.

Bit 22 **PC15VALUE**: PC15 value
If the LSE is disabled and PC15MODE = 1, PC15VALUE configures the PC15 output data.

Bit 21 **PC14MODE**: PC14 mode
0: PC14 is controlled by the GPIO configuration registers. Consequently PC14 is floating in Standby mode.
1: PC14 is forced to push-pull output if LSE is disabled.

Bit 20 **PC14VALUE**: PC14 value
If the LSE is disabled and PC14MODE = 1, PC14VALUE configures the PC14 output data.

Bit 19 **PC13MODE**: PC13 mode
0: PC13 is controlled by the GPIO configuration registers. Consequently PC13 is floating in Standby mode.
1: PC13 is forced to push-pull output if all RTC functions are disabled.

Bit 18 **PC13VALUE**: RTC_ALARM output type/PC13 value
If PC13 is used to output RTC_ALARM, PC13VALUE configures the output configuration:
0: RTC_ALARM is an open-drain output
1: RTC_ALARM is a push-pull output
If all RTC functions are disabled and PC13MODE = 1, PC13VALUE configures the PC13 output data.

Bits 17:16 Reserved, must be kept at reset value.

Bit 15 **TAMPPUDIS**: RTC_TAMPx pull-up disable
This bit determines if each of the RTC_TAMPx pins are pre-charged before each sample.
0: Precharge RTC_TAMPx pins before sampling (enable internal pull-up)
1: Disable precharge of RTC_TAMPx pins.
Bits 14:13 **TAMPPRCH[1:0]**: RTC_TAMPx precharge duration
These bit determines the duration of time during which the pull-up/is activated before each sample. TAMPPRCH is valid for each of the RTC_TAMPx inputs.
- 0x0: 1 RTCCLK cycle
- 0x1: 2 RTCCLK cycles
- 0x2: 4 RTCCLK cycles
- 0x3: 8 RTCCLK cycles

Bits 12:11 **TAMPFLT[1:0]**: RTC_TAMPx filter count
These bit determines the number of consecutive samples at the specified level (TAMP*TRG) needed to activate a Tamper event. TAMPPFLT is valid for each of the RTC_TAMPx inputs.
- 0x0: Tamper event is activated on edge of RTC_TAMPx input transitions to the active level (no internal pull-up on RTC_TAMPx input).
- 0x1: Tamper event is activated after 2 consecutive samples at the active level.
- 0x2: Tamper event is activated after 4 consecutive samples at the active level.
- 0x3: Tamper event is activated after 8 consecutive samples at the active level.

Bits 10:8 **TAMPFREQ[2:0]**: Tamper sampling frequency
Determines the frequency at which each of the RTC_TAMPx inputs are sampled.
- 0x0: RTCCLK / 32768 (1 Hz when RTCCLK = 32768 Hz)
- 0x1: RTCCLK / 16384 (2 Hz when RTCCLK = 32768 Hz)
- 0x2: RTCCLK / 8192 (4 Hz when RTCCLK = 32768 Hz)
- 0x3: RTCCLK / 4096 (8 Hz when RTCCLK = 32768 Hz)
- 0x4: RTCCLK / 2048 (16 Hz when RTCCLK = 32768 Hz)
- 0x5: RTCCLK / 1024 (32 Hz when RTCCLK = 32768 Hz)
- 0x6: RTCCLK / 512 (64 Hz when RTCCLK = 32768 Hz)
- 0x7: RTCCLK / 256 (128 Hz when RTCCLK = 32768 Hz)

Bit 7 **TAMPTS**: Activate timestamp on tamper detection event
- 0: Tamper detection event does not cause a timestamp to be saved
- 1: Save timestamp on tamper detection event
TAMPTS is valid even if TSE=0 in the RTC_CR register.

Bit 6 **TAMP3TRG**: Active level for RTC_TAMP3 input
if TAMPPFLT != 00:
- 0: RTC_TAMP3 input staying low triggers a tamper detection event.
- 1: RTC_TAMP3 input staying high triggers a tamper detection event.
if TAMPPFLT = 00:
- 0: RTC_TAMP3 input rising edge triggers a tamper detection event.
- 1: RTC_TAMP3 input falling edge triggers a tamper detection event.

Bit 5 **TAMP3E**: RTC_TAMP3 detection enable
- 0: RTC_TAMP3 input detection disabled
- 1: RTC_TAMP3 input detection enabled

Bit 4 **TAMP2TRG**: Active level for RTC_TAMP2 input
if TAMPPFLT != 00:
- 0: RTC_TAMP2 input staying low triggers a tamper detection event.
- 1: RTC_TAMP2 input staying high triggers a tamper detection event.
if TAMPPFLT = 00:
- 0: RTC_TAMP2 input rising edge triggers a tamper detection event.
- 1: RTC_TAMP2 input falling edge triggers a tamper detection event.
Caution: When TAMPFLT = 0, TAMPxE must be reset when TAMPxTRG is changed to avoid spuriously setting TAMPxF.
25.7.16  RTC alarm A sub second register (RTC_ALRMASSR)

This register can be written only when ALRAE is reset in RTC_CR register, or in initialization mode.

This register is write protected. The write access procedure is described in RTC register write protection on page 597

Address offset: 0x44

RTC domain reset value: 0x0000 0000

System reset: not affected

Bits 31:28  Reserved, must be kept at reset value.

Bits 27:24  MASKSS[3:0]: Mask the most-significant bits starting at this bit

0: No comparison on sub seconds for Alarm A. The alarm is set when the seconds unit is incremented (assuming that the rest of the fields match).

1: SS[14:1] are don’t care in Alarm A comparison. Only SS[0] is compared.

2: SS[14:2] are don’t care in Alarm A comparison. Only SS[1:0] are compared.

... 12: SS[14:12] are don’t care in Alarm A comparison. SS[11:0] are compared.

15: All 15 SS bits are compared and must match to activate alarm.

The overflow bits of the synchronous counter (bits 15) is never compared. This bit can be different from 0 only after a shift operation.

Bits 23:15  Reserved, must be kept at reset value.

Bits 14:0  SS[14:0]: Sub seconds value

This value is compared with the contents of the synchronous prescaler counter to determine if Alarm A is to be activated. Only bits 0 up MASKSS-1 are compared.
25.7.17 RTC backup registers (RTC_BKPxR)

Address offset: 0x50 to 0x60
RTC domain reset value: 0x0000 0000
System reset: not affected

Bits 31:0 BKP[31:0]
The application can write or read data to and from these registers.
They are powered-on by VBAT when VDD is switched off, so that they are not reset by
System reset, and their contents remain valid when the device operates in low-power mode.
This register is reset on a tamper detection event, as long as TAMPxF=1.

25.7.18 RTC register map

Table 85. RTC register map and reset values

26 Inter-integrated circuit (I2C) interface

26.1 Introduction

The I\textsuperscript{2}C (inter-integrated circuit) bus interface handles communications between the microcontroller and the serial I\textsuperscript{2}C bus. It provides multimaster capability, and controls all I\textsuperscript{2}C bus-specific sequencing, protocol, arbitration and timing. It supports Standard-mode (Sm), Fast-mode (Fm) and Fast-mode Plus (Fm+).

It is also SMBus (system management bus) and PMBus\textsuperscript{®} (power management bus) compatible.

DMA can be used to reduce CPU overload.

26.2 I2C main features

- I\textsuperscript{2}C bus specification rev03 compatibility:
  - Slave and master modes
  - Multimaster capability
  - Standard-mode (up to 100 kHz)
  - Fast-mode (up to 400 kHz)
  - Fast-mode Plus (up to 1 MHz)
  - 7-bit and 10-bit addressing mode
  - Multiple 7-bit slave addresses (2 addresses, 1 with configurable mask)
  - All 7-bit addresses acknowledge mode
  - General call
  - Programmable setup and hold times
  - Easy to use event management
  - Optional clock stretching
  - Software reset
- 1-byte buffer with DMA capability
- Programmable analog and digital noise filters

The following additional features are also available, depending on the product implementation (see Section 26.3: I2C implementation):

- SMBus specification rev 3.0 compatibility:
  - Hardware PEC (packet error checking) generation and verification with ACK control
  - Command and data acknowledge control
  - Address resolution protocol (ARP) support
  - Host and device support
  - SMBus alert
  - Timeouts and idle condition detection
- PMBus rev 1.3 standard compatibility
- Independent clock: a choice of independent clock sources allowing the I2C communication speed to be independent from the PCLK reprogramming
• Wake-up from Stop mode on address match.

26.3 I2C implementation

This manual describes the full set of features implemented in I2C1. I2C2 supports a smaller set of features, but is otherwise identical to I2C1. The differences are listed below.

1. X = supported.

26.4 I2C functional description

In addition to receiving and transmitting data, this interface converts them from serial to parallel format and vice versa. The interrupts are enabled or disabled by software. The interface is connected to the I²C bus by a data pin (SDA) and by a clock pin (SCL). It can be connected with a standard (up to 100 kHz), Fast-mode (up to 400 kHz) or Fast-mode Plus (up to 1 MHz) I²C bus.

This interface can also be connected to an SMBus with the data pin (SDA) and clock pin (SCL).

If SMBus feature is supported, the additional optional SMBus Alert pin (SMBA) is also available.
26.4.1 I2C1 block diagram

The block diagram of the I2C1 interface is shown in Figure 217.

Figure 217. I2C1 block diagram

The I2C1 is clocked by an independent clock source, which allows the I2C to operate independently from the PCLK frequency.

For I2C I/Os supporting 20 mA output current drive for Fast-mode Plus operation, the driving capability is enabled through control bits in the system configuration controller (SYSCFG). Refer to Section 26.3: I2C implementation.

26.4.2 I2C2 block diagram

The block diagram of the I2C2 interface is shown in Figure 218.
26.4.3 I2C pins and internal signals

26.4.4 I2C clock requirements

The I2C kernel is clocked by I2CCLK.

The I2CCLK period \( t_{I2CCLK} \) must respect the following conditions:

\[
t_{I2CCLK} < \left( t_{LOW} - t_{filters} \right) / 4 \quad \text{and} \quad t_{I2CCLK} < t_{HIGH}
\]

with:

- \( t_{LOW} \): SCL low time and \( t_{HIGH} \): SCL high time
- \( t_{filters} \): when enabled, sum of the delays brought by the analog filter and by the digital filter.

Analog filter delay is maximum 260 ns. Digital filter delay is DNF \( \times t_{I2CCLK} \).

The PCLK clock period \( t_{PCLK} \) must respect the following condition:

\[
t_{PCLK} < 4 / 3 t_{SCL}
\]

with \( t_{SCL} \): SCL period

**Caution:** When the I2C kernel is clocked by PCLK, this clock must respect the conditions for \( t_{I2CCLK} \).

26.4.5 Mode selection

The interface can operate in one of the four following modes:

- Slave transmitter
- Slave receiver
- Master transmitter
- Master receiver

By default, it operates in slave mode. The interface automatically switches from slave to master when it generates a START condition, and from master to slave if an arbitration loss or a STOP generation occurs, allowing multimaster capability.

**Communication flow**

In Master mode, the I2C interface initiates a data transfer and generates the clock signal. A serial data transfer always begins with a START condition and ends with a STOP condition. Both START and STOP conditions are generated in master mode by software.

In Slave mode, the interface is capable of recognizing its own addresses (7- or 10-bit), and the general call address. The general call address detection can be enabled or disabled by software. The reserved SMBus addresses can also be enabled by software.
Data and addresses are transferred as 8-bit bytes, MSB first. The first byte(s) following the START condition contain the address (one in 7-bit mode, two in 10-bit mode). The address is always transmitted in Master mode.

A ninth clock pulse follows the eight clock cycles of a byte transfer, during which the receiver must send an acknowledge bit to the transmitter (see Figure 219).

**Figure 219. i2C bus protocol**

![I2C bus protocol diagram](MS19854V1)

Acknowledge can be enabled or disabled by software. The I2C interface addresses can be selected by software.

### 26.4.6 I2C initialization

**Enabling and disabling the peripheral**

The I2C peripheral clock must be configured and enabled in the clock controller, then the I2C can be enabled by setting the PE bit in the I2C_CR1 register.

When the I2C is disabled (PE = 0), the I2C performs a software reset. Refer to Section 26.4.7 for more details.

**Noise filters**

Before enabling the I2C peripheral by setting the PE bit in I2C_CR1 register, the user must configure the noise filters, if needed. By default, an analog noise filter is present on the SDA and SCL inputs. This analog filter is compliant with the I2C specification, which requires the suppression of spikes with a pulse width up to 50 ns in Fast-mode and Fast-mode Plus. The user can disable this analog filter by setting the ANFOFF bit, and/or select a digital filter by configuring the DNF[3:0] bit in the I2C_CR1 register.

When the digital filter is enabled, the level of the SCL or the SDA line is internally changed only if it remains stable for more than DNF x I2CCLK periods. This allows spikes with a programmable length of 1 to 15 I2CCLK periods to be suppressed.
Table 89. Comparison of analog vs. digital filters

<td></td>
</tr>
</tbody>
</table>

**Caution:** Changing the filter configuration is not allowed when the I2C is enabled.
I2C timings

The timings must be configured in order to guarantee correct data hold and setup times, used in master and slave modes. This is done by programming the PRESC[3:0], SCLDEL[3:0] and SDADEL[3:0] bits in the I2C_TIMINGR register.

The STM32CubeMX tool calculates and provides the I2C_TIMINGR content in the I2C configuration window.

**Figure 220. Setup and hold timings**

![Diagram showing I2C timings with annotations for data hold time and data setup time](image)

Data hold time: in case of transmission, the data is sent on SDA output after the SDADEL delay, if it is already available in I2C_TXDR.

Data setup time: in case of transmission, the SCLDEL counter starts when the data is sent on SDA output.
When the SCL falling edge is internally detected, a delay is inserted before sending SDA output. This delay is $t_{SDADEL} = SDADEL \times t_{PRESC} + t_{2CCLK}$ where $t_{PRESC} = (PRESC+1) \times t_{2CCLK}$.

$T_{SDADEL}$ impacts the hold time $t_{HD;DAT}$.

The total SDA output delay is:

$t_{SYNC1} + \{SDADEL \times (PRESC+1) + 1\} \times t_{I2CCLK}$

$t_{SYNC1}$ duration depends on these parameters:

- SCL falling slope
- When enabled, input delay brought by the analog filter: $t_{AF(min)} < t_{AF} < t_{AF(max)}$
- When enabled, input delay brought by the digital filter: $t_{DNF} = DNF \times t_{I2CCLK}$
- Delay due to SCL synchronization to I2CCLK clock (two to three I2CCLK periods)

In order to bridge the undefined region of the SCL falling edge, the user must program $SDADEL$ in such a way that:

\[
\left\{t_{f(max)} + t_{HD;DAT(min)} - t_{AF(min)} - \left[(DFN+3) \times t_{I2CCLK}\right]\right\} / \{(PRESC+1) \times t_{I2CCLK}\} \leq SDADEL
\]

Note: $t_{AF(min)} / t_{AF(max)}$ are part of the equation only when the analog filter is enabled. Refer to device datasheet for $t_{AF}$ values.

The maximum $t_{HD;DAT}$ can be 3.45 µs, 0.9 µs and 0.45 µs for Standard-mode, Fast-mode and Fast-mode Plus, but must be less than the maximum of $t_{VD;DAT}$ by a transition time. This maximum must only be met if the device does not stretch the LOW period ($t_{LOW}$) of the SCL signal. If the clock stretches the SCL, the data must be valid by the set-up time before it releases the clock.

The SDA rising edge is usually the worst case, so in this case the previous equation becomes:

$SDADEL \leq \left\{t_{VD;DAT(max)} - t_{r(max)} - 260 \text{ ns} - \left[(DFN+4) \times t_{I2CCLK}\right]\right\} / \{(PRESC+1) \times t_{I2CCLK}\}$

Note: This condition can be violated when NOSTRETCH $= 0$, because the device stretches SCL low to guarantee the set-up time, according to the SCLDEL value.

Refer to Table 90 for $t_r$, $t_{HD;DAT}$ and $t_{VD;DAT}$ standard values.

After $t_{SDADEL}$ delay, or after sending SDA output in case the slave had to stretch the clock because the data was not yet written in I2C_TxDR register, SCL line is kept at low level during the setup time. This setup time is $t_{SCLDEL} = (SCLDEL+1) \times t_{PRESC}$ where $t_{PRESC} = (PRESC+1) \times t_{I2CCLK}$.

$t_{SCLDEL}$ impacts the setup time $t_{SU;DAT}$.

In order to bridge the undefined region of the SDA transition (rising edge usually worst case), the user must program SCLDEL in such a way that:

$\left\{t_{r(max)} + t_{SU;DAT(min)} \right\} / \{(PRESC+1) \times t_{I2CCLK}\} - 1 \leq SCLDEL$

Refer to Table 90 for $t_r$ and $t_{SU;DAT}$ standard values.

The SDA and SCL transition time values to be used are the ones in the application. Using the maximum values from the standard increases the constraints for the SDADEL and SCLDEL calculation, but ensures the feature whatever the application.

Note: At every clock pulse, after SCL falling edge detection, the I2C master or slave stretches SCL low during at least $[(SDADEL + SCLDEL + 1) \times (PRESC + 1) + 1] \times t_{I2CCLK}$ in both
transmission and reception modes. In transmission mode, if the data is not yet written in I2C_TXDR when SDADEL counter is finished, the I2C keeps on stretching SCL low until the next data is written. Then new data MSB is sent on SDA output, and SCLDEL counter starts, continuing stretching SCL low to guarantee the data setup time.

If NOSTRETCH = 1 in slave mode, the SCL is not stretched. Consequently the SDADEL must be programmed in such a way to guarantee also a sufficient setup time.

</tbody>
</table>

Additionally, in master mode, the SCL clock high and low levels must be configured by programming the PRESC[3:0], SCLH[7:0] and SCLL[7:0] bits in the I2C_TIMINGR register.

- When the SCL falling edge is internally detected, a delay is inserted before releasing the SCL output. This delay is \( t_{SCLL} = (SCLL + 1) \times t_{PRESC} \), where \( t_{PRESC} = (PRESC + 1) \times t_{I2CCLK} \). \( t_{SCLL} \) impacts the SCL low time \( t_{LOW} \).
- When the SCL rising edge is internally detected, a delay is inserted before forcing the SCL output to low level. This delay is \( t_{SCLH} = (SCLH + 1) \times t_{PRESC} \), where \( t_{PRESC} = (PRESC+1) \times t_{I2CCLK} \). \( t_{SCLH} \) impacts the SCL high time \( t_{HIGH} \).

Refer to I²C master initialization for more details.

Caution: Changing the timing configuration is not allowed when the I2C is enabled.

The I2C slave NOSTRETCH mode must also be configured before enabling the peripheral. Refer to I²C slave initialization for more details.

Caution: Changing the NOSTRETCH configuration is not allowed when the I2C is enabled.
26.4.7 Software reset

A software reset can be performed by clearing the PE bit in the I2C_CR1 register. In that case I2C lines SCL and SDA are released. Internal states machines are reset and communication control bits, as well as status bits come back to their reset value. The configuration registers are not impacted.

Here is the list of impacted register bits:
1. I2C_CR2 register: START, STOP, NACK
2. I2C_ISR register: BUSY, TXE, TXIS, RXNE, ADDR, NACKF, TCR, TC, STOPF, BERR, ARLO, OVR

and in addition when the SMBus feature is supported:
1. I2C_CR2 register: PECBYTE
2. I2C_ISR register: PECERR, TIMEOUT, ALERT

PE must be kept low during at least three APB clock cycles in order to perform the software reset. This is ensured by writing the following software sequence:
1. Write PE = 0
2. Check PE = 0
3. Write PE = 1
26.4.8 Data transfer

The data transfer is managed through transmit and receive data registers and a shift register.

Reception

The SDA input fills the shift register. After the eighth SCL pulse (when the complete data byte is received), the shift register is copied into I2C_RXDR register if it is empty (RXNE = 0). If RXNE = 1, meaning that the previous received data byte has not yet been read, the SCL line is stretched low until I2C_RXDR is read. The stretch is inserted between the eighth and ninth SCL pulse (before the acknowledge pulse).

Figure 222. Data reception
Transmission

If the I2C_TXDR register is not empty (TXE=0), its content is copied into the shift register after the ninth SCL pulse (the acknowledge pulse). Then the shift register content is shifted out on SDA line. If TXE = 1, meaning that no data is written yet in I2C_TXDR, SCL line is stretched low until I2C_TXDR is written. The stretch is done after the ninth SCL pulse.

![Figure 223. Data transmission](image)

Hardware transfer management

The I2C has a byte counter embedded in hardware in order to manage byte transfer and to close the communication in various modes such as:

- NACK, STOP and ReSTART generation in master mode
- ACK control in slave receiver mode
- PEC generation/checking when SMBus feature is supported

The byte counter is always used in master mode. By default it is disabled in slave mode, but it can be enabled by software by setting the SBC (slave byte control) bit in the I2C_CR1 register.

The number of bytes to be transferred is programmed in the NBYTES[7:0] bit field in the I2C_CR2 register. If the number of bytes to be transferred (NBYTES) is greater than 255, or if a receiver wants to control the acknowledge value of a received data byte, the reload mode must be selected by setting the RELOAD bit in the I2C_CR2 register. In this mode, the TCR flag is set when the number of bytes programmed in NBYTES is transferred, and an interrupt is generated if TCIE is set. SCL is stretched as long as TCR flag is set. TCR is cleared by software when NBYTES is written to a non-zero value.

When the NBYTES counter is reloaded with the last number of bytes, RELOAD bit must be cleared.
When RELOAD=0 in master mode, the counter can be used in two modes:

- **Automatic end mode** (AUTOEND = ‘1’ in the I2C_CR2 register). In this mode, the master automatically sends a STOP condition once the number of bytes programmed in the NBYTES[7:0] bit field is transferred.

- **Software end mode** (AUTOEND = ‘0’ in the I2C_CR2 register). In this mode, software action is expected once the number of bytes programmed in the NBYTES[7:0] bit field is transferred; the TC flag is set and an interrupt is generated if the TCIE bit is set. The SCL signal is stretched as long as the TC flag is set. The TC flag is cleared by software when the START or STOP bit is set in the I2C_CR2 register. This mode must be used when the master wants to send a RESTART condition.

**Caution:** The AUTOEND bit has no effect when the RELOAD bit is set.

#### 26.4.9 I2C slave mode

**I2C slave initialization**

In order to work in slave mode, the user must enable at least one slave address. Two registers I2C_OAR1 and I2C_OAR2 are available in order to program the slave own addresses OA1 and OA2.

- OA1 can be configured either in 7-bit mode (by default) or in 10-bit addressing mode by setting the OA1MODE bit in the I2C_OAR1 register.

OA1 is enabled by setting the OA1EN bit in the I2C_OAR1 register.

- If additional slave addresses are required, the second slave address OA2 can be configured. Up to 7 OA2 LSB can be masked by configuring the OA2MSK[2:0] bits in the I2C_OAR2 register. Therefore for OA2MSK configured from 1 to 6, only OA2[7:2], OA2[7:3], OA2[7:4], OA2[7:5], OA2[7:6] or OA2[7] are compared with the received address. As soon as OA2MSK is not equal to 0, the address comparator for OA2 excludes the I2C reserved addresses (0000 XXX and 1111 XXX), which are not acknowledged. If OA2MSK=7, all received 7-bit addresses are acknowledged (except reserved addresses). OA2 is always a 7-bit address.

These reserved addresses can be acknowledged if they are enabled by the specific enable bit, if they are programmed in the I2C_OAR1 or I2C_OAR2 register with OA2MSK=0.

OA2 is enabled by setting the OA2EN bit in the I2C_OAR2 register.

- The general call address is enabled by setting the GCEN bit in the I2C_CR1 register.

When the I2C is selected by one of its enabled addresses, the ADDR interrupt status flag is set, and an interrupt is generated if the ADDRIE bit is set.
By default, the slave uses its clock stretching capability, which means that it stretches the SCL signal at low level when needed, in order to perform software actions. If the master does not support clock stretching, the I2C must be configured with NOSTRETCH = 1 in the I2C_CR1 register.

After receiving an ADDR interrupt, if several addresses are enabled the user must read the ADDCODE[6:0] bits in the I2C_ISR register in order to check which address matched. DIR flag must also be checked in order to know the transfer direction.

**Slave clock stretching (NOSTRETCH = 0)**

In default mode, the I2C slave stretches the SCL clock in the following situations:

- When the ADDR flag is set: the received address matches with one of the enabled slave addresses. This stretch is released when the ADDR flag is cleared by software setting the ADDRCF bit.
- In transmission, if the previous data transmission is completed and no new data is written in I2C_TXDR register, or if the first data byte is not written when the ADDR flag is cleared (TXE = 1). This stretch is released when the data is written to the I2C_TXDR register.
- In reception when the I2C_RXDR register is not read yet and a new data reception is completed. This stretch is released when I2C_RXDR is read.
- When TCR = 1 in Slave Byte Control mode, reload mode (SBC=1 and RELOAD=1), meaning that the last data byte has been transferred. This stretch is released when then TCR is cleared by writing a non-zero value in the NBYTES[7:0] field.
- After SCL falling edge detection, the I2C stretches SCL low during
  \[(SDADEL+SCLDEL+1) \times (PRESC+1) + 1\] \times I2CCLK.

**Slave without clock stretching (NOSTRETCH = 1)**

When NOSTRETCH = 1 in the I2C_CR1 register, the I2C slave does not stretch the SCL signal.

- The SCL clock is not stretched while the ADDR flag is set.
- In transmission, the data must be written in the I2C_TXDR register before the first SCL pulse corresponding to its transfer occurs. If not, an underrun occurs, the OVR flag is set in the I2C_ISR register and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register. The OVR flag is also set when the first data transmission starts and the STOPF bit is still set (has not been cleared). Therefore, if the user clears the STOPF flag of the previous transfer only after writing the first data to be transmitted in the next transfer, he ensures that the OVR status is provided, even for the first data to be transmitted.
- In reception, the data must be read from the I2C_RXDR register before the ninth SCL pulse (ACK pulse) of the next data byte occurs. If not an overrun occurs, the OVR flag is set in the I2C_ISR register and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.
Slave byte control mode

In order to allow byte ACK control in slave reception mode, the Slave byte control mode must be enabled by setting the SBC bit in the I2C_CR1 register. This is required to be compliant with SMBus standards.

The Reload mode must be selected in order to allow byte ACK control in slave reception mode (RELOAD = 1). To get control of each byte, NBYTES must be initialized to 0x1 in the ADDR interrupt subroutine, and reloaded to 0x1 after each received byte. When the byte is received, the TCR bit is set, stretching the SCL signal low between the eighth and ninth SCL pulses. The user can read the data from the I2C_RXDR register, and then decide to acknowledge it or not by configuring the ACK bit in the I2C_CR2 register. The SCL stretch is released by programming NBYTES to a non-zero value: the acknowledge or not-acknowledge is sent and next byte can be received.

NBYTES can be loaded with a value greater than 0x1, and in this case, the reception flow is continuous during NBYTES data reception.

Note: The SBC bit must be configured when the I2C is disabled, or when the slave is not addressed, or when ADDR = 1.
The RELOAD bit value can be changed when ADDR = 1, or when TCR = 1.

Caution: The Slave byte control mode is not compatible with NOSTRETCH mode. Setting SBC when NOSTRETCH = 1 is not allowed.

Figure 224. Slave initialization flow

```
Slave initialization

Initial settings

Clear {OA1EN, OA2EN} in I2C_OAR1 and I2C_OAR2

Configure {OA1[9:0], OA1MODE, OA1EN, OA2[6:0], OA2MSK[2:0], OA2EN, GCEN}

Configure SBC in I2C_CR1*

Enable interrupts and/or DMA in I2C_CR1

End

*SBC must be set to support SMBus features
```
For a code example refer to A.14.3: I2C configured in slave mode code example.

**Slave transmitter**

A transmit interrupt status (TXIS) is generated when the I2C_TXDR register becomes empty. An interrupt is generated if the TXIE bit is set in the I2C_CR1 register.

The TXIS bit is cleared when the I2C_TXDR register is written with the next data byte to be transmitted.

When a NACK is received, the NACKF bit is set in the I2C_ISR register and an interrupt is generated if the NACKIE bit is set in the I2C_CR1 register. The slave automatically releases the SCL and SDA lines in order to let the master perform a STOP or a RESTART condition. The TXIS bit is not set when a NACK is received.

When a STOP is received and the STOPIE bit is set in the I2C_CR1 register, the STOPF flag is set in the I2C_ISR register and an interrupt is generated. In most applications, the SBC bit is usually programmed to ‘0’. In this case, if TXE = 0 when the slave address is received (ADDR = 1), the user can choose either to send the content of the I2C_TXDR register as the first data byte, or to flush the I2C_TXDR register by setting the TXE bit in order to program a new data byte.

In Slave byte control mode (SBC = 1), the number of bytes to be transmitted must be programmed in NBYTES in the address match interrupt subroutine (ADDR = 1). In this case, the number of TXIS events during the transfer corresponds to the value programmed in NBYTES.

**Caution:** When NOSTRETCH = 1, the SCL clock is not stretched while the ADDR flag is set, so the user cannot flush the I2C_TXDR register content in the ADDR subroutine, in order to program the first data byte. The first data byte to be sent must be previously programmed in the I2C_TXDR register:

- This data can be the data written in the last TXIS event of the previous transmission message.
- If this data byte is not the one to be sent, the I2C_TXDR register can be flushed by setting the TXE bit in order to program a new data byte. The STOPF bit must be cleared only after these actions, in order to guarantee that they are executed before the first data transmission starts, following the address acknowledge. If STOPF is still set when the first data transmission starts, an underrun error is generated (the OVR flag is set).
- If a TXIS event is needed, (transmit interrupt or transmit DMA request), the user must set the TXIS bit in addition to the TXE bit, in order to generate a TXIS event.

26.4.10 I2C master mode

I2C master initialization

Before enabling the peripheral, the I2C master clock must be configured by setting the SCLH and SCLL bits in the I2C_TIMINGR register.

The STM32CubeMX tool calculates and provides the I2C_TIMINGR content in the I2C Configuration window.

A clock synchronization mechanism is implemented in order to support multi-master environment and slave clock stretching.

In order to allow clock synchronization:
- The low level of the clock is counted using the SCLL counter, starting from the SCL low level internal detection.
- The high level of the clock is counted using the SCLH counter, starting from the SCL high level internal detection.

The I2C detects its own SCL low level after a \( t_{SYNC1} \) delay depending on the SCL falling edge, SCL input noise filters (analog + digital) and SCL synchronization to the I2CxCLK clock. The I2C releases SCL to high level once the SCLL counter reaches the value programmed in the SCLL[7:0] bits in the I2C_TIMINGR register.

The I2C detects its own SCL high level after a \( t_{SYNC2} \) delay depending on the SCL rising edge, SCL input noise filters (analog + digital) and SCL synchronization to I2CxCLK clock. The I2C ties SCL to low level once the SCLH counter is reached reaches the value programmed in the SCLH[7:0] bits in the I2C_TIMINGR register.

Consequently the master clock period is:

\[
t_{SCL} = t_{SYNC1} + t_{SYNC2} + \left( [(SCLH+1) + (SCLL+1)] \times (PRES+1) \times t_{I2CCLK} \right)
\]

The duration of \( t_{SYNC1} \) depends on these parameters:
- SCL falling slope
- When enabled, input delay induced by the analog filter.
- When enabled, input delay induced by the digital filter: DNF \( \times t_{I2CCLK} \)
- Delay due to SCL synchronization with I2CCLK clock (two to three I2CCLK periods)

The duration of \( t_{SYNC2} \) depends on these parameters:
- SCL rising slope
- When enabled, input delay induced by the analog filter.
- When enabled, input delay induced by the digital filter: DNF \( \times t_{I2CCLK} \)
- Delay due to SCL synchronization with I2CCLK clock (two to three I2CCLK periods)
Figure 231. Master clock generation

SCL master clock generation

- SCL high level detected
  - SCLH counter starts
- SCL released
  - SCL driven low
- SCL low level detected
  - SCLL counter starts

SCL master clock synchronization

Note: $SCLL$ is also used to generate the $t_{BUF}$ and $t_{SU:STA}$ timings. $SCLH$ is also used to generate the $t_{HD:STA}$ and $t_{SU:STO}$ timings.

Refer to Section 26.4.11: I2C_TIMINGR register configuration examples for examples of I2C_TIMINGR settings vs. I2CCLK frequency.

**Master communication initialization (address phase)**

In order to initiate the communication, the user must program the following parameters for the addressed slave in the I2C_CR2 register:

- Addressing mode (7-bit or 10-bit): ADD10
- Slave address to be sent: SADD[9:0]
- Transfer direction: RD_WRN
- In case of 10-bit address read: HEAD10R bit. HEAD10R must be configure to indicate if the complete address sequence must be sent, or only the header in case of a direction change.
- The number of bytes to be transferred: NBYTES[7:0]. If the number of bytes is equal to or greater than 255 bytes, NBYTES[7:0] must initially be filled with 0xFF.

The user must then set the START bit in I2C_CR2 register. Changing all the above bits is not allowed when START bit is set.

Then the master automatically sends the START condition followed by the slave address as soon as it detects that the bus is free (BUSY = 0) and after a delay of $t_{BUF}$.

In case of an arbitration loss, the master automatically switches back to slave mode and can acknowledge its own address if it is addressed as a slave.
Note: The START bit is reset by hardware when the slave address has been sent on the bus, whatever the received acknowledge value. The START bit is also reset by hardware if an arbitration loss occurs.

In 10-bit addressing mode, when the slave address first 7 bits are NACKed by the slave, the master re-launches automatically the slave address transmission until ACK is received. In this case ADDRCF must be set if a NACK is received from the slave, in order to stop sending the slave address.

If the I2C is addressed as a slave (ADDR = 1) while the START bit is set, the I2C switches to slave mode and the START bit is cleared, when the ADDRCF bit is set.

Note: The same procedure is applied for a repeated start condition. In this case BUSY = 1.

Figure 232. Master initialization flow

For code examples refer to A.14.1: I2C configured in master mode to receive code example and A.14.2: I2C configured in master mode to transmit code example.

Initialization of a master receiver addressing a 10-bit address slave

- If the slave address is in 10-bit format, the user can choose to send the complete read sequence by clearing the HEAD10R bit in the I2C_CR2 register. In this case the master automatically sends the following complete sequence after the START bit is set:
  (Re)Start + Slave address 10-bit header Write + Slave address second byte + REStart + Slave address 10-bit header Read

Figure 233. 10-bit address read access with HEAD10R = 0
If the master addresses a 10-bit address slave, transmits data to this slave and then reads data from the same slave, a master transmission flow must be done first. Then a repeated start is set with the 10 bit slave address configured with HEAD10R = 1. In this case the master sends this sequence: ReStart + Slave address 10-bit header Read.

Master transmitter

In the case of a write transfer, the TXIS flag is set after each byte transmission, after the ninth SCL pulse when an ACK is received.

A TXIS event generates an interrupt if the TXIE bit is set in the I2C_CR1 register. The flag is cleared when the I2C_TXDR register is written with the next data byte to be transmitted.

The number of TXIS events during the transfer corresponds to the value programmed in NBYTES[7:0]. If the total number of data bytes to be sent is greater than 255, reload mode must be selected by setting the RELOAD bit in the I2C_CR2 register. In this case, when NBYTES data have been transferred, the TCR flag is set and the SCL line is stretched low until NBYTES[7:0] is written to a non-zero value.

The TXIS flag is not set when a NACK is received.

- When RELOAD=0 and NBYTES data have been transferred:
  - In automatic end mode (AUTOEND = 1), a STOP is automatically sent.
  - In software end mode (AUTOEND = 0), the TC flag is set and the SCL line is stretched low in order to perform software actions:

    A RESTART condition can be requested by setting the START bit in the I2C_CR2 register with the proper slave address configuration, and number of bytes to be transferred. Setting the START bit clears the TC flag and the START condition is sent on the bus.

    A STOP condition can be requested by setting the STOP bit in the I2C_CR2 register. Setting the STOP bit clears the TC flag and the STOP condition is sent on the bus.

- If a NACK is received: the TXIS flag is not set, and a STOP condition is automatically sent after the NACK reception. the NACKF flag is set in the I2C_ISR register, and an interrupt is generated if the NACKIE bit is set.

Example I2C master transmitter 2 bytes, automatic end mode (STOP)

Example I2C master transmitter 2 bytes, software end mode (RESTART)

For a code example refer to A.14.4: I2C master transmitter code example.
Master receiver

In the case of a read transfer, the RXNE flag is set after each byte reception, after the eighth SCL pulse. An RXNE event generates an interrupt if the RXIE bit is set in the I2C_CR1 register. The flag is cleared when I2C_RXDR is read.

If the total number of data bytes to be received is greater than 255, reload mode must be selected by setting the RELOAD bit in the I2C_CR2 register. In this case, when NBYTES[7:0] data have been transferred, the TCR flag is set and the SCL line is stretched low until NBYTES[7:0] is written to a non-zero value.

- When RELOAD=0 and NBYTES[7:0] data have been transferred:
  - In automatic end mode (AUTOEND=1), a NACK and a STOP are automatically sent after the last received byte.
  - In software end mode (AUTOEND=0), a NACK is automatically sent after the last received byte, the TC flag is set and the SCL line is stretched low in order to allow software actions:
    A RESTART condition can be requested by setting the START bit in the I2C_CR2 register with the proper slave address configuration, and number of bytes to be transferred. Setting the START bit clears the TC flag and the START condition, followed by slave address, are sent on the bus.
    A STOP condition can be requested by setting the STOP bit in the I2C_CR2 register. Setting the STOP bit clears the TC flag and the STOP condition is sent on the bus.

1. SCL period tSCL is greater than tSCLL + tSCLH due to SCL internal detection delay. Values provided for tSCL are examples only.
This section is relevant only when the SMBus feature is supported. Refer to Section 26.3: I2C implementation.

Introduction

The system management bus (SMBus) is a two-wire interface through which various devices can communicate with each other and with the rest of the system. It is based on I²C principles of operation. The SMBus provides a control bus for system and power management related tasks.

This peripheral is compatible with the SMBus specification (http://smbus.org).

The system management bus specification refers to three types of devices

- A slave is a device that receives or responds to a command.
- A master is a device that issues commands, generates the clocks and terminates the transfer.
- A host is a specialized master that provides the main interface to the system’s CPU. A host must be a master-slave and must support the SMBus host notify protocol. Only one host is allowed in a system.

This peripheral can be configured as master or slave device, and also as a host.

</tbody>
</table>

1. The SCL period tSCL is greater than tSCLL + tSCLH due to the SCL internal detection delay. Values provided for tSCL are only examples.
2. tSYNC1 + tSYNC2 minimum value is 4 x tI2CCLK = 83.3 ns. Example with tSYNC1 + tSYNC2 = 1000 ns
3. tSYNC1 + tSYNC2 minimum value is 4 x tI2CCLK = 83.3 ns. Example with tSYNC1 + tSYNC2 = 750 ns
4. tSYNC1 + tSYNC2 minimum value is 4 x tI2CCLK = 83.3 ns. Example with tSYNC1 + tSYNC2 = 250 ns
Bus protocols

There are eleven possible command protocols for any given device. A device may use any or all of the eleven protocols to communicate. The protocols are Quick Command, Send Byte, Receive Byte, Write Byte, Write Word, Read Byte, Read Word, Process Call, Block Read, Block Write and Block Write-Block Read Process Call. These protocols must be implemented by the user software.

For more details on these protocols, refer to SMBus specification (http://smbus.org).

Address resolution protocol (ARP)

SMBus slave address conflicts can be resolved by dynamically assigning a new unique address to each slave device. In order to provide a mechanism to isolate each device for the purpose of address assignment each device must implement a unique device identifier (UDID). This 128-bit number is implemented by software.

This peripheral supports the Address Resolution Protocol (ARP). The SMBus Device Default Address (0b1100 001) is enabled by setting SMBDEN bit in I2C_CR1 register. The ARP commands must be implemented by the user software.

Arbitration is also performed in slave mode for ARP support.

For more details of the SMBus address resolution protocol, refer to SMBus specification (http://smbus.org).

Received command and data acknowledge control

A SMBus receiver must be able to NACK each received command or data. In order to allow the ACK control in slave mode, the Slave Byte Control mode must be enabled by setting SBC bit in I2C_CR1 register. Refer to Slave byte control mode for more details.

Host notify protocol

This peripheral supports the host notify protocol by setting the SMBHEN bit in the I2C_CR1 register. In this case the host acknowledges the SMBus host address (0b0001 000).

When this protocol is used, the device acts as a master and the host as a slave.

SMBus alert

The SMBus ALERT optional signal is supported. A slave-only device can signal the host through the SMBALERT# pin that it wants to talk. The host processes the interrupt and simultaneously accesses all SMBALERT# devices through the alert response address (0b0001 100). Only the device(s) which pulled SMBALERT# low acknowledges the alert response address.

When configured as a slave device(SMBHEN=0), the SMBA pin is pulled low by setting the ALERTEN bit in the I2C_CR1 register. The Alert Response Address is enabled at the same time.

When configured as a host (SMBHEN=1), the ALERT flag is set in the I2C_ISR register when a falling edge is detected on the SMBA pin and ALERTEN=1. An interrupt is generated if theERRIE bit is set in the I2C_CR1 register. When ALERTEN=0, the ALERT line is considered high even if the external SMBA pin is low.

If the SMBus ALERT pin is not needed, the SMBA pin can be used as a standard GPIO if ALERTEN=0.
Packet error checking

A packet error checking mechanism has been introduced in the SMBus specification to improve reliability and communication robustness. The packet error checking is implemented by appending a packet error code (PEC) at the end of each message transfer. The PEC is calculated by using the $C(x) = x^8 + x^2 + x + 1$ CRC-8 polynomial on all the message bytes (including addresses and read/write bits).

The peripheral embeds a hardware PEC calculator and allows a not acknowledge to be sent automatically when the received byte does not match with the hardware calculated PEC.

Timeouts

This peripheral embeds hardware timers in order to be compliant with the three timeouts defined in SMBus specification.

Table 96. SMBus timeout specifications

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Parameter</th>
<th>Limits</th>
<th>Unit</th>
</tr>
</thead>
<tbody>
<tr>
<td>$t_{\text{TIMEOUT}}$</td>
<td>Detect clock low timeout</td>
<td>Min 25</td>
<td>Max 35</td>
</tr>
<tr>
<td>$t_{\text{LOW:SEXT}}^{(1)}$</td>
<td>Cumulative clock low extend time (slave device)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>$t_{\text{LOW:MEXT}}^{(2)}$</td>
<td>Cumulative clock low extend time (master device)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

1. $t_{\text{LOW:SEXT}}$ is the cumulative time a given slave device is allowed to extend the clock cycles in one message from the initial START to the STOP. It is possible that, another slave device or the master also extends the clock causing the combined clock low extend time to be greater than $t_{\text{LOW:SEXT}}$. Therefore, this parameter is measured with the slave device as the sole target of a full-speed master.

2. $t_{\text{LOW:MEXT}}$ is the cumulative time a master device is allowed to extend its clock cycles within each byte of a message as defined from START-to-ACK, ACK-to-ACK, or ACK-to-STOP. It is possible that a slave device or another master also extends the clock causing the combined clock low time to be greater than $t_{\text{LOW:MEXT}}$ on a given byte. Therefore, this parameter is measured with a full speed slave device as the sole target of the master.

Figure 241. Timeout intervals for $t_{\text{LOW:SEXT}}, t_{\text{LOW:MEXT}}$
Bus idle detection

A master can assume that the bus is free if it detects that the clock and data signals have been high for $t_{\text{IDLE}}$ greater than $t_{\text{HIGH,MAX}}$. (refer to Table 90)

This timing parameter covers the condition where a master has been dynamically added to the bus and may not have detected a state transition on the SMBCLK or SMBDAT lines. In this case, the master must wait long enough to ensure that a transfer is not currently in progress. The peripheral supports a hardware bus idle detection.

26.4.13 SMBus initialization

This section is relevant only when SMBus feature is supported. Refer to Section 26.3: I2C implementation.

In addition to I2C initialization, some other specific initialization must be done in order to perform SMBus communication:

Received command and data acknowledge control (Slave mode)

A SMBus receiver must be able to NACK each received command or data. In order to allow ACK control in slave mode, the Slave byte control mode must be enabled by setting the SBC bit in the I2C_CR1 register. Refer to Slave byte control mode for more details.

Specific address (Slave mode)

The specific SMBus addresses must be enabled if needed. Refer to Bus idle detection for more details.

- The SMBus device default address (0b1100 001) is enabled by setting the SMBDEN bit in the I2C_CR1 register.
- The SMBus host address (0b0001 000) is enabled by setting the SMBHEN bit in the I2C_CR1 register.
- The alert response address (0b0001100) is enabled by setting the ALERTEN bit in the I2C_CR1 register.

Packet error checking

PEC calculation is enabled by setting the PECEN bit in the I2C_CR1 register. Then the PEC transfer is managed with the help of a hardware byte counter: NBYTES[7:0] in the I2C_CR2 register. The PECEN bit must be configured before enabling the I2C.

The PEC transfer is managed with the hardware byte counter, so the SBC bit must be set when interfacing the SMBus in slave mode. The PEC is transferred after NBYTES - 1 data have been transferred when the PECBYTE bit is set and the RELOAD bit is cleared. If RELOAD is set, PECBYTE has no effect.

Caution: Changing the PECEN configuration is not allowed when the I2C is enabled.

</tr>
</tbody>
</table>
**Timeout detection**

The timeout detection is enabled by setting the TIMOUTEN and TEXTEN bits in the I2C_TIMEOUTR register. The timers must be programmed in such a way that they detect a timeout before the maximum time given in the SMBus specification.

- **t_TIMEOUT check**
  
  In order to enable the t_TIMEOUT check, the 12-bit TIMEOUTA[11:0] bits must be programmed with the timer reload value in order to check the t_TIMEOUT parameter. The TIDLE bit must be configured to ‘0’ in order to detect the SCL low level timeout.
  
  Then the timer is enabled by setting the TIMOUTEN in the I2C_TIMEOUTR register. If SCL is tied low for a time greater than (TIMEOUTA+1) x 2048 x t_I2CCLK, the TIMEOUT flag is set in the I2C_ISR register.
  
  Refer to Table 98.

**Caution:** Changing the TIMEOUTA[11:0] bits and TIDLE bit configuration is not allowed when the TIMOUTEN bit is set.

- **t_LOW:SEXT and t_LOW:MEXT check**
  
  Depending on if the peripheral is configured as a master or as a slave, The 12-bit TIMEOUTB timer must be configured in order to check t_LOW:SEXT for a slave and t_LOW:MEXT for a master. As the standard specifies only a maximum, the user can choose the same value for both.
  
  Then the timer is enabled by setting the TEXTEN bit in the I2C_TIMEOUTR register. If the SMBus peripheral performs a cumulative SCL stretch for a time greater than (TIMEOUTB+1) x 2048 x t_I2CCLK, and in the timeout interval described in Bus idle detection section, the TIMEOUT flag is set in the I2C_ISR register.
  
  Refer to Table 99.

**Caution:** Changing the TIMEOUTB configuration is not allowed when the TEXTEN bit is set.

**Bus idle detection**

In order to enable the t_IDLE check, the 12-bit TIMEOUTA[11:0] field must be programmed with the timer reload value in order to obtain the t_IDLE parameter. The TIDLE bit must be configured to ‘1’ in order to detect both SCL and SDA high level timeout.

Then the timer is enabled by setting the TIMOUTEN bit in the I2C_TIMEOUTR register. If both the SCL and SDA lines remain high for a time greater than (TIMEOUTA+1) x 4 x t_I2CCLK, the TIMEOUT flag is set in the I2C_ISR register.

Refer to Table 100.

**Caution:** Changing the TIMEOUTA and TIDLE configuration is not allowed when the TIMOUTEN is set.
26.4.14 SMBus: I2C_TIMEOUTR register configuration examples

26.4.15 SMBus slave mode

This section is relevant only when the SMBus feature is supported. Refer to Section 26.3: I2C implementation.

In addition to I2C slave transfer management (refer to Section 26.4.9: I2C slave mode) some additional software flows are provided to support the SMBus.

**SMBus slave transmitter**

When the IP is used in SMBus, SBC must be programmed to ‘1’ in order to allow the PEC transmission at the end of the programmed number of data bytes. When the PECBYTE bit is set, the number of bytes programmed in NBYTES[7:0] includes the PEC transmission. In that case the total number of TXIS interrupts is NBYTES - 1 and the content of the I2C_PECR register is automatically transmitted if the master requests an extra byte after the NBYTES - 1 data transfer.
Caution: The PECBYTE bit has no effect when the RELOAD bit is set.

**Figure 242. Transfer sequence flow for SMBus slave transmitter N bytes + PEC**

- Slave initialization
- Read ADDCODE and DIR in I2C_ISR
  - I2C_ISR.ADDR = 1?
    - No
    - Yes
      - I2C_ISR.ADDR = 1?
        - No
        - Yes
          - Write I2C_TXDR.TXDATA

**Figure 243. Transfer bus diagrams for SMBus slave transmitter (SBC = 1)**

Example SMBus slave transmitter 2 bytes + PEC,

Legend:
- transmission
- reception
- SCL stretch

EV1: ADDR ISR: check ADDCODE, program NBYTES=3, set PECBYTE, set ADDRCF
EV2: TXIS ISR: wr data1
EV3: TXIS ISR: wr data2

NBYTES = 3

MS19867V2

MS19869V2
**SMBus Slave receiver**

When the I2C is used in SMBus mode, SBC must be programmed to '1' in order to allow the PEC checking at the end of the programmed number of data bytes. In order to allow the ACK control of each byte, the reload mode must be selected (RELOAD=1). Refer to *Slave byte control mode* for more details.

In order to check the PEC byte, the RELOAD bit must be cleared and the PECBYTE bit must be set. In this case, after NBYTES - 1 data have been received, the next received byte is compared with the internal I2C_PECR register content. A NACK is automatically generated if the comparison does not match, and an ACK is automatically generated if the comparison matches, whatever the ACK bit value. Once the PEC byte is received, it is copied into the I2C_RXDR register like any other data, and the RXNE flag is set.

In the case of a PEC mismatch, the PECERR flag is set and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

If no ACK software control is needed, the user can program PECBYTE=1 and, in the same write operation, program NBYTES with the number of bytes to be received in a continuous flow. After NBYTES - 1 are received, the next received byte is checked as being the PEC.

**Caution:** The PECBYTE bit has no effect when the RELOAD bit is set.
Figure 244. Transfer sequence flow for SMBus slave receiver N bytes + PEC

1. Slave initialization

- I2C_ISR.ADDR = 1?
  - Yes: Read ADDCODE and DIR in I2C_ISR
    - I2C_CR2.NBYTES = 1, RELOAD=1
    - PECBYTE=1
    - Set I2C_ICR.ADDRCF
  - No: SCL stretched

- I2C_ISR.RXNE = 1? I2C_ISR.TCR = 1?
  - Yes: Read I2C_RXDR.RXDATA
    - Program I2C_CR2.NACK = 0
    - I2C_CR2.NBYTES = 1
    - N = N - 1
  - No: N = 1?
    - Yes: Read I2C_RXDR.RXDATA
      - Program RELOAD = 0
      - NACK = 0 and NBYTES = 1
    - No: I2C_ISR.RXNE = 1?
      - Yes: Read I2C_RXDR.RXDATA
      - End
This section is relevant only when the SMBus feature is supported. Refer to Section 26.3: I2C implementation.

In addition to I2C master transfer management (refer to Section 26.4.10: I2C master mode), some additional software flows are provided to support the SMBus.

**SMBus master transmitter**

When the SMBus master wants to transmit the PEC, the PECBYTE bit must be set and the number of bytes must be programmed in the NBYTES[7:0] field, before setting the START bit. In this case the total number of TXIS interrupts is NBYTES - 1. So if the PECBYTE bit is set when NBYTES = 0x1, the content of the I2C_PECR register is automatically transmitted.

If the SMBus master wants to send a STOP condition after the PEC, automatic end mode must be selected (AUTOEND = 1). In this case, the STOP condition automatically follows the PEC transmission.
When the SMBus master wants to send a RESTART condition after the PEC, software mode must be selected (AUTOEND=0). In this case, once NBYTES - 1 have been transmitted, the I2C_PECR register content is transmitted and the TC flag is set after the PEC transmission, stretching the SCL line low. The RESTART condition must be programmed in the TC interrupt subroutine.

**Caution:** The PECBYTE bit has no effect when the RELOAD bit is set.

### Figure 246. Bus transfer diagrams for SMBus master transmitter

**Example SMBus master transmitter 2 bytes + PEC, automatic end mode (STOP)**

| INIT: program Slave address, program NBYTES = 3, AUTOEND=1, set PECBYTE, set START |
| EV1: TXIS ISR: wr data1 |
| EV2: TXIS ISR: wr data2 |

**Example SMBus master transmitter 2 bytes + PEC, software end mode (RESTART)**

| INIT: program Slave address, program NBYTES = 3, AUTOEND=0, set PECBYTE, set START |
| EV1: TXIS ISR: wr data1 |
| EV2: TXIS ISR: wr data2 |
| EV3: TC ISR: program Slave address, program NBYTES = N, set START |
**SMBus master receiver**

When the SMBus master wants to receive the PEC followed by a STOP at the end of the transfer, automatic end mode can be selected (AUTOEND = 1). The PECBYTE bit must be set and the slave address must be programmed, before setting the START bit. In this case, after NBYTES - 1 data have been received, the next received byte is automatically checked versus the I2C_PECR register content. A NACK response is given to the PEC byte, followed by a STOP condition.

When the SMBus master receiver wants to receive the PEC byte followed by a RESTART condition at the end of the transfer, software mode must be selected (AUTOEND=0). The PECBYTE bit must be set and the slave address must be programmed, before setting the START bit. In this case, after NBYTES - 1 data have been received, the next received byte is automatically checked versus the I2C_PECR register content. The TC flag is set after the PEC byte reception, stretching the SCL line low. The RESTART condition can be programmed in the TC interrupt subroutine.

**Caution:** The PECBYTE bit has no effect when the RELOAD bit is set.
26.4.16 Wake-up from Stop mode on address match

This section is relevant only when wake-up from Stop mode feature is supported. Refer to Section 26.3: I2C implementation.

The I2C is able to wake-up the MCU from Stop mode (APB clock is off), when it is addressed. All addressing modes are supported.

Wake-up from Stop mode is enabled by setting the WUPEN bit in the I2C_CR1 register. The HSI oscillator must be selected as the clock source for I2CCLK in order to allow wake-up from Stop mode.

During Stop mode, the HSI is switched off. When a START is detected, the I2C interface switches the HSI on, and stretches SCL low until HSI is woken up.

HSI is then used for the address reception.
In case of an address match, the I2C stretches SCL low during MCU wake-up time. The stretch is released when ADDR flag is cleared by software, and the transfer goes on normally.

If the address does not match, the HSI is switched off again and the MCU is not woken up.

Note: If the I2C clock is the system clock, or if WUPEN = 0, the HSI is not switched on after a START is received.

Only an ADDR interrupt can wake-up the MCU. Therefore do not enter Stop mode when the I2C is performing a transfer as a master, or as an addressed slave after the ADDR flag is set. This can be managed by clearing SLEEPDEEP bit in the ADDR interrupt routine and setting it again only after the STOPF flag is set.

Caution: The digital filter is not compatible with the wake-up from Stop mode feature. If the DNF bit is not equal to 0, setting the WUPEN bit has no effect.

Caution: This feature is available only when the I2C clock source is the HSI oscillator.

Caution: Clock stretching must be enabled (NOSTRETCH = 0) to ensure proper operation of the wake-up from Stop mode feature.

Caution: If wake-up from Stop mode is disabled (WUPEN = 0), the I2C peripheral must be disabled before entering Stop mode (PE = 0).

26.4.17 Error conditions

The following errors are the conditions which may cause communication to fail.

Bus error (BERR)

A bus error is detected when a START or a STOP condition is detected and is not located after a multiple of nine SCL clock pulses. A START or a STOP condition is detected when a SDA edge occurs while SCL is high.

The bus error flag is set only if the I2C is involved in the transfer as master or addressed slave (i.e not during the address phase in slave mode).

In case of a misplaced START or RESTART detection in slave mode, the I2C enters address recognition state like for a correct START condition.

When a bus error is detected, the BERR flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

Arbitration lost (ARLO)

An arbitration loss is detected when a high level is sent on the SDA line, but a low level is sampled on the SCL rising edge.

- In master mode, arbitration loss is detected during the address phase, data phase and data acknowledge phase. In this case, the SDA and SCL lines are released, the START control bit is cleared by hardware and the master switches automatically to slave mode.

- In slave mode, arbitration loss is detected during data phase and data acknowledge phase. In this case, the transfer is stopped, and the SCL and SDA lines are released.

When an arbitration loss is detected, the ARLO flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.
Overrun/underrun error (OVR)

An overrun or underrun error is detected in slave mode when NOSTRETCH = 1 and:

- In reception when a new byte is received and the RXDR register has not been read yet. The new received byte is lost, and a NACK is automatically sent as a response to the new byte.
- In transmission:
  - When STOPF=1 and the first data byte must be sent. The content of the I2C_TXDR register is sent if TXE = 0, 0xFF if not.
  - When a new byte must be sent and the I2C_TXDR register has not been written yet, 0xFF is sent.

When an overrun or underrun error is detected, the OVR flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

Packet error checking error (PECERR)

This section is relevant only when the SMBus feature is supported. Refer to Section 26.3: I2C implementation.

A PEC error is detected when the received PEC byte does not match with the I2C_PECR register content. A NACK is automatically sent after the wrong PEC reception.

When a PEC error is detected, the PECERR flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

Timeout error (TIMEOUT)

This section is relevant only when the SMBus feature is supported. Refer to Section 26.3: I2C implementation.

A timeout error occurs for any of these conditions:

- TIDLE = 0 and SCL remained low for the time defined in the TIMEOUTA[11:0] bits: this is used to detect a SMBus timeout.
- TIDLE = 1 and both SDA and SCL remained high for the time defined in the TIMEOUTA [11:0] bits: this is used to detect a bus idle condition.
- Master cumulative clock low extend time reached the time defined in the TIMEOUTB[11:0] bits (SMBus tLOW:MEXT parameter)
- Slave cumulative clock low extend time reached the time defined in TIMEOUTB[11:0] bits (SMBus tLOW:SEXT parameter)

When a timeout violation is detected in master mode, a STOP condition is automatically sent.

When a timeout violation is detected in slave mode, SDA and SCL lines are automatically released.

When a timeout error is detected, the TIMEOUT flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

Alert (ALERT)

This section is relevant only when the SMBus feature is supported. Refer to Section 26.3: I2C implementation.
The ALERT flag is set when the I2C interface is configured as a Host (SMBHEN = 1), the alert pin detection is enabled (ALERTEN = 1) and a falling edge is detected on the SMBA pin. An interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

### 26.4.18 DMA requests

#### Transmission using DMA

DMA (direct memory access) can be enabled for transmission by setting the TXDMAEN bit in the I2C_CR1 register. Data is loaded from an SRAM area configured using the DMA peripheral (see Section 11: Direct memory access controller (DMA) on page 359) to the I2C_TXDR register whenever the TXIS bit is set.

Only the data are transferred with DMA.

- In master mode: the initialization, the slave address, direction, number of bytes and START bit are programmed by software (the transmitted slave address cannot be transferred with DMA). When all data are transferred using DMA, the DMA must be initialized before setting the START bit. The end of transfer is managed with the NBYTES counter. Refer to Master transmitter.

For a code example refer to A.14.8: I2C configured in master mode to transmit with DMA code example.

- In slave mode:
  - With NOSTRETCH = 0, when all data are transferred using DMA, the DMA must be initialized before the address match event, or in ADDR interrupt subroutine, before clearing ADDR.
  - With NOSTRETCH = 1, the DMA must be initialized before the address match event.

- For instances supporting SMBus: the PEC transfer is managed with NBYTES counter. Refer to SMBus slave transmitter and SMBus master transmitter.

**Note:** If DMA is used for transmission, the TXIE bit does not need to be enabled.

#### Reception using DMA

DMA (direct memory access) can be enabled for reception by setting the RXDMAEN bit in the I2C_CR1 register. Data is loaded from the I2C_RXDR register to an SRAM area configured using the DMA peripheral (refer to Section 10: Direct memory access controller (DMA) on page 188) whenever the RXNE bit is set. Only the data (including PEC) are transferred with DMA.

- In Master mode, the initialization, the slave address, direction, number of bytes and START bit are programmed by software. When all data are transferred using DMA, the DMA must be initialized before setting the START bit. The end of transfer is managed with the NBYTES counter.

- In Slave mode with NOSTRETCH = 0, when all data are transferred using DMA, the DMA must be initialized before the address match event, or in the ADDR interrupt subroutine, before clearing the ADDR flag.

- If SMBus is supported (see Section 26.3: I2C implementation): the PEC transfer is managed with the NBYTES counter. Refer to SMBus Slave receiver and SMBus master receiver.

**Note:** If DMA is used for reception, the RXIE bit does not need to be enabled.
For a code example refer to A.14.9: I2C configured in slave mode to receive with DMA code example.

26.4.19 Debug mode

When the microcontroller enters debug mode (core halted), the SMBus timeout either continues to work normally or stops, depending on the DBG_I2Cx_SMBUS_TIMEOUT configuration bits in the DBG module.

26.5 I2C low-power modes

Table 101. Effect of low-power modes on the I2C

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>

1. The ADDR match event can wake up the device from Stop mode only if the I2C instance supports the Wake-up from Stop mode feature. Refer to Section 26.3: I2C implementation.
26.7  I2C registers

Refer to Section 1.2 on page 42 for a list of abbreviations used in register descriptions.

The peripheral registers are accessed by words (32-bit).

26.7.1  I2C control register 1 (I2C_CR1)

Address offset: 0x00
Reset value: 0x0000 0000

Access: No wait states, except if a write access occurs while a write access to this register is ongoing. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to $2 \times PCLK1 + 6 \times I2CCLK$.

<table>
<thead>
<tr>
<th>Bits 31:24</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
</table>

**Bit 23**  PECEN: PEC enable

0: PEC calculation disabled
1: PEC calculation enabled

*Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'. Refer to Section 26.3: I2C implementation.*

**Bit 22**  ALERTEN: SMBus alert enable

0: The SMBus alert pin (SMBA) is not supported in host mode (SMBHEN = 1). In device mode (SMBHEN=0), the SMBA pin is released and the Alert Response Address header is disabled (0001100x followed by NACK).
1: The SMBus alert pin is supported in host mode (SMBHEN = 1). In device mode (SMBHEN=0), the SMBA pin is driven low and the Alert Response Address header is enabled (0001100x followed by ACK).

*Note: When ALERTEN=0, the SMBA pin can be used as a standard GPIO. If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'. Refer to Section 26.3: I2C implementation.*

**Bit 21**  SMBDEN: SMBus device default address enable

0: Device default address disabled. Address 0b1100001x is NACKed.
1: Device default address enabled. Address 0b11000001x is ACKed.

*Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'. Refer to Section 26.3: I2C implementation.*

**Bit 20**  SMBHEN: SMBus host address enable

0: Host address disabled. Address 0b0001000x is NACKed.
1: Host address enabled. Address 0b0001000x is ACKed.

*Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'. Refer to Section 26.3: I2C implementation.*
Bit 19 **GCEN**: General call enable
0: General call disabled. Address 0b00000000 is NACKed.
1: General call enabled. Address 0b00000000 is ACKed.

Bit 18 **WUPEN**: Wake-up from Stop mode enable
0: Wake-up from Stop mode disable.
1: Wake-up from Stop mode enable.

**Note**: If the Wake-up from Stop mode feature is not supported, this bit is reserved and forced by hardware to ‘0’. Refer to Section 26.3: I2C implementation.

**Note**: WUPEN can be set only when DNF = ‘0000’

Bit 17 **NOSTRETCH**: Clock stretching disable
This bit is used to disable clock stretching in slave mode. It must be kept cleared in master mode.
0: Clock stretching enabled
1: Clock stretching disabled

**Note**: This bit can only be programmed when the I2C is disabled (PE = 0).

Bit 16 **SBC**: Slave byte control
This bit is used to enable hardware byte control in slave mode.
0: Slave byte control disabled
1: Slave byte control enabled

Bit 15 **RXDMAEN**: DMA reception requests enable
0: DMA mode disabled for reception
1: DMA mode enabled for reception

Bit 14 **TXDMAEN**: DMA transmission requests enable
0: DMA mode disabled for transmission
1: DMA mode enabled for transmission

Bit 13 Reserved, must be kept at reset value.

Bit 12 **ANFOFF**: Analog noise filter OFF
0: Analog noise filter enabled
1: Analog noise filter disabled

**Note**: This bit can only be programmed when the I2C is disabled (PE = 0).

Bits 11:8 **DNF[3:0]**: Digital noise filter
These bits are used to configure the digital noise filter on SDA and SCL input. The digital filter, filters spikes with a length of up to DNF[3:0] * tI2CCLK
0000: Digital filter disabled
0001: Digital filter enabled and filtering capability up to 1 tI2CCLK
... 1111: digital filter enabled and filtering capability up to 15 tI2CCLK

**Note**: If the analog filter is also enabled, the digital filter is added to the analog filter.
This filter can only be programmed when the I2C is disabled (PE = 0).
Bit 7 **ERRIE**: Error interrupts enable
0: Error detection interrupts disabled
1: Error detection interrupts enabled

*Note: Any of these errors generate an interrupt:*
- Arbitration Loss (ARLO)
- Bus Error detection (BERR)
- Overrun/Underrun (OVR)
- Timeout detection (TIMEOUT)
- PEC error detection (PECERR)
- Alert pin event detection (ALERT)

Bit 6 **TCIE**: Transfer complete interrupt enable
0: Transfer complete interrupt disabled
1: Transfer complete interrupt enabled

*Note: Any of these events generate an interrupt:*
- Transfer complete (TC)
- Transfer complete reload (TCR)

Bit 5 **STOPIE**: Stop detection Interrupt enable
0: Stop detection (STOPF) interrupt disabled
1: Stop detection (STOPF) interrupt enabled

Bit 4 **NACKIE**: Not acknowledge received Interrupt enable
0: Not acknowledge (NACKF) received interrupts disabled
1: Not acknowledge (NACKF) received interrupts enabled

Bit 3 **ADDRIE**: Address match Interrupt enable (slave only)
0: Address match (ADDR) interrupts disabled
1: Address match (ADDR) interrupts enabled

Bit 2 **RXIE**: RX Interrupt enable
0: Receive (RXNE) interrupt disabled
1: Receive (RXNE) interrupt enabled

Bit 1 **TXIE**: TX Interrupt enable
0: Transmit (TXIS) interrupt disabled
1: Transmit (TXIS) interrupt enabled

Bit 0 **PE**: Peripheral enable
0: Peripheral disable
1: Peripheral enable

*Note: When PE = 0, the I2C SCL and SDA lines are released. Internal state machines and status bits are put back to their reset value. When cleared, PE must be kept low for at least three APB clock cycles.
26.7.2 I2C control register 2 (I2C_CR2)

Address offset: 0x04

Reset value: 0x0000 0000

Access: No wait states, except if a write access occurs while a write access to this register is ongoing. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to 2 x PCLK1 + 6 x I2CCLK.

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **PECBYTE**: Packet error checking byte

This bit is set by software, and cleared by hardware when the PEC is transferred, or when a STOP condition or an Address matched is received, also when PE = 0.
0: No PEC transfer.
1: PEC transmission/reception is requested

*Note:* Writing ‘0’ to this bit has no effect.

This bit has no effect when RELOAD is set.
This bit has no effect is slave mode when SBC = 0.
If the SMBus feature is not supported, this bit is reserved and forced by hardware to ‘0’.
Refer to Section 26.3: I2C implementation.

Bit 25 **AUTOEND**: Automatic end mode (master mode)

This bit is set and cleared by software.
0: software end mode: TC flag is set when NBYTES data are transferred, stretching SCL low.
1: Automatic end mode: a STOP condition is automatically sent when NBYTES data are transferred.

*Note:* This bit has no effect in slave mode or when the RELOAD bit is set.

Bit 24 **RELOAD**: NBYTES reload mode

This bit is set and cleared by software.
0: The transfer is completed after the NBYTES data transfer (STOP or RESTART follows).
1: The transfer is not completed after the NBYTES data transfer (NBYTES is reloaded). TCR flag is set when NBYTES data are transferred, stretching SCL low.

Bits 23:16 **NBYTES[7:0]**: Number of bytes

The number of bytes to be transmitted/received is programmed there. This field is don’t care in slave mode with SBC = 0.

*Note:* Changing these bits when the START bit is set is not allowed.
Bit 15  **NACK**: NACK generation (slave mode)

- The bit is set by software, cleared by hardware when the NACK is sent, or when a STOP condition or an Address matched is received, or when PE = 0.
- 0: an ACK is sent after current received byte.
- 1: a NACK is sent after current received byte.

**Note**: Writing '0' to this bit has no effect.

- This bit is used in slave mode only: in master receiver mode, NACK is automatically generated after last byte preceding STOP or RESTART condition, whatever the NACK bit value.
- When an overrun occurs in slave receiver NOSTRETCH mode, a NACK is automatically generated whatever the NACK bit value.
- When hardware PEC checking is enabled (PECBYTE = 1), the PEC acknowledge value does not depend on the NACK value.

Bit 14  **STOP**: Stop generation (master mode)

- The bit is set by software, cleared by hardware when a STOP condition is detected, or when PE = 0.

**In Master mode**:
- 0: No Stop generation.
- 1: Stop generation after current byte transfer.

**Note**: Writing '0' to this bit has no effect.

Bit 13  **START**: Start generation

- This bit is set by software, and cleared by hardware after the Start followed by the address sequence is sent, by an arbitration loss, by a timeout error detection, or when PE = 0. It can also be cleared by software by writing ‘1’ to the ADDRCF bit in the I2C_ICR register.
- 0: No Start generation.
- 1: Restart/Start generation:
  - If the I2C is already in master mode with AUTOEND = 0, setting this bit generates a Repeated start condition when RELOAD=0, after the end of the NBYTES transfer.
  - Otherwise setting this bit generates a START condition once the bus is free.

**Note**: Writing '0' to this bit has no effect.

- The START bit can be set even if the bus is BUSY or I2C is in slave mode.
- This bit has no effect when RELOAD is set.

Bit 12  **HEAD10R**: 10-bit address header only read direction (master receiver mode)

- 0: The master sends the complete 10 bit slave address read sequence: Start + 2 bytes 10bit address in write direction + Restart + 1st 7 bits of the 10 bit address in read direction.
- 1: The master only sends the 1st 7 bits of the 10 bit address, followed by Read direction.

**Note**: Changing this bit when the START bit is set is not allowed.

Bit 11  **ADD10**: 10-bit addressing mode (master mode)

- 0: The master operates in 7-bit addressing mode,
- 1: The master operates in 10-bit addressing mode

**Note**: Changing this bit when the START bit is set is not allowed.

Bit 10  **RD_WRN**: Transfer direction (master mode)

- 0: Master requests a write transfer.
- 1: Master requests a read transfer.

**Note**: Changing this bit when the START bit is set is not allowed.
Bits 9:0 **SADD[9:0]**: Slave address (master mode)

- **In 7-bit addressing mode (ADD10 = 0):**
  - SADD[7:1] must be written with the 7-bit slave address to be sent. The bits SADD[9], SADD[8] and SADD[0] are don't care.
- **In 10-bit addressing mode (ADD10 = 1):**
  - SADD[9:0] must be written with the 10-bit slave address to be sent.

*Note: Changing these bits when the START bit is set is not allowed.*

### 26.7.3 I2C own address 1 register (I2C_OAR1)

Address offset: 0x08

Reset value: 0x0000 0000

Access: No wait states, except if a write access occurs while a write access to this register is ongoing. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to 2 x PCLK1 + 6 x I2CCLK.

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **OA1EN**: Own address 1 enable
- 0: Own address 1 disabled. The received slave address OA1 is NACKed.
- 1: Own address 1 enabled. The received slave address OA1 is ACKed.

Bits 14:11 Reserved, must be kept at reset value.

Bit 10 **OA1MODE**: Own address 1 10-bit mode
- 0: Own address 1 is a 7-bit address.
- 1: Own address 1 is a 10-bit address.

*Note: This bit can be written only when OA1EN = 0.*

Bits 9:0 **OA1[9:0]**: Interface own slave address

- 7-bit addressing mode: OA1[7:1] contains the 7-bit own slave address. The bits OA1[9], OA1[8] and OA1[0] are don't care.
- 10-bit addressing mode: OA1[9:0] contains the 10-bit own slave address.

*Note: These bits can be written only when OA1EN = 0.*
26.7.4 I2C own address 2 register (I2C_OAR2)

Address offset: 0x0C
Reset value: 0x0000 0000

Access: No wait states, except if a write access occurs while a write access to this register is ongoing. In this case, wait states are inserted in the second write access, until the previous one is completed. The latency of the second write access can be up to 2x PCLK1 + 6 x I2CCLK.

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **OA2EN**: Own address 2 enable
- 0: Own address 2 disabled. The received slave address OA2 is NACKed.
- 1: Own address 2 enabled. The received slave address OA2 is ACKed.

Bits 14:11 Reserved, must be kept at reset value.

Bits 10:8 **OA2MSK[2:0]**: Own address 2 masks
- 000: No mask
- 010: OA2[2:1] are masked and don’t care. Only OA2[7:3] are compared.
- 100: OA2[4:1] are masked and don’t care. Only OA2[7:5] are compared.
- 111: OA2[7:1] are masked and don’t care. No comparison is done, and all (except reserved) 7-bit received addresses are acknowledged.

*Note*: These bits can be written only when OA2EN = 0.
As soon as OA2MSK is not equal to 0, the reserved I2C addresses (0b0000xxx and 0b1111xxx) are not acknowledged even if the comparison matches.

Bits 7:1 **OA2[7:1]**: Interface address

- 7-bit addressing mode: 7-bit address

*Note*: These bits can be written only when OA2EN = 0.

Bit 0 Reserved, must be kept at reset value.

</tbody>
</table>

**Bits 31:28** **PRESC[3:0]**: Timing prescaler  
This field is used to prescale I2CCLK in order to generate the clock period \( t_{\text{PRESC}} \) used for data setup and hold counters (refer to **I2C timings**) and for SCL high and low level counters (refer to **I2C master initialization**).  
\[ t_{\text{PRESC}} = (\text{PRESC} + 1) \times t_{\text{I2CCLK}} \]

**Bits 27:24** Reserved, must be kept at reset value.

**Bits 23:20** **SCLDEL[3:0]**: Data setup time  
This field is used to generate a delay \( t_{\text{SCLDEL}} \) between SDA edge and SCL rising edge. In master mode and in slave mode with NOSTRETCH = 0, the SCL line is stretched low during \( t_{\text{SCLDEL}} \).  
\[ t_{\text{SCLDEL}} = (\text{SCLDEL} + 1) \times t_{\text{PRESC}} \]

Note: \( t_{\text{SCLDEL}} \) is used to generate \( t_{\text{SU:DAT}} \) timing.

**Bits 19:16** **SDADEL[3:0]**: Data hold time  
This field is used to generate the delay \( t_{\text{SDADEL}} \) between SCL falling edge and SDA edge. In master mode and in slave mode with NOSTRETCH = 0, the SCL line is stretched low during \( t_{\text{SDADEL}} \).  
\[ t_{\text{SDADEL}} = t_{\text{SDADEL}} \times t_{\text{PRESC}} \]

Note: \( t_{\text{SDADEL}} \) is used to generate \( t_{\text{HD:DAT}} \) timing.

**Bits 15:8** **SCLH[7:0]**: SCL high period (master mode)  
This field is used to generate the SCL high period in master mode.  
\[ t_{\text{SCLH}} = (\text{SCLH} + 1) \times t_{\text{PRESC}} \]

Note: \( t_{\text{SCLH}} \) is also used to generate \( t_{\text{SU:STO}} \) and \( t_{\text{HD:STA}} \) timing.

**Bits 7:0** **SCLL[7:0]**: SCL low period (master mode)  
This field is used to generate the SCL low period in master mode.  
\[ t_{\text{SCLL}} = (\text{SCLL} + 1) \times t_{\text{PRESC}} \]

Note: \( t_{\text{SCLL}} \) is also used to generate \( t_{\text{BUF}} \) and \( t_{\text{SU:STA}} \) timings.

**Note:** This register must be configured when the I2C is disabled (PE = 0).

**Note:** The STM32CubeMX tool calculates and provides the I2C_TIMINGR content in the I2C Configuration window.
26.7.6 I2C timeout register (I2C_TIMEOUTR)

Address offset: 0x14
Reset value: 0x0000 0000

Access: No wait states, except if a write access occurs while a write access to this register is ongoing. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to 2 x PCLK1 + 6 x I2CCLK.

### Table: I2C_TIMEOUTR Register

<table>
<thead>
<tr>
<th>Field</th>
<th>Offset</th>
<th>Access</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TEXTEN</td>
<td>31</td>
<td>rw</td>
<td>Extended clock timeout enable</td>
</tr>
<tr>
<td>TIMOUTEN</td>
<td>15</td>
<td>rw</td>
<td>Clock timeout enable</td>
</tr>
<tr>
<td>TIDLE</td>
<td>14</td>
<td>rw</td>
<td>Bus idle timeout detection</td>
</tr>
<tr>
<td>TIMEOUTB</td>
<td>13</td>
<td>rw</td>
<td>Bus timeout B</td>
</tr>
<tr>
<td>TIMEOUTA</td>
<td>12</td>
<td>rw</td>
<td>Bus timeout A</td>
</tr>
</tbody>
</table>

#### Bit 31 TEXTEN: Extended clock timeout enable
- 0: Extended clock timeout detection is disabled
- 1: Extended clock timeout detection is enabled. When a cumulative SCL stretch for more than t_LOW:EXT is done by the I2C interface, a timeout error is detected (TIMEOUT=1).

Bits 30:28 Reserved, must be kept at reset value.

#### Bit 27:16 TIMEOUTB[11:0]: Bus timeout B
This field is used to configure the cumulative clock extension timeout:
- In master mode, the master cumulative clock low extend time (t_LOW:MEXT) is detected
- In slave mode, the slave cumulative clock low extend time (t_LOW:SEXT) is detected
  \[ t_{LOW:EXT} = (TIMEOUTB+1) \times 2048 \times t_{I2CCLK} \]

Note: These bits can be written only when TEXTEN=0.

#### Bit 15 TIMOUTEN: Clock timeout enable
- 0: SCL timeout detection is disabled
- 1: SCL timeout detection is enabled: when SCL is low for more than t_TIMEOUT (TIDLE=0) or high for more than t_IDLE (TIDLE=1), a timeout error is detected (TIMEOUT=1).

Bits 14:13 Reserved, must be kept at reset value.

#### Bit 12 TIDLE: Idle clock timeout detection
- 0: TIMEOUTA is used to detect SCL low timeout
- 1: TIMEOUTA is used to detect both SCL and SDA high timeout (bus idle condition)

Note: This bit can be written only when TIMOUTEN=0.

#### Bits 11:0 TIMEOUTA[11:0]: Bus Timeout A
This field is used to configure:
- The SCL low timeout condition t_TIMEOUT when TIDLE=0
- The bus idle condition (both SCL and SDA high) when TIDLE=1
  \[ t_{SCL} = (TIMEOUTA+1) \times 4 \times t_{I2CCLK} \]
  \[ t_{IDLE} = (TIMEOUTA+1) \times 4 \times t_{I2CCLK} \]

Note: These bits can be written only when TIMOUTEN=0.

Note: If the SMBus feature is not supported, this register is reserved and forced by hardware to “0x00000000”. Refer to Section 26.3: I2C implementation.
26.7.7 I2C interrupt and status register (I2C_ISR)

Address offset: 0x18
Reset value: 0x0000 0001
Access: No wait states

</tbody>
</table>

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:17 **ADDCODE[6:0]**: Address match code (Slave mode)

These bits are updated with the received address when an address match event occurs (ADDR = 1).

In the case of a 10-bit address, ADDCODE provides the 10-bit header followed by the 2 MSBs of the address.

Bit 16 **DIR**: Transfer direction (Slave mode)

This flag is updated when an address match event occurs (ADDR = 1).

0: Write transfer, slave enters receiver mode.
1: Read transfer, slave enters transmitter mode.

Bit 15 **BUSY**: Bus busy

This flag indicates that a communication is in progress on the bus. It is set by hardware when a START condition is detected. It is cleared by hardware when a STOP condition is detected, or when PE = 0.

Bit 14 Reserved, must be kept at reset value.

Bit 13 **ALERT**: SMBus alert

This flag is set by hardware when SMBHEN=1 (SMBus host configuration), ALERTEN=1 and a SMBALERT event (falling edge) is detected on SMBA pin. It is cleared by software by setting the ALERTCF bit.

**Note:** This bit is cleared by hardware when PE = 0.

*If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'. Refer to Section 26.3: I2C implementation.*

Bit 12 **TIMEOUT**: Timeout or tLOW detection flag

This flag is set by hardware when a timeout or extended clock timeout occurred. It is cleared by software by setting the TIMEOUTCF bit.

**Note:** This bit is cleared by hardware when PE = 0.

*If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'. Refer to Section 26.3: I2C implementation.*
Bit 11 **PECERR**: PEC Error in reception

This flag is set by hardware when the received PEC does not match with the PEC register content. A NACK is automatically sent after the wrong PEC reception. It is cleared by software by setting the PECCF bit.

*Note: This bit is cleared by hardware when PE = 0.*

If the SMBus feature is not supported, this bit is reserved and forced by hardware to '0'. Refer to Section 26.3: I2C implementation.

Bit 10 **OVR**: Overrun/Underrun (slave mode)

This flag is set by hardware in slave mode with NOSTRETCH = 1, when an overrun/underrun error occurs. It is cleared by software by setting the OVRCF bit.

*Note: This bit is cleared by hardware when PE = 0.*

Bit 9 **ARLO**: Arbitration lost

This flag is set by hardware in case of arbitration loss. It is cleared by software by setting the ARLOCF bit.

*Note: This bit is cleared by hardware when PE = 0.*

Bit 8 **BERR**: Bus error

This flag is set by hardware when a misplaced Start or STOP condition is detected whereas the peripheral is involved in the transfer. The flag is not set during the address phase in slave mode. It is cleared by software by setting BERRCF bit.

*Note: This bit is cleared by hardware when PE = 0.*

Bit 7 **TCR**: Transfer Complete Reload

This flag is set by hardware when RELOAD=1 and NBYTES data have been transferred. It is cleared by software when NBYTES is written to a non-zero value.

*Note: This bit is cleared by hardware when PE = 0.*

This flag is only for master mode, or for slave mode when the SBC bit is set.

Bit 6 **TC**: Transfer Complete (master mode)

This flag is set by hardware when RELOAD=0, AUTOEND=0 and NBYTES data have been transferred. It is cleared by software when START bit or STOP bit is set.

*Note: This bit is cleared by hardware when PE = 0.*

Bit 5 **STOPF**: Stop detection flag

This flag is set by hardware when a STOP condition is detected on the bus and the peripheral is involved in this transfer:

– either as a master, provided that the STOP condition is generated by the peripheral.
– or as a slave, provided that the peripheral has been addressed previously during this transfer.

It is cleared by software by setting the STOPCF bit.

*Note: This bit is cleared by hardware when PE = 0.*

Bit 4 **NACKF**: Not Acknowledge received flag

This flag is set by hardware when a NACK is received after a byte transmission. It is cleared by software by setting the NACKCF bit.

*Note: This bit is cleared by hardware when PE = 0.*

Bit 3 **ADDR**: Address matched (slave mode)

This bit is set by hardware as soon as the received slave address matched with one of the enabled slave addresses. It is cleared by software by setting ADDRCF bit.

*Note: This bit is cleared by hardware when PE = 0.*
Bit 2 **RXNE**: Receive data register not empty (receivers)

This bit is set by hardware when the received data is copied into the I2C_RXDR register, and is ready to be read. It is cleared when I2C_RXDR is read.

*Note: This bit is cleared by hardware when PE = 0.*

Bit 1 **TXIS**: Transmit interrupt status (transmitters)

This bit is set by hardware when the I2C_TXDR register is empty and the data to be transmitted must be written in the I2C_TXDR register. It is cleared when the next data to be sent is written in the I2C_TXDR register.

This bit can be written to ‘1’ by software when NOSTRETCH = 1 only, in order to generate a TXIS event (interrupt if TXIE=1 or DMA request if TXDMAEN = 1).

*Note: This bit is cleared by hardware when PE = 0.*

Bit 0 **TXE**: Transmit data register empty (transmitters)

This bit is set by hardware when the I2C_TXDR register is empty. It is cleared when the next data to be sent is written in the I2C_TXDR register.

This bit can be written to ‘1’ by software in order to flush the transmit data register I2C_TXDR.

*Note: This bit is set by hardware when PE = 0.*

### 26.7.8 I2C interrupt clear register (I2C_ICR)

**Address offset:** 0x1C

**Reset value:** 0x0000 0000

**Access:** No wait states

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>

|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|---|

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **ALERTCF**: Alert flag clear

Writing 1 to this bit clears the ALERT flag in the I2C_ISR register.

*Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to ‘0’. Refer to Section 26.3: I2C implementation.*

Bit 12 **TIMOUTCF**: Timeout detection flag clear

Writing 1 to this bit clears the TIMEOUT flag in the I2C_ISR register.

*Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to ‘0’. Refer to Section 26.3: I2C implementation.*

Bit 11 **PECCF**: PEC Error flag clear

Writing 1 to this bit clears the PECERR flag in the I2C_ISR register.

*Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to ‘0’. Refer to Section 26.3: I2C implementation.*
Bit 10  **OVRCF**: Overrun/Underrun flag clear  
Writing 1 to this bit clears the OVR flag in the I2C_ISR register.

Bit 9  **ARLOCF**: Arbitration lost flag clear  
Writing 1 to this bit clears the ARLO flag in the I2C_ISR register.

Bit 8  **BERRCF**: Bus error flag clear  
Writing 1 to this bit clears the BERRF flag in the I2C_ISR register.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5  **STOPCF**: STOP detection flag clear  
Writing 1 to this bit clears the STOPF flag in the I2C_ISR register.

Bit 4  **NACKCF**: Not Acknowledge flag clear  
Writing 1 to this bit clears the NACKF flag in I2C_ISR register.

Bit 3  **ADDRCF**: Address matched flag clear  
Writing 1 to this bit clears the ADDR flag in the I2C_ISR register. Writing 1 to this bit also clears the START bit in the I2C_CR2 register.

Bits 2:0 Reserved, must be kept at reset value.

### 26.7.9 I2C PEC register (I2C_PECR)

Address offset: 0x20  
Reset value: 0x0000 0000  
Access: No wait states

<table>
<thead>
<tr>

</tr>
</thead>
</table>

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **PEC[7:0]**: Packet error checking register  
This field contains the internal PEC when PECEN=1.  
The PEC is cleared by hardware when PE = 0.

**Note:** If the SMBus feature is not supported, this register is reserved and forced by hardware to “0x00000000”. Refer to Section 26.3: I2C implementation.
26.7.10  I2C receive data register (I2C_RXDR)

Address offset: 0x24
Reset value: 0x0000 0000
Access: No wait states

<table>
<thead>

27 Universal synchronous/asynchronous receiver transmitter (USART/UART)

27.1 Introduction

The universal synchronous asynchronous receiver transmitter (USART) offers a flexible means of Full-duplex data exchange with external equipment requiring an industry standard NRZ asynchronous serial data format. The USART offers a very wide range of baud rates using a programmable baud rate generator.

It supports synchronous one-way communication and Half-duplex Single-wire communication, as well as multiprocessor communications. It also supports the LIN (Local Interconnect Network), Smartcard protocol and IrDA (Infrared Data Association) SIR ENDEC specifications and Modem operations (CTS/RTS).

High speed data communication is possible by using the DMA (direct memory access) for multibuffer configuration.

27.2 USART main features

- Full-duplex asynchronous communications
- NRZ standard format (mark/space)
- Configurable oversampling method by 16 or 8 to give flexibility between speed and clock tolerance
- A common programmable transmit and receive baud rate of up to 6 Mbit/s when the clock frequency is 48 MHz and oversampling is by 8
- Dual clock domain allowing:
  - USART functionality and wake-up from Stop mode
  - Convenient baud rate programming independent from the PCLK reprogramming
- Auto baud rate detection
- Programmable data word length (7, 8 or 9 bits)
- Programmable data order with MSB-first or LSB-first shifting
- Configurable stop bits (1 or 2 stop bits)
- Synchronous mode and clock output for synchronous communications
- Single-wire Half-duplex communications
- Continuous communications using DMA
- Received/transmitted bytes are buffered in reserved SRAM using centralized DMA
- Separate enable bits for transmitter and receiver
- Separate signal polarity control for transmission and reception
- Swappable Tx/Rx pin configuration
- Hardware flow control for modem and RS-485 transceiver
• Communication control/error detection flags
• Parity control:
  – Transmits parity bit
  – Checks parity of received data byte
• Fourteen interrupt sources with flags
• Multiprocessor communications
  The USART enters Mute mode if the address does not match.
• Wake-up from Mute mode (by idle line detection or address mark detection)

27.3 USART extended features
• LIN master synchronous break send capability and LIN slave break detection capability
  – 13-bit break generation and 10/11-bit break detection when USART is hardware configured for LIN
• IrDA SIR encoder decoder supporting 3/16 bit duration for normal mode
• Smartcard mode
  – Supports the T=0 and T=1 asynchronous protocols for smartcards as defined in the ISO/IEC 7816-3 standard
  – 0.5 and 1.5 stop bits for smartcard operation
• Support for ModBus communication
  – Timeout feature
  – CR/LF character recognition
## 27.4 USART implementation

3. CK is always available when CLKEN = 1, regardless of the UE bit value.
27.5 **USART functional description**

Any USART bidirectional communication requires a minimum of two pins: Receive data In (RX) and Transmit data Out (TX):

- **RX**: Receive data Input.
  
  This is the serial data input. Oversampling techniques are used for data recovery by discriminating between valid incoming data and noise.

- **TX**: Transmit data Output.
  
  When the transmitter is disabled, the output pin returns to its I/O port configuration. When the transmitter is enabled and nothing is to be transmitted, the TX pin is at high level. In Single-wire and Smartcard modes, this I/O is used to transmit and receive the data.

Serial data are transmitted and received through these pins in normal USART mode. The frames are comprised of:

- An Idle Line prior to transmission or reception
- A start bit
- A data word (7, 8 or 9 bits) least significant bit first
- 0.5, 1, 1.5, 2 stop bits indicating that the frame is complete
- The USART interface uses a baud rate generator
- A status register (USART_ISR)
- Receive and transmit data registers (USART_RDR, USART_TDR)
- A baud rate register (USART_BRR)
- A guard-time register (USART_GTPR) in case of Smartcard mode.

Refer to [Section 27.8: USART registers](#) on page 744 for the definitions of each bit.

The following pin is required to interface in synchronous mode and Smartcard mode:

- **CK**: Clock output. This pin outputs the transmitter data clock for synchronous transmission corresponding to SPI master mode (no clock pulses on start bit and stop bit, and a software option to send a clock pulse on the last data bit). In parallel, data can be received synchronously on RX. This can be used to control peripherals that have shift registers (e.g. LCD drivers). The clock phase and polarity are software programmable. In Smartcard mode, CK output can provide the clock to the smartcard.

The following pins are required in RS232 Hardware flow control mode:

- **CTS**: Clear To Send blocks the data transmission at the end of the current transfer (when high)
- **RTS**: Request to send indicates that the USART is ready to receive data (when low).

The following pin is required in RS485 Hardware control mode:

- **DE**: Driver Enable activates the transmission mode of the external transceiver.

*Note:* DE and RTS share the same pin.
Figure 248. USART block diagram

1. For details on coding USARTDIV in the USART_BRR register, refer to Section 27.5.4: USART baud rate generation.
2. \( f_{CK} \) can be \( f_{LSE} \cdot f_{HSI} \cdot f_{PCLK} \cdot f_{SYS} \).
27.5.1 USART character description

The word length can be selected as being either 7 or 8 or 9 bits by programming the M[1:0] bits in the USART_CR1 register (see Figure 249).

• 7-bit character length: M[1:0] = 10
• 8-bit character length: M[1:0] = 00
• 9-bit character length: M[1:0] = 01

Note: The 7-bit mode is supported only on some USARTs. In addition, not all modes are supported in 7-bit data length mode. Refer to Section 27.4: USART implementation for additional information.

By default, the signal (TX or RX) is in low state during the start bit. It is in high state during the stop bit.

These values can be inverted, separately for each signal, through polarity configuration control.

An Idle character is interpreted as an entire frame of “1”s (the number of “1”s includes the number of stop bits).

A Break character is interpreted on receiving “0”s for a frame period. At the end of the break frame, the transmitter inserts 2 stop bits.

Transmission and reception are driven by a common baud rate generator, the clock for each is generated when the enable bit is set respectively for the transmitter and receiver.

The details of each block is given below.
Figure 249. Word length programming

**LBCL bit controls last data clock pulse**

MS33194V2
27.5.2 USART transmitter

The transmitter can send data words of either 7, 8 or 9 bits depending on the M bits status. The Transmit Enable bit (TE) must be set in order to activate the transmitter function. The data in the transmit shift register is output on the TX pin and the corresponding clock pulses are output on the CK pin.

Character transmission

During an USART transmission, data shifts out least significant bit first (default configuration) on the TX pin. In this mode, the USART_TDR register consists of a buffer (TDR) between the internal bus and the transmit shift register (see Figure 248).

Every character is preceded by a start bit which is a logic level low for one bit period. The character is terminated by a configurable number of stop bits.

The following stop bits are supported by USART: 0.5, 1, 1.5 and 2 stop bits.

Note: The TE bit must be set before writing the data to be transmitted to the USART_TDR. The TE bit should not be reset during transmission of data. Resetting the TE bit during the transmission will corrupt the data on the TX pin as the baud rate counters will get frozen. The current data being transmitted is lost.

An idle frame is sent after the TE bit is enabled.

Configurable stop bits

The number of stop bits to be transmitted with every character can be programmed in Control register 2, bits 13,12.

- **1 stop bit**: This is the default value of number of stop bits.
- **2 stop bits**: This is supported by normal USART, Single-wire and Modem modes.
- **1.5 stop bits**: To be used in Smartcard mode.
- **0.5 stop bit**: To be used when receiving data in Smartcard mode.

An idle frame transmission will include the stop bits.

A break transmission is 10 low bits (when M[1:0] = 00) or 11 low bits (when M[1:0] = 01) or 9 low bits (when M[1:0] = 10) followed by 2 stop bits (see Figure 250). It is not possible to transmit long breaks (break of length greater than 9/10/11 low bits).
### Character transmission procedure

1. Program the M bits in USART_CR1 to define the word length.
2. Select the desired baud rate using the USART_BRR register.
3. Program the number of stop bits in USART_CR2.
4. Enable the USART by writing the UE bit in USART_CR1 register to 1.
5. Select DMA enable (DMAT) in USART_CR3 if multibuffer communication is to take place. Configure the DMA register as explained in multibuffer communication.
6. Set the TE bit in USART_CR1 to send an idle frame as first transmission.
7. Write the data to send in the USART_TDR register (this clears the TXE bit). Repeat this for each data to be transmitted in case of single buffer.
8. After writing the last data into the USART_TDR register, wait until TC=1. This indicates that the transmission of the last frame is complete. This is required for instance when the USART is disabled or enters the Halt mode to avoid corrupting the last transmission.

For code example, refer to **A.19.1: USART transmitter configuration code example.**

### Single byte communication

Clearing the TXE bit is always performed by a write to the transmit data register.

The TXE bit is set by hardware and it indicates:
- The data has been moved from the USART_TDR register to the shift register and the data transmission has started.
- The USART_TDR register is empty.
- The next data can be written in the USART_TDR register without overwriting the previous data.

For code example, refer to **A.19.2: USART transmit byte code example.**

This flag generates an interrupt if the TXEIE bit is set.
When a transmission is taking place, a write instruction to the USART_TDR register stores the data in the TDR register; next, the data is copied in the shift register at the end of the currently ongoing transmission.

When no transmission is taking place, a write instruction to the USART_TDR register places the data in the shift register, the data transmission starts, and the TXE bit is set.

If a frame is transmitted (after the stop bit) and the TXE bit is set, the TC bit goes high. An interrupt is generated if the TCIE bit is set in the USART_CR1 register.

After writing the last data in the USART_TDR register, it is mandatory to wait for TC=1 before disabling the USART or causing the microcontroller to enter the low-power mode (see Figure 251: TC/TXE behavior when transmitting).

For code example, refer to A.19.3: USART transfer complete code example.

**Break characters**

Setting the SBKRQ bit transmits a break character. The break frame length depends on the M bits (see Figure 249).

If a ‘1’ is written to the SBKRQ bit, a break character is sent on the TX line after completing the current character transmission. The SBKF bit is set by the write operation and it is reset by hardware when the break character is completed (during the stop bits after the break character). The USART inserts a logic 1 signal (STOP) for the duration of 2 bits at the end of the break frame to guarantee the recognition of the start bit of the next frame.

In the case the application needs to send the break character following all previously inserted data, including the ones not yet transmitted, the software should wait for the TXE flag assertion before setting the SBKRQ bit.

**Idle characters**

Setting the TE bit drives the USART to send an idle frame before the first data frame.
27.5.3 USART receiver

The USART can receive data words of either 7, 8 or 9 bits depending on the M bits in the USART_CR1 register.

Start bit detection

The start bit detection sequence is the same when oversampling by 16 or by 8.

In the USART, the start bit is detected when a specific sequence of samples is recognized. This sequence is: 1 1 1 0 X 0 X 0 X 0 X 0.

Figure 252. Start bit detection when oversampling by 16 or 8

Note: If the sequence is not complete, the start bit detection aborts and the receiver returns to the idle state (no flag is set), where it waits for a falling edge.

The start bit is confirmed (RXNE flag set, interrupt generated if RXNEIE=1) if the 3 sampled bits are at 0 (first sampling on the 3rd, 5th and 7th bits finds the 3 bits at 0 and second sampling on the 8th, 9th and 10th bits also finds the 3 bits at 0).

The start bit is validated (RXNE flag set, interrupt generated if RXNEIE=1) but the NF noise flag is set if,

a) for both samplings, 2 out of the 3 sampled bits are at 0 (sampling on the 3rd, 5th and 7th bits and sampling on the 8th, 9th and 10th bits)

or

b) for one of the samplings (sampling on the 3rd, 5th and 7th bits or sampling on the 8th, 9th and 10th bits), 2 out of the 3 bits are found at 0.
If neither conditions a. or b. are met, the start detection aborts and the receiver returns to the idle state (no flag is set).

**Character reception**

During an USART reception, data shifts in least significant bit first (default configuration) through the RX pin. In this mode, the USART_RDR register consists of a buffer (RDR) between the internal bus and the receive shift register.

**Character reception procedure**

1. Program the M bits in USART_CR1 to define the word length.
2. Select the desired baud rate using the baud rate register USART_BRR
3. Program the number of stop bits in USART_CR2.
4. Enable the USART by writing the UE bit in USART_CR1 register to 1.
5. Select DMA enable (DMAR) in USART_CR3 if multibuffer communication is to take place. Configure the DMA register as explained in multibuffer communication.
6. Set the RE bit USART_CR1. This enables the receiver which begins searching for a start bit.

For code example, refer to [A.19.4: USART receiver configuration code example](#).

When a character is received:

- The RXNE bit is set to indicate that the content of the shift register is transferred to the RDR. In other words, data has been received and can be read (as well as its associated error flags).
- An interrupt is generated if the RXNEIE bit is set.
- The error flags can be set if a frame error, noise or an overrun error has been detected during reception. PE flag can also be set with RXNE.
- In multibuffer, RXNE is set after every byte received and is cleared by the DMA read of the Receive data Register.
- In single buffer mode, clearing the RXNE bit is performed by a software read to the USART_RDR register. The RXNE flag can also be cleared by writing 1 to the RXFRQ in the USART_RQR register. The RXNE bit must be cleared before the end of the reception of the next character to avoid an overrun error.

For code example, refer to [A.19.5: USART receive byte code example](#).

**Break character**

When a break character is received, the USART handles it as a framing error.

**Idle character**

When an idle frame is detected, there is the same procedure as for a received data character plus an interrupt if the IDLEIE bit is set.
Overrun error

An overrun error occurs when a character is received when RXNE has not been reset. Data cannot be transferred from the shift register to the RDR register until the RXNE bit is cleared.

The RXNE flag is set after every byte received. An overrun error occurs if RXNE flag is set when the next data is received or the previous DMA request has not been serviced. When an overrun error occurs:

- The ORE bit is set.
- The RDR content will not be lost. The previous data is available when a read to USART_RDR is performed.
- The shift register are overwritten. After that point, any data received during overrun is lost.
- An interrupt is generated if either the RXNEIE bit is set or EIE bit is set.
- The ORE bit is reset by setting the ORECF bit in the ICR register.

Note: The ORE bit, when set, indicates that at least 1 datum has been lost. There are two possibilities:
- if RXNE=1, then the last valid data is stored in the receive register RDR and can be read,
- if RXNE=0, then it means that the last valid data has already been read and thus there is nothing to be read in the RDR. This case can occur when the last valid data is read in the RDR at the same time as the new (and lost) data is received.

Selecting the clock source and the proper oversampling method

The choice of the clock source is done through the Clock Control system (see Section Reset and clock control (RCC)). The clock source must be chosen before enabling the USART (by setting the UE bit).

The choice of the clock source must be done according to two criteria:

- Possible use of the USART in low-power mode
- Communication speed.

The clock source frequency is $f_{\text{CK}}$.

When the dual clock domain with the wake-up from Stop mode is supported, the clock source can be one of the following sources: PCLK (default), LSE, HSI or SYSCLK. Otherwise, the USART clock source is PCLK.

Choosing LSE or HSI as clock source may allow the USART to receive data while the MCU is in low-power mode. Depending on the received data and wake-up mode selection, the USART wakes up the MCU, when needed, in order to transfer the received data by software reading the USART_RDR register or by DMA.

For the other clock sources, the system must be active in order to allow USART communication.

The communication speed range (specially the maximum communication speed) is also determined by the clock source.

The receiver implements different user-configurable oversampling techniques for data recovery by discriminating between valid incoming data and noise. This allows a trade-off between the maximum communication speed and noise/clock inaccuracy immunity.
The oversampling method can be selected by programming the OVER8 bit in the USART_CR1 register and can be either 16 or 8 times the baud rate clock (Figure 253 and Figure 254).

Depending on the application:

- Select oversampling by 8 (OVER8=1) to achieve higher speed (up to \( f_{CK}/8 \)). In this case the maximum receiver tolerance to clock deviation is reduced (refer to Section 27.5.5: Tolerance of the USART receiver to clock deviation on page 718).
- Select oversampling by 16 (OVER8=0) to increase the tolerance of the receiver to clock deviations. In this case, the maximum speed is limited to maximum \( f_{CK}/16 \) where \( f_{CK} \) is the clock source frequency.

Programming the ONEBIT bit in the USART_CR3 register selects the method used to evaluate the logic level. There are two options:

- The majority vote of the three samples in the center of the received bit. In this case, when the 3 samples used for the majority vote are not equal, the NF bit is set.
- A single sample in the center of the received bit.

Depending on the application:

- select the three samples’ majority vote method (ONEBIT=0) when operating in a noisy environment and reject the data when a noise is detected (refer to Figure 105) because this indicates that a glitch occurred during the sampling.
- select the single sample method (ONEBIT=1) when the line is noise-free to increase the receiver’s tolerance to clock deviations (see Section 27.5.5: Tolerance of the USART receiver to clock deviation on page 718). In this case the NF bit will never be set.

When noise is detected in a frame:

- The NF bit is set at the rising edge of the RXNE bit.
- The invalid data is transferred from the Shift register to the USART_RDR register.
- No interrupt is generated in case of single byte communication. However this bit rises at the same time as the RXNE bit which itself generates an interrupt. In case of multibuffer communication an interrupt is issued if the EIE bit is set in the USART_CR3 register.

The NF bit is reset by setting NFCF bit in ICR register.

Note: Oversampling by 8 is not available in LIN, Smartcard and IrDA modes. In those modes, the OVER8 bit is forced to ‘0’ by hardware.

Framing error

A framing error is detected when the stop bit is not recognized on reception at the expected time, following either a de-synchronization or excessive noise.

When the framing error is detected:
- The FE bit is set by hardware
- The invalid data is transferred from the Shift register to the USART_RDR register.
- No interrupt is generated in case of single byte communication. However this bit rises at the same time as the RXNE bit which itself generates an interrupt. In case of multibuffer communication an interrupt is issued if the EIE bit is set in the USART_CR3 register.

The FE bit is reset by writing 1 to the FECF in the USART_ICR register.

Configurable stop bits during reception

The number of stop bits to be received can be configured through the control bits of Control Register 2 - it can be either 1 or 2 in normal mode and 0.5 or 1.5 in Smartcard mode.

- **0.5 stop bit (reception in Smartcard mode):** No sampling is done for 0.5 stop bit. As a consequence, no framing error and no break frame can be detected when 0.5 stop bit is selected.
- **1 stop bit:** Sampling for 1 stop Bit is done on the 8th, 9th and 10th samples.
- **1.5 stop bits (Smartcard mode):** When transmitting in Smartcard mode, the device must check that the data is correctly sent. Thus the receiver block must be enabled (RE =1 in the USART_CR1 register) and the stop bit is checked to test if the smartcard has detected a parity error. In the event of a parity error, the smartcard forces the data signal low during the sampling - NACK signal-, which is flagged as a framing error. Then, the FE flag is set with the RXNE at the end of the 1.5 stop bits. Sampling for 1.5 stop bits is done on the 16th, 17th and 18th samples (1 baud clock period after the beginning of the stop bit). The 1.5 stop bits can be decomposed into 2 parts: one 0.5 baud clock period during which nothing happens, followed by 1 normal stop bit period during which sampling occurs halfway through. Refer to Section 27.5.13: USART Smartcard mode on page 729 for more details.
- **2 stop bits:** Sampling for 2 stop bits is done on the 8th, 9th and 10th samples of the first stop bit. If a framing error is detected during the first stop bit the framing error flag is set. The second stop bit is not checked for framing error. The RXNE flag is set at the end of the first stop bit.
27.5.4 USART baud rate generation

The baud rate for the receiver and transmitter (Rx and Tx) are both set to the same value as programmed in the USART_BRR register.

**Equation 1: Baud rate for standard USART (SPI mode included) (OVER8 = 0 or 1)**

In case of oversampling by 16, the equation is:

\[
\text{Tx/Rx baud} = \frac{f_{CK}}{\text{USARTDIV}}
\]

In case of oversampling by 8, the equation is:

\[
\text{Tx/Rx baud} = \frac{2 \times f_{CK}}{\text{USARTDIV}}
\]

**Equation 2: Baud rate in Smartcard, LIN and IrDA modes (OVER8 = 0)**

In Smartcard, LIN and IrDA modes, only Oversampling by 16 is supported:

\[
\text{Tx/Rx baud} = \frac{f_{CK}}{\text{USARTDIV}}
\]

USARTDIV is an unsigned fixed point number that is coded on the USART_BRR register.

- When OVER8 = 0, BRR = USARTDIV.
- When OVER8 = 1

**Note:** The baud counters are updated to the new value in the baud registers after a write operation to USART_BRR. Hence the baud rate register value should not be changed during communication.

In case of oversampling by 16 or 8, USARTDIV must be greater than or equal to 16d.

**How to derive USARTDIV from USART_BRR register values**

**Example 1**

To obtain 9600 baud with \( f_{CK} = 8 \text{ MHz} \).

- In case of oversampling by 16:
  - USARTDIV = 8 000 000/9600
  - BRR = USARTDIV = 833d = 0341h
- In case of oversampling by 8:
  - USARTDIV = 2 \times 8 000 000/9600
  - USARTDIV = 1666,66 (1667d = 683h)
  - BRR[3:0] = 3h 1 = 1h
  - BRR = 0x681
Example 2

To obtain 921.6 kbaud with $f_{\text{CK}} = 48$ MHz.

- In case of oversampling by 16:
  \[ \text{USARTDIV} = \frac{48\,000\,000}{921\,600} \]
  \[ \text{BRR} = \text{USARTDIV} = 52d = 34h \]

- In case of oversampling by 8:
  \[ \text{USARTDIV} = \frac{2 \times 48\,000\,000}{921\,600} \]
  \[ \text{USARTDIV} = 104 \ (104d = 68h) \]
  \[ \text{BRR}[3:0] = \text{USARTDIV}[3:0] >> 1 = 8h >> 1 = 4h \]
  \[ \text{BRR} = 0x64 \]

1. The lower the CPU clock the lower the accuracy for a particular baud rate. The upper limit of the achievable baud rate can be fixed with these data.
27.5.5 Tolerance of the USART receiver to clock deviation

The asynchronous receiver of the USART works correctly only if the total clock system deviation is less than the tolerance of the USART receiver. The causes which contribute to the total deviation are:

- **DTRA**: Deviation due to the transmitter error (which also includes the deviation of the transmitter’s local oscillator)
- **DQUANT**: Error due to the baud rate quantization of the receiver
- **DREC**: Deviation of the receiver’s local oscillator
- **DTCL**: Deviation due to the transmission line (generally due to the transceivers which can introduce an asymmetry between the low-to-high transition timing and the high-to-low transition timing)

\[
DTRA + DQUANT + DREC + DTCL + DWU < \text{USART receiver’s tolerance}
\]

where

- **DWU** is the error due to sampling point deviation when the wake-up from Stop mode is used.
- **\( M[1:0] = 01 \)**:
  \[
  DWU = \frac{t_{\text{WUUSART}}}{11 \times T_{\text{bit}}}
  \]
- **\( M[1:0] = 00 \)**:
  \[
  DWU = \frac{t_{\text{WUUSART}}}{10 \times T_{\text{bit}}}
  \]
- **\( M[1:0] = 10 \)**:
  \[
  DWU = \frac{t_{\text{WUUSART}}}{9 \times T_{\text{bit}}}
  \]

\( t_{\text{WUUSART}} \) is the time between:

- The detection of start bit falling edge
- The instant when clock (requested by the peripheral) is ready and reaching the peripheral and regulator is ready.

In STM32F0xx, \( t_{\text{WUUSART}} \) corresponds to \( t_{\text{WUSTOP}} \) value provided in the datasheet.

The USART receiver can receive data correctly at up to the maximum tolerated deviation specified in Table 107 and Table 108 depending on the following choices:

- 9-, 10- or 11-bit character length defined by the M bits in the USART_CR1 register
- Oversampling by 8 or 16 defined by the OVER8 bit in the USART_CR1 register
- Bits BRR[3:0] of USART_BRR register are equal to or different from 0000.
- Use of 1 bit or 3 bits to sample the data, depending on the value of the ONEBIT bit in the USART_CR3 register.
Note: The data specified in Table 107 and Table 108 may slightly differ in the special case when the received frames contain some Idle frames of exactly 10-bit durations when M bits = 00 (11-bit durations when M bits = 01 or 9-bit durations when M bits = 10).

### 27.5.6 USART auto baud rate detection

The USART is able to detect and automatically set the USART_BRR register value based on the reception of one character. Automatic baud rate detection is useful under two circumstances:

- The communication speed of the system is not known in advance
- The system is using a relatively low accuracy clock source and this mechanism allows the correct baud rate to be obtained without measuring the clock deviation.

The clock source frequency must be compatible with the expected communication speed (in case only modes 0 and 1 are supported, oversampling by 16 must be selected and baud rate between \( f_{\text{CK}}/65535 \) and \( f_{\text{CK}}/16 \). Otherwise, in case of 4 modes are supported: when oversampling by 16, the baud rate is between \( f_{\text{CK}}/65535 \) and \( f_{\text{CK}}/16 \); when oversampling by 8, the baud rate is between \( f_{\text{CK}}/65535 \) and \( f_{\text{CK}}/8 \).

Before activating the auto baud rate detection, the auto baud rate detection mode must be chosen. There are various modes based on different character patterns.

They can be chosen through the ABRMOD[1:0] field in the USART_CR2 register. In these auto baud rate modes, the baud rate is measured several times during the synchronization data reception and each measurement is compared to the previous one.
These modes are:

- **Mode 0**: Any character starting with a bit at 1. In this case the USART measures the duration of the Start bit (falling edge to rising edge).

- **Mode 1**: Any character starting with a 10xx bit pattern. In this case, the USART measures the duration of the Start and of the 1st data bit. The measurement is done falling edge to falling edge, ensuring better accuracy in the case of slow signal slopes.

- **Mode 2**: A 0x7F character frame (it may be a 0x7F character in LSB first mode or a 0xFE in MSB first mode). In this case, the baud rate is updated first at the end of the start bit (BRs), then at the end of bit 6 (based on the measurement done from falling edge to falling edge: BR6). Bit 0 to bit 6 are sampled at BRs while further bits of the character are sampled at BR6.

- **Mode 3**: A 0x55 character frame. In this case, the baud rate is updated first at the end of the start bit (BRs), then at the end of bit 0 (based on the measurement done from falling edge to falling edge: BR0), and finally at the end of bit 6 (BR6). Bit 0 is sampled at BRs, bit 1 to bit 6 are sampled at BR0, and further bits of the character are sampled at BR6.

  In parallel, another check is performed for each intermediate transition of RX line. An error is generated if the transitions on RX are not sufficiently synchronized with the receiver (the receiver being based on the baud rate calculated on bit 0).

Prior to activating auto baud rate detection, the USART_BRR register must be initialized by writing a non-zero baud rate value.

The automatic baud rate detection is activated by setting the ABREN bit in the USART_CR2 register. The USART will then wait for the first character on the RX line. The auto baud rate operation completion is indicated by the setting of the ABRF flag in the USART_ISR register. If the line is noisy, the correct baud rate detection cannot be guaranteed. In this case the BRR value may be corrupted and the ABRE error flag is set. This also happens if the communication speed is not compatible with the automatic baud rate detection range (bit duration not between 16 and 65536 clock periods (oversampling by 16) and not between 8 and 65536 clock periods (oversampling by 8)).

The RXNE interrupt will signal the end of the operation.

At any later time, the auto baud rate detection may be relaunched by resetting the ABRF flag (by writing a 0).

*Note:* *If the USART is disabled (UE=0) during an auto baud rate operation, the BRR value may be corrupted.*

### 27.5.7 Multiprocessor communication using USART

In multiprocessor communication, the following bits are to be kept cleared:

- LINEN bit in the USART_CR2 register,
- HDSEL, IREN and SCEN bits in the USART_CR3 register.

It is possible to perform multiprocessor communication with the USART (with several USARTs connected in a network). For instance one of the USARTs can be the master, its TX output connected to the RX inputs of the other USARTs. The others are slaves, their respective TX outputs are logically ANDed together and connected to the RX input of the master.
In multiprocessor configurations it is often desirable that only the intended message recipient should actively receive the full message contents, thus reducing redundant USART service overhead for all non addressed receivers.

The non addressed devices may be placed in mute mode by means of the muting function. In order to use the mute mode feature, the MME bit must be set in the USART_CR1 register.

In mute mode:
- None of the reception status bits can be set.
- All the receive interrupts are inhibited.
- The RWU bit in USART_ISR register is set to 1. RWU can be controlled automatically by hardware or by software, through the MMRQ bit in the USART_RQR register, under certain conditions.

The USART can enter or exit from mute mode using one of two methods, depending on the WAKE bit in the USART_CR1 register:
- Idle Line detection if the WAKE bit is reset,
- Address Mark detection if the WAKE bit is set.

**Idle line detection (WAKE=0)**

The USART enters mute mode when the MMRQ bit is written to 1 and the RWU is automatically set.

It wakes up when an Idle frame is detected. Then the RWU bit is cleared by hardware but the IDLE bit is not set in the USART_ISR register. An example of mute mode behavior using Idle line detection is given in Figure 255.

**Figure 255. Mute mode using Idle line detection**

![Mute mode diagram](image)

**Note:** If the MMRQ is set while the IDLE character has already elapsed, mute mode will not be entered (RWU is not set).

If the USART is activated while the line is IDLE, the idle state is detected after the duration of one IDLE frame (not only after the reception of one character frame).

**4-bit/7-bit address mark detection (WAKE=1)**

In this mode, bytes are recognized as addresses if their MSB is a ‘1’ otherwise they are considered as data. In an address byte, the address of the targeted receiver is put in the 4
or 7 LSBs. The choice of 7 or 4-bit address detection is done using the ADDM7 bit. This 4-bit/7-bit word is compared by the receiver with its own address which is programmed in the ADD bits in the USART_CR2 register.

**Note:** In 7-bit and 9-bit data modes, address detection is done on 6-bit and 8-bit addresses (ADD[5:0] and ADD[7:0]) respectively.

The USART enters mute mode when an address character is received which does not match its programmed address. In this case, the RWU bit is set by hardware. The RXNE flag is not set for this address byte and no interrupt or DMA request is issued when the USART enters mute mode.

The USART also enters mute mode when the MMRQ bit is written to 1. The RWU bit is also automatically set in this case.

The USART exits from mute mode when an address character is received which matches the programmed address. Then the RWU bit is cleared and subsequent bytes are received normally. The RXNE bit is set for the address character since the RWU bit has been cleared.

An example of mute mode behavior using address mark detection is given in Figure 256.

27.5.8 **Modbus communication using USART**

The USART offers basic support for the implementation of Modbus/RTU and Modbus/ASCII protocols. Modbus/RTU is a half duplex, block transfer protocol. The control part of the protocol (address recognition, block integrity control and command interpretation) must be implemented in software.

The USART offers basic support for the end of the block detection, without software overhead or other resources.

**Modbus/RTU**

In this mode, the end of one block is recognized by a “silence” (idle line) for more than 2 character times. This function is implemented through the programmable timeout function.

The timeout function and interrupt must be activated, through the RTOEN bit in the USART_CR2 register and the RTOIE in the USART_CR1 register. The value corresponding to a timeout of 2 character times (for example 22 x bit duration) must be programmed in the

---

Universal synchronous/asynchronous receiver transmitter (USART/UART) RM0091

722/1017 RM0091 Rev 10
RTO register. When the receive line is idle for this duration, after the last stop bit is received, an interrupt is generated, informing the software that the current block reception is completed.

**Modbus/ASCII**

In this mode, the end of a block is recognized by a specific (CR/LF) character sequence. The USART manages this mechanism using the character match function.

By programming the LF ASCII code in the ADD[7:0] field and by activating the character match interrupt (CMIE=1), the software is informed when a LF has been received and can check the CR/LF in the DMA buffer.

### 27.5.9 USART parity control

Parity control (generation of parity bit in transmission and parity checking in reception) can be enabled by setting the PCE bit in the USART_CR1 register. Depending on the frame length defined by the M bits, the possible USART frame formats are as listed in Table 109.

<table>
<thead>

</tr>
</tbody>
</table>

1. Legends: SB: start bit, STB: stop bit, PB: parity bit. In the data register, the PB is always taking the MSB position (9th, 8th or 7th, depending on the M bits value).

#### Even parity

The parity bit is calculated to obtain an even number of “1s” inside the frame of the 6, 7 or 8 LSB bits (depending on M bits values) and the parity bit.

As an example, if data=00110101, and 4 bits are set, then the parity bit is 0 if even parity is selected (PS bit in USART_CR1 = 0).

#### Odd parity

The parity bit is calculated to obtain an odd number of “1s” inside the frame made of the 6, 7 or 8 LSB bits (depending on M bits values) and the parity bit.

As an example, if data=00110101 and 4 bits set, then the parity bit is 1 if odd parity is selected (PS bit in USART_CR1 = 1).

#### Parity checking in reception

If the parity check fails, the PE flag is set in the USART_ISR register and an interrupt is generated if PEIE is set in the USART_CR1 register. The PE flag is cleared by software writing 1 to the PECF in the USART_ICR register.
Parity generation in transmission

If the PCE bit is set in USART_CR1, then the MSB bit of the data written in the data register is transmitted but is changed by the parity bit (even number of “1s” if even parity is selected (PS=0) or an odd number of “1s” if odd parity is selected (PS=1)).

27.5.10 USART LIN (local interconnection network) mode

This section is relevant only when LIN mode is supported. Please refer to Section 27.4: USART implementation on page 702.

The LIN mode is selected by setting the LINEN bit in the USART_CR2 register. In LIN mode, the following bits must be kept cleared:

- STOP[1:0] and CLKEN in the USART_CR2 register,
- SCEN, HDSEL and IREN in the USART_CR3 register.

For code example, refer to A.19.6: USART LIN mode code example.

LIN transmission

The procedure explained in Section 27.5.2: USART transmitter has to be applied for LIN Master transmission. It must be the same as for normal USART transmission with the following differences:

- Clear the M bits to configure 8-bit word length.
- Set the LINEN bit to enter LIN mode. In this case, setting the SBKRQ bit sends 13 ‘0’ bits as a break character. Then 2 bits of value ‘1’ are sent to allow the next start detection.

LIN reception

When LIN mode is enabled, the break detection circuit is activated. The detection is totally independent from the normal USART receiver. A break can be detected whenever it occurs, during Idle state or during a frame.

When the receiver is enabled (RE=1 in USART_CR1), the circuit looks at the RX input for a start signal. The method for detecting start bits is the same when searching break characters or data. After a start bit has been detected, the circuit samples the next bits exactly like for the data (on the 8th, 9th and 10th samples). If 10 (when the LBDL = 0 in USART_CR2) or 11 (when LBDL=1 in USART_CR2) consecutive bits are detected as ‘0’, and are followed by a delimiter character, the LBDF flag is set in USART_ISR. If the LBDIE bit=1, an interrupt is generated. Before validating the break, the delimiter is checked for as it signifies that the RX line has returned to a high level.

If a ‘1’ is sampled before the 10 or 11 have occurred, the break detection circuit cancels the current detection and searches for a start bit again.

If the LIN mode is disabled (LINEN=0), the receiver continues working as normal USART, without taking into account the break detection.

If the LIN mode is enabled (LINEN=1), as soon as a framing error occurs (i.e. stop bit detected at ‘0’, which is the case for any break frame), the receiver stops until the break detection circuit receives either a ‘1’, if the break word was not complete, or a delimiter character if a break has been detected.

The behavior of the break detector state machine and the break flag is shown on the Figure 257: Break detection in LIN mode (11-bit break length - LBDL bit is set) on page 725.
Examples of break frames are given on Figure 258: Break detection in LIN mode vs. Framing error detection on page 726.

**Figure 257. Break detection in LIN mode (11-bit break length - LBDL bit is set)**

  - Break state machine
  - Break state machine
  - Read samples
  - LBDF
27.5.11 USART synchronous mode

The synchronous mode is selected by writing the CLKEN bit in the USART_CR2 register to 1. In synchronous mode, the following bits must be kept cleared:

- LINEN bit in the USART_CR2 register,
- SCEN, HDSEL and IREN bits in the USART_CR3 register.

In this mode, the USART can be used to control bidirectional synchronous serial communications in master mode. The CK pin is the output of the USART transmitter clock. No clock pulses are sent to the CK pin during start bit and stop bit. Depending on the state of the LBCL bit in the USART_CR2 register, clock pulses are, or are not, generated during the last valid data bit (address mark). The CPOL bit in the USART_CR2 register is used to select the clock polarity, and the CPHA bit in the USART_CR2 register is used to select the phase of the external clock (see Figure 259, Figure 260 and Figure 261).

During the Idle state, preamble and send break, the external CK clock is not activated.

In synchronous mode the USART transmitter works exactly like in asynchronous mode. But as CK is synchronized with TX (according to CPOL and CPHA), the data on TX is synchronous.

In this mode the USART receiver works in a different manner compared to the asynchronous mode. If RE=1, the data is sampled on CK (rising or falling edge, depending on CPOL and CPHA), without any oversampling. A setup and a hold time must be respected (which depends on the baud rate: 1/16 bit duration).
Note: The CK pin works in conjunction with the TX pin. Thus, the clock is provided only if the transmitter is enabled (TE=1) and data is being transmitted (the data register USART_TDR written). This means that it is not possible to receive synchronous data without transmitting data.

The LBCL, CPOL and CPHA bits have to be selected when the USART is disabled (UE=0) to ensure that the clock pulses function correctly.

For code example, refer to A.19.7: USART synchronous mode code example.

Figure 259. USART example of synchronous transmission

![USART example of synchronous transmission](image1)

Figure 260. USART data clock timing diagram (M bits = 00)

![USART data clock timing diagram](image2)
Figure 261. USART data clock timing diagram (M bits = 01)

Note: The function of CK is different in Smartcard mode. Refer to Section 27.5.13: USART Smartcard mode for more details.
27.5.12 **USART Single-wire Half-duplex communication**

Single-wire Half-duplex mode is selected by setting the HDSEL bit in the USART_CR3 register. In this mode, the following bits must be kept cleared:

- LINEN and CLKEN bits in the USART_CR2 register,
- SCEN and IREN bits in the USART_CR3 register.

The USART can be configured to follow a Single-wire Half-duplex protocol where the TX and RX lines are internally connected. The selection between half- and Full-duplex communication is made with a control bit HDSEL in USART_CR3.

As soon as HDSEL is written to 1:

- The TX and RX lines are internally connected
- The RX pin is no longer used
- The TX pin is always released when no data is transmitted. Thus, it acts as a standard I/O in idle or in reception. It means that the I/O must be configured so that TX is configured as alternate function open-drain with an external pull-up.

Apart from this, the communication protocol is similar to normal USART mode. Any conflicts on the line must be managed by software (by the use of a centralized arbiter, for instance). In particular, the transmission is never blocked by hardware and continues as soon as data is written in the data register while the TE bit is set.

For code example, refer to [A.19.11: USART DMA code example](#).

27.5.13 **USART Smartcard mode**

This section is relevant only when Smartcard mode is supported. Please refer to Section 27.4: USART implementation on page 702.

Smartcard mode is selected by setting the SCEN bit in the USART_CR3 register. In Smartcard mode, the following bits must be kept cleared:

- LINEN bit in the USART_CR2 register,
- HDSEL and IREN bits in the USART_CR3 register.

Moreover, the CLKEN bit may be set in order to provide a clock to the smartcard.

The smartcard interface is designed to support asynchronous protocol for smartcards as defined in the ISO 7816-3 standard. Both T=0 (character mode) and T=1 (block mode) are supported.

The USART should be configured as:

- 8 bits plus parity: where word length is set to 8 bits and PCE=1 in the USART_CR1 register
- 1.5 stop bits: where STOP=11 in the USART_CR2 register. It is also possible to choose 0.5 stop bit for receiving.

For code example, refer to [A.19.9: USART smartcard mode code example](#).

In T=0 (character) mode, the parity error is indicated at the end of each character during the guard time period.

*Figure 263* shows examples of what can be seen on the data line with and without parity error.
When connected to a smartcard, the TX output of the USART drives a bidirectional line that is also driven by the smartcard. The TX pin must be configured as open drain.

Smartcard mode implements a single wire half duplex communication protocol.

- Transmission of data from the transmit shift register is guaranteed to be delayed by a minimum of 1/2 baud clock. In normal operation a full transmit shift register starts shifting on the next baud clock edge. In Smartcard mode this transmission is further delayed by a guaranteed 1/2 baud clock.

- In transmission, if the smartcard detects a parity error, it signals this condition to the USART by driving the line low (NACK). This NACK signal (pulling transmit line low for 1 baud clock) causes a framing error on the transmitter side (configured with 1.5 stop bits). The USART can handle automatic re-sending of data according to the protocol. The number of retries is programmed in the SCARCNT bit field. If the USART continues receiving the NACK after the programmed number of retries, it stops transmitting and signals the error as a framing error. The TXE bit can be set using the TXFRQ bit in the USART_RQR register.

- Smartcard auto-retry in transmission: a delay of 2.5 baud periods is inserted between the NACK detection by the USART and the start bit of the repeated character. The TC bit is set immediately at the end of reception of the last repeated character (no guard-time). If the software wants to repeat it again, it must insure the minimum 2 baud periods required by the standard.

- If a parity error is detected during reception of a frame programmed with a 1.5 stop bits period, the transmit line is pulled low for a baud clock period after the completion of the receive frame. This is to indicate to the smartcard that the data transmitted to the USART has not been correctly received. A parity error is NACKed by the receiver if the NACK control bit is set, otherwise a NACK is not transmitted (to be used in T=1 mode). If the received character is erroneous, the RXNE/receive DMA request is not activated. According to the protocol specification, the smartcard must resend the same character. If the received character is still erroneous after the maximum number of retries specified in the SCARCNT bit field, the USART stops transmitting the NACK and signals the error as a parity error.

- Smartcard auto-retry in reception: the BUSY flag remains set if the USART NACKs the card but the card doesn’t repeat the character.
In transmission, the USART inserts the Guard Time (as programmed in the Guard Time register) between two successive characters. As the Guard Time is measured after the stop bit of the previous character, the GT[7:0] register must be programmed to the desired CGT (Character Guard Time, as defined by the 7816-3 specification) minus 12 (the duration of one character).

The assertion of the TC flag can be delayed by programming the Guard Time register. In normal operation, TC is asserted when the transmit shift register is empty and no further transmit requests are outstanding. In Smartcard mode an empty transmit shift register triggers the Guard Time counter to count up to the programmed value in the Guard Time register. TC is forced low during this time. When the Guard Time counter reaches the programmed value TC is asserted high.

The de-assertion of TC flag is unaffected by Smartcard mode.

If a framing error is detected on the transmitter end (due to a NACK from the receiver), the NACK is not detected as a start bit by the receive block of the transmitter. According to the ISO protocol, the duration of the received NACK can be 1 or 2 baud clock periods.

On the receiver side, if a parity error is detected and a NACK is transmitted the receiver does not detect the NACK as a start bit.

**Note:** A break character is not significant in Smartcard mode. A 0x00 data with a framing error is treated as data and not as a break.

No Idle frame is transmitted when toggling the TE bit. The Idle frame (as defined for the other configurations) is not defined by the ISO protocol.

Figure 264 details how the NACK signal is sampled by the USART. In this example the USART is transmitting data and is configured with 1.5 stop bits. The receiver part of the USART is enabled in order to check the integrity of the data and the NACK signal.

**Figure 264. Parity error detection using the 1.5 stop bits**

The USART can provide a clock to the smartcard through the CK output. In Smartcard mode, CK is not associated to the communication but is simply derived from the internal peripheral input clock through a 5-bit prescaler. The division ratio is configured in the prescaler register USART_GTPR. CK frequency can be programmed from $f_{CK}/2$ to $f_{CK}/62$, where $f_{CK}$ is the peripheral input clock.
Block mode (T=1)

In T=1 (block) mode, the parity error transmission is deactivated, by clearing the NACK bit in the UART_CR3 register.

When requesting a read from the smartcard, in block mode, the software must enable the receiver Timeout feature by setting the RTOEN bit in the USART_CR2 register and program the RTO bits field in the RTOR register to the BWT (block wait time) - 11 value. If no answer is received from the smartcard before the expiration of this period, the RTOF flag is set and a timeout interrupt is generated (if RTOIE bit in the USART_CR1 register is set). If the first character is received before the expiration of the period, it is signaled by the RXNE interrupt.

Note: The RXNE interrupt must be enabled even when using the USART in DMA mode to read from the smartcard in block mode. In parallel, the DMA must be enabled only after the first received byte.

After the reception of the first character (RXNE interrupt), the RTO bit fields in the RTOR register must be programmed to the CWT (character wait time) - 11 value, in order to allow the automatic check of the maximum wait time between two consecutive characters. This time is expressed in baudtime units. If the smartcard does not send a new character in less than the CWT period after the end of the previous character, the USART signals this to the software through the RTOF flag and interrupt (when RTOIE bit is set).

Note: The RTO counter starts counting:
- From the end of the stop bit in case STOP = 00.
- From the end of the second stop bit in case of STOP = 10.
- 1 bit duration after the beginning of the STOP bit in case STOP = 11.
- From the beginning of the STOP bit in case STOP = 01.

As in the Smartcard protocol definition, the BWT/CWT values are defined from the beginning (start bit) of the last character. The RTO register must be programmed to BWT - 11 or CWT - 11, respectively, taking into account the length of the last character itself.

A block length counter is used to count all the characters received by the USART. This counter is reset when the USART is transmitting (TXE=0). The length of the block is communicated by the smartcard in the third byte of the block (prologue field). This value must be programmed to the BLEN field in the USART_RTOR register. When using DMA mode, before the start of the block, this register field must be programmed to the minimum value (0x0). With this value, an interrupt is generated after the 4th received character. The software must read the LEN field (third byte), its value must be read from the receive buffer.

In interrupt driven receive mode, the length of the block may be checked by software or by programming the BLEN value. However, before the start of the block, the maximum value of BLEN (0xFF) may be programmed. The real value is programmed after the reception of the third character.

If the block is using the LRC longitudinal redundancy check (1 epilogue byte), the BLEN=LEN. If the block is using the CRC mechanism (2 epilogue bytes), BLEN=LEN+1 must be programmed. The total block length (including prologue, epilogue and information fields) equals BLEN+4. The end of the block is signaled to the software through the EOBF flag and interrupt (when EOBIE bit is set).

In case of an error in the block length, the end of the block is signaled by the RTO interrupt (Character wait Time overflow).

Note: The error checking code (LRC/CRC) must be computed/verified by software.
**Direct and inverse convention**

The Smartcard protocol defines two conventions: direct and inverse.

The direct convention is defined as: LSB first, logical bit value of 1 corresponds to a H state of the line and parity is even. In order to use this convention, the following control bits must be programmed: MSBFIRST=0, DATAINV=0 (default values).

The inverse convention is defined as: MSB first, logical bit value 1 corresponds to an L state on the signal line and parity is even. In order to use this convention, the following control bits must be programmed: MSBFIRST=1, DATAINV=1.

*Note:* When logical data values are inverted (0=H, 1=L), the parity bit is also inverted in the same way.

In order to recognize the card convention, the card sends the initial character, TS, as the first character of the ATR (Answer To Reset) frame. The two possible patterns for the TS are: LHHL LLL LLH and LHHL HHH LLH.

- (H) LHHL LLL LLH sets up the inverse convention: state L encodes value 1 and moment 2 conveys the most significant bit (MSB first), when decoded by inverse convention, the conveyed byte is equal to '3F'.
- (H) LHHL HHH LLH sets up the direct convention: state H encodes value 1 and moment 2 conveys the least significant bit (LSB first), when decoded by direct convention, the conveyed byte is equal to '3B'.

Character parity is correct when there is an even number of bits set to 1 in the nine moments 2 to 10.

As the USART does not know which convention is used by the card, it needs to be able to recognize either pattern and act accordingly. The pattern recognition is not done in hardware, but through a software sequence. Moreover, supposing that the USART is configured in direct convention (default) and the card answers with the inverse convention, TS = LHHL LLL LLH => the USART received character is '03' and the parity is odd.

Therefore, two methods are available for TS pattern recognition:

**Method 1**

The USART is programmed in standard Smartcard mode/direct convention. In this case, the TS pattern reception generates a parity error interrupt and error signal to the card.

- The parity error interrupt informs the software that the card didn’t answer correctly in direct convention. Software then reprograms the USART for inverse convention
- In response to the error signal, the card retries the same TS character, and it is correctly received this time, by the reprogrammed USART

Alternatively, in answer to the parity error interrupt, the software may decide to reprogram the USART and to also generate a new reset command to the card, then wait again for the TS.

**Method 2**

The USART is programmed in 9-bit/no-parity mode, no bit inversion. In this mode it receives any of the two TS patterns as:

- (H) LHHL LLL LLH = 0x103 -> inverse convention to be chosen
- (H) LHHL HHH LLH = 0x13B -> direct convention to be chosen

The software checks the received character against these two patterns and, if any of them match, then programs the USART accordingly for the next character reception.
If none of the two is recognized, a card reset may be generated in order to restart the negotiation.

27.5.14 USART IrDA SIR ENDEC block

This section is relevant only when IrDA mode is supported. Please refer to Section 27.4: USART implementation on page 702.

IrDA mode is selected by setting the IREN bit in the USART_CR3 register. In IrDA mode, the following bits must be kept cleared:

- LINEN, STOP and CLKEN bits in the USART_CR2 register,
- SCEN and HDSEL bits in the USART_CR3 register.

The IrDA SIR physical layer specifies use of a Return to Zero, Inverted (RZI) modulation scheme that represents logic 0 as an infrared light pulse (see Figure 265).

The SIR Transmit encoder modulates the Non Return to Zero (NRZ) transmit bit stream output from USART. The output pulse stream is transmitted to an external output driver and infrared LED. USART supports only bit rates up to 115.2 Kbps for the SIR ENDEC. In normal mode the transmitted pulse width is specified as 3/16 of a bit period.

The SIR receive decoder demodulates the return-to-zero bit stream from the infrared detector and outputs the received NRZ serial bit stream to the USART. The decoder input is normally high (marking state) in the Idle state. The transmit encoder output has the opposite polarity to the decoder input. A start bit is detected when the decoder input is low.

- IrDA is a half duplex communication protocol. If the Transmitter is busy (when the USART is sending data to the IrDA encoder), any data on the IrDA receive line is ignored by the IrDA decoder and if the Receiver is busy (when the USART is receiving decoded data from the IrDA decoder), data on the TX from the USART to IrDA is not encoded. while receiving data, transmission should be avoided as the data to be transmitted could be corrupted.

- A 0 is transmitted as a high pulse and a 1 is transmitted as a 0. The width of the pulse is specified as 3/16th of the selected bit period in normal mode (see Figure 266).

- The SIR decoder converts the IrDA compliant receive signal into a bit stream for USART.

- The SIR receive logic interprets a high state as a logic one and low pulses as logic zeros.

- The transmit encoder output has the opposite polarity to the decoder input. The SIR output is in low state when Idle.

- The IrDA specification requires the acceptance of pulses greater than 1.41 µs. The acceptable pulse width is programmable. Glitch detection logic on the receiver end filters out pulses of width less than 2 PSC periods (PSC is the prescaler value programmed in the USART_GTPR). Pulses of width less than 1 PSC period are always rejected, but those of width greater than one and less than two periods may be accepted or rejected, those greater than 2 periods is accepted as a pulse. The IrDA encoder/decoder doesn’t work when PSC=0.

- The receiver can communicate with a low-power transmitter.

- In IrDA mode, the STOP bits in the USART_CR2 register must be configured to “1 stop bit”.
IrDA low-power mode

Transmitter

In low-power mode the pulse width is not maintained at 3/16 of the bit period. Instead, the width of the pulse is 3 times the low-power baud rate which can be a minimum of 1.42 MHz. Generally, this value is 1.8432 MHz (1.42 MHz < PSC< 2.12 MHz). A low-power mode programmable divisor divides the system clock to achieve this value.

Receiver

Receiving in low-power mode is similar to receiving in normal mode. For glitch detection the USART should discard pulses of duration shorter than 1 PSC period. A valid low is accepted only if its duration is greater than 2 periods of the IrDA low-power Baud clock (PSC value in the USART_GTPR).

Note: A pulse of width less than two and greater than one PSC period(s) may or may not be rejected. The receiver set up time should be managed by software. The IrDA physical layer specification specifies a minimum of 10 ms delay between transmission and reception (IrDA is a half duplex protocol).

Figure 265. IrDA SIR ENDEC- block diagram

Figure 266. IrDA data modulation (3/16) -Normal Mode
27.5.15 USART continuous communication in DMA mode

The USART is capable of performing continuous communication using the DMA. The DMA requests for Rx buffer and Tx buffer are generated independently.

Note: Please refer to Section 27.4: USART implementation on page 702 to determine if the DMA mode is supported. If DMA is not supported, use the USART as explained in Section 27.5.2: USART transmitter or Section 27.5.3: USART receiver. To perform continuous communication, the user can clear the TXE/RXNE flags in the USART_ISR register.

For code example, refer to A.19.11: USART DMA code example.

Transmission using DMA

DMA mode can be enabled for transmission by setting DMAT bit in the USART_CR3 register. Data is loaded from a SRAM area configured using the DMA peripheral (refer to Section 10: Direct memory access controller (DMA) on page 188) to the USART_TDR register whenever the TXE bit is set. To map a DMA channel for USART transmission, use the following procedure (x denotes the channel number):

1. Write the USART_TDR register address in the DMA control register to configure it as the destination of the transfer. The data is moved to this address from memory after each TXE event.
2. Write the memory address in the DMA control register to configure it as the source of the transfer. The data is loaded into the USART_TDR register from this memory area after each TXE event.
3. Configure the total number of bytes to be transferred to the DMA control register.
4. Configure the channel priority in the DMA register.
5. Configure DMA interrupt generation after half/full transfer as required by the application.
6. Clear the TC flag in the USART_ISR register by setting the TCCF bit in the USART_ICR register.
7. Activate the channel in the DMA register.

When the number of data transfers programmed in the DMA Controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector.

In transmission mode, once the DMA has written all the data to be transmitted (the TCIF flag is set in the DMA_ISR register), the TC flag can be monitored to make sure that the USART communication is complete. This is required to avoid corrupting the last transmission before disabling the USART or entering Stop mode. Software must wait until TC=1. The TC flag remains cleared during all data transfers and it is set by hardware at the end of transmission of the last frame.
Reception using DMA

DMA mode can be enabled for reception by setting the DMAR bit in USART_CR3 register. Data is loaded from the USART_RDR register to a SRAM area configured using the DMA peripheral (refer to Section 10: Direct memory access controller (DMA) on page 188) whenever a data byte is received. To map a DMA channel for USART reception, use the following procedure:

1. Write the USART_RDR register address in the DMA control register to configure it as the source of the transfer. The data is moved from this address to the memory after each RXNE event.
2. Write the memory address in the DMA control register to configure it as the destination of the transfer. The data is loaded from USART_RDR to this memory area after each RXNE event.
3. Configure the total number of bytes to be transferred to the DMA control register.
4. Configure the channel priority in the DMA control register.
5. Configure interrupt generation after half/ full transfer as required by the application.
6. Activate the channel in the DMA control register.

When the number of data transfers programmed in the DMA Controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector.
Figure 268. Reception using DMA

Error flagging and interrupt generation in multibuffer communication

In multibuffer communication if any error occurs during the transaction the error flag is asserted after the current byte. An interrupt is generated if the interrupt enable flag is set. For framing error, overrun error and noise flag which are asserted with RXNE in single byte reception, there is a separate error flag interrupt enable bit (EIE bit in the USART_CR3 register), which, if set, enables an interrupt after the current byte if any of these errors occur.

27.5.16 RS232 hardware flow control and RS485 driver enable using USART

It is possible to control the serial data flow between 2 devices by using the CTS input and the RTS output. The Figure 269 shows how to connect 2 devices in this mode:

Figure 269. Hardware flow control between 2 USARTs

Error flagging and interrupt generation in multibuffer communication

In multibuffer communication if any error occurs during the transaction the error flag is asserted after the current byte. An interrupt is generated if the interrupt enable flag is set. For framing error, overrun error and noise flag which are asserted with RXNE in single byte reception, there is a separate error flag interrupt enable bit (EIE bit in the USART_CR3 register), which, if set, enables an interrupt after the current byte if any of these errors occur.

27.5.16 RS232 hardware flow control and RS485 driver enable using USART

It is possible to control the serial data flow between 2 devices by using the CTS input and the RTS output. The Figure 269 shows how to connect 2 devices in this mode:
RS232 RTS and CTS flow control can be enabled independently by writing the RTSE and CTSE bits respectively to 1 (in the USART_CR3 register).

**RS232 RTS flow control**

If the RTS flow control is enabled (RTSE=1), then RTS is deasserted (tied low) as long as the USART receiver is ready to receive a new data. When the receive register is full, RTS is asserted, indicating that the transmission is expected to stop at the end of the current frame. *Figure 270* shows an example of communication with RTS flow control enabled.

![Figure 270. RS232 RTS flow control](image)

**RS232 CTS flow control**

If the CTS flow control is enabled (CTSE=1), then the transmitter checks the CTS input before transmitting the next frame. If CTS is deasserted (tied low), then the next data is transmitted (assuming that data is to be transmitted, in other words, if TXE=0), else the transmission does not occur. When CTS is asserted during a transmission, the current transmission is completed before the transmitter stops.

When CTSE=1, the CTSIF status bit is automatically set by hardware as soon as the CTS input toggles. It indicates when the receiver becomes ready or not ready for communication. An interrupt is generated if the CTSIE bit in the USART_CR3 register is set. *Figure 271* shows an example of communication with CTS flow control enabled.
Note: For correct behavior, CTS must be deasserted at least 3 USART clock source periods before the end of the current character. In addition it should be noted that the CTSCF flag may not be set for pulses shorter than 2 x PCLK periods.

For code example, refer to A.19.12: USART hardware flow control code example.

RS485 Driver Enable

The driver enable feature is enabled by setting bit DEM in the USART_CR3 control register. This allows the user to activate the external transceiver control, through the DE (Driver Enable) signal. The assertion time is the time between the activation of the DE signal and the beginning of the START bit. It is programmed using the DEAT [4:0] bit fields in the USART_CR1 control register. The de-assertion time is the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE signal. It is programmed using the DEDT [4:0] bit fields in the USART_CR1 control register. The polarity of the DE signal can be configured using the DEP bit in the USART_CR3 control register.

In USART, the DEAT and DEDT are expressed in sample time units (1/8 or 1/16 bit duration, depending on the oversampling rate).

27.5.17 Wake-up from Stop mode using USART

The USART is able to wake up the MCU from Stopmode when the UESM bit is set and the USART clock is set to HSI or LSE (refer to Section Reset and clock control (RCC)).

- USART source clock is HSI
  - If during Stop mode the HSI clock is switched OFF, when a falling edge on the USART receive line is detected, the USART interface requests the HSI clock to be switched ON. The HSI clock is then used for the frame reception.
    - If the wake-up event is verified, the MCU wakes up from low-power mode and data reception goes on normally.
    - If the wake-up event is not verified, the HSI clock is switched OFF again, the MCU is not waken up and stays in low-power mode and the clock request is released.
Note: If the USART kernel clock is kept ON during Stop mode, there is no constraint on the maximum baud rate that allows waking up from Stop mode. It is the same as in Run mode.

- USART source clock is LSE
  Same principle as described in case of USART source clock is HSI with the difference that the LSE is ON in Stop mode, but the LSE clock is not propagated to USART if the USART is not requesting it. The LSE clock is not OFF but there is a clock gating to avoid useless consumption.

The MCU wake-up from Stop mode can be done using the standard RXNE interrupt. In this case, the RXNEIE bit must be set before entering Stop mode.

Alternatively, a specific interrupt may be selected through the WUS bit fields.

In order to be able to wake up the MCU from Stop mode, the UESM bit in the USART_CR1 control register must be set prior to entering Stop mode.

When the wake-up event is detected, the WUF flag is set by hardware and a wake-up interrupt is generated if the WUFIE bit is set.

Note: Before entering Stop mode, the user must ensure that the USART is not performing a transfer. BUSY flag cannot ensure that Stop mode is never entered during a running reception.

The WUF flag is set when a wake-up event is detected, independently of whether the MCU is in Stop or in an active mode.

When entering Stop mode just after having initialized and enabled the receiver, the REACK bit must be checked to ensure the USART is actually enabled.

When DMA is used for reception, it must be disabled before entering Stop mode and re-enabled upon exit from Stop mode.

The wake-up from Stop mode feature is not available for all modes. For example it doesn't work in SPI mode because the SPI operates in master mode only.

Using Mute mode with Stop mode

If the USART is put into Mute mode before entering Stop mode:

- Wake-up from Mute mode on idle detection must not be used, because idle detection cannot work in Stop mode.
- If the wake-up from Mute mode on address match is used, then the source of wake-up from Stop mode must also be the address match. If the RXNE flag is set when entering the Stop mode, the interface will remain in mute mode upon address match and wake up from Stop.
- If the USART is configured to wake up the MCU from Stop mode on START bit detection, the WUF flag is set, but the RXNE flag is not set.

Determining the maximum USART baud rate allowing to wake-up correctly from Stop mode when the USART clock source is the HSI clock

The maximum baud rate allowing to wake-up correctly from Stop mode depends on:

- the parameter t\text{WUUSART} provided in the device datasheet
- the USART receiver tolerance provided in the Section 27.5.5: Tolerance of the USART receiver to clock deviation.

Let us take this example: OVER8 = 0, M bits = 01, ONEBIT = 0, BRR [3:0] = 0000.
In these conditions, according to Table 107: Tolerance of the USART receiver when BRR [3:0] = 0000, the USART receiver tolerance is 3.41%.

DTRA + DQUANT + DREC + DTCL + DWU < USART receiver's tolerance

\[
\text{DWU max} = \frac{t_{\text{WUSART}}}{(9 \times \text{Tbit Min})}
\]

\[
\text{Tbit Min} = \frac{t_{\text{WUSART}}}{(9 \times \text{DWU max})}
\]

If we consider an ideal case where the parameters DTRA, DQUANT, DREC and DTCL are at 0%, the DWU max is 3.41%. In reality, we need to consider at least the HSI inaccuracy.

Let us consider HSI inaccuracy = 1%, \( t_{\text{WUSART}} = 3 \mu s \) (values provided as example, for correct values, refer to the device datasheet):

\[
\text{DWU max} = 3.41\% - 1\% = 2.41\%
\]

\[
\text{Tbit min} = 3 \mu s / (11 \times 2.41\%) = 11.32 \mu s
\]

In these conditions, the maximum baud rate allowing to wake-up correctly from Stop mode is 1/11.32 \( \mu s = 88.36 \text{ kbaud} \).

1. The WUF interrupt is active only in Stop mode.

The USART interrupt events are connected to the same interrupt vector (see Figure 272).
- During transmission: Transmission Complete, Clear to Send, Transmit data Register empty or Framing error (in Smartcard mode) interrupt.
- During reception: Idle Line detection, Overrun error, Receive data register not empty, Parity error, LIN break detection, Noise Flag, Framing Error, Character match, etc.

These events generate an interrupt if the corresponding Enable Control Bit is set.

</tbody>
</table>
Bits 20:16  **DEDT[4:0]**: Driver Enable de-assertion time

This 5-bit value defines the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE (Driver Enable) signal. It is expressed in sample time units (1/8 or 1/16 bit duration, depending on the oversampling rate).

If the USART_TDR register is written during the DEDT time, the new data is transmitted only when the DEDT and DEAT times have both elapsed.

This bit field can only be written when the USART is disabled (UE=0).

*Note: If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Please refer to Section 27.4: USART implementation on page 702.*

Bit 15  **OVER8**: Oversampling mode

0: Oversampling by 16
1: Oversampling by 8

This bit can only be written when the USART is disabled (UE=0).

*Note: In LIN, IrDA and modes, this bit must be kept at reset value.*

Bit 14  **CMIE**: Character match interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited
1: A USART interrupt is generated when the CMF bit is set in the USART_ISR register.

Bit 13  **MME**: Mute mode enable

This bit activates the mute mode function of the USART. when set, the USART can switch between the active and mute modes, as defined by the WAKE bit. It is set and cleared by software.

0: Receiver in active mode permanently
1: Receiver can switch between mute mode and active mode.

Bit 12  **M0**: Word length

This bit, with bit 28 (M1), determines the word length. It is set or cleared by software. See Bit 28 (M1) description.

This bit can only be written when the USART is disabled (UE=0).

Bit 11  **WAKE**: Receiver wake-up method

This bit determines the USART wake-up method from Mute mode. It is set or cleared by software.

0: Idle line
1: Address mark

This bit field can only be written when the USART is disabled (UE=0).

Bit 10  **PCE**: Parity control enable

This bit selects the hardware parity control (generation and detection). When the parity control is enabled, the computed parity is inserted at the MSB position (9th bit if M=1; 8th bit if M=0) and parity is checked on the received data. This bit is set and cleared by software.

Once it is set, PCE is active after the current byte (in reception and in transmission).

0: Parity control disabled
1: Parity control enabled

This bit field can only be written when the USART is disabled (UE=0).

Bit 9  **PS**: Parity selection

This bit selects the odd or even parity when the parity generation/detection is enabled (PCE bit set). It is set and cleared by software. The parity is selected after the current byte.

0: Even parity
1: Odd parity

This bit field can only be written when the USART is disabled (UE=0).
Bit 8 **PEIE**: PE interrupt enable

This bit is set and cleared by software.
0: Interrupt is inhibited
1: A USART interrupt is generated whenever PE=1 in the USART_ISR register

Bit 7 **TXEIE**: transmit error interrupt enable

This bit is set and cleared by software.
0: Interrupt is inhibited
1: A USART interrupt is generated whenever TXE=1 in the USART_ISR register

Bit 6 **TCIE**: transmission complete interrupt enable

This bit is set and cleared by software.
0: Interrupt is inhibited
1: A USART interrupt is generated whenever TC=1 in the USART_ISR register

Bit 5 **RXNEIE**: RXNE interrupt enable

This bit is set and cleared by software.
0: Interrupt is inhibited
1: A USART interrupt is generated whenever ORE=1 or RXNE=1 in the USART_ISR register

Bit 4 **IDLEIE**: IDLE interrupt enable

This bit is set and cleared by software.
0: Interrupt is inhibited
1: A USART interrupt is generated whenever IDLE=1 in the USART_ISR register

Bit 3 **TE**: Transmitter enable

This bit enables the transmitter. It is set and cleared by software.
0: Transmitter is disabled
1: Transmitter is enabled

**Note:** During transmission, a “0” pulse on the TE bit ("0" followed by “1”) sends a preamble (idle line) after the current word, except in Smartcard mode. In order to generate an idle character, the TE must not be immediately written to 1. In order to ensure the required duration, the software can poll the TEACK bit in the USART_ISR register.

In Smartcard mode, when TE is set there is a 1 bit-time delay before the transmission starts.
Bit 2 **RE**: Receiver enable

This bit enables the receiver. It is set and cleared by software.
0: Receiver is disabled
1: Receiver is enabled and begins searching for a start bit

Bit 1 **UESM**: USART enable in Stop mode

When this bit is cleared, the USART is not able to wake up the MCU from Stop mode.
When this bit is set, the USART is able to wake up the MCU from Stop mode, provided that the USART clock selection is HSI or LSE in the RCC.

This bit is set and cleared by software.
0: USART not able to wake up the MCU from Stop mode.
1: USART able to wake up the MCU from Stop mode. When this function is active, the clock source for the USART must be HSI or LSE (see Section Reset and clock control (RCC).

**Note:** It is recommended to set the UESM bit just before entering Stop mode and clear it on exit from Stop mode.

If the USART does not support the wake-up from Stop feature, this bit is reserved and must be kept at reset value. Refer to Section 27.4: USART implementation on page 702.

Bit 0 **UE**: USART enable

When this bit is cleared, the USART prescalers and outputs are stopped immediately, and current operations are discarded. The configuration of the USART is kept, but all the status flags, in the USART_ISR are set to their default values. This bit is set and cleared by software.
0: USART prescaler and outputs disabled, low-power mode
1: USART enabled

**Note:** In order to go into low-power mode without generating errors on the line, the TE bit must be reset before and the software must wait for the TC bit in the USART_ISR to be set before resetting the UE bit.

The DMA requests are also reset when UE = 0 so the DMA channel must be disabled before resetting the UE bit.

### 27.8.2 USART control register 2 (USART_CR2)

Bits 31:28  **ADD[7:4]:** Address of the USART node

This bit-field gives the address of the USART node or a character code to be recognized.
This is used in multiprocessor communication during Mute mode or Stop mode, for wake-up with 7-bit address mark detection. The MSB of the character sent by the transmitter should be equal to 1. It may also be used for character detection during normal reception, Mute mode inactive (for example, end of block detection in ModBus protocol). In this case, the whole received character (8-bit) is compared to the ADD[7:0] value and CMF flag is set on match.
This bit field can only be written when reception is disabled (RE = 0) or the USART is disabled (UE=0).

Bits 27:24  **ADD[3:0]:** Address of the USART node

This bit-field gives the address of the USART node or a character code to be recognized.
This is used in multiprocessor communication during Mute mode or Stop mode, for wake-up with address mark detection.
This bit field can only be written when reception is disabled (RE = 0) or the USART is disabled (UE=0).

Bit 23  **RTOEN:** Receiver timeout enable

This bit is set and cleared by software.
0: Receiver timeout feature disabled.
1: Receiver timeout feature enabled.
When this feature is enabled, the RTOF flag in the USART_ISR register is set if the RX line is idle (no reception) for the duration programmed in the RTOR (receiver timeout register).

**Note:** If the USART does not support the Receiver timeout feature, this bit is reserved and must be kept at reset value. Please refer to Section 27.4: USART implementation on page 702.

Bits 22:21  **ABRMOD[1:0]:** Auto baud rate mode

These bits are set and cleared by software.
00: Measurement of the start bit is used to detect the baud rate.
01: Falling edge to falling edge measurement. (the received frame must start with a single bit = 1 -> Frame = Start10xxxxxx)
10: 0x7F frame detection.
11: 0x55 frame detection
This bit field can only be written when ABREN = 0 or the USART is disabled (UE=0).

**Note:** If DATAINV=1 and/or MSBFIRST=1 the patterns must be the same on the line, for example 0xAA for MSBFIRST)

If the USART does not support the auto baud rate feature, this bit is reserved and must be kept at reset value. Please refer to Section 27.4: USART implementation on page 702.

Bit 20  **ABREN:** Auto baud rate enable

This bit is set and cleared by software.
0: Auto baud rate detection is disabled.
1: Auto baud rate detection is enabled.

**Note:** If the USART does not support the auto baud rate feature, this bit is reserved and must be kept at reset value. Please refer to Section 27.4: USART implementation on page 702.

Bit 19  **MSBFIRST:** Most significant bit first

This bit is set and cleared by software.
0: data is transmitted/received with data bit 0 first, following the start bit.
1: data is transmitted/received with the MSB (bit 7/8/9) first, following the start bit.
This bit field can only be written when the USART is disabled (UE=0).
Bit 18 **DATAINV**: Binary data inversion
This bit is set and cleared by software.
0: Logical data from the data register are send/received in positive/direct logic. (1=H, 0=L)
1: Logical data from the data register are send/received in negative/inverse logic. (1=L, 0=H). The parity bit is also inverted.
This bit field can only be written when the USART is disabled (UE=0).

Bit 17 **TXINV**: TX pin active level inversion
This bit is set and cleared by software.
0: TX pin signal works using the standard logic levels (VDD =1/idle, Gnd=0/mark)
1: TX pin signal values are inverted. (VDD =0/mark, Gnd=1/idle).
This allows the use of an external inverter on the TX line.
This bit field can only be written when the USART is disabled (UE=0).

Bit 16 **RXINV**: RX pin active level inversion
This bit is set and cleared by software.
0: RX pin signal works using the standard logic levels (VDD =1/idle, Gnd=0/mark)
1: RX pin signal values are inverted. (VDD =0/mark, Gnd=1/idle).
This allows the use of an external inverter on the RX line.
This bit field can only be written when the USART is disabled (UE=0).

Bit 15 **SWAP**: Swap TX/RX pins
This bit is set and cleared by software.
0: TX/RX pins are used as defined in standard pinout
1: The TX and RX pins functions are swapped. This allows to work in the case of a cross-wired connection to another USART.
This bit field can only be written when the USART is disabled (UE=0).

Bit 14 **LINEN**: LIN mode enable
This bit is set and cleared by software.
0: LIN mode disabled
1: LIN mode enabled
The LIN mode enables the capability to send LIN synchronous breaks (13 low bits) using the SBKRQ bit in the USART_RQR register, and to detect LIN Sync breaks.
This bit field can only be written when the USART is disabled (UE=0).

*Note: If the USART does not support LIN mode, this bit is reserved and must be kept at reset value. Please refer to Section 27.4: USART implementation on page 702.*

Bits 13:12 **STOP[1:0]**: STOP bits
These bits are used for programming the stop bits.
00: 1 stop bit
01: 0.5 stop bit
10: 2 stop bits
11: 1.5 stop bits
This bit field can only be written when the USART is disabled (UE=0).
Bit 11 **CLKEN**: Clock enable

This bit allows the user to enable the CK pin.

- 0: CK pin disabled
- 1: CK pin enabled

This bit can only be written when the USART is disabled (UE=0).

**Note**: If neither synchronous mode nor Smartcard mode is supported, this bit is reserved and must be kept at reset value. Please refer to Section 27.4: USART implementation on page 702.

In order to provide correctly the CK clock to the Smartcard when CK is always available when \( CLKEN = 1 \), regardless of the UE bit value, the steps below must be respected:

- **UE** = 0
- **SCEN** = 1
- GTPR configuration (If PSC needs to be configured, it is recommended to configure PSC and GT in a single access to USART_GTPR register).
- **CLKEN** = 1
- **UE** = 1

Bit 10 **CPOL**: Clock polarity

This bit allows the user to select the polarity of the clock output on the CK pin in synchronous mode. It works in conjunction with the CPHA bit to produce the desired clock/data relationship.

- 0: Steady low value on CK pin outside transmission window
- 1: Steady high value on CK pin outside transmission window

This bit can only be written when the USART is disabled (UE=0).

**Note**: If synchronous mode is not supported, this bit is reserved and must be kept at reset value. Please refer to Section 27.4: USART implementation on page 702.

Bit 9 **CPHA**: Clock phase

This bit is used to select the phase of the clock output on the CK pin in synchronous mode. It works in conjunction with the CPOL bit to produce the desired clock/data relationship (see Figure 260 and Figure 261).

- 0: The first clock transition is the first data capture edge
- 1: The second clock transition is the first data capture edge

This bit can only be written when the USART is disabled (UE=0).

**Note**: If synchronous mode is not supported, this bit is reserved and must be kept at reset value. Please refer to Section 27.4: USART implementation on page 702.

Bit 8 **LBCL**: Last bit clock pulse

This bit is used to select whether the clock pulse associated with the last data bit transmitted (MSB) has to be output on the CK pin in synchronous mode.

- 0: The clock pulse of the last data bit is not output to the CK pin
- 1: The clock pulse of the last data bit is output to the CK pin

**Caution**: The last bit is the 7th or 8th or 9th data bit transmitted depending on the 7 or 8 or 9 bit format selected by the M bits in the USART_CR1 register.

This bit can only be written when the USART is disabled (UE=0).

**Note**: If synchronous mode is not supported, this bit is reserved and must be kept at reset value. Please refer to Section 27.4: USART implementation on page 702.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **LBDIE**: LIN break detection interrupt enable

Break interrupt mask (break detection using break delimiter).

- 0: Interrupt is inhibited
- 1: An interrupt is generated whenever LBDF=1 in the USART_ISR register

**Note**: If LIN mode is not supported, this bit is reserved and must be kept at reset value. Please refer to Section 27.4: USART implementation on page 702.
Bit 5 **LBDL**: LIN break detection length
This bit is for selection between 11 bit or 10 bit break detection.

- 0: 10-bit break detection
- 1: 11-bit break detection

This bit can only be written when the USART is disabled (UE=0).

*Note: If LIN mode is not supported, this bit is reserved and must be kept at reset value. Please refer to Section 27.4: USART implementation on page 702.*

Bit 4 **ADDM7**: 7-bit Address Detection/4-bit Address Detection
This bit is for selection between 4-bit address detection or 7-bit address detection.

- 0: 4-bit address detection
- 1: 7-bit address detection (in 8-bit data mode)

This bit can only be written when the USART is disabled (UE=0)

*Note: In 7-bit and 9-bit data modes, the address detection is done on 6-bit and 8-bit address (ADD[5:0] and ADD[7:0]) respectively.*

Bits 3:0 Reserved, must be kept at reset value.

*Note: The 3 bits (CPOL, CPHA, LBCL) should not be written while the transmitter is enabled.*

Bits 31:25 Reserved, must be kept at reset value.

- Bit 24 Reserved, must be kept at reset value.
- Bit 23 Reserved, must be kept at reset value.
- Bit 22 **WUFIE**: Wake-up from Stop mode interrupt enable
  - This bit is set and cleared by software.
  - 0: Interrupt is inhibited
  - 1: An USART interrupt is generated whenever WUF=1 in the USART_ISR register
  - *Note: WUFIE must be set before entering in Stop mode.*
  - The WUF interrupt is active only in Stop mode.
  - *If the USART does not support the wake-up from Stop feature, this bit is reserved and must be kept at reset value.*
Bits 21:20 **WUS[1:0]**: Wake-up from Stop mode interrupt flag selection

This bit-field specify the event which activates the WUF (wake-up from Stop mode flag).

00: WUF active on address match (as defined by ADD[7:0] and ADDM7)
01: Reserved.
10: WUF active on Start bit detection
11: WUF active on RXNE.

This bit field can only be written when the USART is disabled (UE=0).

*Note:* If the USART does not support the wake-up from Stop feature, this bit is reserved and must be kept at reset value.

Bits 19:17 **SCARCNT[2:0]**: Smartcard auto-retry count

This bit-field specifies the number of retries in transmit and receive, in Smartcard mode.
In transmission mode, it specifies the number of automatic retransmission retries, before generating a transmission error (FE bit set).
In reception mode, it specifies the number of erroneous reception trials, before generating a reception error (RXNE and PE bits set).

This bit field must be programmed only when the USART is disabled (UE=0).

When the USART is enabled (UE=1), this bit field may only be written to 0x0, in order to stop retransmission.

0x0: retransmission disabled - No automatic retransmission in transmit mode.
0x1 to 0x7: number of automatic retransmission attempts (before signaling error)

*Note:* If Smartcard mode is not supported, this bit is reserved and must be kept at reset value. Please refer to Section 27.4: USART implementation on page 702.

Bit 16 Reserved, must be kept at reset value.

Bit 15 **DEP**: Driver enable polarity selection

0: DE signal is active high.
1: DE signal is active low.

This bit can only be written when the USART is disabled (UE=0).

*Note:* If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Please refer to Section 27.4: USART implementation on page 702.

Bit 14 **DEM**: Driver enable mode

This bit allows the user to activate the external transceiver control, through the DE signal.
0: DE function is disabled.
1: DE function is enabled. The DE signal is output on the RTS pin.

This bit can only be written when the USART is disabled (UE=0).

*Note:* If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. *Section 27.4: USART implementation on page 702.*

Bit 13 **DDRE**: DMA Disable on Reception Error

0: DMA is not disabled in case of reception error. The corresponding error flag is set but RXNE is kept 0 preventing from overrun. As a consequence, the DMA request is not asserted, so the erroneous data is not transferred (no DMA request), but next correct received data are transferred (used for Smartcard mode).
1: DMA is disabled following a reception error. The corresponding error flag is set, as well as RXNE. The DMA request is masked until the error flag is cleared. This means that the software must first disable the DMA request (DMAR = 0) or clear RXNE before clearing the error flag.

This bit can only be written when the USART is disabled (UE=0).

*Note:* The reception errors are: parity error, framing error or noise error.
Bit 12 **OVRDIS**: Overrun Disable

This bit is used to disable the receive overrun detection.

- 0: Overrun Error Flag, ORE, is set when received data is not read before receiving new data.
- 1: Overrun functionality is disabled. If new data is received while the RXNE flag is still set the ORE flag is not set and the new received data overwrites the previous content of the USART_RDR register.

This bit can only be written when the USART is disabled (UE=0).

*Note: This control bit allows checking the communication flow without reading the data.*

Bit 11 **ONEBIT**: One sample bit method enable

This bit allows the user to select the sample method. When the one sample bit method is selected the noise detection flag (NF) is disabled.

- 0: Three sample bit method
- 1: One sample bit method

This bit can only be written when the USART is disabled (UE=0).

*Note: ONEBIT feature applies only to data bits, It does not apply to Start bit.*

Bit 10 **CTSIE**: CTS interrupt enable

- 0: Interrupt is inhibited
- 1: An interrupt is generated whenever CTSIF=1 in the USART_ISR register

*Note: If the hardware flow control feature is not supported, this bit is reserved and must be kept at reset value. Please refer to Section 27.4: USART implementation on page 702.*

Bit 9 **CTSE**: CTS enable

- 0: CTS hardware flow control disabled
- 1: CTS mode enabled, data is only transmitted when the CTS input is deasserted (tied to 0).

If the CTS input is asserted while data is being transmitted, then the transmission is completed before stopping. If data is written into the data register while CTS is asserted, the transmission is postponed until CTS is deasserted.

This bit can only be written when the USART is disabled (UE=0)

*Note: If the hardware flow control feature is not supported, this bit is reserved and must be kept at reset value. Please refer to Section 27.4: USART implementation on page 702.*

Bit 8 **RTSE**: RTS enable

- 0: RTS hardware flow control disabled
- 1: RTS output enabled, data is only requested when there is space in the receive buffer. The transmission of data is expected to cease after the current character has been transmitted. The RTS output is deasserted (pulled to 0) when data can be received.

This bit can only be written when the USART is disabled (UE=0)

*Note: If the hardware flow control feature is not supported, this bit is reserved and must be kept at reset value. Please refer to Section 27.4: USART implementation on page 702.*

Bit 7 **DMAT**: DMA enable transmitter

This bit is set/reset by software

- 1: DMA mode is enabled for transmission
- 0: DMA mode is disabled for transmission

Bit 6 **DMAR**: DMA enable receiver

This bit is set/reset by software

- 1: DMA mode is enabled for reception
- 0: DMA mode is disabled for reception
Bit 5 **SCEN**: Smartcard mode enable
   This bit is used for enabling Smartcard mode.
   0: Smartcard Mode disabled
   1: Smartcard Mode enabled
   This bit field can only be written when the USART is disabled (UE=0).
   **Note:** If the USART does not support Smartcard mode, this bit is reserved and must be kept at reset value. Please refer to Section 27.4: USART implementation on page 702.

Bit 4 **NACK**: Smartcard NACK enable
   0: NACK transmission in case of parity error is disabled
   1: NACK transmission during parity error is enabled
   This bit field can only be written when the USART is disabled (UE=0).
   **Note:** If the USART does not support Smartcard mode, this bit is reserved and must be kept at reset value. Please refer to Section 27.4: USART implementation on page 702.

Bit 3 **HDSEL**: Half-duplex selection
   Selection of Single-wire Half-duplex mode
   0: Half duplex mode is not selected
   1: Half duplex mode is selected
   This bit can only be written when the USART is disabled (UE=0).

Bit 2 **IRLP**: IrDA low-power
   This bit is used for selecting between normal and low-power IrDA modes
   0: Normal mode
   1: Low-power mode
   This bit can only be written when the USART is disabled (UE=0).
   **Note:** If IrDA mode is not supported, this bit is reserved and must be kept at reset value. Please refer to Section 27.4: USART implementation on page 702.

Bit 1 **IREN**: IrDA mode enable
   This bit is set and cleared by software.
   0: IrDA disabled
   1: IrDA enabled
   This bit can only be written when the USART is disabled (UE=0).
   **Note:** If IrDA mode is not supported, this bit is reserved and must be kept at reset value. Please refer to Section 27.4: USART implementation on page 702.

Bit 0 **EIE**: Error interrupt enable
   Error Interrupt Enable Bit is required to enable interrupt generation in case of a framing error, overrun error or noise flag (FE=1 or ORE=1 or NF=1 in the USART_ISR register).
   0: Interrupt is inhibited
   1: An interrupt is generated when FE=1 or ORE=1 or NF=1 in the USART_ISR register.
27.8.4 USART baud rate register (USART_BRR)

This register can only be written when the USART is disabled (UE=0). It may be automatically updated by hardware in auto baud rate detection mode.

Address offset: 0x0C

Reset value: 0x0000 0000

<table>

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:8  **GT[7:0]: Guard time value**
- This bit-field is used to program the Guard time value in terms of number of baud clock periods.
- This is used in Smartcard mode. The Transmission Complete flag is set after this guard time value.
- This bit field can only be written when the USART is disabled (UE=0).

*Note: If Smartcard mode is not supported, this bit is reserved and must be kept at reset value. Please refer to Section 27.4: USART implementation on page 702.*

Bits 7:0  **PSC[7:0]: Prescaler value**

**In IrDA Low-power and normal IrDA mode:**

PSC[7:0] = IrDA Normal and Low-Power Baud Rate
- Used for programming the prescaler for dividing the USART source clock to achieve the low-power frequency:
- The source clock is divided by the value given in the register (8 significant bits):
  - 00000000: Reserved - do not program this value
  - 00000001: divides the source clock by 1
  - 00000010: divides the source clock by 2
  - ...

**In Smartcard mode:**

PSC[4:0]: Prescaler value
- Used for programming the prescaler for dividing the USART source clock to provide the Smartcard clock.
- The value given in the register (5 significant bits) is multiplied by 2 to give the division factor of the source clock frequency:
  - 00000: Reserved - do not program this value
  - 00001: divides the source clock by 2
  - 00010: divides the source clock by 4
  - 00011: divides the source clock by 6
  - ...

This bit field can only be written when the USART is disabled (UE=0).

*Note: Bits [7:5] must be kept at reset value if Smartcard mode is used. This bit field is reserved and must be kept at reset value when the Smartcard and IrDA modes are not supported. Please refer to Section 27.4: USART implementation on page 702.*

### 27.8.6 USART receiver timeout register (USART_RTOR)

756/1017  RM0091 Rev 10
Bits 31:24 **BLEN[7:0]: Block Length**

This bit-field gives the Block length in Smartcard T=1 Reception. Its value equals the number of information characters + the length of the Epilogue Field (1-LEC/2-CRC) - 1.

Examples:
- BLEN = 0 -> 0 information characters + LEC
- BLEN = 1 -> 0 information characters + CRC
- BLEN = 255 -> 254 information characters + CRC (total 256 characters)

In Smartcard mode, the Block length counter is reset when TXE=0.

This bit-field can be used also in other modes. In this case, the Block length counter is reset when RE=0 (receiver disabled) and/or when the EOBCF bit is written to 1.

*Note: This value can be programmed after the start of the block reception (using the data from the LEN character in the Prologue Field). It must be programmed only once per received block.*

Bits 23:0 **RTO[23:0]: Receiver timeout value**

This bit-field gives the Receiver timeout value in terms of number of bit duration.

In standard mode, the RTOF flag is set if, after the last received character, no new start bit is detected for more than the RTO value.

In Smartcard mode, this value is used to implement the CWT and BWT. See Smartcard section for more details.

In this case, the timeout measurement is done starting from the Start Bit of the last received character.

*Note: This value must only be programmed once per received character.*

*Note: RTOR can be written on the fly. If the new value is lower than or equal to the counter, the RTOF flag is set.*

*This register is reserved and forced by hardware to “0x00000000” when the Receiver timeout feature is not supported. Please refer to Section 27.4: USART implementation on page 702.*

### 27.8.7 USART request register (USART_RQR)

</tbody>
</table>
Bits 31:5  Reserved, must be kept at reset value.

Bit 4  **TXRFQ**: Transmit data flush request
   Writing 1 to this bit sets the TXE flag.
   This allows to discard the transmit data. This bit must be used only in Smartcard mode,
   when data has not been sent due to errors (NACK) and the FE flag is active in the
   USART_ISR register.
   If the USART does not support Smartcard mode, this bit is reserved and must be kept at
   reset value. Please refer to Section 27.4: USART implementation on page 702.

Bit 3  **RXRFQ**: Receive data flush request
   Writing 1 to this bit clears the RXNE flag.
   This allows to discard the received data without reading it, and avoid an overrun condition.

Bit 2  **MMRQ**: Mute mode request
   Writing 1 to this bit puts the USART in mute mode and sets the RWU flag.

Bit 1  **SBKRQ**: Send break request
   Writing 1 to this bit sets the SBKF flag and request to send a BREAK on the line, as soon as
   the transmit machine is available.
   
   **Note**: In the case the application needs to send the break character following all previously
   inserted data, including the ones not yet transmitted, the software should wait for the
   TXE flag assertion before setting the SBKRQ bit.

Bit 0  **ABRRQ**: Auto baud rate request
   Writing 1 to this bit resets the ABRF and ABRE flags in the USART_ISR and request an
   automatic baud rate measurement on the next received data frame.
   
   **Note**: If the USART does not support the auto baud rate feature, this bit is reserved and must
   be kept at reset value. Please refer to Section 27.4: USART implementation on
   page 702.

Bits 31:25  Reserved, must be kept at reset value.

Bits 24:23  Reserved, must be kept at reset value.
Bit 22 **REACK**: Receive enable acknowledge flag
This bit is set/reset by hardware, when the Receive Enable value is taken into account by the USART.
When the wake-up from Stop mode is supported, the REACK flag can be used to verify that the USART is ready for reception before entering Stop mode.

Bit 21 **TEACK**: Transmit enable acknowledge flag
This bit is set/reset by hardware, when the Transmit Enable value is taken into account by the USART.
It can be used when an idle frame request is generated by writing TE=0, followed by TE=1 in the USART_CR1 register, in order to respect the TE=0 minimum period.

Bit 20 **WUF**: Wake-up from Stop mode flag
This bit is set by hardware, when a wake-up event is detected. The event is defined by the WUS bit field. It is cleared by software, writing a 1 to the WUCF in the USART_ICR register.
An interrupt is generated if WUFIE=1 in the USART_CR3 register.
*Note*: When UESM is cleared, WUF flag is also cleared.
The WUF interrupt is active only in Stop mode.
*If the USART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value.*

Bit 19 **RWU**: Receiver wake-up from Mute mode
This bit indicates if the USART is in mute mode. It is cleared/set by hardware when a wake-up/mute sequence is recognized. The mute mode control sequence (address or IDLE) is selected by the WAKE bit in the USART_CR1 register.
When wake-up on IDLE mode is selected, this bit can only be set by software, writing 1 to the MMRQ bit in the USART_RQR register.
0: Receiver in active mode
1: Receiver in mute mode

Bit 18 **SBKF**: Send break flag
This bit indicates that a send break character was requested. It is set by software, by writing 1 to the SBKRQ bit in the USART_RQR register. It is automatically reset by hardware during the stop bit of break transmission.
0: No break character is transmitted
1: Break character is transmitted

Bit 17 **CMF**: Character match flag
This bit is set by hardware, when the character defined by ADD[7:0] is received. It is cleared by software, writing 1 to the CMCF in the USART_ICR register.
An interrupt is generated if CMIE=1 in the USART_CR1 register.
0: No Character match detected
1: Character Match detected

Bit 16 **BUSY**: Busy flag
This bit is set and reset by hardware. It is active when a communication is ongoing on the RX line (successful start bit detected). It is reset at the end of the reception (successful or not).
0: USART is idle (no reception)
1: Reception on going
Bit 15 **ABRF**: Auto baud rate flag
This bit is set by hardware when the automatic baud rate has been set (RXNE will also be set, generating an interrupt if RXNEIE = 1) or when the auto baud rate operation was completed without success (ABRE=1) (ABRE, RXNE and FE are also set in this case). It is cleared by software, in order to request a new auto baud rate detection, by writing 1 to the ABRRQ in the USART_RQR register.

*Note: If the USART does not support the auto baud rate feature, this bit is reserved and kept at reset value.*

Bit 14 **ABRE**: Auto baud rate error
This bit is set by hardware if the baud rate measurement failed (baud rate out of range or character comparison failed).
It is cleared by software, by writing 1 to the ABRRQ bit in the USART_RQR register.

*Note: If the USART does not support the auto baud rate feature, this bit is reserved and kept at reset value.*

Bit 13 Reserved, must be kept at reset value.

Bit 12 **EOBF**: End of block flag
This bit is set by hardware when a complete block has been received (for example T=1 Smartcard mode). The detection is done when the number of received bytes (from the start of the block, including the prologue) is equal or greater than BLEN + 4. An interrupt is generated if EOBIE = 1 in the USART_CR1 register.

It is cleared by software, writing 1 to EOBCF in the USART_ICR register.

0: End of Block not reached
1: End of Block (number of characters) reached

*Note: If Smartcard mode is not supported, this bit is reserved and kept at reset value. Please refer to Section 27.4: USART implementation on page 702.*

Bit 11 **RTOF**: Receiver timeout
This bit is set by hardware when the timeout value, programmed in the RTOR register has lapsed, without any communication. It is cleared by software, writing 1 to the RTOCF bit in the USART_ICR register.

An interrupt is generated if RTOIE=1 in the USART_CR1 register.
In Smartcard mode, the timeout corresponds to the CWT or BWT timings.

0: Timeout value not reached
1: Timeout value reached without any data reception

*Note: If a time equal to the value programmed in RTOR register separates 2 characters, RTOF is not set. If this time exceeds this value + 2 sample times (2/16 or 2/8, depending on the oversampling method), RTOF flag is set.
The counter counts even if RE = 0 but RTOF is set only when RE = 1. If the timeout has already elapsed when RE is set, then RTOF is set.
If the USART does not support the Receiver timeout feature, this bit is reserved and kept at reset value.*

Bit 10 **CTS**: CTS flag
This bit is set/reset by hardware. It is an inverted copy of the status of the CTS input pin.
0: CTS line set
1: CTS line reset

*Note: If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.*
Bit 9  **CTSIF**: CTS interrupt flag

This bit is set by hardware when the CTS input toggles, if the CTSE bit is set. It is cleared by software, by writing 1 to the CTSCF bit in the USART_ICR register.

An interrupt is generated if CTSIE=1 in the USART_CR3 register.

0: No change occurred on the CTS status line
1: A change occurred on the CTS status line

*Note*: If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.

Bit 8  **LBDF**: LIN break detection flag

This bit is set by hardware when the LIN break is detected. It is cleared by software, by writing 1 to the LBDCF in the USART_ICR.

An interrupt is generated if LBDIE = 1 in the USART_CR2 register.

0: LIN Break not detected
1: LIN break detected

*Note*: If the USART does not support LIN mode, this bit is reserved and kept at reset value. Please refer to Section 27.4: USART implementation on page 702.

Bit 7  **TXE**: Transmit data register empty

This bit is set by hardware when the content of the USART_TDR register has been transferred into the shift register. It is cleared by a write to the USART_TDR register.

The TXE flag can also be cleared by writing 1 to the TXFRQ in the USART_RQR register, in order to discard the data (only in Smartcard T=0 mode, in case of transmission failure).

An interrupt is generated if the TXEIE bit =1 in the USART_CR1 register.

0: data is not transferred to the shift register
1: data is transferred to the shift register

*Note*: This bit is used during single buffer transmission.

Bit 6  **TC**: Transmission complete

This bit is set by hardware if the transmission of a frame containing data is complete and if TXE is set. An interrupt is generated if TCIE=1 in the USART_CR1 register. It is cleared by software, writing 1 to the TCCF in the USART_ICR register or by a write to the USART_TDR register.

An interrupt is generated if TCIE=1 in the USART_CR1 register.

0: Transmission is not complete
1: Transmission is complete

*Note*: If TE bit is reset and no transmission is on going, the TC bit is set immediately.

Bit 5  **RXNE**: Read data register not empty

This bit is set by hardware when the content of the RDR shift register has been transferred to the USART_RDR register. It is cleared by a read to the USART_RDR register. The RXNE flag can also be cleared by writing 1 to the RXFRQ in the USART_RQR register.

An interrupt is generated if RXNEIE=1 in the USART_CR1 register.

0: data is not received
1: Received data is ready to be read.
Bit 4 \textbf{IDLE}: Idle line detected
This bit is set by hardware when an Idle Line is detected. An interrupt is generated if \texttt{IDLEIE=1} in the \texttt{USART\_CR1} register. It is cleared by software, writing 1 to the \texttt{IDLECF} in the \texttt{USART\_ICR} register.

0: No Idle line is detected
1: Idle line is detected
\textit{Note: The IDLE bit will not be set again until the RXNE bit has been set (i.e. a new idle line occurs). If mute mode is enabled (MME=1), IDLE is set if the USART is not mute (RWU=0), whatever the mute mode selected by the WAKE bit. If RWU=1, IDLE is not set.}

Bit 3 \textbf{ORE}: Overrun error
This bit is set by hardware when the data currently being received in the shift register is ready to be transferred into the RDR register while RXNE=1. It is cleared by software, writing 1 to the \texttt{ORECF} in the \texttt{USART\_ICR} register.

An interrupt is generated if \texttt{RXNEIE=1} in the \texttt{USART\_CR1} register, or \texttt{EIE = 1} in the \texttt{USART\_CR3} register.

0: No overrun error
1: Overrun error is detected
\textit{Note: When this bit is set, the RDR register content is not lost but the shift register is overwritten. An interrupt is generated if the ORE flag is set during multibuffer communication if the EIE bit is set. This bit is permanently forced to 0 (no overrun detection) when the OVRDIS bit is set in the USART\_CR3 register.}

Bit 2 \textbf{NF}: START bit Noise detection flag
This bit is set by hardware when noise is detected on a received frame. It is cleared by software, writing 1 to the \texttt{NFCF} bit in the \texttt{USART\_ICR} register.

0: No noise is detected
1: Noise is detected
\textit{Note: This bit does not generate an interrupt as it appears at the same time as the RXNE bit which itself generates an interrupt. An interrupt is generated when the NF flag is set during multibuffer communication if the EIE bit is set.}
\textit{Note: When the line is noise-free, the NF flag can be disabled by programming the ONEBIT bit to 1 to increase the USART tolerance to deviations (Refer to Section 27.5.5: Tolerance of the USART receiver to clock deviation on page 718).}

Bit 1 \textbf{FE}: Framing error
This bit is set by hardware when a de-synchronization, excessive noise or a break character is detected. It is cleared by software, writing 1 to the \texttt{FECF} bit in the \texttt{USART\_ICR} register.
In Smartcard mode, in transmission, this bit is set when the maximum number of transmit attempts is reached without success (the card NACKs the data frame).
An interrupt is generated if \texttt{EIE = 1} in the \texttt{USART\_CR3} register.

0: No Framing error is detected
1: Framing error or break character is detected

Bit 0 \textbf{PE}: Parity error
This bit is set by hardware when a parity error occurs in receiver mode. It is cleared by software, writing 1 to the \texttt{PECF} in the \texttt{USART\_ICR} register.
An interrupt is generated if \texttt{PEIE = 1} in the \texttt{USART\_CR1} register.

0: No parity error
1: Parity error
27.8.9 USART interrupt flag clear register (USART_ICR)

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **WUCF**: Wake-up from Stop mode clear flag
Writing 1 to this bit clears the WUF flag in the USART_ISR register.

*Note: If the USART does not support the wake-up from Stop feature, this bit is reserved and must be kept at reset value.*

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **CMCF**: Character match clear flag
Writing 1 to this bit clears the CMF flag in the USART_ISR register.

Bits 16:13 Reserved, must be kept at reset value.

Bit 12 **EOBCF**: End of block clear flag
Writing 1 to this bit clears the EOBF flag in the USART_ISR register.

*Note: If the USART does not support Smartcard mode, this bit is reserved and must be kept at reset value. Please refer to Section 27.4: USART implementation on page 702.*

Bit 11 **RTOCF**: Receiver timeout clear flag
Writing 1 to this bit clears the RTOF flag in the USART_ISR register.

*Note: If the USART does not support the Receiver timeout feature, this bit is reserved and must be kept at reset value. Please refer to Section 27.4: USART implementation on page 702.*

Bit 10 Reserved, must be kept at reset value.

Bit 9 **CTSCF**: CTS clear flag
Writing 1 to this bit clears the CTSIF flag in the USART_ISR register.

*Note: If the hardware flow control feature is not supported, this bit is reserved and must be kept at reset value. Please refer to Section 27.4: USART implementation on page 702.*

Bit 8 **LBDCF**: LIN break detection clear flag
Writing 1 to this bit clears the LBDF flag in the USART_ISR register.

*Note: If LIN mode is not supported, this bit is reserved and must be kept at reset value. Please refer to Section 27.4: USART implementation on page 702.*

Bit 7 Reserved, must be kept at reset value.

Bit 6 **TCCF**: Transmission complete clear flag
Writing 1 to this bit clears the TC flag in the USART_ISR register.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **IDLECF**: Idle line detected clear flag
Writing 1 to this bit clears the IDLE flag in the USART_ISR register.
Bit 3 **ORECF**: Overrun error clear flag
Writing 1 to this bit clears the ORE flag in the USART_ISR register.

Bit 2 **NCF**: Noise detected clear flag
Writing 1 to this bit clears the NF flag in the USART_ISR register.

Bit 1 **FECF**: Framing error clear flag
Writing 1 to this bit clears the FE flag in the USART_ISR register.

Bit 0 **PECF**: Parity error clear flag
Writing 1 to this bit clears the PE flag in the USART_ISR register.

Bits 31:9 Reserved, must be kept at reset value.

Bits 8:0 TDR[8:0]: Transmit data value
Contains the data character to be transmitted.
The TDR register provides the parallel interface between the internal bus and the output
shift register (see Figure 248).
When transmitting with the parity enabled (PCE bit set to 1 in the USART_CR1 register),
the value written in the MSB (bit 7 or bit 8 depending on the data length) has no effect
because it is replaced by the parity.
Note: This register must be written only when TXE=1.

28 Serial peripheral interface / integrated interchip sound (SPI/I2S)

28.1 Introduction

The SPI/I²S interface can be used to communicate with external devices using the SPI protocol or the I²S audio protocol. SPI or I²S mode is selectable by software. SPI Motorola mode is selected by default after a device reset.

The serial peripheral interface (SPI) protocol supports half-duplex, full-duplex and simplex synchronous, serial communication with external devices. The interface can be configured as master and in this case it provides the communication clock (SCK) to the external slave device. The interface is also capable of operating in multimaster configuration.

The integrated interchip sound (I²S) protocol is also a synchronous serial communication interface. It can operate in slave or master mode with half-duplex communication. Full-duplex operations are possible by combining two I²S blocks. It can address four different audio standards including the Philips I²S standard, the MSB- and LSB-justified standards and the PCM standard.

28.2 SPI main features

- Master or slave operation
- Full-duplex synchronous transfers on three lines
- Half-duplex synchronous transfer on two lines (with bidirectional data line)
- Simplex synchronous transfers on two lines (with unidirectional data line)
- 4 to 16-bit data size selection
- Multimaster mode capability
- 8 master mode baud rate prescalers up to $f_{PCLK}/2$
- Slave mode frequency up to $f_{PCLK}$.
- NSS management by hardware or software for both master and slave: dynamic change of master/slave operations
- Programmable clock polarity and phase
- Programmable data order with MSB-first or LSB-first shifting
- Dedicated transmission and reception flags with interrupt capability
- SPI bus busy status flag
- SPI Motorola support
- Hardware CRC feature for reliable communication:
  - CRC value can be transmitted as last byte in Tx mode
  - Automatic CRC error checking for last received byte
- Master mode fault, overrun flags with interrupt capability
- CRC Error flag
- Two 32-bit embedded Rx and Tx FIFOs with DMA capability
- Enhanced TI and NSS pulse modes support
28.3 I2S main features

- Half-duplex communication (only transmitter or receiver)
- Master or slave operations
- 8-bit programmable linear prescaler to reach accurate audio sample frequencies (from 8 kHz to 192 kHz)
- Data format may be 16-bit, 24-bit or 32-bit
- Packet frame is fixed to 16-bit (16-bit data frame) or 32-bit (16-bit, 24-bit, 32-bit data frame) by audio channel
- Programmable clock polarity (steady state)
- Underrun flag in slave transmission mode, overrun flag in reception mode (master and slave) and Frame Error Flag in reception and transmitter mode (slave only)
- 16-bit register for transmission and reception with one data register for both channel sides
- Supported I²S protocols:
  - I²S Philips standard
  - MSB-justified standard (left-justified)
  - LSB-justified standard (right-justified)
  - PCM standard (with short and long frame synchronization on 16-bit channel frame or 16-bit data frame extended to 32-bit channel frame)
- Data direction is always MSB first
- DMA capability for transmission and reception (16-bit wide)
- Master clock can be output to drive an external audio component. The ratio is fixed at 256 × fₛ for all I2S modes, and to 128 × fₛ for all PCM modes (where fₛ is the audio sampling frequency).

28.5  SPI functional description

28.5.1  General description

The SPI allows synchronous, serial communication between the MCU and external devices. Application software can manage the communication by polling the status flag or using dedicated SPI interrupt. The main elements of SPI and their interactions are shown in the following block diagram Figure 273.

Figure 273. SPI block diagram

Four I/O pins are dedicated to SPI communication with external devices.

- **MISO**: Master In / Slave Out data. In the general case, this pin is used to transmit data in slave mode and receive data in master mode.
- **MOSI**: Master Out / Slave In data. In the general case, this pin is used to transmit data in master mode and receive data in slave mode.
- **SCK**: Serial Clock output pin for SPI masters and input pin for SPI slaves.
- **NSS**: Slave select pin. Depending on the SPI and NSS settings, this pin can be used to either:
  - select an individual slave device for communication
  - synchronize the data frame or
  - detect a conflict between multiple masters

See Section 28.5.5: Slave select (NSS) pin management for details.

The SPI bus allows the communication between one master device and one or more slave devices. The bus consists of at least two wires - one for the clock signal and the other for synchronous data transfer. Other signals can be added depending on the data exchange between SPI nodes and their slave select signal management.
28.5.2 Communications between one master and one slave

The SPI allows the MCU to communicate using different configurations, depending on the device targeted and the application requirements. These configurations use 2 or 3 wires (with software NSS management) or 3 or 4 wires (with hardware NSS management). Communication is always initiated by the master.

**Full-duplex communication**

By default, the SPI is configured for full-duplex communication. In this configuration, the shift registers of the master and slave are linked using two unidirectional lines between the MOSI and the MISO pins. During SPI communication, data is shifted synchronously on the SCK clock edges provided by the master. The master transmits the data to be sent to the slave via the MOSI line and receives data from the slave via the MISO line. When the data frame transfer is complete (all the bits are shifted) the information between the master and slave is exchanged.

**Figure 274. Full-duplex single master/ single slave application**

1. The NSS pins can be used to provide a hardware control flow between master and slave. Optionally, the pins can be left unused by the peripheral. Then the flow has to be handled internally for both master and slave. For more details see Section 28.5.5: Slave select (NSS) pin management.

**Half-duplex communication**

The SPI can communicate in half-duplex mode by setting the BIDIMODE bit in the SPIx_CR1 register. In this configuration, one single cross connection line is used to link the shift registers of the master and slave together. During this communication, the data is synchronously shifted between the shift registers on the SCK clock edge in the transfer direction selected reciprocally by both master and slave with the BDIOE bit in their SPIx_CR1 registers. In this configuration, the master’s MISO pin and the slave’s MOSI pin are free for other application uses and act as GPIOs.
1. The NSS pins can be used to provide a hardware control flow between master and slave. Optionally, the pins can be left unused by the peripheral. Then the flow has to be handled internally for both master and slave. For more details see Section 28.5.5: Slave select (NSS) pin management.

2. In this configuration, the master’s MISO pin and the slave’s MOSI pin can be used as GPIOs.

3. A critical situation can happen when communication direction is changed not synchronously between two nodes working at bidirectional mode and new transmitter accesses the common data line while former transmitter still keeps an opposite value on the line (the value depends on SPI configuration and communication data). Both nodes then fight while providing opposite output levels on the common line temporary till next node changes its direction settings correspondingly, too. It is suggested to insert a serial resistance between MISO and MOSI pins at this mode to protect the outputs and limit the current blowing between them at this situation.

Simplex communications

The SPI can communicate in simplex mode by setting the SPI in transmit-only or in receive-only using the RXONLY bit in the SPIx_CR1 register. In this configuration, only one line is used for the transfer between the shift registers of the master and slave. The remaining MISO and MOSI pins pair is not used for communication and can be used as standard GPIOs.

- **Transmit-only mode (RXONLY=0)**: The configuration settings are the same as for full-duplex. The application has to ignore the information captured on the unused input pin. This pin can be used as a standard GPIO.

- **Receive-only mode (RXONLY=1)**: The application can disable the SPI output function by setting the RXONLY bit. In slave configuration, the MISO output is disabled and the pin can be used as a GPIO. The slave continues to receive data from the MOSI pin while its slave select signal is active (see 28.5.5: Slave select (NSS) pin management). Received data events appear depending on the data buffer configuration. In the master configuration, the MOSI output is disabled and the pin can be used as a GPIO. The clock signal is generated continuously as long as the SPI is enabled. The only way to stop the clock is to clear the RXONLY bit or the SPE bit and wait until the incoming pattern from the MISO pin is finished and fills the data buffer structure, depending on its configuration.
1. The NSS pins can be used to provide a hardware control flow between master and slave. Optionally, the pins can be left unused by the peripheral. Then the flow has to be handled internally for both master and slave. For more details see Section 28.5.5: Slave select (NSS) pin management.

2. An accidental input information is captured at the input of transmitter Rx shift register. All the events associated with the transmitter receive flow must be ignored in standard transmit only mode (e.g. OVR flag).

3. In this configuration, both the MISO pins can be used as GPIOs.

**Note:** Any simplex communication can be alternatively replaced by a variant of the half-duplex communication with a constant setting of the transaction direction (bidirectional mode is enabled while BDIO bit is not changed).

### 28.5.3 Standard multi-slave communication

In a configuration with two or more independent slaves, the master uses GPIO pins to manage the chip select lines for each slave (see Figure 277). The master must select one of the slaves individually by pulling low the GPIO connected to the slave NSS input. When this is done, a standard master and dedicated slave communication is established.
Figure 277. Master and three independent slaves

1. NSS pin is not used on master side at this configuration. It has to be managed internally (SSM=1, SSI=1) to prevent any MODF error.

2. As MISO pins of the slaves are connected together, all slaves must have the GPIO configuration of their MISO pin set as alternate function open-drain (see I/O alternate function input/output section (GPIO)).

28.5.4 Multi-master communication

Unless SPI bus is not designed for a multi-master capability primarily, the user can use build in feature which detects a potential conflict between two nodes trying to master the bus at the same time. For this detection, NSS pin is used configured at hardware input mode.

The connection of more than two SPI nodes working at this mode is impossible as only one node can apply its output on a common data line at time.

When nodes are non active, both stay at slave mode by default. Once one node wants to overtake control on the bus, it switches itself into master mode and applies active level on the slave select input of the other node via dedicated GPIO pin. After the session is completed, the active slave select signal is released and the node mastering the bus temporary returns back to passive slave mode waiting for next session start.
If potentially both nodes raised their mastering request at the same time a bus conflict event appears (see mode fault MODF event). Then the user can apply some simple arbitration process (e.g. to postpone next attempt by predefined different time-outs applied at both nodes).

**Figure 278. Multi-master application**

1. The NSS pin is configured at hardware input mode at both nodes. Its active level enables the MISO line output control as the passive node is configured as a slave.

### 28.5.5 Slave select (NSS) pin management

In slave mode, the NSS works as a standard “chip select” input and lets the slave communicate with the master. In master mode, NSS can be used either as output or input. As an input it can prevent multimaster bus collision, and as an output it can drive a slave select signal of a single slave.

Hardware or software slave select management can be set using the SSM bit in the SPIx_CR1 register:

- **Software NSS management (SSM = 1):** in this configuration, slave select information is driven internally by the SSI bit value in register SPIx_CR1. The external NSS pin is free for other application uses.

- **Hardware NSS management (SSM = 0):** in this case, there are two possible configurations. The configuration used depends on the NSS output configuration (SSOE bit in register SPIx_CR1).
  - **NSS output enable (SSM=0, SSOE = 1):** this configuration is only used when the MCU is set as master. The NSS pin is managed by the hardware. The NSS signal is driven low as soon as the SPI is enabled in master mode (SPE=1), and is kept low until the SPI is disabled (SPE =0). A pulse can be generated between continuous communications if NSS pulse mode is activated (NSSP=1). The SPI cannot work in multimaster configuration with this NSS setting.
  - **NSS output disable (SSM=0, SSOE = 0):** if the microcontroller is acting as the master on the bus, this configuration allows multimaster capability. If the NSS pin is pulled low in this mode, the SPI enters master mode fault state and the device is automatically reconfigured in slave mode. In slave mode, the NSS pin works as a standard “chip select” input and the slave is selected while NSS line is at low level.
28.5.6 Communication formats

During SPI communication, receive and transmit operations are performed simultaneously. The serial clock (SCK) synchronizes the shifting and sampling of the information on the data lines. The communication format depends on the clock phase, the clock polarity and the data frame format. To be able to communicate together, the master and slaves devices must follow the same communication format.

Clock phase and polarity controls

Four possible timing relationships may be chosen by software, using the CPOL and CPHA bits in the SPIx_CR1 register. The CPOL (clock polarity) bit controls the idle state value of the clock when no data is being transferred. This bit affects both master and slave modes. If CPOL is reset, the SCK pin has a low-level idle state. If CPOL is set, the SCK pin has a high-level idle state.

If the CPHA bit is set, the second edge on the SCK pin captures the first data bit transacted (falling edge if the CPOL bit is reset, rising edge if the CPOL bit is set). Data are latched on each occurrence of this clock transition type. If the CPHA bit is reset, the first edge on the SCK pin captures the first data bit transacted (falling edge if the CPOL bit is set, rising edge if the CPOL bit is reset). Data are latched on each occurrence of this clock transition type.

The combination of CPOL (clock polarity) and CPHA (clock phase) bits selects the data capture clock edge.
Figure 280, shows an SPI full-duplex transfer with the four combinations of the CPHA and CPOL bits.

Note: Prior to changing the CPOL/CPHA bits the SPI must be disabled by resetting the SPE bit. The idle state of SCK must correspond to the polarity selected in the SPIx_CR1 register (by pulling up SCK if CPOL=1 or pulling down SCK if CPOL=0).

**Data frame format**

The SPI shift register can be set up to shift out MSB-first or LSB-first, depending on the value of the LSBFIRST bit. The data frame size is chosen by using the DS bits. It can be set from 4-bit up to 16-bit length and the setting applies for both transmission and reception. Whatever the selected data frame size, read access to the FIFO must be aligned with the FRXTH level. When the SPIx_DR register is accessed, data frames are always right-aligned into either a byte (if the data fits into a byte) or a half-word (see Figure 281). During communication, only bits within the data frame are clocked and transferred.
**28.5.7 Configuration of SPI**

The configuration procedure is almost the same for master and slave. For specific mode setups, follow the dedicated sections. When a standard communication is to be initialized, perform these steps:

1. Write proper GPIO registers: Configure GPIO for MOSI, MISO and SCK pins.
2. Write to the SPI_CR1 register:
   a) Configure the serial clock baud rate using the BR[2:0] bits (Note: 4).
   b) Configure the CPOL and CPHA bits combination to define one of the four relationships between the data transfer and the serial clock (CPHA must be cleared in NSSP mode). (Note: 2 - except the case when CRC is enabled at TI mode).
   c) Select simplex or half-duplex mode by configuring RXONLY or BIDIMODE and BIDIOE (RXONLY and BIDIMODE cannot be set at the same time).
   d) Configure the LSBFIRST bit to define the frame format (Note: 2).
   e) Configure the CRCL and CRCEN bits if CRC is needed (while SCK clock signal is at idle state).
   f) Configure SSM and SSI (Notes: 2 & 3).
   g) Configure the MSTR bit (in multimaster NSS configuration, avoid conflict state on NSS if master is configured to prevent MODF error).
3. Write to SPI_CR2 register:
   a) Configure the DS[3:0] bits to select the data length for the transfer.
   b) Configure SSOE (Notes: 1 & 2 & 3).
   c) Set the FRF bit if the TI protocol is required (keep NSSP bit cleared in TI mode).
   d) Set the NSSP bit if the NSS pulse mode between two data units is required (keep CHPA and TI bits cleared in NSSP mode).
   e) Configure the FRXTH bit. The RXFIFO threshold must be aligned to the read access size for the SPIx_DR register.
   f) Initialize LDMA_TX and LDMA_RX bits if DMA is used in packed mode.
4. Write to SPI_CRCPR register: Configure the CRC polynomial if needed.
5. Write proper DMA registers: Configure DMA streams dedicated for SPI Tx and Rx in DMA registers if the DMA streams are used.

**Note:** The minimum data length is 4 bits. If a data length of less than 4 bits is selected, it is forced to an 8-bit data frame size.

![Data alignment when data length is not equal to 8-bit or 16-bit](MS19589V2)
**Note:**

1. Step is not required in slave mode.
2. Step is not required in TI mode.
3. Step is not required in NSSP mode.
4. The step is not required in slave mode except slave working at TI mode.

For code example refer to the Appendix sections A.17.1: SPI master configuration code example and A.17.2: SPI slave configuration code example.

### 28.5.8 Procedure for enabling SPI

It is recommended to enable the SPI slave before the master sends the clock. If not, undesired data transmission might occur. The data register of the slave must already contain data to be sent before starting communication with the master (either on the first edge of the communication clock, or before the end of the ongoing communication if the clock signal is continuous). The SCK signal must be settled at an idle state level corresponding to the selected polarity before the SPI slave is enabled.

The master at full-duplex (or in any transmit-only mode) starts to communicate when the SPI is enabled and TXFIFO is not empty, or with the next write to TXFIFO.

In any master receive only mode (RXONLY=1 or BIDIMODE=1 & BIDOIE=0), master starts to communicate and the clock starts running immediately after SPI is enabled.

For handling DMA, follow the dedicated section.

### 28.5.9 Data transmission and reception procedures

#### RXFIFO and TXFIFO

All SPI data transactions pass through the 32-bit embedded FIFOs. This enables the SPI to work in a continuous flow, and prevents overruns when the data frame size is short. Each direction has its own FIFO called TXFIFO and RXFIFO. These FIFOs are used in all SPI modes except for receiver-only mode (slave or master) with CRC calculation enabled (see Section 28.5.14: CRC calculation).

The handling of FIFOs depends on the data exchange mode (duplex, simplex), data frame format (number of bits in the frame), access size performed on the FIFO data registers (8-bit or 16-bit), and whether or not data packing is used when accessing the FIFOs (see Section 28.5.13: TI mode).

A read access to the SPIx_DR register returns the oldest value stored in RXFIFO that has not been read yet. A write access to the SPIx_DR stores the written data in the TXFIFO at the end of a send queue. The read access must be always aligned with the RXFIFO threshold configured by the FRXTH bit in SPIx_CR2 register. FTLVL[1:0] and FRLVL[1:0] bits indicate the current occupancy level of both FIFOs.

A read access to the SPIx_DR register must be managed by the RXNE event. This event is triggered when data is stored in RXFIFO and the threshold (defined by FRXTH bit) is reached. When RXNE is cleared, RXFIFO is considered to be empty. In a similar way, write access of a data frame to be transmitted is managed by the TXE event. This event is triggered when the TXFIFO level is less than or equal to half of its capacity. Otherwise TXE is cleared and the TXFIFO is considered as full. In this way, RXFIFO can store up to four data frames, whereas TXFIFO can only store up to three when the data frame format is not greater than 8 bits. This difference prevents possible corruption of 3x 8-bit data frames already stored in the TXFIFO when software tries to write more data in 16-bit mode into
TXFIFO. Both TXE and RXNE events can be polled or handled by interrupts. See Figure 283 through Figure 286.

Another way to manage the data exchange is to use DMA (see Communication using DMA (direct memory addressing)).

If the next data is received when the RXFIFO is full, an overrun event occurs (see description of OVR flag at Section 28.5.10: SPI status flags). An overrun event can be polled or handled by an interrupt.

The BSY bit being set indicates ongoing transaction of a current data frame. When the clock signal runs continuously, the BSY flag stays set between data frames at master but becomes low for a minimum duration of one SPI clock at slave between each data frame transfer.

**Sequence handling**

A few data frames can be passed at single sequence to complete a message. When transmission is enabled, a sequence begins and continues while any data is present in the TXFIFO of the master. The clock signal is provided continuously by the master until TXFIFO becomes empty, then it stops waiting for additional data.

In receive-only modes, half-duplex (BIDIMODE=1, BIDIOE=0) or simplex (BIDIMODE=0, RXONLY=1) the master starts the sequence immediately when both SPI is enabled and receive-only mode is activated. The clock signal is provided by the master and it does not stop until either SPI or receive-only mode is disabled by the master. The master receives data frames continuously up to this moment.

While the master can provide all the transactions in continuous mode (SCK signal is continuous) it has to respect slave capability to handle data flow and its content at anytime. When necessary, the master must slow down the communication and provide either a slower clock or separate frames or data sessions with sufficient delays. Be aware there is no underflow error signal for master or slave in SPI mode, and data from the slave is always transacted and processed by the master even if the slave could not prepare it correctly in time. It is preferable for the slave to use DMA, especially when data frames are shorter and bus rate is high.

Each sequence must be encased by the NSS pulse in parallel with the multislave system to select just one of the slaves for communication. In a single slave system it is not necessary to control the slave with NSS, but it is often better to provide the pulse here too, to synchronize the slave with the beginning of each data sequence. NSS can be managed by both software and hardware (see Section 28.5.5: Slave select (NSS) pin management).

When the BSY bit is set it signifies an ongoing data frame transaction. When the dedicated frame transaction is finished, the RXNE flag is raised. The last bit is just sampled and the complete data frame is stored in the RXFIFO.

**Procedure for disabling the SPI**

When SPI is disabled, it is mandatory to follow the disable procedures described in this paragraph. It is important to do this before the system enters a low-power mode when the peripheral clock is stopped. Ongoing transactions can be corrupted in this case. In some modes the disable procedure is the only way to stop continuous communication running.

Master in full-duplex or transmit only mode can finish any transaction when it stops providing data for transmission. In this case, the clock stops after the last data transaction. Special care must be taken in packing mode when an odd number of data frames are
transacted to prevent some dummy byte exchange (refer to Data packing section). Before the SPI is disabled in these modes, the user must follow standard disable procedure. When the SPI is disabled at the master transmitter while a frame transaction is ongoing or next data frame is stored in TXFIFO, the SPI behavior is not guaranteed.

When the master is in any receive only mode, the only way to stop the continuous clock is to disable the peripheral by SPE=0. This must occur in specific time window within last data frame transaction just between the sampling time of its first bit and before its last bit transfer starts (in order to receive a complete number of expected data frames and to prevent any additional “dummy” data reading after the last valid data frame). Specific procedure must be followed when disabling SPI in this mode.

Data received but not read remains stored in RXFIFO when the SPI is disabled, and must be processed the next time the SPI is enabled, before starting a new sequence. To prevent having unread data, ensure that RXFIFO is empty when disabling the SPI, by using the correct disabling procedure, or by initializing all the SPI registers with a software reset via the control of a specific register dedicated to peripheral reset (see the SPIiRST bits in the RCC_APB1RSTR registers).

Standard disable procedure is based on pulling BSY status together with FTLVL[1:0] to check if a transmission session is fully completed. This check can be done in specific cases, too, when it is necessary to identify the end of ongoing transactions, for example:

- When NSS signal is managed by software and master has to provide proper end of NSS pulse for slave, or
- When transactions’ streams from DMA or FIFO are completed while the last data frame or CRC frame transaction is still ongoing in the peripheral bus.

The correct disable procedure is (except when receive only mode is used):
1. Wait until FTLVL[1:0] = 00 (no more data to transmit).
2. Wait until BSY=0 (the last data frame is processed).
3. Disable the SPI (SPE=0).
4. Read data until FRLVL[1:0] = 00 (read all the received data).

The correct disable procedure for certain receive only modes is:
1. Interrupt the receive flow by disabling SPI (SPE=0) in the specific time window while the last data frame is ongoing.
2. Wait until BSY=0 (the last data frame is processed).
3. Read data until FRLVL[1:0] = 00 (read all the received data).

Note: If packing mode is used and an odd number of data frames with a format less than or equal to 8 bits (fitting into one byte) has to be received, FRXTH must be set when FRLVL[1:0] = 01, in order to generate the RXNE event to read the last odd data frame and to keep good FIFO pointer alignment.

**Data packing**

When the data frame size fits into one byte (less than or equal to 8 bits), data packing is used automatically when any read or write 16-bit access is performed on the SPIx_DR register. The double data frame pattern is handled in parallel in this case. At first, the SPI operates using the pattern stored in the LSB of the accessed word, then with the other half stored in the MSB. Figure 282 provides an example of data packing mode sequence handling. Two data frames are sent after the single 16-bit access the SPIx_DR register of the transmitter. This sequence can generate just one RXNE event in the receiver if the
RXFIFO threshold is set to 16 bits (FRXTH=0). The receiver then has to access both data frames by a single 16-bit read of SPIx_DR as a response to this single RXNE event. The RxFIFO threshold setting and the following read access must be always kept aligned at the receiver side, as data can be lost if it is not in line.

A specific problem appears if an odd number of such “fit into one byte” data frames must be handled. On the transmitter side, writing the last data frame of any odd sequence with an 8-bit access to SPIx_DR is enough. The receiver has to change the Rx_FIFO threshold level for the last data frame received in the odd sequence of frames in order to generate the RXNE event.

**Figure 282. Packing data in FIFO for transmission and reception**

1. In this example: Data size DS[3:0] is 4-bit configured, CPOL=0, CPHA=1 and LSBFIRST =0. The Data storage is always right aligned while the valid bits are performed on the bus only, the content of LSB byte goes first on the bus, the unused bits are not taken into account on the transmitter side and padded by zeros at the receiver side.

**Communication using DMA (direct memory addressing)**

To operate at its maximum speed and to facilitate the data register read/write process required to avoid overrun, the SPI features a DMA capability, which implements a simple request/acknowledge protocol.

A DMA access is requested when the TXDMAEN or RXDMAEN enable bit in the SPIx_CR2 register is set. Separate requests must be issued to the Tx and Rx buffers.

- In transmission, a DMA request is issued each time TXE is set to 1. The DMA then writes to the SPIx_DR register.
- In reception, a DMA request is issued each time RXNE is set to 1. The DMA then reads the SPIx_DR register.

See Figure 283 through Figure 286.

When the SPI is used only to transmit data, it is possible to enable only the SPI Tx DMA channel. In this case, the OVR flag is set because the data received is not read. When the SPI is used only to receive data, it is possible to enable only the SPI Rx DMA channel.

In transmission mode, when the DMA has written all the data to be transmitted (the TCIF flag is set in the DMA_ISR register), the BSY flag can be monitored to ensure that the SPI communication is complete. This is required to avoid corrupting the last transmission before disabling the SPI or entering the Stop mode. The software must first wait until FTLVL[1:0]=00 and then until BSY=0.
When starting communication using DMA, to prevent DMA channel management raising error events, these steps must be followed in order:

1. Enable DMA Rx buffer in the RXDMAEN bit in the SPI_CR2 register, if DMA Rx is used.
2. Enable DMA streams for Tx and Rx in DMA registers, if the streams are used.
3. Enable DMA Tx buffer in the TXDMAEN bit in the SPI_CR2 register, if DMA Tx is used.
4. Enable the SPI by setting the SPE bit.

For code example refer to the Appendix sections A.17.5: SPI master configuration with DMA code example and A.17.6: SPI slave configuration with DMA code example.

To close communication it is mandatory to follow these steps in order:

1. Disable DMA streams for Tx and Rx in the DMA registers, if the streams are used.
2. Disable the SPI by following the SPI disable procedure.
3. Disable DMA Tx and Rx buffers by clearing the TXDMAEN and RXDMAEN bits in the SPI_CR2 register, if DMA Tx and/or DMA Rx are used.

**Packing with DMA**

If the transfers are managed by DMA (TXDMAEN and RXDMAEN set in the SPIx_CR2 register) packing mode is enabled/disabled automatically depending on the PSIZE value configured for SPI TX and the SPI RX DMA channel. If the DMA channel PSIZE value is equal to 16-bit and SPI data size is less than or equal to 8-bit, then packing mode is enabled. The DMA then automatically manages the write operations to the SPIx_DR register.

If data packing mode is used and the number of data to transfer is not a multiple of two, the LDMA_TX/LDMA_RX bits must be set. The SPI then considers only one data for the transmission or reception to serve the last DMA transfer (for more details refer to Data packing on page 780.)
Communication diagrams

Some typical timing schemes are explained in this section. These schemes are valid no matter if the SPI events are handled by polling, interrupts or DMA. For simplicity, the LSBFIRST=0, CPOL=0 and CPHA=1 setting is used as a common assumption here. No complete configuration of DMA streams is provided.

The following numbered notes are common for Figure 283 on page 784 through Figure 286 on page 787:

1. The slave starts to control MISO line as NSS is active and SPI is enabled, and is disconnected from the line when one of them is released. Sufficient time must be provided for the slave to prepare data dedicated to the master in advance before its transaction starts.
   At the master, the SPI peripheral takes control at MOSI and SCK signals (occasionally at NSS signal as well) only if SPI is enabled. If SPI is disabled the SPI peripheral is disconnected from GPIO logic, so the levels at these lines depends on GPIO setting exclusively.

2. At the master, BSY stays active between frames if the communication (clock signal) is continuous. At the slave, BSY signal always goes down for at least one clock cycle between data frames.

3. The TXE signal is cleared only if TXFIFO is full.

4. The DMA arbitration process starts just after the TXDMAEN bit is set. The TXE interrupt is generated just after the TXEIE is set. As the TXE signal is at an active level, data transfers to TxFIFO start, until TxFIFO becomes full or the DMA transfer completes.

5. If all the data to be sent can fit into TxFIFO, the DMA Tx TCIF flag can be raised even before communication on the SPI bus starts. This flag always rises before the SPI transaction is completed.

6. The CRC value for a package is calculated continuously frame by frame in the SPIx_TXCRCR and SPIx_RXCRCR registers. The CRC information is processed after the entire data package has completed, either automatically by DMA (Tx channel must be set to the number of data frames to be processed) or by SW (the user must handle CRCNEXT bit during the last data frame processing).
   While the CRC value calculated in SPIx_TXCRCR is simply sent out by transmitter, received CRC information is loaded into RxFIFO and then compared with the SPIx_RXCRCR register content (CRC error flag can be raised here if any difference). This is why the user must take care to flush this information from the FIFO, either by software reading out all the stored content of RxFIFO, or by DMA when the proper number of data frames is preset for Rx channel (number of data frames + number of CRC frames) (see the settings at the example assumption).

7. In data packed mode, TxE and RxNE events are paired and each read/write access to the FIFO is 16 bits wide until the number of data frames are even. If the TxFIFO is ¾ full FTLVL status stays at FIFO full level. That is why the last odd data frame cannot be stored before the TxFIFO becomes ½ full. This frame is stored into TxFIFO with an 8-bit access either by software or automatically by DMA when LDMA_TX control is set.

8. To receive the last odd data frame in packed mode, the Rx threshold must be changed to 8-bit when the last data frame is processed, either by software setting FRXTH=1 or automatically by a DMA internal signal when LDMA_RX is set.
Figure 283. Master full-duplex communication

Assumptions for master full-duplex communication example:
- Data size > 8 bit

If DMA is used:
- Number of Tx frames transacted by DMA is set to 3
- Number of Rx frames transacted by DMA is set to 3

See also: Communication diagrams on page 783 for details about common assumptions and notes.
Assumptions for slave full-duplex communication example:

- Data size > 8 bit

If DMA is used:
- Number of Tx frames transacted by DMA is set to 3
- Number of Rx frames transacted by DMA is set to 3

See also Communication diagrams on page 783 for details about common assumptions and notes.

For code example refer to the Appendix section A.17.3: SPI full duplex communication code example.
Assumptions for master full-duplex communication with CRC example:

- Data size = 16 bit
- CRC enabled

If DMA is used:

- Number of Tx frames transacted by DMA is set to 2
- Number of Rx frames transacted by DMA is set to 3

See also: Communication diagrams on page 783 for details about common assumptions and notes.
Assumptions for master full-duplex communication in packed mode example:

- Data size = 5 bit
- Read/write FIFO is performed mostly by 16-bit access
- FRXTH=0

If DMA is used:

- Number of Tx frames to be transacted by DMA is set to 3
- Number of Rx frames to be transacted by DMA is set to 3
- PSIZE for both Tx and Rx DMA channel is set to 16-bit
- LDMA_TX=1 and LDMA_RX=1

See also: Communication diagrams on page 783 for details about common assumptions and notes.
28.5.10 SPI status flags

Three status flags are provided for the application to completely monitor the state of the SPI bus.

**Tx buffer empty flag (TXE)**

The TXE flag is set when transmission TXFIFO has enough space to store data to send. TXE flag is linked to the TXFIFO level. The flag goes high and stays high until the TXFIFO level is lower or equal to 1/2 of the FIFO depth. An interrupt can be generated if the TXEIE bit in the SPIx_CR2 register is set. The bit is cleared automatically when the TXFIFO level becomes greater than 1/2.

**Rx buffer not empty (RXNE)**

The RXNE flag is set depending on the FRXTH bit value in the SPIx_CR2 register:

- If FRXTH is set, RXNE goes high and stays high until the RXFIFO level is greater or equal to 1/4 (8-bit).
- If FRXTH is cleared, RXNE goes high and stays high until the RXFIFO level is greater than or equal to 1/2 (16-bit).

An interrupt can be generated if the RXNEIE bit in the SPIx_CR2 register is set. The RXNE is cleared by hardware automatically when the above conditions are no longer true.

**Busy flag (BSY)**

The BSY flag is set and cleared by hardware (writing to this flag has no effect).

When BSY is set, it indicates that a data transfer is in progress on the SPI (the SPI bus is busy).

The BSY flag can be used in certain modes to detect the end of a transfer so that the software can disable the SPI or its peripheral clock before entering a low-power mode which does not provide a clock for the peripheral. This avoids corrupting the last transfer.

The BSY flag is also useful for preventing write collisions in a multimaster system.

The BSY flag is cleared under any one of the following conditions:

- When the SPI is correctly disabled
- When a fault is detected in Master mode (MODF bit set to 1)
- In Master mode, when it finishes a data transmission and no new data is ready to be sent
- In Slave mode, when the BSY flag is set to '0' for at least one SPI clock cycle between each data transfer.

**Note:** When the next transmission can be handled immediately by the master (e.g. if the master is in Receive-only mode or its Transmit FIFO is not empty), communication is continuous and the BSY flag remains set to '1' between transfers on the master side. Although this is not the case with a slave, it is recommended to use always the TXE and RXNE flags (instead of the BSY flags) to handle data transmission or reception operations.
28.5.11 SPI error flags

An SPI interrupt is generated if one of the following error flags is set and interrupt is enabled by setting the ERRIE bit.

Overrun flag (OVR)

An overrun condition occurs when data is received by a master or slave and the RXFIFO has not enough space to store this received data. This can happen if the software or the DMA did not have enough time to read the previously received data (stored in the RXFIFO) or when space for data storage is limited e.g. the RXFIFO is not available when CRC is enabled in receive only mode so in this case the reception buffer is limited into a single data frame buffer (see Section 28.5.14: CRC calculation).

When an overrun condition occurs, the newly received value does not overwrite the previous one in the RXFIFO. The newly received value is discarded and all data transmitted subsequently is lost. Clearing the OVR bit is done by a read access to the SPI_DR register followed by a read access to the SPI_SR register.

Mode fault (MODF)

Mode fault occurs when the master device has its internal NSS signal (NSS pin in NSS hardware mode, or SSI bit in NSS software mode) pulled low. This automatically sets the MODF bit. Master mode fault affects the SPI interface in the following ways:

- The MODF bit is set and an SPI interrupt is generated if the ERRIE bit is set.
- The SPE bit is cleared. This blocks all output from the device and disables the SPI interface.
- The MSTR bit is cleared, thus forcing the device into slave mode.

Use the following software sequence to clear the MODF bit:
1. Make a read or write access to the SPIx_SR register while the MODF bit is set.
2. Then write to the SPIx_CR1 register.

To avoid any multiple slave conflicts in a system comprising several MCUs, the NSS pin must be pulled high during the MODF bit clearing sequence. The SPE and MSTR bits can be restored to their original state after this clearing sequence. As a security, hardware does not allow the SPE and MSTR bits to be set while the MODF bit is set. In a slave device the MODF bit cannot be set except as the result of a previous multimaster conflict.

CRC error (CRCERR)

This flag is used to verify the validity of the value received when the CRCEN bit in the SPIx_CR1 register is set. The CRCERR flag in the SPIx_SR register is set if the value received in the shift register does not match the receiver SPIx_RXCRCR value. The flag is cleared by the software.

TI mode frame format error (FRE)

A TI mode frame format error is detected when an NSS pulse occurs during an ongoing communication when the SPI is operating in slave mode and configured to conform to the TI mode protocol. When this error occurs, the FRE flag is set in the SPIx_SR register. The SPI is not disabled when an error occurs, the NSS pulse is ignored, and the SPI waits for the next NSS pulse before starting a new transfer. The data may be corrupted since the error detection may result in the loss of two data bytes.
The FRE flag is cleared when SPIx_SR register is read. If the ERRIE bit is set, an interrupt is generated on the NSS error detection. In this case, the SPI should be disabled because data consistency is no longer guaranteed and communications should be reinitiated by the master when the slave SPI is enabled again.

### 28.5.12 NSS pulse mode

This mode is activated by the NSSP bit in the SPIx_CR2 register and it takes effect only if the SPI interface is configured as Motorola SPI master (FRF=0) with capture on the first edge (SPIx_CR1 CPHA = 0, CPOL setting is ignored). When activated, an NSS pulse is generated between two consecutive data frame transfers when NSS stays at high level for the duration of one clock period at least. This mode allows the slave to latch data. NSSP pulse mode is designed for applications with a single master-slave pair.

*Figure 287* illustrates NSS pin management when NSSP pulse mode is enabled.

*Figure 287. NSSP pulse generation in Motorola SPI master mode*

<table>
<thead>
<tr>
<th>Master continuous transfer (CPOL = 1; CPHA = 0; NSSP= 1)</th>

</thead>
<tbody>
<tr>
<td>NSS output</td>
</tr>
<tr>
<td>SCK output</td>
</tr>
<tr>
<td>MOSI output</td>
</tr>
<tr>
<td>MISO input</td>
</tr>
</tbody>
</table>

Note: Similar behavior is encountered when CPOL = 0. In this case the sampling edge is the *rising* edge of SCK, and NSS assertion and deassertion refer to this sampling edge.

### 28.5.13 TI mode

**TI protocol in master mode**

The SPI interface is compatible with the TI protocol. The FRF bit of the SPIx_CR2 register can be used to configure the SPI to be compliant with this protocol.

The clock polarity and phase are forced to conform to the TI protocol requirements whatever the values set in the SPIx_CR1 register. NSS management is also specific to the TI protocol which makes the configuration of NSS management through the SPIx_CR1 and SPIx_CR2 registers (SSM, SSI, SSOE) impossible in this case.

In slave mode, the SPI baud rate prescaler is used to control the moment when the MISO pin state changes to HiZ when the current transaction finishes (see *Figure 288*). Any baud rate can be used, making it possible to determine this moment with optimal flexibility. However, the baud rate is generally set to the external master clock baud rate. The delay for the MISO signal to become HiZ (t\textsubscript{release}) depends on internal resynchronization and on the...
baud rate value set in through the BR[2:0] bits in the SPIx_CR1 register. It is given by the formula:

\[
\frac{t_{\text{baud rate}}}{2} + 4 \times t_{\text{pclk}} < t_{\text{release}} < \frac{t_{\text{baud rate}}}{2} + 6 \times t_{\text{pclk}}
\]

If the slave detects a misplaced NSS pulse during a data frame transaction the TIFRE flag is set.

If the data size is equal to 4-bits or 5-bits, the master in full-duplex mode or transmit-only mode uses a protocol with one more dummy data bit added after LSB. TI NSS pulse is generated above this dummy bit clock cycle instead of the LSB in each period.

This feature is not available for Motorola SPI communications (FRF bit set to 0).

*Figura 288: TI mode transfer* shows the SPI communication waveforms when TI mode is selected.

**Figure 288. TI mode transfer**

28.5.14 CRC calculation

Two separate CRC calculators are implemented in order to check the reliability of transmitted and received data. The SPI offers CRC8 or CRC16 calculation independently of the frame data length, which can be fixed to 8-bit or 16-bit. For all the other data frame lengths, no CRC is available.

**CRC principle**

CRC calculation is enabled by setting the CRCEN bit in the SPIx_CR1 register before the SPI is enabled (SPE = 1). The CRC value is calculated using an odd programmable polynomial on each bit. The calculation is processed on the sampling clock edge defined by the CPHA and CPOL bits in the SPIx_CR1 register. The calculated CRC value is checked automatically at the end of the data block as well as for transfer managed by CPU or by the DMA. When a mismatch is detected between the CRC calculated internally on the received data and the CRC sent by the transmitter, a CRCERR flag is set to indicate a data corruption error. The right procedure for handling the CRC calculation depends on the SPI configuration and the chosen transfer management.
**Note:** The polynomial value should only be odd. No even values are supported.

**CRC transfer managed by CPU**

Communication starts and continues normally until the last data frame has to be sent or received in the SPIx_DR register. Then CRCNEXT bit has to be set in the SPIx_CR1 register to indicate that the CRC frame transaction follows after the transaction of the currently processed data frame. The CRCNEXT bit must be set before the end of the last data frame transaction. CRC calculation is frozen during CRC transaction.

The received CRC is stored in the RXFIFO like a data byte or word. That is why in CRC mode only, the reception buffer has to be considered as a single 16-bit buffer used to receive only one data frame at a time.

A CRC-format transaction usually takes one more data frame to communicate at the end of data sequence. However, when setting an 8-bit data frame checked by 16-bit CRC, two more frames are necessary to send the complete CRC.

When the last CRC data is received, an automatic check is performed comparing the received value and the value in the SPIx_RXCRC register. Software has to check the CRCERR flag in the SPIx_SR register to determine if the data transfers were corrupted or not. Software clears the CRCERR flag by writing ‘0’ to it.

After the CRC reception, the CRC value is stored in the RXFIFO and must be read in the SPIx_DR register in order to clear the RXNE flag.

**CRC transfer managed by DMA**

When SPI communication is enabled with CRC communication and DMA mode, the transmission and reception of the CRC at the end of communication is automatic (with the exception of reading CRC data in receive only mode). The CRCNEXT bit does not have to be handled by the software. The counter for the SPI transmission DMA channel has to be set to the number of data frames to transmit excluding the CRC frame. On the receiver side, the received CRC value is handled automatically by DMA at the end of the transaction but user must take care to flush out received CRC information from RXFIFO as it is always loaded into it. In full-duplex mode, the counter of the reception DMA channel can be set to the number of data frames to receive including the CRC, which means, for example, in the specific case of an 8-bit data frame checked by 16-bit CRC:

\[
\text{DMA}_\text{RX} = \text{Numb}\_\text{of}\_\text{data} + 2
\]

In receive only mode, the DMA reception channel counter should contain only the amount of data transferred, excluding the CRC calculation. Then based on the complete transfer from DMA, all the CRC values must be read back by software from FIFO as it works as a single buffer in this mode.

At the end of the data and CRC transfers, the CRCERR flag in the SPIx_SR register is set if corruption occurred during the transfer.

If packing mode is used, the LDMA_RX bit needs managing if the number of data is odd.

**Resetting the SPIx_TXCRC and SPIx_RXCRC values**

The SPIx_TXCRC and SPIx_RXCRC values are cleared automatically when new data is sampled after a CRC phase. This allows the use of DMA circular mode (not available in receive-only mode) in order to transfer data without any interruption, (several data blocks covered by intermediate CRC checking phases).
If the SPI is disabled during a communication the following sequence must be followed:

1. Disable the SPI
2. Clear the CRCEN bit
3. Enable the CRCEN bit
4. Enable the SPI

**Note:** When the SPI interface is configured as a slave, the NSS internal signal needs to be kept low during transaction of the CRC phase once the CRCNEXT signal is released. That is why the CRC calculation cannot be used at NSS Pulse mode when NSS hardware mode should be applied at slave normally.

At TI mode, despite the fact that clock phase and clock polarity setting is fixed and independent on SPIx_CR1 register, the corresponding setting CPOL=0 CPHA=1 has to be kept at the SPIx_CR1 register anyway if CRC is applied. In addition, the CRC calculation has to be reset between sessions by SPI disable sequence with re-enable the CRCEN bit described above at both master and slave side, else CRC calculation can be corrupted at this specific mode.

### 28.6 SPI interrupts

During SPI communication an interrupt can be generated by the following events:

- Transmit TXFIFO ready to be loaded
- Data received in Receive RXFIFO
- Master mode fault
- Overrun error
- TI frame format error
- CRC protocol error

Interrupts can be enabled and disabled separately.

28.7 I2S functional description

28.7.1 I2S general description

The block diagram of the I2S is shown in Figure 289.

The SPI can function as an audio I2S interface when the I2S capability is enabled (by setting the I2SMOD bit in the SPIx_I2SCFGR register). This interface mainly uses the same pins, flags and interrupts as the SPI.

1. MCK is mapped on the MISO pin.
The I2S shares three common pins with the SPI:

- **SD**: Serial Data (mapped on the MOSI pin) to transmit or receive the two time-multiplexed data channels (in half-duplex mode only).
- **WS**: Word Select (mapped on the NSS pin) is the data control signal output in master mode and input in slave mode.
- **CK**: Serial Clock (mapped on the SCK pin) is the serial clock output in master mode and serial clock input in slave mode.

An additional pin can be used when a master clock output is needed for some external audio devices:

- **MCK**: Master Clock (mapped separately) is used, when the I2S is configured in master mode (and when the MCKOE bit in the SPIx_I2SPR register is set), to output this additional clock generated at a preconfigured frequency rate equal to $256 \times f_S$ for all I2S modes, and to $128 \times f_S$ for all PCM modes, where $f_S$ is the audio sampling frequency.

The I2S uses its own clock generator to produce the communication clock when it is set in master mode. This clock generator is also the source of the master clock output. Two additional registers are available in I2S mode. One is linked to the clock generator configuration SPIx_I2SPR and the other one is a generic I2S configuration register SPIx_I2SCFGR (audio standard, slave/master mode, data format, packet frame, clock polarity, etc.).

The SPIx_CR1 register and all CRC registers are not used in the I2S mode. Likewise, the SSOE bit in the SPIx_CR2 register and the MODF and CRCERR bits in the SPIx_SR are not used.

The I2S uses the same SPI register for data transfer (SPIx_DR) in 16-bit wide mode.

### 28.7.2 I2S full duplex

*Figure 290* shows how to perform full-duplex communications using two SPI/I2S instances. In this case, the WS and CK IOs of both SPI/I2S must be connected together.

For the master full-duplex mode, one of the SPI/I2S block must be programmed in master (I2SCFG = ‘10’ or ‘11’), and the other SPI/I2S block must be programmed in slave (I2SCFG = ‘00’ or ‘01’). The MCK can be generated or not, depending on the application needs.

For the slave full-duplex mode, both SPI/I2S blocks must be programmed in slave. One of them in the slave receiver (I2SCFG = ‘01’), and the other in the slave transmitter (I2SCFG = ‘00’). The master external device then provides the bit clock (CK) and the frame synchronization (WS).

Note that the full-duplex mode can be used for all the supported standards: I2S Philips, MSB-justified, LSB-justified and PCM.

For the full-duplex mode, both SPI/I2S instances must use the same standard, with the same parameters: I2SMOD, I2SSTD, CKPOL, PCMSYNC, DATLEN and CHLEN must contain the same value on both instances.
28.7.3 Supported audio protocols

The three-line bus has to handle only audio data generally time-multiplexed on two channels: the right channel and the left channel. However there is only one 16-bit register for transmission or reception. So, it is up to the software to write into the data register the appropriate value corresponding to each channel side, or to read the data from the data register and to identify the corresponding channel by checking the CHSIDE bit in the SPIx_SR register. Channel left is always sent first followed by the channel right (CHSIDE has no meaning for the PCM protocol).

Four data and packet frames are available. Data may be sent with a format of:

- 16-bit data packed in a 16-bit frame
- 16-bit data packed in a 32-bit frame
- 24-bit data packed in a 32-bit frame
- 32-bit data packed in a 32-bit frame

When using 16-bit data extended on 32-bit packet, the first 16 bits (MSB) are the significant bits, the 16-bit LSB is forced to 0 without any need for software action or DMA request (only one read/write operation).

The 24-bit and 32-bit data frames need two CPU read or write operations to/from the SPIx_DR register or two DMA operations if the DMA is preferred for the application. For 24-bit data frame specifically, the 8 non-significant bits are extended to 32 bits with 0-bits (by hardware).

For all data formats and communication standards, the most significant bit is always sent first (MSB first).
The I²S interface supports four audio standards, configurable using the I2SSTD[1:0] and PCMSYNC bits in the SPIx_I2SCFGR register.

**I²S Philips standard**

For this standard, the WS signal is used to indicate which channel is being transmitted. It is activated one CK clock cycle before the first bit (MSB) is available.

*Figure 291. I²S Philips protocol waveforms (16/32-bit full accuracy)*

Data are latched on the falling edge of CK (for the transmitter) and are read on the rising edge (for the receiver). The WS signal is also latched on the falling edge of CK.

*Figure 292. I²S Philips standard waveforms (24-bit frame)*

This mode needs two write or read operations to/from the SPIx_DR register.

- In transmission mode:
  
  If 0x8EAA33 has to be sent (24-bit):
In reception mode:
If data 0x8EAA33 is received:

Only the 8 MSB are sent to compare the 24 bits
8 LSBs have no meaning and can be anything

When 16-bit data frame extended to 32-bit channel frame is selected during the I2S configuration phase, only one access to the SPIx_DR register is required. The 16 remaining bits are forced by hardware to 0x0000 to extend the data to 32-bit format.

If the data to transmit or the received data are 0x76A3 (0x76A30000 extended to 32-bit), the operation shown in Figure 296 is required.

**Figure 296. Example of 16-bit data frame extended to 32-bit channel frame**

<table>
<thead>
<tr>
<th>Only one access to SPIx_DR</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x76A3</td>
</tr>
</tbody>
</table>

MS19595V1
For transmission, each time an MSB is written to SPIx_DR, the TXE flag is set and its interrupt, if allowed, is generated to load the SPIx_DR register with the new value to send. This takes place even if 0x0000 have not yet been sent because it is done by hardware.

For reception, the RXNE flag is set and its interrupt, if allowed, is generated when the first 16 MSB half-word is received.

In this way, more time is provided between two write or read operations, which prevents underrun or overrun conditions (depending on the direction of the data transfer).

**MSB justified standard**

For this standard, the WS signal is generated at the same time as the first data bit, which is the MSBit.

**Figure 297. MSB Justified 16-bit or 32-bit full-accuracy length**

Data are latched on the falling edge of CK (for transmitter) and are read on the rising edge (for the receiver).

**Figure 298. MSB justified 24-bit frame length**
LSB justified standard

This standard is similar to the MSB justified standard (no difference for the 16-bit and 32-bit full-accuracy frame formats).

The sampling of the input and output signals is the same as for the I²S Philips standard.

- In transmission mode:
  If data 0x3478AE have to be transmitted, two write operations to the SPIx_DR register are required by software or by DMA. The operations are shown below.
Figure 302. Operations required to transmit 0x3478AE

<table>
<thead>

</tbody>
</table>

Only the 8 LSB of the half-word are significant. A field of 0x00 is forced instead of the 8 MSBs.

Figure 304. LSB justified 16-bit extended to 32-bit packet frame

When 16-bit data frame extended to 32-bit channel frame is selected during the I2S configuration phase, Only one access to the SPIx_DR register is required. The 16 remaining bits are forced by hardware to 0x0000 to extend the data to 32-bit format. In this case it corresponds to the half-word MSB.

If the data to transmit or the received data are 0x76A3 (0x0000 76A3 extended to 32-bit), the operation shown in Figure 305 is required.
In transmission mode, when a TXE event occurs, the application has to write the data to be transmitted (in this case 0x76A3). The 0x000 field is transmitted first (extension on 32-bit). The TXE flag is set again as soon as the effective data (0x76A3) is sent on SD.

In reception mode, RXNE is asserted as soon as the significant half-word is received (and not the 0x0000 field).

In this way, more time is provided between two write or read operations to prevent underrun or overrun conditions.

**PCM standard**

For the PCM standard, there is no need to use channel-side information. The two PCM modes (short and long frame) are available and configurable using the PCMSYNC bit in SPIx_I2SCFGR register.

In PCM mode, the output signals (WS, SD) are sampled on the rising edge of CK signal. The input signals (WS, SD) are captured on the falling edge of CK.

Note that CK and WS are configured as output in MASTER mode.

For long frame synchronization, the WS signal assertion time is fixed to 13 bits in master mode.

For short frame synchronization, the WS synchronization signal is only one cycle long.
Figure 307. PCM standard waveforms (16-bit extended to 32-bit packet frame)

Note: For both modes (master and slave) and for both synchronizations (short and long), the number of bits between two consecutive pieces of data (and so two synchronization signals) needs to be specified (DATLEN and CHLEN bits in the SPIx_I2SCFGR register) even in slave mode.

28.7.4 Start-up description

The Figure 308 shows how the serial interface is handled in MASTER mode, when the SPI/I2S is enabled (via I2SE bit). It shows as well the effect of CKPOL on the generated signals.
In slave mode, the user has to enable the audio interface before the WS becomes active. This means that the I2SE bit must be set to 1 when WS = 1 for I²S Philips standard, or when WS = 0 for other standards.
28.7.5 Clock generator

The I²S bit rate determines the data flow on the I²S data line and the I²S clock signal frequency.

\[
\text{I²S bit rate} = \text{number of bits per channel} \times \text{number of channels} \times \text{sampling audio frequency}
\]

For a 16-bit audio, left and right channel, the I²S bit rate is calculated as follows:

\[
\text{I²S bit rate} = 16 \times 2 \times f_s
\]

It is: I²S bit rate = 32 x 2 x f_s if the packet length is 32-bit wide.

Figure 309. Audio sampling frequency definition

When the master mode is configured, a specific action needs to be taken to properly program the linear divider in order to communicate with the desired audio frequency.

Figure 310. I²S clock generator architecture

1. Where x can be 2 or 3.
Figure 310 presents the communication clock architecture. The I2SxCLK clock is provided by the reset and clock controller (RCC) of the product. The I2SxCLK clock can be asynchronous with respect to the SPI/I2S APB clock.

Warning: In addition, it is mandatory to keep the I2SxCLK frequency higher or equal to the APB clock used by the SPI/I2S block. If this condition is not respected the SPI/I2S does not work properly.

The audio sampling frequency may be 192 kHz, 96 kHz, 48 kHz, 44.1 kHz, 32 kHz, 22.05 kHz, 16 kHz, 11.025 kHz or 8 kHz (or any other value within this range).

In order to reach the desired frequency, the linear divider needs to be programmed according to the formulas below:

For I²S modes:

When the master clock is generated (MCKOE in the SPIx_I2SPR register is set):

\[
F_s = \frac{F_{I2SxCLK}}{256 \times ((2 \times I2SDIV) + ODD)}
\]

When the master clock is disabled (MCKOE bit cleared):

\[
F_s = \frac{F_{I2SxCLK}}{32 \times (CHLEN + 1) \times ((2 \times I2SDIV) + ODD)}
\]

CHLEN = 0 when the channel frame is 16-bit wide and,
CHLEN = 1 when the channel frame is 32-bit wide.

For PCM modes:

When the master clock is generated (MCKOE in the SPIx_I2SPR register is set):

\[
F_s = \frac{F_{I2SxCLK}}{128 \times ((2 \times I2SDIV) + ODD)}
\]

When the master clock is disabled (MCKOE bit cleared):

\[
F_s = \frac{F_{I2SxCLK}}{16 \times (CHLEN + 1) \times ((2 \times I2SDIV) + ODD)}
\]

CHLEN = 0 when the channel frame is 16-bit wide and,
CHLEN = 1 when the channel frame is 32-bit wide.

Where \(F_s\) is the audio sampling frequency, and \(F_{I2SxCLK}\) is the frequency of the kernel clock provided to the SPI/I2S block.
**Note:**  
*I2SDIV must be strictly higher than 1.*

The following table provides example precision values for different clock configurations.

**Note:**  
*Other configurations are possible that allow optimum clock precision.*

28.7.6  I²S master mode

The I²S can be configured in master mode. This means that the serial clock is generated on the CK pin as well as the Word Select signal WS. Master clock (MCK) may be output or not, controlled by the MCKOE bit in the SPIx_I2SPR register.

Procedure

1. Select the I2SDIV[7:0] bits in the SPIx_I2SPR register to define the serial clock baud rate to reach the proper audio sample frequency. The ODD bit in the SPIx_I2SPR register also has to be defined.
2. Select the CKPOL bit to define the steady level for the communication clock. Set the MCKOE bit in the SPIx_I2SPR register if the master clock MCK needs to be provided to the external DAC/ADC audio component (the I2SDIV and ODD values should be computed depending on the state of the MCK output, for more details refer to Section 28.7.5: Clock generator).
3. Set the I2SMOD bit in the SPIx_I2SCFGR register to activate the I²S functions and choose the I²S standard through the I2SSTD[1:0] and PCMSYNC bits, the data length through the DATLEN[1:0] bits and the number of bits per channel by configuring the CHLEN bit. Select also the I²S master mode and direction (Transmitter or Receiver) through the I2SCFG[1:0] bits in the SPIx_I2SCFGR register.
4. If needed, select all the potential interrupt sources and the DMA capabilities by writing the SPIx_CR2 register.
5. The I2SE bit in SPIx_I2SCFGR register must be set.

WS and CK are configured in output mode. MCK is also an output, if the MCKOE bit in SPIx_I2SPR is set.

Transmission sequence

The transmission sequence begins when a half-word is written into the Tx buffer.

Lets assume the first data written into the Tx buffer corresponds to the left channel data. When data are transferred from the Tx buffer to the shift register, TXE is set and data corresponding to the right channel have to be written into the Tx buffer. The CHSIDE flag indicates which channel is to be transmitted. It has a meaning when the TXE flag is set because the CHSIDE flag is updated when TXE goes high.

A full frame has to be considered as a left channel data transmission followed by a right channel data transmission. It is not possible to have a partial frame where only the left channel is sent.

The data half-word is parallel loaded into the 16-bit shift register during the first bit transmission, and then shifted out, serially, to the MOSI/SD pin, MSB first. The TXE flag is set after each transfer from the Tx buffer to the shift register and an interrupt is generated if the TXEIE bit in the SPIx_CR2 register is set.

For more details about the write operations depending on the I²S standard mode selected, refer to Section 28.7.3: Supported audio protocols).

To ensure a continuous audio data transmission, it is mandatory to write the SPIx_DR register with the next data to transmit before the end of the current transmission.
To switch off the I2S, by clearing I2SE, it is mandatory to wait for TXE = 1 and BSY = 0.

**Reception sequence**

The operating mode is the same as for transmission mode except for the point 3 (refer to the procedure described in Section 28.7.6: I2S master mode), where the configuration should set the master reception mode through the I2SCFG[1:0] bits.

Whatever the data or channel length, the audio data are received by 16-bit packets. This means that each time the Rx buffer is full, the RXNE flag is set and an interrupt is generated if the RXNEIE bit is set in SPIx_CR2 register. Depending on the data and channel length configuration, the audio value received for a right or left channel may result from one or two receptions into the Rx buffer.

Clearing the RXNE bit is performed by reading the SPIx_DR register.

CHSIDE is updated after each reception. It is sensitive to the WS signal generated by the I2S cell.

For more details about the read operations depending on the I2S standard mode selected, refer to Section 28.7.3: Supported audio protocols.

If data are received while the previously received data have not been read yet, an overrun is generated and the OVR flag is set. If the ERRIE bit is set in the SPIx_CR2 register, an interrupt is generated to indicate the error.

To switch off the I2S, specific actions are required to ensure that the I2S completes the transfer cycle properly without initiating a new data transfer. The sequence depends on the configuration of the data and channel lengths, and on the audio protocol mode selected. In the case of:

- 16-bit data length extended on 32-bit channel length (DATLEN = 00 and CHLEN = 1) using the LSB justified mode (I2SSTD = 10)
  a) Wait for the second to last RXNE = 1 (n – 1)
  b) Then wait 17 I2S clock cycles (using a software loop)
  c) Disable the I2S (I2SE = 0)
- 16-bit data length extended on 32-bit channel length (DATLEN = 00 and CHLEN = 1) in MSB justified, I2S or PCM modes (I2SSTD = 00, I2SSTD = 01 or I2SSTD = 11, respectively)
  a) Wait for the last RXNE
  b) Then wait 1 I2S clock cycle (using a software loop)
  c) Disable the I2S (I2SE = 0)
- For all other combinations of DATLEN and CHLEN, whatever the audio mode selected through the I2SSTD bits, carry out the following sequence to switch off the I2S:
  a) Wait for the second to last RXNE = 1 (n – 1)
  b) Then wait one I2S clock cycle (using a software loop)
  c) Disable the I2S (I2SE = 0)

**Note:** The BSY flag is kept low during transfers.

### 28.7.7 I2S slave mode

For the slave configuration, the I2S can be configured in transmission or reception mode. The operating mode is following mainly the same rules as described for the I2S master.
configuration. In slave mode, there is no clock to be generated by the I²S interface. The clock and WS signals are input from the external master connected to the I²S interface. There is then no need, for the user, to configure the clock.

The configuration steps to follow are listed below:

1. Set the I2SMOD bit in the SPIx_I2SCFGR register to select I²S mode and choose the I²S standard through the I2SSTD[1:0] bits, the data length through the DATLEN[1:0] bits and the number of bits per channel for the frame configuring the CHLEN bit. Select also the mode (transmission or reception) for the slave through the I2SCFG[1:0] bits in SPIx_I2SCFGR register.
2. If needed, select all the potential interrupt sources and the DMA capabilities by writing the SPIx_CR2 register.
3. The I2SE bit in SPIx_I2SCFGR register must be set.

Transmission sequence

The transmission sequence begins when the external master device sends the clock and when the NSS_WS signal requests the transfer of data. The slave has to be enabled before the external master starts the communication. The I2S data register has to be loaded before the master initiates the communication.

For the I2S, MSB justified and LSB justified modes, the first data item to be written into the data register corresponds to the data for the left channel. When the communication starts, the data are transferred from the Tx buffer to the shift register. The TXE flag is then set in order to request the right channel data to be written into the I2S data register.

The CHSIDE flag indicates which channel is to be transmitted. Compared to the master transmission mode, in slave mode, CHSIDE is sensitive to the WS signal coming from the external master. This means that the slave needs to be ready to transmit the first data before the clock is generated by the master. WS assertion corresponds to left channel transmitted first.

Note: The I2SE has to be written at least two PCLK cycles before the first clock of the master comes on the CK line.

The data half-word is parallel-loaded into the 16-bit shift register (from the internal bus) during the first bit transmission, and then shifted out serially to the MOSI/SD pin MSB first. The TXE flag is set after each transfer from the Tx buffer to the shift register and an interrupt is generated if the TXEIE bit in the SPIx_CR2 register is set.

Note that the TXE flag should be checked to be at 1 before attempting to write the Tx buffer.

For more details about the write operations depending on the I²S standard mode selected, refer to Section 28.7.3: Supported audio protocols.

To secure a continuous audio data transmission, it is mandatory to write the SPIx_DR register with the next data to transmit before the end of the current transmission. An underrun flag is set and an interrupt may be generated if the data are not written into the SPIx_DR register before the first clock edge of the next data communication. This indicates to the software that the transferred data are wrong. If the ERRIE bit is set into the SPIx_CR2 register, an interrupt is generated when the UDR flag in the SPIx_SR register goes high. In this case, it is mandatory to switch off the I2S and to restart a data transfer starting from the left channel.

To switch off the I2S, by clearing the I2SE bit, it is mandatory to wait for TXE = 1 and BSY = 0.
Reception sequence

The operating mode is the same as for the transmission mode except for the point 1 (refer to the procedure described in Section 28.7.7: I²S slave mode), where the configuration should set the master reception mode using the I2SCFG[1:0] bits in the SPIx_I2SCFGR register.

Whatever the data length or the channel length, the audio data are received by 16-bit packets. This means that each time the RX buffer is full, the RXNE flag in the SPIx_SR register is set and an interrupt is generated if the RXNEIE bit is set in the SPIx_CR2 register. Depending on the data length and channel length configuration, the audio value received for a right or left channel may result from one or two receptions into the RX buffer.

The CHSIDE flag is updated each time data are received to be read from the SPIx_DR register. It is sensitive to the external WS line managed by the external master component.

Clearing the RXNE bit is performed by reading the SPIx_DR register.

For more details about the read operations depending the I²S standard mode selected, refer to Section 28.7.3: Supported audio protocols.

If data are received while the preceding received data have not yet been read, an overrun is generated and the OVR flag is set. If the bit ERRIE is set in the SPIx_CR2 register, an interrupt is generated to indicate the error.

To switch off the I2S in reception mode, I2SE has to be cleared immediately after receiving the last RXNE = 1.

Note: The external master components should have the capability of sending/receiving data in 16-bit or 32-bit packets via an audio channel.

28.7.8 I²S status flags

Three status flags are provided for the application to fully monitor the state of the I²S bus.

Busy flag (BSY)

The BSY flag is set and cleared by hardware (writing to this flag has no effect). It indicates the state of the communication layer of the I²S.

When BSY is set, it indicates that the I²S is busy communicating. There is one exception in master receive mode (I2SCFG = 11) where the BSY flag is kept low during reception.

The BSY flag is useful to detect the end of a transfer if the software needs to disable the I²S. This avoids corrupting the last transfer. For this, the procedure described below must be strictly respected.

The BSY flag is set when a transfer starts, except when the I²S is in master receiver mode.

The BSY flag is cleared:

- When a transfer completes (except in master transmit mode, in which the communication is supposed to be continuous)
- When the I²S is disabled

When communication is continuous:

- In master transmit mode, the BSY flag is kept high during all the transfers
- In slave mode, the BSY flag goes low for one I²S clock cycle between each transfer

Note: Do not use the BSY flag to handle each data transmission or reception. It is better to use the TXE and RXNE flags instead.
**Tx buffer empty flag (TXE)**

When set, this flag indicates that the Tx buffer is empty and the next data to be transmitted can then be loaded into it. The TXE flag is reset when the Tx buffer already contains data to be transmitted. It is also reset when the I2S is disabled (I2SE bit is reset).

**RX buffer not empty (RXNE)**

When set, this flag indicates that there are valid received data in the RX Buffer. It is reset when SPIx_DR register is read.

**Channel Side flag (CHSIDE)**

In transmission mode, this flag is refreshed when TXE goes high. It indicates the channel side to which the data to transfer on SD has to belong. In case of an underrun error event in slave transmission mode, this flag is not reliable and I2S needs to be switched off and switched on before resuming the communication.

In reception mode, this flag is refreshed when data are received into SPIx_DR. It indicates from which channel side data have been received. Note that in case of error (like OVR) this flag becomes meaningless and the I2S should be reset by disabling and then enabling it (with configuration if it needs changing).

This flag has no meaning in the PCM standard (for both Short and Long frame modes).

When the OVR or UDR flag in the SPIx_SR is set and the ERRIE bit in SPIx_CR2 is also set, an interrupt is generated. This interrupt can be cleared by reading the SPIx_SR status register (once the interrupt source has been cleared).

### 28.7.9 I2S error flags

There are three error flags for the I2S cell.

**Underrun flag (UDR)**

In slave transmission mode this flag is set when the first clock for data transmission appears while the software has not yet loaded any value into SPIx_DR. It is available when the I2SMOD bit in the SPIx_I2SCFGR register is set. An interrupt may be generated if the ERRIE bit in the SPIx_CR2 register is set.

The UDR bit is cleared by a read operation on the SPIx_SR register.

**Overrun flag (OVR)**

This flag is set when data are received and the previous data have not yet been read from the SPIx_DR register. As a result, the incoming data are lost. An interrupt may be generated if the ERRIE bit is set in the SPIx_CR2 register.

In this case, the receive buffer contents are not updated with the newly received data from the transmitter device. A read operation to the SPIx_DR register returns the previous correctly received data. All other subsequently transmitted half-words are lost.

Clearing the OVR bit is done by a read operation on the SPIx_DR register followed by a read access to the SPIx_SR register.

**Frame error flag (FRE)**

This flag can be set by hardware only if the I2S is configured in Slave mode. It is set if the external master is changing the WS line while the slave is not expecting this change. If the
synchronization is lost, the following steps are required to recover from this state and resynchronize the external master device with the I2S slave device:

1. Disable the I2S.
2. Enable it again when the correct level is detected on the WS line (WS line is high in I²S mode or low for MSB- or LSB-justified or PCM modes.

Desynchronization between master and slave devices may be due to noisy environment on the CK communication clock or on the WS frame synchronization line. An error interrupt can be generated if the ERRIE bit is set. The desynchronization flag (FRE) is cleared by software when the status register is read.

28.7.10 DMA features

In I²S mode, the DMA works in exactly the same way as it does in SPI mode. There is no difference except that the CRC feature is not available in I²S mode since there is no data transfer protection system.

28.8 I²S interrupts

Table 116 provides the list of I²S interrupts.

<td>BIDIMODE</td>
<td>Bidirectional data mode enable. This bit enables half-duplex communication using common single bidirectional data line. Keep RXONLY bit clear when bidirectional mode is active. 0: 2-line unidirectional data mode selected 1: 1-line bidirectional data mode selected Note: This bit is not used in I2S mode.</td>
</tr>
<tr>
<td>14</td>
<td>BIDIOE</td>
<td>Output enable in bidirectional mode. This bit combined with the BIDIMODE bit selects the direction of transfer in bidirectional mode. 0: Output disabled (receive-only mode) 1: Output enabled (transmit-only mode) Note: In master mode, the MOSI pin is used and in slave mode, the MISO pin is used. This bit is not used in I2S mode.</td>
</tr>
<tr>
<td>13</td>
<td>CRCEN</td>
<td>Hardware CRC calculation enable 0: CRC calculation disabled 1: CRC calculation enabled Note: This bit should be written only when SPI is disabled (SPE = '0') for correct operation. This bit is not used in I2S mode.</td>
</tr>
<tr>
<td>12</td>
<td>CRCNEXT</td>
<td>Transmit CRC next 0: Next transmit value is from Tx buffer. 1: Next transmit value is from Tx CRC register. Note: This bit has to be written as soon as the last data is written in the SPIx_DR register. This bit is not used in I2S mode.</td>
</tr>
<tr>
<td>11</td>
<td>CRCL</td>
<td>CRC length. This bit is set and cleared by software to select the CRC length. 0: 8-bit CRC length 1: 16-bit CRC length Note: This bit should be written only when SPI is disabled (SPE = '0') for correct operation. This bit is not used in I2S mode.</td>
</tr>
</tbody>
</table>
Bit 10 **RXONLY**: Receive only mode enabled.
This bit enables simplex communication using a single unidirectional line to receive data exclusively. Keep BIDIMODE bit clear when receive only mode is active. This bit is also useful in a multislave system in which this particular slave is not accessed, the output from the accessed slave is not corrupted.
0: Full-duplex (Transmit and receive)
1: Output disabled (Receive-only mode)

*Note: This bit is not used in I²S mode.*

Bit 9 **SSM**: Software slave management
When the SSM bit is set, the NSS pin input is replaced with the value from the SSI bit.
0: Software slave management disabled
1: Software slave management enabled

*Note: This bit is not used in I²S mode and SPI TI mode.*

Bit 8 **SSI**: Internal slave select
This bit has an effect only when the SSM bit is set. The value of this bit is forced onto the NSS pin and the I/O value of the NSS pin is ignored.

*Note: This bit is not used in I²S mode and SPI TI mode.*

Bit 7 **LSBFIRST**: Frame format
0: data is transmitted/received with the MSB first
1: data is transmitted/received with the LSB first

*Note: 1. This bit should not be changed when communication is ongoing.
2. This bit is not used in I²S mode and SPI TI mode.*

Bit 6 **SPE**: SPI enable
0: Peripheral disabled
1: Peripheral enabled

*Note: When disabling the SPI, follow the procedure described in Procedure for disabling the SPI on page 779.
This bit is not used in I²S mode.*

Bits 5:3 **BR[2:0]**: Baud rate control
000: f_PCLK/2
001: f_PCLK/4
010: f_PCLK/8
011: f_PCLK/16
100: f_PCLK/32
101: f_PCLK/64
110: f_PCLK/128
111: f_PCLK/256

*Note: These bits should not be changed when communication is ongoing.
These bits are not used in I²S mode.*

Bit 2 **MSTR**: Master selection
0: Slave configuration
1: Master configuration

*Note: This bit should not be changed when communication is ongoing.
This bit is not used in I²S mode.*
28.9.2 SPI control register 2 (SPIx_CR2)

Address offset: 0x04
Reset value: 0x0700

Bit 1 **CPOL:** Clock polarity
0: CK to 0 when idle
1: CK to 1 when idle
*Note:* This bit should not be changed when communication is ongoing.
This bit is not used in I²S mode and SPI TI mode except the case when CRC is applied at TI mode.

Bit 0 **CPHA:** Clock phase
0: The first clock transition is the first data capture edge
1: The second clock transition is the first data capture edge
*Note:* This bit should not be changed when communication is ongoing.
This bit is not used in I²S mode and SPI TI mode except the case when CRC is applied at TI mode.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **LDMA_TX:** Last DMA transfer for transmission
This bit is used in data packing mode, to define if the total number of data to transmit by DMA is odd or even. It has significance only if the TXDMAEN bit in the SPIx_CR2 register is set and if packing mode is used (data length <= 8-bit and write access to SPIx_DR is 16-bit wide). It has to be written when the SPI is disabled (SPE = 0 in the SPIx_CR1 register).
0: Number of data to transfer is even
1: Number of data to transfer is odd
*Note:* Refer to Procedure for disabling the SPI on page 779 if the CRCEN bit is set.
This bit is not used in I²S mode.

Bit 13 **LDMA_RX:** Last DMA transfer for reception
This bit is used in data packing mode, to define if the total number of data to receive by DMA is odd or even. It has significance only if the RXDMAEN bit in the SPIx_CR2 register is set and if packing mode is used (data length <= 8-bit and write access to SPIx_DR is 16-bit wide). It has to be written when the SPI is disabled (SPE = 0 in the SPIx_CR1 register).
0: Number of data to transfer is even
1: Number of data to transfer is odd
*Note:* Refer to Procedure for disabling the SPI on page 779 if the CRCEN bit is set.
This bit is not used in I²S mode.

Bit 12 **FRXTH:** FIFO reception threshold
This bit is used to set the threshold of the RXFIFO that triggers an RXNE event
0: RXNE event is generated if the FIFO level is greater than or equal to 1/2 (16-bit)
1: RXNE event is generated if the FIFO level is greater than or equal to 1/4 (8-bit)
*Note:* This bit is not used in I²S mode.
Bits 11:8 DS[3:0]: Data size
These bits configure the data length for SPI transfers.
- 0000: Not used
- 0001: Not used
- 0010: Not used
- 0011: 4-bit
- 0100: 5-bit
- 0101: 6-bit
- 0110: 7-bit
- 0111: 8-bit
- 1000: 9-bit
- 1001: 10-bit
- 1010: 11-bit
- 1011: 12-bit
- 1100: 13-bit
- 1101: 14-bit
- 1110: 15-bit
- 1111: 16-bit
If software attempts to write one of the “Not used” values, they are forced to the value “0111” (8-bit)
Note: These bits are not used in I$_2$S mode.

Bit 7 TXEIE: Tx buffer empty interrupt enable
- 0: TXE interrupt masked
- 1: TXE interrupt not masked. Used to generate an interrupt request when the TXE flag is set.

Bit 6 RXNEIE: RX buffer not empty interrupt enable
- 0: RXNE interrupt masked
- 1: RXNE interrupt not masked. Used to generate an interrupt request when the RXNE flag is set.

Bit 5 ERRIE: Error interrupt enable
This bit controls the generation of an interrupt when an error condition occurs (CRCERR, OVR, MODF in SPI mode, FRE at TI mode, and UDR, OVR, and FRE in I$_2$S mode).
- 0: Error interrupt is masked
- 1: Error interrupt is enabled

Bit 4 FRF: Frame format
- 0: SPI Motorola mode
- 1: SPI TI mode
Note: This bit must be written only when the SPI is disabled (SPE=0).
This bit is not used in I$_2$S mode.

Bit 3 NSSP: NSS pulse management
This bit is used in master mode only, it allows the SPI to generate an NSS pulse between two consecutive data when doing continuous transfers. In the case of a single data transfer, it forces the NSS pin high level after the transfer.
It has no meaning if CPHA = ‘1’, or FRF = ‘1’.
- 0: No NSS pulse
- 1: NSS pulse generated
Note: 1. This bit must be written only when the SPI is disabled (SPE=0).
2. This bit is not used in I$_2$S mode and SPI TI mode.
Bit 2 **SSOE:** SS output enable
0: SS output is disabled in master mode and the SPI interface can work in multimaster configuration
1: SS output is enabled in master mode and when the SPI interface is enabled. The SPI interface cannot work in a multimaster environment.

*Note:* This bit is not used in I²S mode and SPI TI mode.

Bit 1 **TXDMAEN:** Tx buffer DMA enable
When this bit is set, a DMA request is generated whenever the TXE flag is set.
0: Tx buffer DMA disabled
1: Tx buffer DMA enabled

Bit 0 **RXDMAEN:** Rx buffer DMA enable
When this bit is set, a DMA request is generated whenever the RXNE flag is set.
0: Rx buffer DMA disabled
1: Rx buffer DMA enabled

### 28.9.3 SPI status register (SPIx_SR)

Address offset: 0x08
Reset value: 0x0002

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:11 **FTLVL[1:0]:** FIFO transmission level
These bits are set and cleared by hardware.
00: FIFO empty
01: 1/4 FIFO
10: 1/2 FIFO
11: FIFO full (considered as FULL when the FIFO threshold is greater than 1/2)

*Note:* This bit is not used in I²S mode.

Bits 10:9 **FRLVL[1:0]:** FIFO reception level
These bits are set and cleared by hardware.
00: FIFO empty
01: 1/4 FIFO
10: 1/2 FIFO
11: FIFO full

*Note:* These bits are not used in I²S mode and in SPI receive-only mode while CRC calculation is enabled.

Bit 8 **FRE:** Frame format error
This flag is used for SPI in TI slave mode and I²S slave mode. Refer to **Section 28.5.11: SPI error flags** and **Section 28.7.9: I²S error flags**.
This flag is set by hardware and reset when SPIx_SR is read by software.
0: No frame format error
1: A frame format error occurred
Bit 7  **BSY**: Busy flag
0: SPI (or I2S) not busy 
1: SPI (or I2S) is busy in communication or Tx buffer is not empty
This flag is set and cleared by hardware.
*Note*: The BSY flag must be used with caution: refer to *Section 28.5.10: SPI status flags* and *Procedure for disabling the SPI* on page 779.

Bit 6  **OVR**: Overrun flag
0: No overrun occurred 
1: Overrun occurred
This flag is set by hardware and reset by a software sequence. Refer to *I2S error flags on page 812* for the software sequence.

Bit 5  **MODF**: Mode fault
0: No mode fault occurred 
1: Mode fault occurred
This flag is set by hardware and reset by a software sequence. Refer to *Section : Mode fault (MODF) on page 789* for the software sequence.
*Note*: This bit is not used in I2S mode.

Bit 4  **CRCERR**: CRC error flag
0: CRC value received matches the SPIx_RXCRCR value 
1: CRC value received does not match the SPIx_RXCRCR value
*Note*: This flag is set by hardware and cleared by software writing 0.
*This bit is not used in I2S mode.*

Bit 3  **UDR**: Underrun flag
0: No underrun occurred 
1: Underrun occurred
This flag is set by hardware and reset by a software sequence. Refer to *I2S error flags on page 812* for the software sequence.
*Note*: This bit is not used in SPI mode.

Bit 2  **CHSIDE**: Channel side
0: Channel Left has to be transmitted or has been received 
1: Channel Right has to be transmitted or has been received
*Note*: This bit is not used in SPI mode. It has no significance in PCM mode.

Bit 1  **TXE**: Transmit buffer empty
0: Tx buffer not empty 
1: Tx buffer empty

Bit 0  **RXNE**: Receive buffer not empty
0: Rx buffer empty 
1: Rx buffer not empty
28.9.4 SPI data register (SPIx_DR)

DR[15:0]: Data register
Data received or to be transmitted
The data register serves as an interface between the Rx and Tx FIFOs. When the data register is read, RxFIFO is accessed while the write to data register accesses TxFIFO (See Section 28.5.9: Data transmission and reception procedures).
Note: Data is always right-aligned. Unused bits are ignored when writing to the register, and read as zero when the register is read. The Rx threshold setting must always correspond with the read access currently used.

28.9.5 SPI CRC polynomial register (SPIx_CRCPR)

CRCPOLY[15:0]: CRC polynomial register
This register contains the polynomial for the CRC calculation.
The CRC polynomial (0x0007) is the reset value of this register. Another polynomial can be configured as required.

Note: The polynomial value should be odd only. No even value is supported.

28.9.6 SPI Rx CRC register (SPIx_RXCRCR)

Address offset: 0x14
Reset value: 0x0000

</tbody>
</table>
Bits 15:0 **RXCRC[15:0]: Rx CRC register**

When CRC calculation is enabled, the RXCRC[15:0] bits contain the computed CRC value of the subsequently received bytes. This register is reset when the CRCEN bit in SPIx_CR1 register is written to 1. The CRC is calculated serially using the polynomial programmed in the SPIx_CRCPR register.

Only the 8 LSB bits are considered when the CRC frame format is set to be 8-bit length (CRCL bit in the SPIx_CR1 is cleared). CRC calculation is done based on any CRC8 standard.

The entire 16-bits of this register are considered when a 16-bit CRC frame format is selected (CRCL bit in the SPIx_CR1 register is set). CRC calculation is done based on any CRC16 standard.

*Note: A read to this register when the BSY Flag is set could return an incorrect value. These bits are not used in I²S mode.*

### 28.9.7 SPI Tx CRC register (SPIx_TXCRCR)

</tbody>
</table>

Bits 15:0 **TXCRC[15:0]: Tx CRC register**

When CRC calculation is enabled, the TXCRC[7:0] bits contain the computed CRC value of the subsequently transmitted bytes. This register is reset when the CRCEN bit of SPIx_CR1 is written to 1. The CRC is calculated serially using the polynomial programmed in the SPIx_CRCPR register.

Only the 8 LSB bits are considered when the CRC frame format is set to be 8-bit length (CRCL bit in the SPIx_CR1 is cleared). CRC calculation is done based on any CRC8 standard.

The entire 16-bits of this register are considered when a 16-bit CRC frame format is selected (CRCL bit in the SPIx_CR1 register is set). CRC calculation is done based on any CRC16 standard.

*Note: A read to this register when the BSY flag is set could return an incorrect value. These bits are not used in I²S mode.*

### 28.9.8 SPIx_I2S configuration register (SPIx_I2SCFGR)

</tbody>
</table>

Bits 15: Reserved, must be kept at reset value.
Bit 11  **I2SMOD**: I2S mode selection
   0: SPI mode is selected
   1: I2S mode is selected

   *Note:* This bit should be configured when the SPI or I2S is disabled.

Bit 10  **I2SE**: I2S enable
   0: I2S peripheral is disabled
   1: I2S peripheral is enabled

   *Note:* This bit is not used in SPI mode.

Bits 9:8  **I2SCFG[1:0]**: I2S configuration mode
   00: Slave - transmit
   01: Slave - receive
   10: Master - transmit
   11: Master - receive

   *Note:* These bits should be configured when the I2S is disabled.
   They are not used in SPI mode.

Bit 7  **PCMSYNC**: PCM frame synchronization
   0: Short frame synchronization
   1: Long frame synchronization

   *Note:* This bit has a meaning only if I2SSTD = 11 (PCM standard is used).
   It is not used in SPI mode.

Bit 6  Reserved, must be kept at reset value.

Bits 5:4  **I2SSTD[1:0]**: I2S standard selection
   00: I2S Philips standard
   01: MSB justified standard (left justified)
   10: LSB justified standard (right justified)
   11: PCM standard

   For more details on I2S standards, refer to Section 28.7.3 on page 796

   *Note:* For correct operation, these bits should be configured when the I2S is disabled.
   They are not used in SPI mode.

Bit 3  **CKPOL**: Inactive state clock polarity
   0: I2S clock inactive state is low level
   1: I2S clock inactive state is high level

   *Note:* For correct operation, this bit should be configured when the I2S is disabled.
   It is not used in SPI mode.

   The bit CKPOL does not affect the CK edge sensitivity used to receive or transmit the SD and WS signals.

Bits 2:1  **DATLEN[1:0]**: Data length to be transferred
   00: 16-bit data length
   01: 24-bit data length
   10: 32-bit data length
   11: Not allowed

   *Note:* For correct operation, these bits should be configured when the I2S is disabled.
   They are not used in SPI mode.
Bit 0 **CHLEN**: Channel length (number of bits per audio channel)
   - 0: 16-bit wide
   - 1: 32-bit wide
   The bit write operation has a meaning only if DATLEN = 00 otherwise the channel length is fixed to 32-bit by hardware whatever the value filled in.
   Note: For correct operation, this bit should be configured when the I2S is disabled.
   It is not used in SPI mode.

### 28.9.9 SPIx_I2S prescaler register (SPIx_I2SPR)

Address offset: 0x20
Reset value: 0x0002

</tr>
</tbody>
</table>

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **MCKOE**: Master clock output enable
   - 0: Master clock output is disabled
   - 1: Master clock output is enabled
   Note: This bit should be configured when the I2S is disabled. It is used only when the I2S is in master mode.
   It is not used in SPI mode.

Bit 8 **ODD**: Odd factor for the prescaler
   - 0: Real divider value is = I2SDIV * 2
   - 1: Real divider value is = (I2SDIV * 2) + 1
   Refer to Section 28.7.4 on page 803
   Note: This bit should be configured when the I2S is disabled. It is used only when the I2S is in master mode.
   It is not used in SPI mode.

Bits 7:0 **I2SDIV[7:0]**: I2S linear prescaler
   - I2SDIV[7:0] = 0 or I2SDIV[7:0] = 1 are forbidden values.
   Refer to Section 28.7.4 on page 803.
   Note: These bits should be configured when the I2S is disabled. They are used only when the I2S is in master mode.
   They are not used in SPI mode.
Table 117 shows the SPI/I2S register map and reset values.

| Offset | Register        | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

Refer to Section 2.2 on page 46 for the register boundary addresses.
29 Controller area network (bxCAN)

29.1 Introduction

The Basic Extended CAN peripheral, named bxCAN, interfaces the CAN network. It supports the CAN protocols version 2.0A and B. It has been designed to manage a high number of incoming messages efficiently with a minimum CPU load. It also meets the priority requirements for transmit messages.

For safety-critical applications, the CAN controller provides all hardware functions for supporting the CAN Time Triggered Communication option.

29.2 bxCAN main features

- Supports CAN protocol version 2.0 A, B Active
- Bit rates up to 1 Mbit/s
- Supports the Time Triggered Communication option

Transmission
- Three transmit mailboxes
- Configurable transmit priority
- Time stamp on SOF transmission

Reception
- Two receive FIFOs with three stages
- Scalable filter banks:
  - 14 filter banks for single CAN
- Identifier list feature
- Configurable FIFO overrun
- Time stamp on SOF reception

Time-triggered communication option
- Disable automatic retransmission mode
- 16-bit free running timer
- Time stamp sent in last two data bytes

Management
- Maskable interrupts
- Software-efficient mailbox mapping at a unique address space

29.3 bxCAN general description

In today CAN applications, the number of nodes in a network is increasing and often several networks are linked together via gateways. Typically the number of messages in the system (to be handled by each node) has significantly increased. In addition to the application messages, network management and diagnostic messages have been introduced.

- An enhanced filtering mechanism is required to handle each type of message.
Furthermore, application tasks require more CPU time, therefore real-time constraints caused by message reception have to be reduced.

- A receive FIFO scheme allows the CPU to be dedicated to application tasks for a long time period without losing messages.

The standard HLP (Higher Layer Protocol) based on standard CAN drivers requires an efficient interface to the CAN controller.

**Figure 311. CAN network topology**

**29.3.1 CAN 2.0B active core**

The bxCAN module handles the transmission and the reception of CAN messages fully autonomously. Standard identifiers (11-bit) and extended identifiers (29-bit) are fully supported by hardware.

**29.3.2 Control, status and configuration registers**

The application uses these registers to:

- Configure CAN parameters, e.g. baud rate
- Request transmissions
- Handle receptions
- Manage interrupts
- Get diagnostic information

**29.3.3 Tx mailboxes**

Three transmit mailboxes are provided to the software for setting up messages. The transmission scheduler decides which mailbox has to be transmitted first.

**29.3.4 Acceptance filters**

The bxCAN provides up to 14 scalable/configurable identifier filter banks in single CAN configuration, for selecting the incoming messages, that the software needs and discarding the others.
Receive FIFO

Two receive FIFOs are used by hardware to store the incoming messages. Three complete messages can be stored in each FIFO. The FIFOs are managed completely by hardware.

Figure 312. Single-CAN block diagram

29.4 bxCAN operating modes

bxCAN has three main operating modes: initialization, normal and Sleep. After a hardware reset, bxCAN is in Sleep mode to reduce power consumption and an internal pull-up is active on CANTX. The software requests bxCAN to enter initialization or Sleep mode by setting the INRQ or SLEEP bits in the CAN_MCR register. Once the mode has been entered, bxCAN confirms it by setting the INAK or SLAK bits in the CAN_MSR register and the internal pull-up is disabled. When neither INAK nor SLAK are set, bxCAN is in normal mode. Before entering normal mode bxCAN always has to synchronize on the CAN bus. To synchronize, bxCAN waits until the CAN bus is idle, this means 11 consecutive recessive bits have been monitored on CANRX.

29.4.1 Initialization mode

The software initialization can be done while the hardware is in Initialization mode. To enter this mode the software sets the INRQ bit in the CAN_MCR register and waits until the hardware has confirmed the request by setting the INAK bit in the CAN_MSR register.

To leave Initialization mode, the software clears the INQR bit. bxCAN has left Initialization mode once the INAK bit has been cleared by hardware.

While in Initialization Mode, all message transfers to and from the CAN bus are stopped and the status of the CAN bus output CANTX is recessive (high).

Entering Initialization Mode does not change any of the configuration registers.

To initialize the CAN Controller, software has to set up the Bit Timing (CAN_BTR) and CAN options (CAN_MCR) registers.
To initialize the registers associated with the CAN filter banks (mode, scale, FIFO assignment, activation and filter values), software has to set the FINIT bit (CAN_FMR). Filter initialization also can be done outside the initialization mode.

*Note:* When FINIT=1, CAN reception is deactivated.
The filter values also can be modified by deactivating the associated filter activation bits (in the CAN_FA1R register).
If a filter bank is not used, it is recommended to leave it non active (leave the corresponding FACT bit cleared).
For code example refer to the Appendix section A.11.1: bxCAN initialization mode code example.

### 29.4.2 Normal mode

Once the initialization is complete, the software must request the hardware to enter Normal mode to be able to synchronize on the CAN bus and start reception and transmission.

The request to enter Normal mode is issued by clearing the INRQ bit in the CAN_MCR register. The bxCAN enters Normal mode and is ready to take part in bus activities when it has synchronized with the data transfer on the CAN bus. This is done by waiting for the occurrence of a sequence of 11 consecutive recessive bits (Bus Idle state). The switch to Normal mode is confirmed by the hardware by clearing the INAK bit in the CAN_MSR register.

The initialization of the filter values is independent from Initialization Mode but must be done while the filter is not active (corresponding FACTx bit cleared). The filter scale and mode configuration must be configured before entering Normal Mode.

### 29.4.3 Sleep mode (low-power)

To reduce power consumption, bxCAN has a low-power mode called Sleep mode. This mode is entered on software request by setting the SLEEP bit in the CAN_MCR register. In this mode, the bxCAN clock is stopped, however software can still access the bxCAN mailboxes.

If software requests entry to initialization mode by setting the INRQ bit while bxCAN is in Sleep mode, it must also clear the SLEEP bit.

bxCAN can be woken up (exit Sleep mode) either by software clearing the SLEEP bit or on detection of CAN bus activity.

On CAN bus activity detection, hardware automatically performs the wake-up sequence by clearing the SLEEP bit if the AWUM bit in the CAN_MCR register is set. If the AWUM bit is cleared, software has to clear the SLEEP bit when a wake-up interrupt occurs, in order to exit from Sleep mode.

*Note:* If the wake-up interrupt is enabled (WKUIE bit set in CAN_IER register) a wake-up interrupt is generated on detection of CAN bus activity, even if the bxCAN automatically performs the wake-up sequence.

After the SLEEP bit has been cleared, Sleep mode is exited once bxCAN has synchronized with the CAN bus, refer to Figure 313. The Sleep mode is exited once the SLAK bit has been cleared by hardware.
29.5 Test mode

Test mode can be selected by the SILM and LBKM bits in the CAN_BTR register. These bits must be configured while bxCAN is in Initialization mode. Once test mode has been selected, the INRQ bit in the CAN_MCR register must be reset to enter Normal mode.

29.5.1 Silent mode

The bxCAN can be put in Silent mode by setting the SILM bit in the CAN_BTR register. In Silent mode, the bxCAN is able to receive valid data frames and valid remote frames, but sends only recessive bits on the CAN bus and cannot start a transmission. If the bxCAN has to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the CAN Core monitors this dominant bit, although the CAN bus may remain in recessive state. Silent mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits (Acknowledge bits, Error frames).
29.5.2 Loop back mode

The bxCAN can be set in Loop Back Mode by setting the LBKM bit in the CAN_BTR register. In Loop Back Mode, the bxCAN treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) in a Receive mailbox.

This mode is provided for self-test functions. To be independent of external events, the CAN Core ignores acknowledge errors (no dominant bit sampled in the acknowledge slot of a data / remote frame) in Loop Back Mode. In this mode, the bxCAN performs an internal feedback from its Tx output to its Rx input. The actual value of the CANRX input pin is disregarded by the bxCAN. The transmitted messages can be monitored on the CANTX pin.

29.5.3 Loop back combined with silent mode

It is also possible to combine Loop back mode and Silent mode by setting the LBKM and SILM bits in the CAN_BTR register. This mode can be used for a “Hot Selftest”, meaning the bxCAN can be tested like in Loop back mode but without affecting a running CAN system connected to the CANTX and CANRX pins. In this mode, the CANRX pin is disconnected from the bxCAN and the CANTX pin is held recessive.
29.6 Behavior in debug mode

When the microcontroller enters the debug mode (Cortex®-M0 core halted), the bxCAN continues to work normally or stops, depending on:

- the DBG_CAN1_STOP bit in the DBG module for the single mode.
- the DBF bit in CAN_MCR. For more details, refer to Section 29.9.2: CAN control and status registers.

29.7 bxCAN functional description

29.7.1 Transmission handling

In order to transmit a message, the application must select one empty transmit mailbox, set up the identifier, the data length code (DLC) and the data before requesting the transmission by setting the corresponding TXRQ bit in the CAN_TIxR register. Once the mailbox has left empty state, the software no longer has write access to the mailbox registers. Immediately after the TXRQ bit has been set, the mailbox enters pending state and waits to become the highest priority mailbox, see Transmit Priority. As soon as the mailbox has the highest priority it is scheduled for transmission. The transmission of the message of the scheduled mailbox starts (enter transmit state) when the CAN bus becomes idle. Once the mailbox has been successfully transmitted, it becomes empty again. The hardware indicates a successful transmission by setting the RQCP and TXOK bits in the CAN_TSR register.

If the transmission fails, the cause is indicated by the ALST bit in the CAN_TSR register in case of an Arbitration Lost, and/or the TERR bit, in case of transmission error detection.

For code example refer to the Appendix section A.11.2: bxCAN transmit code example.

Transmit priority

By identifier

When more than one transmit mailbox is pending, the transmission order is given by the identifier of the message stored in the mailbox. The message with the lowest identifier value has the highest priority according to the arbitration of the CAN protocol. If the identifier values are equal, the lower mailbox number is scheduled first.
By transmit request order

The transmit mailboxes can be configured as a transmit FIFO by setting the TXFP bit in the CAN_MCR register. In this mode the priority order is given by the transmit request order.

This mode is very useful for segmented transmission.

Abort

A transmission request can be aborted by the user setting the ABRQ bit in the CAN_TSR register. In pending or scheduled state, the mailbox is aborted immediately. An abort request while the mailbox is in transmit state can have two results. If the mailbox is transmitted successfully the mailbox becomes empty with the TXOK bit set in the CAN_TSR register. If the transmission fails, the mailbox becomes scheduled, the transmission is aborted and becomes empty with TXOK cleared. In all cases the mailbox becomes empty again at least at the end of the current transmission.

Non automatic retransmission mode

This mode has been implemented in order to fulfill the requirement of the Time Triggered Communication option of the CAN standard. To configure the hardware in this mode the NART bit in the CAN_MCR register must be set.

In this mode, each transmission is started only once. If the first attempt fails, due to an arbitration loss or an error, the hardware does not automatically restart the message transmission.

At the end of the first transmission attempt, the hardware considers the request as completed and sets the RQCP bit in the CAN_TSR register. The result of the transmission is indicated in the CAN_TSR register by the TXOK, ALST and TERR bits.

Figure 317. Transmit mailbox states
29.7.2 Time triggered communication mode

In this mode, the internal counter of the CAN hardware is activated and used to generate the time stamp value stored in the CAN_RDTxR/CAN_TDTxR registers, respectively (for Rx and Tx mailboxes). The internal counter is incremented each CAN bit time (refer to Section 29.7.7). The internal counter is captured on the sample point of the Start Of Frame bit in both reception and transmission.

29.7.3 Reception handling

For the reception of CAN messages, three mailboxes organized as a FIFO are provided. In order to save CPU load, simplify the software and guarantee data consistency, the FIFO is managed completely by hardware. The application accesses the messages stored in the FIFO through the FIFO output mailbox.

Valid message

A received message is considered as valid when it has been received correctly according to the CAN protocol (no error until the last but one bit of the EOF field) and it passed through the identifier filtering successfully, see Section 29.7.4.

Figure 318. Receive FIFO states
FIFO management

Starting from the empty state, the first valid message received is stored in the FIFO which becomes pending_1. The hardware signals the event setting the FMP[1:0] bits in the CAN_RFR register to the value 01b. The message is available in the FIFO output mailbox. The software reads out the mailbox content and releases it by setting the RFOM bit in the CAN_RFR register. The FIFO becomes empty again. If a new valid message has been received in the meantime, the FIFO stays in pending_1 state and the new message is available in the output mailbox.

For code example refer to the Appendix section A.11.3: bxCAN receive code example.

If the application does not release the mailbox, the next valid message is stored in the FIFO which enters pending_2 state (FMP[1:0] = 10b). The storage process is repeated for the next valid message putting the FIFO into pending_3 state (FMP[1:0] = 11b). At this point, the software must release the output mailbox by setting the RFOM bit, so that a mailbox is free to store the next valid message. Otherwise the next valid message received causes a loss of message. Refer also to Section 29.7.5.

Overrun

Once the FIFO is in pending_3 state (i.e. the three mailboxes are full) the next valid message reception leads to an overrun and a message is lost. The hardware signals the overrun condition by setting the FOVR bit in the CAN_RFR register. Which message is lost depends on the configuration of the FIFO:

- If the FIFO lock function is disabled (RFLM bit in the CAN_MCR register cleared) the last message stored in the FIFO is overwritten by the new incoming message. In this case the latest messages are always available to the application.
- If the FIFO lock function is enabled (RFLM bit in the CAN_MCR register set) the most recent message is discarded and the software has the three oldest messages in the FIFO available.

Reception related interrupts

Once a message has been stored in the FIFO, the FMP[1:0] bits are updated and an interrupt request is generated if the FMPIE bit in the CAN_IER register is set.

When the FIFO becomes full (i.e. a third message is stored) the FULL bit in the CAN_RFR register is set and an interrupt is generated if the FFIE bit in the CAN_IER register is set.

On overrun condition, the FOVR bit is set and an interrupt is generated if the FOVIE bit in the CAN_IER register is set.

29.7.4 Identifier filtering

In the CAN protocol the identifier of a message is not associated with the address of a node but related to the content of the message. Consequently a transmitter broadcasts its message to all receivers. On message reception a receiver node decides - depending on the identifier value - whether the software needs the message or not. If the message is needed, it is copied into the SRAM. If not, the message must be discarded without intervention by the software.

To fulfill this requirement the bxCAN Controller provides 14 configurable and scalable filter banks (13-0) to the application, in order to receive only the messages the software needs.
This hardware filtering saves CPU resources which would be otherwise needed to perform filtering by software. Each filter bank \( x \) consists of two 32-bit registers, \( \text{CAN}_F \text{RxR}_0 \) and \( \text{CAN}_F \text{RxR}_1 \).

**Scalable width**

To optimize and adapt the filters to the application needs, each filter bank can be scaled independently. Depending on the filter scale a filter bank provides:

- One 32-bit filter for the STDID\([10:0]\), EXTID\([17:0]\), IDE and RTR bits.
- Two 16-bit filters for the STDID\([10:0]\), RTR, IDE and EXTID\([17:15]\) bits.

Refer to *Figure 319*.

Furthermore, the filters can be configured in mask mode or in identifier list mode.

**Mask mode**

In **mask** mode the identifier registers are associated with mask registers specifying which bits of the identifier are handled as “must match” or as “don’t care”.

**Identifier list mode**

In **identifier list** mode, the mask registers are used as identifier registers. Thus instead of defining an identifier and a mask, two identifiers are specified, doubling the number of single identifiers. All bits of the incoming identifier must match the bits specified in the filter registers.

**Filter bank scale and mode configuration**

The filter banks are configured by means of the corresponding CAN_FMR register. To configure a filter bank it must be deactivated by clearing the FACT bit in the CAN_FAR register. The filter scale is configured by means of the corresponding FSC\( x \) bit in the CAN_FS1R register, refer to *Figure 319*. The **identifier list** or **identifier mask** mode for the corresponding Mask/Identifier registers is configured by means of the FBM\( x \) bits in the CAN_FMR register.

To filter a group of identifiers, configure the Mask/Identifier registers in mask mode.

To select single identifiers, configure the Mask/Identifier registers in identifier list mode.

Filters not used by the application should be left deactivated.

Each filter within a filter bank is numbered (called the **Filter Number**) from 0 to a maximum dependent on the mode and the scale of each of the filter banks.

Concerning the filter configuration, refer to *Figure 319*. 
Once a message has been received in the FIFO it is available to the application. Typically, application data is copied into SRAM locations. To copy the data to the right location the application has to identify the data by means of the identifier. To avoid this, and to ease the access to the SRAM locations, the CAN controller provides a filter match index.

This index is stored in the mailbox together with the message according to the filter priority rules. Thus each received message has its associated filter match index.

The filter match index can be used in two ways:
- Compare the filter match index with a list of expected values.
- Use the filter match index as an index on an array to access the data destination location.

For non masked filters, the software no longer has to compare the identifier.

If the filter is masked the software reduces the comparison to the masked bits only.

The index value of the filter number does not take into account the activation state of the filter banks. In addition, two independent numbering schemes are used, one for each FIFO. Refer to Figure 320 for an example.
Figure 320. Example of filter numbering

Filter priority rules

Depending on the filter combination it may occur that an identifier passes successfully through several filters. In this case the filter match value stored in the receive mailbox is chosen according to the following priority rules:

- A 32-bit filter takes priority over a 16-bit filter.
- For filters of equal scale, priority is given to the Identifier List mode over the Identifier Mask mode.
- For filters of equal scale and mode, priority is given by the filter number (the lower the number, the higher the priority).
The example above shows the filtering principle of the bxCAN. On reception of a message, the identifier is compared first with the filters configured in identifier list mode. If there is a match, the message is stored in the associated FIFO and the index of the matching filter is stored in the filter match index. As shown in the example, the identifier matches with Identifier #2 thus the message content and FMI 2 is stored in the FIFO.

If there is no match, the incoming identifier is then compared with the filters configured in mask mode.

If the identifier does not match any of the identifiers configured in the filters, the message is discarded by hardware without disturbing the software.

### 29.7.5 Message storage

The interface between the software and the hardware for the CAN messages is implemented by means of mailboxes. A mailbox contains all information related to a message: identifier, data, control, status and time stamp information.

**Transmit mailbox**

The software sets up the message to be transmitted in an empty transmit mailbox. The status of the transmission is indicated by hardware in the CAN_TSR register.
Receive mailbox

When a message has been received, it is available to the software in the FIFO output mailbox. Once the software has handled the message (e.g. read it) the software must release the FIFO output mailbox by means of the RFOM bit in the CAN_RFR register to make the next incoming message available. The filter match index is stored in the MFMI field of the CAN_RDTxR register. The 16-bit time stamp value is stored in the TIME[15:0] field of CAN_RDTxR.

**Figure 322. CAN error state diagram**

![CAN error state diagram]

**29.7.6 Error management**

The error management as described in the CAN protocol is handled entirely by hardware using a Transmit Error Counter (TEC value, in CAN_ESR register) and a Receive Error Counter (REC value, in the CAN_ESR register), which get incremented or decremented according to the error condition. For detailed information about TEC and REC management, refer to the CAN standard.
Both of them may be read by software to determine the stability of the network. Furthermore, the CAN hardware provides detailed information on the current error status in CAN_ESR register. By means of the CAN_IER register (ERRIE bit, etc.), the software can configure the interrupt generation on error detection in a very flexible way.

**Bus-Off recovery**

The Bus-Off state is reached when TEC is greater than 255, this state is indicated by BOFF bit in CAN_ESR register. In Bus-Off state, the bxCAN is no longer able to transmit and receive messages.

Depending on the ABOM bit in the CAN_MCR register, bxCAN recovers from Bus-Off (become error active again) either automatically or on software request. But in both cases the bxCAN has to wait at least for the recovery sequence specified in the CAN standard (128 occurrences of 11 consecutive recessive bits monitored on CANRX).

If ABOM is set, the bxCAN starts the recovering sequence automatically after it has entered Bus-Off state.

If ABOM is cleared, the software must initiate the recovering sequence by requesting bxCAN to enter and to leave initialization mode.

*Note:* In initialization mode, bxCAN does not monitor the CANRX signal, therefore it cannot complete the recovery sequence. To recover, bxCAN must be in normal mode.

**29.7.7 Bit timing**

The bit timing logic monitors the serial bus-line and performs sampling and adjustment of the sample point by synchronizing on the start-bit edge and resynchronizing on the following edges.

Its operation may be explained simply by splitting nominal bit time into three segments as follows:

- **Synchronization segment (SYNC_SEG):** a bit change is expected to occur within this time segment. It has a fixed length of one time quantum (1 x tq).

- **Bit segment 1 (BS1):** defines the location of the sample point. It includes the PROP_SEG and PHASE_SEG1 of the CAN standard. Its duration is programmable between 1 and 16 time quanta but may be automatically lengthened to compensate for positive phase drifts due to differences in the frequency of the various nodes of the network.

- **Bit segment 2 (BS2):** defines the location of the transmit point. It represents the PHASE_SEG2 of the CAN standard. Its duration is programmable between 1 and 8 time quanta but may also be automatically shortened to compensate for negative phase drifts.

The resynchronization jump width (SJW) defines an upper bound to the amount of lengthening or shortening of the bit segments. It is programmable between 1 and 4 time quanta.

A valid edge is defined as the first transition in a bit time from dominant to recessive bus level provided the controller itself does not send a recessive bit.

If a valid edge is detected in BS1 instead of SYNC_SEG, BS1 is extended by up to SJW so that the sample point is delayed.

Conversely, if a valid edge is detected in BS2 instead of SYNC_SEG, BS2 is shortened by up to SJW so that the transmit point is moved earlier.
As a safeguard against programming errors, the configuration of the Bit timing register (CAN_BTR) is only possible while the device is in Standby mode.

**Note:** For a detailed description of the CAN bit timing and resynchronization mechanism, refer to the ISO 11898 standard.

![Figure 323. Bit timing](image)

Baud Rate = \( \frac{1}{\text{NominalBitTime}} \)

\[
\text{NominalBitTime} = 1 \times t_q + t_{BS1} + t_{BS2}
\]

with:

- \( t_{BS1} = t_q \times (TS1[3:0] + 1) \),
- \( t_{BS2} = t_q \times (TS2[2:0] + 1) \),
- \( t_q = (BRP[9:0] + 1) \times t_{PCLK} \)

where \( t_q \) refers to the Time quantum

\( t_{PCLK} \) = time period of the APB clock,

BRP[9:0], TS1[3:0] and TS2[2:0] are defined in the CAN_BTR Register.

**Legend and notes**

- $0 \leq N \leq 8$
- SOF: Start of frame
- RTR: Remote transmission request
- IDE: Identifier extension bit
- r0: Reserved bit
- DLC: Data length code
- CRC: Cyclic redundancy code
- Error flag: 6 dominant bits if node is error active, else 6 recessive bits
- Suspend transmission: applies to error passive nodes only
- EOF: End of frame
- ACK: Acknowledge bit
- Ctrl: Control
29.8 bxCAN interrupts

Four interrupt vectors are dedicated to bxCAN. Each interrupt source can be independently enabled or disabled by means of the CAN interrupt enable register (CAN_IER).

Figure 325. Event flags and interrupt generation

---

**Figure 325. Event flags and interrupt generation**

- CAN_IER
  - TRANSMIT INTERRUPT
  - FIFO 0 INTERRUPT
  - FIFO 1 INTERRUPT
  - STATUS CHANGE ERROR INTERRUPT

- CAN_TSR
  - CAN_RF0R
  - CAN_RF1R
  - CAN_ESR
  - CAN_MSR
• The **transmit interrupt** can be generated by the following events:
  – Transmit mailbox 0 becomes empty, RQCP0 bit in the CAN_TSR register set.
  – Transmit mailbox 1 becomes empty, RQCP1 bit in the CAN_TSR register set.
  – Transmit mailbox 2 becomes empty, RQCP2 bit in the CAN_TSR register set.
• The **FIFO 0 interrupt** can be generated by the following events:
  – Reception of a new message, FMP0 bits in the CAN_RF0R register are not ‘00’.
  – FIFO0 full condition, FULL0 bit in the CAN_RF0R register set.
  – FIFO0 overrun condition, FOVR0 bit in the CAN_RF0R register set.
• The **FIFO 1 interrupt** can be generated by the following events:
  – Reception of a new message, FMP1 bits in the CAN_RF1R register are not ‘00’.
  – FIFO1 full condition, FULL1 bit in the CAN_RF1R register set.
  – FIFO1 overrun condition, FOVR1 bit in the CAN_RF1R register set.
• The **error and status change interrupt** can be generated by the following events:
  – Error condition, for more details on error conditions refer to the CAN Error Status register (CAN_ESR).
  – Wake-up condition, SOF monitored on the CAN Rx signal.
  – Entry into Sleep mode.

29.9 **CAN registers**

The peripheral registers have to be accessed by words (32 bits).

29.9.1 **Register access protection**

Erroneous access to certain configuration registers can cause the hardware to temporarily disturb the whole CAN network. Therefore the CAN_BTR register can be modified by software only while the CAN hardware is in initialization mode.

Although the transmission of incorrect data does not cause problems at the CAN network level, it can severely disturb the application. A transmit mailbox can be only modified by software while it is in empty state, refer to **Figure 317: Transmit mailbox states**.

The filter values can be modified either deactivating the associated filter banks or by setting the FINIT bit. Moreover, the modification of the filter configuration (scale, mode and FIFO assignment) in CAN_FMxR, CAN_FSxR and CAN_FFAR registers can only be done when the filter initialization mode is set (FINIT=1) in the CAN_FMR register.

29.9.2 **CAN control and status registers**

Refer to **Section 1.2** for a list of abbreviations used in register descriptions.

**CAN master control register (CAN_MCR)**

Address offset: 0x00
Reset value: 0x0001 0002
Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **DBF**: Debug freeze
- 0: CAN working during debug
- 1: CAN reception/transmission frozen during debug. Reception FIFOs can still be accessed/controlled normally.

Bit 15 **RESET**: bxCAN software master reset
- 0: Normal operation.
- 1: Force a master reset of the bxCAN -> Sleep mode activated after reset (FMP bits and CAN_MCR register are initialized to the reset values). This bit is automatically reset to 0.

Bits 14:8 Reserved, must be kept at reset value.

Bit 7 **TTCM**: Time triggered communication mode
- 0: Time Triggered Communication mode disabled.
- 1: Time Triggered Communication mode enabled

*Note: For more information on Time Triggered Communication mode, refer to Section 29.7.2: Time triggered communication mode.*

Bit 6 **ABOM**: Automatic bus-off management
This bit controls the behavior of the CAN hardware on leaving the Bus-Off state.
- 0: The Bus-Off state is left on software request, once 128 occurrences of 11 recessive bits have been monitored and the software has first set and cleared the INRQ bit of the CAN_MCR register.
- 1: The Bus-Off state is left automatically by hardware once 128 occurrences of 11 recessive bits have been monitored.

For detailed information on the Bus-Off state refer to Section 29.7.6: Error management.

Bit 5 **AWUM**: Automatic wake-up mode
This bit controls the behavior of the CAN hardware on message reception during Sleep mode.
- 0: The Sleep mode is left on software request by clearing the SLEEP bit of the CAN_MCR register.
- 1: The Sleep mode is left automatically by hardware on CAN message detection.

The SLEEP bit of the CAN_MCR register and the SLAK bit of the CAN_MSR register are cleared by hardware.

Bit 4 **NART**: No automatic retransmission
- 0: The CAN hardware automatically retransmits the message until it has been successfully transmitted according to the CAN standard.
- 1: A message is transmitted only once, independently of the transmission result (successful, error or arbitration lost).
Bit 3 **RFLM**: Receive FIFO locked mode
- **0**: Receive FIFO not locked on overrun. Once a receive FIFO is full the next incoming message overwrites the previous one.
- **1**: Receive FIFO locked against overrun. Once a receive FIFO is full the next incoming message is discarded.

Bit 2 **TXFP**: Transmit FIFO priority
This bit controls the transmission order when several mailboxes are pending at the same time.
- **0**: Priority driven by the identifier of the message
- **1**: Priority driven by the request order (chronologically)

Bit 1 **SLEEP**: Sleep mode request
This bit is set by software to request the CAN hardware to enter the Sleep mode. Sleep mode is entered as soon as the current CAN activity (transmission or reception of a CAN frame) has been completed.
- This bit is cleared by software to exit Sleep mode.
- This bit is cleared by hardware when the AWUM bit is set and a SOF bit is detected on the CAN Rx signal.
- This bit is set after reset - CAN starts in Sleep mode.

Bit 0 **INRQ**: Initialization request
The software clears this bit to switch the hardware into normal mode. Once 11 consecutive recessive bits have been monitored on the Rx signal the CAN hardware is synchronized and ready for transmission and reception. Hardware signals this event by clearing the INAK bit in the CAN_MSR register.
- Software sets this bit to request the CAN hardware to enter initialization mode. Once software has set the INRQ bit, the CAN hardware waits until the current CAN activity (transmission or reception) is completed before entering the initialization mode. Hardware signals this event by setting the INAK bit in the CAN_MSR register.

### CAN master status register (CAN_MSR)

</table>

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **RX**: CAN Rx signal  
Monitors the actual value of the CAN_RX Pin.

Bit 10 **SAMP**: Last sample point  
The value of RX on the last sample point (current received bit value).
RM0091 Controller area network (bxCAN)

Bit 9 **RXM**: Receive mode
The CAN hardware is currently receiver.

Bit 8 **TXM**: Transmit mode
The CAN hardware is currently transmitter.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **SLAK**: Sleep acknowledge interrupt
When SLKIE=1, this bit is set by hardware to signal that the bxCAN has entered Sleep Mode. When set, this bit generates a status change interrupt if the SLKIE bit in the CAN_IER register is set.
This bit is cleared by software or by hardware, when SLAK is cleared.
*Note:* When SLKIE=0, no polling on SLAKI is possible. *In this case the SLAK bit can be polled.*

Bit 3 **WKUI**: Wake-up interrupt
This bit is set by hardware to signal that a SOF bit has been detected while the CAN hardware was in Sleep mode. Setting this bit generates a status change interrupt if the WKUIE bit in the CAN_IER register is set.
This bit is cleared by software.

Bit 2 **ERRI**: Error interrupt
This bit is set by hardware when a bit of the CAN_ESR has been set on error detection and the corresponding interrupt in the CAN_IER is enabled. Setting this bit generates a status change interrupt if the ERRIE bit in the CAN_IER register is set.
This bit is cleared by software.

Bit 1 **SLAK**: Sleep acknowledge
This bit is set by hardware and indicates to the software that the CAN hardware is now in Sleep mode. This bit acknowledges the Sleep mode request from the software (set SLEEP bit in CAN_MCR register).
This bit is cleared by hardware when the CAN hardware has left Sleep mode (to be synchronized on the CAN bus). To be synchronized the hardware has to monitor a sequence of 11 consecutive recessive bits on the CAN RX signal.
*Note:* The process of leaving Sleep mode is triggered when the SLEEP bit in the CAN_MCR register is cleared. Refer to the AWUM bit of the CAN_MCR register description for detailed information for clearing SLEEP bit

Bit 0 **INAK**: Initialization acknowledge
This bit is set by hardware and indicates to the software that the CAN hardware is now in initialization mode. This bit acknowledges the initialization request from the software (set INRQ bit in CAN_MCR register).
This bit is cleared by hardware when the CAN hardware has left the initialization mode (to be synchronized on the CAN bus). To be synchronized the hardware has to monitor a sequence of 11 consecutive recessive bits on the CAN RX signal.

**CAN transmit status register (CAN_TSR)**
Address offset: 0x08
Reset value: 0x1C00 0000
Bit 31  LOW2: Lowest priority flag for mailbox 2
This bit is set by hardware when more than one mailbox are pending for transmission and mailbox 2 has the lowest priority.

Bit 30  LOW1: Lowest priority flag for mailbox 1
This bit is set by hardware when more than one mailbox are pending for transmission and mailbox 1 has the lowest priority.

Bit 29  LOW0: Lowest priority flag for mailbox 0
This bit is set by hardware when more than one mailbox are pending for transmission and mailbox 0 has the lowest priority.

Note: The LOW[2:0] bits are set to 0 when only one mailbox is pending.

Bit 28  TME2: Transmit mailbox 2 empty
This bit is set by hardware when no transmit request is pending for mailbox 2.

Bit 27  TME1: Transmit mailbox 1 empty
This bit is set by hardware when no transmit request is pending for mailbox 1.

Bit 26  TME0: Transmit mailbox 0 empty
This bit is set by hardware when no transmit request is pending for mailbox 0.

Bits 25:24  CODE[1:0]: Mailbox code
In case at least one transmit mailbox is free, the code value is equal to the number of the next transmit mailbox free.
In case all transmit mailboxes are pending, the code value is equal to the number of the transmit mailbox with the lowest priority.

Bit 23  ABRQ2: Abort request for mailbox 2
Set by software to abort the transmission request for the corresponding mailbox.
Cleared by hardware when the mailbox becomes empty.
Setting this bit has no effect when the mailbox is not pending for transmission.

Bits 22:20  Reserved, must be kept at reset value.

Bit 19  TERR2: Transmission error of mailbox 2
This bit is set when the previous TX failed due to an error.

Bit 18  ALST2: Arbitration lost for mailbox 2
This bit is set when the previous TX failed due to an arbitration lost.

Bit 17  TXOK2: Transmission OK of mailbox 2
The hardware updates this bit after each transmission attempt.
0: The previous transmission failed
1: The previous transmission was successful
This bit is set by hardware when the transmission request on mailbox 2 has been completed successfully. Refer to Figure 317.
Bit 16 **RQCP2**: Request completed mailbox2
Set by hardware when the last request (transmit or abort) has been performed.
Cleared by software writing a “1” or by hardware on transmission request (TXRQ2 set in CAN_TMID2R register).
Clearing this bit clears all the status bits (TXOK2, ALST2 and TERR2) for Mailbox 2.

Bit 15 **ABRQ1**: Abort request for mailbox 1
Set by software to abort the transmission request for the corresponding mailbox.
Cleared by hardware when the mailbox becomes empty.
Setting this bit has no effect when the mailbox is not pending for transmission.

Bits 14:12 Reserved, must be kept at reset value.

Bit 11 **TERR1**: Transmission error of mailbox1
This bit is set when the previous TX failed due to an error.

Bit 10 **ALST1**: Arbitration lost for mailbox1
This bit is set when the previous TX failed due to an arbitration lost.

Bit 9 **TXOK1**: Transmission OK of mailbox1
The hardware updates this bit after each transmission attempt.
0: The previous transmission failed
1: The previous transmission was successful
This bit is set by hardware when the transmission request on mailbox 1 has been completed successfully. Refer to *Figure 317*.

Bit 8 **RQCP1**: Request completed mailbox1
Set by hardware when the last request (transmit or abort) has been performed.
Cleared by software writing a “1” or by hardware on transmission request (TXRQ1 set in CAN_TI1R register).
Clearing this bit clears all the status bits (TXOK1, ALST1 and TERR1) for Mailbox 1.

Bit 7 **ABRQ0**: Abort request for mailbox0
Set by software to abort the transmission request for the corresponding mailbox.
Cleared by hardware when the mailbox becomes empty.
Setting this bit has no effect when the mailbox is not pending for transmission.

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **TERR0**: Transmission error of mailbox0
This bit is set when the previous TX failed due to an error.

Bit 2 **ALST0**: Arbitration lost for mailbox0
This bit is set when the previous TX failed due to an arbitration lost.

Bit 1 **TXOK0**: Transmission OK of mailbox0
The hardware updates this bit after each transmission attempt.
0: The previous transmission failed
1: The previous transmission was successful
This bit is set by hardware when the transmission request on mailbox 1 has been completed successfully. Refer to *Figure 317*.

Bit 0 **RQCP0**: Request completed mailbox0
Set by hardware when the last request (transmit or abort) has been performed.
Cleared by software writing a “1” or by hardware on transmission request (TXRQ0 set in CAN_TIOR register).
Clearing this bit clears all the status bits (TXOK0, ALST0 and TERR0) for Mailbox 0.

Bits 31:6  Reserved, must be kept at reset value.

Bit 5  **RFOM0**: Release FIFO 0 output mailbox

Set by software to release the output mailbox of the FIFO. The output mailbox can only be released when at least one message is pending in the FIFO. Setting this bit when the FIFO is empty has no effect. If at least two messages are pending in the FIFO, the software has to release the output mailbox to access the next message.

Cleared by hardware when the output mailbox has been released.

Bit 4  **FOVR0**: FIFO 0 overrun

This bit is set by hardware when a new message has been received and passed the filter while the FIFO was full.

This bit is cleared by software.

Bit 3  **FULL0**: FIFO 0 full

Set by hardware when three messages are stored in the FIFO.

This bit is cleared by software.

Bit 2  Reserved, must be kept at reset value.

Bits 1:0  **FMP0[1:0]**: FIFO 0 message pending

These bits indicate how many messages are pending in the receive FIFO.

FMP is increased each time the hardware stores a new message into the FIFO. FMP is decreased each time the software releases the output mailbox by setting the RFOM0 bit.

Controller area network (bxCAN)

RM0091

Bit 5 **RFOM1**: Release FIFO 1 output mailbox
   Set by software to release the output mailbox of the FIFO. The output mailbox can only be
   released when at least one message is pending in the FIFO. Setting this bit when the FIFO
   is empty has no effect. If at least two messages are pending in the FIFO, the software has to
   release the output mailbox to access the next message.
   Cleared by hardware when the output mailbox has been released.

Bit 4 **FOVR1**: FIFO 1 overrun
   This bit is set by hardware when a new message has been received and passed the filter
   while the FIFO was full.
   This bit is cleared by software.

Bit 3 **FULL1**: FIFO 1 full
   Set by hardware when three messages are stored in the FIFO.
   This bit is cleared by software.

Bit 2 Reserved, must be kept at reset value.

Bits 1:0 **FMP1[1:0]**: FIFO 1 message pending
   These bits indicate how many messages are pending in the receive FIFO1.
   FMP1 is increased each time the hardware stores a new message in to the FIFO1. FMP is
   decreased each time the software releases the output mailbox by setting the RFOM1 bit.

**CAN interrupt enable register (CAN_IER)**

Address offset: 0x14

Reset value: 0x0000 0000

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **SLKIE**: Sleep interrupt enable
   0: No interrupt when SLAKI bit is set.
   1: Interrupt generated when SLAKI bit is set.

Bit 16 **WKUIE**: Wake-up interrupt enable
   0: No interrupt when WKUI is set.
   1: Interrupt generated when WKUI bit is set.

Bit 15 **ERRIE**: Error interrupt enable
   0: No interrupt is generated when an error condition is pending in the CAN_ESR.
   1: An interrupt is generation when an error condition is pending in the CAN_ESR.

Bits 14:12 Reserved, must be kept at reset value.
Bit 11 **LECIE**: Last error code interrupt enable
0: ERRI bit is not set when the error code in LEC[2:0] is set by hardware on error detection.
1: ERRI bit is set when the error code in LEC[2:0] is set by hardware on error detection.

Bit 10 **BOFIE**: Bus-off interrupt enable
0: ERRI bit is not set when BOFF is set.
1: ERRI bit is set when BOFF is set.

Bit 9 **EPVIE**: Error passive interrupt enable
0: ERRI bit is not set when EPVF is set.
1: ERRI bit is set when EPVF is set.

Bit 8 **EWGIE**: Error warning interrupt enable
0: ERRI bit is not set when EWGF is set.
1: ERRI bit is set when EWGF is set.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **FOVIE1**: FIFO overrun interrupt enable
0: No interrupt when FOVR is set.
1: Interrupt generation when FOVR is set.

Bit 5 **FFIE1**: FIFO full interrupt enable
0: No interrupt when FULL bit is set.
1: Interrupt generated when FULL bit is set.

Bit 4 **FMPIE1**: FIFO message pending interrupt enable
0: No interrupt generated when state of FMP[1:0] bits are not 00b.
1: Interrupt generated when state of FMP[1:0] bits are not 00b.

Bit 3 **FOVIE0**: FIFO overrun interrupt enable
0: No interrupt when FOVR bit is set.
1: Interrupt generated when FOVR bit is set.

Bit 2 **FFIE0**: FIFO full interrupt enable
0: No interrupt when FULL bit is set.
1: Interrupt generated when FULL bit is set.

Bit 1 **FMPIE0**: FIFO message pending interrupt enable
0: No interrupt generated when state of FMP[1:0] bits are not 00b.
1: Interrupt generated when state of FMP[1:0] bits are not 00b.

Bit 0 **TMEIE**: Transmit mailbox empty interrupt enable
0: No interrupt when RQCPx bit is set.
1: Interrupt generated when RQCPx bit is set.

*Note: Refer to Section 29.8: bxCAN interrupts.*
**CAN error status register (CAN_ESR)**

Address offset: 0x18  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit</th>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
</table>
| 31-24 | REC[7:0] | Receive error counter  
The implementing part of the fault confinement mechanism of the CAN protocol. In case of an error during reception, this counter is incremented by 1 or by 8 depending on the error condition as defined by the CAN standard. After every successful reception the counter is decremented by 1 or reset to 120 if its value was higher than 128. When the counter value exceeds 127, the CAN controller enters the error passive state. |
| 23-16 | TEC[7:0] | Least significant byte of the 9-bit transmit error counter  
The implementing part of the fault confinement mechanism of the CAN protocol. |
| 15-7 | Reserved | Must be kept at reset value. |
| 6-4 | LEC[2:0] | Last error code  
This field is set by hardware and holds a code which indicates the error condition of the last error detected on the CAN bus. If a message has been transferred (reception or transmission) without error, this field is cleared to 0.  
The LEC[2:0] bits can be set to value 0b111 by software. They are updated by hardware to indicate the current communication status.  
000: No error  
001: Stuff error  
010: Form error  
011: Acknowledgment error  
100: Bit recessive error  
101: Bit dominant error  
110: CRC error  
111: Set by software |
| 3 | Reserved | Must be kept at reset value. |
| 2 | BOFF | Bus-off flag  
This bit is set by hardware when it enters the bus-off state. The bus-off state is entered on TEC overflow, greater than 255, refer to Section 29.7.6: Error management. |
| 1 | EPVF | Error passive flag  
This bit is set by hardware when the Error passive limit has been reached (Receive Error Counter or Transmit Error Counter > 127). |
| 0 | EWGF | Error warning flag  
This bit is set by hardware when the warning limit has been reached (Receive Error Counter or Transmit Error Counter ≥ 96). |
### CAN bit timing register (CAN_BTR)

Address offset: 0x1C  
Reset value: 0x0123 0000  
This register can only be accessed by the software when the CAN hardware is in initialization mode.

**Bit 31** **SILM**: Silent mode (debug)  
0: Normal operation  
1: Silent Mode

**Bit 30** **LBKM**: Loop back mode (debug)  
0: Loop Back Mode disabled  
1: Loop Back Mode enabled

Bits 29:26 Reserved, must be kept at reset value.

**Bits 25:24** **SJW[1:0]**: Resynchronization jump width  
These bits define the maximum number of time quanta the CAN hardware is allowed to lengthen or shorten a bit to perform the resynchronization.  
\[ t_{RJW} = t_q \times (SJW[1:0] + 1) \]

**Bit 23** Reserved, must be kept at reset value.

**Bits 22:20** **TS2[2:0]**: Time segment 2  
These bits define the number of time quanta in Time Segment 2.  
\[ t_{BS2} = t_q \times (TS2[2:0] + 1) \]

**Bits 19:16** **TS1[3:0]**: Time segment 1  
These bits define the number of time quanta in Time Segment 1.  
\[ t_{BS1} = t_q \times (TS1[3:0] + 1) \]

For more information on bit timing, refer to Section 29.7.7: Bit timing.

Bits 15:10 Reserved, must be kept at reset value.

**Bits 9:0** **BRP[9:0]**: Baud rate prescaler  
These bits define the length of a time quanta.  
\[ t_q = (BRP[9:0]+1) \times t_{PCLK} \]
29.9.3 CAN mailbox registers

This chapter describes the registers of the transmit and receive mailboxes. Refer to Section 29.7.5: Message storage for detailed register mapping.

Transmit and receive mailboxes have the same registers except:
- The FMI field in the CAN_RDTxR register.
- A receive mailbox is always write protected.
- A transmit mailbox is write-enabled only while empty, corresponding TME bit in the CAN_TSR register set.

There are three TX mailboxes and two RX mailboxes. Each RX Mailbox allows access to a 3-level depth FIFO, the access being offered only to the oldest received message in the FIFO.

Each mailbox consist of four registers.

FIFO0 FIFO1 Three Tx Mailboxes

CAN TX mailbox identifier register (CAN_TlxR) (x = 0..2)

Address offsets: 0x180, 0x190, 0x1A0

Reset value: 0xXXXX XXXX (except bit 0, TXRQ = 0)

All TX registers are write protected when the mailbox is pending transmission (TMEx reset).

This register also implements the TX request control (bit 0) - reset value 0.

Bits 31:21 **STID[10:0]/EXID[28:18]**: Standard identifier or extended identifier

The standard identifier or the MSBs of the extended identifier (depending on the IDE bit value).

Bit 20:3 **EXID[17:0]**: Extended identifier

The LSBs of the extended identifier.
Bit 2 **IDE**: Identifier extension  
This bit defines the identifier type of message in the mailbox.  
0: Standard identifier.  
1: Extended identifier.

Bit 1 **RTR**: Remote transmission request  
0: Data frame  
1: Remote frame

Bit 0 **TXRQ**: Transmit mailbox request  
Set by software to request the transmission for the corresponding mailbox.  
Cleared by hardware when the mailbox becomes empty.

**CAN mailbox data length control and time stamp register**  
(CAN_TDTxR) (x = 0..2)  
All bits of this register are write protected when the mailbox is not in empty state.  
Address offsets: 0x184, 0x194, 0x1A4  
Reset value: 0xXXXX XXXX

858/1017 RM0091 Rev 10
Bits 31:16  \textbf{TIME}[15:0]: Message time stamp  
This field contains the 16-bit timer value captured at the SOF detection.

Bits 15:8 \textbf{FMI}[7:0]: Filter match index  
This register contains the index of the filter the message stored in the mailbox passed through. For more details on identifier filtering, refer to Section 29.7.4: Identifier filtering.

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 \textbf{DLC}[3:0]: Data length code  
This field defines the number of data bytes a data frame contains (0 to 8). It is 0 in the case of a remote frame request.

**CAN receive FIFO mailbox data low register (CAN\_RDLxR) (x = 0..1)**

All bits of this register are write protected when the mailbox is not in empty state.

Address offsets: 0x1B8, 0x1C8

Reset value: 0xXXXX XXXX

All RX registers are write protected.

Bits 31:1  Reserved, must be kept at reset value.

Bit 0  FINIT: Filter initialization mode

Initialization mode for filter banks

0: Active filters mode.

1: Initialization mode for the filters.

CAN filter mode register (CAN_FM1R)

Address offset: 0x204
Reset value: 0x0000 0000

This register can be written only when the filter initialization mode is set (FINIT=1) in the CAN_FMR register.
CAN filter scale register (CAN_FS1R)

Address offset: 0x20C
Reset value: 0x0000 0000

This register can be written only when the filter initialization mode is set (FINIT=1) in the CAN_FMR register.

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:0 \textbf{FBMx}: Filter mode
Mode of the registers of Filter x.
0: Two 32-bit registers of filter bank x are in Identifier Mask mode.
1: Two 32-bit registers of filter bank x are in Identifier List mode.

Notes:
- Refer to Figure 319: Filter bank scale configuration - Register organization.

CAN filter FIFO assignment register (CAN_FFA1R)

Address offset: 0x214
Reset value: 0x0000 0000

This register can be written only when the filter initialization mode is set (FINIT=1) in the CAN_FMR register.

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:0 \textbf{FSCx}: Filter scale configuration
These bits define the scale configuration of Filters 13-0.
0: Dual 16-bit scale configuration
1: Single 32-bit scale configuration

Note:
- Refer to Figure 319: Filter bank scale configuration - Register organization.
**Controller area network (bxCAN)**

- **Bits 31:14** Reserved, must be kept at reset value.
- **Bits 13:0** **FACTx**: Filter active  
  The software sets this bit to activate Filter x. To modify the Filter x registers (CAN_FxR[0:7]), the FACTx bit must be cleared or the FINIT bit of the CAN_FMR register must be set.  
  0: Filter x is not active  
  1: Filter x is active
Filter bank i register x (CAN_FiRx) (i = 0..13, x = 1, 2)

Address offsets: 0x240 to 0x2AC
Reset value: 0xXXXX XXXX

There are 14 filter banks, i= 0 to 13. Each filter bank i is composed of two 32-bit registers, CAN_FiR[2:1].

This register can only be modified when the FACTx bit of the CAN_FAxR register is cleared or when the FINIT bit of the CAN_FMR register is set.

In all configurations:

Bits 31:0 FB[31:0]: Filter bits

- **Identifier**
  Each bit of the register specifies the level of the corresponding bit of the expected identifier.
  0: Dominant bit is expected
  1: Recessive bit is expected

- **Mask**
  Each bit of the register specifies whether the bit of the associated identifier register must match with the corresponding bit of the expected identifier or not.
  0: Do not care, the bit is not used for the comparison
  1: Must match, the bit of the incoming identifier must have the same level has specified in the corresponding identifier register of the filter.

**Note:** Depending on the scale and mode configuration of the filter, the function of each register can differ. For the filter mapping, functions description and mask registers association, refer to Section 29.7.4: Identifier filtering.

A Mask/Identifier register in mask mode has the same bit mapping as in identifier list mode.

For the register mapping/addresses of the filter banks refer to Table 120.
### 29.9.5 bxCAN register map

Refer to Section 2.2 on page 46 for the register boundary addresses.

30 Universal serial bus full-speed device interface (USB)

This section applies to STM32F04x, STM32F072 and STM32F078 devices only.

30.1 Introduction

The USB peripheral implements an interface between a full-speed USB 2.0 bus and the APB bus.

USB suspend/resume are supported, which allows to stop the device clocks for low-power consumption.

30.2 USB main features

- USB specification version 2.0 full-speed compliant
- Configurable number of endpoints from 1 to 8
- Up to 1024 bytes of dedicated packet buffer memory SRAM (last 256 Bytes are exclusively shared with CAN peripheral)
- Cyclic redundancy check (CRC) generation/checking, Non-return-to-zero Inverted (NRZI) encoding/decoding and bit-stuffing
- Isochronous transfers support
- Double-buffered bulk/isochronous endpoint support
- USB Suspend/Resume operations
- Frame locked clock pulse generation
- USB 2.0 Link Power Management support
- Battery Charging Specification Revision 1.2 support
- USB connect / disconnect capability (controllable embedded pull-up resistor on USB_DP line)

30.3 USB implementation

Table 121 describes the USB implementation in the devices.

<table>

30.4 USB functional description

*Figure 327* shows the block diagram of the USB peripheral.

![Figure 327. USB peripheral block diagram](image)

The USB peripheral provides an USB-compliant connection between the host PC and the function implemented by the microcontroller. Data transfer between the host PC and the system memory occurs through a dedicated packet buffer memory accessed directly by the USB peripheral. This dedicated memory size is up to 1024 bytes, and up to 16 monodirectional or 8 bidirectional endpoints can be used. The USB peripheral interfaces with the USB host, detecting token packets, handling data transmission/reception, and processing handshake packets as required by the USB standard. Transaction formatting is performed by the hardware, including CRC generation and checking.

Each endpoint is associated with a buffer description block indicating where the endpoint-related memory area is located, how large it is or how many bytes must be transmitted. When a token for a valid function/endpoint pair is recognized by the USB peripheral, the related data transfer (if required and if the endpoint is configured) takes
place. The data buffered by the USB peripheral is loaded in an internal 16-bit register and memory access to the dedicated buffer is performed. When all the data has been transferred, if needed, the proper handshake packet over the USB is generated or expected according to the direction of the transfer.

At the end of the transaction, an endpoint-specific interrupt is generated, reading status registers and/or using different interrupt response routines. The microcontroller can determine:

- which endpoint has to be served,
- which type of transaction took place, if errors occurred (bit stuffing, format, CRC, protocol, missing ACK, over/underrun, etc.).

Special support is offered to isochronous transfers and high throughput bulk transfers, implementing a double buffer usage, which allows to always have an available buffer for the USB peripheral while the microcontroller uses the other one.

The unit can be placed in low-power mode (SUSPEND mode), by writing in the control register, whenever required. At this time, all static power dissipation is avoided, and the USB clock can be slowed down or stopped. The detection of activity at the USB inputs, while in low-power mode, wakes the device up asynchronously. A special interrupt source can be connected directly to a wake-up line to allow the system to immediately restart the normal clock generation and/or support direct clock start/stop.

30.4.1 Description of USB blocks

The USB peripheral implements all the features related to USB interfacing, which include the following blocks:

- **USB Physical Interface (USB PHY):** This block is maintaining the electrical interface to an external USB host. It contains the differential analog transceiver itself, controllable embedded pull-up resistor (connected to USB_DP line) and support for Battery Charging Detection (BCD), multiplexed on same USB_DP and USB_DM lines. The output enable control signal of the analog transceiver (active low) is provided externally on USB_NOE. It can be used to drive some activity LED or to provide information about the actual communication direction to some other circuitry.

- **Serial Interface Engine (SIE):** The functions of this block include: synchronization pattern recognition, bit-stuffing, CRC generation and checking, PID verification/generation, and handshake evaluation. It must interface with the USB transceivers and uses the virtual buffers provided by the packet buffer interface for local data storage. This unit also generates signals according to USB peripheral events, such as Start of Frame (SOF), USB_Reset, Data errors etc. and to Endpoint related events like end of transmission or correct reception of a packet; these signals are then used to generate interrupts.

- **Timer:** This block generates a start-of-frame locked clock pulse and detects a global suspend (from the host) when no traffic has been received for 3 ms.

- **Packet Buffer Interface:** This block manages the local memory implementing a set of buffers in a flexible way, both for transmission and reception. It can choose the proper buffer according to requests coming from the SIE and locate them in the memory addresses pointed by the Endpoint registers. It increments the address after each exchanged byte until the end of packet, keeping track of the number of exchanged bytes and preventing the buffer to overrun the maximum capacity.
Endpoint-Related Registers: Each endpoint has an associated register containing the endpoint type and its current status. For mono-directional/single-buffer endpoints, a single register can be used to implement two distinct endpoints. The number of registers is 8, allowing up to 16 mono-directional/single-buffer or up to 7 double-buffer endpoints in any combination. For example the USB peripheral can be programmed to have 4 double buffer endpoints and 8 single-buffer/mono-directional endpoints.

Control Registers: These are the registers containing information about the status of the whole USB peripheral and used to force some USB events, such as resume and power-down.

Interrupt Registers: These contain the Interrupt masks and a record of the events. They can be used to inquire an interrupt reason, the interrupt status or to clear the status of a pending interrupt.

Note: * Endpoint 0 is always used for control transfer in single-buffer mode.

The USB peripheral is connected to the APB bus through an APB interface, containing the following blocks:

- Packet Memory: This is the local memory that physically contains the Packet Buffers. It can be used by the Packet Buffer interface, which creates the data structure and can be accessed directly by the application software. The size of the Packet Memory is up to 1024 bytes, structured as 512 half-words of 16 bits.

- Arbiter: This block accepts memory requests coming from the APB bus and from the USB interface. It resolves the conflicts by giving priority to APB accesses, while always reserving half of the memory bandwidth to complete all USB transfers. This time-duplex scheme implements a virtual dual-port SRAM that allows memory access, while an USB transaction is happening. Multiword APB transfers of any length are also allowed by this scheme.

- Register Mapper: This block collects the various byte-wide and bit-wide registers of the USB peripheral in a structured 16-bit wide half-word set addressed by the APB.

- APB Wrapper: This provides an interface to the APB for the memory and register. It also maps the whole USB peripheral in the APB address space.

- Interrupt Mapper: This block is used to select how the possible USB events can generate interrupts and map them to the NVIC.

### 30.5 Programming considerations

In the following sections, the expected interactions between the USB peripheral and the application program are described, in order to ease application software development.

#### 30.5.1 Generic USB device programming

This part describes the main tasks required of the application software in order to obtain USB compliant behavior. The actions related to the most general USB events are taken into account and paragraphs are dedicated to the special cases of double-buffered endpoints and Isochronous transfers. Apart from system reset, action is always initiated by the USB peripheral, driven by one of the USB events described below.
30.5.2 System and power-on reset

Upon system and power-on reset, the first operation the application software should perform is to provide all required clock signals to the USB peripheral and subsequently de-assert its reset signal so to be able to access its registers. The whole initialization sequence is hereafter described.

As a first step application software needs to activate register macrocell clock and de-assert macrocell specific reset signal using related control bits provided by device clock management logic.

After that, the analog part of the device related to the USB transceiver must be switched on using the PDWN bit in CNTR register, which requires a special handling. This bit is intended to switch on the internal voltage references that supply the port transceiver. This circuit has a defined startup time (\(t_{\text{STARTUP}}\) specified in the datasheet) during which the behavior of the USB transceiver is not defined. It is thus necessary to wait this time, after setting the PDWN bit in the CNTR register, before removing the reset condition on the USB part (by clearing the FRES bit in the CNTR register). Clearing the ISTR register then removes any spurious pending interrupt before any other macrocell operation is enabled.

At system reset, the microcontroller must initialize all required registers and the packet buffer description table, to make the USB peripheral able to properly generate interrupts and data transfers. All registers not specific to any endpoint must be initialized according to the needs of application software (choice of enabled interrupts, chosen address of packet buffers, etc.). Then the process continues as for the USB reset case (see further paragraph).

USB reset (RESET interrupt)

When this event occurs, the USB peripheral is put in the same conditions it is left by the system reset after the initialization described in the previous paragraph: communication is disabled in all endpoint registers (the USB peripheral will not respond to any packet). As a response to the USB reset event, the USB function must be enabled, having as USB address 0, implementing only the default control endpoint (endpoint address is 0 too). This is accomplished by setting the Enable Function (EF) bit of the USB_DADDR register and initializing the EP0R register and its related packet buffers accordingly. During USB enumeration process, the host assigns a unique address to this device, which must be written in the ADD[6:0] bits of the USB_DADDR register, and configures any other necessary endpoint.

When a RESET interrupt is received, the application software is responsible to enable again the default endpoint of USB function 0 within 10 ms from the end of reset sequence which triggered the interrupt.

Structure and usage of packet buffers

Each bidirectional endpoint may receive or transmit data from/to the host. The received data is stored in a dedicated memory buffer reserved for that endpoint, while another memory buffer contains the data to be transmitted by the endpoint. Access to this memory is performed by the packet buffer interface block, which delivers a memory access request and waits for its acknowledgment. Since the packet buffer memory has to be accessed by the microcontroller also, an arbitration logic takes care of the access conflicts, using half APB cycle for microcontroller access and the remaining half for the USB peripheral access. In this way, both the agents can operate as if the packet memory is a dual-port SRAM, without being aware of any conflict even when the microcontroller is performing back-to-
back accesses. The USB peripheral logic uses a dedicated clock. The frequency of this
dedicated clock is fixed by the requirements of the USB standard at 48 MHz, and this can be
different from the clock used for the interface to the APB bus. Different clock configurations
are possible where the APB clock frequency can be higher or lower than the USB peripheral
one.

Note: Due to USB data rate and packet memory interface requirements, the APB clock must have
a minimum frequency of 10 MHz to avoid data overrun/underrun problems.

Each endpoint is associated with two packet buffers (usually one for transmission and the
other one for reception). Buffers can be placed anywhere inside the packet memory
because their location and size is specified in a buffer description table, which is also
located in the packet memory at the address indicated by the USB_BTABLE register. Each
table entry is associated to an endpoint register and it is composed of four 16-bit half-words
so that table start address must always be aligned to an 8-byte boundary (the lowest three
bits of USB_BTABLE register are always “000”). Buffer descriptor table entries are
described in the Section 30.6.2: Buffer descriptor table. If an endpoint is unidirectional and it
is neither an Isochronous nor a double-buffered bulk, only one packet buffer is required (the
one related to the supported transfer direction). Other table locations related to unsupported
transfer directions or unused endpoints, are available to the user. Isochronous and double-
buffered bulk endpoints have special handling of packet buffers (Refer to Section 30.5.4:
Isochronous transfers and Section 30.5.3: Double-buffered endpoints respectively). The
relationship between buffer description table entries and packet buffer areas is depicted in
Figure 328.

Figure 328. Packet buffer areas with examples of buffer description table locations
Each packet buffer is used either during reception or transmission starting from the bottom. The USB peripheral will never change the contents of memory locations adjacent to the allocated memory buffers; if a packet bigger than the allocated buffer length is received (buffer overrun condition) the data are copied to the memory only up to the last available location.

**Endpoint initialization**

The first step to initialize an endpoint is to write appropriate values to the ADDRxn_TX/ADDRxn_RX registers so that the USB peripheral finds the data to be transmitted already available and the data to be received can be buffered. The EP_TYPE bits in the USB_EPnR register must be set according to the endpoint type, eventually using the EP_KIND bit to enable any special required feature. On the transmit side, the endpoint must be enabled using the STAT_TX bits in the USB_EPnR register and COUNTn_TX must be initialized. For reception, STAT_Rx bits must be set to enable reception and COUNTn_RX must be written with the allocated buffer using the BL_SIZE and NUM_BLOCK fields. Unidirectional endpoints, except Isochronous and double-buffered bulk endpoints, need to initialize only bits and registers related to the supported direction. Once the transmission and/or reception are enabled, register USB_EPnR and locations ADDRxn_TX/ADDRxn_RX, COUNTn_TX/COUNTn_RX (respectively), should not be modified by the application software, as the hardware can change their value on the fly. When the data transfer operation is completed, notified by a CTR interrupt event, they can be accessed again to re-enable a new operation.

**IN packets (data transmission)**

When receiving an IN token packet, if the received address matches a configured and valid endpoint, the USB peripheral accesses the contents of ADDRxn_TX and COUNTn_TX locations inside the buffer descriptor table entry related to the addressed endpoint. The content of these locations is stored in its internal 16 bit registers ADDR and COUNT (not accessible by software). The packet memory is accessed again to read the first byte to be transmitted (Refer to *Structure and usage of packet buffers on page 873*) and starts sending a DATA0 or DATA1 PID according to USB_EPnR bit DTOG_TX. When the PID is completed, the first byte, read from buffer memory, is loaded into the output shift register to be transmitted on the USB bus. After the last data byte is transmitted, the computed CRC is sent. If the addressed endpoint is not valid, a NAK or STALL handshake packet is sent instead of the data packet, according to STAT_TX bits in the USB_EPnR register.

The ADDR internal register is used as a pointer to the current buffer memory location while COUNT is used to count the number of remaining bytes to be transmitted. Each half-word read from the packet buffer memory is transmitted over the USB bus starting from the least significant byte. Transmission buffer memory is read starting from the address pointed by ADDRxn_TX for COUNTn_TX/2 half-words. If a transmitted packet is composed of an odd number of bytes, only the lower half of the last half-word accessed is used.

On receiving the ACK receipt by the host, the USB_EPnR register is updated in the following way: DTOG_TX bit is toggled, the endpoint is made invalid by setting STAT_TX=10 (NAK) and bit CTR_TX is set. The application software must first identify the endpoint, which is requesting microcontroller attention by examining the EP_ID and DIR bits in the USB_ISTR register. Servicing of the CTR_TX event starts clearing the interrupt bit; the application software then prepares another buffer full of data to be sent, updates the COUNTn_TX table location with the number of byte to be transmitted during the next transfer, and finally sets STAT_TX to ‘11 (VALID) to re-enable transmissions. While the STAT_TX bits are equal to ‘10 (NAK), any IN request addressed to that endpoint is NAKed,
indicating a flow control condition: the USB host will retry the transaction until it succeeds. It is mandatory to execute the sequence of operations in the above mentioned order to avoid losing the notification of a second IN transaction addressed to the same endpoint immediately following the one which triggered the CTR interrupt.

**OUT and SETUP packets (data reception)**

These two tokens are handled by the USB peripheral more or less in the same way; the differences in the handling of SETUP packets are detailed in the following paragraph about control transfers. When receiving an OUT/SETUP PID, if the address matches a valid endpoint, the USB peripheral accesses the contents of the ADDRn_RX and COUNTn_RX locations inside the buffer descriptor table entry related to the addressed endpoint. The content of the ADDRn_RX is stored directly in its internal register ADDR. While COUNT is now reset and the values of BL_SIZE and NUM_BLOCK bit fields, which are read within COUNTn_RX content are used to initialize BUF_COUNT, an internal 16 bit counter, which is used to check the buffer overrun condition (all these internal registers are not accessible by software). Data bytes subsequently received by the USB peripheral are packed in half-words (the first byte received is stored as least significant byte) and then transferred to the packet buffer starting from the address contained in the internal ADDR register while BUF_COUNT is decremented and COUNT is incremented at each byte transfer. When the end of DATA packet is detected, the correctness of the received CRC is tested and only if no errors occurred during the reception, an ACK handshake packet is sent back to the transmitting host.

In case of wrong CRC or other kinds of errors (bit-stuff violations, frame errors, etc.), data bytes are still copied in the packet memory buffer, at least until the error detection point, but ACK packet is not sent and the ERR bit in USB_ISTR register is set. However, there is usually no software action required in this case: the USB peripheral recovers from reception errors and remains ready for the next transaction to come. If the addressed endpoint is not valid, a NAK or STALL handshake packet is sent instead of the ACK, according to bits STAT_RX in the USB_EPnR register and no data is written in the reception memory buffers.

Reception memory buffer locations are written starting from the address contained in the ADDRn_RX for a number of bytes corresponding to the received data packet length, CRC included (i.e. data payload length + 2), or up to the last allocated memory location, as defined by BL_SIZE and NUM_BLOCK, whichever comes first. In this way, the USB peripheral never writes beyond the end of the allocated reception memory buffer area. If the length of the data packet payload (actual number of bytes used by the application) is greater than the allocated buffer, the USB peripheral detects a buffer overrun condition. In this case, a STALL handshake packet is sent instead of the usual ACK to notify the problem to the host, no interrupt is generated and the transaction is considered failed.

When the transaction is completed correctly, by sending the ACK handshake packet, the internal COUNT register is copied back in the COUNTn_RX location inside the buffer description table entry, leaving unaffected BL_SIZE and NUM_BLOCK fields, which normally do not require to be re-written, and the USB_EPnR register is updated in the following way: DTOG_RX bit is toggled, the endpoint is made invalid by setting STAT_RX = ‘10 (NAK) and bit CTR_RX is set. If the transaction has failed due to errors or buffer overrun condition, none of the previously listed actions take place. The application software must first identify the endpoint, which is requesting microcontroller attention by examining the EP_ID and DIR bits in the USB_ISTR register. The CTR_RX event is serviced by first determining the transaction type (SETUP bit in the USB_EPnR register); the application software must clear the interrupt flag bit and get the number of received bytes reading the COUNTn_RX location inside the buffer description table entry related to the endpoint being
processed. After the received data is processed, the application software should set the STAT_RX bits to ‘11 (Valid) in the USB_EPnR, enabling further transactions. While the STAT_RX bits are equal to ‘10 (NAK), any OUT request addressed to that endpoint is NAKed, indicating a flow control condition: the USB host will retry the transaction until it succeeds. It is mandatory to execute the sequence of operations in the above mentioned order to avoid losing the notification of a second OUT transaction addressed to the same endpoint following immediately the one which triggered the CTR interrupt.

Control transfers

Control transfers are made of a SETUP transaction, followed by zero or more data stages, all of the same direction, followed by a status stage (a zero-byte transfer in the opposite direction). SETUP transactions are handled by control endpoints only and are very similar to OUT ones (data reception) except that the values of DTOG_TX and DTOG_RX bits of the addressed endpoint registers are set to 1 and 0 respectively, to initialize the control transfer, and both STAT_TX and STAT_RX are set to ‘10 (NAK) to let software decide if subsequent transactions must be IN or OUT depending on the SETUP contents. A control endpoint must check SETUP bit in the USB_EPnR register at each CTR_RX event to distinguish normal OUT transactions from SETUP ones. A USB device can determine the number and direction of data stages by interpreting the data transferred in the SETUP stage, and is required to STALL the transaction in the case of errors. To do so, at all data stages before the last, the unused direction should be set to STALL, so that, if the host reverses the transfer direction too soon, it gets a STALL as a status stage.

While enabling the last data stage, the opposite direction should be set to NAK, so that, if the host reverses the transfer direction (to perform the status stage) immediately, it is kept waiting for the completion of the control operation. If the control operation completes successfully, the software will change NAK to VALID, otherwise to STALL. At the same time, if the status stage is an OUT, the STATUS_OUT (EP_KIND in the USB_EPnR register) bit should be set, so that an error is generated if a status transaction is performed with non-zero data. When the status transaction is serviced, the application clears the STATUS_OUT bit and sets STAT_RX to VALID (to accept a new command) and STAT_TX to NAK (to delay a possible status stage immediately following the next setup).

Since the USB specification states that a SETUP packet cannot be answered with a handshake different from ACK, eventually aborting a previously issued command to start the new one, the USB logic doesn’t allow a control endpoint to answer with a NAK or STALL packet to a SETUP token received from the host.

When the STAT_RX bits are set to ‘01 (STALL) or ‘10 (NAK) and a SETUP token is received, the USB accepts the data, performing the required data transfers and sends back an ACK handshake. If that endpoint has a previously issued CTR_RX request not yet acknowledged by the application (i.e. CTR_RX bit is still set from a previously completed reception), the USB discards the SETUP transaction and does not answer with any handshake packet regardless of its state, simulating a reception error and forcing the host to send the SETUP token again. This is done to avoid losing the notification of a SETUP transaction addressed to the same endpoint immediately following the transaction, which triggered the CTR_RX interrupt.
30.5.3 Double-buffered endpoints

All different endpoint types defined by the USB standard represent different traffic models, and describe the typical requirements of different kind of data transfer operations. When large portions of data are to be transferred between the host PC and the USB function, the bulk endpoint type is the most suited model. This is because the host schedules bulk transactions so as to fill all the available bandwidth in the frame, maximizing the actual transfer rate as long as the USB function is ready to handle a bulk transaction addressed to it. If the USB function is still busy with the previous transaction when the next one arrives, it will answer with a NAK handshake and the host PC will issue the same transaction again until the USB function is ready to handle it, reducing the actual transfer rate due to the bandwidth occupied by re-transmissions. For this reason, a dedicated feature called ‘double-buffering’ can be used with bulk endpoints.

When ‘double-buffering’ is activated, data toggle sequencing is used to select, which buffer is to be used by the USB peripheral to perform the required data transfers, using both ‘transmission’ and ‘reception’ packet memory areas to manage buffer swapping on each successful transaction in order to always have a complete buffer to be used by the application, while the USB peripheral fills the other one. For example, during an OUT transaction directed to a ‘reception’ double-buffered bulk endpoint, while one buffer is being filled with new data coming from the USB host, the other one is available for the microcontroller software usage (the same would happen with a ‘transmission’ double-buffered bulk endpoint and an IN transaction).

Since the swapped buffer management requires the usage of all 4 buffer description table locations hosting the address pointer and the length of the allocated memory buffers, the USB_EPnR registers used to implement double-buffered bulk endpoints are forced to be used as unidirectional ones. Therefore, only one STAT bit pair must be set at a value different from '00 (Disabled): STAT_RX if the double-buffered bulk endpoint is enabled for reception, STAT_TX if the double-buffered bulk endpoint is enabled for transmission. In case it is required to have double-buffered bulk endpoints enabled both for reception and transmission, two USB_EPnR registers must be used.

To exploit the double-buffering feature and reach the highest possible transfer rate, the endpoint flow control structure, described in previous chapters, has to be modified, in order to switch the endpoint status to NAK only when a buffer conflict occurs between the USB peripheral and application software, instead of doing it at the end of each successful transaction. The memory buffer which is currently being used by the USB peripheral is defined by the DTOG bit related to the endpoint direction: DTOG_RX (bit 14 of USB_EPnR register) for ‘reception’ double-buffered bulk endpoints or DTOG_TX (bit 6 of USB_EPnR register) for ‘transmission’ double-buffered bulk endpoints. To implement the new flow control scheme, the USB peripheral should know which packet buffer is currently in use by the application software, so to be aware of any conflict. Since in the USB_EPnR register, there are two DTOG bits but only one is used by USB peripheral for data and buffer sequencing (due to the unidirectional constraint required by double-buffering feature) the other one can be used by the application software to show which buffer it is currently using. This new buffer flag is called SW_BUF. In the following table the correspondence between USB_EPnR register bits and DTOG/SW_BUF definition is explained, for the cases of ‘transmission’ and ‘reception’ double-buffered bulk endpoints.
The memory buffer which is currently being used by the USB peripheral is defined by DTOG buffer flag, while the buffer currently in use by application software is identified by SW_BUF buffer flag. The relationship between the buffer flag value and the used packet buffer is the same in both cases, and it is listed in the following table.

1. Endpoint in NAK Status.

Double-buffering feature for a bulk endpoint is activated by:
- Writing EP_TYPE bit field at ‘00 in its USB_EPnR register, to define the endpoint as a bulk, and
- Setting EP_KIND bit at ‘1 (DBL_BUF), in the same register.

The application software is responsible for DTOG and SW_BUF bits initialization according to the first buffer to be used; this has to be done considering the special toggle-only property that these two bits have. The end of the first transaction occurring after having set DBL_BUF, triggers the special flow control of double-buffered bulk endpoints, which is used for all other transactions addressed to this endpoint until DBL_BUF remain set. At the end of each transaction the CTR_RX or CTR_TX bit of the addressed endpoint USB_EPnR register is set, depending on the enabled direction. At the same time, the affected DTOG bit in the USB_EPnR register is hardware toggled making the USB peripheral buffer swapping completely software independent. Unlike common transactions, and the first one after
DBL_BUF setting, STAT bit pair is not affected by the transaction termination and its value remains ‘11 (Valid). However, as the token packet of a new transaction is received, the actual endpoint status is masked as ‘10 (NAK) when a buffer conflict between the USB peripheral and the application software is detected (this condition is identified by DTOG and SW_BUF having the same value, see Table 123 on page 879). The application software responds to the CTR event notification by clearing the interrupt flag and starting any required handling of the completed transaction. When the application packet buffer usage is over, the software toggles the SW_BUF bit, writing ‘1 to it, to notify the USB peripheral about the availability of that buffer. In this way, the number of NAKed transactions is limited only by the application elaboration time of a transaction data: if the elaboration time is shorter than the time required to complete a transaction on the USB bus, no re-transmissions due to flow control will take place and the actual transfer rate is limited only by the host PC.

The application software can always override the special flow control implemented for double-buffered bulk endpoints, writing an explicit status different from ‘11 (Valid) into the STAT bit pair of the related USB_EPnR register. In this case, the USB peripheral will always use the programmed endpoint status, regardless of the buffer usage condition.

### 30.5.4 Isochronous transfers

The USB standard supports full speed peripherals requiring a fixed and accurate data production/consume frequency, defining this kind of traffic as ‘Isochronous’. Typical examples of this data are: audio samples, compressed video streams, and in general any sort of sampled data having strict requirements for the accuracy of delivered frequency. When an endpoint is defined to be 'isochronous' during the enumeration phase, the host allocates in the frame the required bandwidth and delivers exactly one IN or OUT packet each frame, depending on endpoint direction. To limit the bandwidth requirements, no re-transmission of failed transactions is possible for Isochronous traffic; this leads to the fact that an isochronous transaction does not have a handshake phase and no ACK packet is expected or sent after the data packet. For the same reason, Isochronous transfers do not support data toggle sequencing and always use DATA0 PID to start any data packet.

The Isochronous behavior for an endpoint is selected by setting the EP_TYPE bits at ‘10 in its USB_EPnR register; since there is no handshake phase the only legal values for the STAT_RX/STAT_TX bit pairs are ‘00 (Disabled) and ‘11 (Valid), any other value will produce results not compliant to USB standard. Isochronous endpoints implement double-buffering to ease application software development, using both ‘transmission’ and ‘reception’ packet memory areas to manage buffer swapping on each successful transaction in order to have always a complete buffer to be used by the application, while the USB peripheral fills the other.

The memory buffer which is currently used by the USB peripheral is defined by the DTOG bit related to the endpoint direction (DTOG_RX for ‘reception’ isochronous endpoints, DTOG_TX for ‘transmission’ isochronous endpoints, both in the related USB_EPnR register) according to Table 124.
As it happens with double-buffered bulk endpoints, the USB_EPnR registers used to implement Isochronous endpoints are forced to be used as unidirectional ones. In case it is required to have Isochronous endpoints enabled both for reception and transmission, two USB_EPnR registers must be used.

The application software is responsible for the DTOG bit initialization according to the first buffer to be used; this has to be done considering the special toggle-only property that these two bits have. At the same time, the affected DTOG bit in the USB_EPnR register is hardware toggled making buffer swapping completely software independent. STAT bit pair is not affected by transaction completion; since no flow control is possible for Isochronous transfers due to the lack of handshake phase, the endpoint remains always ‘11 (Valid). CRC errors or buffer-overrun conditions occurring during Isochronous OUT transfers are anyway considered as correct transactions and they always trigger an CTR_RX event. However, CRC errors will anyway set the ERR bit in the USB_ISTR register to notify the software of the possible data corruption.

30.5.5 **Suspend/Resume events**

The USB standard defines a special peripheral state, called SUSPEND, in which the average current drawn from the USB bus must not be greater than 2.5 mA. This requirement is of fundamental importance for bus-powered devices, while self-powered devices are not required to comply to this strict power consumption constraint. In suspend mode, the host PC sends the notification by not sending any traffic on the USB bus for more than 3 ms: since a SOF packet must be sent every 1 ms during normal operations, the USB peripheral detects the lack of 3 consecutive SOF packets as a suspend request from the host PC and set the SUSP bit to ‘1 in USB_ISTR register, causing an interrupt if enabled. Once the device is suspended, its normal operation can be restored by a so called RESUME sequence, which can be started from the host PC or directly from the peripheral itself, but it is always terminated by the host PC. The suspended USB peripheral must be anyway able to detect a RESET sequence, reacting to this event as a normal USB reset event.
The actual procedure used to suspend the USB peripheral is device dependent since according to the device composition, different actions may be required to reduce the total consumption.

A brief description of a typical suspend procedure is provided below, focused on the USB-related aspects of the application software routine responding to the SUSP notification of the USB peripheral:

1. Set the FSUSP bit in the USB_CNTR register to 1. This action activates the suspend mode within the USB peripheral. As soon as the suspend mode is activated, the check on SOF reception is disabled to avoid any further SUSP interrupts being issued while the USB is suspended.
2. Remove or reduce any static power consumption in blocks different from the USB peripheral.
3. Set LP_MODE bit in USB_CNTR register to 1 to remove static power consumption in the analog USB transceivers but keeping them able to detect resume activity.
4. Optionally turn off external oscillator and device PLL to stop any activity inside the device.

When an USB event occurs while the device is in SUSPEND mode, the RESUME procedure must be invoked to restore nominal clocks and regain normal USB behavior. Particular care must be taken to insure that this process does not take more than 10 ms when the wakening event is an USB reset sequence (See “Universal Serial Bus Specification” for more details). The start of a resume or reset sequence, while the USB peripheral is suspended, clears the LP_MODE bit in USB_CNTR register asynchronously. Even if this event can trigger an WKUP interrupt if enabled, the use of an interrupt response routine must be carefully evaluated because of the long latency due to system clock restart; to have the shorter latency before re-activating the nominal clock it is suggested to put the resume procedure just after the end of the suspend one, so its code is immediately executed as soon as the system clock restarts. To prevent ESD discharges or any other kind of noise from waking-up the system (the exit from suspend mode is an asynchronous event), a suitable analog filter on data line status is activated during suspend; the filter width is about 70 ns.

The following is a list of actions a resume procedure should address:

1. Optionally turn on external oscillator and/or device PLL.
2. Clear FSUSP bit of USB_CNTR register.
3. If the resume triggering event has to be identified, bits RXDP and RXDM in the USB_FNR register can be used according to Table 125, which also lists the intended software action in all the cases. If required, the end of resume or reset sequence can be detected monitoring the status of the above mentioned bits by checking when they reach the “10” configuration, which represent the Idle bus state; moreover at the end of a reset sequence the RESET bit in USB_ISTR register is set to 1, issuing an interrupt if enabled, which should be handled as usual.

<table>
<thead>
<tr>
<th>[RXDP,RXDM] status</th>
<th>Wake-up event</th>
<th>Required resume software action</th>
</tr>
</thead>
<tbody>
<tr>
<td>“00”</td>
<td>Root reset</td>
<td>None</td>
</tr>
<tr>
<td>“10”</td>
<td>None (noise on bus)</td>
<td>Go back in Suspend mode</td>
</tr>
</tbody>
</table>
A device may require to exit from suspend mode as an answer to particular events not directly related to the USB protocol (e.g. a mouse movement wakes up the whole system). In this case, the resume sequence can be started by setting the RESUME bit in the USB_CNTR register to 1 and resetting it to 0 after an interval between 1 ms and 15 ms (this interval can be timed using ESOF interrupts, occurring with a 1 ms period when the system clock is running at nominal frequency). Once the RESUME bit is clear, the resume sequence is completed by the host PC and its end can be monitored again using the RXDP and RXDM bits in the USB_FNR register.

Table 125. Resume event detection (continued)

<table>
<thead>
<tr>
<th>[RXDP,RXDM] status</th>

</tbody>
</table>

Note: The RESUME bit must be anyway used only after the USB peripheral has been put in suspend mode, setting the FSUSP bit in USB_CNTR register to 1.
30.6 USB and USB SRAM registers

The USB peripheral registers can be divided into the following groups:
- Common Registers: Interrupt and Control registers
- Endpoint Registers: Endpoint configuration and status

The USB SRAM registers cover:
- Buffer Descriptor Table: Location of packet memory used to locate data buffers (see Section 2.2: Memory organization to find USB SRAM base address).

All register addresses are expressed as offsets with respect to the USB peripheral registers base address, except the buffer descriptor table locations, which starts at the USB SRAM base address offset by the value specified in the USB_BTABLE register.

Refer to Section 1.2 on page 42 for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

30.6.1 Common registers

These registers affect the general behavior of the USB peripheral defining operating mode, interrupt handling, device address and giving access to the current frame number updated by the host PC.

</tr>
</tbody>
</table>

This register contains the status of all the interrupt sources allowing application software to determine, which events caused an interrupt request.

The upper part of this register contains single bits, each of them representing a specific event. These bits are set by the hardware when the related event occurs; if the corresponding bit in the USB_CNTR register is set, a generic interrupt request is generated. The interrupt routine, examining each bit, will perform all necessary actions, and finally it will clear the serviced bits. If any of them is not cleared, the interrupt is considered to be still pending, and the interrupt line is kept high again. If several bits are set simultaneously, only a single interrupt is generated.

Endpoint transaction completion can be handled in a different way to reduce interrupt response latency. The CTR bit is set by the hardware as soon as an endpoint successfully completes a transaction, generating a generic interrupt request if the corresponding bit in USB_CNTR is set. An endpoint dedicated interrupt condition is activated independently from the CTRM bit in the USB_CNTR register. Both interrupt conditions remain active until software clears the pending bit in the corresponding USB_EPnR register (the CTR bit is actually a read only bit). For endpoint-related interrupts, the software can use the Direction of Transaction (DIR) and EP_ID read-only bits to identify, which endpoint made the last interrupt request and called the corresponding interrupt service routine.

The user can choose the relative priority of simultaneously pending USB_ISTR events by specifying the order in which software checks USB_ISTR bits in an interrupt service routine. Only the bits related to events, which are serviced, are cleared. At the end of the service routine, another interrupt is requested, to service the remaining conditions.

To avoid spurious clearing of some bits, it is recommended to clear them with a load instruction where all bits which must not be altered are written with 1, and all bits to be cleared are written with ’0’ (these bits can only be cleared by software). Read-modify-write cycles should be avoided because between the read and the write operations another bit
could be set by the hardware and the next write will clear it before the microprocessor has the time to serve the event.

The following describes each bit in detail:

**Bit 15  CTR:** Correct transfer  
This bit is set by the hardware to indicate that an endpoint has successfully completed a transaction; using DIR and EP_ID bits software can determine which endpoint requested the interrupt. This bit is read-only.

**Bit 14  PMAOVR:** Packet memory area over / underrun  
This bit is set if the microcontroller has not been able to respond in time to an USB memory request. The USB peripheral handles this event in the following way: During reception an ACK handshake packet is not sent, during transmission a bit-stuff error is forced on the transmitted stream; in both cases the host will retry the transaction. The PMAOVR interrupt should never occur during normal operations. Since the failed transaction is retried by the host, the application software has the chance to speed-up device operations during this interrupt handling, to be ready for the next transaction retry; however this does not happen during Isochronous transfers (no Isochronous transaction is anyway retried) leading to a loss of data in this case. This bit is read/write but only ‘0’ can be written and writing ‘1’ has no effect.

**Bit 13  ERR:** Error  
This flag is set whenever one of the errors listed below has occurred:  
NANS: No ANSWer. The timeout for a host response has expired.  
CRC: Cyclic Redundancy Check error. One of the received CRCs, either in the token or in the data, was wrong.  
BST: Bit Stuffing error. A bit stuffing error was detected anywhere in the PID, data, and/or CRC.  
FVIO: Framing format Violation. A non-standard frame was received (EOP not in the right place, wrong token sequence, etc.).  
The USB software can usually ignore errors, since the USB peripheral and the PC host manage retransmission in case of errors in a fully transparent way. This interrupt can be useful during the software development phase, or to monitor the quality of transmission over the USB bus, to flag possible problems to the user (e.g. loose connector, too noisy environment, broken conductor in the USB cable and so on). This bit is read/write but only ‘0’ can be written and writing ‘1’ has no effect.

**Bit 12  WKUP:** Wake-up  
This bit is set to 1 by the hardware when, during suspend mode, activity is detected that wakes up the USB peripheral. This event asynchronously clears the LP_MODE bit in the CTR register and activates the USB_WAKEUP line, which can be used to notify the rest of the device (e.g. wake-up unit) about the start of the resume process. This bit is read/write but only ‘0’ can be written and writing ‘1’ has no effect.

**Bit 11  SUSP:** Suspend mode request  
This bit is set by the hardware when no traffic has been received for 3 ms, indicating a suspend mode request from the USB bus. The suspend condition check is enabled immediately after any USB reset and it is disabled by the hardware when the suspend mode is active (FSUSP=1) until the end of resume sequence. This bit is read/write but only ‘0’ can be written and writing ‘1’ has no effect.
Bit 10  **RESET**: USB reset request

Set when the USB peripheral detects an active USB RESET signal at its inputs. The USB peripheral, in response to a RESET, just resets its internal protocol state machine, generating an interrupt if RESETM enable bit in the USB_CNTR register is set. Reception and transmission are disabled until the RESET bit is cleared. All configuration registers do not reset: the microcontroller must explicitly clear these registers (this is to ensure that the RESET interrupt can be safely delivered, and any transaction immediately followed by a RESET can be completed). The function address and endpoint registers are reset by an USB reset event.

This bit is read/write but only ‘0’ can be written and writing ‘1’ has no effect.

Bit 9  **SOF**: Start of frame

This bit signals the beginning of a new USB frame and it is set when a SOF packet arrives through the USB bus. The interrupt service routine may monitor the SOF events to have a 1 ms synchronization event to the USB host and to safely read the USB_FNR register which is updated at the SOF packet reception (this could be useful for isochronous applications).

This bit is read/write but only ‘0’ can be written and writing ‘1’ has no effect.

Bit 8  **ESOF**: Expected start of frame

This bit is set by the hardware when an SOF packet is expected but not received. The host sends an SOF packet each 1 ms, but if the device does not receive it properly, the Suspend Timer issues this interrupt. If three consecutive ESOF interrupts are generated (i.e. three SOF packets are lost) without any traffic occurring in between, a SUSP interrupt is generated. This bit is set even when the missing SOF packets occur while the Suspend Timer is not yet locked. This bit is read/write but only ‘0’ can be written and writing ‘1’ has no effect.

Bit 7  **L1REQ**: LPM L1 state request

This bit is set by the hardware when LPM command to enter the L1 state is successfully received and acknowledged. This bit is read/write but only ‘0’ can be written and writing ‘1’ has no effect.

Bits 6:5 Reserved, must be kept at reset value.

Bit 4  **DIR**: Direction of transaction

This bit is written by the hardware according to the direction of the successful transaction, which generated the interrupt request.

If DIR bit=0, CTR_TX bit is set in the USB_EPnR register related to the interrupting endpoint. The interrupting transaction is of IN type (data transmitted by the USB peripheral to the host PC).

If DIR bit=1, CTR_RX bit or both CTR_TX/CTR_RX are set in the USB_EPnR register related to the interrupting endpoint. The interrupting transaction is of OUT type (data received by the USB peripheral from the host PC) or two pending transactions are waiting to be processed.

This information can be used by the application software to access the USB_EPnR bits related to the triggering transaction since it represents the direction having the interrupt pending. This bit is read-only.
Bits 3:0 **EP_ID[3:0]: Endpoint Identifier**
These bits are written by the hardware according to the endpoint number, which generated the interrupt request. If several endpoint transactions are pending, the hardware writes the endpoint identifier related to the endpoint having the highest priority defined in the following way: Two endpoint sets are defined, in order of priority: Isochronous and double-buffered bulk endpoints are considered first and then the other endpoints are examined. If more than one endpoint from the same set is requesting an interrupt, the EP_ID bits in USBISTR register are assigned according to the lowest requesting endpoint register, EP0R having the highest priority followed by EP1R and so on. The application software can assign a register to each endpoint according to this priority scheme, so as to order the concurring endpoint requests in a suitable way. These bits are read only.

**USB frame number register (USB_FNR)**

Address offset: 0x48
Reset value: 0x0XXX where X is undefined

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<td>LSOF[1:0]: Lost SOF</td>
</tr>
<tr>
<td>10:0</td>
<td>FN[10:0]: Frame number</td>
</tr>
</tbody>
</table>

Bit 15 **RXDP**: Receive data + line status
This bit can be used to observe the status of received data plus upstream port data line. It can be used during end-of-suspend routines to help determining the wake-up event.

Bit 14 **RXDM**: Receive data - line status
This bit can be used to observe the status of received data minus upstream port data line. It can be used during end-of-suspend routines to help determining the wake-up event.

Bit 13 **LCK**: Locked
This bit is set by the hardware when at least two consecutive SOF packets have been received after the end of an USB reset condition or after the end of an USB resume sequence. Once locked, the frame timer remains in this state until an USB reset or USB suspend event occurs.

Bits 12:11 **LSOF[1:0]: Lost SOF**
These bits are written by the hardware when an ESOF interrupt is generated, counting the number of consecutive SOF packets lost. At the reception of an SOF packet, these bits are cleared.

Bits 10:0 **FN[10:0]: Frame number**
This bit field contains the 11-bits frame number contained in the last received SOF packet. The frame number is incremented for every frame sent by the host and it is useful for Isochronous transfers. This bit field is updated on the generation of an SOF interrupt.

**USB device address (USB_DADDR)**

Bits 15:8 Reserved

Bit 7 \textbf{EF}: Enable function
This bit is set by the software to enable the USB device. The address of this device is contained in the following ADD[6:0] bits. If this bit is at '0 no transactions are handled, irrespective of the settings of USB_EPnR registers.

Bits 6:0 \textbf{ADD[6:0]}: Device address
These bits contain the USB function address assigned by the host PC during the enumeration process. Both this field and the Endpoint Address (EA) field in the associated USB_EPnR register must match with the information contained in a USB token in order to handle a transaction to the required endpoint.

</tbody>
</table>

Bits 15:3 \textbf{BTABLE[15:3]}: Buffer table
These bits contain the start address of the buffer allocation table inside the dedicated packet memory. This table describes each endpoint buffer location and size and it must be aligned to an 8 byte boundary (the 3 least significant bits are always '0'). At the beginning of every transaction addressed to this device, the USB peripheral reads the element of this table related to the addressed endpoint, to get its buffer start location and the buffer size (Refer to \textit{Structure and usage of packet buffers on page 873}).

Bits 2:0 Reserved, forced by hardware to 0.
Bits 15:8 Reserved, must be kept at reset value.

Bits 7:4 **BESL[3:0]:** BESL value
These bits contain the BESL value received with last ACKed LPM Token

Bit 3 **REMWAKE:** bRemoteWake value
This bit contains the bRemoteWake value received with last ACKed LPM Token

Bit 2 Reserved

Bit 1 **LPMACK:** LPM Token acknowledge enable
0: the valid LPM Token is NYET.
1: the valid LPM Token is ACK.
The NYET/ACK is returned only on a successful LPM transaction:
No errors in both the EXT token and the LPM token (else ERROR)
A valid bLinkState = 0001B (L1) is received (else STALL)

Bit 0 **LPMEN:** LPM support enable
This bit is set by the software to enable the LPM support within the USB device. If this bit is at ‘0’ no LPM transactions are handled.

**Battery charging detector (USB_BCDR)**

Address offset: 0x58

Bit 15 **DPPU:** DP pull-up control
This bit is set by software to enable the embedded pull-up on the DP line. Clearing it to ‘0’ can be used to signalize disconnect to the host when needed by the user software.

Bits 14:8 Reserved, must be kept at reset value.

Bit 7 **PS2DET:** DM pull-up detection status
This bit is active only during PD and gives the result of comparison between DM voltage level and V_{LGC} threshold. In normal situation, the DM level should be below this threshold. If it is above, it means that the DM is externally pulled high. This can be caused by connection to a PS2 port (which pulls-up both DP and DM lines) or to some proprietary charger not following the BCD specification.
0: Normal port detected (connected to SDP, ACA, CDP or DCP).
1: PS2 port or proprietary charger detected.

Bit 6 **SDET:** Secondary detection (SD) status
This bit gives the result of SD.
0: CDP detected.
1: DCP detected.

Bit 5 **PDET:** Primary detection (PD) status
This bit gives the result of PD.
0: no BCD support detected (connected to SDP or proprietary device).
1: BCD support detected (connected to ACA, CDP or DCP).
Endpoint-specific registers

The number of these registers varies according to the number of endpoints that the USB peripheral is designed to handle. The USB peripheral supports up to 8 bidirectional endpoints. Each USB device must support a control endpoint whose address (EA bits) must be set to 0. The USB peripheral behaves in an undefined way if multiple endpoints are enabled having the same endpoint number value. For each endpoint, an USB_EPnR register is available to store the endpoint specific information.

USB endpoint n register (USB_EPnR), n=[0..7]

Address offset: 0x00 to 0x1C

Reset value: 0x0000

</tr>
</tbody>
</table>

They are also reset when an USB reset is received from the USB bus or forced through bit FRES in the CTRL register, except the CTR_RX and CTR_TX bits, which are kept unchanged to avoid missing a correct packet notification immediately followed by an USB reset event. Each endpoint has its USB_EPnR register where n is the endpoint identifier.

Read-modify-write cycles on these registers should be avoided because between the read and the write operations some bits could be set by the hardware and the next write would modify them before the CPU has the time to detect the change. For this purpose, all bits affected by this problem have an ‘invariant’ value that must be used whenever their modification is not required. It is recommended to modify these registers with a load instruction where all the bits, which can be modified only by the hardware, are written with their ‘invariant’ value.
Bit 15 **CTR_RX**: Correct transfer for reception
This bit is set by the hardware when an OUT/SETUP transaction is successfully completed on this endpoint; the software can only clear this bit. If the CTRM bit in USB_CNTR register is set accordingly, a generic interrupt condition is generated together with the endpoint related interrupt condition, which is always activated. The type of occurred transaction, OUT or SETUP, can be determined from the SETUP bit described below. A transaction ended with a NAK or STALL handshake does not set this bit, since no data is actually transferred, as in the case of protocol errors or data toggle mismatches. This bit is read/write but only ‘0’ can be written, writing ‘1’ has no effect.

Bit 14 **DTOG_RX**: Data toggle, for reception transfers
If the endpoint is not Isochronous, this bit contains the expected value of the data toggle bit (0=DATA0, 1=DATA1) for the next data packet to be received. Hardware toggles this bit, when the ACK handshake is sent to the USB host, following a data packet reception having a matching data PID value; if the endpoint is defined as a control one, hardware clears this bit at the reception of a SETUP PID addressed to this endpoint. If the endpoint is using the double-buffering feature this bit is used to support packet buffer swapping too (Refer to Section 30.5.3: Double-buffered endpoints). If the endpoint is Isochronous, this bit is used only to support packet buffer swapping since no data toggling is used for this sort of endpoints and only DATA0 packet are transmitted (Refer to Section 30.5.4: Isochronous transfers). Hardware toggles this bit just after the end of data packet reception, since no handshake is used for isochronous transfers. This bit can also be toggled by the software to initialize its value (mandatory when the endpoint is not a control one) or to force specific data toggle/packet buffer usage. When the application software writes ‘0, the value of DTOG_RX remains unchanged, while writing ‘1 makes the bit value toggle. This bit is read/write but it can be only toggled by writing ‘1.

Bits 13:12 **STAT_RX [1:0]**: Status bits, for reception transfers
These bits contain information about the endpoint status, which are listed in Table 126: Reception status encoding on page 895. These bits can be toggled by software to initialize their value. When the application software writes ‘0, the value remains unchanged, while writing ‘1 makes the bit value toggle. Hardware sets the STAT_RX bits to NAK when a correct transfer has occurred (CTR_RX=1) corresponding to a OUT or SETUP (control only) transaction addressed to this endpoint, so the software has the time to elaborate the received data before it acknowledge a new transaction. Double-buffered bulk endpoints implement a special transaction flow control, which control the status based upon buffer availability condition (Refer to Section 30.5.3: Double-buffered endpoints). If the endpoint is defined as Isochronous, its status can be only ‘VALID’ or ‘DISABLED’, so that the hardware cannot change the status of the endpoint after a successful transaction. If the software sets the STAT_RX bits to ‘STALL’ or ‘NAK’ for an Isochronous endpoint, the USB peripheral behavior is not defined. These bits are read/write but they can be only toggled by writing ‘1.

Bit 11 **SETUP**: Setup transaction completed
This bit is read-only and it is set by the hardware when the last completed transaction is a SETUP. This bit changes its value only for control endpoints. It must be examined, in the case of a successful receive transaction (CTR_RX event), to determine the type of transaction occurred. To protect the interrupt service routine from the changes in SETUP bits due to next incoming tokens, this bit is kept frozen while CTR_RX bit is at 1; its state changes when CTR_RX is at 0. This bit is read-only.
Bits 10:9 **EP_TYPE[1:0]:** Endpoint type

These bits configure the behavior of this endpoint as described in *Table 127: Endpoint type encoding on page 895*. Endpoint 0 must always be a control endpoint and each USB function must have at least one control endpoint which has address 0, but there may be other control endpoints if required. Only control endpoints handle SETUP transactions, which are ignored by endpoints of other kinds. SETUP transactions cannot be answered with NAK or STALL. If a control endpoint is defined as NAK, the USB peripheral will not answer, simulating a receive error, in the receive direction when a SETUP transaction is received. If the control endpoint is defined as STALL in the receive direction, then the SETUP packet is accepted anyway, transferring data and issuing the CTR interrupt. The reception of OUT transactions is handled in the normal way, even if the endpoint is a control one.

Bulk and interrupt endpoints have very similar behavior and they differ only in the special feature available using the EP_KIND configuration bit.

The usage of Isochronous endpoints is explained in *Section 30.5.4: Isochronous transfers*

Bit 8 **EP_KIND:** Endpoint kind

The meaning of this bit depends on the endpoint type configured by the EP_TYPE bits. *Table 128* summarizes the different meanings.

**DBL_BUF:** This bit is set by the software to enable the double-buffering feature for this bulk endpoint. The usage of double-buffered bulk endpoints is explained in *Section 30.5.3: Double-buffered endpoints*.

**STATUS_OUT:** This bit is set by the software to indicate that a status out transaction is expected: in this case all OUT transactions containing more than zero data bytes are answered 'STALL' instead of 'ACK'. This bit may be used to improve the robustness of the application to protocol errors during control transfers and its usage is intended for control endpoints only. When STATUS_OUT is reset, OUT transactions can have any number of bytes, as required.

Bit 7 **CTR_TX:** Correct Transfer for transmission

This bit is set by the hardware when an IN transaction is successfully completed on this endpoint; the software can only clear this bit. If the CTRM bit in the USB_CNTR register is set accordingly, a generic interrupt condition is generated together with the endpoint related interrupt condition, which is always activated.

A transaction ended with a NAK or STALL handshake does not set this bit, since no data is actually transferred, as in the case of protocol errors or data toggle mismatches.

This bit is read/write but only '0' can be written.

Bit 6 **DTOG_TX:** Data Toggle, for transmission transfers

If the endpoint is non-isochronous, this bit contains the required value of the data toggle bit (0=DATA0, 1=DATA1) for the next data packet to be transmitted. Hardware toggles this bit when the ACK handshake is received from the USB host, following a data packet transmission. If the endpoint is defined as a control one, hardware sets this bit to 1 at the reception of a SETUP PID addressed to this endpoint.

If the endpoint is using the double buffer feature, this bit is used to support packet buffer swapping too (Refer to *Section 30.5.3: Double-buffered endpoints*).

If the endpoint is Isochronous, this bit is used to support packet buffer swapping since no data toggling is used for this sort of endpoints and only DATA0 packet are transmitted (Refer to *Section 30.5.4: Isochronous transfers*). Hardware toggles this bit just after the end of data packet transmission, since no handshake is used for Isochronous transfers.

This bit can also be toggled by the software to initialize its value (mandatory when the endpoint is not a control one) or to force a specific data toggle/packet buffer usage. When the application software writes '0', the value of DTOG_TX remains unchanged, while writing '1' makes the bit value toggle. This bit is read/write but it can only be toggled by writing 1.
Bits 5:4  **STAT_TX [1:0]:** Status bits, for transmission transfers

These bits contain the information about the endpoint status, listed in *Table 129.* These bits can be toggled by the software to initialize their value. When the application software writes '0', the value remains unchanged, while writing '1' makes the bit value toggle. Hardware sets the STAT_TX bits to NAK, when a correct transfer has occurred (CTR_TX=1) corresponding to a IN or SETUP (control only) transaction addressed to this endpoint. It then waits for the software to prepare the next set of data to be transmitted. Double-buffered bulk endpoints implement a special transaction flow control, which controls the status based on buffer availability condition (Refer to *Section 30.5.3: Double-buffered endpoints*).

If the endpoint is defined as Isochronous, its status can only be "VALID" or "DISABLED". Therefore, the hardware cannot change the status of the endpoint after a successful transaction. If the software sets the STAT_TX bits to ‘STALL’ or ‘NAK’ for an Isochronous endpoint, the USB peripheral behavior is not defined. These bits are read/write but they can be only toggled by writing ‘1.

Bits 3:0  **EA[3:0]:** Endpoint address

Software must write in this field the 4-bit address used to identify the transactions directed to this endpoint. A value must be written before enabling the corresponding endpoint.

### Buffer descriptor table

**Note:** The buffer descriptor table is located inside the packet buffer memory in the separate "USB SRAM" address space.

Although the buffer descriptor table is located inside the packet buffer memory ("USB SRAM" area), its entries can be considered as additional registers used to configure the location and size of the packet buffers used to exchange data between the USB macro cell and the device.

The first packet memory location is located at USB SRAM base address. The buffer descriptor table entry associated with the USB_EPnR registers is described below. The packet memory should be accessed only by byte (8-bit) or half-word (16-bit) accesses. Word (32-bit) accesses are not allowed.

A thorough explanation of packet buffers and the buffer descriptor table usage can be found in Structure and usage of packet buffers on page 873.

#### Transmission buffer address n (USB_ADDRn_TX)

*Address offset: [USB_BTABLE] + n*8*

**Note:**

*In case of double-buffered or isochronous endpoints in the IN direction, this address location is referred to as USB_ADDRn_TX_0.*

*In case of double-buffered or isochronous endpoints in the OUT direction, this address location is used for USB_ADDRn_RX_0.*

<table>
<thead>
<tr>
<th>Bits 15:1 ADDRn_TX[15:1]: Transmission buffer address</th>
</tr>
</thead>
<tbody>
<tr>
<td>These bits point to the starting address of the packet buffer containing data to be transmitted by the endpoint associated with the USB_EPnR register at the next IN token addressed to it.</td>
</tr>
<tr>
<td>Bit 0 Must always be written as '0' since packet memory is half-word wide and all packet buffers must be half-word aligned.</td>
</tr>
</tbody>
</table>

#### Transmission byte count n (USB_COUNTn_TX)

*Address offset: [USB_BTABLE] + n*8 + 2*

**Note:**

*In case of double-buffered or isochronous endpoints in the IN direction, this address location is referred to as USB_COUNTn_TX_0.*

*In case of double-buffered or isochronous endpoints in the OUT direction, this address location is used for USB_COUNTn_RX_0.*
Bits 15:10 These bits are not used since packet size is limited by USB specifications to 1023 bytes. Their value is not considered by the USB peripheral.

Bits 9:0 **COUNTn_TX[9:0]**: Transmission byte count
These bits contain the number of bytes to be transmitted by the endpoint associated with the USB_EPnR register at the next IN token addressed to it.

**Reception buffer address n (USB_ADDRn_RX)**
Address offset: [USB_BTABLE] + n*8 + 4

**Note:**
In case of double-buffered or isochronous endpoints in the OUT direction, this address location is referred to as USB_ADDRn_RX_1.
In case of double-buffered or isochronous endpoints in the IN direction, this address location is used for USB_ADDRn_TX_1.

Bits 15:1 **ADDRn_RX[15:1]**: Reception buffer address
These bits point to the starting address of the packet buffer, which will contain the data received by the endpoint associated with the USB_EPnR register at the next OUT/SETUP token addressed to it.

Bit 0 This bit must always be written as ‘0’ since packet memory is half-word wide and all packet buffers must be half-word aligned.

**Reception byte count n (USB_COUNTn_RX)**
Address offset: [USB_BTABLE] + n*8 + 6

**Note:**
In case of double-buffered or isochronous endpoints in the OUT direction, this address location is referred to as USB_COUNTn_RX_1.
In case of double-buffered or isochronous endpoints in the IN direction, this address location is used for USB_COUNTn_TX_1.

</table>

This table location is used to store two different values, both required during packet reception. The most significant bits contains the definition of allocated buffer size, to allow buffer overflow detection, while the least significant part of this location is written back by the USB peripheral at the end of reception to give the actual number of received bytes. Due to the restrictions on the number of available bits, buffer size is represented using the number of allocated memory blocks, where block size can be selected to choose the trade-off between fine-granularity/small-buffer and coarse-granularity/large-buffer. The size of allocated buffer is a part of the endpoint descriptor and it is normally defined during the
enumeration process according to its maxPacketSize parameter value (See “Universal Serial Bus Specification”).

Bit 15 **BL_SIZE**: Block size
This bit selects the size of memory block used to define the allocated buffer area.
- If BL_SIZE=0, the memory block is 2-byte large, which is the minimum block allowed in a half-word wide memory. With this block size the allocated buffer size ranges from 2 to 62 bytes.
- If BL_SIZE=1, the memory block is 32-byte large, which allows to reach the maximum packet length defined by USB specifications. With this block size the allocated buffer size theoretically ranges from 32 to 1024 bytes, which is the longest packet size allowed by USB standard specifications. However, the applicable size is limited by the available buffer memory.

Bits 14:10 **NUM_BLOCK[4:0]**: Number of blocks
These bits define the number of memory blocks allocated to this packet buffer. The actual amount of allocated memory depends on the BL_SIZE value as illustrated in Table 130.

Bits 9:0 **COUNTn_RX[9:0]**: Reception byte count
These bits contain the number of bytes received by the endpoint associated with the USB_EPnR register during the last OUT/SETUP transaction addressed to it.

31 HDMI-CEC controller (CEC)

This applies to STM32F05x, STM32F04x, STM32F07x and STM32F09x devices only.

31.1 Introduction

Consumer electronics control (CEC) is part of HDMI (high-definition multimedia interface) standard. It contains a protocol that provides high-level control functions between various audiovisual products. CEC operates at low speeds, with minimum processing and memory overhead.

The HDMI-CEC controller provides hardware support for this protocol.

31.2 HDMI-CEC controller main features

- Complies with HDMI-CEC v1.4 specification
- 32 kHz CEC kernel with 2 clock source options
  - HSI RC oscillator with fixed prescaler (HSI/244)
  - LSE oscillator
- Works in Stop mode for ultra-low-power applications
- Configurable signal-free time before start of transmission
  - Automatic by hardware, according to CEC state and transmission history
  - Fixed by software (7 timing options)
- Configurable peripheral address (OAR)
- Supports Listen mode
  - Enables reception of CEC messages sent to destination address different from OAR without interfering with the CEC line
- Configurable Rx-tolerance margin
  - Standard tolerance
  - Extended tolerance
- Receive-error detection
  - Bit rising error (BRE), with optional stop of reception (BRESTP)
  - Short bit period error (SBPE)
  - Long bit period error (LBPE)
- Configurable error-bit generation
  - on BRE detection (BREGEN)
  - on LBPE detection (LBPEGEN)
  - always generated on SBPE detection
- Transmission error detection (TXERR)
- Arbitration lost detection (ARBLST)
  - with automatic transmission retry
- Transmission underrun detection (TXUDR)
- Reception overrun detection (RXOVR)
31.3 HDMI-CEC functional description

31.3.1 HDMI-CEC pin

The CEC bus consists of a single bidirectional line that is used to transfer data in and out of the device. It is connected to a +3.3 V supply voltage via a 27 kΩ pull-up resistor. The output stage of the device must have an open-drain or open-collector to allow a wired-AND connection.

The HDMI-CEC controller manages the CEC bidirectional line as an alternate function of a standard GPIO, assuming that it is configured as alternate function open drain. The 27 kΩ pull-up must be added externally to the microcontroller.

To not interfere with the CEC bus when the application power is removed, it is mandatory to isolate the CEC pin from the bus in such conditions. This can be done by using a MOS transistor, as shown on Figure 329.

31.3.2 HDMI-CEC block diagram

Figure 329. HDMI-CEC block diagram

31.3.3 Message description

All transactions on the CEC line consist of an initiator and one or more followers. The initiator is responsible for sending the message structure and the data. The follower is the recipient of any data and is responsible for setting any acknowledgment bits.

A message is conveyed in a single frame that consists of a start bit followed by a header block and optionally an opcode and a variable number of operand blocks.
All these blocks are made of a 8-bit payload - most significant bit is transmitted first - followed by an end of message (EOM) bit and an acknowledge (ACK) bit.

The EOM bit is set in the last block of a message and kept reset in all others. In case a message contains additional blocks after an EOM is indicated, those additional blocks must be ignored. The EOM bit may be set in the header block to ‘ping’ other devices, to make sure they are active.

The acknowledge bit is always set to high impedance by the initiator so that it can be driven low either by the follower that has read its own address in the header, or by the follower that needs to reject a broadcast message.

The header consists of the source logical address field, and the destination logical address field. Note that the special address 0xF is used for broadcast messages.

**Figure 330. Message structure**

![Figure 330. Message structure](MS31004V1)

**Figure 331. Blocks**

![Figure 331. Blocks](MS31005V1)

**31.3.4 Bit timing**

The format of the start bit is unique and identifies the start of a message. It must be validated by its low duration and its total duration.

All remaining data bits in the message, after the start bit, have consistent timing. The high-to-low transition at the end of the data bit is the start of the next data bit except for the final bit where the CEC line remains high.
31.4 Arbitration

All devices transmitting - or retransmitting - a message onto the CEC line must ensure that it has been inactive for a number of bit periods. This signal-free time is defined as the time starting from the final bit of the previous frame and depends on the initiating device and the current status as shown in the figure below.

Since only one initiator is allowed at any one time, an arbitration mechanism is provided to avoid conflict when more than one initiator begins transmitting at the same time.

CEC line arbitration starts with the leading edge of the start bit and continues until the end of the initiator address bits within the header block. During this period, the initiator must monitor the CEC line, if whilst driving the line to high impedance it reads it back to 0. Assuming then it has lost arbitration, it stops transmitting and becomes a follower.
Figure 334. Arbitration phase

A configurable time window is counted before starting the transmission.

In the SFT = 0 configuration, HDMI-CEC performs automatic SFT calculation ensuring compliance with the HDMI-CEC standard:

- 2.5 data bit periods if the CEC is the last bus initiator with unsuccessful transmission
- 4 data bit periods if the CEC is the new bus initiator
- 6 data bit periods if the CEC is the last bus initiator with successful transmission

This is done to guarantee the maximum priority to a failed transmission and the lowest one to the last initiator that completed successfully its transmission.

Otherwise there is the possibility to configure the SFT bits to count a fixed timing value. Possible values are 0.5, 1.5, 2.5, 3.5, 4.5, 5.5, 6.5 data bit periods.

31.4.1 SFT option bit

In case of SFTOPT = 0 configuration, SFT starts being counted when the start-of-transmission command is set by software (TXSOM = 1).

In case of SFTOPT = 1, SFT starts automatically being counted by the HDMI-CEC device when a bus-idle or line error condition is detected. If the SFT timer is completed at the time TXSOM command is set then transmission starts immediately without latency. If the SFT timer is still running instead, the system waits until the timer elapses before transmission can start.
In case of SFTOPT = 1 a bus-event condition starting the SFT timer is detected in the following cases:

- In case of a regular end of transmission/reception, when TXEND/RXEND bits are set at the minimum nominal data bit duration of the last bit in the message (ACK bit).
- In case of a transmission error detection, SFT timer starts when the TXERR transmission error is detected (TXERR = 1).
- In case of a missing acknowledge from the CEC follower, the SFT timer starts when the TXACKE bit is set, that is at the nominal sampling time of the ACK bit.
- In case of a transmission underrun error, the SFT timer starts when the TXUDR bit is set at the end of the ACK bit.
- In case of a receive error detection implying reception abort, the SFT timer starts at the same time the error is detected. If an error bit is generated, then SFT starts being counted at the end of the error bit.
- In case of a wrong start bit or of any uncodified low impedance bus state from idle, the SFT timer is restarted as soon as the bus comes back to hi-impedance idleness.

31.5 Error handling

31.5.1 Bit error

If a data bit - excluding the start bit - is considered invalid, the follower is expected to notify such error by generating a low bit period on the CEC line of 1.4 to 1.6 times the nominal data bit period (3.6 ms nominally).

![Figure 336. Error bit timing](image)

31.5.2 Message error

A message is considered lost and therefore may be retransmitted under the following conditions:

- a message is not acknowledged in a directly addressed message
- a message is negatively acknowledged in a broadcast message
- a low impedance is detected on the CEC line while it is not expected (line error)

Three kinds of error flag can be detected when the CEC interface is receiving a data bit:

31.5.3 Bit rising error (BRE)

BRE (bit rising error) is set when a bit rising edge is detected outside the windows where it is expected (see Figure 337). BRE flag also generates a CEC interrupt if the BREIE = 1.
In the case of a BRE detection, the message reception can be stopped according to the BRESTP bit value and an error bit can be generated if BREGEN bit is set.

When BRE is detected in a broadcast message with BRESTP = 1 an error bit is generated even if BREGEN = 0 to enforce initiator’s retry of the failed transmission. Error bit generation can be disabled by configuring BREGEN = 0, BRDNOGEN = 1.

31.5.4 Short bit period error (SBPE)

SBPE is set when a bit falling edge is detected earlier than expected (see Figure 337). SBPE flag also generates a CEC interrupt if the SBPEIE = 1.

An error bit is always generated on the line in case of a SBPE error detection. An error bit is not generated upon SBPE detection only when Listen mode is set (LSTN = 1) and the following conditions are met:

- A directly addressed message is received containing SBPE
- A broadcast message is received containing SBPE AND BRDNOGEN = 1

31.5.5 Long bit period error (LBPE)

LBPE is set when a bit falling edge is not detected in a valid window (see Figure 337). LBPE flag also generates a CEC interrupt if the LBPEIE = 1.

LBPE always stops the reception, an error bit is generated on the line when LBPEGEN bit is set.

When LBPE is detected in a broadcast message an error bit is generated even if LBPEGEN = 0 to enforce initiator’s retry of the failed transmission. Error bit generation can be disabled by configuring LBPEGEN = 0, BRDNOGEN = 1.

Note: The BREGEN = 1, BRESTP = 0 configuration must be avoided.

![Figure 337. Error handling](MS31011V1)
31.5.6 Transmission error detection (TXERR)

The CEC initiator sets the TXERR flag if detecting low impedance on the CEC line when it is transmitting high impedance and is not expecting a follower asserted bit. TXERR flag also generates a CEC interrupt if the TXERRIE = 1.

TXERR assertion stops the message transmission. Application is in charge to retry the failed transmission up to five times.

TXERR checks are performed differently depending on the different states of the CEC line and on the RX tolerance configuration.

### 31.6 HDMI-CEC interrupts

An interrupt can be produced:

- during reception if a receive block transfer is finished or if a receive error occurs.
- during transmission if a transmit block transfer is finished or if a transmit error occurs.

Bits 31:3 Reserved, must be kept at reset value.

**Bit 2 TXEOM**: Tx end of message

The TXEOM bit is set by software to command transmission of the last byte of a CEC message. TXEOM is cleared by hardware at the same time and under the same conditions as for TXSOM.

0: TXDR data byte is transmitted with EOM = 0
1: TXDR data byte is transmitted with EOM = 1

*Note:* **TXEOM must be set when CECEN = 1.**

*TXEOM must be set before writing transmission data to TXDR.*

*If TXEOM is set when TXSOM = 0, transmitted message consists of 1 byte (HEADER) only (PING message).*

**Bit 1 TXSOM**: Tx start of message

TXSOM is set by software to command transmission of the first byte of a CEC message. If the CEC message consists of only one byte, TXEOM must be set before of TXSOM.

Start-bit is effectively started on the CEC line after SFT is counted. If TXSOM is set while a message reception is ongoing, transmission starts after the end of reception.

TXSOM is cleared by hardware after the last byte of the message is sent with a positive acknowledge (TXEND = 1), in case of transmission underrun (TXUDR = 1), negative acknowledge (TXACKE = 1), and transmission error (TXERR = 1). It is also cleared by CECEN = 0. It is not cleared and transmission is automatically retried in case of arbitration lost (ARBLST = 1).

TXSOM can be also used as a status bit informing application whether any transmission request is pending or under execution. The application can abort a transmission request at any time by clearing the CECEN bit.

0: No CEC transmission is on-going
1: CEC transmission command

*Note:* **TXSOM must be set when CECEN = 1.**

*TXSOM must be set when transmission data is available into TXDR.*

*HEADER first four bits containing own peripheral address are taken from TXDR[7:4], not from CEC_CFGR.OAR that is used only for reception.*
31.7.2 CEC configuration register (CEC_CFG)

This register is used to configure the HDMI-CEC controller.

Address offset: 0x04
Reset value: 0x0000 0000

**Caution:** It is mandatory to write CEC_CFG only when CECEN = 0.

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>LSTN: Listen mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>LSTN bit is set and cleared by software.</td>

</tr>
<tr>
<td>0: CEC peripheral receives only message addressed to its own address (OAR). Messages addressed to different destination are ignored. Broadcast messages are always received.</td>
<td></td>
</tr>
<tr>
<td>1: CEC peripheral receives messages addressed to its own address (OAR) with positive acknowledge. Messages addressed to different destination are received, but without interfering with the CEC bus: no acknowledge sent.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Bits 30:16</th>
<th>OAR[14:0]: Own addresses configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>The OAR bits are set by software to select which destination logical addresses has to be considered in receive mode. Each bit, when set, enables the CEC logical address identified by the given bit position.</td>
<td></td>
</tr>
<tr>
<td>At the end of HEADER reception, the received destination address is compared with the enabled addresses. In case of matching address, the incoming message is acknowledged and received. In case of non-matching address, the incoming message is received only in listen mode (LSTN = 1), but without acknowledge sent. Broadcast messages are always received.</td>
<td></td>
</tr>
<tr>
<td>Example:</td>
<td></td>
</tr>
<tr>
<td>OAR = 0b0000 0000 0010 0001 means that CEC acknowledges addresses 0x0 and 0x5. Consequently, each message directed to one of these addresses is received.</td>
<td></td>
</tr>
</tbody>
</table>

| Bit 15:9 | Reserved, must be kept at reset value. |

<th>SFTOP: SFT option bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>The SFTOPT bit is set and cleared by software.</td>
<td></td>
</tr>
<tr>
<td>0: SFT timer starts when TXSOM is set by software.</td>
<td></td>
</tr>
<tr>
<td>1: SFT timer starts automatically at the end of message transmission/reception.</td>
<td></td>
</tr>
</tbody>
</table>
Bit 7 **BRDNOGEN**: Avoid error-bit generation in broadcast
The BRDNOGEN bit is set and cleared by software.
0: BRE detection with BRESTP = 1 and BREGEN = 0 on a broadcast message generates an error-bit on the CEC line. LBPE detection with LBPEGEN = 0 on a broadcast message generates an error-bit on the CEC line.
1: Error-bit is not generated in the same condition as above. An error-bit is not generated even in case of an SBPE detection in a broadcast message if listen mode is set.

Bit 6 **LBPEGEN**: Generate error-bit on long bit period error
The LBPEGEN bit is set and cleared by software.
0: LBPE detection does not generate an error-bit on the CEC line.
1: LBPE detection generates an error-bit on the CEC line.

*Note: If BRDNOGEN = 0, an error-bit is generated upon LBPE detection in broadcast even if LBPEGEN = 0.*

Bit 5 **BREGEN**: Generate error-bit on bit rising error
The BREGEN bit is set and cleared by software.
0: BRE detection does not generate an error-bit on the CEC line.
1: BRE detection generates an error-bit on the CEC line (if BRESTP is set).

*Note: If BRDNOGEN = 0, an error-bit is generated upon BRE detection with BRESTP = 1 in broadcast even if BREGEN = 0.*

Bit 4 **BRESTP**: Rx-stop on bit rising error
The BRESTP bit is set and cleared by software.
0: BRE detection does not stop reception of the CEC message. Data bit is sampled at 1.05 ms.
1: BRE detection stops message reception.

Bit 3 **RXTOL**: Rx-tolerance
The RXTOL bit is set and cleared by software.
0: Standard tolerance margin:
  – Start-bit: +/- 200 µs rise, +/- 200 µs fall
  – Data-bit: +/- 200 µs rise. +/- 350 µs fall
1: Extended tolerance
  – Start-bit: +/- 400 µs rise, +/- 400 µs fall
  – Data-bit: +/- 300 µs rise, +/- 500 µs fall

Bits 2:0 **SFT[2:0]**: Signal free time
SFT bits are set by software. In the SFT = 0x0 configuration, the number of nominal data bit periods waited before transmission is ruled by hardware according to the transmission history. In all the other configurations the SFT number is determined by software.
0x0
  – 2.5 data-bit periods if CEC is the last bus initiator with unsuccessful transmission (ARBLST = 1, TXERR = 1, TXUDR = 1 or TXACKE = 1)
  – 4 data-bit periods if CEC is the new bus initiator
  – 6 data-bit periods if CEC is the last bus initiator with successful transmission (TXEOM = 1)
0x1: 0.5 nominal data bit periods
0x2: 1.5 nominal data bit periods
0x3: 2.5 nominal data bit periods
0x4: 3.5 nominal data bit periods
0x5: 4.5 nominal data bit periods
0x6: 5.5 nominal data bit periods
0x7: 6.5 nominal data bit periods
31.7.3  **CEC Tx data register (CEC_TXDR)**

Address offset: 0x8  
Reset value: 0x0000 0000

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 31| 30| 29| 28| 27| 26| 25| 24| 23| 22| 21| 20| 19| 18| 17| 16|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

Bits 31:8  Reserved, must be kept at reset value.

Bits 7:0  **TXD[7:0]:** Tx data  

TXD is a write-only register containing the data byte to be transmitted.

31.7.4  **CEC Rx data register (CEC_RXDR)**

Address offset: 0xC  
Reset value: 0x0000 0000

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 31| 30| 29| 28| 27| 26| 25| 24| 23| 22| 21| 20| 19| 18| 17| 16|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

Bits 31:8  Reserved, must be kept at reset value.

Bits 7:0  **RXD[7:0]:** Rx data  

RXD is read-only and contains the last data byte that has been received from the CEC line.

31.7.5  **CEC interrupt and status register (CEC_ISR)**

Address offset: 0x10  
Reset value: 0x0000 0000

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 31| 30| 29| 28| 27| 26| 25| 24| 23| 22| 21| 20| 19| 18| 17| 16|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

STI
Bits 31:13 Reserved, must be kept at reset value.

Bit 12 TXACKE: Tx-missing acknowledge error
In transmission mode, TXACKE is set by hardware to inform application that no acknowledge was received. In case of broadcast transmission, TXACKE informs application that a negative acknowledge was received. TXACKE aborts message transmission and clears TXSOM and TXEOM controls.
TXACKE is cleared by software write at 1.

Bit 11 TXERR: Tx-error
In transmission mode, TXERR is set by hardware if the CEC initiator detects low impedance on the CEC line while it is released. TXERR aborts message transmission and clears TXSOM and TXEOM controls.
TXERR is cleared by software write at 1.

Bit 10 TXUDR: Tx-buffer underrun
In transmission mode, TXUDR is set by hardware if application was not in time to load TXDR before of next byte transmission. TXUDR aborts message transmission and clears TXSOM and TXEOM control bits.
TXUDR is cleared by software write at 1

Bit 9 TXEND: End of transmission
TXEND is set by hardware to inform application that the last byte of the CEC message has been successfully transmitted. TXEND clears the TXSOM and TXEOM control bits.
TXEND is cleared by software write at 1.

Bit 8 TXBR: Tx-byte request
TXBR is set by hardware to inform application that the next transmission data has to be written to TXDR. TXBR is set when the 4th bit of currently transmitted byte is sent. Application must write the next byte to TXDR within six nominal data-bit periods before transmission underrun error occurs (TXUDR).
TXBR is cleared by software write at 1.

Bit 7 ARBLST: Arbitration lost
ARBLST is set by hardware to inform application that CEC device is switching to reception due to arbitration lost event following the TXSOM command. ARBLST can be due either to a contending CEC device starting earlier or starting at the same time but with higher HEADER priority. After ARBLST assertion TXSOM bit keeps pending for next transmission attempt.
ARBLST is cleared by software write at 1.

Bit 6 RXACKE: Rx-missing acknowledge
In receive mode, RXACKE is set by hardware to inform application that no acknowledge was seen on the CEC line. RXACKE applies only for broadcast messages and in listen mode also for not directly addressed messages (destination address not enabled in OAR). RXACKE aborts message reception.
RXACKE is cleared by software write at 1.

Bit 5 LBPE: Rx-long bit period error
LBPE is set by hardware in case a data-bit waveform is detected with long bit period error. LBPE is set at the end of the maximum bit-extension tolerance allowed by RXTOL, in case falling edge is still longing. LBPE always stops reception of the CEC message. LBPE generates an error-bit on the CEC line if LBPEGEN = 1. In case of broadcast, error-bit is generated even in case of LBPEGEN = 0.
LBPE is cleared by software write at 1.
31.7.6 CEC interrupt enable register (CEC_IER)

Address offset: 0x14
Reset value: 0x0000 0000

Caution: It is mandatory to write CEC_IER only when CECEN = 0.

Refer to Section 2.2 for the register boundary addresses.
32 Debug support (DBG)

32.1 Overview

The STM32F0xx devices are built around a Cortex®-M0 core, which contains hardware extensions for advanced debugging features. The debug extensions allow the core to be stopped either on a given instruction fetch (breakpoint) or data access (watchpoint). When stopped, the core's internal state and the system's external state may be examined. Once examination is complete, the core and the system may be restored and program execution resumed.

The debug features are used by the debugger host when connecting to and debugging the STM32F0xx MCUs.

One interface for debug is available:
- Serial wire

Figure 339. Block diagram of STM32F0xx MCU and Cortex®-M0-level debug support

The debug features embedded in the Cortex®-M0 core are a subset of the Arm CoreSight Design Kit. The Arm Cortex®-M0 core provides integrated on-chip debug support. It is comprised of:
- SW-DP: Serial wire
- BPU: Break point unit
- DWT: Data watchpoint trigger
It also includes debug features dedicated to the STM32F0xx:

- Flexible debug pinout assignment
- MCU debug box (support for low-power modes, control over peripheral clocks, etc.)

Note: For further information on debug functionality supported by the Arm Cortex®-M0 core, refer to the Cortex®-M0 Technical Reference Manual (see Section 32.2: Reference Arm documentation).

### 32.2 Reference Arm documentation

- Cortex®-M0 Technical Reference Manual (TRM)
  It is available from:  
  [http://infocenter.arm.com](http://infocenter.arm.com)
- Arm Debug Interface V5
- Arm CoreSight Design Kit revision r1p1 Technical Reference Manual

### 32.3 Pinout and debug port pins

The STM32F0xx MCUs are available in various packages with different numbers of available pins.
32.3.1 SWD port pins

Two pins are used as outputs for the SW-DP as alternate functions of general purpose I/Os. These pins are available on all packages.

<table>
<thead>
<tr>
<th>SW-DP pin name</th>
<th>SW debug port assignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>SWDIO</td>
<td>Serial Wire Data Input/Output, PA13</td>
</tr>
<tr>
<td>SWCLK</td>
<td>Serial Wire Clock, PA14</td>
</tr>
</tbody>
</table>

32.3.2 SW-DP pin assignment

After reset (SYSRESETn or PORESETn), the pins used for the SW-DP are assigned as dedicated pins, immediately usable by the debugger host.

However, the MCU offers the possibility to disable the SWD port and can then release the associated pins for general-purpose I/O (GPIO) usage. For more details on how to disable SW-DP port pins, refer to Section 8.3.2: I/O pin alternate function multiplexer and mapping on page 151.

32.3.3 Internal pull-up and pull-down on SWD pins

Once the SW I/O is released by the user software, the GPIO controller takes control of these pins. The reset states of the GPIO control registers put the I/Os in the equivalent states:

- SWDIO: input pull-up
- SWCLK: input pull-down

Having embedded pull-up and pull-down resistors removes the need to add external resistors.

32.4 ID codes and locking mechanism

There are several ID codes inside the MCU. ST strongly recommends the tool manufacturers (for example Keil, IAR, Raisonance) to lock their debugger using the MCU device ID located at address 0x40015800.

Only the DEV_ID[15:0] should be used for identification by the debugger/programmer tools (the revision ID must not be taken into account).
32.4.1 MCU device ID code

The STM32F0xx products integrate an MCU ID code. This ID identifies the ST MCU part number and the die revision.

This code is accessible by the software debug port (two pins) or by the user software.

For code example refer to the Appendix section A.12.1: DBG read device ID code example.

**DBGMCU_IDCODE**

Address: 0x40015800

Only 32-bit access supported. Read-only

32.5 SWD port

32.5.1 SWD protocol introduction

This synchronous serial protocol uses two pins:
- SWCLK: clock from host to target
- SWDIO: bidirectional

The protocol allows two banks of registers (DPACC registers and APACC registers) to be read and written to.

Bits are transferred LSB-first on the wire.

For SWDIO bidirectional management, the line must be pulled-up on the board (100 kΩ recommended by Arm).

Each time the direction of SWDIO changes in the protocol, a turnaround time is inserted where the line is not driven by the host nor the target. By default, this turnaround time is one bit time, however this can be adjusted by configuring the SWCLK frequency.

32.5.2 SWD protocol sequence

Each sequence consist of three phases:
1. Packet request (8 bits) transmitted by the host
2. Acknowledge response (3 bits) transmitted by the target
3. Data transfer phase (33 bits) transmitted by the host or the target

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Start</td>
<td>Must be “1”</td>
</tr>
</tbody>
</table>
| 1   | APnDP| 0: DP Access  
|     |      | 1: AP Access |
| 2   | RnW  | 0: Write Request  
|     |      | 1: Read Request |
| 4:3 | A[3:2]| Address field of the DP or AP registers (refer to Table 143 on page 928) |
| 5   | Parity| Single bit parity of preceding bits |
| 6   | Stop | 0 |
| 7   | Park | Not driven by the host. Must be read as “1” by the target because of the pull-up |

Refer to the Cortex®-M0 TRM for a detailed description of DPACC and APACC registers.

The packet request is always followed by the turnaround time (default 1 bit) where neither the host nor target drive the line.
The ACK Response must be followed by a turnaround time only if it is a READ transaction or if a WAIT or FAULT acknowledge has been received.

### Table 140. ACK response (3 bits)

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| 0..2 | ACK   | 001: FAULT  
|     |       | 010: WAIT  
|     |       | 100: OK      |

The DATA transfer must be followed by a turnaround time only if it is a READ transaction.

### Table 141. DATA transfer (33 bits)

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0..31</td>
<td>WDATA or RDATA</td>
<td>Write or Read data</td>
</tr>
<tr>
<td>32</td>
<td>Parity</td>
<td>Single parity of the 32 data bits</td>
</tr>
</tbody>
</table>

The DATA transfer must be followed by a turnaround time only if it is a READ transaction.

### 32.5.3 SW-DP state machine (reset, idle states, ID code)

The State Machine of the SW-DP has an internal ID code which identifies the SW-DP. It follows the JEP-106 standard. This ID code is the default Arm one and is set to **0x0BB11477** (corresponding to Cortex®-M0).

**Note:** Note that the SW-DP state machine is inactive until the target reads this ID code.

- The SW-DP state machine is in **RESET STATE** either after power-on reset, or after the line is high for more than 50 cycles
- The SW-DP state machine is in **IDLE STATE** if the line is low for at least two cycles after **RESET state**.
- After **RESET state**, it is **mandatory** to first enter into an **IDLE state** AND to perform a **READ access** of the DP-SW ID CODE register. Otherwise, the target will issue a FAULT acknowledge response on another transactions.

Further details of the SW-DP state machine can be found in the Cortex®-M0 TRM and the CoreSight Design Kit r1p0 TRM.

### 32.5.4 DP and AP read/write accesses

- Read accesses to the DP are not posted: the target response can be immediate (if ACK=OK) or can be delayed (if ACK=WAIT).
- Read accesses to the AP are posted. This means that the result of the access is returned on the next transfer. If the next access to be done is NOT an AP access, then the DP-RDBUFF register must be read to obtain the result.
- The READOK flag of the DP-CTRL/STAT register is updated on every AP read access or RDBUFF read request to know if the AP read access was successful.
- The SW-DP implements a write buffer (for both DP or AP writes), that enables it to accept a write operation even when other transactions are still outstanding. If the write buffer is full, the target acknowledge response is “WAIT”. With the exception of
IDCODE read or CTRL/STAT read or ABORT write which are accepted even if the write buffer is full.

- Because of the asynchronous clock domains SWCLK and HCLK, two extra SWCLK cycles are needed after a write transaction (after the parity bit) to make the write effective internally. These cycles should be applied while driving the line low (IDLE state).
  This is particularly important when writing the CTRL/STAT for a power-up request. If the next transaction (requiring a power-up) occurs immediately, it will fail.
### 32.5.5 SW-DP registers

Access to these registers are initiated when APnDP=0

Table 142. SW-DP registers

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Read</td>
<td></td>
<td>IDCODE</td>
<td>The manufacturer code is set to the default Arm code for Cortex-M0: 0x0BB11477 (identifies the SW-DP)</td>
</tr>
<tr>
<td>00</td>
<td>Write</td>
<td></td>
<td>ABORT</td>
<td></td>
</tr>
</tbody>
</table>
| 01     | Read/Write | 0                              | DP-CTRL/STAT | Purpose is to:  
|        |         |                                 |            | – request a system or debug power-up  
|        |         |                                 |            | – configure the transfer operation for AP accesses  
|        |         |                                 |            | – control the pushed compare and pushed verify operations.  
|        |         |                                 |            | – read some status flags (overrun, power-up acknowledges) |
| 01     | Read/Write | 1                              | WIRE CONTROL | Purpose is to configure the physical serial port protocol (like the duration of the turnaround time) |
| 10     | Read    |                                 | READ RESEND | Enables recovery of the read data from a corrupted debugger transfer, without repeating the original AP transfer. |
| 10     | Write   |                                 | SELECT     | The purpose is to select the current access port and the active 4-words register window |
| 11     | Read/Write |                               | READ BUFFER | This read buffer is useful because AP accesses are posted (the result of a read AP request is available on the next AP transaction).  
|        |         |                                 |            | This read buffer captures data from the AP, presented as the result of a previous read, without initiating a new transaction |
32.5.6 SW-AP registers

Access to these registers are initiated when APnDP=1

There are many AP Registers addressed as the combination of:
- The shifted value A[3:2]
- The current value of the DP SELECT register.

<table>
<thead>
<tr>
<th>Address</th>
<th>A[3:2] value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x0</td>
<td>00</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
</tbody>
</table>
| 0x4     | 01           | DP CTRL/STAT register. Used to:
|         |              | – Request a system or debug power-up |
|         |              | – Configure the transfer operation for AP accesses |
|         |              | – Control the pushed compare and pushed verify operations. |
|         |              | – Read some status flags (overrun, power-up acknowledges) |
| 0x8     | 10           | DP SELECT register: Used to select the current access port and the active 4-words register window. |
|         |              | – Bits 31:24: APSEL: select the current AP |
|         |              | – Bits 23:8: reserved |
|         |              | – Bits 7:4: APBANKSEL: select the active 4-words register window on the current AP |
|         |              | – Bits 3:0: reserved |
| 0xC     | 11           | DP RDBUFF register: Used to allow the debugger to get the final result after a sequence of operations (without requesting new JTAG-DP operation) |

32.6 Core debug

Core debug is accessed through the core debug registers. Debug access to these registers is by means of the debug access port. It consists of four registers:

<table>
<thead>
<tr>
<th>Register</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DHCSR</td>
<td>The 32-bit Debug Halting Control and Status Register</td>
</tr>
<tr>
<td></td>
<td>This provides status information about the state of the processor enable core debug halt and step the processor</td>
</tr>
<tr>
<td>DCRSR</td>
<td>The 17-bit Debug Core Register Selector Register:</td>
</tr>
<tr>
<td></td>
<td>This selects the processor register to transfer data to or from.</td>
</tr>
<tr>
<td>DCRDR</td>
<td>The 32-bit Debug Core Register Data Register:</td>
</tr>
<tr>
<td></td>
<td>This holds data for reading and writing registers to and from the processor selected by the DCRSR (Selector) register.</td>
</tr>
<tr>
<td>DEMCR</td>
<td>The 32-bit Debug Exception and Monitor Control Register:</td>
</tr>
<tr>
<td></td>
<td>This provides Vector Catching and Debug Monitor Control.</td>
</tr>
</tbody>
</table>
These registers are not reset by a system reset. They are only reset by a power-on reset. Refer to the Cortex®-M0 TRM for further details.

To Halt on reset, it is necessary to:

- enable the bit0 (VC_CORRESET) of the Debug and Exception Monitor Control Register
- enable the bit0 (C_DEBUGEN) of the Debug Halting Control and Status Register

### 32.7 BPU (Break Point Unit)

The Cortex-M0 BPU implementation provides four breakpoint registers. The BPU is a subset of the Flash Patch and Breakpoint (FPB) block available in Armv7-M (Cortex-M3 & Cortex-M4).

#### 32.7.1 BPU functionality

The processor breakpoints implement PC based breakpoint functionality.

Refer to the Armv6-M ARM and the Arm CoreSight Components Technical Reference Manual for more information about the BPU CoreSight identification registers, and their addresses and access types.

### 32.8 DWT (Data Watchpoint)

The Cortex-M0 DWT implementation provides two watchpoint register sets.

#### 32.8.1 DWT functionality

The processor watchpoints implement both data address and PC based watchpoint functionality, a PC sampling register, and support comparator address masking, as described in the Armv6-M ARM.

#### 32.8.2 DWT Program Counter Sample Register

A processor that implements the data watchpoint unit also implements the Armv6-M optional *DWT Program Counter Sample Register* (DWT_PCSR). This register permits a debugger to periodically sample the PC without halting the processor. This provides coarse grained profiling. See the *ARMv6-M ARM* for more information.

The Cortex-M0 DWT_PCSR records both instructions that pass their condition codes and those that fail.

### 32.9 MCU debug component (DBGMCU)

The MCU debug component helps the debugger provide support for:

- Low-power modes
- Clock control for timers, watchdog and I2C during a breakpoint
32.9.1 Debug support for low-power modes

To enter low-power mode, the instruction WFI or WFE must be executed. The MCU implements several low-power modes which can either deactivate the CPU clock or reduce the power of the CPU.

The core does not allow FCLK or HCLK to be turned off during a debug session. As these are required for the debugger connection, during a debug, they must remain active. The MCU integrates special means to allow the user to debug software in low-power modes.

For this, the debugger host must first set some debug configuration registers to change the low-power mode behavior:

- In Sleep mode: FCLK and HCLK are still active. Consequently, this mode does not impose any restrictions on the standard debug features.
- In Stop/Standby mode, the DBG_STOP bit must be previously set by the debugger. This enables the internal RC oscillator clock to feed FCLK and HCLK in Stop mode.

For code example refer to the Appendix section A.12.2: DBG debug in Low-power mode code example.

32.9.2 Debug support for timers, watchdog and I²C

During a breakpoint, it is necessary to choose how the counter of timers and watchdog should behave:

- They can continue to count inside a breakpoint. This is usually required when a PWM is controlling a motor, for example.
- They can stop to count inside a breakpoint. This is required for watchdog purposes.

For the I²C, the user can choose to block the SMBUS timeout during a breakpoint.
### 32.9.3 Debug MCU configuration register (DBGMCU_CR)

This register allows the configuration of the MCU under DEBUG. This concerns:

- Low-power mode support

This DBGMCU_CR is mapped at address 0x4001 5804.

It is asynchronously reset by the PORRESET (and not the system reset). It can be written by the debugger under system reset.

If the debugger host does not support these features, it is still possible for the user software to write to these registers.

**Address:** 0x40015804

Only 32-bit access supported

**POR Reset:** 0x0000 0000 (not reset by system reset)

<table>
<thead>
<tr>

<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:3</td>
<td>Reserved, must be kept at reset value.</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>DBG_STANDBY: Debug Standby mode</td>
<td></td>
</tr>
<tr>
<td></td>
<td>0: (FCLK=Off, HCLK=Off) The whole digital part is unpowered.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>From software point of view, exiting from Standby is identical than fetching reset vector (except a few status bit indicated that the MCU is resuming from Standby)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>1: (FCLK=On, HCLK=On) In this case, the digital part is not unpowered and FCLK and HCLK are provided by the internal RC oscillator which remains active. In addition, the MCU generate a system reset during Standby mode so that exiting from Standby is identical than fetching from reset</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>DBG_STOP: Debug Stop mode</td>
<td></td>
</tr>
<tr>
<td></td>
<td>0: (FCLK=Off, HCLK=Off) In STOP mode, the clock controller disables all clocks (including HCLK and FCLK). When exiting from STOP mode, the clock configuration is identical to the one after RESET (CPU clocked by the 8 MHz internal RC oscillator (HSI)). Consequently, the software must reprogram the clock controller to enable the PLL, the Xtal, etc.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>1: (FCLK=On, HCLK=On) In this case, when entering STOP mode, FCLK and HCLK are provided by the internal RC oscillator which remains active in STOP mode. When exiting STOP mode, the software must reprogram the clock controller to enable the PLL, the Xtal, etc. (in the same way it would do in case of DBG_STOP=0)</td>
<td></td>
</tr>
</tbody>
</table>

**Note:** A side effect is that Systick, if enabled, continues to receive the clock and can consequently generate periodic interrupts and potentially wake up events.
32.9.4  **Debug MCU APB1 freeze register (DBGMCU_APB1_FZ)**

The DBGMCU_APB1_FZ register is used to configure the MCU under DEBUG. It concerns some APB peripherals:

- Timer clock counter freeze
- I2C SMBUS timeout freeze
- System window watchdog and independent watchdog counter freeze support

This DBGMCU_APB1_FZ is mapped at address 0x4001 5808.

The register is asynchronously reset by the POR (and not the system reset). It can be written by the debugger under system reset.

Address offset: 0x08

Only 32-bit access are supported.

Power on reset (POR): 0x0000 0000 (not reset by system reset)

   1: The counter clock of TIM2 is stopped when the core is halted
32.9.5 Debug MCU APB2 freeze register (DBGMCU_APB2_FZ)

The DBGMCU_APB2_FZ register is used to configure the MCU under DEBUG. It concerns some APB peripherals:

- Timer clock counter freeze

This register is mapped at address 0x4001580C.

It is asynchronously reset by the POR (and not the system reset). It can be written by the debugger under system reset.

Address offset: 0x0C

Only 32-bit access is supported.

POR: 0x0000 0000 (not reset by system reset)

33 Device electronic signature

The device electronic signature is stored in the System memory area of the Flash memory module, and can be read using the debug interface or by the CPU. It contains factory-programmed identification and calibration data that allow the user firmware or other external devices to automatically match to the characteristics of the STM32F0xx microcontroller.

33.1 Unique device ID register (96 bits)

The unique device identifier is ideally suited:

- for use as serial numbers (for example USB string serial numbers or other end applications)
- for use as part of the security keys in order to increase the security of code in Flash memory while using and combining this unique ID with software cryptographic primitives and protocols before programming the internal Flash memory
- to activate secure boot processes, etc.

The 96-bit unique device identifier provides a reference number which is unique for any device and in any context. These bits cannot be altered by the user.

Appendix A  Code examples

A.1  Introduction

This appendix shows the code examples of the sequence described in this document.

These code examples are extracted from the STM32F0xx Snippet firmware package STM32SnippetsF0 available on www.st.com.

These code examples used the peripheral bit and register description from the CMSIS header file (stm32f0xx.h).

Code lines starting with // should be uncommented if the given register has been modified before.

A.2  Flash operation code examples

A.2.1  Flash memory unlocking sequence

/* (1) Wait till no operation is on going */
/* (2) Check that the Flash is unlocked */
/* (3) Perform unlock sequence */
while (((FLASH->SR & FLASH_SR_BSY) != 0) /* (1) */) {
  /* For robust implementation, add here time-out management */
}
if (((FLASH->CR & FLASH_CR_LOCK) != 0) /* (2) */) {
  FLASH->KEYR = FLASH_FKEY1; /* (3) */
  FLASH->KEYR = FLASH_FKEY2;
}

A.2.2  Main Flash programming sequence

/* (1) Set the PG bit in the FLASH_CR register to enable programming */
/* (2) Perform the data write (half-word) at the desired address */
/* (3) Wait until the BSY bit is reset in the FLASH_SR register */
/* (4) Check the EOP flag in the FLASH_SR register */
/* (5) clear it by software by writing it at 1 */
/* (6) Reset the PG Bit to disable programming */
FLASH->CR |= FLASH_CR_PG; /* (1) */
*(__IO uint16_t*)(flash_addr) = data; /* (2) */
while (((FLASH->SR & FLASH_SR_BSY) != 0) /* (3) */) {
  /* For robust implementation, add here time-out management */
}
if ((FLASH->SR & FLASH_SR_EOP) != 0) /* (4) */
{
  FLASH->SR = FLASH_SR_EOP; /* (5) */
}
else
{
  /* Manage the error cases */
}
FLASH->CR &= ~FLASH_CR_PG; /* (6) */

A.2.3 Page erase sequence

/* (1) Set the PER bit in the FLASH_CR register to enable page erasing */
/* (2) Program the FLASH_AR register to select a page to erase */
/* (3) Set the STRT bit in the FLASH_CR register to start the erasing */
/* (4) Wait until the BSY bit is reset in the FLASH_SR register */
/* (5) Check the EOP flag in the FLASH_SR register */
/* (6) Clear EOP flag by software by writing EOP at 1 */
/* (7) Reset the PER Bit to disable the page erase */
FLASH->CR |= FLASH_CR_PER; /* (1) */
FLASH->AR = page_addr; /* (2) */
FLASH->CR |= FLASH_CR_STRT; /* (3) */
while ((FLASH->SR & FLASH_SR_BSY) != 0) /* (4) */
{
  /* For robust implementation, add here time-out management */
}
if ((FLASH->SR & FLASH_SR_EOP) != 0) /* (5) */
{
  FLASH->SR = FLASH_SR_EOP; /* (6) */
}
else
{
  /* Manage the error cases */
}
FLASH->CR &= ~FLASH_CR_PER; /* (7) */
A.2.4 Mass erase sequence

/* (1) Set the MER bit in the FLASH_CR register to enable mass erasing */
/* (2) Set the STRT bit in the FLASH_CR register to start the erasing */
/* (3) Wait until the BSY bit is reset in the FLASH_SR register */
/* (4) Check the EOP flag in the FLASH_SR register */
/* (5) Clear EOP flag by software by writing EOP at 1 */
/* (6) Reset the PER Bit to disable the mass erase */
FLASH->CR |= FLASH_CR_MER; /* (1) */
FLASH->CR |= FLASH_CR_STRT; /* (2) */
while ((FLASH->SR & FLASH_SR_BSY) != 0) /* (3) */
{
    /* For robust implementation, add here time-out management */
}
if ((FLASH->SR & FLASH_SR_EOP) != 0) /* (4) */
{
    FLASH->SR = FLASH_SR_EOP; /* (5) */
}
else
{
    /* Manage the error cases */
}
FLASH->CR &= ~FLASH_CR_MER; /* (6) */

A.2.5 Option byte unlocking sequence

/* (1) Wait till no operation is on going */
/* (2) Check that the Flash is unlocked */
/* (3) Perform unlock sequence for Flash */
/* (4) Check that the Option Bytes are unlocked */
/* (5) Perform unlock sequence for Option Bytes */
while ((FLASH->SR & FLASH_SR_BSY) != 0) /* (1) */
{
    /* For robust implementation, add here time-out management */
}
if ((FLASH->CR & FLASH_CR_LOCK) != 0) /* (2) */
{
    FLASH->KEYR = FLASH_FKEY1; /* (3) */
    FLASH->KEYR = FLASH_FKEY2;
}
if ((FLASH->CR & FLASH_CR_OPTWRE) == 0) /* (4) */
{
    FLASH->OPTKEYR = FLASH_OPTKEY1; /* (5) */
    FLASH->OPTKEYR = FLASH_OPTKEY2;
}
A.2.6 Option byte programming sequence

/* (1) Set the PG bit in the FLASH_CR register to enable programming */
/* (2) Perform the data write */
/* (3) Wait until the BSY bit is reset in the FLASH_SR register */
/* (4) Check the EOP flag in the FLASH_SR register */
/* (5) Clear the EOP flag by software by writing it at 1 */
/* (6) Reset the PG Bit to disable programming */
FLASH->CR |= FLASH_CR_OPTPG; /* (1) */
*opt_addr = data; /* (2) */
while (!(FLASH->SR & FLASH_SR_BSY)) /* (3) */
{
    /* For robust implementation, add here time-out management */
}
if (!(FLASH->SR & FLASH_SR_EOP)) /* (4) */
{
    FLASH->SR = FLASH_SR_EOP; /* (5) */
}
else
{
    /* Manage the error cases */
}
FLASH->CR &= ~FLASH_CR_OPTPG; /* (6) */

A.2.7 Option byte erasing sequence

/* (1) Set the OPTER bit in the FLASH_CR register to enable option byte erasing */
/* (2) Set the STRT bit in the FLASH_CR register to start the erasing */
/* (3) Wait until the BSY bit is reset in the FLASH_SR register */
/* (4) Check the EOP flag in the FLASH_SR register */
/* (5) Clear EOP flag by software by writing EOP at 1 */
/* (6) Reset the PER Bit to disable the page erase */
FLASH->CR |= FLASH_CR_OPTER; /* (1) */
FLASH->CR |= FLASH_CR_STRT; /* (2) */
while (!(FLASH->SR & FLASH_SR_BSY)) /* (3) */
{
    /* For robust implementation, add here time-out management */
}
if (!(FLASH->SR & FLASH_SR_EOP)) /* (4) */
{
    FLASH->SR = FLASH_SR_EOP; /* (5) */
}
else
{
    /* Manage the error cases */
}
FLASH->CR &= ~FLASH_CR_OPTER; /* (6) */
A.3 Clock controller

A.3.1 HSE start sequence code example

```c
/**
 * Description: This function enables the interrupt on HSE ready,
 * and start the HSE as external clock.
 */
_INLINE void StartHSE(void)
{
    /* Configure NVIC for RCC */
    /* (1) Enable Interrupt on RCC */
    NVIC_EnableIRQ(RCC_CRS_IRQn); /* (1)*/

    /* (2) Set priority for RCC */
    NVIC_SetPriority(RCC_CRS_IRQn, 0); /* (2) */

    /* (1) Enable interrupt on HSE ready */
    /* (2) Enable the CSS */
    Enable the HSE and set HSEBYP to use the external clock
    instead of an oscillator
    Enable HSE */
    /* Note : the clock is switched to HSE in the RCC_CRS_IRQHandler ISR */
    RCC->CIR |= RCC_CIR_HSERDYIE; /* (1) */
    RCC->CR |= RCC_CR_CSSON | RCC_CR_HSEBYP | RCC_CR_HSEON; /* (2) */
}

/**
 * Description: This function handles RCC interrupt request
 * and switch the system clock to HSE.
 */
void RCC_CRS_IRQHandler(void)
{
    /* (1) Check the flag HSE ready */
    /* (2) Clear the flag HSE ready */
    /* (3) Switch the system clock to HSE */

    if ((RCC->CIR & RCC_CIR_HSERDYF) != 0) /* (1) */
    {
        RCC->CIR |= RCC_CIR_HSERDYC; /* (2) */
        RCC->CFGR = ((RCC->CFGR & (~RCC_CFGR_SW)) | RCC_CFGR_SW_0); /* (3) */
    }
    else
    {
        /* Report an error */
    }
}
```
A.3.2 PLL configuration modification code example

/* (1) Test if PLL is used as System clock */
/* (2) Select HSI as system clock */
/* (3) Wait for HSI switched */
/* (4) Disable the PLL */
/* (5) Wait until PLLRDY is cleared */
/* (6) Set the PLL multiplier to 6 */
/* (7) Enable the PLL */
/* (8) Wait until PLLRDY is set */
/* (9) Select PLL as system clock */
/* (10) Wait until the PLL is switched on */
if ((RCC->CFGR & RCC_CFGR_SWS) == RCC_CFGR_SWS_PLL) /* (1) */
{
    RCC->CFGR &= (uint32_t)(~RCC_CFGR_SW); /* (2) */
    while ((RCC->CFGR & RCC_CFGR_SWS) != RCC_CFGR_SWS_HSI) /* (3) */
    {
        /* For robust implementation, add here time-out management */
    }
} RCC->CR &= (uint32_t)(~RCC_CR_PLLON); /* (4) */
while((RCC->CR & RCC_CR_PLLRDY) != 0) /* (5) */
{
    /* For robust implementation, add here time-out management */
} RCC->CFGR = RCC->CFGR & (~RCC_CFGR_PLLMUL) | (RCC_CFGR_PLLMUL6); /* (6) */
RCC->CR |= RCC_CR_PLLON; /* (7) */
while((RCC->CR & RCC_CR_PLLRDY) == 0) /* (8) */
{
    /* For robust implementation, add here time-out management */
} RCC->CFGR |= (uint32_t)(RCC_CFGR_SW_PLL); /* (9) */
while ((RCC->CFGR & RCC_CFGR_SWS) != RCC_CFGR_SWS_PLL) /* (10) */
{
    /* For robust implementation, add here time-out management */
}

A.3.3 MCO selection code example

/* Select system clock to be output on the MCO without prescaler */
RCC->CFGR |= RCC_CFGR_MCO_SYSCLK;
**A.3.4 Clock measurement configuration with TIM14 code example**

```c
/**
 * Description: This function configures the TIM14 as input capture and enables the interrupt on TIM14
 */
__INLINE void ConfigureTIM14asInputCapture(void)
{
    /* (1) Enable the peripheral clock of Timer 14 */
    /* (2) Select the active input TI1, Program the input filter, and prescaler */
    /* (3) Enable interrupt on Capture/Compare */
    RCC->APB1ENR |= RCC_APB1ENR_TIM14EN; /* (1) */
    TIM14->CCMR1 |= TIM_CCMR1_IC1F_0 | TIM_CCMR1_IC1F_1 |
                   TIM_CCMR1_CC1S_0 | TIM_CCMR1_IC1PSC_1; /* (2) */
    TIM14->DIER |= TIM_DIER_CC1IE; /* (3) */

    /* (4) Enable Interrupt on TIM14 */
    /* (5) Set priority for TIM14 */
    NVIC_EnableIRQ(TIM14_IRQn); /* (4) */
    NVIC_SetPriority(TIM14_IRQn, 0); /* (5) */

    /* (6) Select HSE/32 as input on TI1 */
    /* (7) Enable counter */
    /* (8) Enable capture */
    TIM14->OR |= TIM14_OR_TI1_RMP_1; /* (6) */
    TIM14->CR1 |= TIM_CR1_CEN; /* (7) */

    | TIM_CCMR1_IC1F_0 | TIM_CCMR1_IC1F_1; /* (1) */
TIMx->CCER |= TIM_CCER_CC1E; /* (2) */
TIMx->DIER |= TIM_DIER_CC1IE; /* (3) */
TIMx->CR1 |= TIM_CR1_CEN; /* (4) */
A.9.4 Input capture data management code example

This code must be inserted in the Timer interrupt subroutine.

```c
if ((TIMx->SR & TIM_SR_CC1IF) != 0)
{
    if ((TIMx->SR & TIM_SR_CC1OF) != 0) /* Check the overflow */
    {
        /* Overflow error management */
        gap = 0; /* Reinitialize the laps computing */
        TIMx->SR &= ~(TIM_SR_CC1OF | TIM_SR_CC1IF); /* Clear the flags */
        return;
    }
    if (gap == 0) /* Test if it is the first rising edge */
    {
        counter0 = TIMx->CCR1; /* Read the capture counter which clears the
                                 CC1ICF */
        gap = 1; /* Indicate that the first rising edge has yet been detected */
    }
    else
    {
        counter1 = TIMx->CCR1; /* Read the capture counter which clears the
                                 CC1ICF */
        if (counter1 > counter0) /* Check capture counter overflow */
        {
            Counter = counter1 - counter0;
        }
        else
        {
            Counter = counter1 + 0xFFFF - counter0 + 1;
        }
        counter0 = counter1;
    }
}
else
{
    /* Unexpected Interrupt */
    /* Manage an error for robust application */
}
```

**Note:** This code manages only a single counter overflow. To manage many counter overflows the update interrupt must be enabled (UIE = 1) and properly managed.
A.9.5 PWM input configuration code example

/* (3) 8 data bit, 1 start bit, 1 stop bit, no parity, reception and
transmission enabled */
USART1->BRR = 480000 / 96; /* (1) */
USART1->CR3 = USART_CR3_DMAT | USART_CR3_DMAR; /* (2) */
USART1->CR1 = USART_CR1_TE | USART_CR1_RE | USART_CR1_UE; /* (3) */
/* Polling idle frame Transmission */
while ((USART1->ISR & USART_ISR_TC) != USART_ISR_TC)
{
    /* add time out here for a robust application */
}
USART1->ICR |= USART_ICR_TCCF; /* Clear TC flag */
USART1->CR1 |= USART_CR1_TCIE; /* Enable TC interrupt */
A.19.12 USART hardware flow control code example

/* (1) oversampling by 16, 9600 baud */
/* (2) RTS and CTS enabled */
/* (3) 8 data bit, 1 start bit, 1 stop bit, no parity, reception and transmission enabled */
USART1->BRR = 480000 / 96; /* (1) */
USART1->CR3 = USART_CR3_RTSE | USART_CR3_CTSE; /* (2) */
USART1->CR1 = USART_CR1_TE | USART_CR1_RXNEIE
            | USART_CR1_RE | USART_CR1_UE; /* (3) */
/* Polling idle frame Transmission */
while ((USART1->ISR & USART_ISR_TC) != USART_ISR_TC)
{
    /* add time out here for a robust application */
}
USART1->ICR |= USART_ICR_TCCF; /* Clear TC flag */
USART1->CR1 |= USART_CR1_TCIE; /* Enable TC interrupt */

A.20 WWDG code example

A.20.1 WWDG configuration code example

/* (1) Set prescaler to have a roll-over each about 5.5ms, set window value (about 2.25ms) */
/* (2) Refresh WWDG before activate it */
/* (3) Activate WWDG */
WWDG->CFR = 0x60; /* (1) */
WWDG->CR = WWDG_REFRESH; /* (2) */
WWDG->CR |= WWDG_CR_WDGA; /* (3) */
Important security notice

The STMicroelectronics group of companies (ST) places a high value on product security, which is why the ST product(s) identified in this documentation may be certified by various security certification bodies and/or may implement our own security measures as set forth herein. However, no level of security certification and/or built-in security measures can guarantee that ST products are resistant to all forms of attacks. As such, it is the responsibility of each of ST’s customers to determine if the level of security provided in an ST product meets the customer needs both in relation to the ST product alone, as well as when combined with other components and/or software for the customer end product or application. In particular, take note that:

- ST products may have been certified by one or more security certification bodies, such as Platform Security Architecture (www.psacertified.org) and/or Security Evaluation standard for IoT Platforms (www.trustcb.com). For details concerning whether the ST product(s) referenced herein have received security certification along with the level and current status of such certification, either visit the relevant certification standards website or go to the relevant product page on www.st.com for the most up to date information. As the status and/or level of security certification for an ST product can change from time to time, customers should re-check security certification status/level as needed. If an ST product is not shown to be certified under a particular security standard, customers should not assume it is certified.
- Certification bodies have the right to evaluate, grant and revoke security certification in relation to ST products. These certification bodies are therefore independently responsible for granting or revoking security certification for an ST product, and ST does not take any responsibility for mistakes, evaluations, assessments, testing, or other activity carried out by the certification body with respect to any ST product.
- Industry-based cryptographic algorithms (such as AES, DES, or MD5) and other open standard technologies which may be used in conjunction with an ST product are based on standards which were not developed by ST. ST does not take responsibility for any flaws in such cryptographic algorithms or open technologies or for any methods which have been or may be developed to bypass, decrypt or crack such algorithms or technologies.
- While robust security testing may be done, no level of certification can absolutely guarantee protections against all attacks, including, for example, against advanced attacks which have not been tested for, against new or unidentified forms of attack, or against any form of attack when using an ST product outside of its specification or intended use, or in conjunction with other components or software which are used by customer to create their end product or application. ST is not responsible for resistance against such attacks. As such, regardless of the incorporated security features and/or any information or support that may be provided by ST, each customer is solely responsible for determining if the level of attacks tested for meets their needs, both in relation to the ST product alone and when incorporated into a customer end product or application.
- All security features of ST products (inclusive of any hardware, software, documentation, and the like), including but not limited to any enhanced security features added by ST, are provided on an "AS IS" BASIS. AS SUCH, TO THE EXTENT PERMITTED BY APPLICABLE LAW, ST DISCLAIMS ALL WARRANTIES, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO THE IMPLIED WARRANTIES OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE, unless the applicable written and signed contract terms specifically provide otherwise.
## Revision history

<table>
<thead>
<tr>
<th>Date</th>
<th>Revision</th>
<th>Changes</th>
</tr>
</thead>
<tbody>
<tr>
<td>06-Apr-2012</td>
<td>1</td>
<td><strong>Initial release</strong></td>
</tr>
<tr>
<td>08-Aug-2012</td>
<td>2</td>
<td><strong>Documentation conventions</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added ‘Always read...’ in Section 1.1: List of abbreviations for registers</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Memory map</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added boot configuration link in Table 1: STM32F05xxx memory map and peripheral register boundary addresses</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added Footnote under Table 3: Boot modes</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Remove ‘DCode’ after ‘CPU’ in Section : DMA bus</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Replaced sentence and added Physical remap paragraph in Section 2.5: Boot configuration</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Corrected Prefetch buffer and added paragraph in Section 1.2.2: Read operations</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Removed sentence ‘It is set after the first...’, removed note and added description of bit 5 in Section 1.5.1: Flash access control register (FLASH_ACR)</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>CRC</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Replaced references to bits 4:3 and 2:1 in Section 6.4.3: Control register (CRC_CR)</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>PWR</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Replaced ‘POR’, ‘PDR’ and ‘PVD’ by ‘VPOR’, ‘VPDR’ and ‘VPVD’ in Figure 2 and Figure 3</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Modified “When VDDA is different from VDD...” paragraph in Section 1.1.1: Independent A/D and D/A converter supply and reference voltage</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Moved arrow in Figure 2: Power on reset/power down reset waveform</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Corrected WKUP1 in Section 1.4.2: Power control/status register (PWR_CSR)</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>RCC</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added Power reset in Section 1.1.2: System reset</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added paragraph ‘For more details on how to measure...’ in Section 1.2.2: HSI clock</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added ‘LSE’ and ‘LSI’ bullets in Section 1.2.12: Clock-out capability</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added ‘/1’, ‘LSI’ and ‘LSE’ in Figure 2: Clock tree (STM32F03x and STM32F05x devices)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added the sentence “... drive the HSI clock ...” to Section 1.2.2: HSI clock</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added “independent” to the title of Section 1.2.11: Independent watchdog clock</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Replaced the first sentence after Figure 5: Frequency measurement with TIM14 in capture mode</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added the sentence “When the system is in stop mode...” in Section : The input capture channel of the Timer 14 can be a GPIO line or an internal clock of the MCU. This selection is performed through the TI1_RMP [1:0] bits in the TIM14.OR register. The possibilities available are the following ones.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added Section 1.2.13: Internal/external clock measurement with TIM14 and Section 1.3: Low-power modes</td>
</tr>
</tbody>
</table>

Table 146. Document revision history (continued)

<table>
<thead>
<tr>
<th>Date</th>
<th>Revision</th>
<th>Changes</th>
</tr>
</thead>
<tbody>
<tr>
<td>08-Aug-2012</td>
<td>2 (cont'd)</td>
<td>- Modified description of Bit 19 and Bits 15:8 in Section 1.4.1: Clock control register (RCC_CR)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Replaced text under ‘PLLXTPRE’ and modified description of bits 26:24 in Section 1.4.2: Clock configuration register (RCC_CFR)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Modified the formatting in the register of Section 1.4.4 and Section 1.4.5: APB peripheral reset register 1 (RCC_APB1RSTR)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Modified title of Bit 0 in the registers of Section 1.4.7: APB peripheral clock enable register 2 (RCC_APB2ENR)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Replaced ‘IWWDGRSTF’ by ‘IWDGRSTF’ and added PORV18RSTDF POR/PDR for bit 23 in Section 1.4.10: Control/status register (RCC_CSR)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Modified Section 1.4.4: APB peripheral reset register 2 (RCC_APB2RSTR) to Section 1.4.8: APB peripheral clock enable register 1 (RCC_APB1ENR) title name.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>GPIO</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Replaced SWDAT in Section 9.3.1: General-purpose I/O (GPIO)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Added specific reset values in Section 9.4.3: GPIO port output speed register (GPIOx_OSPEEDR) (x = A..F)</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>DMA</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Added ‘I2C1’, ‘TIM15’, ‘TIM16 and ‘TIM17’ to Figure 21: DMA block diagram</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>ADC</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Changed JITOFF_D2 and JITOFF_D4 to JITOFF_DIV4 and JITOFF_DIV2 in Section 13.12.5: ADC configuration register 2 (ADC_CFRG2) and Section 13.12.11: ADC register map</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Replaced ‘SMPR’ with ‘SMP’ in Section 13.12.11: ADC register map</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>DAC</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Replaced note in Section 14.2: DAC1 main features</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>COMP</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Replaced ‘bandgap’ with ‘VREFINT’ and added PA12 to COMP2_OUT in Figure 92: Comparator 1 and 2 block diagrams</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Added the sentence “Reset and clock enable bits....” to Section 15.3.3: COMP reset and clocks</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Modified COMP2MODE and COMP1MODE bit description in Section 15.6.1: COMP control and status register (COMP_CSR)</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Timers</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Added OCCS bit in Section 1.4.3: TIM2 and TIM3 slave mode control register (TIM2_SMCR and TIM3_SMCR) and Section 1.4.3: TIM1 slave mode control register (TIM1_SMCR)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Mapped ‘TI1_RMP’ to bit 0 and 1 in Section 1.4.10: TIM14 capture/compare register 1 (TIM14_CCR1)</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Infrared</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Infrared function output changed to IR_OUT</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>RTC</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Removed VCC in Section 25.6.19: RTC backup registers (RTC_BKPxR)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Removed Tamper3 in RTC ISR and TAFCR registers</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- RTC ordered before WDG</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>IWDG</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Replaced ‘IWWDG’ occurrences by ‘IWDG’</td>
</tr>
<tr>
<td>Date</td>
<td>Revision</td>
<td>Changes</td>
</tr>
<tr>
<td>------------</td>
<td>----------</td>
<td>-------------------------------------------------------------------------</td>
</tr>
<tr>
<td>08-Aug-2012</td>
<td>2 (cont’d)</td>
<td>I2C</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Modified Section 24.4.5: I2C initialization, Section 24.4.6: Software reset</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Removed ‘SWRST’ in Section 24.7.1: Control register 1 (I2Cx_CR1) and Section 24.7.7: Interrupt and Status register (I2Cx_ISR)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>USART</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Removed “with a 12-bit mantissa and 4-bit fraction” in Section 25.5: USART functional description</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Changed Equation in Section 25.5.5: Tolerance of the USART receiver to clock deviation</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Changed reset values length in Section 25.7: USART registers</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Corrected reset values for ‘DEP’, ‘TC’, ‘RDR’ and ‘TDR’ in Table 90: USART register map and reset values</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Debug</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Removed ‘Control of the trace..’ bullet in Section 1.9: MCU debug component (DBGMCU)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Replaced IDCODE values in Section 1.5.3: SW-DP state machine (reset, idle states, ID code) and Section 1.5.5: SW-DP registers</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Replaced “APB low” to APB1 in Section 1.9.2: Debug support for timers, watchdog and I^C</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Corrected Figure 1: Block diagram of STM32F0xx MCU and Cortex®-M0-level debug support</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Modified the title of Section 1.3.1: SWD port pins</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Modified Section 1.3.2: SW-DP pin assignment and Section 1.3.3: Internal pull-up &amp; pull-down on SWD pins</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Modified titles in Section 1.5: SWD port and replaced ‘SWDAT’</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Removed ‘DBG SLEEP’ in Section 1.9.3: Debug MCU configuration register (DBGMCU_CR)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added ‘System’ to window watchdog in Section 1.9.4: Debug MCU APB1 freeze register (DBGMCU_APB1_FZ)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Marked bit 0, 5, 6 and 7 as reserved in Section 1.9.6: DBG register map</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Unique ID</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Removed Bold from ‘base address’ in Section 32.1: Unique device ID register (96 bits)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Date</th>
<th>Revision</th>
<th>Changes</th>
</tr>
</thead>
<tbody>
<tr>
<td>10-May-2013</td>
<td>3</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added part numbers STM32F06x throughout the document.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Updated document title.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Documentation conventions</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added “(w_r0)” to Section 1.1: List of abbreviations for registers.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added reference to PM0215 in Related documents.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Updated Glossary.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>System and memory overview</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Modified Sections BusMatrix and AHB to APB bridge.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added Note: in Section 2.3: Embedded SRAM.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Embedded Flash memory</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Updated Table 4: Access status versus protection level and execution modes.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Modified phrasing of Level 2: no debug paragraph in Section 1.3.1: Read protection.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added description of information block in Section 1.2.1: Flash memory organization.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Renamed “FKEYR” to “FKEY” and renamed “OPTKEYR” to “OPTKEY”.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Renamed and modified Section 1.5.7: Flash Option byte register (FLASH_OBR).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Modified information about reset value in Section 1.5.2: Flash key register (FLASH_KEYR), Section 1.5.3: Flash option key register (FLASH_OPTKEYR), Section 1.5.7: Flash Option byte register (FLASH_OBR) and Section 1.5.8: Write protection register (FLASH_WRPR).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Modified Section Unlocking the Flash memory, item 5. in Main Flash memory programming, procedure in sections Page Erase and Mass Erase.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added Note: in Page Erase and Mass Erase.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Updated Table 6: Flash interface - register map and reset values.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Option bytes</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Reworked Section 2: Option bytes.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>PWR</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Modified introduction of Section 1.1: Power supplies.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added bullet “In STM32F06x devices...” in Section 1.1.4: Voltage regulator.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added section External NPOR signal.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added Caution: in Section 1.3: Low-power modes and in Section 1.3.5: Standby mode.</td>
</tr>

</table>
| 10-May-2013 | 3 (cont’d) | **RCC**  
  – Inverted order of sections **Section 1.1.1: Power reset** and **Section 1.1.2: System reset.**  
  – Added Caution: in **External crystal/ceramic resonator (HSE crystal) and Caution: in Section 1.2.5: LSE clock**  
  – Added bullet “The timer clock frequencies are automatically fixed by hardware...” in **Section 1.2: Clocks.**  
  – Updated **Section 1.1.1: Power reset, Section 1.1.2: System reset, Section 1.1.3: RTC domain reset, Calibration of the HSI14, Section 1.2.12: Clock-out capability, Section 1.2.13: Internal/external clock measurement with TIM14, Section 1.4.2: Clock configuration register (RCC_CFGR), Section 1.4.4: APB peripheral reset register 2 (RCC_APB2RSTR), Section 1.4.12: Clock configuration register 2 (RCC_CFGR2), Section 1.4.13: Clock configuration register 3 (RCC_CFGR3).**  
  – Modified **Figure 1: Simplified diagram of the reset circuit and Figure 2: Clock tree (STM32F03x and STM32F05x devices).**  
  – Replaced FORCE_OBL with OBL_LAUNCH in **Option byte loader reset.**  
  – Deleted **Section 7.2.13: Clock-independent system clock sources for TIM14.**  
  – Added USART3EN, UART4EN and UART5EN in **Table 1: RCC register map and reset values.**  
  – Modified reset values of RCC_CSR register in **Table 1: RCC register map and reset values.**  
  – Modified reset value and description of Bit 23 in **Section 1.4.10: Control/status register (RCC_CSR).**  
  – Specified Bit 8 as obsolete in **Section 1.4.13: Clock configuration register 3 (RCC_CFGR3).**  
  **GPIO**  
  – Updated **Section 9.1: Introduction.**  
  – Removed “Analog” arrows in **Figure 17: Basic structure of a five-volt tolerant I/O port bit.**  
  – Renamed **Section 9.4.11: GPIO port bit reset register (GPIOx_BRR) (x = A..F).**  
  **SYSCFG**  
  – Modified values of register bits 23, 22 and 20.  
  **Interrupts and events**  
  – Added Priority numbers and modified description of EXTI4_15 in **Table 1: Vector table.**  
  **ADC**  
  – Rephrased part of **Section 13.4.1: Calibration (ADCAL).**  
  – Replaced AUTDLY with WAIT in sections **13.5.5: Example timing diagrams (single/continuous modes hardware/software triggers) and 13.12.4: ADC configuration register 1 (ADC_CFRG1).**  
  – Updated **Figure 25: ADC block diagram.**  
  – Replaced “0x44...0x2FC” with “0x44...0x304” in **Table 44: ADC register map and reset values.** |
Table 146. Document revision history (continued)

<table>
<thead>
<tr>
<th>Date</th>
<th>Revision</th>
<th>Changes</th>
</tr>
</thead>
</table>
| 10-May-2013| 3 (cont'd) | DAC  
– Corrected name of Table 66: External triggers.  
– Replaced every occurrence of “DAC1” with “DAC”.  
COMP  
– Replaced “COMP1SW1 : Comparator enable” with “COMP1SW1 : Comparator 1 non inverting input DAC switch” in Section 15.6.1: COMP control and status register (COMP_CSR).  
TIM2 and TIM3  
– Corrected Figure 106: Advanced-control timer block diagram.  
TIM14  
– Updated Figure 17: TIM16 and TIM17 block diagram.  
TIM15/16/17  
– Updated Section 2.1: TIM15/16/17 introduction, Section 2.3: TIM16 and TIM17 main features and Section 2.4.4: Clock sources.  
– Removed Note in Section 2.6.1: TIM16 and TIM17 control register 1 (TIM16_CR1 and TIM17_CR1).  
– Marked as "reserved": Bits 14 and 6 in Section 2.6.3: TIM16 and TIM17 DMA/interrupt enable register (TIM16_DIER and TIM17_DIER), bits 6 and 0 in Section 2.6.4: TIM16 and TIM17 status register (TIM16_SR and TIM17_SR), and bit 6 in Section 2.6.5: TIM16 and TIM17 event generation register (TIM16_EGR and TIM17_EGR).  
– Updated Table 7: TIM16 and TIM17 register map and reset values.  
RTC  
– Replaced “power-on reset” with “backup domain reset” throughout Section 25: Real-time clock (RTC).  
– Removed “the backup registers are reset when a tamper detection event occurs” in Section 25.2: RTC main features.  
– Updated RTC backup registers.  
– Updated RTC_ISR register reset values in Section 25.3.9: Resetting the RTC and Section 25.6.4: RTC initialization and status register (RTC_ISR).  
I2C  
– Updated case of digital filter enabled and Table 81: Comparison of analog vs. digital filters.  
– Added note for WUPEN in Section 26.7.1: Control register 1 (I2Cx_CR1).  
– Corrected Figure 275: Transfer sequence flowchart for I2C master transmitter for N>255 bytes.  
– Removed maximum values of parameter “Data hold time” and added row “Data valid time” in Table 90: I2C-SMBUS specification data setup and hold times.  
– Updated sub-sections I2C timings and Slave clock stretching (NOSTRETCH = 0). |

<td></td>
<td></td>
<td>– Removed note on bit 19 (RWU) in Section 25.7.8: Interrupt &amp; status register (USART_ISR).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>SPI/I2S</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Reorganized SPI initialization and sequence handling sections.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Corrected and updated SPI disabling and DMA handling procedures.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Updated description of NSSP and TI modes.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Corrected DMA CRC management.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Removed CRC interrupt capability.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Changed RXONLY and BIDIMODE bit description.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Modified sections : Simplex communications on page 828 and : Data frame format on page 833, 28.5.7: Procedure for enabling SPI on page 835, Figure 318: Hardware/software slave select management, Figure 319: Data clock timing diagram, Figure 320: Data alignment when data length is not equal to 8-bit or 16-bit, Figure 327: TI mode transfer.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Modified reset value of SPIx_I2SPR in Section 28.9.9: SPIx_I2S prescaler register (SPIx_I2SPR).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added Figure 322: Master full duplex communication, Figure 323: Slave full duplex communication, Figure 324: Master full duplex communication with CRC, Figure 325: Master full duplex communication in packed mode.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>TSC</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Replaced “Power-on reset value” with “Reset value” in Section 17.6.2: TSC interrupt enable register (TSC_IER).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Debug</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Renamed Section 1.3.2: SW-DP pin assignment.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Changed description of Bits 11:0 in Section 1.4.1: MCU device ID code.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Modified notes regarding IDCODE register in Table 5: SW-DP registers.</td>
</tr>
</tbody>

<th>Revision</th>
<th>Changes</th>
</tr>
</thead>
<tbody>
<tr>
<td>21-May-2013</td>
<td>4</td>
<td>ADC</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added note in Section 13.5.2: Programmable resolution (RES) - fast conversion mode: RES[1:0] can be changed only when ADEN=0.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added bit CKMODE.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Rewrote Section 13.4.2: ADC on-off control (ADEN, ADDIS, ADRDY) and Section 13.4.3: ADC clock (CKMODE).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added Figure 28: ADC clock scheme.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Fixed issues concerning CKMODE &amp; JITOFF bits. Now bits JITOFF_DIV4/DIV2 bits are replaced with bits CKMODE[1:0] at the same position and with same decoding as v1.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Changed note on ADRDY in Section 13.4.2: ADC on-off control (ADEN, ADDIS, ADRDY).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Extended Section 13.12.8: ADC channel selection register (ADC_CHSELR) (added channel 18).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Removed reference to TSVREFE bit in Section 13.9: Temperature sensor and internal reference voltage and referred to TSEN/VREFEN instead.</td>
</tr>
<tr>
<td>09-Jan-2014</td>
<td>5</td>
<td>Cover page</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Changed part numbers in title and introduction on page 1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Renamed low-density to STM32F03x</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Renamed medium-density to STM32F05x</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Renamed STM32F06x to STM32F0x8</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added STM32F07x microcontrollers (STM32F071xB and STM32F072xx).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Expanded the Flash memory range to 128 Kbytes.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added Section 8: Clock recovery system (CRS), Section 29: Controller area network (bxCAN) and Section 30: Universal serial bus full-speed device interface (USB).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Document conventions</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Updated Section 1.2: Glossary.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>System and memory overview</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added ‘TIM7, USART3, USART4, CAN and USB’ and ’7 channels DMA’ in Figure 1: System architecture (all features).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added ‘CRS, TIM7, USART3, USART4, CAN and USB’ in Table 1: STM32F0xx peripheral register boundary addresses.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Updated Table 1: STM32F0xx peripheral register boundary addresses.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added Table 2: STM32F0xx memory boundary addresses</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added 16 KB-RAM for STM32F07x devices in Section 2.3: Embedded SRAM.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added USB in Embedded boot loader.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Embedded Flash memory</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added Table 2: Flash memory organization (STM32F07x devices).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added ‘WRP[31:16]’ in Section 1.5.8: Write protection register (FLASH_WRPR) and Table 6: Flash interface - register map and reset values.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Option bytes</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added row ‘0x1FFF F80C’ in Table 8: Option byte organization.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Updated Section 2.1.3: Write protection option bytes.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Updated Table 9: Option byte map and ST production values.</td>
</tr>
</tbody>
</table>
CRC
– Introduced programmable polynomial feature in Section 6.2: CRC main features, Section 6.4.3: Control register (CRC_CR) and Section 6.4.6: CRC register map.
– Added Section: Polynomial programmability and Section 6.4.5: CRC polynomial (CRC_POL).

PWR
– Added STM32F07x device features
– Updated Figure 1: Power supply overview
– Added Section 1.1.2: Independent I/O supply rail
– Added bits 10 to 15 in Section 1.4.2: Power control/status register (PWR_CSR)

RCC
– Renamed “backup domain” to “RTC domain”.
– Added HSI48 48 MHz RC oscillator clock and USART2 features for STM32F07x devices.
– Modified Section 1.2: Clocks and Section 1.2.2: HSI clock, Section 1.2.4: PLL, Section 1.2.7: System clock (SYSCLK) selection, Section 1.2.12: Clock-out capability, Section 1.3: Low-power modes.
– Added Figure 3: Clock tree (STM32F04x and STM32F07x devices) and Section 1.2.3: HSI48 clock.
– Updated register descriptions for STM32F07x devices in Section 1.4.2: Clock configuration register (RCC_CFGR), Section 1.4.3: Clock interrupt register (RCC_CIR), Section 1.4.5: APB peripheral reset register 1 (RCC_APB1RSTR), Section 1.4.6: AHB peripheral clock enable register (RCC_AHBENR), Section 1.4.8: APB peripheral clock enable register 1 (RCC_APB1ENR), Section 1.4.11: AHB peripheral reset register (RCC_AHBRRSTR), Section 1.4.13: Clock configuration register 3 (RCC_CFGR3), and Section 1.4.14: Clock control register 2 (RCC_CR2) and updated Table 1: RCC register map and reset values.

GPIO
– Added port E in ranges of all registers except LCKR.
– Modified Section 9.1: Introduction.
– Replaced VDD with VDDIO in Figure 17: Basic structure of an I/O port bit, Figure 18: Input floating/pull up/pull down configurations, Figure 19: Output configuration, Figure 20: Alternate function configuration and Figure 21: High impedance-analog configuration.

SYSCFG
– Added bits [30:24] and 21 for STM32F07x devices in Section 1.1.1: SYSCFG configuration register 1 (SYSCFG_CFGR1).
– Added pin PE[x] for bits [15:0] in Section 1.1.2: SYSCFG external interrupt configuration register 1 (SYSCFG_EXTICR1), pins PD[x] and PE[x] for bits [15:0] in Section 1.1.3: SYSCFG external interrupt configuration register 2 (SYSCFG_EXTICR2), pins PD[x], PE[x] and PF[x] for bits [15:0] in Section 1.1.4: SYSCFG external interrupt configuration register 3 (SYSCFG_EXTICR3) and Section 1.1.5: SYSCFG external interrupt configuration register 4 (SYSCFG_EXTICR4).
– Updated Table 1: SYSCFG register map and reset values.

<td></td>
<td></td>
<td>– Updated Section 13.9: Temperature sensor and internal reference voltage</td>
</tr>
<tr>
<td></td>
<td></td>
<td>DAC</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added second channel DAC_OUT2, Noise-wave generation, Triangular-wave generation and dual mode for STM32F07x devices</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Updated Section 14.2: DAC1 main features</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added Section 14.4: Dual mode functional description (STM32F07x devices)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added Section 14.4: Noise generation</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added Section 14.5: DMA request</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added bits 29 to 16 and bits 11 to 6 in Section 14.6.1: DAC control register (DAC_CR)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added bit ‘SWTRIG2’ in Section 14.6.2: DAC software trigger register (DAC_SWTRIGR)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added Section 14.8.6: DAC channel2 12-bit right-aligned data holding register (DAC_DHR12R2), Section 14.8.7: DAC channel2 12-bit left-aligned data holding register (DAC_DHR12L2), Section 14.8.8: DAC channel2 8-bit right-aligned data holding register (DAC_DHR8R2), Section 14.8.9: Dual DAC 12-bit right-aligned data holding register (DAC_DHR12RD), Section 14.8.10: Dual DAC 12-bit left-aligned data holding register (DAC_DHR12LD), Section 14.8.11: Dual DAC 8-bit right-aligned data holding register (DAC_DHR8RD), Section 14.8.13: DAC channel2 data output register (DAC_DOR2)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added bit 29 in Section 14.6.7: DAC status register (DAC_SR)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Basic timer (TIM6/TIM7)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added TIM7 for STM32F07x devices in Section 1: Basic timer (TIM6/TIM7)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>RTC</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Renamed “backup domain to “RTC domain”</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added RTC_TAMP3 and wakeup interrupt for STM32F07x devices</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added Table 67: STM32F0xx RTC implementation</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added Section 25.3.6: Periodic auto-wakeup, Section : Programming the wakeup timer</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Corrected bit SHPF read and clear parameters in Section 25.6.4: RTC initialization and status register (RTC_ISR)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>I2C</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Added Table 74: STM32F0xx I2C implementation</td>
</tr>
<tr>
<td></td>
<td></td>
<td>– Updated Table 90: I2C-SMBUS specification data setup and hold times</td>
</tr>
</tbody>
</table>
09-Jan-2014  5 (cont’d)

- Replaced 50ns into tAF(min) and 260ns into tAF(max) in section I2C timings

**USART**
- Added number of auto baud rate detection mode in Table 90: STM32F0xx USART implementation.
- Removed mentions of mantissa and fraction in Figure 288: USART block diagram and Section 27.7.4: Baud rate register (USARTx_BRR).
- Sections RTS flow control and CTS flow control renamed RS232 RTS flow control and RS232 CTS flow control. Added case of idle character in Section 27.5.1: USART character description. Added recommendation of TE reset during data transmission in Section : Character transmission. Updated Section : Break characters.
- Removed note related to USART disabling procedure in Section : Single byte communication.
- Added case of oversampling by 8 in Section 27.5.6: Auto baud rate detection.
- Renamed Section 27.5.16 RS232 Hardware flow control and RS485 Driver Enable.
- Added check that no transfer is ongoing before entering stop mode in Section 27.5.17: Wakeup from Stop mode; added case of RXNE set in Section : Using Mute mode with Stop mode.
- Updated Table 111: USART register map and reset values.
- Modified Table 90: STM32F0xx USART implementation.
- Added note related to smartcard mode in Section 27.7.1: Control register 1 (USARTx_CR1).
- Added sequence to deliver SCLK clock to smartcards, in CLKEN description of Section 27.7.2: Control register 2 (USARTx_CR2).
- Added note related to PSC configuration in Section 27.7.5: Guard time and prescaler register (USARTx_GTPR).
- Added support of 7-bit data word length; added 6 LSB bits in Section 27.5.1: USART character description, Section 27.5.9: Parity control, Section : Even parity and Section : Odd parity, Section 27.5.5: Tolerance of the USART receiver to clock deviation, renamed M bit M0 in Section 27.7.1: Control register 1 (USARTx_CR1).
- Added 2 auto baud rate detection modes: modes 2 and 3 in Section 27.5.6: Auto baud rate detection.
- Replaced in Bit 2 MMRQ Section 25.7.7: Request register (USART_RQR) "resets the RWU flag” by "sets the RWU flag”
- Added “In Smartcard, LIN and IrDA modes, only Oversampling by 16 is supported” in Section 25.5.4: Baud rate generation
- Corrected and updated stop bits in Figure 198: Word length programming

**SPI**
- Modified Table 98: STM32F0xx SPI implementation

**TSC**
- Added Groups 7 and 8 and channels 19 to 24 in Section 17: Touch sensing controller (TSC). Added Table 106: Capacitive sensing GPIOs

**DEBUG**
- Added STM32F07x ID in bits DEV_IDx in Section 1.4.1: MCU device ID code
- Added bit 5 ‘DBG_TIM7_STOP’ and bit 25 ‘DBG_CAN_STOP’ to Section 1.9.4: Debug MCU APB1 freeze register (DBGMCU_APB1_FZ)

</table>
| 06-May-2014| 6        | **Cover page**  
- Updated for STingray adding STM32F042x4x6 and STM32F048x6 devices.  
**MMAP**  
- updated Table 2: STM32F0xx memory boundary addresses  
- updated Section 2.5: Boot configuration  
**Embedded Flash memory**  
- Updated Section 1.2.1: Flash memory organization, Table 4: Access status versus protection level and execution modes and Section 1.5: Flash register description  
- Option byte : updated Section 2.1: Option byte description  
**RCC**  
- Updated with STM32F04x devices : Section 1.2: Clocks and Figure 3: Clock tree (STM32F04x and STM32F07x devices).  
**CRS**  
- Updated adding STM32F04x devices.  
**GPIO**  
- Updated Figure 17: Basic structure of an I/O port bit  
**SYSCFG**  
- Updated SYSCFG Registers  
**DMA** updated  
**IRTIM**  
- Updated Figure 252: IR internal hardware connections with TIM16 and TIM17.  
**IWDG**  
- updated Section 24.3: IWDG functional description.step6 moved to step1.  
- updated Section 24.4: IWDG registers.Moved Note From IWDG_WINR to IWDG_SR register.  
- Added STM32F04x  
**RTC**  
- Updated Figure 256: RTC block diagram title.  
- Updated Table 67: STM32F0xx RTC implementation.  
- Updated 25.3: RTC functional description.  
**I2C**  
- Added STM32F04x in Table 74: STM32F0xx I2C implementation  
**USART**  
- Changed Stingray adding STM32F04x in Table 90: STM32F0xx USART implementation, 27.5: USART functional description and 27.7: USART registers.  
- Updated Table 109: Frame formats in USART IP  
- Changed Stingray adding STM32F04x in Table 98.: STM32F0xx SPI implementation. |

  Debug support (DBG)  
  Section 32.4.1: MCU device ID code |
| 29-Jul-2015 | 8        | System and memory overview  
  – Corrected the original memory space value for STM32F09x devices in Section 2.5: Boot configuration.  
  CRS  
  – Added the note in SYNCSRC[1:0] description of CRS configuration register (CRS_CFGR) in Section 8.6.2: CRS configuration register (CRS_CFGR).  
  Interrupts and events  
  – Corrected the definition for EXTI line 31 in Section 12.2.5: External and internal interrupt/event line mapping  
  Appendix A Code examples  
  – Global update of Section Appendix A: Code examples: now displayed with colors. |
| 20-Jan-2017 | 9        | The order of functions (peripherals) changed.  
  Updated the following sections:  
  System and memory overview  
  – Table 13: STM32L4Rxxx and STM32L4Sxxx peripheral register boundary addresses OrcaZero  
  – Section 2.3: Embedded SRAM  
  – Section 2.5: Boot configuration  
  Embedded Flash memory  
  – Section 3.5.4: Flash status register (FLASH_SR)  
  – Section 3.5.7: Flash Option byte register (FLASH_OBR)  
  – Section 4: Option bytes  
  Power control (PWR)  
  – Section 5.4.2: Power control/status register (PWR_CSR)  
  Reset and clock control (RCC)  
  – Section 6.2.10: RTC clock  
  – Section 6.4.9: RTC domain control register (RCC_BDCR)  
  – Table 19: RCC register map and reset values  
  – Section 6.4.14: Clock control register 2 (RCC_CR2)  
  General-purpose I/Os (GPIO)  
  – Section 8.3.2: I/O pin alternate function multiplexer and mapping  
  – Section 8.4.12: GPIO register map  
  – AFRLy field names changed to AFSELy in Section 8.4.9: GPIO alternate function low register (GPIOx_AFRFL) (x = A to F), Section 8.4.10: GPIO alternate function high register (GPIOx_AFRFH) (x = A to F) |

### Table 146. Document revision history (continued)

<table>
<thead>
<tr>
<th>Date</th>
<th>Revision</th>
<th>Changes</th>
</tr>
</thead>
</table>
| 18-May-2022| 10       | Updated Introduction, Embedded boot loader, Prefetch controller, Section 3.3.1: Read protection, Section 5.2.1: Power on reset (POR) / power down reset (PDR), Section 5.2.2: Programmable voltage detector (PVD), Section 8.1: Introduction, Section 8.3.2: I/O pin alternate function multiplexer and mapping, Calculating the actual VDDA voltage using the internal reference voltage, Section 19.4.5: TIM14 capture/compare mode register 1 [alternate] (TIM14_CCMR1), Section 19.4.6: TIM14 capture/compare mode register 1 [alternate] (TIM14_CCMR1), Section 20.4.1: Time-base unit, Section 20.4.4: Clock sources, Section 20.4.10: PWM mode, Section 20.4.13: One-pulse mode, Section 20.5.7: TIM15 capture/compare mode register 1 [alternate] (TIM15_CCMR1), Section 20.6.6: TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1)(x = 16 to 17), Section 20.6.7: TIMx capture/compare mode register 1 [alternate] (TIMx_CCMR1)(x = 16 to 17), Section 25.4.16: Alarm output, Section 26.4.2: I2C2 block diagram, and Hardware transfer management.
|            |          | Added Section 20.5.8: TIM15 capture/compare mode register 1 [alternate] (TIM15_CCMR1), note in Section 32.9.3: Debug MCU configuration register (DBGMCU_CR), and Important security notice.
|            |          | Updated Figure 1: System architecture, Figure 2: Memory map, Figure 6: Power supply overview, Figure 16: Basic structure of an I/O port bit, Figure 17: Input floating / pull up / pull down configurations, Figure 18: Output configuration, Figure 19: Alternate function configuration, Figure 63: Advanced-control timer block diagram, Figure 187: Capture/compare channel 1 main circuit, Figure 227: Transfer bus diagrams for I2C slave transmitter (mandatory events only), Figure 230: Transfer bus diagrams for I2C slave receiver (mandatory events only), Figure 237: Transfer bus diagrams for I2C master transmitter (mandatory events only), Figure 240: Transfer bus diagrams for I2C master receiver (mandatory events only), and footnote 2 of Figure 276: Simplex single master/single slave application (master in transmit-only/ slave in receive-only mode).
|            |          | Updated Table 7: Access status versus protection level and execution modes, Table 36: Vector table, Table 85: RTC register map and reset values, and Table 138: DEV_ID and REV_ID field values.
|            |          | Minor text edits across the whole document.
