Bits 31:22 Reserved, must be kept at reset value.

Bits 19:17 Reserved, must be kept at reset value.

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 MSM: Master/slave mode
0: No action
1: The effect of an event on the trigger input (TRGI) is delayed to allow a perfect synchronization between the current timer and its slaves (through TRGO). It is useful if we want to synchronize several timers on a single external event.

Bits 21, 20, 6, 5, 4 TS[4:0]: Trigger selection
This bit field selects the trigger input to be used to synchronize the counter.
- 00000: Internal Trigger 0 (ITR0)
- 00001: Internal Trigger 1 (ITR1)
- 00010: Internal Trigger 2 (ITR2)
- 00011: Internal Trigger 3 (ITR3)
- 00100: TI1 Edge Detector (TI1F_ED)
- 00101: Filtered Timer Input 1 (TI1FP1)
- 00110: Filtered Timer Input 2 (TI2FP2)
- Other: Reserved

See Table 366: TIMx Internal trigger connection on page 1953 for more details on ITRx meaning for each Timer.

Note: These bits must be changed only when they are not used (e.g. when SMS=000) to avoid wrong edge detections at the transition.

Bit 3 Reserved, must be kept at reset value.
43.5.4 TIM15 DMA/interrupt enable register (TIM15_DIER)

Address offset: 0x0C

Bit 15  Reserved, must be kept at reset value.
Bit 14  **TDE**: Trigger DMA request enable
0: Trigger DMA request disabled
1: Trigger DMA request enabled

Bit 13  **COMDE**: COM DMA request enable
0: COM DMA request disabled
1: COM DMA request enabled

Bits 16, 2, 1, 0 **SMS[3:0]**: Slave mode selection

When external signals are selected the active edge of the trigger signal (TRGI) is linked to the polarity selected on the external input (see Input Control register and Control register description.

0000: Slave mode disabled - if CEN = ‘1’ then the prescaler is clocked directly by the internal clock.
0001: Reserved
0010: Reserved
0011: Reserved
0100: Reset Mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter and generates an update of the registers.
0101: Gated Mode - The counter clock is enabled when the trigger input (TRGI) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.
0110: Trigger Mode - The counter starts at a rising edge of the trigger TRGI (but it is not reset). Only the start of the counter is controlled.
0111: External Clock Mode 1 - Rising edges of the selected trigger (TRGI) clock the counter.
1000: Combined reset + trigger mode - Rising edge of the selected trigger input (TRGI) reinitializes the counter, generates an update of the registers and starts the counter.
Other codes: reserved.

Note: The gated mode must not be used if Ti1F_ED is selected as the trigger input (TS=‘00100’). Indeed, Ti1F_ED outputs 1 pulse for each transition on Ti1F, whereas the gated mode checks the level of the trigger signal.

Note: The clock of the slave peripherals (timer, ADC, ...) receiving the TRGO or the TRGO2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

**Table 366. TIMx Internal trigger connection**
43.5.5 TIM15 status register (TIM15_SR)

Address offset: 0x10

Reset value: 0x0000

| Bit | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
|     |     |     |     |     |     | rc_w0 | rc_w0 | rc_w0 | rc_w0 | rc_w0 | rc_w0 | rc_w0 | rc_w0 | rc_w0 |

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 **CC2OF**: Capture/Compare 2 overcapture flag
   Refer to CC1OF description

Bit 9 **CC1OF**: Capture/Compare 1 overcapture flag
   This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to '0'.
   0: No overcapture has been detected
   1: The counter value has been captured in TIMx_CCR1 register while CC1IF flag was already set

Bit 8 Reserved, must be kept at reset value.
Bit 7 **BIF**: Break interrupt flag
This flag is set by hardware as soon as the break input goes active. It can be cleared by software if the break input is not active.
0: No break event occurred
1: An active level has been detected on the break input

Bit 6 **TIF**: Trigger interrupt flag
This flag is set by hardware on the TRG trigger event (active edge detected on TRGI input when the slave mode controller is enabled in all modes but gated mode, both edges in case gated mode is selected). It is set when the counter starts or stops when gated mode is selected. It is cleared by software.
0: No trigger event occurred
1: Trigger interrupt pending

Bit 5 **COMIF**: COM interrupt flag
This flag is set by hardware on a COM event (once the capture/compare control bits –CCxE, CCxNE, OCxM– have been updated). It is cleared by software.
0: No COM event occurred
1: COM interrupt pending

Bits 4:3 Reserved, must be kept at reset value.

Bit 2 **CC2IF**: Capture/Compare 2 interrupt flag
refer to **CC1IF** description

Bit 1 **CC1IF**: Capture/Compare 1 interrupt flag
This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIMx_CCR1 register (input capture mode only).
0: No compare match / No input capture occurred
1: A compare match or an input capture occurred

**If channel CC1 is configured as output**: this flag is set when the content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the content of TIMx_CCR1 is greater than the content of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in down-counting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIMx_CR1 register for the full description.

**If channel CC1 is configured as input**: this bit is set when counter value has been captured in TIMx_CCR1 register (an edge has been detected on IC1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIMx_CCER).

Bit 0 **UIF**: Update interrupt flag
This bit is set by hardware on an update event. It is cleared by software.
0: No update occurred.
1: Update interrupt pending. This bit is set by hardware when the registers are updated:
– At overflow regarding the repetition counter value (update if repetition counter = 0) and if the UDIS=0 in the TIMx_CR1 register.
– When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if URS=0 and UDIS=0 in the TIMx_CR1 register.
– When CNT is reinitialized by a trigger event (refer to **Section 43.5.3: TIM15 slave mode control register (TIM15_SMCR)**), if URS=0 and UDIS=0 in the TIMx_CR1 register.

- **IC2F[3:0]**: Input capture 2 filter
- **IC2PSC[1:0]**: Input capture 2 prescaler
- **CC2S[1:0]**: Capture/Compare 2 selection
  - 00: CC2 channel is configured as output
  - 01: CC2 channel is configured as input, IC2 is mapped on TI2
  - 10: CC2 channel is configured as input, IC2 is mapped on TI1
  - 11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)

Note: **CC2S bits are writable only when the channel is OFF (CC2E = ‘0’ in TIMx_CCER).**
43.5.8 TIM15 capture/compare mode register 1 [alternate] (TIM15_CCMR1)

Address offset: 0x18
Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and output mode.

**Output compare mode:**
### General-purpose timers (TIM15/TIM16/TIM17)

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |

|   |   |   |   |   |   |   |   | OC2M[2:0] | OC2 PE | OC2 FE | CC2S[1:0] | Res. | OC1M[2:0] | OC1 PE | OC1 FE | CC1S[1:0] | rw | rw | rw | rw |

**Description:**

- Bits 31:25: Reserved, must be kept at reset value.
- Bits 23:17: Reserved, must be kept at reset value.
- Bit 15: Reserved, must be kept at reset value.

**Bits 24, 14, 12: ** **OC2M[3:0]:** Output Compare 2 mode

- Bit 11: **OC2PE:** Output Compare 2 preload enable
- Bit 10: **OC2FE:** Output Compare 2 fast enable

**Bits 9, 8:** **CC2S[1:0]:** Capture/Compare 2 selection

This bit-field defines the direction of the channel (input/output) as well as the used input.

- 00: CC2 channel is configured as output.
- 01: CC2 channel is configured as input, IC2 is mapped on TI2.
- 10: CC2 channel is configured as input, IC2 is mapped on TI1.
- 11: CC2 channel is configured as input, IC2 is mapped on TRC. This mode is working only if an internal trigger input is selected through the TS bit (TIMx_SMCR register).

**Note:** CC2S bits are writable only when the channel is OFF (CC2E = '0' in TIMx_CCER).

- Bit 7: Reserved, must be kept at reset value.
Bits 16, 6:4 **OC1M[3:0]**: Output Compare 1 mode

These bits define the behavior of the output reference signal OC1REF from which OC1 and OC1N are derived. OC1REF is active high whereas OC1 and OC1N active level depends on CC1P and CC1NP bits.

0000: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs.

0001: Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0010: Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0011: Toggle - OC1REF toggles when TIMx_CNT=TIMx_CCR1.

0100: Force inactive level - OC1REF is forced low.

0101: Force active level - OC1REF is forced high.

0110: PWM mode 1 - Channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else inactive.

0111: PWM mode 2 - Channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else active.

1000: Retriggable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

1001: Retriggable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on TRGI signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

1010: Reserved

1011: Reserved

1100: Combined PWM mode 1 - OC1REF has the same behavior as in PWM mode 1. OC1REFC is the logical OR between OC1REF and OC2REF.

1101: Combined PWM mode 2 - OC1REF has the same behavior as in PWM mode 2. OC1REFC is the logical AND between OC1REF and OC2REF.

1110: Reserved

1111: Reserved

Note: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S='00' (the channel is configured in output).

In PWM mode, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.

On channels that have a complementary output, this bit field is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the OC1M active bits take the new value from the preloaded bits only when a COM event is generated.

The OC1M[3] bit is not contiguous, located in bit 16.
Bit 3 **OC1PE**: Output Compare 1 preload enable
0: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken in account immediately.
1: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded in the active register at each update event.
*Note*: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S='00' (the channel is configured in output).

Bit 2 **OC1FE**: Output Compare 1 fast enable
This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIMx_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.
0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.
1: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently of the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/Compare 1 selection
This bit-field defines the direction of the channel (input/output) as well as the used input.
00: CC1 channel is configured as output.
01: CC1 channel is configured as input, IC1 is mapped on TI1.
10: CC1 channel is configured as input, IC1 is mapped on TI2.
11: CC1 channel is configured as input, IC1 is mapped on TRC. This mode is working only if an internal trigger input is selected through TS bit (TIMx_SMCR register)
*Note*: CC1S bits are writable only when the channel is OFF (CC1E = '0' in TIMx_CCER).

### 43.5.9 TIM15 capture/compare enable register (TIM15_CCER)

</tbody>
</table>

Bits 15:8 Reserved, must be kept at reset value.

- **Bit 7 CC2NP**: Capture/Compare 2 complementary output polarity
  - Refer to CC1NP description

- **Bit 6** Reserved, must be kept at reset value.

- **Bit 5 CC2P**: Capture/Compare 2 output polarity
  - Refer to CC1P description

- **Bit 4 CC2E**: Capture/Compare 2 output enable
  - Refer to CC1E description
Bit 3 CC1NP: Capture/Compare 1 complementary output polarity
CC1 channel configured as output:
0: OC1N active high
1: OC1N active low
CC1 channel configured as input:
This bit is used in conjunction with CC1P to define the polarity of TI1FP1 and TI2FP1. Refer to CC1P description.

**Note:** This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S="00" (the channel is configured in output).

On channels that have a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1NP active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bit 2 CC1NE: Capture/Compare 1 complementary output enable
0: Off - OC1N is not active. OC1N level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.
1: On - OC1N signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.

Bit 1 CC1P: Capture/Compare 1 output polarity
0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)
1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)

When CC1 channel is configured as input, both CC1NP/CC1P bits select the active polarity of TI1FP1 and TI2FP1 for trigger or capture operations.

CC1NP=0, CC1P=0: non-inverted/rising edge. The circuit is sensitive to TIxFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode). TIxFP1 is not inverted (trigger operation in gated mode or encoder mode).

CC1NP=0, CC1P=1: inverted/falling edge. The circuit is sensitive to TIxFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode). TIxFP1 is inverted (trigger operation in gated mode or encoder mode).

CC1NP=1, CC1P=0: non-inverted/both edges. The circuit is sensitive to both TIxFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode). TIxFP1 is not inverted (trigger operation in gated mode). This configuration must not be used in encoder mode.

CC1NP=1, CC1P=1: this configuration is reserved, it must not be used.

**Note:** This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

On channels that have a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1P active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bit 0 CC1E: Capture/Compare 1 output enable
0: Capture mode disabled / OC1 is not active (see below)
1: Capture mode enabled / OC1 signal is output on the corresponding output pin

When CC1 channel is configured as output, the OC1 level depends on MOE, OSSI, OSSR, OIS1, OIS1N and CC1NE bits, regardless of the CC1E bits state. Refer to Table 367 for details.
### Table 367. Output control bits for complementary OCx and OCxN channels with break feature (TIM15)

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **REP[7:0]**: Repetition counter value

These bits allow the user to set-up the update rate of the compare registers (i.e. periodic transfers from preload to active registers) when preload registers are enable, as well as the update interrupt generation rate, if this interrupt is enable.

Each time the REP_CNT related downcounter reaches zero, an update event is generated and it restarts counting from REP value. As REP_CNT is reloaded with REP value only at the repetition update event U_RC, any write to the TIMx_RCR register is not taken in account until the next repetition update event.

It means in PWM mode (REP+1) corresponds to the number of PWM periods in edge-aligned mode.

43.5.14 TIM15 capture/compare register 1 (TIM15_CCR1)

Bits 15:0 **CCR1[15:0]**: Capture/Compare 1 value

**If channel CC1 is configured as output:**

CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value). It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on OC1 output.

**If channel CC1 is configured as input:**

CCR1 is the counter value transferred by the last input capture 1 event (IC1).
43.5.15  TIM15 capture/compare register 2 (TIM15_CCR2)

Address offset: 0x38
Reset value: 0x0000

<table>
<thead>
<tr>
<th>Bits 15:0 CCR2[15:0]: Capture/Compare 2 value</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signalled on OC2 output.</td>
</tr>
<tr>
<td>If channel CC2 is configured as input:</td>
</tr>
<tr>
<td>CCR2 is the counter value transferred by the last input capture 2 event (IC2).</td>
</tr>
</tbody>
</table>

43.5.16  TIM15 break and dead-time register (TIM15_BDTR)

Address offset: 0x44
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>MOE AOE BKP BKE OSSR OSSI LOCK[1:0] DTG[7:0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>rw  rw  rw  rw  rw  rw  rw  rw  rw  rw  rw</td>
</tr>
</tbody>
</table>

Note: As the BKF[3:0], AOE, BKP, BKE, OSSR, OSSI and DTG[7:0] bits may be write-locked depending on the LOCK configuration, it may be necessary to configure all of them during the first write access to the TIMx_BDTR register.
Bits 31:20  Reserved, must be kept at reset value.

Bits 19:16  **BKF[3:0]:** Break filter

This bit-field defines the frequency used to sample the BRK input signal and the length of the digital filter applied to BRK. The digital filter is made of an event counter in which N events are needed to validate a transition on the output:

- 0000: No filter, BRK acts asynchronously
- 0001: $f_{SAMPLING} = f_{CK\_INT}$, $N=2$
- 0010: $f_{SAMPLING} = f_{CK\_INT}$, $N=4$
- 0011: $f_{SAMPLING} = f_{CK\_INT}$, $N=8$
- 0100: $f_{SAMPLING} = f_{DTS}/2$, $N=6$
- 0101: $f_{SAMPLING} = f_{DTS}/2$, $N=8$
- 0110: $f_{SAMPLING} = f_{DTS}/4$, $N=6$
- 0111: $f_{SAMPLING} = f_{DTS}/4$, $N=8$
- 1000: $f_{SAMPLING} = f_{DTS}/8$, $N=6$
- 1001: $f_{SAMPLING} = f_{DTS}/8$, $N=8$
- 1010: $f_{SAMPLING} = f_{DTS}/16$, $N=5$
- 1011: $f_{SAMPLING} = f_{DTS}/16$, $N=6$
- 1100: $f_{SAMPLING} = f_{DTS}/16$, $N=8$
- 1101: $f_{SAMPLING} = f_{DTS}/32$, $N=5$
- 1110: $f_{SAMPLING} = f_{DTS}/32$, $N=6$
- 1111: $f_{SAMPLING} = f_{DTS}/32$, $N=8$

Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 15  **MOE:** Main output enable

This bit is cleared asynchronously by hardware as soon as the break input is active. It is set by software or automatically depending on the AOE bit. It is acting only on the channels which are configured in output.

- 0: OC and OCN outputs are disabled or forced to idle state depending on the OSSI bit.
- 1: OC and OCN outputs are enabled if their respective enable bits are set (CCxE, CCxNE in TIMx_CCER register)

See OC/OCN enable description for more details (Section 43.5.9: TIM15 capture/compare enable register (TIM15_CCER) on page 1961).

Bit 14  **AOE:** Automatic output enable

- 0: MOE can be set only by software
- 1: MOE can be set by software or automatically at the next update event (if the break input is not be active)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 13  **BKP:** Break polarity

- 0: Break input BRK is active low
- 1: Break input BRK is active high

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 12  **BKE:** Break enable

- 0: Break inputs (BRK and CCS clock failure event) disabled
- 1: Break inputs (BRK and CCS clock failure event) enabled

This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.
Bit 11  **OSSR**: Off-state selection for Run mode

This bit is used when MOE=1 on channels that have a complementary output which are configured as outputs. OSSR is not implemented if no complementary output is implemented in the timer.

See OC/OCN enable description for more details (Section 43.5.9: TIM15 capture/compare enable register (TIM15_CCMRx) on page 1961).

0: When inactive, OC/OCN outputs are disabled (the timer releases the output control which is taken over by the GPIO, which forces a Hi-Z state)
1: When inactive, OC/OCN outputs are enabled with their inactive level as soon as CCxE=1 or CCxNE=1 (the output is still controlled by the timer).

**Note:** This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 10  **OSSI**: Off-state selection for Idle mode

This bit is used when MOE=0 on channels configured as outputs.

See OC/OCN enable description for more details (Section 43.5.9: TIM15 capture/compare enable register (TIM15_CCMRx) on page 1961).

0: When inactive, OC/OCN outputs are disabled (OC/OCN enable output signal=0)
1: When inactive, OC/OCN outputs are forced first with their idle level as soon as CCxE=1 or CCxNE=1. OC/OCN enable output signal=1)

**Note:** This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 9:8  **LOCK[1:0]**: Lock configuration

These bits offer a write protection against software errors.

00: LOCK OFF - No bit is write protected
01: LOCK Level 1 = DTG bits in TIMx_BDTR register, OISx and OISxN bits in TIMx_CR2 register and BKE/BKP/AOE bits in TIMx_BDTR register can no longer be written
10: LOCK Level 2 = LOCK Level 1 + CC Polarity bits (CCxP/CCxNP bits in TIMx_CCER register, as long as the related channel is configured in output through the CCxS bits) as well as OSSR and OSSI bits can no longer be written.
11: LOCK Level 3 = LOCK Level 2 + CC Control bits (OCxM and OCxPE bits in TIMx_CCMRx registers, as long as the related channel is configured in output through the CCxS bits) can no longer be written.

**Note:** The LOCK bits can be written only once after the reset. Once the TIMx_BDTR register has been written, their content is frozen until the next reset.

Bits 7:0  **DTG[7:0]**: Dead-time generator setup

This bit-field defines the duration of the dead-time inserted between the complementary outputs. DT correspond to this duration.

DTG[7:5] = 0xx => DT = DTG[7:0] x tdtg with tdtg = tDTS
DTG[7:5] = 10x => DT = (64+DTG[5:0]) x tdtg with tdtg = 2 x tDTS
DTG[7:5] = 110 => DT = (32+DTG[4:0]) x tdtg with tdtg = 8 x tDTS
DTG[7:5] = 111 => DT = (32+DTG[4:0]) x tdtg with tdtg = 16 x tDTS

Example if tDTS = 125 ns (8 MHz), dead-time possible values are:
0 to 15875 ns by 125 ns steps,
16 µs to 31750 ns by 250 ns steps,
32 µs to 63 µs by 1 µs steps,
64 µs to 126 µs by 2 µs steps

**Note:** This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).
43.5.17 TIM15 DMA control register (TIM15_DCR)

Address offset: 0x48
Reset value: 0x0000

<table>
<thead>
<tr>

<td>rw</td>
</tr>
</tbody>
</table>

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 DBL[4:0]: DMA burst length
This 5-bit field defines the length of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address).
00000: 1 transfer,
00001: 2 transfers,
00010: 3 transfers,
...
10001: 18 transfers.

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 DBA[4:0]: DMA base address
This 5-bit field defines the base-address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register.
Example:
00000: TIMx_CR1,
00001: TIMx_CR2,
00010: TIMx_SMCR,
...

43.5.18 TIM15 DMA address for full transfer (TIM15_DMAR)

Address offset: 0x4C
Reset value: 0x0000

<table>

</tr>
</tbody>
</table>

Bits 15:0 DMAB[15:0]: DMA register for burst accesses
A read or write operation to the DMAR register accesses the register located at the address
(TIMx_CR1 address) + (DBA + DMA index) x 4
where TIMx_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIMx_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIMx_DCR).
### 43.5.19  TIM15 alternate register 1 (TIM15_AF1)

Address offset: 0x60  
Reset value: 0x0000 0001

<table>
<thead>
<tr>
<th>Bit 31:16</th>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits 31:12</td>
<td>Reserved, must be kept at reset value.</td>

</tbody>
</table>
| Bit 11    | **BKCMP2P**: BRK COMP2 input polarity | This bit selects the COMP2 input sensitivity. It must be programmed together with the BKP polarity bit.  
0: COMP2 input is active low  
1: COMP2 input is active high  
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register). |
| Bit 10    | **BKCMP1P**: BRK COMP1 input polarity | This bit selects the COMP1 input sensitivity. It must be programmed together with the BKP polarity bit.  
0: COMP1 input is active low  
1: COMP1 input is active high  
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register). |
| Bit 9     | **BKINP**: BRK BKIN input polarity | This bit selects the BKIN alternate function input sensitivity. It must be programmed together with the BKP polarity bit.  
0: BKIN input is active low  
1: BKIN input is active high  
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register). |
| Bit 8     | **BKDF1BK0E**: BRK dfsdm1_break[0] enable | This bit enables the dfsdm1_break[0] for the timer’s BRK input. dfsdm1_break[0] output is ‘ORed’ with the other BRK sources.  
0: dfsdm1_break[0]input disabled  
1: dfsdm1_break[0]input enabled  
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register). |
| Bits 7:3  | Reserved, must be kept at reset value. |
| Bit 2     | **BKCMP2E**: BRK COMP2 enable | This bit enables the COMP2 for the timer’s BRK input. COMP2 output is ‘ORed’ with the other BRK sources.  
0: COMP2 input disabled  
1: COMP2 input enabled  
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register). |
Bit 1  **BKCMP1E**: BRK COMP1 enable

This bit enables the COMP1 for the timer’s BRK input. COMP1 output is ‘ORed’ with the other BRK sources.

- 0: COMP1 input disabled
- 1: COMP1 input enabled

*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 0  **BKINE**: BRK BKIN input enable

This bit enables the BKIN alternate function input for the timer’s BRK input. BKIN input is ‘ORed’ with the other BRK sources.

- 0: BKIN input disabled
- 1: BKIN input enabled

*Note:* This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Refer to Section 2.3 on page 134 for the register boundary addresses.
43.6 TIM16/TIM17 registers

Refer to Section 1.2 for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

43.6.1 TIMx control register 1 (TIMx_CR1)(x = 16 to 17)

Address offset: 0x00
Reset value: 0x0000

|    |    |    |    |    | UIFRE MAP |    |    |    |    |    |    | CKD[1:0] |    |    |    |    | OPM |    |    |    |
|----|----|----|----|----|----------|----|----|----|----|----|----|----------|----|----|----|----|----|----|----|
| 15 | 14 | 13 | 12 | 11 |  9   |  8  |  7  |  6  |  5  |  4  |  3  |  2  |  1  |  0  |
|    |    |    |    |    |  rw  |  rw |  rw |  rw |  rw |  rw |  rw |  rw |  rw |  rw |

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **UIFREMAP**: UIF status bit remapping
0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.
1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division
This bit-field indicates the division ratio between the timer clock (CK_INT) frequency and the
dead-time and sampling clock (tDTS) used by the dead-time generators and the digital filters
(TIx).
00: tDTS = tCK_INT
01: tDTS = 2 * tCK_INT
10: tDTS = 4 * tCK_INT
11: Reserved, do not program this value

Bit 7 **ARPE**: Auto-reload preload enable
0: TIMx_ARR register is not buffered
1: TIMx_ARR register is buffered

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM**: One pulse mode
0: Counter is not stopped at update event
1: Counter stops counting at the next update event (clearing the bit CEN)

Bit 2 **URS**: Update request source
This bit is set and cleared by software to select the UEV event sources.
0: Any of the following events generate an update interrupt or DMA request if enabled.
These events can be:
– Counter overflow/underflow
– Setting the UG bit
– Update generation through the slave mode controller
1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.
Bit 1 **UDIS**: Update disable
This bit is set and cleared by software to enable/disable UEV event generation.
0: UEV enabled. The Update (UEV) event is generated by one of the following events:
  – Counter overflow/underflow
  – Setting the UG bit
  – Update generation through the slave mode controller
Buffered registers are then loaded with their preload values.
1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable
0: Counter disabled
1: Counter enabled

*Note*: External clock and gated mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.

### 43.6.2 TIMx control register 2 (TIMx_CR2)(x = 16 to 17)

Address offset: 0x04

Reset value: 0x0000

**Bits 15:10** Reserved, must be kept at reset value.

**Bit 9 **OIS1N**: Output Idle state 1 (OC1N output)
0: OC1N=0 after a dead-time when MOE=0
1: OC1N=1 after a dead-time when MOE=0

*Note*: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

**Bit 8 **OIS1**: Output Idle state 1 (OC1 output)
0: OC1=0 (after a dead-time if OC1N is implemented) when MOE=0
1: OC1=1 (after a dead-time if OC1N is implemented) when MOE=0

*Note*: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

**Bits 7:4** Reserved, must be kept at reset value.

**Bit 3 **CCDS**: Capture/compare DMA selection
0: CCx DMA request sent when CCx event occurs
1: CCx DMA requests sent when update event occurs

**Bit 2 **CCUS**: Capture/compare control update selection
0: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit only.
1: When capture/compare control bits are preloaded (CCPC=1), they are updated by setting the COMG bit or when an rising edge occurs on TRGI.

*Note*: This bit acts only on channels that have a complementary output.

**Bit 1** Reserved, must be kept at reset value.
Bit 0 \textbf{CCPC}: Capture/compare preloaded control
0: CCxE, CCxNE and OCxM bits are not preloaded
1: CCxE, CCxNE and OCxM bits are preloaded, after having been written, they are updated only when COM bit is set.

\textit{Note}: This bit acts only on channels that have a complementary output.

### 43.6.3 TIMx DMA/interrupt enable register (TIMx_DIER)(x = 16 to 17)

<tr>
<td></td>
<td>1: A compare match or an input capture occurred</td>
<td></td>
</tr>
</tbody>
</table>

**If channel CC1 is configured as output:** this flag is set when the content of the counter TIMx_CNT matches the content of the TIMx_CCR1 register. When the content of TIMx_CCR1 is greater than the content of TIMx_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in down-counting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIMx_CR1 register for the full description.

**If channel CC1 is configured as input:** this bit is set when counter value has been captured in TIMx_CCR1 register (an edge has been detected on IC1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIMx_CCER).
Bit 0 **UIF**: Update interrupt flag

This bit is set by hardware on an update event. It is cleared by software.

0: No update occurred.
1: Update interrupt pending. This bit is set by hardware when the registers are updated:
   - At overflow regarding the repetition counter value (update if repetition counter = 0) and if the UDIS=0 in the TIMx_CR1 register.
   - When CNT is reinitialized by software using the UG bit in TIMx_EGR register, if URS=0 and UDIS=0 in the TIMx_CR1 register.

43.6.5 **TIMx event generation register (TIMx_EGR)(x = 16 to 17)**

Address offset: 0x14

Reset value: 0x0000

<table>

</tr>
</tbody>
</table>

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **BG**: Break generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action.
1: A break event is generated. MOE bit is cleared and BIF flag is set. Related interrupt or DMA transfer can occur if enabled.

Bit 6 Reserved, must be kept at reset value.

Bit 5 **COMG**: Capture/Compare control update generation

This bit can be set by software, it is automatically cleared by hardware.

0: No action
1: When the CCPC bit is set, it is possible to update the CCxE, CCxNE and OCxM bits

*Note: This bit acts only on channels that have a complementary output.*

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **CC1G**: Capture/Compare 1 generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action.
1: A capture/compare event is generated on channel 1:

**If channel CC1 is configured as output:**

CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled.

**If channel CC1 is configured as input:**

The current value of the counter is captured in TIMx_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 **UG**: Update generation

This bit can be set by software, it is automatically cleared by hardware.

0: No action.
1: Reinitialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected).
**43.6.6 TIMx capture/compare mode register 1 (TIMx_CCMR1)(x = 16 to 17)**

Address offset: 0x18  
Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode.

**Input capture mode:**

Bits 31:8 Reserved, must be kept at reset value.

**Bits 7:4 IC1F[3:0]: Input capture 1 filter**

This bit-field defines the frequency used to sample TI1 input and the length of the digital filter applied to TI1. The digital filter is made of an event counter in which \( N \) consecutive events are needed to validate a transition on the output:

- 0000: No filter, sampling is done at \( f_{DTS} \)
- 0001: \( f_{SAMPLING} = \frac{f_{CK~INT}}{2}, N=2 \)
- 0010: \( f_{SAMPLING} = \frac{f_{CK~INT}}{4}, N=4 \)
- 0011: \( f_{SAMPLING} = \frac{f_{CK~INT}}{8}, N=8 \)
- 0100: \( f_{SAMPLING} = \frac{f_{DTS}}{4}, N=6 \)
- 0101: \( f_{SAMPLING} = \frac{f_{DTS}}{2}, N=8 \)
- 0110: \( f_{SAMPLING} = \frac{f_{DTS}}{8}, N=6 \)
- 0111: \( f_{SAMPLING} = \frac{f_{DTS}}{16}, N=5 \)
- 1000: \( f_{SAMPLING} = \frac{f_{DTS}}{32}, N=5 \)
- 1001: \( f_{SAMPLING} = \frac{f_{DTS}}{64}, N=8 \)
- 1010: \( f_{SAMPLING} = \frac{f_{DTS}}{128}, N=6 \)
- 1011: \( f_{SAMPLING} = \frac{f_{DTS}}{256}, N=8 \)
- 1100: \( f_{SAMPLING} = \frac{f_{DTS}}{512}, N=6 \)
- 1101: \( f_{SAMPLING} = \frac{f_{DTS}}{1024}, N=8 \)
- 1110: \( f_{SAMPLING} = \frac{f_{DTS}}{2048}, N=6 \)
- 1111: \( f_{SAMPLING} = \frac{f_{DTS}}{4096}, N=8 \)

**Bits 3:2 IC1PSC[1:0]: Input capture 1 prescaler**

This bit-field defines the ratio of the prescaler acting on CC1 input (IC1). The prescaler is reset as soon as CC1E='0' (TIMx_CCER register).

- 00: no prescaler, capture is done each time an edge is detected on the capture input
- 01: capture is done once every 2 events
- 10: capture is done once every 4 events
- 11: capture is done once every 8 events
Bits 1:0 **CC1S[1:0]: Capture/Compare 1 Selection**

This bit-field defines the direction of the channel (input/output) as well as the used input.
- 00: CC1 channel is configured as output
- 01: CC1 channel is configured as input, IC1 is mapped on TI1
- Others: Reserved

*Note: CC1S bits are writable only when the channel is OFF (CC1E = ‘0’ in TIMx_CCR).*

### 43.6.7 TIMx capture/compare mode register 1 [alternate]

*(TIMx_CCMR1)(x = 16 to 17)*

**Address offset: 0x18**

**Reset value: 0x0000 0000**

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function in input and in output mode.

**Output compare mode:**

</tbody>
</table>

Bits 31:17 Reserved, must be kept at reset value.

Bits 15:7 Reserved, must be kept at reset value.
Bits 16, 6:4 **OC1M[3:0]:** Output Compare 1 mode

These bits define the behavior of the output reference signal OC1REF from which OC1 and OC1N are derived. OC1REF is active high whereas OC1 and OC1N active level depends on CC1P and CC1NP bits.

0000: Frozen - The comparison between the output compare register TIMx_CCR1 and the counter TIMx_CNT has no effect on the outputs. This mode can be used when the timer serves as a software timebase. When the frozen mode is enabled during timer operation, the output keeps the state (active or inactive) it had before entering the frozen state.

0001: Set channel 1 to active level on match. OC1REF signal is forced high when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0010: Set channel 1 to inactive level on match. OC1REF signal is forced low when the counter TIMx_CNT matches the capture/compare register 1 (TIMx_CCR1).

0011: Toggle - OC1REF toggles when TIMx_CNT=TIMx_CCR1.

0100: Force inactive level - OC1REF is forced low.

0101: Force active level - OC1REF is forced high.

0110: PWM mode 1 - Channel 1 is active as long as TIMx_CNT<TIMx_CCR1 else inactive.

0111: PWM mode 2 - Channel 1 is inactive as long as TIMx_CNT<TIMx_CCR1 else active.

All other values: Reserved

Note: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S='00' (the channel is configured in output).

In PWM mode 1 or 2, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.

The OC1M[3] bit is not contiguous, located in bit 16.

Bit 3 **OC1PE:** Output Compare 1 preload enable

0: Preload register on TIMx_CCR1 disabled. TIMx_CCR1 can be written at anytime, the new value is taken in account immediately.

1: Preload register on TIMx_CCR1 enabled. Read/Write operations access the preload register. TIMx_CCR1 preload value is loaded in the active register at each update event.

Note: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S='00' (the channel is configured in output).

Bit 2 **OC1FE:** Output Compare 1 fast enable

This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIMx_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.

0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.

1: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently of the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OC1FE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]:** Capture/Compare 1 selection

This bit-field defines the direction of the channel/input/output as well as the used input.

00: CC1 channel is configured as output

01: CC1 channel is configured as input, IC1 is mapped on TI1

Others: Reserved

Note: CC1S bits are writable only when the channel is OFF (CC1E = ‘0’ in TIMx_CCRER).
### 43.6.8 TIMx capture/compare enable register (TIMx_CCER)\((x = 16 \text{ to } 17)\)

</tbody>
</table>

Bits 15:4  Reserved, must be kept at reset value.

**Bit 3 CC1NP:** Capture/Compare 1 complementary output polarity  
CC1 channel configured as output:  
0: OC1N active high  
1: OC1N active low  
CC1 channel configured as input:  
This bit is used in conjunction with CC1P to define the polarity of TI1FP1 and TI2FP1. Refer to the description of CC1P.  
**Note:** This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register) and CC1S=“00” (the channel is configured in output).  
On channels that have a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1NP active bit takes the new value from the preloaded bit only when a commutation event is generated.
Bit 2 **CC1NE**: Capture/Compare 1 complementary output enable
0: Off - OC1N is not active. OC1N level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.
1: On - OC1N signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.

Bit 1 **CC1P**: Capture/Compare 1 output polarity
0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)
1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)

When CC1 channel is configured as input, both CC1NP/CC1P bits select the active polarity of TI1FP1 and TI2FP1 for trigger or capture operations.
CC1NP=0, CC1P=0: non-inverted/rising edge. The circuit is sensitive to T1xFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode). T1xFP1 is not inverted (trigger operation in gated mode or encoder mode).
CC1NP=0, CC1P=1: inverted/falling edge. The circuit is sensitive to T1xFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode). T1xFP1 is inverted (trigger operation in gated mode or encoder mode).
CC1NP=1, CC1P=0: non-inverted/both edges/ The circuit is sensitive to both T1xFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode). T1xFP1 is not inverted (trigger operation in gated mode). This configuration must not be used in encoder mode.
CC1NP=1, CC1P=1: this configuration is reserved, it must not be used.

Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

On channels that have a complementary output, this bit is preloaded. If the CCPC bit is set in the TIMx_CR2 register then the CC1P active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bit 0 **CC1E**: Capture/Compare 1 output enable
0: Capture mode disabled / OC1 is not active (see below)
1: Capture mode enabled / OC1 signal is output on the corresponding output pin

When CC1 channel is configured as output, the OC1 level depends on MOE, OSSI, OSSR, OIS1, OIS1N and CC1NE bits, regardless of the CC1E bits state. Refer to Table 369 for details.
Table 369. Output control bits for complementary OCx and OCxN channels with break feature (TIM16/17)

<table>
<thead>
<tr>
<th>Control bits</th>
<th>Output states&lt;sup&gt;(1)&lt;/sup&gt;</th>

<td>1</td>
</tr>
</tbody>
</table>

1. When both outputs of a channel are not used (control taken over by GPIO controller), the OISx, OISxN, CCxP and CCxNP bits must be kept cleared.

Note: The state of the external I/O pins connected to the complementary OCx and OCxN channels depends on the OCx and OCxN channel state and GPIO control and alternate function registers.

43.6.9 TIMx counter (TIMx_CNT)(x = 16 to 17)

Address offset: 0x24
## 31.5.10 TIMx prescaler (TIMx_PSC)(x = 16 to 17)

Address offset: 0x28
Reset value: 0x0000

<table>
<thead>

</tr>
</tbody>
</table>

Bits 15:0 **PSC[15:0]**: Prescaler value

The counter clock frequency (CK_CNT) is equal to \( f_{CK\_PSC} / (\text{PSC}[15:0] + 1) \).

PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in “reset mode”).

## 31.5.11 TIMx auto-reload register (TIMx_ARR)(x = 16 to 17)

Address offset: 0x2C
Reset value: 0xFFF0

<table>
<thead>
<tr>
<th>Bit 15:0</th>

<td>rw</td>
</tr>
</tbody>
</table>

Bits 15:0 **ARR[15:0]**: Auto-reload value

ARR is the value to be loaded in the actual auto-reload register. Refer to the Section 31.4.1: Time-base unit on page 1915 for more details about ARR update and behavior.

The counter is blocked while the auto-reload value is null.
### 43.6.12 TIMx repetition counter register (TIMx_RCR)(x = 16 to 17)

Address offset: 0x30
Reset value: 0x0000

<p>| | | | | | | | | | | | | |</p>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 `REP[7:0]`: Repetition counter value
These bits allow the user to set-up the update rate of the compare registers (i.e. periodic transfers from preload to active registers) when preload registers are enable, as well as the update interrupt generation rate, if this interrupt is enable. Each time the REP_CNT related downcounter reaches zero, an update event is generated and it restarts counting from REP value. As REP_CNT is reloaded with REP value only at the repetition update event U_RC, any write to the TIMx_RCR register is not taken in account until the next repetition update event.
It means in PWM mode (REP+1) corresponds to the number of PWM periods in edge-aligned mode.

### 43.6.13 TIMx capture/compare register 1 (TIMx_CCR1)(x = 16 to 17)

Address offset: 0x34
Reset value: 0x0000

<p>| | | | | | | | | | | | | |</p>
<table>
<thead>

<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 15:0 `CCR1[15:0]`: Capture/Compare 1 value

If channel CC1 is configured as output:
CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIMx_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIMx_CNT and signaled on OC1 output.

If channel CC1 is configured as input:
CCR1 is the counter value transferred by the last input capture 1 event (IC1).
43.6.14 TIMx break and dead-time register (TIMx_BDTR)(x = 16 to 17)

Address offset: 0x44
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>
<th>24</th>
<th>23</th>

<td>OSSR</td>
<td>LOCK[1:0]</td>
<td>DTG[7:0]</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Note: As the BKF[3:0], AOE, BKP, BKE, OSSR, OSSR and DTG[7:0] bits may be write-locked depending on the LOCK configuration, it may be necessary to configure all of them during the first write access to the TIMx_BDTR register.

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:16 BKF[3:0]: Break filter
This bit-field defines the frequency used to sample BRK input and the length of the digital filter applied to BRK. The digital filter is made of an event counter in which N events are needed to validate a transition on the output:
0000: No filter, BRK acts asynchronously
0001: fSAMPLING=fCK_INT, N=2
0010: fSAMPLING=fCK_INT, N=4
0011: fSAMPLING=fCK_INT, N=8
0100: fSAMPLING=fDTS/2, N=6
0101: fSAMPLING=fDTS/2, N=8
0110: fSAMPLING=fDTS/4, N=6
0111: fSAMPLING=fDTS/4, N=8
1000: fSAMPLING=fDTS/8, N=6
1001: fSAMPLING=fDTS/8, N=8
1010: fSAMPLING=fDTS/16, N=5
1011: fSAMPLING=fDTS/16, N=6
1100: fSAMPLING=fDTS/16, N=8
1101: fSAMPLING=fDTS/32, N=5
1110: fSAMPLING=fDTS/32, N=6
1111: fSAMPLING=fDTS/32, N=8
This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 15 MOE: Main output enable
This bit is cleared asynchronously by hardware as soon as the break input is active. It is set by software or automatically depending on the AOE bit. It is acting only on the channels which are configured in output.
0: OC and OCN outputs are disabled or forced to idle state depending on the OSSR bit.
1: OC and OCN outputs are enabled if their respective enable bits are set (CCxE, CCxNE in TIMx_CCER register)

See OC/OCN enable description for more details (Section 43.6.8: TIMx capture/compare enable register (TIMx_CCER)(x = 16 to 17) on page 1982).
Bit 14  **AOE**: Automatic output enable
0: MOE can be set only by software
1: MOE can be set by software or automatically at the next update event (if the break input is not be active)

*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Bit 13  **BKP**: Break polarity
0: Break input BRK is active low
1: Break input BRK is active high

*Note*: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 12  **BKE**: Break enable
0: Break inputs (BRK and CCS clock failure event) disabled
1: Break inputs (BRK and CCS clock failure event) enabled

*Note*: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIMx_BDTR register).

Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 11  **OSSR**: Off-state selection for Run mode

This bit is used when MOE=1 on channels that have a complementary output which are configured as outputs. OSSR is not implemented if no complementary output is implemented in the timer.

See OC/OCN enable description for more details (Section 43.6.8: TIMx capture/compare enable register (TIMx_CCER)(x = 16 to 17) on page 1982).

0: When inactive, OC/OCN outputs are disabled (the timer releases the output control which is taken over by the GPIO, which forces a Hi-Z state)
1: When inactive, OC/OCN outputs are enabled with their inactive level as soon as CCxE=1 or CCxNE=1 (the output is still controlled by the timer).

*Note*: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).
Bit 10  **OSSI**: Off-state selection for Idle mode  
This bit is used when MOE=0 on channels configured as outputs.  
See OC/OCN enable description for more details (Section 43.6.8: TIMx capture/compare enable register (TIMx_CCRER)(x = 16 to 17) on page 1982).  
0: When inactive, OC/OCN outputs are disabled (OC/OCN enable output signal=0)  
1: When inactive, OC/OCN outputs are forced first with their idle level as soon as CCxExE=1 or CCxNE=1, OC/OCN enable output signal=1)  

**Note**: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIMx_BDTR register).

Bits 9:8  **LOCK[1:0]**: Lock configuration  
These bits offer a write protection against software errors.  
00: LOCK OFF - No bit is write protected  
01: LOCK Level 1 = DTG bits in TIMx_BDTR register, OISx and OISxN bits in TIMx_CR2 register and BKE/BKP/AOE bits in TIMx_BDTR register can no longer be written.  
10: LOCK Level 2 = LOCK Level 1 + CC Polarity bits (CCxP/CCxNP bits in TIMx_CCRER register, as long as the related channel is configured in output through the CCxS bits) as well as OSSR and OSSI bits can no longer be written.  
11: LOCK Level 3 = LOCK Level 2 + CC Control bits (OCxM and OCxPE bits in TIMx_CCMRx registers, as long as the related channel is configured in output through the CCxS bits) can no longer be written.  

**Note**: The LOCK bits can be written only once after the reset. Once the TIMx_BDTR register has been written, their content is frozen until the next reset.

Bits 7:0  **DTG[7:0]**: Dead-time generator setup  
This bit-field defines the duration of the dead-time inserted between the complementary outputs. DT correspond to this duration.  
**Example if tDTS = 125 ns (8 MHz), dead-time possible values are:**  
0 to 15875 ns by 125 ns steps,  
16 µs to 31750 ns by 250 ns steps,  
32 µs to 63 µs by 1 µs steps,  
64 µs to 126 µs by 2 µs steps  

**Note**: This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).

### 43.6.15 TIMx DMA control register (TIMx_DCR)(x = 16 to 17)

**Address offset**: 0x48  
**Reset value**: 0x0000

</tbody>
</table>

**Note**: This bit-field can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIMx_BDTR register).
Bits 15:13  Reserved, must be kept at reset value.

Bits 12:8  **DBL[4:0]: DMA burst length**

This 5-bit field defines the length of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIMx_DMAR address), i.e. the number of transfers. Transfers can be in half-words or in bytes (see example below).

- 00000: 1 transfer,
- 00001: 2 transfers,
- 00010: 3 transfers,
- ...
- 10001: 18 transfers.

Bits 7:5  Reserved, must be kept at reset value.

Bits 4:0  **DBA[4:0]: DMA base address**

This 5-bit field defines the base-address for DMA transfers (when read/write access are done through the TIMx_DMAR address). DBA is defined as an offset starting from the address of the TIMx_CR1 register.

Example:
- 00000: TIMx_CR1,
- 00001: TIMx_CR2,
- 00010: TIMx_SMCR,
- ...

Example: Let us consider the following transfer: DBL = 7 transfers and DBA = TIMx_CR1. In this case the transfer is done to/from 7 registers starting from the TIMx_CR1 address.

### 43.6.16  TIMx DMA address for full transfer (TIMx_DMAR)(x = 16 to 17)

Address offset: 0x4C

Reset value: 0x0000

</tbody>
</table>

**DMAB[15:0]: DMA register for burst accesses**

A read or write operation to the DMAR register accesses the register located at the address 

\[(TIMx_CR1\text{ address}) + (DBA + \text{DMA index}) \times 4\]

where TIMx_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIMx_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIMx_DCR).
43.6.17 TIM16 alternate function register 1 (TIM16_AF1)

Address offset: 0x60
Reset value: 0x0000 0001

44 Basic timers (TIM6/TIM7)

44.1 TIM6/TIM7 introduction

The basic timers TIM6 and TIM7 consist of a 16-bit auto-reload counter driven by a programmable prescaler.

They may be used as generic timers for time base generation but they are also specifically used to drive the digital-to-analog converter (DAC). In fact, the timers are internally connected to the DAC and are able to drive it through their trigger outputs.

The timers are completely independent, and do not share any resources.

44.2 TIM6/TIM7 main features

Basic timer (TIM6/TIM7) features include:
- 16-bit auto-reload upcounter
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535
- Synchronization circuit to trigger the DAC
- Interrupt/DMA generation on the update event: counter overflow

Figure 556. Basic timer block diagram

- Interrupt & DMA output

MS33142V1
44.3 TIM6/TIM7 functional description

44.3.1 Time-base unit

The main block of the programmable timer is a 16-bit upcounter with its related auto-reload register. The counter clock can be divided by a prescaler.

The counter, the auto-reload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:
- Counter Register (TIMx_CNT)
- Prescaler Register (TIMx_PSC)
- Auto-Reload Register (TIMx_ARR)

The auto-reload register is preloaded. The preload register is accessed each time an attempt is made to write or read the auto-reload register. The contents of the preload register are transferred into the shadow register permanently or at each update event UEV, depending on the auto-reload preload enable bit (ARPE) in the TIMx_CR1 register. The update event is sent when the counter reaches the overflow value and if the UDIS bit equals 0 in the TIMx_CR1 register. It can also be generated by software. The generation of the update event is described in detail for each configuration.

The counter is clocked by the prescaler output CK_CNT, which is enabled only when the counter enable bit (CEN) in the TIMx_CR1 register is set.

Note that the actual counter enable signal CNT_EN is set 1 clock cycle after CEN.

Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIMx_PSC register). It can be changed on the fly as the TIMx_PSC control register is buffered. The new prescaler ratio is taken into account at the next update event.

Figure 557 and Figure 558 give some examples of the counter behavior when the prescaler ratio is changed on the fly.
Figure 557. Counter timing diagram with prescaler division change from 1 to 2

Figure 558. Counter timing diagram with prescaler division change from 1 to 4
44.3.2 Counting mode

The counter counts from 0 to the auto-reload value (contents of the TIMx_ARR register), then restarts from 0 and generates a counter overflow event.

An update event can be generated at each counter overflow or by setting the UG bit in the TIMx_EGR register (by software or by using the slave mode controller).

The UEV event can be disabled by software by setting the UDIS bit in the TIMx_CR1 register. This avoids updating the shadow registers while writing new values into the preload registers. In this way, no update event occurs until the UDIS bit has been cleared, however, the counter and the prescaler counter both restart from 0 (but the prescale rate does not change). In addition, if the URS (update request selection) bit in the TIMx_CR1 register is set, setting the UG bit generates an update event UEV, but the UIF flag is not set (so no interrupt or DMA request is sent).

When an update event occurs, all the registers are updated and the update flag (UIF bit in the TIMx_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (contents of the TIMx_PSC register)
- The auto-reload shadow register is updated with the preload value (TIMx_ARR)

The following figures show some examples of the counter behavior for different clock frequencies when TIMx_ARR = 0x36.

Figure 562. Counter timing diagram, internal clock divided by N

Figure 563. Counter timing diagram, update event when ARPE = 0 (TIMx_ARR not preloaded)
44.3.3 UIF bit remapping

The IUFREMAP bit in the TIMx_CR1 register forces a continuous copy of the Update Interrupt Flag UIF into the timer counter register’s bit 31 (TIMxCNT[31]). This allows to atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. In particular cases, it can ease the calculations by avoiding race conditions caused for instance by a processing shared between a background task (counter reading) and an interrupt (Update Interrupt).

There is no latency between the assertions of the UIF and UIFCPY flags.

44.3.4 Clock source

The counter clock is provided by the Internal clock (CK_INT) source.

The CEN (in the TIMx_CR1 register) and UG bits (in the TIMx_EGR register) are actual control bits and can be changed only by software (except for UG that remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock CK_INT.

Figure 565 shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.
44.3.5 Debug mode

When the microcontroller enters the debug mode (Cortex®-M7 with FPU core - halted), the TIMx counter either continues to work normally or stops, depending on the DBG_TIMx_STOP configuration bit in the DBGMCU module. For more details, refer to Section 63.5.8: Microcontroller debug unit (DBGMCU).

44.4 TIM6/TIM7 registers

Refer to Section 1.2 on page 106 for a list of abbreviations used in register descriptions. The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

44.4.1 TIMx control register 1 (TIMx_CR1)(x = 6 to 7)

Address offset: 0x00
Reset value: 0x0000

```
+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+
| 15   | 14   | 13   | 12   | 11   | 10   | 9    | 8     | 7     | 6    | 5    | 4    | 3    | 2    | 1    | 0     |
+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+
+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+
| rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   | rw   |
+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+
```

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **UIFREMAP**: UIF status bit remapping

0: No remapping. UIF status bit is not copied to TIMx_CNT register bit 31.
1: Remapping enabled. UIF status bit is copied to TIMx_CNT register bit 31.

Bits 10:8 Reserved, must be kept at reset value.
Bit 7 **ARPE**: Auto-reload preload enable
   0: TIMx_ARR register is not buffered.
   1: TIMx_ARR register is buffered.

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM**: One-pulse mode
   0: Counter is not stopped at update event
   1: Counter stops counting at the next update event (clearing the CEN bit).

Bit 2 **URS**: Update request source
   This bit is set and cleared by software to select the UEV event sources.
   0: Any of the following events generates an update interrupt or DMA request if enabled.
   These events can be:
      – Counter overflow/underflow
      – Setting the UG bit
      – Update generation through the slave mode controller
   1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1 **UDIS**: Update disable
   This bit is set and cleared by software to enable/disable UEV event generation.
   0: UEV enabled. The Update (UEV) event is generated by one of the following events:
      – Counter overflow/underflow
      – Setting the UG bit
      – Update generation through the slave mode controller
   Buffered registers are then loaded with their preload values.
   1: UEV disabled. The Update event is not generated, shadow registers keep their value
      (ARR, PSC). However the counter and the prescaler are reinitialized if the UG bit is set or if
      a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable
   0: Counter disabled
   1: Counter enabled

*Note: Gated mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.*

CEN is cleared automatically in one-pulse mode, when an update event occurs.
44.4.2 TIMx control register 2 (TIMx_CR2)(x = 6 to 7)

Address offset: 0x04
Reset value: 0x0000

| Bits 15:7 | Reserved, must be kept at reset value. |
| Bit 6:4 | MMS[2:0]: Master mode selection |
| These bits are used to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows: |
| 000: Reset - the UG bit from the TIMx_EGR register is used as a trigger output (TRGO). If reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on TRGO is delayed compared to the actual reset. |
| 001: Enable - the Counter enable signal, CNT_EN, is used as a trigger output (TRGO). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic OR between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on TRGO, except if the master/slave mode is selected (see the MSM bit description in the TIMx_SMCR register). |
| 010: Update - The update event is selected as a trigger output (TRGO). For instance a master timer can then be used as a prescaler for a slave timer. |
| Note: The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer. |
| Bits 3:0 | Reserved, must be kept at reset value. |

44.4.3 TIMx DMA/Interrupt enable register (TIMx_DIER)(x = 6 to 7)

Address offset: 0x0C
Reset value: 0x0000

| Bits 15:9 | Reserved, must be kept at reset value. |
| Bit 8 | UDE: Update DMA request enable |
| 0: Update DMA request disabled. |
| 1: Update DMA request enabled. |
| Bits 7:1 | Reserved, must be kept at reset value. |
| Bit 0 | UIE: Update interrupt enable |
| 0: Update interrupt disabled. |
| 1: Update interrupt enabled. |
44.4.4 TMx status register (TIMx_SR)(x = 6 to 7)
Address offset: 0x10
Reset value: 0x0000

<table>
<thead>
<tr>
<th>15</th>

<th>5</th>
<th>4</th>
<th>3</th>
<th>2</th>
<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **UIF**: Update interrupt flag
This bit is set by hardware on an update event. It is cleared by software.
0: No update occurred.
1: Update interrupt pending. This bit is set by hardware when the registers are updated:
– At overflow or underflow regarding the repetition counter value and if UDIS = 0 in the TIMx_CR1 register.
– When CNT is reinitialized by software using the UG bit in the TIMx_EGR register, if URS = 0 and UDIS = 0 in the TIMx_CR1 register.

44.4.5 TMx event generation register (TIMx_EGR)(x = 6 to 7)
Address offset: 0x14
Reset value: 0x0000

<table>
<thead>
<tr>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>UG</td>
</tr>
</tbody>
</table>

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **UG**: Update generation
This bit can be set by software, it is automatically cleared by hardware.
0: No action.
1: Re-initializes the timer counter and generates an update of the registers. Note that the prescaler counter is cleared too (but the prescaler ratio is not affected).

44.4.6 TMx counter (TIMx_CNT)(x = 6 to 7)
Address offset: 0x24
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>31</th>

<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 15:0 PSC[15:0]: Prescaler value
The counter clock frequency CK_CNT is equal to fCK_PSC / (PSC[15:0] + 1).
PSC contains the value to be loaded into the active prescaler register at each update event.
(including when the counter is cleared through UG bit of TIMx_EGR register or through trigger controller when configured in “reset mode”).

44.4.8 TIMx auto-reload register (TIMx_ARR)(x = 6 to 7)

Address offset: 0x2C
Reset value: 0xFFFF

<table>
<thead>
<tr>
<th>15</th>
<th>14</th>
<th>13</th>
<th>12</th>

<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 15:0 ARR[15:0]: Prescaler value
ARR is the value to be loaded into the actual auto-reload register.
Refer to Section 44.3.1: Time-base unit on page 1998 for more details about ARR update and behavior.
The counter is blocked while the auto-reload value is null.
### TIMx register map

TIMx registers are mapped as 16-bit addressable registers as described in the table below:

| Offset | Register name | Offset 31 | Offset 30 | Offset 29 | Offset 28 | Offset 27 | Offset 26 | Offset 25 | Offset 24 | Offset 23 | Offset 22 | Offset 21 | Offset 20 | Offset 19 | Offset 18 | Offset 17 | Offset 16 | Offset 15 | Offset 14 | Offset 13 | Offset 12 | Offset 11 | Offset 10 | Offset 9 | Offset 8 | Offset 7 | Offset 6 | Offset 5 | Offset 4 | Offset 3 | Offset 2 | Offset 1 | Offset 0 |
|--------|---------------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|
| 0x00   | TIMx_CR1      | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | MMS[2:0]  | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         |
| 0x04   | TIMx_CR2      | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         |
| 0x08   | Reserved      |           |           |           |           |           |           |           |           |           |           |           |           |           |           |           |           |           |           |           |           |           |           |           |           |           |           |           |           |           |           |           |           |           |           |           |
| 0x0C   | TIMx_DIER     | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0         |

Refer to Section 2.3 on page 134 for the register boundary addresses.
45 Low-power timer (LPTIM)

45.1 Introduction

The LPTIM is a 16-bit timer that benefits from the ultimate developments in power consumption reduction. Thanks to its diversity of clock sources, the LPTIM is able to keep running in all power modes except for Standby mode. Given its capability to run even with no internal clock source, the LPTIM can be used as a “Pulse Counter” which can be useful in some applications. Also, the LPTIM capability to wake up the system from low-power modes, makes it suitable to realize “Timeout functions” with extremely low power consumption.

The LPTIM introduces a flexible clock scheme that provides the needed functionalities and performance, while minimizing the power consumption.

45.2 LPTIM main features

- 16 bit upcounter
- 3-bit prescaler with 8 possible dividing factors (1,2,4,8,16,32,64,128)
- Selectable clock
  - Internal clock sources: configurable internal clock source (see RCC section)
  - External clock source over LPTIM input (working with no embedded oscillator running, used by Pulse Counter application)
- 16 bit ARR autoreload register
- 16 bit compare register
- Continuous/One-shot mode
- Selectable software/hardware input trigger
- Programmable Digital Glitch filter
- Configurable output: Pulse, PWM
- Configurable I/O polarity
- Encoder mode
45.3 LPTIM implementation

Table 372 describes LPTIM implementation on STM32H745/755 and STM32H747/757 devices.

45.4.4 LPTIM reset and clocks

The LPTIM can be clocked using several clock sources. It can be clocked using an internal clock signal which can be any configurable internal clock source selectable through the RCC (see RCC section for more details). Also, the LPTIM can be clocked using an external clock signal injected on its external Input1. When clocked with an external clock source, the LPTIM may run in one of these two possible configurations:

- The first configuration is when the LPTIM is clocked by an external signal but in the same time an internal clock signal is provided to the LPTIM from configurable internal clock source (see RCC section).
- The second configuration is when the LPTIM is solely clocked by an external clock source through its external Input1. This configuration is the one used to realize Timeout function or Pulse counter function when all the embedded oscillators are turned off after entering a low-power mode.

Programming the CKSEL and COUNTMODE bits allows controlling whether the LPTIM will use an external clock source or an internal one.

When configured to use an external clock source, the CKPOL bits are used to select the external clock signal active edge. If both edges are configured to be active ones, an internal clock signal should also be provided (first configuration). In this case, the internal clock signal frequency should be at least four times higher than the external clock signal frequency.

45.4.5 Glitch filter

The LPTIM inputs, either external (mapped to GPIOs) or internal (mapped on the chip-level to other embedded peripherals), are protected with digital filters that prevent any glitches and noise perturbations to propagate inside the LPTIM. This is in order to prevent spurious counts or triggers.

Before activating the digital filters, an internal clock source should first be provided to the LPTIM. This is necessary to guarantee the proper operation of the filters.
The digital filters are divided into two groups:

- The first group of digital filters protects the LPTIM external inputs. The digital filters sensitivity is controlled by the CKFLT bits.
- The second group of digital filters protects the LPTIM internal trigger inputs. The digital filters sensitivity is controlled by the TRGFLT bits.

Note: The digital filters sensitivity is controlled by groups. It is not possible to configure each digital filter sensitivity separately inside the same group.

The filter sensitivity acts on the number of consecutive equal samples that should be detected on one of the LPTIM inputs to consider a signal level change as a valid transition. Figure 569 shows an example of glitch filter behavior in case of a 2 consecutive samples programmed.

Figure 569. Glitch filter timing diagram

Note: In case no internal clock signal is provided, the digital filter must be deactivated by setting the CKFLT and TRGFLT bits to ‘0’. In that case, an external analog filter may be used to protect the LPTIM external inputs against glitches.

45.4.6 Prescaler

The LPTIM 16-bit counter is preceded by a configurable power-of-2 prescaler. The prescaler division ratio is controlled by the PRESC[2:0] 3-bit field. The table below lists all the possible division ratios:

<table>
<thead>
<tr>

</tbody>
</table>
45.4.7 Trigger multiplexer

The LPTIM counter may be started either by software or after the detection of an active edge on one of the 8 trigger inputs.

TRIGEN[1:0] is used to determine the LPTIM trigger source:

- When TRIGEN[1:0] equals ‘00’, The LPTIM counter is started as soon as one of the CNTSTRT or the SNGSTRT bits is set by software. The three remaining possible values for the TRIGEN[1:0] are used to configure the active edge used by the trigger inputs. The LPTIM counter starts as soon as an active edge is detected.
- When TRIGEN[1:0] is different than ‘00’, TRIGSEL[2:0] is used to select which of the 8 trigger inputs is used to start the counter.

The external triggers are considered asynchronous signals for the LPTIM. So after a trigger detection, a two-counter-clock period latency is needed before the timer starts running due to the synchronization.

If a new trigger event occurs when the timer is already started it will be ignored (unless timeout function is enabled).

**Note:** The timer must be enabled before setting the SNGSTRT/CNTSTRT bits. Any write on these bits when the timer is disabled will be discarded by hardware.

**Note:** When starting the counter by software (TRIGEN[1:0] = 00), there is a delay of 3 kernel clock cycles between the LPTIM_CR register update (set one of SNGSTRT or CNTSTRT bits) and the effective start of the counter.

45.4.8 Operating mode

The LPTIM features two operating modes:

- The Continuous mode: the timer is free running, the timer is started from a trigger event and never stops until the timer is disabled
- One-shot mode: the timer is started from a trigger event and stops when reaching the ARR value.

**One-shot mode**

To enable the one-shot counting, the SNGSTRT bit must be set.

A new trigger event will re-start the timer. Any trigger event occurring after the counter starts and before the counter reaches ARR will be discarded.

In case an external trigger is selected, each external trigger event arriving after the SNGSTRT bit is set, and after the counter register has stopped (contains zero value), will start the counter for a new one-shot counting cycle as shown in Figure 570.
Set-once mode activated:

It should be noted that when the WAVE bit-field in the LPTIM_CFR register is set, the Set-once mode is activated. In this case, the counter is only started once following the first trigger, and any subsequent trigger event is discarded as shown in Figure 571.

Continuous mode

To enable the continuous counting, the CNTSTRT bit must be set.

In case an external trigger is selected, an external trigger event arriving after CNTSTRT is set will start the counter for continuous counting. Any subsequent external trigger event will be discarded as shown in Figure 572.

In case of software start (TRIGEN[1:0] = ‘00’), setting CNTSTRT will start the counter for continuous counting.
45.4.9 Timeout function

The detection of an active edge on one selected trigger input can be used to reset the LPTIM counter. This feature is controlled through the TIMOUT bit.

The first trigger event will start the timer, any successive trigger event will reset the counter and the timer will restart.

A low-power timeout function can be realized. The timeout value corresponds to the compare value; if no trigger occurs within the expected time frame, the MCU is waked-up by the compare match event.

45.4.10 Waveform generation

Two 16-bit registers, the LPTIM_ARR (autoreload register) and LPTIM_CMP (compare register), are used to generate several different waveforms on LPTIM output.

The timer can generate the following waveforms:

- The PWM mode: the LPTIM output is set as soon as the counter value in LPTIM_CNT exceeds the compare value in LPTIM_CMP. The LPTIM output is reset as soon as a match occurs between the LPTIM_ARR and the LPTIM_CNT registers.
- The One-pulse mode: the output waveform is similar to the one of the PWM mode for the first pulse, then the output is permanently reset.
- The Set-once mode: the output waveform is similar to the One-pulse mode except that the output is kept to the last signal level (depends on the output configured polarity).

The above described modes require that the LPTIM_ARR register value be strictly greater than the LPTIM_CMP register value.
The LPTIM output waveform can be configured through the WAVE bit as follow:

- Resetting the WAVE bit to '0' forces the LPTIM to generate either a PWM waveform or a One pulse waveform depending on which bit is set: CNTSTRT or SNGSTRT.
- Setting the WAVE bit to ‘1’ forces the LPTIM to generate a Set-once mode waveform.

The WAVPOL bit controls the LPTIM output polarity. The change takes effect immediately, so the output default value will change immediately after the polarity is re-configured, even before the timer is enabled.

Signals with frequencies up to the LPTIM clock frequency divided by 2 can be generated. Figure 573 below shows the three possible waveforms that can be generated on the LPTIM output. Also, it shows the effect of the polarity change using the WAVPOL bit.

**Figure 573. Waveform generation**

45.4.11 Register update

The LPTIM_ARR register and LPTIM_CMP register are updated immediately after the APB bus write operation, or at the end of the current period if the timer is already started.

The PRELOAD bit controls how the LPTIM_ARR and the LPTIM_CMP registers are updated:

- When the PRELOAD bit is reset to ‘0’, the LPTIM_ARR and the LPTIM_CMP registers are immediately updated after any write access.
- When the PRELOAD bit is set to ‘1’, the LPTIM_ARR and the LPTIM_CMP registers are updated at the end of the current period, if the timer has been already started.

The LPTIM APB interface and the LPTIM kernel logic use different clocks, so there is some latency between the APB write and the moment when these values are available to the
counter comparator. Within this latency period, any additional write into these registers must be avoided.

The ARROK flag and the CMPOK flag in the LPTIM_ISR register indicate when the write operation is completed to respectively the LPTIM_ARR register and the LPTIM_CMP register.

After a write to the LPTIM_ARR register or the LPTIM_CMP register, a new write operation to the same register can only be performed when the previous write operation is completed. Any successive write before respectively the ARROK flag or the CMPOK flag be set, will lead to unpredictable results.

45.4.12 Counter mode

The LPTIM counter can be used to count external events on the LPTIM Input1 or it can be used to count internal clock cycles. The CKSEL and COUNTMODE bits control which source will be used for updating the counter.

In case the LPTIM is configured to count external events on Input1, the counter can be updated following a rising edge, falling edge or both edges depending on the value written to the CKPOL[1:0] bits.

The count modes below can be selected, depending on CKSEL and COUNTMODE values:

- **CKSEL = 0**: the LPTIM is clocked by an internal clock source
  - **COUNTMODE = 0**: The LPTIM is configured to be clocked by an internal clock source and the LPTIM counter is configured to be updated following each internal clock pulse.
  - **COUNTMODE = 1**: The LPTIM external Input1 is sampled with the internal clock provided to the LPTIM. Consequently, in order not to miss any event, the frequency of the changes on the external Input1 signal should never exceed the frequency of the internal clock provided to the LPTIM. Also, the internal clock provided to the LPTIM must not be prescaled (PRESC[2:0] = 000).

- **CKSEL = 1**: the LPTIM is clocked by an external clock source
  COUNTMODE value is don’t care.

  In this configuration, the LPTIM has no need for an internal clock source (except if the glitch filters are enabled). The signal injected on the LPTIM external Input1 is used as system clock for the LPTIM. This configuration is suitable for operation modes where no embedded oscillator is enabled.

  For this configuration, the LPTIM counter can be updated either on rising edges or falling edges of the input1 clock signal but not on both rising and falling edges.

  Since the signal injected on the LPTIM external Input1 is also used to clock the LPTIM kernel logic, there is some initial latency (after the LPTIM is enabled) before the counter is incremented. More precisely, the first five active edges on the LPTIM external Input1 (after LPTIM is enable) are lost.

45.4.13 Timer enable

The ENABLE bit located in the LPTIM_CR register is used to enable/disable the LPTIM kernel logic. After setting the ENABLE bit, a delay of two counter clock is needed before the LPTIM is actually enabled.
The LPTIM_CFGR and LPTIM_IER registers must be modified only when the LPTIM is disabled.

45.4.14 Timer counter reset

In order to reset the content of LPTIM_CNT register to zero, two reset mechanisms are implemented:

- The synchronous reset mechanism: the synchronous reset is controlled by the COUNTRST bit in the LPTIM_CR register. After setting the COUNTRST bit-field to '1', the reset signal is propagated in the LPTIM kernel clock domain. So it is important to note that a few clock pulses of the LPTIM kernel logic will elapse before the reset is taken into account. This will make the LPTIM counter count few extra pluses between the time when the reset is trigger and it become effective. Since the COUNTRST bit is located in the APB clock domain and the LPTIM counter is located in the LPTIM kernel clock domain, a delay of 3 clock cycles of the kernel clock is needed to synchronize the reset signal issued by the APB clock domain when writing '1' to the COUNTRST bit.

- The asynchronous reset mechanism: the asynchronous reset is controlled by the RSTARE bit located in the LPTIM_CR register. When this bit is set to '1', any read access to the LPTIM_CNT register will reset its content to zero. Asynchronous reset should be triggered within a timeframe in which no LPTIM core clock is provided. For example when LPTIM Input1 is used as external clock source, the asynchronous reset should be applied only when there is enough insurance that no toggle will occur on the LPTIM Input1.

It should be noted that to read reliably the content of the LPTIM_CNT register two successive read accesses must be performed and compared. A read access can be considered reliable when the value of the two read accesses is equal. Unfortunately when asynchronous reset is enabled there is no possibility to read twice the LPTIM_CNT register.

---

**Warning:** There is no mechanism inside the LPTIM that prevents the two reset mechanisms from being used simultaneously. So developer should make sure that these two mechanisms are used exclusively.

---

45.4.15 Encoder mode

This mode allows handling signals from quadrature encoders used to detect angular position of rotary elements. Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the auto-reload value programmed into the LPTIM_ARR register (0 up to ARR or ARR down to 0 depending on the direction). Therefore LPTIM_ARR must be configured before starting the counter. From the two external input signals, Input1 and Input2, a clock signal is generated to clock the LPTIM counter. The phase between those two signals determines the counting direction.

The Encoder mode is only available when the LPTIM is clocked by an internal clock source. The signals frequency on both Input1 and Input2 inputs must not exceed the LPTIM internal clock frequency divided by 4. This is mandatory in order to guarantee a proper operation of the LPTIM.
Direction change is signaled by the two Down and Up flags in the LPTIM_ISR register. Also, an interrupt can be generated for both direction change events if enabled through the DOWNIE bit.

To activate the Encoder mode the ENC bit has to be set to ‘1’. The LPTIM must first be configured in Continuous mode.

When Encoder mode is active, the LPTIM counter is modified automatically following the speed and the direction of the incremental encoder. Therefore, its content always represents the encoder’s position. The count direction, signaled by the Up and Down flags, correspond to the rotation direction of the encoder rotor.

According to the edge sensitivity configured using the CKPOL[1:0] bits, different counting scenarios are possible. The following table summarizes the possible combinations, assuming that Input1 and Input2 do not switch at the same time.

**Table 386. Encoder counting scenarios**

<table>
<thead>
<tr>
<th>Active edge</th>
<th>Level on opposite signal (Input1 for Input2, Input2 for Input1)</th>
<th>Input1 signal</th>
<th>Input2 signal</th>
</tr>
</thead>
<tbody>
<tr>

<td>Down</td>
<td>Up</td>
</tr>
<tr>
<td></td>
<td>Low</td>
<td>Up</td>
<td>Down</td>
</tr>
</tbody>
</table>

The following figure shows a counting sequence for Encoder mode where both-edge sensitivity is configured.

**Caution:** In this mode the LPTIM must be clocked by an internal clock source, so the CKSEL bit must be maintained to its reset value which is equal to ‘0’. Also, the prescaler division ratio must be equal to its reset value which is 1 (PRESC[2:0] bits must be ‘000’).
45.4.16 Debug mode

When the microcontroller enters debug mode (core halted), the LPTIM counter either continues to work normally or stops, depending on the DBG_LPTIM_STOP configuration bit in the DBG module.

45.5 LPTIM low-power modes

Table 387. Effect of low-power modes on the LPTIM

</tbody>
</table>
45.6 LPTIM interrupts

The following events generate an interrupt/wake-up event, if they are enabled through the LPTIM_IER register:

- Compare match
- Auto-reload match (whatever the direction if encoder mode)
- External trigger event
- Autoreload register write completed
- Compare register write completed
- Direction change (encoder mode), programmable (up / down / both).

*Note:* If any bit in the LPTIM_IER register (Interrupt Enable Register) is set after that its corresponding flag in the LPTIM_ISR register (Status Register) is set, the interrupt is not asserted.

<table>

#### Bits 31:7 Reserved, must be kept at reset value.

**Bit 6 DOWN**: Counter direction change up to down

In Encoder mode, DOWN bit is set by hardware to inform application that the counter direction has changed from up to down. DOWN flag can be cleared by writing 1 to the DOWNCF bit in the LPTIM_ICR register.

*Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Please refer to Section 45.3: LPTIM implementation.*

**Bit 5 UP**: Counter direction change down to up

In Encoder mode, UP bit is set by hardware to inform application that the counter direction has changed from down to up. UP flag can be cleared by writing 1 to the UPCF bit in the LPTIM_ICR register.

*Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Please refer to Section 45.3: LPTIM implementation.*

**Bit 4 ARROK**: Autoreload register update OK

ARROK is set by hardware to inform application that the APB bus write operation to the LPTIM_ARR register has been successfully completed. ARROK flag can be cleared by writing 1 to the ARROKCF bit in the LPTIM_ICR register.

**Bit 3 CMPOK**: Compare register update OK

CMPOK is set by hardware to inform application that the APB bus write operation to the LPTIM_CMP register has been successfully completed. CMPOK flag can be cleared by writing 1 to the CMPOKCF bit in the LPTIM_ICR register.

**Bit 2 EXTTRIG**: External trigger edge event

EXTTRIG is set by hardware to inform application that a valid edge on the selected external trigger input has occurred. If the trigger is ignored because the timer has already started, then this flag is not set. EXTTRIG flag can be cleared by writing 1 to the EXTTRIGCF bit in the LPTIM_ICR register.

**Bit 1 ARRM**: Autoreload match

ARRM is set by hardware to inform application that LPTIM_CNT register’s value reached the LPTIM_ARR register’s value. ARRM flag can be cleared by writing 1 to the ARRMCF bit in the LPTIM_ICR register.

**Bit 0 CMPM**: Compare match

The CMPM bit is set by hardware to inform application that LPTIM_CNT register value reached the LPTIM_CMP register’s value. CMPM flag can be cleared by writing 1 to the CMPMCF bit in the LPTIM_ICR register.

Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Please refer to Section 45.3: LPTIM implementation.
Bits 31:7  Reserved, must be kept at reset value.

Bit 6  **DOWNIE**: Direction change to down Interrupt Enable
0: DOWN interrupt disabled
1: DOWN interrupt enabled

*Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Please refer to Section 45.3: LPTIM implementation.*

Bit 5  **UPIE**: Direction change to UP Interrupt Enable
0: UP interrupt disabled
1: UP interrupt enabled

*Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Please refer to Section 45.3: LPTIM implementation.*

Bit 4  **ARROKIE**: Autoreload register update OK Interrupt Enable
0: ARROK interrupt disabled
1: ARROK interrupt enabled

Bit 3  **CMPOKIE**: Compare register update OK Interrupt Enable
0: CMPOK interrupt disabled
1: CMPOK interrupt enabled

*Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Please refer to Section 45.3: LPTIM implementation.*

Bit 2  **EXTTRIGIE**: External trigger valid edge Interrupt Enable
0: EXTTRIG interrupt disabled
1: EXTTRIG interrupt enabled

Bit 1  **ARRMIE**: Autoreload match Interrupt Enable
0: ARRM interrupt disabled
1: ARRM interrupt enabled

Bit 0  **CMPMIE**: Compare match Interrupt Enable
0: CMPM interrupt disabled
1: CMPM interrupt enabled

**Caution**: The LPTIM_IER register must only be modified when the LPTIM is disabled (ENABLE bit reset to ‘0’)

### 45.7.4 LPTIM configuration register (LPTIM_CFGR)

Bits 31:30  Reserved, must be kept at reset value.

Bit 29  Reserved, must be kept at reset value.

Bits 28:25  Reserved, must be kept at reset value.
Bit 24  **ENC**: Encoder mode enable
The ENC bit controls the Encoder mode
0: Encoder mode disabled
1: Encoder mode enabled
*Note: If the LPTIM does not support encoder mode feature, this bit is reserved. Please refer to Section 45.3: LPTIM implementation.*

Bit 23  **COUNTMODE**: counter mode enabled
The COUNTMODE bit selects which clock source is used by the LPTIM to clock the counter:
0: the counter is incremented following each internal clock pulse
1: the counter is incremented following each valid clock pulse on the LPTIM external Input1

Bit 22  **PRELOAD**: Registers update mode
The PRELOAD bit controls the LPTIM_ARR and the LPTIM_CMP registers update modality
0: Registers are updated after each APB bus write access
1: Registers are updated at the end of the current LPTIM period

Bit 21  **WAVPOL**: Waveform shape polarity
The WAVPOL bit controls the output polarity
0: The LPTIM output reflects the compare results between LPTIM_CNT and LPTIM_CMP registers
1: The LPTIM output reflects the inverse of the compare results between LPTIM_CNT and LPTIM_CMP registers

Bit 20  **WAVE**: Waveform shape
The WAVE bit controls the output shape
0: Deactivate Set-once mode
1: Activate the Set-once mode

Bit 19  **TIMOUT**: Timeout enable
The TIMOUT bit controls the Timeout feature
0: A trigger event arriving when the timer is already started will be ignored
1: A trigger event arriving when the timer is already started will reset and restart the counter

Bits 18:17  **TRIGEN[1:0]**: Trigger enable and polarity
The TRIGEN bits controls whether the LPTIM counter is started by an external trigger or not. If the external trigger option is selected, three configurations are possible for the trigger active edge:
00: software trigger (counting start is initiated by software)
01: rising edge is the active edge
10: falling edge is the active edge
11: both edges are active edges

Bit 16  Reserved, must be kept at reset value.
Bits 15:13 **TRIGSEL[2:0]**: Trigger selector

The TRIGSEL bits select the trigger source that will serve as a trigger event for the LPTIM among the below 8 available sources:

- 000: lptim_ext_trig0
- 001: lptim_ext_trig1
- 010: lptim_ext_trig2
- 011: lptim_ext_trig3
- 100: lptim_ext_trig4
- 101: lptim_ext_trig5
- 110: lptim_ext_trig6
- 111: lptim_ext_trig7

See [Section 45.4.3: LPTIM input and trigger mapping](#) for details.

Bit 12 Reserved, must be kept at reset value.

Bits 11:9 **PRESC[2:0]**: Clock prescaler

The PRESC bits configure the prescaler division factor. It can be one among the following division factors:

- 000: /1
- 001: /2
- 010: /4
- 011: /8
- 100: /16
- 101: /32
- 110: /64
- 111: /128

Bit 8 Reserved, must be kept at reset value.

Bits 7:6 **TRGFLT[1:0]**: Configurable digital filter for trigger

The TRGFLT value sets the number of consecutive equal samples that should be detected when a level change occurs on an internal trigger before it is considered as a valid level transition. An internal clock source must be present to use this feature.

- 00: any trigger active level change is considered as a valid trigger
- 01: trigger active level change must be stable for at least 2 clock periods before it is considered as valid trigger.
- 10: trigger active level change must be stable for at least 4 clock periods before it is considered as valid trigger.
- 11: trigger active level change must be stable for at least 8 clock periods before it is considered as valid trigger.

Bit 5 Reserved, must be kept at reset value.
Bits 4:3 CKFLT[1:0]: Configurable digital filter for external clock

The CKFLT value sets the number of consecutive equal samples that should be detected when a level change occurs on an external clock signal before it is considered as a valid level transition. An internal clock source must be present to use this feature.

00: any external clock signal level change is considered as a valid transition
01: external clock signal level change must be stable for at least 2 clock periods before it is considered as valid transition.
10: external clock signal level change must be stable for at least 4 clock periods before it is considered as valid transition.
11: external clock signal level change must be stable for at least 8 clock periods before it is considered as valid transition.

Bits 2:1 CKPOL[1:0]: Clock polarity

If LPTIM is clocked by an external clock source:

When the LPTIM is clocked by an external clock source, CKPOL bits is used to configure the active edge or edges used by the counter:

00: the rising edge is the active edge used for counting.
01: the falling edge is the active edge used for counting.
10: both edges are active edges. When both external clock signal edges are considered active ones, the LPTIM must also be clocked by an internal clock source with a frequency equal to at least four times the external clock frequency.
11: not allowed

Refer to Section 45.4.15: Encoder mode for more details about Encoder mode sub-modes.

Bit 0 CKSEL: Clock selector

The CKSEL bit selects which clock source the LPTIM will use:

0: LPTIM is clocked by internal clock source (APB clock or any of the embedded oscillators)
1: LPTIM is clocked by an external clock source through the LPTIM external Input1

Caution: The LPTIM_CFGR register must only be modified when the LPTIM is disabled (ENABLE bit reset to ‘0’).

45.7.5 LPTIM control register (LPTIM_CR)

Address offset: 0x010
Reset value: 0x0000 0000
Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **RSTARE**: Reset after read enable
This bit is set and cleared by software. When RSTARE is set to ‘1’, any read access to LPTIM_CNT register will asynchronously reset LPTIM_CNT register content.
This bit can be set only when the LPTIM is enabled.

**Caution:** This bitfield is write-only. This means that the bit cannot be read back to verify the value which has been written. As an example, if this bit is set to 1, attempting to read it back will return 0 even if the "Reset after read" function is enabled (due to the fact that this bitfield has previously been written to 1). To turn off the "Reset after read" or to make sure that it has already been turned off, this bit should be reset (by programming it to 0) even if it already contains 0.

Bit 3 **COUNTRST**: Counter reset
This bit is set by software and cleared by hardware. When set to '1' this bit will trigger a synchronous reset of the LPTIM_CNT counter register. Due to the synchronous nature of this reset, it only takes place after a synchronization delay of 3 LPTimer core clock cycles (LPTimer core clock may be different from APB clock).
This bit can be set only when the LPTIM is enabled. It is automatically reset by hardware.

**Caution:** COUNTRST must never be set to '1' by software before it is already cleared to '0' by hardware. Software should consequently check that COUNTRST bit is already cleared to '0' before attempting to set it to '1'.

Bit 2 **CNTSTRT**: Timer start in Continuous mode
This bit is set by software and cleared by hardware.
In case of software start (TRIGEN[1:0] = '00'), setting this bit starts the LPTIM in Continuous mode.
If the software start is disabled (TRIGEN[1:0] different than '00'), setting this bit starts the timer in Continuous mode as soon as an external trigger is detected.
If this bit is set when a single pulse mode counting is ongoing, then the timer will not stop at the next match between the LPTIM_ARR and LPTIM_CNT registers and the LPTIM counter keeps counting in Continuous mode.
This bit can be set only when the LPTIM is enabled. It will be automatically reset by hardware.

Bit 1 **SNGSTRT**: LPTIM start in Single mode
This bit is set by software and cleared by hardware.
In case of software start (TRIGEN[1:0] = '00'), setting this bit starts the LPTIM in single pulse mode.
If the software start is disabled (TRIGEN[1:0] different than '00'), setting this bit starts the LPTIM in single pulse mode as soon as an external trigger is detected.
If this bit is set when the LPTIM is in continuous counting mode, then the LPTIM will stop at the following match between LPTIM_ARR and LPTIM_CNT registers.
This bit can only be set when the LPTIM is enabled. It will be automatically reset by hardware.

Bit 0 **ENABLE**: LPTIM enable
The ENABLE bit is set and cleared by software.
0:LPTIM is disabled
1:LPTIM is enabled
### 45.7.6 LPTIM compare register (LPTIM_CMP)

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 CNT[15:0]: Counter value

When the LPTIM is running with an asynchronous clock, reading the LPTIM_CNT register may return unreliable values. So in this case it is necessary to perform two consecutive read accesses and verify that the two returned values are identical.

It should be noted that for a reliable LPTIM_CNT register read access, two consecutive read accesses must be performed and compared. A read access can be considered reliable when the values of the two consecutive read accesses are equal.

45.7.9 LPTIM configuration register 2 (LPTIM_CFGR2)

Address offset: 0x024
Reset value: 0x0000 0000

</tbody>
</table>

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:4 IN2SEL[1:0]: LPTIM input 2 selection

The IN2SEL bits control the LPTIM Input 2 multiplexer, which connect LPTIM Input 2 to one of the available inputs.
00: lptim_in2_mux0
01: lptim_in2_mux1
10: lptim_in2_mux2
11: lptim_in2_mux3

For connection details refer to Section 45.4.3: LPTIM input and trigger mapping.

Note: If the LPTIM does not support encoder mode feature, these bits are reserved. Please refer to Section 45.3: LPTIM implementation.

Bits 3:2 Reserved, must be kept at reset value.
Bits 1:0 **IN1SEL[1:0]:** LPTIM input 1 selection

The IN1SEL bits control the LPTIM Input 1 multiplexer, which connects LPTIM Input 1 to one of the available inputs.
- 00: lptim_in1_mux0
- 01: lptim_in1_mux1
- 10: lptim_in1_mux2
- 11: lptim_in1_mux3

For connection details refer to Section 45.4.3: LPTIM input and trigger mapping.

**Caution:** The LPTIM_CFGR2 register must only be modified when the LPTIM is disabled (ENABLE bit reset to '0').

### 45.7.10 LPTIM3 configuration register 2 (LPTIM3_CFGR2)

Address offset: 0x024

Reset value: 0x0000 0000

- **Bits 31:2** Reserved, must be kept at reset value.
- **Bits 1:0** **IN1SEL[1:0]:** LPTIM3 Input1 selection

The IN1SEL bits control the LPTIM3 Input 1 multiplexer, which connects LPTIM3 Input 1 to one of the available inputs.
- 00: lptim_in1_mux0
- 01: lptim_in1_mux1
- 10: lptim_in1_mux2
- 11: lptim_in1_mux3

For connection details refer to Table 384: LPTIM3 input 1 connection.

**Caution:** The LPTIM3_CFGR2 registers must only be modified when the LPTIM is disabled (ENABLE bit reset to '0').
### LPTIM register map

The following table summarizes the LPTIM registers.

| Offset | Register name | Offset | Register name | Offset | Register name | Offset | Register name | Offset | Register name | Offset | Register name | Offset | Register name | Offset | Register name | Offset | Register name | Offset | Register name | Offset | Register name |

1. If LPTIM does not support encoder mode feature, this bit is reserved. Please refer to Section 45.3: LPTIM implementation.

Refer to Section 2.3 on page 134 for the register boundary addresses.
46 Watchdog overview

The devices feature four embedded watchdog blocks which offer a combination of high safety, timing accuracy and flexibility. Option bytes allow adapting the behavior of the watchdogs to the user application.

46.1 Watchdog main features

- Two independent watchdogs (IWDG1/2), each dedicated to a CPU
- Two window watchdogs (WWDG1/2), each dedicated to a CPU
- Each CPU can receive an interrupt if the other CPU has been reset due to a window watchdog timeout.
- Each CPU can receive the early interrupt of its dedicated window watchdog.
- Watchdog functions can be configured through option bytes.

46.2 Watchdog brief functional description

IWDG1 and WWDG1 are dedicated to CPU1, while IWDG2 and WWDG2 are dedicated to CPU2.

Both watchdog peripherals (Independent and Window) allow detecting and resolving malfunctions due to software or hardware failures.

The window watchdogs (WWDG1/2) clocks are derived from the APB clocks and have a configurable time window that can be programmed to detect abnormally late or early application behavior. The WWDGs are best suited for monitoring software execution.

Each WWDG provides a reset and an early interrupt signal.

As shown in Figure 575, the early wakeup interrupt output (wwdg1_ewit) of WWDG1 is connected to CPU1 interrupt controller.

The WWDG1 reset signal output (wwdg1_out_rst) is input to the reset and clock controller (RCC), and generates either a CPU1 reset or a system reset according to the value of WW1RSC bit in RCC_GRC register. In both cases, the wwdg1_out_rst also resets the WWDG1 block.

In addition, the wwdg1_out_rst signal is connected to CPU2 interrupt controller via the EXTI block. This function allows each core to be interrupted when the other core has a failure due to a window watchdog reset.

WWDG2 connection is completely symmetrical compared to WWDG1 connection.

Note: The WWDG1 and WWDG2 are hard-wired to be used by CPU1 and CPU2, respectively. There is no register protection. As a result it is not recommended that CPU1 uses WWDG2, and CPU2, WWDG1.

Refer to Section 47: System window watchdog (WWDG) for a detailed description of WWDG blocks.

The independent watchdogs (IWDG1/2) are clocked by the low-speed clock (LSI) and thus stay active even if the main clock fails. They are consequently best suited for applications.
which require the watchdog to run totally independently of the main application. The IWDGs are ideal solutions to recover from unexpected software or hardware failures.

Refer to Section 48: Independent watchdog (IWDG) for a detailed description of IWDG blocks.

Note: Like WWDG blocks, IWDG1 block is designed to work with CPU1, and IWDG2 with CPU2.

Figure 575. Watchdog high-level block diagram
46.2.1 Enabling the watchdog clock

Enabling WWDG1/2 clock

Each core can enable the window watchdog clocks via the RCC block. Setting the WWDG1EN bit in RCC_C1_D1APB1ENR register enables WWDG1 block clock, while setting WWDG2EN bit in RCC_C2_D2APB1LENR register enables WWDG2 block clock.

The software cannot stop WWDG1 and WWDG2 down-counting by setting WWDG1EN and WWDG2EN bit to ‘0’, respectively.

CPU1 can also enable the WWDG1 block via the RCC_D1APB1ENR register, while CPU2 cannot program the WWDG1EN bit through this register.

Similarly, CPU2 can also enable the WWDG2 block via the RCC_D2APB1LENR register, while CPU1 cannot program the WWDG2EN bit through this register.

Enabling IWDG1/2 clock

The independent watchdogs do not need their clock to be enabled by the RCC block. IWDG1 is implicitly allocated to CPU1, and IWDG2 to CPU2. An option byte allows IWDG1 and IWDG2 to be automatically enabled after a system reset. Refer to Section 48.3: IWDG functional description for additional information.

46.2.2 Window watchdog reset scope

The reset scope of the window watchdogs can be controlled via WW1RSC and WW2RSC bits in the RCC_GRC register (see Section 9.7.36: RCC global control register (RCC_GCR)).

After a system reset, WW[2:1]RSC bits are set to ‘0’, meaning that the reset scope of the WWDG1/2 is by default limited to CPU1 and CPU2.

When the WW1RSC bit is set to ‘1’, the WWDG1 will generate a system reset if a timeout occurs. The software cannot set the WW1RSC bit back to ‘0’ once it has been set to ‘1’.

A similar description applies to WW2RSC bit with respect to WWDG2 block.

46.2.3 Watchdog behavior versus CPU state

A WWDG block is frozen when the corresponding CPU enters CSTOP mode. When the domain goes in DSTANDBY, the WWDG block located into this domain is reset.

IWDG blocks remain always enabled once enabled. Two option bytes allow freezing IWDG down-counting:

- IWDG_FZ_STOP option byte allows freezing WWDG1/2 down-counting when the CPU1/CPU2 is entering CSTOP mode or deeper low-power mode (DxSTOP, DxSTANDBY or product Standby mode).
- IWDG_FZ_STANDBY option byte allows freezing WWDG1/2 down-counting only when the product enters Standby mode.

Refer to Section 4.4: FLASH option bytes for a detailed description of the option bytes.
47 System window watchdog (WWDG)

47.1 Introduction

The system window watchdog (WWDG) is used to detect the occurrence of a software fault, usually generated by external interference or by unforeseen logical conditions, which causes the application program to abandon its normal sequence.

The watchdog circuit generates a reset on expiry of a programmed time period, unless the program refreshes the contents of the down-counter before the T6 bit is cleared. A reset is also generated if the 7-bit down-counter value (in the control register) is refreshed before the down-counter reaches the window register value. This implies that the counter must be refreshed in a limited window.

The WWDG clock is prescaled from the APB clock and has a configurable time-window that can be programmed to detect abnormally late or early application behavior.

The WWDG is best suited for applications requiring the watchdog to react within an accurate timing window.

47.2 WWDG main features

- Programmable free-running down-counter
- Conditional reset
  - Reset (if watchdog activated) when the down-counter value becomes lower than 0x40
  - Reset (if watchdog activated) if the down-counter is reloaded outside the window (see Figure 577)
- Early wake-up interrupt (EWI): triggered (if enabled and the watchdog activated) when the down-counter is equal to 0x40

47.3 WWDG functional description

If the watchdog is activated (the WDGA bit is set in the WWDG_CR register), and when the 7-bit down-counter (T[6:0] bits) is decremented from 0x40 to 0x3F (T6 becomes cleared), it initiates a reset. If the software reloads the counter while the counter is greater than the value stored in the window register, then a reset is generated.

The application program must write in the WWDG_CR register at regular intervals during normal operation to prevent a reset. This operation can take place only when the counter value is lower than or equal to the window register value, and higher than 0x3F. The value to be stored in the WWDG_CR register must be between 0xFF and 0xC0.

Refer to Figure 576 and to Section 47.3.2: WWDG internal signals for the WWDG block diagram.
47.3.1 WWDG block diagram

Figure 576. Watchdog block diagram

47.3.2 WWDG internal signals

Table 390 gives the list of WWDG internal signals.

</tr>
</tbody>
</table>

47.3.3 Enabling the watchdog

The watchdog is always disabled after a reset. It is enabled by setting the WDGA bit in the WWDG_CR register, then it cannot be disabled again except by a reset.

47.3.4 Controlling the down-counter

This down-counter is free-running, counting down even if the watchdog is disabled. When the watchdog is enabled, the T6 bit must be set to prevent generating an immediate reset.

The T[5:0] bits contain the number of increments that represent the time delay before the watchdog produces a reset. The timing varies between a minimum and a maximum value, due to the unknown status of the prescaler when writing to the WWDG_CR register (see Figure 577). The WWDG configuration register (WWDG_CFR) contains the high limit of the window: to prevent a reset, the down-counter must be reloaded when its value is lower than or equal to the window register value, and greater than 0x3F. Figure 577 describes the window watchdog process.

Note: The T6 bit can be used to generate a software reset (the WDGA bit is set and the T6 bit is cleared).
47.3.5 How to program the watchdog timeout

Use the formula in Figure 577 to calculate the WWDG timeout.

**Warning:** When writing to the WWDG_CR register, always write 1 in the T6 bit to avoid generating an immediate reset.

---

The formula to calculate the timeout value is given by:

\[ t_{WWDG} = t_{PCLK} \times 4096 \times 2^{WDGTB[2:0]} \times (T[5:0] + 1) \] (ms)

where:

- \( t_{WWDG} \): WWDG timeout
- \( t_{PCLK} \): APB clock period measured in ms
- \( 4096 \): value corresponding to internal divider
As an example, if APB frequency is 48 MHz, WDGTB[2:0] is set to 3, and T[5:0] is set to 63:

$$t_{\text{WWDG}} = \left(\frac{1}{48000}\right) \times 4096 \times 2^3 \times (63 + 1) = 43.69\text{ms}$$

Refer to the datasheet for the minimum and maximum values of $t_{\text{WWDG}}$.

### 47.3.6 Debug mode

When the CPU1/2 enter debug mode, WWDG1 and WWDG2 counters either continue to work normally or stop, depending on DBGMCU_APB3LFZ1/2 and DBGMCU_APB1LFZ1/2, respectively. For more details, refer to Section 63: Debug infrastructure.

### 47.4 WWDG interrupts

The early wake-up interrupt (EWI) can be used if specific safety operations or data logging must be performed before the reset is generated. To enable the early wake-up interrupt, the application must:

- Write EWIF bit of WWDG_SR register to 0, to clear unwanted pending interrupt
- Write EWI bit of WWDG_CFR register to 1, to enable interrupt

When the down-counter reaches the value 0x40, a watchdog interrupt is generated, and the corresponding interrupt service routine (ISR) can be used to trigger specific actions (such as communications or data logging), before resetting the device.

In some applications, the EWI interrupt can be used to manage a software system check and/or system recovery/graceful degradation, without generating a WWDG reset. In this case the corresponding ISR must reload the WWDG counter to avoid the WWDG reset, then trigger the required actions.

The watchdog interrupt is cleared by writing '0' to the EWIF bit in the WWDG_SR register.

**Note:** When the watchdog interrupt cannot be served (for example due to a system lock in a higher priority task), the WWDG reset is eventually generated.

### 47.5 WWDG registers

Refer to Section 1.2 on page 106 for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by halfwords (16-bit) or words (32-bit).
## WWDG control register (WWDG_CR)

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **WDGA**: Activation bit

- This bit is set by software and only cleared by hardware after a reset. When WDGA = 1, the watchdog can generate a reset.
- 0: Watchdog disabled
- 1: Watchdog enabled

Bits 6:0 **T[6:0]**: 7-bit counter (MSB to LSB)

- These bits contain the value of the watchdog counter, decremented every \((4096 \times 2^{WWDGTB[2:0]})\) PCLK cycles. A reset is produced when it is decremented from 0x40 to 0x3F (T6 becomes cleared).

</thead>
</table>

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:11 **WWDGTB[2:0]**: Timer base

- The timebase of the prescaler can be modified as follows:
  - 000: CK counter clock (PCLK div 4096) div 1
  - 001: CK counter clock (PCLK div 4096) div 2
  - 010: CK counter clock (PCLK div 4096) div 4
  - 011: CK counter clock (PCLK div 4096) div 8
  - 100: CK counter clock (PCLK div 4096) div 16
  - 101: CK counter clock (PCLK div 4096) div 32
  - 110: CK counter clock (PCLK div 4096) div 64
  - 111: CK counter clock (PCLK div 4096) div 128

Bit 10 Reserved, must be kept at reset value.
Bit 9 **EWI**: Early wake-up interrupt enable
   
   Set by software and cleared by hardware after a reset. When set, an interrupt occurs whenever the counter reaches the value 0x40.

Bits 8:7 Reserved, must be kept at reset value.

Bits 6:0 **W[6:0]**: 7-bit window value
   
   These bits contain the window value to be compared with the down-counter.

### 47.5.3 WWDG status register (WWDG_SR)

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **EWIF**: Early wake-up interrupt flag
   
   This bit is set by hardware when the counter has reached the value 0x40. It must be cleared by software by writing 0. Writing 1 has no effect. This bit is also set if the interrupt is not enabled.

### 47.5.4 WWDG register map

The following table gives the WWDG register map and reset values.

Refer to *Section 2.3 on page 134* for the register boundary addresses.
48 Independent watchdog (IWDG)

48.1 Introduction

The devices feature an embedded watchdog peripheral that offers a combination of high safety level, timing accuracy and flexibility of use. The Independent watchdog peripheral detects and solves malfunctions due to software failure, and triggers system reset when the counter reaches a given timeout value.

The independent watchdog (IWDG) is clocked by its own dedicated low-speed clock (LSI) and thus stays active even if the main clock fails.

The IWDG is best suited for applications that require the watchdog to run as a totally independent process outside the main application, but have lower timing accuracy constraints. For further information on the window watchdog, refer to Section 47: System window watchdog (WWDG).

48.2 IWDG main features

- Free-running downcounter
- Clocked from an independent RC oscillator (can operate in Standby and Stop modes)
- Conditional reset
  - Reset (if watchdog activated) when the downcounter value becomes lower than 0x000
  - Reset (if watchdog activated) if the downcounter is reloaded outside the window

48.3 IWDG functional description

48.3.1 IWDG block diagram

*Figure 578* shows the functional blocks of the independent watchdog module.

1. The register interface is located in the VDD voltage domain. The watchdog function is located in the VDD voltage domain, still functional in Stop and Standby modes.
When the independent watchdog is started by writing the value 0x0000 CCCC in the *IWDG key register (IWDG_KR)*, the counter starts counting down from the reset value of 0xFFF. When it reaches the end of count value (0x000) a reset signal is generated (IWDG reset).

Whenever the key value 0x0000 AAAA is written in the *IWDG key register (IWDG_KR)*, the IWDG_RLR value is reloaded in the counter and the watchdog reset is prevented.

Once running, the IWDG cannot be stopped.

### 48.3.2 IWDG internal signals

*Table 392* gives the list of IWDG internal signals.

<table>
<thead>
<tr>
<th>Signal name</th>
<th>Signal type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lsi_ck</td>
<td>Digital</td>
<td>LSI clock</td>
</tr>
<tr>
<td>iwdg1_out_rst, iwdg2_out_rst</td>
<td>Digital</td>
<td>IWDG1 and IWDG2 reset signal outputs</td>
</tr>
</tbody>
</table>

### 48.3.3 Window option

The IWDG can also work as a window watchdog by setting the appropriate window in the *IWDG window register (IWDG_WINR)*.

If the reload operation is performed while the counter is greater than the value stored in the *IWDG window register (IWDG_WINR)*, then a reset is provided.

The default value of the *IWDG window register (IWDG_WINR)* is 0x0000 0FF, so if it is not updated, the window option is disabled.

As soon as the window value is changed, a reload operation is performed in order to reset the downcounter to the *IWDG reload register (IWDG_RLR)* value and ease the cycle number calculation to generate the next reload.

#### Configuring the IWDG when the window option is enabled

1. Enable the IWDG by writing 0x0000 CCCC in the *IWDG key register (IWDG_KR)*.
2. Enable register access by writing 0x0000 5555 in the *IWDG key register (IWDG_KR)*.
3. Write the IWDG prescaler by programming *IWDG prescaler register (IWDG_PR)* from 0 to 7.
4. Write the *IWDG reload register (IWDG_RLR)*.
5. Wait for the registers to be updated (IWDG_SR = 0x0000 0000).
6. Write to the *IWDG window register (IWDG_WINR)*. This automatically refreshes the counter value in the *IWDG reload register (IWDG_RLR)*.

*Note:* Writing the window value allows the counter value to be refreshed by the RLR when *IWDG status register (IWDG_SR)* is set to 0x0000 0000.

#### Configuring the IWDG when the window option is disabled

When the window option it is not used, the IWDG can be configured as follows:
1. Enable the IWDG by writing 0x0000 CCCC in the IWDG key register (IWDG_KR).
2. Enable register access by writing 0x0000 5555 in the IWDG key register (IWDG_KR).
3. Write the prescaler by programming the IWDG prescaler register (IWDG_PR) from 0 to 7.
4. Write the IWDG reload register (IWDG_RLR).
5. Wait for the registers to be updated (IWDG_SR = 0x0000 0000).
6. Refresh the counter value with IWDG_RLR (IWDG_KR = 0x0000 AAAA).

48.3.4 Hardware watchdog

If the “Hardware watchdog” feature is enabled through the device option bits, the watchdog is automatically enabled at power-on, and generates a reset unless the IWDG key register (IWDG_KR) is written by the software before the counter reaches end of count or if the downcounter is reloaded inside the window.

48.3.5 Low-power freeze

Depending on the IWDG_FZ_STOP and IWDG_FZ_STBY options configuration, the IWDG can continue counting or not during the Stop mode and the Standby mode, respectively. If the IWDG is kept running during Stop or Standby modes, it can wake up the device from this mode. Refer to Section 4.4.5: Description of user and system option bytes for more details.

48.3.6 Register access protection

Write access to IWDG prescaler register (IWDG_PR), IWDG reload register (IWDG_RLR) and IWDG window register (IWDG_WINR) is protected. To modify them, the user must first write the code 0x0000 5555 in the IWDG key register (IWDG_KR). A write access to this register with a different value breaks the sequence and register access is protected again. This is the case of the reload operation (writing 0x0000 AAAA).

A status register is available to indicate that an update of the prescaler or of the downcounter reload value or of the window value is ongoing.

48.3.7 Debug mode

When the device enters Debug mode (core halted), the IWDG counter either continues to work normally or stops, depending on the configuration of the corresponding bit in DBGMCU freeze register.
48.4 **IWDG registers**

Refer to Section 1.2 on page 106 for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

48.4.1 **IWDG key register (IWDG_KR)**

Address offset: 0x00

Reset value: 0x0000 0000 (reset by Standby mode)

Bits 31:16: Reserved, must be kept at reset value.

Bits 15:0 **KEY[15:0]:** Key value (write only, read 0x0000)

These bits must be written by software at regular intervals with the key value 0xAAAA, otherwise the watchdog generates a reset when the counter reaches 0.

Writing the key value 0x5555 to enable access to the IWDG_PR, IWDG_RLR and IWDG_WINR registers (see Section 48.3.6: Register access protection)

Writing the key value 0xCCCC starts the watchdog (except if the hardware watchdog option is selected)
### 48.4.2 IWDG prescaler register (IWDG_PR)

**Address offset:** 0x04  
**Reset value:** 0x0000 0000

<table>

</tbody>
</table>

Bits 31:3  **Reserved, must be kept at reset value.**

Bits 2:0  **PR[2:0]: Prescaler divider**

These bits are write access protected see Section 48.3.6: Register access protection. They are written by software to select the prescaler divider feeding the counter clock. PVU bit of the IWDG status register (IWDG_SR) must be reset in order to be able to change the prescaler divider.

- 000: divider /4
- 001: divider /8
- 010: divider /16
- 011: divider /32
- 100: divider /64
- 101: divider /128
- 110: divider /256
- 111: divider /256

**Note:** Reading this register returns the prescaler value from the VDD voltage domain. This value may not be up to date/valid if a write operation to this register is ongoing. For this reason the value read from this register is valid only when the PVU bit in the IWDG status register (IWDG_SR) is reset.
48.4.3  IWDG reload register (IWDG_RLR)

Address offset: 0x08

<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 31:12  Reserved, must be kept at reset value.

Bits 11:0  **RL[11:0]**: Watchdog counter reload value

These bits are write access protected see Register access protection. They are written by software to define the value to be loaded in the watchdog counter each time the value 0xAAAA is written in the IWDG key register (IWDGKR). The watchdog counter counts down from this value. The timeout period is a function of this value and the clock prescaler. Refer to the datasheet for the timeout information.

The RVU bit in the IWDG status register (IWDG_SR) must be reset to be able to change the reload value.

*Note*: Reading this register returns the reload value from the VDD voltage domain. This value may not be up to date/valid if a write operation to this register is ongoing on it. For this reason the value read from this register is valid only when the RVU bit in the IWDG status register (IWDG_SR) is reset.
### 48.4.4 IWDG status register (IWDG_SR)

Address offset: 0x0C  
Reset value: 0x0000 0000 (not reset by Standby mode)

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>

<td>6</td>
<td>5</td>
<td>4</td>
<td>3</td>
<td>2</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bits 31:3 Reserved, must be kept at reset value.

- **Bit 2 WVU**: Watchdog counter window value update
  This bit is set by hardware to indicate that an update of the window value is ongoing. It is reset by hardware when the reload value update operation is completed in the $V_{DD}$ voltage domain (takes up to five RC 40 kHz cycles).
  Window value can be updated only when WVU bit is reset.

- **Bit 1 RVU**: Watchdog counter reload value update
  This bit is set by hardware to indicate that an update of the reload value is ongoing. It is reset by hardware when the reload value update operation is completed in the $V_{DD}$ voltage domain (takes up to five RC 40 kHz cycles).
  Reload value can be updated only when RVU bit is reset.

- **Bit 0 PVU**: Watchdog prescaler value update
  This bit is set by hardware to indicate that an update of the prescaler value is ongoing. It is reset by hardware when the prescaler update operation is completed in the $V_{DD}$ voltage domain (takes up to five RC 40 kHz cycles).
  Prescaler value can be updated only when PVU bit is reset.

**Note:** If several reload, prescaler, or window values are used by the application, it is mandatory to wait until RVU bit is reset before changing the reload value, to wait until PVU bit is reset before changing the prescaler value, and to wait until WVU bit is reset before changing the window value. However, after updating the prescaler and/or the reload/window value it is not necessary to wait until RVU or PVU or WVU is reset before continuing code execution except in case of low-power mode entry.
48.4.5 IWDG window register (IWDG_WINR)

Address offset: 0x10
Reset value: 0x0000 0FFF (reset by Standby mode)

</tr>
</thead>
</table>

|             |             |             |             |             |             |WIN[11:0]|
|-------------|-------------|-------------|-------------|-------------|-------------|
| rw          | rw          | rw          | rw          | rw          | rw          | rw          | rw          | rw          | rw          | rw          | rw          | rw          | rw          | rw          |

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **WIN[11:0]**: Watchdog counter window value

These bits are write access protected, see Section 48.3.6, they contain the high limit of the window value to be compared with the downcounter.

To prevent a reset, the downcounter must be reloaded when its value is lower than the window register value and greater than 0x0

The WVU bit in the IWDG status register (IWDG_SR) must be reset in order to be able to change the reload value.

**Note**: Reading this register returns the reload value from the VDD voltage domain. This value may not be valid if a write operation to this register is ongoing. For this reason the value read from this register is valid only when the WVU bit in the IWDG status register (IWDG_SR) is reset.
### 48.4.6 IWDG register map

Refer to *Section 2.3 on page 134* for the register boundary addresses.
49 Real-time clock (RTC)

49.1 Introduction

The RTC provides an automatic wake-up to manage all low-power modes.

The real-time clock (RTC) is an independent BCD timer/counter. The RTC provides a time-of-day clock/calendar with programmable alarm interrupts.

The RTC includes also a periodic programmable wake-up flag with interrupt capability.

Two 32-bit registers contain the seconds, minutes, hours (12- or 24-hour format), day (day of week), date (day of month), month, and year, expressed in binary coded decimal format (BCD). The sub-seconds value is also available in binary format.

Compensations for 28-, 29- (leap year), 30-, and 31-day months are performed automatically. Daylight saving time compensation can also be performed.

Additional 32-bit registers contain the programmable alarm subseconds, seconds, minutes, hours, day, and date.

A digital calibration feature is available to compensate for any deviation in crystal oscillator accuracy.

After Backup domain reset, all RTC registers are protected against possible parasitic write accesses.

As long as the supply voltage remains in the operating range, the RTC never stops, regardless of the device status (Run mode, low-power mode or under reset).
49.2 RTC main features

The RTC unit main features are the following (see Figure 580: Detailed RTC block diagram):

- Calendar with subseconds, seconds, minutes, hours (12 or 24 format), day (day of week), date (day of month), month, and year.
- Daylight saving compensation programmable by software.
- Programmable alarm with interrupt function. The alarm can be triggered by any combination of the calendar fields.
- Automatic wake-up unit generating a periodic flag that triggers an automatic wake-up interrupt.
- Reference clock detection: a more precise second source clock (50 or 60 Hz) can be used to enhance the calendar precision.
- Accurate synchronization with an external clock using the subsecond shift feature.
- Digital calibration circuit (periodic counter correction): 0.95 ppm accuracy, obtained in a calibration window of several seconds.
- Time-stamp function for event saving
- Tamper detection event with configurable filter and internal pull-up
- Maskable interrupts/events:
  - Alarm A
  - Alarm B
  - Wake-up interrupt
  - Time-stamp
  - Tamper detection
- 32 backup registers.

49.3 RTC functional description

49.3.1 RTC block diagram

Figure 579. RTC block overview

1. x is an integer index starting from 1, the number of tampers depends on devices.
Figure 580. Detailed RTC block diagram

1. x is an integer index starting from 1, the number of tampers depends on devices.
The RTC includes:

- **Two alarms**
- **Three tamper events from I/Os**
  - Tamper detection erases the backup registers and the backup RAM.
  - In addition, the tamper detection forbids software access to the backup SRAM until its erase operation is finished. Refer to Section 49.3.15: Tamper detection
  - The tamper3 event detection is generated either by an event on I/O, or by an over or under voltage of the RTC power supply domain, or by an over or under temperature detection. These voltage and temperature monitor detections are enabled in the PWR control register 2 (PWR_CR2).
- **One timestamp event from I/O**
- **Tamper event detection can generate a timestamp event**
- **Timestamp can be generated when a switch to V_{BAT} occurs**
- **32 x 32-bit backup registers**
  - The backup registers (RTC_BKPxR) are implemented in the RTC domain that remains powered-on by V_{BAT} when the VDD power is switched off.
- **Output functions:** RTC_OUT which selects one of the following two outputs:
  - RTC_CALIB: 512 Hz or 1Hz clock output (with an LSE frequency of 32.768 kHz). This output is enabled by setting the COE bit in the RTC_CR register.
  - RTC_ALARM: This output is enabled by configuring the OSEL[1:0] bits in the RTC_CR register which select the Alarm A, Alarm B or Wakeup outputs.
- **Input functions:**
  - RTC_TS: timestamp event
  - RTC_TAMP1: tamper1 event detection
  - RTC_TAMP2: tamper2 event detection
  - RTC_TAMP3: tamper3 event detection
  - RTC_REFIN: 50 or 60 Hz reference clock input

1. Refer to device datasheet for RTC_TAMPx availability.
49.3.2  RTC pins and internal signals

49.3.3  GPIOs controlled by the RTC

RTC_OUT, RTC_Ts and RTC_TAMP1 are mapped on the same pin (PC13). PC13 pin configuration is controlled by the RTC, whatever the PC13 GPIO configuration, except for the RTC_ALARM output open-drain mode. The RTC functions mapped on PC13 are available in all low-power modes and in VBAT mode.

The output mechanism follows the priority order shown in Table 395.

Table 395. RTC pin PC13 configuration

<table>
<thead>
<tr>
<th>PC13 Pin configuration and function</th>
<th>OSEL[1:0] bits (RTC_ALARM output enable)</th>

The table below summarizes the RTC pins and functions capability in all modes.
49.3.4 Clock and prescalers

The RTC clock source (RTCCLK) is selected through the clock controller among the LSE clock, the LSI oscillator clock, and the HSE clock. For more information on the RTC clock source configuration, refer to Section 9: Reset and Clock Control (RCC).

A programmable prescaler stage generates a 1 Hz clock which is used to update the calendar. To minimize power consumption, the prescaler is split into 2 programmable prescalers (see Figure 580: Detailed RTC block diagram):

- A 7-bit asynchronous prescaler configured through the PREDIV_A bits of the RTC_PRER register.
- A 15-bit synchronous prescaler configured through the PREDIV_S bits of the RTC_PRER register.

Note: When both prescalers are used, it is recommended to configure the asynchronous prescaler to a high value to minimize consumption.

The asynchronous prescaler division factor is set to 128, and the synchronous division factor to 256, to obtain an internal clock frequency of 1 Hz (ck_spre) with an LSE frequency of 32.768 kHz.

The minimum division factor is 1 and the maximum division factor is $2^{22}$.

This corresponds to a maximum input frequency of around 4 MHz.

$f_{ck\_apre}$ is given by the following formula:

$$f_{ck\_apre} = \frac{f_{RTCCLK}}{PREDIV_A + 1}$$

The $ck\_apre$ clock is used to clock the binary RTC_SSR subseconds downcounter. When it reaches 0, RTC_SSR is reloaded with the content of PREDIV_S.

$f_{ck\_spre}$ is given by the following formula:

$$f_{ck\_spre} = \frac{f_{RTCCLK}}{(PREDIV_S + 1) \times (PREDIV_A + 1)}$$

The ck_spre clock can be used either to update the calendar or as timebase for the 16-bit wake-up auto-reload timer. To obtain short timeout periods, the 16-bit wake-up auto-reload timer can also run with the RTCCLK divided by the programmable 4-bit asynchronous prescaler (see Section 49.3.7: Periodic auto-wake-up for details).

### 49.3.5 Real-time clock and calendar

The RTC calendar time and date registers are accessed through shadow registers which are synchronized with PCLK (APB clock). They can also be accessed directly in order to avoid waiting for the synchronization duration.

- RTC_SSR for the subseconds
- RTC_TR for the time
- RTC_DR for the date

Every RTCCLK period, the current calendar value is copied into the shadow registers, and the RSF bit of RTC_ISR register is set (see Section 49.6.4: RTC initialization and status register (RTC_ISR)). The copy is not performed in Stop and Standby mode. When exiting these modes, the shadow registers are updated after up to 1 RTCCLK period.

When the application reads the calendar registers, it accesses the content of the shadow registers. It is possible to make a direct access to the calendar registers by setting the BYPSHAD control bit in the RTC_CR register. By default, this bit is cleared, and the user accesses the shadow registers.

When reading the RTC_SSR, RTC_TR or RTC_DR registers in BYPSHAD=0 mode, the frequency of the APB clock \( f_{APB} \) must be at least 7 times the frequency of the RTC clock \( f_{RTCCLK} \).

The shadow registers are reset by system reset.

### 49.3.6 Programmable alarms

The RTC unit provides programmable alarm: Alarm A and Alarm B. The description below is given for Alarm A, but can be translated in the same way for Alarm B.

The programmable alarm function is enabled through the ALRAE bit in the RTC_CR register. The ALRAF is set to 1 if the calendar subseconds, seconds, minutes, hours, date or day match the values programmed in the alarm registers RTC_ALRMASSR and RTC_ALRMAR. Each calendar field can be independently selected through the MSKx bits of the RTC_ALRMAR register, and through the MASKSSx bits of the RTC_ALRMASSR register. The alarm interrupt is enabled through the ALRAIE bit in the RTC_CR register.

**Caution:** If the seconds field is selected (MSK1 bit reset in RTC_ALRMAR), the synchronous prescaler division factor set in the RTC_PRER register must be at least 3 to ensure correct behavior.

Alarm A and Alarm B (if enabled by bits OSEL[1:0] in RTC_CR register) can be routed to the RTC_ALARM output. RTC_ALARM output polarity can be configured through bit POL the RTC_CR register.

### 49.3.7 Periodic auto-wake-up

The periodic wake-up flag is generated by a 16-bit programmable auto-reload down-counter. The wake-up timer range can be extended to 17 bits.

The wake-up function is enabled through the WUTE bit in the RTC_CR register.
The wake-up timer clock input can be:

- **RTC clock (RTCCLOCK) divided by 2, 4, 8, or 16.**
  
  When RTCCLOCK is LSE(32.768 kHz), this allows to configure the wake-up interrupt period from 122 µs to 32 s, with a resolution down to 61 µs.

- **ck_spread (usually 1 Hz internal clock)**
  
  When ck_spread frequency is 1 Hz, this allows to achieve a wake-up time from 1 s to around 36 hours with one-second resolution. This large programmable time range is divided in 2 parts:
  - from 1 s to 18 hours when WUCKSEL[2:1] = 10
  - and from around 18 h to 36 h when WUCKSEL[2:1] = 11. In this last case, 216 is added to the 16-bit counter current value. When the initialization sequence is complete (see Programming the wake-up timer on page 2065), the timer starts counting down. When the wake-up function is enabled, the down-counting remains active in low-power modes. In addition, when it reaches 0, the WUTF flag is set in the RTC_ISR register, and the wake-up counter is automatically reloaded with its reload value (RTC_WUTR register value).

  The WUTF flag must then be cleared by software.

  When the periodic wake-up interrupt is enabled by setting the WUTIE bit in the RTC_CR register, it can exit the device from low-power modes.

  The periodic wake-up flag can be routed to the RTC_ALARM output provided it has been enabled through bits OSEL[1:0] of RTC_CR register. RTC_ALARM output polarity can be configured through the POL bit in the RTC_CR register.

  System reset, as well as low-power modes (Sleep, Stop and Standby) have no influence on the wake-up timer.

### 49.3.8 RTC initialization and configuration

#### RTC register access

The RTC registers are 32-bit registers. The APB interface introduces 2 wait-states in RTC register accesses except on read accesses to calendar shadow registers when BYPShAD=0.

#### RTC register write protection

After system reset, the RTC registers are protected against parasitic write access by clearing the DBP bit in the PWR_CR1 register (refer to the power control section). DBP bit must be set in order to enable RTC registers write access.

After Backup domain reset, all the RTC registers are write-protected. Writing to the RTC registers is enabled by writing a key into the Write Protection register, RTC_WPR.

The following steps are required to unlock the write protection on all the RTC registers except for RTC_TAMPCR, RTC_BKPxR, RTC_OR and RTC_ISR[13:8].

1. Write ‘0xCA’ into the RTC_WPR register.
2. Write ‘0x53’ into the RTC_WPR register.

Writing a wrong key reactivates the write protection.

The protection mechanism is not affected by system reset.
Calendar initialization and configuration

To program the initial time and date calendar values, including the time format and the prescaler configuration, the following sequence is required:

1. Set INIT bit to 1 in the RTC_ISR register to enter initialization mode. In this mode, the calendar counter is stopped and its value can be updated.
2. Poll INITF bit of in the RTC_ISR register. The initialization phase mode is entered when INITF is set to 1. It takes around 2 RTCCLK clock cycles (due to clock synchronization).
3. To generate a 1 Hz clock for the calendar counter, program both the prescaler factors in RTC_PRER register.
4. Load the initial time and date values in the shadow registers (RTC_TR and RTC_DR), and configure the time format (12 or 24 hours) through the FMT bit in the RTC_CR register.
5. Exit the initialization mode by clearing the INIT bit. The actual calendar counter value is then automatically loaded and the counting restarts after 4 RTCCLK clock cycles.

When the initialization sequence is complete, the calendar starts counting.

Note: After a system reset, the application can read the INITS flag in the RTC_ISR register to check if the calendar has been initialized or not. If this flag equals 0, the calendar has not been initialized since the year field is set at its Backup domain reset default value (0x00).

To read the calendar after initialization, the software must first check that the RSF flag is set in the RTC_ISR register.

Daylight saving time

The daylight saving time management is performed through bits SUB1H, ADD1H, and BKP of the RTC_CR register.

Using SUB1H or ADD1H, the software can subtract or add one hour to the calendar in one single operation without going through the initialization procedure.

In addition, the software can use the BKP bit to memorize this operation.

Programming the alarm

A similar procedure must be followed to program or update the programmable alarms. The procedure below is given for Alarm A but can be translated in the same way for Alarm B.

1. Clear ALRAE in RTC_CR to disable Alarm A.
2. Program the Alarm A registers (RTC_ALRMASSR/RTC_ALRMAR).
3. Set ALRAE in the RTC_CR register to enable Alarm A again.

Note: Each change of the RTC_CR register is taken into account after around 2 RTCCLK clock cycles due to clock synchronization.

Programming the wake-up timer

The following sequence is required to configure or change the wake-up timer auto-reload value (WUT[15:0] in RTC_WUTR):
1. Clear WUTE in RTC_CR to disable the wake-up timer.
2. Poll WUTWF until it is set in RTC_ISR to make sure the access to wake-up auto-reload counter and to WUCKSEL[2:0] bits is allowed. It takes around 2 RTCCCLK clock cycles (due to clock synchronization).
3. Program the wake-up auto-reload value WUT[15:0], and the wake-up clock selection (WUCKSEL[2:0] bits in RTC_CR). Set WUTE in RTC_CR to enable the timer again. The wake-up timer restarts down-counting. The WUTWF bit is cleared up to 2 RTCCCLK clock cycles after WUTE is cleared, due to clock synchronization.

49.3.9 Reading the calendar

When BYPSHAD control bit is cleared in the RTC_CR register

To read the RTC calendar registers (RTC_SSR, RTC_TR and RTC_DR) properly, the APB clock frequency ($f_{PCLK}$) must be equal to or greater than seven times the RTC clock frequency ($f_{RTCCCLK}$). This ensures a secure behavior of the synchronization mechanism.

If the APB clock frequency is less than seven times the RTC clock frequency, the software must read the calendar time and date registers twice. If the second read of the RTC_TR gives the same result as the first read, this ensures that the data is correct. Otherwise a third read access must be done. In any case the APB clock frequency must never be lower than the RTC clock frequency.

The RSF bit is set in RTC_ISR register each time the calendar registers are copied into the RTC_SSR, RTC_TR and RTC_DR shadow registers. The copy is performed every RTCCCLK cycle. To ensure consistency between the 3 values, reading either RTC_SSR or RTC_TR locks the values in the higher-order calendar shadow registers until RTC_DR is read. In case the software makes read accesses to the calendar in a time interval smaller than 1 RTCCCLK period: RSF must be cleared by software after the first calendar read, and then the software must wait until RSF is set before reading again the RTC_SSR, RTC_TR and RTC_DR registers.

After waking up from low-power mode (Stop or Standby), RSF must be cleared by software. The software must then wait until it is set again before reading the RTC_SSR, RTC_TR and RTC_DR registers.

The RSF bit must be cleared after wake-up and not before entering low-power mode.

After a system reset, the software must wait until RSF is set before reading the RTC_SSR, RTC_TR and RTC_DR registers. Indeed, a system reset resets the shadow registers to their default values.

After an initialization (refer to Calendar initialization and configuration on page 2065): the software must wait until RSF is set before reading the RTC_SSR, RTC_TR and RTC_DR registers.

After synchronization (refer to Section 49.3.11: RTC synchronization): the software must wait until RSF is set before reading the RTC_SSR, RTC_TR and RTC_DR registers.

When the BYPSHAD control bit is set in the RTC_CR register (bypass shadow registers)

Reading the calendar registers gives the values from the calendar counters directly, thus eliminating the need to wait for the RSF bit to be set. This is especially useful after exiting from low-power modes (STOP or Standby), since the shadow registers are not updated during these modes.
When the BYPASHAD bit is set to 1, the results of the different registers might not be coherent with each other if an RTCCLK edge occurs between two read accesses to the registers. Additionally, the value of one of the registers may be incorrect if an RTCCLK edge occurs during the read operation. The software must read all the registers twice, and then compare the results to confirm that the data is coherent and correct. Alternatively, the software can just compare the two results of the least-significant calendar register.

Note: While BYPASHAD=1, instructions which read the calendar registers require one extra APB cycle to complete.

### 49.3.10 Resetting the RTC

The calendar shadow registers (RTC_SSR, RTC_TR and RTC_DR) and some bits of the RTC status register (RTC_ISR) are reset to their default values by all available system reset sources.

On the contrary, the following registers are reset to their default values by a Backup domain reset and are not affected by a system reset: the RTC current calendar registers, the RTC control register (RTC_CR), the prescaler register (RTC_PRER), the RTC calibration register (RTC_CALR), the RTC shift register (RTC_SHIFTR), the RTC timestamp registers (RTC_TSSSR, RTC_TSTR and RTC_TSDR), the RTC tamper configuration register (RTC_TAMPCR), the RTC backup registers (RTC_BKPxR), the wake-up timer register (RTC_WUTR), the Alarm A and Alarm B registers (RTC_ALRMASSR/RTC_ALRMAR and RTC_ALRMBSSR/RTC_ALRMBR), and the Option register (RTC_OR).

In addition, when it is clocked by the LSE, the RTC keeps on running under system reset if the reset source is different from the Backup domain reset one (refer to the RTC clock section of the Reset and clock controller for details on the list of RTC clock sources not affected by system reset). When a Backup domain reset occurs, the RTC is stopped and all the RTC registers are set to their reset values.

### 49.3.11 RTC synchronization

The RTC can be synchronized to a remote clock with a high degree of precision. After reading the sub-second field (RTC_SSR or RTC_TSSSR), a calculation can be made of the precise offset between the times being maintained by the remote clock and the RTC. The RTC can then be adjusted to eliminate this offset by “shifting” its clock by a fraction of a second using RTC_SHIFTR.

RTC_SSR contains the value of the synchronous prescaler counter. This allows one to calculate the exact time being maintained by the RTC down to a resolution of $1 / (PREDIV_S + 1)$ seconds. As a consequence, the resolution can be improved by increasing the synchronous prescaler value ($PREDIV_S[14:0]$). The maximum resolution allowed (30.52 μs with a 32768 Hz clock) is obtained with $PREDIV_S$ set to $0x7FFF$.

However, increasing $PREDIV_S$ means that $PREDIV_A$ must be decreased in order to maintain the synchronous prescaler output at 1 Hz. In this way, the frequency of the asynchronous prescaler output increases, which may increase the RTC dynamic consumption.

The RTC can be finely adjusted using the RTC shift control register (RTC_SHIFTR). Writing to RTC_SHIFTR can shift (either delay or advance) the clock by up to a second with a resolution of $1 / (PREDIV_S + 1)$ seconds. The shift operation consists of adding the $SUBFS[14:0]$ value to the synchronous prescaler counter $SS[15:0]$: this will delay the clock.
If at the same time the ADD1S bit is set, this results in adding one second and at the same time subtracting a fraction of second, so this will advance the clock.

**Caution:** Before initiating a shift operation, the user must check that SS[15] = 0 in order to ensure that no overflow will occur.

As soon as a shift operation is initiated by a write to the RTC_SHIFTR register, the SHPF flag is set by hardware to indicate that a shift operation is pending. This bit is cleared by hardware as soon as the shift operation has completed.

**Caution:** This synchronization feature is not compatible with the reference clock detection feature: firmware must not write to RTC_SHIFTR when REFCKON=1.

### 49.3.12 RTC reference clock detection

The update of the RTC calendar can be synchronized to a reference clock, RTC_REFIN, which is usually the mains frequency (50 or 60 Hz). The precision of the RTC_REFIN reference clock should be higher than the 32.768 kHz LSE clock. When the RTC_REFIN detection is enabled (REFCKON bit of RTC_CR set to 1), the calendar is still clocked by the LSE, and RTC_REFIN is used to compensate for the imprecision of the calendar update frequency (1 Hz).

Each 1 Hz clock edge is compared to the nearest RTC_REFIN clock edge (if one is found within a given time window). In most cases, the two clock edges are properly aligned. When the 1 Hz clock becomes misaligned due to the imprecision of the LSE clock, the RTC shifts the 1 Hz clock a bit so that future 1 Hz clock edges are aligned. Thanks to this mechanism, the calendar becomes as precise as the reference clock.

The RTC detects if the reference clock source is present by using the 256 Hz clock (ck_apre) generated from the 32.768 kHz quartz. The detection is performed during a time window around each of the calendar updates (every 1 s). The window equals 7 ck_apre periods when detecting the first reference clock edge. A smaller window of 3 ck_apre periods is used for subsequent calendar updates.

Each time the reference clock is detected in the window, the synchronous prescaler which outputs the ck_spre clock is forced to reload. This has no effect when the reference clock and the 1 Hz clock are aligned because the prescaler is being reloaded at the same moment. When the clocks are not aligned, the reload shifts future 1 Hz clock edges a little for them to be aligned with the reference clock.

If the reference clock halts (no reference clock edge occurred during the 3 ck_apre window), the calendar is updated continuously based solely on the LSE clock. The RTC then waits for the reference clock using a large 7 ck_apre period detection window centered on the ck_spre edge.

When the RTC_REFIN detection is enabled, PREDIV_A and PREDIV_S must be set to their default values:
- PREDIV_A = 0x007F
- PREDIV_S = 0x00FF

**Note:** RTC_REFIN clock detection is not available in Standby mode.

### 49.3.13 RTC smooth digital calibration

The RTC frequency can be digitally calibrated with a resolution of about 0.954 ppm with a range from -487.1 ppm to +488.5 ppm. The correction of the frequency is performed using
series of small adjustments (adding and/or subtracting individual RTCCLK pulses). These adjustments are fairly well distributed so that the RTC is well calibrated even when observed over short durations of time.

The smooth digital calibration is performed during a cycle of about $2^{20}$ RTCCLK pulses, or 32 seconds when the input frequency is 32768 Hz. This cycle is maintained by a 20-bit counter, cal_cnt[19:0], clocked by RTCCLK.

The smooth calibration register (RTC_CALR) specifies the number of RTCCLK clock cycles to be masked during the 32-second cycle:

- Setting the bit CALM[0] to 1 causes exactly one pulse to be masked during the 32-second cycle.
- Setting CALM[1] to 1 causes two additional cycles to be masked.
- Setting CALM[2] to 1 causes four additional cycles to be masked.
- and so on up to CALM[8] set to 1 which causes 256 clocks to be masked.

**Note:** CALM[8:0] (RTC_CALR) specifies the number of RTCCLK pulses to be masked during the 32-second cycle. Setting the bit CALM[0] to '1' causes exactly one pulse to be masked during the 32-second cycle at the moment when cal_cnt[19:0] is 0x80000; CALM[1]=1 causes two other cycles to be masked (when cal_cnt is 0x40000 and 0xC0000); CALM[2]=1 causes four other cycles to be masked (cal_cnt = 0x20000/0x60000/0xA0000/0xE0000); and so on up to CALM[8]=1 which causes 256 clocks to be masked (cal_cnt = 0xXX800).

While CALM allows the RTC frequency to be reduced by up to 487.1 ppm with fine resolution, the bit CALP can be used to increase the frequency by 488.5 ppm. Setting CALP to ‘1’ effectively inserts an extra RTCCLK pulse every 211 RTCCLK cycles, which means that 512 clocks are added during every 32-second cycle.

Using CALM together with CALP, an offset ranging from -511 to +512 RTCCLK cycles can be added during the 32-second cycle, which translates to a calibration range of -487.1 ppm to +488.5 ppm with a resolution of about 0.954 ppm.

The formula to calculate the effective calibrated frequency (Fcal) given the input frequency (FRTCCLK) is as follows:

$$F_{cal} = F_{RTCCLK} \times \left[1 + \frac{(CALP \times 512 - CALM)}{220 + CALM - CALP \times 512}\right]$$

**Calibration when PREDIV_A<3**

The CALP bit can not be set to 1 when the asynchronous prescaler value (PREDIV_A bits in RTC_PRER register) is less than 3. If CALP was already set to 1 and PREDIV_A bits are set to a value less than 3, CALP is ignored and the calibration operates as if CALP was equal to 0.

To perform a calibration with PREDIV_A less than 3, the synchronous prescaler value (PREDIV_S) should be reduced so that each second is accelerated by 8 RTCCLK clock cycles, which is equivalent to adding 256 clock cycles every 32 seconds. As a result, between 255 and 256 clock pulses (corresponding to a calibration range from 243.3 to 244.1 ppm) can effectively be added during each 32-second cycle using only the CALM bits.

With a nominal RTCCLK frequency of 32768 Hz, when PREDIV_A equals 1 (division factor of 2), PREDIV_S should be set to 16379 rather than 16383 (4 less). The only other interesting case is when PREDIV_A equals 0, PREDIV_S should be set to 32759 rather than 32767 (8 less).

If PREDIV_S is reduced in this way, the formula given the effective frequency of the
calibrated input clock is as follows:

\[ F_{\text{CAL}} = F_{\text{RTCCLK}} \times \left[ 1 + \frac{(256 - \text{CALM})}{(2^{20} + \text{CALM} - 256)} \right] \]

In this case, \( \text{CALM}[7:0] \) equals 0x100 (the midpoint of the CALM range) is the correct setting if RTCCLK is exactly 32768.00 Hz.

**Verifying the RTC calibration**

RTC precision is ensured by measuring the precise frequency of RTCCLK and calculating the correct CALM value and CALP values. An optional 1 Hz output is provided to allow applications to measure and verify the RTC precision.

Measuring the precise frequency of the RTC over a limited interval can result in a measurement error of up to 2 RTCCLK clock cycles over the measurement period, depending on how the digital calibration cycle is aligned with the measurement period.

However, this measurement error can be eliminated if the measurement period is the same length as the calibration cycle period. In this case, the only error observed is the error due to the resolution of the digital calibration.

- By default, the calibration cycle period is 32 seconds.

Using this mode and measuring the accuracy of the 1 Hz output over exactly 32 seconds guarantees that the measure is within 0.477 ppm (0.5 RTCCLK cycles over 32 seconds, due to the limitation of the calibration resolution).

- \( \text{CALW16} \) bit of the RTC\_CALR register can be set to 1 to force a 16-second calibration cycle period.

In this case, the RTC precision can be measured during 16 seconds with a maximum error of 0.954 ppm (0.5 RTCCLK cycles over 16 seconds). However, since the calibration resolution is reduced, the long term RTC precision is also reduced to 0.954 ppm: CALM[0] bit is stuck at 0 when \( \text{CALW16} \) is set to 1.

- \( \text{CALW8} \) bit of the RTC\_CALR register can be set to 1 to force an 8-second calibration cycle period.

In this case, the RTC precision can be measured during 8 seconds with a maximum error of 1.907 ppm (0.5 RTCCLK cycles over 8s). The long term RTC precision is also reduced to 1.907 ppm: \( \text{CALM}[1:0] \) bits are stuck at 00 when \( \text{CALW8} \) is set to 1.

**Re-calibration on-the-fly**

The calibration register (RTC\_CALR) can be updated on-the-fly while RTC\_ISR/INITF=0, by using the follow process:

1. Poll the RTC\_ISR/RECALPF (re-calibration pending flag).
2. If it is set to 0, write a new value to RTC\_CALR, if necessary. RECALPF is then automatically set to 1
3. Within three \( \text{ck\_apre} \) cycles after the write operation to RTC\_CALR, the new calibration settings take effect.

**49.3.14 Time-stamp function**

Time-stamp is enabled by setting the TSE or ITSE bits of RTC\_CR register to 1.

When TSE is set:
The calendar is saved in the time-stamp registers (RTC_TSSSR, RTC_TSTR, RTC_TSDR) when a time-stamp event is detected on the RTC_TS pin.

When ITSE is set:

The calendar is saved in the time-stamp registers (RTC_TSSSR, RTC_TSTR, RTC_TSDR) when an internal time-stamp event is detected. The internal timestamp event is generated by the switch to the VBAT supply.

When a time-stamp event occurs, due to internal or external event, the time-stamp flag bit (TSF) in RTC_ISR register is set. In case the event is internal, the ITSF flag is also set in RTC_ISR register.

By setting the TSIE bit in the RTC_CR register, an interrupt is generated when a time-stamp event occurs.

If a new time-stamp event is detected while the time-stamp flag (TSF) is already set, the time-stamp overflow flag (TSOVF) flag is set and the time-stamp registers (RTC_TSTR and RTC_TSDR) maintain the results of the previous event.

Note: TSF is set 2 ck_apre cycles after the time-stamp event occurs due to synchronization process.

There is no delay in the setting of TSOVF. This means that if two time-stamp events are close together, TSOVF can be seen as ‘1’ while TSF is still ‘0’. As a consequence, it is recommended to poll TSOVF only after TSF has been set.

Caution: If a time-stamp event occurs immediately after the TSF bit is supposed to be cleared, then both TSF and TSOVF bits are set. To avoid masking a time-stamp event occurring at the same moment, the application must not write ‘0’ into TSF bit unless it has already read it to ‘1’.

Optionally, a tamper event can cause a time-stamp to be recorded. See the description of the TAMPTS control bit in Section 49.6.16: RTC tamper configuration register (RTC_TAMPCR).

49.3.15 Tamper detection

The RTC_TAMPx input events can be configured either for edge detection, or for level detection with filtering.

The tamper detection can be configured for the following purposes:
- erase the RTC backup registers and backup SRAM (default configuration)
- generate an interrupt, capable to wake-up from Stop and Standby modes
- generate a hardware trigger for the low-power timers

RTC backup registers

The backup registers (RTC_BKPxR) are not reset by system reset or when the device wakes up from Standby mode.

The backup registers are reset when a tamper detection event occurs (see Section 49.6.20: RTC backup registers (RTC_BKPxR) and Tamper detection initialization on page 2072) except if the TAMPxNOERASE bit is set, or if TAMPxMF is set in the RTC_TAMPCR register.
Tamper detection initialization

Each input can be enabled by setting the corresponding TAMPxE bits to 1 in the RTC_TAMPCR register.

Each RTC_TAMPx tamper detection input is associated with a flag TAMPxF in the RTC_ISR register.

When TAMPxMF is cleared:

The TAMPxF flag is asserted after the tamper event on the pin, with the latency provided below:

- 3 ck_apre cycles when TAMPFLT differs from 0x0 (Level detection with filtering)
- 3 ck_apre cycles when TAMPTS=1 (Timestamp on tamper event)
- No latency when TAMPFLT=0x0 (Edge detection) and TAMPTS=0

A new tamper occurring on the same pin during this period and as long as TAMPxF is set cannot be detected.

When TAMPxMF is set:

A new tamper occurring on the same pin cannot be detected during the latency described above and 2.5 ck_rtc additional cycles.

By setting the TAMPIE bit in the RTC_TAMPCR register, an interrupt is generated when a tamper detection event occurs (when TAMPxF is set). Setting TAMPIE is not allowed when one or more TAMPxMF is set.

When TAMPIE is cleared, each tamper pin event interrupt can be individually enabled by setting the corresponding TAMPxIE bit in the RTC_TAMPCR register. Setting TAMPxIE is not allowed when the corresponding TAMPxMF is set.

Trigger output generation on tamper event

The tamper event detection can be used as trigger input by the low-power timers.

When TAMPxMF bit in cleared in RTC_TAMPCR register, the TAMPxF flag must be cleared by software in order to allow a new tamper detection on the same pin.

When TAMPxMF bit is set, the TAMPxF flag is masked, and kept cleared in RTC_ISR register. This configuration allows to trig automatically the low-power timers in Stop mode, without requiring the system wakeup to perform the TAMPxF clearing. In this case, the backup registers are not cleared.

Timestamp on tamper event

With TAMPTS set to ‘1’, any tamper event causes a timestamp to occur. In this case, either the TSF bit or the TSOVF bit are set in RTC_ISR, in the same manner as if a normal timestamp event occurs. The affected tamper flag register TAMPxF is set at the same time that TSF or TSOVF is set.

Edge detection on tamper inputs

If the TAMPFLT bits are “00”, the RTC_TAMPx pins generate tamper detection events when either a rising edge or a falling edge is observed depending on the corresponding TAMPxTRG bit. The internal pull-up resistors on the RTC_TAMPx inputs are deactivated when edge detection is selected.
Caution: When using the edge detection, it is recommended to check by software the tamper pin level just after enabling the tamper detection (by reading the GPIO registers), and before writing sensitive values in the backup registers, to ensure that an active edge did not occur before enabling the tamper event detection.

When TAMPFLT="00" and TAMPxTRG = 0 (rising edge detection), a tamper event may be detected by hardware if the tamper input is already at high level before enabling the tamper detection.

After a tamper event has been detected and cleared, the RTC_TAMPx should be disabled and then re-enabled (TAMPxE set to 1) before re-programming the backup registers (RTC_BKPxR). This prevents the application from writing to the backup registers while the RTC_TAMPx input value still indicates a tamper detection. This is equivalent to a level detection on the RTC_TAMPx input.

Note: Tamper detection is still active when VDD power is switched off. To avoid unwanted resetting of the backup registers, the pin to which the RTC_TAMPx is mapped should be externally tied to the correct level.

Level detection with filtering on RTC_TAMPx inputs

Level detection with filtering is performed by setting TAMPFLT to a non-zero value. A tamper detection event is generated when either 2, 4, or 8 (depending on TAMPFLT) consecutive samples are observed at the level designated by the TAMPxTRG bits.

The RTC_TAMPx inputs are precharged through the I/O internal pull-up resistance before its state is sampled, unless disabled by setting TAMPPUDIS to 1. The duration of the precharge is determined by the TAMPPRCH bits, allowing for larger capacitances on the RTC_TAMPx inputs.

The trade-off between tamper detection latency and power consumption through the pull-up can be optimized by using TAMPFREQ to determine the frequency of the sampling for level detection.

Note: Refer to the datasheets for the electrical characteristics of the pull-up resistors.

49.3.16 Calibration clock output

When the COE bit is set to 1 in the RTC_CR register, a reference clock is provided on the RTC_CALIB device output.

If the COSEL bit in the RTC_CR register is reset and PREDIV_A = 0x7F, the RTC_CALIB frequency is fRTCCLK/64. This corresponds to a calibration output at 512 Hz for an RTCCLK frequency at 32.768 kHz. The RTC_CALIB duty cycle is irregular: there is a light jitter on falling edges. It is therefore recommended to use rising edges.

When COSEL is set and “PREDIV_S+1” is a non-zero multiple of 256 (i.e: PREDIV_S[7:0] = 0xFF), the RTC_CALIB frequency is fRTCCLK/(256 * (PREDIV_A+1)). This corresponds to a calibration output at 1 Hz for prescaler default values (PREDIV_A = 0x7F, PREDIV_S = 0xFF), with an RTCCLK frequency at 32.768 kHz. The 1 Hz output is affected when a shift operation is on going and may toggle during the shift operation (SHPF=1).

Note: When COSEL bit is cleared, the RTC_CALIB output is the output of the 6th stage of the asynchronous prescaler.

When COSEL bit is set, the RTC_CALIB output is the output of the 8th stage of the synchronous prescaler.
49.3.17 Alarm output

The OSEL[1:0] control bits in the RTC_CR register are used to activate the alarm output RTC_ALARM, and to select the function which is output. These functions reflect the contents of the corresponding flags in the RTC_ISR register.

The polarity of the output is determined by the POL control bit in RTC_CR so that the opposite of the selected flag bit is output when POL is set to 1.

Note: Once the RTC_ALARM output is enabled, it has priority over RTC_CALIB (COE bit is don't care and must be kept cleared).

49.4 RTC low-power modes

Table 398. Effect of low-power modes on RTC

<table>
<thead>
<tr>
<th>Mode</th>

</tr>
<tr>
<td></td>
<td>exit the Standby mode.</td>
</tr>
</tbody>
</table>

49.5 RTC interrupts

All RTC interrupts are connected to the EXTI controller. Refer to Section 21: Extended interrupt and event controller (EXTI).

To enable the RTC Alarm interrupt, the following sequence is required:
1. Configure and enable the EXTI line corresponding to the RTC Alarm event in interrupt mode and select the rising edge sensitivity.
2. Configure and enable the RTC_ALARM IRQ channel in the NVIC.
3. Configure the RTC to generate RTC alarms.

To enable the RTC Tamper interrupt, the following sequence is required:
1. Configure and enable the EXTI line corresponding to the RTC Tamper event in interrupt mode and select the rising edge sensitivity.
2. Configure and enable the RTC_TAMP_STAMP IRQ channel in the NVIC.
3. Configure the RTC to detect the RTC tamper event.

To enable the RTC TimeStamp interrupt, the following sequence is required:
1. Configure and enable the EXTI line corresponding to the RTC TimeStamp event in interrupt mode and select the rising edge sensitivity.
2. Configure and enable the RTC_TAMP_STAMP IRQ channel in the NVIC.
3. Configure the RTC to detect the RTC time-stamp event.
To enable the Wakeup timer interrupt, the following sequence is required:

1. Configure and enable the EXTI line corresponding to the Wakeup timer even in interrupt mode and select the rising edge sensitivity.
2. Configure and Enable the RTC_WKUP IRQ channel in the NVIC.
3. Configure the RTC to detect the RTC Wakeup timer event.

### Table 399. Interrupt control bits

1. Wakeup from STOP and Standby modes is possible only when the RTC clock source is LSE or LSI.

### 49.6 RTC registers

Refer to *Section 1.2 on page 106* of the reference manual for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by words (32-bit).

#### 49.6.1 RTC time register (RTC_TR)

The RTC_TR is the calendar time shadow register. This register must be written in initialization mode only. Refer to *Calendar initialization and configuration on page 2065* and *Reading the calendar on page 2066*.

This register is write protected. The write access procedure is described in *RTC register write protection on page 2064*.

Address offset: 0x00

Backup domain reset value: 0x0000 0000

System reset: 0x0000 0000 when BYPSHAD = 0. Not affected when BYPSHAD = 1.
49.6.2 RTC date register (RTC_DR)

The RTC_DR is the calendar date shadow register. This register must be written in initialization mode only. Refer to Calendar initialization and configuration on page 2065 and Reading the calendar on page 2066.

This register is write protected. The write access procedure is described in RTC register write protection on page 2064.

Address offset: 0x04

Backup domain reset value: 0x0000 2101

System reset: 0x0000 2101 when BYPSHAD = 0. Not affected when BYPSHAD = 1.

| Bits 31:24 | Reserved, must be kept at reset value. |
| Bits 23:20 | YT[3:0]: Year tens in BCD format |
| Bits 19:16 | YU[3:0]: Year units in BCD format |
| Bits 15:13 | WDU[2:0]: Week day units |
| | 000: forbidden |
| | 001: Monday |
| | ... |
| | 111: Sunday |
| Bit 12 | MT: Month tens in BCD format |
| Bits 11:8 | MU[3:0]: Month units in BCD format |
Bits 7:6  Reserved, must be kept at reset value.
Bits 5:4  DT[1:0]: Date tens in BCD format
Bits 3:0  DU[3:0]: Date units in BCD format
### 49.6.3 RTC control register (RTC_CR)

Address offset: 0x08  
Backup domain reset value: 0x0000 0000  
System reset: not affected

| Bit 31:25 | Reserved, must be kept at reset value. |
| Bit 24   | **ITSE**: timestamp on internal event enable  
|          | 0: internal event timestamp disabled  
|          | 1: internal event timestamp enabled |
| Bit 23   | **COE**: Calibration output enable  
|          | This bit enables the RTC_CALIB output  
|          | 0: Calibration output disabled  
|          | 1: Calibration output enabled |
| Bits 22:21 | **OSEL[1:0]**: Output selection  
|          | These bits are used to select the flag to be routed to RTC_ALARM output  
|          | 00: Output disabled  
|          | 01: Alarm A output enabled  
|          | 10: Alarm B output enabled  
|          | 11: Wake-up output enabled |
| Bit 20   | **POL**: Output polarity  
|          | This bit is used to configure the polarity of RTC_ALARM output  
|          | 0: The pin is high when ALRAF/ALRBF/WUTF is asserted (depending on OSEL[1:0])  
|          | 1: The pin is low when ALRAF/ALRBF/WUTF is asserted (depending on OSEL[1:0]). |
| Bit 19   | **COSEL**: Calibration output selection  
|          | When COE=1, this bit selects which signal is output on RTC_CALIB.  
|          | 0: Calibration output is 512 Hz (with default prescaler setting)  
|          | 1: Calibration output is 1 Hz (with default prescaler setting)  
|          | These frequencies are valid for RTCCLK at 32.768 kHz and prescalers at their default values (PREDIV_A=127 and PREDIV_S=255). Refer to Section 49.3.16: Calibration clock output |
| Bit 18   | **BKP**: Backup  
|          | This bit can be written by the user to memorize whether the daylight saving time change has been performed or not. |
Bit 17 **SUB1H**: Subtract 1 hour (winter time change)
When this bit is set, 1 hour is subtracted to the calendar time if the current hour is not 0. This bit is always read as 0.
Setting this bit has no effect when current hour is 0.
0: No effect
1: Subtracts 1 hour to the current time. This can be used for winter time change outside initialization mode.

Bit 16 **ADD1H**: Add 1 hour (summer time change)
When this bit is set, 1 hour is added to the calendar time. This bit is always read as 0.
0: No effect
1: Adds 1 hour to the current time. This can be used for summer time change outside initialization mode.

Bit 15 **TSIE**: Time-stamp interrupt enable
0: Time-stamp Interrupt disable
1: Time-stamp Interrupt enable

Bit 14 **WUTIE**: Wake-up timer interrupt enable
0: Wake-up timer interrupt disabled
1: Wake-up timer interrupt enabled

Bit 13 **ALRBE**: Alarm B interrupt enable
0: Alarm B Interrupt disable
1: Alarm B Interrupt enable

Bit 12 **ALRAE**: Alarm A interrupt enable
0: Alarm A interrupt disabled
1: Alarm A interrupt enabled

Bit 11 **TSE**: timestamp enable
0: timestamp disable
1: timestamp enable

Bit 10 **WUTE**: Wake-up timer enable
0: Wake-up timer disabled
1: Wake-up timer enabled

*Note: When the wake-up timer is disabled, wait for WUTWF=1 before enabling it again.*

Bit 9 **ALRBE**: Alarm B enable
0: Alarm B disabled
1: Alarm B enabled

Bit 8 **ALRAE**: Alarm A enable
0: Alarm A disabled
1: Alarm A enabled

Bit 7 Reserved, must be kept at reset value.

Bit 6 **FMT**: Hour format
0: 24 hour/day format
1: AM/PM hour format
Bit 5 **BYPHAD**: Bypass the shadow registers
   0: Calendar values (when reading from RTC_SSR, RTC_TR, and RTC_DR) are taken from the shadow registers, which are updated once every two RTCCLK cycles.
   1: Calendar values (when reading from RTC_SSR, RTC_TR, and RTC_DR) are taken directly from the calendar counters.
   Note: If the frequency of the APB clock is less than seven times the frequency of RTCCLK, BYPHAD must be set to ‘1’.

Bit 4 **REFCKON**: RTC_REFIN reference clock detection enable (50 or 60 Hz)
   0: RTC_REFIN detection disabled
   1: RTC_REFIN detection enabled
   Note: *PREDIV_S* must be 0x00FF.

Bit 3 **TSEDGE**: Time-stamp event active edge
   0: RTC_TS input rising edge generates a time-stamp event
   1: RTC_TS input falling edge generates a time-stamp event
   TSE must be reset when TSEDGE is changed to avoid unwanted TSF setting.

Bits 2:0 **WUCKSEL[2:0]**: Wake-up clock selection
   000: RTC/16 clock is selected
   001: RTC/8 clock is selected
   010: RTC/4 clock is selected
   011: RTC/2 clock is selected
   10x: ck_spre (usually 1 Hz) clock is selected
   11x: ck_spre (usually 1 Hz) clock is selected and $2^{16}$ is added to the WUT counter value
   (see note below)

   **Note:** Bits 7, 6 and 4 of this register can be written in initialization mode only (RTC_ISR/INITF = 1).

   **WUT** = Wake-up unit counter value. $WUT = (0x0000 \text{ to } 0xFFFF) + 0x10000$ added when $WUCKSEL[2:1 = 11]$.

   Bits 2 to 0 of this register can be written only when RTC_CR WUTE bit = 0 and RTC_ISR WUTWF bit = 1.

   It is recommended not to change the hour during the calendar hour increment as it could mask the incrementation of the calendar hour.

   ADD1H and SUB1H changes are effective in the next second.

   This register is write protected. The write access procedure is described in RTC register write protection on page 2064.

   **Caution:** TSE must be reset when TSEDGE is changed to avoid spuriously setting of TSF.
49.6.4 RTC initialization and status register (RTC_ISR)

This register is write protected (except for RTC_ISR[13:8] bits). The write access procedure is described in RTC register write protection on page 2064.

Address offset: 0x0C

Backup domain reset value: 0x0000 0007

System reset: not affected except INIT, INITF, and RSF bits which are cleared to ‘0’

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 ITSF: Internal tTime-stamp flag
This flag is set by hardware when a time-stamp on the internal event occurs.
This flag is cleared by software by writing 0, and must be cleared together with TSF bit by writing 0 in both bits.

Bit 16 RECALPF: Recalibration pending Flag
The RECALPF status flag is automatically set to ‘1’ when software writes to the RTC_CALR register, indicating that the RTC_CALR register is blocked. When the new calibration settings are taken into account, this bit returns to ‘0’. Refer to Re-calibration on-the-fly.

Bit 15 TAMP3F: RTC_TAMP3 detection flag
This flag is set by hardware when a tamper detection event is detected on the RTC_TAMP3 input.
It is cleared by software writing 0

Bit 14 TAMP2F: RTC_TAMP2 detection flag
This flag is set by hardware when a tamper detection event is detected on the RTC_TAMP2 input.
It is cleared by software writing 0

Bit 13 TAMP1F: RTC_TAMP1 detection flag
This flag is set by hardware when a tamper detection event is detected on the RTC_TAMP1 input.
It is cleared by software writing 0

Bit 12 TSOVF: Time-stamp overflow flag
This flag is set by hardware when a time-stamp event occurs while TSF is already set.
This flag is cleared by software by writing 0. It is recommended to check and then clear TSOVF only after clearing the TSF bit. Otherwise, an overflow might not be noticed if a time-stamp event occurs immediately before the TSF bit is cleared.

Bit 11 TSF: Time-stamp flag
This flag is set by hardware when a time-stamp event occurs.
This flag is cleared by software by writing 0. If ITSF flag is set, TSF must be cleared together with ITSF by writing 0 in both bits.
Bit 10 **WUTF**: Wake-up timer flag
This flag is set by hardware when the wake-up auto-reload counter reaches 0.
This flag is cleared by software by writing 0.
This flag must be cleared by software at least 1.5 RTCCLK periods before WUTF is set to 1 again.

Bit 9 **ALRBF**: Alarm B flag
This flag is set by hardware when the time/date registers (RTC_TR and RTC_DR) match the
Alarm B register (RTC_ALRMBR).
This flag is cleared by software by writing 0.

Bit 8 **ALRAF**: Alarm A flag
This flag is set by hardware when the time/date registers (RTC_TR and RTC_DR) match the
Alarm A register (RTC_ALRMAR).
This flag is cleared by software by writing 0.

Bit 7 **INIT**: Initialization mode
0: Free running mode
1: Initialization mode used to program time and date register (RTC_TR and RTC_DR), and
prescaler register (RTC_PRER). Counters are stopped and start counting from the new
value when INIT is reset.

Bit 6 **INITF**: Initialization flag
When this bit is set to 1, the RTC is in initialization state, and the time, date and prescaler
registers can be updated.
0: Calendar registers update is not allowed
1: Calendar registers update is allowed

Bit 5 **RSF**: Registers synchronization flag
This bit is set by hardware each time the calendar registers are copied into the shadow
registers (RTC_SSR, RTC_TR and RTC_DR). This bit is cleared by hardware in initialization
mode, while a shift operation is pending (SHPF=1), or when in bypass shadow register mode
(BYPShAD=1). This bit can also be cleared by software.
It is cleared either by software or by hardware in initialization mode.
0: Calendar shadow registers not yet synchronized
1: Calendar shadow registers synchronized

Bit 4 **INITS**: Initialization status flag
This bit is set by hardware when the calendar year field is different from 0 (Backup domain
reset state).
0: Calendar has not been initialized
1: Calendar has been initialized

Bit 3 **SHPF**: Shift operation pending
0: No shift operation is pending
1: A shift operation is pending
This flag is set by hardware as soon as a shift operation is initiated by a write to the
RTC_SHIFTR register. It is cleared by hardware when the corresponding shift operation has
been executed. Writing to the SHPF bit has no effect.
Bit 2  **WUTWF**: Wake-up timer write flag  
This bit is set by hardware up to 2 RTCCLK cycles after the WUTE bit has been set to 0 in RTC_CR, and is cleared up to 2 RTCCLK cycles after the WUTE bit has been set to 1. The wake-up timer values can be changed when WUTE bit is cleared and WUTWF is set.  
0: Wake-up timer configuration update not allowed  
1: Wake-up timer configuration update allowed

Bit 1  **ALRBWF**: Alarm B write flag  
This bit is set by hardware when Alarm B values can be changed, after the ALRBE bit has been set to 0 in RTC_CR.  
It is cleared by hardware in initialization mode.  
0: Alarm B update not allowed  
1: Alarm B update allowed

Bit 0  **ALRAWF**: Alarm A write flag  
This bit is set by hardware when Alarm A values can be changed, after the ALRAE bit has been set to 0 in RTC_CR.  
It is cleared by hardware in initialization mode.  
0: Alarm A update not allowed  
1: Alarm A update allowed

**Note:** The bits ALRAF, ALRBF, WUTF and TSF are cleared 2 APB clock cycles after programming them to 0.
49.6.5 RTC prescaler register (RTC_PRER)

This register must be written in initialization mode only. The initialization must be performed in two separate write accesses. Refer to Calendar initialization and configuration on page 2065.

This register is write protected. The write access procedure is described in RTC register write protection on page 2064.

Address offset: 0x10

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:16 PREDIV_A[6:0]: Asynchronous prescaler factor
This is the asynchronous division factor:
ck_apre frequency = RTCCLK frequency/(PREDIV_A+1)

Bit 15 Reserved, must be kept at reset value.

Bits 14:0 PREDIV_S[14:0]: Synchronous prescaler factor
This is the synchronous division factor:
ck_spre frequency = ck_apre frequency/(PREDIV_S+1)
49.6.6 RTC wake-up timer register (RTC_WUTR)

This register can be written only when WUTWF is set to 1 in RTC_ISR.

This register is write protected. The write access procedure is described in RTC register write protection on page 2064.

Address offset: 0x14

Backup domain reset value: 0x0000 FFFF

System reset: not affected

WUT[15:0]

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 WUT[15:0]: Wake-up auto-reload value bits

When the wake-up timer is enabled (WUTE set to 1), the WUTF flag is set every (WUT[15:0] + 1) ck_wut cycles. The ck_wut period is selected through WUCKSEL[2:0] bits of the RTC_CR register.

When WUCKSEL[2] = 1, the wake-up timer becomes 17-bits and WUCKSEL[1] effectively becomes WUT[16] the most-significant bit to be reloaded into the timer.

The first assertion of WUTF occurs (WUT+1) ck_wut cycles after WUTE is set. Setting WUT[15:0] to 0x0000 with WUCKSEL[2:0] =011 (RTCCLK/2) is forbidden.
49.6.7 **RTC alarm A register (RTC_ALRMAR)**

This register can be written only when ALRAWF is set to 1 in RTC_ISR, or in initialization mode.

This register is write protected. The write access procedure is described in *RTC register write protection on page 2064*.

Address offset: 0x1C

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **SS[15:0]**: Sub second value
**SS[15:0]** is the value in the synchronous prescaler counter. The fraction of a second is given by the formula below:
Second fraction = (PREDIV_S - SS) / (PREDIV_S + 1)

*Note: SS can be larger than PREDIV_S only after a shift operation. In that case, the correct time/date is one second less than as indicated by RTC_TR/RTC_DR.*
49.6.11  RTC shift control register (RTC_SHIFTR)

This register is write protected. The write access procedure is described in RTC register write protection on page 2064.

Address offset: 0x2C
Backup domain reset value: 0x0000 0000
System reset: not affected

**Bit 31  ADD1S: Add one second**
0: No effect
1: Add one second to the clock/calendar

This bit is write only and is always read as zero. Writing to this bit has no effect when a shift operation is pending (when SHPF=1, in RTC_ISR).

This function is intended to be used with SUBFS (see description below) in order to effectively add a fraction of a second to the clock in an atomic operation.

**Bits 30:15 Reserved, must be kept at reset value.**

**Bits 14:0  SUBFS[14:0]: Subtract a fraction of a second**

These bits are write only and is always read as zero. Writing to this bit has no effect when a shift operation is pending (when SHPF=1, in RTC_ISR).

The value which is written to SUBFS is added to the synchronous prescaler counter. Since this counter counts down, this operation effectively subtracts from (delays) the clock by:

\[ \text{Delay (seconds)} = \frac{\text{SUBFS}}{\text{PREDIV}_S + 1} \]

A fraction of a second can effectively be added to the clock (advancing the clock) when the ADD1S function is used in conjunction with SUBFS, effectively advancing the clock by:

\[ \text{Advance (seconds)} = (1 - \frac{\text{SUBFS}}{\text{PREDIV}_S + 1}) \]

**Note:** Writing to SUBFS causes RSF to be cleared. Software can then wait until RSF=1 to be sure that the shadow registers have been updated with the shifted time.
### 49.6.12 RTC timestamp time register (RTC_TSTR)

The content of this register is valid only when TSF is set to 1 in RTC_ISR. It is cleared when TSF bit is reset.

- **Address offset**: 0x30
- **Backup domain reset value**: 0x0000 0000
- **System reset**: not affected

</tr>
</tbody>
</table>

Bits 31:16 **Reserved**, must be kept at reset value.

- **Bit 15** **CALP**: Increase frequency of RTC by 488.5 ppm
  0: No RTCCLK pulses are added.
  1: One RTCCLK pulse is effectively inserted every $2^{11}$ pulses (frequency increased by 488.5 ppm).

  This feature is intended to be used in conjunction with CALM, which lowers the frequency of the calendar with a fine resolution. If the input frequency is 32768 Hz, the number of RTCCLK pulses added during a 32-second window is calculated as follows: $(512 \times \text{CALP}) - \text{CALM}$.

  Refer to *Section 49.3.13: RTC smooth digital calibration*.

- **Bit 14** **CALW8**: Use an 8-second calibration cycle period
  When CALW8 is set to ‘1’, the 8-second calibration cycle period is selected.

  **Note:** CALM[1:0] are stuck at “00” when CALW8=’1’. Refer to *Section 49.3.13: RTC smooth digital calibration*.

- **Bit 13** **CALW16**: Use a 16-second calibration cycle period
  When CALW16 is set to ‘1’, the 16-second calibration cycle period is selected. This bit must not be set to ‘1’ if CALW8=1.

  **Note:** CALM[0] is stuck at ‘0’ when CALW16=’1’. Refer to *Section 49.3.13: RTC smooth digital calibration*.

Bits 12:9 **Reserved**, must be kept at reset value.

**Bits 8:0** **CALM[8:0]**: Calibration minus

- The frequency of the calendar is reduced by masking CALM out of $2^{20}$ RTCCLK pulses (32 seconds if the input frequency is 32768 Hz). This decreases the frequency of the calendar with a resolution of 0.9537 ppm.

  To increase the frequency of the calendar, this feature should be used in conjunction with CALP. See *Section 49.3.13: RTC smooth digital calibration on page 2068*. 
49.6.16 RTC tamper configuration register (RTC_TAMPCR)

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **TAMP3MF**: Tamper 3 mask flag
0: Tamper 3 event generates a trigger event and TAMP3F must be cleared by software to allow next tamper event detection.
1: Tamper 3 event generates a trigger event. TAMP3F is masked and internally cleared by hardware. The backup registers and the backup SRAM are not erased.

*Note: The Tamper 3 interrupt must not be enabled when TAMP3MF is set.*

Bit 23 **TAMP3NOERASE**: Tamper 3 no erase
0: Tamper 3 event erases the backup registers and the backup SRAM.
1: Tamper 3 event does not erase the backup registers and the backup SRAM.

Bit 22 **TAMP3IE**: Tamper 3 interrupt enable
0: Tamper 3 interrupt is disabled if TAMPIE = 0.
1: Tamper 3 interrupt enabled.

Bit 21 **TAMP2MF**: Tamper 2 mask flag
0: Tamper 2 event generates a trigger event and TAMP2F must be cleared by software to allow next tamper event detection.
1: Tamper 2 event generates a trigger event. TAMP2F is masked and internally cleared by hardware. The backup registers and the backup SRAM are not erased.

*Note: The Tamper 2 interrupt must not be enabled when TAMP2MF is set.*

Bit 20 **TAMP2NOERASE**: Tamper 2 no erase
0: Tamper 2 event erases the backup registers and the backup SRAM.
1: Tamper 2 event does not erase the backup registers and the backup SRAM.

Bit 19 **TAMP2IE**: Tamper 2 interrupt enable
0: Tamper 2 interrupt is disabled if TAMPIE = 0.
1: Tamper 2 interrupt enabled.

Bit 18 **TAMP1MF**: Tamper 1 mask flag
0: Tamper 1 event generates a trigger event and TAMP1F must be cleared by software to allow next tamper event detection.
1: Tamper 1 event generates a trigger event. TAMP1F is masked and internally cleared by hardware. The backup registers and the backup SRAM are not erased.

*Note: The Tamper 1 interrupt must not be enabled when TAMP1MF is set.*
Bit 17 **TAMP1NOERASE**: Tamper 1 no erase
   0: Tamper 1 event erases the backup registers and the backup SRAM.
   1: Tamper 1 event does not erase the backup registers and the backup SRAM.

Bit 16 **TAMP1IE**: Tamper 1 interrupt enable
   0: Tamper 1 interrupt is disabled if TAMP1E = 0.
   1: Tamper 1 interrupt enabled.

Bit 15 **TAMPPUDIS**: RTC_TAMPx pull-up disable
   This bit determines if each of the RTC_TAMPx pins are precharged before each sample.
   0: Precharge RTC_TAMPx pins before sampling (enable internal pull-up)
   1: Disable precharge of RTC_TAMPx pins.

Bits 14:13 **TAMPPRCH[1:0]**: RTC_TAMPx precharge duration
   These bit determines the duration of time during which the pull-up/is activated before each sample. TAMPPRCH is valid for each of the RTC_TAMPx inputs.
   0x0: 1 RTCCLK cycle
   0x1: 2 RTCCLK cycles
   0x2: 4 RTCCLK cycles
   0x3: 8 RTCCLK cycles

Bits 12:11 **TAMPFLT[1:0]**: RTC_TAMPx filter count
   These bits determines the number of consecutive samples at the specified level (TAMP*TRG) needed to activate a Tamper event. TAMPFLT is valid for each of the RTC_TAMPx inputs.
   0x0: Tamper event is activated on edge of RTC_TAMPx input transitions to the active level (no internal pull-up on RTC_TAMPx input).
   0x1: Tamper event is activated after 2 consecutive samples at the active level.
   0x2: Tamper event is activated after 4 consecutive samples at the active level.
   0x3: Tamper event is activated after 8 consecutive samples at the active level.

Bits 10:8 **TAMPFREQ[2:0]**: Tamper sampling frequency
   Determines the frequency at which each of the RTC_TAMPx inputs are sampled.
   0x0: RTCCLOCK / 32768 (1 Hz when RTCCLOCK = 32768 Hz)
   0x1: RTCCLOCK / 16384 (2 Hz when RTCCLOCK = 32768 Hz)
   0x2: RTCCLOCK / 8192 (4 Hz when RTCCLOCK = 32768 Hz)
   0x3: RTCCLOCK / 4096 (8 Hz when RTCCLOCK = 32768 Hz)
   0x4: RTCCLOCK / 2048 (16 Hz when RTCCLOCK = 32768 Hz)
   0x5: RTCCLOCK / 1024 (32 Hz when RTCCLOCK = 32768 Hz)
   0x6: RTCCLOCK / 512 (64 Hz when RTCCLOCK = 32768 Hz)
   0x7: RTCCLOCK / 256 (128 Hz when RTCCLOCK = 32768 Hz)

Bit 7 **TAMPTS**: Activate timestamp on tamper detection event
   0: Tamper detection event does not cause a timestamp to be saved
   1: Save timestamp on tamper detection event
   TAMPTS is valid even if TSE=0 in the RTC_CR register.

Bit 6 **TAMP3TRG**: Active level for RTC_TAMP3 input
   if TAMPFLT ≠ 00:
      0: RTC_TAMP3 input staying low triggers a tamper detection event.
      1: RTC_TAMP3 input staying high triggers a tamper detection event.
   if TAMPFLT = 00:
      0: RTC_TAMP3 input rising edge triggers a tamper detection event.
      1: RTC_TAMP3 input falling edge triggers a tamper detection event.
Caution: When TAMPFLT = 0, TAMPxE must be reset when TAMPxTRG is changed to avoid spuriously setting TAMPxF.
### 49.6.17 RTC alarm A sub second register (RTC_ALRMASSR)

This register can be written only when ALRAE is reset in RTC_CR register, or in initialization mode.

This register is write protected. The write access procedure is described in [RTC register write protection on page 2064](#).

Address offset: 0x44

Backup domain reset value: 0x0000 0000

System reset: not affected

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MASKSS[3:0]</td>
<td>Mask the most-significant bits starting at this bit</td>
</tr>
<tr>
<td>SS[14:0]</td>
<td>Sub seconds value</td>
</tr>
</tbody>
</table>

#### MASKSS[3:0]

0: No comparison on sub seconds for Alarm A. The alarm is set when the seconds unit is incremented (assuming that the rest of the fields match).

1: SS[14:1] are don’t care in Alarm A comparison. Only SS[0] is compared.

2: SS[14:2] are don’t care in Alarm A comparison. Only SS[1:0] are compared.

... 12: SS[14:12] are don’t care in Alarm A comparison. SS[11:0] are compared.

15: All 15 SS bits are compared and must match to activate alarm.

The overflow bits of the synchronous counter (bits 15) is never compared. This bit can be different from 0 only after a shift operation.

#### SS[14:0]

Reserved, must be kept at reset value.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits 31:28</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
<tr>
<td>Bits 27:24</td>
<td>MASKSS[3:0]: Mask the most-significant bits starting at this bit</td>
</tr>

<td>Bits 23:15</td>
<td>Reserved, must be kept at reset value.</td>
</tr>
<tr>
<td>Bits 14:0</td>
<td>SS[14:0]: Sub seconds value</td>
</tr>
</tbody>
</table>

This value is compared with the contents of the synchronous prescaler counter to determine if Alarm A is to be activated. Only bits 0 up MASKSS-1 are compared.
49.6.18 RTC alarm B sub second register (RTC_ALRMBSSR)

This register can be written only when ALRBE is reset in RTC_CR register, or in initialization mode.

This register is write protected. The write access procedure is described in Section: RTC register write protection.

Address offset: 0x48
Backup domain reset value: 0x0000 0000
System reset: not affected

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:24 MASKSS[3:0]: Mask the most-significant bits starting at this bit
0x0: No comparison on sub seconds for Alarm B. The alarm is set when the seconds unit is incremented (assuming that the rest of the fields match).
0x1: SS[14:1] are don’t care in Alarm B comparison. Only SS[0] is compared.
0x2: SS[14:2] are don’t care in Alarm B comparison. Only SS[1:0] are compared.
0x3: SS[14:3] are don’t care in Alarm B comparison. Only SS[2:0] are compared.
... 
0xC: SS[14:12] are don’t care in Alarm B comparison. SS[11:0] are compared.
0xD: SS[14:13] are don’t care in Alarm B comparison. SS[12:0] are compared.
0xE: SS[14] is don’t care in Alarm B comparison. SS[13:0] are compared.
0xF: All 15 SS bits are compared and must match to activate alarm.

The overflow bits of the synchronous counter (bits 15) is never compared. This bit can be different from 0 only after a shift operation.

Bits 23:15 Reserved, must be kept at reset value.

Bits 14:0 SS[14:0]: Sub seconds value
This value is compared with the contents of the synchronous prescaler counter to determine if Alarm B is to be activated. Only bits 0 up to MASKSS-1 are compared.
49.6.19 RTC option register (RTC_OR)

Refer to Section 2.3 on page 134 for the register boundary addresses.
50 Inter-integrated circuit (I2C) interface

50.1 Introduction

The I²C (inter-integrated circuit) bus interface handles communications between the microcontroller and the serial I²C bus. It provides multimaster capability, and controls all I²C bus-specific sequencing, protocol, arbitration and timing. It supports Standard-mode (Sm), Fast-mode (Fm) and Fast-mode Plus (Fm+).

The I²C bus interface is also SMBus (system management bus) and PMBus® (power management bus) compatible.

DMA can be used to reduce CPU overload.

50.2 I2C main features

- I²C bus specification rev03 compatibility:
  - Slave and master modes
  - Multimaster capability
  - Standard-mode (up to 100 kHz)
  - Fast-mode (up to 400 kHz)
  - Fast-mode Plus (up to 1 MHz)
  - 7-bit and 10-bit addressing mode
  - Multiple 7-bit slave addresses (2 addresses, 1 with configurable mask)
  - All 7-bit addresses acknowledge mode
  - General call
  - Programmable setup and hold times
  - Easy to use event management
  - Optional clock stretching
  - Software reset
- 1-byte buffer with DMA capability
- Programmable analog and digital noise filters

The following features are also available, depending upon product implementation (see Section 50.3):

- SMBus specification rev 3.0 compatibility:
  - Hardware PEC (packet error checking) generation and verification with ACK control
  - Command and data acknowledge control
  - Address resolution protocol (ARP) support
  - Host and device support
  - SMBus alert
  - Timeouts and idle condition detection
- PMBus rev 1.3 standard compatibility
- Independent clock: a choice of independent clock sources allowing the I2C communication speed to be independent from the i2c_pclk reprogramming
50.3 I2C implementation

This manual describes the full set of features implemented in I2C peripheral. In the STM32H7xxx devices I2C1, I2C2, I2C3 and I2C4 implement the full set of features as shown in the following table.

50.4 I2C functional description

In addition to receiving and transmitting data, this interface converts them from serial to parallel format and vice versa. The interrupts are enabled or disabled by software. The interface is connected to the I2C bus by a data pin (SDA) and by a clock pin (SCL). It can be connected with a standard (up to 100 kHz), Fast-mode (up to 400 kHz) or Fast-mode Plus (up to 1 MHz) I2C bus.

This interface can also be connected to an SMBus with data (SDA) and clock (SCL) pins. If the SMBus feature is supported, the optional SMBus Alert pin (SMBA) is also available.
50.4.1 I2C block diagram

The block diagram of the I2C interface is shown in Figure 582.

Figure 582. I2C block diagram

The I2C is clocked by an independent clock source, which allows the I2C to operate independently from the i2c_pclk frequency.

For I2C I/Os supporting 20 mA output current drive for Fast-mode Plus operation, the driving capability is enabled through control bits in the system configuration controller (SYSCFG). Refer to Section 50.3: I2C implementation.

Table 402. I2C input/output pins

50.4.3 I2C clock requirements

The I2C kernel is clocked by i2c_ker_ck.

The i2c_ker_ck period $t_{I2CCLK}$ must respect the following conditions:

- $t_{I2CCLK} < \frac{(t_{LOW} - t_{filters})}{4}$
- $t_{I2CCLK} < t_{HIGH}$

with:

- $t_{LOW}$: SCL low time
- $t_{HIGH}$: SCL high time
- $t_{filters}$: when enabled, sum of the delays brought by the analog and by the digital filters.

The digital filter delay is $DNF \times t_{I2CCLK}$.

The i2c_pclk clock period $t_{PCLK}$ must respect the condition:

- $t_{PCLK} < \frac{4}{3} t_{SCL} (t_{SCL}: SCL period)$

Caution: When the I2C kernel is clocked by i2c_pclk, this clock must respect the conditions for $t_{I2CCLK}$.

50.4.4 Mode selection

The interface can operate in one of the four following modes:

- Slave transmitter
- Slave receiver
- Master transmitter
- Master receiver
By default, it operates in slave mode. The interface automatically switches from slave to master when it generates a START condition, and from master to slave if an arbitration loss or a STOP generation occurs, allowing multimaster capability.

**Communication flow**

In master mode, the I2C interface initiates a data transfer and generates the clock signal. A serial data transfer always begins with a START condition, and ends with a STOP condition. Both START and STOP conditions are generated in master mode by software.

In slave mode, the interface is capable of recognizing its own addresses (7- or 10-bit), and the general call address. The general call address detection can be enabled or disabled by software. The reserved SMBus addresses can be enabled also by software.

Data and addresses are transferred as 8-bit bytes, MSB first. The first byte(s) following the START condition contains the address (one in 7-bit mode, two in 10-bit mode). The address is always transmitted in master mode.

A ninth clock pulse follows the eight clock cycles of a byte transfer, during which the receiver must send an acknowledge bit to the transmitter (see Figure 583).

**Figure 583. I2C bus protocol**

Acknowledgment can be enabled or disabled by software. The I2C interface addresses can be selected by software.

**50.4.5 I2C initialization**

**Enabling and disabling the peripheral**

The I2C peripheral clock must be configured and enabled in the clock controller, then the I2C can be enabled by setting the PE bit in the I2C_CR1 register.

When the I2C is disabled (PE = 0), the I2C performs a software reset. Refer to Section 50.4.6 for more details.

**Noise filters**

Before enabling the I2C peripheral by setting the PE bit in I2C_CR1 register, the user must configure the noise filters, if needed. By default, an analog noise filter is present on the SDA and SCL inputs. This filter is compliant with the I2C specification, which requires the suppression of spikes with pulse width up to 50 ns in Fast-mode and Fast-mode Plus. The
user can disable this analog filter by setting the ANFOFF bit, and/or select a digital filter by configuring the DNF[3:0] bit in the I2C_CR1 register.

When the digital filter is enabled, the level of the SCL or the SDA line is internally changed only if it remains stable for more than DNF x i2c_ker_ck periods. This allows to suppress spikes with a programmable length of one to fifteen i2c_ker_ck periods.

<table>
<thead>
<tr>

<tr>
<td>Digital filter: Wake-up from Stop mode on address match is not available when the digital filter is enabled</td>
</tr>
</tbody>
</table>

**Caution:** The filter configuration cannot be changed when the I2C is enabled.

**I2C timings**

The timings must be configured to guarantee correct data hold and setup times, in master and slave modes. This is done by programming the PRESC[3:0], SCLDEL[3:0] and SDADEL[3:0] bits in the I2C_TIMINGR register.

The STM32CubeMX tool calculates and provides the I2C_TIMINGR content in the I2C configuration window.
When the SCL falling edge is internally detected, a delay \( t_{SDADEL} \) impacting the hold time \( t_{HD;DAT} \) is inserted before sending SDA output: \( t_{SDADEL} = SDADEL \times t_{PRESC} + t_{I2CCLK} \), where \( t_{PRESC} = (PRESC + 1) \times t_{I2CCLK} \).

The total SDA output delay is:

\[
t_{SYNC1} + \left\{ SDADEL \times (PRESC + 1) + 1 \right\} \times t_{I2CCLK}
\]

\( t_{SYNC1} \) duration depends upon:

- SCL falling slope
- When enabled, input delay brought by the analog filter: \( t_{AF\text{ (min)}} < t_{AF} < t_{AF\text{ (max)}} \)
- When enabled, input delay brought by the digital filter: \( t_{DNF} = DNF \times t_{I2CCLK} \)
- Delay due to SCL synchronization to \( i2c\_ker\_ck \) clock (two to three \( i2c\_ker\_ck \) periods)

To bridge the undefined region of the SCL falling edge, the user must program \( SDADEL \) in such a way that:

\[
\left\{ t_f (\text{max}) + t_{HD;DAT\ (min)} - t_{AF\ (min)} - \left\{ (DNF + 3) \times t_{I2CCLK} \right\} / \left\{ (PRESC + 1) \times t_{I2CCLK} \right\} \right\} \leq SDADEL
\]
Inter-integrated circuit (I2C) interface

SDADEL ≤ \{t_{\text{HD;DAT}}(\text{max}) - t_{\text{AF}}(\text{max}) - [(DNF + 4) x t_{\text{I2CCLK}}]\} / \{(\text{PRESC} + 1) x t_{\text{I2CCLK}}\}

Note: \(t_{\text{AF}}(\text{min}) / t_{\text{AF}}(\text{max})\) are part of the equation only when the analog filter is enabled. Refer to the device datasheet for \(t_{\text{AF}}\) values.

The maximum \(t_{\text{HD;DAT}}\) can be 3.45 μs for Standard-mode, 0.9 μs for Fast-mode, 0.45 μs for Fast-mode Plus. It must be lower than the maximum of \(t_{\text{VD;DAT}}\) by a transition time. This maximum must only be met if the device does not stretch the LOW period (\(t_{\text{LOW}}\)) of the SCL signal. If the clock stretches the SCL, the data must be valid by the set-up time before it releases the clock.

The SDA rising edge is usually the worst case. In this case the previous equation becomes:

SDADEL ≤ \{t_{\text{VD;DAT}}(\text{max}) - t_{\text{r}}(\text{max}) - t_{\text{AF}}(\text{max}) - [(DNF + 4) x t_{\text{I2CCLK}}]\} / \{(\text{PRESC} + 1) x t_{\text{I2CCLK}}\}.

Note: This condition can be violated when NOSTRETCH = 0, because the device stretches SCL low to guarantee the set-up time, according to the SCLDEL value.

Refer to Table 405 for \(t_{\text{r}}\), \(t_{\text{HD;DAT}}\), and \(t_{\text{VD;DAT}}\) standard values.

- After \(t_{\text{SDADEL}}\) or after sending SDA output when the slave had to stretch the clock because the data was not yet written in I2C_TXDR register, SCL line is kept at low level during the set-up time. This setup time is \(t_{\text{SCLDEL}} = (SCLDEL + 1) x t_{\text{PRESC}}\), where \(t_{\text{PRESC}} = (\text{PRESC} + 1) x t_{\text{I2CCLK}}\). 

To bridge the undefined region of the SDA transition (rising edge usually worst case), the user must program SCLDEL in such a way that:

\{\left[ t_{\text{r}}(\text{max}) + t_{\text{SU;DAT}}(\text{min}) \right] / \left[ (\text{PRESC} + 1) x t_{\text{I2CCLK}} \right]\} - 1 \leq \text{SCLDEL}

Refer to Table 405 for \(t_{\text{r}}\) and \(t_{\text{SU;DAT}}\) standard values.

The SDA and SCL transition time values to use are the ones in the application. Using the maximum values from the standard increases the constraints for the SDADEL and SCLDEL calculation, but ensures the feature, whatever the application.

Note: At every clock pulse, after SCL falling edge detection, the I2C master or slave stretches SCL low during at least \([(\text{SDADEL} + \text{SCLDEL} + 1) x (\text{PRESC} + 1) + 1] x t_{\text{I2CCLK}}\) in both transmission and reception modes. In transmission mode, if the data is not yet written in I2C_TXDR when SDADEL counter is finished, the I2C keeps on stretching SCL low until the next data is written. Then new data MSB is sent on SDA output, and SCLDEL counter starts, continuing stretching SCL low to guarantee the data setup time.

If NOSTRETCH = 1 in slave mode, the SCL is not stretched, hence the SDADEL must be programmed so that it guarantees a sufficient setup time.

</tr>
</tbody>
</table>
Additionally, in master mode, the SCL clock high and low levels must be configured by programming the PRESC[3:0], SCLH[7:0] and SCLL[7:0] bit fields in the I2C_TIMINGR register.

- When the SCL falling edge is internally detected, a delay is inserted before releasing the SCL output.
  This delay is \( t_{SCLL} = (SCLL + 1) \times t_{PRESC} \) where \( t_{PRESC} = (PRESC + 1) \times t_{I2CCLK} \).  
  \( t_{SCLL} \) impacts the SCL low time \( t_{LOW} \).

- When the SCL rising edge is internally detected, a delay is inserted before forcing the SCL output to low level. This delay is \( t_{SCLH} = (SCLH + 1) \times t_{PRESC} \), where \( t_{PRESC} = (PRESC + 1) \times t_{I2CCLK} \).  
  \( t_{SCLH} \) impacts the SCL high time \( t_{HIGH} \).

Refer to I2C master initialization for more details.

**Caution:** Changing the timing configuration is not allowed when the I2C is enabled.

The I2C slave NOSTRETCH mode must also be configured before enabling the peripheral. Refer to I2C slave initialization for more details.

**Caution:** Changing the NOSTRETCH configuration is not allowed when the I2C is enabled.

Additionally, in master mode, the SCL clock high and low levels must be configured by programming the PRESC[3:0], SCLH[7:0] and SCLL[7:0] bit fields in the I2C_TIMINGR register.

- When the SCL falling edge is internally detected, a delay is inserted before releasing the SCL output.
  This delay is \( t_{SCLL} = (SCLL + 1) \times t_{PRESC} \) where \( t_{PRESC} = (PRESC + 1) \times t_{I2CCLK} \).  
  \( t_{SCLL} \) impacts the SCL low time \( t_{LOW} \).

- When the SCL rising edge is internally detected, a delay is inserted before forcing the SCL output to low level. This delay is \( t_{SCLH} = (SCLH + 1) \times t_{PRESC} \), where \( t_{PRESC} = (PRESC + 1) \times t_{I2CCLK} \).  
  \( t_{SCLH} \) impacts the SCL high time \( t_{HIGH} \).

Refer to I2C master initialization for more details.

**Caution:** Changing the timing configuration is not allowed when the I2C is enabled.

The I2C slave NOSTRETCH mode must also be configured before enabling the peripheral. Refer to I2C slave initialization for more details.

**Caution:** Changing the NOSTRETCH configuration is not allowed when the I2C is enabled.
### 50.4.6 Software reset

A software reset can be performed by clearing the PE bit in the I2C_CR1 register. In that case I2C lines SCL and SDA are released. Internal states machines are reset and communication control bits, as well as status bits, come back to their reset value. The configuration registers are not impacted.

Impacted register bits:
1. I2C_CR2 register: START, STOP, NACK
2. I2C_ISR register: BUSY, TXE, TXIS, RXNE, ADDR, NACKF, TCR, TC, STOPF, BERR, ARLO, OVR

In addition when the SMBus feature is supported:
1. I2C_CR2 register: PECBYTE
2. I2C_ISR register: PECERR, TIMEOUT, ALERT

PE must be kept low during at least three APB clock cycles to perform the software reset. This is ensured by the following software sequence:
1. Write PE = 0
2. Check PE = 0
3. Write PE = 1
50.4.7 Data transfer

The data transfer is managed through transmit and receive data registers and a shift register.

Reception

The SDA input fills the shift register. After the eighth SCL pulse (when the complete data byte is received), the shift register is copied into I2C_RXDR register if it is empty (RXNE = 0). If RXNE = 1, meaning that the previous received data byte has not yet been read, the SCL line is stretched low until I2C_RXDR is read. The stretch is inserted between the eighth and ninth SCL pulse (before the acknowledge pulse).

Figure 586. Data reception
Transmission

If the I2C_TXDR register is not empty (TXE = 0), its content is copied into the shift register after the ninth SCL pulse (the acknowledge pulse). Then the shift register content is shifted out on SDA line. If TXE = 1, meaning that no data is written yet in I2C_TXDR, SCL line is stretched low until I2C_TXDR is written. The stretch is done after the ninth SCL pulse.

**Figure 587. Data transmission**

![Data transmission diagram]

Hardware transfer management

The I2C features an embedded byte counter to manage byte transfer and to close the communication in various modes, such as:

- NACK, STOP and ReSTART generation in master mode
- ACK control in slave receiver mode
- PEC generation/checking when SMBus feature is supported

The byte counter is always used in master mode. By default, it is disabled in slave mode. It can be enabled by software by setting the SBC (slave byte control) bit in the I2C_CR1 register.

The number of bytes to be transferred is programmed in the NBYTES[7:0] bit field in the I2C_CR2 register. If the number of bytes to be transferred (NBYTES) is greater than 255, or if a receiver wants to control the acknowledge value of a received data byte, the reload mode must be selected by setting the RELOAD bit in the I2C_CR2 register. In this mode, the TCR flag is set when the number of bytes programmed in NBYTES is transferred, and an interrupt is generated if TCIE is set. SCL is stretched as long as TCR flag is set. TCR is cleared by software when NBYTES is written to a non-zero value.

When the NBYTES counter is reloaded with the last number of bytes, RELOAD bit must be cleared.
When RELOAD = 0 in master mode, the counter can be used in two modes:

- **Automatic end** (AUTOEND = 1 in the I2C_CR2 register). In this mode, the master automatically sends a STOP condition once the number of bytes programmed in the NBYTES[7:0] bit field is transferred.

- **Software end** (AUTOEND = 0 in the I2C_CR2 register). In this mode, software action is expected once the number of bytes programmed in the NBYTES[7:0] bit field is transferred; the TC flag is set and an interrupt is generated if the TCIE bit is set. The SCL signal is stretched as long as the TC flag is set. The TC flag is cleared by software when the START or STOP bit is set in the I2C_CR2 register. This mode must be used when the master wants to send a RESTART condition.

**Caution:** The AUTOEND bit has no effect when the RELOAD bit is set.

---

#### 50.4.8 I2C slave mode

**I2C slave initialization**

To work in slave mode, the user must enable at least one slave address. Registers I2C_OAR1 and I2C_OAR2 are available to program the slave own addresses OA1 and OA2.

- OA1 can be configured either in 7-bit mode (by default), or in 10-bit addressing mode by setting the OA1MODE bit in the I2C_OAR1 register.
  
  OA1 is enabled by setting the OA1EN bit in the I2C_OAR1 register.

- If additional slave addresses are required, the second slave address OA2 can be configured. Up to seven OA2 LSB can be masked by configuring the OA2MSK[2:0] bits in the I2C_OAR2 register. Therefore for OA2MSK configured from 1 to 6, only OA2[7:2], OA2[7:3], OA2[7:4], OA2[7:5], OA2[7:6] or OA2[7] are compared with the received address. As soon as OA2MSK is not equal to 0, the address comparator for OA2 excludes the I2C reserved addresses (0000 XXX and 1111 XXX), which are not acknowledged. If OA2MSK = 7, all received 7-bit addresses are acknowledged (except reserved addresses). OA2 is always a 7-bit address.

  These reserved addresses can be acknowledged if they are enabled by the specific enable bit, if they are programmed in the I2C_OAR1 or I2C_OAR2 register with O2MSK = 0.

  OA2 is enabled by setting the OA2EN bit in the I2C_OAR2 register.

- The general call address is enabled by setting the GCEN bit in the I2C_CR1 register.

When the I2C is selected by one of its enabled addresses, the ADDR interrupt status flag is set, and an interrupt is generated if the ADDRIE bit is set.

By default, the slave uses its clock stretching capability, which means that it stretches the SCL signal at low level when needed, to perform software actions. If the master does not
support clock stretching, the I2C must be configured with NOSTRETCH = 1 in the I2C_CR1 register.

After receiving an ADDR interrupt, if several addresses are enabled, the user must read the ADDCODE[6:0] bits in the I2C_ISR register to check which address matched. DIR flag must also be checked to know the transfer direction.

**Slave clock stretching (NOSTRETCH = 0)**

In default mode, the I2C slave stretches the SCL clock in the following situations:

- When the ADDR flag is set: the received address matches with one of the enabled slave addresses. This stretch is released when the ADDR flag is cleared by software setting the ADDRCF bit.
- In transmission, if the previous data transmission is completed and no new data is written in I2C_TXDR register, or if the first data byte is not written when the ADDR flag is cleared (TXE = 1). This stretch is released when the data is written to the I2C_TXDR register.
- In reception when the I2C_RXDR register is not read yet and a new data reception is completed. This stretch is released when I2C_RXDR is read.
- When TCR = 1 in Slave byte control mode, reload mode (SBC = 1 and RELOAD = 1), meaning that the last data byte has been transferred. This stretch is released when then TCR is cleared by writing a non-zero value in the NBYTES[7:0] field.
- After SCL falling edge detection, the I2C stretches SCL low during $[(SDADEL + SCLDEL + 1) \times (PRESC+1) + 1] \times t_{\text{I2CCLK}}$.

**Slave without clock stretching (NOSTRETCH = 1)**

When NOSTRETCH = 1 in the I2C_CR1 register, the I2C slave does not stretch the SCL signal.

- The SCL clock is not stretched while the ADDR flag is set.
- In transmission, the data must be written in the I2C_TXDR register before the first SCL pulse corresponding to its transfer occurs. If not, an underrun occurs, the OVR flag is set in the I2C_ISR register and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register. The OVR flag is also set when the first data transmission starts and the STOPF bit is still set (has not been cleared). Therefore, if the user clears the STOPF flag of the previous transfer only after writing the first data to be transmitted in the next transfer, it ensures that the OVR status is provided, even for the first data to be transmitted.
- In reception, the data must be read from the I2C_RXDR register before the ninth SCL pulse (ACK pulse) of the next data byte occurs. If not, an overrun occurs, the OVR flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.
Slave byte control mode

To allow byte ACK control in slave reception mode, the Slave byte control mode must be enabled by setting the SBC bit in the I2C_CR1 register. This is required to be compliant with SMBus standards.

The Reload mode must be selected to allow byte ACK control in slave reception mode (RELOAD = 1). To get control of each byte, NBYTES must be initialized to 0x1 in the ADDR interrupt subroutine, and reloaded to 0x1 after each received byte. When the byte is received, the TCR bit is set, stretching the SCL signal low between the eighth and ninth SCL pulses. The user can read the data from the I2C_RXDR register, and then decide to acknowledge it or not by configuring the ACK bit in the I2C_CR2 register. The SCL stretch is released by programming NBYTES to a non-zero value: the acknowledge or not-acknowledge is sent, and the next byte can be received.

NBYTES can be loaded with a value greater than 0x1, and in this case, the reception flow is continuous during NBYTES data reception.

Note: The SBC bit must be configured when the I2C is disabled, or when the slave is not addressed, or when ADDR = 1.

The RELOAD bit value can be changed when ADDR = 1, or when TCR = 1.

Caution: The Slave byte control mode is not compatible with NOSTRETCH mode. Setting SBC when NOSTRETCH = 1 is not allowed.

Figure 588. Slave initialization flow

1. SBC must be set to support SMBus features.
Slave transmitter

A transmit interrupt status (TXIS) is generated when the I2C_TXDR register becomes empty. An interrupt is generated if the TXIE bit is set in the I2C_CR1 register.

The TXIS bit is cleared when the I2C_TXDR register is written with the next data byte to be transmitted.

When a NACK is received, the NACKF bit is set in the I2C_ISR register, and an interrupt is generated if the NACKIE bit is set in the I2C_CR1 register. The slave automatically releases the SCL and SDA lines to let the master perform a STOP or a RESTART condition. The TXIS bit is not set when a NACK is received.

When a STOP is received and the STOPIE bit is set in the I2C_CR1 register, the STOPF flag is set in the I2C_ISR register and an interrupt is generated. In most applications, the SBC bit is usually programmed to 0. In this case, if TXE = 0 when the slave address is received (ADDR = 1), the user can choose either to send the content of the I2C_TXDR register as the first data byte, or to flush the I2C_TXDR register by setting the TXE bit in order to program a new data byte.

In Slave byte control mode (SBC = 1), the number of bytes to be transmitted must be programmed in NBYTES in the address match interrupt subroutine (ADDR = 1). In this case, the number of TXIS events during the transfer corresponds to the value programmed in NBYTES.

Caution: When NOSTRETCH = 1, the SCL clock is not stretched while the ADDR flag is set, so the user cannot flush the I2C_TXDR register content in the ADDR subroutine, to program the first data byte. The first data byte to be sent must be previously programmed in the I2C_TXDR register:

- This data can be the one written in the last TXIS event of the previous transmission message.
- If this data byte is not the one to be sent, the I2C_TXDR register can be flushed by setting the TXE bit in order to program a new data byte. The STOPF bit must be cleared only after these actions, in order to guarantee that they are executed before the first data transmission starts, following the address acknowledge.

If STOPF is still set when the first data transmission starts, an underrun error is generated (the OVR flag is set).

If a TXIS event (transmit interrupt or transmit DMA request) is needed, the user must set the TXIS bit in addition to the TXE bit, to generate the event.

50.4.9 I2C master mode

I2C master initialization

Before enabling the peripheral, the I2C master clock must be configured by setting the SCLH and SCLL bits in the I2C_TIMINGR register.

The STM32CubeMX tool calculates and provides the I2C_TIMINGR content in the I2C Configuration window.

A clock synchronization mechanism is implemented in order to support multi-master environment and slave clock stretching.

In order to allow clock synchronization:

- The low level of the clock is counted using the SCLL counter, starting from the SCL low level internal detection.
- The high level of the clock is counted using the SCLH counter, starting from the SCL high level internal detection.

The I2C detects its own SCL low level after a $t_{SYNC1}$ delay depending on the SCL falling edge, SCL input noise filters (analog and digital), and SCL synchronization to the I2CxCLK clock. The I2C releases SCL to high level once the SCLL counter reaches the value programmed in the SCLL[7:0] bits in the I2C_TIMINGR register.

The I2C detects its own SCL high level after a $t_{SYNC2}$ delay depending on the SCL rising edge, SCL input noise filters (analog + digital) and SCL synchronization to I2CxCLK clock. The I2C ties SCL to low level once the SCLH counter reaches the value programmed in the SCLH[7:0] bits in the I2C_TIMINGR register.

Consequently the master clock period is:

$$t_{SCL} = t_{SYNC1} + t_{SYNC2} + ((SCLH+1) + (SCLL+1)) \times (PRESC+1) \times t_{I2CCLK}$$

The duration of $t_{SYNC1}$ depends upon:

- SCL falling slope
- When enabled, input delay induced by the analog filter
- When enabled, input delay induced by the digital filter: $DNF \times t_{I2CCLK}$
- Delay due to SCL synchronization with $i2c_ker_ck$ clock (two to three $i2c_ker_ck$ periods)

The duration of $t_{SYNC2}$ depends upon:

- SCL rising slope
- When enabled, input delay induced by the analog filter
- When enabled, input delay induced by the digital filter: $DNF \times t_{I2CCLK}$
- Delay due to SCL synchronization with $i2c_ker_ck$ clock (two to three $i2c_ker_ck$ periods)

Note: \( ^{2} \text{C} \) and \( ^{2} \text{C} \) are also used to generate, respectively, the \( t_{\text{BUF}} / t_{\text{SU:STA}} \) and the \( t_{\text{HD:STA}} / t_{\text{SU:STO}} \) timings.

Refer to Section 50.4.10 for examples of \( ^{2} \text{C} \) TIMINGR settings vs. \( ^{2} \text{C} \)_ker_\_ck frequency.

### Master communication initialization (address phase)

To initiate the communication, program the following parameters for the addressed slave in the \( ^{2} \text{C} \)_CR2 register:

- Addressing mode (7-bit or 10-bit): ADD10
- Slave address to be sent: SADD[9:0]
- Transfer direction: RD_WRN
- In case of 10-bit address read: HEAD10R bit. HEAD10R must be configure to indicate if the complete address sequence must be sent, or only the header in case of a direction change.
- The number of bytes to be transferred: NBYTES[7:0]. If this number is equal to or greater than 255 bytes, NBYTES[7:0] must initially be filled with 0xFF.

The user must then set the START bit in \( ^{2} \text{C} \)_CR2 register. Changing all the above bits is not allowed when START bit is set.

Then the master automatically sends the START condition followed by the slave address as soon as it detects that the bus is free (BUSY = 0) and after a \( t_{\text{BUF}} \) delay.

In case of an arbitration loss, the master automatically switches back to slave mode and can acknowledge its own address if it is addressed as a slave.
Note: The START bit is reset by hardware when the slave address is sent on the bus, whatever the received acknowledge value. The START bit is also reset by hardware if an arbitration loss occurs.

In 10-bit addressing mode, when the slave address first seven bits are NACKed by the slave, the master relaunches automatically the slave address transmission until ACK is received. In this case ADDRCF must be set if a NACK is received from the slave, to stop sending the slave address.

If the I2C is addressed as a slave (ADDR = 1) while the START bit is set, the I2C switches to slave mode, and the START bit is cleared, when the ADDRCF bit is set.

Note: The same procedure is applied for a repeated start condition. In this case BUSY = 1.

**Figure 596. Master initialization flow**

Initialization of a master receiver addressing a 10-bit address slave

- If the slave address is in 10-bit format, the user can choose to send the complete read sequence by clearing the HEAD10R bit in the I2C_CR2 register. In this case the master automatically sends the following complete sequence after the START bit is set:
  - (Re)Start + Slave address 10-bit header Write + Slave address second byte + (Re)Start + Slave address 10-bit header Read

**Figure 597. 10-bit address read access with HEAD10R = 0**
• If the master addresses a 10-bit address slave, transmits data to this slave and then reads data from the same slave, a master transmission flow must be done first. Then a repeated start is set with the 10-bit slave address configured with HEAD10R = 1. In this case the master sends this sequence: ReStart + Slave address 10-bit header Read.

**Figure 598. 10-bit address read access with HEAD10R = 1**

Master transmitter

In the case of a write transfer, the TXIS flag is set after each byte transmission, after the ninth SCL pulse when an ACK is received.

A TXIS event generates an interrupt if the TXIE bit is set in the I2C_CR1 register. The flag is cleared when the I2C_TXDR register is written with the next data byte to be transmitted.

The number of TXIS events during the transfer corresponds to the value programmed in NBYTES[7:0]. If the total number of data bytes to be sent is greater than 255, reload mode must be selected by setting the RELOAD bit in the I2C_CR2 register. In this case, when NBYTES data have been transferred, the TCR flag is set and the SCL line is stretched low until NBYTES[7:0] is written to a non-zero value.

The TXIS flag is not set when a NACK is received.

• When RELOAD = 0 and NBYTES data have been transferred:
  – In automatic end mode (AUTOEND = 1), a STOP is automatically sent.
  – In software end mode (AUTOEND = 0), the TC flag is set and the SCL line is stretched low, to perform software actions:
    A RESTART condition can be requested by setting the START bit in the I2C_CR2 register with the proper slave address configuration, and number of bytes to be transferred. Setting the START bit clears the TC flag and the START condition is sent on the bus.
    A STOP condition can be requested by setting the STOP bit in the I2C_CR2 register. Setting the STOP bit clears the TC flag and the STOP condition is sent on the bus.

• If a NACK is received: the TXIS flag is not set, and a STOP condition is automatically sent after the NACK reception. the NACKF flag is set in the I2C_ISR register, and an interrupt is generated if the NACKFIE bit is set.

50.4.11 SMBus specific features

This section is relevant only when the SMBus feature is supported (refer to Section 50.3).

Introduction

The system management bus (SMBus) is a two-wire interface through which various devices can communicate with each other and with the rest of the system. It is based on I²C principles of operation. The SMBus provides a control bus for system and power management related tasks.

This peripheral is compatible with the SMBus specification (http://smbus.org).

The system management bus specification refers to three types of devices

- A slave is a device that receives or responds to a command.
- A master is a device that issues commands, generates the clocks, and terminates the transfer.
- A host is a specialized master that provides the main interface to the system’s CPU. A host must be a master-slave and must support the SMBus host notify protocol. Only one host is allowed in a system.

This peripheral can be configured as master or slave device, and also as a host.

Bus protocols

There are eleven possible command protocols for any given device. A device can use any or all of them to communicate. The protocols are Quick Command, Send Byte, Receive Byte, Write Byte, Write Word, Read Byte, Read Word, Process Call, Block Read, Block

1. t_{SCL} is greater than t_{SCLL} + t_{SCLH} due to the SCL internal detection delay. Values provided for t_{SCL} are only examples.
2. t_{SYNC1} + t_{SYNC2} minimum value is 4x t_{I²CCLK} = 83.3 ns. Example with t_{SYNC1} + t_{SYNC2} = 1000 ns
3. t_{SYNC1} + t_{SYNC2} minimum value is 4x t_{I²CCLK} = 83.3 ns. Example with t_{SYNC1} + t_{SYNC2} = 750 ns
4. t_{SYNC1} + t_{SYNC2} minimum value is 4x t_{I²CCLK} = 83.3 ns. Example with t_{SYNC1} + t_{SYNC2} = 250 ns
Write, and Block Write-Block Read Process Call. These protocols must be implemented by the user software.

For more details on these protocols, refer to SMBus specification (http://smbus.org).

**Address resolution protocol (ARP)**

SMBus slave address conflicts can be resolved by dynamically assigning a new unique address to each slave device. To provide a mechanism to isolate each device for the purpose of address assignment, each device must implement a unique device identifier (UDID). This 128-bit number is implemented by software.

This peripheral supports the Address Resolution Protocol (ARP). The SMBus Device Default Address (0b1100 001) is enabled by setting SMBDEN bit in I2C_CR1 register. The ARP commands must be implemented by the user software.

Arbitration is also performed in slave mode for ARP support.

For more details of the SMBus address resolution protocol, refer to SMBus specification (http://smbus.org).

**Received command and data acknowledge control**

A SMBus receiver must be able to NACK each received command or data. In order to allow the ACK control in slave mode, the Slave byte control mode must be enabled by setting SBC bit in I2C_CR1 register. Refer to **Slave byte control mode** for more details.

**Host notify protocol**

This peripheral supports the host notify protocol by setting the SMBHEN bit in the I2C_CR1 register. In this case the host acknowledges the SMBus host address (0b0001 000).

When this protocol is used, the device acts as a master and the host as a slave.

**SMBus alert**

The SMBus ALERT optional signal is supported. A slave-only device can signal the host through the SMBALERT# pin that it wants to talk. The host processes the interrupt and simultaneously accesses all SMBALERT# devices through the alert response address (0b0001 100). Only the device(s) which pulled SMBALERT# low acknowledges the alert response address.

When configured as a slave device(SMBHEN = 0), the SMBA pin is pulled low by setting the ALERTEN bit in the I2C_CR1 register. The Alert Response Address is enabled at the same time.

When configured as a host (SMBHEN = 1), the ALERT flag is set in the I2C_ISR register when a falling edge is detected on the SMBA pin and ALERTEN = 1. An interrupt is generated if the ERRIE bit is set in the I2C_CR1 register. When ALERTEN = 0, the ALERT line is considered high even if the external SMBA pin is low.

If the SMBus ALERT pin is not needed, the SMBA pin can be used as a standard GPIO if ALERTEN = 0.

**Packet error checking**

A packet error checking mechanism has been introduced in the SMBus specification to improve reliability and communication robustness. The packet error checking is implemented by appending a packet error code (PEC) at the end of each message transfer.
The PEC is calculated by using the \( C(x) = x^8 + x^2 + x + 1 \) CRC-8 polynomial on all the message bytes (including addresses and read/write bits).

The peripheral embeds a hardware PEC calculator and allows a not acknowledge to be sent automatically when the received byte does not match with the hardware calculated PEC.

**Timeouts**

This peripheral embeds hardware timers to be compliant with the three timeouts defined in the SMBus specification.

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Parameter</th>
<th>Limits</th>
<th>Unit</th>
</tr>
</thead>
<tbody>
<tr>
<td>( t_{\text{TIMEOUT}} )</td>
<td>Detect clock low timeout</td>
<td>25</td>
<td>35</td>
</tr>
<tr>
<td>( t_{\text{LOW:SEXT}} )(^{(1)})</td>
<td>Cumulative clock low extend time (slave device)</td>

<td>25</td>
</tr>
<tr>
<td>( t_{\text{LOW:MEXT}} )(^{(2)})</td>
<td>Cumulative clock low extend time (master device)</td>
<td>-</td>
<td>10</td>
</tr>
</tbody>
</table>

1. \( t_{\text{LOW:SEXT}} \) is the cumulative time a given slave device is allowed to extend the clock cycles in one message from the initial START to the STOP. It is possible that another slave device or the master also extends the clock causing the combined clock low extend time to be greater than \( t_{\text{LOW:SEXT}} \). Therefore, this parameter is measured with the slave device as the sole target of a full-speed master.

2. \( t_{\text{LOW:MEXT}} \) is the cumulative time a master device is allowed to extend its clock cycles within each byte of a message as defined from START-to-ACK, ACK-to-ACK, or ACK-to-STOP. It is possible that a slave device or another master also extends the clock, causing the combined clock low time to be greater than \( t_{\text{LOW:MEXT}} \) on a given byte. Therefore, this parameter is measured with a full speed slave device as the sole target of the master.

**Figure 605. Timeout intervals for \( t_{\text{LOW:SEXT}} \), \( t_{\text{LOW:MEXT}} \)**
Bus idle detection

A master can assume that the bus is free if it detects that the clock and data signals have been high for \( t_{IDLE} > t_{HIGH,MAX} \) (refer to \textit{I2C timings}).

This timing parameter covers the condition where a master has been dynamically added to the bus, and may not have detected a state transition on the SMBCLK or SMBDAT lines. In this case, the master must wait long enough to ensure that a transfer is not currently in progress. The peripheral supports a hardware bus idle detection.

**50.4.12 SMBus initialization**

This section is relevant only when SMBus feature is supported (see \textit{Section 50.3}).

In addition to I2C initialization, some other specific initialization must be done to perform SMBus communication.

Received command and data acknowledge control (slave mode)

A SMBus receiver must be able to NACK each received command or data. To allow ACK control in slave mode, the Slave byte control mode must be enabled by setting the SBC bit in the I2C_CR1 register. Refer to \textit{Slave byte control mode} for more details.

Specific address (slave mode)

The specific SMBus addresses must be enabled if needed. Refer to \textit{Bus idle detection} for more details.

- The SMBus device default address (0b1100 001) is enabled by setting the SMBDEN bit in the I2C_CR1 register.
- The SMBus host address (0b0001 000) is enabled by setting the SMBHEN bit in the I2C_CR1 register.
- The alert response address (0b0001100) is enabled by setting the ALERTEN bit in the I2C_CR1 register.

Packet error checking

PEC calculation is enabled by setting the PECEN bit in the I2C_CR1 register. Then the PEC transfer is managed with the help of the hardware byte counter NBYTES[7:0] in the I2C_CR2 register. The PECEN bit must be configured before enabling the I2C.

The PEC transfer is managed with the hardware byte counter, so the SBC bit must be set when interfacing the SMBus in slave mode. The PEC is transferred after NBYTES - 1 data have been transferred when the PECBYTE bit is set and the RELOAD bit is cleared. If RELOAD is set, PECBYTE has no effect.

**Caution:** Changing the PECEN configuration is not allowed when the I2C is enabled.

</tr>
</tbody>
</table>
Timeout detection

The timeout detection is enabled by setting the TIMOUTEN and TEXTEN bits in the I2C_TIMEOUTR register. The timers must be programmed in such a way that they detect a timeout before the maximum time given in the SMBus specification.

- \( t_{\text{TIMEOUT}} \) check
  
  To enable the \( t_{\text{TIMEOUT}} \) check, the 12-bit TIMEOUTA[11:0] bits must be programmed with the timer reload value, to check the \( t_{\text{TIMEOUT}} \) parameter. The TIDLE bit must be configured to 0 to detect the SCL low level timeout.

  Then the timer is enabled by setting the TIMOUTEN in the I2C_TIMEOUTR register.

  If SCL is tied low for a time greater than \((\text{TIMEOUTA} + 1) \times 2048 \times t_{\text{I2CCLK}}\), the TIMEOUT flag is set in the I2C_ISR register.

  Refer to Table 413.

Caution: Changing the TIMEOUTA[11:0] bits and TIDLE bit configuration is not allowed when the TIMOUTEN bit is set.

- \( t_{\text{LOW:SEXT}} \) and \( t_{\text{LOW:MEXT}} \) check

  Depending on if the peripheral is configured as a master or as a slave, the 12-bit TIMEOUTB timer must be configured to check \( t_{\text{LOW:SEXT}} \) for a slave, and \( t_{\text{LOW:MEXT}} \) for a master. As the standard specifies only a maximum, the user can choose the same value for both. The timer is then enabled by setting the TEXTEN bit in the I2C_TIMEOUTR register.

  If the SMBus peripheral performs a cumulative SCL stretch for a time greater than \((\text{TIMEOUTB} + 1) \times 2048 \times t_{\text{I2CCLK}}\), and in the timeout interval described in Bus idle detection section, the TIMEOUT flag is set in the I2C_ISR register.

  Refer to Table 414.

Caution: Changing the TIMEOUTB configuration is not allowed when the TEXTEN bit is set.

Bus idle detection

To enable the \( t_{\text{IDLE}} \) check, the 12-bit TIMEOUTA[11:0] field must be programmed with the timer reload value, to obtain the \( t_{\text{IDLE}} \) parameter. The TIDLE bit must be configured to ‘1’ to detect both SCL and SDA high level timeout. The timer is then enabled by setting the TIMOUTEN bit in the I2C_TIMEOUTR register.

If both the SCL and SDA lines remain high for a time greater than \((\text{TIMEOUTA} + 1) \times 4 \times t_{\text{I2CCLK}}\), the TIMEOUT flag is set in the I2C_ISR register.

Refer to Table 415.

Caution: Changing TIMEOUTA and TIDLE configuration is not allowed when TIMOUTEN is set.
50.4.13 SMBus: I2C_TIMEOUTR register configuration examples

50.4.14 SMBus slave mode

This section is relevant only when the SMBus feature is supported (refer to Section 50.3).

In addition to I2C slave transfer management (refer to Section 50.4.8), additional software flows are provided to support the SMBus.

SMBus slave transmitter

When the IP is used in SMBus, SBC must be programmed to 1 to enable the PEC transmission at the end of the programmed number of data bytes. When the PECBYTE bit is set, the number of bytes programmed in NBYTES[7:0] includes the PEC transmission. In that case the total number of TXIS interrupts is NBYTES - 1, and the content of the I2C_PECR register is automatically transmitted if the master requests an extra byte after the NBYTES - 1 data transfer.

Caution: The PECBYTE bit has no effect when the RELOAD bit is set.
Figure 606. Transfer sequence flow for SMBus slave transmitter N bytes + PEC

- Slave initialization
- I2C_ISR.ADDR = 1?
  - No
  - Read ADDCODE and DIR in I2C_ISR
    - I2C_CR2.NBYTES = N + 1
    - PECBYTE=1
    - Set I2C_ICR.ADDRCF
  - Yes
- I2C_ISR.TXIS = 1?
  - No
  - Write I2C_TXDR.TXDATA
  - SCL stretched
  - Yes

Legend:
- Transmission
- Reception
- SCL stretch

NBYTES 3
SMBus slave receiver

When the I2C is used in SMBus mode, SBC must be programmed to 1 to allow the PEC checking at the end of the programmed number of data bytes. To allow the ACK control of each byte, the reload mode must be selected (RELOAD = 1). Refer to Slave byte control mode for more details.

To check the PEC byte, the RELOAD bit must be cleared and the PECBYTE bit must be set. In this case, after NBYTES - 1 data have been received, the next received byte is compared with the internal I2C_PECR register content. A NACK is automatically generated if the comparison does not match, and an ACK is automatically generated if the comparison matches, whatever the ACK bit value. Once the PEC byte is received, it is copied into the I2C_RXDR register like any other data, and the RXNE flag is set.

In the case of a PEC mismatch, the PECERR flag is set and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

If no ACK software control is needed, the user can program PECBYTE = 1 and, in the same write operation, program NBYTES with the number of bytes to be received in a continuous flow. After NBYTES - 1 are received, the next received byte is checked as being the PEC.

Caution: The PECBYTE bit has no effect when the RELOAD bit is set.
Figure 608. Transfer sequence flow for SMBus slave receiver N bytes + PEC

     - I2C_CR2.NBYTES = 1
     - N = N - 1
   - No: Continue
7. If N = 1?
   - Yes: Read I2C_RXDR.RXDATA
     - Program RELOAD = 0
     - NACK = 0 and NBYTES = 1
   - No: Continue
8. If I2C_ISR.RXNE = 1?
   - Yes: Read I2C_RXDR.RXDATA
   - No: Continue
9. End
This section is relevant only when the SMBus feature is supported (refer to Section 50.3).

In addition to I2C master transfer management (refer to Section 50.4.9), additional software flows are provided to support the SMBus.

**SMBus master transmitter**

When the SMBus master wants to transmit the PEC, the PECBYTE bit must be set and the number of bytes must be programmed in the NBYTES[7:0] field, before setting the START bit. In this case the total number of TXIS interrupts is NBYTES - 1. So if the PECBYTE bit is set when NBYTES = 0x1, the content of the I2C_PECR register is automatically transmitted.

If the SMBus master wants to send a STOP condition after the PEC, automatic end mode must be selected (AUTOEND = 1). In this case, the STOP condition automatically follows the PEC transmission.

When the SMBus master wants to send a RESTART condition after the PEC, software mode must be selected (AUTOEND = 0). In this case, once NBYTES - 1 have been
transmitted, the I2C_PECR register content is transmitted and the TC flag is set after the PEC transmission, stretching the SCL line low. The RESTART condition must be programmed in the TC interrupt subroutine.

**Caution:** The PECBYTE bit has no effect when the RELOAD bit is set.

**Figure 610. Bus transfer diagrams for SMBus master transmitter**

**Example SMBus master transmitter 2 bytes + PEC, automatic end mode (STOP)**

- INIT: program Slave address, program NBYTES = 3, AUTOEND=1, set PECBYTE, set START
- EV1: TXIS ISR: wr data1
- EV2: TXIS ISR: wr data2

**Example SMBus master transmitter 2 bytes + PEC, software end mode (RESTART)**

- INIT: program Slave address, program NBYTES = 3, AUTOEND=0, set PECBYTE, set START
- EV1: TXIS ISR: wr data1
- EV2: TXIS ISR: wr data2
- EV3: TC ISR: program Slave address, program NBYTES = N, set START
SMBus master receiver

When the SMBus master wants to receive the PEC followed by a STOP at the end of the transfer, automatic end mode can be selected (AUTOEND = 1). The PECBYTE bit must be set and the slave address must be programmed, before setting the START bit. In this case, after NBYTES - 1 data have been received, the next received byte is automatically checked versus the I2C_PECR register content. A NACK response is given to the PEC byte, followed by a STOP condition.

When the SMBus master receiver wants to receive the PEC byte followed by a RESTART condition at the end of the transfer, software mode must be selected (AUTOEND = 0). The PECBYTE bit must be set and the slave address must be programmed, before setting the START bit. In this case, after NBYTES - 1 data have been received, the next received byte is automatically checked versus the I2C_PECR register content. The TC flag is set after the PEC byte reception, stretching the SCL line low. The RESTART condition can be programmed in the TC interrupt subroutine.

Caution: The PECBYTE bit has no effect when the RELOAD bit is set.
50.4.15 Wake-up from Stop mode on address match

This section is relevant only when wake-up from Stop mode feature is supported (refer to Section 50.3).

The I2C is able to wake-up the MCU from Stop mode (APB clock is off), when it is addressed. All addressing modes are supported.

Wake-up from Stop mode is enabled by setting the WUPEN bit in the I2C_CR1 register. The HSI or CSI oscillator must be selected as the clock source for I2CCLK in order to allow wake-up from Stop mode.

During Stop mode, the HSI or CSI is switched off. When a START is detected, the I2C interface switches the HSI or CSI on, and stretches SCL low until HSI or CSI is woken up.

HSI or CSI is then used for the address reception.
In case of an address match, the I2C stretches SCL low during MCU wake-up time. The stretch is released when ADDR flag is cleared by software, and the transfer goes on normally.

If the address does not match, the HSI or CSI is switched off again and the MCU is not woken up.

**Note:** If the I2C clock is the system clock, or if WUPEN = 0, the HSI or CSI is not switched on after a START is received.

Only an ADDR interrupt can wake up the MCU. Therefore do not enter Stop mode when the I2C is performing a transfer as a master, or as an addressed slave after the ADDR flag is set. This can be managed by clearing SLEEPDEEP bit in the ADDR interrupt routine and setting it again only after the STOPF flag is set.

**Caution:** The digital filter is not compatible with the wake-up from Stop mode feature. If the DNF bit is not equal to 0, setting the WUPEN bit has no effect.

**Caution:** This feature is available only when the I2C clock source is the HSI or CSI oscillator.

**Caution:** Clock stretching must be enabled (NOSTRETCH = 0) to ensure proper operation of the wake-up from Stop mode feature.

**Caution:** If wake up from Stop mode is disabled (WUPEN = 0), the I2C peripheral must be disabled before entering Stop mode (PE = 0).

### 50.4.16 Error conditions

The following errors are the conditions that can cause a communication fail.

**Bus error (BERR)**

A bus error is detected when a START or a STOP condition is detected and is not located after a multiple of nine SCL clock pulses. A START or a STOP condition is detected when an SDA edge occurs while SCL is high.

The bus error flag is set only if the I2C is involved in the transfer as master or addressed slave (i.e not during the address phase in slave mode).

In case of a misplaced START or RESTART detection in slave mode, the I2C enters address recognition state like for a correct START condition.

When a bus error is detected, the BERR flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

**Arbitration lost (ARLO)**

An arbitration loss is detected when a high level is sent on the SDA line, but a low level is sampled on the SCL rising edge.

- In master mode, arbitration loss is detected during the address phase, data phase and data acknowledge phase. In this case, the SDA and SCL lines are released, the START control bit is cleared by hardware and the master switches automatically to slave mode.
- In slave mode, arbitration loss is detected during data phase and data acknowledge phase. In this case, the transfer is stopped, and the SCL and SDA lines are released.

When an arbitration loss is detected, the ARLO flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.
Overrun/underrun error (OVR)

An overrun or underrun error is detected in slave mode when NOSTRETCH = 1 and:
- In reception when a new byte is received and the RXDR register has not been read yet. The new received byte is lost, and a NACK is automatically sent as a response to the new byte.
- In transmission:
  - When STOPF = 1 and the first data byte must be sent. The content of the I2C_TXDR register is sent if TXE = 0, 0xFF if not.
  - When a new byte must be sent and the I2C_TXDR register has not been written yet, 0xFF is sent.

When an overrun or underrun error is detected, the OVR flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

Packet error checking error (PECERR)

This section is relevant only when the SMBus feature is supported (refer to Section 50.3).

A PEC error is detected when the received PEC byte does not match with the I2C_PECR register content. A NACK is automatically sent after the wrong PEC reception.

When a PEC error is detected, the PECERR flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

Timeout error (TIMEOUT)

This section is relevant only when the SMBus feature is supported (refer to Section 50.3).

A timeout error occurs for any of these conditions:
- TIDLE = 0 and SCL remained low for the time defined in the TIMEOUTA[11:0] bits: this is used to detect an SMBus timeout.
- TIDLE = 1 and both SDA and SCL remained high for the time defined in the TIMEOUTA [11:0] bits: this is used to detect a bus idle condition.
- Master cumulative clock low extend time reached the time defined in the TIMEOUTB[11:0] bits (SMBus tLOW:MEXT parameter).
- Slave cumulative clock low extend time reached the time defined in TIMEOUTB[11:0] bits (SMBus tLOW:SEXT parameter).

When a timeout violation is detected in master mode, a STOP condition is automatically sent.

When a timeout violation is detected in slave mode, SDA and SCL lines are automatically released.

When a timeout error is detected, the TIMEOUT flag is set in the I2C_ISR register, and an interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.

Alert (ALERT)

This section is relevant only when the SMBus feature is supported (refer to Section 50.3).

The ALERT flag is set when the I2C interface is configured as a Host (SMBHEN = 1), the alert pin detection is enabled (ALERTEN = 1) and a falling edge is detected on the SMBA pin. An interrupt is generated if the ERRIE bit is set in the I2C_CR1 register.
50.4.17 DMA requests

Transmission using DMA

DMA (direct memory access) can be enabled for transmission by setting the TXDMAEN bit in the I2C_CR1 register. Data is loaded from an SRAM area configured using the DMA peripheral (see Section 16: Direct memory access controller (DMA) on page 674) to the I2C_TXDR register whenever the TXIS bit is set.

Only the data are transferred with DMA.

- In master mode: the initialization, the slave address, direction, number of bytes and START bit are programmed by software (the transmitted slave address cannot be transferred with DMA). When all data are transferred using DMA, the DMA must be initialized before setting the START bit. The end of transfer is managed with the NBYTES counter. Refer to Master transmitter.

- In slave mode:
  - With NOSTRETCH = 0, when all data are transferred using DMA, the DMA must be initialized before the address match event, or in ADDR interrupt subroutine, before clearing ADDR.
  - With NOSTRETCH = 1, the DMA must be initialized before the address match event.

- For instances supporting SMBus: the PEC transfer is managed with NBYTES counter. Refer to SMBus slave transmitter and SMBus master transmitter.

Note: If DMA is used for transmission, the TXIE bit does not need to be enabled.

Reception using DMA

DMA (direct memory access) can be enabled for reception by setting the RXDMAEN bit in the I2C_CR1 register. Data is loaded from the I2C_RXDR register to an SRAM area configured using the DMA peripheral (refer to Section 16: Direct memory access controller (DMA) on page 674) whenever the RXNE bit is set. Only the data (including PEC) are transferred with DMA.

- In master mode, the initialization, the slave address, direction, number of bytes and START bit are programmed by software. When all data are transferred using DMA, the DMA must be initialized before setting the START bit. The end of transfer is managed with the NBYTES counter.

- In slave mode with NOSTRETCH = 0, when all data are transferred using DMA, the DMA must be initialized before the address match event, or in the ADDR interrupt subroutine, before clearing the ADDR flag.

- If SMBus is supported (see Section 50.3) the PEC transfer is managed with the NBYTES counter. Refer to SMBus slave receiver and SMBus master receiver.

Note: If DMA is used for reception, the RXIE bit does not need to be enabled.

50.4.18 Debug mode

When the microcontroller enters debug mode (core halted), the SMBus timeout either continues to work normally or stops, depending on the DBG_I2Cx_ configuration bits in the DBG module.
50.5 **I2C low-power modes**

Table 416. Effect of low-power modes on the I2C

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sleep</td>
<td>No effect. I2C interrupts cause the device to exit the Sleep mode.</td>
</tr>
<tr>
<td>Stop(1)</td>
<td>The I2C registers content is kept. WUPEN = 1 and I2C is clocked by an internal oscillator (HSI or CSI): the address recognition is functional. The I2C address match condition causes the device to exit the Stop mode. WUPEN = 0: the I2C must be disabled before entering Stop mode.</td>
</tr>
<tr>
<td>Standby</td>
<td>The I2C peripheral is powered down and must be reinitialized after exiting Standby mode.</td>
</tr>
</tbody>
</table>

1. Refer to *Section 50.3* for information about the Stop modes supported by each instance. If wake-up from a specific Stop mode is not supported, the instance must be disabled before entering this Stop mode.
### 50.6 I2C interrupts

The following table gives the list of I2C interrupt requests.

50.7 I2C registers

Refer to Section 1.2 on page 106 for the list of abbreviations used in register descriptions.

The registers are accessed by words (32-bit).

50.7.1 I2C control register 1 (I2C_CR1)

Address offset: 0x00
Reset value: 0x0000 0000

Access: no wait states, except if a write access occurs while a write access is ongoing. In this case, wait states are inserted in the second write access, until the previous one is completed. The latency of the second write access can be up to $2 \times i2c_pclk + 6 \times i2c_ker_ck$.

- **Bits 31:24**: Reserved, must be kept at reset value.

  - **Bit 23 PECEN**: PEC enable
    - 0: PEC calculation disabled
    - 1: PEC calculation enabled
    - Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 50.3.

  - **Bit 22 ALERTEN**: SMBus alert enable
    - 0: The SMBus alert pin (SMBA) is not supported in host mode (SMBHEN = 1). In device mode (SMBHEN = 0), the SMBA pin is released and the Alert Response Address header is disabled (0001100x followed by NACK).
    - 1: The SMBus alert pin is supported in host mode (SMBHEN = 1). In device mode (SMBHEN = 0), the SMBA pin is driven low and the Alert Response Address header is enabled (0001100x followed by ACK).
    - Note: When ALERTEN = 0, the SMBA pin can be used as a standard GPIO.
    - If the SMBus feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 50.3.

  - **Bit 21 SMBDEN**: SMBus device default address enable
    - 0: Device default address disabled. Address 0b1100001x is NACKed.
    - 1: Device default address enabled. Address 0b1100001x is ACKed.
    - Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 50.3.

  - **Bit 20 SMBHEN**: SMBus host address enable
    - 0: Host address disabled. Address 0b0001000x is NACKed.
    - 1: Host address enabled. Address 0b0001000x is ACKed.
    - Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 50.3.
Bit 19 **GCEN**: General call enable
0: General call disabled. Address 0b00000000 is NACKed.
1: General call enabled. Address 0b00000000 is ACKed.

Bit 18 **WUPEN**: Wake-up from Stop mode enable
0: Wake-up from Stop mode disabled.
1: Wake-up from Stop mode enabled.

*Note:* If the wake-up from Stop mode feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 50.3.

*Note:* WUPEN can be set only when DNF = 0000.

Bit 17 **NOSTRETCH**: Clock stretching disable
This bit is used to disable clock stretching in slave mode. It must be kept cleared in master mode.
0: Clock stretching enabled
1: Clock stretching disabled

*Note:* This bit can be programmed only when the I2C is disabled (PE = 0).

Bit 16 **SBC**: Slave byte control
This bit is used to enable hardware byte control in slave mode.
0: Slave byte control disabled
1: Slave byte control enabled

Bit 15 **RXDMAEN**: DMA reception requests enable
0: DMA mode disabled for reception
1: DMA mode enabled for reception

Bit 14 **TXDMAEN**: DMA transmission requests enable
0: DMA mode disabled for transmission
1: DMA mode enabled for transmission

Bit 13 Reserved, must be kept at reset value.

Bit 12 **ANFOFF**: Analog noise filter OFF
0: Analog noise filter enabled
1: Analog noise filter disabled

*Note:* This bit can be programmed only when the I2C is disabled (PE = 0).

Bits 11:8 **DNF[3:0]**: Digital noise filter
These bits are used to configure the digital noise filter on SDA and SCL input. The digital filter, filters spikes with a length of up to DNF[3:0] * tI2CCLK
0000: Digital filter disabled
0001: Digital filter enabled and filtering capability up to one tI2CCLK
... 1111: digital filter enabled and filtering capability up to fifteen tI2CCLK

*Note:* If the analog filter is enabled, the digital filter is added to it. This filter can be programmed only when the I2C is disabled (PE = 0).
Bit 7 **ERRIE**: Error interrupts enable
   0: Error detection interrupts disabled
   1: Error detection interrupts enabled
   
   **Note**: Any of these errors generates an interrupt:
   - Arbitration loss (ARLO)
   - Bus error detection (BERR)
   - Overrun/underrun (OVR)
   - Timeout detection (TIMEOUT)
   - PEC error detection (PECERR)
   - Alert pin event detection (ALERT)

Bit 6 **TCIE**: Transfer complete interrupt enable
   0: Transfer complete interrupt disabled
   1: Transfer complete interrupt enabled
   
   **Note**: Any of these events generates an interrupt:
   - Transfer complete (TC)
   - Transfer complete reload (TCR)

Bit 5 **STOPIE**: Stop detection interrupt enable
   0: Stop detection (STOPF) interrupt disabled
   1: Stop detection (STOPF) interrupt enabled

Bit 4 **NACKIE**: Not acknowledge received interrupt enable
   0: Not acknowledge (NACKF) received interrupts disabled
   1: Not acknowledge (NACKF) received interrupts enabled

Bit 3 **ADDRIE**: Address match interrupt enable (slave only)
   0: Address match (ADDR) interrupts disabled
   1: Address match (ADDR) interrupts enabled

Bit 2 **RXIE**: RX interrupt enable
   0: Receive (RXNE) interrupt disabled
   1: Receive (RXNE) interrupt enabled

Bit 1 **TXIE**: TX interrupt enable
   0: Transmit (TXIS) interrupt disabled
   1: Transmit (TXIS) interrupt enabled

Bit 0 **PE**: Peripheral enable
   0: Peripheral disabled
   1: Peripheral enabled
   
   **Note**: When PE = 0, the I2C SCL and SDA lines are released. Internal state machines and status bits are put back to their reset value. When cleared, PE must be kept low for at least three APB clock cycles.

**50.7.2 I2C control register 2 (I2C_CR2)**

Address offset: 0x04

Reset value: 0x0000 0000

Access: no wait states, except if a write access occurs while a write access is ongoing. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to 2 x i2c_pclk + 6 x i2c_ker_ck.

</tr>
</tbody>
</table>

Bits 31:27  Reserved, must be kept at reset value.

Bit 26 **PECBYTE**: Packet error checking byte

This bit is set by software, and cleared by hardware when the PEC is transferred, or when a STOP condition or an Address matched is received, also when PE = 0.

0: No PEC transfer
1: PEC transmission/reception is requested

**Note:** Writing 0 to this bit has no effect.

This bit has no effect when RELOAD is set, and in slave mode when SBC = 0.

**Note:** If the SMBus feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 50.3.

Bit 25 **AUTOEND**: Automatic end mode (master mode)

This bit is set and cleared by software.

0: software end mode: TC flag is set when NBYTES data are transferred, stretching SCL low.
1: Automatic end mode: a STOP condition is automatically sent when NBYTES data are transferred.

**Note:** This bit has no effect in slave mode or when the RELOAD bit is set.

Bit 24 **RELOAD**: NBYTES reload mode

This bit is set and cleared by software.

0: The transfer is completed after the NBYTES data transfer (STOP or RESTART follows).
1: The transfer is not completed after the NBYTES data transfer (NBYTES is reloaded). TCR flag is set when NBYTES data are transferred, stretching SCL low.

Bits 23:16 **NBYTES[7:0]**: Number of bytes

The number of bytes to be transmitted/received is programmed there. This field is don’t care in slave mode with SBC = 0.

**Note:** Changing these bits when the START bit is set is not allowed.

Bit 15 **NACK**: NACK generation (slave mode)

The bit is set by software, cleared by hardware when the NACK is sent, or when a STOP condition or an Address matched is received, or when PE = 0.

0: an ACK is sent after current received byte.
1: a NACK is sent after current received byte.

**Note:** Writing 0 to this bit has no effect.

This bit is used only in slave mode: in master receiver mode, NACK is automatically generated after last byte preceding STOP or RESTART condition, whatever the NACK bit value.

When an overrun occurs in slave receiver NOSTRETCH mode, a NACK is automatically generated, whatever the NACK bit value.

When hardware PEC checking is enabled (PECBYTE = 1), the PEC acknowledge value does not depend on the NACK value.
**Bit 14 STOP:** Stop generation (master mode)
The bit is set by software, cleared by hardware when a STOP condition is detected, or when PE = 0.

*In master mode:*
0: No Stop generation
1: Stop generation after current byte transfer

*Note:* Writing 0 to this bit has no effect.

**Bit 13 START:** Start generation
This bit is set by software, and cleared by hardware after the Start followed by the address sequence is sent, by an arbitration loss, by a timeout error detection, or when PE = 0. It can also be cleared by software by writing 1 to the ADDRCF bit in the I2C_ICR register.
0: No Start generation
1: Restart/Start generation:
   If the I2C is already in master mode with AUTOEND = 0, setting this bit generates a Repeated start condition when RELOAD = 0, after the end of the NBYTES transfer. Otherwise, setting this bit generates a START condition once the bus is free.

*Note:* Writing 0 to this bit has no effect.

The START bit can be set even if the bus is BUSY or I2C is in slave mode.
This bit has no effect when RELOAD is set.

**Bit 12 HEAD10R:** 10-bit address header only read direction (master receiver mode)
0: The master sends the complete 10-bit slave address read sequence: Start + 2 bytes 10-bit address in write direction + restart + first seven bits of the 10-bit address in read direction.
1: The master sends only the first seven bits of the 10-bit address, followed by read direction.

*Note:* Changing this bit when the START bit is set is not allowed.

**Bit 11 ADD10:** 10-bit addressing mode (master mode)
0: The master operates in 7-bit addressing mode
1: The master operates in 10-bit addressing mode

*Note:* Changing this bit when the START bit is set is not allowed.

**Bit 10 RD_WRN:** Transfer direction (master mode)
0: Master requests a write transfer
1: Master requests a read transfer

*Note:* Changing this bit when the START bit is set is not allowed.

**Bits 9:0 SADD[9:0]:** Slave address (master mode)

*In 7-bit addressing mode (ADD10 = 0):*
SADD[7:1] must be written with the 7-bit slave address to be sent. Bits SADD[9], SADD[8] and SADD[0] are don't care.

*In 10-bit addressing mode (ADD10 = 1):*
SADD[9:0] must be written with the 10-bit slave address to be sent.

*Note:* Changing these bits when the START bit is set is not allowed.

### 50.7.3 I2C own address 1 register (I2C_OAR1)

Address offset: 0x08
Reset value: 0x0000 0000

Access: no wait states, except if a write access occurs while a write access is ongoing. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to 2 x i2c_pclk + 6 x i2c_ker_ck.
50.7.4 I2C own address 2 register (I2C_OAR2)

Address offset: 0x0C
Reset value: 0x0000 0000

Access: no wait states, except if a write access occurs while a write access is ongoing. In this case, wait states are inserted in the second write access, until the previous one is completed. The latency of the second write access can be up to 2x i2c_pclk + 6 x i2c_ker_ck.

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **OA2EN**: Own address 2 enable

0: Own address 2 disabled. The received slave address OA2 is NACKed.
1: Own address 2 enabled. The received slave address OA2 is ACKed.

Bits 14:11 Reserved, must be kept at reset value.

Bit 10 **OA2MODE**: Own address 2 10-bit mode

0: Own address 2 is a 7-bit address.
1: Own address 2 is a 10-bit address.

*Note: These bits can be written only when OA2EN = 0.*
Bits 10:8 **OA2MSK[2:0]**: Own address 2 masks

- 000: No mask
- 010: OA2[2:1] are masked and don’t care. Only OA2[7:3] are compared.
- 100: OA2[4:1] are masked and don’t care. Only OA2[7:5] are compared.
- 111: OA2[7:1] are masked and don’t care. No comparison is done, and all (except reserved) 7-bit received addresses are acknowledged.

*Note: These bits can be written only when OA2EN = 0.*

As soon as OA2MSK ≠ 0, the reserved I2C addresses (0b0000xxx and 0b1111xxx) are not acknowledged, even if the comparison matches.

Bits 7:1 **OA2[7:1]**: Interface address

7-bit addressing mode: 7-bit address

*Note: These bits can be written only when OA2EN = 0.*

Bit 0 Reserved, must be kept at reset value.

### 50.7.5 **I2C timing register (I2C_TIMINGR)**

Address offset: 0x10

Reset value: 0x0000 0000

Access: no wait states

**Bits 31:28 PRESC[3:0]**: Timing prescaler

This field is used to prescale i2c_ker_ck to generate the clock period \( t_{PRESC} \) used for data setup and hold counters (refer to I2C timings), and for SCL high and low level counters (refer to I2C master initialization).

\[ t_{PRESC} = (PreSc + 1) \times i2cCLK \]

**Bits 27:24** Reserved, must be kept at reset value.

**Bits 23:20 SCLDEL[3:0]**: Data setup time

This field is used to generate a delay \( t_{SCLDEL} = (SCLDEL + 1) \times t_{PRESC} \) between SDA edge and SCL rising edge. In master and in slave modes with NOSTRETCH = 0, the SCL line is stretched low during \( t_{SCLDEL} \).

*Note: \( t_{SCLDEL} \) is used to generate \( t_{SU/DAT} \) timing.*
50.7.6 I2C timeout register (I2C_TIMEOUTR)

Address offset: 0x14
Reset value: 0x0000 0000

Access: no wait states, except if a write access occurs while a write access is ongoing. In this case, wait states are inserted in the second write access until the previous one is completed. The latency of the second write access can be up to 2 x i2c_pclk + 6 x i2c_ker_ck.

If the SMBus feature is not supported, this register is reserved, and its bits are forced by hardware to 0. Refer to Section 50.3.

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:17 ADDCODE[6:0]: Address match code (slave mode)

These bits are updated with the received address when an address match event occurs (ADDR = 1). In the case of a 10-bit address, ADDCODE provides the 10-bit header followed by the two MSBs of the address.

Bit 16 DIR: Transfer direction (slave mode)

This flag is updated when an address match event occurs (ADDR = 1).
0: Write transfer, slave enters receiver mode.
1: Read transfer, slave enters transmitter mode.
Bit 15 **BUSY**: Bus busy
This flag indicates that a communication is in progress on the bus. It is set by hardware when a START condition is detected, and cleared by hardware when a STOP condition is detected, or when PE = 0.

Bit 14 Reserved, must be kept at reset value.

Bit 13 **ALERT**: SMBus alert
This flag is set by hardware when SMBHEN = 1 (SMBus host configuration), ALERTEN = 1 and an SMBALERT event (falling edge) is detected on SMBA pin. It is cleared by software by setting the ALERTCF bit.

Note: This bit is cleared by hardware when PE = 0.
Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 50.3.

Bit 12 **TIMEOUT**: Timeout or t LOW detection flag
This flag is set by hardware when a timeout or extended clock timeout occurred. It is cleared by software by setting the TIMEOUTCF bit.

Note: This bit is cleared by hardware when PE = 0.
Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 50.3.

Bit 11 **PECERR**: PEC error in reception
This flag is set by hardware when the received PEC does not match with the PEC register content. A NACK is automatically sent after the wrong PEC reception. It is cleared by software by setting the PECCF bit.

Note: This bit is cleared by hardware when PE = 0.
Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 50.3.

Bit 10 **OVR**: Overrun/underrun (slave mode)
This flag is set by hardware in slave mode with NOSTRETCH = 1, when an overrun/underrun error occurs. It is cleared by software by setting the OVRCF bit.

Note: This bit is cleared by hardware when PE = 0.

Bit 9 **ARLO**: Arbitration lost
This flag is set by hardware in case of arbitration loss. It is cleared by software by setting the ARLOCF bit.

Note: This bit is cleared by hardware when PE = 0.

Bit 8 **BERR**: Bus error
This flag is set by hardware when a misplaced Start or STOP condition is detected whereas the peripheral is involved in the transfer. The flag is not set during the address phase in slave mode. It is cleared by software by setting the BERRCF bit.

Note: This bit is cleared by hardware when PE = 0.

Bit 7 **TCR**: Transfer complete reload
This flag is set by hardware when RELOAD = 1 and NBYTES data have been transferred. It is cleared by software when NBYTES is written to a non-zero value.

Note: This bit is cleared by hardware when PE = 0.
This flag is only for master mode, or for slave mode when the SBC bit is set.

Bit 6 **TC**: Transfer complete (master mode)
This flag is set by hardware when RELOAD = 0, AUTOEND = 0 and NBYTES data have been transferred. It is cleared by software when START bit or STOP bit is set.

Note: This bit is cleared by hardware when PE = 0.

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 ALERTCF: Alert flag clear
   Note: Writing 1 to this bit clears the ALERT flag in the I2C_ISR register.
   Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 50.3.

Bit 12 TIMEOUTCF: Timeout detection flag clear
   Writing 1 to this bit clears the TIMEOUT flag in the I2C_ISR register.
   Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 50.3.

Bit 11 PECCF: PEC error flag clear
   Writing 1 to this bit clears the PECERR flag in the I2C_ISR register.
   Note: If the SMBus feature is not supported, this bit is reserved and forced by hardware to 0. Refer to Section 50.3.

Bit 10 OVRCF: Overrun/underrun flag clear
   Writing 1 to this bit clears the OVR flag in the I2C_ISR register.

Bit 9 ARLOCF: Arbitration lost flag clear
   Writing 1 to this bit clears the ARLO flag in the I2C_ISR register.

Bit 8 BERRCF: Bus error flag clear
   Writing 1 to this bit clears the BERRF flag in the I2C_ISR register.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 STOPCF: STOP detection flag clear
   Writing 1 to this bit clears the STOPF flag in the I2C_ISR register.

Bit 4 NACKCF: Not acknowledge flag clear
   Writing 1 to this bit clears the NACKF flag in I2C_ISR register.

Bit 3 ADDRCF: Address matched flag clear
   Writing 1 to this bit clears the ADDR flag in the I2C_ISR register. Writing 1 to this bit also clears the START bit in the I2C_CR2 register.

Bits 2:0 Reserved, must be kept at reset value.

50.7.9 I2C PEC register (I2C_PECR)

Address offset: 0x20
Reset value: 0x0000 0000
Access: no wait states

If the SMBus feature is not supported, this register is reserved, and its bits are forced by hardware to 0. Refer to Section 50.3.
50.7.10 I2C receive data register (I2C_RXDR)

Address offset: 0x24
Reset value: 0x0000 0000
Access: no wait states

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **PEC[7:0]**: Packet error checking register
This field contains the internal PEC when PECEN=1.
The PEC is cleared by hardware when PE = 0.

50.7.11 I2C transmit data register (I2C_TXDR)

Address offset: 0x28
Reset value: 0x0000 0000
Access: no wait states

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **TXDATA[7:0]**: 8-bit transmit data
Data byte to be transmitted to the I2C bus

Note: These bits can be written only when TXE = 1.
## 50.7.12 I2C register map

Refer to Section 2.3 on page 134 for the register boundary addresses.
51 Universal synchronous/asynchronous receiver transmitter (USART/UART)

This section describes the universal synchronous asynchronous receiver transmitter (USART).

51.1 USART introduction

The USART offers a flexible means to perform Full-duplex data exchange with external equipments requiring an industry standard NRZ asynchronous serial data format. A very wide range of baud rates can be achieved through a fractional baud rate generator.

The USART supports both synchronous one-way and Half-duplex Single-wire communications, as well as LIN (local interconnection network), Smartcard protocol, IrDA (infrared data association) SIR ENDEC specifications, and Modem operations (CTS/RTS). Multiprocessor communications are also supported.

High-speed data communications are possible by using the DMA (direct memory access) for multibuffer configuration.
51.2 USART main features

- Full-duplex asynchronous communication
- NRZ standard format (mark/space)
- Configurable oversampling method by 16 or 8 to achieve the best compromise between speed and clock tolerance
- Baud rate generator systems
- Two internal FIFOs for transmit and receive data
  Each FIFO can be enabled/disabled by software and come with a status flag.
- A common programmable transmit and receive baud rate
- Dual clock domain with dedicated kernel clock for peripherals independent from PCLK
- Auto baud rate detection
- Programmable data word length (7, 8 or 9 bits)
- Programmable data order with MSB-first or LSB-first shifting
- Configurable stop bits (1 or 2 stop bits)
- Synchronous master/slave mode and clock output/input for synchronous communications
- SPI slave transmission underrun error flag
- Single-wire Half-duplex communications
- Continuous communications using DMA
- Received/transmitted bytes are buffered in reserved SRAM using centralized DMA.
- Separate enable bits for transmitter and receiver
- Separate signal polarity control for transmission and reception
- Swappable Tx/Rx pin configuration
- Hardware flow control for modem and RS-485 transceiver
- Communication control/error detection flags
- Parity control:
  - Transmits parity bit
  - Checks parity of received data byte
- Interrupt sources with flags
- Multiprocessor communications: wake-up from Mute mode by idle line detection or address mark detection
- Wake-up from Stop mode
51.3 **USART extended features**

- LIN master synchronous break send capability and LIN slave break detection capability
  - 13-bit break generation and 10/11 bit break detection when USART is hardware configured for LIN
- IrDA SIR encoder decoder supporting 3/16 bit duration for normal mode
- Smartcard mode
  - Supports the \( T = 0 \) and \( T = 1 \) asynchronous protocols for smartcards as defined in the ISO/IEC 7816-3 standard
  - 0.5 and 1.5 stop bits for Smartcard operation
- Support for Modbus communication
  - Timeout feature
  - CR/LF character recognition

51.4 **USART implementation**

The table(s) below describe(s) USART implementation. It(they) also include(s) LPUART for comparison.

**Table 419. USART / LPUART features**

1. \( X = \) supported.
51.5 UART functional description

51.5.1 UART block diagram

The simplified block diagram given in Figure 613 shows two fully-independent clock domains:

- The **usart_pclk** clock domain
  The **usart_pclk** clock signal feeds the peripheral bus interface. It must be active when accesses to the USART registers are required.

- The **usart_ker_ck** kernel clock domain.
  The **usart_ker_ck** is the USART clock source. It is independent from **usart_pclk** and delivered by the RCC. The USART registers can consequently be written/read even when the **usart_ker_ck** clock is stopped.
  When the dual clock domain feature is disabled, the **usart_ker_ck** clock is the same as the **usart_pclk** clock.

There is no constraint between **usart_pclk** and **usart_ker_ck**: **usart_ker_ck** can be faster or slower than **usart_pclk**. The only limitation is the software ability to manage the communication fast enough.

When the USART operates in SPI slave mode, it handles data flow using the serial interface clock derived from the external CK signal provided by the external master SPI device. The **usart_ker_ck** clock must be at least 3 times faster than the clock on the CK input.
51.5.2 USART signals

USART bidirectional communications

USART bidirectional communications require a minimum of two pins: Receive Data In (RX) and Transmit Data Out (TX):
- **RX** (Receive Data Input)
  RX is the serial data input. Oversampling techniques are used for data recovery. They discriminate between valid incoming data and noise.
- **TX** (Transmit Data Output)
  When the transmitter is disabled, the output pin returns to its I/O port configuration. When the transmitter is enabled and no data needs to be transmitted, the TX pin is High. In Single-wire and Smartcard modes, this I/O is used to transmit and receive data.

RS232 Hardware flow control mode

The following pins are required in RS232 Hardware flow control mode:
- **CTS** (Clear To Send)
  When driven high, this signal blocks the data transmission at the end of the current transfer.
- **RTS** (Request To Send)
  When it is low, this signal indicates that the USART is ready to receive data.

RS485 Hardware control mode

The following pin is required in RS485 Hardware control mode:
- **DE** (Driver Enable)
  This signal activates the transmission mode of the external transceiver.

*Note: DE and RTS share the same pin.*

Synchronous master/slave mode and Smartcard mode

The following pin is required in synchronous master/slave mode and Smartcard mode:
- **CK**
  This pin acts as Clock output in Synchronous master and Smartcard modes. It acts as Clock input in Synchronous slave mode.
  In Synchronous Master mode, this pin outputs the transmitter data clock for synchronous transmission corresponding to SPI master mode (no clock pulses on start bit and stop bit, and a software option to send a clock pulse on the last data bit). In parallel, data can be received synchronously on RX pin. This mechanism can be used to control peripherals featuring shift registers (e.g. LCD drivers). The clock phase and polarity are software programmable.
  In Smartcard mode, CK output provides the clock to the smartcard.
- **NSS**
  This pin acts as Slave Select input in Synchronous slave mode.

*Note: NSS and CTS share the same pin.*
51.5.3 USART character description

The word length can be set to 7, 8 or 9 bits, by programming the M bits (M0: bit 12 and M1: bit 28) in the USART_CR1 register (see Figure 614):

- 7-bit character length: M[1:0] = ‘10’
- 8-bit character length: M[1:0] = ‘00’
- 9-bit character length: M[1:0] = ‘01’

Note: In 7-bit data length mode, the Smartcard mode, LIN master mode and auto baud rate (0x7F and 0x55 frames detection) are not supported.

By default, the signal (TX or RX) is in low state during the start bit. It is in high state during the stop bit.

These values can be inverted, separately for each signal, through polarity configuration control.

An Idle character is interpreted as an entire frame of “1”s (the number of “1”s includes the number of stop bits).

A Break character is interpreted on receiving “0”s for a frame period. At the end of the break frame, the transmitter inserts 2 stop bits.

Transmission and reception are driven by a common baud rate generator. The transmission and reception clock are generated when the enable bit is set for the transmitter and receiver, respectively.

A detailed description of each block is given below.
Figure 614. Word length programming

9-bit word length (M = 01), 1 Stop bit

```

** LBCL bit controls last data clock pulse
51.5.4 USART FIFOs and thresholds

The USART can operate in FIFO mode.

The USART comes with a Transmit FIFO (TXFIFO) and a Receive FIFO (RXFIFO). The FIFO mode is enabled by setting FIFOEN in USART_CR1 register (bit 29). This mode is supported only in UART, SPI and Smartcard modes.

Since the maximum data word length is 9 bits, the TXFIFO is 9-bit wide. However the RXFIFO default width is 12 bits. This is due to the fact that the receiver does not only store the data in the FIFO, but also the error flags associated to each character (Parity error, Noise error and Framing error flags).

Note: The received data is stored in the RXFIFO together with the corresponding flags. However, only the data are read when reading the RDR.

The status flags are available in the USART_ISR register.

It is possible to configure the TXFIFO and RXFIFO levels at which the Tx and RX interrupts are triggered. These thresholds are programmed through RXFTCFG and TXFTCFG bitfields in USART_CR3 control register.

In this case:
- The RXFT flag is set in the USART_ISR register and the corresponding interrupt (if enabled) is generated, when the number of received data in the RXFIFO reaches the threshold programmed in the RXFTCFG bits fields.
  This means that the RXFIFO is filled until the number of data in the RXFIFO is equal to the programmed threshold.
  RXFTCFG data have been received: one data in USART_RDR and (RXFTCFG - 1) data in the RXFIFO. As an example, when the RXFTCFG is programmed to ‘101’, the RXFT flag is set when a number of data corresponding to the FIFO size has been received (FIFO size -1 data in the RXFIFO and 1 data in the USART_RDR). As a result, the next received data is not set the overrun flag.
- The TXFT flag is set in the USART_ISR register and the corresponding interrupt (if enabled) is generated when the number of empty locations in the TXFIFO reaches the threshold programmed in the TXFTCFG bits fields.
  This means that the TXFIFO is emptied until the number of empty locations in the TXFIFO is equal to the programmed threshold.

51.5.5 USART transmitter

The transmitter can send data words of either 7 or 8 or 9 bits, depending on the M bit status. The Transmit Enable bit (TE) must be set in order to activate the transmitter function. The data in the transmit shift register is output on the TX pin while the corresponding clock pulses are output on the CK pin.

Character transmission

During an USART transmission, data shifts out the least significant bit first (default configuration) on the TX pin. In this mode, the USART_TDR register consists of a buffer (TDR) between the internal bus and the transmit shift register.

When FIFO mode is enabled, the data written to the transmit data register (USART_TDR) are queued in the TXFIFO.
Every character is preceded by a start bit which corresponds to a low logic level for one bit period. The character is terminated by a configurable number of stop bits.

The number of stop bits can be configured to 0.5, 1, 1.5 or 2.

Note: The TE bit must be set before writing the data to be transmitted to the USART_TDR. The TE bit should not be reset during data transmission. Resetting the TE bit during the transmission corrupts the data on the TX pin as the baud rate counters get frozen. The current data being transmitted are then lost.

An idle frame is sent when the TE bit is enabled.

Configurable stop bits

The number of stop bits to be transmitted with every character can be programmed in USART_CR2, bits 13,12.

- **1 stop bit**: This is the default value of number of stop bits.
- **2 stop bits**: This is supported by normal USART, Single-wire and Modem modes.
- **1.5 stop bits**: To be used in Smartcard mode.

An idle frame transmission includes the stop bits.

A break transmission features 10 low bits (when M[1:0] = ‘00’) or 11 low bits (when M[1:0] = ‘01’) or 9 low bits (when M[1:0] = ‘10’) followed by 2 stop bits (see Figure 615). It is not possible to transmit long breaks (break of length greater than 9/10/11 low bits).

**Figure 615. Configurable stop bits**
Character transmission procedure

To transmit a character, follow the sequence below:

1. Program the M bits in USART_CR1 to define the word length.
2. Select the desired baud rate using the USART_BRR register.
3. Program the number of stop bits in USART_CR2.
4. Enable the USART by writing the UE bit in USART_CR1 register to 1.
5. Select DMA enable (DMAT) in USART_CR3 if multibuffer communication must take place. Configure the DMA register as explained in Section 51.5.19: Continuous communication using USART and DMA.
6. Set the TE bit in USART_CR1 to send an idle frame as first transmission.
7. Write the data to send in the USART_TDR register. Repeat this for each data to be transmitted in case of single buffer.
   - When FIFO mode is disabled, writing a data to the USART_TDR clears the TXE flag.
   - When FIFO mode is enabled, writing a data to the USART_TDR adds one data to the TXFIFO. Write operations to the USART_TDR are performed when TXFNF flag is set. This flag remains set until the TXFIFO is full.
8. When the last data is written to the USART_TDR register, wait until TC = 1.
   - When FIFO mode is disabled, this indicates that the transmission of the last frame is complete.
   - When FIFO mode is enabled, this indicates that both TXFIFO and shift register are empty.

This check is required to avoid corrupting the last transmission when the USART is disabled or enters Halt mode.
Single byte communication

- When FIFO mode is disabled
  Writing to the transmit data register always clears the TXE bit. The TXE flag is set by hardware. It indicates that:
  - the data have been moved from the USART_TDR register to the shift register and the data transmission has started;
  - the USART_TDR register is empty;
  - the next data can be written to the USART_TDR register without overwriting the previous data.
  This flag generates an interrupt if the TXEIE bit is set.
  When a transmission is ongoing, a write instruction to the USART_TDR register stores the data in the TDR buffer. It is then copied in the shift register at the end of the current transmission.
  When no transmission is ongoing, a write instruction to the USART_TDR register places the data in the shift register, the data transmission starts, and the TXE bit is set.

- When FIFO mode is enabled, the TXFNF (TXFIFO not full) flag is set by hardware to indicate that:
  - the TXFIFO is not full;
  - the USART_TDR register is empty;
  - the next data can be written to the USART_TDR register without overwriting the previous data. When a transmission is ongoing, a write operation to the USART_TDR register stores the data in the TXFIFO. Data are copied from the TXFIFO to the shift register at the end of the current transmission.
  When the TXFIFO is not full, the TXFNF flag stays at ‘1’ even after a write operation to USART_TDR register. It is cleared when the TXFIFO is full. This flag generates an interrupt if the TXFNFIE bit is set.
  Alternatively, interrupts can be generated and data can be written to the FIFO when the TXFIFO threshold is reached. In this case, the CPU can write a block of data defined by the programmed trigger level.
  If a frame is transmitted (after the stop bit) and the TXE flag (TXFE in case of FIFO mode) is set, the TC flag goes high. An interrupt is generated if the TCIE bit is set in the USART_CR1 register.

After writing the last data to the USART_TDR register, it is mandatory to wait until TC is set before disabling the USART or causing the device to enter the low-power mode (see Figure 616: TC/TXE behavior when transmitting).

</tbody>
</table>

Note: When FIFO management is enabled, the TXFNF flag is used for data transmission.

**Break characters**

Setting the SBKRQ bit transmits a break character. The break frame length depends on the M bit (see Figure 614).

If a ‘1’ is written to the SBKRQ bit, a break character is sent on the TX line after completing the current character transmission. The SBKF bit is set by the write operation and it is reset by hardware when the break character is completed (during the stop bits after the break character). The USART inserts a logic 1 signal (stop) for the duration of 2 bits at the end of the break frame to guarantee the recognition of the start bit of the next frame.

When the SBKRQ bit is set, the break character is sent at the end of the current transmission.

When FIFO mode is enabled, sending the break character has priority on sending data even if the TXFIFO is full.

**Idle characters**

Setting the TE bit drives the USART to send an idle frame before the first data frame.

51.5.6 **USART receiver**

The USART can receive data words of either 7 or 8 or 9 bits depending on the M bits in the USART_CR1 register.

**Start bit detection**

The start bit detection sequence is the same when oversampling by 16 or by 8.

In the USART, the start bit is detected when a specific sequence of samples is recognized. This sequence is: 1 1 1 0 X 0 X 0X 0X 0 X 0X 0.
Figure 617. Start bit detection when oversampling by 16 or 8

</tr>
</tbody>
</table>

Note: If the sequence is not complete, the start bit detection aborts and the receiver returns to the idle state (no flag is set), where it waits for a falling edge.

The start bit is confirmed (RXNE flag set and interrupt generated if RXNEIE = 1, or RXFNE flag set and interrupt generated if RXFNEIE = 1 if FIFO mode enabled) if the 3 sampled bits are at '0' (first sampling on the 3rd, 5th and 7th bits finds the 3 bits at '0' and second sampling on the 8th, 9th and 10th bits also finds the 3 bits at '0').

The start bit is validated but the NE noise flag is set if,

a) for both samplings, 2 out of the 3 sampled bits are at '0' (sampling on the 3rd, 5th and 7th bits and sampling on the 8th, 9th and 10th bits) or

b) for one of the samplings (sampling on the 3rd, 5th and 7th bits or sampling on the 8th, 9th and 10th bits), 2 out of the 3 bits are found at '0'.

If neither of the above conditions are met, the start detection aborts and the receiver returns to the idle state (no flag is set).
Character reception
During an USART reception, data are shifted out least significant bit first (default configuration) through the RX pin.

Character reception procedure
To receive a character, follow the sequence below:
1. Program the M bits in USART_CR1 to define the word length.
2. Select the desired baud rate using the baud rate register USART_BRR.
3. Program the number of stop bits in USART_CR2.
4. Enable the USART by writing the UE bit in USART_CR1 register to ‘1’.
5. Select DMA enable (DMAR) in USART_CR3 if multibuffer communication is to take place. Configure the DMA register as explained in Section 51.5.19: Continuous communication using USART and DMA.
6. Set the RE bit USART_CR1. This enables the receiver which begins searching for a start bit.

When a character is received:
- When FIFO mode is disabled, the RXNE bit is set to indicate that the content of the shift register is transferred to the RDR. In other words, data have been received and can be read (as well as their associated error flags).
- When FIFO mode is enabled, the RXFNE bit is set to indicate that the RXFIFO is not empty. Reading the USART_RDR returns the oldest data entered in the RXFIFO.
- When a data is received, it is stored in the RXFIFO together with the corresponding error bits.
- An interrupt is generated if the RXNEIE (RXFNEIE when FIFO mode is enabled) bit is set.
- The error flags can be set if a frame error, noise, parity or an overrun error was detected during reception.
- In multibuffer communication mode:
  - When FIFO mode is disabled, the RXNE flag is set after every byte reception. It is cleared when the DMA reads the Receive data Register.
  - When FIFO mode is enabled, the RXFNE flag is set when the RXFIFO is not empty. After every DMA request, a data is retrieved from the RXFIFO. A DMA request is triggered when the RXFIFO is not empty i.e. when there are data to be read from the RXFIFO.
- In single buffer mode:
  - When FIFO mode is disabled, clearing the RXNE flag is done by performing a software read from the USART_RDR register. The RXNE flag can also be cleared by programming RXFRQ bit to ‘1’ in the USART_RQR register. The RXNE flag must be cleared before the end of the reception of the next character to avoid an overrun error.
  - When FIFO mode is enabled, the RXFNE is set when the RXFIFO is not empty. After every read operation from USART_RDR, a data is retrieved from the RXFIFO. When the RXFIFO is empty, the RXFNE flag is cleared. The RXFNE flag can also be cleared by programming RXFRQ bit to ‘1’ in USART_RQR. When the RXFIFO is full, the first entry in the RXFIFO must be read before the end of the reception of the next character, to avoid an overrun error. The RXFNE flag generates an interrupt if the RXFNEIE bit is set. Alternatively, interrupts can be
generated and data can be read from RXFIFO when the RXFIFO threshold is reached. In this case, the CPU can read a block of data defined by the programmed threshold.

**Break character**

When a break character is received, the USART handles it as a framing error.

**Idle character**

When an idle frame is detected, it is handled in the same way as a data character reception except that an interrupt is generated if the IDLEIE bit is set.

**Overrun error**

- **FIFO mode disabled**
  
  An overrun error occurs if a character is received and RXNE has not been reset. Data can not be transferred from the shift register to the RDR register until the RXNE bit is cleared. The RXNE flag is set after every byte reception.
  
  An overrun error occurs if RXNE flag is set when the next data is received or the previous DMA request has not been serviced. When an overrun error occurs:
  
  - the ORE bit is set;
  - the RDR content is not lost. The previous data is available by reading the USART_RDR register.
  - the shift register is overwritten. After that, any data received during overrun is lost.
  - an interrupt is generated if either the RXNEIE or the EIE bit is set.

- **FIFO mode enabled**
  
  An overrun error occurs when the shift register is ready to be transferred and the receive FIFO is full.
  
  Data can not be transferred from the shift register to the USART_RDR register until there is one free location in the RXFIFO. The RXFNE flag is set when the RXFIFO is not empty.
  
  An overrun error occurs if the RXFIFO is full and the shift register is ready to be transferred. When an overrun error occurs:
  
  - The ORE bit is set.
  - The first entry in the RXFIFO is not lost. It is available by reading the USART_RDR register.
  - The shift register is overwritten. After that point, any data received during overrun is lost.
  - An interrupt is generated if either the RXFNEIE or EIE bit is set.

The ORE bit is reset by setting the ORECF bit in the USART_ICR register.

*Note:* The ORE bit, when set, indicates that at least 1 data has been lost.

When the FIFO mode is disabled, there are two possibilities

- if RXNE = 1, then the last valid data is stored in the receive register (RDR) and can be read,
- if RXNE = 0, the last valid data has already been read and there is nothing left to be read in the RDR register. This case can occur when the last valid data is read in the RDR register at the same time as the new (and lost) data is received.
Selecting the clock source and the appropriate oversampling method

The choice of the clock source is done through the Clock Control system (see Section Reset and clock control (RCC)). The clock source must be selected through the UE bit before enabling the USART.

The clock source must be selected according to two criteria:

- Possible use of the USART in low-power mode
- Communication speed.

The clock source frequency is `usart_ker_ck`.

When the dual clock domain and the wake-up from low-power mode features are supported, the `usart_ker_ck` clock source can be configurable in the RCC (see Section Reset and clock control (RCC)). Otherwise the `usart_ker_ck` clock is the same as `usart_pclk`.

The `usart_ker_ck` clock can be divided by a programmable factor, defined in the USART_PRES register.

![Figure 618. usart_ker_ck clock divider block diagram](image)

Some `usart_ker_ck` sources enable the USART to receive data while the MCU is in low-power mode. Depending on the received data and wake-up mode selected, the USART wakes up the MCU, when needed, in order to transfer the received data, by performing a software read to the USART_RDR register or by DMA.

For the other clock sources, the system must be active to enable USART communications.

The communication speed range (specially the maximum communication speed) is also determined by the clock source.

The receiver implements different user-configurable oversampling techniques (except in synchronous mode) for data recovery by discriminating between valid incoming data and noise. This enables obtaining the best a trade-off between the maximum communication speed and noise/clock inaccuracy immunity.

The oversampling method can be selected by programming the OVER8 bit in the USART_CR1 register either to 16 or 8 times the baud rate clock (see Figure 619 and Figure 620).

Depending on your application:

- select oversampling by 8 (OVER8 = 1) to achieve higher speed (up to `usart_ker_ck_pres/8`). In this case the maximum receiver tolerance to clock deviation is reduced (refer to Section 51.5.8: Tolerance of the USART receiver to clock deviation on page 2189)
- select oversampling by 16 (OVER8 = 0) to increase the tolerance of the receiver to clock deviations. In this case, the maximum speed is limited to maximum
usart_ker_ck_pres/16 (where usart_ker_ck_pres is the USART input clock divided by a prescaler).

Programming the ONEBIT bit in the USART_CR3 register selects the method used to evaluate the logic level. Two options are available:

- The majority vote of the three samples in the center of the received bit. In this case, when the 3 samples used for the majority vote are not equal, the NE bit is set.
- A single sample in the center of the received bit

Depending on your application:

- select the three sample majority vote method (ONEBIT = 0) when operating in a noisy environment and reject the data when a noise is detected (refer to Figure 420) because this indicates that a glitch occurred during the sampling.
- select the single sample method (ONEBIT = 1) when the line is noise-free to increase the receiver tolerance to clock deviations (see Section 51.5.8: Tolerance of the USART receiver to clock deviation on page 2189). In this case the NE bit is never set.

When noise is detected in a frame:

- The NE bit is set at the rising edge of the RXNE bit (RXFNE in case of FIFO mode enabled).
- The invalid data is transferred from the Shift register to the USART_RDR register.
- No interrupt is generated in case of single byte communication. However this bit rises at the same time as the RXNE bit (RXFNE in case of FIFO mode enabled) which itself generates an interrupt. In case of multibuffer communication an interrupt is issued if the EIE bit is set in the USART_CR3 register.

The NE bit is reset by setting NECF bit in USART_ICR register.

Note: Noise error is not supported in SPI mode.

Oversampling by 8 is not available in the Smartcard, IrDA and LIN modes. In those modes, the OVER8 bit is forced to '0' by hardware.
Framing error

A framing error is detected when the stop bit is not recognized on reception at the expected time, following either a de-synchronization or excessive noise.

When the framing error is detected:
- the FE bit is set by hardware;
- the invalid data is transferred from the Shift register to the USART_RDR register (RXFIFO in case FIFO mode is enabled).
- no interrupt is generated in case of single byte communication. However this bit rises at the same time as the RXNE bit (RXFNE in case FIFO mode is enabled) which itself generates an interrupt. In case of multibuffer communication an interrupt is issued if the EIE bit is set in the USART_CR3 register.

The FE bit is reset by writing ‘1’ to the FECF in the USART_ICR register.

Note: Framing error is not supported in SPI mode.
Configurable stop bits during reception

The number of stop bits to be received can be configured through the control bits of USART_CR: it can be either 1 or 2 in normal mode and 0.5 or 1.5 in Smartcard mode.

- **0.5 stop bit (reception in Smartcard mode):** no sampling is done for 0.5 stop bit. As a consequence, no framing error and no break frame can be detected when 0.5 stop bit is selected.

- **1 stop bit:** sampling for 1 stop bit is done on the 8th, 9th and 10th samples.

- **1.5 stop bits (Smartcard mode):**
  
  When transmitting in Smartcard mode, the device must check that the data are correctly sent. The receiver block must consequently be enabled (RE = 1 in USART_CR1) and the stop bit is checked to test if the Smartcard has detected a parity error.

  In the event of a parity error, the Smartcard forces the data signal low during the sampling (NACK signal), which is flagged as a framing error. The FE flag is then set through RXNE flag (RXFNE if the FIFO mode is enabled) at the end of the 1.5 stop bit. Sampling for 1.5 stop bits is done on the 16th, 17th and 18th samples (1 baud clock period after the beginning of the stop bit). The 1.5 stop bit can be broken into 2 parts: one 0.5 baud clock period during which nothing happens, followed by 1 normal stop bit period during which sampling occurs halfway through (refer to Section 51.5.16: USART receiver timeout on page 2203 for more details).

- **2 stop bits:**
  
  Sampling for 2 stop bits is done on the 8th, 9th and 10th samples of the first stop bit. The framing error flag is set if a framing error is detected during the first stop bit. The second stop bit is not checked for framing error. The RXNE flag (RXFNE if the FIFO mode is enabled) is set at the end of the first stop bit.

**51.5.7 USART baud rate generation**

The baud rate for the receiver and transmitter (Rx and Tx) are both set to the value programmed in the USART_BRR register.

**Equation 1: baud rate for standard USART (SPI mode included) (OVER8 = '0' or '1')**

In case of oversampling by 16, the baud rate is given by the following formula:

\[
\text{Tx/Rx baud} = \frac{\text{usart_ker_ckpres}}{\text{USARTDIV}}
\]

In case of oversampling by 8, the baud rate is given by the following formula:

\[
\text{Tx/Rx baud} = \frac{2 \times \text{usart_ker_ckpres}}{\text{USARTDIV}}
\]

**Equation 2: baud rate in Smartcard, LIN and IrDA modes (OVER8 = 0)**

The baud rate is given by the following formula:

\[
\text{Tx/Rx baud} = \frac{\text{usart_ker_ckpres}}{\text{USARTDIV}}
\]
USARTDIV is an unsigned fixed point number that is coded on the USART_BRR register.

- When OVER8 = 0, BRR = USARTDIV.
- When OVER8 = 1

**Note:** The baud counters are updated to the new value in the baud registers after a write operation to USART_BRR. Hence the baud rate register value should not be changed during communication.

In case of oversampling by 16 and 8, USARTDIV must be greater than or equal to 16.

### How to derive USARTDIV from USART_BRR register values

#### Example 1
To obtain 9600 baud with `usart_ker_ck_pres = 8 MHz`:

- In case of oversampling by 16:
  
  \[
  \text{USARTDIV} = \frac{8\,000\,000}{9600} \approx 833
  \]

  \[
  \text{BRR} = \text{USARTDIV} = 0d833 = 0x0341
  \]

- In case of oversampling by 8:
  
  \[
  \text{USARTDIV} = 2 \times \frac{8\,000\,000}{9600} \approx 1667
  \]

  \[
  \text{USARTDIV} = 0d1667 = 0x683
  \]

  \[
  \text{BRR}[3:0] = 0x3 >> 1 = 0x1
  \]

  \[
  \text{BRR} = 0x681
  \]

#### Example 2
To obtain 921.6 Kbaud with `usart_ker_ck_pres = 48 MHz`:

- In case of oversampling by 16:
  
  \[
  \text{USARTDIV} = \frac{48\,000\,000}{921\,600} \approx 52
  \]

  \[
  \text{BRR} = \text{USARTDIV} = 0d52 = 0x34
  \]

- In case of oversampling by 8:
  
  \[
  \text{USARTDIV} = 2 \times \frac{48\,000\,000}{921\,600} \approx 104
  \]

  \[
  \text{USARTDIV} = 0d104 = 0x68
  \]

  \[
  \text{BRR}[3:0] = \text{USARTDIV}[3:0] >> 1 = 0x8 >> 1 = 0x4
  \]

  \[
  \text{BRR} = 0x64
  \]

### 51.5.8 Tolerance of the USART receiver to clock deviation

The USART asynchronous receiver operates correctly only if the total clock system deviation is less than the tolerance of the USART receiver.
The causes which contribute to the total deviation are:

- **DTRA**: deviation due to the transmitter error (which also includes the deviation of the transmitter’s local oscillator)
- **DQUANT**: error due to the baud rate quantization of the receiver
- **DREC**: deviation of the receiver local oscillator
- **DTCL**: deviation due to the transmission line (generally due to the transceivers which can introduce an asymmetry between the low-to-high transition timing and the high-to-low transition timing)

\[ \text{DTRA} + \text{DQUANT} + \text{DREC} + \text{DTCL} + \text{DWU} < \text{USAR T receiver tolerance} \]

where

- \( \text{DWU} \) is the error due to sampling point deviation when the wake-up from low-power mode is used.

  - when \( M[1:0] = 01 \):
    \[
    \text{DWU} = \frac{t_{\text{WUUSART}}}{11 \times T_{\text{bit}}}
    \]
  - when \( M[1:0] = 00 \):
    \[
    \text{DWU} = \frac{t_{\text{WUUSART}}}{10 \times T_{\text{bit}}}
    \]
  - when \( M[1:0] = 10 \):
    \[
    \text{DWU} = \frac{t_{\text{WUUSART}}}{9 \times T_{\text{bit}}}
    \]

\( t_{\text{WUUSART}} \) is the time between the detection of the start bit falling edge and the instant when the clock (requested by the peripheral) is ready and reaching the peripheral, and the regulator is ready.

The USART receiver can receive data correctly at up to the maximum tolerated deviation specified in Table 421, Table 422, depending on the following settings:

- 9-, 10- or 11-bit character length defined by the M bits in the USART_CR1 register
- Oversampling by 8 or 16 defined by the OVER8 bit in the USART_CR1 register
- Bits BRR[3:0] of USART_BRR register are equal to or different from 0000.
- Use of 1 bit or 3 bits to sample the data, depending on the value of the ONEBIT bit in the USART_CR3 register.

### USART auto baud rate detection

The USART can detect and automatically set the USART_BRR register value based on the reception of one character. Automatic baud rate detection is useful under two circumstances:

- The communication speed of the system is not known in advance.
- The system is using a relatively low accuracy clock source and this mechanism enables the correct baud rate to be obtained without measuring the clock deviation.

The clock source frequency must be compatible with the expected communication speed.

- When oversampling by 16, the baud rate ranges from `usart_ker_ck_pres/65535` and `usart_ker_ck_pres/16`.
- When oversampling by 8, the baud rate ranges from `usart_ker_ck_pres/65535` and `usart_ker_ck_pres/8`.

Before activating the auto baud rate detection, the auto baud rate detection mode must be selected through the ABRMOD[1:0] field in the USART_CR2 register. There are four modes based on different character patterns. In these auto baud rate modes, the baud rate is measured several times during the synchronization data reception and each measurement is compared to the previous one.

**Note:** The data specified in Table 421 and Table 422 may slightly differ in the special case when the received frames contain some Idle frames of exactly 10-bit times when M bits = 00 (11-bit times when M = 01 or 9-bit times when M = 10).
These modes are the following:

- **Mode 0**: Any character starting with a bit at ‘1’.
  
  In this case the USART measures the duration of the start bit (falling edge to rising edge).

- **Mode 1**: Any character starting with a 10xx bit pattern.
  
  In this case, the USART measures the duration of the Start and of the 1st data bit. The measurement is done falling edge to falling edge, to ensure a better accuracy in the case of slow signal slopes.

- **Mode 2**: A 0x7F character frame (it may be a 0x7F character in LSB first mode or a 0xFE in MSB first mode).
  
  In this case, the baud rate is updated first at the end of the start bit (BRs), then at the end of bit 6 (based on the measurement done from falling edge to falling edge: BR6). Bit 0 to bit 6 are sampled at BRs while further bits of the character are sampled at BR6.

- **Mode 3**: A 0x55 character frame.
  
  In this case, the baud rate is updated first at the end of the start bit (BRs), then at the end of bit 0 (based on the measurement done from falling edge to falling edge: BR0), and finally at the end of bit 6 (BR6). Bit 0 is sampled at BRs, bit 1 to bit 6 are sampled at BR0, and further bits of the character are sampled at BR6. In parallel, another check is performed for each intermediate RX line transition. An error is generated if the transitions on RX are not sufficiently synchronized with the receiver (the receiver being based on the baud rate calculated on bit 0).

Prior to activating the auto baud rate detection, the USART_BRR register must be initialized by writing a non-zero baud rate value.

The automatic baud rate detection is activated by setting the ABREN bit in the USART_CR2 register. The USART then waits for the first character on the RX line. The auto baud rate operation completion is indicated by the setting of the ABRF flag in the USART_ISR register. If the line is noisy, the correct baud rate detection cannot be guaranteed. In this case the BRR value may be corrupted and the ABRE error flag is set. This also happens if the communication speed is not compatible with the automatic baud rate detection range (bit duration not between 16 and 65536 clock periods (oversampling by 16) and not between 8 and 65536 clock periods (oversampling by 8)).

The auto baud rate detection can be re-launched later by resetting the ABRF flag (by writing a ‘0’).

When FIFO management is disabled and an auto baud rate error occurs, the ABRE flag is set through RXNE and FE bits.

When FIFO management is enabled and an auto baud rate error occurs, the ABRE flag is set through RXFNE and FE bits.

If the FIFO mode is enabled, the auto baud rate detection should be made using the data on the first RXFIFO location. So, prior to launching the auto baud rate detection, make sure that the RXFIFO is empty by checking the RXFNE flag in USART_ISR register.

**Note:** The BRR value might be corrupted if the USART is disabled (UE = 0) during an auto baud rate operation.
51.5.10 USART multiprocessor communication

It is possible to perform USART multiprocessor communications (with several USARTs connected in a network). For instance one of the USARTs can be the master with its TX output connected to the RX inputs of the other USARTs, while the others are slaves with their respective TX outputs logically ANDed together and connected to the RX input of the master.

In multiprocessor configurations, it is often desirable that only the intended message recipient actively receives the full message contents, thus reducing redundant USART service overhead for all non addressed receivers.

The non-addressed devices can be placed in Mute mode by means of the muting function. To use the Mute mode feature, the MME bit must be set in the USART_CR1 register.

Note: When FIFO management is enabled and MME is already set, MME bit must not be cleared and then set again quickly (within two usart_ker_ck cycles), otherwise Mute mode might remain active.

When the Mute mode is enabled:
- none of the reception status bits can be set;
- all the receive interrupts are inhibited;
- the RWU bit in USART_ISR register is set to ‘1’. RWU can be controlled automatically by hardware or by software, through the MMRQ bit in the USART_RQR register, under certain conditions.

The USART can enter or exit from Mute mode using one of two methods, depending on the WAKE bit in the USART_CR1 register:
- Idle Line detection if the WAKE bit is reset,
- Address Mark detection if the WAKE bit is set.

Idle line detection (WAKE = 0)

The USART enters Mute mode when the MMRQ bit is written to ‘1’ and the RWU is automatically set.

The USART wakes up when an Idle frame is detected. The RWU bit is then cleared by hardware but the IDLE bit is not set in the USART_ISR register. An example of Mute mode behavior using Idle line detection is given in Figure 621.
Figure 621. Mute mode using Idle line detection

Note: If the MMRQ is set while the IDLE character has already elapsed, Mute mode is not entered (RWU is not set).

If the USART is activated while the line is IDLE, the idle state is detected after the duration of one IDLE frame (not only after the reception of one character frame).

4-bit/7-bit address mark detection (WAKE = 1)

In this mode, bytes are recognized as addresses if their MSB is a ‘1’, otherwise they are considered as data. In an address byte, the address of the targeted receiver is put in the 4 or 7 LSBs. The choice of 7 or 4 bit address detection is done using the ADDM7 bit. This 4-bit/7-bit word is compared by the receiver with its own address which is programmed in the ADD bits in the USART_CR2 register.

Note: In 7-bit and 9-bit data modes, address detection is done on 6-bit and 8-bit addresses (ADD[5:0] and ADD[7:0]) respectively.

The USART enters Mute mode when an address character is received which does not match its programmed address. In this case, the RWU bit is set by hardware. The RXNE flag is not set for this address byte and no interrupt or DMA request is issued when the USART enters Mute mode. When FIFO management is enabled, the software should ensure that there is at least one empty location in the RXFIFO before entering Mute mode.

The USART also enters Mute mode when the MMRQ bit is written to 1. The RWU bit is also automatically set in this case.

The USART exits from Mute mode when an address character is received which matches the programmed address. Then the RWU bit is cleared and subsequent bytes are received normally. The RXNE/RXFNE bit is set for the address character since the RWU bit has been cleared.

Note: When FIFO management is enabled, when MMRQ is set while the receiver is sampling last bit of a data, this data may be received before effectively entering in Mute mode.

An example of Mute mode behavior using address mark detection is given in Figure 622.
51.5.11 **USART Modbus communication**

The USART offers basic support for the implementation of Modbus/RTU and Modbus/ASCII protocols. Modbus/RTU is a Half-duplex, block-transfer protocol. The control part of the protocol (address recognition, block integrity control and command interpretation) must be implemented in software.

The USART offers basic support for the end of the block detection, without software overhead or other resources.

**Modbus/RTU**

In this mode, the end of one block is recognized by a “silence” (idle line) for more than 2 character times. This function is implemented through the programmable timeout function.

The timeout function and interrupt must be activated, through the RTOEN bit in the USART_CR2 register and the RTOIE in the USART_CR1 register. The value corresponding to a timeout of 2 character times (for example 22 x bit time) must be programmed in the RTO register. When the receive line is idle for this duration, after the last stop bit is received, an interrupt is generated, informing the software that the current block reception is completed.

**Modbus/ASCII**

In this mode, the end of a block is recognized by a specific (CR/LF) character sequence. The USART manages this mechanism using the character match function.

By programming the LF ASCII code in the ADD[7:0] field and by activating the character match interrupt (CMIE = 1), the software is informed when a LF has been received and can check the CR/LF in the DMA buffer.
51.5.12 USART parity control

Parity control (generation of parity bit in transmission and parity checking in reception) can be enabled by setting the PCE bit in the USART_CR1 register. Depending on the frame length defined by the M bits, the possible USART frame formats are as listed in Table 423.

1. Legends: SB: start bit, STB: stop bit, PB: parity bit. In the data register, the PB is always taking the MSB position (8th or 7th, depending on the M bit value).

Even parity

The parity bit is calculated to obtain an even number of “1s” inside the frame of the 6, 7 or 8 LSB bits (depending on M bit values) and the parity bit.

As an example, if data = 00110101 and 4 bits are set, the parity bit is equal to 0 if even parity is selected (PS bit in USART_CR1 = 0).

Odd parity

The parity bit is calculated to obtain an odd number of “1s” inside the frame made of the 6, 7 or 8 LSB bits (depending on M bit values) and the parity bit.

As an example, if data = 00110101 and 4 bits set, then the parity bit is equal to 1 if odd parity is selected (PS bit in USART_CR1 = 1).

Parity checking in reception

If the parity check fails, the PE flag is set in the USART_ISR register and an interrupt is generated if PEIE is set in the USART_CR1 register. The PE flag is cleared by software writing 1 to the PECF in the USART_ICR register.

Parity generation in transmission

If the PCE bit is set in USART_CR1, then the MSB bit of the data written in the data register is transmitted but is changed by the parity bit (even number of “1s” if even parity is selected (PS = 0) or an odd number of “1s” if odd parity is selected (PS=1).
51.5.13 USART LIN (local interconnection network) mode

This section is relevant only when LIN mode is supported. Refer to Section 51.4: USART implementation on page 2172.

The LIN mode is selected by setting the LINEN bit in the USART_CR2 register. In LIN mode, the following bits must be kept cleared:
- CLKEN in the USART_CR2 register,
- STOP[1:0], SCEN, HDSEL and IREN in the USART_CR3 register.

LIN transmission

The procedure described in Section 51.5.4 has to be applied for LIN Master transmission. It must be the same as for normal USART transmission with the following differences:
- Clear the M bit to configure 8-bit word length.
- Set the LINEN bit to enter LIN mode. In this case, setting the SBKRQ bit sends 13 '0' bits as a break character. Then two bits of value '1' are sent to enable the next start detection.

LIN reception

When LIN mode is enabled, the break detection circuit is activated. The detection is totally independent from the normal USART receiver. A break can be detected whenever it occurs, during Idle state or during a frame.

When the receiver is enabled (RE = 1 in USART_CR1), the circuit looks at the RX input for a start signal. The method for detecting start bits is the same when searching break characters or data. After a start bit has been detected, the circuit samples the next bits exactly like for the data (on the 8th, 9th and 10th samples). If 10 (when the LBDL = 0 in USART_CR2) or 11 (when LBDL = 1 in USART_CR2) consecutive bits are detected as '0', and are followed by a delimiter character, the LBDF flag is set in USART_ISR. If the LBDIE bit = 1, an interrupt is generated. Before validating the break, the delimiter is checked for as it signifies that the RX line has returned to a high level.

If a '1' is sampled before the 10 or 11 have occurred, the break detection circuit cancels the current detection and searches for a start bit again.

If the LIN mode is disabled (LINEN = 0), the receiver continues working as normal USART, without taking into account the break detection.

If the LIN mode is enabled (LINEN = 1), as soon as a framing error occurs (i.e. stop bit detected at '0', which is the case for any break frame), the receiver stops until the break detection circuit receives either a '1', if the break word was not complete, or a delimiter character if a break has been detected.

The behavior of the break detector state machine and the break flag is shown on the Figure 623: Break detection in LIN mode (11-bit break length - LBDL bit is set) on page 2198.

Examples of break frames are given on Figure 624: Break detection in LIN mode vs. Framing error detection on page 2199.

MSv31156V1
51.5.14 **USART synchronous mode**

**Master mode**

The synchronous master mode is selected by programming the CLKEN bit in the USART_CR2 register to ‘1’. In synchronous mode, the following bits must be kept cleared:

- LINEN bit in the USART_CR2 register,
- SCEN, HDSEL and IREN bits in the USART_CR3 register.

In this mode, the USART can be used to control bidirectional synchronous serial communications in master mode. The CK pin is the output of the USART transmitter clock. No clock pulses are sent to the CK pin during start bit and stop bit. Depending on the state of the LBCL bit in the USART_CR2 register, clock pulses are, or are not, generated during the last valid data bit (address mark). The CPOL bit in the USART_CR2 register is used to select the clock polarity, and the CPHA bit in the USART_CR2 register is used to select the phase of the external clock (see Figure 625, Figure 626 and Figure 627).

During the Idle state, preamble and send break, the external CK clock is not activated.

In synchronous master mode, the USART transmitter operates exactly like in asynchronous mode. However, since CK is synchronized with TX (according to CPOL and CPHA), the data on TX is synchronous.

In synchronous master mode, the USART receiver operates in a different way compared to asynchronous mode. If RE is set to 1, the data are sampled on CK (rising or falling edge, depending on CPOL and CPHA), without any oversampling. A given setup and a hold time must be respected (which depends on the baud rate: 1/16 bit time).
Note: In master mode, the CK pin operates in conjunction with the TX pin. Thus, the clock is provided only if the transmitter is enabled (TE = 1) and data are being transmitted (USART_TDR data register written). This means that it is not possible to receive synchronous data without transmitting data.

Figure 625. USART example of synchronous master transmission

Figure 626. USART data clock timing diagram in synchronous master mode (M bits = 00)
Figure 627. USART data clock timing diagram in synchronous master mode
(M bits = 01)

Slave mode

The synchronous slave mode is selected by programming the SLVEN bit in the
USART_CR2 register to ‘1’. In synchronous slave mode, the following bits must be kept
cleared:
- LINEN and CLKEN bits in the USART_CR2 register,
- SCEN, HDSEL and IREN bits in the USART_CR3 register.

In this mode, the USART can be used to control bidirectional synchronous serial
communications in slave mode. The CK pin is the input of the USART in slave mode.

Note: When the peripheral is used in SPI slave mode, the frequency of peripheral clock source
(usart_ker_ck_pres) must be greater than 3 times the CK input frequency.

The CPOL bit and the CPHA bit in the USART_CR2 register are used to select the clock
polarity and the phase of the external clock, respectively (see Figure 628).

An underrun error flag is available in slave transmission mode. This flag is set when the first
clock pulse for data transmission appears while the software has not yet loaded any value to
USART_TDR.

The slave supports the hardware and software NSS management.
Slave Select (NSS) pin management

The hardware or software slave select management can be set through the DIS_NSS bit in the USART_CR2 register:

- **Software NSS management (DIS_NSS = 1)**
  
  The SPI slave is always selected and NSS input pin is ignored.
  
  The external NSS pin remains free for other application uses.

- **Hardware NSS management (DIS_NSS = 0)**

  The SPI slave selection depends on NSS input pin. The slave is selected when NSS is low and deselected when NSS is high.

**Note:** The LBCL (used only on SPI master mode), CPOL and CPHA bits have to be selected when the USART is disabled (UE = 0) to ensure that the clock pulses function correctly.

In SPI slave mode, the USART must be enabled before starting the master communications (or between frames while the clock is stable). Otherwise, if the USART slave is enabled while the master is in the middle of a frame, it becomes desynchronized with the master. The data register of the slave needs to be ready before the first edge of the communication clock or before the end of the ongoing communication, otherwise the SPI slave transmits zeros.

**SPI Slave underrun error**

When an underrun error occurs, the UDR flag is set in the USART_ISR register, and the SPI slave goes on sending the last data until the underrun error flag is cleared by software.

The underrun flag is set at the beginning of the frame. An underrun error interrupt is triggered if EIE bit is set in the USART_CR3 register.

The underrun error flag is cleared by setting bit UDRCF in the USART_ICR register.
In case of underrun error, it is still possible to write to the TDR register. Clearing the underrun error enables sending new data.

If an underrun error occurred and there is no new data written in TDR, then the TC flag is set at the end of the frame.

Note: An underrun error may occur if the moment the data is written to the USART_TDR is too close to the first CK transmission edge. To avoid this underrun error, the USART_TDR should be written 3 \texttt{usart\_ker\_ck} cycles before the first CK edge.

51.5.15 **USART single-wire Half-duplex communication**

Single-wire Half-duplex mode is selected by setting the HDSEL bit in the USART_CR3 register. In this mode, the following bits must be kept cleared:

- LINEN and CLKEN bits in the USART_CR2 register,
- SCEN and IREN bits in the USART_CR3 register.

The USART can be configured to follow a Single-wire Half-duplex protocol where the TX and RX lines are internally connected. The selection between half- and Full-duplex communication is made with a control bit HDSEL in USART_CR3.

As soon as HDSEL is written to ‘1’:

- The TX and RX lines are internally connected.
- The RX pin is no longer used.
- The TX pin is always released when no data is transmitted. Thus, it acts as a standard I/O in idle or in reception. It means that the I/O must be configured so that TX is configured as alternate function open-drain with an external pull-up.

Apart from this, the communication protocol is similar to normal USART mode. Any conflict on the line must be managed by software (for instance by using a centralized arbiter). In particular, the transmission is never blocked by hardware and continues as soon as data are written in the data register while the TE bit is set.

51.5.16 **USART receiver timeout**

The receiver timeout feature is enabled by setting the RTOEN bit in the USART_CR2 control register.

The timeout duration is programmed using the RTO bitfields in the USART_RTOR register.

The receiver timeout counter starts counting:

- from the end of the stop bit if STOP = ‘00’ or STOP = ‘11’
- from the end of the second stop bit if STOP = ‘10’.
- from the beginning of the stop bit if STOP = ‘01’.

When the timeout duration has elapsed, the RTOF flag in the USART_ISR register is set. A timeout is generated if RTOIE bit in USART_CR1 register is set.
51.5.17 USART Smartcard mode

This section is relevant only when Smartcard mode is supported. Refer to Section 51.4: USART implementation on page 2172.

Smartcard mode is selected by setting the SCEN bit in the USART_CR3 register. In Smartcard mode, the following bits must be kept cleared:

- LINEN bit in the USART_CR2 register,
- HDSEL and IREN bits in the USART_CR3 register.

The CLKEN bit can also be set to provide a clock to the Smartcard.

The Smartcard interface is designed to support asynchronous Smartcard protocol as defined in the ISO 7816-3 standard. Both T = 0 (character mode) and T = 1 (block mode) are supported.

The USART should be configured as:

- 8 bits plus parity: M = 1 and PCE = 1 in the USART_CR1 register
- 1.5 stop bits when transmitting and receiving data: STOP = '11' in the USART_CR2 register. It is also possible to choose 0.5 stop bit for reception.

In T = 0 (character) mode, the parity error is indicated at the end of each character during the guard time period. Figure 629 shows examples of what can be seen on the data line with and without parity error.

**Figure 629. ISO 7816-3 asynchronous protocol**

When connected to a Smartcard, the TX output of the USART drives a bidirectional line that is also driven by the Smartcard. The TX pin must be configured as open drain.

Smartcard mode implements a single wire half duplex communication protocol.

- Transmission of data from the transmit shift register is guaranteed to be delayed by a minimum of 1/2 baud clock. In normal operation a full transmit shift register starts shifting on the next baud clock edge. In Smartcard mode this transmission is further delayed by a guaranteed 1/2 baud clock.
- In transmission, if the Smartcard detects a parity error, it signals this condition to the USART by driving the line low (NACK). This NACK signal (pulldown transmit line low for 1 baud clock) causes a framing error on the transmitter side (configured with 1.5 stop bits). The USART can handle automatic re-sending of data according to the protocol.
The number of retries is programmed in the SCARCNT bitfield. If the USART continues receiving the NACK after the programmed number of retries, it stops transmitting and signals the error as a framing error. The TXE bit (TXFNF bit in case FIFO mode is enabled) may be set using the TXFRQ bit in the USART_RQR register.

- Smartcard auto-retry in transmission: A delay of 2.5 baud periods is inserted between the NACK detection by the USART and the start bit of the repeated character. The TC bit is set immediately at the end of reception of the last repeated character (no guardtime). If the software wants to repeat it again, it must insure the minimum 2 baud periods required by the standard.

- If a parity error is detected during reception of a frame programmed with a 1.5 stop bit period, the transmit line is pulled low for a baud clock period after the completion of the receive frame. This is to indicate to the Smartcard that the data transmitted to the USART has not been correctly received. A parity error is NACKed by the receiver if the NACK control bit is set, otherwise a NACK is not transmitted (to be used in T = 1 mode). If the received character is erroneous, the RXNE (RXFNE in case FIFO mode is enabled)/receive DMA request is not activated. According to the protocol specification, the Smartcard must resend the same character. If the received character is still erroneous after the maximum number of retries specified in the SCARCNT bitfield, the USART stops transmitting the NACK and signals the error as a parity error.

- Smartcard auto-retry in reception: the BUSY flag remains set if the USART NACKs the card but the card doesn't repeat the character.

- In transmission, the USART inserts the Guard Time (as programmed in the Guard Time register) between two successive characters. As the Guard Time is measured after the stop bit of the previous character, the GT[7:0] register must be programmed to the desired CGT (Character Guard Time, as defined by the 7816-3 specification) minus 12 (the duration of one character).

- The assertion of the TC flag can be delayed by programming the Guard Time register. In normal operation, TC is asserted when the transmit shift register is empty and no further transmit requests are outstanding. In Smartcard mode an empty transmit shift register triggers the Guard Time counter to count up to the programmed value in the Guard Time register. TC is forced low during this time. When the Guard Time counter reaches the programmed value TC is asserted high. The TCBGT flag can be used to detect the end of data transfer without waiting for guard time completion. This flag is set just after the end of frame transmission and if no NACK has been received from the card.

- The deassertion of TC flag is unaffected by Smartcard mode.

- If a framing error is detected on the transmitter end (due to a NACK from the receiver), the NACK is not detected as a start bit by the receive block of the transmitter. According to the ISO protocol, the duration of the received NACK can be 1 or 2 baud clock periods.

- On the receiver side, if a parity error is detected and a NACK is transmitted the receiver does not detect the NACK as a start bit.

Note: Break characters are not significant in Smartcard mode. A 0x00 data with a framing error is treated as data and not as a break.

No Idle frame is transmitted when toggling the TE bit. The Idle frame (as defined for the other configurations) is not defined by the ISO protocol.

Figure 630 shows how the NACK signal is sampled by the USART. In this example the USART is transmitting data and is configured with 1.5 stop bits. The receiver part of the USART is enabled in order to check the integrity of the data and the NACK signal.
The USART can provide a clock to the Smartcard through the CK output. In Smartcard mode, CK is not associated to the communication but is simply derived from the internal peripheral input clock through a 5-bit prescaler. The division ratio is configured in the USART_GTPR register. CK frequency can be programmed from \( \text{usrat_ker_ck_pres}/2 \) to \( \text{usrat_ker_ck_pres}/62 \), where \( \text{usrat_ker_ck_pres} \) is the peripheral input clock divided by a programmed prescaler.

### Block mode (T = 1)

In \( T = 1 \) (block) mode, the parity error transmission can be deactivated by clearing the NACK bit in the USART_CR3 register.

When requesting a read from the Smartcard, in block mode, the software must program the RTOR register to the BWT (block wait time) - 11 value. If no answer is received from the card before the expiration of this period, a timeout interrupt is generated. If the first character is received before the expiration of the period, it is signaled by the RXNE/RXFNE interrupt.

**Note:** The RXNE/RXFNE interrupt must be enabled even when using the USART in DMA mode to read from the Smartcard in block mode. In parallel, the DMA must be enabled only after the first received byte.

After the reception of the first character (RXNE/RXFNE interrupt), the RTO register must be programmed to the CWT (character wait time -11 value), in order to enable the automatic check of the maximum wait time between two consecutive characters. This time is expressed in baud time units. If the Smartcard does not send a new character in less than the CWT period after the end of the previous character, the USART signals it to the software through the RTOF flag and interrupt (when RTOIE bit is set).

**Note:** As in the Smartcard protocol definition, the BWT/CWT values should be defined from the beginning (start bit) of the last character. The RTO register must be programmed to BWT - 11 or CWT -11, respectively, taking into account the length of the last character itself.

A block length counter is used to count all the characters received by the USART. This counter is reset when the USART is transmitting. The length of the block is communicated by the Smartcard in the third byte of the block (prologue field). This value must be programmed to the BLEN field in the USART_RTOR register. When using DMA mode, before the start of the block, this register field must be programmed to the minimum value.
(0x0). With this value, an interrupt is generated after the 4th received character. The software must read the LEN field (third byte), its value must be read from the receive buffer.

In interrupt driven receive mode, the length of the block may be checked by software or by programming the BLEN value. However, before the start of the block, the maximum value of BLEN (0xFF) may be programmed. The real value is programmed after the reception of the third character.

If the block is using the LRC longitudinal redundancy check (1 epilogue byte), the BLEN = LEN. If the block is using the CRC mechanism (2 epilog bytes), BLEN = LEN+1 must be programmed. The total block length (including prologue, epilogue and information fields) equals BLEN+4. The end of the block is signaled to the software through the EOBF flag and interrupt (when EOBIE bit is set).

In case of an error in the block length, the end of the block is signaled by the RTO interrupt (Character Wait Time overflow).

Note: The error checking code (LRC/CRC) must be computed/verified by software.

Direct and inverse convention

The Smartcard protocol defines two conventions: direct and inverse.

The direct convention is defined as: LSB first, logical bit value of 1 corresponds to a H state of the line and parity is even. In order to use this convention, the following control bits must be programmed: MSBFIRST = 0, DATAINV = 0 (default values).

The inverse convention is defined as: MSB first, logical bit value 1 corresponds to an L state on the signal line and parity is even. In order to use this convention, the following control bits must be programmed: MSBFIRST = 1, DATAINV = 1.

Note: When logical data values are inverted (0 = H, 1 = L), the parity bit is also inverted in the same way.

In order to recognize the card convention, the card sends the initial character, TS, as the first character of the ATR (Answer To Reset) frame. The two possible patterns for the TS are: LHHL LLL LLH and LHHL HHH LLH.

- (H) LHHL LLL LLH sets up the inverse convention: state L encodes value 1 and moment 2 conveys the most significant bit (MSB first). When decoded by inverse convention, the conveyed byte is equal to ‘3F’.
- (H) LHHL HHH LLH sets up the direct convention: state H encodes value 1 and moment 2 conveys the least significant bit (LSB first). When decoded by direct convention, the conveyed byte is equal to ‘3B’.

Character parity is correct when there is an even number of bits set to 1 in the nine moments 2 to 10.

As the USART does not know which convention is used by the card, it needs to be able to recognize either pattern and act accordingly. The pattern recognition is not done in hardware, but through a software sequence. Moreover, assuming that the USART is configured in direct convention (default) and the card answers with the inverse convention, TS = LHHL LLL LLH results in a USART received character of 03 and an odd parity.
Therefore, two methods are available for TS pattern recognition:

**Method 1**

The USART is programmed in standard Smartcard mode/direct convention. In this case, the TS pattern reception generates a parity error interrupt and error signal to the card.

- The parity error interrupt informs the software that the card did not answer correctly in direct convention. Software then reprograms the USART for inverse convention.
- In response to the error signal, the card retries the same TS character, and it is correctly received this time, by the reprogrammed USART.

Alternatively, in answer to the parity error interrupt, the software may decide to reprogram the USART and to also generate a new reset command to the card, then wait again for the TS.

**Method 2**

The USART is programmed in 9-bit/no-parity mode, no bit inversion. In this mode it receives any of the two TS patterns as:

(H) LHHL LLL LLH = 0x103: inverse convention to be chosen
(H) LHHL HHH LLH = 0x13B: direct convention to be chosen

The software checks the received character against these two patterns and, if any of them match, then programs the USART accordingly for the next character reception.

If none of the two is recognized, a card reset may be generated in order to restart the negotiation.

**51.5.18 USART IrDA SIR ENDEC block**

This section is relevant only when IrDA mode is supported. Refer to Section 51.4: USART implementation on page 2172.

IrDA mode is selected by setting the IREN bit in the USART_CR3 register. In IrDA mode, the following bits must be kept cleared:

- LINEN, STOP and CLKEN bits in the USART_CR2 register,
- SCEN and HDSEL bits in the USART_CR3 register.

The IrDA SIR physical layer specifies use of a Return to Zero, Inverted (RZI) modulation scheme that represents logic 0 as an infrared light pulse (see Figure 631).

The SIR Transmit encoder modulates the Non Return to Zero (NRZ) transmit bit stream output from USART. The output pulse stream is transmitted to an external output driver and infrared LED. USART supports only bit rates up to 115.2 kbaud for the SIR ENDEC. In normal mode the transmitted pulse width is specified as 3/16 of a bit period.

The SIR receive decoder demodulates the return-to-zero bit stream from the infrared detector and outputs the received NRZ serial bit stream to the USART. The decoder input is normally high (marking state) in the Idle state. The transmit encoder output has the opposite polarity to the decoder input. A start bit is detected when the decoder input is low.

- IrDA is a half duplex communication protocol. If the Transmitter is busy (when the USART is sending data to the IrDA encoder), any data on the IrDA receive line is ignored by the IrDA decoder and if the Receiver is busy (when the USART is receiving decoded data from the USART), data on the TX from the USART to IrDA is not
encoded. While receiving data, transmission should be avoided as the data to be transmitted could be corrupted.

- A ‘0’ is transmitted as a high pulse and a ‘1’ is transmitted as a ‘0’. The width of the pulse is specified as 3/16th of the selected bit period in normal mode (see Figure 632).
- The SIR decoder converts the IrDA compliant receive signal into a bit stream for USART.
- The SIR receive logic interprets a high state as a logic one and low pulses as logic zeros.
- The transmit encoder output has the opposite polarity to the decoder input. The SIR output is in low state when Idle.
- The IrDA specification requires the acceptance of pulses greater than 1.41 µs. The acceptable pulse width is programmable. Glitch detection logic on the receiver end filters out pulses of width less than 2 PSC periods (PSC is the prescaler value programmed in the USART_GTPR). Pulses of width less than 1 PSC period are always rejected, but those of width greater than one and less than two periods may be accepted or rejected, those greater than two periods are accepted as a pulse. The IrDA encoder/decoder doesn’t work when PSC = 0.
- The receiver can communicate with a low-power transmitter.
- In IrDA mode, the stop bits in the USART_CR2 register must be configured to ‘1 stop bit’.

**IrDA low-power mode**

- **Transmitter**
  In low-power mode, the pulse width is not maintained at 3/16 of the bit period. Instead, the width of the pulse is 3 times the low-power baud rate which can be a minimum of 1.42 MHz. Generally, this value is 1.8432 MHz (1.42 MHz < PSC < 2.12 MHz). A low-power mode programmable divisor divides the system clock to achieve this value.

- **Receiver**
  Receiving in low-power mode is similar to receiving in normal mode. For glitch detection the USART should discard pulses of duration shorter than 1/PSC. A valid low is accepted only if its duration is greater than 2 periods of the IrDA low-power Baud clock (PSC value in the USART_GTPR).

**Note:** A pulse of width less than two and greater than one PSC period(s) may or may not be rejected.

_The receiver set up time should be managed by software. The IrDA physical layer specification specifies a minimum of 10 ms delay between transmission and reception (IrDA is a half duplex protocol)._
Figure 631. IrDA SIR ENDEC block diagram

Figure 632. IrDA data modulation (3/16) - Normal mode
51.5.19 Continuous communication using USART and DMA

The USART is capable of performing continuous communications using the DMA. The DMA requests for Rx buffer and Tx buffer are generated independently.

*Note:* Refer to Section 51.4: USART implementation on page 2172 to determine if the DMA mode is supported. If DMA is not supported, use the USART as explained in Section 51.5.6. To perform continuous communications when the FIFO is disabled, clear the TXE/ RXNE flags in the USART_ISR register.

Transmission using DMA

DMA mode can be enabled for transmission by setting DMAT bit in the USART_CR3 register. Data are loaded from an SRAM area configured using the DMA peripheral (refer to the corresponding Direct memory access controller section) to the USART_TDR register whenever the TXE flag (TXFNF flag if FIFO mode is enabled) is set. To map a DMA channel for USART transmission, use the following procedure (x denotes the channel number):

1. Write the USART_TDR register address in the DMA control register to configure it as the destination of the transfer. The data is moved to this address from memory after each TXE (or TXFNF if FIFO mode is enabled) event.
2. Write the memory address in the DMA control register to configure it as the source of the transfer. The data is loaded into the USART_TDR register from this memory area after each TXE (or TXFNF if FIFO mode is enabled) event.
3. Configure the total number of bytes to be transferred to the DMA control register.
4. Configure the channel priority in the DMA register.
5. Configure DMA interrupt generation after half/ full transfer as required by the application.
6. Clear the TC flag in the USART_ISR register by setting the TCCF bit in the USART_ICR register.
7. Activate the channel in the DMA register.

When the number of data transfers programmed in the DMA Controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector.

In transmission mode, once the DMA has written all the data to be transmitted (the TCIF flag is set in the DMA_ISR register), the TC flag can be monitored to make sure that the USART communication is complete. This is required to avoid corrupting the last transmission before disabling the USART or before the system enters a low-power mode when the peripheral clock is disabled. Software must wait until TC = 1. The TC flag remains cleared during all data transfers and it is set by hardware at the end of transmission of the last frame.
When FIFO management is enabled, the DMA request is triggered by Transmit FIFO not full (i.e. TXFNF = 1).

Reception using DMA

DMA mode can be enabled for reception by setting the DMAR bit in USART_CR3 register. Data are loaded from the USART_RDR register to an SRAM area configured using the DMA peripheral (refer to the corresponding Direct memory access controller section) whenever a data byte is received. To map a DMA channel for USART reception, use the following procedure:

1. Write the USART_RDR register address in the DMA control register to configure it as the source of the transfer. The data is moved from this address to the memory after each RXNE (RXFNE in case FIFO mode is enabled) event.
2. Write the memory address in the DMA control register to configure it as the destination of the transfer. The data is loaded from USART_RDR to this memory area after each RXNE (RXFNE in case FIFO mode is enabled) event.
3. Configure the total number of bytes to be transferred to the DMA control register.
4. Configure the channel priority in the DMA control register.
5. Configure interrupt generation after half/ full transfer as required by the application.
6. Activate the channel in the DMA control register.

When the number of data transfers programmed in the DMA Controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector.
Figure 634. Reception using DMA

Note: When FIFO management is enabled, the DMA request is triggered by Receive FIFO not empty (i.e. RXFNE = 1).

Error flagging and interrupt generation in multibuffer communication

If any error occurs during a transaction in multibuffer communication mode, the error flag is asserted after the current byte. An interrupt is generated if the interrupt enable flag is set. For framing error, overrun error and noise flag which are asserted with RXNE (RXFNE in case FIFO mode is enabled) in single byte reception, there is a separate error flag interrupt enable bit (EIE bit in the USART_CR3 register), which, if set, enables an interrupt after the current byte if any of these errors occur.

51.5.20 RS232 Hardware flow control and RS485 Driver Enable

It is possible to control the serial data flow between 2 devices by using the CTS input and the RTS output. The Figure 635 shows how to connect 2 devices in this mode:

Figure 635. Hardware flow control between 2 USARTs
RS232 RTS and CTS flow control can be enabled independently by writing the RTSE and CTSE bits to ‘1’ in the USART_CR3 register.

**RS232 RTS flow control**

If the RTS flow control is enabled (RTSE = 1), then RTS is deasserted (tied low) as long as the USART receiver is ready to receive a new data. When the receive register is full, RTS is asserted, indicating that the transmission is expected to stop at the end of the current frame. *Figure 636* shows an example of communication with RTS flow control enabled.

*Figure 636. RS232 RTS flow control*

![RS232 RTS flow control diagram]

Note: When FIFO mode is enabled, RTS is asserted only when RXFIFO is full.

**RS232 CTS flow control**

If the CTS flow control is enabled (CTSE = 1), then the transmitter checks the CTS input before transmitting the next frame. If CTS is deasserted (tied low), then the next data is transmitted (assuming that data is to be transmitted, in other words, if TXE/TXFE = 0), else the transmission does not occur. When CTS is asserted during a transmission, the current transmission is completed before the transmitter stops.

When CTSE = 1, the CTSIF status bit is automatically set by hardware as soon as the CTS input toggles. It indicates when the receiver becomes ready or not ready for communication. An interrupt is generated if the CTSIE bit in the USART_CR3 register is set. *Figure 637* shows an example of communication with CTS flow control enabled.
Note: For correct behavior, CTS must be deasserted at least 3 USART clock source periods before the end of the current character. In addition it should be noted that the CTSCF flag may not be set for pulses shorter than 2 x PCLK periods.

RS485 driver enable

The driver enable feature is enabled by setting bit DEM in the USART_CR3 control register. This enables the user to activate the external transceiver control, through the DE (Driver Enable) signal. The assertion time is the time between the activation of the DE signal and the beginning of the start bit. It is programmed using the DEAT [4:0] bitfields in the USART_CR1 control register. The deassertion time is the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE signal. It is programmed using the DEDT [4:0] bitfields in the USART_CR1 control register. The polarity of the DE signal can be configured using the DEP bit in the USART_CR3 control register.

In USART, the DEAT and DEDT are expressed in sample time units (1/8 or 1/16 bit time, depending on the oversampling rate).
51.5.21 USART low-power management

The USART has advanced low-power mode functions, that enables transferring properly data even when the usart_pclk clock is disabled.

The USART is able to wake up the MCU from low-power mode when the UESM bit is set.

When the usart_pclk is gated, the USART provides a wake-up interrupt (usart_wkup) if a specific action requiring the activation of the usart_pclk clock is needed:

- If FIFO mode is disabled
  usart_pclk clock has to be activated to empty the USART data register.
  In this case, the usart_wkup interrupt source is RXNE set to ‘1’. The RXNEIE bit must be set before entering low-power mode.

- If FIFO mode is enabled
  usart_pclk clock has to be activated to:
  - to fill the TXFIFO
  - or to empty the RXFIFO
  In this case, the usart_wkup interrupt source can be:
  - RXFIFO not empty. In this case, the RXFNEIE bit must be set before entering low-power mode.
  - RXFIFO full. In this case, the RXFFIE bit must be set before entering low-power mode, the number of received data corresponds to the RXFIFO size, and the RXFF flag is not set.
  - TXFIFO empty. In this case, the TXFEIE bit must be set before entering low-power mode.

This enables sending/receiving the data in the TXFIFO/RXFIFO during low-power mode.

To avoid overrun/underrun errors and transmit/receive data in low-power mode, the usart_wkup interrupt source can be one of the following events:

- TXFIFO threshold reached. In this case, the TXFTIE bit must be set before entering low-power mode.
- RXFIFO threshold reached. In this case, the RXFTIE bit must be set before entering low-power mode.

For example, the application can set the threshold to the maximum RXFIFO size if the wake-up time is less than the time required to receive a single byte across the line.

Using the RXFIFO full, TXFIFO empty, RXFIFO not empty and RXFIFO/TXFIFO threshold interrupts to wake up the MCU from low-power mode enables doing as many USART transfers as possible during low-power mode with the benefit of optimizing consumption.

Alternatively, a specific usart_wkup interrupt can be selected through the WUS bitfields.

When the wake-up event is detected, the WUF flag is set by hardware and a usart_wkup interrupt is generated if the WUFIE bit is set.
**Note:** Before entering low-power mode, make sure that no USART transfers are ongoing. Checking the BUSY flag cannot ensure that low-power mode is never entered when data reception is ongoing.

The WUF flag is set when a wake-up event is detected, independently of whether the MCU is in low-power or active mode.

When entering low-power mode just after having initialized and enabled the receiver, the REACK bit must be checked to make sure the USART is enabled.

When DMA is used for reception, it must be disabled before entering low-power mode and re-enabled when exiting from low-power mode.

When the FIFO is enabled, waking up from low-power mode on address match is only possible when Mute mode is enabled.

**Using Mute mode with low-power mode**

If the USART is put into Mute mode before entering low-power mode:

- Wake-up from Mute mode on idle detection must not be used, because idle detection cannot work in low-power mode.
- If the wake-up from Mute mode on address match is used, then the low-power mode wake-up source must also be the address match. If the RXNE flag was set when entering the low-power mode, the interface remains in Mute mode upon address match and wake up from low-power mode.

**Note:** When FIFO management is enabled, Mute mode can be used with wake-up from low-power mode without any constraints (i.e. the two points mentioned above about Mute and low-power mode are valid only when FIFO management is disabled).

**Wake-up from low-power mode when USART kernel clock (usart_ker_ck) is OFF in low-power mode**

If during low-power mode, the usart_ker_ck clock is switched OFF when a falling edge on the USART receive line is detected, the USART interface requests the usart_ker_ck clock to be switched ON thanks to the usart_ker_ck_req signal. usart_ker_ck is then used for the frame reception.

If the wake-up event is verified, the MCU wakes up from low-power mode and data reception goes on normally.

If the wake-up event is not verified, usart_ker_ck is switched OFF again, the MCU is not woken up and remains in low-power mode, and the kernel clock request is released.

The example below shows the case of a wake-up event programmed to “address match detection” and FIFO management disabled.
Figure 638 shows the USART behavior when the wake-up event is verified.

**Figure 638. Wake-up event verified (wake-up event = address match, FIFO disabled)**

<table>

</tr>
</tbody>
</table>

Address match event WUF = 1
USART sends a wakeup event to the MCU

Note: The figures above are valid when address match or any received frame is used as wake-up event. If the wake-up event is the start bit detection, the USART sends the wake-up event to the MCU at the end of the start bit.

Figure 639 shows the USART behavior when the wake-up event is not verified.

**Figure 639. Wake-up event not verified (wake-up event = address match, FIFO disabled)**

<table>

</tbody>
</table>

Address does not match

Note: The figures above are valid when address match or any received frame is used as wake-up event. If the wake-up event is the start bit detection, the USART sends the wake-up event to the MCU at the end of the start bit.
Determining the maximum USART baud rate that enables to correctly wake up the device from low-power mode

The maximum baud rate that enables to correctly wake up the device from low-power mode depends on the wake-up time parameter (refer to the device datasheet) and on the USART receiver tolerance (see Section 51.5.8: Tolerance of the USART receiver to clock deviation).

Let us take the example of OVER8 = 0, M bits = '01', ONEBIT = 0 and BRR [3:0] = 0000. In these conditions, according to Table 421: Tolerance of the USART receiver when BRR [3:0] = 0000, the USART receiver tolerance equals 3.41%.

\[
D_{WU} = t_{WU} + D_{TRA} + D_{QUANT} + D_{REC} + D_{TCL} + D_{WU} < \text{USART receiver tolerance}
\]

\[
T_{\text{bit Min}} = \frac{t_{WU}}{(11 \times D_{WU})}
\]

where \( t_{WU} \) is the wake-up time from low-power mode.

If we consider the ideal case where DTRA, DQUANT, DREC and DTCL parameters are at 0%, the maximum value of DWU is 3.41%. In reality, we need to consider at least the usart_ker_ck inaccuracy.

For example, if HSI is used as usart_ker_ck, and the HSI inaccuracy is of 1%, then we obtain:

\[
t_{WU} = 3 \mu s \text{ (values provided only as examples; for correct values, refer to the device datasheet)}.
\]

\[
D_{WU} = 3.41\% - 1\% = 2.41\%
\]

\[
T_{\text{bit min}} = \frac{3 \mu s}{(11 \times 2.41\%)} = 11.32 \mu s.
\]

As a result, the maximum baud rate that enables to wake up correctly from low-power mode is: \( 1/11.32 \mu s = 88.36 \text{ Kbaud} \).

51.6 USART in low-power modes

1. The USART can wake up the device from Stop mode only if the peripheral instance supports the wake-up from Stop mode feature. Refer to Section 51.4: USART implementation for the list of supported Stop modes.
51.8 **USART registers**

Refer to *Section 1.2 on page 106* for a list of abbreviations used in register descriptions.

The peripheral registers have to be accessed by words (32 bits).

### 51.8.1 USART control register 1 (USART_CR1)

Address offset: 0x00

Reset value: 0x0000 0000

The same register can be used in FIFO mode enabled (this section) and FIFO mode disabled (next section).

#### FIFO mode enabled

Bit 31 **RXFFIE**: RXFIFO full interrupt enable

- This bit is set and cleared by software.
- 0: Interrupt inhibited
- 1: USART interrupt generated when RXFF = 1 in the USART_ISR register

Bit 30 **TXFEIE**: TXFIFO empty interrupt enable

- This bit is set and cleared by software.
- 0: Interrupt inhibited
- 1: USART interrupt generated when TXFE = 1 in the USART_ISR register

Bit 29 **FIFOEN**: FIFO mode enable

- This bit is set and cleared by software.
- 0: FIFO mode is disabled.
- 1: FIFO mode is enabled.

This bitfield can only be written when the USART is disabled (UE = 0).

*Note: FIFO mode can be used on standard UART communication, in SPI master/slave mode and in Smartcard modes only. It must not be enabled in IrDA and LIN modes.*
Bit 28  M1: Word length
This bit must be used in conjunction with bit 12 (M0) to determine the word length. It is set or cleared by software.
M[1:0] = '00': 1 start bit, 8 Data bits, n Stop bit
M[1:0] = '01': 1 start bit, 9 Data bits, n Stop bit
M[1:0] = '10': 1 start bit, 7 Data bits, n Stop bit
This bit can only be written when the USART is disabled (UE = 0).

Note: In 7-bits data length mode, the Smartcard mode, LIN master mode and auto baud rate (0x7F and 0x55 frames detection) are not supported.

Bit 27  EOBIE: End-of-block interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated when the EOBF flag is set in the USART_ISR register

Note: If the USART does not support Smartcard mode, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation on page 2172.

Bit 26  RTOIE: Receiver timeout interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated when the RTOF bit is set in the USART_ISR register.

Note: If the USART does not support the Receiver timeout feature, this bit is reserved and must be kept at reset value. Section 51.4: USART implementation on page 2172.

Bits 25:21  DEAT[4:0]: Driver enable assertion time
This 5-bit value defines the time between the activation of the DE (Driver Enable) signal and the beginning of the start bit. It is expressed in sample time units (1/8 or 1/16 bit time, depending on the oversampling rate).
This bitfield can only be written when the USART is disabled (UE = 0).

Note: If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation on page 2172.

Bits 20:16  DEDT[4:0]: Driver enable deassertion time
This 5-bit value defines the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE (Driver Enable) signal. It is expressed in sample time units (1/8 or 1/16 bit time, depending on the oversampling rate).
If the USART_TDR register is written during the DEDT time, the new data is transmitted only when the DEDT and DEAT times have both elapsed.
This bitfield can only be written when the USART is disabled (UE = 0).

Note: If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation on page 2172.

Bit 15  OVER8: Oversampling mode
0: Oversampling by 16
1: Oversampling by 8
This bit can only be written when the USART is disabled (UE = 0).

Note: In LIN, IrDA and Smartcard modes, this bit must be kept cleared.

Bit 14  CMIE: Character match interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated when the CMF bit is set in the USART_ISR register.
Bit 13 **MME**: Mute mode enable
This bit enables the USART Mute mode function. When set, the USART can switch between active and Mute mode, as defined by the WAKE bit. It is set and cleared by software.
0: Receiver in active mode permanently
1: Receiver can switch between Mute mode and active mode.

Bit 12 **M0**: Word length
This bit is used in conjunction with bit 28 (M1) to determine the word length. It is set or cleared by software (refer to bit 28 (M1) description).
This bit can only be written when the USART is disabled (UE = 0).

Bit 11 **WAKE**: Receiver wake-up method
This bit determines the USART wake-up method from Mute mode. It is set or cleared by software.
0: Idle line
1: Address mark
This bitfield can only be written when the USART is disabled (UE = 0).

Bit 10 **PCE**: Parity control enable
This bit selects the hardware parity control (generation and detection). When the parity control is enabled, the computed parity is inserted at the MSB position (9th bit if M = 1; 8th bit if M = 0) and the parity is checked on the received data. This bit is set and cleared by software. Once it is set, PCE is active after the current byte (in reception and in transmission).
0: Parity control disabled
1: Parity control enabled
This bitfield can only be written when the USART is disabled (UE = 0).

Bit 9 **PS**: Parity selection
This bit selects the odd or even parity when the parity generation/detection is enabled (PCE bit set). It is set and cleared by software. The parity is selected after the current byte.
0: Even parity
1: Odd parity
This bitfield can only be written when the USART is disabled (UE = 0).

Bit 8 **PEIE**: PE interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever PE = 1 in the USART_ISR register

Bit 7 **TXFNFIE**: TXFIFO not-full interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever TXFNF = 1 in the USART_ISR register

Bit 6 **TCIE**: Transmission complete interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever TC = 1 in the USART_ISR register

Bit 5 **RXFNEIE**: RXFIFO not empty interrupt enable
This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated whenever ORE = 1 or RXFNE = 1 in the USART_ISR register
Bit 4 **IDLEIE**: IDLE interrupt enable
   This bit is set and cleared by software.
   0: Interrupt inhibited
   1: USART interrupt generated whenever IDLE = 1 in the USART_ISR register

Bit 3 **TE**: Transmitter enable
   This bit enables the transmitter. It is set and cleared by software.
   0: Transmitter is disabled
   1: Transmitter is enabled

   **Note:** During transmission, a low pulse on the TE bit (‘0’ followed by ‘1’) sends a preamble (idle line) after the current word, except in Smartcard mode. In order to generate an idle character, the TE must not be immediately written to ‘1’. To ensure the required duration, the software can poll the TEACK bit in the USART_ISR register.

   In Smartcard mode, when TE is set, there is a 1 bit-time delay before the transmission starts.

Bit 2 **RE**: Receiver enable
   This bit enables the receiver. It is set and cleared by software.
   0: Receiver is disabled
   1: Receiver is enabled and begins searching for a start bit

Bit 1 **UESM**: USART enable in low-power mode
   When this bit is cleared, the USART cannot wake up the MCU from low-power mode.
   When this bit is set, the USART can wake up the MCU from low-power mode.
   This bit is set and cleared by software.
   0: USART not able to wake up the MCU from low-power mode.
   1: USART able to wake up the MCU from low-power mode.

   **Note:** It is recommended to set the UESM bit just before entering low-power mode and clear it when exit from low-power mode.

   If the USART does not support the wake-up from Stop feature, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation on page 2172.

Bit 0 **UE**: USART enable
   When this bit is cleared, the USART prescalers and outputs are stopped immediately, and all current operations are discarded. The USART configuration is kept, but all the USART_ISR status flags are reset. This bit is set and cleared by software.
   0: USART prescaler and outputs disabled, low-power mode
   1: USART enabled

   **Note:** To enter low-power mode without generating errors on the line, the TE bit must be previously reset and the software must wait for the TC bit in the USART_ISR to be set before resetting the UE bit.

   The DMA requests are also reset when UE = 0 so the DMA channel must be disabled before resetting the UE bit.

   In Smartcard mode, (SCEN = 1), the CK is always available when CKEN = 1, regardless of the UE bit value.
51.8.2 USART control register 1 [alternate] (USART_CR1)

Address offset: 0x00
Reset value: 0x0000 0000

The same register can be used in FIFO mode enabled (previous section) and FIFO mode disabled (this section).

FIFO mode disabled

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 FIFOEN: FIFO mode enable
This bit is set and cleared by software.

0: FIFO mode is disabled.
1: FIFO mode is enabled.

This bitfield can only be written when the USART is disabled (UE = 0).

Note: FIFO mode can be used on standard UART communication, in SPI master/slave mode and in Smartcard modes only. It must not be enabled in IrDA and LIN modes.

Bit 28 M1: Word length
This bit must be used in conjunction with bit 12 (M0) to determine the word length. It is set or cleared by software.

M[1:0] = ’00’: 1 start bit, 8 Data bits, n Stop bit
M[1:0] = ’01’: 1 start bit, 9 Data bits, n Stop bit
M[1:0] = ’10’: 1 start bit, 7 Data bits, n Stop bit

This bit can only be written when the USART is disabled (UE = 0).

Note: In 7-bits data length mode, the Smartcard mode, LIN master mode and auto baud rate (0x7F and 0x55 frames detection) are not supported.

Bit 27 EOBIE: End of Block interrupt enable
This bit is set and cleared by software.

0: Interrupt inhibited
1: USART interrupt generated when the EOBF flag is set in the USART_ISR register

Note: If the USART does not support Smartcard mode, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation on page 2172.

Bit 26 RTOIE: Receiver timeout interrupt enable
This bit is set and cleared by software.

0: Interrupt inhibited
1: USART interrupt generated when the RTOF bit is set in the USART_ISR register.

Note: If the USART does not support the Receiver timeout feature, this bit is reserved and must be kept at reset value. Section 51.4: USART implementation on page 2172.
Bits 25:21 **DEAT[4:0]:** Driver enable assertion time

This 5-bit value defines the time between the activation of the DE (Driver Enable) signal and the beginning of the start bit. It is expressed in sample time units (1/8 or 1/16 bit time, depending on the oversampling rate).

This bitfield can only be written when the USART is disabled (UE = 0).

*Note: If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation on page 2172.*

Bits 20:16 **DEDT[4:0]:** Driver enable deassertion time

This 5-bit value defines the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE (Driver Enable) signal. It is expressed in sample time units (1/8 or 1/16 bit time, depending on the oversampling rate).

If the USART_TDR register is written during the DEDT time, the new data is transmitted only when the DEDT and DEAT times have both elapsed.

This bitfield can only be written when the USART is disabled (UE = 0).

*Note: If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation on page 2172.*

Bit 15 **OVER8:** Oversampling mode

0: Oversampling by 16
1: Oversampling by 8

This bit can only be written when the USART is disabled (UE = 0).

*Note: In LIN, IrDA and Smartcard modes, this bit must be kept cleared.*

Bit 14 **CMIE:** Character match interrupt enable

This bit is set and cleared by software.
0: Interrupt inhibited
1: USART interrupt generated when the CMF bit is set in the USART_ISR register.

Bit 13 **MME:** Mute mode enable

This bit enables the USART Mute mode function. When set, the USART can switch between active and Mute mode, as defined by the WAKE bit. It is set and cleared by software.
0: Receiver in active mode permanently
1: Receiver can switch between Mute mode and active mode.

Bit 12 **M0:** Word length

This bit is used in conjunction with bit 28 (M1) to determine the word length. It is set or cleared by software (refer to bit 28 (M1) description).

This bit can only be written when the USART is disabled (UE = 0).

Bit 11 **WAKE:** Receiver wake-up method

This bit determines the USART wake-up method from Mute mode. It is set or cleared by software.
0: Idle line
1: Address mark

This bitfield can only be written when the USART is disabled (UE = 0).

Bit 10 **PCE:** Parity control enable

This bit selects the hardware parity control (generation and detection). When the parity control is enabled, the computed parity is inserted at the MSB position (9th bit if M = 1; 8th bit if M = 0) and the parity is checked on the received data. This bit is set and cleared by software. Once it is set, PCE is active after the current byte (in reception and in transmission).
0: Parity control disabled
1: Parity control enabled

This bitfield can only be written when the USART is disabled (UE = 0).
Bit 9  **PS**: Parity selection  
This bit selects the odd or even parity when the parity generation/detection is enabled (PCE bit set). It is set and cleared by software. The parity is selected after the current byte.  
0: Even parity  
1: Odd parity  
This bitfield can only be written when the USART is disabled (UE = 0).  

Bit 8  **PEIE**: PE interrupt enable  
This bit is set and cleared by software.  
0: Interrupt inhibited  
1: USART interrupt generated whenever PE = 1 in the USART_ISR register  

Bit 7  **TXEIE**: Transmit data register empty  
This bit is set and cleared by software.  
0: Interrupt inhibited  
1: USART interrupt generated whenever TXE = 1 in the USART_ISR register  

Bit 6  **TCIE**: Transmission complete interrupt enable  
This bit is set and cleared by software.  
0: Interrupt inhibited  
1: USART interrupt generated whenever TC = 1 in the USART_ISR register  

Bit 5  **RXNEIE**: Receive data register not empty  
This bit is set and cleared by software.  
0: Interrupt inhibited  
1: USART interrupt generated whenever ORE = 1 or RXNE = 1 in the USART_ISR register  

Bit 4  **IDLEIE**: IDLE interrupt enable  
This bit is set and cleared by software.  
0: Interrupt inhibited  
1: USART interrupt generated whenever IDLE = 1 in the USART_ISR register  

Bit 3  **TE**: Transmitter enable  
This bit enables the transmitter. It is set and cleared by software.  
0: Transmitter is disabled  
1: Transmitter is enabled  

**Note:** During transmission, a low pulse on the TE bit (‘0’ followed by ‘1’) sends a preamble (idle line) after the current word, except in Smartcard mode. In order to generate an idle character, the TE must not be immediately written to ‘1’. To ensure the required duration, the software can poll the TEACK bit in the USART_ISR register.  
In Smartcard mode, when TE is set, there is a 1 bit-time delay before the transmission starts.
**Bit 2 RE: Receiver enable**

This bit enables the receiver. It is set and cleared by software.

- 0: Receiver is disabled
- 1: Receiver is enabled and begins searching for a start bit

**Bit 1 UESM: USART enable in low-power mode**

When this bit is cleared, the USART cannot wake up the MCU from low-power mode.

When this bit is set, the USART can wake up the MCU from low-power mode.

- 0: USART not able to wake up the MCU from low-power mode.
- 1: USART able to wake up the MCU from low-power mode.

**Note:** It is recommended to set the UESM bit just before entering low-power mode and clear it when exit from low-power mode.

*If the USART does not support the wake-up from Stop feature, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation on page 2172.*

**Bit 0 UE: USART enable**

When this bit is cleared, the USART prescalers and outputs are stopped immediately, and all current operations are discarded. The USART configuration is kept, but all the USART_ISR status flags are reset. This bit is set and cleared by software.

- 0: USART prescaler and outputs disabled, low-power mode
- 1: USART enabled

**Note:** To enter low-power mode without generating errors on the line, the TE bit must be previously reset and the software must wait for the TC bit in the USART_ISR to be set before resetting the UE bit.

*The DMA requests are also reset when UE = 0 so the DMA channel must be disabled before resetting the UE bit.*

*In Smartcard mode, (SCEN = 1), the CK pin is always available when CLKEN = 1, regardless of the UE bit value.*

## 51.8.3 USART control register 2 (USART_CR2)

**Notes:**

1. The DMA requests are also reset when UE = 0 so the DMA channel must be disabled before resetting the UE bit.
2. In Smartcard mode, (SCEN = 1), the CK pin is always available when CLKEN = 1, regardless of the UE bit value.
Bits 31:24  **ADD[7:0]**: Address of the USART node

These bits give the address of the USART node in Mute mode or a character code to be recognized in low-power or Run mode:

- In Mute mode: they are used in multiprocessor communication to wake up from Mute mode with 4-bit/7-bit address mark detection. The MSB of the character sent by the transmitter should be equal to 1. In 4-bit address mark detection, only ADD[3:0] bits are used.
- In low-power mode: they are used for wake up from low-power mode on character match. When WUS[1:0] is programmed to 0b00 (WUF active on address match), the wake-up from low-power mode is performed when the received character corresponds to the character programmed through ADD[6:0] or ADD[3:0] bitfield (depending on ADDM7 bit), and WUF interrupt is enabled by setting WUFIE bit. The MSB of the character sent by transmitter should be equal to 1.
- In Run mode with Mute mode inactive (for example, end-of-block detection in ModBus protocol): the whole received character (8 bits) is compared to ADD[7:0] value and CMF flag is set on match. An interrupt is generated if the CMIE bit is set.

These bits can only be written when the reception is disabled (RE = 0) or when the USART is disabled (UE = 0).

Bit 23  **RTOEN**: Receiver timeout enable

This bit is set and cleared by software.

0: Receiver timeout feature disabled.
1: Receiver timeout feature enabled.

When this feature is enabled, the RTOF flag in the USART_ISR register is set if the RX line is idle (no reception) for the duration programmed in the RTOR (receiver timeout register).

**Note**: If the USART does not support the Receiver timeout feature, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation on page 2172.

Bits 22:21  **ABRMOD[1:0]**: Auto baud rate mode

These bits are set and cleared by software.

00: Measurement of the start bit is used to detect the baud rate.
01: Falling edge to falling edge measurement (the received frame must start with a single bit = 1 and Frame = Start10xxxxxx)
10: 0x7F frame detection.
11: 0x55 frame detection

This bitfield can only be written when ABREN = 0 or the USART is disabled (UE = 0).

**Note**: If DATAINV = 1 and/or MSBFIRST = 1 the patterns must be the same on the line, for example 0xAA for MSBFIRST

If the USART does not support the auto baud rate feature, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation on page 2172.

Bit 20  **ABREN**: Auto baud rate enable

This bit is set and cleared by software.
0: Auto baud rate detection is disabled.
1: Auto baud rate detection is enabled.

**Note**: If the USART does not support the auto baud rate feature, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation on page 2172.

Bit 19  **MSBFIRST**: Most significant bit first

This bit is set and cleared by software.
0: data is transmitted/received with data bit 0 first, following the start bit.
1: data is transmitted/received with the MSB (bit 7/8) first, following the start bit.

This bitfield can only be written when the USART is disabled (UE = 0).
Bit 18  **DATAINV**: Binary data inversion  
This bit is set and cleared by software.  
0: Logical data from the data register are send/received in positive/direct logic. (1 = H, 0 = L)  
1: Logical data from the data register are send/received in negative/inverse logic. (1 = L, 0 = H).  
The parity bit is also inverted.  
This bitfield can only be written when the USART is disabled (UE = 0).

Bit 17  **TXINV**: TX pin active level inversion  
This bit is set and cleared by software.  
0: TX pin signal works using the standard logic levels (VDD =1/idle, Gnd = 0/mark)  
1: TX pin signal values are inverted (VDD =0/mark, Gnd = 1/idle).  
This enables the use of an external inverter on the TX line.  
This bitfield can only be written when the USART is disabled (UE = 0).

Bit 16  **RXINV**: RX pin active level inversion  
This bit is set and cleared by software.  
0: RX pin signal works using the standard logic levels (VDD =1/idle, Gnd = 0/mark)  
1: RX pin signal values are inverted (VDD =0/mark, Gnd = 1/idle).  
This enables the use of an external inverter on the RX line.  
This bitfield can only be written when the USART is disabled (UE = 0).

Bit 15  **SWAP**: Swap TX/RX pins  
This bit is set and cleared by software.  
0: TX/RX pins are used as defined in standard pinout  
1: The TX and RX pins functions are swapped. This enables to work in the case of a cross-wired connection to another UART.  
This bitfield can only be written when the USART is disabled (UE = 0).

Bit 14  **LINEN**: LIN mode enable  
This bit is set and cleared by software.  
0: LIN mode disabled  
1: LIN mode enabled  
The LIN mode enables the capability to send LIN synchronous breaks (13 low bits) using the SBKRQ bit in the USART_CR1 register, and to detect LIN Sync breaks.  
This bitfield can only be written when the USART is disabled (UE = 0).  

**Note**: If the USART does not support LIN mode, this bit is reserved and must be kept at reset value.  
Refer to Section 51.4: USART implementation on page 2172.

Bits 13:12  **STOP[1:0]**: Stop bits  
These bits are used for programming the stop bits.  
00: 1 stop bit  
01: 0.5 stop bit.  
10: 2 stop bits  
11: 1.5 stop bits  
This bitfield can only be written when the USART is disabled (UE = 0).
Bit 11 **CLKEN**: Clock enable
This bit enables the user to enable the CK pin.
0: CK pin disabled
1: CK pin enabled
This bit can only be written when the USART is disabled (UE = 0).

*Note:* If neither synchronous mode nor Smartcard mode is supported, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation on page 2172.

In Smartcard mode, in order to provide correctly the CK clock to the smartcard, the steps below must be respected:

- **UE** = 0
- **SCEN** = 1
- **GTPR** configuration
- **CLKEN** = 1
- **UE** = 1

Bit 10 **CPOL**: Clock polarity
This bit enables the user to select the polarity of the clock output on the CK pin in synchronous mode. It works in conjunction with the CPHA bit to produce the desired clock/data relationship.

0: Steady low value on CK pin outside transmission window
1: Steady high value on CK pin outside transmission window

This bit can only be written when the USART is disabled (UE = 0).

*Note:* If synchronous mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation on page 2172.

Bit 9 **CPHA**: Clock phase
This bit is used to select the phase of the clock output on the CK pin in synchronous mode. It works in conjunction with the CPOL bit to produce the desired clock/data relationship (see Figure 619 and Figure 620).

0: The first clock transition is the first data capture edge
1: The second clock transition is the first data capture edge

This bit can only be written when the USART is disabled (UE = 0).

*Note:* If synchronous mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation on page 2172.

Bit 8 **LBCL**: Last bit clock pulse
This bit is used to select whether the clock pulse associated with the last data bit transmitted (MSB) has to be output on the CK pin in synchronous mode.

0: The clock pulse of the last data bit is not output to the CK pin
1: The clock pulse of the last data bit is output to the CK pin

*Caution:* The last bit is the 7th or 8th or 9th data bit transmitted depending on the 7 or 8 or 9 bit format selected by the M bit in the USART_CR1 register.

This bit can only be written when the USART is disabled (UE = 0).

*Note:* If synchronous mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation on page 2172.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **LBDIE**: LIN break detection interrupt enable
Break interrupt mask (break detection using break delimiter).

0: Interrupt is inhibited
1: An interrupt is generated whenever LBDF = 1 in the USART_ISR register

*Note:* If LIN mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation on page 2172.
Bit 5  **LBDL**: LIN break detection length
   - This bit is for selection between 11 bit or 10 bit break detection.
     0: 10-bit break detection
     1: 11-bit break detection
   - This bit can only be written when the USART is disabled (UE = 0).
   - **Note**: If LIN mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation on page 2172.

Bit 4  **ADDM7**: 7-bit address detection/4-bit address detection
   - This bit is for selection between 4-bit address detection or 7-bit address detection.
     0: 4-bit address detection
     1: 7-bit address detection (in 8-bit data mode)
   - This bit can only be written when the USART is disabled (UE = 0)
   - **Note**: In 7-bit and 9-bit data modes, the address detection is done on 6-bit and 8-bit address (ADD[5:0] and ADD[7:0]) respectively.

Bit 3  **DIS_NSS**: NSS pin enable
   - When the DIS_NSS bit is set, the NSS pin input is ignored.
     0: SPI slave selection depends on NSS input pin.
     1: SPI slave is always selected and NSS input pin is ignored.
   - **Note**: When SPI slave mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation on page 2172.

Bits 2:1  Reserved, must be kept at reset value.

Bit 0  **SLVEN**: Synchronous Slave mode enable
   - When the SLVEN bit is set, the synchronous slave mode is enabled.
     0: Slave mode disabled.
     1: Slave mode enabled.
   - **Note**: When SPI slave mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation on page 2172.

**51.8.4 USART control register 3 (USART_CR3)**

Address offset: 0x08
Reset value: 0x0000 0000

**Note**: The CPOL, CPHA and LBCL bits should not be written while the transmitter is enabled.
Bits 31:29 **TXFTCFG[2:0]**: TXFIFO threshold configuration
- 000: TXFIFO reaches 1/8 of its depth
- 001: TXFIFO reaches 1/4 of its depth
- 010: TXFIFO reaches 1/2 of its depth
- 011: TXFIFO reaches 3/4 of its depth
- 100: TXFIFO reaches 7/8 of its depth
- 101: TXFIFO becomes empty
- Remaining combinations: Reserved

Bit 28 **RXFTIE**: RXFIFO threshold interrupt enable
This bit is set and cleared by software.
- 0: Interrupt inhibited
- 1: USART interrupt generated when Receive FIFO reaches the threshold programmed in RXFTCFG.

Bits 27:25 **RXFTCFG[2:0]**: Receive FIFO threshold configuration
- 000: Receive FIFO reaches 1/8 of its depth
- 001: Receive FIFO reaches 1/4 of its depth
- 010: Receive FIFO reaches 1/2 of its depth
- 011: Receive FIFO reaches 3/4 of its depth
- 100: Receive FIFO reaches 7/8 of its depth
- 101: Receive FIFO becomes full
- Remaining combinations: Reserved

Bit 24 **TCBGTIE**: Transmission complete before guard time, interrupt enable
This bit is set and cleared by software.
- 0: Interrupt inhibited
- 1: USART interrupt generated whenever TCBGT=1 in the USART_ISR register

*Note: If the USART does not support the Smartcard mode, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation on page 2172.*

Bit 23 **TXFTIE**: TXFIFO threshold interrupt enable
This bit is set and cleared by software.
- 0: Interrupt inhibited
- 1: USART interrupt generated when TXFIFO reaches the threshold programmed in TXFTCFG.

Bit 22 **WUFIE**: Wake-up from low-power mode interrupt enable
This bit is set and cleared by software.
- 0: Interrupt inhibited
- 1: USART interrupt generated whenever WUF = 1 in the USART_ISR register

*Note: WUFIE must be set before entering in low-power mode.*

The WUF interrupt is active only in low-power mode.

*If the USART does not support the wake-up from Stop feature, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation on page 2172.*
Bits 21:20 **WUS[1:0]**: Wake-up from low-power mode interrupt flag selection
This bitfield specifies the event which activates the WUF (wake-up from low-power mode flag).
00: WUF active on address match (as defined by ADD[7:0] and ADDM7)
01: Reserved.
10: WUF active on start bit detection
11: WUF active on RXNE/RXFNE.
This bitfield can only be written when the USART is disabled (UE = 0).
*If the USART does not support the wake-up from Stop feature, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation on page 2172.*

Bits 19:17 **SCARCNT[2:0]**: Smartcard auto-retry count
This bitfield specifies the number of retries for transmission and reception in Smartcard mode.
In transmission mode, it specifies the number of automatic retransmission retries, before generating a transmission error (FE bit set).
In reception mode, it specifies the number or erroneous reception trials, before generating a reception error (RXNE/RXFNE and PE bits set).
This bitfield must be programmed only when the USART is disabled (UE = 0). When the USART is enabled (UE = 1), this bitfield may only be written to 0x0, in order to stop retransmission.
0x0: retransmission disabled - No automatic retransmission in transmit mode.
0x1 to 0x7: number of automatic retransmission attempts (before signaling error)
*Note: If Smartcard mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation on page 2172.*

Bit 16 Reserved, must be kept at reset value.

Bit 15 **DEP**: Driver enable polarity selection
0: DE signal is active high.
1: DE signal is active low.
This bit can only be written when the USART is disabled (UE = 0).
*Note: If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation on page 2172.*

Bit 14 **DEM**: Driver enable mode
This bit enables the user to activate the external transceiver control, through the DE signal.
0: DE function is disabled.
1: DE function is enabled. The DE signal is output on the RTS pin.
This bit can only be written when the USART is disabled (UE = 0).
*Note: If the Driver Enable feature is not supported, this bit is reserved and must be kept at reset value. Section 51.4: USART implementation on page 2172.*

Bit 13 **DDRE**: DMA Disable on reception error
0: DMA is not disabled in case of reception error. The corresponding error flag is set but RXNE is kept 0 preventing from overrun. As a consequence, the DMA request is not asserted, so the erroneous data is not transferred (no DMA request), but next correct received data is transferred (used for Smartcard mode).
1: DMA is disabled following a reception error. The corresponding error flag is set, as well as RXNE. The DMA request is masked until the error flag is cleared. This means that the software must first disable the DMA request (DMAR = 0) or clear RXNE/RXFNE is case FIFO mode is enabled) before clearing the error flag.
This bit can only be written when the USART is disabled (UE=0).
*Note: The reception errors are: parity error, framing error or noise error.*
Bit 12 **OVRDIS**: Overrun disable

This bit is used to disable the receive overrun detection.

0: Overrun Error Flag, ORE, is set when received data is not read before receiving new data.

1: Overrun functionality is disabled. If new data is received while the RXNE flag is still set the ORE flag is not set and the new received data overwrites the previous content of the USART_RDR register. When FIFO mode is enabled, the RXFIFO is bypassed and data is written directly in USART_RDR register. Even when FIFO management is enabled, the RXNE flag is to be used.

This bit can only be written when the USART is disabled (UE = 0).

*Note: This control bit enables checking the communication flow w/o reading the data*

Bit 11 **ONEBIT**: One sample bit method enable

This bit enables the user to select the sample method. When the one sample bit method is selected the noise detection flag (NE) is disabled.

0: Three sample bit method

1: One sample bit method

This bit can only be written when the USART is disabled (UE = 0).

Bit 10 **CTSE**: CTS interrupt enable

0: Interrupt is inhibited

1: An interrupt is generated whenever CTSIF = 1 in the USART_ISR register

*Note: If the hardware flow control feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation on page 2172.*

Bit 9 **CTSE**: CTS enable

0: CTS hardware flow control disabled

1: CTS mode enabled, data is only transmitted when the CTS input is deasserted (tied to 0). If the CTS input is asserted while data is being transmitted, then the transmission is completed before stopping. If data is written into the data register while CTS is asserted, the transmission is postponed until CTS is deasserted.

This bit can only be written when the USART is disabled (UE = 0)

*Note: If the hardware flow control feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation on page 2172.*

Bit 8 **RTSE**: RTS enable

0: RTS hardware flow control disabled

1: RTS output enabled, data is only requested when there is space in the receive buffer. The transmission of data is expected to cease after the current character has been transmitted. The RTS output is deasserted (pulled to 0) when data can be received.

This bit can only be written when the USART is disabled (UE = 0).

*Note: If the hardware flow control feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation on page 2172.*

Bit 7 **DMAT**: DMA enable transmitter

This bit is set/reset by software

1: DMA mode is enabled for transmission

0: DMA mode is disabled for transmission

Bit 6 **DMAR**: DMA enable receiver

This bit is set/reset by software

1: DMA mode is enabled for reception

0: DMA mode is disabled for reception
Bit 5 **SCEN**: Smartcard mode enable
This bit is used for enabling Smartcard mode.
0: Smartcard Mode disabled
1: Smartcard Mode enabled
This bitfield can only be written when the USART is disabled (UE = 0).
*Note:* If the USART does not support Smartcard mode, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation on page 2172.

Bit 4 **NACK**: Smartcard NACK enable
0: NACK transmission in case of parity error is disabled
1: NACK transmission during parity error is enabled
This bitfield can only be written when the USART is disabled (UE = 0).
*Note:* If the USART does not support Smartcard mode, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation on page 2172.

Bit 3 **HDSEL**: Half-duplex selection
Selection of Single-wire Half-duplex mode
0: Half duplex mode is not selected
1: Half duplex mode is selected
This bit can only be written when the USART is disabled (UE = 0).

Bit 2 **IRLP**: IrDA low-power
This bit is used for selecting between normal and low-power IrDA modes
0: Normal mode
1: Low-power mode
This bit can only be written when the USART is disabled (UE = 0).
*Note:* If IrDA mode is not supported, this bit is reserved and must be kept at reset value.
Refer to Section 51.4: USART implementation on page 2172.

Bit 1 **IREN**: IrDA mode enable
This bit is set and cleared by software.
0: IrDA disabled
1: IrDA enabled
This bit can only be written when the USART is disabled (UE = 0).
*Note:* If IrDA mode is not supported, this bit is reserved and must be kept at reset value.
Refer to Section 51.4: USART implementation on page 2172.

Bit 0 **EIE**: Error interrupt enable
Error Interrupt Enable Bit is required to enable interrupt generation in case of a framing error, overrun error noise flag or SPI slave underrun error (FE = 1 or ORE = 1 or NE = 1 or UDR = 1 in the USART_ISR register).
0: Interrupt inhibited
1: interrupt generated when FE = 1 or ORE = 1 or NE = 1 or UDR = 1 (in SPI slave mode) in the USART_ISR register.
51.8.5  **USART baud rate register (USART\_BRR)**

This register can only be written when the USART is disabled (UE = 0). It may be automatically updated by hardware in auto baud rate detection mode.

Address offset: 0x0C

Reset value: 0x0000 0000

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

rw  rw  rw  rw  rw  rw  rw  rw  rw  rw  rw  rw  rw  rw  rw  rw

rw  rw  rw  rw  rw  rw  rw  rw  rw  rw  rw  rw  rw  rw  rw  rw
Universal synchronous/asynchronous receiver transmitter (USART/UART)

Address offset: 0x14
Reset value: 0x0000 0000

**51.8.7  USART receiver timeout register (USART_RTOR)**

**Bits 31:16**  Reserved, must be kept at reset value.

**Bits 15:8  GT[7:0]: Guard time value**
This bitfield is used to program the Guard time value in terms of number of baud clock periods.
This is used in Smartcard mode. The Transmission Complete flag is set after this guard time value.
This bitfield can only be written when the USART is disabled (UE = 0).

*Note:  If Smartcard mode is not supported, this bit is reserved and must be kept at reset value.*
*Refer to Section 51.4: USART implementation on page 2172.*

**Bits 7:0  PSC[7:0]: Prescaler value**

In **IrDA low-power and normal IrDA mode:**
PSC[7:0] = IrDA Normal and Low-Power baud rate
PSC[7:0] is used to program the prescaler for dividing the USART source clock to achieve the low-power frequency; the source clock is divided by the value given in the register (8 significant bits):

In **Smartcard mode:**
PSC[4:0] = Prescaler value
PSC[4:0] is used to program the prescaler for dividing the USART source clock to provide the Smartcard clock. The value given in the register (5 significant bits) is multiplied by 2 to give the division factor of the source clock frequency:

- 00000: Reserved - do not program this value
- 00001: Divides the source clock by 1 (IrDA mode) / by 2 (Smartcard mode)
- 00010: Divides the source clock by 2 (IrDA mode) / by 4 (Smartcard mode)
- 00011: Divides the source clock by 3 (IrDA mode) / by 6 (Smartcard mode)
  ...
- 11111: Divides the source clock by 31 (IrDA mode) / by 62 (Smartcard mode)
- 0010 0000: Divides the source clock by 32 (IrDA mode)
  ...
- 1111 1111: Divides the source clock by 255 (IrDA mode)

This bitfield can only be written when the USART is disabled (UE = 0).

*Note:  Bits [7:5] must be kept cleared if Smartcard mode is used.*
*This bitfield is reserved and forced by hardware to '0' when the Smartcard and IrDA modes are not supported. Refer to Section 51.4: USART implementation on page 2172.*
Bits 31:24 **BLEN[7:0]:** Block length
This bitfield gives the Block length in Smartcard T = 1 Reception. Its value equals the number of information characters + the length of the Epilogue Field (1-LEC/2-CRC) - 1.
Examples:
- BLEN = 0: 0 information characters + LEC
- BLEN = 1: 0 information characters + CRC
- BLEN = 255: 254 information characters + CRC (total 256 characters))
In Smartcard mode, the Block length counter is reset when TXE = 0 (TXFE = 0 in case FIFO mode is enabled).
This bitfield can be used also in other modes. In this case, the Block length counter is reset when RE = 0 (receiver disabled) and/or when the EOBBCF bit is written to 1.
**Note:** This value can be programmed after the start of the block reception (using the data from the LEN character in the Prologue Field). It must be programmed only once per received block.

Bits 23:0 **RTO[23:0]:** Receiver timeout value
This bitfield gives the Receiver timeout value in terms of number of bits during which there is no activity on the RX line.
In standard mode, the RTOF flag is set if, after the last received character, no new start bit is detected for more than the RTO value.
In Smartcard mode, this value is used to implement the CWT and BWT. See Smartcard chapter for more details. In the standard, the CWT/BWT measurement is done starting from the start bit of the last received character.
**Note:** This value must only be programmed once per received character.

**Note:** RTOR can be written on-the-fly. If the new value is lower than or equal to the counter, the RTOF flag is set.
This register is reserved and forced by hardware to "0x00000000" when the Receiver timeout feature is not supported. Refer to Section 51.4: USART implementation on page 2172.

Bits 31:5  Reserved, must be kept at reset value.

Bit 4  \textbf{TXFRQ}: Transmit data flush request

When FIFO mode is disabled, writing ‘1’ to this bit sets the TXE flag. This enables to discard the transmit data. This bit must be used only in Smartcard mode, when data have not been sent due to errors (NACK) and the FE flag is active in the \textbf{USART_ISR} register. If the \textbf{USART} does not support Smartcard mode, this bit is reserved and must be kept at reset value.

When FIFO is enabled, TXFRQ bit is set to flush the whole FIFO. This sets the TXFE flag (Transmit FIFO empty, bit 23 in the \textbf{USART_ISR} register). Flushing the Transmit FIFO is supported in both UART and Smartcard modes.

\textit{Note}: In FIFO mode, the TXFNF flag is reset during the flush request until \textit{TxFIFO is empty in order to ensure that no data are written in the data register.}

Bit 3  \textbf{RXFRQ}: Receive data flush request

Writing 1 to this bit empties the entire receive FIFO i.e. clears the bit RXFNE. This enables to discard the received data without reading them, and avoid an overrun condition.

Bit 2  \textbf{MMRQ}: Mute mode request

Writing 1 to this bit puts the \textbf{USART} in Mute mode and resets the RWU flag.

Bit 1  \textbf{SBKRQ}: Send break request

Writing 1 to this bit sets the SBKF flag and request to send a BREAK on the line, as soon as the transmit machine is available.

\textit{Note}: When the application needs to send the break character following all previously inserted data, including the ones not yet transmitted, the software should wait for the TXE flag assertion before setting the SBKRQ bit.

Bit 0  \textbf{ABRRQ}: Auto baud rate request

Writing 1 to this bit resets the ABRF and ABRE flags in the \textbf{USART_ISR} and requests an automatic baud rate measurement on the next received data frame.

\textit{Note}: If the \textbf{USART} does not support the auto baud rate feature, this bit is reserved and must be kept at reset value. Refer to \textit{Section 51.4: USART implementation on page 2172.}

### 51.8.9  USART interrupt and status register (\textbf{USART_ISR})

Address offset: 0x1C

Reset value: 0x0X0 00C0

X = 2 if FIFO/Smartcard mode is enabled

X = 0 if FIFO is enabled and Smartcard mode is disabled

The same register can be used in FIFO mode enabled (this section) and FIFO mode disabled (next section).

#### FIFO mode enabled

Bits 31:28  Reserved, must be kept at reset value.

Bit 27 **TXFT**: TXFIFO threshold flag
   This bit is set by hardware when the TXFIFO reaches the threshold programmed in TXFTCFG of USART_CR3 register i.e. the TXFIFO contains TXFTCFG empty locations. An interrupt is generated if the TXFTIE bit = 1 (bit 31) in the USART_CR3 register.
   0: TXFIFO does not reach the programmed threshold.
   1: TXFIFO reached the programmed threshold.

Bit 26 **RXFT**: RXFIFO threshold flag
   This bit is set by hardware when the threshold programmed in RXFTCFG in USART_CR3 register is reached. This means that there are (RXFTCFG - 1) data in the Receive FIFO and one data in the USART_RDR register. An interrupt is generated if the RXFTIE bit = 1 (bit 27) in the USART_CR3 register.
   0: Receive FIFO does not reach the programmed threshold.
   1: Receive FIFO reached the programmed threshold.

Note: When the RXFTCFG threshold is configured to ‘101’, RXFT flag is set if 16 data are available i.e. 15 data in the RXFIFO and 1 data in the USART_RDR. Consequently, the 17th received data does not cause an overrun error. The overrun error occurs after receiving the 18th data.

Bit 25 **TCBGT**: Transmission complete before guard time flag
   This bit is set when the last data written in the USART_TDR has been transmitted correctly out of the shift register.
   It is set by hardware in Smartcard mode, if the transmission of a frame containing data is complete and if the smartcard did not send back any NACK. An interrupt is generated if TCBGTIE = 1 in the USART_CR3 register.
   This bit is cleared by software, by writing 1 to the TCBGTCF in the USART_ICR register or by a write to the USART_TDR register.
   0: Transmission is not complete or transmission is complete unsuccessfully (i.e. a NACK is received from the card)
   1: Transmission is complete successfully (before Guard time completion and there is no NACK from the smart card).

Note: If the USART does not support the Smartcard mode, this bit is reserved and kept at reset value. If the USART supports the Smartcard mode and the Smartcard mode is enabled, the TCBGT reset value is ‘1’. Refer to Section 51.4: USART implementation on page 2172.

Bit 24 **RXFF**: RXFIFO full
   This bit is set by hardware when the number of received data corresponds to RXFIFO size + 1 (RXFIFO full + 1 data in the USART_RDR register.
   An interrupt is generated if the RXFFIE bit = 1 in the USART_CR1 register.
   0: RXFIFO not full.
   1: RXFIFO Full.

Bit 23 **TXFE**: TXFIFO empty
   This bit is set by hardware when TXFIFO is empty. When the TXFIFO contains at least one data, this flag is cleared. The TXFE flag can also be set by writing 1 to the bit TXFRQ (bit 4) in the USART_RQR register.
   An interrupt is generated if the TXFEIE bit = 1 (bit 30) in the USART_CR1 register.
   0: TXFIFO not empty.
   1: TXFIFO empty.
Bit 22 **REACK**: Receive enable acknowledge flag
- This bit is set/reset by hardware, when the Receive Enable value is taken into account by the USART.
- It can be used to verify that the USART is ready for reception before entering low-power mode.
- **Note**: If the USART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value. Refer to Section 51.4: USART implementation on page 2172.

Bit 21 **TEACK**: Transmit enable acknowledge flag
- This bit is set/reset by hardware, when the Transmit Enable value is taken into account by the USART.
- It can be used when an idle frame request is generated by writing TE = 0, followed by TE = 1 in the USART_CR1 register, in order to respect the TE = 0 minimum period.

Bit 20 **WUF**: Wake-up from low-power mode flag
- This bit is set by hardware, when a wake-up event is detected. The event is defined by the WUS bitfield. It is cleared by software, writing a 1 to the WUCF in the USART_ICR register.
- An interrupt is generated if WUFE = 1 in the USART_CR3 register.
- **Note**: When UESM is cleared, WUF flag is also cleared.
- The WUF interrupt is active only in low-power mode.
- If the USART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value. Refer to Section 51.4: USART implementation on page 2172.

Bit 19 **RWU**: Receiver wake-up from Mute mode
- This bit indicates if the USART is in Mute mode. It is cleared/set by hardware when a wake-up/mute sequence is recognized. The Mute mode control sequence (address or IDLE) is selected by the WAKE bit in the USART_CR1 register.
- When wake-up on IDLE mode is selected, this bit can only be set by software, writing 1 to the MMRQ bit in the USART_RQR register.
- 0: Receiver in active mode
- 1: Receiver in Mute mode
- **Note**: If the USART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value. Refer to Section 51.4: USART implementation on page 2172.

Bit 18 **SBKF**: Send break flag
- This bit indicates that a send break character was requested. It is set by software, by writing 1 to the SBKRD bit in the USART_CR3 register. It is automatically reset by hardware during the stop bit of break transmission.
- 0: Break character transmitted
- 1: Break character requested by setting SBKRD bit in USART_RQR register

Bit 17 **CMF**: Character match flag
- This bit is set by hardware, when a character defined by ADD[7:0] is received. It is cleared by software, writing 1 to the CMCF in the USART_ICR register.
- An interrupt is generated if CMIE = 1 in the USART_CR1 register.
- 0: No Character match detected
- 1: Character Match detected

Bit 16 **BUSY**: Busy flag
- This bit is set and reset by hardware. It is active when a communication is ongoing on the RX line (successful start bit detected). It is reset at the end of the reception (successful or not).
- 0: USART is idle (no reception)
- 1: Reception on going
Bit 15 **ABRF**: Auto baud rate flag

This bit is set by hardware when the automatic baud rate has been set (RXFNE is also set, generating an interrupt if RXFNEIE = 1) or when the auto baud rate operation was completed without success (ABRE = 1) (ABRE, RXFNE and FE are also set in this case). It is cleared by software, in order to request a new auto baud rate detection, by writing 1 to the ABRRQ in the USART_RQR register.

*Note*: If the USART does not support the auto baud rate feature, this bit is reserved and kept at reset value.

Bit 14 **ABRE**: Auto baud rate error

This bit is set by hardware if the baud rate measurement failed (baud rate out of range or character comparison failed).

It is cleared by software, by writing 1 to the ABRRQ bit in the USART_RQR register.

*Note*: If the USART does not support the auto baud rate feature, this bit is reserved and kept at reset value.

Bit 13 **UDR**: SPI slave underrun error flag

In slave transmission mode, this flag is set when the first clock pulse for data transmission appears while the software has not yet loaded any value into USART_TDR. This flag is reset by setting UDRCF bit in the USART_ICR register.

0: No underrun error

1: Underrun error

*Note*: If the USART does not support the SPI slave mode, this bit is reserved and kept at reset value. Refer to Section 51.4: USART implementation on page 2172.

Bit 12 **EOBF**: End of block flag

This bit is set by hardware when a complete block has been received (for example T = 1 Smartcard mode). The detection is done when the number of received bytes (from the start of the block, including the prologue) is equal or greater than BLEN + 4.

An interrupt is generated if the EOBIE = 1 in the USART_CR1 register.

It is cleared by software, writing 1 to the EOBCF in the USART_ICR register.

0: End of Block not reached

1: End of Block (number of characters) reached

*Note*: If Smartcard mode is not supported, this bit is reserved and kept at reset value. Refer to Section 51.4: USART implementation on page 2172.

Bit 11 **RTOF**: Receiver timeout

This bit is set by hardware when the timeout value, programmed in the RTOR register has lapsed, without any communication. It is cleared by software, writing 1 to the RTOCF bit in the USART_ICR register.

An interrupt is generated if RTOIE = 1 in the USART_CR2 register.

In Smartcard mode, the timeout corresponds to the CWT or BWT timings.

0: Timeout value not reached

1: Timeout value reached without any data reception

*Note*: If a time equal to the value programmed in RTOR register separates 2 characters, RTOF is not set. If this time exceeds this value + 2 sample times (2/16 or 2/8, depending on the oversampling method), RTOF flag is set.

The counter counts even if RE = 0 but RTOF is set only when RE = 1. If the timeout has already elapsed when RE is set, then RTOF is set.

*Note*: If the USART does not support the Receiver timeout feature, this bit is reserved and kept at reset value.
Bit 10 **CTS**: CTS flag
This bit is set/reset by hardware. It is an inverted copy of the status of the CTS input pin.
0: CTS line set
1: CTS line reset

*Note*: If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.

Bit 9 **CTSIF**: CTS interrupt flag
This bit is set by hardware when the CTS input toggles, if the CTSE bit is set. It is cleared by software, by writing 1 to the CTSCF bit in the USART_ICR register.
An interrupt is generated if CTSIE = 1 in the USART_CR3 register.
0: No change occurred on the CTS status line
1: A change occurred on the CTS status line

*Note*: If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.

Bit 8 **LBDF**: LIN break detection flag
This bit is set by hardware when the LIN break is detected. It is cleared by software, by writing 1 to the LBDCF in the USART_ICR.
An interrupt is generated if LBDIE = 1 in the USART_CR2 register.
0: LIN Break not detected
1: LIN break detected

*Note*: If the USART does not support LIN mode, this bit is reserved and kept at reset value. Refer to Section 51.4: USART implementation on page 2172.

Bit 7 **TXFNF**: TXFIFO not full
TXFNF is set by hardware when TXFIFO is not full meaning that data can be written in the USART_TDR. Every write operation to the USART_TDR places the data in the TXFIFO. This flag remains set until the TXFIFO is full. When the TXFIFO is full, this flag is cleared indicating that data can not be written into the USART_TDR.
An interrupt is generated if the TXFNFIE bit =1 in the USART_CR1 register.
0: Transmit FIFO is full
1: Transmit FIFO is not full

*Note*: The TXFNF is kept reset during the flush request until TXFIFO is empty. After sending the flush request (by setting TXFRQ bit), the flag TXFNF should be checked prior to writing in TXFIFO (TXFNF and TXFE are set at the same time).
This bit is used during single buffer transmission.

Bit 6 **TC**: Transmission complete
This bit indicates that the last data written in the USART_TDR has been transmitted out of the shift register.
It is set by hardware when the transmission of a frame containing data is complete and when TXFE is set.
An interrupt is generated if TCIE = 1 in the USART_CR1 register.
TC bit is is cleared by software, by writing 1 to the TCCF in the USART_ICR register or by a write to the USART_TDR register.
0: Transmission is not complete
1: Transmission is complete

*Note*: If TE bit is reset and no transmission is on going, the TC bit is immediately set.
Bit 5 **RXFNE**: RXFIFO not empty
RXFNE bit is set by hardware when the RXFIFO is not empty, meaning that data can be read from the USART_RDR register. Every read operation from the USART_RDR frees a location in the RXFIFO.
RXFNE is cleared when the RXFIFO is empty. The RXFNE flag can also be cleared by writing 1 to the RXFRQ in the USART_RQR register.
An interrupt is generated if RXFNEIE = 1 in the USART_CR1 register.
0: Data is not received
1: Received data is ready to be read.

Bit 4 **IDLE**: Idle line detected
This bit is set by hardware when an Idle Line is detected. An interrupt is generated if IDLEIE = 1 in the USART_CR1 register. It is cleared by software, writing 1 to the IDLECF in the USART_ICR register.
0: No Idle line is detected
1: Idle line is detected

*Note: The IDLE bit is not set again until the RXFNE bit has been set (i.e. a new idle line occurs).

If Mute mode is enabled (MME = 1), IDLE is set if the USART is not mute (RWU = 0), whatever the Mute mode selected by the WAKE bit. If RWU = 1, IDLE is not set.

Bit 3 **ORE**: Overrun error
This bit is set by hardware when the data currently being received in the shift register is ready to be transferred into the USART_RDR register while RXFF = 1. It is cleared by a software, writing 1 to the ORECF, in the USART_ICR register.
An interrupt is generated if RXFNEIE = 1 in the USART_CR1 register, or EIE = 1 in the USART_CR3 register.
0: No overrun error
1: Overrun error is detected

*Note: When this bit is set, the USART_RDR register content is not lost but the shift register is overwritten. An interrupt is generated if the ORE flag is set during multi buffer communication if the EIE bit is set.

This bit is permanently forced to 0 (no overrun detection) when the bit OVRDIS is set in the USART_CR3 register.
Bit 2 **NE**: Noise detection flag

This bit is set by hardware when noise is detected on a received frame. It is cleared by software, writing 1 to the NECF bit in the USART_ICR register.

0: No noise is detected
1: Noise is detected

**Note:** This bit does not generate an interrupt as it appears at the same time as the RXFNE bit which itself generates an interrupt. An interrupt is generated when the NE flag is set during multi buffer communication if the EIE bit is set.

When the line is noise-free, the NE flag can be disabled by programming the ONEBIT bit to 1 to increase the USART tolerance to deviations (Refer to Section 51.5.8: Tolerance of the USART receiver to clock deviation on page 2189).

This error is associated with the character in the USART_RDR.

Bit 1 **FE**: Framing error

This bit is set by hardware when a de-synchronization, excessive noise or a break character is detected. It is cleared by software, writing 1 to the FECF bit in the USART_ICR register.

When transmitting data in Smartcard mode, this bit is set when the maximum number of transmit attempts is reached without success (the card NACKs the data frame).

An interrupt is generated if EIE = 1 in the USART_CR3 register.

0: No Framing error is detected
1: Framing error or break character is detected

**Note:** This error is associated with the character in the USART_RDR.

Bit 0 **PE**: Parity error

This bit is set by hardware when a parity error occurs in receiver mode. It is cleared by software, writing 1 to the PECF in the USART_ICR register.

An interrupt is generated if PEIE = 1 in the USART_CR1 register.

0: No parity error
1: Parity error

**Note:** This error is associated with the character in the USART_RDR.

### 51.8.10 USART interrupt and status register [alternate] (USART_ISR)

Address offset: 0x1C

Reset value: 0x0000 00C0

The same register can be used in FIFO mode enabled (previous section) and FIFO mode disabled (this section).

**FIFO mode disabled**

Bits 31:26  Reserved, must be kept at reset value.

Bit 25 **TCBGT**: Transmission complete before guard time flag

This bit is set when the last data written in the USART_TDR has been transmitted correctly out of the shift register.

It is set by hardware in Smartcard mode, if the transmission of a frame containing data is complete and if the smartcard did not send back any NACK. An interrupt is generated if TCBGTE = 1 in the USART_CR3 register.

This bit is cleared by software, by writing 1 to the TCBGTCF in the USART_ICR register or by a write to the USART_TDR register.

0: Transmission is not complete or transmission is complete unsuccessfully (i.e. a NACK is received from the card)
1: Transmission is complete successfully (before Guard time completion and there is no NACK from the smart card).

*Note: If the USART does not support the Smartcard mode, this bit is reserved and kept at reset value. If the USART supports the Smartcard mode and the Smartcard mode is enabled, the TCBGT reset value is ‘1’. Refer to Section 51.4: USART implementation on page 2172.*

Bits 24:23  Reserved, must be kept at reset value.

Bit 22 **REACK**: Receive enable acknowledge flag

This bit is set/reset by hardware, when the Receive Enable value is taken into account by the USART.

It can be used to verify that the USART is ready for reception before entering low-power mode.

*Note: If the USART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value. Refer to Section 51.4: USART implementation on page 2172.*

Bit 21 **TEACK**: Transmit enable acknowledge flag

This bit is set/reset by hardware, when the Transmit Enable value is taken into account by the USART.

It can be used when an idle frame request is generated by writing TE = 0, followed by TE = 1 in the USART_CR1 register, in order to respect the TE = 0 minimum period.

Bit 20 **WUF**: Wake-up from low-power mode flag

This bit is set by hardware, when a wake-up event is detected. The event is defined by the WUS bitfield. It is cleared by software, writing a 1 to the WUCF in the USART_ICR register.

An interrupt is generated if WUFIE = 1 in the USART_CR3 register.

*Note: When UESM is cleared, WUF flag is also cleared. The WUF interrupt is active only in low-power mode. If the USART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value. Refer to Section 51.4: USART implementation on page 2172.*

Bit 19 **RWU**: Receiver wake-up from Mute mode

This bit indicates if the USART is in Mute mode. It is cleared/set by hardware when a wake-up/mute sequence is recognized. The Mute mode control sequence (address or IDLE) is selected by the WAKE bit in the USART_CR1 register.

When wake-up on IDLE mode is selected, this bit can only be set by software, writing 1 to the MMRQ bit in the USART_RQR register.

0: Receiver in active mode
1: Receiver in Mute mode

*Note: If the USART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value. Refer to Section 51.4: USART implementation on page 2172.*
Bit 18 **SBKF**: Send break flag
This bit indicates that a send break character was requested. It is set by software, by writing 1 to the SBKRQ bit in the USART_CR3 register. It is automatically reset by hardware during the stop bit of break transmission.
0: Break character transmitted
1: Break character requested by setting SBKRQ bit in USART_RQR register

Bit 17 **CMF**: Character match flag
This bit is set by hardware, when a the character defined by ADD[7:0] is received. It is cleared by software, writing 1 to the CMCF in the USART_ICR register. An interrupt is generated if CMIE = 1 in the USART_CR1 register.
0: No Character match detected
1: Character Match detected

Bit 16 **BUSY**: Busy flag
This bit is set and reset by hardware. It is active when a communication is ongoing on the RX line (successful start bit detected). It is reset at the end of the reception (successful or not).
0: USART is idle (no reception)
1: Reception on going

Bit 15 **ABRF**: Auto baud rate flag
This bit is set by hardware when the automatic baud rate has been set (RXNE is also set, generating an interrupt if RXNEIE = 1) or when the auto baud rate operation was completed without success (ABRE = 1) (ABRE, RXNE and FE are also set in this case). It is cleared by software, in order to request a new auto baud rate detection, by writing 1 to the ABRQQ in the USART_RQR register.
*Note: If the USART does not support the auto baud rate feature, this bit is reserved and kept at reset value.*

Bit 14 **ABRE**: Auto baud rate error
This bit is set by hardware if the baud rate measurement failed (baud rate out of range or character comparison failed).
It is cleared by software, by writing 1 to the ABRRQ bit in the USART_RQR register.
*Note: If the USART does not support the auto baud rate feature, this bit is reserved and kept at reset value.*

Bit 13 **UDR**: SPI slave underrun error flag
In slave transmission mode, this flag is set when the first clock pulse for data transmission appears while the software has not yet loaded any value into USART_TDR. This flag is reset by setting UDRCF bit in the USART_ICR register.
0: No underrun error
1: underrun error
*Note: If the USART does not support the SPI slave mode, this bit is reserved and kept at reset value. Refer to Section 51.4: USART implementation on page 2172.*

Bit 12 **EOBF**: End of block flag
This bit is set by hardware when a complete block has been received (for example T = 1 Smartcard mode). The detection is done when the number of received bytes (from the start of the block, including the prologue) is equal or greater than BLEN + 4.
An interrupt is generated if the EOBIE = 1 in the USART_CR1 register.
It is cleared by software, writing 1 to the EOBCF in the USART_ICR register.
0: End of Block not reached
1: End of Block (number of characters) reached
*Note: If Smartcard mode is not supported, this bit is reserved and kept at reset value. Refer to Section 51.4: USART implementation on page 2172.*
Bit 11  **RTOF**: Receiver timeout  
This bit is set by hardware when the timeout value, programmed in the RTOR register has lapsed, without any communication. It is cleared by software, writing 1 to the RTOCF bit in the USART_ICR register.  
An interrupt is generated if RTOIE = 1 in the USART_CR2 register.  
In Smartcard mode, the timeout corresponds to the CWT or BWT timings.  
0: Timeout value not reached  
1: Timeout value reached without any data reception  
*Note:* If a time equal to the value programmed in RTOR register separates 2 characters, RTOF is not set. If this time exceeds this value + 2 sample times (2/16 or 2/8, depending on the oversampling method), RTOF flag is set.  
The counter counts even if RE = 0 but RTOF is set only when RE = 1. If the timeout has already elapsed when RE is set, then RTOF is set.  
If the USART does not support the Receiver timeout feature, this bit is reserved and kept at reset value.  

Bit 10 **CTS**: CTS flag  
This bit is set/reset by hardware. It is an inverted copy of the status of the CTS input pin.  
0: CTS line set  
1: CTS line reset  
*Note:* If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.  

Bit 9 **CTSIF**: CTS interrupt flag  
This bit is set by hardware when the CTS input toggles, if the CTSE bit is set. It is cleared by software, by writing 1 to the CTSCF bit in the USART_ICR register.  
An interrupt is generated if CTSIE = 1 in the USART_CR3 register.  
0: No change occurred on the CTS status line  
1: A change occurred on the CTS status line  
*Note:* If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.  

Bit 8 **LBDF**: LIN break detection flag  
This bit is set by hardware when the LIN break is detected. It is cleared by software, by writing 1 to the LBDCF in the USART_ICR.  
An interrupt is generated if LBDIE = 1 in the USART_CR2 register.  
0: LIN Break not detected  
1: LIN break detected  
*Note:* If the USART does not support LIN mode, this bit is reserved and kept at reset value.  
Refer to Section 51.4: USART implementation on page 2172.  

Bit 7 **TXE**: Transmit data register empty  
TXE is set by hardware when the content of the USART_TDR register has been transferred into the shift register. It is cleared by writing to the USART_TDR register. The TXE flag can also be set by writing 1 to the TXFRQ in the USART_RQR register, in order to discard the data (only in Smartcard T = 0 mode, in case of transmission failure).  
An interrupt is generated if the TXEIE bit = 1 in the USART_CR1 register.  
0: Data register full  
1: Data register not full
Bit 6 **TC**: Transmission complete
This bit indicates that the last data written in the USART_TDR has been transmitted out of the shift register.
It is set by hardware when the transmission of a frame containing data is complete and when TXE is set.
An interrupt is generated if TCIE = 1 in the USART_CR1 register.
TC bit is is cleared by software, by writing 1 to the TCCF in the USART_ICR register or by a write to the USART_TDR register.
0: Transmission is not complete
1: Transmission is complete

*Note*: If TE bit is reset and no transmission is on going, the TC bit is set immediately.

Bit 5 **RXNE**: Read data register not empty
RXNE bit is set by hardware when the content of the USART_RDR shift register has been transferred to the USART_RDR register. It is cleared by reading from the USART_RDR register. The RXNE flag can also be cleared by writing 1 to the RXFRQ in the USART_RQR register.
An interrupt is generated if RXNEIE = 1 in the USART_CR1 register.
0: Data is not received
1: Received data is ready to be read.

Bit 4 **IDLE**: Idle line detected
This bit is set by hardware when an Idle Line is detected. An interrupt is generated if IDLEIE = 1 in the USART_CR1 register. It is cleared by software, writing 1 to the IDLECF in the USART_ICR register.
0: No Idle line is detected
1: Idle line is detected

*Note*: The IDLE bit is not set again until the RXNE bit has been set (i.e. a new idle line occurs).
If Mute mode is enabled (MME = 1), IDLE is set if the USART is not mute (RWU = 0), whatever the Mute mode selected by the WAKE bit. If RWU = 1, IDLE is not set.

Bit 3 **ORE**: Overrun error
This bit is set by hardware when the data currently being received in the shift register is ready to be transferred into the USART_RDR register while RXNE = 1. It is cleared by a software, writing 1 to the ORECF, in the USART_ICR register.
An interrupt is generated if RXNEIE = 1 or EIE = 1 in the LPUART_CR1 register, or EIE = 1 in the USART_CR3 register.
0: No overrun error
1: Overrun error is detected

*Note*: When this bit is set, the USART_RDR register content is not lost but the shift register is overwritten. An interrupt is generated if the ORE flag is set during multi buffer communication if the EIE bit is set.
This bit is permanently forced to 0 (no overrun detection) when the bit OVRDIS is set in the USART_CR3 register.
Bit 2 **NE**: Noise detection flag
This bit is set by hardware when noise is detected on a received frame. It is cleared by software, writing 1 to the NECF bit in the USART_ICR register.
0: No noise is detected
1: Noise is detected

*Note:* This bit does not generate an interrupt as it appears at the same time as the RXNE bit which itself generates an interrupt. An interrupt is generated when the NE flag is set during multi buffer communication if the EIE bit is set.

When the line is noise-free, the NE flag can be disabled by programming the ONEBIT bit to 1 to increase the USART tolerance to deviations (Refer to Section 51.5.8: Tolerance of the USART receiver to clock deviation on page 2189).

Bit 1 **FE**: Framing error
This bit is set by hardware when a de-synchronization, excessive noise or a break character is detected. It is cleared by software, writing 1 to the FECF bit in the USART_ICR register.

When transmitting data in Smartcard mode, this bit is set when the maximum number of transmit attempts is reached without success (the card NACKs the data frame).
An interrupt is generated if EIE = 1 in the USART_CR3 register.
0: No Framing error is detected
1: Framing error or break character is detected

Bit 0 **PE**: Parity error
This bit is set by hardware when a parity error occurs in receiver mode. It is cleared by software, writing 1 to the PECF in the USART_ICR register.
An interrupt is generated if PEIE = 1 in the USART_CR1 register.
0: No parity error
1: Parity error

### 51.8.11 USART interrupt flag clear register (USART_ICR)

Address offset: 0x20
Reset value: 0x0000 0000

<table>

</tr>
</tbody>
</table>
Bits 16:14  Reserved, must be kept at reset value.

Bit 13  **UDRCF**: SPI slave underrun clear flag  
       Writing 1 to this bit clears the UDRF flag in the USART_ISR register.  
       *Note:* If the USART does not support SPI slave mode, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation on page 2172.

Bit 12  **EOBCF**: End of block clear flag  
       Writing 1 to this bit clears the EOBF flag in the USART_ISR register.  
       *Note:* If the USART does not support Smartcard mode, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation on page 2172.

Bit 11  **RTOCF**: Receiver timeout clear flag  
       Writing 1 to this bit clears the RTOF flag in the USART_ISR register.  
       *Note:* If the USART does not support the Receiver timeout feature, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation on page 2172.

Bit 10  Reserved, must be kept at reset value.

Bit 9  **CTSCF**: CTS clear flag  
       Writing 1 to this bit clears the CTSIF flag in the USART_ISR register.  
       *Note:* If the hardware flow control feature is not supported, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation on page 2172.

Bit 8  **LBDCF**: LIN break detection clear flag  
       Writing 1 to this bit clears the LBDF flag in the USART_ISR register.  
       *Note:* If LIN mode is not supported, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation on page 2172.

Bit 7  **TCBGTCF**: Transmission complete before Guard time clear flag  
       Writing 1 to this bit clears the TCBGT flag in the USART_ISR register.

Bit 6  **TCCF**: Transmission complete clear flag  
       Writing 1 to this bit clears the TC flag in the USART_ISR register.

Bit 5  **TXFECF**: TXFIFO empty clear flag  
       Writing 1 to this bit clears the TXFE flag in the USART_ISR register.

Bit 4  **IDLECF**: Idle line detected clear flag  
       Writing 1 to this bit clears the IDLE flag in the USART_ISR register.

Bit 3  **ORECF**: Overrun error clear flag  
       Writing 1 to this bit clears the ORE flag in the USART_ISR register.

Bit 2  **NECF**: Noise detected clear flag  
       Writing 1 to this bit clears the NE flag in the USART_ISR register.

Bit 1  **FECF**: Framing error clear flag  
       Writing 1 to this bit clears the FE flag in the USART_ISR register.

Bit 0  **PECF**: Parity error clear flag  
       Writing 1 to this bit clears the PE flag in the USART_ISR register.
### 51.8.12 USART receive data register (USART_RDR)

Bits 31:9  Reserved, must be kept at reset value.  

Bits 8:0  **RDR[8:0]**: Receive data value  
Contains the received data character.  
The RDR register provides the parallel interface between the input shift register and the internal bus (see *Figure 613*).  
When receiving with the parity enabled, the value read in the MSB bit is the received parity bit.

### 51.8.13 USART transmit data register (USART_TDR)

Bits 31:9  Reserved, must be kept at reset value.  

Bits 8:0  **TDR[8:0]**: Transmit data value  
Contains the data character to be transmitted.  
The USART_TDR register provides the parallel interface between the internal bus and the output shift register (see *Figure 613*).  
When transmitting with the parity enabled (PCE bit set to 1 in the USART_CR1 register), the value written in the MSB (bit 7 or bit 8 depending on the data length) has no effect because it is replaced by the parity.  
*Note:*  This register must be written only when TXE/TXNF = 1.
51.8.14 **USART prescaler register (USART_PRESC)**

This register can only be written when the USART is disabled (UE = 0).

**Address offset:** 0x2C

**Reset value:** 0x0000 0000

<table>
<thead>

</thead>
</table>

**Bits 31:4:** Reserved, must be kept at reset value.

**Bits 3:0** **PRESCALER[3:0]:** Clock prescaler

The USART input clock can be divided by a prescaler factor:

- **0000:** input clock not divided
- **0001:** input clock divided by 2
- **0010:** input clock divided by 4
- **0011:** input clock divided by 6
- **0100:** input clock divided by 8
- **0101:** input clock divided by 10
- **0110:** input clock divided by 12
- **0111:** input clock divided by 16
- **1000:** input clock divided by 32
- **1001:** input clock divided by 64
- **1010:** input clock divided by 128
- **1011:** input clock divided by 256
- Remaining combinations: Reserved

**Note:** When **PRESCALER** is programmed with a value different of the allowed ones, programmed prescaler value is 1011 i.e. input clock divided by 256.
The table below gives the USART register map and reset values.

52 Low-power universal asynchronous receiver transmitter (LPUART)

This section describes the low-power universal asynchronous receiver transmitted (LPUART).

52.1 LPUART introduction

The LPUART is an UART which enables bidirectional UART communications with a limited power consumption. Only 32.768 kHz LSE clock is required to enable UART communications up to 9600 baud. Higher baud rates can be reached when the LPUART is clocked by clock sources different from the LSE clock.

Even when the device is in low-power mode, the LPUART can wait for an incoming UART frame while having an extremely low energy consumption. The LPUART includes all necessary hardware support to make asynchronous serial communications possible with minimum power consumption.

It supports Half-duplex Single-wire communications and modem operations (CTS/RTS).

It also supports multiprocessor communications.

DMA (direct memory access) can be used for data transmission/reception.
52.2 LPUART main features

- Full-duplex asynchronous communications
- NRZ standard format (mark/space)
- Programmable baud rate
- From 300 baud to 9600 baud using a 32.768 kHz clock source.
- Higher baud rates can be achieved by using a higher frequency clock source
- Two internal FIFOs to transmit and receive data
  Each FIFO can be enabled/disabled by software and come with status flags for FIFOs states.
- Dual clock domain with dedicated kernel clock for peripherals independent from PCLK.
- Programmable data word length (7 or 8 or 9 bits)
- Programmable data order with MSB-first or LSB-first shifting
- Configurable stop bits (1 or 2 stop bits)
- Single-wire Half-duplex communications
- Continuous communications using DMA
- Received/transmitted bytes are buffered in reserved SRAM using centralized DMA.
- Separate enable bits for transmitter and receiver
- Separate signal polarity control for transmission and reception
- Swappable Tx/Rx pin configuration
- Hardware flow control for modem and RS-485 transceiver
- Transfer detection flags:
  - Receive buffer full
  - Transmit buffer empty
  - Busy and end of transmission flags
- Parity control:
  - Transmits parity bit
  - Checks parity of received data byte
- Four error detection flags:
  - Overrun error
  - Noise detection
  - Frame error
  - Parity error
- Interrupt sources with flags
- Multiprocessor communications: wake-up from Mute mode by idle line detection or address mark detection
52.3 **LPUART implementation**

The table(s) below describe(s) LPUART implementation. It(they) also include(s) USARTs for comparison.

52.4 LPUART functional description

52.4.1 LPUART block diagram

The simplified block diagram given in Figure 640 shows two fully independent clock domains:

- The **lpuart_pck** clock domain
  - The **lpuart_pck** clock signal feeds the peripheral bus interface. It must be active when accesses to the LPUART registers are required.

- The **lpuart_ker_ck** kernel clock domain
  - The **lpuart_ker_ck** is the LPUART clock source. It is independent of the **lpuart_pck** and delivered by the RCC. So, the LPUART registers can be written/read even when the **lpuart_ker_ck** is stopped.
  - When the dual clock domain feature is disabled, the **lpuart_ker_ck** is the same as the **lpuart_pck** clock.

There is no constraint between **lpuart_pck** and **lpuart_ker_ck**: **lpuart_ker_ck** can be faster or slower than **lpuart_pck**, with no more limitation than the ability for the software to manage the communication fast enough.
52.4.2 **LPUART signals**

LPUART bidirectional communications requires a minimum of two pins: Receive Data In (RX) and Transmit Data Out (TX):

- **RX** (Receive Data Input)
  RX is the serial data input.
- **TX** (Transmit Data Output)
  When the transmitter is disabled, the output pin returns to its I/O port configuration. When the transmitter is enabled and nothing is to be transmitted, the TX pin is at high level. In Single-wire mode, this I/O is used to transmit and receive the data.

**RS232 hardware flow control mode**

The following pins are required in RS232 Hardware flow control mode:

- **CTS** (Clear To Send)
  When driven high, this signal blocks the data transmission at the end of the current transfer.
- **RTS** (Request to send)
  When it is low, this signal indicates that the USART is ready to receive data.

**RS485 hardware flow control mode**

The following pin is required in RS485 Hardware control mode:

- **DE** (Driver Enable)
  This signal activates the transmission mode of the external transceiver.

*Note:* *DE and RTS share the same pin.*

52.4.3 **LPUART character description**

The word length can be set to 7 or 8 or 9 bits, by programming the M bits (M0: bit 12 and M1: bit 28) in the LPUART_CR1 register (see Figure 614).

- 7-bit character length: M[1:0] = ‘10’
- 8-bit character length: M[1:0] = ‘00’
- 9-bit character length: M[1:0] = ‘01’

By default, the signal (TX or RX) is in low state during the start bit. It is in high state during the stop bit.

These values can be inverted, separately for each signal, through polarity configuration control.

An *Idle character* is interpreted as an entire frame of “1”s. (The number of “1” ’s includes the number of stop bits).

A *Break character* is interpreted on receiving “0”s for a frame period. At the end of the break frame, the transmitter inserts 2 stop bits.

Transmission and reception are driven by a common baud rate generator. The transmission and reception clocks are generated when the enable bit is set for the transmitter and receiver, respectively.

The details of each block is given below.
52.4.4 LPUART FIFOs and thresholds

The LPUART can operate in FIFO mode.

The LPUART comes with a Transmit FIFO (TXFIFO) and a Receive FIFO (RXFIFO). The FIFO mode is enabled by setting FIFOEN bit (bit 29) in LPUART_CR1 register.

Since the maximum data word length is 9 bits, the TXFIFO is 9-bit wide. However the RXFIFO default width is 12 bits. This is due to the fact that the receiver does not only store
the data in the FIFO, but also the error flags associated to each character (Parity error, Noise error and Framing error flags).

Note: The received data is stored in the RXFIFO together with the corresponding flags. However, only the data are read when reading the RDR.

The status flags are available in the LPUART_ISR register.

It is possible to define the TXFIFO and RXFIFO levels at which the Tx and RX interrupts are triggered. These thresholds are programmed through RXFTCFG and TXFTCFG bitfields in LPUART_CR3 control register.

In this case:

- The RXFT flag is set in the LPUART_ISR register and the corresponding interrupt (if enabled) is generated, when the number of received data in the RXFIFO reaches the threshold programmed in the RXFTCFG bits fields. This means that the RXFIFO is filled until the number of data in the RXFIFO is equal to the programmed threshold.

RXFTCFG data have been received: one data in LPUART_RDR and (RXFTCFG - 1) data in the RXFIFO. As an example, when the RXFTCFG is programmed to ‘101’, the RXFT flag is set when a number of data corresponding to the FIFO size has been received: FIFO size - 1 data in the RXFIFO and 1 data in the LPUART_RDR. As a result, the next received data does not set the overrun flag.

- The TXFT flag is set in the LPUART_ISR register and the corresponding interrupt (if enabled) is generated when the number of empty locations in the TXFIFO reaches the threshold programmed in the TXFTCFG bits fields. This means that the TXFIFO is emptied until the number of empty locations in the TXFIFO is equal to the programmed threshold.

52.4.5 LPUART transmitter

The transmitter can send data words of either 7 or 8 or 9 bits, depending on the M bit status. The Transmit Enable bit (TE) must be set in order to activate the transmitter function. The data in the transmit shift register is output on the TX pin.

Character transmission

During an LPUART transmission, data shifts out least significant bit first (default configuration) on the TX pin. In this mode, the LPUART_TDR register consists of a buffer (TDR) between the internal bus and the transmit shift register (see Figure 640).

When FIFO mode is enabled, the data written to the LPUART_TDR register are queued in the TXFIFO.

Every character is preceded by a start bit which corresponds to a low logic level for one bit period. The character is terminated by a configurable number of stop bits.

The number of stop bits can be 1 or 2.

Note: The TE bit must be set before writing the data to be transmitted to the LPUART_TDR. The TE bit should not be reset during data transmission. Resetting the TE bit during the transmission corrupts the data on the TX pin as the baud rate counters is frozen. The current data being transmitted are lost.

An idle frame is sent after the TE bit is enabled.
Configurable stop bits

The number of stop bits to be transmitted with every character can be programmed in LPUART_CR2 (bits 13,12).

- **1 stop bit:** This is the default value of number of stop bits.
- **2 Stop bits:** This is supported by normal LPUART, Single-wire and Modem modes.

An idle frame transmission includes the stop bits.

A break transmission is 10 low bits (when M[1:0] = '00') or 11 low bits (when M[1:0] = '01') or 9 low bits (when M[1:0] = '10') followed by 2 stop bits. It is not possible to transmit long breaks (break of length greater than 9/10/11 low bits).

### Figure 642. Configurable stop bits

Character transmission procedure

To transmit a character, follow the sequence below:

1. Program the M bits in LPUART_CR1 to define the word length.
2. Select the desired baud rate using the LPUART_BRR register.
3. Program the number of stop bits in LPUART_CR2.
4. Enable the LPUART by writing the UE bit in LPUART_CR1 register to ‘1’.
5. Select DMA enable (DMAT) in LPUART_CR3 if Multi buffer Communication is to take place. Configure the DMA register as explained in Section 52.4.12: Continuous communication using DMA and LPUART.
6. Set the TE bit in LPUART_CR1 to send an idle frame as first transmission.
7. Write the data to send in the LPUART_TDR register. Repeat this operation for each data to be transmitted in case of single buffer.
   - When FIFO mode is disabled, writing a data in the LPUART_TDR clears the TXE flag.
   - When FIFO mode is enabled, writing a data in the LPUART_TDR adds one data to the TXFIFO. Write operations to the LPUART_TDR are performed when TXFNF flag is set. This flag remains set until the TXFIFO is full.
8. When the last data is written to the LPUART_TDR register, wait until TC = 1. This indicates that the transmission of the last frame is complete.
   - When FIFO mode is disabled, this indicates that the transmission of the last frame is complete.
When FIFO mode is enabled, this indicates that both TXFIFO and shift register are empty. This check is required to avoid corrupting the last transmission when the LPUART is disabled or enters Halt mode.

**Single byte communication**

- **When FIFO mode disabled:**
  Writing to the transmit data register always clears the TXE bit. The TXE flag is set by hardware to indicate that:
  - the data have been moved from the LPUART_TDR register to the shift register and data transmission has started;
  - the LPUART_TDR register is empty;
  - the next data can be written to the LPUART_TDR register without overwriting the previous data.
  The TXE flag generates an interrupt if the TXEIE bit is set.
  When a transmission is ongoing, a write instruction to the LPUART_TDR register stores the data in the TDR register, which is copied to the shift register at the end of the current transmission.
  When no transmission is ongoing, a write instruction to the LPUART_TDR register places the data in the shift register, the data transmission starts, and the TXE bit is set.

- **When FIFO mode is enabled,** the TXFNF (TXFIFO Not Full) flag is set by hardware to indicate that:
  - the TXFIFO is not full;
  - the LPUART_TDR register is empty;
  - the next data can be written to the LPUART_TDR register without overwriting the previous data. When a transmission is ongoing, a write operation to the LPUART_TDR register stores the data in the TXFIFO. Data are copied from the TXFIFO to the shift register at the end of the current transmission.
  When the TXFIFO is not full, the TXFNF flag stays at ‘1’ even after a write in LPUART_TDR. It is cleared when the TXFIFO is full. This flag generates an interrupt if TXFNEIE bit is set.
  Alternatively, interrupts can be generated and data can be written to the TXFIFO when the TXFIFO threshold is reached. In this case, the CPU can write a block of data defined by the programmed threshold.
  If a frame is transmitted (after the stop bit) and the TXE flag (TXFE is case of FIFO mode) is set, the TC bit goes high. An interrupt is generated if the TCIE bit is set in the LPUART_CR1 register.
  After writing the last data in the LPUART_TDR register, it is mandatory to wait for TC = 1 before disabling the LPUART or causing the device to enter the low-power mode (see *Figure 643: TC/TXE behavior when transmitting*).
Note: When FIFO management is enabled, the TXFNF flag is used for data transmission.

**Break characters**

Setting the SBKRQ bit transmits a break character. The break frame length depends on the M bits (see Figure 641).

If a ‘1’ is written to the SBKRQ bit, a break character is sent on the TX line after completing the current character transmission. The SBKF bit is set by the write operation and it is reset by hardware when the break character is completed (during the stop bits after the break character). The LPUART inserts a logic 1 signal (STOP) for the duration of 2 bits at the end of the break frame to guarantee the recognition of the start bit of the next frame.

When the SBKRQ bit is set, the break character is sent at the end of the current transmission.

When FIFO mode is enabled, sending the break character has priority on sending data even if the TXFIFO is full.

**Idle characters**

Setting the TE bit drives the LPUART to send an idle frame before the first data frame.

### 52.4.6 LPUART receiver

The LPUART can receive data words of either 7 or 8 or 9 bits depending on the M bits in the LPUART_CR1 register.

**Start bit detection**

In the LPUART, the start bit is detected when a falling edge occurs on the Rx line, followed by a sample taken in the middle of the start bit to confirm that it is still ‘0’. If the start sample is at ‘1’, then the noise error flag (NE) is set, then the start bit is discarded and the receiver waits for a new start bit. Else, the receiver continues to sample all incoming bits normally.
Character reception

During an LPUART reception, data are shifted in least significant bit first (default configuration) through the RX pin. In this mode, the LPUART_RDR register consists of a buffer (RDR) between the internal bus and the received shift register.

Character reception procedure

To receive a character, follow the sequence below:

1. Program the M bits in LPUART_CR1 to define the word length.
2. Select the desired baud rate using the baud rate register LPUART_BRR.
3. Program the number of stop bits in LPUART_CR2.
4. Enable the LPUART by writing the UE bit in LPUART_CR1 register to ‘1’.
5. Select DMA enable (DMAR) in LPUART_CR3 if multibuffer communication is to take place. Configure the DMA register as explained in Section 52.4.12: Continuous communication using DMA and LPUART.
6. Set the RE bit LPUART_CR1. This enables the receiver which begins searching for a start bit.

When a character is received

- When FIFO mode is disabled, the RXNE bit is set. It indicates that the content of the shift register is transferred to the RDR. In other words, data has been received and can be read (as well as its associated error flags).
- When FIFO mode is enabled, the RXFNE bit is set indicating that the RXFIFO is not empty. Reading the LPUART_RDR returns the oldest data entered in the RXFIFO. When a data is received, it is stored in the RXFIFO, together with the corresponding error bits.
- An interrupt is generated if the RXNEIE (RXFNEIE in case of FIFO mode) bit is set.
- The error flags can be set if a frame error, noise or an overrun error has been detected during reception.
- In multibuffer communication mode:
  - When FIFO mode is disabled, the RXNE flag is set after every byte received and is cleared by the DMA read of the Receive Data Register.
  - When FIFO mode is enabled, the RXFNE flag is set when the RXFIFO is not empty. After every DMA request, a data is retrieved from the RXFIFO. DMA request is triggered by RXFIFO is not empty i.e. there is a data in the RXFIFO to be read.
- In single buffer mode:
  - When FIFO mode is disabled, clearing the RXNE flag is done by performing a software read from the LPUART_RDR register. The RXNE flag can also be cleared by writing 1 to the RXFRQ in the LPUART_RQR register. The RXNE bit must be cleared before the end of the reception of the next character to avoid an overrun error.
  - When FIFO mode is enabled, the RXFNE flag is set when the RXFIFO is not empty. After every read operation from the LPUART_RDR register, a data is retrieved from the RXFIFO. When the RXFIFO is empty, the RXFNE flag is cleared. The RXFNE flag can also be cleared by writing 1 to the RXFRQ bit in the LPUART_RQR register. When the RXFIFO is full, the first entry in the RXFIFO must be read before the end of the reception of the next character to avoid an overrun error. The RXFNE flag generates an interrupt if the RXFNEIE bit is set.
Alternatively, interrupts can be generated and data can be read from RXFIFO when the RXFIFO threshold is reached. In this case, the CPU can read a block of data defined by the programmed threshold.

**Break character**

When a break character is received, the LPUART handles it as a framing error.

**Idle character**

When an idle frame is detected, it is handled in the same way as a data character reception except that an interrupt is generated if the IDLEIE bit is set.

**Overrun error**

- **FIFO mode disabled**

  An overrun error occurs when a character is received when RXNE has not been reset. Data can not be transferred from the shift register to the RDR register until the RXNE bit is cleared. The RXNE flag is set after every byte received.

  An overrun error occurs if RXNE flag is set when the next data is received or the previous DMA request has not been serviced. When an overrun error occurs:
  - the ORE bit is set;
  - the RDR content is not lost. The previous data is available when a read to LPUART_RDR is performed.;
  - the shift register is overwritten. After that, any data received during overrun is lost.
  - an interrupt is generated if either the RXNEIE bit or EIE bit is set.

- **FIFO mode enabled**

  An overrun error occurs when the shift register is ready to be transferred when the receive FIFO is full.

  Data can not be transferred from the shift register to the LPUART_RDR register until there is one free location in the RXFIFO. The RXFNE flag is set when the RXFIFO is not empty.

  An overrun error occurs if the RXFIFO is full and the shift register is ready to be transferred. When an overrun error occurs:
  - the ORE bit is set;
  - the first entry in the RXFIFO is not lost. It is available when a read to LPUART_RDR is performed.
  - the shift register is overwritten. After that, any data received during overrun is lost.
  - an interrupt is generated if either the RXFNEIE bit or EIE bit is set.

The ORE bit is reset by setting the ORECF bit in the ICR register.

**Note:** The ORE bit, when set, indicates that at least 1 data has been lost. Therefore, when the FIFO mode is disabled, there are two possibilities

- if RXNE = 1, then the last valid data is stored in the receive register (RDR) and can be read;
- if RXNE = 0, then the last valid data has already been read and there is nothing left to be read in the RDR. This case can occur when the last valid data is read in the RDR at the same time as the new (and lost) data is received.
Selecting the clock source

The choice of the clock source is done through the Clock Control system (see Section Reset and clock controller (RCC)). The clock source must be selected through the UE bit, before enabling the LPUART.

The clock source must be selected according to two criteria:

- Possible use of the LPUART in low-power mode
- Communication speed.

The clock source frequency is \( \text{lpuart}_\text{ker}_\text{ck} \).

When the dual clock domain and the wake-up from low-power mode features are supported, the \( \text{lpuart}_\text{ker}_\text{ck} \) clock source can be configured in the RCC (see Section Reset and clock controller (RCC)). Otherwise, the \( \text{lpuart}_\text{ker}_\text{ck} \) is the same as \( \text{lpuart}_\text{pclk} \).

The \( \text{lpuart}_\text{ker}_\text{ck} \) can be divided by a programmable factor in the LPUART\_PRESC register.

Some \( \text{lpuart}_\text{ker}_\text{ck} \) sources enable the LPUART to receive data while the MCU is in low-power mode. Depending on the received data and wake-up mode selection, the LPUART wakes up the MCU, when needed, in order to transfer the received data by software reading the LPUART\_RDR register or by DMA.

For the other clock sources, the system must be active to enable LPUART communications.

The communication speed range (specially the maximum communication speed) is also determined by the clock source.

The receiver samples each incoming bit as close as possible to the middle of the bit-period. Only a single sample is taken of each of the incoming bits.

*Note:* There is no noise detection for data.

Framing error

A framing error is detected when the stop bit is not recognized on reception at the expected time, following either a de-synchronization or excessive noise.

When the framing error is detected:

- the FE bit is set by hardware;
- the invalid data is transferred from the Shift register to the LPUART\_RDR register.
- no interrupt is generated in case of single byte communication. However this bit rises at the same time as the RXNE bit which itself generates an interrupt. In case of
multibuffer communication, an interrupt is issued if the EIE bit is set in the LPUART_CR3 register.

The FE bit is reset by writing 1 to the FECF in the LPUART_ICR register.

Configurable stop bits during reception

The number of stop bits to be received can be configured through the control bits of LPUART_CR2: it can be either 1 or 2 in normal mode.

- **1 stop bit**: sampling for 1 stop bit is done on the 8th, 9th and 10th samples.
- **2 stop bits**: sampling for the 2 stop bits is done in the middle of the second stop bit. The RXNE and FE flags are set just after this sample i.e. during the second stop bit. The first stop bit is not checked for framing error.

52.4.7 LPUART baud rate generation

The baud rate for the receiver and transmitter (Rx and Tx) are both set to the value programmed in the LPUART_BRR register.

\[
\text{Tx/Rx baud} = \frac{256 \times \text{Ipuartckpres}}{\text{LPUARTDIV}}
\]

LPUARTDIV is defined in the LPUART_BRR register.

**Note:** The baud counters are updated to the new value in the baud registers after a write operation to LPUART_BRR. Hence the baud rate register value should not be changed during communication.

It is forbidden to write values lower than 0x300 in the LPUART_BRR register.

f_{CK} must range from 3 x baud rate to 4096 x baud rate.

The maximum baud rate that can be reached when the LPUART clock source is the LSE, is 9600 baud. Higher baud rates can be reached when the LPUART is clocked by clock sources different from the LSE clock. For example, if the LPUART clock source frequency is 100 MHz, the maximum baud rate that can be reached is about 33 Mbaud.

</table>
52.4.8 Tolerance of the LPUART receiver to clock deviation

The asynchronous receiver of the LPUART works correctly only if the total clock system deviation is less than the tolerance of the LPUART receiver. The causes which contribute to the total deviation are:

- DTRA: deviation due to the transmitter error (which also includes the deviation of the transmitter’s local oscillator)
- DQUANT: error due to the baud rate quantization of the receiver
- DREC: deviation of the receiver local oscillator
- DTCL: deviation due to the transmission line (generally due to the transceivers which can introduce an asymmetry between the low-to-high transition timing and the high-to-low transition timing)

\[
\text{DTRA} + \text{DQUANT} + \text{DREC} + \text{DTCL} + \text{DWU} < \text{LPUART receiver tolerance}
\]

where

DWU is the error due to sampling point deviation when the wake-up from low-power mode is used.

The LPUART receiver can receive data correctly at up to the maximum tolerated deviation specified in Table 430:

- Number of Stop bits defined through STOP[1:0] bits in the LPUART_CCR2 register
- LPUART_BRR register value.

Note: The data specified in Table 430 may slightly differ in the special case when the received frames contain some Idle frames of exactly 10-bit times when M bits = '00' (11-bit times when M = '01' or 9-bit times when M = '10').

52.4.9 LPUART multiprocessor communication

It is possible to perform LPUART multiprocessor communications (with several LPUARTs connected in a network). For instance one of the LPUARTs can be the master, with its TX output connected to the RX inputs of the other LPUARTs. The others are slaves, with their respective TX outputs are logically ANDed together and connected to the RX input of the master.

In multiprocessor configurations it is often desirable that only the intended message recipient actively receives the full message contents, thus reducing redundant LPUART service overhead for all non addressed receivers.

The non addressed devices can be placed in Mute mode by means of the muting function. To use the Mute mode feature, the MME bit must be set in the LPUART_CR1 register.

Note: When FIFO management is enabled and MME is already set, MME bit must not be cleared and then set again quickly (within two lpuart_ker_ck cycles), otherwise Mute mode might remain active.

When the Mute mode is enabled:

- none of the reception status bits can be set;
- all the receive interrupts are inhibited;
- the RWU bit in LPUART_ISR register is set to ‘1’. RWU can be controlled automatically by hardware or by software, through the MMRQ bit in the LPUART_RQR register, under certain conditions.

The LPUART can enter or exit from Mute mode using one of two methods, depending on the WAKE bit in the LPUART_CR1 register:

- Idle Line detection if the WAKE bit is reset,
- Address Mark detection if the WAKE bit is set.

</table>
Idle line detection (WAKE = 0)

The LPUART enters Mute mode when the MMRQ bit is written to 1 and the RWU is automatically set.

The LPUART wakes up when an Idle frame is detected. The RWU bit is then cleared by hardware but the IDLE bit is not set in the LPUART_ISR register. An example of Mute mode behavior using Idle line detection is given in Figure 645.

Figure 645. Mute mode using Idle line detection

![Figure 645. Mute mode using Idle line detection](image)

Note: If the MMRQ is set while the IDLE character has already elapsed, the Mute mode is not entered (RWU is not set).

If the LPUART is activated while the line is IDLE, the idle state is detected after the duration of one IDLE frame (not only after the reception of one character frame).

4-bit/7-bit address mark detection (WAKE = 1)

In this mode, bytes are recognized as addresses if their MSB is a ‘1’ otherwise they are considered as data. In an address byte, the address of the targeted receiver is put in the 4 or 7 LSBs. The choice of 7 or 4 bit address detection is done using the ADDM7 bit. This 4-bit/7-bit word is compared by the receiver with its own address which is programmed in the ADD bits in the LPUART_CR2 register.

Note: In 7-bit and 9-bit data modes, address detection is done on 6-bit and 8-bit addresses (ADD[5:0] and ADD[7:0]) respectively.

The LPUART enters Mute mode when an address character is received which does not match its programmed address. In this case, the RWU bit is set by hardware. The RXNE flag is not set for this address byte and no interrupt or DMA request is issued when the LPUART enters Mute mode.

The LPUART also enters Mute mode when the MMRQ bit is written to ‘1’. The RWU bit is also automatically set in this case.

The LPUART exits from Mute mode when an address character is received which matches the programmed address. Then the RWU bit is cleared and subsequent bytes are received normally. The RXNE/RXFNE bit is set for the address character since the RWU bit has been cleared.

Note: When FIFO management is enabled, when MMRQ bit is set while the receiver is sampling the last bit of a data, this data may be received before effectively entering in Mute mode.
An example of Mute mode behavior using address mark detection is given in Figure 646.

**Figure 646. Mute mode using address mark detection**

In this example, the current address of the receiver is 1 (programmed in the LPUART_CR2 register)

52.4.10 LPUART parity control

Parity control (generation of parity bit in transmission and parity checking in reception) can be enabled by setting the PCE bit in the LPUART_CR1 register. Depending on the frame length defined by the M bits, the possible LPUART frame formats are as listed in Table 431.

</tbody>
</table>

2. In the data register, the PB is always taking the MSB position (8th or 7th, depending on the M bit value).

Even parity

The parity bit is calculated to obtain an even number of “1s” inside the frame which is made of the 6, 7 or 8 LSB bits (depending on M bit values) and the parity bit.

As an example, if data equal 00110101, and 4 bits are set, then the parity bit is equal to 0 if even parity is selected (PS bit in LPUART_CR1 = 0).

Odd parity

The parity bit is calculated to obtain an odd number of “1s” inside the frame made of the 6, 7 or 8 LSB bits (depending on M bit values) and the parity bit.

As an example, if data equal 00110101 and 4 bits set, then the parity bit is equal to 1 if odd parity is selected (PS bit in LPUART_CR1 = 1).
Parity checking in reception

If the parity check fails, the PE flag is set in the LPUART_ISR register and an interrupt is generated if PEIE is set in the LPUART_CR1 register. The PE flag is cleared by software writing 1 to the PECF in the LPUART_ICR register.

Parity generation in transmission

If the PCE bit is set in LPUART_CR1, then the MSB bit of the data written in the data register is transmitted but is changed by the parity bit (even number of “1s” if even parity is selected (PS = 0) or an odd number of “1s” if odd parity is selected (PS = 1)).

52.4.11 LPUART single-wire Half-duplex communication

Single-wire Half-duplex mode is selected by setting the HDSEL bit in the LPUART_CR3 register. In this mode, the following bits must be kept cleared:

- LINEN and CLKEN bits in the LPUART_CR2 register,
- SCEN and IREN bits in the LPUART_CR3 register.

The LPUART can be configured to follow a Single-wire Half-duplex protocol where the TX and RX lines are internally connected. The selection between half- and Full-duplex communication is made with a control bit HDSEL in LPUART_CR3.

As soon as HDSEL is written to ‘1’:

- The TX and RX lines are internally connected.
- The RX pin is no longer used
- The TX pin is always released when no data is transmitted. Thus, it acts as a standard I/O in idle or in reception. It means that the I/O must be configured so that TX is configured as alternate function open-drain with an external pull-up.

Apart from this, the communication protocol is similar to normal LPUART mode. Any conflict on the line must be managed by software (for instance by using a centralized arbiter). In particular, the transmission is never blocked by hardware and continues as soon as data is written in the data register while the TE bit is set.

Note: In LPUART communications, in the case of 1-stop bit configuration, the RXNE flag is set in the middle of the stop bit.

52.4.12 Continuous communication using DMA and LPUART

The LPUART is capable of performing continuous communication using the DMA. The DMA requests for Rx buffer and Tx buffer are generated independently.

Note: Refer to Section 51.4: USART implementation on page 2172 to determine if the DMA mode is supported. If DMA is not supported, use the LPUSRT as explained in Section 51.5.6. To perform continuous communication. When FIFO is disabled, you can clear the TXE/ RXNE flags in the LPUART_ISR register.

Transmission using DMA

DMA mode can be enabled for transmission by setting DMAT bit in the LPUART_CR3 register. Data are loaded from an SRAM area configured using the DMA peripheral (refer to the corresponding Direct memory access controller section) to the LPUART_TDR register whenever the TXE flag (TXFNF flag if FIFO mode is enabled) is set. To map a DMA channel for LPUART transmission, use the following procedure (x denotes the channel number):
1. Write the LPUART_TDR register address in the DMA control register to configure it as the destination of the transfer. The data is moved to this address from memory after each TXE (or TXFNF if FIFO mode is enabled) event.

2. Write the memory address in the DMA control register to configure it as the source of the transfer. The data is loaded into the LPUART_TDR register from this memory area after each TXE (or TXFNF if FIFO mode is enabled) event.

3. Configure the total number of bytes to be transferred to the DMA control register.

4. Configure the channel priority in the DMA register.

5. Configure DMA interrupt generation after half/full transfer as required by the application.

6. Clear the TC flag in the LPUART_ISR register by setting the TCCF bit in the LPUART_ICR register.

7. Activate the channel in the DMA register.

When the number of data transfers programmed in the DMA Controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector.

In transmission mode, once the DMA has written all the data to be transmitted (the TCIF flag is set in the DMA_ISR register), the TC flag can be monitored to make sure that the LPUART communication is complete. This is required to avoid corrupting the last transmission before disabling the LPUART or entering low-power mode. Software must wait until TC = 1. The TC flag remains cleared during all data transfers and it is set by hardware at the end of transmission of the last frame.

**Figure 647. Transmission using DMA**

---

**Note:** When FIFO management is enabled, the DMA request is triggered by Transmit FIFO not full (i.e. TXFNF = 1).
Reception using DMA

DMA mode can be enabled for reception by setting the DMAR bit in LPUART_CR3 register. Data are loaded from the LPUART_RDR register to a SRAM area configured using the DMA peripheral (refer to the corresponding Direct memory access controller (DMA) section) whenever a data byte is received. To map a DMA channel for LPUART reception, use the following procedure:

1. Write the LPUART_RDR register address in the DMA control register to configure it as the source of the transfer. The data is moved from this address to the memory after each RXNE (RXFNE in case FIFO mode is enabled) event.
2. Write the memory address in the DMA control register to configure it as the destination of the transfer. The data is loaded from LPUART_RDR to this memory area after each RXNE (RXFNE in case FIFO mode is enabled) event.
3. Configure the total number of bytes to be transferred to the DMA control register.
4. Configure the channel priority in the DMA control register.
5. Configure interrupt generation after half/full transfer as required by the application.
6. Activate the channel in the DMA control register.

When the number of data transfers programmed in the DMA Controller is reached, the DMA controller generates an interrupt on the DMA channel interrupt vector.

Figure 648. Reception using DMA

Note: When FIFO management is enabled, the DMA request is triggered by Receive FIFO not empty (i.e. RXFNE = 1).

Error flagging and interrupt generation in multibuffer communication

If any error occurs during a transaction in multibuffer communication mode, the error flag is asserted after the current byte. An interrupt is generated if the interrupt enable flag is set. For framing error, overrun error and noise flag which are asserted with RXNE (RXFNE in case FIFO mode is enabled) in single byte reception, there is a separate error flag interrupt
enable bit (EIE bit in the LPUART_CR3 register), which, if set, enables an interrupt after the current byte if any of these errors occur.

52.4.13 RS232 Hardware flow control and RS485 Driver Enable

It is possible to control the serial data flow between 2 devices by using the CTS input and the RTS output. The Figure 635 shows how to connect 2 devices in this mode:

RS232 RTS and CTS flow control can be enabled independently by writing the RTSE and CTSE bits respectively to 1 (in the LPUART_CR3 register).

RS232 RTS flow control

If the RTS flow control is enabled (RTSE = 1), then RTS is deasserted (tied low) as long as the LPUART receiver is ready to receive a new data. When the receive register is full, RTS is asserted, indicating that the transmission is expected to stop at the end of the current frame. Figure 650 shows an example of communication with RTS flow control enabled.

Note: When FIFO mode is enabled, RTS is asserted only when RXFIFO is full.
RS232 CTS flow control

If the CTS flow control is enabled (CTSE = 1), then the transmitter checks the CTS input before transmitting the next frame. If CTS is deasserted (tied low), then the next data is transmitted (assuming that data is to be transmitted, in other words, if TXE/TXFE = 0), else the transmission does not occur. When CTS is asserted during a transmission, the current transmission is completed before the transmitter stops.

When CTSE = 1, the CTSIF status bit is automatically set by hardware as soon as the CTS input toggles. It indicates when the receiver becomes ready or not ready for communication. An interrupt is generated if the CTSIE bit in the LPUART_CR3 register is set. Figure 651 shows an example of communication with CTS flow control enabled.

![Figure 651. RS232 CTS flow control](image)

**Note:** For correct behavior, CTS must be deasserted at least 3 LPUART clock source periods before the end of the current character. In addition it should be noted that the CTSCF flag may not be set for pulses shorter than 2 x PCLK periods.

RS485 driver enable

The driver enable feature is enabled by setting bit DEM in the LPUART_CR3 control register. This enables activating the external transceiver control, through the DE (Driver Enable) signal. The assertion time is the time between the activation of the DE signal and the beginning of the start bit. It is programmed using the DEAT [4:0] bitfields in the LPUART_CR1 control register. The deassertion time is the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE signal. It is programmed using the DEDT [4:0] bitfields in the LPUART_CR1 control register. The polarity of the DE signal can be configured using the DEP bit in the LPUART_CR3 control register.
The LPUART DEAT and DEDT are expressed in LPUART clock source (f$_{CK}$) cycles:

- The Driver enable assertion time equals
  - $(1 + (DEAT \times P)) \times f_{CK}$, if $P \neq 0$
  - $(1 + DEAT) \times f_{CK}$, if $P = 0$

- The Driver enable deassertion time equals
  - $(1 + (DEDT \times P)) \times f_{CK}$, if $P \neq 0$
  - $(1 + DEDT) \times f_{CK}$, if $P = 0$

where $P = BRR[20:11]$

### 52.4.14 LPUART low-power management

The LPUART has advanced low-power mode functions that enable it to transfer properly data even when the lpuart_pclk clock is disabled.

The LPUART is able to wake up the MCU from low-power mode when the UESM bit is set. When the lpuart_pclk is gated, the LPUART provides a wake-up interrupt (lpuart_wkup) if a specific action requiring the activation of the lpuart_pclk clock is needed:

- If FIFO mode is disabled

  - lpuart_pclk clock has to be activated to empty the LPUART data register.
  - In this case, the lpuart_wkup interrupt source is the RXNE set to ‘1’. The RXNEIE bit must be set before entering low-power mode.

- If FIFO mode is enabled

  - lpuart_pclk clock has to be activated
  - to fill the TXFIFO
  - or to empty the RXFIFO
  - In this case, the lpuart_wkup interrupt source can be:
    - RXFIFO not empty. In this case, the RXFNEIE bit must be set before entering low-power mode.
    - RXFIFO full. In this case, the RXFIE bit must be set before entering low-power mode, the number of received data corresponds to the RXFIFO size, and the RXFF flag is not set.
    - TXFIFO empty. In this case, the TXFEIE bit must be set before entering low-power mode.
  - This enables sending/receiving the data in the TXFIFO/RXFIFO during low-power mode.

To avoid overrun/underrun errors and transmit/receive data in low-power mode, the lpuart_wkup interrupt source can be one of the following events:

- TXFIFO threshold reached. In this case, the TXFTIE bit must be set before entering low-power mode.
- RXFIFO threshold reached. In this case, the RXFTIE bit must be set before entering low-power mode.

For example, the application can set the threshold to the maximum RXFIFO size if the wake-up time is less than the time to receive a single byte across the line.

Using the RXFIFO full, TXFIFO empty, RXFIFO not empty and RXFIFO/TXFIFO threshold interrupts to wake up the MCU from low-power mode enables doing as many LPUART transfers as possible during low-power mode with the benefit of optimizing consumption.
Alternatively, a specific lpuart_wkup interrupt may be selected through the WUS bitfields. When the wake-up event is detected, the WUF flag is set by hardware and lpuart_wkup interrupt is generated if the WUFIE bit is set.

**Note:** Before entering low-power mode, make sure that no LPUART transfer is ongoing. Checking the BUSY flag cannot ensure that low-power mode is never entered when data reception is ongoing.

The WUF flag is set when a wake-up event is detected, independently of whether the MCU is in low-power or in an active mode.

When entering low-power mode just after having initialized and enabled the receiver, the REACK bit must be checked to ensure the LPUART is actually enabled.

When DMA is used for reception, it must be disabled before entering low-power mode and re-enabled upon exit from low-power mode.

When FIFO is enabled, the wake-up from low-power mode on address match is only possible when Mute mode is enabled.

### Using Mute mode with low-power mode

If the LPUART is put into Mute mode before entering low-power mode:

- Wake-up from Mute mode on idle detection must not be used, because idle detection cannot work in low-power mode.
- If the wake-up from Mute mode on address match is used, then the low-power mode wake-up source from must also be the address match. If the RXNE flag was set when entering the low-power mode, the interface remains in Mute mode upon address match and wake up from low-power mode.

**Note:** When FIFO management is enabled, Mute mode is used with wake-up from low-power mode without any constraints (i.e. the two points mentioned above about mute and low-power mode are valid only when FIFO management is disabled).

### Wake-up from low-power mode when LPUART kernel clock lpuart_ker_ck is OFF in low-power mode

If during low-power mode, the lpuart_ker_ck clock is switched OFF, when a falling edge on the LPUART receive line is detected, the LPUART interface requests the lpuart_ker_ck clock to be switched ON thanks to the lpuart_ker_ck_req signal. The lpuart_ker_ck is then used for the frame reception.

If the wake-up event is verified, the MCU wakes up from low-power mode and data reception goes on normally.

If the wake-up event is not verified, the lpuart_ker_ck is switched OFF again, the MCU is not waken up and stays in low-power mode and the kernel clock request is released.

The example below shows the case of wake-up event programmed to “address match detection” and FIFO management disabled.

*Figure 652* shows the behavior when the wake-up event is verified.
Figure 652. Wake-up event verified (wake-up event = address match, FIFO disabled)

Address match event WUF = '1'
LPUART sends a wakeup event to the MCU

Data reception goes on

Figure 653 shows the behavior when the wake-up event is not verified.

Figure 653. Wake-up event not verified (wake-up event = address match, FIFO disabled)

Address does not match

MSv40860V2

Note: The above figures are valid when address match or any received frame is used as wake-up event. In the case the wake-up event is the start bit detection, the LPUART sends the wake-up event to the MCU at the end of the start bit.
Determining the maximum LPUART baud rate that enables to correctly wake up the MCU from low-power mode

The maximum baud rate that enables to correctly wake up the MCU from low-power mode depends on the wake-up time parameter (refer to the device datasheet) and on the LPUART receiver tolerance (see Section 52.4.8: Tolerance of the LPUART receiver to clock deviation).

Let us take the example of OVER8 = 0, M bits = ‘01’, ONEBIT = 0 and BRR [3:0] = 0000.

In these conditions, according to Table 430: Tolerance of the LPUART receiver, the LPUART receiver tolerance equals 3.41%.

\[
\begin{align*}
D_{WU_{\text{max}}} &= t_{WULPUART} / (11 \times T_{\text{bit Min}}) \\
T_{\text{bit Min}} &= t_{WULPUART} / (11 \times D_{WU_{\text{max}}})
\end{align*}
\]

where \( t_{WULPUART} \) is the wake-up time from low-power mode.

If we consider the ideal case where DTRA, DQUANT, DREC and DTCL parameters are at 0%, the maximum value of DWU is 3.41%. In reality, we need to consider at least the lpuart_ker_ck inaccuracy.

For example, if HSI is used as lpuart_ker_ck, and the HSI inaccuracy is of 1%, then we obtain:

\[
\begin{align*}
t_{WULPUART} &= 3 \mu s \quad \text{(values provided only as examples; for correct values, refer to the device datasheet).} \\
D_{WU_{\text{max}}} &= 3.41\% - 1\% = 2.41\% \\
T_{\text{bit min}} &= 3 \mu s / (11 \times 2.41\%) = 11.32 \mu s.
\end{align*}
\]

As a result, the maximum baud rate that enables to wake up correctly from low-power mode is: \( 1/11.32 \mu s = 88.36 \text{ kbaud} \).

### 52.5 LPUART in low-power modes

<table>

</table>
1. The LPUART can wake up the device from Stop mode only if the peripheral instance supports the wake-up from Stop mode feature. Refer to Section 52.3: LPUART implementation for the list of supported Stop modes.

2. RXFF flag is asserted if the LPUART receives n+1 data (n being the RXFIFO size): n data in the RXFIFO and 1 data in LPUART_RDR. In Stop mode, LPUART_RDR is not clocked. As a result, this register is not written and once n data are received and written in the RXFIFO, the RXFF interrupt is asserted (RXFF flag is not set).

3. When OVRDIS = 0.

52.7 LPUART registers

Refer to Section 1.2 on page 106 for a list of abbreviations used in register descriptions.

The peripheral registers have to be accessed by words (32 bits).

52.7.1 LPUART control register 1 (LPUART_CR1)

Address offset: 0x00

Reset value: 0x0000 0000

The same register can be used in FIFO mode enabled (this section) and FIFO mode disabled (next section).

FIFO mode enabled

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
<th>Value</th>

1: FIFO mode is enabled |

Bit 31 RXFFIE: RXFIFO full interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited
1: An LPUART interrupt is generated when RXFF = 1 in the LPUART_ISR register

Bit 30 TXFEIE: TXFIFO empty interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited
1: An LPUART interrupt is generated when TXFE = 1 in the LPUART_ISR register

Bit 29 FIFOEN: FIFO mode enable
This bit is set and cleared by software.
0: FIFO mode is disabled.
1: FIFO mode is enabled.
Bit 28  **M1**: Word length
This bit must be used in conjunction with bit 12 (M0) to determine the word length. It is set or cleared by software.
- M[1:0] = '00': 1 Start bit, 8 Data bits, n Stop bit
- M[1:0] = '01': 1 Start bit, 9 Data bits, n Stop bit
- M[1:0] = '10': 1 Start bit, 7 Data bits, n Stop bit
This bit can only be written when the LPUART is disabled (UE = 0).

**Note**: In 7-bit data length mode, the Smartcard mode, LIN master mode and Auto baud rate (0x7F and 0x55 frames detection) are not supported.

Bits 27:26  Reserved, must be kept at reset value.

Bits 25:21  **DEAT[4:0]**: Driver enable assertion time
This 5-bit value defines the time between the activation of the DE (Driver Enable) signal and the beginning of the start bit. It is expressed in Lpuart_ker_ck clock cycles. For more details, refer Section 51.5.20: RS232 Hardware flow control and RS485 Driver Enable.
This bitfield can only be written when the LPUART is disabled (UE = 0).

Bits 20:16  **DEDT[4:0]**: Driver enable deassertion time
This 5-bit value defines the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE (Driver Enable) signal. It is expressed in Lpuart_ker_ck clock cycles. For more details, refer Section 52.4.13: RS232 Hardware flow control and RS485 Driver Enable.
If the LPUART_TDR register is written during the DEDT time, the new data is transmitted only when the DEDT and DEAT times have both elapsed.
This bitfield can only be written when the LPUART is disabled (UE = 0).

Bit 15  Reserved, must be kept at reset value.

Bit 14  **CMIE**: Character match interrupt enable
This bit is set and cleared by software.
- 0: Interrupt is inhibited
- 1: A LPUART interrupt is generated when the CMF bit is set in the LPUART_ISR register.

Bit 13  **MME**: Mute mode enable
This bit activates the Mute mode function of the LPUART. When set, the LPUART can switch between the active and Mute modes, as defined by the WAKE bit. It is set and cleared by software.
- 0: Receiver in active mode permanently
- 1: Receiver can switch between Mute mode and active mode.

Bit 12  **M0**: Word length
This bit is used in conjunction with bit 28 (M1) to determine the word length. It is set or cleared by software (refer to bit 28 (M1) description).
This bit can only be written when the LPUART is disabled (UE = 0).

Bit 11  **WAKE**: Receiver wake-up method
This bit determines the LPUART wake-up method from Mute mode. It is set or cleared by software.
- 0: Idle line
- 1: Address mark
This bitfield can only be written when the LPUART is disabled (UE = 0).
Bit 10 **PCE**: Parity control enable
- This bit selects the hardware parity control (generation and detection). When the parity control is enabled, the computed parity is inserted at the MSB position (9th bit if \( M = 1 \); 8th bit if \( M = 0 \)) and parity is checked on the received data. This bit is set and cleared by software. Once it is set, PCE is active after the current byte (in reception and in transmission).
- 0: Parity control disabled
- 1: Parity control enabled
- This bitfield can only be written when the LPUART is disabled (UE = 0).

Bit 9 **PS**: Parity selection
- This bit selects the odd or even parity when the parity generation/detection is enabled (PCE bit set). It is set and cleared by software. The parity is selected after the current byte.
- 0: Even parity
- 1: Odd parity
- This bitfield can only be written when the LPUART is disabled (UE = 0).

Bit 8 **PEIE**: PE interrupt enable
- This bit is set and cleared by software.
- 0: Interrupt is inhibited
- 1: An LPUART interrupt is generated whenever PE = 1 in the LPUART_ISR register

Bit 7 **TXFNFIE**: TXFIFO not full interrupt enable
- This bit is set and cleared by software.
- 0: Interrupt is inhibited
- 1: A LPUART interrupt is generated whenever TXE/TXFNF = 1 in the LPUART_ISR register

Bit 6 **TCIE**: Transmission complete interrupt enable
- This bit is set and cleared by software.
- 0: Interrupt is inhibited
- 1: An LPUART interrupt is generated whenever TC = 1 in the LPUART_ISR register

Bit 5 **RXFNEIE**: RXFIFO not empty interrupt enable
- This bit is set and cleared by software.
- 0: Interrupt is inhibited
- 1: A LPUART interrupt is generated whenever ORE = 1 or RXNE/RXFNE = 1 in the LPUART_ISR register

Bit 4 **IDLEIE**: IDLE interrupt enable
- This bit is set and cleared by software.
- 0: Interrupt is inhibited
- 1: An LPUART interrupt is generated whenever IDLE = 1 in the LPUART_ISR register

Bit 3 **TE**: Transmitter enable
- This bit enables the transmitter. It is set and cleared by software.
- 0: Transmitter is disabled
- 1: Transmitter is enabled

**Note:** During transmission, a low pulse on the TE bit (“0” followed by “1”) sends a preamble (idle line) after the current word. In order to generate an idle character, the TE must not be immediately written to 1. In order to ensure the required duration, the software can poll the TEACK bit in the LPUART_ISR register.

When TE is set there is a 1 bit-time delay before the transmission starts.
Bit 2  **RE**: Receiver enable
- This bit enables the receiver. It is set and cleared by software.
- 0: Receiver is disabled
- 1: Receiver is enabled and begins searching for a start bit

Bit 1  **UESM**: LPUART enable in Stop mode
- When this bit is cleared, the LPUART is not able to wake up the MCU from low-power mode.
- When this bit is set, the LPUART is able to wake up the MCU from low-power mode, provided that the LPUART clock selection is HSI or LSE in the RCC.
- This bit is set and cleared by software.
- 0: LPUART not able to wake up the MCU from low-power mode.
- 1: LPUART able to wake up the MCU from low-power mode. When this function is active, the clock source for the LPUART must be HSI or LSE (see RCC chapter)

**Note**: *It is recommended to set the UESM bit just before entering low-power mode and clear it on exit from low-power mode.*

Bit 0  **UE**: LPUART enable
- When this bit is cleared, the LPUART prescalers and outputs are stopped immediately, and current operations are discarded. The configuration of the LPUART is kept, but all the status flags, in the LPUART_ISR are reset. This bit is set and cleared by software.
- 0: LPUART prescaler and outputs disabled, low-power mode
- 1: LPUART enabled

**Note**: *To enter low-power mode without generating errors on the line, the TE bit must be reset before and the software must wait for the TC bit in the LPUART_ISR to be set before resetting the UE bit. The DMA requests are also reset when UE = 0 so the DMA channel must be disabled before resetting the UE bit.*

### 52.7.2 LPUART control register 1 [alternate] (LPUART_CR1)

Address offset: 0x00
Reset value: 0x0000 0000

The same register can be used in FIFO mode enabled (previous section) and FIFO mode disabled (this section).

#### FIFO mode disabled

Bits 31:30  Reserved, must be kept at reset value.

Bit 29  **FIFOEN**: FIFO mode enable
This bit is set and cleared by software.
0: FIFO mode is disabled.
1: FIFO mode is enabled.

Bit 28  **M1**: Word length
This bit must be used in conjunction with bit 12 (M0) to determine the word length. It is set or cleared by software.
- M[1:0] = '00': 1 Start bit, 8 Data bits, n Stop bit
- M[1:0] = '01': 1 Start bit, 9 Data bits, n Stop bit
- M[1:0] = '10': 1 Start bit, 7 Data bits, n Stop bit
This bit can only be written when the LPUART is disabled (UE = 0).

*Note: In 7-bit data length mode, the Smartcard mode, LIN master mode and Auto baud rate (0x7F and 0x55 frames detection) are not supported.*

Bits 27:26  Reserved, must be kept at reset value.

Bits 25:21  **DEAT[4:0]**: Driver enable assertion time
This 5-bit value defines the time between the activation of the DE (Driver Enable) signal and the beginning of the start bit. It is expressed in lpuart_ker_ck clock cycles. For more details, refer to *Section 51.5.20: RS232 Hardware flow control and RS485 Driver Enable.*
This bitfield can only be written when the LPUART is disabled (UE = 0).

Bits 20:16  **DEDT[4:0]**: Driver enable deassertion time
This 5-bit value defines the time between the end of the last stop bit, in a transmitted message, and the de-activation of the DE (Driver Enable) signal. It is expressed in lpuart_ker_ck clock cycles. For more details, refer to *Section 52.4.13: RS232 Hardware flow control and RS485 Driver Enable.*
If the LPUART_TDR register is written during the DEDT time, the new data is transmitted only when the DEDT and DEAT times have both elapsed.
This bitfield can only be written when the LPUART is disabled (UE = 0).

Bit 15  Reserved, must be kept at reset value.

Bit 14  **CMIE**: Character match interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited
1: A LPUART interrupt is generated when the CMF bit is set in the LPUART_ISR register.

Bit 13  **MME**: Mute mode enable
This bit activates the Mute mode function of the LPUART. When set, the LPUART can switch between the active and Mute modes, as defined by the WAKE bit. It is set and cleared by software.
0: Receiver in active mode permanently
1: Receiver can switch between Mute mode and active mode.

Bit 12  **M0**: Word length
This bit is used in conjunction with bit 28 (M1) to determine the word length. It is set or cleared by software (refer to bit 28 (M1) description).
This bit can only be written when the LPUART is disabled (UE = 0).
Bit 11  **WAKE**: Receiver wake-up method
This bit determines the LPUART wake-up method from Mute mode. It is set or cleared by software.
0: Idle line
1: Address mark
This bitfield can only be written when the LPUART is disabled (UE = 0).

Bit 10  **PCE**: Parity control enable
This bit selects the hardware parity control (generation and detection). When the parity control is enabled, the computed parity is inserted at the MSB position (9th bit if M = 1; 8th bit if M = 0) and parity is checked on the received data. This bit is set and cleared by software.
Once it is set, PCE is active after the current byte (in reception and in transmission).
0: Parity control disabled
1: Parity control enabled
This bitfield can only be written when the LPUART is disabled (UE = 0).

Bit 9  **PS**: Parity selection
This bit selects the odd or even parity when the parity generation/detection is enabled (PCE bit set). It is set and cleared by software. The parity is selected after the current byte.
0: Even parity
1: Odd parity
This bitfield can only be written when the LPUART is disabled (UE = 0).

Bit 8  **PEIE**: PE interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited
1: An LPUART interrupt is generated whenever PE = 1 in the LPUART_ISR register

Bit 7  **TXEIE**: Transmit data register empty
This bit is set and cleared by software.
0: Interrupt is inhibited
1: A LPUART interrupt is generated whenever TXE/TXFNF = 1 in the LPUART_ISR register

Bit 6  **TCIE**: Transmission complete interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited
1: An LPUART interrupt is generated whenever TC = 1 in the LPUART_ISR register

Bit 5  **RXNEIE**: Receive data register not empty
This bit is set and cleared by software.
0: Interrupt is inhibited
1: A LPUART interrupt is generated whenever ORE = 1 or RXNE/RXFNE = 1 in the LPUART_ISR register

Bit 4  **IDLEIE**: IDLE interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited
1: An LPUART interrupt is generated whenever IDLE = 1 in the LPUART_ISR register
Bit 3 **TE**: Transmitter enable
This bit enables the transmitter. It is set and cleared by software.
- 0: Transmitter is disabled
- 1: Transmitter is enabled

*Note*: During transmission, a low pulse on the TE bit ("0" followed by "1") sends a preamble (idle line) after the current word. In order to generate an idle character, the TE must not be immediately written to 1. In order to ensure the required duration, the software can poll the TEACK bit in the LPUART_ISR register.

*When TE is set there is a 1 bit-time delay before the transmission starts.*

Bit 2 **RE**: Receiver enable
This bit enables the receiver. It is set and cleared by software.
- 0: Receiver is disabled
- 1: Receiver is enabled and begins searching for a start bit

Bit 1 **UESM**: LPUART enable in Stop mode
When this bit is cleared, the LPUART is not able to wake up the MCU from low-power mode. When this bit is set, the LPUART is able to wake up the MCU from low-power mode, provided that the LPUART clock selection is HSI or LSE in the RCC.
This bit is set and cleared by software.
- 0: LPUART not able to wake up the MCU from low-power mode.
- 1: LPUART able to wake up the MCU from low-power mode. When this function is active, the clock source for the LPUART must be HSI or LSE (see RCC chapter)

*Note*: It is recommended to set the UESM bit just before entering low-power mode and clear it on exit from low-power mode.

Bit 0 **UE**: LPUART enable
When this bit is cleared, the LPUART prescalers and outputs are stopped immediately, and current operations are discarded. The configuration of the LPUART is kept, but all the status flags, in the LPUART_ISR are reset. This bit is set and cleared by software.
- 0: LPUART prescaler and outputs disabled, low-power mode
- 1: LPUART enabled

*Note*: To enter low-power mode without generating errors on the line, the TE bit must be reset before and the software must wait for the TC bit in the LPUART_ISR to be set before resetting the UE bit.

The DMA requests are also reset when UE = 0 so the DMA channel must be disabled before resetting the UE bit.

### 52.7.3 LPUART control register 2 (LPUART_CR2)

RM0399 Rev 4 2291/3556
Bits 31:24 ADD[7:0]: Address of the LPUART node
These bits give the address of the LPUART node in Mute mode or a character code to be recognized in low-power or Run mode:

- In Mute mode: they are used in multiprocessor communication to wake up from Mute mode with 4-bit/7-bit address mark detection. The MSB of the character sent by the transmitter should be equal to 1. In 4-bit address mark detection, only ADD[3:0] bits are used.
- In low-power mode: they are used for wake up from low-power mode on character match. When WUS[1:0] is programmed to 0b00 (WUF active on address match), the wake-up from low-power mode is performed when the received character corresponds to the character programmed through ADD[6:0] or ADD[3:0] bitfield (depending on ADDM7 bit), and WUF interrupt is enabled by setting WUFIE bit. The MSB of the character sent by transmitter should be equal to 1.
- In Run mode with Mute mode inactive (for example, end-of-block detection in ModBus protocol): the whole received character (8 bits) is compared to ADD[7:0] value and CMF flag is set on match. An interrupt is generated if the CMIE bit is set.

These bits can only be written when the reception is disabled (RE = 0) or when the USART is disabled (UE = 0).

Bits 23:20 Reserved, must be kept at reset value.

Bit 19 MSBFIRST: Most significant bit first
This bit is set and cleared by software.
0: data is transmitted/received with data bit 0 first, following the start bit.
1: data is transmitted/received with the MSB (bit 7/8) first, following the start bit.
This bitfield can only be written when the LPUART is disabled (UE = 0).

Bit 18 DATAINV: Binary data inversion
This bit is set and cleared by software.
0: Logical data from the data register are send/received in positive/direct logic. (1 = H, 0 = L)
1: Logical data from the data register are send/received in negative/inverse logic. (1 = L, 0 = H).
The parity bit is also inverted.
This bitfield can only be written when the LPUART is disabled (UE = 0).

Bit 17 TXINV: TX pin active level inversion
This bit is set and cleared by software.
0: TX pin signal works using the standard logic levels (VDD = 1/idle, Gnd = 0/mark)
1: TX pin signal values are inverted (VDD = 0/mark, Gnd = 1/idle).
This enables the use of an external inverter on the TX line.
This bitfield can only be written when the LPUART is disabled (UE = 0).

Bit 16 RXINV: RX pin active level inversion
This bit is set and cleared by software.
0: RX pin signal works using the standard logic levels (VDD = 1/idle, Gnd = 0/mark)
1: RX pin signal values are inverted (VDD = 0/mark, Gnd = 1/idle).
This enables the use of an external inverter on the RX line.
This bitfield can only be written when the LPUART is disabled (UE = 0).

Bit 15 SWAP: Swap TX/RX pins
This bit is set and cleared by software.
0: TX/RX pins are used as defined in standard pinout
1: The TX and RX pins functions are swapped. This enables to work in the case of a cross-wired connection to another UART.
This bitfield can only be written when the LPUART is disabled (UE = 0).

Bit 14 Reserved, must be kept at reset value.

**Bits 13:12 STOP[1:0]: STOP bits**  
These bits are used for programming the stop bits.  
00: 1 stop bit  
01: Reserved.  
10: 2 stop bits  
11: Reserved  
This bitfield can only be written when the LPUART is disabled (UE = 0).

**Bits 11:5 Reserved, must be kept at reset value.**

**Bit 4 ADDM7: 7-bit address detection/4-bit address detection**  
This bit is for selection between 4-bit address detection or 7-bit address detection.  
0: 4-bit address detection  
1: 7-bit address detection (in 8-bit data mode)  
This bit can only be written when the LPUART is disabled (UE = 0)  
**Note:** In 7-bit and 9-bit data modes, the address detection is done on 6-bit and 8-bit address (ADD[5:0] and ADD[7:0]) respectively.

**Bits 3:0 Reserved, must be kept at reset value.**
Bits 31:29  **TXFTCFG[2:0]**: TXFIFO threshold configuration

- 000: TXFIFO reaches 1/8 of its depth.
- 001: TXFIFO reaches 1/4 of its depth.
- 110: TXFIFO reaches 1/2 of its depth.
- 100: TXFIFO reaches 7/8 of its depth.
- 101: TXFIFO becomes empty.

Remaining combinations: Reserved.

Bit 28  **RXFTIE**: RXFIFO threshold interrupt enable

This bit is set and cleared by software.

- 0: Interrupt is inhibited
- 1: An LPUART interrupt is generated when Receive FIFO reaches the threshold programmed in RXFTCFG.

Bits 27:25  **RXFTCFG[2:0]**: Receive FIFO threshold configuration

- 000: Receive FIFO reaches 1/8 of its depth.
- 001: Receive FIFO reaches 1/4 of its depth.
- 110: Receive FIFO reaches 1/2 of its depth.
- 011: Receive FIFO reaches 3/4 of its depth.
- 100: Receive FIFO reaches 7/8 of its depth.
- 101: Receive FIFO becomes full.

Remaining combinations: Reserved.

Bit 24 Reserved, must be kept at reset value.

Bit 23  **TXFTIE**: TXFIFO threshold interrupt enable

This bit is set and cleared by software.

- 0: Interrupt is inhibited
- 1: A LPUART interrupt is generated when TXFIFO reaches the threshold programmed in TXFTCFG.

Bit 22  **WUFIE**: Wake-up from low-power mode interrupt enable

This bit is set and cleared by software.

- 0: Interrupt is inhibited
- 1: An LPUART interrupt is generated whenever WUF = 1 in the LPUART_ISR register

**Note:** WUFIE must be set before entering in low-power mode.

The WUF interrupt is active only in low-power mode.

If the LPUART does not support the wake-up from Stop feature, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation.

Bits 21:20  **WUS[1:0]**: Wake-up from low-power mode interrupt flag selection

This bitfield specifies the event which activates the WUF (wake-up from low-power mode flag).

- 00: WUF active on address match (as defined by ADD[7:0] and ADDM7)
- 01: Reserved.
- 10: WUF active on Start bit detection
- 11: WUF active on RXNE.

This bitfield can only be written when the LPUART is disabled (UE = 0).

**Note:** If the LPUART does not support the wake-up from Stop feature, this bit is reserved and must be kept at reset value. Refer to Section 51.4: USART implementation.

Bits 19:16 Reserved, must be kept at reset value.
Bit 15 **DEP**: Driver enable polarity selection
0: DE signal is active high.
1: DE signal is active low.
This bit can only be written when the LPUART is disabled (UE = 0).

Bit 14 **DEM**: Driver enable mode
This bit enables the user to activate the external transceiver control, through the DE signal.
0: DE function is disabled.
1: DE function is enabled. The DE signal is output on the RTS pin.
This bit can only be written when the LPUART is disabled (UE = 0).

Bit 13 **DDRE**: DMA disable on reception error
0: DMA is not disabled in case of reception error. The corresponding error flag is set but RXNE is kept 0 preventing from overrun. As a consequence, the DMA request is not asserted, so the erroneous data is not transferred (no DMA request), but next correct received data is transferred.
1: DMA is disabled following a reception error. The corresponding error flag is set, as well as RXNE. The DMA request is masked until the error flag is cleared. This means that the software must first disable the DMA request (DMAR = 0) or clear RXNE before clearing the error flag.
This bit can only be written when the LPUART is disabled (UE = 0).
*Note: The reception errors are: parity error, framing error or noise error.*

Bit 12 **OVRDIS**: Overrun disable
This bit is used to disable the receive overrun detection.
0: Overrun Error Flag, ORE is set when received data is not read before receiving new data.
1: Overrun functionality is disabled. If new data is received while the RXNE flag is still set the ORE flag is not set and the new received data overwrites the previous content of the LPUART_RDR register.
This bit can only be written when the LPUART is disabled (UE = 0).
*Note: This control bit enables checking the communication flow w/o reading the data.*

Bit 11 Reserved, must be kept at reset value.

Bit 10 **CTSIE**: CTS interrupt enable
0: Interrupt is inhibited
1: An interrupt is generated whenever CTSIF = 1 in the LPUART_ISR register

Bit 9 **CTSE**: CTS enable
0: CTS hardware flow control disabled
1: CTS mode enabled, data is only transmitted when the CTS input is deasserted (tied to 0).
If the CTS input is asserted while data is being transmitted, then the transmission is completed before stopping. If data is written into the data register while CTS is asserted, the transmission is postponed until CTS is deasserted.
This bit can only be written when the LPUART is disabled (UE = 0)

Bit 8 **RTSE**: RTS enable
0: RTS hardware flow control disabled
1: RTS output enabled, data is only requested when there is space in the receive buffer. The transmission of data is expected to cease after the current character has been transmitted. The RTS output is deasserted (pulled to 0) when data can be received.
This bit can only be written when the LPUART is disabled (UE = 0).

Bit 7 **DMAT**: DMA enable transmitter
This bit is set/reset by software
0: DMA mode is disabled for transmission
1: DMA mode is enabled for transmission
52.7.5 LPUART baud rate register (LPUART_BRR)

This register can only be written when the LPUART is disabled (UE = 0). It may be automatically updated by hardware in auto baud rate detection mode.

Address offset: 0x0C

Reset value: 0x0000 0000

| Bit 31:20 | Reserved, must be kept at reset value. |
| Bit 19:0 | **BRR[19:0]**: LPUART baud rate |

**Note:** It is forbidden to write values lower than 0x300 in the LPUART_BRR register.

Provided that LPUART_BRR must be \( \geq 0x300 \) and LPUART_BRR is 20 bits, a care should be taken when generating high baud rates using high fck values. fck must be in the range \([3 \times \text{baud rate..4096 \times \text{baud rate}}]\).
52.7.6  LPUART request register (LPUART_RQR)

Address offset: 0x18
Reset value: 0x0000 0000

**Bit 4** TXFRQ: Transmit data flush request

This bit is used when FIFO mode is enabled. TXFRQ bit is set to flush the whole FIFO. This sets the flag TXFE (TXFIFO empty, bit 23 in the LPUART_ISR register).

*Note: In FIFO mode, the TXFNF flag is reset during the flush request until TxFIFO is empty in order to ensure that no data are written in the data register.*

**Bit 3** RXFRQ: Receive data flush request

Writing 1 to this bit clears the RXNE flag.

This enables discarding the received data without reading it, and avoid an overrun condition.

**Bit 2** MMRQ: Mute mode request

Writing 1 to this bit puts the LPUART in Mute mode and resets the RWU flag.

**Bit 1** SBKRQ: Send break request

Writing 1 to this bit sets the SBKF flag and request to send a BREAK on the line, as soon as the transmit machine is available.

*Note: If the application needs to send the break character following all previously inserted data, including the ones not yet transmitted, the software should wait for the TXE flag assertion before setting the SBKRQ bit.*

**Bit 0** Reserved, must be kept at reset value.

52.7.7  LPUART interrupt and status register (LPUART_ISR)

Address offset: 0x1C
Reset value: 0x0080 00C0

The same register can be used in FIFO mode enabled (this section) and FIFO mode disabled (next section).

**FIFO mode enabled**

*Note: In FIFO mode, the TXFNF flag is reset during the flush request until TxFIFO is empty in order to ensure that no data are written in the data register.*

**Bit 4** TXFRQ: Transmit data flush request

This bit is used when FIFO mode is enabled. TXFRQ bit is set to flush the whole FIFO. This sets the flag TXFE (TXFIFO empty, bit 23 in the LPUART_ISR register).

*Note: In FIFO mode, the TXFNF flag is reset during the flush request until TxFIFO is empty in order to ensure that no data are written in the data register.*

**Bit 3** RXFRQ: Receive data flush request

Writing 1 to this bit clears the RXNE flag.

This enables discarding the received data without reading it, and avoid an overrun condition.

**Bit 2** MMRQ: Mute mode request

Writing 1 to this bit puts the LPUART in Mute mode and resets the RWU flag.

**Bit 1** SBKRQ: Send break request

Writing 1 to this bit sets the SBKF flag and request to send a BREAK on the line, as soon as the transmit machine is available.

*Note: If the application needs to send the break character following all previously inserted data, including the ones not yet transmitted, the software should wait for the TXE flag assertion before setting the SBKRQ bit.*

**Bit 0** Reserved, must be kept at reset value.
Bits 31:28  Reserved, must be kept at reset value.

Bit 27  **TXFT**: TXFIFO threshold flag

This bit is set by hardware when the TXFIFO reaches the threshold programmed in TXFTCFG in LPUART_CR3 register i.e. the TXFIFO contains TXFTCFG empty locations. An interrupt is generated if the TXFTIE bit = 1 (bit 31) in the LPUART_CR3 register.

0: TXFIFO does not reach the programmed threshold.
1: TXFIFO reached the programmed threshold.

Bit 26  **RXFT**: RXFIFO threshold flag

This bit is set by hardware when the RXFIFO reaches the threshold programmed in RXFTCFG in LPUART_CR3 register i.e. the Receive FIFO contains RXFTCFG data. An interrupt is generated if the RXFTIE bit = 1 (bit 27) in the LPUART_CR3 register.

0: Receive FIFO does not reach the programmed threshold.
1: Receive FIFO reached the programmed threshold.

Bit 25  Reserved, must be kept at reset value.

Bit 24  **RXFF**: RXFIFO full

This bit is set by hardware when the number of received data corresponds to RXFIFO size + 1 (RXFIFO full + 1 data in the LPUART_RDR register. An interrupt is generated if the RXFFIE bit = 1 in the LPUART_CR1 register.

0: RXFIFO is not full
1: RXFIFO is full

Bit 23  **TXFE**: TXFIFO empty

This bit is set by hardware when TXFIFO is empty. When the TXFIFO contains at least one data, this flag is cleared. The TXFE flag can also be set by writing 1 to the bit TXFRQ (bit 4) in the LPUART_RQR register. An interrupt is generated if the TXFEIE bit = 1 (bit 30) in the LPUART_CR1 register.

0: TXFIFO is not empty
1: TXFIFO is empty

Bit 22  **REACK**: Receive enable acknowledge flag

This bit is set/reset by hardware, when the Receive Enable value is taken into account by the LPUART. It can be used to verify that the LPUART is ready for reception before entering low-power mode.

*Note: If the LPUART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value.*

Bit 21  **TEACK**: Transmit enable acknowledge flag

This bit is set/reset by hardware, when the Transmit Enable value is taken into account by the LPUART. It can be used when an idle frame request is generated by writing TE = 0, followed by TE = 1 in the LPUART_CR1 register, in order to respect the TE = 0 minimum period.

Bit 20  **WUF**: Wake-up from low-power mode flag

This bit is set by hardware, when a wake-up event is detected. The event is defined by the WUS bitfield. It is cleared by software, writing a 1 to the WUCF in the LPUART_ICR register. An interrupt is generated if WUFIE = 1 in the LPUART_CR3 register.

*Note: When UESM is cleared, WUF flag is also cleared.*

The WUF interrupt is active only in low-power mode.

*If the LPUART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value*
Bit 19 **RWU**: Receiver wake-up from Mute mode
This bit indicates if the LPUART is in Mute mode. It is cleared/set by hardware when a wake-up/mute sequence is recognized. The Mute mode control sequence (address or IDLE) is selected by the WAKE bit in the LPUART_CR1 register.
When wake-up on IDLE mode is selected, this bit can only be set by software, writing 1 to the MMRQ bit in the LPUART_RQR register.
0: Receiver in Active mode
1: Receiver in Mute mode
*Note:* If the LPUART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value.

Bit 18 **SBKF**: Send break flag
This bit indicates that a send break character was requested. It is set by software, by writing 1 to the SBKRQ bit in the LPUART_CR3 register. It is automatically reset by hardware during the stop bit of break transmission.
0: Break character transmitted
1: Break character requested by setting SBKRQ bit in LPUART_RQR register

Bit 17 **CMF**: Character match flag
This bit is set by hardware, when a the character defined by ADD[7:0] is received. It is cleared by software, writing 1 to the CMCF in the LPUART_ICR register.
An interrupt is generated if CMIE = 1 in the LPUART_CR1 register.
0: No Character match detected
1: Character Match detected

Bit 16 **BUSY**: Busy flag
This bit is set and reset by hardware. It is active when a communication is ongoing on the RX line (successful start bit detected). It is reset at the end of the reception (successful or not).
0: LPUART is idle (no reception)
1: Reception on going

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 **CTS**: CTS flag
This bit is set/reset by hardware. It is an inverted copy of the status of the CTS input pin.
0: CTS line set
1: CTS line reset
*Note:* If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.

Bit 9 **CTSIF**: CTS interrupt flag
This bit is set by hardware when the CTS input toggles, if the CTSE bit is set. It is cleared by software, by writing 1 to the CTSCF bit in the LPUART_ICR register.
An interrupt is generated if CTSIE = 1 in the LPUART_CR3 register.
0: No change occurred on the CTS status line
1: A change occurred on the CTS status line
*Note:* If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.

Bit 8 Reserved, must be kept at reset value.
Bit 7 **TXFNF**: TXFIFO not full

TXFNF is set by hardware when TXFIFO is not full, and so data can be written in the LPUART_TDR. Every write in the LPUART_TDR places the data in the TXFIFO. This flag remains set until the TXFIFO is full. When the TXFIFO is full, this flag is cleared indicating that data can not be written into the LPUART_TDR.

The TXFNF is kept reset during the flush request until TXFIFO is empty. After sending the flush request (by setting TXFRQ bit), the flag TXFNF should be checked prior to writing in TXFIFO (TXFNF and TXFE are set at the same time).

An interrupt is generated if the TXFNFIE bit = 1 in the LPUART_CR1 register.

- 0: Data register is full/Transmit FIFO is full.
- 1: Data register/Transmit FIFO is not full.

*Note: This bit is used during single buffer transmission.*

Bit 6 **TC**: Transmission complete

This bit is set by hardware if the transmission of a frame containing data is complete and if TXFF is set. An interrupt is generated if TCIE = 1 in the LPUART_CR1 register. It is cleared by software, writing 1 to the TCCF in the LPUART_ICR register or by a write to the LPUART_TDR register.

An interrupt is generated if TCIE = 1 in the LPUART_CR1 register.

- 0: Transmission is not complete
- 1: Transmission is complete

*Note: If TE bit is reset and no transmission is on going, the TC bit is set immediately.*

Bit 5 **RXFNE**: RXFIFO not empty

RXFNE bit is set by hardware when the RXFIFO is not empty, and so data can be read from the LPUART_RDR register. Every read of the LPUART_RDR frees a location in the RXFIFO. It is cleared when the RXFIFO is empty.

The RXFNE flag can also be cleared by writing 1 to the RXFRQ in the LPUART_RQR register.

An interrupt is generated if RXFNEIE = 1 in the LPUART_CR1 register.

- 0: Data is not received
- 1: Received data is ready to be read.

Bit 4 **IDLE**: Idle line detected

This bit is set by hardware when an Idle line is detected. An interrupt is generated if IDLEIE = 1 in the LPUART_CR1 register. It is cleared by software, writing 1 to the IDLECF in the LPUART_ICR register.

- 0: No Idle line is detected
- 1: Idle line is detected

*Note: The IDLE bit is not set again until the RXFNE bit has been set (i.e. a new idle line occurs).*

*If Mute mode is enabled (MME = 1), IDLE is set if the LPUART is not mute (RWU = 0), whatever the Mute mode selected by the WAKE bit. If RWU = 1, IDLE is not set.*
Bit 3  **ORE**: Overrun error

This bit is set by hardware when the data currently being received in the shift register is ready to be transferred into the LPUART_RDR register while RXFF = 1. It is cleared by a software, writing 1 to the ORECF, in the LPUART_ICR register.

An interrupt is generated if RXFNEIE = 1 or EIE = 1 in the LPUART_CR1 register, or EIE = 1 in the LPUART_CR3 register.

0: No overrun error
1: Overrun error is detected

*Note:* When this bit is set, the LPUART_RDR register content is not lost but the shift register is overwritten. An interrupt is generated if the ORE flag is set during multi buffer communication if the EIE bit is set.

This bit is permanently forced to 0 (no overrun detection) when the bit OVRDIS is set in the LPUART_CR3 register.

Bit 2  **NE**: Start bit noise detection flag

This bit is set by hardware when noise is detected on the start bit of a received frame. It is cleared by software, writing 1 to the NECF bit in the LPUART_ICR register.

0: No noise is detected
1: Noise is detected

*Note:* This bit does not generate an interrupt as it appears at the same time as the RXFNE bit which itself generates an interrupt. An interrupt is generated when the NE flag is set during multi buffer communication if the EIE bit is set.

This error is associated with the character in the LPUART_RDR.

Bit 1  **FE**: Framing error

This bit is set by hardware when a de-synchronization, excessive noise or a break character is detected. It is cleared by software, writing 1 to the FECF bit in the LPUART_ICR register.

When transmitting data in Smartcard mode, this bit is set when the maximum number of transmit attempts is reached without success (the card NACKs the data frame).

An interrupt is generated if EIE = 1 in the LPUART_CR3 register.

0: No Framing error is detected
1: Framing error or break character is detected

*Note:* This error is associated with the character in the LPUART_RDR.

Bit 0  **PE**: Parity error

This bit is set by hardware when a parity error occurs in receiver mode. It is cleared by software, writing 1 to the PECF in the LPUART_ICR register.

An interrupt is generated if PEIE = 1 in the LPUART_CR1 register.

0: No parity error
1: Parity error

*Note:* This error is associated with the character in the LPUART_RDR.
52.7.8  **LPUART interrupt and status register [alternate] (LPUART_ISR)**

Address offset: 0x1C
Reset value: 0x0000 00C0

The same register can be used in FIFO mode enabled (previous section) and FIFO mode disabled (this section).

**FIFO mode disabled**

Bits 31:23  Reserved, must be kept at reset value.

Bit 22  **REACK**: Receive enable acknowledge flag

This bit is set/reset by hardware when the Receive Enable value is taken into account by the LPUART.
It can be used to verify that the LPUART is ready for reception before entering low-power mode.

*Note: If the LPUART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value.*

Bit 21  **TEACK**: Transmit enable acknowledge flag

This bit is set/reset by hardware, when the Transmit Enable value is taken into account by the LPUART.
It can be used when an idle frame request is generated by writing TE = 0, followed by TE = 1 in the LPUART_CR1 register, in order to respect the TE = 0 minimum period.

Bit 20  **WUF**: Wake-up from low-power mode flag

This bit is set by hardware, when a wake-up event is detected. The event is defined by the WUS bitfield. It is cleared by software, writing a 1 to the WUCF in the LPUART_ICR register.
An interrupt is generated if WUFIE = 1 in the LPUART_CR3 register.

*Note: When UESM is cleared, WUF flag is also cleared.*

The WUF interrupt is active only in low-power mode.

*If the LPUART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value.*

Bit 19  **RWU**: Receiver wake-up from Mute mode

This bit indicates if the LPUART is in Mute mode. It is cleared/set by hardware when a wake-up/mute sequence is recognized. The Mute mode control sequence (address or IDLE) is selected by the WAKE bit in the LPUART_CR1 register.
When wake-up on IDLE mode is selected, this bit can only be set by software, writing 1 to the MMRQ bit in the LPUART_RQR register.
0: Receiver in active mode
1: Receiver in Mute mode

*Note: If the LPUART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value.*
Bit 18 **SBKF**: Send break flag  
This bit indicates that a send break character was requested. It is set by software, by writing 1 to the SBKRQ bit in the LPUART_CR3 register. It is automatically reset by hardware during the stop bit of break transmission.  
0: Break character transmitted  
1: Break character requested by setting SBKRQ bit in LPUART_RQR register

Bit 17 **CMF**: Character match flag  
This bit is set by hardware, when a the character defined by ADD[7:0] is received. It is cleared by software, writing 1 to the CMCF in the LPUART_ICR register. An interrupt is generated if CMIE = 1 in the LPUART_CR1 register.  
0: No Character match detected  
1: Character Match detected

Bit 16 **BUSY**: Busy flag  
This bit is set and reset by hardware. It is active when a communication is ongoing on the RX line (successful start bit detected). It is reset at the end of the reception (successful or not).  
0: LPUART is idle (no reception)  
1: Reception on going

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 **CTS**: CTS flag  
This bit is set/reset by hardware. It is an inverted copy of the status of the CTS input pin.  
0: CTS line set  
1: CTS line reset  
*Note: If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.*

Bit 9 **CTSF**: CTS interrupt flag  
This bit is set by hardware when the CTS input toggles, if the CTSE bit is set. It is cleared by software, by writing 1 to the CTSCF bit in the LPUART_ICR register. An interrupt is generated if CTSIE = 1 in the LPUART_CR3 register.  
0: No change occurred on the CTS status line  
1: A change occurred on the CTS status line  
*Note: If the hardware flow control feature is not supported, this bit is reserved and kept at reset value.*

Bit 8 Reserved, must be kept at reset value.

Bit 7 **TXE**: Transmit data register empty/TXFIFO not full  
TXE is set by hardware when the content of the LPUART_TDR register has been transferred into the shift register. It is cleared by a write to the LPUART_TDR register. An interrupt is generated if the TXEIE bit = 1 in the LPUART_CR1 register.  
0: Data register full  
1: Data register not full  
*Note: This bit is used during single buffer transmission.*
Bit 6  **TC**: Transmission complete

This bit is set by hardware if the transmission of a frame containing data is complete and if TXE is set. An interrupt is generated if TCIE = 1 in the LPUART_CR1 register. It is cleared by software, writing 1 to the TCCF in the LPUART_ICR register or by a write to the LPUART_TDR register.

An interrupt is generated if TCIE = 1 in the LPUART_CR1 register.

0: Transmission is not complete
1: Transmission is complete

**Note:** If TE bit is reset and no transmission is on going, the TC bit is immediately set.

Bit 5  **RXNE**: Read data register not empty

RXNE bit is set by hardware when the content of the LPUART_RDR shift register has been transferred to the LPUART_RDR register. It is cleared by reading from the LPUART_RDR register. The RXNE flag can also be cleared by writing 1 to the RXFRQ in the LPUART_RQR register.

An interrupt is generated if RXNEIE = 1 in the LPUART_CR1 register.

0: Data is not received
1: Received data is ready to be read.

Bit 4  **IDLE**: Idle line detected

This bit is set by hardware when an Idle Line is detected. An interrupt is generated if IDLEIE = 1 in the LPUART_CR1 register. It is cleared by software, writing 1 to the IDLECF in the LPUART_ICR register.

0: No Idle line is detected
1: Idle line is detected

**Note:** The IDLE bit is not set again until the RXNE bit has been set (i.e. a new idle line occurs).

If Mute mode is enabled (MME = 1), IDLE is set if the LPUART is not mute (RWU = 0), whatever the Mute mode selected by the WAKE bit. If RWU = 1, IDLE is not set.

Bit 3  **ORE**: Overrun error

This bit is set by hardware when the data currently being received in the shift register is ready to be transferred into the LPUART_RDR register while RXNE = 1. It is cleared by software, writing 1 to the ORECF, in the LPUART_ICR register.

An interrupt is generated if RXNEIE = 1 or EIE = 1 in the LPUART_CR1 register, or EIE = 1 in the LPUART_CR3 register.

0: No overrun error
1: Overrun error is detected

**Note:** When this bit is set, the LPUART_RDR register content is not lost but the shift register is overwritten. An interrupt is generated if the ORE flag is set during multi buffer communication if the EIE bit is set.

This bit is permanently forced to 0 (no overrun detection) when the bit OVRDIS is set in the LPUART_CR3 register.
Bit 2 **NE**: Start bit noise detection flag

This bit is set by hardware when noise is detected on the start bit of a received frame. It is cleared by software, writing 1 to the NECF bit in the LPUART_ICR register.

0: No noise is detected
1: Noise is detected

*Note: This bit does not generate an interrupt as it appears at the same time as the RXNE bit which itself generates an interrupt. An interrupt is generated when the NE flag is set during multi buffer communication if the EIE bit is set.*

Bit 1 **FE**: Framing error

This bit is set by hardware when a de-synchronization, excessive noise or a break character is detected. It is cleared by software, writing 1 to the FECF bit in the LPUART_ICR register.

When transmitting data in Smartcard mode, this bit is set when the maximum number of transmit attempts is reached without success (the card NACKs the data frame).

An interrupt is generated if EIE = 1 in the LPUART_CR3 register.

0: No Framing error is detected
1: Framing error or break character is detected

Bit 0 **PE**: Parity error

This bit is set by hardware when a parity error occurs in receiver mode. It is cleared by software, writing 1 to the PECF in the LPUART_ICR register.

An interrupt is generated if PEIE = 1 in the LPUART_CR1 register.

0: No parity error
1: Parity error

### 52.7.9 LPUART interrupt flag clear register (LPUART_ICR)

**Bits 31:21**: Reserved, must be kept at reset value.

Bit 20 **WUCF**: Wake-up from low-power mode clear flag

Writing 1 to this bit clears the WUF flag in the LPUART_ISR register.

*Note: If the LPUART does not support the wake-up from Stop feature, this bit is reserved and kept at reset value. Refer to Section 51.4: USART implementation.*

**Bits 19:18**: Reserved, must be kept at reset value.

Bit 17 **CMCF**: Character match clear flag

Writing 1 to this bit clears the CMF flag in the LPUART_ISR register.

**Bits 16:10**: Reserved, must be kept at reset value.

Bit 9 **CTSCF**: CTS clear flag

Writing 1 to this bit clears the CTSIF flag in the LPUART_ISR register.
Low-power universal asynchronous receiver transmitter (LPUART) RM0399

Bits 31:9: Reserved, must be kept at reset value.
Bits 8:0: **RDR[8:0]**: Receive data value
Contains the received data character.
The RDR register provides the parallel interface between the input shift register and the internal bus (see Figure 640).
When receiving with the parity enabled, the value read in the MSB bit is the received parity bit.

2306/3556 RM0399 Rev 4
Bits 31:9  Reserved, must be kept at reset value.

Bits 8:0  **TDR[8:0]**: Transmit data value
Contains the data character to be transmitted.
The TDR register provides the parallel interface between the internal bus and the output shift register (see *Figure 640*).
When transmitting with the parity enabled (PCE bit set to 1 in the LPUART_CR1 register), the value written in the MSB (bit 7 or bit 8 depending on the data length) has no effect because it is replaced by the parity.

*Note*: This register must be written only when TXE/TXFNF = 1.

### 52.7.12 LPUART prescaler register (LPUART_PRESC)

This register can only be written when the LPUART is disabled (UE = 0).

Bits 31:4  Reserved, must be kept at reset value.

Bits 3:0  **PRESCALER[3:0]**: Clock prescaler
The LPUART input clock can be divided by a prescaler:

- 0000: input clock not divided
- 0001: input clock divided by 2
- 0010: input clock divided by 4
- 0011: input clock divided by 6
- 0100: input clock divided by 8
- 0101: input clock divided by 10
- 0110: input clock divided by 12
- 0111: input clock divided by 16
- 1000: input clock divided by 32
- 1001: input clock divided by 64
- 1010: input clock divided by 128
- 1011: input clock divided by 256

Remaining combinations: Reserved.

*Note*: When PRESCALER is programmed with a value different of the allowed ones, programmed prescaler value is 1011 i.e. input clock divided by 256.

53 Serial peripheral interface (SPI)

53.1 Introduction

The serial peripheral interface (SPI) can be used to communicate with external devices while using the specific synchronous protocol. The (SPI) interface supports a half-duplex, full-duplex and simplex synchronous, serial communication with external devices. The interface can be configured as master or slave and is capable of operating in multi slave or multi master configurations. In case of master configuration it provides the communication clock (SCK) to the external slave device. The slave select signal can be provided by the master and accepted by the slave optionally, too. The Motorola data format is used by default, but some other specific modes are supported as well.
53.2 **SPI main features**

- Full-duplex synchronous transfers on three lines
- Half-duplex synchronous transfer on two lines (with bidirectional data line)
- Simplex synchronous transfers on two lines (with unidirectional data line)
- From 4-bit up to 32-bit data size selection\(^{(a)}\)
- Multi master or multi slave mode capability
- Dual clock domain, separated clock for the peripheral kernel which can be independent of APB bus clock
- 8 master mode baud rate prescalers up to kernel frequency/2
- Protection of configuration and setting
- Hardware or software management of SS for both master and slave
- Adjustable minimum delays between data and between SS and data flow
- Configurable SS signal polarity and timing, MISO x MOSI swap capability
- Programmable clock polarity and phase
- Programmable data order with MSB-first or LSB-first shifting
- Programmable number of data within a transaction to control SS and CRC
- Dedicated transmission and reception flags with interrupt capability
- Slave transmission and/or reception capability in Stop mode (no clock provided to the peripheral) with wake up
- SPI Motorola and TI formats support
- Hardware CRC feature can verify integrity of the communication at the end of transaction by:
  - Adding CRC value at Tx mode
  - Automatic CRC error checking for Rx mode
- Error detection with interrupt capability in case of data overrun, CRC error, data underrun, the mode fault and the frame error at dependency on the operating mode
- Two 8-bit width embedded Rx and Tx FIFOs (FIFO size depends on instance)
- Configurable FIFO thresholds (data packing)
- Capability to handle data streams by system DMA controller
- Configurable behavior at slave underrun condition (support of cascaded circular buffers)

### 53.4 SPI functional description

#### 53.4.1 SPI block diagram

The SPI allows a synchronous, serial communication between the MCU and external devices. The application software can manage the communication by polling the status flag or using a dedicated SPI interrupt. The main elements of SPI and their interactions are shown in the following block diagram at Figure 654.
The simplified scheme of Figure 654 shows three fully independent clock domains:

- The spi_pclk clock domain,
- The spi_ker_ck kernel clock domain,
- The serial interface clock domain,

All the control and status signals between these domains are strictly synchronized. There is no specific constraint concerning the frequency ratio between these clock signals. The user has to consider a ratio compatible with the data flow speed in order to avoid any data underrun or overrun events only.

The spi_pclk clock signal feeds the peripheral bus interface. It has to be active when it accesses to the SPI registers are required.

The SPI master needs the spi_ker_ck kernel clock coming from RCC active during communication to feed the serial interface SCK clock via the clock generator divider.

The SPI working in slave mode handles data flow using the serial interface clock derived from the external SCK signal provided by external master SPI device. That is why the SPI slave is able to receive and send data even when the spi_pclk and spi_ker_ck clock signals are inactive.

As a consequence, a specific slave logic working within the serial interface clock domain needs some additional traffic to be setup correctly (e.g. when underrun or overrun is evaluated see Section 53.5.2: SPI error flags for details). This cannot be done when the bus becomes into idle. At specific case the slave even requires the clock generator working (see Section 53.5.1: TI mode).

53.4.2 SPI signals

Four I/O pins are dedicated to SPI communication with external devices.

- **MISO:** Master In / Slave Out data. In the general case, this pin is used to transmit data in slave mode and receive data in master mode.
- **MOSI:** Master Out / Slave In data. In the general case, this pin is used to transmit data in master mode and receive data in slave mode.
- **SCK:** Serial Clock output pin for SPI masters and input pin for SPI slaves.
- **SS:** Slave select pin. Depending on the SPI and SS settings, this pin can be used to either:
  - Select an individual slave device for communication
  - Synchronize the data frame or
  - Detect a conflict between multiple masters
  See Section 53.4.7: Slave select (SS) pin management for details.

The SPI bus allows the communication between one master device and one or more slave devices. The bus consists of at least two wires: one for the clock signal and the other for synchronous data transfer. Other signals can be added depending on the data exchange between SPI nodes and their slave select signal management. The functionality between MOSI and MISO pins can be inverted in any SPI mode (see the IOSWP bit at SPI_CFG2 register).

All these pins are shared with I2S if this mode is implemented at the instance. See Section 53.9.2: Pin sharing with SPI function.
53.4.3 SPI communication general aspects

The SPI allows the MCU to communicate using different configurations, depending on the device targeted and the application requirements. These configurations use 2 or 3 wires (with software SS management) or 3/4 wires (with hardware SS management). The communication is always initiated and controlled by the master. The master provides a clock signal on the SCK line and selects or synchronizes slave(s) for communication by SS line when it is managed by HW. The data between the master and the slave flow on the MOSI and/or MISO lines. The direction of data flow is highlighted by black arrows at the following topology figures.

53.4.4 Communications between one master and one slave

The communication flow may use one of 3 possible modes: full-duplex (3 wires), half-duplex (2 wires) or simplex (2 wires). The SS signal is optional in single master-slave configuration and is often not connected between the two communication nodes. Nevertheless, the SS signal can be helpful at this configuration to synchronize the data flow and it is used by default at some specific SPI modes (e.g. TI mode).

Full-duplex communication

By default, the SPI is configured for full-duplex communication (bits COMM[1:0]=00 in the SPI_CFG2 register). In this configuration, the shift registers of the master and slave are linked using two unidirectional lines between the MOSI and the MISO pins. During the SPI communication, the data are shifted synchronously on the SCK clock edges provided by the master. The master transmits the data to be sent to the slave via the MOSI line and receives data from the slave via the MISO line simultaneously. When the data frame transfer is complete (all the bits are shifted) the information between the master and slave is exchanged.

Figure 655. Full-duplex single master/ single slave application

1. To apply SS pins interconnection is not mandatory to make the SPI interface working (see Section 53.4.7: Slave select (SS) pin management for details).

Half-duplex communication

The SPI can communicate in half-duplex mode by setting COMM[1:0]=11 in the SPI_CFG2 register. In this configuration, one single cross connection line is used to link the shift registers of the master and slave together. During this communication, the data are synchronously shifted between the shift registers on the SCK clock edge in the transfer direction selected reciprocally by both master and slave with the HDDIR bit in their SPI_CR1 registers. Note that the SPI has to be disabled when changing direction of the
communication. In this configuration, the MISO pin at master and the MOSI pin at slave are free for other application uses and act as GPIOs.

**Figure 656. Half-duplex single master/ single slave application**

1. To apply SS pins interconnection is not mandatory to make the SPI interface working (see Section 53.4.7: Slave select (SS) pin management for details).

2. In this configuration, the MISO pin at master and MOSI pin at slave can be used as GPIOs.

3. A critical situation can happen when communication direction is changed not synchronously between two nodes working at bidirectional mode and new transmitter accesses the common data line while former transmitter still keeps an opposite value on the line (the value depends on SPI configuration and communicated data). Both nodes can fight with opposite outputs levels on the line temporary till next node change its direction setting correspondingly, too. It is suggested to insert serial resistance between MISO and MOSI pins at this mode to protect the outputs and limit the current blowing between them at this situation.

### Simplex communications

The SPI can communicate in simplex mode by setting the SPI in transmit-only or in receive-only using the COMM[1:0] field in the SPI_CFG2 register. In this configuration, only one line is used for the transfer between the shift registers of the master and slave. The remaining MISO or MOSI pins pair is not used for communication and can be used as standard GPIOs.

- **Transmit-only mode:** COMM[1:0]=01
  
  The master in transmit-only mode generates the clock as long as there are data available in the TxFIFO and the master transfer is on-going.

  The slave in transmit only mode sends data as long as it receives a clock on the SCK pin and the SS pin (or SW managed internal signal) is active (see Section 53.4.7: Slave select (SS) pin management).

- **Receive-only mode:** COMM[1:0]=10

  In master mode, the MOSI output is disabled and may be used as GPIO. The clock signal is generated continuously as long as the SPI is enabled and the CSTART bit in the SPI_CR1 register is set. The clock is stopped either by SW explicitly requesting this by setting the CSUSP bit in the SPI_CR1 register or automatically when the RxFIFO is full, when the MASRX bit in the SPI_CR1 is set.

  In slave configuration, the MISO output is disabled and the pin can be used as a GPIO. The slave continues to receive data from the MOSI pin while its slave select signal is active (see Section 53.4.7: Slave select (SS) pin management).

**Note:** At whatever master and slave modes, the data pin dedicated for transmission can be replaced by the data pin dedicated for reception and vice versa by changing the IOSWP bit value in the SPI_CFG2 register. (This bit may only be modified when the SPI is disabled). Any simplex communication can be replaced by a variant of the half duplex communication
with a constant setting of the transaction direction (bidirectional mode is enabled, while the HDDIR bit is never changed).

Figure 657. Simplex single master/single slave application (master in transmit-only/slave in receive-only mode)

1. To apply SS pins interconnection is not mandatory to make the SPI interface working (see Section 53.4.7: Slave select (SS) pin management for details).
2. In this configuration, both the MISO pins can be used as GPIOs.

53.4.5 Standard multislave communication

In a configuration with two or more independent slaves, the master uses a star topology with dedicated GPIO pins to manage the chip select lines for each slave separately (see Figure 658.). The master must select one of the slaves individually by pulling low the GPIO connected to the slave SS input (only one slave can control data on common MISO line at time). When this is done, a communication between the master and the selected slave is established. Except the simplicity, the advantage of this topology is that a specific SPI configuration can be applied for each slave as all the communication sessions are performed separately just within single master-slave pair. Optionally, when there is no need to read any information from slaves, the master can transmit the same information to the multiple slaves.
1. Master single SS pin hardware output functionality cannot support this topology (to be replaced by set of GPIOs under SW control) and user should avoid SPI AF setting at the pin (see Section 53.4.7: Slave select (SS) pin management for details).

2. If the application cannot ensure that no more than a single SS active signal is provided by the master at time, it is better to configure the MISO pins into open drain configuration with an external pull-up at MISO line to prevent any conflict between interconnected outputs of the slaves on the line. Else the push-pull configuration can be applied without an extra resistor for the slaves. (see Section 12.3.7: I/O alternate function input/output on page 573.)

The master can handle the SPI communication with all the slaves in time when a circular topology is applied (see Figure 659). All the slaves behave like simple shift registers applied at serial chain under common slave select and clock control. All the information is shifted simultaneously around the circle while returning back to the master. Sessions have fixed the length where the number of data frames transacted by the master is equal to the number of slaves. Then when a first data frame is transacted in the chain, the master just sends information dedicated for the last slave node in the chain via the first slave node input while the first information received by the master comes from the last node output at this time. Correspondingly, the lastly transacted data finishing the session is dedicated for the first slave node while its firstly outgoing data just reaches the master input after its circling around the chain passing through all the other slaves during the session. The data format
configuration and clock setting has to be the same for all the nodes in the chain at this topology. As the receive and transmit shift registers are separated internally, a trick with intentional underrun has to be applied at the TxFIFO slaves when information is transacted between the receiver and the transmitter by hardware. In this case, the transmission underrun feature is configured at a mode repeating lastly received data frame (UDRCFG[1:0]=01). A session can start optionally with a single data pattern written into the TxFIFO by each slave (usually slave status information is applied) before the session starts. In this case the underrun happens in fact after this first data frame is transacted (underrun detection has to be set at end of data transaction at slaves UDRDET[1:0]=01). To be able to clear the internal underrun condition immediately and restart the session by the TxFIFO content again, the user has to disable and enable the SPI between sessions and fill the TxFIFO by a new single data pattern.

**Figure 659. Master and three slaves at circular (daisy chain) topology**

1. Underrun feature is used at slaves at this configuration when slaves are able to transmit data received previously into the Rx shift register once their TxFIFOs become empty.
53.4.6 Multimaster communication

Unless the SPI bus is not designed for a multimaster capability primarily, the user can use build in feature which detects a potential conflict between two nodes trying to master the bus at the same time. For this detection, the SS pin is used configured at hardware input mode. The connection of more than two SPI nodes working at this mode is impossible as only one node can apply its output on a common data line at time.

When nodes are non active, both stay at slave mode by default. Once one node wants to overtake control on the bus, it switches itself into master mode and applies active level on the slave select input of the other node via the dedicated GPIO pin. After the session is completed, the active slave select signal is released and the node mastering the bus temporary returns back to passive slave mode waiting for next session start.

If potentially both nodes raised their mastering request at the same time a bus conflict event appears (see mode fault MODF event). Then the user can apply some simple arbitration process (e.g. to postpone next attempt by predefined different time-outs applied at both nodes).

Figure 660. Multimaster application

1. The SS pin is configured at hardware input mode at both nodes. Its active level enable the MISO line output control as passive node is configured as a slave.

53.4.7 Slave select (SS) pin management

In slave mode, the SS works as a standard 'chip select' input and lets the slave communicate with the master. In master mode, the SS can be used either as an output or an input. As an input it can prevent a multi master bus collision, and as an output it can drive a slave select signal of a single slave. The SS signal can be managed internally (software management of the SS input) or externally when both the SS input and output are associated with the SS pin (hardware SS management). The user can configure which level of this input/output external signal (present on the SS pin) is considered as active one by the SSIOP bit setting. The SS level is considered as active if it is equal to SSIOP.
The hardware or software slave select management can be set using the SSM bit in the SPI_CFG2 register:

- **Software SS management (SSM = 1):** in this configuration, slave select information is driven internally by the SSI bit value in the register SPI_CR1. The external SS pin is free for other application uses (as GPIO or other alternate function).

- **Hardware SS management (SSM = 0):** in this case, there are two possible configurations. The configuration used depends on the SS output configuration (SSOE bit in register SPI_CFG2).
  - **SS output enable (SSOE = 1):** this configuration is only used when the MCU is set as master. The SS pin is managed by the hardware. The functionality is tied to CSTART and EOT control. As a consequence, the master must apply proper TSIZE>0 setting to control the SS output correctly. Even if SPI AF is not applied at the SS pin (it can be used as a standard GPIO then), SSOE=1 setting should be kept anyway to assure default SS input level and prevent any mode fault evaluation at input of the master SS internal logic applicable at a multimaster topology exclusively.
    a) When SSOM = 0 and SP = 000, the SS signal is driven to the active level as soon as the master transfer starts (CSTART=1) and it is kept active until its EOT flag is set or the transmission is suspended.
    b) When SP = 001, a pulse is generated as defined by the TI mode.
    c) When SSOM=1, SP=000 and MIDI>1 the SS is pulsed inactive between data frames, and kept inactive for a number of SPI clock periods defined by the MIDI value decremented by one (1 to 14).
  - **SS output disable (SSM=0, SSOE = 0):**
    a) If the microcontroller is acting as the master on the bus, this configuration allows multi master capability. If the SS pin is pulled into an active level in this mode, the SPI enters master mode fault state and the SPI device is automatically reconfigured in slave mode (MASTER=0).
    b) In slave mode, the SS pin works as a standard ‘chip select’ input and the slave is selected while the SS line is at its active level.

*Note:* The purpose of automatic switching into Slave mode at mode fault condition is to avoid the possible conflicts on data and clock line. As the SPE is automatically reset at this condition, both Rx and Tx FIFOs are flushed and current data is lost.

*Note:* When the SPI slave is enabled at the hardware SS management mode, all the traffics are ignored even in case of the SS is found at active level till the slave detects a start of the SS signal (its transition from non-active to active level) just synchronizing the slave with the master. That is why the hardware management mode cannot be used when the external SS pin is fixed. There is no such protection at the SS software management. Then the SSI bit must be changed when there is no traffic on the bus and the SCK signal is at idle state level between transfers exclusively in this case.
When a hardware output SS control is applied (SSM=0, SSOE=1), by configuration of MIDI[3:0] and MSSI[3:0] bitfields the user can control timing of the SS signal between data frames and insert an extra delay at begin of every transaction (to separate the SS and clock starts). This can be useful when the slave needs to slow down the flow to obtain sufficient room for correct data handling (see Figure 662: Data flow timing control (SSOE=1, SSOM=0, SSM=0)).

2. CPHA=0, CPOL=0, SSOP=0, LSBFRST=0.

Additionally, bit SSOM=1 setting invokes specific mode which interleaves pulses between data frames if there is a sufficient space to provide them (MIDI[3:0] has to be set greater than one SPI period). Some configuration examples are shown at Figure 663: SS interleaving pulses between data (SSOE=1, SSOM=1, SSM=0).
Figure 663. SS interleaving pulses between data (SVOE=1, SSOM=1, SSM=0)

I. CPHA=0, CPOL=0, SSOP=0, LSBFRST=0

II. CPHA=1, CPOL=0, SSOP=0, LSBFRST=0

III. CPHA=0, CPOL=1, SSOP=1, LSBFRST=1

IV. CPHA=1, CPOL=1, SSOP=1, LSBFRST=1
2. SS interleaves between data when MIDI[3:0]>1.

53.4.8 Communication formats

During SPI communication, receive and transmit operations are performed simultaneously. The serial clock (SCK) synchronizes the shifting and sampling of the information on the data lines. The communication format depends on the clock phase, the clock polarity and the data frame format. To be able to communicate together, the master and slave devices must follow the same communication format and be synchronized correctly.

Clock phase and polarity controls

Four possible timing relationships may be chosen by software, using the CPOL and CPHA bits in the SPI_CFG2 register. The CPOL (clock polarity) bit controls the idle state value of the clock when no data are being transferred. This bit affects both master and slave modes. If CPOL is reset, the SCK pin has a low-level idle state. If CPOL is set, the SCK pin has a high-level idle state.

If the CPHA bit is set, the second edge on the SCK pin captures the first data bit transacted (falling edge if the CPOL bit is reset, rising edge if the CPOL bit is set). Data are latched on each occurrence of this clock transition type. If the CPHA bit is reset, the first edge on the SCK pin captures the first data bit transacted (falling edge if the CPOL bit is set, rising edge if the CPOL bit is reset). Data are latched on each occurrence of this clock transition type.

The combination of the CPOL (clock polarity) and CPHA (clock phase) bits selects the data capture clock edges (dotted lines at Figure 664: Data clock timing diagram).

Figure 664, shows an SPI full-duplex transfer with the four combinations of the CPHA and CPOL bits.

Note: Prior to changing the CPOL/CPHA bits the SPI must be disabled by resetting the SPE bit. The idle state of SCK must correspond to the polarity selected in the SPI_CFG2 register (by pulling the SCK pin up if CPOL=1 or pulling it down if CPOL=0).
The order of data bits depends on LSBFRST bit setting.

**Data frame format**

The SPI shift register can be set up to shift out MSB-first or LSB-first, depending on the value of the LSBFRST bit in SPI_CFG2 register. The data frame size is chosen by using the DSIZE[4:0] bits. It can be set from 4-bit up to 32-bit length and the setting applies for both transmission and reception. When the SPI_TXDR/SPI_RXDR registers are accessed, data frames are always right-aligned into either a byte (if the data fit into a byte), a half-word or a word (see Figure 665).

If the access is a multiple of the configured data size, data packing is applied automatically. During communication, only bits within the data frame are clocked and transferred.
**53.4.9 Configuration of SPI**

The configuration procedure is almost the same for the master and the slave. For specific mode setups, follow the dedicated chapters. When a standard communication has to be initialized, perform these steps prior SPI is enabled:

1. Write the proper GPIO registers: Configure GPIO alternate functions at MOSI, MISO, SCK and SS pins if applied.
2. Write to the SPI_CFG1 and SPI_CFG2 registers to set up proper values of all not reserved bits and bitfields included there with next exceptions:
   a) SSOM, SSOE, MBR[2:0], MIDI[3:0] and MSSI[3:0] are required and taken into account at master mode exclusively.
   b) UDRDET[1:0] and UDRCFG[1:0] are required and taken into account at slave mode only. The MBR[2:0] setting is taken into account only when slave is configured at TI mode.
   c) CRCSIZE[4:0] is required if CRCEN is set,
   d) CPOL, CPHA, LSBFRST, SSOM, SSOE, SSIOP, MSSI, MIDI and SSM are not required at TI mode.
   e) Once the AFCNTR bit is set at SPI_CFG2 register, all the SPI outputs start to be propagated onto the associated GPIO pins regardless the peripheral enable so any later configurations changes of the SPI_CFG1 and SPI_CFG2 registers can affect level of signals at these pins.
   f) The I2SMOD bit at SPI_I2SCFGR register has to be kept cleared to prevent any unexpected influence of occasional I2S configuration.
3. Write to the SPI_CR2 register to select length of the transfer, if it is not known TSIZE has to be programmed to zero.
4. Write to SPI_CRCPOLY and into TCRCINI, RCRCINI and CRC33_17 bits at SPI_CR1 register to configure the CRC polynomial and CRC calculation if needed.
5. Configure DMA streams dedicated for the SPI Tx and Rx in DMA registers if the DMA streams are used (see chapter Communication using DMA).
6. Configure SSI, HDDIR and MASRX at SPI_CR1 register if required.
7. Program the IOLOCK bit in the SPI_CFG1 register if the configuration protection is required (for safety).

---

**Figure 665. Data alignment when data size is not equal to 8-bit, 16-bit or 32-bit**

<table>
<thead>
<tr>
<th>Data size</th>
<th>Bit alignment</th>
<th>Example: DSIZE[4:0]</th>

**Note:** The minimum data length is 4 bits. If a data length of less than 4 bits is selected, it is forced to an 4-bit data frame size.
53.4.10 Procedure for enabling SPI

It is recommended to configure and enable the SPI slave before the master sends the clock but there is no impact if the configuration and enabling procedure is done while a traffic is ongoing on the bus suppose SS signal is managed by hardware at slave or kept inactive by slave software when software management of the SS signal is applied (see Section 53.4.7: Slave select (SS) pin management). The data register of the slave transmitter must contain data to be sent before the master starts its clocking. The SCK signal must be settled to idle state level corresponding to the selected polarity before the SPI slave is selected by SS else following transaction may be desynchronized.

When the SPI slave is enabled at the hardware SS management mode all the traffics are ignored even in case of the SS is found at active level till the slave detects a start of the SS signal (its transition from non-active to active level) just synchronizing the slave with the master. That is why the hardware management mode cannot be used when external SS pin is fixed. There is no such protection at the SS software management. In this case the SSI bit must be changed when there is no traffic on the bus and the SCK signal is at idle state level between transfers exclusively in this case.

The master at full duplex (or in any transmit-only mode) starts to communicate when the SPI is enabled, the CSTART bit is set and the TxFIFO is not empty, or with the next write to TxFIFO.

In any master receive only mode, the master starts to communicate and the clock starts running after the SPI is enabled and the CSTART bit is set.

For handling DMA, see Section 53.4.14: Communication using DMA (direct memory addressing).

53.4.11 SPI data transmission and reception procedures

The setting of data communication format follows the basic principle that sure number of data with a flexible size must be transferred within a session (transaction) while, optionally, the data handling can be cumulated effectively into a single access of the SPI data registers (data packing) or even grouped into a sequence of such services if data is collected at consistent bigger data packets. The data handling services are based upon FIFO packet occupancy events. That is why the complete data packet must be serviced exclusively upon a dedicated packet flag.

To understand better the next detailed content of this section, the user should capture the configuration impact and meaning of the following items at first:

Data size (DSIZE) - defines data frame (sets the number of bits at single data frame).

FIFO threshold (FTHLV) - defines data packet, sets the number of data frames at single data packet and so the occurrence of the packet occupancy events to handle SPI data registers either by software or by DMA.

Data access – a way how to handle the SPI data register content when the transfer data between the application and the SPI FIFOs upon a packet event. It depends on the packet size configuration. Optionally, multiply data can be handled effectively by a single access of the register (by data packing) or by sequence of such accesses (when servicing a bigger data packet).

FIFO size – capacity or space to absorb available data. It depends on the data size and the internal hardware efficiency how the data is compressed and organized within this space. The FTHLV setting must respect the FIFO capacity to store two data packets at least.
**Transaction size (TSIZE)** – defines total number of data frames involved at a transaction session overall possibly covered by several data packet services. There is no need to align this number with the packet size (handling of a last not aligned data packet is supported if TSIZE is programmed properly).

**Data handling via RxFIFO and TxFIFO**

All SPI data transitions pass through the embedded FIFOs organized by bytes (N x 8-bit). The size of the FIFOs (N) is product and the peripheral instance dependent. This enables the SPI to work in a continuous flow, and prevents overruns when the data frame size is short or the interrupt/DMA latency is too long. Each direction has its own FIFO called TxFIFO and RxFIFO, respectively.

The handling of the FIFOs content is based on servicing data packet events exclusively raised by dedicated FIFO packet occupancy flags (TXP, RXP or DXP). The flags occurrence depends on the data exchange mode (duplex, simplex), the data frame size (number of bits in the frame) and how data are organized at data packets. The frequency of the packet events can be decreased significantly when data are organized into packets via defining the FIFOs threshold. Several data frames grouped at packet can be then handled effectively based on a single FIFO occupancy packet event either by a single SPI data register access or their sequence what consumes less system performance. The user can control the access type by casting the data register address to force a concrete CPU instruction applied for the register read or write. The access then can be 8-bit, 16-bit or 32-bit but single data frame must be always accessed at least. It is crucial to keep the setting of the packet size (FTHLVL) and the data size (FSIZE) always balanced with the applied data registers access (no matter if a single access or their sequence is applied) just to apply and complete service of a single data packet upon its event. This principle, occurrence and clearing capabilities of the FIFO occupancy flags are common no matter if DMA, interrupt, or polling is applied.

A read access to the SPI_RXDR register returns the oldest value stored in the RxFIFO that has not been read yet. A write access to the SPI_TXDR stores the written data in the TxFIFO at the end of a send queue.

A read access to the SPI_RXDR register must be managed by the RXP event. This flag is set by hardware when at least one complete data packet (defined as receiver threshold by FTHLV[3:0] bits at the SPI_CFG1 register) is available at the reception FIFO while reception is active. The RXP is cleared as soon as less data than a complete single packet is available in the RxFIFO, when reading SPI_RXDR by software or by DMA.

The RXP triggers an interrupt if the RXPIE bit is set.

Upon setting of the RXP flag, the application performs the due number of SPI data register reads to download the content of one data packet. Once a complete data packet is downloaded, the application software or DMA checks the RXP value to see if other packets are pending into the receive FIFO and, if so, downloads them packet by packet until the RXP reads 0. RxFIFO can store up to N data frames (for frame size <= 8-bit), N/2 data frames (for 8-bit < frame <= 16-bit), N/3 data frames (for 16-bit < frame <= 24-bit) or N/4 data frames (if data frame >24-bit) where N is the size of the FIFO in bytes.

At the end of a reception, it may happen that some data may still be available in the RxFIFO, without reaching the FTHLVL level, thus the RXP is not set. In this case, the number of remaining RX data frames in the FIFO is indicated by RXWNE and RXPLVL fields in the SPI_SR register. It happens when number of the last data received in a transfer cannot fully accomplish the configured packet size in the case transfer size and packet size are not aligned. Nevertheless the application software can still perform the standard number of reads from the RxFIFO used for the previous complete data packets without drawbacks:
only the consistent data (completed data frames) are popped from the RxFIFO while redundant reads (or any uncompleted data) are reading 0. Thanks to that, the application software can treat all the data in a transfer in the same way and is off-loaded to foresee the reception of the last data in a transfer and from calculating the due number of reads to be popped from RxFIFO.

In a similar way, write access of a data frame to be transmitted is managed by the TXP event. This flag is set by hardware when there is enough space for the application to push at least one complete data packet (defined at FTHLV[3:0] bits at SPI_CFG1 register) into the transmission FIFO while transmission is active. The TXP is cleared as soon as the TxFIFO is filled by software a/o by DMA and space currently available for any next complete data packet is lost. This can lead to oscillations of the TXP signal when data are released out from the TxFIFO while a new packet is stored frame by frame. Any write to the TxFIFO is ignored when there is no sufficient room to store at least a single data frame (TXP event is not respected), when TXTF is set or when the SPI is disabled.

The TXP triggers an interrupt if the TXPIE bit is set or a/o a DMA request if TXDMAEN is set. The TXPIE mask is cleared by hardware when the TXTF flag is set.

Upon setting of the TXP flag application software performs the due number of SPI data register writes to upload the content of one entire data packet. Once new complete data packet is uploaded, the application software or DMA checks the TXP value to see if other packets can be pushed into the TxFIFO and, if so, uploads them packet by packet until TXP reads 0 at the end of any packet load.

The number of last data in a transfer can be shorter than the configured packet size in the case when the transfer size and the packet size are not aligned. Nevertheless the application can still perform the standard number of data register writes used for the previous packets without drawbacks: only the consistent data are pushed into the TxFIFO while redundant writes are discarded. Thanks to that, the application software can treat all the data in a transfer in the same way and is off-loaded to foresee the transmission of the last data in a transfer and from calculating the due number of writes to push the last data into TxFIFO. Just for the last data case, the TXP event is asserted by SPI once there is enough space into TxFIFO to store remaining data to complete current transfer.

Both TXP and RXP events can be polled or handled by interrupts. The DXP bit can be monitored as a common TXP and RXP event at full duplex mode.

Upon setting of the DXP flag the application software performs the due number of writes to the SPI data register to upload the content of one entire data packet for transmission, followed by the same number of reads from the SPI data register to download the content of one data packet. Once one data packet is uploaded and one is downloaded, the application software or DMA checks the DXP value to see if other packets can be pushed and popped in sequence and, if so, uploads/downloads them packet by packet until DXP reads 0.

The DXP triggers an interrupt if the DXPIE bit is set. The DXPIE mask is cleared by hardware when the TXTF flag is set.

The DXP is useful in Full-Duplex communication in order to optimize performance in data uploading/downloading, and reducing the number of interrupts or DMA sequences required to support an SPI transfer thus minimizing the request for CPU bandwidth and system power especially when SPI is operated in Stop mode.

When relay on the DXP interrupt exclusively, the user must consider the drawback of such a simplification when TXP and RXP events are serviced by common procedures because the TXP services are delayed by purpose in this case. This is due to fact that the TXP events precede the reception RXP ones normally to allow the TXP servicing prior transaction of
the last frame fully emptying the TxFIFO else master cannot provide a continuous SCK
clock flow and the slave can even face an underrun condition. The possible solution is to
prefill the TxFIFO by few data packets ahead prior the session starts and to handle all the
data received after the TXTF event by EOT exclusively at the end of the transaction (as
TXTF suppresses the DXP interrupts at the end of the transaction). In case of CRC
computation is enabled, the user must calculate with additional space to accommodate the
CRC frame at RxFIFO when relying on EOT exclusively at the end of transaction.

Another way to manage the data exchange is to use DMA (see Communication using DMA
direct memory addressing).

If the next data is received when the RxFIFO is full, an overrun event occurs (see
description of OVR flag at Section 53.5.2: SPI error flags). An overrun event can be polled
or handled by an interrupt.

This may happen in slave mode or master mode (full duplex or receive only with MASRX =
0). In master receive only mode, with MASRX = 1, the generated clock stops automatically
when the RxFIFO is full, therefore overrun is prevented.

Both RxFIFO and TxFIFO content is kept flushed when SPI is disabled (SPE=0).

Transaction handling

A few data frames can be passed at single transaction to complete a message. The user
can handle number of data within a message thanks to values stored into TSIZE and TSER
fields. In principle, the transaction of a message starts when the SPI is enabled by setting
CSTART bit and finishes when the total number of required data is transacted. The end of
transaction controls the CRC and the hardware SS management when applied. To restart
the internal state machine properly, SPI is strongly suggested to be disabled and re-enabled
before next transaction starts despite its setting is not changed. If TSIZE is kept at zero
while CSTART is set, an endless transaction is initialized (no control of transfer size is
applied). During an endless transaction, the number of transacted data aligned with FIFOs
threshold is supported exclusively. If the number of data (or its grouping into packets) is
unpredictable, the user must keep the FIFO threshold setting (packet size) at single data
(FTHLV=0) to assure that each data frame raises its own packet event to be serviced by the
application or DMA.

The transaction can be suspended at any time thanks to CSUSP which clears the CSTART
bit. SPI must be always disabled after such software suspension and re-enabled before the
next transaction starts.

In master mode, the user can extend the number of data within the current session. When
the number of data programmed into TSIZE is transacted and if TSER contains a non-zero
value, the content of TSER is copied into TSIZE, and TSER value is cleared automatically.
The transaction is then extended by a number of data corresponding to the value reloaded
into TSIZE. The EOT event is not raised in this case as the transaction continues. After the
reload operation, the TSERF flag is set and an interrupt is raised if TSERFIE is set. The
user can write the next non-zero value into TSER after the TSER is cleared by hardware but
still before the next reload occurs, so an unlimited number of data can be transacted while
repeating this process.

When any data extension is applied, it always starts by aligned data packet. That is why it is
suggested to keep number of data to be extended always aligned with packet size else the
last data packet just before the extension is applied has to be handled as an incomplete one
(see data packing chapter). If overall number of data is not aligned, the user must implement
the rest not aligned number of data into TSER just at the last extension cycle and then handle the last incomplete packet of data standardly within EOT event handler.

For example, if the user wants to transfer 23 bytes while applies data number extension at configuration of 8-bit data size, data packet set to 4 data and 32-bit access to FIFO is used then whatever next sequence is correct

- TSIZE=16 TSER=7;
- TSIZE=12 TSER=8; last extension TSER=3;

As the last not aligned MSB byte is ignored just within the last (6th) access of the FIFO.

When a not aligned sequence is applied for data to be extended like at the following cases

- TSIZE=15 TSER=8 or
- TSIZE=8 TSER=7; last extension TSER=8;

The MSB byte is ignored within the 4th access of the FIFO while the other accesses handle always 4 data at the FIFO.

When the transmission is enabled, a sequence begins and continues while any data is present in the TxFIFO of the master. The clock signal is provided permanently by the master until TxFIFO becomes empty, then it stops, waiting for additional data.

In receive-only modes, half duplex (COMM[1:0]=11, HDDIR=0) or simplex (COMM[1:0]=10) the master starts the sequence when SPI is enabled and transaction is released by setting the CSTART bit. The clock signal is provided by the master and it does not stop until either SPI or receive-only mode is disabled/suspended by the master. The master receives data frames permanently up to this moment. The reception can be suspended either by SW control, writing 1 to the CSUSP bit in the SPI_CR1 register, or automatically when MASRX=1 and RxFIFO becomes full. The reception is automatically stopped also when the number of frames programmed in TSIZE and TSER fields of the SPI_CR2 register has been completed.

In order to disable the master receive only mode, the SPI must be suspended at first. When the SPI is suspended, the current frame is completed, before changing the configuration.

Caution: If SPE is written to 0 at master, while reception is ongoing without any suspending, the clock is stopped without completing the current frame, and the RxFIFO is flushed.

While the master can provide all the transactions in continuous mode (SCK signal is continuous) it has to respect slave capability to handle data flow and its content at anytime. When necessary, the master must slow down the communication and provide either a slower clock or separate frames or data sessions with sufficient delays by MIDI[3:0] bits setting or provide an initial delay by setting MSSI[1:0] which postpones any transaction start to give slave sufficient room for preparing data. Be aware data from the slave are always transacted and processed by the master even if the slave could not prepare it correctly in time. It is preferable for the slave to use DMA, especially when data frames are short, FIFO is accessed by bytes and the SPI bus rate is high.

In order to add some SW control on the SPI communication flow from a slave transmitter node, a specific value written in the SPI_UDRDR (SPI Underrun Data Register) may be used. On slave side, when TxFIFO becomes empty, this value is sent out automatically as next data and may be interpreted by SW on the master receiver side (either simply dropped or interpreted as a XOFF like command, in order to suspend the master receiver by SW).

At multislave star topology, a single slave can be only enabled for the output data at a time. The slave just selected for the communication with the master needs to detect a change of its SS input into active level before the communication with the master starts. In a single
slave system it is not necessary to control the slave with SS, but it is often better to provide the pulse here too, to synchronize the slave with the beginning of each data sequence. The SS can be managed by both software and hardware (*Section 53.4.7: Slave select (SS) pin management*).

### 53.4.12 Procedure for disabling the SPI

When SPI is disabled, it is mandatory to follow the disable procedures described in this paragraph.

At the master mode, it is important to do this before the system enters a low-power mode when the peripheral clock is stopped. Otherwise, ongoing transactions may be corrupted in this case.

In slave mode, the SPI communication can continue when the `spi_pclk` and `spi_ker_ck` clocks are stopped, without interruption, until any end of communication or data service request condition is reached. The `spi_pclk` can generally be stopped by setting the system into STOP mode. Refer to the RCC section for further information.

The master in full duplex or transmit only mode can finish any transaction when it stops providing data for transmission. In this case, the clock stops after the last data transaction. TXC flag can be polled (or interrupt enabled with EOTIE=1) in order to wait for the last data frame to be sent.

When the master is in any receive only mode, in order to stop the peripheral, the SPI communication must be first suspended, by setting CSUSP to 1.

The data received but not read remain stored in RxFIFO when the SPI is suspended.

When SPI is disabled, RxFIFO is flushed. To prevent losing unread data, the user has to ensure that RxFIFO is empty when disabling the SPI, by reading all remaining data (as indicated by the RXP, RXWNE and RXPLVL fields in the SPI_SR register).

The standard disable procedure is based on polling EOT and/or TXC status to check if a transmission session is (fully) completed. This check can be done in specific cases, too, when it is necessary to identify the end of ongoing transactions, for example:

- When the master handles SS signal by a GPIO not related to SPI (for example at case of multislave star topology) and it has to provide proper end of SS pulse for slave, or
- When transaction streams from DMA or FIFO are completed while the last data frame or CRC frame transaction is still ongoing in the peripheral bus.

When TSIZE>0, EOT and TXC signals are equal so the polling of EOT is reliable at whatever SPI communication mode to check end of the bus activity. When TSIZE=0, the user has to check TXC, SUSP or FIFO occupancy flags in according with the applied SPI mode and way of the data flow termination.

The correct disable procedure in master mode, except when receive only mode is used, is:

1. Wait until TXC=1 and/or EOT=1 (no more data to transmit and last data frame sent). When CRC is used, it is sent automatically after the last data in the block is processed. TXC/EOT is set when CRC frame is completed in this case. When a transmission is suspended the software has to wait till CSTART bit is cleared.
2. Read all RxFIFO data (until RXWNE=0 and RXPLVL=00)
3. Disable the SPI (SPE=0).

The correct disable procedure for master receive only modes is:
1. Wait on EOT or break the receive flow by suspending SPI (CSUSP=1)
2. Wait until SUSP=1 (the last data frame is processed) if receive flow is suspended.
3. Read all Rx_FIFO data (until RXWNE=0 and RXPLVL=00)
4. Disable the SPI (SPE=0).

In slave mode, any ongoing data are lost when disabling the SPI.

53.4.13 Data packing

From user point of view there are two ways of data packing which can overlay each other:

- Type of access when data are written to Tx_FIFO or read from Rx_FIFO
  *Multiple data can be pushed or fetched effectively by single access if data size is multiplied less than access performed upon SPI_TXDR or SPI_RXDR registers.*

- Number of data to be handled during the single software service
  *It is convenient to group data into packets and cumulate the FIFO services overall the data packet content exclusively instead of handling data frame by frame separately. The user can define packets by FIFO threshold settings. Then all the FIFO occupancy events are related to that threshold level while required services are signaled by proper flags with interrupt and/or wake up capabilities.*

When the data frame size fits into one byte (less than or equal to 8 bits), the data packing is used automatically when any read or write 16-bit or 32-bit access is performed on the SPI_RXDR/SPI_TXDR register. The multiple data frame pattern is handled in parallel in this case. At first, the SPI operates using the pattern stored in the LSB of the accessed word, then with the other data stored in the MSB. *Figure 666 provides an example of data packing mode sequence handling.* While DSIZE[3:0] is configured to 4-bit there, two or four data frames are written in the Tx_FIFO after the single 16-bit or 32-bit access the SPI_TXDR register of the transmitter.

When the data frame size is between 9-bit and 16-bit, data packing is used automatically when a 32-bit access is done. The least significant half-word is used first. (regardless of the LSBFRST value)

This sequence can generate two or four RXP events in the receiver if the Rx_FIFO threshold is set to 1 frame (and data is read on a frame basis, unpacked), or it can generate a single RXP event if the FTHLV[3:0] field in the SPI_CFG1 register is programmed to a multiple of the frames to be read in a packed mode (16-bit or 32-bit read access).

The data are aligned in accordance with *Figure 665: Data alignment when data size is not equal to 8-bit, 16-bit or 32-bit.* The valid bits are performed on the bus exclusively. Unused bits are not cared at transmitter while padded by zeros at receiver.

When short data frames (<8-bit or < 16-bit) are used together with a larger data access mode (16-bit or 32-bit), the FTHLV value must be programmed as a multiple of the number of frames/data access (i.e. multiple of 4 if 32-bit access is used to up to 8-bit frames or multiple of 2 if 16-bit access is used to up to 8-bit frames or 32-bit access to up to 16-bit frames.).

The Rx_FIFO threshold setting must always be higher than the following read access size, as spurious extra data would be read otherwise.

The FIFO data access less than the configured data size is forbidden. One complete data frame has to be always accessed at minimum.

A specific problem appears if an incomplete data packet is available at FIFO: less than 4x8-bit frames or one single 16-bit frame is available.
There are two ways of dealing with this problem:

**A. without using TSIZE field**

On transmitter side, writing the last data frame of any odd sequence with an 8-bit/16-bit access to SPI_TXDR is enough.

On receiver side, the remaining data may be read by any access. Any extra data read are padded with zeros. Polling the RXWNE and RXPLVL may be used to detect when the RX data are available in the RxFIFO. (a time out may be used at system level in order to detect the polling)

**B. using the TSIZE field**

On transmitter side, the transaction is stopped by the master when it faces EOT event.

In reception, the RXP flag is not set when EOT is set. In the case when the number of data to be received (TSIZE) is not a multiple of packet size, the number of remaining data is indicated by the RXWNE and RXPLVL fields in the SPI_SR register. The remaining data can be read by any access. Any extra read is padded by zeros.

![Figure 666. Packing data in FIFO for transmission and reception](image)

1. DSIZE[3:0] is configured to 4-bit, data is right aligned, valid bits are performed only on the bus, their order depends on LSBFRST, if it is set, the order is reversed at all the data frames.

### 53.4.14 Communication using DMA (direct memory addressing)

To operate at its maximum speed and to facilitate the data register read/write process required to avoid overrun, the SPI features a DMA capability, which implements a simple request/acknowledge protocol.

A DMA access is requested when the TXDMAEN or RXDMAEN enable bits in the SPI_CFG1 register are set. Separate requests must be issued to the Tx and Rx buffers to fulfill the service of the defined packet.

- In transmission, a series of DMA requests is triggered each time TXP is set to 1. The DMA then performs series of writes to the SPI_TXDR register.
- In reception, a series of DMA requests is triggered each time RXP is set to 1. The DMA then performs series of reads from the SPI_RXDR register. When EOT is set at the end of transaction and last data packet is incomplete then DMA request is activated automatically in according with RXWNE and RXPLVL[1:0] setting to read rest of data.
If the SPI is programmed in receive only mode, UDR is never set.

If the SPI is programmed in a transmit mode, TXP and UDR can be eventually set at slave side, because transmit data may not be available. In this case, some data are sent on the TX line according with the UDR management selection.

When the SPI is used at a simplex mode, the user must enable the adequate DMA channel only while keeping the complementary unused channel and disabled.

If the SPI is programmed in transmit only mode, RXP and OVR are never set.

If the SPI is programmed in full-duplex mode, RXP and OVR are eventually set, because received data are not read.

In transmission mode, when the DMA or the user has written all the data to be transmitted (the TXTF flag is set at SPI_SR register), the EOT (or TXC at case TISEZE=0) flag can be monitored to ensure that the SPI communication is complete. This is required to avoid corrupting the last transmission before disabling the SPI or before disabling the spi_pclk in master mode. The software must first wait until EOT=1 and/or TXC=1.

When starting communication using DMA, to prevent DMA channel management raising error events, these steps must be followed in order:
1. Enable DMA Rx buffer in the RXDMAEN bit in the SPI_CFG1 register, if DMA Rx is used.
2. Enable DMA requests for Tx and Rx in DMA registers, if the DMA is used.
3. Enable DMA Tx buffer in the TXDMAEN bit in the SPI_CFG1 register, if DMA Tx is used.
4. Enable the SPI by setting the SPE bit.

To close communication it is mandatory to follow these steps in order:
1. Disable DMA request for Tx and Rx in the DMA registers, if the DMA issued.
2. Disable the SPI by following the SPI disable procedure.
3. Disable DMA Tx and Rx buffers by clearing the TXDMAEN and RXDMAEN bits in the SPI_CFG1 register, if DMA Tx and/or DMA Rx are used.

Data packing with DMA

If the transfers are managed by DMA (TXDMAEN and RXDMAEN set in the SPI_CFG1 register) the packing mode is enabled/disabled automatically depending on the PSIZE value configured for SPI TX and the SPI RX DMA channel.

If the DMA channel PSIZE value is equal to 16-bit or 32-bit and SPI data size is less than or equal to 8-bit, then packing mode is enabled. Similarly, if the DMA channel PSIZE value is equal to 32-bit and SPI data size is less than or equal to 16-bit, then packing mode is enabled. The DMA then automatically manages the write operations to the SPI_TXDR register.

Regardless data packing mode is used and the number of data to transfer is not a multiple of the DMA data size (16-bit or 32-bit) while the frame size is smaller, DMA completes the transfer automatically in according with the TSIZE field setting.

Alternatively, last data frames may be written by software, in the single/unpacked mode.

To configure any DMA data access less than the configured data size is forbidden. One complete data frame has to be always accessed at minimum.
53.5 SPI specific modes and control

53.5.1 TI mode

By specific setting of the SP[2:0] bit field at the SPI_CFG2 register the SPI can be configured to be compliant with TI protocol. The SCK and SS signals polarity, phase and flow as well as the bits order are fixed so the setting of CPOL, CPHA, LSBFRST, SSOM, SSOE, SSIOP and SSM is not required when the SPI is at TI mode configuration. The SS signal synchronizes the protocol by pulses over the LSB data bit as it is shown at the Figure 667: TI mode transfer.

![Figure 667. TI mode transfer](image)

In slave mode, the clock generator is used to define time when the slave output at MISO pin becomes to HiZ when the current transaction finishes. The master baud rate setting (MBR[2:0] at SPI_CFG1) is applied and any baud rate can be used to determine this moment with optimal flexibility. The delay for the MISO signal to become HiZ (TRELEASE) depends on internal re-synchronization, too, which takes next additional 2-4 periods of the clock signal feeding the generator. It is given by formula:

\[
\frac{T_{baud}}{2} + 2 \times T_{spi\_ker\_ck} \leq T_{release} \leq \frac{T_{baud}}{2} + 4 \times T_{spi\_ker\_ck}
\]

If the slave detects misplaced SS pulse during data transaction the TIFRE flag is set.

53.5.2 SPI error flags

An SPI interrupt is generated if one of the following error flags is set and interrupt is enabled by setting the corresponding Interrupt Enable bit.

**Overrun flag (OVR)**

An overrun condition occurs when data are received by a master or slave and the RxFIFO has not enough space to store these received data. This can happen if the software or the DMA did not have enough time to read the previously received data (stored in the RxFIFO).

When an overrun condition occurs, the OVR flag is set and the newly received value does not overwrite the previous one in the RxFIFO. The newly received value is discarded and all
data transmitted subsequently are lost. OVR flag triggers an interrupt if OVRIE bit is set. Clearing the OVR bit is done by a writing 1 to the OVR bit in the SPI_IFCR. To prevent any next overrun event the clearing must be done after RxFIFO is emptied by software reads. It is suggested to release the RxFIFO space as much as possible, this means to read out all the available data packets based on the RXP flag indication. At master mode, the user can prevent the RxFIFO overrun by automatic communication suspend (MASRX bit).

**Underrun flag (UDR)**

At a slave-transmitting mode, the underrun condition is captured internally by hardware if no data is available for transmission in the slave TxFIFO at the moment specified by UDRDET bits. The UDR flag setting is then propagated into the status register by hardware (see note below). UDR triggers an interrupt if the UDRIE bit is set.

Once the underrun is captured next provided data for transmission depends on the UDRCFG bits. The slave can provide out either data stored lastly to its TxFIFO or the data received previously from the master or a constant pattern stored by the user at the UDRDR register. The second configuration can be used at circular topography structure (see Figure 659). Standard transmission is re-enabled once the software clears the UDR flag and this clearing is propagated into SPI logic by hardware. The user must write some data into TxFIFO prior clearing UDR flag to prevent any next underrun condition occurrence capture.

When the configuration UDRDET[1:0]=00 is applied, the underrun condition is evaluated whenever master starts to communicate a new data frame while TxFIFO is empty. Then single additional dummy (accidental) data is always inserted between last valid data and proper underrun pattern defined by UDRCFG[1:0]. This does not happen when any other UDRDET[1:0] configuration is applied suppose the slave's TxFIFO is not empty when underrun condition is checked (see Figure 668: Optional configurations of slave behavior at detection of underrun condition).

The data transacted by slave is unpredictable especially when the transaction starts or continues while TxFIFO is empty and underrun condition is either not yet captured or just cleared. Typically, this is the case when UDRDET[1:0]=00 or SPI is just enabled or when a transaction with a defined size just starts. First bits can be corrupted in this case, as well, when slave software writes first data into the empty TxFIFO too close prior the data transaction starts (propagation of the data into TxFIFO takes few APB clock cycles). If the user cannot ensure to write data into the empty TxFIFO in time the UDRDET[1:0]=00 setting must be avoided.

To handle the underrun control feature correctly the user must avoid next critical encroachments especially

- Any fill of empty TxFIFO when master starts clocking (at UDRDET[1:0]=00 especially)
- Any clear of UDR flag while TxFIFO is empty
- Any setting of UDRDET[1:0]=00 together with UDRCFG[1:0]=10 (to avoid repetition of undefined dummy data)
- Any setting of UDRDET[1:0]=10 when underrun must be detected after each data frame while SS signal does not toggle between the frames
- Any setting of UDRDET[1:0]=10 while SS is managed by software

UDR propagation latency at SCK domain (see note)

*) Depends on UDRCFG[1:0] setting
Note: The hardware propagation of an UDR event needs additional traffic on the bus. It always takes few extra SPI clock cycles after the event happens (both underrun captured by hardware and cleared by software). If clearing of the UDR flag by software is applied close to the end of data frame transaction or when the SCK line is at idle in between the frames, the next extra underrun pattern is sent initially by slave prior the valid data from TxFIFO becomes transacted again. The user can prevent this by SPI disable/enable action between sessions to restart the underrun logic and so initiate the next session by the valid data.

**Mode fault (MODF)**

Mode fault occurs when the master device has its internal SS signal (SS pin in SS hardware mode, or SSI bit in SS software mode) pulled low. This automatically affects the SPI interface in the following ways:

- The MODF bit is set and the interrupt request is triggered if the MODFIE bit is set.
- The SPE bit is forced to zero while MODF bit is set. This blocks all the peripheral outputs and disables the SPI interface.
- The MASTER bit is cleared, thus forcing the device into slave mode.

MODF is cleared by writing 1 to the MODFC bit in the SPI_IFCR.

To avoid any multiple slave conflicts in a system comprising several MCUs, the SS pin must be pulled to its non-active level before re-enabling the SPI, by setting the SPE bit.

As a security, hardware does not allow the SPE bit to be set while the MODF bit is set. In a slave device the MODF bit cannot be set except as the result of a previous multi master conflict.

A correct SW procedure when master overtakes the bus at multi master system must be the following one:

- Switch into master mode while SSOE=0 (potential conflict can appear when another master occupies the bus. MODF is raised in this case which prevents any next node switching into master mode)
- Put GPIO pin dedicated for another master SS control into active level
- Perform data transaction
- Put GPIO pin dedicated for another master SS control into non active level
- Switch back to slave mode

**CRC error (CRCE)**

This flag is used to verify the validity of the value received when the CRCEN bit in the SPI_CFG1 register is set. The CRCE flag in the SPI_SR register is set if the value received in the shift register does not match the receiver SPI_RXCRC value, after the last data is received (as defined by TSIZE). The CRCE flag triggers an interrupt if RCEIE bit is set. Clearing the bit CRCE is done by a writing 1 to the CRCEC bit in the SPI_IFCR.

**TI mode frame format error (TIFRE)**

A TI mode frame format error is detected when an SS pulse occurs during an ongoing communication when the SPI is operating in slave mode and configured to conform to the TI mode protocol. When this error occurs, the TIFRE flag is set in the SPI_SR register. The SPI is not disabled when an error occurs, the SS pulse is ignored, and the SPI waits for the next SS pulse before starting a new transfer. The data may be corrupted since the error detection may result in the loss of few data bytes.
The TIFRE flag is cleared by writing 1 to the TIFREC bit in the SPI_IFCR. If the TIFREIE bit is set, an interrupt is generated on the SS error detection. As data consistency is no longer guaranteed, communication must be re-initiated by software between master and slave.

53.5.3 CRC computation

Two separate 33-bit or two separate 17-bit CRC calculators are implemented in order to check the reliability of transmitted and received data. The SPI offers any CRC polynomial length (number of bits involved in the CRC computation) from 5 to 33 bits when maximum data size is 32-bit and from 5 to 17 bits for the peripheral instances where maximum data size is limited to 16-bit.

The length of the polynomial is defined by the most significant bit of the value stored in the SPI_CRCPOLY register. It must be greater than the data frame size (in bits) defined in the DSIZE[4:0] bitfield of the SPI_CFG1 register. To obtain a full-size polynomial, the polynomial length must exceed the maximum data size of the peripheral instance, and the CRC33_17 bit of the SPI_CR1 register must be set to select the most significant bit of the polynomial string. For example, to select the standard CRC16-CCITT (XMODEM) polynomial \(x^{16} + x^{12} + x^5 + 1\), write 0x11021 to the SPI_CRCPOLY register for a 32-bit instance, whereas to obtain the full size for a 16-bit instance, write 0x1021 with the CRC33_17 bit set.

The CRCSIZE field in the SPI_CFG1 then defines how many the most significant bits from CRC calculation registers are transacted and compared as CRC frame. It is defined independently from the data frame length, but it must be either equal or an integer multiple of the data frame size while its size cannot exceed the maximum data size of the instance.

To fully benefit from the CRC calculation capability, the polynomial length setting must correspond to the CRC pattern size, else the bits unused at the calculation are transacted and expected all zero at the end of the CRC pattern if its size is set greater than the polynomial length.

CRC principle

The CRC calculation is enabled by setting the CRCEN bit in the SPI_CFG1 register before the SPI is enabled (SPE = 1). The CRC value is then calculated using the CRC polynomial defined by the CRCPOLY register and CRC33_17 bit. When SPI is enabled, the CRC polynomial can be changed but only in case when there is no traffic on the bus.

The CRC computation is done, bit by bit, on the sampling clock edge defined by the CPHA and CPOL bits in the SPI_CR1 register. The calculated CRC value is checked automatically at the end of the data block defined by the SPI_CR2 register exclusively.

When a mismatch is detected between the CRC calculated internally on the received data and the CRC received from the transmitter, a CRCERR flag is set to indicate a data corruption error. The right procedure for handling the CRC depends on the SPI configuration and the chosen transfer management.

CRC transfer management

Communication starts and continues normally until the last data frame has to be sent or received in the SPI_DR register.

The length of the transfer has to be defined by TSIZE and TSER. When the desired number of data is transacted, the TXCRC is transmitted and the data received on the line are compared to the RXCRC value.
TSIZE cannot be set to 0xFFFF value if CRC is enabled. A correct way of sending e.g. 65535 data with CRC is to set:
- TSIZE= 0xFFFF and TSER=1 when data packet is configured to keep one data respective
- TSIZE= 0xFFFC and TSER=3 when data packet keeps 4 data (to ensure the TSIZE value aligned with packet size when its extension is applied).

In transmission, the CRC computation is frozen during CRC transaction and the TXCRC is transmitted, in a frame of length equal to the CRCSIZE field value.

In reception, the RXCRC is also frozen when desired number of data is transacted. Information to be compared with the RXCRC register content is then received in a frame of length equal to the CRCSIZE value.

Once the CRC frame is completed, an automatic check is performed comparing the received CRC value and the value calculated in the SPI_RXCRC register. Software has to check the CRCERR flag in the SPI SR register to determine if the data transfers were corrupted or not. Software clears the CRCERR flag by writing 1 to the CRCERR.

The user takes no care about any flushing redundant CRC information, it is done automatically.

**Resetting the SPI_TXCRC and SPI_RXCRC values**

The SPI_TXCRC and SPI_RXCRC values are initialized automatically when new data is sampled after a CRC phase. This allows the use of DMA circular mode in order to transfer data without any interruption (several data blocks covered by intermediate CRC checking phases). Initialization patterns for receiver and transmitter can be configured either to zero or to all ones in dependency on setting bits TCRCINI and RCRCINI at SPI_CR1 register.

The CRC values are reset when the SPI is disabled.

### 53.6 Low-power mode management

The SPI has advanced low-power mode functions allowing it to transfer properly data between the FIFOs and the serial interface even when the **spi_pclk** clock is disabled.

In master mode the **spi_ker_ck** kernel clock is needed in order to provide the timings of the serial interface.

In slave mode, the **spi_ker_ck** clock can be removed as well during the transfer of data between the FIFOs and the serial interface. In this mode the clock is provided by the external SPI device.

When the **spi_pclk** clock is gated, (and the **spi_ker_ck** clock as well if the SPI is in slave), the SPI provides a wakeup event signal (**spi_wkup**) if a specific action requiring the activation of the **spi_pclk** clock is needed, such as:

- To fill-up the TxFIFO,
- To empty the RxFIFO,
- Other signaling: end of transfer, errors...

The generation of **spi_ker_ck** and **spi_pclk** clock are controlled by the RCC block according to register settings and the processors modes. Refer to the RCC section for details.
The `spi_pclk` clock request stays pending till a flag with enabled interrupt is set. That is why it is important to service these pending requests and clear their flag as soon as possible at system sensitive to the low power consumption especially and the application must acknowledge all pending interrupts events before switching the SPI to low-power mode (i.e. removing `spi_pclk`).

The Figure 669 shows an example of the clock handling when the SPI2S is working in low-power mode. The example is given for a transmit mode.

In master mode the `spi_ker_ck` clock is required for the timing generation.

The Figure 669 shows two kinds of supported scenarios for the handling of the `spi_ker_ck` kernel clock in slave mode:

- In most of the slave modes, the `spi_ker_ck` kernel clock can be disabled,
- In some products, the `spi_ker_ck` kernel clock activation may follow the system state.

The figure clearly shows that the `spi_pclk` must be provided to the SPI2S, when data need to be transferred from the memory to the SPI2S TxFIFO. Here is the description of the most important steps:

- **Step 1**
  The TxFIFO level goes below the programmed threshold, this event (TXP) activates the `spi_wkup` signal. This signal is generally used to wake-up the system from low-power mode, and thus to activate the bus clock (`spi_pclk`).

- **Step 2**
  When `spi_pclk` is activated, the `spi_it` is also activated, and the product is ready to fill-up the TxFIFO either by DMA or by software. Note as well that for some product the system wake-up automatically enables the `spi_ker_ck` kernel clock as well.

- **Step 3**
  When the amount of empty locations in the TxFIFO is less than FTHLV, then the `spi_wkup` and `spi_it` signals are deactivated, but the fill-up of the TxFIFO may
continue. Note that `spi_wkup` falling edge is aligned with the serial interface clock domain, and the falling edge of the `spi_it` is aligned with the `spi_pclk` clock domain.

- **Step 4**
  The fill-up of the TxFIFO is completed; the software can switch the system back to low-power mode until the next `spi_wkup` occurs.
53.7 SPI wakeup and interrupts

*Table 436* gives an overview of the SPI events capable to generate interrupt events (spi_it). Some of them feature wake-up from low-power mode capability additionally (spi_wkup).

Most of them can be enabled and disabled independently while using specific interrupt enable control bits.

The flags associated with the events are cleared by specific methods. Refer to the description of SPI registers for more details about the event flags. All the pending interrupt requests stay active if the SPI is disabled. A not cleared request with an enabled interrupt generates a spi_pclk clock request and so increases the overall consumption.

1. Refer to SPI2S register description for more details about the event flags.
2. The TXC flag behavior depends on the TSIZE setting. When TSIZE>0, the flag fully follows the EOT one including its clearing by EOTC.
53.8 **I2S main features**

- Full duplex communication
- Half-duplex communication (only transmitter or receiver)
- Master or slave operations
- 8-bit programmable linear prescaler
- Data length may be 16, 24 or 32 bits\(^{(a)}\)
- Channel length can be 16 or 32 in master, any value in slave
- Programmable clock polarity
- Error flags signaling for improved reliability: Underrun, Overrun and Frame Error
- Embedded Rx and TxFIFOs
- Supported I2S protocols:
  - I2S Philips standard
  - MSB-Justified standard (Left-Justified)
  - LSB-Justified standard (Right-Justified)
  - PCM standard (with short and long frame synchronization)
- Data ordering programmable (LSb or MSb first)
- DMA capability for transmission and reception
- Master clock can be output to drive an external audio component:
  - \( F_{MCK} = 256 \times F_{WS} \) for all I2S modes
  - \( F_{MCK} = 128 \times F_{WS} \) for all PCM modes

*Note:* \( F_{MCK} \) is the master clock frequency and \( F_{WS} \) is the audio sampling frequency.

---

\(^{(a)}\) 24- and 32-bit data width are not always available. Refer to *Section 53.3: SPI implementation.*
53.9 I2S functional description

53.9.1 I2S general description

The block diagram shown on Figure 654 also applies for I2S mode.

The SPI/I2S block can work on I2S/PCM mode, when the bit I2SMOD is set to 1. A dedicated register (SPI_I2SCFGR) is available for configuring the dedicated I2S parameters, which include the clock generator, and the serial link interface.

The I2S/PCM function uses the clock generator to produce the communication clock when the SPI/I2S is set in master mode. This clock generator is also the source of the master clock output (MCK).

Resources such as Rx_FIFO, Tx_FIFO, DMA and parts of interrupt signaling are shared with SPI function. The low-power mode function is also available in I2S mode, refer to Section 53.6: Low-power mode management and Section 53.10: I2S wakeup and interrupts.

53.9.2 Pin sharing with SPI function

The I2S shares four common pins with the SPI:

- SDO: Serial Data Output (mapped on the MOSI pin) to transmit the audio samples in master, and to receive the audio sample in slave. Refer to Section : Serial Data Line swapping on page 2354.

- SDI: Serial Data Input (mapped on the MISO pin) to receive the audio samples in master, and to transmit the audio sample in slave. Refer to Section : Serial Data Line swapping on page 2354.

- WS: Word Select (mapped on the SS pin) is the frame synchronization. It is configured as output in master mode, and as input for slave mode.

- CK: Serial Clock (mapped on the SCK pin) is the serial bit clock. It is configured as output in master mode, and as input for slave mode.

An additional pin can be used when a master clock output is needed for some external audio devices:

- MCK: the Master Clock (mapped separately) is used when the I2S is configured in master mode.
53.9.3 Bitfields usable in I2S/PCM mode

When the I2S/PCM mode is selected (I2SMOD = ‘1’), some bitfields are no longer relevant, and must be forced to a specific value in order to guarantee the behavior of the I2S/PCM function. Table 437 shows the list of bits and fields available in the I2S/PCM mode, and indicates which must be forced to a specific value.

Table 437. Bitfields usable in PCM/I2S mode

</tbody>
</table>
53.9.4 Slave and master modes

The SPI/I2S block supports master and slave mode for both I2S and PCM protocols.

In master mode, both CK, WS and MCK signals are set to output.

In slave mode, both CK and WS signals are set to input. The signal MCK cannot be used in slave mode.

In order to improve the robustness of the SPI/I2S block in slave mode, the peripheral re-synchronizes each reception and transmission on WS signal. This means that:

- In I2S Philips standard, the shift-in or shift-out of each data is triggered one bit clock after each transition of WS.
- In I2S MSB justified standard, the shift-in or shift-out of each data is triggered as soon as a transition of WS is detected.
- In PCM standard, the shift-in or shift-out of each data is triggered one bit clock after the active edge of WS.

Note: This re-synchronization mechanism is not available for the I2S LSB justified standard.

Note: Note as well that there is no need to provide a kernel clock when the SPI/I2S is configured in slave mode.

53.9.5 Supported audio protocols

The I2S/PCM interface supports four audio standards, configurable using the I2SSTD[1:0] and PCMSYNC bits in the SPI_I2SCFGR register.

In the I2S protocol, the audio data are time-multiplexed on two channels: the left channel and the right channel. The WS signal is used to indicate which channel shall be considered as the left, and which one is the right.

In I2S master mode, four frames formats are supported:

- 16-bit data packed in a 16-bit channel
- 16-bit data packed in a 32-bit channel
- 24-bit data packed in a 32-bit channel\(^{(a)}\)
- 32-bit data packed in a 32-bit channel\(^{(a)}\)

In PCM master mode, three frames formats are supported:

- 16-bit data packed in a 16-bit channel
- 16-bit data packed in a 32-bit channel
- 24-bit data packed in a 32-bit channel\(^{(a)}\)

\(^{(a)}\) 24- and 32-bit data width are not always available. Refer to Section 53.3: SPI implementation.
The figure hereafter shows the main definition used in this section: data length, channel length and frame length.

1. The channel length (CHLEN) must always be higher or equal to the data length (DATLEN).
I²S Philips standard

The I²S Philips standard is selected by setting I2SSTD to 0b00. This standard is supported in master and slave mode.

In this standard, the WS signal toggles one CK clock cycle before the first bit (MSb in I²S Philips standard) is available. A falling edge transition of WS indicates that the next data transferred is the left channel, and a rising edge transition indicates that the next data transferred is the right channel.

![Master I²S Philips protocol waveforms (16/32-bit full accuracy)](image)

1. 24- and 32-bit data width are not always supported (DATLEN = 01 or 10). Refer to Section 53.3: SPI implementation for the supported data sizes.

CKPOL is set to 0 in order to match the I²S Philips protocol. See Selection of the CK sampling edge for information concerning the handling of WS signal.

Figure 671 shows an example of waveform generated by the SPI/I²S in the case where the channel length is equal to the data length. More precisely, this is true when CHLEN = 0 and DATLEN = 0b00 or when CHLEN = 1 and DATLEN = 0b10.

See Control of the WS Inversion for information concerning the handling of WS signal.

![I²S Philips standard waveforms](image)

1. 24- and 32-bit data width are not always supported (DATLEN = 01 or 10). Refer to Section 53.3: SPI implementation for the supported data sizes.
In the case where the channel length is bigger than the data length, the remaining bits are forced to zero when the SPI/I2S is configured in transmit mode. This is applicable for both master and slave mode.

**MSB justified standard**

For this standard, the WS signal toggles when the first data bit is provided. The data transferred represents the left channel if WS is high, and the right channel if WS is low.

**Figure 673. Master MSB Justified 16-bit or 32-bit full-accuracy length**

![Diagram showing MSB justified data transfer](image1)

1. 24- and 32-bit data width are not always supported (DATLEN = 01 or 10). Refer to Section 53.3: SPI implementation for the supported data sizes.

CKPOL is set to 0 in order to match the I2S MSB justified protocol. See Selection of the CK sampling edge for information concerning the handling of WS signal.

See Control of the WS Inversion for information concerning the handling of WS signal.

**Figure 674. Master MSB justified 16 or 24-bit data length**

![Diagram showing MSB justified data transfer](image2)

1. 24- and 32-bit data width are not always supported (DATLEN = 01 or 10). Refer to Section 53.3: SPI implementation for the supported data sizes.

In the case where the channel length is bigger than the data length, the remaining bits are forced to zero when the SPI/I2S is configured in master transmit mode. In slave transmit the remaining bits are forced to the value of the first bit of the next data to be generated in order to avoid timing issues (see **Figure 675**).
Figure 675. Slave MSB justified

1. 24- and 32-bit data width are not always supported (DATLEN = 01 or 10). Refer to Section 53.3: SPI implementation for the supported data sizes.

LSB justified standard

This standard is similar to the MSB justified standard in master mode (no difference for the 16 and 32-bit full-accuracy frame formats). The LSB justified 16 or 32-bit full-accuracy format give similar waveforms than MSB justified mode (see Figure 673) because the channel and data have the same length.

Note: In the LSB justified format, only 16 and 32-bit channel length are supported in master and slave mode. This is due to the fact that it is not possible to transfer properly the data if the channel length is not known by transmitter and receiver side.

Figure 676. LSB justified 16 or 24-bit data length

1. 24- and 32-bit data width are not always supported (DATLEN = 01 or 10). Refer to Section 53.3: SPI implementation for the supported data sizes.

CKPOL is set to 0 in order to match the I2S LSB justified protocol. See Selection of the CK sampling edge for information concerning the handling of WS signal.

See Control of the WS Inversion for information concerning the handling of WS signal.
PCM standard

For the PCM standard, there is no need to use channel-side information. The two PCM modes (short and long frame) are available and configurable using the PCMSYNC bit in SPI_I2SCFGR register.

Note: The difference between the PCM long and short frame, is just the width of the frame synchronization: for both protocols, the active edge of the frame is generated (or is expected for the Slave mode) one CK clock cycle before the first bit.

Figure 677. Master PCM when the frame length is equal the data length

For long frame synchronization, the WS signal assertion time is fixed to 13 bits in master mode.

A data size of 16 or 24 bits can be used when the channel length is set to 32 bits.

For short frame synchronization, the WS synchronization signal is only one cycle long.

See Control of the WS Inversion for information concerning the handling of WS signal.

Figure 678. Master PCM standard waveforms (16 or 24-bit data length)

1. 24- and 32-bit data width are not always supported (DATLEN = 01 or 10). Refer to Section 53.3: SPI implementation for the supported data sizes.

If the PCM protocol is used in slave mode, frame lengths can be different from 16 or 32 bits. As shown in Figure 679, in slave mode various pulse widths of WS can be accepted as the start of frame is detected by a rising edge of WS. The only constraint is that the WS must go back to its inactive state for at least one CK cycle.
Additional Serial Interface Flexibility

Variable frame length in slave

In slave mode, channel lengths different from 16 or 32 bits can be accepted, as long as the channel length is bigger than the data length. This is true for all protocols except for I2S LSB justified protocol.

Data ordering

For all data formats and communication standards, it is possible to select the data ordering (MSb or LSb first) thanks to the bit LSBFRST located into SPI configuration register 2 (SPI_CFG2).

Selection of the CK sampling edge

The CKPOL bit located into SPI/I2S configuration register (SPI_I2SCFGR) allows the user to choose the sampling edge polarity of the CK for slave and master modes, for all protocols.

- When CKPOL = 0, serial data SDO and WS (when master) are changed on the falling edge of CK and the serial data SDI and WS (when slave) are read on the rising edge.
- When CKPOL = 1, serial data SDO and WS (when master) are changed on the rising edge of CK and the serial data SDI and WS (when slave) are read on the falling edge.

Control of the WS Inversion

It is possible to invert the default WS signal polarity for master and slave modes, for all protocols, by setting WSINV to 1. By default the WS polarity is the following:

- In I2S Philips Standard, WS is low for left channel, and high for right channel
- In MSB/LSB justified mode, WS is high for left channel, and low for right channel
- In PCM mode, the start of frame is indicated by a rising edge of WS.
When WSINV is set to 1, the WS polarity is inverted, then:

- In I2S Philips Standard, WS is high for left channel, and low for right channel
- In MSB/LSB justified mode, WS is low for left channel, and high for right channel
- In PCM mode, the start of frame is indicated by a falling edge of WS.

WSINV is located into SPI/I2S configuration register (SPI_I2SCFGR).

### Control of the I/Os

The SPI/I2S block allows the settling of the WS and CK signals to their inactive state before enabling the SPI/I2S thanks to the AFCNTR bit of SPI configuration register 2 (SPI_CFG2).

This can be done by programming CKPOL and WSINV using the following sequence:

Assuming that AFCNTR is initially set to 0

- Set I2SMOD = 1, (In order to inform the hardware that the CK and WS polarity is controlled via CKPOL and WSINV).
- Set bits CKPOL and WSINV to the wanted value.
- Set AFCNTR = 1.
  
  Then the inactive level of CK and WS I/Os is set according to CKPOL and WSINV values, even if the SPI/I2S is not yet enabled.
  
  Then performs the activation sequence of the I2S/PCM

Table 438 shows the level of WS and CK signals, when the AFCNTR bit is set to 1, and before the SPI/I2S block is enabled (i.e. inactive level). Note that the level of WS depends also on the protocol selected.

#### Table 438. WS and CK level before SPI/I2S is enabled when AFCNTR = 1

</table>

Note: To avoid electrical conflicts on WS and CK, the AFCNTR bit must not be set to 1 when the SPI2S is in slave mode.

### Serial Data Line swapping

The SPI/I2S offers the possibility to swap the function of SDI and SDO lines thanks to IOSWP bit located into SPI configuration register 2 (SPI_CFG2). Table 439 gives details on this feature.

53.9.7 Startup sequence

When the bit SPE is set to 0, the user is not allowed to read and write into the SPI_RXDR and SPI_TXDR registers, but the access to other registers is allowed.

When the application wants to use the SPI/I2S block the user has to proceed as follow:
1. Ensure that the SPE is set to 0, otherwise write SPE to 0.
2. Program all the configuration and control registers according to the wanted configuration. Refer to Section 53.9.16 for detailed programming examples.
3. Clear all the status flags by setting the SUSPC, TIFREC, OVRC and UDRC bits of SPI_IFCR register. Note that if the flag SUSP is not cleared (via SUSPC bit) the CSTART control bit has no effect.
4. Set the SPE bit to 1, in order to activate the SPI/I2S block. When this bit is set, the serial interface is still disabled, but the DMA and interrupt services are working, allowing for example, the data transfer into the TxFIFO.
5. Set bit CSTART to 1, in order to activate the serial interface.

As shown in Figure 680, in I2S Philips standard master TX, the generation of the WS and CK signals starts after a resynchronization delay (SYNC_DLY2) when CSTART goes to 1 and the TxFIFO is not empty. Note that the bit clock CK is activated 4 rising edges before the falling edge of WS in order to ensure that the external slave device can detect properly WS transition. Other standards behave similarly.
1. In this figure, the MCK is enabled before setting the bit SPE to 1. See MCK generation for more information.

2. Note that the level of WS and CK signals are controlled by the SPI/I2S block during the configuration phase as soon as the AFCNTR bit is set to 1

Note: Due to clock domain resynchronization, the CSTART bit is taken into account by the hardware after about 3 periods of CK clock (SYNC_DLY1).

In slave mode, once the bit CSTART is set to 1, the data transfer starts when the start-of-frame condition is met:

- For I2S Philips standard, the start-of-frame condition is a falling edge of WS signal. The transmission/reception starts one bit clock later. If WSINV = 1, then the start-of-frame condition is a rising edge.
- For other protocols, the start-of-frame condition is a rising edge of WS signal. The transmission/reception starts at rising edge of WS for MSB aligned protocol. The transmission/reception starts one bit clock later for PCM protocol. If WSINV = 1, then the start-of-frame condition is a falling edge.

Figure 681 shows an example of startup sequence in I2S Philips standard, slave mode.

Note: Due to clock domain resynchronization, the CSTART bit is taken into account by the hardware after 2 periods of CK clock (SYNC_DLY).
53.9.8 Stop sequence

The application can stop the I2S/PCM transfers by setting the SPE bit to 0. In that case the communication is stopped immediately, without waiting for the end of the current frame.

In master mode it is also possible to stop the I2S/PCM transfers at the end of the current frame. For that purpose, the user has to set the bit CSUSP to 1, and polls the CSTART bit until it goes to 0. The CSTART bit goes to 0 when the current stereo (if an I2S mode was selected) or mono sample are completely shifted in or out. Then the SPE bit can be set to 0.

The Figure 682 shows an example of stop sequence in the case of master mode. The CSUSP bit is set to 1, during the transmission of left sample, the transfer continue until the last bit of the right sample is transferred. Then CSTART and CSUSP go back to 0, CK and WS signals go back to their inactive state, and the user can set SPE to 0.

Figure 682. Stop sequence, I2S Philips standard, master

Note: In slave mode, the stop sequence is only controlled by the SPE bit.

53.9.9 Clock generator

When the I2S or PCM is configured in master mode, the user needs to program the clock generator in order to produce the Frame Synchronization (WS), the bit clock (CK) and the master clock (MCK) at the desired frequency.

If the I2S or PCM is used in slave mode, there is no need to configure the clock generator.
The frequency generated on MCK, CK and WS depends mainly on I2SDIV, ODD, CHLEN and MCKOE. The bit MCKOE indicates if a master clock need to be generated or not. The master clock has a frequency 128 or 256 times higher than the frame synchronization. This master clock is often required to provide a reference clock to external audio codecs.

Note: In master mode, there is no specific constraints on the ratio between the bus clock rate \(F_{pclk}\) and the bit clock \(F_{CK}\). The bus clock frequency must be high enough in order to support the data throughput.

When the master clock is generated (MCKOE = 1), the frequency of the frame synchronization is given by the following formula in I2S mode:

\[
F_{WS} = \frac{F_{i2s\_clk}}{256 \times \{2 \times \text{I2SDIV} + \text{ODD}\}}
\]

and by this formula in PCM mode:

\[
F_{WS} = \frac{F_{i2s\_clk}}{128 \times \{2 \times \text{I2SDIV} + \text{ODD}\}}
\]

In addition, the frequency of the MCK \(F_{MCK}\) is given by the formula:

\[
F_{MCK} = \frac{F_{i2s\_clk}}{\{2 \times \text{I2SDIV} + \text{ODD}\}}
\]

When the master clock is disabled (MCKOE = 0), the frequency of the frame synchronization is given by the following formula in I2S mode:

\[
F_{WS} = \frac{F_{i2s\_clk}}{32 \times (\text{CHLEN} + 1) \times \{2 \times \text{I2SDIV} + \text{ODD}\}}
\]

And by this formula in PCM mode:

\[
F_{WS} = \frac{F_{i2s\_clk}}{16 \times (\text{CHLEN} + 1) \times \{2 \times \text{I2SDIV} + \text{ODD}\}}
\]
Where \( F_{WS} \) is the frequency of the frame synchronization, and \( F_{i2s\_clk} \) is the frequency of the kernel clock provided to the SPI/I2S block.

**Note:** CHLEN and ODD can be either 0 or 1. 
\( i2SDIV \) can take any values from 0 to 255 when ODD = 0, but when ODD = 1, the value \( i2SDIV = 1 \) is not allowed. 
When \( i2SDIV = 0 \), then \((2 \times i2SDIV) + ODD\) is forced to 1.

**Note:** When \((2 \times i2SDIV) + ODD\) is odd, the duty cycle of MCK or the CK signals is not 50%. Care must be taken when odd ratio is used: it can impact margin on setup and hold time. For example if \((2 \times i2SDIV) + ODD\) = 5, then the duty cycle can be 40%.

Table 440 provides examples of clock generator programming for I2S modes.

**MCK generation**
The master clock MCK can be generated regardless to the SPE bit. The MCK generating is controlled by the following bits:
- I2SMOD must equal to 1,
- I2SCFG must select a master mode,
- MCKOE must be set to 1

53.9.10 Internal FIFOs

The I2S interface can use a dedicated FIFO for the RX and the TX path. The samples to transmit can be written into the TxFIFO via the SPI_TXDR register. The reading of RxFIFO is performed via the SPI_RXDR register.

Data alignment and ordering

It is possible to select the data alignment into the SPI_RXDR and SPI_TXDR registers thanks to the DATFMT bit.

Note as well that the format of the data located into the SPI_RXDR or SPI_TXDR depends as well on the way those registers are accessed via the APB bus.

Figure 684 shows the allowed settings between APB access sizes, DATFMT and DATLEN.

Note: Caution shall be taken when the APB access size is 32 bits, and DATLEN = 0. For read operation the RxFIFO must contain at least two data, otherwise the read data are invalid. In the same way, for write operation, the TxFIFO must have at least two empty locations, otherwise a data can be lost.

Data alignment and ordering

It is possible to select the data alignment into the SPI_RXDR and SPI_TXDR registers thanks to the DATFMT bit.

</tbody>
</table>

1. In I2S mode, the sample N represents the left sample, and the sample N+1 is the right sample.
2. 24- and 32-bit data width are not always supported (DATLEN = 01 or 10). Refer to Section 53.3: SPI implementation for the supported data sizes.

It is possible to generate an interrupt or a DMA request according to a programmable FIFO threshold levels. The FIFO threshold is common to RX and TxFIFOs can be adjusted via FTHLV.

In I2S mode, the left and right audio samples are interleaved into the FIFOs. It means that for transmit operations, the user has to start to fill-up the TxFIFO with a left sample, followed by a right sample, and so on. For receive mode, the first data read from the RxFIFO is supposed to represent a left channel, the next one is a right channel, and so on.

Note that the read and write pointers of the FIFOs are reset when the bit SPE is set to 0.

Refer to Section 53.9.11 and Section 53.9.15 for additional information.
FIFO size optimization

The basic element of the FIFO is the byte. This allows an optimization of the FIFO locations. For example when the data size is fixed to 24 bits, each audio sample takes 3 basic FIFO elements.

For example, a FIFO with 16 basic elements can have a depth of:
- 8 samples, if the DATLEN = 0 (16 bits),
- 5 samples, if the DATLEN = 1 (24 bits)\(^{(a)}\),
- 4 samples, if the DATLEN = 2 (32 bits)\(^{(a)}\).

53.9.11 FIFOs status flags

Two status flags are provided for the application to fully monitor the state of the I2S interface. Both flags can generate an interrupt request. The receive interrupt is generated if RXPIE bit is enabled, the transmit interrupt is generated if TXPIE bit is enabled. Those bits are located into the SPI_IER register.

**TxFIFO threshold reached (TXP)**

When set, this flag indicates that the TxFIFO contains at least FTHLV empty locations. thus FTHLV new data to be transmitted can be written into SPI_TXDR. The TXP flag is reset when the amount of empty locations is lower than FTHLV. Note that TXP = 1, when the I2S is disabled (SPE bit is reset).

**RxFIFO threshold reached (RXP)**

When set, this flag indicates that there is at least FTHLV valid data into the RxFIFO, thus the user can read those data via SPI_RXDR. It is reset when the RxFIFO contains less than FTHLV data.

See [Section 53.10](#) for additional information on interrupt function in I2S mode.

53.9.12 Handling of underrun situation

In transmit mode, the UDR flag is set when a new data needs to be loaded into the shift register while the TxFIFO is already empty. In such a situation at least a data is lost.

In I2S mode, there is a hardware mechanism in order to prevent misalignment situation (left and right channel swapped). As shown in the following figure, when an underrun occurs, the peripheral re-plays the last valid data on left and right channels as long as conditions of restart are not met. The transmission restarts:

- When there is enough data into the TxFIFO, and
- When the UDR flag is cleared by the software, and
- When the restart condition is met:
  - if the underrun occurs when a right channel data needs to be transmitted, the transmission restarts when a right channel needs to be transmitted, or
  - if the underrun occurs when a left channel data needs to be transmitted, the transmission restarts when a left channel needs to be transmitted.

\(^{(a)}\) 24- and 32-bit data width are not always supported (DATLEN = 01 or 10). Refer to [Section 53.3: SPI implementation](#) for the supported data sizes.
The UDR flag can trigger an interrupt if the UDRIE bit in the SPI_IER register is set. The UDR bit is cleared by writing UDRC bit of SPI_IFCR register to 1.

When the block is configured in PCM mode, the transmission restarts at the start of the next frame when there is enough data into the TxFIFO, and the UDR flag is cleared by software.

**Note:** A *underrun situation can occur in master or slave mode. In master mode, when an underrun occurs, the WS, CK and MCK signal are not gated. Due to resynchronization, any change on the UDR flag is taken into account by the hardware after at least 2 periods of CK clock.*

### 53.9.13 Handling of overrun situation

The OVR flag is set when received data need to written into the RxFIFO, while the RxFIFO is already full. As a result, some incoming data are lost.

In I2S mode, there is a hardware mechanism in order to prevent misalignment situation (left and right channel swapped). As shown in the following figure, when an overrun occurs, the peripheral stops writing data into the RxFIFO as long as conditions of restart are not met. When there is enough room into the RxFIFO, and the OVR flag is cleared, the block starts by writing next the right channel into the RxFIFO if the overrun occurred when a right channel data was received or by writing the next left channel if the overrun occurred when a left channel data was received.
An interrupt may be generated if the OVRIE bit is set in the SPI_IER register. The OVR bit is cleared by writing OVRC bit of SPI_IFCR register to 1.

When the block is configured in PCM mode, after an overrun error, the peripheral stops writing data into the RxFIFO as long as restart conditions are not met. When there is enough room in the RxFIFO, and the OVR flag is cleared, the next received data are written into the RxFIFO.

Note: An overrun situation can occur in master or slave mode. In master mode, when an overrun occurs, the WS, CK and MCK signal are not gated.

53.9.14 Frame error detection

When configured in slave mode, the SPI/I2S block detects two kinds of frame errors:

- A frame synchronization received while the shift-in or shift-out of the previous data is not completed (early frame error). This mode is selected with FIXCH = 0.
- A frame synchronization occurring at an unexpected position. This mode is selected with FIXCH = 1.

In slave mode, if the frame length provided by the external master device is different from 32 or 64 bits, the user has to set FIXCH to 0. As the SPI/I2S synchronize each transfer with the WS there is no misalignment risk, but in a noisy environment, if a glitch occurs in the CK signal, a sample may be affected and the application is not aware of this.

If the frame length provided by the external master device is equal to 32 or 64 bits, then the user can set FIXCH to 1 and adjust accordingly CHLEN. As the SPI/I2S synchronize each transfer with the WS there is still no misalignment risk, and if the amount of bit clock between each channel boundary is different from CHLEN, the frame error flag (TIFRE) is set to 1.

Figure 687 shows an example of frame error detection. The SPI/I2S block is in slave mode and the amount of bit clock periods for left channel are not enough to shift-in or shift-out the data. The figure shows that the on-going transfer is interrupted and the next one is started in order to remain aligned to the WS signal.
An interrupt can be generated if the TIFREIE bit is set. The frame error flag (TIFRE) is cleared by writing the TIFREC bit of the SPI_IFCR register to 1.

It is possible to extend the coverage of the frame error flag by setting the bit FIXCH to 1. When this bit is set to 1, then the SPI/I2S is expecting fixed channel lengths in slave mode. This means that the expected channel length can be 16 or 32 bits, according to CHLEN. As shown in Figure 688, in this mode the SPI/I2S block is able to detect if the WS signal is changing at the expected moment (too early or too late).

Note: Figure 687 and Figure 688 show the mechanism for the slave transmit mode, but this is also true for slave receive and slave full-duplex.

The frame error detection can be generally due to noisy environment disturbing the good reception of WS or CK signals.

Note: The SPI/I2S is not able to recover properly if an overrun and an early frame occur within the same frame. In this case the user has to disable and re-enable the SPI/I2S.

### 53.9.15 DMA Interface

The I2S/PCM mode shares the same DMA requests lines than the SPI function. There is a separated DMA channel for TX and RX paths. Each DMA channel can be enabled via RXDMAEN and TXDMAEN bits of SPI_CFG1 register.

In receive mode, the DMA interface is working as follow:
1. The hardware evaluates the RxFIFO level,
2. If the RxFIFO contains at least FTHLV samples, then FTHLV DMA requests are generated,
   – When the FTHLV DMA requests are completed, the hardware loops to step 1
3. If the RxFIFO contains less than FTHLV samples, no DMA request is generated, and the hardware loop to step 1

In transmit mode, the DMA interface is working as follow:
1. The hardware evaluates the TxFIFO level,
2. If the TxFIFO contains at least FTHLV empty locations, then FTHLV DMA requests are generated,
   – When the FTHLV DMA requests are completed, the hardware loops to step 1
3. If the TxFIFO contains less than FTHLV empty locations, no DMA request is generated, and the hardware loop to step 1
53.9.16 Programming examples

Master I2S Philips standard, transmit

This example shows how to program the interface for supporting the Philips I2S standard in master transmit mode, with a sampling rate of 48 kHz, using the master clock. The assumption taken is that SPI/I2S is receiving a kernel clock (i2s_clk) of 61.44 MHz from the clock controller of the circuit.

Start Procedure

1. Enable the bus interface clock (pclk or hclk), release the reset signal if needed in order to be able to program the SPI/I2S block.
2. Ensure that the SPI/I2S block receives properly a kernel frequency (at 61.44 MHz in this example).
3. Ensure that SPE is set to 0.
4. Program the clock generator in order to provide the MCK clock and to have a frame synchronization rate at exactly 48 kHz. So I2SDIV = 2, ODD = 1, and MCKOE = 1.
5. Program the serial interface protocol: CKPOL = 0, WSINV = 0, LSBFRST = 0, CHLEN = 1 (32 bits per channel) DATLEN = 1 (24 bits), I2SSTD = 0 (Philips Standard), I2SCFG = 2 (master transmit), I2SMOD = 1, for I2S/PCM mode. The register SPI_I2SCFGR must be updated before going to next steps.
6. Adjust the FIFO threshold, by setting the wanted value into FTHLV. For example if a threshold of 2 audio samples is required, FTHLV = 1.
7. Clear all status flag registers.
8. Enable the flags who shall generate an interrupt such as UDRIE. Note that TIFRE is not meaningful in master mode.
9. If the data transfer uses DMA:
   a) Program the DMA peripheral,
   b) Initialize the memory buffer with valid audio samples,
   c) Enable the DMA channel,
10. If the data transfer is done via interrupt, then the user has to enable the interrupt by setting the TXPIE bit to 1.
11. Set SPE to 1, as soon as this bit is set to one the following actions may happen:
    – If the interrupt generation is enabled, the SPI/I2S generates an interrupt request allowing the interrupt handler to fill-up the TxFIFO.
    – If the DMA transfer are enabled (TXDMAEN = 1), the SPI/I2S generates DMA requests in order to fill-up the TxFIFO
12. Finally, the user has to ensure that the TxFIFO is not empty before enabling the serial interface. This is important in order to avoid an underrun condition when the interface is enabled. Then the SPI/I2S block can be enabled by setting the bit CSTART to 1. CSTART bit is located into SPI_CR1 register.

Stop Procedure in master mode

1. Set the bit CSUSP to 1, in order to stop on-going transfers
2. Check the value of CSTART bit until it goes to 0
3. Stop DMA peripheral, bus clock...
4. Set bit SPE to 0 in order to disable the SPI/I2S block
Slave I2S Philips standard, receive

This example shows how to program the interface for supporting the I2S Philips standard protocol in slave receiver mode, with a sampling rate of 48 kHz. Note that in slave mode the SPI/I2S block cannot control the sample rate of the received samples. In this example we took the assumption that the external master device is delivering an I2S frame structure with a channel length of 24 bits. So we cannot use the capability offered for frame error detection when FIXCH is set to 1.

Procedure

1. Via the RCC block, enable the bus interface and the kernel clocks, assert and release the reset signal if needed.
2. Program the AFMUX in order to select the wanted I/Os. In the current example CK, WS, SDI.
3. Program the serial interface protocol: CKPOL = 0, WSINV = 0, LSBFRST = 0, FIXCH = 0 (because channel length is different from 16 and 32 bits), DATLExn = 0 (16 bits), I2SSTD = 0 (Philips protocol), I2SCFG = 1 (slave RX), I2SMOD = 1, for I2S mode.
4. Adjust the FIFO threshold, by setting the wanted value into FTHLV. For example if a threshold of 2 audio samples is required, FTHLV = 1.
5. Clear all status flag registers.
6. Enable the flags who shall generate an interrupt such as UDRIE and TIFRE.
7. If the data transfer uses DMA:
   – Program the DMA peripheral: one RX channel
   – Enable the DMA channel,
   – In the SPI/I2S block, enable the DMA by setting the RXDMAEN bit to 1.
8. If the data transfer is done via interrupt, then the user has to enable the interrupt by setting the RXPIE bit to 1.
9. Set SPE to 1.
10. Finally the user can set the bit CSTART to 1 in order to enable the serial interface. The SPI/I2S starts to store data into the RxFIFO on the next occurrence of left data transmitted by the external master device.

Stop Procedure in slave mode

1. Set bit SPE to 0 in order to disable the SPI/I2S block
2. Stop DMA peripheral, bus clock...
### 53.10 I2S wakeup and interrupts

In PCM/I2S mode an interrupt (**spi_it**) or a wakeup event signal (**spi_wkup**) can be generated according to the events described in the Table 441.

Interrupt events can be enabled and disabled separately.

#### Table 441. I2S interrupt requests

Bits 31:17 Reserved, must be kept at reset value.

- **Bit 16 IOLock**: locking the AF configuration of associated I/Os  
  - This bit is set by software and cleared by hardware whenever SPE bit is changed from 1 to 0.  
  - 0: AF configuration is not locked  
  - 1: AF configuration is locked  
  - When this bit is set, the SPI_CFG2 register content cannot be modified. This bit can be set when SPI is disabled only else it is write protected. It is cleared and cannot be set when the MODF bit is set.

- **Bit 15 TCRCINI**: CRC calculation initialization pattern control for transmitter  
  - 0: All zero pattern is applied  
  - 1: All ones pattern is applied

- **Bit 14 RCRCINI**: CRC calculation initialization pattern control for receiver  
  - 0: all zero pattern is applied  
  - 1: all ones pattern is applied

- **Bit 13 CRC33_17**: 32-bit CRC polynomial configuration  
  - 0: full size (33-bit or 17-bit) CRC polynomial is not used  
  - 1: full size (33-bit or 17-bit) CRC polynomial is used

- **Bit 12 SSI**: internal SS signal input level  
  - This bit has an effect only when the SSM bit is set. The value of this bit is forced onto the peripheral SS input and the I/O value of the SS pin is ignored.

- **Bit 11 HDDIR**: Rx/Tx direction at Half-duplex mode  
  - In Half-Duplex configuration the HDDIR bit establishes the Rx/Tx direction of the data transfer. This bit is ignored in Full-Duplex or any Simplex configuration.  
  - 0: SPI is Receiver  
  - 1: SPI is transmitter
Bit 10 **CSUSP**: master suspend request

This bit reads as zero.

In master mode, when this bit is set by software, CSTART bit is reset at the end of the current frame and communication is suspended. The user has to check SUSP flag to check end of the frame transaction.

The master mode communication must be suspended (using this bit or keeping TXDR empty) before disabling the SPI or going to low-power mode. This bit can be used in SPI or I2S mode.

After software suspension, the SUSP flag has to be cleared and the SPI disabled and re-enabled before any next transaction starts.

Bit 9 **CSTART**: master transfer start

This bit is set by software to start an SPI or I2S/PCM communication. In SPI mode, it is cleared by hardware when End Of Transfer (EOT) flag is set or when a transaction suspend request is accepted. In I2S/PCM mode, it is also cleared by hardware as described in the section stop sequence.

0: master transfer is at idle
1: master transfer is on-going or temporary suspended by automatic suspend

In SPI mode, the bit is taken into account at master mode only. If transmission is enabled, communication starts or continues only if any data is available in the transmission FIFO.

Bit 8 **MASRX**: master automatic SUSP in Receive mode

This bit is set and cleared by software to control continuous SPI transfer in master receiver mode and automatic management in order to avoid overrun condition.

0: SPI flow/clock generation is continuous, regardless of overrun condition. (data are lost)
1: SPI flow is suspended temporary on RxFIFO full condition, before reaching overrun condition. The SUSP flag is set when SPI communication is suspended.

When SPI communication is suspended by hardware automatically, it could happen that few bits of next frame are already clocked out due to internal synchronization delay.

That is why the automatic suspension is not quite reliable when size of data drops below 8 bits. In this case, a safe suspension can be achieved by combination with delay inserted between data frames applied when MIDI parameter keeps a non zero value; sum of data size and the interleaved SPI cycles must always produce interval at length of 8 SPI clock periods at minimum. After software clearing of the SUSP bit, the communication resumes and continues by subsequent bits transaction without any next constraint. Prior the SUSP bit is cleared, the user must release the RxFIFO space as much as possible by reading out all the data packets available at RxFIFO based on the RXP flag indication to prevent any subsequent suspension.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **SPE**: serial peripheral enable

This bit is set by and cleared by software.
0: serial peripheral disabled.
1: serial peripheral enabled

When SPE=1, the SPI data transfer is enabled, the configuration registers SPI_CFG1, SPI_CFG2, CRCPOLY and UDRDR and the IOLOCK bit in SPI_CR1 are write protected. They can be changed only when SPE=0.

When SPE=0 any SPI operation is stopped and disabled, all the not cleared requests with enabled interrupt stay pending and propagates the spi_plck clock request, the SS output is deactivated at master, internal state machine is reseted, all the FIFOs content is flushed, CRC calculation initialized, receive data register is read zero.

SPE is cleared and cannot be set when MODF error flag is active.
### 53.11.2 SPI control register 2 (SPI_CR2)

Address offset: 0x04  
Reset value: 0x0000 0000

TSIZE[15:0]

Bits 31:16  
**TSER[15:0]:** number of data transfer extension to be reload into TSIZE just when a previous number of data stored at TSIZE is transacted  
This register can be set by software when its content is cleared only. It is cleared by hardware once TSIZE reload is done. The TSER value must be programmed in advance before CTSIZE counter reaches zero otherwise the reload is not taken into account and traffic terminates with normal EOT event.

Bits 15:0  
**TSIZE[15:0]:** number of data at current transfer  
When these bits are changed by software, the SPI must be disabled. The field can be updated by hardware optionally, too, to be reloaded by the TSER value if applicable.  
Endless transaction is initialized when CSTART is set while zero value is stored at TSIZE. TSIZE cannot be set to 0xFFFF value when CRC is enabled.

### 53.11.3 SPI configuration register 1 (SPI_CFG1)

Address offset: 0x08  
Reset value: 0x0007 0007

*Content of this register is write protected when SPI is enabled, except TXDMAEN and RXDMAEN bits.*

Bit 31  
Reserved, must be kept at reset value.
Bits 30:28 **MBR[2:0]**: master baud rate
- 000: SPI master clock/2
- 001: SPI master clock/4
- 010: SPI master clock/8
- 011: SPI master clock/16
- 100: SPI master clock/32
- 101: SPI master clock/64
- 110: SPI master clock/128
- 111: SPI master clock/256

*Note: MBR setting is considered at slave working at TI mode, too (see Section 53.5.1: TI mode).*

Bits 27:23 Reserved, must be kept at reset value.

Bit 22 **CRCEN**: hardware CRC computation enable
- 0: CRC calculation disabled
- 1: CRC calculation Enabled

Bit 21 Reserved, must be kept at reset value.

Bits 20:16 **CRCSIZE[4:0]**: length of CRC frame to be transacted and compared
- Most significant bits are taken into account from polynomial calculation when CRC result is transacted or compared. The length of the polynomial is not affected by this setting.
- 00000: reserved
- 00001: reserved
- 00010: reserved
- 00011: 4-bits
- 00100: 5-bits
- 00101: 6-bits
- 00110: 7-bits
- 00111: 8-bits
- .....  
- 1101: 30-bits
- 1110: 31-bits
- 1111: 32-bits
- The value must be set equal or multiply of data size (DSIZE[4:0]). Its maximum size cannot exceed the DSIZE maximum at the instance.

*Note: If CRC calculation is disabled by CRCEN=0, the CRCSIZE field must be kept at its default setting.*

*Note: The most significant bit at CRCSIZE bit field is reserved at the peripheral instances where the data size is limited to 16-bit.*

Bit 15 **TXDMAEN**: Tx DMA stream enable
- 0: Tx DMA disabled
- 1: Tx DMA enabled

Bit 14 **RXDMAEN**: Rx DMA stream enable
- 0: Rx-DMA disabled
- 1: Rx-DMA enabled

Bit 13 Reserved, must be kept at reset value.
Bits 12:11 **UDRDET[1:0]**: detection of underrun condition at slave transmitter
- 00: underrun is detected at begin of data frame (no protection of 1-st bit)
- 01: underrun is detected at end of last data frame
- 10: underrun is detected by begin of active SS signal
- 11: reserved
For more details see *Figure 668: Optional configurations of slave behavior at detection of underrun condition*.

Bits 10:9 **UDRCFG[1:0]**: behavior of slave transmitter at underrun condition
- 00: slave sends a constant pattern defined by the user at SPI_UDRDR register
- 01: slave repeats lastly received data frame from master
- 10: slave repeats its lastly transmitted data frame
- 11: reserved
When slave is configured at transmit only mode (COMM[1:0]=01), slave repeats all zeros pattern at UDRCFG[1:0]=01 setting.
For more details see *Figure 668: Optional configurations of slave behavior at detection of underrun condition*.

Bits 8:5 **FTHLV[3:0]**: FIFO threshold level
Defines number of data frames at single data packet. The size of the packet must not exceed 1/2 of FIFO space.
- 0000: 1-data
- 0001: 2-data
- 0010: 3-data
- 0011: 4-data
- 0100: 5-data
- 0101: 6-data
- 0110: 7-data
- 0111: 8-data
- 1000: 9-data
- 1001: 10-data
- 1010: 11-data
- 1011: 12-data
- 1100: 13-data
- 1101: 14-data
- 1110: 15-data
- 1111: 16-data
SPI interface is more efficient if configured packet sizes are aligned with data register access parallelism:
- If SPI data register is accessed as a 16-bit register and DSIZE ≤ 8 bits, better to select FTHLV=2, 4, 6 ..
- If SPI data register is accessed as a 32-bit register and DSIZE>8bit, better to select FTHLV=2, 4, 6 .., while if DSIZE ≤ 8 bits, better to select FTHLV = 4, 8, 12 ..
Bits 4:0 **DSIZE[4:0]**: number of bits in at single SPI data frame

- 00000: not used
- 00001: not used
- 00010: not used
- 00011: 4-bits
- 00100: 5-bits
- 00101: 6-bits
- 00110: 7-bits
- 00111: 8-bits
- .....  
- 11101: 30-bits
- 11110: 31-bits
- 11111: 32-bits

*Note: The most significant bit at DSIZE bit field is reserved at the peripheral instances where data size is limited to 16-bit.*

### 53.11.4 SPI configuration register 2 (SPI_CFG2)

**Address offset**: 0x0C

**Reset value**: 0x0000 0000

*The content of this register is write protected when SPI is enabled or IOLOCK bit is set at SPI_CR1 register.*

**Bit 31** **AFCNTR**: alternate function GPIOs control

- This bit is taken into account when SPE=0 only
  0: the peripheral takes no control of GPIOs while it is disabled
  1: the peripheral keeps always control of all associated GPIOs

When SPI master has to be disabled temporary for a specific configuration reason (e.g. CRC reset, CPHA or HDDIR change) setting this bit prevents any glitches on the associated outputs configured at alternate function mode by keeping them forced at state corresponding the current SPI configuration. This bit must be never used at slave mode as any slave transmitter must not force its MISO output once the SPI is disabled.

*Note: This bit can be also used in PCM and I2S modes.*

**Bit 30** **SSOM**: SS output management in master mode

- This bit is taken into account in master mode when SSOE is enabled. It allows to configure SS output between two consecutive data transfers.
  0: SS is kept at active level till data transfer is completed, it becomes inactive with EOT flag
  1: SPI data frames are interleaved with SS non active pulses when MIDI[3:0]>1
### Serial peripheral interface (SPI)

#### Bit 29 SSOE: SS output enable
- **This bit is taken into account at master mode only**
- 0: SS output is disabled and the SPI can work in multimaster configuration
- 1: SS output is enabled. The SPI cannot work in a multimaster environment. It forces the SS pin at inactive level after the transfer is completed or SPI is disabled with respect to SSOM, MIDI, MSSI, SSIOP bits setting

#### Bit 28 SSIOP: SS input/output polarity
- 0: low level is active for SS signal
- 1: high level is active for SS signal

#### Bit 27 Reserved, must be kept at reset value.

#### Bit 26 SSM: software management of SS signal input
- 0: SS input value is determined by the SS PAD
- 1: SS input value is determined by the SSI bit
- When master uses hardware SS output (SSM=0 and SSOE=1), the SS signal input is forced to non active state internally to prevent master mode fault error.

#### Bit 25 CPOL: clock polarity
- 0: SCK signal is at 0 when idle
- 1: SCK signal is at 1 when idle

#### Bit 24 CPHA: clock phase
- 0: the first clock transition is the first data capture edge
- 1: the second clock transition is the first data capture edge

#### Bit 23 LSBFRST: data frame format
- 0: MSB transmitted first
- 1: LSB transmitted first

*Note: This bit can be also used in PCM and I2S modes.*

#### Bit 22 MASTER: SPI master
- 0: SPI Slave
- 1: SPI Master

#### Bits 21:19 SP[2:0]: Serial protocol
- 000: SPI Motorola
- 001: SPI TI
- others: Reserved, must not be used

#### Bits 18:17 COMM[1:0]: SPI communication mode
- 00: full-duplex
- 01: simplex transmitter
- 10: simplex receiver
- 11: half-duplex

#### Bit 16 Reserved, must be kept at reset value.

#### Bit 15 IOSWP: swap functionality of MISO and MOSI pins
- 0: no swap
- 1: MOSI and MISO are swapped
- When this bit is set, the function of MISO and MOSI pins alternate functions are inverted.
- Original MISO pin becomes MOSI and original MOSI pin becomes MISO.

*Note: This bit can be also used in PCM and I2S modes.*

#### Bits 14:8 Reserved, must be kept at reset value.
Bits 7:4 **MIDI[3:0]:** master Inter-Data Idleness  
Specifies minimum time delay (expressed in SPI clock cycles periods) inserted between two consecutive data frames in master mode.  
0000: no delay  
0001: 1 clock cycle period delay  
...  
1111: 15 clock cycle periods delay  
*Note: This feature is not supported in TI mode.*  

Bits 3:0 **MSSI[3:0]:** master SS idleness  
Specifies an extra delay, expressed in number of SPI clock cycle periods, inserted additionally between active edge of SS and first data of a session start in master mode when SSOE is enabled.  
0000: no extra delay  
0001: 1 clock cycle period delay added  
...  
1111: 15 clock cycle periods delay added  
*Note: This feature is not supported in TI mode.*

   0: EOT/SUSP/TXC interrupt disabled
   1: EOT/SUSP/TXC interrupt enabled

Bit 2 **DXPIE**: DXP interrupt enabled
   DXPIE is set by software and cleared by TXTF flag set event.
   0: DXP interrupt disabled
   1: DXP interrupt enabled

Bit 1 **TXPIE**: TXP interrupt enable
   TXPIE is set by software and cleared by TXTF flag set event.
   0: TXP interrupt disabled
   1: TXP interrupt enabled

Bit 0 **RXPIE**: RXP Interrupt Enable
   0: RXP interrupt disabled
   1: RXP interrupt enabled

### 53.11.6 SPI/I2S status register (SPI_SR)

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bits 31:16 CTSIZE[15:0]: number of data frames remaining in current TSIZE session
The value is not quite reliable when traffic is ongoing on bus and at LP mode too.

Bit 15 **RXWNE**: RxFIFO word not empty
   0: less than four bytes of RxFIFO space is occupied by data
   1: at least four bytes of RxFIFO space is occupied by data

Note: *This bit value does not depend on DSIZE setting and keeps together with RXPLVL[1:0] information about RxFIFO occupancy by residual data.*
Bits 14:13  **RXPLVL[1:0]:** RxFIFO packing level

When RXWNE=0 and data size is set up to 16-bit, the value gives number of remaining data frames persisting at RxFIFO.

- 00: no next frame is available at RxFIFO
- 01: 1 frame is available
- 10: 2 frames are available*
- 11: 3 frames are available*

(*) optional count when the data size is set up to 8-bit.

When the frame size is greater than 16-bit, these bits read as 00. In consequence, the single data frame received at the FIFO cannot be detected neither by RWNE nor by RXPLVL bits if data size is set from 17 to 24 bits. The user then must apply other methods like TSIZE>0 or FTHLV=0.

Bit 12  **TXC:** TxFIFO transmission complete

The flag behavior depends on TSIZE setting.

When TSIZE=0 the TXC is changed by hardware exclusively and it raises each time the TxFIFO becomes empty and there is no activity on the bus.

If TSIZE <>0 there is no specific reason to monitor TXC as it just copies the EOT flag value including its software clearing. The TXC generates an interrupt when EOTIE is set.

- 0: Current data transaction is still ongoing, data is available in TxFIFO or last frame transmission is on going.
- 1: Last TxFIFO frame transmission completed

Bit 11  **SUSP:** suspension status

In Master mode, SUSP is set by hardware when a CSUSP request is done, either as soon as the current frame is completed after CSUSP request is done or at master automatic suspend receive mode (MASRX bit is set at SPI_CR1 register) on RxFIFO full condition. SUSP generates an interrupt when EOTIE is set.

This bit has to be cleared prior SPI is disabled by write 1 to SUSPC bit at SPI_IFCR

- 0: SPI not suspended (master mode active or other mode).
- 1: Master mode is suspended (current frame completed)

Bit 10  **TSERF:** additional number of SPI data to be transacted was reload

This bit is cleared by write 1 to TSERFC bit at SPI_IFCR or by writing the TSER[15:0] (SPI_CR2) register

- 0: no acceptance
- 1: additional number of data accepted, current transaction continues

Bit 9  **MODF:** mode fault

- 0: no mode fault
- 1: mode fault detected

This bit is cleared by write 1 to MODFC bit at SPI_IFCR. When MODF is set, the SPE and IOLOCK bits at the SPI_CR1 register are reset and their setting is blocked.

Bit 8  **TIFRE:** TI frame format error

- 0: no TI Frame Error
- 1: TI Frame Error detected

This bit is cleared by write 1 to TIFREC bit at SPI_IFCR

Bit 7  **CRCE:** CRC error

- 0: no CRC error
- 1: CRC error detected

This bit is cleared by write 1 to CRCEC bit at SPI_IFCR
Bit 6 **OVR**: overrun
0: no overrun
1: overrun detected
This bit is cleared by write 1 to OVRC bit at SPI_IFCR

Bit 5 **UDR**: underrun
0: no underrun
1: underrun detected
This bit is cleared by write 1 to UDRC bit at SPI_IFCR

Note: In SPI mode, the UDR flag applies to Slave mode only. In I2S/PCM mode, (when available) this flag applies to Master and Slave mode.

Bit 4 **TXTF**: transmission transfer filled
0: upload of TxFIFO is on-going or not started
1: TxFIFO upload is finished
TXTF is set by hardware as soon as all of the data packets in a transfer have been submitted for transmission by application software or DMA, that is when TSIZE number of data have been pushed into the TxFIFO.
This bit is cleared by software write 1 to TXTFC bit at SPI_IFCR
TXTF flag triggers an interrupt if TXTFIE bit is set.
TXTF setting clears the TXIE and DXPIE masks so to off-load application software from calculating when to disable TXP and DXP interrupts.

Bit 3 **EOT**: end of transfer
EOT is set by hardware as soon as a full transfer is complete, that is when TSIZE number of data have been transmitted and/or received on the SPI. EOT is cleared by software write 1 to EOTC bit at SPI_IFCR.
EOT flag triggers an interrupt if EOTIE bit is set.
If DXP flag is used until TXTF flag is set and DXPIE is cleared, EOT can be used to download the last packets contained into RxFIFO in one-shot.
0: transfer is on-going or not started
1: transfer complete
In master, EOT event terminates the data transaction and handles SS output optionally. When CRC is applied, the EOT event is extended over the CRC frame transaction.

Bit 2 **DXP**: duplex packet
0: TxFIFO is Full and/or RxFIFO is Empty
1: Both TxFIFO has space for write and RxFIFO contains for read a single packet at least
The DXP flag is set whenever both TXP and RXP flags are set regardless the SPI mode.

Bit 1 **TXP**: Tx-packet space available
0: there is not enough space to locate next data packet at TxFIFO
1: TxFIFO has enough free location to host 1 data packet
TXP flag is changed by hardware. It monitors overall space currently available at TxFIFO if SPI is enabled. It has to be checked once a complete data packet is stored at TxFIFO.

Bit 0 **RXP**: Rx-packet available
0: RxFIFO is empty or a not complete data packet is received
1: RxFIFO contains at least 1 data packet
RXP flag is changed by hardware. It monitors number of overall data currently available at RxFIFO if SPI is enabled. It has to be checked once a data packet is completely read out from RxFIFO.
53.11.7  SPI/I2S interrupt/status flags clear register (SPI_IFCR)

Bits 31:0 **TXDR[31:0]**: transmit data register

The register serves as an interface with TxFIFO. A write to it accesses TxFIFO.

Note: data is always right-aligned. Unused bits are ignored when writing to the register, and read as zero when the register is read.

Note: DR can be accessed byte-wise (8-bit access): in this case only one data-byte is written by single access.

halfword-wise (16 bit access) in this case 2 data-bytes or 1 halfword-data can be written by single access.

word-wise (32 bit access). In this case 4 data-bytes or 2 halfword-data or word-data can be written by single access.

Write access of this register less than the configured data size is forbidden.

Bits 31:0 **RXDR[31:0]**: receive data register

The register serves as an interface with RxFIFO. When it is read, RxFIFO is accessed.

Note: Data is always right-aligned. Unused bits are read as zero when the register is read.

Writing to the register is ignored.

Note: DR can be accessed byte-wise (8-bit access): in this case only one data-byte is read by single access.

halfword-wise (16 bit access) in this case 2 data-bytes or 1 halfword-data can be read by single access.

word-wise (32 bit access). In this case 4 data-bytes or 2 halfword-data or word-data can be read by single access.

Read access of this register less than the configured data size is forbidden.
53.11.10 SPI polynomial register (SPI_CRCPOLY)

Address offset: 0x40  
Reset value: 0x0000 0107  
The content of this register is write protected when SPI is enabled.

</tbody>
</table>

Bits 31-0 CRCPOLY[31:0]: CRC polynomial register  
This register contains the polynomial for the CRC calculation.  
The default 9-bit polynomial setting 0x107 corresponds to default 8-bit setting of DSIZE. It is compatible with setting 0x07 used at some other ST products with fixed length of the polynomial string where the most significant bit of the string is always kept hidden.  
The length of the polynomial is given by the most significant bit of the value stored at this register. It has to be set greater than DSIZE. CRC33_17 bit has to be set additionally with CRCPOLY register when DSIZE is configured to maximum 32-bit or 16-bit size and CRC is enabled (to keep polynomial length greater than data size).  
Bits 31-16 are reserved at the peripheral instances with data size limited to 16-bit. There is no constrain when 32-bit access is applied at these addresses. Reserved bits 31-16 are always read zero while any write to them is ignored.

</tbody>
</table>
Bits 31:0 **TXCRC[31:0]**: CRC register for transmitter

When CRC calculation is enabled, the TXCRC[31:0] bits contain the computed CRC value of the subsequently transmitted bytes. CRC calculation is initialized when the CRCEN bit of SPI_CR1 is written to 1 or when a data block is transacted completely. The CRC is calculated serially using the polynomial programmed in the SPI_CRCPOLY register.

The number of bits considered at calculation depends on SPI_CRCPOLY register and CRCSIZE bits settings at SPI_CFG1 register.

**Note:** A read to this register when the communication is ongoing could return an incorrect value.

Not used for the I²S mode.

Bits 31-16 are reserved at the peripheral instances with data size limited to 16-bit. There is no constrain when 32-bit access is applied at these addresses. Reserved bits 31-16 are always read zero while any write to them is ignored.

**Note:** The configuration of CRCSIZE bit field is not taken into account when the content of this register is read by software. No masking is applied for unused bits at this case.

Bits 31:0 **RXCRC[31:0]**: CRC register for receiver

When CRC calculation is enabled, the RXCRC[31:0] bits contain the computed CRC value of the subsequently received bytes. CRC calculation is initialized when the CRCEN bit of SPI_CR1 is written to 1 or when a data block is transacted completely. The CRC is calculated serially using the polynomial programmed in the SPI_CRCPOLY register.

The number of bits considered at calculation depends on SPI_CRCPOLY register and CRCSIZE bits settings at SPI_CFG1 register.

**Note:** A read to this register when the communication is ongoing could return an incorrect value.

Not used for the I²S mode.

Bits 31-16 are reserved at the peripheral instances with data size limited to 16-bit. There is no constrain when 32-bit access is applied at these addresses. Reserved bits 31-16 are always read zero while any write to them is ignored.

**Note:** The configuration of CRCSIZE bit field is not taken into account when the content of this register is read by software. No masking is applied for unused bits at this case.
53.11.13  SPI underrun data register (SPI_UDRDR)

Address offset: 0x4C
Reset value: 0x0000 0000
The content of this register is write protected when SPI is enabled.

Bits 31:0  **UDRDR[31:0]**: data at slave underrun condition
The register is taken into account at slave mode and at underrun condition only. The number of bits considered depends on DSIZE bit settings at SPI_CFG1 register. Underrun condition handling depends on setting if UDRDET and UDRCFG bits at SPI_CFG1 register. Bits 31-16 are reserved at the peripheral instances with data size limited to 16-bit. There is no constrain when 32-bit access is applied at these addresses. Reserved bits 31-16 are always read zero while any write to them is ignored.

53.11.14  SPI/I2S configuration register (SPI_I2SCFGR)

Address offset: 0x50
Reset value: 0x0000 0000

*Note:*  *All documented bits in this register must be configured when the I2S is disabled (SPE = 0). These bits are not used in SPI mode except for I2SMOD which needs to be kept at 0 in SPI mode.*

Bits 31:26  Reserved, must be kept at reset value.
Bit 25  **MCKOE**: master clock output enable
0: Master clock output is disabled
1: Master clock output is enabled

Bit 24  **ODD**: odd factor for the prescaler
0: Real divider value is = I2SDIV *2
1: Real divider value is = (I2SDIV * 2) + 1
Refer to *Section 53.9.9: Clock generator* for details
### Bits 23:16 I2SDIV[7:0]: \(^{2}\)S linear prescaler

I2SDIV can take any values except the value 1, when ODD is also equal to 1. Refer to Section 53.9.9: Clock generator for details

- Bit 15 Reserved, must be kept at reset value.

- Bit 14 DATFMT: data format
  - 0: the data inside the SPI_RXDR or SPI_TXDR are right aligned
  - 1: the data inside the SPI_RXDR or SPI_TXDR are left aligned.

- Bit 13 WSINV: Word select inversion
  - This bit is used to invert the default polarity of WS signal.
  - 0: In I2S Philips standard, the left channel transfer starts one CK cycle after the WS falling edge, and the right channel one CK cycle after the WS rising edge.
  - In MSB or LSB justified mode, the left channel is transferred when WS is HIGH, and the right channel when WS is LOW.
  - In PCM mode, the data transfer starts one CK cycle after the rising edge of WS.
  - 1: In I2S Philips standard, the left channel transfer starts one CK cycle after the WS rising edge, and the right channel one CK cycle after the WS falling edge.
  - In MSB or LSB justified mode, the left channel is transferred when WS is LOW, and right channel when WS is HIGH.
  - In PCM mode, the data transfer starts one CK cycle after the rising edge of WS.

- Bit 12 FIXCH: fixed channel length in slave
  - 0: the channel length in slave mode is different from 16 or 32 bits (CHLEN not taken into account)
  - 1: the channel length in slave mode is supposed to be 16 or 32 bits (according to CHLEN)

- Bit 11 CKPOL: serial audio clock polarity
  - 0: the signals generated by the SPI/I2S (i.e. SDO and WS) are changed on the falling edge of CK and the signals received by the SPI/I2S (i.e. SDI and WS) are read of the rising edge of CK.
  - 1: the signals generated by the SPI/I2S (i.e. SDO and WS) are changed on the rising edge of CK and the signals received by the SPI/I2S (i.e. SDI and WS) are read of the falling edge of CK.

- Bit 10 CHLEN: channel length (number of bits per audio channel)
  - 0: 16-bit wide
  - 1: 32-bit wide
  - The selected channel length must always be higher or equal to the data length (DATLEN).

- Bits 9:8 DATLEN[1:0]: data length to be transferred
  - 00: 16-bit data length
  - 01: 24-bit data length
  - 10: 32-bit data length
  - 11: not allowed
  - The selected data length must never be higher than the channel length (CHLEN).

*Note: Data width of 24 and 32 bits are not always supported, (DATLEN = 01 or 10), refer to Section 53.3: SPI implementation to check the supported data size.*

- Bit 7 PCMSYNC: PCM frame synchronization
  - 0: short frame synchronization
  - 1: long frame synchronization

- Bit 6 Reserved, must be kept at reset value.
Bits 5:4  **I2STD[1:0]:** I2S standard selection
- 00: I2S Philips standard.
- 01: MSB justified standard (left justified)
- 10: LSB justified standard (right justified)
- 11: PCM standard

For more details on I2S standards, refer to *Section 53.9.5: Supported audio protocols*

Bits 3:1  **I2SCFG[2:0]:** I2S configuration mode
- 000: slave - transmit
- 001: slave - receive
- 010: master - transmit
- 011: master - receive
- 100: slave - full duplex
- 101: master - full duplex
- others, not used

Bit 0  **I2SMOD:** I2S mode selection
- 0: SPI mode is selected
- 1: I2S/PCM mode is selected

Refer to Section 2.3 on page 134 for the register boundary addresses.
54 Serial audio interface (SAI)

54.1 Introduction

The SAI interface (serial audio interface) offers a wide set of audio protocols due to its flexibility and wide range of configurations. Many stereo or mono audio applications may be targeted. I2S standards, LSB or MSB-justified, PCM/DSP, TDM, and AC’97 protocols may be addressed for example. SPDIF output is offered when the audio block is configured as a transmitter.

To bring this level of flexibility and reconfigurability, the SAI contains two independent audio subblocks. Each block has its own clock generator and I/O line controller.

The SAI works in master or slave configuration. The audio subblocks are either receiver or transmitter and work synchronously or not (with respect to the other one).

The SAI can be connected with other SAIs to work synchronously.

54.2 SAI main features

- Two independent audio subblocks which can be transmitters or receivers with their respective FIFO.
- 8-word integrated FIFOs for each audio subblock.
- Synchronous or asynchronous mode between the audio subblocks.
- Possible synchronization between multiple SAIs.
- Master or slave configuration independent for both audio subblocks.
- Clock generator for each audio block to target independent audio frequency sampling when both audio subblocks are configured in master mode.
- Data size configurable: 8-, 10-, 16-, 20-, 24-, 32-bit.
- Audio protocol: I2S, LSB or MSB-justified, PCM/DSP, TDM, AC’97
- PDM interface, supporting up to 4 microphone pairs
- SPDIF output available if required.
- Up to 16 slots available with configurable size.
- Number of bits by frame can be configurable.
- Frame synchronization active level configurable (offset, bit length, level).
- First active bit position in the slot is configurable.
- LSB first or MSB first for data transfer.
- Mute mode.
- Stereo/Mono audio frame capability.
- Communication clock strobing edge configurable (SCK).
- Error flags with associated interrupts if enabled respectively.
  - Overrun and underrun detection,
  - Anticipated frame synchronization signal detection in slave mode,
  - Late frame synchronization signal detection in slave mode,
  - Codec not ready for the AC’97 mode in reception.
• Interrupt sources when enabled:
  – Errors,
  – FIFO requests.
• 2-channel DMA interface.

54.4 SAI functional description

54.4.1 SAI block diagram

Figure 689 shows the SAI block diagram while Table 444 and Table 445 list SAI internal and external signals.
1. These signals might not be available for all SAI instances. Refer to Section 54.3: SAI implementation for details.

The SAI is mainly composed of two audio subblocks with their own clock generator. Each audio block integrates a 32-bit shift register controlled by their own functional state machine. Data are stored or read from the dedicated FIFO. FIFO may be accessed by the CPU, or by DMA in order to leave the CPU free during the communication. Each audio block is independent. They can be synchronous with each other.

An I/O line controller manages a set of 4 dedicated pins (SD, SCK, FS, MCLK) for a given audio block in the SAI. Some of these pins can be shared if the two subblocks are declared as synchronous to leave some free to be used as general purpose I/Os. The MCLK pin can be output, or not, depending on the application, the decoder requirement and whether the audio block is configured as the master.

If one SAI is configured to operate synchronously with another one, even more I/Os can be freed (except for pins SD_x).

The functional state machine can be configured to address a wide range of audio protocols. Some registers are present to set-up the desired protocols (audio frame waveform generator).

The audio subblock can be a transmitter or receiver, in master or slave mode. The master mode means the SCK_x bit clock and the frame synchronization signal are generated from the SAI, whereas in slave mode, they come from another external or internal master. There is a particular case for which the FS signal direction is not directly linked to the master or slave mode definition. In AC’97 protocol, it is an SAI output even if the SAI (link controller) is set-up to consume the SCK clock (and so to be in Slave mode).
54.4.2 SAI pins and internal signals

Each audio subblock of the SAI can be configured to be master or slave via MODE bits in the SAI_xCR1 register of the selected audio block.

Master mode

In master mode, the SAI delivers the timing signals to the external connected device:

- The bit clock and the frame synchronization are output on pin SCK_x and FS_x, respectively.
- If needed, the SAI can also generate a master clock on MCLK_x pin.

Both SCK_x, FS_x and MCLK_x are configured as outputs.
Slave mode
The SAI expects to receive timing signals from an external device.

- If the SAI subblock is configured in asynchronous mode, then SCK_x and FS_x pins are configured as inputs.
- If the SAI subblock is configured to operate synchronously with another SAI interface or with the second audio subblock, the corresponding SCK_x and FS_x pins are left free to be used as general purpose I/Os.

In slave mode, MCLK_x pin is not used and can be assigned to another function.
It is recommended to enable the slave device before enabling the master.

Configuring and enabling SAI modes
Each audio subblock can be independently defined as a transmitter or receiver through the MODE bit in the SAI_xCR1 register of the corresponding audio block. As a result, SAI_SD_x pin is respectively configured as an output or an input.

Two master audio blocks in the same SAI can be configured with two different MCLK and SCK clock frequencies. In this case they have to be configured in asynchronous mode.

Each of the audio blocks in the SAI are enabled by SAIEN bit in the SAI_xCR1 register. As soon as this bit is active, the transmitter or the receiver is sensitive to the activity on the clock line, data line and synchronization line in slave mode.

In master TX mode, enabling the audio block immediately generates the bit clock for the external slaves even if there is no data in the FIFO. However FS signal generation is conditioned by the presence of data in the FIFO. After the FIFO receives the first data to transmit, this data is output to external slaves. If there is no data to transmit in the FIFO, 0 values are then sent in the audio frame with an underrun flag generation.

In slave mode, the audio frame starts when the audio block is enabled and when a start of frame is detected.

In Slave TX mode, no underrun event is possible on the first frame after the audio block is enabled, because the mandatory operating sequence in this case is:
1. Write into the SAI_xDR (by software or by DMA).
2. Wait until the FIFO threshold (FLH) flag is different from 0b000 (FIFO empty).
3. Enable the audio block in slave transmitter mode.

54.4.4 SAI synchronization mode
There are two levels of synchronization, either at audio subblock level or at SAI level.

Internal synchronization
An audio subblock can be configured to operate synchronously with the second audio subblock in the same SAI. In this case, the bit clock and the frame synchronization signals are shared to reduce the number of external pins used for the communication. The audio block configured in synchronous mode sees its own SCK_x, FS_x, and MCLK_x pins released back as GPIOs while the audio block configured in asynchronous mode is the one for which FS_x and SCK_x ad MCLK_x I/O pins are relevant (if the audio block is considered as master).
Typically, the audio block in synchronous mode can be used to configure the SAI in full duplex mode. One of the two audio blocks can be configured as a master and the other as slave, or both as slaves with one asynchronous block (corresponding SYNCEN[1:0] bits set to 00 in SAI_xCR1) and one synchronous block (corresponding SYNCEN[1:0] bits set to 01 in the SAI_xCR1).

Note: Due to internal resynchronization stages, PCLK APB frequency must be higher than twice the bit rate clock frequency.

External synchronization

The audio subblocks can also be configured to operate synchronously with another SAI. This can be done as follow:

1. The SAI, which is configured as the source from which the other SAI is synchronized, has to define which of its audio subblock is supposed to provide the FS and SCK signals to other SAI. This is done by programming SYNCOUT[1:0] bits.
2. The SAI which receives the synchronization signals, has to select which SAI provides the synchronization by setting the proper value on SYNCIN[1:0] bits. For each of the two SAI audio subblocks, the user must then specify if it operates synchronously with the other SAI via the SYNCEN bit.

Note: SYNCIN[1:0] and SYNCOUT[1:0] bits are located into the SAI_GCR register, and SYNCEN bits into SAI_xCR1 register.

If both audio subblocks in a given SAI need to be synchronized with another SAI, it is possible to choose one of the following configurations:

- Configure each audio block to be synchronous with another SAI block through the SYNCEN[1:0] bits.
- Configure one audio block to be synchronous with another SAI through the SYNCEN[1:0] bits. The other audio block is then configured as synchronous with the second SAI audio block through SYNCEN[1:0] bits.

The following table shows how to select the proper synchronization signal depending on the SAI block used. For example SAI2 can select the synchronization from SAI1 by setting SAI2 SYNCIN to 0. If SAI1 wants to select the synchronization coming from SAI2, SAI1 SYNCIN must be set to 1. Positions noted as ‘Reserved’ must not be used.

54.4.5 Audio data size

The audio frame can target different data sizes by configuring bit DS[2:0] in the SAI_xCR1 register. The data sizes may be 8, 10, 16, 20, 24 or 32 bits. During the transfer, either the MSB or the LSB of the data are sent first, depending on the configuration of bit LSBFIRST in the SAI_xCR1 register.
54.4.6 Frame synchronization

The FS signal acts as the Frame synchronization signal in the audio frame (start of frame). The shape of this signal is completely configurable in order to target the different audio protocols with their own specificities concerning this Frame synchronization behavior. This reconfigurability is done using register SAI_xFRCR. Figure 690 illustrates this flexibility.

Figure 690. Audio frame

In AC’97 mode or in SPDIF mode (bit PRTCFG[1:0] = 10 or PRTCFG[1:0] = 01 in the SAI_xCR1 register), the frame synchronization shape is forced to match the AC’97 protocol. The SAI_xFRCR register value is ignored.

Each audio block is independent and consequently each one requires a specific configuration.

Frame length

- Master mode
  The audio frame length can be configured to up to 256 bit clock cycles, by setting FRL[7:0] field in the SAI_xFRCR register.

  If the frame length is greater than the number of declared slots for the frame, the remaining bits to transmit is extended to 0 or the SD line is released to Hi-z depending the state of bit TRIS in the SAI_xCR2 register (refer to FS signal role). In reception mode, the remaining bit is ignored.

  If bit NODIV is cleared, (FRL+1) must be equal to a power of 2, from 8 to 256, to ensure that an audio frame contains an integer number of MCLK pulses per bit clock cycle.

  If bit NODIV is set, the (FRL+1) field can take any value from 8 to 256. Refer to Section 54.4.8: SAI clock generator.

- Slave mode
  The audio frame length is mainly used to specify to the slave the number of bit clock cycles per audio frame sent by the external master. It is used mainly to detect from the master any anticipated or late occurrence of the Frame synchronization signal during an ongoing audio frame. In this case an error is generated. For more details refer to Section 54.4.14: Error flags.

  In slave mode, there are no constraints on the FRL[7:0] configuration in the SAI_xFRCR register.

  The number of bits in the frame is equal to FRL[7:0] + 1.

  The minimum number of bits to transfer in an audio frame is 8.
Frame synchronization polarity

FSPOL bit in the SAI_xFRCR register sets the active polarity of the FS pin from which a frame is started. The start of frame is edge sensitive.

In slave mode, the audio block waits for a valid frame to start transmitting or receiving. Start of frame is synchronized to this signal. It is effective only if the start of frame is not detected during an ongoing communication and assimilated to an anticipated start of frame (refer to Section 54.4.14: Error flags).

In master mode, the frame synchronization is sent continuously each time an audio frame is complete until the SAIEN bit in the SAI_xCR1 register is cleared. If no data are present in the FIFO at the end of the previous audio frame, an underrun condition is managed as described in Section 54.4.14: Error flags, but the audio communication flow is not interrupted.

Frame synchronization active level length

The FSALL[6:0] bits of the SAI_xFRCR register enable the configuration of the length of the active level of the Frame synchronization signal. The length can be set from 1 to 128 bit clock cycles.

As an example, the active length can be half of the frame length in I2S, LSB or MSB-justified modes, or one-bit wide for PCM/DSP or TDM.

Frame synchronization offset

Depending on the audio protocol targeted in the application, the Frame synchronization signal can be asserted when transmitting the last bit or the first bit of the audio frame (this is the case in I2S standard protocol and in MSB-justified protocol, respectively). FSOFF bit in the SAI_xFRCR register enables to choose one of the two configurations.

FS signal role

The FS signal can have a different meaning depending on the FS function. FSDEF bit in the SAI_xFRCR register selects which meaning it has:

- 0: start of frame, like for instance the PCM/DSP, TDM, AC’97, audio protocols,
- 1: start of frame and channel side identification within the audio frame like for the I2S, the MSB or LSB-justified protocols.

When the FS signal is considered as a start of frame and channel side identification within the frame, the number of declared slots must be considered to be half the number for the left channel and half the number for the right channel. If the number of bit clock cycles on half audio frame is greater than the number of slots dedicated to a channel side, and TRIS = 0, 0 is sent for transmission for the remaining bit clock cycles in the SAI_xCR2 register. Otherwise if TRIS = 1, the SD line is released to HI-Z. In reception mode, the remaining bit clock cycles are not considered until the channel side changes.
Figure 691. FS role is start of frame + channel side identification (FSDEF = TRIS = 1)

1. The frame length must be even.

If FSDEF bit in SAI_xFRCR is kept clear, so FS signal is equivalent to a start of frame, and if the number of slots defined in NBSLOT[3:0] in SAI_xSLOTR multiplied by the number of bits by slot configured in SLOTSZ[1:0] in SAI_xSLOTR is less than the frame size (bit FRL[7:0] in the SAI_xFRCR register), then:

- if TRIS = 0 in the SAI_xCR2 register, the remaining bit after the last slot is forced to 0 until the end of frame in case of transmitter,
- if TRIS = 1, the line is released to HI-Z during the transfer of these remaining bits. In reception mode, these bits are discarded.
The FS signal is not used when the audio block in transmitter mode is configured to get the SPDIF output on the SD line. The corresponding FS I/O is released and left free for other purposes.

54.4.7 Slot configuration

The slot is the basic element in the audio frame. The number of slots in the audio frame is equal to \( NBSLOT[3:0] + 1 \).

The maximum number of slots per audio frame is fixed at 16.

For AC'97 protocol or SPDIF (when bit PRTCFG[1:0] = 10 or PRTCFG[1:0] = 01), the number of slots is automatically set to target the protocol specification, and the value of \( NBSLOT[3:0] \) is ignored.

Each slot can be defined as a valid slot, or not, by setting SLOTEN[15:0] bits of the SAI_xSLOTR register.

When a invalid slot is transferred, the SD data line is either forced to 0 or released to HI-Z depending on TRIS bit configuration (refer to Output data line management on an inactive slot) in transmitter mode. In receiver mode, the received value from the end of this slot is ignored. Consequently, there is no FIFO access and so no request to read or write the FIFO linked to this inactive slot status.

The slot size is also configurable as shown in Figure 693. The size of the slots is selected by setting SLOTSZ[1:0] bits in the SAI_xSLOTR register. The size is applied identically for each slot in an audio frame.
It is possible to choose the position of the first data bit to transfer within the slots. This offset is configured by FBOFF[4:0] bits in the SAI_xSLOTR register. 0 values are injected in transmitter mode from the beginning of the slot until this offset position is reached. In reception, the bit in the offset phase is ignored. This feature targets the LSB justified protocol (if the offset is equal to the slot size minus the data size).

It is mandatory to respect the following conditions to avoid bad SAI behavior:

- \( \text{FBOFF} \leq (\text{SLOTSZ} - \text{DS}) \),
- \( \text{DS} \leq \text{SLOTSZ} \),
- \( \text{NBSLOT} \times \text{SLOTSZ} \leq \text{FRL} \) (frame length),

The number of slots must be even when bit FSDEF in the SAI_xFRCR register is set.

In AC‘97 and SPDIF protocol (bit PRTCFG[1:0] = 10 or PRTCFG[1:0] = 01), the slot size is automatically set as defined in Section 54.4.11: AC‘97 link controller.
54.4.8 SAI clock generator

Each audio block has its own clock generator. The clock generator builds the master clock (MCLK_x) and bit clock (SCK_x) signals from the sai_x_ker_ck. The sai_x_ker_ck clock is delivered by the clock controller of the product (RCC).

Generation of the master clock (MCLK_x)

The clock generator provides the master clock (MCLK_x) when the audio block is defined as Master or Slave. The master clock is generated as soon as the MCKEN bit is set to 1 even if the SAIEN bit for the corresponding block is set to 0. This feature can be useful if the MCLK_x clock is used as system clock for an external audio device, since it enables the generation of the MCLK_x before activating the audio stream.

To generate a master clock on MCLK_x output before transferring the audio samples, the user application has to follow the sequence below:
1. Check that SAIEN = 0.
2. Program the MCKDIV[5:0] divider to the required value.
3. Set the MCKEN bit to 1.
4. Later, the application can configure other parts of the SAI, and sets the SAIEN bit to 1 to start the transfer of audio samples.

To avoid disturbances on the clock generated on MCLK_x output, the following operations are not recommended:
- Changing MCKDIV when MCKEN = 1
- Setting MCKEN to 0 if the SAIEN = 1

The SAI guarantees that there is no spurs on MCLK_x output when the MCLK_x is switched ON and OFF via MCKEN bit (with SAIEN = 0).

Table 447 shows MCLK_x activation conditions.

<table>
<thead>
<tr>
<th>MCLKEN</th>

</tr>
<tr>
<td>X</td>
<td>0</td>
<td></td>
<td>Enabled</td>
</tr>
</tbody>
</table>

Note: MCLK_x can also be generated in AC’97 mode, when MCLKEN is set to 1.
Generation of the bit clock (SCK_x)

The clock generator provides the bit clock (SCK_x) when the audio block is defined as Master. The frame synchronization (FS_x) is also derived from the signals provided by the clock generator.

In Slave mode, the value of NODIV and OSR fields are ignored, and the SCK_x clock is not generated.

The bit clock strobing edge of SCK_x can be configured through the CKSTR fields, which is functional both in master and slave mode.

*Figure 695* illustrates the architecture of the audio block clock generator.

![Figure 695. Audio block clock generator overview](image)

The NODIV bit must be used to force the ratio between the master clock (MCLK_x) and the frame synchronization (FS_x) frequency to 256 or 512.

- If NODIV is set to 0, the frequency ratio between the frame synchronization and the master clock is fixed to 512 or 256, according to OSR value, but the frame length must be a power of 2. More details are given hereafter.
- If NODIV is set to 1, the application can adjust the frequency of the bit clock (SCK_x) via MCKDIV. In addition there is no restriction on the frame length value as long as the frame length is bigger or equal to 8 (i.e. FRL[7:0] > 6). The frame synchronization frequency depends on MCKDIV and frame length (FRL[7:0]). In that case, the frequency of the MCLK_x is equal to the SCK_x.

The NODIV, MCKEN, SAIEN, OVR, CKSTR and MCKDIV[5:0] bits belong to the SAI_xCR1 register, while FRL[7:0] belongs to SAI_xFRCR.
Clock generator programming when NODIV = 0

In that case, MCLK\_x frequency is:

- \( F_{\text{MCLK\_x}} = 256 \times F_{\text{FS\_x}} \) if OSR = 0
- \( F_{\text{MCLK\_x}} = 512 \times F_{\text{FS\_x}} \) if OSR = 1

When MCKDIV is different from 0, MCLK\_x frequency is given by the formula below:

\[
F_{\text{MCLK\_x}} = \frac{F_{\text{sai\_x\_ker\_ck}}}{\text{MCKDIV}}
\]

The frame synchronization frequency is given by:

\[
F_{\text{FS\_x}} = \frac{F_{\text{sai\_x\_ker\_ck}}}{\text{MCKDIV} \times (\text{OSR} + 1) \times 256}
\]

The bit clock frequency (SCK\_x) is given by the following formula:

\[
F_{\text{SCK\_x}} = \frac{F_{\text{sai\_x\_ker\_ck}} \times (\text{FRL} + 1)}{\text{MCKDIV} \times (\text{OSR} + 1) \times 256}
\]

**Note:** When NODIV is equal to 0, \((\text{FRL} + 1)\) must be a power of two. In addition \((\text{FRL} + 1)\) must range between 8 and 256. \((\text{FRL} + 1)\) represents the number of bit clock in the audio frame.

When MCKDIV division ratio is odd, the MCLK duty cycle is not 50%. The bit clock signal (SCK\_x) can also have a duty cycle different from 50% if MCKDIV is odd, if OSR is equal to 0, and if \((\text{FRL} + 1) = 2^8\).

It is recommended, to program MCKDIV to an even value or to big values (higher than 10).

**Note that** MCKDIV = 0 gives the same result as MCKDIV = 1.

Clock generator programming when NODIV = 1

When MCKDIV is different from 0, the frequency of the bit clock (SCK\_x) is given in the formula below:

\[
F_{\text{SCK\_x}} = F_{\text{MCLK\_x}} = \frac{F_{\text{sai\_x\_ker\_ck}}}{\text{MCKDIV}}
\]

The frequency of the frame synchronization (FS\_x) is given by the following formula:

\[
F_{\text{FS\_x}} = \frac{F_{\text{sai\_x\_ker\_ck}}}{(\text{FRL} + 1) \times \text{MCKDIV}}
\]

**Note:** When NODIV is set to 1, \((\text{FRL} + 1)\) can take any values from 8 to 256.

**Note that** MCKDIV = 0 gives the same result as MCKDIV = 1.
54.4.9 Internal FIFOs

Each audio block in the SAI has its own FIFO. Depending if the block is defined to be a transmitter or a receiver, the FIFO can be written or read, respectively. There is therefore only one FIFO request linked to FREQ bit in the SAI_xSR register.

An interrupt is generated if FREQIE bit is enabled in the SAI_xIM register. This depends on:
- FIFO threshold setting (FLVL bits in SAI_xCR2)
- Communication direction (transmitter or receiver). Refer to Interrupt generation in transmitter mode and Interrupt generation in reception mode.

Interrupt generation in transmitter mode

The interrupt generation depends on the FIFO configuration in transmitter mode:
- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO empty (FTH[2:0] set to 0b000), an interrupt is generated (FREQ bit set by hardware to 1 in SAI_xSR register) if no data are available in SAI_xDR register (FLVL[2:0] bits in SAI_xSR is less than 001b). This Interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when the FIFO is no more empty (FLVL[2:0] bits in SAI_xSR are different from 0b000) i.e one or more data are stored in the FIFO.
- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO quarter full (FTH[2:0] set to 001b), an interrupt is generated (FREQ bit set by hardware to 1 in SAI_xSR register) if less than a quarter of the FIFO contains data (FLVL[2:0] bits in SAI_xSR is less than 0b010). This Interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when at least a quarter of the FIFO contains data (FLVL[2:0] bits in SAI_xSR are higher or equal to 0b010).
- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO half full (FTH[2:0] set to 0b010), an interrupt is generated (FREQ bit set by hardware to 1 in

1. N is an integer value between 3 and 8.
SAI_xSR register) if less than half of the FIFO contains data (FLVL[2:0] bits in SAI_xSR are less than 011b). This interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when at least half of the FIFO contains data (FLVL[2:0] bits in SAI_xSR are higher or equal to 011b).

- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO three quarter full (FTH[2:0] set to 011b), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI_xSR register) if less than three quarters of the FIFO contain data (FLVL[2:0] bits in SAI_xSR are less than 0b100). This interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when at least three quarters of the FIFO contain data (FLVL[2:0] bits in SAI_xSR are higher or equal to 0b100).

- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO full (FTH[2:0] set to 0b100), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI_xSR register) if the FIFO is not full (FLVL[2:0] bits in SAI_xSR is less than 101b). This interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when the FIFO is full (FLVL[2:0] bits in SAI_xSR is equal to 101b value).

**Interrupt generation in reception mode**

The interrupt generation depends on the FIFO configuration in reception mode:

- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO empty (FTH[2:0] set to 0b000), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI_xSR register) if at least one data is available in SAI_xDR register (FLVL[2:0] bits in SAI_xSR is higher or equal to 001b). This interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when the FIFO becomes empty (FLVL[2:0] bits in SAI_xSR is equal to 0b000) i.e no data are stored in FIFO.

- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO quarter full (FTH[2:0] set to 0b010), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI_xSR register) if at least one quarter of the FIFO data locations are available (FLVL[2:0] bits in SAI_xSR is higher or equal to 0b010). This interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when less than a quarter of the FIFO data locations become available (FLVL[2:0] bits in SAI_xSR is less than 0b010).

- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO half full (FTH[2:0] set to 0b100), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI_xSR register) if at least half of the FIFO data locations are available (FLVL[2:0] bits in SAI_xSR is higher or equal to 011b). This interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when less than half of the FIFO data locations become available (FLVL[2:0] bits in SAI_xSR is less than 011b).

- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO three quarter full (FTH[2:0] set to 0b11b), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI_xSR register) if at least three quarters of the FIFO data locations are available (FLVL[2:0] bits in SAI_xSR is higher or equal to 0b100). This interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when the FIFO has less than three quarters of the FIFO data locations available (FLVL[2:0] bits in SAI_xSR is less than 0b100).

- When the FIFO threshold bits in SAI_xCR2 register are configured as FIFO full (FTH[2:0] set to 0b100), an interrupt is generated (FREQ bit is set by hardware to 1 in SAI_xSR register) if the FIFO is full (FLVL[2:0] bits in SAI_xSR is equal to 101b). This interrupt (FREQ bit in SAI_xSR register) is cleared by hardware when the FIFO is not full (FLVL[2:0] bits in SAI_xSR is less than 101b).
Like interrupt generation, the SAI can use the DMA if DMAEN bit in the SAI_xCR1 register is set. The FREQ bit assertion mechanism is the same as the interrupt generation mechanism described above for FREQIE.

Each FIFO is an 8-word FIFO. Each read or write operation from/to the FIFO targets one word FIFO location whatever the access size. Each FIFO word contains one audio slot. FIFO pointers are incremented by one word after each access to the SAI_xDR register.

Data must be right aligned when it is written in the SAI_xDR.

Data received are right aligned in the SAI_xDR.

The FIFO pointers can be reinitialized when the SAI is disabled by setting bit FFLUSH in the SAI_xCR2 register. If FFLUSH is set when the SAI is enabled the data present in the FIFO are lost automatically.

54.4.10 PDM interface

The PDM (Pulse Density Modulation) interface is provided in order to support digital microphones. Up to 4 digital microphone pairs can be connected in parallel. Depending on product implementation, less microphones can be supported (refer to Section 54.3: SAI implementation).

Figure 696 shows a typical connection of a digital microphone pair via a PDM interface. Both microphones share the same bitstream clock and data line. Thanks to a configuration pin (LR), a microphone can provide valid data on SAI_CK[m] rising edge while the other provides valid data on SAI_CK[m] falling edge (m being the number of clock lines).

![Figure 696. PDM typical connection and timing](image)

1. \( n \) refers to the number of data lines and \( p \) to the number of microphone pairs.

The PDM function is intended to be used in conjunction with SAI_A subblock configured in TDM master mode. It cannot be used with SAI_B subblock. The PDM interface uses the timing signals provided by the TDM interface of SAI_A and adapts them to generate a bitstream clock (SAI_CK[m]).
The data processing sequence into the PDM is the following:

1. The PDM interface builds the bitstream clock from the bit clock received from the TDM interface of SAI_A.
2. The bitstream data received from the microphones (SAI_D[n]) are de-interleaved and go through a 7-bit delay line in order to fine-tune the delay of each microphone with the accuracy of the bitstream clock.
3. The shift registers translate each serial bitstream into bytes.
4. The last operation consists in shifting-out the resulting bytes to SAI_A via the serial data line of the TDM interface.

Figure 697 hereafter shows the block diagram of PDM interface, with a detailed view of a de-interleaver.

Note: The PDM interface does not embed the decimation filter required to build-up the PCM audio samples from the bitstream. It is up to the application software to perform this operation.

Figure 697. Detailed PDM interface block diagram

1. n refers to the number of data lines and p to the number of microphone pairs.
2. These signals might not be available in all SAI instances. Refer to Section 54.3: SAI implementation for details.

The PDM interface can be enabled through the PDMEN bit in SAI_PDMCR register. However the PDM interface must be enabled prior to enabling SAI_A block.

To reduce the memory footprint, the user can select the amount of microphones the application needs. This can be done through MICNBR[1:0] bits. It is possible to select
between 2, 4, 6 or 8 microphones. For example, if the application is using 3 microphones, the user has to select 4.

**Enabling the PDM interface**

To enable the PDM interface, follow the sequence below:

1. Configure SAI_A in TDM master mode (see Table 449).
2. Configure the PDM interface as follows:
   a) Define the number of digital microphones via MICNBR.
   b) Enable the bitstream clock needed in the application by setting the corresponding bits on CKEN to 1.
3. Enable the PDM interface, via PDMEN bit.
4. Enable the SAI_A.

**Note:** Once the PDM interface and SAI_A are enabled, the first 2 TDMA frames received on SAI_ADR are invalid and must be dropped.

**Start-up sequence**

*Figure 698* shows the start-up sequence: Once the PDM interface is enabled, it waits for the frame synchronization event prior to starting the acquisition of the microphone samples. After 8 SAI_CK clock periods, a data byte coming from each microphone is available, and transferred to the SAI, via the TDM interface.

**Figure 698. Start-up sequence**

**SAI_ADR data format**

The arrangement of the data coming from the microphone into the SAI_ADR register depends on the following parameters:

- The amount of microphones
- The slot width selected
- LSBFIRST bit.

The slot width defines the amount of significant bits into each word available into the SAI_ADR.
When a slot width of 32 bits is selected, each data available into the SAI_ADR contains 32 useful bits. This reduces the amount of words stored into the memory. However the counterpart is that the software has to perform some operations to de-interleave the data of each microphone.

In the other hand, when the slot width is set to 8 bits, each data available into the SAI_ADR contain 8 useful bits. This increases the amount of words stored into the memory. However, it offers the advantage to avoid extra processing since each word contains information from one microphone.

**SAI_ADR data format example**

- **32-bit slot width** (DS = 0b111 and SLOTSZ = 0). Refer to *Figure 699*.
  
  For an 8 microphone configuration, two consecutive words read from the SAI_ADR register contain a data byte from each microphone.
  
  For a 4 microphones configuration, each word read from the SAI_ADR register contains a data byte from each microphone.

*Figure 699. SAI_ADR format in TDM, 32-bit slot width*

- **16-bit slot width** (DS = 0b100 and SLOTSZ = 0). Refer to *Figure 700*.
  
  For an 8 microphone configuration, four consecutive words read from the SAI_ADR register contain a data byte from each microphone. Note that the 16-bit data of SAI_ADR are right aligned.
  
  For 4 or 2 microphone configuration, the SAI behavior is similar to 8-microphone configurations. Up to 2 words of 16 bits are required to acquire a byte from 4 microphones and a single word for 2 microphones.
**Using a 8-bit slot width** (DS = 0b010 and SLOTSZ = 0). Refer to *Figure 701*.

For an 8 microphone configuration, 8 consecutive words read from the SAI_ADR register contain a byte of data from each microphone. Note that the 8-bit data of SAI_ADR are right aligned.

For 4 or 2 microphone configuration, the SAI behavior is similar to 8 microphone configurations. Up to 4 words of 8 bits are required to acquire a byte from 4 microphones and 2 words from 2 microphones.
Figure 701. SAI_ADR format in TDM, 8-bit slot width

TDM configuration for PDM interface

SAI_A TDM interface is internally connected to the PDM interface to get the microphone samples. The user application must configure the PDM interface as shown in Table 449 to ensure a good connection with the PDM interface.

Adjusting the bitstream clock rate
To properly program the SAI TDM interface, the user application must take into account the settings given in Table 449, and follow the below sequence:

1. Adjust the bit clock frequency \( F_{SCK_A} \) according to the required frequency for the PDM bitstream clock, using the following formula:

\[
F_{SCK_A} = F_{PDM_CK} \times (MICNBR + 1) \times 2
\]

MICNBR can be 0,1,2 or 3 (0 = 2 microphones, see Section 54.6.18)

2. Set the frame length (FRL) using the following formula

\[
FRL = (16 \times (MICNBR + 1)) - 1
\]

3. Configure the slot size (DS) to a multiple of (FRL+1).

Adjusting the delay lines

When the PDM interface is enabled, the application can adjust on-the-fly the delay cells of each microphone input via SAI_PDMDLY register.

The new delays values become effective after two TDM frames.

---

1. Refer to Table 449: TDM settings for additional information on TDM configuration. The sai_a_ker_ck clock frequency provided to the SAI must be a multiple of the SCK_A frequency, and MCKDIV must be programmed accordingly.

2. The above sai_a_ker_ck frequencies are given as examples only. Refer to section Reset and clock controller (RCC) to check if they can be generated on the device.

3. The table above gives allowed settings for a decimation ratio of 64.

---

1. Refer to Table 449: TDM settings for additional information on TDM configuration. The sai_a_ker_ck clock frequency provided to the SAI must be a multiple of the SCK_A frequency, and MCKDIV must be programmed accordingly.

2. The above sai_a_ker_ck frequencies are given as examples only. Refer to section Reset and clock controller (RCC) to check if they can be generated on the device.

3. The table above gives allowed settings for a decimation ratio of 64.
54.4.11 AC’97 link controller

The SAI is able to work as an AC’97 link controller. In this protocol:

- The slot number and the slot size are fixed.
- The frame synchronization signal is perfectly defined and has a fixed shape.

To select this protocol, set PRTCFG[1:0] bits in the SAI_xCR1 register to 10. When AC’97 mode is selected, only data sizes of 16 or 20 bits can be used, otherwise the SAI behavior is not guaranteed.

- NBSLOT[3:0] and SLOTSZ[1:0] bits are consequently ignored.
- The number of slots is fixed to 13 slots. The first one is 16-bit wide and all the others are 20-bit wide (data slots).
- FBOFF[4:0] bits in the SAI_xSLOTR register are ignored.
- The SAI_xFRCR register is ignored.
- The MCLK is not used.

The FS signal from the block defined as asynchronous is configured automatically as an output, since the AC’97 controller link drives the FS signal whatever the master or slave configuration.

Figure 702 shows an AC’97 audio frame structure.

Figure 702. AC’97 audio frame

Note: In AC’97 protocol, bit 2 of the tag is reserved (always 0), so bit 2 of the TAG is forced to 0 level whatever the value written in the SAI FIFO.

For more details about tag representation, refer to the AC’97 protocol standard.

One SAI can be used to target an AC’97 point-to-point communication.

Using two SAIs (for devices featuring two embedded SAIs) enables the control of three external AC’97 decoders as illustrated in Figure 703.

In SAI1, the audio block A must be declared as asynchronous master transmitter whereas the audio block B is defined to be slave receiver and internally synchronous to the audio block A.

The SAI2 is configured for audio block A and B both synchronous with the external SAI1 in slave receiver mode.
In receiver mode, the SAI acting as an AC’97 link controller requires no FIFO request and so no data storage in the FIFO when the Codec ready bit in the slot 0 is decoded low. If bit CNRDYIE is enabled in the SAI_xIM register, flag CNRDY is set in the SAI_xSR register and an interrupt is generated. This flag is dedicated to the AC’97 protocol.

**Clock generator programming in AC’97 mode**

In AC’97 mode, the frame length is fixed at 256 bits, and its frequency must be set to 48 kHz. The formulas given in **Section 54.4.8: SAI clock generator** must be used with FRL = 255, in order to generate the proper frame rate (F_{FS_x}).
54.4.12 SPDIF output

The SPDIF interface is available in transmitter mode only. It supports the audio IEC60958. To select SPDIF mode, set PRTCFG[1:0] bit to 01 in the SAI_xCR1 register.

For SPDIF protocol:
- Only SD data line is enabled.
- FS, SCK, MCLK I/Os pins are left free.
- MODE[1] bit is forced to 0 to select the master mode in order to enable the clock generator of the SAI and manage the data rate on the SD line.
- The data size is forced to 24 bits. The value set in DS[2:0] bits in the SAI_xCR1 register is ignored.
- The clock generator must be configured to define the symbol-rate, knowing that the bit clock must be twice the symbol-rate. The data is coded in Manchester protocol.
- The SAI_xFRCR and SAI_xSLOTTR registers are ignored. The SAI is configured internally to match the SPDIF protocol requirements as shown in Figure 704.

Figure 704. SPDIF format

A SPDIF block contains 192 frames. Each frame is composed of two 32-bit sub-frames, generally one for the left channel and one for the right channel. Each sub-frame is composed of a SOPD pattern (4-bit) to specify if the sub-frame is the start of a block (and so is identifying a channel A) or if it is identifying a channel A somewhere in the block, or if it is referring to channel B (see Table 451). The next 28 bits of channel information are composed of 24 bits data + 4 status bits.
The data stored in SAI_xDR has to be filled as follows:

- SAI_xDR[26:24] contain the Channel status, User and Validity bits.
- SAI_xDR[23:0] contain the 24-bit data for the considered channel.

If the data size is 20 bits, then data must be mapped on SAI_xDR[23:4].
If the data size is 16 bits, then data must be mapped on SAI_xDR[23:8].
SAI_xDR[23] always represents the MSB.

**Figure 705. SAI_xDR register ordering**

Note: The transfer is performed always with LSB first.

The SAI first sends the adequate preamble for each sub-frame in a block. The SAI_xDR is then sent on the SD line (manchester coded). The SAI ends the sub-frame by transferring the Parity bit calculated as described in Table 452.

**Table 452. Parity bit calculation**

<table>
<thead>
<tr>
<th>SAI_xDR[26:0]</th>

</tr>
</thead>
<tbody>
<tr>
<td>odd number of 0</td>
<td>0</td>
</tr>
<tr>
<td>odd number of 1</td>
<td>1</td>
</tr>
</tbody>
</table>

The underrun is the only error flag available in the SAI_xSR register for SPDIF mode since the SAI can only operate in transmitter mode. As a result, the following sequence must be
executed to recover from an underrun error detected via the underrun interrupt or the underrun status bit:

1. Disable the DMA stream (via the DMA peripheral) if the DMA is used.
2. Disable the SAI and check that the peripheral is physically disabled by polling the SAIEN bit in SAI_xCR1 register.
3. Clear the COVRUNDR flag in the SAI_xCLRFR register.
4. Flush the FIFO by setting the FFLUSH bit in SAI_xCR2.
   The software needs to point to the address of the future data corresponding to a start of new block (data for preamble B). If the DMA is used, the DMA source base address pointer must be updated accordingly.
5. Enable again the DMA stream (DMA peripheral) if the DMA used to manage data transfers according to the new source base address.
6. Enable again the SAI by setting SAIEN bit in SAI_xCR1 register.

**Clock generator programming in SPDIF generator mode**

For the SPDIF generator, the SAI provides a bit clock twice faster as the symbol-rate. The table hereafter shows usual examples of symbol rates with respect to the audio sampling rate.

<table>
<thead>
<tr>
<th>Audio sampling frequencies ($F_S$)</th>
<th>Symbol-rate</th>
</tr>
</thead>
<tbody>
<tr>
<td>44.1 kHz</td>
<td>2.8224 MHz</td>
</tr>
<tr>
<td>48 kHz</td>
<td>3.072 MHz</td>
</tr>
<tr>
<td>96 kHz</td>
<td>6.144 MHz</td>
</tr>
<tr>
<td>192 kHz</td>
<td>12.288 MHz</td>
</tr>
</tbody>
</table>

More generally, the relationship between the audio sampling frequency ($F_S$) and the bit clock rate ($F_{SCK_x}$) is given by the formula:

$$F_S = \frac{F_{SCK_x}}{128}$$

The bit clock rate is obtained as follows:

$$F_{SCK_x} = \frac{F_{sai_x_ker_ck}}{MCKDIV}$$

**Note:** The above formulas are valid only if NODIV is set to 1 in SAI_ACR1 register.
54.4.13 Specific features

The SAI interface embeds specific features which can be useful depending on the audio protocol selected. These functions are accessible through specific bits of the SAI_xCR2 register.

Mute mode

The mute mode can be used when the audio subblock is a transmitter or a receiver.

Audio subblock in transmission mode

In transmitter mode, the mute mode can be selected at anytime. The mute mode is active for entire audio frames. The MUTE bit in the SAI_xCR2 register enables the mute mode when it is set during an ongoing frame.

The mute mode bit is strobed only at the end of the frame. If it is set at this time, the mute mode is active at the beginning of the new audio frame and for a complete frame, until the next end of frame. The bit is then strobed to determine if the next frame is still a mute frame.

If the number of slots set through NBSLOT[3:0] bits in the SAI_xSLOTR register is lower than or equal to 2, it is possible to specify if the value sent in mute mode is 0 or if it is the last value of each slot. The selection is done via MUTEVAL bit in the SAI_xCR2 register.

If the number of slots set in NBSLOT[3:0] bits in the SAI_xSLOTR register is greater than 2, MUTEVAL bit in the SAI_xCR2 is meaningless as 0 values are sent on each bit on each slot.

The FIFO pointers are still incremented in mute mode. This means that data present in the FIFO and for which the mute mode is requested are discarded.

Audio subblock in reception mode

In reception mode, it is possible to detect a mute mode sent from the external transmitter when all the declared and valid slots of the audio frame receive 0 for a given consecutive number of audio frames (MUTECNT[5:0] bits in the SAI_xCR2 register).

When the number of MUTE frames is detected, the MUTEDET flag in the SAI_xSR register is set and an interrupt can be generated if MUTEDETIE bit is set in SAI_xCR2.

The mute frame counter is cleared when the audio subblock is disabled or when a valid slot receives at least one data in an audio frame. The interrupt is generated just once, when the counter reaches the value specified in MUTECNT[5:0] bits. The interrupt event is then reinitialized when the counter is cleared.

Note: The mute mode is not available for SPDIF audio blocks.

Mono/stereo mode

In transmitter mode, the mono mode can be addressed, without any data preprocessing in memory, assuming the number of slots is equal to 2 (NBSLOT[3:0] = 0001 in SAI_xSLOTR).

In this case, the access time to and from the FIFO is reduced by 2 since the data for slot 0 is duplicated into data slot 1.

To enable the mono mode,

1. Set MONO bit to 1 in the SAI_xCR1 register.
2. Set NBSLOT to 1 and SLOTEN to 3 in SAI_xSLOTR.
In reception mode, the MONO bit can be set and is meaningful only if the number of slots is equal to 2 as in transmitter mode. When it is set, only slot 0 data are stored in the FIFO. The data belonging to slot 1 are discarded since, in this case, it is supposed to be the same as the previous slot. If the data flow in reception mode is a real stereo audio flow with a distinct and different left and right data, the MONO bit is meaningless. The conversion from the output stereo file to the equivalent mono file is done by software.

**Companding mode**

Telecommunication applications can require to process the data to be transmitted or received using a data companding algorithm.

Depending on the COMP[1:0] bits in the SAI_xCR2 register (used only when Free protocol mode is selected), the application software can choose to process or not the data before sending it on SD serial output line (compression) or to expand the data after the reception on SD serial input line (expansion) as illustrated in Figure 706. The two companding modes supported are the µ-Law and the A-Law log which are a part of the CCITT G.711 recommendation.

The companding standard used in the United States and Japan is the µ-Law. It supports 14 bits of dynamic range (COMP[1:0] = 10 in the SAI_xCR2 register).

The European companding standard is A-Law and supports 13 bits of dynamic range (COMP[1:0] = 11 in the SAI_xCR2 register).

Both µ-Law or A-Law companding standard can be computed based on 1’s complement or 2’s complement representation depending on the CPL bit setting in the SAI_xCR2 register.

In µ-Law and A-Law standards, data are coded as 8 bits with MSB alignment. Companded data are always 8-bit wide. For this reason, DS[2:0] bits in the SAI_xCR1 register are forced to 010 when the SAI audio block is enabled (SAIEN bit = 1 in the SAI_xCR1 register) and when one of these two companding modes selected through the COMP[1:0] bits.

If no companding processing is required, COMP[1:0] bits must be kept clear.
Expansion and compression mode are automatically selected through the SAI_xCR2:
- If the SAI audio block is configured to be a transmitter, and if the COMP[1] bit is set in the SAI_xCR2 register, the compression mode is applied.
- If the SAI audio block is declared as a receiver, the expansion algorithm is applied.

**Output data line management on an inactive slot**

In transmitter mode, it is possible to choose the behavior of the SD line output when an inactive slot is sent on the data line (via TRIS bit).
- Either the SAI forces 0 on the SD output line when an inactive slot is transmitted, or
- The line is released in HI-z state at the end of the last bit of data transferred, to release the line for other transmitters connected to this node.

It is important to note that the two transmitters cannot attempt to drive the same SD output pin simultaneously, which may result in a short circuit. To ensure a gap between transmissions, if the data is lower than 32-bit, the data can be extended to 32-bit by setting bit SLOTSZ[1:0] = 10 in the SAI_xSLOTR register. The SD output pin is then tri-stated at the end of the LSB of the active slot (during the padding to 0 phase to extend the data to 32-bit) if the following slot is declared inactive.

In addition, if the number of slots multiplied by the slot size is lower than the frame length, the SD output line is tri-stated when the padding to 0 is done to complete the audio frame. **Figure 707** illustrates these behaviors.
When the selected audio protocol uses the FS signal as a start of frame and a channel side identification (bit FSDEF = 1 in the SAI_xFRCR register), the tristate mode is managed according to Figure 708 (where bit TRIS in the SAI_xCR1 register = 1, and FSDEF=1, and half frame length is higher than number of slots/2, and NBSLOT=6).
Figure 708. Tristate on output data line in a protocol like I2S

If the TRIS bit in the SAI_xCR2 register is cleared, all the High impedance states on the SD output line on Figure 707 and Figure 708 are replaced by a drive with a value of 0.

54.4.14 Error flags

The SAI implements the following error flags:
- FIFO overrun/underrun
- Anticipated frame synchronization detection
- Late frame synchronization detection
- Codec not ready (AC’97 exclusively)
- Wrong clock configuration in master mode.

FIFO overrun/underrun (OVRUDR)

The FIFO overrun/underrun bit is called OVRUDR in the SAI_xSR register.

The overrun or underrun errors share the same bit since an audio block can be either receiver or transmitter and each audio block in a given SAI has its own SAI_xSR register.

Overrun

When the audio block is configured as receiver, an overrun condition may appear if data are received in an audio frame when the FIFO is full and not able to store the received data. In this case, the received data are lost, the flag OVRUDR in the SAI_xSR register is set and an interrupt is generated if OVRUDRIE bit is set in the SAI_xIM register. The slot number, from which the overrun occurs, is stored internally. No more data are stored into the FIFO until it becomes free to store new data. When the FIFO has at least one data free, the SAI audio block receiver stores new data (from new audio frame) from the slot number which was stored internally when the overrun condition was detected. This avoids data slot de-alignment in the destination memory (refer to Figure 709).

The OVRUDR flag is cleared when COVRUDR bit is set in the SAI_xCLRFR register.
Underrun

An underrun may occur when the audio block in the SAI is a transmitter and the FIFO is empty when data need to be transmitted. If an underrun is detected, the slot number for which the event occurs is stored and MUTE value (00) is sent until the FIFO is ready to transmit the data corresponding to the slot for which the underrun was detected (refer to Figure 710). This avoids desynchronization between the memory pointer and the slot in the audio frame.

The underrun event sets the OVRUDR flag in the SAI_xSR register and an interrupt is generated if the OVRUDRIE bit is set in the SAI_xIM register. To clear this flag, set COVRUDR bit in the SAI_xCLRFR register.

The underrun event can occur when the audio subblock is configured as master or slave.
Anticipated frame synchronization detection (AFSDET)

The AFSDET flag is used only in slave mode. It is never asserted in master mode. It indicates that a frame synchronization (FS) has been detected earlier than expected since the frame length, the frame polarity, the frame offset are defined and known.

Anticipated frame detection sets the AFSDET flag in the SAI_xSR register.

This detection has no effect on the current audio frame which is not sensitive to the anticipated FS. This means that “parasitic” events on signal FS are flagged without any perturbation of the current audio frame.

An interrupt is generated if the AFSDETIE bit is set in the SAI_xIM register. To clear the AFSDET flag, CAFSDET bit must be set in the SAI_xCLRFR register.

To resynchronize with the master after an anticipated frame detection error, four steps are required:

1. Disable the SAI block by resetting SAIEN bit in SAI_xCR1 register. To make sure the SAI is disabled, read back the SAIEN bit and check it is set to 0.
2. Flush the FIFO via FFLUS bit in SAI_xCR2 register.
3. Enable again the SAI peripheral (SAIEN bit set to 1).
4. The SAI block waits for the assertion on FS to restart the synchronization with master.

Note: The AFSDET flag is not asserted in AC’97 mode since the SAI audio block acts as a link controller and generates the FS signal even when declared as slave. It has no meaning in SPDIF mode since the FS signal is not used.

Late frame synchronization detection

The LFSDET flag in the SAI_xSR register can be set only when the SAI audio block operates as a slave. The frame length, the frame polarity and the frame offset configuration are known in register SAI_xFRCR.

If the external master does not send the FS signal at the expecting time thus generating the signal too late, the LFSDET flag is set and an interrupt is generated if LFSDETIE bit is set in the SAI_xIM register.

The LFSDET flag is cleared when CLFSDET bit is set in the SAI_xCLRFR register.

The late frame synchronization detection flag is set when the corresponding error is detected. The SAI needs to be resynchronized with the master (see sequence described in Anticipated frame synchronization detection (AFSDET)).

In a noisy environment, glitches on the SCK clock may be wrongly detected by the audio block state machine and shift the SAI data at a wrong frame position. This event can be detected by the SAI and reported as a late frame synchronization detection error.

There is no corruption if the external master is not managing the audio data frame transfer in continuous mode, which must not be the case in most applications. In this case, the LFSDET flag is set.

Note: The LFSDET flag is not asserted in AC’97 mode since the SAI audio block acts as a link controller and generates the FS signal even when declared as slave. It has no meaning in SPDIF mode since the signal FS is not used by the protocol.
Codec not ready (CNRDY AC’97)

The CNRDY flag in the SAI_xSR register is relevant only if the SAI audio block is configured to operate in AC’97 mode (PRTCFG[1:0] = 10 in the SAI_xCR1 register). If CNRDYIE bit is set in the SAI_xIM register, an interrupt is generated when the CNRDY flag is set.

CNRDY is asserted when the Codec is not ready to communicate during the reception of the TAG 0 (slot0) of the AC’97 audio frame. In this case, no data are automatically stored into the FIFO since the Codec is not ready, until the TAG 0 indicates that the Codec is ready. All the active slots defined in the SAI_xSLOTAR register are captured when the Codec is ready.

To clear CNRDY flag, CCNRDY bit must be set in the SAI_xCLRFR register.

Wrong clock configuration in master mode (with NODIV = 0)

When the audio block operates as a master (MODE[1] = 0) and NODIV bit is equal to 0, the WCKCFG flag is set as soon as the SAI is enabled if the following conditions are met:

- (FRL+1) is not a power of 2, and
- (FRL+1) is not between 8 and 256.

MODE, NODIV, and SAIEN bits belong to SAI_xCR1 register and FRL to SAI_xFRCR register.

If WCKCFGIE bit is set, an interrupt is generated when WCKCFG flag is set in the SAI_xSR register. To clear this flag, set CWCKCFG bit in the SAI_xCLRFR register.

When WCKCFG bit is set, the audio block is automatically disabled, thus performing a hardware clear of SAIEN bit.

54.4.15 Disabling the SAI

The SAI audio block can be disabled at any moment by clearing SAIEN bit in the SAI_xCR1 register. All the already started frames are automatically completed before the SAI is stops working. SAIEN bit remains High until the SAI is completely switched-off at the end of the current audio frame transfer.

If an audio block in the SAI operates synchronously with the other one, the one which is the master must be disabled first.

54.4.16 SAI DMA interface

To free the CPU and to optimize bus bandwidth, each SAI audio block has an independent DMA interface to read/write from/to the SAI_xDR register (to access the internal FIFO). There is one DMA channel per audio subblock supporting basic DMA request/acknowledge protocol.

To configure the audio subblock for DMA transfer, set DMAEN bit in the SAI_xCR1 register. The DMA request is managed directly by the FIFO controller depending on the FIFO threshold level (for more details refer to Section 54.4.9: Internal FIFOs). DMA transfer direction is linked to the SAI audio subblock configuration:

- If the audio block operates as a transmitter, the audio block FIFO controller outputs a DMA request to load the FIFO with data written in the SAI_xDR register.
- If the audio block is operates as a receiver, the DMA request is related to read operations from the SAI_xDR register.
Follow the sequence below to configure the SAI interface in DMA mode:
1. Configure SAI and FIFO threshold levels to specify when the DMA request is launched.
2. Configure SAI DMA channel.
3. Enable the DMA.
4. Enable the SAI interface.

*Note:* Before configuring the SAI block, the SAI DMA channel must be disabled.

### 54.5 SAI interrupts

The SAI supports 7 interrupt sources as shown in Table 454.

</tbody>
</table>

Note: Since the audio block defaults to operate as a transmitter after reset, the MODE[1:0] bits must be configured before setting DMAEN to avoid a DMA request in receiver mode.
Bit 16 **SAIEN**: Audio block enable
This bit is set by software.
To switch off the audio block, the application software must program this bit to 0 and poll the bit till it
reads back 0, meaning that the block is completely disabled. Before setting this bit to 1, check that it
is set to 0, otherwise the enable command is not taken into account.
This bit enables to control the state of the SAI audio block. If it is disabled when an audio frame
transfer is ongoing, the ongoing transfer completes and the cell is fully disabled at the end of this
audio frame transfer.
0: SAI audio block disabled
1: SAI audio block enabled.

*Note:* When the SAI block (A or B) is configured in master mode, the clock must be present on the
SAI block input before setting SAIEN bit.

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **OUTDRIV**: Output drive
This bit is set and cleared by software.
0: Audio block output driven when SAIEN is set
1: Audio block output driven immediately after the setting of this bit.

*Note:* This bit has to be set before enabling the audio block and after the audio block configuration.

Bit 12 **MONO**: Mono mode
This bit is set and cleared by software. It is meaningful only when the number of slots is equal to 2.
When the mono mode is selected, slot 0 data are duplicated on slot 1 when the audio block operates
as a transmitter. In reception mode, the slot1 is discarded and only the data received from slot 0 are
stored. Refer to *Section: Mono/stereo mode* for more details.
0: Stereo mode
1: Mono mode.

Bits 11:10 **SYNCEN[1:0]**: Synchronization enable
These bits are set and cleared by software. They must be configured when the audio subblock is
disabled.
00: audio subblock in asynchronous mode.
01: audio subblock is synchronous with the other internal audio subblock. In this case, the audio
subblock must be configured in slave mode
10: audio subblock is synchronous with an external SAI embedded peripheral. In this case the audio
subblock must be configured in Slave mode.
11: Reserved

*Note:* The audio subblock must be configured as asynchronous when SPDIF mode is enabled.

Bit 9 **CKSTR**: Clock strobing edge
This bit is set and cleared by software. It must be configured when the audio block is disabled. This
bit has no meaning in SPDIF audio protocol.
0: Signals generated by the SAI change on SCK rising edge, while signals received by the SAI are
sampled on the SCK falling edge.
1: Signals generated by the SAI change on SCK falling edge, while signals received by the SAI are
sampled on the SCK rising edge.

Bit 8 **LSBFIRST**: Least significant bit first
This bit is set and cleared by software. It must be configured when the audio block is disabled. This
bit has no meaning in AC’97 audio protocol since AC’97 data are always transferred with the MSB
first. This bit has no meaning in SPDIF audio protocol since in SPDIF data are always transferred
with LSB first.
0: Data are transferred with MSB first
1: Data are transferred with LSB first
54.6.3 SAI configuration register 1 (SAI_BCR1)

Address offset: 0x024
Reset value: 0x0000 0040
Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **MCKEN**: Master clock generation enable
- 0: The master clock is not generated
- 1: The master clock is generated independently of SAIEN bit

Bit 26 **OSR**: Oversampling ratio for master clock
- This bit is meaningful only when NODIV bit is set to 0.
- 0: Master clock frequency = F_FS x 256
- 1: Master clock frequency = F_FS x 512

Bits 25:20 **MCKDIV[5:0]**: Master clock divider
- These bits are set and cleared by software.
- 000000: Divides by 1 the kernel clock input (sai_x_ker_ck).
- Otherwise, The master clock frequency is calculated according to the formula given in Section 54.4.8: SAI clock generator.
- These bits have no meaning when the audio block is slave.
- They have to be configured when the audio block is disabled.

Bit 19 **NODIV**: No divider
- This bit is set and cleared by software.
- 0: the ratio between the Master clock generator and frame synchronization is fixed to 256 or 512
- 1: the ratio between the Master clock generator and frame synchronization depends on FRL[7:0]

Bit 18 Reserved, must be kept at reset value.

Bit 17 **DMAEN**: DMA enable
- This bit is set and cleared by software.
- 0: DMA disabled
- 1: DMA enabled

*Note: Since the audio block defaults to operate as a transmitter after reset, the MODE[1:0] bits must be configured before setting DMAEN to avoid a DMA request in receiver mode.*

Bit 16 **SAIEN**: Audio block enable
- This bit is set by software.
- To switch off the audio block, the application software must program this bit to 0 and poll the bit till it reads back 0, meaning that the block is completely disabled. Before setting this bit to 1, check that it is set to 0, otherwise the enable command is not taken into account.
- This bit enables to control the state of the SAI audio block. If it is disabled when an audio frame transfer is ongoing, the ongoing transfer completes and the cell is fully disabled at the end of this audio frame transfer.
- 0: SAI audio block disabled
- 1: SAI audio block enabled.

*Note: When the SAI block (A or B) is configured in master mode, the clock must be present on the SAI block input before setting SAIEN bit.*

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **OUTDRIV**: Output drive
- This bit is set and cleared by software.
- 0: Audio block output driven when SAIEN is set
- 1: Audio block output driven immediately after the setting of this bit.

*Note: This bit has to be set before enabling the audio block and after the audio block configuration.*
Bit 12 **MONO**: Mono mode

This bit is set and cleared by software. It is meaningful only when the number of slots is equal to 2. When the mono mode is selected, slot 0 data are duplicated on slot 1 when the audio block operates as a transmitter. In reception mode, the slot 1 is discarded and only the data received from slot 0 are stored. Refer to Section: Mono/stereo mode for more details.

- 0: Stereo mode
- 1: Mono mode.

Bits 11:10 **SYNCEN[1:0]**: Synchronization enable

These bits are set and cleared by software. They must be configured when the audio subblock is disabled.

- 00: audio subblock in asynchronous mode.
- 01: audio subblock is synchronous with the other internal audio subblock. In this case, the audio subblock must be configured in slave mode.
- 10: audio subblock is synchronous with an external SAI embedded peripheral. In this case the audio subblock must be configured in Slave mode.
- 11: Reserved

*Note: The audio subblock must be configured as asynchronous when SPDIF mode is enabled.*

Bit 9 **CKSTR**: Clock strobing edge

This bit is set and cleared by software. It must be configured when the audio block is disabled. This bit has no meaning in SPDIF audio protocol.

- 0: Signals generated by the SAI change on SCK rising edge, while signals received by the SAI are sampled on the SCK falling edge.
- 1: Signals generated by the SAI change on SCK falling edge, while signals received by the SAI are sampled on the SCK rising edge.

Bit 8 **LSBFIRST**: Least significant bit first

This bit is set and cleared by software. It must be configured when the audio block is disabled. This bit has no meaning in AC’97 audio protocol since AC’97 data are always transferred with the MSB first. This bit has no meaning in SPDIF audio protocol since in SPDIF data are always transferred with LSB first.

- 0: Data are transferred with MSB first
- 1: Data are transferred with LSB first

Bits 7:5 **DS[2:0]**: Data size

These bits are set and cleared by software. These bits are ignored when the SPDIF protocols are selected (bit PRTCFG[1:0]), because the frame and the data size are fixed in such case. When the companding mode is selected through COMP[1:0] bits, DS[1:0] are ignored since the data size is fixed to 8 bits by the algorithm.

These bits must be configured when the audio block is disabled.

- 000: Reserved
- 001: Reserved
- 010: 8 bits
- 011: 10 bits
- 100: 16 bits
- 101: 20 bits
- 110: 24 bits
- 111: 32 bits
Bit 4  Reserved, must be kept at reset value.

Bits 3:2  **PRTCFG[1:0]: Protocol configuration**

These bits are set and cleared by software. These bits have to be configured when the audio block is disabled.

00: Free protocol. Free protocol enables to use the powerful configuration of the audio block to address a specific audio protocol (such as I2S, LSB/MSB justified, TDM, PCM/DSP...) by setting most of the configuration register bits as well as frame configuration register.

01: SPDIF protocol

10: AC’97 protocol

11: Reserved

Bits 1:0  **MODE[1:0]: SAIx audio block mode**

These bits are set and cleared by software. They must be configured when SAIx audio block is disabled.

00: Master transmitter

01: Master receiver

10: Slave transmitter

11: Slave receiver

Note: When the audio block is configured in SPDIF mode, the master transmitter mode is forced (MODE[1:0] = 00). In Master transmitter mode, the audio block starts generating the FS and the clocks immediately.

### 54.6.4  SAI configuration register 2 (SAI_ACR2)

Address offset: 0x008

Reset value: 0x0000 0000

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:14  COMP[1:0]: Compingding mode.
These bits are set and cleared by software. The μ-Law and the A-Law log are a part of the CCITT G.711 recommendation, the type of complement that is used depends on CPL bit.
The data expansion or data compression are determined by the state of bit MODE[0].
The data compression is applied if the audio block is configured as a transmitter.
The data expansion is automatically applied when the audio block is configured as a receiver.
Refer to Section: Compingding mode for more details.
00: No companding algorithm
01: Reserved.
10: μ-Law algorithm
11: A-Law algorithm
Note: Companding mode is applicable only when Free protocol mode is selected.

Bit 13  CPL: Complement bit.
This bit is set and cleared by software.
It defines the type of complement to be used for companding mode
0: 1’s complement representation.
1: 2’s complement representation.
Note: This bit has effect only when the companding mode is μ-Law algorithm or A-Law algorithm.

Bits 12:7  MUTECTN[5:0]: Mute counter.
These bits are set and cleared by software. They are used only in reception mode.
The value set in these bits is compared to the number of consecutive mute frames detected in reception. When the number of mute frames is equal to this value, the flag MUTEDET is set and an interrupt is generated if bit MUTEDETIE is set.
Refer to Section: Mute mode for more details.

Bit 6  MUTEVAL: Mute value.
This bit is set and cleared by software. It must be written before enabling the audio block: SAIEN.
This bit is meaningful only when the audio block operates as a transmitter, the number of slots is lower or equal to 2 and the MUTE bit is set.
If more slots are declared, the bit value sent during the transmission in mute mode is equal to 0, whatever the value of MUTEVAL.
if the number of slot is lower or equal to 2 and MUTEVAL = 1, the MUTE value transmitted for each slot is the one sent during the previous frame.
Refer to Section: Mute mode for more details.
0: Bit value 0 is sent during the mute mode.
1: Last values are sent during the mute mode.
Note: This bit is meaningless and must not be used for SPDIF audio blocks.

Bit 5  MUTE: Mute.
This bit is set and cleared by software. It is meaningful only when the audio block operates as a transmitter. The MUTE value is linked to value of MUTEVAL if the number of slots is lower or equal to 2, or equal to 0 if it is greater than 2.
Refer to Section: Mute mode for more details.
0: No mute mode.
1: Mute mode enabled.
Note: This bit is meaningless and must not be used for SPDIF audio blocks.
Bit 4 **TRIS**: Tristate management on data line.
This bit is set and cleared by software. It is meaningful only if the audio block is configured as a transmitter. This bit is not used when the audio block is configured in SPDIF mode. It must be configured when SAI is disabled.
Refer to **Section : Output data line management on an inactive slot** for more details.
0: SD output line is still driven by the SAI when a slot is inactive.
1: SD output line is released (Hi-Z) at the end of the last data bit of the last active slot if the next one is inactive.

Bit 3 **FFLUSH**: FIFO flush.
This bit is set by software. It is always read as 0. This bit must be configured when the SAI is disabled.
0: No FIFO flush.
1: FIFO flush. Programming this bit to 1 triggers the FIFO Flush. All the internal FIFO pointers (read and write) are cleared. In this case data still present in the FIFO are lost (no more transmission or received data lost). Before flushing, SAI DMA stream/interrupt must be disabled.

Bits 2:0 **FTH[2:0]**: FIFO threshold.
This bit is set and cleared by software.
000: FIFO empty
001: ¼ FIFO
010: ½ FIFO
011: ¾ FIFO
100: FIFO full
101: Reserved
110: Reserved
111: Reserved

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:14  **COMP[1:0]**: Compressing mode.
- These bits are set and cleared by software. The µ-Law and the A-Law log are a part of the CCITT G.711 recommendation, the type of complement that is used depends on CPL bit.
- The data expansion or data compression are determined by the state of bit MODE[0].
- The data compression is applied if the audio block is configured as a transmitter.
- The data expansion is automatically applied when the audio block is configured as a receiver.
- Refer to **Section : Companding mode** for more details.
- 00: No companding algorithm
- 01: Reserved.
- 10: µ-Law algorithm
- 11: A-Law algorithm

*Note: Companding mode is applicable only when Free protocol mode is selected.*

Bit 13  **CPL**: Complement bit.
- This bit is set and cleared by software.
- It defines the type of complement to be used for companding mode
  - 0: 1's complement representation.
  - 1: 2's complement representation.

*Note: This bit has effect only when the companding mode is µ-Law algorithm or A-Law algorithm.*

Bits 12:7  **MUTECNT[5:0]**: Mute counter.
- These bits are set and cleared by software. They are used only in reception mode.
- The value set in these bits is compared to the number of consecutive mute frames detected in reception. When the number of mute frames is equal to this value, the flag MUTEDET is set and an interrupt is generated if bit MUTEDETIE is set.
- Refer to **Section : Mute mode** for more details.

Bit 6  **MUTEVAL**: Mute value.
- This bit is set and cleared by software. It must be written before enabling the audio block: SAIEN.
- This bit is meaningful only when the audio block operates as a transmitter, the number of slots is lower or equal to 2, and the MUTE bit is set.
- If more slots are declared, the bit value sent during the transmission in mute mode is equal to 0, whatever the value of MUTEVAL.
- if the number of slot is lower or equal to 2 and MUTEVAL = 1, the MUTE value transmitted for each slot is the one sent during the previous frame.
- Refer to **Section : Mute mode** for more details.
- 0: Bit value 0 is sent during the mute mode.
- 1: Last values are sent during the mute mode.

*Note: This bit is meaningless and must not be used for SPDIF audio blocks.*

Bit 5  **MUTE**: Mute.
- This bit is set and cleared by software. It is meaningful only when the audio block operates as a transmitter. The MUTE value is linked to value of MUTEVAL if the number of slots is lower or equal to 2, or equal to 0 if it is greater than 2.
- Refer to **Section : Mute mode** for more details.
- 0: No mute mode.
- 1: Mute mode enabled.

*Note: This bit is meaningless and must not be used for SPDIF audio blocks.*
54.6.6 SAI frame configuration register (SAI_AFRCR)

Address offset: 0x00C
Reset value: 0x0000 0007

**Note:** This register has no meaning in AC’97 and SPDIF audio protocol.

---

**Bit 4 TRIS:** Tristate management on data line.
This bit is set and cleared by software. It is meaningful only if the audio block is configured as a transmitter. This bit is not used when the audio block is configured in SPDIF mode. It must be configured when SAI is disabled.
Refer to Section: Output data line management on an inactive slot for more details.
0: SD output line is still driven by the SAI when a slot is inactive.
1: SD output line is released (HI-Z) at the end of the last data bit of the last active slot if the next one is inactive.

**Bit 3 FFLUSH:** FIFO flush.
This bit is set by software. It is always read as 0. This bit must be configured when the SAI is disabled.
0: No FIFO flush.
1: FIFO flush. Programming this bit to 1 triggers the FIFO Flush. All the internal FIFO pointers (read and write) are cleared. In this case data still present in the FIFO are lost (no more transmission or received data lost). Before flushing, SAI DMA stream/interrupt must be disabled.

**Bits 2:0 FTH[2:0]:** FIFO threshold.
This bit is set and cleared by software.
000: FIFO empty
001: ¼ FIFO
010: ½ FIFO
011: ¾ FIFO
100: FIFO full
101: Reserved
110: Reserved
111: Reserved
Bits 31:19 Reserved, must be kept at reset value.

Bit 18 **FSOFF**: Frame synchronization offset.
- This bit is set and cleared by software. It is meaningless and is not used in AC’97 or SPDIF audio block configuration. This bit must be configured when the audio block is disabled.
  - 0: FS is asserted on the first bit of the slot 0.
  - 1: FS is asserted one bit before the first bit of the slot 0.

Bit 17 **FSPOL**: Frame synchronization polarity.
- This bit is set and cleared by software. It is used to configure the level of the start of frame on the FS signal. It is meaningless and is not used in AC’97 or SPDIF audio block configuration.
  - 0: FS is active low (falling edge)
  - 1: FS is active high (rising edge)

Bit 16 **FSDEF**: Frame synchronization definition.
- This bit is set and cleared by software.
  - 0: FS signal is a start frame signal
  - 1: FS signal is a start of frame signal + channel side identification
  When the bit is set, the number of slots defined in the SAI_xSLOTR register has to be even. It means that half of this number of slots are dedicated to the left channel and the other slots for the right channel (e.g: this bit has to be set for I2S or MSB/LSB-justified protocols...).
  This bit is meaningless and is not used in AC’97 or SPDIF audio block configuration. It must be configured when the audio block is disabled.

Bit 15 Reserved, must be kept at reset value.

Bits 14:8 **FSALL[6:0]**: Frame synchronization active level length.
- These bits are set and cleared by software. They specify the length in number of bit clock (SCK) + 1 (FSALL[6:0] + 1) of the active level of the FS signal in the audio frame
- These bits are meaningless and are not used in AC’97 or SPDIF audio block configuration.
- They must be configured when the audio block is disabled.

Bits 7:0 **FRL[7:0]**: Frame length.
- These bits are set and cleared by software. They define the audio frame length expressed in number of SCK clock cycles: the number of bits in the frame is equal to FRL[7:0] + 1.
  - The minimum number of bits to transfer in an audio frame must be equal to 8, otherwise the audio block behaves in an unexpected way. This is the case when the data size is 8 bits and only one slot 0 is defined in NBSLOT[4:0] of SAI_xSLOTR register (NBSLOT[3:0] = 0000).
  - In master mode, if the master clock (available on MCLK_x pin) is used, the frame length must be aligned with a number equal to a power of 2, ranging from 8 to 256. When the master clock is not used (NODIV = 1), it is recommended to program the frame length to an value ranging from 8 to 256. These bits are meaningless and are not used in AC’97 or SPDIF audio block configuration. They must be configured when the audio block is disabled.
54.6.7  SAI frame configuration register (SAI_BFRCR)

Address offset: 0x02C
Reset value: 0x0000 0007

Note: This register has no meaning in AC'97 and SPDIF audio protocol

Bits 31:19 Reserved, must be kept at reset value.

Bit 18  FSOFF: Frame synchronization offset.
This bit is set and cleared by software. It is meaningless and is not used in AC'97 or SPDIF audio block configuration. This bit must be configured when the audio block is disabled.
0: FS is asserted on the first bit of the slot 0.
1: FS is asserted one bit before the first bit of the slot 0.

Bit 17  FSPOL: Frame synchronization polarity.
This bit is set and cleared by software. It is used to configure the level of the start of frame on the FS signal. It is meaningless and is not used in AC'97 or SPDIF audio block configuration.
This bit must be configured when the audio block is disabled.
0: FS is active low (falling edge)
1: FS is active high (rising edge)

Bit 16  FSDEF: Frame synchronization definition.
This bit is set and cleared by software.
0: FS signal is a start frame signal
1: FS signal is a start of frame signal + channel side identification
When the bit is set, the number of slots defined in the SAI_xSLOTR register has to be even. It means that half of this number of slots is dedicated to the left channel and the other slots for the right channel (e.g. this bit has to be set for I2S or MSB/LSB-justified protocols...).
This bit is meaningless and is not used in AC'97 or SPDIF audio block configuration. It must be configured when the audio block is disabled.
Serial audio interface (SAI) RM0399

Bit 15  Reserved, must be kept at reset value.

Bits 14:8  **FSALL[6:0]:** Frame synchronization active level length.
These bits are set and cleared by software. They specify the length in number of bit clock (SCK) + 1 (FSALL[6:0] + 1) of the active level of the FS signal in the audio frame.
These bits are meaningless and are not used in AC’97 or SPDIF audio block configuration.
They must be configured when the audio block is disabled.

Bits 7:0  **FRL[7:0]:** Frame length.
These bits are set and cleared by software. They define the audio frame length expressed in number of SCK clock cycles: the number of bits in the frame is equal to FRL[7:0] + 1.
The minimum number of bits to transfer in an audio frame must be equal to 8, otherwise the audio block behaves in an unexpected way. This is the case when the data size is 8 bits and only one slot 0 is defined in NBSLOT[4:0] of SAI_xSLOTR register (NBSLOT[3:0] = 0000).
In master mode, if the master clock (available on MCLK_x pin) is used, the frame length must be aligned with a number equal to a power of 2, ranging from 8 to 256. When the master clock is not used (NODIV = 1), it is recommended to program the frame length to an value ranging from 8 to 256.
These bits are meaningless and are not used in AC’97 or SPDIF audio block configuration.

**54.6.8 SAI slot register (SAI_ASLOTR)**

Address offset: 0x010
Reset value: 0x0000 0000

*Note:* This register has no meaning in AC’97 and SPDIF audio protocol.

0: Inactive slot.
1: Active slot.
The slot must be enabled when the audio block is disabled.
They are ignored in AC’97 or SPDIF mode.

Bits 31:16 **SLOTEN[15:0]:** Slot enable.
These bits are set and cleared by software.
Each SLOTEN bit corresponds to a slot position from 0 to 15 (maximum 16 slots).
0: Inactive slot.
1: Active slot.
The slot must be enabled when the audio block is disabled.
They are ignored in AC’97 or SPDIF mode.

Bits 15:12  Reserved, must be kept at reset value.

Bits 11:8  **NBSLOT[3:0]:** Number of slots in an audio frame.
These bits are set and cleared by software.
The value set in this bitfield represents the number of slots + 1 in the audio frame (including the number of inactive slots). The maximum number of slots is 16.
The number of slots must be even if FSDEF bit in the SAI_xFRCR register is set.
The number of slots must be configured when the audio block is disabled.
They are ignored in AC’97 or SPDIF mode.
Bits 7:6 **SLOTSZ[1:0]**: Slot size

This bits is set and cleared by software.

The slot size must be higher or equal to the data size. If this condition is not respected, the behavior of the SAI is undetermined.

Refer to *Output data line management on an inactive slot* for information on how to drive SD line.

These bits must be set when the audio block is disabled.

They are ignored in AC’97 or SPDIF mode.

00: The slot size is equivalent to the data size (specified in DS[3:0] in the SAI_xCR1 register).

01: 16-bit

10: 32-bit

11: Reserved

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **FBOFF[4:0]**: First bit offset

These bits are set and cleared by software.

The value set in this bitfield defines the position of the first data transfer bit in the slot. It represents an offset value. In transmission mode, the bits outside the data field are forced to 0. In reception mode, the extra received bits are discarded.

These bits must be set when the audio block is disabled.

They are ignored in AC’97 or SPDIF mode.

### 54.6.9 SAI slot register (SAI_BSLOTR)

Address offset: 0x030

Reset value: 0x0000 0000

**Note:** This register has no meaning in AC’97 and SPDIF audio protocol.
Bits 31:16 **SLOTEN[15:0]**: Slot enable.
   These bits are set and cleared by software.
   Each SLOTEN bit corresponds to a slot position from 0 to 15 (maximum 16 slots).
   0: Inactive slot.
   1: Active slot.
   The slot must be enabled when the audio block is disabled.
   They are ignored in AC'97 or SPDIF mode.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **NBSLOT[3:0]**: Number of slots in an audio frame.
   These bits are set and cleared by software.
   The value set in this bitfield represents the number of slots + 1 in the audio frame (including the number of inactive slots).
   The maximum number of slots is 16.
   The number of slots must be even if FSDEF bit in the SAI_xFRCR register is set.
   The number of slots must be configured when the audio block is disabled.
   They are ignored in AC'97 or SPDIF mode.

Bits 7:6 **SLOTSZ[1:0]**: Slot size
   This bits is set and cleared by software.
   The slot size must be higher or equal to the data size. If this condition is not respected, the behavior of the SAI is undetermined.
   Refer to Output data line management on an inactive slot for information on how to drive SD line.
   These bits must be set when the audio block is disabled.
   They are ignored in AC'97 or SPDIF mode.
   00: The slot size is equivalent to the data size (specified in DS[3:0] in the SAI_xCR1 register).
   01: 16-bit
   10: 32-bit
   11: Reserved

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **FBOFF[4:0]**: First bit offset
   These bits are set and cleared by software.
   The value set in this bitfield defines the position of the first data transfer bit in the slot. It represents an offset value. In transmission mode, the bits outside the data field are forced to 0. In reception mode, the extra received bits are discarded.
   These bits must be set when the audio block is disabled.
   They are ignored in AC'97 or SPDIF mode.

2442/3556
Bits 31:7  Reserved, must be kept at reset value.

Bit 6 **LFSDETIE**: Late frame synchronization detection interrupt enable.
   This bit is set and cleared by software.
   0: Interrupt is disabled
   1: Interrupt is enabled
   When this bit is set, an interrupt is generated if the LFSDET bit is set in the SAI_xSR register.
   This bit is meaningless in AC'97, SPDIF mode or when the audio block operates as a master.

Bit 5 **AFSDETIE**: Anticipated frame synchronization detection interrupt enable.
   This bit is set and cleared by software.
   0: Interrupt is disabled
   1: Interrupt is enabled
   When this bit is set, an interrupt is generated if the AFSDET bit in the SAI_xSR register is set.
   This bit is meaningless in AC'97, SPDIF mode or when the audio block operates as a master.

Bit 4 **CNRDYIE**: Codec not ready interrupt enable (AC'97).
   This bit is set and cleared by software.
   0: Interrupt is disabled
   1: Interrupt is enabled
   When the interrupt is enabled, the audio block detects in the slot 0 (tag0) of the AC'97 frame if the
   Codec connected to this line is ready or not. If it is not ready, the CNRDY flag in the SAI_xSR
   register is set and an interrupt is generated.
   This bit has a meaning only if the AC'97 mode is selected through PRTCFG[1:0] bits and the audio
   block is operates as a receiver.

Bit 3 **FREQIE**: FIFO request interrupt enable.
   This bit is set and cleared by software.
   0: Interrupt is disabled
   1: Interrupt is enabled
   When this bit is set, an interrupt is generated if the FREQ bit in the SAI_xSR register is set.
   Since the audio block defaults to operate as a transmitter after reset, the MODE bit must be
   configured before setting FREQIE to avoid a parasitic interrupt in receiver mode.

Bit 2 **WCKCFGIE**: Wrong clock configuration interrupt enable.
   This bit is set and cleared by software.
   0: Interrupt is disabled
   1: Interrupt is enabled
   This bit is taken into account only if the audio block is configured as a master (MODE[1] = 0) and
   NODIV = 0.
   It generates an interrupt if the WCKCFG flag in the SAI_xSR register is set.
   *Note: This bit is used only in Free protocol mode and is meaningless in other modes.*

Bit 1 **MUTEDETIE**: Mute detection interrupt enable.
   This bit is set and cleared by software.
   0: Interrupt is disabled
   1: Interrupt is enabled
   When this bit is set, an interrupt is generated if the MUTEDET bit in the SAI_xSR register is set.
   This bit has a meaning only if the audio block is configured in receiver mode.

Bit 0 **OVRUDRIE**: Overrun/underrun interrupt enable.
   This bit is set and cleared by software.
   0: Interrupt is disabled
   1: Interrupt is enabled
   When this bit is set, an interrupt is generated if the OVRUDR bit in the SAI_xSR register is set.
54.6.11 SAI interrupt mask register (SAI_BIM)

Address offset: 0x034
Reset value: 0x0000 0000

Bit 6 LFSDETIE: Late frame synchronization detection interrupt enable.
This bit is set and cleared by software.
0: Interrupt is disabled
1: Interrupt is enabled
When this bit is set, an interrupt is generated if the LFSDET bit is set in the SAI_xSR register.
This bit is meaningless in AC’97, SPDIF mode or when the audio block operates as a master.

Bit 5 AFSDETIE: Anticipated frame synchronization detection interrupt enable.
This bit is set and cleared by software.
0: Interrupt is disabled
1: Interrupt is enabled
When this bit is set, an interrupt is generated if the AFSDET bit in the SAI_xSR register is set.
This bit is meaningless in AC’97, SPDIF mode or when the audio block operates as a master.

Bit 4 CNRDIYIE: Codec not ready interrupt enable (AC’97).
This bit is set and cleared by software.
0: Interrupt is disabled
1: Interrupt is enabled
When the interrupt is enabled, the audio block detects in the slot 0 (tag0) of the AC’97 frame if the Codec connected to this line is ready or not. If it is not ready, the CNRDIY flag in the SAI_xSR register is set and an interrupt is generated.
This bit has a meaning only if the AC’97 mode is selected through PRTCFCFG[1:0] bits and the audio block is operates as a receiver.

Bit 3 FREQIE: FIFO request interrupt enable.
This bit is set and cleared by software.
0: Interrupt is disabled
1: Interrupt is enabled
When this bit is set, an interrupt is generated if the FREQ bit in the SAI_xSR register is set.
Since the audio block defaults to operate as a transmitter after reset, the MODE bit must be configured before setting FREQIE to avoid a parasitic interrupt in receiver mode.
54.6.12 SAI status register (SAI_ASR)

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 FLVL[2:0]: FIFO level threshold.
- This bit is read only. The FIFO level threshold flag is managed only by hardware and its setting depends on SAI block configuration (transmitter or receiver mode).
- 000: FIFO empty (transmitter and receiver modes)
- 001: FIFO ≤ ¼ but not empty (transmitter mode), FIFO < ¼ but not empty (receiver mode)
- 010: ¼ < FIFO ≤ ½ (transmitter mode), ¼ ≤ FIFO < ½ (receiver mode)
- 011: ½ < FIFO ≤ ¾ (transmitter mode), ½ ≤ FIFO < ¾ (receiver mode)
- 100: ¾ < FIFO but not full (transmitter mode), ¾ ≤ FIFO but not full (receiver mode)
- 101: FIFO full (transmitter and receiver modes)
- Others: Reserved

Bits 15:7 Reserved, must be kept at reset value.

Bit 2 WCKCFGIE: Wrong clock configuration interrupt enable.
- This bit is set and cleared by software.
- 0: Interrupt is disabled
- 1: Interrupt is enabled
- This bit is taken into account only if the audio block is configured as a master (MODE[1] = 0) and NODIV = 0.
- It generates an interrupt if the WCKCFG flag in the SAI_xSR register is set.

Note: This bit is used only in Free protocol mode and is meaningless in other modes.

Bit 1 MUTEDETIE: Mute detection interrupt enable.
- This bit is set and cleared by software.
- 0: Interrupt is disabled
- 1: Interrupt is enabled
- When this bit is set, an interrupt is generated if the MUTEDET bit in the SAI_xSR register is set.
- This bit has a meaning only if the audio block is configured in receiver mode.

Bit 0 OVRUDR: Overrun/underrun interrupt enable.
- This bit is set and cleared by software.
- 0: Interrupt is disabled
- 1: Interrupt is enabled
- When this bit is set, an interrupt is generated if the OVRUDR bit in the SAI_xSR register is set.
Bit 6 **LFSDET**: Late frame synchronization detection.
   This bit is read only.
   0: No error.
   1: Frame synchronization signal is not present at the right time.
   This flag can be set only if the audio block is configured in slave mode.
   It is not used in AC’97 or SPDIF mode.
   It can generate an interrupt if LFSDETIE bit is set in the SAI_xIM register.
   This flag is cleared when the software sets bit CLFSDET in SAI_xCLRFR register.

Bit 5 **AFSDET**: Anticipated frame synchronization detection.
   This bit is read only.
   0: No error.
   1: Frame synchronization signal is detected earlier than expected.
   This flag can be set only if the audio block is configured in slave mode.
   It is not used in AC’97 or SPDIF mode.
   It can generate an interrupt if AFSDETIE bit is set in SAI_xIM register.
   This flag is cleared when the software sets CAFSDET bit in SAI_xCLRFR register.

Bit 4 **CNRDY**: Codec not ready.
   This bit is read only.
   0: External AC’97 Codec is ready
   1: External AC’97 Codec is not ready
   This bit is used only when the AC’97 audio protocol is selected in the SAI_xCR1 register and
   configured in receiver mode.
   It can generate an interrupt if CNRDYIE bit is set in SAI_xIM register.
   This flag is cleared when the software sets CCNRDY bit in SAI_xCLRFR register.

Bit 3 **FREQ**: FIFO request.
   This bit is read only.
   0: No FIFO request.
   1: FIFO request to read or to write the SAI_xDR.
   The request depends on the audio block configuration:
   – If the block is configured in transmission mode, the FIFO request is related to a write request
     operation in the SAI_xDR.
   – If the block configured in reception, the FIFO request related to a read request operation from the
     SAI_xDR.
   This flag can generate an interrupt if FREQIE bit is set in SAI_xIM register.
Bit 2 WCKCFG: Wrong clock configuration flag.
This bit is read only.
0: Clock configuration is correct
1: Clock configuration does not respect the rule concerning the frame length specification defined in Section 54.4.6: Frame synchronization (configuration of FRL[7:0] bit in the SAI_xFRCR register)
This bit is used only when the audio block operates in master mode (MODE[1] = 0) and NODIV = 0.
It can generate an interrupt if WCKCFGIE bit is set in SAI_xIM register.
This flag is cleared when the software sets CWCKCFG bit in SAI_xCLRFR register.

Bit 1 MUTEDET: Mute detection.
This bit is read only.
0: No MUTE detection on the SD input line
1: MUTE value detected on the SD input line (0 value) for a specified number of consecutive audio frame
This flag is set if consecutive 0 values are received in each slot of a given audio frame and for a consecutive number of audio frames (set in the MUTECNT bit in the SAI_xCR2 register).
It can generate an interrupt if MUTEDETIE bit is set in SAI_xIM register.
This flag is cleared when the software sets CMUTEDET in the SAI_xCLRFR register.

Bit 0 OVRUDR: Overrun / underrun.
This bit is read only.
0: No overrun/underrun error.
1: Overrun/underrun error detection.
The overrun and underrun conditions can occur only when the audio block is configured as a receiver and a transmitter, respectively.
It can generate an interrupt if OVRUDRIE bit is set in SAI_xIM register.
This flag is cleared when the software sets COVRUDR bit in SAI_xCLRFR register.

Bits 31:19  Reserved, must be kept at reset value.

Bits 18:16  **FLVL[2:0]**: FIFO level threshold.
This bit is read only. The FIFO level threshold flag is managed only by hardware and its setting depends on SAI block configuration (transmitter or receiver mode).
- 000: FIFO empty (transmitter and receiver modes)
- 001: FIFO \(\leq \frac{1}{4}\) but not empty (transmitter mode), FIFO \(\leq \frac{1}{4}\) but not empty (receiver mode)
- 010: \(\frac{1}{4} < \text{FIFO} \leq \frac{1}{2}\) (transmitter mode), \(\frac{1}{4} < \text{FIFO} < \frac{1}{2}\) (receiver mode)
- 011: \(\frac{1}{2} < \text{FIFO} \leq \frac{3}{4}\) (transmitter mode), \(\frac{1}{2} < \text{FIFO} < \frac{3}{4}\) (receiver mode)
- 100: \(\frac{3}{4} < \text{FIFO}\) but not full (transmitter mode), \(\frac{3}{4} < \text{FIFO}\) but not full (receiver mode)
- 101: FIFO full (transmitter and receiver modes)
Others: Reserved

Bits 15:7  Reserved, must be kept at reset value.

Bit 6  **LFSDET**: Late frame synchronization detection.
This bit is read only.
- 0: No error.
- 1: Frame synchronization signal is not present at the right time.
This flag can be set only if the audio block is configured in slave mode.
It is not used in AC’97 or SPDIF mode.
It can generate an interrupt if LFSDETIE bit is set in the SAI_xIM register.
This flag is cleared when the software sets bit CLFSDET in SAI_xCLRFR register.

Bit 5  **AFSDET**: Anticipated frame synchronization detection.
This bit is read only.
- 0: No error.
- 1: Frame synchronization signal is detected earlier than expected.
This flag can be set only if the audio block is configured in slave mode.
It is not used in AC’97 or SPDIF mode.
It can generate an interrupt if AFSDETIE bit is set in SAI_xIM register.
This flag is cleared when the software sets CAFSDET bit in SAI_xCLRFR register.

Bit 4  **CNRDY**: Codec not ready.
This bit is read only.
- 0: External AC’97 Codec is ready
- 1: External AC’97 Codec is not ready
This bit is used only when the AC’97 audio protocol is selected in the SAI_xCR1 register and configured in receiver mode.
It can generate an interrupt if CNRDYIE bit is set in SAI_xIM register.
This flag is cleared when the software sets CCNRDY bit in SAI_xCLRFR register.

Bit 3  **FREQ**: FIFO request.
This bit is read only.
- 0: No FIFO request.
- 1: FIFO request to read or to write the SAI_xDR.
The request depends on the audio block configuration:
  - If the block is configured in transmission mode, the FIFO request is related to a write request operation in the SAI_xDR.
  - If the block configured in reception, the FIFO request related to a read request operation from the SAI_xDR.
This flag can generate an interrupt if FREQIE bit is set in SAI_xIM register.
Bit 2 **WCKCFG**: Wrong clock configuration flag.
This bit is read only.
0: Clock configuration is correct
1: Clock configuration does not respect the rule concerning the frame length specification defined in [Section 54.4.6: Frame synchronization](#) (configuration of FRL[7:0] bit in the SAI_xFRCR register)
This bit is used only when the audio block operates in master mode (MODE[1] = 0) and NODIV = 0.
It can generate an interrupt if WCKCFGIE bit is set in SAI_xIM register.
This flag is cleared when the software sets CWCKCFG bit in SAI_xCLRFR register.

Bit 1 **MUTEDET**: Mute detection.
This bit is read only.
0: No MUTE detection on the SD input line
1: MUTE value detected on the SD input line (0 value) for a specified number of consecutive audio frames
This flag is set if consecutive 0 values are received in each slot of a given audio frame and for a consecutive number of audio frames (set in the MUTECT bit in the SAI_xCR2 register).
It can generate an interrupt if MUTEDETIE bit is set in SAI_xIM register.
This flag is cleared when the software sets bit CMUTEDET in the SAI_xCLRFR register.

Bit 0 **OVRUDR**: Overrun / underrun.
This bit is read only.
0: No overrun/underrun error.
1: Overrun/underrun error detection.
The overrun and underrun conditions can occur only when the audio block is configured as a receiver and a transmitter, respectively.
It can generate an interrupt if OVRUDRIE bit is set in SAI_xIM register.
This flag is cleared when the software sets COVRUDR bit in SAI_xCLRFR register.

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 CLFSDET: Clear late frame synchronization detection flag.
This bit is write only.
Programming this bit to 1 clears the LFSDET flag in the SAI_xSR register.
This bit is not used in AC'97 or SPDIFF mode.
Reading this bit always returns the value 0.

Bit 5 CAFSDET: Clear anticipated frame synchronization detection flag.
This bit is write only.
Programming this bit to 1 clears the AFSDET flag in the SAI_xSR register.
It is not used in AC'97 or SPDIFF mode.
Reading this bit always returns the value 0.

Bit 4 CCNRDY: Clear Codec not ready flag.
This bit is write only.
Programming this bit to 1 clears the CNRDY flag in the SAI_xSR register.
This bit is used only when the AC'97 audio protocol is selected in the SAI_xCR1 register.
Reading this bit always returns the value 0.

Bit 3 Reserved, must be kept at reset value.

Bit 2 CWCKCFG: Clear wrong clock configuration flag.
This bit is write only.
Programming this bit to 1 clears the WCKCFG flag in the SAI_xSR register.
This bit is used only when the audio block is set as master (MODE[1] = 0) and NODIV = 0 in the SAI_xCR1 register.
Reading this bit always returns the value 0.

Bit 1 CMUTEDET: Mute detection flag.
This bit is write only.
Programming this bit to 1 clears the MUTEDET flag in the SAI_xSR register.
Reading this bit always returns the value 0.

Bit 0 COVRUDR: Clear overrun / underrun.
This bit is write only.
Programming this bit to 1 clears the OVRUDR flag in the SAI_xSR register.
Reading this bit always returns the value 0.

**Bits 31:0 DATA[31:0]: Data**

- A write to this register loads the FIFO provided the FIFO is not full.
- A read from this register empties the FIFO if the FIFO is not empty.

Refer to Section 2.3 for the register boundary addresses.
55 SPDIF receiver interface (SPDIFRX)

55.1 SPDIFRX interface introduction

The SPDIFRX interface handles S/PDIF audio protocol.

55.2 SPDIFRX main features

- Up to 4 inputs available
- Automatic symbol rate detection
- Maximum symbol rate: 12.288 MHz
- Stereo stream from 8 to 192 kHz\(^{(a)}\) supported
- Supports audio IEC-60958 and IEC-61937, consumer applications
- Parity bit management
- Communication using DMA for audio samples
- Communication using DMA for control and user channel information
- Interrupt capabilities

55.3 SPDIFRX functional description

The SPDIFRX peripheral, is designed to receive an S/PDIF flow compliant with IEC-60958 and IEC-61937. These standards support simple stereo streams up to high sample rate, and compressed multi-channel surround sound, such as those defined by Dolby or DTS.

The receiver provides all the necessary features to detect the symbol rate, and decode the incoming data. It is possible to use a dedicated path for the user and channel information in order to ease the interface handling. *Figure 711* shows a simplified block diagram.

The SPDIFRX_DC block is responsible of the decoding of the S/PDIF stream received from SPDIFRX_IN[4:1] inputs. This block re-sample the incoming signal, decode the manchester stream, recognize frames, sub-frames and blocks elements. It delivers to the REG_IF part, decoded data, and associated status flags.

This peripheral can be fully controlled via the APB bus, and can handle two DMA channels:
- A DMA channel dedicated to the transfer of audio samples
- A DMA channel dedicated to the transfer of IEC60958 channel status and user information

Interrupt services are also available either as an alternative function to the DMA, or for signaling error or key status of the peripheral.

The SPDIFRX also offers a signal named spdifrx_frame_sync, which toggles every time that a sub-frame’s preamble is detected. So the duty cycle is 50%, and the frequency equal to the frame rate.

This signal can be connected to timer events, in order to compute frequency drift.

---

\(a\). Check the RCC capabilities in order to verify which sampling rates can be supported.
1. \( n \) is fixed to 4, and \( x \) is set to 1.

55.3.1 SPDIFRX pins and internal signals

Table 456 lists the SPDIFRX internal input/output signals, Table 457 the SPDIFRX pins (alternate functions).

55.3.2 S/PDIF protocol (IEC-60958)

S/PDIF block

A S/PDIF frame is composed of two sub-frames (see Figure 712). Each sub-frame contains 32 bits (or time slots):

- Bits 0 to 3 carry one of the synchronization preambles
- Bits 4 to 27 carry the audio sample word in linear 2's complement representation. The most significant bit (MSB) is carried by bit 27. When a 20-bit coding range is used, bits 8 to 27 carry the audio sample word with the LSB in bit 8.
- Bit 28 (validity bit “V”) indicates if the data is valid (for converting it to analog for example)
- Bit 29 (user data bit “U”) carries the user data information like the number of tracks of a Compact Disk.
- Bit 30 (channel status bit “C”) carries the channel status information like sample rate and protection against copy.
- Bit 31 (parity bit “P”) carries a parity bit such that bits 4 to 31 inclusive carry an even number of ones and an even number of zeroes (even parity).

![Figure 712. S/PDIF sub-frame format](image)

For linear coded audio applications, the first sub-frame (left or “A” channel in stereophonic operation and primary channel in monophonic operation) normally starts with preamble “M”. However, the preamble changes to preamble “B” once every 192 frames to identify the start of the block structure used to organize the channel status and user information. The second sub-frame (right or “B” channel in stereophonic operation and secondary channel in monophonic operation) always starts with preamble “W”.

A S/PDIF block contains 192 pairs of sub-frames of 32 bits.

![Figure 713. S/PDIF block format](image)

NOTE

For historical reasons preambles “B”, “M” and “W” are, for use in professional applications, referred to as “Z”, “X” and “Y”, respectively.
Synchronization preambles

The preambles patterns are inverted or not according to the previous half-bit value. This previous half-bit value is the level of the line before enabling a transfer for the first “B” preamble of the first frame. For the others preambles, this previous half-bit value is the second half-bit of the parity bit of the previous sub-frame. The preambles patterns B, M and W are described in the Figure 714.

Figure 714. S/PDIF Preambles

Coding of information bits

In order to minimize the DC component value on the transmission line, and to facilitate clock recovery from the data stream, bits 4 to 31 are encoded in biphase-mark. Each bit to be transmitted is represented by a symbol comprising two consecutive binary states. The first state of a symbol is always different from the second state of the previous symbol. The second state of the symbol is identical to the first if the bit to be transmitted is logical 0. However, it is different if the bit is logical 1. These states are named “UI” (unit interval) in the IEC-60958 specification.

The 24 data bits are transferred LSB first.
55.3.3 SPDIFRX decoder (SPDIFRX_DC)

Main principle

The technique used by the SPDIFRX in order to decode the S/PDIF stream is based on the measurement of the time interval between two consecutive edges. Three kinds of time intervals may be found into an S/PDIF stream:

- The long time interval, having a duration of 3 x UI, noted TL. It appears only during preambles.
- The medium time interval, having a duration of 2 x UI, noted TM. It appears both in some preambles or into the information field.
- The short time interval, having a duration of 1 x UI, noted TS. It appears both in some preambles or into the information field.

The SPDIFRX_DC block is responsible of the decoding of the received S/PDIF stream. It takes care of the following functions:

- Resampling and filtering of the incoming signal
- Estimation of the time-intervals
- Estimation of the symbol rate and synchronization
- Decoding of the serial data, and check of integrity
- Detection of the block, and sub-frame preambles
- Continuous tracking of the symbol rate
Figure 716 gives a detailed view of the SPDIFRX decoder.

**Figure 716. SPDIFRX decoder**

1. 'n' is fixed to 4, and 'x' is set to 1.

**Noise filtering and rising/falling edge detection**

The S/PDIF signal received on the selected SPDIFRX_IN is re-sampled using the spdifrx_ker_ck clock (acquisition clock). A simple filtering is applied in order to cancel spurs. This is performed by the stage detecting the edge transitions. The edge transitions are detected as follows:

- A rising edge is detected when the sequence 0 followed by two 1 is sampled.
- A falling edge is detected when the sequence 1 followed by two 0 is sampled.
- After a rising edge, a falling edge sequence is expected.
- After a falling edge, a rising edge sequence is expected.

**Figure 717. Noise filtering and edge detection**

**Longest and shortest transition detector**

The longest and shortest transition detector block detects the maximum (MAX_CNT) and minimum (MIN_CNT) duration between two transitions. The TRCNT counter is used to measure the time interval duration. It is clocked by the spdifrx_ker_ck signal. On every transition pulse, the counter value is stored and the counter is reset to start counting again.
The maximum duration is normally found during the preamble period. This maximum duration is sent out as MAX_CNT. The minimum duration is sent out as MIN_CNT.

The search of the longest and shortest transition is stopped when the transition timer expires. The transition timer is like a watchdog timer that generates a trigger after 70 transitions of the incoming signal. Note that counting 70 transitions insures a delay a bit longer than a sub-frame.

Note that when the TRCNT overflows due to a too long time interval between two pulses, the SPDIFRX is stopped and the flag TERR of SPDIFRX_SR register is set to 1.

**Transition coder and preamble detector**

The transition coder and preamble detector block receives the MAX_CNT and MIN_CNT. It also receives the current transition width from the TRCNT counter (see Figure 716). This block encodes the current transition width by comparing the current transition width with two different thresholds, names TH\textsubscript{HI} and TH\textsubscript{LO}.

- If the current transition width is less than (TH\textsubscript{LO} - 1), then the data received is half part of data bit ‘1’, and is coded as TS.
- If the current transition width is greater than (TH\textsubscript{LO} - 1), and less than TH\textsubscript{HI}, then the data received is data bit ‘0’, and is coded as TM.
- If the current transition width is greater than TH\textsubscript{HI}, then the data received is the long pulse of preambles, and is coded as TL.
- Else an error code is generated (FERR flag is set).

The thresholds TH\textsubscript{HI} and TH\textsubscript{LO} are elaborated using two different methods.

If the peripheral is doing its initial synchronization (‘coarse synchronization’), then the thresholds are computed as follow:

- \( TH\textsubscript{LO} = \frac{MAX\_CNT}{2} \)
- \( TH\textsubscript{HI} = \frac{MIN\_CNT + MAX\_CNT}{2} \)

Once the ‘coarse synchronization’ is completed, then the SPDIFRX uses a more accurate reference in order to elaborate the thresholds. The SPDIFRX measures the length of 24 symbols (WIDTH24) for defining TH\textsubscript{LO} and the length of 40 symbols (WIDTH40) for TH\textsubscript{HI}. TH\textsubscript{HI} and TH\textsubscript{LO} are computed as follow:

- \( TH\textsubscript{LO} = \frac{WIDTH24}{32} \)
- \( TH\textsubscript{HI} = \frac{WIDTH40}{32} \)

This second synchronization phase is called the ‘fine synchronization’. Refer to Figure 720 for additional information.
As shown in the figure hereafter, \( TH_{LO} \) is ideally equal to 1.5 UI, and to \( TH_{HI} 2.5 \) UI.

### Figure 718. Thresholds

The preamble detector checks four consecutive transitions of a specific sequence to determine if they form the part of preamble. Let us say TRANS0, TRANS1, TRANS2 and TRANS3 represent four consecutive transitions encoded as mentioned above. Table 458 shows the values of these four transitions to form a preamble. Absence of this pattern indicates that these transitions form part of the data in the sub frame and bi-phase decoder decode them.

#### Table 458. Transition sequence for preamble

<td>TM</td>
</tr>
</tbody>
</table>

### Bi-phase decoder

The Bi-phase decoder decodes the input bi-phase marked data stream using the transition information provided by the transition coder and preamble detector block. It first waits for the preamble detection information. After the preamble detection, it decodes the following transition information:

- If the incoming transition information is TM then it is decoded as a ‘0’.
- Two consecutive TS are decoded as a ‘1’.
- Any other transition sequence generates an error signal (FERR set to 1).

After decoding 28 data bits this way, this module looks for the following preamble data. If the new preamble is not what is expected, then this block generates an error signal (FERR set to 1). Refer to Section 55.3.9: Reception errors, for additional information on error flags.

### Data packing

This block is responsible of the decoding of the IEC-60958 frames and blocks. It also handles the writing into the RX_BUF or into SPDIFRX_CSR register.
55.3.4 SPDIFRX tolerance to clock deviation

The SPDIFRX tolerance to clock deviation depends on the number of sample clock cycles in one bit slot. The fastest spdifrx_ker_ck is, the more robust the reception is. The ratio between spdifrx_ker_ck frequency and the symbol rate must be at least 11.

Two kinds of phenomenon (at least) can degrade the reception quality:
- The cycle-to-cycle jitter which reflects the difference of transition length between two consecutive transitions.
- The long term jitter which reflects a cumulative effect of the cycle-to-cycle jitter. It can be seen as a low-frequency symbol modulation.

55.3.5 SPDIFRX synchronization

The synchronization phase starts when setting SPDIFRXEN to 01 or 11. Figure 719 shows the synchronization process.

If the bit WFA of SPDIFRX_CR register is set to 1, then the peripheral must first detect activity on the selected SPDIFRX_IN line before starting the synchronization process. The activity detection is performed by detecting four transitions on the selected SPDIFRX_IN. The peripheral remains in this state until transitions are not detected. This function can be particularly helpful because the SPDIFRX switches in COARSE SYNC mode only if activity is present on the selected SPDIFRX_IN input, avoiding synchronization errors. See Section 55.4: Programming procedures for additional information.

The user can still set the SPDIFRX into STATE_IDLE by setting SPDIFRXEN to 0. If the WFA is set to 0, the peripheral starts the coarse synchronization without checking activity.

The next step consists on doing a first estimate of the thresholds (COARSE SYNC), in order to perform the fine synchronization (FINE SYNC). Due to disturbances of the SPDIFRX line, it can happen that the process is not executed first time right. For this purpose, the user can program the number of allowed re-tries (NBTR) before setting SERR error flag. When the SPDIFRX is able to measure properly the duration of 24 and 40 consecutive symbols then the FINE SYNC is completed, the threshold values are updated, and the flag SYNCD is set to 1. Refer to Section : Transition coder and preamble detector for additional information.

Two kinds of errors are detected:
- An overflow of the TRCNT, which generally means that there is no valid S/PDIF stream in the input line. This overflow is indicated by TERR flag.
- The number of retries reached the programmed value. This means that strong jitter is present on the S/PDIF signal. This error is indicated by SERR flag.

When the first FINE SYNC is completed, the reception of channel status (C) and user data (U) starts when the next “B” preamble is detected (see Figure 723). Then the user can read IEC-60958 C and U bits through SPDIFRX_CSR register. According to this information the user can then select the proper settings for DRFMT and RXSTEO. For example if the user detects that the current audio stream transports encoded data, then he can put RXSTEO to 0, and DRFMT to 10 prior to start data reception. Note that DRFMT and RXSTEO cannot be modified when SPDIFRXEN = 11. Writes to these fields are ignored if SPDIFRXEN is already 11, though these field can be changed with the same write instruction that causes SPDIFRXEN to become 11.

Then the SPDIFRX waits for SPDIFRXEN = 11 and the “B” preamble before starting saving audio samples.
Figure 719. Synchronization flowchart

Initial Sync Process

Wait for 4 transitions if WFA = 1, else skip this step

Symb. decoding (1) OK ?

Set SYNCD to 1

(1) - The decoding is considered OK, when the symbols are properly decoded, and preamble occurs at the expected position

Refer to Frame structure and synchronization error for additional information concerning TRCNT overflow.

The FINE SYNC process is re-triggered every frame in order to update thresholds as shown in Figure 720 in order to continuously track S/PDIF synchronization.
55.3.6 SPDIFRX handling

The software can control the state of the SPDIFRX through SPDIFRXEN field. The SPDIFRX can be into one of the following states:

- **STATE_IDLE:**
  The peripheral is disabled, the spdifrx_ker_ck domain is reset. The spdifrx_pclk domain is functional.

- **STATE_SYNC:**
  The peripheral is synchronized to the stream, thresholds are updated regularly, user and channel status can be read via interrupt of DMA. The audio samples are not provided to receive buffer.

- **STATE_RCV:**
  The peripheral is synchronized to the stream, thresholds are updated regularly, user, channel status and audio samples can be read via interrupt or DMA channels. When SPDIFRXEN goes to 11, the SPDIFRX waits for “B” preamble before starting saving audio samples.

- **STOP_STATE:**
  The peripheral is no longer synchronized, the reception of the user, channel status and audio samples are stopped. It is expected that the software re-starts the SPDIFRX.

*Figure 721* shows the possible states of the SPDIFRX, and how to transition from one state to the other. The bits under software control are followed by the mention “(SW)”, the bits under SPDIFRX control are followed by the mention “(HW)”. 

![Diagram of SPDIFRX state transitions](image-url)
Figure 721. SPDIFRX States

When SPDIFRX is in STATE_IDLE:
- The software can transition to STATE_SYNC by setting SPDIFRXEN to 01 or 11

When SPDIFRX is in STATE_SYNC:
- If the synchronization fails or if the received data are not properly decoded with no chance of recovery without a re-synchronization (FERR or SERR or TERR = 1), the SPDIFRX goes to STATE_STOP, and waits for software acknowledge.
- When the synchronization phase is completed, if SPDIFRXEN = 01 the peripheral remains in this state.
- At any time the software can set SPDIFRXEN to 0, then SPDIFRX returns immediately to STATE_IDLE. If a DMA transfer is on-going, it is properly completed.
- The SPDIFRX goes to STATE_RCV if SPDIFRXEN = 11 and if the SYNCD = 1

When SPDIFRX is in STATE_RCV:
- If the received data are not properly decoded with no chance of recovery without a re-synchronization (FERR or SERR or TERR = 1), the SPDIFRX goes to STATE_STOP, and waits for software acknowledge.
- At any time the software can set SPDIFRXEN to 0, then SPDIFRX returns immediately to STATE_IDLE. If a DMA transfer is on-going, it is properly completed.

When SPDIFRX is in STATE_STOP:
- The SPDIFRX stops reception and synchronization, and waits for the software to set the bit SPDIFRXEN to 0, in order to clear the error flags.

NOTE: SYNCD is an internal event informing that the SPDIFRX is properly synchronized.
When SPDFRXEN is set to 0, the SPDFRX is disabled, meaning that all the state machines are reset, and RX_BUF is flushed. Note as well that flags FERR, SERR and TERR are reset.

55.3.7 Data reception management

The SPDFRX offers a double buffer for the audio sample reception. A 32-bit buffer located into the spdifrx_ker_ck clock domain (RX_BUF), and the SPDFRX_FMTx_DR register. The valid data contained into the RX_BUF are immediately transferred into SPDFRX_FMTx_DR if SPDFRX_FMTx_DR is empty.

The valid data contained into the RX_BUF are transferred into SPDFRX_FMTx_DR when the two following conditions are reached:

- The transition between the parity bit (P) and the next preamble is detected (this indicated that the word is completely received).
- The SPDFRX_FMTx_DR is empty.

Having a 2-word buffer gives more flexibility for the latency constraint.

The maximum latency allowed is \( T_{SAMPLE} - 2T_{PCLK} - 2T_{spdifrx_ker_ck} \)

Where \( T_{SAMPLE} \) is the audio sampling rate of the received stereo audio samples, \( T_{PCLK} \) is the period of spdifrx_pclk clock, and \( T_{spdifrx_ker_ck} \) is the period of spdifrx_ker_ck clock.

The SPDFRX offers the possibility to use either DMA (spdifrx_dat_dma and spdifrx_ctrl_dma) or interrupts for transferring the audio samples into the memory. The recommended option is DMA, refer to Section 55.3.11: DMA interface for additional information.

The SPDFRX offers several way on handling the received data. The user can either have a separate flow for control information and audio samples, or get them all together.

For each sub-frame, the data reception register SPDFRX_FMTx_DR contains the 24 data bits, and optionally the V, U, C, PE status bits, and the PT (see Mixing data and control flow).

Note that PE bit stands for parity rrror bit, and is set to 1 when a parity error is detected in the decoded sub-frame.

The PT field carries the preamble type (B, M or W).

V, U and C are a direct copy of the value received from the S/PDIF interface.

The bit DRFMT allows the selection between 3 audio formats as shown in Figure 722.

This document describes 3 data registers: SPDFRX_FMTx[2:0] (x = 2 to 0), but in reality there is only one physical data register, having 3 possible formats:

- When DRFMT = 0, the format of the data register is the one described by SPDFRX_FMT0_DR
- When DRFMT = 1, the format of the data register is the one described by SPDFRX_FMT1_DR
- When DRFMT = 2, the format of the data register is the one described by SPDFRX_FMT2_DR
Figure 722. SPDIFRX_FMTx_DR register format

Setting DRFMT to 00 or 01, offers the possibility to have the data either right or left aligned into the SPDIFRX_FMTx_DR register. The status information can be enabled or forced to zero according to the way the software wants to handle them.

The format given by DRFMT= 10 is interesting in non-linear mode, as only 16 bits per sub-frame are used. By using this format, the data of two consecutive sub-frames are stored into SPDIFRX_FMTx_DR, dividing by two the amount of memory footprint. Note that when RXSTEO = 1, there is no misalignment risks (i.e. data from ChA are always stored into SPDIFRX_FMTx_DR[31:16]). If RXSTEO = 0, then there is a misalignment risk is case of overrun situation. In that case SPDIFRX_FMTx_DR[31:16] always contain the oldest value and SPDIFRX_FMTx_DR[15:0] the more recent value (see Figure 724).

In this format the status information cannot be mixed with data, but the user can still get them through SPDIFRX_CSR register, and use a dedicated DMA channel or interrupt to transfer them to memory (see Section 55.3.8: Dedicated control flow)

Mixing data and control flow

The user can choose to use this mode in order to get the full flexibility of the handling of the control flow. The user can select which field must be kept into the data register (SPDIFRX_FMTx_DR).

- When bit PMSK = 1, the parity error information is masked (set to 0), otherwise it is copied into SPDIFRX_FMTx_DR.
- When bit VMSK = 1, the validity information is masked (set to 0), otherwise it is copied into SPDIFRX_FMTx_DR.
• When bit CUMSK = 1, the channel status, and used data information are masked (set to 0), otherwise they are copied into SPDIFRX_FMTx_DR.
• When bit PTMSK = 1, the preamble type is masked (set to 0), otherwise it is copied into SPDIFRX_FMTx_DR.

55.3.8 Dedicated control flow

The SPDIFRX offers the possibility to catch both user data and channel status information via a dedicated DMA channel. This feature allows the SPDIFRX to acquire continuously the channel status and user information. The acquisition starts at the beginning of a IEC 60958 block. Two fields are available to control this path: CBDMAEN and SPDIFRXEN. When SPDIFRXEN is set to 01 or 0x11, the acquisition is started, after completion of the synchronization phase. When 8 channel status and 16 user data bits are received, they are packed and stored into SPDIFRX_CSR register. A DMA request is triggered if the bit CBDMAEN is set to 1 (see Figure 723).

If CS[0] corresponds to the first bit of a new block, the bit SOB is set to 1. Refer to Section 55.5.8: SPDIFRX channel status register (SPDIFRX_CSR). A bit is available (CHSEL) in order to select if the user wants to select channel status information (C) from the channel A or B.

Figure 723. Channel/user data format

Note: Once the first start of block is detected (B preamble), the SPDIFRX is checking the preamble type every 8 frames.

Note: Overrun error on SPDIFRX_FMTx_DR register does not affect this path.
55.3.9 Reception errors

Frame structure and synchronization error

The SPDIFRX, detects errors, when one of the following condition occurs:

- The FERR bit is set to 1 on the following conditions:
  - For each of the 28 information bits, if one symbol transition sequence is not correct: for example if short pulses are not grouped by pairs.
  - If preambles occur to an unexpected place, or an expected preamble is not received.
- The SERR bit is set when the synchronization fails, because the number of re-tries exceeded the programmed value.
- The TERR bit is set when the counter used to estimate the width between two transitions overflows (TRCNT).

The overflow occurs when no transition is detected during 8192 periods of spdifrx_ker_ck clock. It represents at most a time interval of 11.6 frames.

When one of those flags goes to 1, the traffic on selected SPDIFRX_IN is then ignored, an interrupt is generated if the IFEIE bit of the SPDIFRX_CR register is set.

The normal procedure when one of those errors occur is:

- Set SPDIFRXEN to 0 in order to clear the error flags
- Set SPDIFRXEN to 01 or 11 in order to restart the SPDIFRX

Refer to Figure 721 for additional information.

Parity error

For each sub-frame, an even number of zeros and ones is expected inside the 28 information bits. If not, the parity error bit PERR is set in the SPDIFRX_SR register and an interrupt is generated if the parity interrupt enable PERRIE bit is set in the SPDIFRX_CR register. The reception of the incoming data is not paused, and the SPDIFRX continue to deliver data to SPDIFRX_FMTx_DR even if the interrupt is still pending.

The interrupt is acknowledged by clearing the PERR flag through PERRCF bit.

If the software wants to guarantee the coherency between the data read in the SPDIFRX_FMTx_DR register and the value of the bit PERR, the bit PMSK must be set to 0.

Overrun error

If both SPDIFRX_FMTx_DR and RX_BUF are full, while the SPDIFRX_DC needs to write a new sample in RX_BUF, this new sample is dropped, and an overrun condition is triggered. The overrun error flag OVR is set in the SPDIFRX_SR register and an interrupt is generated if the OVRIE bit of the SPDIFRX.CR register is set.

If the RXSTEO bit is set to 0, then as soon as the RX_BUF is empty, the SPDIFRX stores the next incoming data, even if the OVR flag is still pending. The main purpose is to reduce as much as possible the amount of lost samples. Note that the behavior is similar independently of DRFMT value. See Figure 724.
If the RXSTEO bit is set to 1, it means that stereo data are transported, then the SPDIFRX has to avoid misalignment between left and right channels. So the peripheral has to drop a second sample even if there is room inside the RX_BUF in order to avoid misalignment. Then the incoming samples can be written normally into the RX_BUF even if the OVR flag is still pending. Refer to Figure 725.

The OVR flag is cleared by software, by setting the OVRCF bit to 1.
55.3.10 Clocking strategy

The SPDIFRX block needs two different clocks:
- The APB clock (spdifrx_pclk), which is used for the register interface,
- The spdifrx_ker_ck which is mainly used by the SPDIFRX_DC part. Those clocks are not supposed to be phase locked, so all signals crossing those clock domains are re-synchronized (SYNC block on Figure 711).

In order to decode properly the incoming S/PDIF stream the SPDIFRX_DC must re-sample the received data with a clock at least 11 times higher than the maximum symbol rate, or 704 times higher than the audio sample rate. For example if the user expects to receive a symbol rate to up to 12.288 MHz, the sample rate must be at least 135.2 MHz. The clock used by the SPDIFRX_DC is the spdifrx_ker_ck.

The frequency of the spdifrx_pclk must be at least equal to the symbol rate.

Table 459. Minimum spdifrx_ker_ck frequency versus audio sampling rate(1)

<td>12.288 MHz</td>
<td>135.2 MHz</td>
<td>For 192 kHz stream</td>
</tr>
</tbody>
</table>

1. Check the RCC capabilities in order to verify which sampling rates can be supported.

55.3.11 DMA interface

The SPDIFRX interface is able to perform communication using the DMA.

Note: The user must refer to product specifications for availability of the DMA controller.

The SPDIFRX offers two independent DMA channels:
- A DMA channel dedicated to the data transfer
- A DMA channel dedicated to the channel status and user data transfer
The DMA mode for the data can be enabled for reception by setting the RXDMAEN bit in the SPDIFRX_CR register. In this case, as soon as the SPDIFRX_FMTx_DR is not empty, the SPDIFRX interface sends a transfer request to the DMA. The DMA reads the data received through the SPDIFRX_FMTx_DR register without CPU intervention.

For the use of DMA for the control data refer to Section 55.3.8: Dedicated control flow.

### 55.3.12 Interrupt generation

An interrupt line is shared between:
- Reception events for data flow (RXNE)
- Reception event for control flow (CSRNE)
- Data corruption detection (PERR)
- Transfer flow interruption (OVR)
- Frame structure and synchronization errors (SERR, TERR and FERR)
- Start of new block interrupt (SBD)
- Synchronization done (SYNCD)

#### Figure 726. SPDIFRX interface interrupt mapping diagram
Clearing interrupt source

- RXNE is cleared when SPDIFRX_FMTx_DR register is read
- CSRNE is cleared when SPDIFRX_CSR register is read
- FERR is cleared when SPDIFRXEN is set to 0
- SERR is cleared when SPDIFRXEN is set to 0
- TERR is cleared when SPDIFRXEN is set to 0
- Others are cleared through SPDIFRX_IFCR register

Note: The SBD event can only occur when the SPDIFRX is synchronized to the input stream (SYNCD = 1).
The SBD flag behavior is not guaranteed when the sub-frame which contains the B preamble is lost due to an overrun.

55.3.13 Register protection

The SPDIFRX block embeds some hardware protection avoid erroneous use of control registers. The table hereafter shows the bit field properties according to the SPDIFRX state.

<table>
<thead>
<tr>
<th>Registers</th>
<th>Field</th>
<th>SPDIFRXEN</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>00 (STATE_IDLE)</td>

<td>rw</td>
</tr>
<tr>
<td></td>
<td>RXDMAEN</td>
<td>rw</td>
</tr>
<tr>
<td>SPDIFRX_IMR</td>
<td>All fields</td>
<td>rw</td>
</tr>
</tbody>
</table>

The table clearly shows that fields such as INSEL must be programmed when the SPDIFRX is in STATE_IDLE. In the others SPDIFRX states, the hardware prevents writing to this field.

Note: Even if the hardware allows the writing of CBDMAEN and RXDMAEN “on-the-fly”, it is not recommended to enable the DMA when the SPDIFRX already receives data. Each of the mask bits (such as PMSK, VMSK) can be changed “on-the-fly” at any SPDIFRX state, but any change does not affect data which are already hold in SPDIFRX_FMTx_DR.
55.4 Programming procedures

The following example illustrates a complete activation sequence of the SPDIFRX block. The data path and channel status and user information both use a dedicated DMA channel. The activation sequence is then split into the following steps:

- Wait for valid data on the selected SPDIFRX_IN input
- Synchronize to the S/PDIF stream
- Read the channel status and user information in order to setup the complete audio path
- Start data acquisition

A simple way to check if valid data are available into the SPDIFRX_IN line is to switch the SPDIFRX into the STATE_SYNC, with bit WFA set to 1. The description hereafter focuses on detection. It is also possible to implement this function as follows:

- The software has to check from time to time (i.e. every 100 ms for example) if the SPDIFRX can find synchronization. This can be done by checking if the bit TERR is set. When it is set it indicates that no activity as been found.
- Connect the SPDIFRX_IN input to an external interrupt event block in order to detect transitions of SPDIFRX_IN line. When activity is detected, then SPDIFRXEN can be set to 01 or 11.

For those two implementations, the bit WFA is set to 0.

55.4.1 Initialization phase

- The initialization function looks like this:
- Configure the DMA transfer for both audio samples and IEC60958 channel status and user information (DMA channel selection and activation, priority, number of data to transfer, circular/no circular mode, DMA interrupts)
- Configure the destination address:
  - Configure the address of the SPDIFRX_CSR register as source address for IEC60958 channel status and user information
  - Configure the address of the SPDIFRX_FMTx_DR register as source address for audio samples
  - Enable the generation of the spdifrx_ker_ck. Refer to Table 459 in order to define the minimum clock frequency versus supported audio sampling rate. Note that the audio sampling rate of the received stream is not known in advance. This means that the user has to select a spdifrx_ker_ck frequency at least 704 times higher than the maximum audio sampling rate the application is supposed to handle; for example if the application is able to handle streams to up to 96 kHz, then \( F_{\text{spdifrx\_ker\_ck}} \) must be at least \( 704 \times 96 \text{ kHz} = 67.6 \text{ MHz} \)
- Enable interrupt for errors and event signaling (IFEIE = SYNCDIE = OVRIE, PERRIE = 1, others set to 0). Note that SYNCDIE can be set to 0.
• Configure the SPDIFRX_CR register:
  – INSEL must select the wanted input
  – NBTR = 2, WFA = 1 (16 re-tries allowed, wait for activity before going to synchronization phase),
  – PTMSK = CUMSK = 1 (Preamble, C and U bits are not mixed with data)
  – VMSK = PMSK = 0 (Parity error and validity bit mixed with data)
  – CHSEL = 0 (channels status are read from sub-frame A)
  – DRFMT = 01 (data aligned to the left)
  – RXSTEO = 1 (expected stereo mode linear)
  – CBDMAEN = RXDMAEN = 1 (enable DMA channels)
  – SPDIFRXEN = 01 (switch SPDIFRX to STATE_SYNC)

• The CPU can enter in WFI mode

Then the CPU receives interrupts coming either from DMA or SPDIFRX.

55.4.2 Handling of interrupts coming from SPDIFRX

When an interrupt from the SPDIFRX is received, then the software has to check what is the source of the interrupt by reading the SPDIFRX_SR register.

• If SYNCD is set to 1, then it means that the synchronization is properly completed. No action has to be performed in our case as the DMA is already programmed. The software just needs to wait for DMA interrupt in order to read channel status information. The SYNCD flag must be cleared by setting SYNCDCF bit of SPDIFRX_IFCR register to 1.

• If TERR or SERR or FERR are set to 1, the software has to set SPDIFRXEN to 0, and re-start from the initialization phase.
  – TERR indicates that a time-out occurs either during synchronization phase or after.
  – SERR indicates that the synchronization fails because the maximum allowed re-tries are reached.
  – FERR indicates that the reading of information after synchronization fails (such as unexpected preamble, bad data decoding).

• If PERR is set to 1, it means that a parity error is detected, so one of the received audio sample or the channel status or user data bits are corrupted. The action taken here depends on the application: one action can be to drop the current channel status block as it is not reliable. There is no need to re-start from the initialization phase, as the synchronization is not lost. The PERR flag must be cleared by setting PERRCF bit of SPDIFRX_IFCR register to 1.

55.4.3 Handling of interrupts coming from DMA

If an interrupt comes from the DMA channel used of the channel status (SPDIFRX_CSR):

If no error occurred (that is PERR), the CPU can start the decoding of channel information. For example bit 1 of the channel status informs the user if the current stream is linear or not. This information is very important in order to set-up the proper
processing chain. In the same way, bits 24 to 27 of the channel status give the sampling frequency of the stream incoming stream.

Thanks to that information, the user can then configure the RXSTEO bit and DRFMT field prior to start the data reception. For example if the current stream is non linear PCM then RXSTEO is set to 0, and DRFMT is set to 10. Then the user can enable the data reception by setting SPDIFRXEN to 11.

The SOB bit, when set to 1 indicates the start of a new block. This information helps the software to identify the bit 0 of the channel status. Note that if the DMA generates an interrupt every time 24 values are transferred into the memory, then the first word always corresponds to the start of a new block.

If an interrupt comes from the DMA channel used of the audio samples (SPDIFRX_FMTx_DR):

The process performed here depends of the data type (linear or non-linear), and on the data format selected.

For example in linear mode, if PE or V bit is set a special processing can be performed locally in order to avoid spurs on output. In non-linear mode those bits are not important as data frame have their own checksum.

### 55.5 SPDIFRX interface registers

#### 55.5.1 SPDIFRX control register (SPDIFRX_CR)

Only 32-bit accesses are allowed in this register.

Address offset: 0x00

Reset value: 0x0000 0000

</tr>
</tbody>
</table>

Bit 15 Reserved, must be kept at reset value.
Bit 14  **WFA**: Wait for activity\(^{(1)}\)
This bit is set/reset by software.
1: The SPDIFRX waits for activity on SPDIFRX_IN line (4 transitions) before performing the synchronization.
0: The SPDIFRX does not wait for activity on SPDIFRX_IN line before performing the synchronization.

Bits 13:12  **NBTR[1:0]**: Maximum allowed re-tries during synchronization phase\(^{(1)}\)
00: No re-try is allowed (only one attempt)
01: 3 re-tries allowed
10: 15 re-tries allowed
11: 63 re-tries allowed

Bit 11  **CHSEL**: Channel selection\(^{(1)}\)
This bit is set/reset by software.
1: The control flow takes the channel status from channel B.
0: The control flow takes the channel status from channel A.

Bit 10  **CBDMAEN**: Control buffer DMA enable for control flow\(^{(1)}\)
This bit is set/reset by software.
1: DMA mode is enabled for reception of channel status and used data information.
0: DMA mode is disabled for reception of channel status and used data information.
*Note: When this bit is set, the DMA request is made whenever the CSRNE flag is set.*

Bit 9  **PTMSK**: Mask of preamble type bits\(^{(1)}\)
This bit is set/reset by software.
1: The preamble type bits are not copied into the SPDIFRX_FMTx_DR, zeros are written instead.
0: The preamble type bits are copied into the SPDIFRX_FMTx_DR.

Bit 8  **CUMSK**: Mask of channel status and user bits\(^{(1)}\)
This bit is set/reset by software.
1: The channel status and user bits are not copied into the SPDIFRX_FMTx_DR, zeros are written instead.
0: The channel status and user bits are copied into the SPDIFRX_FMTx_DR.

Bit 7  **VMSK**: Mask of validity bit\(^{(1)}\)
This bit is set/reset by software.
1: The validity bit is not copied into the SPDIFRX_FMTx_DR, a zero is written instead.
0: The validity bit is copied into the SPDIFRX_FMTx_DR.

Bit 6  **PMSK**: Mask parity error bit\(^{(1)}\)
This bit is set/reset by software.
1: The parity error bit is not copied into the SPDIFRX_FMTx_DR, a zero is written instead.
0: The parity error bit is copied into the SPDIFRX_FMTx_DR.

Bits 5:4  **DRFMT[1:0]**: RX data format\(^{(1)}\)
This bit is set/reset by software.
11: reserved
10: Data sample are packed by setting two 16-bit sample into a 32-bit word.
01: Data samples are aligned in the left (MSB)
00: Data samples are aligned in the right (LSB).
Bit 3  **RXSTEO**: Stereo mode\(^{(1)}\)

This bit is set/reset by software.

1: The peripheral is in stereo mode.
0: The peripheral is in mono mode.

*Note*: This bit is used in case of overrun situation in order to handle misalignment.

Bit 2  **RXDMAEN**: Receiver DMA enable for data flow\(^{(1)}\)

This bit is set/reset by software.

1: DMA mode is enabled for reception.
0: DMA mode is disabled for reception.

*Note*: When this bit is set, the DMA request is made whenever the RXNE flag is set.

Bits 1:0  **SPDIFRXEN[1:0]**: Peripheral block enable\(^{(1)}\)

This field is modified by software.

It must be used to change the peripheral phase among the three possible states: STATE_IDLE, STATE_SYNC and STATE_RCV.

00: Disable SPDIFRX (STATE_IDLE).
01: Enable SPDIFRX synchronization only.
10: Reserved
11: Enable SPDIF receiver.

*Note*: It is not possible to transition from STATE_RCV to STATE_SYNC, the user must first go the STATE_IDLE.

it is possible to transition from STATE_IDLE to STATE_RCV: in that case the peripheral transitions from STATE_IDLE to STATE_SYNC and as soon as the synchronization is performed goes to STATE_RCV.

1. Refer to Section 55.3.13: Register protection for additional information on fields properties.

### 55.5.2  SPDIFRX interrupt mask register (SPDIFRX_IMR)

Address offset: 0x04

Reset value: 0x0000 0000

Bits 31:7  Reserved, must be kept at reset value.

Bit 6  **IFEIE**: Serial interface error interrupt enable

This bit is set and cleared by software.

0: Interrupt is inhibited.
1: A SPDIFRX interface interrupt is generated whenever SERR = 1, TERR = 1, or FERR = 1 in the SPDIFRX_SR register.

Bit 5  **SYNCDIE**: Synchronization done

This bit is set and cleared by software.

0: Interrupt is inhibited.
1: A SPDIFRX interface interrupt is generated whenever SYNCD = 1 in the SPDIFRX_SR register.
Bit 4 **SBLKIE**: Synchronization block detected interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited.
1: A SPDIFRX interface interrupt is generated whenever SBD = 1 in the SPDIFRX_SR register.

Bit 3 **OVRIE**: Overrun error interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited.
1: A SPDIFRX interface interrupt is generated whenever OVR=1 in the SPDIFRX_SR register.

Bit 2 **PERRIE**: Parity error interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited.
1: A SPDIFRX interface interrupt is generated whenever PERR=1 in the SPDIFRX_SR register.

Bit 1 **CSNIE**: Control buffer ready interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited.
1: A SPDIFRX interface interrupt is generated whenever CSRNE = 1 in the SPDIFRX_SR register.

Bit 0 **RXNEIE**: RXNE interrupt enable
This bit is set and cleared by software.
0: Interrupt is inhibited.
1: A SPDIFRX interface interrupt is generated whenever RXNE=1 in the SPDIFRX_SR register.

### 55.5.3 SPDIFRX status register (SPDIFRX_SR)
Address offset: 0x08
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31-16</th>
<th>WIDTH[14:0]</th>
<th>Bit 15-9</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>r r r r r r r r r r r r r r r</td>
<td>TERR SERR FERR SYNCD SBD OVR PERR CSRNE RXNE</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Bit 31: Reserved, must be kept at reset value.

Bits 30:16 **WIDTH[14:0]**: duration of 5 symbols counted with spdifrx_ker_ck
This value represents the amount of spdifrx_ker_ck clock periods contained on a length of 5 consecutive symbols. This value can be used to estimate the S/PDIF symbol rate. Its accuracy is limited by the frequency of spdifrx_ker_ck.

For example if the spdifrx_ker_ck is fixed to 84 MHz, and WIDTH5 = 147d. The estimated sampling rate of the S/PDIF stream is:
\[
Fs = 5 \times F_{spdifrx_ker_ck} / (WIDTH5 \times 64) \approx 44.6 \text{ kHz},
\]
so the closest standard sampling rate is 44.1 kHz.

Note that WIDTH5 is updated by the hardware when SYNCD goes high, and then every frame.

Bits 15:9: Reserved, must be kept at reset value.

</tbody>
</table>

*Note: When this bit is set, the SPDIFRX_FMTx_DR register content is not lost but the last data received are.*
Bit 2 **PERR**: Parity error
This bit is set by hardware when the data and status bits of the sub-frame received contain an odd number of 0 and 1.
This flag is cleared by writing a 1 to its corresponding bit on SPDIFRX_IFCR register.
An interrupt is generated if PIE = 1 in the SPDIFRX_IMR register.
0: No parity error
1: Parity error

Bit 1 **CSRN**E: Control buffer register not empty
This bit is set by hardware when a valid control information is ready.
This flag is cleared when reading SPDIFRX_CSR register.
An interrupt is generated if CBRDYIE = 1 in the SPDIFRX_IMR register.
0: No control word available on SPDIFRX_CSR register
1: A control word is available on SPDIFRX_CSR register.

Bit 0 **RXNE**: Read data register not empty
This bit is set by hardware when a valid data is available into SPDIFRX_FMTx_DR register.
This flag is cleared by reading the SPDIFRX_FMTx_DR register.
An interrupt is generated if RXNEIE=1 in the SPDIFRX_IMR register.
0: Data is not received.
1: Received data is ready to be read.

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **SYNCD**CF: clears the synchronization done flag
Writing 1 in this bit clears the flag SYNCD in the SPDIFRX_SR register.
Reading this bit always returns the value 0.

Bit 4 **SB**DCF: clears the synchronization block detected flag
Writing 1 in this bit clears the flag SBD in the SPDIFRX_SR register.
Reading this bit always returns the value 0.

Bit 3 **OVR**CF: clears the overrun error flag
Writing 1 in this bit clears the flag OVR in the SPDIFRX_SR register.
Reading this bit always returns the value 0.

Bit 2 **PERR**CF: clears the parity error flag
Writing 1 in this bit clears the flag PERR in the SPDIFRX_SR register.
Reading this bit always returns the value 0.

Bits 1:0 Reserved, must be kept at reset value.
55.5.5  SPDIFRX data input register (SPDIFRX_FMT0_DR)

Address offset: 0x10
Reset value: 0x0000 0000

This register can take three different formats according to DRFMT. Here is the format when DRFMT = 00:

| 0: CS[0] is not the first bit of a new block |
| 1: CS[0] is the first bit of a new block |
| Bit 23-16 | CS[7:0]: channel A status information |
| Bit CS[0] is the oldest value |
| Bit 15-0 | USR[15:0]: user data information |
| Bit USR[0] is the oldest value, and comes from channel A, USR[1] comes channel B. |
| So USR[n] bits come from channel A is n is even, otherwise they come from channel B. |

55.5.9 SPDIFRX debug information register (SPDIFRX_DIR)

Address offset: 0x18
Reset value: 0x0000 0000

| Bit 31-29 | Reserved, must be kept at reset value. |
| Bit 28-16 | TLO[12:0]: threshold LOW (TLO = 1.5 x UI / Tspdifrx_ker_ck) |
| This field contains the current threshold LOW estimation. This value can be used to estimate the sampling rate of the received stream. The accuracy of TLO is limited to a period of the spdifrx_ker_ck. The sampling rate can be estimated as follow: |
| Sampling Rate = [2 x TLO x Tspdifrx_ker_ck +/- Tspdifrx_ker_ck] x 2/3 |
| Note that TLO is updated by the hardware when SYNCD goes high, and then every frame. |
| Bit 15-13 | Reserved, must be kept at reset value. |
Bits 12:0 THI[12:0]: threshold HIGH (THI = 2.5 x UI / Tspdifrx_ker_ck)
This field contains the current threshold HIGH estimation. This value can be used to estimate the sampling rate of the received stream. The accuracy of THI is limited to a period of the spdifrx_ker_ck. The sampling rate can be estimated as follow:
Sampling Rate = [2 x THI x Tspdifrx_ker_ck +/- Tspdifrx_ker_ck] x 2/5
Note that THI is updated by the hardware when SYNCD goes high, and then every frame.

56 Single wire protocol master interface (SWPMI)

56.1 Introduction

The single wire protocol master interface (SWPMI) is the master interface corresponding to the contactless front-end (CLF) defined in the ETSI TS 102 613 technical specification.

The principle of the Single wire protocol (SWP) is based on the transmission of digital information in full duplex mode:

- S1 signal (from Master to Slave) is transmitted by a digital modulation (L or H) in the voltage domain (refer to\ Figure 727: S1 signal coding),
- S2 signal (from Slave to Master) is transmitted by a digital modulation (L or H) in the current domain (refer to\ Figure 728: S2 signal coding).

\begin{figure}[h]
\centering
\includegraphics[width=0.8\textwidth]{swpmi_s1_signal_coding}
\caption{S1 signal coding}
\end{figure}

\begin{figure}[h]
\centering
\includegraphics[width=0.8\textwidth]{swpmi_s2_signal_coding}
\caption{S2 signal coding}
\end{figure}
56.2 SWPMI main features

The SWPMI module main features are the following (see Figure 56.3.4: SWP bus states):

- Full-duplex communication mode
- Automatic SWP bus state management
- Automatic handling of Start of frame (SOF)
- Automatic handling of End of frame (EOF)
- Automatic handling of stuffing bits
- Automatic CRC-16 calculation and generation in transmission
- Automatic CRC-16 calculation and checking in reception
- 32-bit Transmit data register
- 32-bit Receive data register
- Multi software buffer mode for efficient DMA implementation and multi frame buffering
- Configurable bit-rate up to 2 Mbit/s
- Configurable interrupts
- CRC error, underrun, overrun flags
- Frame reception and transmission complete flags
- Slave resume detection flag
- Loopback mode for test purpose
- Embedded SWPMI_IO transceiver compliant with ETSI TS 102 613 technical specification
- Dedicated mode to output SWPMI_RX, SWPMI_TX and SWPMI_SUSPEND signals on GPIOs, in case of external transceiver connection
56.3  SWPMI functional description

56.3.1  SWPMI block diagram

Refer to the bit SWPSRC in Section 9.7.19: RCC domain 2 kernel clock configuration register (RCC_D2CCIP1R) to select the swpmi_ker_ck (SWPMI core clock source).

Note: In order to support the exit from Stop mode by a RESUME by slave, it is mandatory to select HSI for swpmi_ker_ck. If this feature is not required, swpmi_pclk can be selected, and SWPMI must be disabled before entering the Stop mode.

56.3.2  SWPMI pins and internal signals

Table 462 lists the SWPMI slave inputs and output signals connected to package pins or balls, while Table 463 shows the internal SWPMI signals.

56.3.3 SWP initialization and activation

The initialization and activation will set the SWPMI_IO state from low to high.

When using the internal transceiver, the procedure is the following:

1. Configure the SWP_CLASS bit in SWPMI_OR register according to the VDD voltage (3 V or 1.8 V),
2. Set SWPTEN in SWPMI_CR register to enable the SWPMI_IO transceiver and set the SWPMI_IO to low level (SWP bus DEACTIVATED)
3. Wait for the RDYF flag in SWPMI_SR register to be set (polling the flag or enabling the interrupt with RDYIE bit in SWPMI_IER register),
4. Set SWPACT bit in SWPMI_CR register to ACTIVATE the SWP i.e. to move from DEACTIVATED to SUSPENDED.
56.3.4 SWP bus states

The SWP bus can have the following states: DEACTIVATED, SUSPENDED, ACTIVATED. Several transitions are possible:

- ACTIVATE: transition from DEACTIVATED to SUSPENDED state,
- SUSPEND: transition from ACTIVATED to SUSPENDED state,
- RESUME by master: transition from SUSPENDED to ACTIVATED state initiated by the master,
- RESUME by slave: transition from SUSPENDED to ACTIVATED state initiated by the slave,
- DEACTIVATE: transition from SUSPENDED to DEACTIVATED state.

ACTIVATE

During and just after reset, the SWPMI_IO is configured in analog mode. Refer to Section 56.3.3: SWP initialization and activation to activate the SWP bus.

SUSPEND

The SWP bus stays in the ACTIVATED state as long as there is a communication with the slave, either in transmission or in reception. The SWP bus switches back to the SUSPENDED state as soon as there is no more transmission or reception activity, after 7 idle bits.

RESUME by master

Once the SWPMI is enabled, the user can request a SWPMI frame transmission. The SWPMI first sends a transition sequence and 8 idle bits (RESUME by master) before starting the frame transmission. The SWP moves from the SUSPENDED to ACTIVATED state after the RESUME by master (refer to Figure 730: SWP bus states).

RESUME by slave

Once the SWPMI is enabled, the SWP can also move from the SUSPENDED to ACTIVATED state if the SWPMI receives a RESUME from the slave. The RESUME by slave sets the SRF flag in the SWPMI_ISR register.

DEACTIVATE

Deactivate request

If no more communication is required, and if SWP is in the SUSPENDED mode, the user can request to switch the SWP to the DEACTIVATED mode by disabling the SWPMI peripheral. The software must set DEACT bit in the SWPMI_CR register in order to request the DEACTIVATED mode. If no RESUME by slave is detected by SWPMI, the DEACTF flag is set in the SWPMI_ISR register and the SWPACT bit is cleared in the SWPMI_ICR register. In case a RESUME by slave is detected by the SWPMI while the software is setting DEACT bit, the SRF flag is set in the SWPMI_ISR register, DEACTF is kept cleared, SWPACT is kept set and DEACT bit is cleared.

In order to activate SWP again, the software must clear DEACT bit in the SWPMI_CR register before setting SWPACT bit.
**Deactivate mode**

In order to switch the SWP to the DEACTIVATED mode immediately, ignoring any possible incoming RESUME by slave, the user must clear SWPACT bit in the SWPMI_CR register.

*Note:* In order to further reduce current consumption, configure the SWPMI_IO port as output push pull low in GPIO controller and then clear the SWPTEN bit in SWPMI_CR register (refer to Section 12: General-purpose I/Os (GPIO)).

---

**Figure 730. SWP bus states**

---

### 56.3.5 SWPMI_IO (internal transceiver) bypass

A SWPMI_IO (transceiver), compliant with ETSI TS 102 613 technical specification, is embedded in the microcontroller. Nevertheless, this is possible to bypass it by setting SWP_TBYP bit in SWPMI_OR register. In this case, the SWPMI_IO is disabled and the SWPMI_RX, SWPMI_TX and SWPMI_SUSPEND signals are available as alternate functions on three GPIOs (refer to “Pinouts and pin description” in product datasheet). This configuration is selected to connect an external transceiver.

*Note:* In SWPMI_IO bypass mode, SWPTEN bit in SWPMI_CR register must be kept cleared.

### 56.3.6 SWPMI bit rate

The bit rate must be set in the SWPMI_BRR register, according to the following formula:

\[ F_{SWP} = F_{swpmi\_ker\_ck} / (BR[7:0]+1) \times 4 \]

*Note:* The maximum bitrate is 2 Mbit/s.
56.3.7 SWPMI frame handling

The SWP frame is composed of a Start of frame (SOF), a Payload from 1 to 30 bytes, a 16-bit CRC and an End of frame (EOF) (Refer to Figure 731: SWP frame structure).

Figure 731. SWP frame structure

The SWPMI embeds one 32-bit data register for transmission (SWPMI_TDR), and one 32-bit data register for reception (SWPMI_RDR).

In transmission, the SOF insertion, the CRC calculation and insertion, and the EOF insertion are managed automatically by the SWPMI. The user only has to provide the Payload content and size. A frame transmission starts as soon as data is written into the SWPMI_TDR register. Dedicated flags indicate an empty transmit data register and a complete frame transmission event.

In reception, the SOF deletion, the CRC calculation and checking, and the EOF deletion are managed automatically by the SWPMI. The user only has to read the Payload content and size. Dedicated flags indicate a full receive data register, a complete frame reception and possibly CRC error events.

The stuffing bits insertion (in transmission) and stuffing bits deletion (in reception) are managed automatically by the SWPMI core. These operations are transparent for the user.

56.3.8 Transmission procedure

Before starting any frame transmission, the user must activate the SWP. Refer to Section 56.3.3: SWP initialization and activation.

There are several possible software implementations for a frame transmission: No software buffer mode, Single software buffer mode, and Multi software buffer mode.

The software buffer usage requires the use of a DMA channel to transfer data from the software buffer in the RAM memory to the transmit data register in the SWPMI peripheral.

No software buffer mode

This mode does not require the use of DMA. The SWP frame transmission handling is done by polling status flags in the main loop or inside the SWPMI interrupt routine. There is a 32-bit transmit data register (SWPMI_TDR) in the SWPMI, thus writing to this register will trigger the transmission of up to 4 bytes.

The No software buffer mode is selected by clearing TXDMA bit in the SWPMI_CR register.

The frame transmission is started by the first write to the SWPMI_TDR register. The low significant byte of the first 32-bit word (bits [7:0]) written into the SWPMI_TDR register indicates the number of data bytes in the payload, and the 3 other bytes of this word must
contain the first 3 bytes of the payload (bits [15:8] contain the first byte of the payload, bits [23:16] the second byte and bits [31:24] the third byte). Then, the following writes to the SWPMI_TDR register will only contain the following payload data bytes, up to 4 for each write.

**Note:** The low significant byte of the first 32-bit word written into the SWPMI_TDR register is coding the number of data bytes in the payload. This number could be from 1 to 30. Any other value in the low significant byte will be ignored and the transmission will not start.

Writing to the SWPMI_TDR register will induce the following actions:
- Send the transition sequence and 8 idle bits (RESUME by master) if the SWP bus state is SUPENDED (this will not happen if the SWP bus state is already ACTIVATED),
- Send a Start of frame (SOF),
- Send the payload according to the SWPMI_TRD register content. If the number of bytes in the payload is greater than 3, the SWPMI_TDR needs to be refilled by software, each time the TXE flag in the SWPMI_ISR register is set, and as long as the TXBEF flag is not set in the SWPMI_ISR register,
- Send the 16-bit CRC, automatically calculated by the SWPMI core,
- Send an End of frame (EOF).

The TXE flag is cleared automatically when the software is writing to the SWPMI_TDR register.

Once the complete frame is sent, provided that no other frame transmission has been requested (i.e. SWPMI_TDR has not been written again after the TXBEF flag setting), TCF and SUSP flags are set in the SWPMI_ISR register 7 idle bits after the EOF transmission, and an interrupt is generated if TCIE bit is set in the SWPMI_IER register (refer to Figure 732: SWPMI No software buffer mode transmission).

</tbody>
</table>

If another frame transmission is requested before the end of the EOF transmission, the TCF flag is not set and the frame will be consecutive to the previous one, with only one idle bit in between (refer to Figure 733: SWPMI No software buffer mode transmission, consecutive frames).
Single software buffer mode

This mode allows to transmit a complete SWP frame without a CPU intervention, using the DMA. The DMA will refill the 32-bit SWPMI_TDR register, and the software can poll the end of the frame transmission using the SWPMI_TXBEF flag.

The Single software buffer mode is selected by setting TXDMA bit and clearing TXMODE bit in the SWPMI_CR register.

The DMA channel or stream must be configured in following mode (refer to DMA section):
- memory to memory mode disabled,
- memory increment mode enabled,
- memory size set to 32-bit,
- peripheral size set to 32-bit,
- peripheral increment mode disabled,
- circular mode disabled,
- data transfer direction set to read from memory.
- the number of words to be transferred must be set according to the SWP frame length,
- the source address is the SWP frame buffer in RAM,
- the destination address is the SWPMI_TDR register.

Then the user must:
1. Set TXDMA bit in the SWPMI_CR register,
2. Set TXBEIE bit in the SWPMI_IER register,
3. Fill the buffer in the RAM memory (with the number of data bytes in the payload on the least significant byte of the first word),
4. Enable stream or channel in DMA module to start DMA transfer and frame transmission.

A DMA request is issued by SWPMI when TXE flag in SWPMI_ISR is set. The TXE flag is cleared automatically when the DMA is writing to the SWPMI_TDR register.
In the SWPMI interrupt routine, the user must check TXBEF bit in the SWPMI_ISR register. If it is set, and if another frame needs to be transmitted, the user must:
1. Disable stream or channel in DMA module
2. Update the buffer in the RAM memory with the content of the next frame to be sent
3. Configure the total number of words to be transferred in DMA module
4. Enable stream or channel in DMA module to start next frame transmission
5. Set CTXBEF bit in the SWPMI_ICR register to clear the TXBEF flag

**Multi software buffer mode**

This mode allows to work with several frame buffers in the RAM memory, in order to ensure a continuous transmission, keeping a very low CPU load, and allowing more latency for buffer update by software thanks to the DMA. The software can check the DMA counters at any time and update SWP frames accordingly in the RAM memory.

The Multi software buffer mode must be used in combination with DMA in circular mode.

Each transmission buffer in the RAM memory must have a fixed length of eight 32-bit words, whatever the number of bytes in the SWP frame payload. The transmission buffers in the RAM memory must be filled by the software, keeping an offset of 8 between two consecutive ones. The first data byte of the buffer is the number of bytes of the frame payload. See the buffer example in *Figure 734: SWPMI Multi software buffer mode transmission*.

The Multi software buffer mode is selected by setting both TXDMA and TXMODE bits in SWPMI_CR register.

For example, in order to work with 4 transmission buffers, the user must configure the DMA as follows:

The DMA channel or stream must be configured in following mode (refer to DMA section):
- memory to memory mode disabled,
- memory increment mode enabled,
- memory size set to 32-bit,
- peripheral size set to 32-bit,
- peripheral increment mode disabled,
- circular mode enabled,
- data transfer direction set to read from memory,
- the number of words to be transferred must be set to 32 (8 words per buffer),
- the source address is the buffer1 in RAM,
- the destination address is the SWPMI_TDR register.

Then, the user must:
1. Set TXDMA in the SWPMI_CR register
2. Set TXBEIE in the SWPMI_IER register
3. Fill buffer1, buffer2, buffer3 and buffer4 in the RAM memory (with the number of data bytes in the payload on the least significant byte of the first word)
4. Enable stream or channel in DMA module to start DMA.
In the SWPMI interrupt routine, the user must check TXBEF bit in the SWPMI_ISR register. If it is set, the user must set CTXBEF bit in SWPMI_ICR register to clear TXBEF flag and the user can update buffer1 in the RAM memory.

In the next SWPMI interrupt routine occurrence, the user will update buffer2, and so on.

The Software can also read the DMA counter (number of data to transfer) in the DMA registers in order to retrieve the frame which has already been transferred from the RAM memory and transmitted. For example, if the software works with 4 transmission buffers, and if the DMA counter equals 17, it means that two buffers are ready for updating in the RAM area. This is useful in case several frames are sent before the software can handle the SWPMI interrupt. If this happens, the software will have to update several buffers.

When there are no more frames to transmit, the user must disable the circular mode in the DMA module. The transmission will stop at the end of the buffer4 transmission.

If the transmission needs to stop before (for example at the end of buffer2), the user must set the low significant byte of the first word to 0 in buffer3 and buffer4.

TXDMA bit in the SWPMI_CR register will be cleared by hardware as soon as the number of data bytes in the payload is read as 0 in the least significant byte of the first word.

```
56.3.9 Reception procedure

Before starting any frame reception, the user must activate the SWP (refer to Section 56.3.3: SWP initialization and activation).

Once SWPACT bit is set in the SWPMI_CR register, a RESUME from slave state sets the SRF flag in the SWPMI_ISR register and automatically enables the SWPMI for the frame reception.

If the SWP bus is already in the ACTIVATED state (for example because a frame transmission is ongoing), the SWPMI core does not need any RESUME by slave state, and the reception can take place immediately.

There are several possible software implementations for a frame reception:

- No software buffer mode,
- Single software buffer mode,
- Multi software buffer mode.

The software buffer usage requires the use of a DMA channel to transfer data from the receive data register in the SWPMI peripheral to the software buffer in the RAM memory.

No software buffer mode

This mode does not require the use of DMA. The SWP frame reception handling is done by polling status flags in the main loop or inside the SWPMI interrupt routine. There is a 32-bit receive data register (SWPMI_RDR) in the SWPMI, allowing to receive up to 4 bytes before reading this register.

The No software buffer mode is selected by resetting RXDMA bit in the SWPMI_CR register.

Once a Start of frame (SOF) is received, the following bytes (payload) are stored in the SWPMI_RDR register. Once the SWPMI_RDR is full, the RXNE flag is set in SWPMI_ISR and an interrupt is generated if RIE bit is set in SWPMI_IER register. The user can read the SWPMI_RDR register and the RXNE flag is cleared automatically when the software is reading the SWPMI_RDR register.

Once the complete frame has been received, including the CRC and the End of frame (EOF), both RXNE and RXBFF flags are set in the SWPMI_ISR register. The user must read the last byte(s) of the payload in the SWPMI_RDR register and set CRXBFF flag in SWPMI_ICR in order to clear the RXBFF flag. The number of data bytes in the payload is available in the SWPMI_RFL register. Again, the RXNE flag is reset automatically when the software is reading the SWPMI_RDR register (refer to Figure 735: SWPMI No software buffer mode reception).

Reading the SWPMI_RDR register while RXNE is cleared will return 0.
### Single software buffer mode

This mode allows to receive a complete SWP frame without any CPU intervention using the DMA. The DMA transfers received data from the 32-bit SWPMI_RDR register to the RAM memory, and the software can poll the end of the frame reception using the SWPMI_RBFF flag.

The Single software buffer mode is selected by setting RXDMA bit and clearing RXMODE bit in the SWPMI_CR register.

The DMA must be configured as follows:

The DMA channel or stream must be configured in following mode (refer to DMA section):
- memory to memory mode disabled,
- memory increment mode enabled,
- memory size set to 32-bit,
- peripheral size set to 32-bit,
- peripheral increment mode disabled,
- circular mode disabled,
- data transfer direction set to read from peripheral,
- the number of words to be transfered must be set to 8,
- the source address is the SWPMI_RDR register,
- the destination address is the SWP frame buffer in RAM.

Then the user must:
1. Set RXDMA bit in the SWPMI_CR register
2. Set RXBFIE bit in the SWPMI_IER register
3. Enable stream or channel in DMA module.

A DMA request is issued by SWPMI when RXNE flag is set in SWPMI_ISR. The RXNE flag is cleared automatically when the DMA is reading the SWPMI_RDR register.
In the SWPMI interrupt routine, the user must check RXBFF bit in the SWPMI_ISR register. If it is set, the user must:

1. Disable stream or channel in DMA module
2. Read the number of bytes in the received frame payload in the SWPMI_RFL register
3. Read the frame payload in the RAM buffer
4. Enable stream or channel in DMA module
5. Set CRXBFF bit in the SWPMI_ICR register to clear RXBFF flag (refer to Figure 736: SWPMI single software buffer mode reception).

**Figure 736. SWPMI single software buffer mode reception**

Multi software buffer mode

This mode allows to work with several frame buffers in the RAM memory, in order to ensure a continuous reception, keeping a very low CPU load, using the DMA. The frame payloads are stored in the RAM memory, together with the frame status flags. The software can check the DMA counters and status flags at any time to handle the received SWP frames in the RAM memory.

The Multi software buffer mode must be used in combination with the DMA in circular mode. The Multi software buffer mode is selected by setting both RXDMA and RXMODE bits in SWPMI_CR register.
In order to work with \( n \) reception buffers in RAM, the DMA channel or stream must be configured in following mode (refer to DMA section):
- memory to memory mode disabled,
- memory increment mode enabled,
- memory size set to 32-bit,
- peripheral size set to 32-bit,
- peripheral increment mode disabled,
- circular mode enabled,
- data transfer direction set to read from peripheral,
- the number of words to be transfered must be set to \( 8 \times n \) (8 words per buffer),
- the source address is the SWPMI_TDR register,
- the destination address is the buffer1 address in RAM

Then the user must:
1. Set RXDMA in the SWPMI_CR register
2. Set RXBFIE in the SWPMI_IER register
3. Enable stream or channel in the DMA module.

In the SWPMI interrupt routine, the user must check RXBFF in the SWPMI_ISR register. If it is set, the user must set CRXBFF bit in the SWPMI_ICR register to clear RXBFF flag and the user can read the first frame payload received in the first buffer (at the RAM address set in DMA2_CMAR1).

The number of data bytes in the payload is available in bits [23:16] of the last 8th word.

In the next SWPMI interrupt routine occurrence, the user will read the second frame received in the second buffer (address set in DMA2_CMAR1 + 8), and so on (refer to Figure 737: SWPMI Multi software buffer mode reception).

In case the application software cannot ensure to handle the SMPMI interrupt before the next frame reception, each buffer status is available in the most significant byte of the 8th buffer word:
- The CRC error flag (equivalent to RXBERF flag in the SWPMI_ISR register) is available in bit 24 of the 8th word. Refer to Section 56.3.10: Error management for an CRC error description.
- The receive overrun flag (equivalent to RXOVRF flag in the SWPMI_ISR register) is available in bit 25 of the 8th word. Refer to Section 56.3.10: Error management for an overrun error description.
- The receive buffer full flag (equivalent to RXBFF flag in the SWPMI_ISR register) is available in bit 26 of the 8th word.

In case of a CRC error, both RXBFF and RXBERF flags are set, thus bit 24 and bit 26 are set.

In case of an overrun, an overrun flag is set, thus bit 25 is set. The receive buffer full flag is set only in case of an overrun during the last word reception; then, both bit 25 and bit 26 are set for the current and the next frame reception.

The software can also read the DMA counter (number of data to transfer) in the DMA registers in order to retrieve the frame which has already been received and transferred into the RAM memory through DMA. For example, if the software works with 4 reception buffers,
and if the DMA counter equals 17, it means that two buffers are ready for reading in the RAM area.

In Multi software buffer reception mode, if the software is reading bits 24, 25 and 26 of the 8th word, it does not need to clear RXBERF, RXOVRF and RXBFF flags after each frame reception.

Figure 7. SWPMI Multi software buffer mode reception

### 56.3.10 Error management

#### Underrun during payload transmission

During the transmission of the frame payload, a transmit underrun is indicated by the TXUNRF flag in the SWPMI_ISR register. An interrupt is generated if TXBUNREIE bit is set in the SWPMI_IER register.

If a transmit underrun occurs, the SWPMI stops the payload transmission and sends a corrupted CRC (the first bit of the first CRC byte sent is inverted), followed by an EOF. If DMA is used, TXDMA bit in the SWPMI_CR register is automatically cleared.
Any further write to the SWPMI_TDR register while TXUNRF is set will be ignored. The user must set CTXUNRF bit in the SWPMI_ICR register to clear TXUNRF flag.

**Overrun during payload reception**

During the reception of the frame payload, a receive overrun is indicated by RXOVRF flag in the SWPMI_ISR register. If a receive overrun occurs, the SWPMI does not update SWPMI_RDR with the incoming data. The incoming data will be lost.

The reception carries on up to the EOF and, if the overrun condition disappears, the RXBFF flag is set. When RXBFF flag is set, the user can check the RXOVRF flag. The user must set CRXOVRF bit in the SWPMI_ICR register to clear RXBOVR flag.

If the user wants to detect the overrun immediately, RXBOVREIE bit in the SWPMI_IER register can be set in order to generate an interrupt as soon as the overrun occurs.

The RXOVRF flag is set at the same time as the RXNE flag, two SWPMI_RDR reads after the overrun event occurred. It indicates that at least one received byte was lost, and the loaded word in SWPMI_RDR contains the bytes received just before the overrun.

In Multi software buffer mode, if RXOVRF flag is set for the last word of the received frame, then the overrun bit (bit 25 of the 8th word) is set for both the current and the next frame.

**CRC error during payload reception**

Once the two CRC bytes have been received, if the CRC is wrong, the RXBERF flag in the SWPMI_ISR register is set after the EOF reception. An interrupt is generated if RXBEIE bit in the SWPMI_IER register is set (refer to Figure 738: SWPMI single buffer mode reception with CRC error). The user must set CRXBERF bit in SWPMI_ICR to clear RXBERF flag.

**Figure 738. SWPMI single buffer mode reception with CRC error**

| SWP input | SOF | DC | D1 | D2 | D3 | D4 | D5 | D6 | D7 | D8 | D9 | D10 | D11 | D12 | CRC | EOF |
|-----------|-----|----|----|----|----|----|----|----|----|----|----|----|----|-----|-----|
| SWPMI_RDR | x-x-x | x | D3-02-01-00 | x | D7-06-05-04 | D11-01-09-D8 | x-x-D13-D12 |
| SWPMI_RFL | x | x | 14D |
| SUSPEND | set by HW, cleared by SW |
| RXNE | set by HW, cleared by SW or DMA |
| RXFF | set by SW |
| RXBERF | set by HW |

SW reads SWPMI_RDR

SW detects error with RXBERF flag

**Missing or corrupted stuffing bit during payload reception**

When a stuffing bit is missing or is corrupted in the payload, RXBERF and RXBFF flags are set in SWPMI_ISR after the EOF reception.
Corrupted EOF reception

Once an SOF has been received, the SWPMI accumulates the received bytes until the reception of an EOF (ignoring any possible SOF). Once an EOF has been received, the SWPMI is ready to start a new frame reception and waits for an SOF.

In case of a corrupted EOF, RXBERF and RXBFF flags will be set in the SWPMI_ISR register after the next EOF reception.

Note: In case of a corrupted EOF reception, the payload reception carries on, thus the number of bytes in the payload might get the value 31 if the number of received bytes is greater than 30. The number of bytes in the payload is read in the SWPMI_RFL register or in bits [23:16] of the 8th word of the buffer in the RAM memory, depending on the operating mode.

56.3.11 Loopback mode

The loopback mode can be used for test purposes. The user must set LPBK bit in the SWPMI_CR register in order to enable the loopback mode.

When the loopback mode is enabled, SWPMI_TX and SWPMI_RX signals are connected together. As a consequence, all frames sent by the SWPMI will be received back.

56.4 SWPMI low-power modes

<table>

56.5 SWPMI interrupts

All SWPMI interrupts are connected to the NVIC.

To enable the SWPMI interrupt, the following sequence is required:
1. Configure and enable the SWPMI interrupt channel in the NVIC
2. Configure the SWPMI to generate SWPMI interrupts (refer to the SWPMI_IER register).

56.6.2 SWPMI Bitrate register (SWPMI_BRR)

Address offset: 0x04

Reset value: 0x0000 0001

| Bit 31:8 | Reserved, must be kept at reset value.
| Bit 7:0  | BR[7:0]: Bitrate prescaler

This field must be programmed to set SWP bus bitrate, taking into account the $F_{\text{swpmi\_ker\_ck}}$ programmed in the RCC (Reset and Clock Control), according to the following formula:

$$F_{\text{swp}} = F_{\text{swpmi\_ker\_ck}} / ((\text{BR}[7:0]+1) \times 4)$$

Note: The programmed bitrate must stay within the following range: from 100 kbit/s up to 2 Mbit/s.

$\text{BR}[7:0]$ cannot be written while SWPACT bit is set in the SWPMI_CR register.

Bits 31:12  Reserved, must be kept at reset value.

Bit 11  **RDYF**: transceiver ready flag

This bit is set by hardware as soon as transceiver is ready. After setting the SWPTEN bit in SWPMI_CR register to enable the SWPMI_IO transceiver, software must wait for this flag to be set before setting the SWPACT bit to activate the SWP bus.

0: transceiver not ready
1: transceiver ready

Bit 10  **DEACTF**: DEACTIVATED flag

This bit is a status flag, acknowledging the request to enter the DEACTIVATED mode.

0: SWP bus is in ACTIVATED or SUSPENDED state
1: SWP bus is in DEACTIVATED state

If a RESUME by slave state is detected by the SWPMI while DEACT bit is set by software, the SRF flag will be set, DEACTF will not be set and SWP will move in ACTIVATED state.

Bit 9  **SUSP**: SUSPEND flag

This bit is a status flag, reporting the SWP bus state

0: SWP bus is in ACTIVATED state
1: SWP bus is in SUSPENDED or DEACTIVATED state

Bit 8  **SRF**: Slave resume flag

This bit is set by hardware to indicate a RESUME by slave detection. It is cleared by software, writing 1 to CSRF bit in the SWPMI_ICR register.

0: No Resume by slave state detected
1: A Resume by slave state has been detected during the SWP bus SUSPENDED state

Bit 7  **TCF**: Transfer complete flag

This flag is set by hardware as soon as both transmission and reception are completed and SWP is switched to the SUSPENDED state. It is cleared by software, writing 1 to CTCF bit in the SWPMI_ICR register.

0: Transmission or reception is not completed
1: Both transmission and reception are completed and SWP is switched to the SUSPENDED state

Bit 6  **TXE**: Transmit data register empty

This flag indicates the transmit data register status

0: Data written in transmit data register SWPMI_TDR is not transmitted yet
1: Data written in transmit data register SWPMI_TDR has been transmitted and SWPMI_TDR can be written to again
Bit 5  **RXNE**: Receive data register not empty  
This flag indicates the receive data register status  
0: Data is not received in the SWPMI_RDR register  
1: Received data is ready to be read in the SWPMI_RDR register

Bit 4  **TXUNRF**: Transmit underrun error flag  
This flag is set by hardware to indicate an underrun during the payload transmission i.e.  
SWPMI_TDR has not been written in time by the software or the DMA. It is cleared by  
software, writing 1 to the CTXUNRF bit in the SWPMI_ICR register.  
0: No underrun error in transmission  
1: Underrun error in transmission detected

Bit 3  **RXOVRF**: Receive overrun error flag  
This flag is set by hardware to indicate an overrun during the payload reception, i.e.  
SWPMI_RDR has not be read in time by the software or the DMA. It is cleared by software,  
writing 1 to CRXOVRF bit in the SWPMI_ICR register.  
0: No overrun in reception  
1: Overrun in reception detected

Bit 2  **RXBERF**: Receive CRC error flag  
This flag is set by hardware to indicate a CRC error in the received frame. It is set  
synchronously with RXBFF flag. It is cleared by software, writing 1 to CRXBERF bit in the  
SWPMI_ICR register.  
0: No CRC error in reception  
1: CRC error in reception detected

Bit 1  **TXBEF**: Transmit buffer empty flag  
This flag is set by hardware to indicate that no more SWPMI_TDR update is required to  
complete the current frame transmission. It is cleared by software, writing 1 to CTXBEF bit in  
the SWPMI_ICR register.  
0: Frame transmission buffer no yet emptied  
1: Frame transmission buffer has been emptied

Bit 0  **RXBFF**: Receive buffer full flag  
This flag is set by hardware when the final word for the frame under reception is available in  
SWPMI_RDR. It is cleared by software, writing 1 to CRXBFF bit in the SWPMI_ICR register.  
0: The last word of the frame under reception has not yet arrived in SWPMI_RDR  
1: The last word of the frame under reception has arrived in SWPMI_RDR

Bit 7  **TCIE**: Transmit complete interrupt enable
       0: Interrupt is inhibited
       1: An SWPMI interrupt is generated whenever TCF flag is set in the SWPMI_ISR register

Bit 6  **TIE**: Transmit interrupt enable
       0: Interrupt is inhibited
       1: An SWPMI interrupt is generated whenever TXE flag is set in the SWPMI_ISR register

Bit 5  **RIE**: Receive interrupt enable
       0: Interrupt is inhibited
       1: An SWPMI interrupt is generated whenever RXNE flag is set in the SWPMI_ISR register

Bit 4  **TXUNREIE**: Transmit underrun error interrupt enable
       0: Interrupt is inhibited
       1: An SWPMI interrupt is generated whenever TXBUNRF flag is set in the SWPMI_ISR register

Bit 3  **RXOVREIE**: Receive overrun error interrupt enable
       0: Interrupt is inhibited
       1: An SWPMI interrupt is generated whenever RXBOVRF flag is set in the SWPMI_ISR register

Bit 2  **RXBEIE**: Receive CRC error interrupt enable
       0: Interrupt is inhibited
       1: An SWPMI interrupt is generated whenever RXBERF flag is set in the SWPMI_ISR register

Bit 1  **TXBEIE**: Transmit buffer empty interrupt enable
       0: Interrupt is inhibited
       1: An SWPMI interrupt is generated whenever TXBEF flag is set in the SWPMI_ISR register

Bit 0  **RXBFIE**: Receive buffer full interrupt enable
       0: Interrupt is inhibited
       1: An SWPMI interrupt is generated whenever RXBFF flag is set in the SWPMI_ISR register

Bits 31:2 Reserved, must be kept at reset value.

**Bit 1 SWP_CLASS**: SWP class selection
This bit is used to select the SWP class (refer to *Section 56.3.3: SWP initialization and activation*).

- 0: Class C: SWPMI_IO uses directly VDD voltage to operate in class C. This configuration must be selected when VDD is in the range [1.62 V to 1.98 V]
- 1: Class B: SWPMI_IO uses an internal voltage regulator to operate in class B. This configuration must be selected when VDD is in the range [2.70 V to 3.30 V]

**Bit 0 SWP_TBYP**: SWP transceiver bypass
This bit is used to bypass the internal transceiver (SWPMI_IO), and connect an external transceiver.

- 0: Internal transceiver is enabled. The external interface for SWPMI is SWPMI_IO (SWPMI_RX, SWPMI_TX and SWPMI_SUSPEND signals are not available on GPIOs)
- 1: Internal transceiver is disabled. SWPMI_RX, SWPMI_TX and SWPMI_SUSPEND signals are available as alternate function on GPIOs. This configuration is selected to connect an external transceiver

57 Management data input/output (MDIOS)

57.1 MDIOS introduction

An MDIO bus can be useful in systems where a master chip needs to manage (configure and get status data from) one or multiple slave chips. The bus protocol uses only two signals:

- MDC: the management data clock
- MDIO: the data line carrying the opcode (write or read), the slave (port) address, the MDIOS register address, and the data

In each transaction, the master either reads the contents of an MDIOS register in one of its slaves, or it writes data to an MDIOS register in one of its slaves.

The MDIOS peripheral serves as a slave interface to a MDIO bus. A MDIO master can use the MDC/MDIO lines to write and read 32 16-bit MDIOS registers, which are held in the MDIOS. These MDIOS registers are managed by the firmware. This allows the MDIO master to configure the application running on the STM32 and get status information from it.

The MDIOS can operate in Stop mode, optionally waking up the STM32 if the MDIO master performs a read or a write to one of its MDIOS registers.

57.2 MDIOS main features

The MDIOS includes the following features:

- 32 MDIOS register addresses, each of which is managed using separate input and output data registers:
  - 32 x 16-bit firmware read/write, MDIOS read-only output data registers
  - 32 x 16-bit firmware read-only, MDIOS write-only input data registers
- Configurable slave (port) address
- Independently maskable interrupts/events:
  - MDIOS register write
  - MDIOS register read
  - MDIOS protocol error
- Able to operate in and wake up from Stop mode

57.3.3 MDIOS protocol

The MDIOS protocol uses two signals:
- MDIOS_MDC: the clock, always driven by the master
- MDIOS_MDIO: signal carrying the opcode, address, and bidirectional data
Each transaction is performed using a frame, which contains 32 bits (each passed serially):

- 14 control bits, driven by the master
  - 2 start bits: always 01
  - 2 opcode bits: read = 10, write = 01
  - 5 port address bits, indicating which slave device is being addressed
  - 5 MDIOS register address bits, up to 32 MDIOS registers can be addressed in each slave
- 2 turnaround state bits
  - On write operations, the master drives 10
  - On read operations, the first bit is high-impedance, and the second bit is driven by the slave to 0
- 16 data bits
  - On write operations, data written to slave MDIOS register is driven by the master
  - On read operations, data read from slave MDIOS register is driven by the slave

Each frame is usually preceded by a preamble, where the MDIO stays at one for 32 MDC clocks. The master can continue to keep MDIO at one, indicating the idle condition, when it has no frame to send.

When MDIO signal is driven by the master, MDIOS samples it using the rising edge of MDC. When MDIOS drives MDIO, the output changes on the rising edge of MDC.

**Figure 740. MDIO protocol write frame waveform**

![MDIO protocol write frame waveform](MSV39128V1)

**Figure 741. MDIO protocol read frame waveform**

![MDIO protocol read frame waveform](MSV39127V1)

### 57.3.4 MDIOS enabling and disabling

The MDIOS is enabled by setting the EN bit in MDIOS_CR. When EN = 1, the MDIOS monitors the MDIO bus and service frames addressed to one of its MDIOS registers.

When the MDIOS is enabled (setting EN to one), the same write operation to MDIOS_CR must properly set the PORT_ADDRESS[4:0] field to indicate the slave port address. A frame is ignored by the MDIOS if its port address is not the same as PORT_ADDRESS[4:0] (presumably intended for another slave).
When EN = 0, the MDIOS ignores the frames being transmitted on the MDC/MDIO lines, and the IP is in a reduced consumption mode. Clearing EN also clears all of the DIN registers. If EN is cleared while the MDIOS is driving read data, it immediately releases the bus and does not drive the rest of the data. If EN is cleared while the MDIOS is receiving a frame, the frame is aborted and the data is lost.

When the MDIOS is enabled, disabled and reenabled, the status flags are not cleared. For a correct operation, the firmware must clear the status flag before reenabling the MDIOS.

57.3.5 MDIOS data

From the point of view of the MDIO master, there are 32 16-bit MDIOS registers in the MDIOS, which can be written and read. In reality, for each MDIOS register 'x' there are two sets of registers: MDIOS_DINRx and MDIOS_DOUTRx.

Input data

When the MDIO master transmits a frame, which writes to MDIOS register 'x' in the MDIOS, it is MDIOS_DINRx, which is updated with the incoming data. The registers MDIOS_DINR0 to MDIOS_DINR31 can be read by the firmware, but they can be written only by the MDIO master via the MDIO bus.

The contents of MDIOS_DINRx change immediately after the MDC rising edge when the last data bit is sampled.

If the firmware happens to read the contents of MDIOS_DINRx at the moment that it is being updated, there is a possibility that the value read is corrupted (a bit-by-bit cross between the old value and the new value). For this reason, the firmware must assure that two subsequent reads from the same MDIOS_DINRx give the same value and assure that the data is stable when it is read. In the very worst case, the firmware needs to read four times MDIOS_DINRx to:

1. Get the old value
2. Get an incoherent value (when reading at the moment the register changes)
3. Get the new value
4. Confirm the new value

If the firmware uses the WRF interrupt and can guarantee that it reads the MDIOS_DINRx register before any new MDIOS write frame completes, the firmware can perform a single read.

If the MDIO master performs a write operation with a register address, which is greater than 31, the MDIOS ignores the frame (the data is not saved and no flag is set).

Output data

When the MDIOS receives a frame, which requests to read register 'x', it returns the value found in MDIOS_DOUTRx. Thus, if the MDIO master expects to read the same value, which it previously wrote to MDIOS register 'x', the firmware must copy the data from MDIOS_DINRx to MDIOS_DOUTRx each time new data is written to MDIOS_DINRx. For correct operation, the firmware must copy the data to the MDIOS_DOUTRx register within a preamble (if the master sends preambles before each frame) plus 15 cycles time.

When an MDIOS register is read via the MDIO bus, the MDIOS passes the 16-bit value (from the corresponding MDIOS_DOUTRx) to the MDIOS clock domain during the 15th cycle of the read frame. If the firmware attempts to write MDIOS_DOUTRx while the MDIO
master is currently reading MDIOS register ‘x’, the firmware write operation is ignored if it occurs during the 15th cycle of the frame (during a one-MDC-cycle window). Therefore, after writing MDIOS\_DOUTRx, the firmware must read back the same MDIOS\_DOUTRx and confirm that the value was actually written. If MDIOS\_DOUTRx does not contain the value, which was written, the firmware can simply try writing and rereading again.

If the MDIOS frequency is very slow compared to the mdios\_pclk frequency, it is better not to tie up the CPU by continuously writing and rereading MDIOS\_DOUTRx.

Note: The read flag (RDFx) is set as soon as the MDIOS\_DOUTRx DOUT[15:0] value is passed to the MDIOS clock domain. Thus, when a write to MDIOS\_DOUTRx is ignored (when the value read back is not the value, which was just written), the firmware can use a read interrupt to know when it is able to write MDIOS\_DOUTRx.

Respect the following procedure if the MDC clock is very slow:
1. Write MDIOS\_DOUTRx.
2. Assure that all of the read flags are zero (MDIOS\_RDFR = 0x0000). Clear the flags if necessary using MDIOS\_CRDFR.
3. Read back the same MDIOS\_DOUTRx and compare the value with the value, which was written in step 1.
4. If the values are the same, the procedure is done. Otherwise, continue to step 5.
5. Enable read interrupts by setting the RDIE bit in MDIOS\_CR1.
6. In the interrupt routine, assure that RDFx is set (no other read flags are set before bit x).
7. There is a 31 cycle + preamble time window (if the master sends a preamble before each frame) to write MDIOS\_DOUTRx safely without doing a read-back and compare. If this maximum delay cannot be guaranteed, go back to step 1.

If the MDIO master performs a read operation with a register address, which is greater than 31, the MDIOS returns a data value of all zeros.

### 57.3.6 MDIOS APB frequency

Whenever the firmware reads from MDIOS\_DINRx or writes to MDIOS\_DOUTRx, the frequency of the APB bus must be at least 1.5 times the MDC frequency. For example, if MDC is at 20 MHz, the APB must be at 30 MHz or faster.

### 57.3.7 Write/read flags and interrupts

When MDIOS register ‘x’ is written via the MDIO bus, the WRFx bit in MDIOS\_WRFR is set. WRFx becomes one at the moment that MDIOS\_DINRx is updated, which is when the last data bit is sampled on a write frame. An interrupt is generated if WRIEN = 1 (in MDIOS\_CR). WRFx is cleared by software by writing 1 to CWRFx (in MDIOS\_CWRFR).

When MDIOS register ‘x’ is read via the MDIO bus, the RDFx bit in MDIOS\_RDFR is set. RDFx becomes one at the moment that MDIOS\_DOUTRx is copied to the MDC clock domain, which is on the 15th cycle of a read frame. An interrupt is generated if RDIEN = 1 (in MDIOS\_CR). RDFx is cleared by software by writing 1 to CRDFx (in MDIOS\_CRDFR).
57.3.8 **MDIOS error management**

There are three types of errors with their corresponding error flags:

- Preamble error: PERF (bit 0 of MDIOS_SR)
- Start error: SERF (bit 1 of MDIOS_SR)
- Turnaround error: TERF (bit 2 of MDIOS_SR)

Each error flag is set by hardware when the corresponding error condition occurs. Each flag can be cleared by writing ‘1’ to the corresponding bit in the clear flag register (MDIOS_CLRFR).

An interrupt occurs if any of the three error flags is set while EIE = 1 (MDIOS_CR).

Besides, setting an error flag, the MDIOS performs no action for a frame in which an error is detected: MDIOS_DINRx are not updated and the MDIO line is not forced during the data phase.

For a given frame, errors do not accumulate. For example, if a preamble error is detected, no check is done for a start error or a turnaround error for the rest of the current frame.

When DPC = 0, following a detected error, all new frames, and errors are ignored until a complete full preamble has been detected.

When DPC = 1 (disable preamble check, MDIOS_CR[7]), all frames and new errors are ignored as long as one of the error flags is set. As soon as the error bit is cleared, the MDIOS starts looking for a start sequence. Thus, the application must clear the error flag only when it is sure that no frame is currently in progress. Otherwise, the MDIOS likely misinterprets the bits being sent and becomes desynchronized with the master.

**Preamble errors**

A preamble error occurs when a start sequence begins (with MDIO sampled at 0) without being immediately preceded by a preamble (MDIO sampled at 1 for at least 32 consecutive clocks).

Preamble errors are not reported after the MDIOS is first enabled (EN = 1 in MDIOS_CR) until after a full preamble is received. This is to avoid an error condition when the peripheral frame detection is enabled while a preamble or frame is already in progress. In this case, the MDIOS ignores the first frame (since it did not first detect a full preamble), but does not set PERF.

If the DPC bit (disable preamble check, MDIOS_CR[7]) is set, the MDIO master can send frames without preceding preambles and no preamble error is signaled. When DPC = 1, the application must assure that the master is not in the process of sending a frame at the moment that the MDIOS is enabled (EN is set). Otherwise, the slave might become desynchronized with the master.

**Start errors**

A start error occurs when an illegal start sequence occurs or if an illegal command is given. The start sequence must always be 01, and the command must be either 01 (write) or 10 (read).

As with preamble errors, start errors are not reported until after a full preamble is received.
Turnaround errors

A turnaround error occurs when an error is detected in the turnaround bits of write frames. The 15th bit of the write frame must be 1 and the 16th bit must be 0.

Turnaround errors are only reported after a full preamble is received, there is no start error, the port address in the current frame matches, and the register address is in the supported range 0 to 31.

57.3.9 MDIOS in Stop mode

The MDIOS can operate in Stop mode, responding to all reads, performing all writes, and causing the STM32 to wake up from Stop mode on MDIOS interrupts.

57.3.10 MDIOS interrupts

There is a single interrupt vector for the three types of interrupts (write, read, and error). Any of these interrupt sources can wake the STM32 up from Stop mode. All interrupt flags need to be cleared in order to clear the interrupt line.

</tr>
</tbody>
</table>

Bits 31:13 Reserved, must be kept at reset value.

Bits 12:8 PORT_ADDRESS[4:0]: slave address
Can be written only when the peripheral is disabled (EN = 0).
If the address given by the MDIO master matches PORT_ADDRESS[4:0], the MDIOS services the frame. Otherwise, the frame is ignored.
57.4.2 MDIOS write flag register (MDIOS_WRFR)

Address offset: 0x004

</tr>
</tbody>
</table>

Note: When this bit is set, the application must be sure that no frame is currently in progress when the MDIOS is enabled. Otherwise, the MDIOS can become desynchronized with the master.

Note: When this bit is set, an interrupt is generated if any of the error flags (PERF, SERF, or TERF in the MDIOS_SR register) is set.

Note: When this bit is set, an interrupt is generated if any of the read flags (RDF[31:0] in the MDIOS_RDFR register) is set.

Note: When this bit is set, an interrupt is generated if any of the read flags (WRF[31:0] in the MDIOS_WRFR register) is set.

Bit 0 EN: peripheral enable
0: MDIOS is disabled.
1: MDIOS is enabled and monitoring the MDIO bus (MDC/MDIO).
57.4.3 MDIOS clear write flag register (MDIOS_CWRFR)

Address offset: 0x008

Power-on reset value: 0x0000 0000

</tbody>
</table>

Bits 31:0 WRF[31:0]: write flags for MDIOS registers 0 to 31.
Each bit is set by hardware when the MDIO master performs a write to the corresponding MDIOS register. An interrupt is generated if WRIE (in MDIOS_CR) is set.
Each bit is cleared by software by writing ‘1’ to the corresponding CWRF bit in the MDIOS_CWRFR register.
For WRFx:
0: MDIOS register x is not written by the MDIO master.
1: MDIOS register x is written by the MDIO master and the data is available in DIN[15:0] in the MDIOS_DINRx register.

57.4.4 MDIOS read flag register (MDIOS_RDFR)

Address offset: 0x00C

</tbody>
</table>

Bits 31:0 RDF[31:0]: read flags for MDIOS registers 0 to 31.
Each bit is set by hardware when the MDIO master performs a read from the corresponding MDIOS register. An interrupt is generated if RDIE (in MDIOS_CR) is set.
Each bit is cleared by software by writing one to the corresponding CRDF bit in the MDIOS_CRDFR register.
For RDFx:
0: MDIOS register x is not read by the MDIO master.
1: MDIOS register x is read by the MDIO master.

58 Secure digital input/output MultiMediaCard interface (SDMMC)

58.1 SDMMC main features

The SD/SDIO, embedded MultiMediaCard (eMMC) host interface (SDMMC) provides an interface between the AHB bus and SD memory cards, SDIO cards and eMMC devices.

The MultiMediaCard system specifications are available through the MultiMediaCard Association website at www.jedec.org, published by the MMCA technical committee.

SD memory card and SD I/O card system specifications are available through the SD card Association website at www.sdcard.org.

The SDMMC features include the following:

  - Card support for three different databus modes: 1-bit (default), 4-bit and 8-bit (HS200 SDMMC_CK speed limited to maximum allowed I/O speed)
- Full compatibility with previous versions of MultiMediaCards (backward compatibility).
- Full compliance with SD memory card specifications version 4.1.
  - (SDR104 SDMMC_CK speed limited to maximum allowed I/O speed, SPI mode and UHS-II mode not supported).
- Full compliance with SDIO card specification version 4.0.
  - Card support for two different databus modes: 1-bit (default) and 4-bit.
  - (SDR104 SDMMC_CK speed limited to maximum allowed I/O speed, SPI mode and UHS-II mode not supported).
- Data transfer up to 208 Mbyte/s for the 8-bit mode.
  - (depending maximum allowed I/O speed).
- Data and command output enable signals to control external bidirectional drivers.

The MultiMediaCard/SD bus connects cards to the host.

The current version of the SDMMC supports only one SD/SDIO/eMMC card at any one time and a stack of eMMC.

58.2 SDMMC implementation

</tr>
</tbody>
</table>
1. X = supported.

58.3 SDMMC bus topology

Communication over the bus is based on command/response and data transfers.

The basic transaction on the SD/SDIO/eMMC bus is the command/response transaction. These types of bus transaction transfer their information directly within the command or response structure. In addition, some operations have a data token.

Data transfers are done in the following ways:
- Block mode: data block(s) with block size $2^N$ bytes with $N$ in the range 0-14.
- SDIO multibyte mode: single data block with block size range 1-512 bytes
- eMMC Stream mode: continuous data stream

Data transfers to/from eMMC cards are done in data blocks or streams.

**Figure 742. SDMMC “no response” and “no data” operations**

**Figure 743. SDMMC (multiple) block read operation**

*Note:* The Stop Transmission command is not required at the end of a eMMC multiple block read with predefined block count.
Figure 744. SDMMC (multiple) block write operation

Note: The Stop Transmission command is not required at the end of an eMMC multiple block write with predefined block count.

Note: The SDMMC does not send any data as long as the Busy signal is asserted (SDMMC_D0 pulled low).

Figure 745. SDMMC (sequential) stream read operation

Figure 746. SDMMC (sequential) stream write operation

Stream data transfer operates only in a 1-bit wide bit bus configuration on SDMMC_D0 in single data rate modes (DS, HS, and SDR).
58.4 SDMMC operation modes

Table 473. SDMMC operation modes SD and SDIO

<table>
<thead>
<tr>
<th>SDIO Bus Speed modes (1)(2)</th>

1. SDR single data rate signaling.
2. DDR double data rate signaling. (data is sampled on both SDMMC_CK clock edges).
3. e-MMC bus speed with 8bit bus width.
4. Maximum frequency depending on maximum allowed I/O speed.
5. Supported signal voltage level depends on I/O port characteristics, refer to device datasheet.

HS200 mode requires variable delay support using sampling point tuning.
58.5 **SDMMC functional description**

The SDMMC consists of four parts:

- The AHB slave interface accesses the SDMMC adapter registers, and generates interrupt signals and IDMA control signals.
- The SDMMC adapter block provides all functions specific to the eMMC/SD/SD I/O card such as the clock generation unit, command and data transfer.
- The internal DMA (IDMA) block with its AHB master interface.
- A delay block (DLYB) taking care of the receive data sample clock alignment. The delay block is NOT part of the SDMMC. A delay block is mandatory when supporting SDR104 or HS200.

58.5.1 **SDMMC block diagram**

*Figure 747* shows the SDMMC block diagram.

![SDMMC block diagram](image)

58.5.2 **SDMMC pins and internal signals**

*Table 475* lists the SDMMC internal input/output signals, *Table 476* the SDMMC pins (alternate functions).

58.5.3 General description

The SDMMC_D[7:0] lines have different operating modes:

- By default, SDMMC_D0 line is used for data transfer. After initialization, the host can change the databus width.
- For an eMMC, 1-bit (SDMMC_D0), 4-bit (SDMMC_D[3:0]) or 8-bit (SDMMC_D[7:0]) data bus widths can be used.
- For an SD or an SDIO card, 1-bit (SDMMC_D0) or 4-bit (SDMMC_D[3:0]) can be used. All data lines operate in push-pull mode.

To allow the connection of an external driver (a voltage switch transceiver), the direction of data flow on the data lines is indicated with I/O direction signals. The SDMMC_D0DIR signal indicates the I/O direction for the SDMMC_D0 data line, the SDMMC_D123DIR for the SDMMC_D[3:1] data lines.

SDMMC_CMD only operates in push-pull mode:

To allow the connection of an external driver (a voltage switch transceiver), the direction of data flow on the SDMMC_CMD line is indicated with the I/O direction signal SDMMC_CDIR.
SDMMC_CK clock to the card originates from sdmmc_ker_ck:

- When the sdmmc_ker_ck clock has 50 % duty cycle, it can be used even in bypass mode (CLKDIV = 0).
- When the sdmmc_ker_ck duty cycle is not 50 %, the CLKDIV must be used to divide it by 2 or more (CLKDIV > 0).
- The phase relation between the SDMMC_CMD / SDMMC_D[7:0] outputs and the SDMMC_CK can be selected through the NEGEDGE bit. The phase relation depends on the CLKDIV, NEGEDGE, and DDR settings. See Figure 748.

**Figure 748. SDMMC Command and data phase relation**

By default, the sdmmc_io_in_ck feedback clock input is selected for sampling incoming data in the SDMMC receive path. It is derived from the SDMMC_CK pin.

For tuning the phase of the sampling clock to accommodate the receive data timing, the DLYB delay block available on the device can be connected between sdmmc_io_in_ck signal (DLYB input dlyb_in_ck) and sdmmc_fb_ck clock input of SDMMC (DLYB output dlyb_out_ck). Selecting the sdmmc_fb_ck clock input in the receive path then enables using the phase-tuned sampling clock for the incoming data. This is required for SDMMC to support the SDR104 and HS200 operating mode and optional for SDR50 and DDR50 modes.
When using an external driver (a voltage switch transceiver), the SDMMC_CKIN feedback clock input can be selected to sample the receive data.

For an SD/SDIO/eMMC card, the clock frequency can vary between 0 and 208 MHz (limited by maximum I/O speed).

Depending on the selected bus mode (SDR or DDR), one bit or two bits are transferred on SDMMC_D[7:0] lines with each clock cycle. The SDMMC_CMD line transfers only one bit per clock cycle.

### 58.5.4 SDMMC adapter

The SDMMC adapter (see Figure 747: SDMMC block diagram) is a multimedia/secure digital memory card bus master that provides an interface to a MultiMediaCard stack or to a secure digital memory card. It consists of the following subunits:

- Control unit
- Data transmit path
- Command path
- Data receive path
- Response path
- Receive data path clock multiplexer
- Delay block (DLYB), external to the SDMMC
- Adapter register block
- Data FIFO
- Internal DMA (IDMA)

**Note:** The adapter registers and FIFO use the AHB clock domain (sdmmc_hclk). The control unit, command path and data transmit path use the SDMMC adapter clock domain (sdmmc_ker_ck). The response path and data receive path use the SDMMC adapter feedback clock domain from the sdmmc_io_in_ck, or SDMMC_CKIN, or from the sdmmc_fb_ck generated by DLYB.

The DLYB delay block on the device can be used in conjunction with the SDMMC adapter, to tune the phase of the sampling clock for incoming data in SDMMC receive mode. It is required for the SDMMC to support the SDR104 and HS200 operating mode and optional for SDR50 and DDR50 modes.

### Adapter register block

The adapter register block contains all system control registers, the SDMMC command and response registers and the data FIFO.

This block also generates the signals from the corresponding bit location in the SDMMC Clear register that clear the static flags in the SDMMC adapter.

### Control unit

The control unit illustrated in Figure 749, contains the power management functions, the SDMMC_CK clock management with divider, and the I/O direction management.
The power management subunit disables the card bus output signals during the power-off and power-up phases.

There are three power phases:
- power-off
- power-up
- power-on

The clock management subunit uses the sdmmc_ker_ck to generate the SDMMC_CK and provides the division control. It also takes care of stopping the SDMMC_CK for i.e. flow control.

The clock outputs are inactive:
- after reset
- during the power-off or power-up phases
- if the power saving mode (register bit PWRSAV) is enabled and the card bus is in the Idle state for eight clock periods. The clock is stopped eight cycles after both the command/response CPSM and data path DPSM subunits have enter the Idle phase. The clock is restarted when the command/response CPSM or data path DPSM is activated (enabled).

The I/O management subunit takes care of the SDMMC_Dn and SDMMC_CMD I/O direction signals, which controls the external voltage transceiver.

**Command/response path**

The command/response path subunit transfers commands and responses on the SDMMC_CMD line. The command path is clocked on the SDMMC_CK and sends commands to the card. The response path is clocked on the sdmmc_rx_ck and receives responses from the card.
Command/response path state machine (CPSM)

- When the command register is written to and the enable bit is set, command transfer starts. When the command has been sent the CRC is appended and the command path state machine (CPSM) sets the status flags and:
  - if a response is not required enters the Idle state.
  - If a response is required, it waits for the response.

- When the response is received,
  - for a response with CRC, the received CRC code and the internally generated code are compared, and the appropriate status flag is set according the result.
  - for a response without CRC, no CRC is checked, and the appropriate status flag is not set.

When ever the CPSM is active, i.e. not in the Idle state, the CPSMACT bit is set.
- **Idle**: The command path is inactive. When the command control register is written and the enable bit (CPSMEN) is set, the CPSM activates the SDMMC_CK clock (when stopped due to power save PWRSAV bit) and moves
  - to the Send state when WAITPEND = 0 and BOOTEN = 0.
  - to the Pending state when WAITPEND = 1.
  - to the Boot state when BOOTEN = 1.

- **Send**: The command is sent and the CRC is appended.
  - When CMDTRANS bit is set or when BOOTEN bit is set and BOOTMODE is alternative boot, and the DTDIR = receive, the CPSM DataEnable signal is issued to the DPSM at the end of the command.
  - When the CMDTRANS bit is set and the CMDSEND bit is 0 the interrupt period is terminated at the end of the command.
  - When CMDSTOP bit is set the CPSM Abort signal is issued to the DPSM at the end of the command.
  - If no response is expected (WAITRESP = 00) the CPSM moves to the Idle state and the CMDSENT flag is set. When BOOTMODE = 1 and BOOTEN = 0 the CMDSENT flag is delayed 56 cycles after the command end bit, otherwise the
CMDSENT flag is generated immediately after the command end bit. The RESPCMDR and RESPxR registers are not modified.

- If a command response is expected (WAITRESP = not 00) the CPSM moves to the Wait state and start the response timeout.

- **Wait:** The command path waits for a response.
  - When WAITINT bit is 0 the command timer starts running and the CPSM waits for a start bit.
    a) If a start bit is detected before the timeout the CPSM moves to the Receive state.
    b) If the timeout is reached before the CPSM detect a response start bit, the timeout flag (CTIMEOUT) is set and the CPSM moves to the Idle state.

- **Receive:** The command response is received. Depending the response mode bits WAITRESP in the command control register, the response can be either short or long, with CRC or without CRC. The received CRC code when present is verified against the internally generated CRC code.
  - When the CMDTRANS bit is set and the CMDREND bit is set and the SDIO Response bit BS = 0 (response bit [39]), the interrupt period is started after the response.
  - When the CMDTRANS bit is set and the CMDREND bit is set and the SDIO Response bit BS = 1 (response bit [39]), the interrupt period is terminated after the response.
  - When the CMDTRANS bit is set and the CMDREND bit is set and the SDIO Response bit DF = 1 (response bit [32]) the interrupt period is terminated after the response.
  - When the CRC status passes or no CRC is present the CMDREND flag is set, the CPSM moves to the Idle state.

- **Pending:** According the pending WAITPEND bit in the command register, the CPSM enters the pending state.
  - When DATALENGTH <= 5 bytes the CPSM moves to the Sent state and generates the DataEnable signal to start the data transfer aligned with the CMD12 Stop Transmission command.
  - When DATALENGTH > 5 bytes, the CPSM DataEnable signal is issued to the DPSM to start the data transfer. The CPSM waits for a send CMD signal from the
DPSM before moving to the Send state. This enables i.e. the CMD12 Stop Transmission command to be sent aligned with the data.

- When writing WAITPEND to 0, the CPSM moves to the Send state.

- **Boot**: If the BOOTEN bit is set in the command register, the CPSM enters the Boot state, and when:
  - BOOTMODE = 0 the SDMMC_CMD line is driven low and when CMDTRANS bit is set and the DTDIR = receive, the CPSM DataEnable signal is issued to the DPSM. This enables normal boot operation. This state is left at the end of the boot procedure by clearing the register bit BOOTEN, which cause the SDMMC_CMD line to be driven high and the CPSM Abort signal is issued to the DPSM, before moving to the Idle state. The CMDSENT flag is generated 56 cycles after SDMMC_CMD line is high.
  - BOOTMODE = 1, move to the Send state. This enables sending of the CMD0 (boot). Clearing BOOTEN has no effect.

**Note:** The CPSM remains in the Idle state for at least eight SDMMC_CK periods to meet the \(N_{CC}\) and \(N_{RC}\) timing constraints. \(N_{CC}\) is the minimum delay between two host commands, and \(N_{RC}\) is the minimum delay between the host command and the card response.

**Note:** The response timeout has a fixed value of 64 SDMMC_CK clock periods.

A command is a token that starts an operation. Commands are sent from the host to either a single card (addressed command) or all connected cards (broadcast command are available for eMMC V3.31 or previous). Commands are transferred serially on the SDMMC_CMD line. All commands have a fixed length of 48 bits. The general format for a command token for SD-Memory cards, SDIO cards, and eMMC cards is shown in Table 478.

Next to the command data there are command type (WAITRESP) bits controlling the command path state machine (CPSM). These bits also determine whether the command requires a response, and whether the response is short (48 bit) or long (136 bits) long, and if a CRC is present or not.

A response is a token that is sent from an addressed card or synchronously from all connected cards to the host as an answer to a previous received command. All responses are sent via the command line SDMMC_CMD. The response transmission always starts with the left bit of the bit string corresponding to the response code word. The code length depends on the response type. Response tokens R1, R2, R3, R4, R5, and R6 have various
coding schemes, depending on their content. The general formats for the response tokens for SD-Memory cards, SDIO cards, and eMMC cards are shown in Table 479, Table 480 and Table 481.

A response always starts with a start bit (always 0), followed by the bit indicating the direction of transmission (card = 0). A value denoted by x in the tables below indicates a variable entry. Most responses, except some, are protected by a CRC. Every command code word is terminated by the end bit (always 1).

The response token data is stored in 5 registers, four containing the 32-bits card status, OCR register, argument or 127-bits CID or CSD register including internal CRC, and one register containing the 6-bits command index.

</table>

The command/response path operates in a half-duplex mode, so that either commands can be sent or responses can be received. If the CPSM is not in the Send state, the
SDMMC_CMD output is in the Hi-Z state. Data sent on SDMMC_CMD are synchronous with the SDMMC_CK according the NEGEDGE register bit see Figure 748.

The command and short response with CRC, the CRC generator calculates the CRC checksum for all 40 bits before the CRC code. This includes the start bit, transmission bit, command index, and command argument (or card status).

For the long response the CRC checksum is calculated only over the 120 bits of R2 CID or CSD. Note that the start bit, transmission bit and the six reserved bits are not used in the CRC calculation.

The CRC checksum is a 7-bit value:
\[
\text{CRC}[6:0] = \text{remainder } [\text{(M(x) } \times x^7 \text{ ) / G(x)}]
\]
\[
G(x) = x^7 + x^3 + 1
\]
\[
M(x) = (\text{first bit} \times x^n + (\text{second bit}) \times x^{n-1} + \ldots + (\text{last bit before CRC}) \times x^0
\]

Where \( n = 39 \) or 119.

The CPSM can send a number of specific commands to handle various operating modes when CPSMEN is set, see Table 482.

1. When CMDTRANS is set, also a stop_transmission command must be send to move the DPSM to Idle.

**Data path**

The data path subunit transfers data on the SDMMC_D[7:0] lines to and from cards. The data transmit path is clocked on the SDMMC_CK and sends data to the card. The data receive path is clocked on the sdmmc_rx_ck and receives data from the card. Figure 752 shows the data path block diagram.
The card data bus width can be programmed in the clock control register bits WIDBUS. The supported data bus width modes are:

- If the wide bus mode is not enabled, only one bit is transferred over SDMMC_D0.
- If the 4-bit wide bus mode is enabled, data is transferred at four bits over SDMMC_D[3:0].
- If the 8-bit wide bus mode is enabled, data is transferred at eight bits over SDMMC_D[7:0].

Next to the data bus width the data sampling mode can be programmed in the clock control register bit DDR. The supported data sampling modes are:

- Single data rate signaling (SDR), data is clocked on the rising edge of the clock.
- Double data rate signaling (DDR), data is clocked on the both edges of the clock. DDR mode is only supported in wide bus mode (4-bit wide and 8-bit wide).

Note: The data sampling mode only applies to the SDMMC_D[7:0] lines. (not applicable to the SDMMC_CMD line.)
In DDR mode, data is sampled on both edges of the SDMMC_CK according to the following rules, see also Figure 753 and Figure 754:

- On the rising edge of the clock odd bytes are sampled.
- On the falling edge of the clock even bytes are sampled.
- Data payload size is always a multiple of 2 Bytes.
- Two CRC16 are computed per data line
  - Odd bits CRC16 clocked on the falling edge of the clock.
  - Even bits CRC16 clocked on the rising edge of the clock.
- Start, end bits and idle conditions are full cycle.
- CRC status / boot acknowledgment and busy signaling are full cycle and are only sampled on the rising edge of the clock.

In DDR mode the SDMMC_CK clock division must be >= 2.

**Data path state machine (DPSM)**

Depending on the transfer direction (send or receive), the data path state machine (DPSM) moves to the Wait_S or Wait_R state when it is enabled:

- Send: the DPSM moves to the Wait_S state. If there is data in the transmit FIFO, the DPSM moves to the Send state, and the data path subunit starts sending data to a card.
- Receive: the DPSM moves to the Wait_R state and waits for a start bit. When it receives a start bit, the DPSM moves to the Receive state, and the data path subunit starts receiving data from a card.
For boot operation with acknowledgment the DPSM moves to the Wait_Ack state and waits for the boot acknowledgment before moving to the Wait_R state.

The DPSM operates at SDMMC_CK. The DPSM has the following states, as shown in Figure 755. When ever the DPSM is active, i.e. not in the Idle state, the DPSMACT bit is set.

**Figure 755. Data path state machine (DPSM)**

- **Idle** state: the data path is inactive, and the SDMMC_D[7:0] outputs are according the PWRCTRL setting. The DPSM is activated either by sending a command with CMDTRANS bit set or by setting the DTEN bit, or by detecting Busy on SDMMC_D0 (that is, after a command with R1b response).

  When not busy, the DPSM activates the SDMMC_CK clock (when stopped due to power save PWRSAV bit), loads the data counter with a new (DATALENGTH) value and:
  - When the data direction bit (DTDIR) indicates send, moves to the Wait_S.
  - When the data direction bit (DTDIR) indicates receive, moves to the - Wait_R when BOOTACKEN register bit is clear.
    - Wait_Ack when BOOTACKEN register bit is set and start the acknowledgment timeout.

  When busy the DPSM keeps the SDMMC_CK clock active and move to the Busy state.
Note: **DTEN must not be used to start data transfer with SD, SDIO and eMMC cards.**

- **Wait_Ack** state: the data path waits for the boot acknowledgment token.
  - The DPSM moves to the Wait_R state if it receives an error free acknowledgment before a timeout.
  - When a pattern different from the acknowledgment is received an acknowledgment status error is generated, and the ack fail status flag (ACKFAIL) is set. The DPSM stays in Wait_Ack.
  - If it reaches a timeout (ACKTIME) before it detects a start bit, it sets the timeout status flag (ACKTIMEOUT). The DPSM stays in Wait_Ack.
  - When the CPSM Abort signal is set it moves to the Idle state and sets the DABORT flag.

- **Wait_R** state: the data path, if the data counter is not zero and data is not hold, waits for a start bit on SDMMC_D[n:0]. If the data counter is zero or data is hold, wait for the FIFO to be empty.
  - In block mode, if a start bit is received before a timeout the DPSM moves to the Receive state and loads the data block counter with DBLOCKSIZE.
  - In SDIO multibyte mode, if a start bit is received before a timeout the DPSM moves to the Receive state and loads the data block counter with DATABLOCKSIZE.
  - In stream mode, if a start bit is received before a timeout the DPSM moves to the Receive state and loads the data counter with DATABLOCKSIZE.
  - if the data counter (DATACOUNT) equals zero (end of data) the DPSM moves to the Idle state when the receive FIFO is empty and the DATAEND flag is set.
  - If it reaches a timeout (DATATIME) before it detects a start bit, it sets the timeout status flag (DTIMEOUT) and the DPSM stays in the Wait_R state.
  - If the CPSM Abort signal is set:
    - If DATACOUNT > 0, the DPSM moves to the Idle state when the FIFO is empty and when IDMAEN = 0 reset with FIFORST, and sets the DABORT flag.
    - If DATACOUNT is zero normal operation is continued, there is no DABORT flag since the transfer has completed normally.
  - if the DTHOLD bit is set:
    - When DATACOUNT > 0, the DPSM moves to the Idle state when the receive FIFO is empty and when IDMAEN = 0 reset with FIFORST, and issues the DHOLD flag. When holding the timeout is disabled. When an CPSM Abort signal is received during holding, the transfer is aborted.
- When DATACOUNT = 0, the transfer is completed normally and there is no DHOLD flag.
  - When DPSM has been started with DTEN, after an error (DTIMEOUT) the DPSM moves to the Idle state when the FIFO is empty and when IDMAEN = 0 reset with FIFORST.
- **R_W state**: the data path Read Wait the bus.
  - The DPSM moves to the Wait_R state when the Read Wait stop bit (RWSTOP) is set, and start the receive timeout.
  - If the CPSM Abort signal is set, wait for the FIFO to be empty and when IDMAEN = 0 reset with FIFORST, then moves to the Idle state and sets the DABORT flag.
- **Receive state**: the data path receives serial data from a card. Pack the data in bytes and written it to the data FIFO. Depending on the transfer mode selected in the data control register (DTMODE), the data transfer mode can be either block or stream:
  - In block mode, when the data block size (DBLOCKSIZE) number of data bytes are received, the DPSM waits until it receives the CRC code.
  - In SDIO multibyte mode, when the data block size (DATALENGTH) number of data bytes are received, the DPSM waits until it receives the CRC code.
  a) If the received CRC code matches the internally generated CRC code, the DPSM moves to the
     - R_W state when RWSTART = 1 and DATACOUNT > zero, the DBCKEND flag is set.
     - Wait_R state otherwise.
  b) If the received CRC code fails the internally generated CRC code any further data reception is prevented.
     - When not all data has been received (DATACOUNT > 0), the CRC fail status flag (DCRCFAIL) is set and the DPSM stays in the Receive state.
     - When all data has been received (DATACOUNT = 0), wait for the FIFO to be empty after which the CRC fail status flag (DCRCFAIL) is set and the DPSM moves to the Idle state.
  - In stream mode, the DPSM receives data while the data counter DATACOUNT > 0. When the counter is zero, the remaining data in the shift register is written to the data FIFO, and the DPSM moves to the Wait_R state.
  - When a FIFO overrun error occurs, the DPSM sets the FIFO overrun error flag (RXOVERR) and any further data reception is prevented. The DPSM stays in the Receive state.
  - When an CPSM Abort signal is received:
    - If the CPSM Abort signal is received before the 2 last bits of the data with DATACOUNT = 0, the transfer is aborted. The remaining data in the shift register is written to the data FIFO, wait for the FIFO to be empty and when IDMAEN = 0 reset with FIFORST, then the DPSM moves to the Idle state and the DABORT flag is set.
    - If the CPSM Abort signal is received during or after the 2 last bits of the transfer with DATACOUNT=0, the transfer is completed normally. The DPSM stays in the Receive state no DABORT flag is generated.
  - When DPSM has been started with DTEN, after an error (DCRCFAIL when DATACOUNT > 0, or RXOVERR) the DPSM moves to the Idle state when the FIFO is empty and when IDMAEN = 0 reset with FIFORST.
• **Wait_S state:** the data path waits for data to be available from the FIFO.
  - If the data counter DATACOUNT > 0, waits until the data FIFO empty flag (TXFIFOE) is de-asserted and DTHOLD is not set, and moves to the Send state.
  - If the data counter (DATACOUNT) = 0 the DPSM moves to the Idle state.
    - When DTHOLD is disabled, the DATAEND flag is set.
    - When DTHOLD is enabled, the DHOLD flag is set.
  - When DTHOLD is set and the DATACOUNT > 0
    - When IDMA is enabled, the DBCKEND flag is set and subsequently the FIFO is flushed, furthermore the DPSM moves to the Idle state and the DHOLD flag is set.
    - When IDMA is disabled the DBCKEND flag is set. Wait for the FIFO to be reset by software with FIFORST, then DPSM moves to the Idle state and issues the DHOLD flag.
  - When DTHOLD is set and DATACOUNT = 0 the transfer is completed normally.
  - When receiving the CPSM Abort signal
    - If the CPSM Abort signal is received before the 2 last bits of the data with DATACOUNT = 0, the transfer is aborted, wait for the FIFO to be empty and when IDMAEN = 0 reset with FIFORST, then the DPSM moves to the Idle state and sets the DABORT flag.
    - If the CPSM Abort signal is received during or after the 2 last bits of the transfer with DATACOUNT=0, normal operation is continued, there is no DABORT flag since the transfer has completed normally.

*Note:* The DPSM remains in the Wait_S state for at least two clock periods to meet the $N_{WR}$ timing requirements, where $N_{WR}$ is the number of clock cycles between the reception of the card response and the start of the data transfer from the host.

• **Send state:** the DPSM starts sending data to a card. Depending on the transfer mode bit in the data control register, the data transfer mode can be either block, SDIO multibyte or stream:
  - In block mode, when the data block size (DBLOCKSIZE) number of data bytes are send, the DPSM sends an internally generated CRC code and end bit, and moves to the Busy state and start the transmit timeout.
  - In SDIO multibyte mode, when the data block size (DATALENGTH) number of data bytes are send, the DPSM sends an internally generated CRC code and end bit, and moves to the Busy state and start the transmit timeout.
  - In stream mode, the DPSM sends data to a card while the data counter DATACOUNT > 0. When the data counter reaches zero moves to the Busy state and start the transmit timeout.
    Before sending the last stream Byte according to DATACOUNT, the DPSM issues a trigger on the send CMD signal. This signal is used by the CPSM to send any pending command. (i.e. CMD12 Stop Transmission command)
    - If a FIFO underrun error occurs, the DPSM sets the FIFO underrun error flag (TXUNDEERR). The DPSM stays in the Send state.
    - When receiving the CPSM Abort signal
      - If the CPSM Abort signal is received before the 2 last bits of the transfer with DATACOUNT=0, the transfer is aborted. The DPSM sends a last data bit followed by an end bit. The FIFO is disabled/flushed, and the DPSM moves to the Busy state to wait for not busy before setting the DABORT flag.
      - If the CPSM Abort signal is received during or after the 2 last bits of the transfer
with DATACOUNT=0, the transfer is completed normally, there is no DABORT flag.

- **Busy** state: the DPSM waits for the CRC status token when expected, and wait for a not busy signal:
  - If a CRC status token is expected and indicate "non-erroneous transmission" or when there is no CRC expected:
    - it moves to the Wait_S state when SDMMC_D0 is not low (the card is not busy).
    - When the card is busy SDMMC_D0 is low it remains in the Busy state.
  - If a CRC status token is expected and indicates "erroneous transmission".
    - When not all data has been send (DATACOUNT > 0). The DPSM waits for not busy after which the CRC fail status flag (DCRCFAIL) is set. The FIFO is disabled/flushed and the DPSM stays in the Busy state.
    - When all data has been send (DATACOUNT = 0). The DPSM waits for not busy after which the CRC fail status flag (DCRCFAIL) is set and the DPSM moves to the Idle state.
  - If a CRC status (Ncrc) timeout occurs while the DPSM is in the Busy state, it sets the data timeout flag (DTIMEOUT) and stays in the Busy state.
  - If a busy timeout occurs while the DPSM is in the Busy state, it sets the data timeout flag (DTIMEOUT) and stays in the Busy state.
  - When receiving the CPSM Abort signal in the Busy state:
    - If the CPSM Abort signal is received before the 2 last bits of the CRC response with DATACOUNT > 0, the data transfer is aborted. The DPSM waits for not busy and the FIFO to be disabled/flushed before moving to the Idle state and the DABORT flag is set.
    - If the CPSM Abort signal is received during or after the 2 last bits of the CRC response when DATACOUNT=0 or when no CRC is expected and DATACOUNT = 0 and there has been no DTIMEOUT error, the DPSM stays in the Busy state no DABORT flag is generated, since the transfer may completed normally.
    - If the CPSM Abort signal is received when a DTIMEOUT error has occurred the DPSM waits for not busy and the FIFO to be disabled/flushed before moving to the Idle state and the DABORT flag is set.
  - When entering the Busy state due to an abort in the Send state, the DPSM waits for not busy before moving to the Idle state and the DABORT flag is set.
  - When DPSM has been started with DTEN, after an error (DCRCFAIL when DATACOUNT > 0, or DTIMEOUT) the DPSM moves to the Idle state when the FIFO is reset.
  - When the DPSM has been started due to Busy on SDMMC_D0, waits for not busy after which the Busy end status flag (BUSYD0END) is set and the DPSM moves to the Idle state.
The data timer (DATATIME) is enabled when the DPSM is in the Wait_R or Busy state 2 cycles after the data block end bit, or data read command end bit, or R1b response, and generates the data timeout error (DTIMEOUT):

- When transmitting data, the timeout occurs
  - when a CRC status is expected and no start bit is received within 8 SDMMC_CK cycles, the DTIMEOUT flag is set.
  - when the Busy state takes longer than the programmed timeout period, the DTIMEOUT flag is set.
- When receiving data, the timeout occurs
  - when there is still data to be received DTCOUNT > 0 and no start bit is received before the programmed timeout period, the DTIMEOUT flag is set.
- After a R1b response, the timeout occurs
  - when the Busy state takes longer than the programmed timeout period, the DTIMEOUT flag is set.

When DATATIME = 0,

- In receive the start bit must be present 2 cycles after the data block end bit or data read command end bit.
- In transmit busy is timed out 2 cycles after the CRC token end bit or stream data end bit.
- After a R1b response busy is timed out 2 cycles after the response end bit.

Data can be transferred from the card to the host (transmit, send) or vice versa (receive). Data are transferred via the SDMMC_Dn data lines, they are stored in a FIFO.

### Table 485. Data token format

<table>
<thead>
<tr>
<th>Description</th>
<th>Start bit</th>
<th>Data(1)</th>
<th>CRC16</th>
<th>End bit</th>
<th>DTMODE</th>

**Data FIFO**

The data FIFO (first-in-first-out) subunit contains the transmit and receive data buffer. A single FIFO is used for either transmit or receive as selected by the DTDIR bit. The FIFO contain a 32-bit wide, 16-word deep data buffer and control logic. Because the data FIFO operates in the AHB clock domain (sdmmc_hclk), all signals from the subunits in the SDMMC clock domain (SDMMC_CK/sdmmc_rx_ck) are resynchronized.
The FIFO can be in one of the following states:
- The transmit FIFO refers to the transmit logic and data buffer when sending data out to the card. (DTDIR = 0)
- The receive FIFO refers to the receive logic and data buffer when receiving data in from the card. (DTDIR = 1)

The end of a correctly completed SDMMC data transfer from the FIFO is indicated by the DATAEND flags driven by the data path subunit. Any incorrect (aborted) SDMMC data transfer from the FIFO is indicated by one of the error flags (DCRCFAIL, DTIMEOUT, DABORT) driven by the data path subunit, or one of the FIFO error flags (TXUNDERR, RXOVERR) driven by the FIFO control.

The data FIFO can be accessed in the following ways, see Table 488.

### Table 488. Data FIFO access

<table>
<thead>
<tr>
<th>Data FIFO access</th>
<th>IDMAEN</th>
</tr>
</thead>
<tbody>
<tr>
<td>From firmware via AHB slave interface</td>
<td>0</td>
</tr>
<tr>
<td>From IDMA via AHB master interface</td>
<td>1</td>
</tr>
</tbody>
</table>

Transmit FIFO:

Data can be written to the transmit FIFO when the DPSM has been activated (DPSMACT = 1).

When IDMAEN = 1 the FIFO is fully handled by the IDMA.

When IDMAEN = 0 the FIFO is controlled by firmware via the AHB slave interface. The transmit FIFO is accessible via sequential addresses. The transmit FIFO contains a data output register that holds the data word pointed to by the read pointer. When the data path subunit has loaded its shift register, it increments the read pointer and drives new data out. The transmit FIFO is handled in the following way:

1. Write the data length into `DATALENGTH` and the block length in `DBLOCKSIZE`.
   - For block data transfer (DTMODE = 0), `DATALENGTH` must be an integer multiple of `DBLOCKSIZE`.
2. Set the SDMMC in transmit mode (DTDIR = 0).
   - Configures the FIFO in transmit mode.
3. Enable the data transfer
   - either by sending a command from the CPSM with the CMDTRANS bit set
   - or by setting DTEN bit
4. When (DPSMACT = 1) write data to the FIFO.
   - The DPSM stays in the Wait_S state until FIFO is full (TXFIFOF = 1), or the number indicated by `DATALENGTH`. 

- The SDMMC keeps sending data as long as FIFO is not empty, hardware flow control during data transfer is used to prevent FIFO underrun.

5. Write data to the FIFO.
   - When the FIFO is handled by software, wait until the FIFO is half empty (TXFIFOHE flag), write data to the FIFO until FIFO is full (TXFIFOF = 1), or last data has been written.
   - When the FIFO is handled by the IDMA, the IDMA transfers the FIFO date.

6. When last data has been written wait for end of data (DATAEND flag)
   - SDMMC has completely sent all data and the DPSM is disabled (DPSMACT = 0).

In case of a data transfer error or transfer hold when IDMAEN = 0, firmware must stop writing to the FIFO and flush and reset the FIFO with the FIFORST register bit.

The transmit FIFO status flags are listed in Table 489.

### Table 489. Transmit FIFO status flags

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TXFIFOF</td>
<td>Set to high when all transmit FIFO words contain valid data.</td>
</tr>
<tr>
<td>TXFIFOE</td>
<td>Set to high when the transmit FIFO does not contain valid data.</td>
</tr>
<tr>
<td>TXFIFOHE</td>
<td>Set to high when half or more transmit FIFO words are empty.</td>
</tr>
<tr>
<td>TXUNDERR</td>
<td>Set to high when an underrun error occurs. This flag is cleared by writing to the SDMMC Clear register.</td>
</tr>
</tbody>
</table>

Receive FIFO:

Data can be read from the receive FIFO when the DPSM is activated (DPSMACT = 1).

When IDMAEN = 1 the FIFO is fully handled by the IDMA.

When IDMAEN = 0 the FIFO is controlled by firmware via the AHB slave interface. When the data path subunit receives a word of data, it drives the data on the write databus. The write pointer is incremented after the write operation completes. On the read side, the contents of the FIFO word pointed to by the current value of the read pointer is driven onto the read databus. The receive FIFO is accessible via sequential addresses.

The receive FIFO is handled in the following way:
1. Write the data length into DATALENGTH and the block length in DBLOCKSIZE.
   – For block data transfer (DTMODE = 0), DATALENGTH must be an integer multiple of DBLOCKSIZE.
2. Set the SDMMC in receive mode (DTDIR = 1).
   – Configures the FIFO in receive mode.
3. Enable the DPSM transfer
   – either by sending a command from the CPSM with the CMDTRANS bit set
   – or by setting DTEN bit.
4. When (DPSMACT = 1) the FIFO is ready to receive data.
   – The DPSM writes the received data to the FIFO.
     - The SDMMC keeps receiving data as long as FIFO is not full, hardware flow control during the data transfer is used to prevent FIFO overrun.
5. Read data from the FIFO.
   – When the FIFO is handled by software, wait until the FIFO is half full (RXFIFOHF flag), read data from the FIFO until FIFO is empty (RXFIFOE = 1).
     - When last data has been received, read data from the FIFO until FIFO is empty (DATAEND = 1).
   – When the FIFO is handled by the IDMA, the IDMA transfers the FIFO data.
6. SDMMC has completely received all data and the DPSM is disabled (DPSMACT = 0).

   In case of a data transfer hold when IDMAEN = 0, the firmware must read the remaining data until the FIFO is empty and reset the FIFO with the FIFORST register bit. This causes the DPSM to go to the Idle state (DPSMACT = 0).

   In case of a data transfer error when IDMAEN = 0, the firmware must stop reading the FIFO and flush and reset the FIFO with the FIFORST register bit. This causes the DPSM to go to the Idle state (DPSMACT = 0).

The receive FIFO status flags are listed in Table 490.

<table>
<thead>
<tr>
<th>Flag</th>

</tr>
<tr>
<td>RXFIFOHF</td>
<td>Set to high when half or more receive FIFO words contain valid data.</td>
</tr>
<tr>
<td>RXOVERR</td>
<td>Set to high when an overrun error occurs. This flag is cleared by writing to the SDMMC Clear register.</td>
</tr>
</tbody>
</table>

**CLKMUX unit**

The CLKMUX selects the source for clock sdmmc_rx_ck to be used with the received data and command response. The receive data clock source can be selected by the clock control register bit SELCLKRX, between:

- sdmmc_io_in_ck bus master main feedback clock.
- SDMMC_CKIN external bus feedback clock.
- sdmmc_fb_ck bus tuned feedback clock.

The sdmmc_io_in_ck is selected when there is no external driver, with DS and HS.
The SDMMC_CKIN is selected when there is an external driver with SDR12, SDR25, SDR50 and DDR50.

The sdmmc_fb_ck clock input must be selected when the DLYB block on the device is used with SDR104, HS200 and optionally with SDR50 and DDR50 modes.

The sdmmc_rx_ck source must be changed when the CPSM and DPSM are in the Idle state.

### 58.5.5 SDMMC AHB slave interface

The AHB slave interface generates the interrupt requests, and accesses the SDMMC adapter registers and the data FIFO. It consists of a data path, register decoder, and interrupt logic.

#### SDMMC FIFO

The FIFO access is restricted to word access only:
- **In transmit FIFO mode**
  - Data are written to the FIFO in words (32-bits) until all data according DATALENGTH has been transferred. When the DATALENGTH is not an integer multiple of 4, the last remaining data (1, 2 or 3 bytes) are written with a word transfer.
- **In receive FIFO mode**
  - Data are read from the FIFO in words (32-bits) until all data according DATALENGTH has been transferred. When the DATALENGTH is not an integer multiple of 4, the last remaining data (1, 2 or 3 bytes) are read with a word transfer padded with 0 value bytes.

When accessing the FIFO with half word or byte accesses an AHB bus fault is generated.

#### SDMMC interrupts

The interrupt logic generates an interrupt request signal that is asserted when at least one of the unmasked status flags is active. A mask register is provided to allow selection of the conditions that generate an interrupt. A status flag generates the interrupt request if a corresponding mask flag is set. Some status flags require an implicit clear in the clear register.

### 58.5.6 SDMMC AHB master interface

The AHB master interface is used to transfer the data between a memory and the FIFO using the SDMMC IDMA.
SDMMC IDMA

Direct memory access (DMA) is used to provide high-speed transfer between the SDMMC FIFO and the memory. The AHB master optimizes the bandwidth of the system bus. The SDMMC internal DMA (IDMA) provides one channel to be used either for transmit or receive.

The IDMA is enabled by the IDMAEN bit and supports burst transfers of 8 beats.

- In transmit burst transfer mode:
  - Data are fetched in burst from memory whenever the FIFO is empty for the number of burst transfers, until all data according DATALENGTH has been transferred. When the DATALENGTH is not an integer multiple of the burst size the remaining, smaller than burst size data is transferred using single transfer mode. When the DATALENGTH is not an integer multiple of 4, the last remaining data (1, 2 or 3 bytes) are fetched with a word transfer.

- In receive burst transfer mode:
  - Data are stored in burst in to memory whenever the FIFO contains the number of burst transfers, until all data according DATALENGTH has been transferred. When the DATALENGTH is not an integer multiple of the burst transfer the remaining, smaller than burst size data, is transferred using single transfer mode. When the DATALENGTH is not an integer multiple of 4, the last remaining data (1, 2 or 3 bytes) are stored with halfword and or byte transfers.

In addition the IDMA provides the following channel configurations selected by bit IDMABMODE:

- single buffered channel
- double buffered channel

Single buffered channel

In single buffer configuration the data at the memory side is accessed in a linear matter starting from the base address IDMABASE0. When the IDMA has finished transferring all data the and the DPSM has completed the transfer the DATAEND flag is set.

Double buffered channel

In double buffer configuration the data at the memory side is subsequently accessed from 2 buffers, one located from base address IDMABASE0 and a second located from base address IDMABASE1. This allows firmware to process one memory buffer while the IDMA is accessing the other memory buffer. The size of the memory buffers is defined by IDMABSIZE. The buffer size must be an integer multiple of the burst size. It is possible to update the base address of the buffers on-the-fly when the channel is enabled, the following rule apply:

- When IDMABACT bit is ‘0’ the IDMA hardware uses the IDMABASE0 to access memory. When attempting to write to this register by Firmware the write is discarded, IDMABASE0 data is not changed. Firmware is authorized to write IDMABBASE1.
- When IDMABACT bit is ‘1’ the IDMA hardware uses the IDMABASE1 to access memory. When attempting to write to this register by Firmware the write is discarded, IDMABASE1 data is not changed. Firmware is authorized to write IDMABASE0.

When the IDMA has finished transferring the data of one buffer the buffer transfer complete flag (IDMABTC) is set and the IDMABACT bit toggles where after the IDMA continues
transferring data from the other buffer. When the IDMA has finished transferring all data and the DPSM has completed the transfer the DATAEND flag is set.

The IDMABASEn address must be word aligned.

**IDMA transfer error management**

An IDMA transfer error can occur:

- When reading or writing a reserved address space.

On a IDMA transfer error subsequent IDMA transfers are disabled and an IDMATE flag is set. Depending when the IDMA transfer error occurs, it normally causes the generation of a TXUNDERR or RXOVERR error.

The behavior of the IDMATE flag depend on when the IDMA transfer error occurs during the SDMMC transfer:

- An IDMA transfer error is detected before any SDMMC transfer error (TXUNDERR, RXOVERR, DCRCFAIL, or DTIMEOUT):
  - The IDMATE flag is set at the same time as the SDMMC transfer error flag.
  - The TXUNDERR, RXOVERR, DCRCFAIL, or DTIMEOUT interrupt is generated.

- An IDMA transfer error is detected during a STOP_TRANSMISSION command:
  - The IDMATE flag is set at the same time as the DABORT flag.
  - The DABORT interrupt is generated.

- An IDMA transfer error is detected at the end of the SDMMC transfer (D HOLD, or DATAEND):
  - The IDMATE flag is set at the end of the SDMMC transfer.
  - A SDMMC transfer end interrupt is generated and a DHOLD or DATAEND flag is set.

The IDMATE is generated on an other SDMMC transfer interrupt (TXUNDERR, RXOVERR, DCRCFAIL, DTIMEOUT, DABORT, DHOLD, or DATAEND).

**58.5.7 MDMA request generation**

The internal trigger lines from the SDMMC allow passing direct request to MDMA controller to enable successive transfers from/to different internal RAM addresses without CPU use.

When a data transfer from/to the card completes successfully, the DATAEND flag of the status register is set. The event is signaled to an MDMA request input through the sdmmc_dataend_trg output. It can trigger the clearance of the DATAEND and CMDREND flags and, eventually, a new transfer start, through MDMA direct access to the SDMMC control and configuration registers, thus without CPU intervention.

When a command response is received successfully, the CMDREND flag of the status register is set. When a busy state following an R1b response ends, the BUSYD0 flag of the status register falls down and the BUSYD0END flag rises. The sdmmc_cmdend_trg output connected to the MDMA is set when the sequence command response associated with an eventual busy signal ends. In this way, the MDMA can manage STOP_TRANSMISSION command (needed to support open mode transfers) by clearing CMDREND and BUSYD0END status flags.

When using LINUX operating system, data to be transferred through SDMMC bus are contained in separate 1- to 4-Kbyte blocks of the device internal memory at non-consecutive addresses. The double buffer mode allows changing the address targeted by the IDMA in
the internal memory. Each time a buffer transfer is completed, the IDMABTC flag of the status register is set. By signaling this event to MDMA through the sdmmc_buffend_trg output connected to an MDMA request input, the new buffer address base can alternatively fill the IDMABASE0 / IDMABASE1 fields without CPU intervention.

The actions to program in the MDMA according to the SDMMC requests are provided in the following table:

**Table 491. SDMMC connections to MDMA**

**58.5.8 AHB and SDMMC_CK clock relation**

The AHB must at least have 3x more bandwidth than the SDMMC bus bandwidth i.e. for SDR50 4-bit mode (50 Mbyte/s) the minimum sdmmc_hclk frequency is 37.5 MHz (150 Mbyte/s).

58.6 Card functional description

58.6.1 SD I/O mode

The following features are SDMMC specific operations:
- SDIO interrupts
- SDIO suspend/resume operation (write and read suspend)
- SDIO Read Wait operation by stopping the clock
- SDIO Read Wait operation by SDMMC_D2 signaling

SD I/O interrupts

To allow the SD I/O card to interrupt the host, an interrupt function is available on pin 8 (shared with SDMMC_D1 in 4-bit mode) on the SD interface. The use of the interrupt is optional for each card or function within a card. The SD I/O interrupt is level-sensitive, which means that the interrupt line must be held active (low) until it is either recognized and acted upon by the host or deasserted due to the end of the interrupt period. After the host has serviced the interrupt, the interrupt status bit is cleared via an I/O write to the appropriate bit in the SD I/O card internal registers. The interrupt output of all SD I/O cards is active low and the application must provide external pull-up resistors on all data lines (SDMMC_D[3:0]).

In SD 1-bit mode pin 8 is dedicated to the interrupt function (IRQ), and there are no timing constraints on interrupts.

In SD 4-bit mode the host samples the level of pin 8 (SDMMC_D1/IRQ) into the interrupt detector only during the interrupt period. At all other times, the host interrupt ignores this value. The interrupt period begins when interrupts are enabled at the card and SDIOEN bit is set see register settings in Table 493.

In 4-bit mode the card can generate a synchronous or asynchronous interrupt as indicated by the card CCCR register SAI and EAI bits.
- Synchronous interrupt, require the SDMMC_CK to be active.
- Asynchronous interrupt, can be generated when the SDMMC_CK is stopped, 4 cycles after the start of the card interrupt period following the last data block.
The timing of the interrupt period is depended on the bus speed mode:

In DS, HS, SDR12, and SDR25 mode, selected by register bit BUSSPEED, the interrupt period is synchronous to the SD clock:

- The interrupt period ends at the next clock from the end bit of a command that transfers data block(s) (Command sent with the CMDTRANS bit is set), or when the DTEN bit is set.
- The interrupt period resumes 2 SDMMC_CK after the completion of the data block.
- At the data block gap the interrupt period is limited to 2 SDMMC_CK cycles.

*Note:* DTEN must not be used to start data transfer with SD and eMMC cards.

---

**Figure 757. Asynchronous interrupt generation**

![Asynchronous interrupt generation diagram]

**Figure 758. Synchronous interrupt period data read**

![Synchronous interrupt period data read diagram]
In SDR50, SDR104, and DDR50, selected by register bit BUSSPEED, due to propagation delay from the card to host, the interrupt period is asynchronous.

- The card interrupt period ends after 0 to 2 SDMMC_CK cycles after the end bit of a command that transfers data block(s) (Command sent with the CMDTRANS bit is set), or when the DTEN bit is set. At the host the interrupt period ends after the end bit of a command that transfers data block(s). A card interrupt issued in the 1 to 2 cycles after the command end bit are not detected by the host during this interrupt period.

- The card interrupt period resumes 2 to 4 SDMMC_CK after the completion of the last data block. The host resumes the interrupt period always 2 cycles after the last data block.

- There is NO interrupt period at the data block gap.

*Note:* DTEN must not be used to start data transfer with SD and eMMC cards.
When transferring Open-ended multiple block data and using DTMODE “block data transfer ending with STOP_TRANSMISSION command”, the SDMMC masks the interrupt period after the last data block until the end of the CMD12 STOP_TRANSMISSION command.

The interrupt period is applicable for both memory and I/O operations.
In 4-bit mode interrupts can be differentiated from other signaling according Table 494.

SD I/O suspend and resume
This function is NOT supported in SDIO version 4.00 or later.

Within a multifunction SD I/O or a card with both I/O and memory functions, there are multiple devices (I/O and memory) that share access to the eMMC/SD bus. To share access to the host among multiple devices, SD I/O and combo cards optionally implement the concept of suspend/resume. When a card supports suspend/resume, the host can temporarily halt (suspend) a data transfer operation to one function or memory to free the bus for a higher-priority transfer to a different function or memory. After this higher-priority transfer is complete, the original transfer is restarted (resume) where it left off.

To perform the suspend/resume operation on the bus, the host performs the following steps:
1. Determines the function currently using the SDMMC_D[3:0] line(s)
2. Requests the lower-priority or slower transaction to suspend
3. Waits for the transaction suspension to complete
4. Begins the higher-priority transaction
5. Waits for the completion of the higher priority transaction
6. Restores the suspended transaction

The card receiving a suspend command responds with its current bus status. Only when the bus has been suspended by the card the bus status indicates suspension completed.

There are different suspend cases conditions:
- Suspend request accepted prior to the start of data transfer.
- Suspend request not accepted, (due to data being transferred at the same time), the host keeps checking the request until it is accepted. (data transfer has suspended)
- Suspend request during write busy.
- Suspend request with write multiple.
- Suspend request during Read Wait.

For the host to know if the bus has been released it must check the status of the suspend request, suspension completed.

When the bus status of the suspend request response indicates suspension completed, the card has released the bus. At this time the state of the suspended operation must be saved where after an other operation can start.

The suspend command must be sent with the CMDSUSPEND bit set. This makes possible to start the interrupt period after the suspend command response when the bus is suspended (response bit BS = 0).
The hardware does not save the number of remaining data to be transferred when resuming the suspended operation. It is up to firmware to determine the data that has been transferred and resume with the correct remaining number of data bytes.

While receiving data from the card, the SDMMC can suspend the read operation after the read data block end (DPSM in Wait_R). After receiving the suspend acknowledgment response from the card the following steps must be taken by firmware:

1. The normal receive process must be stopped by setting DTHOLD bit.
   a) The remaining number of data bytes in the FIFO must be read until the receive FIFO is empty (RXFIFOE flag is set), and when IDMAEN = 0 the FIFO must be reset with FIFORST.

2. The confirmation that all data has been read from the FIFO, and that the suspend is completed is indicated by the DHOLD flag.
   a) The remaining number of data bytes (multiple of data blocks) still to be read when resuming the operation must be determined from the remaining number of bytes indicated by the DATACOUNT.

*Note:* When a DTIMEOUT flag occurs during the suspend procedure, this must be ignored.

To resume receiving data from the card, the following steps must be taken by firmware:

1. The remaining number of data bytes (multiple of data blocks) must be programmed in DATALENGTH.

2. The DPSM must be configured to receive data in the DTDIR bit.

3. The resume command must be sent from the CPSM, with the CMDTRANS bit set and the CMDSUSPEND bit set, which ends the interrupt period when data transfer is resumed (response bit DF = 1) and enabled the DPSM, after which the card resumes sending data.

While sending data to the card, the SDMMC can suspend the write operation after the write data block CRC status end (DPSM in Busy). Before sending the suspend command to the card the following steps must be taken by firmware:

1. Enable DHOLD flag (and DBCKEND flag when IDMAEN = 0)

2. The DPSM must be prevented from start sending a new data block by setting DTHOLD.

3. When IDMAEN = 0: When receiving the DBCKEND flag the data transfer is stopped. Firmware can stop filling the FIFO, after which the FIFO must be reset with FIFORST. Any bytes still in the FIFO need to be rewritten when resuming the operation.

4. When receiving the DHOLD flag the data transfer is stopped. The remaining number of data bytes still to be written when resuming must be determined from the remaining number of bytes indicated by the DATACOUNT.

5. To suspend the card the suspend command must be sent by the CPSM with the CMDSUSPEND bit set. This makes possible to start the interrupt period after the suspend command response when the bus is suspended (response bit BS = 0).

To resume sending data to the card, the following steps must be taken by firmware:

1. The remaining number of data bytes must be programmed in DATALENGTH.

2. The DPSM must be configured for transmission with DTDIR set and enabled by having the CPSM send the resume command with the CMDTRANS bit set and the CMDSUSPEND bit set. This ends the interrupt period and start the data transfer. The
DPSM either goes to the Wait_S state when SDMMC_D0 does not signal busy, or goes to the Busy state when busy is signaled.

3. When IDMAEN = 1: The IDMA needs to be reprogrammed for the remaining bytes to be transferred.

4. When IDMAEN = 0: Firmware must start filling the FIFO with the remaining data.

**SD I/O Read Wait**

There are 2 methods to pause the data transfer during the Block gap:

1. Stopping the SDMMC_CK.
2. Using Read Wait signaling on SDMMC_D2.

The SDMMC can perform a Read Wait with register settings according **Table 493**.

Depending the SDMMC operation mode (DS, HS, SDR12, SDR25) or (SDR50, SDR104, DDR) each method has a different characteristic.

The timing for pause read operation by stopping the SDMMC_CK for DS, HS, SDR12, and SDR25, the SDMMC_CK may be stopped 2 SDMMC_CK cycles after the end bit. When ready the host resumes by restarting clock, see **Figure 762**.

**Figure 762. Clock stop with SDMMC_CK for DS, HS, SDR12, SDR25**

The timing for pause read operation by stopping the SDMMC_CK for SDR50, SDR104, and DDR50, the SDMMC_CK may be stopped minimum 2 SDMMC_CK cycles and maximum 5 SDMMC_CK cycles, after the end bit. When ready the host resumes by restarting clock, see **Figure 763**. (In DDR50 mode the SDMMC_CK must only be stopped after the falling edge, when the clock line is low.)

**Figure 763. Clock stop with SDMMC_CK for DDR50, SDR50, SDR104**
In Read Wait SDMMC\_CK clock stopping, when RWSTART is set, the DSPM stops the clock after the end bit of the current received data block CRC. The clock start again after writing 1 to the RWSTOP bit, where after the DPSM waits for a start bit from the card.

As SDMMC\_CK is stopped, no command can be issued to the card. During a Read Wait interval, the SDMMC can still detect SDIO interrupts on SDMMC\_D1.

The optional Read Wait signaling on SDMMC\_D2 (RW) operation is defined only for the SD 1-bit and 4-bit modes. The Read Wait operation enables the host to signal a card that is reading multiple registers (I\_O\_RW\_EXTENDED, CMD53) to temporarily stall the data transfer while allowing the host to send commands to any function within the SD I/O device.

To determine when a card supports the Read Wait protocol, the host must test capability bits in the internal card registers.

The timing for Read Wait with a SDMMC\_CK less than 50MHz (DS, HS, SDR12, SDR25) is based on the interrupt period generated by the card on SDMMC\_D1. The host by asserting SDMMC\_D2 low during the interrupt period requests the card to enter Read Wait. To exit Read Wait the host must raise SDMMC\_D2 high during one SDMMC\_CK cycles before making it Hi-Z, see Figure 764.

Figure 764. Read Wait with SDMMC\_CK < 50 MHz

For SDR50, SDR104 with a SDMMC\_CK more than 50MHz, and DDR50, the card treats the Read Wait request on SDMMC\_D2 as an asynchronous event. The host by asserting SDMMC\_D2 low after minimum 2 SDMMC\_CK cycles and maximum 5 SDMMC\_CK cycles, request the card to enter Read Wait. To exit Read Wait the host must raise SDMMC\_D2 high during one SDMMC\_CK cycles before making it Hi-Z. The host must raise SDMMC\_D2 on the SDMMC\_CK clock (see Figure 765).
In Read Wait SDMMC_D2 signaling, when RWSTART is set, the DPSM drives SDMMC_D2 after the end bit of the current received data block CRC. The Read Wait signaling on SDMMC_D2 is removed when writing 1 to the RWSTOP bit. The DPSM remains in R_W state for two more SDMMC_CK clock cycles to drive SDMMC_D2 to 1 for one clock cycle (in accordance with SDIO specification), where after the DPSM waits for a start bit from the card.

During the Read Wait signaling on SDMMC_D2 commands can be issued to the card. During the Read Wait interval, the SDMMC can detect SDIO interrupts on SDMMC_D1.

58.6.2 CMD12 send timing

CMD12 is used to stop/abort the data transfer, the card data transmission is terminated two clock cycles after the end bit of the Stop Transmission command.

**Table 495. CMD12 use cases**

<table>
<thead>
<tr>
<th>Data operation</th>
<th>Stop Transmission command CMD12</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SDMMC stream write</td>
<td>The data transfer is stopped/aborted by sending the Stop Transmission command.</td>
<td></td>
</tr>
<tr>
<td>SDMMC open ended multiple block write</td>
<td>The data transfer is stopped/aborted by sending the Stop Transmission command. If the card detects an error, the host must abort the operation by sending the Stop Transmission command.</td>
<td></td>
</tr>
<tr>
<td>SDMMC block write with predefined block count</td>
<td>The Stop Transmission command is not required at the end of this type of multiple block write. (sending the Stop Transmission command after the card has received the last block is regarded as an illegal command.) If the card detects an error, the host must abort the operation by sending the Stop Transmission command.</td>
<td></td>
</tr>
<tr>
<td>SDMMC stream read</td>
<td>The data transfer is stopped/aborted by sending the Stop Transmission command.</td>
<td></td>
</tr>
</tbody>
</table>
All data write and read commands can be aborted any time by a Stop Transmission command CMD12. The following data abort procedure applies during an ongoing data transfer:

1. Load CMD12 Stop Transmission command in registers and set the CMDSTOP bit.
   a) This causes the CPSM Abort signal to be generated when the command is sent to the DPSM.

2. Configure the CPSM to send a command immediately (clear WAITPEND bit).
   a) The card, when sending data, stops data transfer 2 cycles after the Stop Transmission command end bit.
      The card when no data is being sent, does not start sending any new data.
   b) The host, when sending data, sends one last data bit followed by an end bit after the Stop Transmission command end bit.
      The host when not sending data, does not start sending any new data.

3. When IDMAEN = 0, the FIFO need to be reset with FIFORST.
   a) When writing data to the card. On the CMDREND flag, firmware must stop writing data to the FIFO. Subsequently the FIFO must be reset with FIFORST, this flushes the FIFO.
   b) When reading data from the card. On the CMDREND flag, firmware must read the remaining data from the FIFO. Subsequently the FIFO must be reset with FIFORST.

4. When IDMAEN = 1, hardware takes care of the FIFO.
   a) When writing data to the card. On the CPSM Abort signal, hardware stops the IDMA and subsequently the FIFO is flushed.
   b) When reading data from the card. On the CPSM Abort signal, hardware instructs the IDMA to transfer the remaining data from the FIFO to RAM.

5. When the FIFO is empty/reset the DABORT flag is generated.

**Stream operation and CMD12**

To stop the stream transfer after the last byte to be transfered, the CMD12 end bit timing must be sent aligned with the data stream end of last byte. The following write stream data procedure applies:
1. Initialize the stream data in the DPSM, DTMODE = MCC stream data transfer.
2. Send the WRITE_DATA_STREAM command from the CPSM with CMDTRANS = 1.
3. Preload CMD12 in command registers, with the CMDSTOP bit set.
4. Configure the CPSM to send a command only after a wait pending (WAITPEND = 1) end of last data (according DATALENGTH).
5. Enabling the CPSM to send the STOP_TRANSMISSION command, the stream data end bit and command end bit are aligned.
   a) When DATALENGTH > 5 bytes, Command CMD12 is waited in the CPSM to be aligned with the data transfer end bit.
   b) When DATALENGTH < 5 bytes, Command CMD12 is started before and the DPSM remains in the Wait_S state to align the data transfer end with the CMD12 end bit.
6. The write stream data can be aborted any time by clearing the WAITPEND bit. This causes the Preloaded CMD12 to be sent immediately and stop the write data stream.

**Figure 766. CMD12 stream timing**

To stop the read stream transfer after the last byte, the CMD12 end bit timing must occur after the last data stream byte. The following read stream data procedure applies:
1. Wait for all data to be received by the DPSM and read from the FIFO (DATAEND flag).
   a) The DPSM does not receive more data than indicated by DATALENGTH, even if the card is sending more data.
2. Send CMD12 by the CPSM.
   a) CMD12 stops the card sending data.

*Note: The SDMMC does not receive any more data from the card when DATACOUNT = 0, even when the card continues sending data.*

**Block operation and CMD12**

To stop block transfer at the end of the data, the CMD12 end bit must be sent after the last block end bit.

When writing data to the card the CMD12 end bit must be sent after the write data block CRC token end bit. This requires the CMD12 sending to be tied to the data block transmission timing. To stop an Open-ended Multiple block write, the following procedure applies:
1. Before starting the data transfer, set DTMODE to “block data transfer ending with STOP_TRANSMISSION command”.
2. Wait for all data to be sent by the DPSM and the CRC token to be received, (DATAEND flag).
   a) The DPSM does not send more data than indicated by DATALength.
3. Send CMD12 by the CPSM.
   a) CMD12 sets the card to Idle mode.

When reading data from the card the CMD12 end bit must be sent earliest at the same time as the card read data block last data bit. This requires the CMD12 sending to be tied to the data block reception timing. The following stop Open-ended Multiple block read data block procedure applies:

1. Before starting the data transfer, set DTMODE to “block data transfer ending with STOP_TRANSMISSION command”.
2. Wait for all data to be received by the DPSM and read from the FIFO (DATAEND flag).
   a) The DPSM does not receive more data than indicated by DATALength, even if the card is sending more data.
3. Send CMD12 with CMDSTOP bit set by the CPSM.
   a) CMD12 stops the Card sending more data and set the card to Idle mode. Any ongoing block transfer is aborted by the Card.

Note: The SDMMC does not receive any more data from the card when DATACOUNT = 0, even when the card continues sending data.

58.6.3 Sleep (CMD5)

The e•MMC card may be switched between a Sleep state and a Standby state by CMD5. In the Sleep state the power consumption of the card is minimized and the Vcc power supply may be switched off.

The CMD5 (SLEEP) is used to initiate the state transition from Standby state to Sleep state. The card indicates Busy, pulling down SDMMC_D0, during the transition phase. The Sleep state is reached when the card stops pulling down the SDMMC_D0 line.

To set the card into Sleep state the following procedure applies:

1. Enable interrupt on BUSYD0END.
2. Send CMD5 (SLEEP).
3. On BUSYD0END interrupt, card is in Sleep state
4. Vcc power supply can be switched off

The CMD5 (AWAKE) is used to initiate the state transition from Sleep state to Standby state. The card indicates Busy, pulling down SDMMC_D0, during the transition phase. The Standby state is reached when the card stops pulling down the SDMMC_D0 line.

To set the card into Sleep state the following procedure applies:

1. Switch on Vcc power supply and wait unit minimum operating level is reached.
2. Enable interrupt on BUSYD0END.
3. Send CMD5 (AWAKE).
4. On BUSYD0END interrupt card is in Standby state.

The Vcc power supply can be switched off only after the Sleep state has been reached. The Vcc supply must be reinstalled before CMD5 (AWAKE) is sent.
### 58.6.4 Interrupt mode (Wait-IRQ)

The host and card enter and exit interrupt mode (Wait-IRQ) simultaneously. In interrupt mode there is no data transfer. The only message allowed is an interrupt service request response from the card or the host. For the interrupt mode to work correctly the SDMMC_CK frequency must be set in accordance with the achievable SDMMC_CMD data rate in Open Drain mode, which depend on the capacitive load and pull-up resistor. The CLKDIV must be set >1, and the SETCLKRX must select either the sdmmc_io_in_ck or SDMMC_CLKin source.

The host must ensure that the card is in Standby state before issuing the CMD40 (GO_IRQ_STATE). While waiting for an interrupt response the SDMMC_CK clock signal must be kept active.

A card in interrupt mode (IRQ state):
- is waiting for an internal card interrupt event. Once the event occurs, the card starts to send the interrupt service request response. The response is sent in open-drain mode.
- while waiting for the internal card interrupt event, the card also monitors the SDMMC_CMD line for a start bit. Upon detection of a start bit the card aborts the interrupt mode and switch to Standby state.

The host in interrupt mode (CPSM Wait state waiting for interrupt):
- is waiting for a card interrupt service request response (start bit).
- while waiting for a card interrupt service request response the host may abort the interrupt mode (by clearing the WAITINT register bit), which causes the host to send a interrupt service request response R5 with RCA = 0x0000 in open-drain mode.

When sending the interrupt service request response, the sender bit-wise monitors the SDMMC_CMD bit stream. The sender whose interrupt service request response bit does not correspond to the bit on the SDMMC_CMD line stops sending. In the case of multiple senders only one successfully sends its full interrupt service request response. If the host sends simultaneously, it loses sending after the transmission bit.

To handle the interrupt mode, the following procedure applies:
1. Set the SDMMC_CK frequency in accordance with the achievable SDMMC_CMD data rate in Open-drain mode, CLKDIV must be set >1, and SETCLKRX must select the sdmmc_io_in_ck.

2. Load CMD40 (GO_IRQ_STATE) in the command registers.

3. Enable wait for interrupt by setting WAITINT register bit.

4. Configure the CPSM to send a command immediately.
   a) This causes the CMD40 to be sent and the CPSM to be halted in the Wait state, waiting for an interrupt service request response.

5. To exit the wait for interrupt state (CPSM Wait state):
   a) Upon the detection of an interrupt service request response start bit the CPSM moves to the Receive state where the response is received. The complete reception of the response is indicated by the CMDREND or the command CRC error flags.

   b) To abort the interrupt mode the host clears the WAITINT register bit, which causes the host to send an interrupt service request response by itself. This moves the CPSM to the Receive state. The complete reception of the response is indicated by the CMDREND or the command CRC error flags.

Note: On a simultaneous send interrupt service request response start bit collision the host loses the bus access after the transmission bit.

58.6.5 Boot operation

In boot operation mode the host can read boot data from the card by either one of the 2 boot operation functions:

1. Normal boot. (keeping CMD line low)
2. Alternative boot (sending CMD0 with argument 0xFFFFFFFA)

The boot data can be read according the following configuration options, depending on card register settings:

- The partition from which boot data is read (EXT_CSD Byte[179])
- The boot data size (EXT_CSD Byte[226])
- The bus configuration during boot (EXT_CSD Byte[177])
- Receiving boot acknowledgment from the card. (EXT_CSD Byte[179])

If boot acknowledgment is enabled the card send pattern 010 on SDMMC_D0 within 50ms after boot mode has been requested by either CMD line going low or after CMD0 with argument 0xFFFFFFFA. A boot acknowledgment timeout (ACKTIMEOUT) and acknowledgment status (ACKFAIL) is provided.

Normal boot operation

If the SDMMC_CMD line is held low for at least 74 clock cycles after card power-up or reset, before the first command is issued, the card recognizes that boot mode is being initiated. Within 1 second after the CMD line goes low, the card starts to sent the first boot code data on the SDMMC_Dn line(s). The host must keep the SDMMC_CMD line low until after all boot data has been read. The host can terminate boot mode by pulling the SDMMC_CMD line high.
To perform the normal boot procedure the following steps needed:

1. Reset the card.
2. If a boot acknowledgment is requested enable the BOOTACKEN and set the ACKTIME and enable the ACKFAIL and ACKTIMEOUT interrupt.
3. Enable the data reception by setting the DPSM in receive mode (DTDIR) and the number of data bytes to be received in DATALENGTH.
4. Enable the DTIMEOUT, DATAEND, and CMDSENT interrupts for end of boot command confirmation.
5. Select the normal boot operation mode in BOOTMODE, and enable boot in BOOTEN. The boot procedure is started by enabling the CPSM with CPSMEN. This causes:
   – the SDMMC_CMD to be driven low. (BOOTMODE = normal boot).
   – the ACK timeout to start.
   – DPSM to be enabled.
6. The incorrect reception of the boot acknowledgment can be detected with ACKFAIL flag or ACKTIMEOUT flag when enabled.
   – when an incorrect boot acknowledgment is received the ACKFAIL flag occurs.
   – when the boot acknowledgment is not received in time the ACKTIMEOUT flag occurs.
7. When all boot data has been received the DATAEND flag occurs.
   – when data CRC fails the DCRCFAIL flag is also generated.
   – when the data timeout occurs the DTIMEOUT flag is also generated.
8. When last data has been received, read data from the FIFO until FIFO is empty after which end of data DATAEND flag is generated.
   – SDMMC has completely received all data and the DPSM is disabled.
9. The boot procedure is terminated by firmware clearing BOOTEN, which causes the SDMMC_CMD line to go high. The CMDSENT flag is generated 56 cycles later to indicate that a new command can be sent.
   a) If the boot procedure is aborted by firmware before all data has been received the CPSM Abort signal stops data reception and disables the DPSM which triggers an DABORT flag when enabled.
10. The CMDSENT flag signals the end of the boot procedure and the card is ready to receive a new command.
Alternative boot operation

After card power-up or reset, if the host send CMD0 with the argument 0xFFFFFFFFFA after 74 clock cycles before CMD0 is issued, the card recognizes that boot mode is being initiated. Within 1 second after the CMD0 with argument 0xFFFFFFFFFA has been sent, the card starts to send the first boot code data on the SDMMC_Dn line(s). The master terminates boot operation by sending CMD0 (Reset).

Figure 769. Alternative boot mode operation

To perform the alternative boot procedure the following steps needed:

1. Move the SDMMC to power-off state, and reset the card
2. Move the SDMMC to power-on state. This guarantees the 74 SCDMMC_CK cycles to be clocked before any command.
3. if a boot acknowledgment is requested enable the BOOTACKEN and set the ACKTIME and enable the ACKTIMEOUT flag.
4. enable the data reception by setting the DPSM in receive mode (DTDIR) and the number of data to be received in DATALENGTH. Enable the DTIMEOUT and DATAEND flags.
5. Select the alternative boot operation mode in BOOTMODE, load the CMD0 with the 0xFFFFFFFFFA argument in the command registers. Enable CMDSENT flag for end of
boot command confirmation, and enable boot in BOOTEN. The boot procedure is
started by enabling the CPSM with CPSMEN. This causes:
– the loaded command and argument to be sent out. (BOOTMODE = alternative
boot).
– the ACK timeout to start.
– DPSM to be enabled.
6. When the command has been sent the CMDSENT flag is generated, at which time the
BOOTEN bit must be cleared.
7. the reception of the boot acknowledgment can be detected with ACKFAIL flag when
enabled.
– when the boot acknowledgment is not received in time the ACKTIMEOUT flag
occurs.
8. when all boot data has been received the DATAEND flag occurs.
– when data CRC fails the DCRCFAIL flag is also generated.
– when the data timeout occurs the DTIMEOUT flag is also generated.
9. When last data has been received, read data from the FIFO until FIFO is empty after
which end of data DATAEND flag is generated.
– SDMMC has completely received all data and the DPSM is disabled.
10. The BOOTEN bit must be cleared, before terminating the boot procedure by sending
CMD0 (Reset) with BOOTMODE = alternative boot. This causes the CMDSENT flag to
occur 56 cycles after the Command.
– if the boot procedure is aborted by firmware before all data has been received the
CPMS Abort signal stops the data transfer and disable the DPSM which triggers
DABORT flag when enabled.
11. The CMDSENT flag signals the end of the boot procedure and the card is ready to
receive a new command. When the RESET command has been sent successfully, the
BOOTMODE control bit has to be cleared to terminate the boot operation.

58.6.6 Response R1b handling
When sending commands which have a R1b response the busy signaling is reflected in the
BUSYD0 register bit and the release of busy with the BUSYD0END flag. The SDMMC_D0
line is sampled at the end of the R1b response and signaled in the BUSYD0 register bit. The
BUSYD0 register bit is reset to not busy when the SDMMC_D0 line release busy, at the
same time the BUSYD0END flag is generated.

Figure 770. Command response R1b busy signaling
The expected maximum busy time must be set in the DATATIME register before sending the command. When enabled, the DTIMEOUT flag is set when after the R1b response busy stays active longer then the programmed time.

To detect the SDMMC_D0 busy signaling when sending a Command with R1b response the following procedure applies:
- Enable CMDREND flag
- Send Command through CPSM.
- On the CMDREND flag check the BUSYD0 register bit.
  - If BUSYD0 signals not busy, signal busy release to the Firmware
  - If BUSYD0 signals busy, wait for BUSYD0END flag
- On BUSYD0END flag signal busy released to the firmware.
- On DTIMEOUT flag busy is active longer then programmed time.

58.6.7 Reset and card cycle power

**Reset**

Following reset the SDMMC is in the reset state. In this state the SDMMC is disabled and no command nor data can be transfered. The SDMMC_D[7:0], and SDMMC_CMD are in HiZ and the SDMMC_CK is driven low.

Before moving to the power-on state the SDMMC must be configured.

In the power-on state the SDMMC_CK clock is running. First 74 SDMMC_CK cycles are clocked after which the SDMMC is enabled and command and data can be transfered.

The SDMMC states are controlled by Firmware with the PWRCTRL register bits according Figure 771..

![Figure 771. SDMMC state control](image)

**Card cycle power**

To perform a card cycle power the following procedure applies:
1. Reset the SDMMC with the RCC.SDMMCxRST register bit. This resets the SDMMC to the reset state and the CPSM and DPSM to the Idle state.
2. Disable the Vcc power to the card.
3. Set the SDMMC in power-cycle state. This makes that the SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are driven low, to prevent the card from being supplied through the signal lines.
4. After minimum 1 ms enable the Vcc power to the card.
5. After the power ramp period set the SDMMC to the power-off state for minimum 1 ms. The SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are set to drive “1”.
6. After the 1 ms delay set the SDMMC to power-on state in which the SDMMC_CK clock is enabled.
7. After 74 SDMMC_CK cycles the first command can be sent to the card.

**58.7 Hardware flow control**

The hardware flow control during data transfer functionality is used to avoid FIFO underrun (TX mode) and overrun (RX mode) errors.

The behavior is to stop SDMMC_CK during data transfer and freeze the SDMMC state machines. The data transfer is stalled when the FIFO is unable to transmit or receive data. The data transfer remains stalled until the transmit FIFO is half full or all data according DATALENght has been stored, or until the receive FIFO is half empty. Only state machines clocked by SDMMC_CK are frozen, the AHB interfaces are still alive. The FIFO can thus be filled or emptied even if flow control is activated.

To enable hardware flow control during data transfer, the HWFC_EN register bit must be set to 1. After reset hardware flow control is disabled.
Hardware flow control must only be used when the SDMMC_Dn data is cycle-aligned with the SDMMC_CK. Whenever the sdmmc_fb_ck from the DLYB delay block is used, i.e in the case of SDR104 mode with a tOP and DtOP delay > 1 cycle, hardware flow control cannot be used.

58.8 Ultra-high-speed phase I (UHS-I) voltage switch

UHS-I mode (SDR12, SDR25, SDR50, SDR104, and DDR50) requires the support for 1.8V signaling. After power up the card starts in 3.3V mode. CMD11 invokes the voltage switch sequence to the 1.8V mode. When the voltage sequence is completed successfully the card enters UHS-I mode with default SDR12 and card input and output timings are changed.

Figure 773. CMD11 signal voltage switch sequence

To perform the signal voltage switch sequence the following steps are needed:
1. Before starting the Voltage Switch procedure, the SDMMC_CK frequency must be set in the range 100 kHz - 400 kHz.
2. The host starts the Voltage Switch procedure by setting the VSWITCHEN bit before sending the CMD11.
3. The card returns an R1 response.
   – if the response CRC is pass, the Voltage Switch procedure continues the host does no longer drive the CMD and SDMMC_D[3:0] signals until completion of the voltage switch sequence. Some cycles after the response the SDMMC_CK is stopped and the CKSTOP flag is set.
   – if the response CRC is fail (CCRCFAIL flag) or no response is received before the timeout (CTIMEOUT flag), the Voltage Switch procedure is stopped.
4. The card drives CMD and SDMMC_D[3:0] to low at the next clock after the R1 response.
5. The host, after having received the R1 response, may monitor the SDMMC_D0 line using the BUSYD0 register bit. The SDMMC_D0 line is sampled two SDMMC_CK clock cycles after the Response. The Firmware may read the BUSYD0 register bit following the CKSTOP flag.
   – When the BUSYD0 is detected low the host firmware switches the Voltage regulator to 1.8V, after which it instructs the SDMMC to start the timing critical
section of the Voltage Switch sequence by setting register bit VSWITCH. The hardware continues to stop the SDMMC_CK by holding it low for at least 5 ms.

- When the BUSYD0 is detected high the host aborts the Voltage Switch sequence and cycle power the card.

6. The card after detecting SDMMC_CK low begins switching signaling voltage to 1.8 V.
7. The host SDMMC hardware after at least 5 ms restarts the SDMMC_CK.
8. The card within 1 ms from detecting SDMMC_CK transition drives CMD and DAT[3:0] high for at least 1 SDMMC_CK cycle and then stop driving CMD and DAT[3:0].
9. The host SDMMC hardware, 1 ms after the SDMMC_CK has been restarted, the SDMMC_D0 is sampled into BUSYD0 and the VSWEND flag is set.
10. The host, on the VSWEND flag, checks SDMMC_D0 line using the BUSYD0 register bit, to confirm completion of voltage switch sequence:
   - When BUSYD0 is detected high, Voltage Switch has been completed successfully.
   - When BUSYD0 is detected low, Voltage Switch has failed, the host cycles the card power.

The minimum 5 ms time to stop the SDMMC_CK is derived from the internal un-gated SDMMC_CK clock, which has a maximum frequency of 25 MHz (SD mode), as set by the clock divider CLKDIV. The >5 ms time is counted by $2^{12}$ cycles (10.24 ms @ 400 kHz). If a lower SDMMC_CK frequency is selected by the clock divider CLKDIV the time for the SDMMC_CK clock to be stopped is longer.

The maximum 1 ms time for the card to drive the SDMMC_Dn and SDMMC_CMD lines high is derived from the internal ungated SDMMC_CK which has a maximum frequency of 25 MHz (SD mode), as set by the clock divider CLKDIV. The SDMMC checks the lines after >1 ms time which is counted by $2^8$ cycles (1.28 ms @ 25 MHz). If a lower SDMMC_CK frequency is selected by the clock divider CLKDIV the time to check the lines is longer.

The signal voltage level is supported through an external voltage translation transceiver like STMicroelectronics ST6G3244ME.
To interface with an external driver (a voltage switch transceiver), next to the standard signals the SDMMC uses the following signals:

**SDMMC_CKIN** feedback input clock

**SDMMC_CDIR** I/O direction control for the CMD signal.

**SDMMC_D0DIR** I/O direction control for the SDMMC_D0 signal.

**SDMMC_D123DIR** I/O direction control for the SDMMC_D1, SDMMC_D2 and SDMMC_D3 signals.

The voltage transceiver signals **EN** and **SEL** are to be handled through general-purpose I/O.

The polarity of the SDMMC_CDIR, SDMMC_D0DIR and SDMMC_D123DIR signals can be selected through SDMMCPOWER.DIRPOL control bit.

58.10 SDMMC registers

The device communicates to the system via 32-bit control registers accessible via AHB slave interface.

The peripheral registers have to be accessed by words (32-bit). Byte (8-bit) and halfword (16-bit) accesses trigger an AHB bus error.

58.10.1 SDMMC power control register (SDMMC_POWER)

Address offset: 0x000

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit 31:5</th>
<th>Bit 4</th>
<th>Bit 3</th>
<th>Bit 2</th>
<th>Bits 1:0</th>
</tr>
</thead>
<tbody>
<tr>

<td>PWRCTRL[1:0]</td>
</tr>
<tr>
<td></td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 DIRPOL: Data and command direction signals polarity selection
This bit can only be written when the SDMMC is in the power-off state (PWRCTRL = 00).
0: Voltage transceiver IOs driven as output when direction signal is low.
1: Voltage transceiver IOs driven as output when direction signal is high.

Bit 3 VSWITCHEN: Voltage switch procedure enable
This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).
This bit is used to stop the SDMMC_CK after the voltage switch command response:
0: SDMMC_CK clock kept unchanged after successfully received command response.
1: SDMMC_CK clock stopped after successfully received command response.

Bit 2 VSWITCH: Voltage switch sequence start
This bit is used to start the timing critical section of the voltage switch sequence:
0: Voltage switch sequence not started and not active.
1: Voltage switch sequence started or active.

Bits 1:0 PWRCTRL[1:0]: SDMMC state control bits
These bits can only be written when the SDMMC is not in the power-on state (PWRCTRL ≠ 11).
These bits are used to define the functional state of the SDMMC signals:
00: After reset, Reset: the SDMMC is disabled and the clock to the Card is stopped, SDMMC_D[7:0], and SDMMC_CMD are HiZ and SDMMC_CK is driven low. When written 00, power-off: the SDMMC is disabled and the clock to the card is stopped, SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are driven low.
01: Reserved. (When written 01, PWRCTRL value does not change)
10: Power-cycle, the SDMMC is disabled and the clock to the card is stopped, SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are driven low.
11: Power-on: the card is clocked, The first 74 SDMMC_CK cycles the SDMMC is still disabled. After the 74 cycles the SDMMC is enabled and the SDMMC_D[7:0], SDMMC_CMD and SDMMC_CK are controlled according the SDMMC operation. Any further write is ignored, PWRCTRL value keeps 11.
58.10.2 SDMMC clock control register (SDMMC_CLKCR)

Address offset: 0x004
Reset value: 0x0000 0000

The SDMMC_CLKCR register controls the SDMMC_CK output clock, the sdmmc_rx_ck receive clock, and the bus width.

| Bit 31:22 | Reserved, must be kept at reset value. |
| Bit 21:20 | SELCLKRX[1:0]: Receive clock selection |
| Bit 19    | BUSSPEED: Bus speed for selection of SDMMC operating modes |
| Bit 18    | DDR: Data rate signaling selection |
| Bit 17    | HWFC_EN: Hardware flow control enable |

Bits 31:22: Reserved, must be kept at reset value.

Bits 21:20: **SELCLKRX[1:0]**: Receive clock selection

- These bits can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)
- 00: sdmmc_io_in_ck selected as receive clock
- 01: SDMMC_CKIN feedback clock selected as receive clock
- 10: sdmmc_fb_ck tuned feedback clock selected as receive clock.
- 11: Reserved (select sdmmc_io_in_ck)

Bit 19: **BUSSPEED**: Bus speed for selection of SDMMC operating modes

- This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)
- 0: DS, HS, SDR12, SDR25, Legacy compatible, High speed SDR, High speed DDR bus speed mode selected
- 1: SDR50, DDR50, SDR104, HS200 bus speed mode selected.

Bit 18: **DDR**: Data rate signaling selection

- This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)
- DDR rate must only be selected with 4-bit or 8-bit wide bus mode. (WIDBUS > 00). DDR = 1 has no effect when WIDBUS = 00 (1-bit wide bus).
- DDR rate must only be selected with clock division >1. (CLKDIV > 0)
- 0: SDR Single data rate signaling
- 1: DDR double data rate signaling

Bit 17: **HWFC_EN**: Hardware flow control enable

- This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)
- 0: Hardware flow control is disabled
- 1: Hardware flow control is enabled

When Hardware flow control is enabled, the meaning of the TXFIFOE and RXFIFOF flags change, see SDMMC status register definition in Section 58.10.11.
Bit 16 **NEGEDGE**: SDMMC_CK dephasing selection bit for data and command
This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0).
When clock division = 1 (CLKDIV = 0), this bit has no effect. Data and Command change on SDMMC_CK falling edge.
0: When clock division >1 (CLKDIV > 0) and DDR = 0:
  – Command and data changed on the sdmcc_ker_ck falling edge succeeding the rising edge of SDMMC_CK.
  – SDMMC_CK edge occurs on sdmcc_ker_ck rising edge.
  – SDMMC_CK edge occurs on sdmcc_ker_ck rising edge.
1: When clock division >1 (CLKDIV > 0) and DDR = 0:
  – Command and data changed on the same sdmcc_ker_ck rising edge generating the SDMMC_CK falling edge.
  – SDMMC_CK edge occurs on sdmcc_ker_ck rising edge.
When clock division >1 (CLKDIV > 0) and DDR = 1:
  – Command changed on the sdmcc_ker_ck falling edge succeeding the rising edge of SDMMC_CK.
  – Data changed on the sdmcc_ker_ck falling edge succeeding a SDMMC_CK edge.
  – SDMMC_CK edge occurs on sdmcc_ker_ck rising edge.

Bits 15:14 **WIDBUS[1:0]**: Wide bus mode enable bit
This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)
00: Default 1-bit wide bus mode: SDMMC_D0 used (Does not support DDR)
01: 4-bit wide bus mode: SDMMC_D[3:0] used
10: 8-bit wide bus mode: SDMMC_D[7:0] used

Bit 13 Reserved, must be kept at reset value.

Bit 12 **PWRSAV**: Power saving configuration bit
This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0)
For power saving, the SDMMC_CK clock output can be disabled when the bus is idle by setting PWRSAV:
0: SDMMC_CK clock is always enabled
1: SDMMC_CK is only enabled when the bus is active

Bits 11:10 Reserved, must be kept at reset value.

Bits 9:0 **CLKDIV[9:0]**: Clock divide factor
This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0).
This field defines the divide factor between the input clock (sdmmcc_ker_ck) and the output clock (SDMMC_CK): SDMMC_CK frequency = sdmmcc_ker_ck / [2 * CLKDIV].
0x000: SDMMC_CK frequency = sdmmcc_ker_ck / 1 (Does not support DDR)
0x001: SDMMC_CK frequency = sdmmcc_ker_ck / 2
0x002: SDMMC_CK frequency = sdmmcc_ker_ck / 4
0x0XX: etc..
0x080: SDMMC_CK frequency = sdmmcc_ker_ck / 256
0xXXX: etc..
0x3FF: SDMMC_CK frequency = sdmmcc_ker_ck / 2046
Note: 1 While the SD/SDIO card or eMMC is in identification mode, the SDMMC_CK frequency must be less than 400 kHz.
2 The clock frequency can be changed to the maximum card bus frequency when relative card addresses are assigned to all cards.
3 At least seven sdmmc_hclk clock periods are needed between two write accesses to this register. SDMMC_CK can also be stopped during the Read Wait interval for SD I/O cards: in this case the SDMMC_CLKCR register does not control SDMMC_CK.

58.10.3 SDMMC argument register (SDMMC_ARGR)

Address offset: 0x008
Reset value: 0x0000 0000
The SDMMC_ARGR register contains a 32-bit command argument, which is sent to a card as part of a command message.

<table>
<thead>
<tr>
<th>Bits 31:0 CMDARG[31:0]: Command argument</th>
</tr>
</thead>
<tbody>
<tr>
<td>These bits can only be written by firmware when CPSM is disabled (CPSMEN = 0). Command argument sent to a card as part of a command message. If a command contains an argument, it must be loaded into this register before writing a command to the command register.</td>
</tr>
</tbody>
</table>

58.10.4 SDMMC command register (SDMMC_CMDR)

Address offset: 0x00C
Reset value: 0x0000 0000
The SDMMC_CMDR register contains the command index and command type bits. The command index is sent to a card as part of a command message. The command type bits control the command path state machine (CPSM).
Bits 31:17  Reserved, must be kept at reset value.

Bit 16  **CMDSUSPEND**: The CPSM treats the command as a Suspend or Resume command and signals interrupt period start/end

   - This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).
   - CMDSUSPEND = 1 and CMDTRANS = 0 Suspend command, start interrupt period when response bit BS=0.
   - CMDSUSPEND = 1 and CMDTRANS = 1 Resume command with data, end interrupt period when response bit DF=1.

Bit 15  **BOOTEN**: Enable boot mode procedure

- 0: Boot mode procedure disabled
- 1: Boot mode procedure enabled

Bit 14  **BOOTMODE**: Select the boot mode procedure to be used

   - This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0)
   - 0: Normal boot mode procedure selected
   - 1: Alternative boot mode procedure selected

Bit 13  **DTHOLD**: Hold new data block transmission and reception in the DPSM

   - If this bit is set, the DPSM does not move from the Wait_S state to the Send state or from the Wait_R state to the Receive state.

Bit 12  **CPSMEN**: Command path state machine (CPSM) enable bit

   - This bit is written 1 by firmware, and cleared by hardware when the CPSM enters the Idle state.
   - If this bit is set, the CPSM is enabled.
   - When DTEN = 1, no command is transferred nor boot procedure is started. CPSMEN is cleared to 0.
   - During Read Wait with SDMMC_CK stopped no command is sent and CPSMEN is kept 0.

Bit 11  **WAITPEND**: CPSM waits for end of data transfer (CmdPend internal signal) from DPSM

   - This bit when set, the CPSM waits for the end of data transfer trigger before it starts sending a command.
   - WAITPEND is only taken into account when DTMODE = MMC stream data transfer, WIDBUS = 1-bit wide bus mode, DPSMACT = 1 and DTDIR = from host to card.

Bit 10  **WAITINT**: CPSM waits for interrupt request

   - If this bit is set, the CPSM disables command timeout and waits for an card interrupt request (Response).
   - If this bit is cleared in the CPSM Wait state, it causes the abort of the interrupt mode.

Bits 9:8  **WAITRESP[1:0]**: Wait for response bits

   - This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).
   - They are used to configure whether the CPSM is to wait for a response, and if yes, which kind of response.
   - 00: No response, expect CMDSENT flag
   - 01: Short response, expect CMDREND or CCRCFAIL flag
   - 10: Short response, expect CMDREND flag (No CRC)
   - 11: Long response, expect CMDREND or CCRCFAIL flag
Bit 7 **CMDSTOP**: The CPSM treats the command as a Stop Transmission command and signals abort to the DPSM.
   
   This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).
   
   If this bit is set, the CPSM issues the abort signal to the DPSM when the command is sent.

Bit 6 **CMDTRANS**: The CPSM treats the command as a data transfer command, stops the interrupt period, and signals DataEnable to the DPSM.
   
   This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).
   
   If this bit is set, the CPSM issues an end of interrupt period and issues DataEnable signal to the DPSM when the command is sent.

Bits 5:0 **CMDINDEX[5:0]**: Command index
   
   This bit can only be written by firmware when CPSM is disabled (CPSMEN = 0).
   
   The command index is sent to the card as part of a command message.

Note: 1 At least seven sdmmc_hclk clock periods are needed between two write accesses to this register.

2 MultiMediaCard can send two kinds of responses: short responses, 48 bits, or long responses, 136 bits. SD card and SD I/O card can send only short responses, the argument can vary according to the type of response: the software distinguishes the type of response according to the send command.

58.10.5 **SDMMC command response register (SDMMC_RESPCMDR)**

Address offset: 0x010

Reset value: 0x0000 0000

The SDMMC_RESPCMDR register contains the command index field of the last command response received. If the command response transmission does not contain the command index field (long or OCR response), the RESPCMD field is unknown, although it must contain 111111b (the value of the reserved field from the response).

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **RESPCMD[5:0]**: Response command index

Read-only bit field. Contains the command index of the last command response received.
58.10.6 SDMMC response x register (SDMMC_RESPxR)

Address offset: 0x010 + 0x004 * x, (x = 1 to 4)
Reset value: 0x0000 0000

The SDMMC_RESP1/2/3/4R registers contain the status of a card, which is part of the received response.

</table>

1. The most significant bit of the card status is received first.
2. The SDMMC_RESP4R register LSB is always 0.

58.10.7 SDMMC data timer register (SDMMC_DTIMER)

Address offset: 0x024
Reset value: 0x0000 0000

The SDMMC_DTIMER register contains the data timeout period, in card bus clock periods.

A counter loads the value from the SDMMC_DTIMER register, and starts decrementing when the data path state machine (DPSM) enters the Wait_R or Busy state. If the timer reaches 0 while the DPSM is in either of these states, the timeout status flag is set.

ST
Bits 31:0 **DATATIME[31:0]**: Data and R1b busy timeout period

- This bit can only be written when the CPSM and DPSM are not active (CPSMACT = 0 and DPSMACT = 0).
- Data and R1b busy timeout period expressed in card bus clock periods.

**Note:** A data transfer must be written to the data timer register and the data length register before being written to the data control register.

### 58.10.8 SDMMC data length register (SDMMC_DLENR)

**Address offset:** 0x028

**Reset value:** 0x0000 0000

The SDMMC_DLENR register contains the number of data bytes to be transferred. The value is loaded into the data counter when data transfer starts.

</tbody>
</table>

**DATALENGTH[24:16]**

- Bits 31:25 Reserved, must be kept at reset value.

**Bits 24:0 **DATALENGTH[24:0]**: Data length value

- This register can only be written by firmware when DPSM is inactive (DPSMACT = 0).
- Number of data bytes to be transferred.
- When DDR = 1 DATALENGTH is truncated to a multiple of 2. (The last odd byte is not transferred)
- When DATALENGTH = 0 no data are transferred, when requested by a CPSMEN and CMDTRANS = 1 also no command is transferred. DTEN and CPSMEN are cleared to 0.

**Note:** For a block data transfer, the value in the data length register must be a multiple of the block size (see SDMMC_DCTRL). A data transfer must be written to the data timer register and the data length register before being written to the data control register.

For an SDMMC multibyte transfer the value in the data length register must be between 1 and 512.
### 58.10.9 SDMMC data control register (SDMMC_DCTRL)

Address offset: 0x02C  
Reset value: 0x0000 0000  
The SDMMC_DCTRL register control the data path state machine (DPSM).

<table>

</tbody>
</table>
| Bit 13    | FIFORST: FIFO reset, flushes any remaining data  
  This bit can only be written by firmware when IDMAEN= 0 and DPSM is active (DPSM present = 1). This bit only takes effect when a transfer error or transfer hold occurs.  
  0: FIFO not affected.  
  1: Flush any remaining data and reset the FIFO pointers. This bit is automatically cleared to 0 by hardware when DPSM gets inactive (DPSM present = 0). |
| Bit 12    | BOOTACKEN: Enable the reception of the boot acknowledgment  
  This bit can only be written by firmware when DPSM is inactive (DPSM present = 0).  
  0: Boot acknowledgment disabled, not expected to be received  
  1: Boot acknowledgment enabled, expected to be received |
| Bit 11    | SDIOEN: SD I/O interrupt enable functions  
  This bit can only be written by firmware when DPSM is inactive (DPSM present = 0).  
  If this bit is set, the DPSM enables the SD I/O card specific interrupt operation. |
| Bit 10    | RWMOD: Read Wait mode  
  This bit can only be written by firmware when DPSM is inactive (DPSM present = 0).  
  0: Read Wait control using SDMMC_D2  
  1: Read Wait control stopping SDMMC_CK |
| Bit 9     | RWSTOP: Read Wait stop  
  This bit is written by firmware and auto cleared by hardware when the DPSM moves from the R_W state to the Wait_R or idle state.  
  0: No Read Wait stop.  
  1: Enable for Read Wait stop when DPSM is in the R_W state. |
| Bit 8     | RWSTART: Read Wait start  
  If this bit is set, Read Wait operation starts. |
Bits 7:4  **DBLOCKSIZE[3:0]**: Data block size

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0). Define the data block length when the block data transfer mode is selected:

- 0000: Block length = $2^0 = 1\text{ byte}$
- 0001: Block length = $2^1 = 2\text{ bytes}$
- 0010: Block length = $2^2 = 4\text{ bytes}$
- 0011: Block length = $2^3 = 8\text{ bytes}$
- 0100: Block length = $2^4 = 16\text{ bytes}$
- 0101: Block length = $2^5 = 32\text{ bytes}$
- 0110: Block length = $2^6 = 64\text{ bytes}$
- 0111: Block length = $2^7 = 128\text{ bytes}$
- 1000: Block length = $2^8 = 256\text{ bytes}$
- 1001: Block length = $2^9 = 512\text{ bytes}$
- 1010: Block length = $2^{10} = 1024\text{ bytes}$
- 1011: Block length = $2^{11} = 2048\text{ bytes}$
- 1100: Block length = $2^{12} = 4096\text{ bytes}$
- 1101: Block length = $2^{13} = 8192\text{ bytes}$
- 1110: Block length = $2^{14} = 16384\text{ bytes}$
- 1111: Reserved

When DATALENGTH is not a multiple of DBLOCKSIZE, the transferred data is truncated at a multiple of DBLOCKSIZE. (None of the remaining data are transferred.)

When DDR = 1, DBLOCKSIZE = 0000 must not be used. (No data are transferred)

Bits 3:2  **DTMODE[1:0]**: Data transfer mode selection

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

- 00: Block data transfer ending on block count.
- 01: SDIO multibyte data transfer.
- 10: eMMC Stream data transfer. (WIDBUS must select 1-bit wide bus mode)
- 11: Block data transfer ending with STOP_TRANSMISSION command (not to be used with DTEN initiated data transfers).

Bit 1  **DTDIR**: Data transfer direction selection

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

- 0: From host to card.
- 1: From card to host.

Bit 0  **DTEN**: Data transfer enable bit

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0). This bit is cleared by Hardware when data transfer completes.

- 0: Do not start data transfer without CPSM data transfer command.
- 1: Start data transfer without CPSM data transfer command.

### 58.10.10  SDMMC data counter register (SDMMC_DCNTR)

**Address offset:** 0x030

**Reset value:** 0x0000 0000

The SDMMC_DCNTR register loads the value from the data length register (see SDMMC_DLENR) when the DPSM moves from the Idle state to the Wait_R or Wait_S state. As data is transferred, the counter decrements the value until it reaches 0. The DPSM then
moves to the Idle state and when there has been no error, and no transmit data transfer
hold, the data status end flag (DATAEND) is set.

Note: This register must be read only after the data transfer is complete, or hold. When reading
after an error event the read data count value may be different from the real number of data
bytes transferred.

**58.10.11 SDMMC status register (SDMMC_STAR)**

Address offset: 0x034

Reset value: 0x0000 0000

The SDMMC_STAR register is a read-only register. It contains two types of flag:
- Static flags (bits [28, 21, 11:0]): these bits remain asserted until they are cleared by
  writing to the SDMMC interrupt Clear register (see SDMMC_ICR)
- Dynamic flags (bits [20:12]): these bits change state depending on the state of the
  underlying logic (for example, FIFO full and empty flags are asserted and deasserted
  as data while written to the FIFO)

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:0 **DATACOUNT[24:0]**: Data count value
When read, the number of remaining data bytes to be transferred is returned. Write has no
effect.

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **IDMABTC**: IDMA buffer transfer complete
The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 27 **IDMATE**: IDMA transfer error
The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 26 **CKSTOP**: SDMMC_CK stopped in Voltage switch procedure
The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.
Bit 25 **VSWEND**: Voltage switch critical timing section completion  
The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 24 **ACKTIMEOUT**: Boot acknowledgment timeout  
The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 23 **ACKFAIL**: Boot acknowledgment received (boot acknowledgment check fail)  
The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 22 **SDIOT**: SDIO interrupt received  
The interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 21 **BUSYD0END**: end of SDMMC_D0 Busy following a CMD response detected  
This indicates only end of busy following a CMD response. This bit does not signal busy due to data transfer. Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.  
0: card SDMMC_D0 signal does NOT signal change from busy to not busy.  
1: card SDMMC_D0 signal changed from busy to NOT busy.

Bit 20 **BUSYD0**: Inverted value of SDMMC_D0 line (Busy), sampled at the end of a CMD response and a second time 2 SDMMC_CK cycles after the CMD response  
This bit is reset to not busy when the SDMMC_D0 line changes from busy to not busy. This bit does not signal busy due to data transfer. This is a hardware status flag only, it does not generate an interrupt.  
0: card signals not busy on SDMMC_D0.  
1: card signals busy on SDMMC_D0.

Bit 19 **RXFIFOE**: Receive FIFO empty  
This is a hardware status flag only, does not generate an interrupt. This bit is cleared when one FIFO location becomes full.

Bit 18 **TXFIFOE**: Transmit FIFO empty  
This bit is cleared when one FIFO location becomes full.

Bit 17 **RXFIFOF**: Receive FIFO full  
This bit is cleared when one FIFO location becomes empty.

Bit 16 **TXFIFOF**: Transmit FIFO full  
This is a hardware status flag only, does not generate an interrupt. This bit is cleared when one FIFO location becomes empty.

Bit 15 **RXFIFOHF**: Receive FIFO half full  
There are at least half the number of words in the FIFO. This bit is cleared when the FIFO becomes half+1 empty.

Bit 14 **TXFIFOHE**: Transmit FIFO half empty  
At least half the number of words can be written into the FIFO. This bit is cleared when the FIFO becomes half+1 full.

Bit 13 **CPMSACT**: Command path state machine active, i.e. not in Idle state  
This is a hardware status flag only, does not generate an interrupt.

Bit 12 **DPMSACT**: Data path state machine active, i.e. not in Idle state  
This is a hardware status flag only, does not generate an interrupt.

Bit 11 **DABORT**: Data transfer aborted by CMD12  
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.
Bit 10  **DBCKEND:** Data block sent/received  
DBCKEND is set when:  
- CRC check passed and DPSM moves to the R_W state  
or  
- IDMAEN = 0 and transmit data transfer hold and DATACOUNT >0 and DPSM moves to  
  Wait_S.  
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 9  **DHOLD:** Data transfer Hold  
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 8  **DATAEND:** Data transfer ended correctly  
DATAEND is set if data counter DATACOUNT is zero and no errors occur, and no transmit  
data transfer hold.  
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 7  **CMDSENT:** Command sent (no response required)  
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 6  **CMDREND:** Command response received (CRC check passed, or no CRC)  
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 5  **RXOVERR:** Received FIFO overrun error  
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 4  **TXUNDERR:** Transmit FIFO underrun error  
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 3  **DTIMEOUT:** Data timeout  
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 2  **CTIMEOUT:** Command response timeout  
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.  
The Command Timeout period has a fixed value of 64 SDMMC_CK clock periods.

Bit 1  **DCRCFAIL:** Data block sent/received (CRC check failed)  
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

Bit 0  **CCRCFAIL:** Command response received (CRC check failed)  
Interrupt flag is cleared by writing corresponding interrupt clear bit in SDMMC_ICR.

**Note:** FIFO interrupt flags must be masked in SDMMC_MASKR when using IDMA mode.
58.10.12 SDMMC interrupt clear register (SDMMC_ICR)

Address offset: 0x038
Reset value: 0x0000 0000

The SDMMC_ICR register is a write-only register. Writing a bit with 1 clears the corresponding bit in the SDMMC_STAR status register.

Bits 31:29 Reserved, must be kept at reset value.

**Bit 28 IDMABTC**: IDMA buffer transfer complete clear bit
- Set by software to clear the IDMABTC flag.
  - 0: IDMABTC not cleared
  - 1: IDMABTC cleared

**Bit 27 IDMATE**: IDMA transfer error clear bit
- Set by software to clear the IDMATE flag.
  - 0: IDMATE not cleared
  - 1: IDMATE cleared

**Bit 26 CKSTOPC**: CKSTOP flag clear bit
- Set by software to clear the CKSTOP flag.
  - 0: CKSTOP not cleared
  - 1: CKSTOP cleared

**Bit 25 VSWENDC**: VSWEND flag clear bit
- Set by software to clear the VSWEND flag.
  - 0: VSWEND not cleared
  - 1: VSWEND cleared

**Bit 24 ACKTIMEOUTC**: ACKTIMEOUT flag clear bit
- Set by software to clear the ACKTIMEOUT flag.
  - 0: ACKTIMEOUT not cleared
  - 1: ACKTIMEOUT cleared

**Bit 23 ACKFAILC**: ACKFAIL flag clear bit
- Set by software to clear the ACKFAIL flag.
  - 0: ACKFAIL not cleared
  - 1: ACKFAIL cleared

**Bit 22 SDIOITC**: SDIOIT flag clear bit
- Set by software to clear the SDIOIT flag.
  - 0: SDIOIT not cleared
  - 1: SDIOIT cleared
Bit 21 **BUSYD0ENDC**: BUSYD0END flag clear bit
Set by software to clear the BUSYD0END flag.
0: BUSYD0END not cleared
1: BUSYD0END cleared

Bits 20:12 Reserved, must be kept at reset value.

Bit 11 **DABORTC**: DABORT flag clear bit
Set by software to clear the DABORT flag.
0: DABORT not cleared
1: DABORT cleared

Bit 10 **DBCKENDC**: DBCKEND flag clear bit
Set by software to clear the DBCKEND flag.
0: DBCKEND not cleared
1: DBCKEND cleared

Bit 9 **DHOLDC**: DHOLD flag clear bit
Set by software to clear the DHOLD flag.
0: DHOLD not cleared
1: DHOLD cleared

Bit 8 **DATAENDC**: DATAEND flag clear bit
Set by software to clear the DATAEND flag.
0: DATAEND not cleared
1: DATAEND cleared

Bit 7 **CMDSENTE**: CMDSENT flag clear bit
Set by software to clear the CMDSENT flag.
0: CMDSENT not cleared
1: CMDSENT cleared

Bit 6 **CMDRENDC**: CMDRENDC flag clear bit
Set by software to clear the CMDRENDC flag.
0: CMDRENDC not cleared
1: CMDRENDC cleared

Bit 5 **RXOVERRC**: RXOVERR flag clear bit
Set by software to clear the RXOVERR flag.
0: RXOVERR not cleared
1: RXOVERR cleared

Bit 4 **TXUNDERRC**: TXUNDERR flag clear bit
Set by software to clear the TXUNDERR flag.
0: TXUNDERR not cleared
1: TXUNDERR cleared

Bit 3 **DTIMEOUTC**: DTIMEOUT flag clear bit
Set by software to clear the DTIMEOUT flag.
0: DTIMEOUT not cleared
1: DTIMEOUT cleared
Bit 2 **CTIMEOUT**: CTIMEOUT flag clear bit  
Set by software to clear the CTIMEOUT flag.  
0: CTIMEOUT not cleared  
1: CTIMEOUT cleared

Bit 1 **DCRCFAIL**: DCRCFAIL flag clear bit  
Set by software to clear the DCRCFAIL flag.  
0: DCRCFAIL not cleared  
1: DCRCFAIL cleared

Bit 0 **CCRCFAIL**: CCRCFAIL flag clear bit  
Set by software to clear the CCRCFAIL flag.  
0: CCRCFAIL not cleared  
1: CCRCFAIL cleared

### 58.10.13 SDMMC mask register (SDMMC_MASKR)

Address offset: 0x03C  
Reset value: 0x0000 0000

The interrupt mask register determines which status flags generate an interrupt request by setting the corresponding bit to 1.

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **IDMABTCIE**: IDMA buffer transfer complete interrupt enable  
Set and cleared by software to enable/disable the interrupt generated when the IDMA has transferred all data belonging to a memory buffer.  
0: IDMA buffer transfer complete interrupt disabled  
1: IDMA buffer transfer complete interrupt enabled

Bit 27 Reserved, must be kept at reset value.

Bit 26 **CKSTOPIE**: Voltage Switch clock stopped interrupt enable  
Set and cleared by software to enable/disable interrupt caused by Voltage Switch clock stopped.  
0: Voltage Switch clock stopped interrupt disabled  
1: Voltage Switch clock stopped interrupt enabled

Bit 25 **VSWENDIE**: Voltage switch critical timing section completion interrupt enable  
Set and cleared by software to enable/disable the interrupt generated when voltage switch critical timing section completion.  
0: Voltage switch critical timing section completion interrupt disabled  
1: Voltage switch critical timing section completion interrupt enabled
### Secure digital input/output MultiMediaCard interface (SDMMC)

#### Bit 24 **ACKTIMEOUTIE**: Acknowledgment timeout interrupt enable
- Set and cleared by software to enable/disable interrupt caused by acknowledgment timeout.
- 0: Acknowledgment timeout interrupt disabled
- 1: Acknowledgment timeout interrupt enabled

#### Bit 23 **ACKFAILIE**: Acknowledgment Fail interrupt enable
- Set and cleared by software to enable/disable interrupt caused by acknowledgment Fail.
- 0: Acknowledgment Fail interrupt disabled
- 1: Acknowledgment Fail interrupt enabled

#### Bit 22 **SDIOITIE**: SDIO mode interrupt received interrupt enable
- Set and cleared by software to enable/disable the interrupt generated when receiving the SDIO mode interrupt.
- 0: SDIO Mode interrupt received interrupt disabled
- 1: SDIO Mode interrupt received interrupt enabled

#### Bit 21 **BUSYD0ENDIE**: BUSYD0END interrupt enable
- Set and cleared by software to enable/disable the interrupt generated when SDMMC_D0 signal changes from busy to NOT busy following a CMD response.
- 0: BUSYD0END interrupt disabled
- 1: BUSYD0END interrupt enabled

Bits 20:19 Reserved, must be kept at reset value.

#### Bit 18 **TXFIFOEIE**: Tx FIFO empty interrupt enable
- Set and cleared by software to enable/disable interrupt caused by Tx FIFO empty.
- 0: Tx FIFO empty interrupt disabled
- 1: Tx FIFO empty interrupt enabled

#### Bit 17 **RXFIFOFIE**: Rx FIFO full interrupt enable
- Set and cleared by software to enable/disable interrupt caused by Rx FIFO full.
- 0: Rx FIFO full interrupt disabled
- 1: Rx FIFO full interrupt enabled

#### Bit 16 Reserved, must be kept at reset value.

#### Bit 15 **RXFIFOHFIE**: Rx FIFO half full interrupt enable
- Set and cleared by software to enable/disable interrupt caused by Rx FIFO half full.
- 0: Rx FIFO half full interrupt disabled
- 1: Rx FIFO half full interrupt enabled

#### Bit 14 **TXFIFOHEIE**: Tx FIFO half empty interrupt enable
- Set and cleared by software to enable/disable interrupt caused by Tx FIFO half empty.
- 0: Tx FIFO half empty interrupt disabled
- 1: Tx FIFO half empty interrupt enabled

Bits 13:12 Reserved, must be kept at reset value.

#### Bit 11 **DABORTIE**: Data transfer aborted interrupt enable
- Set and cleared by software to enable/disable interrupt caused by a data transfer being aborted.
- 0: Data transfer abort interrupt disabled
- 1: Data transfer abort interrupt enabled

#### Bit 10 **DBCKENDIE**: Data block end interrupt enable
- Set and cleared by software to enable/disable interrupt caused by data block end.
- 0: Data block end interrupt disabled
- 1: Data block end interrupt enabled
### Secure digital input/output MultiMediaCard interface (SDMMC)

- **Bit 9 DHOLDIE**: Data hold interrupt enable
  - Set and cleared by software to enable/disable the interrupt generated when sending new data is hold in the DPSM Wait_S state.
  - 0: Data hold interrupt disabled
  - 1: Data hold interrupt enabled

- **Bit 8 DATAENDIE**: Data end interrupt enable
  - Set and cleared by software to enable/disable interrupt caused by data end.
  - 0: Data end interrupt disabled
  - 1: Data end interrupt enabled

- **Bit 7 CMDSENTIE**: Command sent interrupt enable
  - Set and cleared by software to enable/disable interrupt caused by sending command.
  - 0: Command sent interrupt disabled
  - 1: Command sent interrupt enabled

- **Bit 6 CMDRENDIE**: Command response received interrupt enable
  - Set and cleared by software to enable/disable interrupt caused by receiving command response.
  - 0: Command response received interrupt disabled
  - 1: Command Response received interrupt enabled

- **Bit 5 RXOVERRIE**: Rx FIFO overrun error interrupt enable
  - Set and cleared by software to enable/disable interrupt caused by Rx FIFO overrun error.
  - 0: Rx FIFO overrun error interrupt disabled
  - 1: Rx FIFO overrun error interrupt enabled

- **Bit 4 TXUNDERRIE**: Tx FIFO underrun error interrupt enable
  - Set and cleared by software to enable/disable interrupt caused by Tx FIFO underrun error.
  - 0: Tx FIFO underrun error interrupt disabled
  - 1: Tx FIFO underrun error interrupt enabled

- **Bit 3 DTIMEOUTIE**: Data timeout interrupt enable
  - Set and cleared by software to enable/disable interrupt caused by data timeout.
  - 0: Data timeout interrupt disabled
  - 1: Data timeout interrupt enabled

- **Bit 2 CTIMEOUTIE**: Command timeout interrupt enable
  - Set and cleared by software to enable/disable interrupt caused by command timeout.
  - 0: Command timeout interrupt disabled
  - 1: Command timeout interrupt enabled

- **Bit 1 DCRCFAILIE**: Data CRC fail interrupt enable
  - Set and cleared by software to enable/disable interrupt caused by data CRC failure.
  - 0: Data CRC fail interrupt disabled
  - 1: Data CRC fail interrupt enabled

- **Bit 0 CCRCFAILIE**: Command CRC fail interrupt enable
  - Set and cleared by software to enable/disable interrupt caused by command CRC failure.
  - 0: Command CRC fail interrupt disabled
  - 1: Command CRC fail interrupt enabled
58.10.14  SDMMC acknowledgment timer register (SDMMC_ACKTIMER)

Address offset: 0x040
Reset value: 0x0000 0000

The SDMMC_ACKTIMER register contains the acknowledgment timeout period, in SDMMC_CK bus clock periods.

A counter loads the value from the SDMMC_ACKTIMER register, and starts decrementing when the data path state machine (DPSM) enters the Wait_Ack state. If the timer reaches 0 while the DPSM is in this state, the acknowledgment timeout status flag is set.

Note: The data transfer must be written to the acknowledgment timer register before being written to the data control register.

58.10.15  SDMMC data FIFO registers x (SDMMC_FIFORx)

Address offset: 0x080 + 0x004 * x, (x =0 to 15)
Reset value: 0x0000 0000

The receive and transmit FIFOs can be only read or written as word (32-bit) wide registers. The FIFOs contain 16 entries on sequential addresses. This enables the CPU to use its load and store multiple operands to read from/write to the FIFO. The FIFO register interface takes care of correct data alignment inside the FIFO, the FIFO register address used by the CPU does matter.

When accessing SDMMC_FIFOR with half word or byte access an AHB bus fault is generated.
Bits 31:0 **FIFODATA[31:0]**: Receive and transmit FIFO data

This register can only be read or written by firmware when the DPSM is active (DPSMACT = 1).

The FIFO data occupies 16 entries of 32-bit words.

### 58.10.16 SDMMC DMA control register (SDMMC_IDMACTRLR)

Address offset: 0x050

Reset value: 0x0000 0000

The receive and transmit FIFOs can be read or written as 32-bit wide registers. The FIFOs contain 32 entries on 32 sequential addresses. This enables the CPU to use its load and store multiple operands to read from/write to the FIFO.

Bits 31:3 Reserved, must be kept at reset value.

**Bit 2 IDMABACT**: Double buffer mode active buffer indication

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0). When IDMA is enabled this bit is toggled by hardware.

0: When IDMA is enabled, uses buffer0 and firmware write access to IDMABASE0 is prohibited.

1: When IDMA is enabled, uses buffer1 and firmware write access to IDMABASE1 is prohibited.

**Bit 1 IDMABMODE**: Buffer mode selection

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

0: Single buffer mode.

1: Double buffer mode.

**Bit 0 IDMAEN**: IDMA enable

This bit can only be written by firmware when DPSM is inactive (DPSMACT = 0).

0: IDMA disabled

1: IDMA enabled
58.10.17  **SDMMC IDMA buffer size register (SDMMC_IDMABSIZER)**

Address offset: 0x054  
Reset value: 0x0000 0000  
The SDMMC_IDMABSIZER register contains the buffers size when in double buffer configuration.

| Bits 31:13 | Reserved, must be kept at reset value. |
| Bits 12:5  | **IDMABNDT[7:0]**: Number of bytes per buffer |
| This 8-bit value must be multiplied by 8 to get the size of the buffer in 32-bit words and by 32 to get the size of the buffer in bytes.  
Example: IDMABNDT = 0x01: buffer size = 8 words = 32 bytes.  
Example: IDMABNDT = 0x80: buffer size = 1024 words = 4 Kbytes |
| These bits can only be written by firmware when DPSM is inactive (DPSMACT = 0). |

| Bits 4:0  | Reserved, must be kept at reset value. |

58.10.18  **SDMMC IDMA buffer 0 base address register (SDMMC_IDMABASE0R)**

Address offset: 0x058  
Reset value: 0x0000 0000  
The SDMMC_IDMABASE0R register contains the memory buffer base address in single buffer configuration and the buffer 0 base address in double buffer configuration.

| Bits 31:0 | **IDMABASE0[31:16]**: Buffer 0 memory base address bits [31:2], must be word aligned (bit [1:0] are always 0 and read only)  
This register can be written by firmware when DPSM is inactive (DPSMACT = 0), and can dynamically be written by firmware when DPSM active (DPSMACT = 1) and memory buffer 0 is inactive (IDMABACT = '1'). |
58.10.19 SDMMC IDMA buffer 1 base address register (SDMMC_IDMABASE1R)

Address offset: 0x05C
Reset value: 0x0000 0000

The SDMMC_IDMABASE1R register contains the double buffer configuration second buffer memory base address.

<table>

Refer to Section 2.3 on page 134 for the register boundary addresses.
59 Controller area network with flexible data rate (FDCAN)

59.1 Introduction

The controller area network (CAN) subsystem (see Figure 775) consists of two CAN modules, a shared message RAM, and a clock calibration unit. Refer to the product memory organization for the base address of each of them.

FDCAN modules are compliant with ISO 11898-1: 2015 (CAN protocol specification version 2.0 part A, B) and CAN FD protocol specification version 1.0.

In addition, the first CAN module FDCAN1 supports time triggered CAN (TTCAN), specified in ISO 11898-4, including event synchronized time-triggered communication, global system time, and clock drift compensation. The FDCAN1 contains additional registers, specific to the time triggered feature. The CAN FD option can be used together with event-triggered and time triggered CAN communication.

A 10-Kbyte message RAM implements filters, receive FIFOs, receive buffers, transmit event FIFOs, transmit buffers (and triggers for TTCAN). This memory is shared between the FDCAN modules.

The common clock calibration unit is optional. It can be used to generate a calibrated clock for each FDCAN from the HSI internal RC oscillator and the PLL, by evaluating CAN messages received by the FDCAN1.

The CAN subsystem I/O signals and pins are detailed, respectively, in Table 499 and Table 500.

Figure 775. CAN subsystem
59.2 FDCAN main features

- Conform with CAN protocol version 2.0 part A, B, and ISO 11898-1: 2015, -4
- CAN FD with max. 64 data bytes supported
- TTCAN protocol level 1 and level 2 completely in hardware (FDCAN1 only)
- Event synchronized time-triggered communication supported (FDCAN1 only)
- CAN error logging
- AUTOSAR and J1939 support
- Improved acceptance filtering
- Two configurable receive FIFOs
- Separate signaling on reception of high priority messages
- Up to 64 dedicated receive buffers
- Up to 32 dedicated transmit buffers
- Configurable transmit FIFO / queue
- Configurable transmit event FIFO
- FDCAN modules share the same message RAM
- Programmable loop-back test mode
- Maskable module interrupts
- Two clock domains: APB bus interface and CAN core kernel clock
- Power-down support

59.4 FDCAN functional description

**Dual interrupt lines**

The FDCAN peripheral provides two interrupt lines, `fdcan_intr0_it` and `fdcan_intr1_it`. By programming `EINT0` and `EINT1` bits in FDCAN_IIE register, the interrupt lines can be enabled or disabled separately.

**CAN core**

The CAN core contains the protocol controller and the receive/transmit shift registers. It handles all ISO 11898-1:2015 protocol functions, and supports both 11-bit and 29-bit identifiers.

**Sync**

This block synchronizes signals from the APB clock domain to the CAN kernel clock domain, and vice versa.
Tx handler

Controls the message transfer from the message RAM to the CAN core. A maximum of 32 Tx buffers can be configured for transmission. Tx buffers can be used as dedicated Tx buffers, as Tx FIFO, part of a Tx queue, or as a combination of them. A Tx event FIFO stores Tx timestamps together with the corresponding message ID. Transmit cancellation is also supported.

On FDCAN1, the Tx handler also implements the frame synchronization entity (FSE) which controls time-triggered communication according to ISO11898-4. It synchronizes itself with the reference messages on the CAN bus, controls cycle time and global time, and handles transmissions according to the predefined message schedule, the system matrix. It also handles the time marks of the system matrix that are linked to the messages in the message RAM. Stop watch trigger, event trigger, and time mark interrupt are synchronization interfaces.

Rx handler

Controls the transfer of received messages from the CAN core to the external message RAM. The Rx handler supports two receive FIFOs, each of configurable size, and up to 64 dedicated Rx buffers for storage of all messages that have passed acceptance filtering. A dedicated Rx buffer, in contrast to a receive FIFO, is used to store only messages with a specific identifier. An Rx timestamp is stored together with each message. Up to 128 filters can be defined for 11-bit IDs and up to 64 filters for 29-bit IDs.

APB interface

Connects the FDCAN to the APB bus.

Message RAM interface

Connects the FDCAN access to an external 10 Kbytes message RAM through a RAM controller/arbiter.

59.4.1 Operating modes

Software initialization

Software initialization is started by setting INIT bit in FDCAN_CCCR register, either by software or by a hardware reset, or by going Bus_Off. While INIT bit in FDCAN_CCCR register is set, message transfer from and to the CAN bus is stopped, the status of the CAN bus output FDCAN_TX is recessive (high). The counters of the error management logic (EML) are unchanged. Setting INIT bit in FDCAN_CCCR does not change any configuration register. Clearing INIT bit in FDCAN_CCCR finishes the software initialization. Afterwards, the bit stream processor (BSP) synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (Bus_Idle) before it can take part in bus activities and start the message transfer.

Access to the FDCAN configuration registers is only enabled when both INIT bit in FDCAN_CCCR register and CCE bit in FDCAN_CCCR register are set.

CCE bit in FDCAN_CCCR register can be set/cleared only while INIT bit in FDCAN_CCCR is set. CCE bit in FDCAN_CCCR register is automatically cleared when INIT bit in FDCAN_CCCR is cleared.
The following registers are reset when CCE bit in FDCAN_CCCR register is set:

- FDCAN_HPMS - high priority message status
- FDCAN_RXF0S - Rx FIFO 0 status
- FDCAN_RXF1S - Rx FIFO 1 status
- FDCAN_TXFQS - Tx FIFO/queue status
- FDCAN_TXBRP - Tx buffer request pending
- FDCAN_TXBTO - Tx buffer transmission occurred
- FDCAN_TXBCF - Tx buffer cancellation finished
- FDCAN_TXEFS - Tx event FIFO status
- FDCAN_TTOST - TT (time trigger) operation status (FDCAN1 only)
- FDCAN_TTLGT - TT local and global time, only global time FDCAN_TTLGT.GT is reset (FDCAN1 only)
- FDCAN_TTCTC - TT cycle time and count (FDCAN1 only)
- FDCAN_TTCSM - TT cycle sync mark (FDCAN1 only)

The timeout counter value TOC bit in FDCAN_TOCV register is preset to the value configured by TOP bit in FDCAN_TOCC register when CCE bit in FDCAN_CCCR is set.

In addition, the state machines of the Tx handler and Rx handler are held in idle state while CCE bit in FDCAN_CCCR is set.

The following registers can be written only when CCE bit in FDCAN_CCCR register is cleared:

- FDCAN_TXBAR - Tx buffer add request
- FDCAN_TXBCR - Tx buffer cancellation request

TEST bit in FDCAN_CCCR and MON bit in FDCAN_CCCR can be set only by software while both INIT bit and CCE bit in FDCAN_CCCR register are set. Both bits may be reset at any time. DAR bit in FDCAN_CCCR can be set/cleared only while both INIT bit in FDCAN_CCCR and CCE bit in FDCAN_CCCR are set.

**Normal operation**

The FDCAN1 default operating mode after hardware reset is event-driven CAN communication without time triggers (FDCAN_TTOCF.OM = 00). It is required that both INIT bit and CCE bit in FDCAN_CCCR register are set before the TT operation mode can be changed.

Once the FDCAN is initialized and INIT bit in FDCAN_CCCR register is cleared, the FDCAN synchronizes itself to the CAN bus and is ready for communication.

After passing the acceptance filtering, received messages including message ID and DLC are stored into a dedicated Rx buffer or into the Rx FIFO 0 or Rx FIFO 1.

For messages to be transmitted dedicated Tx buffers and/or a Tx FIFO or a Tx queue can be initialized or updated. Automated transmission on reception of remote frames is not supported.

**CAN FD operation**

There are two variants in the CAN FD protocol. The first is the long frame mode (LFM), where the data field of a CAN frame can be longer than eight bytes. The second variant is the fast frame mode (FFM), where the control, data, and CRC fields of a CAN frame are
transmitted with a higher bitrate than the beginning and the end of the frame. Fast frame mode can be used in combination with long frame mode.

The previously reserved bit in CAN frames with 11-bit identifiers and the first previously reserved bit in CAN frames with 29-bit identifiers are now decoded as FDF bit. FDF recessive signifies a CAN FD frame, while FDF dominant signifies a classic CAN frame. In a CAN FD frame, the two bits following FDF, res and BRS, decide whether the bitrate inside this CAN FD frame is switched. A CAN FD bitrate switch is signified by res dominant and BRS recessive. The coding of res recessive is reserved for protocol expansions. If the FDCAN receives a frame with FDF recessive and res recessive, it signals a protocol exception event by setting bit FDCAN_PSR.PXE. When protocol exception handling is enabled (FDCAN_CCCR.PXHD = 0), this causes the operation state to change from receiver (FDCAN_PSR.ACT = 10) to integrating (FDCAN_PSR.ACT = 00) at the next sample point. In case protocol exception handling is disabled (FDCAN_CCCR.PXHD = 1), the FDCAN treats a recessive res bit as a form error and responds with an error frame.

CAN FD operation is enabled by programming FDCAN_CCCR.FDOE. If FDCAN_CCCR.FDOE = 1, transmission and reception of CAN FD frames is enabled. Transmission and reception of classic CAN frames is always possible. Whether a CAN FD or a classic CAN frame is transmitted, it can be configured via bit FDF in the respective Tx buffer element. With FDCAN_CCCR.FDOE = 0, received frames are interpreted as classic CAN frames, which leads to the transmission of an error frame when receiving a CAN FD frame. When CAN FD operation is disabled, no CAN FD frames are transmitted, even if bit FDF of a Tx buffer element is set. FDCAN_CCCR.FDOE and FDCAN_CCCR.BRSE can only be changed while FDCAN_CCCR.INIT and FDCAN_CCCR.CCE are both set.

With FDCAN_CCCR.FDOE = 0, the setting of bits FDF and BRS is ignored and frames are transmitted in classic CAN format. With FDCAN_CCCR.FDOE = 1 and FDCAN_CCCR.BRSE = 0, only bit FDF of a Tx buffer element is evaluated. With FDCAN_CCCR.FDOE = 1 and FDCAN_CCCR.BRSE = 1, transmission of CAN FD frames with bitrate switching is enabled. All Tx buffer elements with bits FDF and BRS set are transmitted in CAN FD format with bitrate switching.

A mode change during CAN operation is only recommended under the following conditions:

- The failure rate in the CAN FD data phase is significant higher than in the CAN FD arbitration phase. In this case disable the CAN FD bitrate switching option for transmissions.
- During system startup all nodes are transmitting classic CAN messages until it is verified that they are able to communicate in CAN FD format. If this is true, all nodes switch to CAN FD operation.
- Wake-up messages in CAN partial networking have to be transmitted in classic CAN format.
- End-of-line programming in case not all nodes are CAN FD capable. Non CAN FD nodes are held in Silent mode until programming has completed. Then all nodes switch back to classic CAN communication.

In the CAN FD format, the coding of the DLC differs from the standard CAN format. DLC codes 0 to 8 have the same coding as in standard CAN, codes 9 to 15 (that in standard CAN all code a data field of 8 bytes) are coded according to Table 502.
In CAN FD fast frames, the bit timing is switched inside the frame, after the BRS (bitrate switch) bit, if this bit is recessive. Before the BRS bit, in the CAN FD arbitration phase, the nominal CAN bit timing is used as defined by the bit timing and prescaler register FDCAN_NBTP. In the following CAN FD data phase, the fast CAN bit timing is used as defined by the fast bit timing and prescaler register FDCAN_DBTP. The bit timing is switched back from the fast timing at the CRC delimiter or when an error is detected, whichever occurs first.

The maximum configurable bitrate in the CAN FD data phase depends on the FDCAN kernel clock frequency. For example, with an FDCAN kernel clock frequency of 20 MHz and the shortest configurable bit time of four time quanta (tq), the bitrate in the data phase is 5 Mbit/s.

In both data frame formats, CAN FD long frames and CAN FD fast frames, the value of the bit ESI (error status indicator) is determined by the transmitter error state at the start of the transmission. If the transmitter is error passive, ESI is transmitted recessive, else it is transmitted dominant. In CAN FD remote frames the ESI bit is always transmitted dominant, independent of the transmitter error state. The data length code of CAN FD remote frames is transmitted as 0.

In case an FDCAN Tx buffer is configured for CAN FD transmission with DLC > 8, the first eight bytes are transmitted as configured in the Tx buffer while the remaining part of the data field is padded with 0xCC. When the FDCAN receives an FDCAN frame with DLC > 8, the first eight bytes of that frame are stored into the matching Rx buffer or Rx FIFO. The remaining bytes are discarded.

**Transceiver delay compensation**

During the data phase of a CAN FD transmission only one node is transmitting, all others are receivers. The length of the bus line has no impact. When transmitting via pin FDCAN_TX the protocol controller receives the transmitted data from its local CAN transceiver via pin FDCAN_RX. The received data is delayed by the CAN transceiver loop delay. If this delay is greater than TSEG1 (time segment before sample point), a bit error is detected. Without transceiver delay compensation, the bitrate in the data phase of a CAN FD frame is limited by the transceivers loop delay.

The FDCAN implements a delay compensation mechanism to compensate the CAN transceiver loop delay, thereby enabling transmission with higher bitrates during the CAN FD data phase, independent from the delay of a specific CAN transceiver.

To check for bit errors during the data phase of transmitting nodes, the delayed transmit data is compared against the received data at the Secondary Sample Point SSP. If a bit error is detected, the transmitter reacts on this bit error at the next following regular sample point. During the arbitration phase the delay compensation is always disabled.

The transmitter delay compensation enables configurations where the data bit time is shorter than the transmitter delay, it is described in detail in the new ISO11898-1. It is enabled by setting bit FDCAN_DBTP.TDC.

---

<td>16</td>
<td>20</td>
<td>24</td>
<td>32</td>
<td>48</td>
<td>64</td>
</tr>
</tbody>
</table>
The received bit is compared against the transmitted bit at the SSP. The SSP position is defined as the sum of the measured delay from the FDCAN transmit output pin FDCAN_TX through the transceiver to the receive input pin FDCAN_RX plus the transmitter delay compensation offset as configured by FDCAN_TDCR.TDCO. The transmitter delay compensation offset is used to adjust the position of the SSP inside the received bit (for example half of the bit time in the data phase). The position of the secondary sample point is rounded down to the next integer number of minimum time quanta (mtq, that is, one period of fdcan_tq_ck clock).

FDCAN_PSR.TDCV shows the actual transmitter delay compensation value, cleared when FDCAN_CCCR.INIT is set, and updated at each transmission of an FD frame while FDCAN_DBTP.TDC is set.

The following boundary conditions have to be considered for the transmitter delay compensation implemented in the FDCAN:

- The sum of the measured delay from FDCANx_TX to FDCANx_RX and the configured transmitter delay compensation offset FDCAN_TDCR.TDCO must be less than six bit times in the data phase.
- The sum of the measured delay from FDCANx_TX to FDCANx_RX and the configured transmitter delay compensation offset FDCAN_TDCR.TDCO must be less than or equal to 127 mtq. If this sum exceeds 127 mtq, the maximum value (127 mtq) is used for transmitter delay compensation.
- The data phase ends at the sample point of the CRC delimiter, which stops checking received bits at the SSPs.

If transmitter delay compensation is enabled by programming FDCAN_DBTP.TDC = 1, the measurement is started within each transmitted CAN FD frame at the falling edge of bit FDF to bit res. The measurement is stopped when this edge is seen at the receive input pin FDCAN_TX of the transmitter. The resolution of this measurement is 1 mtq.

**Figure 777. Transceiver delay measurement**

To avoid that a dominant glitch inside the received FDF bit ends the delay compensation measurement before the falling edge of the received res bit (resulting in a too early SSP position), the use of a transmitter delay compensation filter window can be enabled by programming FDCAN_TDCR.TDCF. This defines a minimum value for the SSP position.
Dominant edges on FDCANx_RX that would result in an earlier SSP position are ignored for transmitter delay measurement. The measurement is stopped when the SSP position is at least FDCAN_TDCR.TDCF and FDCAN_RX is low.

**Restricted operation mode**

In restricted operation mode the node is able to receive data and remote frames and to give acknowledge to valid frames, but it does not send data frames, remote frames, active error frames, or overload frames. In case of an error condition or overload condition, it does not send dominant bits, but waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication. The error counters (FDCAN_ECR.REC, FDCAN_ECR.TEC) are frozen while error logging (FDCAN_ECR.CEL) is active. The software can set the FDCAN into restricted operation mode by setting bit FDCAN_CCCR.ASM. The bit can be set only by software when both FDCAN_CCCR.CCE and FDCAN_CCCR.INIT are set to 1. The bit can be cleared by software at any time.

Restricted operation mode is automatically entered when the Tx handler was not able to read data from the message RAM in time. To leave restricted operation mode, the software has to reset FDCAN_CCCR.ASM.

The restricted operation mode can be used in applications that adapt themselves to different CAN bitrates. In this case the application tests different bitrates and leaves the restricted operation mode after it has received a valid frame.

FDCAN_CCCR.ASM is also controlled by the clock calibration unit. When the calibration process is enabled, the restricted operation mode is entered and the FDCAN_CCCR.ASM bit is set. Once the calibration is completed, FDCAN_CCCR.ASM bit is cleared.

*Note:* The restricted operation mode must not be combined with the loop back mode (internal or external).

**Bus monitoring mode**

The FDCAN is set in bus monitoring mode by setting FDCAN_CCCR.MON bit or when error level S3 (FDCAN_TTOST.EL = 11) is entered. In bus monitoring mode (for more details refer to ISO11898-1, 10.12 bus monitoring), the FDCAN is able to receive valid data frames and valid remote frames, but cannot start a transmission. In this mode, it sends only recessive bits on the CAN bus, if the FDCAN is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the FDCAN monitors this dominant bit, although the CAN bus may remain in recessive state. In bus monitoring mode register FDCAN_TXBRP is held in reset state.

The bus monitoring mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits. Figure 778 shows the connection of FDCAN_TX and FDCAN_RX signals to the FDCAN in bus monitoring mode.
According to the CAN Specification (see ISO11898-1, 6.3.3 recovery management), the FDCAN provides means for automatic retransmission of frames that have lost arbitration or have been disturbed by errors during transmission. By default, automatic retransmission is enabled.

To support time-triggered communication as described in ISO 11898-1: 2015, chapter 9.2, the automatic retransmission may be disabled via FDCAN_CCCR.DAR.

**Frame transmission in disabled automatic retransmission (DAR) mode**

In DAR mode all transmissions are automatically canceled after they started on the CAN bus. A Tx buffer Tx request pending bit FDCAN_TXBRRP.TRPx is reset after successful transmission, when a transmission has not yet been started at the point of cancellation, has been aborted due to lost arbitration, or when an error occurred during frame transmission.

- **Successful transmission:**
  - Corresponding Tx buffer transmission occurred bit FDCAN_TXBTO.TOx set
  - Corresponding Tx buffer cancellation finished bit FDCAN_TXBCF.CFx not set

- **Successful transmission in spite of cancellation:**
  - Corresponding Tx buffer transmission occurred bit FDCAN_TXBTO.TOx set
  - Corresponding Tx buffer cancellation finished bit FDCAN_TXBCF.CFx set

- **Arbitration loss or frame transmission disturbed:**
  - Corresponding Tx buffer transmission occurred bit FDCAN_TXBTO.TOx not set
  - Corresponding Tx buffer cancellation finished bit FDCAN_TXBCF.CFx set

In case of a successful frame transmission, and if storage of Tx events is enabled, a Tx event FIFO element is written with event type ET = 10 (transmission in spite of cancellation).

**Power down (Sleep mode)**

The FDCAN can be set into power down mode controlled by clock stop request input via register FDCAN_CCCR.CSR. As long as the clock stop request is active, bit FDCAN_CCCR.CSR is read as 1.
When all pending transmission requests have completed, the FDCAN waits until bus idle state is detected. Then the FDCAN sets FDCAN_CCCR.INIT to 1 to prevent any further CAN transfers. Now, the FDCAN acknowledges that it is ready for power down by setting FDCAN_CCCR.CSA to 1. In this state, before the clocks are switched off, further register accesses can be made. A write access to FDCAN_CCCR.INIT has no effect. Now the module clock inputs may be switched off.

To leave power down mode, the application has to turn on the module clocks before resetting CC control register flag FDCAN_CCCR.CSR. The FDCAN acknowledges this by resetting FDCAN_CCCR.CSA. Afterwards, the application can restart CAN communication by resetting bit FDCAN_CCCR.INIT.

Test modes

To enable write access to FDCAN test register (see Section 59.5.4), bit FDCAN_CCCR.TEST must be set to 1, thus enabling the configuration of test modes and functions.

Four output functions are available for the CAN transmit pin FDCAN_TX by programming FDCAN_TEST.TX. Additionally to its default function (the serial data output) it can drive the CAN Sample Point signal to monitor the FDCAN bit timing and it can drive constant dominant or recessive values. The actual value at pin FDCAN_RX can be read from FDCAN_TEST.RX. Both functions can be used to check the CAN bus physical layer.

Due to the synchronization mechanism between CAN kernel clock and APB clock domain, there may be a delay of several APB clock periods between writing to FDCAN_TEST.TX until the new configuration is visible at FDCAN_TX output pin. This applies also when reading FDCAN_RX input pin via FDCAN_TEST.RX.

Note: Test modes should be used for production tests or self test only. The software control for FDCAN_TX pin interferes with all CAN protocol functions. It is not recommended to use test modes for application.

External loop back mode

The FDCAN can be set in external loop back mode by programming FDCAN_TEST.LBCK to 1. In loop back mode, the FDCAN treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) into Rx FIFOs. Figure 779 (left side) shows the connection of transmit and receive signals FDCAN_TX and FDCAN_RX to the FDCAN in external loop back mode.

This mode is provided for hardware self-test. To be independent from external stimulation, the FDCAN ignores acknowledge errors (recessive bit sampled in the acknowledge slot of a data/remote frame) in loop back mode. In this mode the FDCAN performs an internal feedback from its transmit output to its receive input. The actual value of the FDCAN_RX input pin is disregarded by the FDCAN. The transmitted messages can be monitored at the FDCAN_TX transmit pin.

Internal loop back mode

Internal loop back mode is entered by programming bits FDCAN_TEST.LBCK and FDCAN_CCCR.MON to 1. This mode can be used for a “Hot Selftest”, meaning the FDCAN can be tested without affecting a running CAN system connected to the FDCAN_TX and FDCAN_RX pins. In this mode, FDCAN_RX pin is disconnected from the FDCAN and FDCAN_TX pin is held recessive. Figure 779 (right side) shows the connection of FDCAN_TX and FDCAN_RX pins to the FDCAN in case of internal loop back mode.
Application watchdog (FDCAN1 only)

The application watchdog is served by reading register FDCAN_TTOST. When the application watchdog is not served in time, bit FDCAN_TTOST.AWE is set, all TTCAN communication is stopped, and the FDCAN1 is set into bus monitoring mode.

The TT application watchdog can be disabled by programming the application watchdog limit FDCAN_TTOCF.AWL to 0x00. The TT application watchdog must not be disabled in a TTCAN application program.

Timestamp generation

For timestamp generation the FDCAN supplies a 16-bit wraparound counter. A prescaler FDCAN_TSCC.TCP can be configured to clock the counter in multiples of CAN bit times (1 … 16). The counter is readable via FDCAN_TSCV.TCV. A write access to register FDCAN_TSCV resets the counter to 0. When the timestamp counter wraps around interrupt flag FDCAN_IR.TSW is set.

On start of frame reception/transmission the counter value is captured and stored into the timestamp section of an Rx buffer/Rx FIFO (RXTS[15:0]) or Tx event FIFO (TXTS[15:0]) element.

By programming bit FDCAN_TSCC.TSS, a 16-bit timestamp can be used.

Timeout counter

To signal timeout conditions for Rx FIFO 0, Rx FIFO 1, and the Tx event FIFO the FDCAN supplies a 16-bit timeout counter. It operates as down-counter and uses the same prescaler controlled by FDCAN_TSCC.TCP as the timestamp counter. The timeout counter is configured via register FDCAN_TOCC. The actual counter value can be read from FDCAN_TOCV.TOC. The timeout counter can only be started while FDCAN_CCCR.INIT = 0. It is stopped when FDCAN_CCCR.INIT = 1, for example when the FDCAN enters Bus_Off state.

The operation mode is selected by FDCAN_TOCC.TOS. When operating in Continuous mode, the counter starts when FDCAN_CCCR.INIT is reset. A write to FDCAN_TOCV...
presets the counter to the value configured by FDCAN_TOCC.TOP and continues
down-counting.

When the timeout counter is controlled by one of the FIFOs, an empty FIFO presets the
counter to the value configured by FDCAN_TOCC.TOP. Down-counting is started when the
first FIFO element is stored. Writing to FDCAN_TOCV has no effect.

When the counter reaches 0, interrupt flag FDCAN_IR.TOO is set. In Continuous mode, the
counter is immediately restarted at FDCAN_TOCC.TOP.

*Note:* The clock signal for the timeout counter is derived from the CAN core sample point signal.
Therefore, the point in time where the timeout counter is decremented can vary due to the
synchronization/re-synchronization mechanism of the CAN core. If the baudrate switch
feature in FDCAN is used, the timeout counter is clocked differently in arbitration and data
fields.

### 59.4.2 Message RAM

The message RAM has a width of 32 bits. The FDCAN module can be configured to allocate
up to 2560 words in the message RAM. It is not necessary to configure each of the sections
listed in *Figure 780*, nor is there any restriction with respect to the sequence of the sections.

![Figure 780. Message RAM configuration](MS41464V2)

When the FDCAN addresses the message RAM it addresses 32-bit words, not single bytes.
The configured start addresses are 32-bit word addresses, that is. only bits 15 to 2 are
evaluated, the two least significant bits are ignored.
Note: The FDCAN does not check for erroneous configuration of the message RAM. In particular, the configuration of the start addresses of the different sections and the number of elements of each section must be done carefully to avoid falsification or loss of data.

Rx handling

The Rx handler controls the acceptance filtering, the transfer of received messages to Rx buffers or to 1 of the two Rx FIFOs, as well as the Rx FIFO put and get Indices.

Acceptance filter

The FDCAN offers the possibility to configure two sets of acceptance filters, one for standard identifiers and one for extended identifiers. These filters can be assigned to Rx buffer, Rx FIFO 0 or Rx FIFO 1. For acceptance filtering each list of filters is executed from element #0 until the first matching element. Acceptance filtering stops at the first matching element. The following filter elements are not evaluated for this message.

The main features are:

- Each filter element can be configured as
  - range filter (from 0 to 128 elements for the 11-bit filter and from 0 to 64 for the 29-bit filter)
  - filter for one or two dedicated IDs
  - classic bit mask filter
- Each filter element is configurable for acceptance or rejection filtering
- Each filter element can be enabled/disabled individually
- Filters are checked sequentially, execution stops with the first matching filter element

Related configuration registers are:

- Global filter configuration (FDCAN_GFC)
- Standard ID filter configuration (FDCAN_SIDFC)
- Extended ID filter configuration (FDCAN_XIDFC)
- Extended ID AND Mask (FDCAN_XIDAM)

Depending on the configuration of the filter element (SFEC / EFEC) a match triggers one of the following actions:

- Store received frame in FIFO 0 or FIFO 1
- Store received frame in Rx buffer
- Store received frame in Rx buffer and generate pulse at filter event pin
- Reject received frame
- Set high priority message interrupt flag FDCAN_IR.HPM
- Set high priority message interrupt flag FDCAN_IR.HPM and store received frame in FIFO 0 or FIFO 1
- Set high priority message interrupt flag FDCAN_IR.HPM and store received frame in FIFO 0 or FIFO 1

Acceptance filtering is started after the complete identifier has been received. After acceptance filtering has completed, and if a matching Rx buffer or Rx FIFO has been found, the message handler starts writing the received message data in 32-bit portions to the
matching Rx buffer or Rx FIFO. If the CAN protocol controller has detected an error condition (for example CRC error), this message is discarded with the following impact:

- **Rx buffer**
  New data flag of matching Rx buffer is not set, but Rx buffer (partly) overwritten with received data. For error type see FDCAN_PSR.LEC and FDCAN_PSR.DLEC.

- **Rx FIFO**
  Put index of matching Rx FIFO is not updated, but related Rx FIFO element (partly) overwritten with received data. For error type see FDCAN_PSR.LEC and FDCAN_PSR.DLEC. In case the matching Rx FIFO is operated in overwrite mode, the boundary conditions described in [Rx FIFO overwrite mode](#) have to be considered.

**Note:** When an accepted message is written to one of the two Rx FIFOs, or into an Rx buffer, the unmodified received identifier is stored independently of the filter(s) used. The result of the acceptance filter process depends strongly upon the sequence of configured filter elements.

**Range filter**

The filter matches for all received frames with message IDs in the range defined by SF1ID / SF2ID and EF1ID / EF2ID.

There are two possibilities when range filtering is used together with extended frames:

- **EFT = 00:** The message ID of received frames is AND-ed with the extended ID AND Mask (FDCAN_XIDAM) before the range filter is applied
- **EFT = 11:** The extended ID AND Mask (FDCAN_XIDAM) is not used for range filtering

**Filter for dedicated IDs**

A filter element can be configured to filter for one or two specific message IDs. To filter for one specific message ID, the filter element must be configured with SF1ID = SF2ID and EF1ID = EF2ID.

**Classic bit mask filter**

Classic bit mask filtering is intended to filter groups of message IDs by masking single bits of a received message ID. With classic bit mask filtering SF1ID / EF1ID is used as message ID filter, while SF2ID / EF2ID is used as filter mask.

A 0 bit at the filter mask marks out the corresponding bit position of the configured ID filter, for example, the value of the received message ID at that bit position is not relevant for acceptance filtering. Only those bits of the received message ID where the corresponding mask bits are one are relevant for acceptance filtering.

In case all mask bits are one, a match occurs only when the received message ID and the message ID filter are identical. If all mask bits are 0, all message IDs match.
Standard message ID filtering

*Figure 781* shows the flow for standard message ID (11-bit Identifier) filtering. The standard message ID filter element is described in *Section 59.4.21*.

**Figure 781. Standard message ID filter path**

Controlled by the global filter configuration (FDCAN_GFC) and the standard ID filter configuration (FDCAN_SIDFC) message ID, remote transmission request bit (RTR), and the Identifier Extension bit (IDE) of received frames are compared against the list of configured filter elements.

Extended message ID filtering

*Figure 782* shows the flow for extended message ID (29-bit Identifier) filtering. The extended message ID filter element is described in *Section 59.4.22*. 
Controller area network with flexible data rate (FDCAN)

Figure 782. Extended message ID filter path

Controlled by the global filter configuration FDCAN_GFC and the extended ID filter configuration FDCAN_XIDFC message ID, remote transmission request bit (RTR), and the Identifier Extension bit (IDE) of received frames are compared against the list of configured filter elements.

The extended ID AND Mask (FDCAN_XIDAM) is AND-ed with the received identifier before the filter list is executed.

Rx FIFOs

Rx FIFO 0 and Rx FIFO 1 can be configured to hold up to 64 elements each. Configuration of the two Rx FIFOs is done via registers FDCAN_RXF0C and FDCAN_RXF1C.
Received messages that passed acceptance filtering are transferred to the Rx FIFO as configured by the matching filter element. For a description of the filter mechanisms available for Rx FIFO 0 and Rx FIFO 1, see **Acceptance filter**. The Rx buffer and FIFO element are described in **Section 59.4.18**.

When an Rx FIFO full condition is signaled by FDCAN_IR.RFnF, no further messages are written to the corresponding Rx FIFO until at least one message has been read out, and the Rx FIFO get index has been incremented. In case a message is received while the corresponding Rx FIFO is full, this message is discarded and interrupt flag FDCAN_IR.RFnL is set.

To avoid an Rx FIFO overflow, the Rx FIFO watermark can be used. When the Rx FIFO fill level reaches the Rx FIFO watermark configured by FDCAN_RXFnC.FnWM, interrupt flag FDCAN_IR.RFnW is set.

When reading from an Rx FIFO, Rx FIFO get index RXFnS[FnGI] + FIFO element size must be added to the corresponding Rx FIFO start address RXFnC[FnSA].

**Rx FIFO blocking mode**

The Rx FIFO blocking mode is configured by RXFnC.FnOM = 0. This is the default operation mode for the Rx FIFOs.

When an Rx FIFO full condition is reached (RXFnS.FnPI = RXFnS.FnGI), no further messages are written to the corresponding Rx FIFO until at least one message has been read out, and the Rx FIFO get index has been incremented. An Rx FIFO full condition is signaled by RXFnS.FnF = 1. In addition, interrupt flag FDCAN_IR.RFnF is set.

In case a message is received while the corresponding Rx FIFO is full, this message is discarded and the message lost condition is signaled by RXFnS.RFnL = 1. In addition, interrupt flag FDCAN_IR.RFnL is set.

**Rx FIFO overwrite mode**

The Rx FIFO overwrite mode is configured by RXFnC.FnOM = 1.

When an Rx FIFO full condition (RXFnS.FnPI = RXFnS.FnGI) is signaled by RXFnS.FnF = 1, the next message accepted for the FIFO overwrites the oldest FIFO message. Put and get index are both incremented by one.

When an Rx FIFO is operated in overwrite mode and an Rx FIFO full condition is signaled, reading of the Rx FIFO elements should start at least at get index + 1. The reason for that is that it can happen that a received message is written to the message RAM (put index) while the CPU is reading from the message RAM (get index). In this case inconsistent data may be read from the respective Rx FIFO element. Adding an offset to the get index when reading from the Rx FIFO avoids this problem. The offset depends on how fast the CPU accesses the Rx FIFO. **Figure 784** shows an offset of two with respect to the get index when reading the Rx FIFO. In this case the two messages stored in elements 1 and 2 are lost.

After reading from the Rx FIFO, the number of the last element read must be written to the Rx FIFO acknowledge index RXFnA.FnA. This increments the get index to that element number. In case the put index has not been incremented to this Rx FIFO element, the Rx FIFO full condition is reset (RXFnS.FnF = 0).

**Dedicated Rx buffers**

The FDCAN supports up to 64 dedicated Rx buffers. The start address of the dedicated Rx buffer section is configured via FDCAN_RXBC.RBSA.
For each Rx buffer a standard or extended message ID filter element with SFEC / EFEC = 111 and SFID2 / EFID2[10:9] = 00 must be configured (see Section 59.4.21 and Section 59.4.22).

After a received message has been accepted by a filter element, the message is stored into the Rx buffer in the message RAM referenced by the filter element. The format is the same as for an Rx FIFO element. In addition, the flag FDCAN_IR.DRX (message stored in dedicated Rx buffer) in the interrupt register is set.

After the last word of a matching received message has been written to the message RAM, the respective New data flag in register NDAT1,2 is set. As long as the New data flag is set, the respective Rx buffer is locked against updates from received matching frames. The New data flags have to be reset by the user by writing a 1 to the respective bit position.

While an Rx buffer New data flag is set, a message ID filter element referencing this specific Rx buffer is not matched, causing the acceptance filtering to continue. The following message ID filter elements may cause the received message to be stored into another Rx buffer, or into an Rx FIFO, or the message may be rejected, depending on filter configuration.

**Rx buffer handling**

- Reset interrupt flag FDCAN_IR.DRX
- Read New data registers
- Read messages from message RAM
- Reset New data flags of processed messages

**Filtering for Debug messages**

Filtering for debug messages is done by configuring one standard/extended message ID filter element for each of the three debug messages. To enable a filter element to filter for debug messages SFEC/EFEC must be programmed to 111. In this case fields SFID1 / SFID2 and EFID1 / EFID2 have a different meaning. While SFID2 / EFID2[10:9] controls the debug message handling state machine, SFID2 / EFID2[5:0] controls the location for storage of a received debug message.

When a debug message is stored, neither the respective New data flag nor FDCAN_IR.DRX are set. The reception of debug messages can be monitored via FDCAN_RXF1S.DMS.

Tx handling

The Tx handler handles transmission requests for the dedicated Tx buffers, the Tx FIFO, and the Tx queue. It controls the transfer of transmit messages to the CAN core, the put and get Indices, and the Tx event FIFO. Up to 32 Tx buffers can be set up for message transmission (see Dedicated Tx buffers). Depending on the configuration of the element size (FDCAN_RXESC), between two and sixteen 32-bit words (Rn = 3 ... 17) are used for storage of a CAN message data field.

Note: AUTOSAR requires at least three Tx queue buffers and support of transmit cancellation.

The Tx handler starts a Tx scan to check for the highest priority pending Tx request (Tx buffer with lowest message ID) when the Tx buffer request pending register FDCAN_TXBRP is updated, or when a transmission has been started.

Transmit pause

This feature is intended for use in CAN systems where the CAN message identifiers are (permanently) specified to specific values and cannot easily be changed. These message identifiers may have a higher CAN arbitration priority than other defined messages, while in a specific application their relative arbitration priority should be inverse. This may lead to a case where one ECU sends a burst of CAN messages that cause another ECU CAN messages to be delayed because that other messages have a lower CAN arbitration priority.

If, as an example, CAN ECU-1 has the feature enabled and is requested by its application software to transmit four messages, after the first successful message transmission, it waits for two CAN bit times of bus idle before it is allowed to start the next requested message. If there are other ECUs with pending messages, those messages are started in the idle time, they would not need to arbitrate with the next message of ECU-1. After having received a

Note: AUTOSAR requires at least three Tx queue buffers and support of transmit cancellation.
message, ECU-1 is allowed to start its next transmission as soon as the received message releases the CAN bus.

The feature is controlled by TXP bit in FDCAN_CCCR register. If the bit is set, the FDCAN, each time it has successfully transmitted a message, pauses for two CAN bit times before starting the next transmission. This enables other CAN nodes in the network to transmit messages even if their messages have lower prior identifiers. Default is disabled (FDCAN_CCCR.TXP = 0).

This feature looses up burst transmissions coming from a single node and it protects against "babbling idiot" scenarios where the application program erroneously requests too many transmissions.

**Dedicated Tx buffers**

Dedicated Tx buffers are intended for message transmission under complete control of the CPU. Each dedicated Tx buffer is configured with a specific message ID. In case that multiple Tx buffers are configured with the same message ID, the Tx buffer with the lowest buffer number is transmitted first.

If the data section has been updated, a transmission is requested by an add request via FDCAN_TXBAR.ARn. The requested messages arbitrate internally with messages from an optional Tx FIFO or Tx queue and externally with messages on the CAN bus, and are sent out according to their message ID.

A dedicated Tx buffer allocates four 32-bit words in the message RAM. Therefore the start address of a dedicated Tx buffer in the message RAM is calculated by adding four times the transmit buffer index (0 … 31) to the Tx buffer start address FDCAN_TXBC.TBSA.

**Tx FIFO**

Tx FIFO operation is configured by programming FDCAN_TXBC.TFQM to 0. Messages stored in the Tx FIFO are transmitted starting with the message referenced by the get index FDCAN_TXFQS.TFGI. After each transmission the get index is incremented cyclically until the Tx FIFO is empty. The Tx FIFO enables transmission of messages with the same message ID from different Tx buffers in the order these messages have been written to the Tx FIFO. The FDCAN calculates the Tx FIFO free level FDCAN_TXFQS.TFFL as difference between get and put index. It indicates the number of available (free) Tx FIFO elements.
New transmit messages have to be written to the Tx FIFO starting with the Tx buffer referenced by the put index FDCAN_TXFQS.TFQPI. An add request increments the put index to the next free Tx FIFO element. When the put index reaches the get index, Tx FIFO full (FDCAN_TXFQS.TFQF = 1) is signaled. In this case no further messages should be written to the Tx FIFO until the next message has been transmitted and the get index has been incremented.

When a single message is added to the Tx FIFO, the transmission is requested by writing a 1 to the FDCAN_TXBAR bit related to the Tx buffer referenced by the Tx FIFO put index.

When multiple (n) messages are added to the Tx FIFO, they are written to n consecutive Tx buffers starting with the put index. The transmissions are then requested via FDCAN_TXBAR. The put index is then cyclically incremented by n. The number of requested Tx buffers should not exceed the number of free Tx buffers as indicated by the Tx FIFO free level.

When a transmission request for the Tx buffer referenced by the get index is canceled, the get index is incremented to the next Tx buffer with pending transmission request and the Tx FIFO free level is recalculated. When transmission cancellation is applied to any other Tx buffer, the get index and the FIFO free level remain unchanged.

A Tx FIFO element allocates four 32-bit words in the message RAM. Therefore the start address of the next available (free) Tx FIFO buffer is calculated by adding four times the put index FDCAN_TXFQS.TFQPI (0 … 31) to the Tx buffer start address FDCAN_TXBC.TBSA.

**Tx queue**

Tx queue operation is configured by programming FDCAN_TXBC.TFQM to 1. Messages stored in the Tx queue are transmitted starting with the message with the lowest message ID (highest priority). In case that multiple queue buffers are configured with the same message ID, the queue buffer with the lowest buffer number is transmitted first.

New messages have to be written to the Tx buffer referenced by the put index FDCAN_TXFQS.TFQPI. An add request cyclically increments the put index to the next free Tx buffer. In case that the Tx queue is full (FDCAN_TXFQS.TFQF = 1), the put index is not valid and no further message should be written to the Tx queue until at least one of the requested messages has been sent out or a pending transmission request has been canceled.

The application may use register FDCAN_TXBRP instead of the put index and may place messages to any Tx buffer without pending transmission request.

A Tx queue buffer allocates four 32-bit words in the message RAM. Therefore the start address of the next available (free) Tx queue buffer is calculated by adding four times the Tx queue put index FDCAN_TXFQS.TFQPI (0 … 31) to the Tx buffer start address FDCAN_TXBC.TBSA.

**Mixed dedicated Tx buffers / Tx FIFO**

In this case the Tx buffers section in the message RAM is subdivided into a set of dedicated Tx buffers and a Tx FIFO. The number of dedicated Tx buffers is configured by FDCAN_TXBC.NDTB. The number of Tx buffers assigned to the Tx FIFO is configured by FDCAN_TXBC.TFQS. In case, FDCAN_TXBC.TFQS is programmed to 0, only dedicated Tx buffers are used.

</tbody>
</table>

**Tx priority setting:**
- Scan all Tx buffers with activated transmission request
- Tx buffer with lowest message ID gets highest priority and is transmitted next
Transmit cancellation

The FDCAN supports transmit cancellation. To cancel a requested transmission from a dedicated Tx buffer or a Tx queue buffer the user has to write a 1 to the corresponding bit position (= number of Tx buffer) of register FDCAN_TXBCR. Transmit cancellation is not intended for Tx FIFO operation.

Successful cancellation is signaled by setting the corresponding bit of register FDCAN_TXBCF to 1.

In case a transmit cancellation is requested while a transmission from a Tx buffer is already ongoing, the corresponding FDCAN_TXBRP bit remains set as long as the transmission is in progress. If the transmission was successful, the corresponding FDCAN_TXBTO and FDCAN_TXBCF bits are set. If the transmission was not successful, it is not repeated and only the corresponding FDCAN_TXBCF bit is set.

Note: If a pending transmission is canceled immediately before this transmission starts, a short time window follows where no transmission is started even if another message is pending in this node. This may enable another node to transmit a message that may have a priority lower than that of the second message in this node.

Tx event handling

To support Tx event handling the FDCAN has implemented a Tx event FIFO. After the FDCAN has transmitted a message on the CAN bus, message ID and timestamp are stored in a Tx event FIFO element. To link a Tx event to a Tx event FIFO element, the message marker from the transmitted Tx buffer is copied into the Tx event FIFO element.

The Tx event FIFO can be configured to a maximum of 32 elements. The Tx event FIFO element is described in Tx FIFO. Depending on the configuration of the element size (FDCAN_TXESC), between two and sixteen 32-bit words (Tn = 3 ..17) are used for storage of a CAN message data field.

The purpose of the Tx event FIFO is to decouple handling transmit status information from transmit message handling i.e. a Tx buffer holds only the message to be transmitted, while the transmit status is stored separately in the Tx event FIFO. This has the advantage, especially when operating a dynamically managed transmit queue, that a Tx buffer can be used for a new message immediately after successful transmission. There is no need to save transmit status information from a Tx buffer before overwriting that Tx buffer.

When a Tx event FIFO full condition is signaled by FDCAN_IR.TEFF, no further elements are written to the Tx event FIFO until at least one element has been read out and the Tx event FIFO get index has been incremented. In case a Tx event occurs while the Tx event FIFO is full, this event is discarded and interrupt flag FDCAN_IR.TEFL is set.

To avoid a Tx event FIFO overflow, the Tx event FIFO watermark can be used. When the Tx event FIFO fill level reaches the Tx event FIFO watermark configured by FDCAN_TXEFC.EFWM, interrupt flag FDCAN_IR.TEFW is set.

When reading from the Tx event FIFO, two times the Tx event FIFO get index FDCAN_TXEFS.EFGI must be added to the Tx event FIFO start address FDCAN_TXEFC.EFSA.

59.4.3 FIFO acknowledge handling

The get indices of Rx FIFO 0, Rx FIFO 1, and the Tx event FIFO are controlled by writing to the corresponding FIFO acknowledge index, see FDCAN Rx FIFO 0 acknowledge register.
(FDCAN_RXF0A), FDCAN Rx FIFO 1 acknowledge register (FDCAN_RXF1A), and FDCAN Tx event FIFO configuration register (FDCAN_TXEFC). Writing to the FIFO acknowledge index sets the FIFO get index to the FIFO acknowledge index plus one and thereby updates the FIFO fill level. There are two use cases:

- When only a single element has been read from the FIFO (the one being pointed to by the get index), this get index value is written to the FIFO acknowledge index.
- When a sequence of elements has been read from the FIFO, it is sufficient to write the FIFO acknowledge index only once at the end of that read sequence (value: index of the last element read), to update the FIFO get index.

Due to the fact that the CPU has free access to the FDCAN message RAM, special care must be taken when reading FIFO elements in an arbitrary order (get index not considered). This might be useful when reading a high priority message from one of the two Rx FIFOs. In this case the FIFO acknowledge index should not be written because this would set the get index to a wrong position and also alters the FIFO fill level. In this case some of the older FIFO elements would be lost.

Note: The application has to ensure that a valid value is written to the FIFO acknowledge index. The FDCAN does not check for erroneous values.

59.4.4 Bit timing

The bit timing logic monitors the serial bus-line and performs sampling and adjustment of the sample point by synchronizing on the start-bit edge and resynchronizing on the following edges.

As shown in Figure 785, its operation may be explained simply by splitting the bit time in three segments, as follows:

- Synchronization segment (SYNC_SEG): a bit change is expected to occur within this time segment, that has a fixed length of one time quantum (1 x tq).
- Bit segment 1 (BS1): defines the location of the sample point. It includes the PROP_SEG and PHASE_SEG1 of the CAN standard, its duration is programmable between 1 and 16 time quanta, but may be automatically lengthened to compensate for positive phase drifts due to differences in the frequency of the various nodes of the network.
- Bit segment 2 (BS2): defines the location of the transmit point. It represents the PHASE_SEG2 of the CAN standard, its duration is programmable between one and eight time quanta, but may also be automatically shortened to compensate for negative phase drifts.

Figure 785. Bit timing
The baudrate is the inverse of bit time (baudrate = 1 / bit time), which, in turn, is the sum of three components. Figure 785 indicates that bit time = t_{SyncSeg} + t_{BS1} + t_{BS2}, where:

- for the nominal bit time
  - \( t_q = (FDCAN\_NBTP\_NBRP[8:0] + 1) \times t_{fdcan\_tq\_ck} \)
  - \( t_{SyncSeg} = 1 \times t_q \)
  - \( t_{BS1} = t_q \times (FDCAN\_NBTP\_NTSEG1[7:0] + 1) \)
  - \( t_{BS2} = t_q \times (FDCAN\_NBTP\_NTSEG2[6:0] + 1) \)

- for the data bit time
  - \( t_q = (FDCAN\_DBTP\_DBRP[4:0] + 1) \times t_{fdcan\_tq\_ck} \)
  - \( t_{SyncSeg} = 1 \times t_q \)
  - \( t_{BS1} = t_q \times (FDCAN\_DBTP\_DTSEG1[4:0] + 1) \)
  - \( t_{BS2} = t_q \times (FDCAN\_DBTP\_DTSEG2[3:0] + 1) \)

The (re)synchronization jump width (SJW) defines an upper bound for the amount of lengthening or shortening of the bit segments. It is programmable between one and four time quanta.

A valid edge is defined as the first transition in a bit time from dominant to recessive bus level, provided the controller itself does not send a recessive bit.

If a valid edge is detected in BS1 instead of SYNC_SEG, BS1 is extended by up to SJW so that the sample point is delayed.

Conversely, if a valid edge is detected in BS2 instead of SYNC_SEG, BS2 is shortened by up to SJW so that the transmit point is moved earlier.

As a safeguard against programming errors, the configuration of the bit timing register is only possible while the device is in Standby mode. Registers FDCAN_DBTP and FDCAN_NBTP (dedicated, respectively, to data and nominal bit timing) are only accessible when FDCAN_CCCR.CCE and FDCAN_CCCR.INIT are set.

Note: For a detailed description of the CAN bit timing and resynchronization mechanism, refer to the ISO 11898-1 standard.

59.4.5 Clock calibration on CAN

After device reset the clock calibration unit (CCU) does not provide a valid clock signal to the FDCAN(s). The CCU must be initialized via FDCAN_CCFG register. The FDCAN_CCFG register can be written only when FDCAN1 has both FDCAN_CCCR.CCE and FDCAN_CCCR.INIT bits set. In consequence the CCU and the FDCAN1 initialization needs to be completed before any FDCAN module can operate.

Clock calibration is bypassed when FDCAN_CCFG.BCC = 1 (see Figure 786).
Operating conditions

The clock calibration on CAN unit is designed to operate under the following conditions:

- a CAN kernel clock frequency $fdcan\_ker\_ck$ up of at least 80 MHz
- FDCAN bitrates:
  - Nominal bitrate: up to 1 Mbit/s
  - Data bitrate: between nominal bitrate and 8 Mbit/s

The clock calibration on FDCAN unit generates a calibrated time quanta clock $fdcan\_tq\_ck$ in the range from 0.5 to 25 MHz.

**Note:** The FDCAN requires that the CAN time quanta clock is always below or equal to the APB clock ($fdcan\_tq\_ck < fdcan\_pclk$). This must be considered when the clock calibration on CAN unit is bypassed ($FDCAN\_CCFG.BCC = 1$).

Calibration accuracy

The calibration accuracy in state Precision_Calibrated depends upon the factors listed below.

- Dynamic clock tolerance at the CAN kernel clock input $fdcan\_ker\_ck$
- Measurement error. For each bit sequence used for calibration measurement, there is a maximum error of one $fdcan\_pclk$ period. The number of bits used for measurement of the bit time is 32 or 64-bit, depending on configuration of $FDCAN\_CCFG.CFL$.
- Tolerable error in calibration mechanism

The distance between two calibration messages must be chosen to fit the clock tolerance requirements of the FDCAN1 module.

**Note:** Dynamic clock tolerance is the clock frequency variation between two calibration messages for example caused by change of temperature or operating voltage.

Functional description

Calibration of the time quanta clock $fdcan\_tq\_ck$ via CAN messages is performed by adapting a clock divider that generates the CAN protocol time quantum $tq$ from the clock $fdcan\_ker\_ck$.

1. First step: basic calibration
   The minimum distance between two consecutive falling edges from recessive to dominant is measured, this time to be assumed two CAN bit times, counted in PLL clock periods. The clock divider ($FDCAN\_CCFG.CDIV$) is updated each time a new
measurement finds a smaller distance between edges. Basic calibration is achieved when the CAN protocol controller detects a valid CAN message.

2. Second step: Precision calibration

The calibration state machine measures the length of a longer bit sequence inside a CAN frame by counting the number of fdcan_ker_clk periods. The length of this bit sequence can be configured to 32 or 64 bits via FDCAN_CCFG.CLF. For a calibration field length of 32/64 bit a calibration message with at least 2/6-byte data field is required. Precision calibration is based on the new clock divider value calculated from the measurement of the longer bit sequence.

A change in the calibration state sets interrupt flag FDCAN_CCU_IR.CSC, if enabled by the interrupt enable FDCAN_CCU_IE.CSCE. It remains set until cleared by writing 1 in FDCAN_CCU_IR.CSC.

Until precision calibration is achieved, FDCANs operate in a restricted mode (no frame transmission, no error or overload flag transmission, no error counting). In case calibration of the fdcan_ker_clk is done by software by evaluating the calibration status from register FDCAN_CCU_CSTAT, FDCANs have to be set to restricted operation mode (FDCAN_CCCR.ASM = 1) until the calibration on CAN unit is in state Precision_Calibrated (see Application).

Precision calibration may be performed only on valid CAN frames transmitted by a node with a stable, quartz-controlled clock. Calibration frames are detected by the FDCAN1 acceptance filtering A filter element and a Rx buffer have to be configured in the FDCAN1 to identify and store calibration messages. After reception of a calibration message the Rx buffer new data flag must be reset to enable signaling of the next calibration message.
In case there is only one CAN transmitter with a quartz clock in the network, this node has to transmit its first message after startup with at least one 1010 binary sequence in the data field or in the identifier. This assures that the non-quartz nodes can enter state Basic_Calibrated and then acknowledge the quartz node messages.

Precision calibration must be repeated in predefined maximum intervals supervised by the calibration watchdog.

**Note:** When the clock calibration on CAN unit transits from state Precision_Calibrated back to Basic_Calibrated, the calibration OK signal is deasserted, the FDCAN1 complete ongoing transmissions, and then enter restricted operation (no frame transmission, no error or overload flag transmission, no error counting).

**Configuration**

The clock calibration on CAN unit is configured via register FDCAN_CCFG, i.e. when FDCAN1 has FDCAN_CCCR.CCE and FDCAN_CCCR.INIT bits set.

For basic calibration the minimum number of oscillator periods between two consecutive falling edges at pin FDCAN1_RX is measured. The number of clock periods depends on the clock frequency applied at input fdcan_ker_ck. In case the measured number of clock periods is below the minimum configured by FDCAN_CCFG.OCPM (as an example, because of a glitch on FDCAN1_RX) the value is discarded and measurement continues.

It is recommended to configure FDCAN_CCFG.OCPM slightly below two CAN bit times:

\[
\text{FDCAN_CCFG.OCPM} < \left( \frac{(2 \times \text{CAN bit time})}{\text{fdcan_ker_ck period}} \right) / 32
\]

The length of the bit field used for precision calibration can be configured to 32 or 64 bits via FDCAN_CCFG.CFL. The number of bits used for precision calibration has an impact on calibration accuracy and the maximum distance between two calibration messages.

The number of time quanta per bit time configured by FDCAN_CCFG.TQBT is used together with the measured number of oscillator clock periods FDCAN_CCU_CSTAT.OCPC to define the number of oscillator clocks per bit time.

When the clock calibration is bypassed by configuring FDCAN_CCFG.BCC = 1, the internal clock divider must be configured via FDCAN_CCFG.CDIV to fulfill the condition fdcan_tq_ck < fdcan_pclk.

**Note:** When clock calibration on CAN is active (FDCAN_CCFG.BCC = 0), the baudrate prescalers of FDCAN modules have to be configured to inactive.

**Status signaling**

The status of the clock calibration on CAN unit can be monitored by reading register FDCAN_CCU_CSTAT. When in state Precision_Calibrated the oscillator clock period counter FDCAN_CCU_CSTAT.OCP signals the number of oscillator clock periods in the calibration field while FDCAN_CCU_CSTAT.TQC signals the number of time quanta in the calibration field.

The calibration state is monitored by FDCAN_CCU_CSTAT.CALS. A change in the calibration state sets interrupt flag FDCAN_CCU_IR.CSC. If enabled by the interrupt enable FDCAN_CCU_IE.CSCE it remains set until cleared by writing 1 in FDCAN_CCU_IR.CSC.

A calibration watchdog event also sets interrupt flag FDCAN_CCU_IR.CWE. If enabled by FDCAN_CCU_IE.CWEE (set to high), it remains active until reset by FDCAN_CCU_IE.CWE.
59.4.6 Application

Clock calibration bypassed

The CCU internal clock divider is configured for division by one (\text{FDCAN\_CCFG.CDIV} = 0x0000). In this operation mode the input clock \text{fdcan\_ker\_ck} is directly routed to the clock output \text{fdcan\_tq\_ck}. In this case \text{fdcan\_tq\_ck} is independent from the configuration and status of FDCAN1 and FDCAN2 connected to the CCU. CAN FD operation is possible with an \text{FDCAN\_ker\_ck} above 80 MHz.

Software calibration

The clock calibration on CAN unit also supports software calibration of \text{fdcan\_ker\_ck} by trimming of an on-chip oscillator. For calculation of the trimming values the user has to read the CCU state from FDCAN\_CCU\_CSTAT. The clock from \text{fdcan\_ker\_ck} is routed to output \text{fdcan\_tq\_ck} (\text{FDCAN\_CCFG.BCC} = 1).

The input clock \text{fdcan\_ker\_ck} must be at least 80 MHz. The clock divider of CCU must be configured via FDCAN\_CCFG.CDIV to bring \text{fdcan\_tq\_ck} to a valid range. All other configuration parameters have to be set via FDCAN\_CCFG. For correct operation of FDCAN1 and FDCAN2, the APB clock \text{fdcan\_pclk} needs to be equal to or higher than the time quanta clock (\text{fdcan\_tq\_ck}). CAN FD operation is not possible.

For startup FDCAN modules have to be both configured for restricted operation (\text{FDCAN\_CCCR.ASM} = 1) before FDCAN\_CCCR.INIT is reset. The input clock \text{fdcan\_ker\_ck} must be adjusted until the clock calibration on CAN unit has reached state Precision\_Calibrated. Now the software can reset FDCAN\_CCCR.ASM and the CANFD1 and CANFD2 can start normal operation.

During operation the software has to check regularly whether the clock calibration on CAN unit is still in state Precision\_Calibrated. In case the clock calibration on CAN unit has left state Precision\_Calibrated due to drift of \text{fdcan\_ker\_ck}, FDCAN modules have to be set into restricted operation mode by programming FDCAN\_CCCR.INIT, FDCAN\_CCCR.CCE, and FDCAN\_CCCR.ASM to 1. After \text{fdcan\_ker\_ck} has been adjusted successfully (clock calibration on CAN unit is in state Precision\_Calibrated), FDCAN modules can resume normal operation.

Note: Trimming accuracy must be to sufficient to meet the CAN clock tolerance requirements for the configured bitrate.

Clock calibration active

This operation mode is entered by resetting FDCAN\_CCFG.BCC to 0. In this operation mode the \text{fdcan\_ker\_ck} is controlled by the CCU.

The generation of CCU output signal \text{fdcan\_tq\_ck} depends upon the state of the FDCAN1. Input clock \text{fdcan\_ker\_ck} must be above 80 MHz. Configuration of the CCU and FDCAN1 is required. CAN FD operation is not possible.

If FDCAN1 turns to Bus\_Off or when its INIT bit is set by the user command (\text{FDCAN\_CCCR.INIT} = 1), the CCU enters state Not\_Calibrated. CANFD1 and CANFD2 enter restricted operation mode.

Note: This is the default operation mode after reset in case the reset value of FDCAN\_CCFG.BCC is configured to 0.
59.4.7 TTCAN operations (FDCAN1 only)

Reference message

A reference message is a data frame characterized by a specific CAN identifier. It is received and accepted by all nodes except the time master (sender of the reference message).

For level 1 the data length must be at least one; for level 0, 2 the data length must be at least four; otherwise, the message is not accepted as reference message. The reference message may be extended by other data up to the sum of eight CAN data bytes. All bits of the identifier except the three LSBs characterize the message as a reference message. The last three bits specify the priorities of up to eight potential time masters. Reserved bits are transmitted as logical 0 and are ignored by the receivers. The reference message is configured via register FDCAN_TTRMC.

The time master transmits the reference message. If the reference message is disturbed by an error, it is retransmitted immediately. In case of a retransmission, the transmitted Master_Ref_Mark is updated. The reference message is sent periodically, but is allowed to stop the periodic transmission (Next_is_Gap bit) and to initiate transmission event-synchronized at the start of the next basic cycle by the current time master or by one of the other potential time masters.

The node transmitting the reference message is the current time master. The time master is allowed to transmit other messages. If the current time master fails, its function is replicated by the potential time master with the highest priority. Nodes that are neither time master nor potential time master are time-receiving nodes.

Level 1

Level 1 operation is configured via FDCAN_TTOCF.OM = 01 and FDCAN_TTOCF.GEN. External clock synchronization is not available in level 1. The information related to the reference message is stored in the first data byte as shown in Table 507. Cycle_Count is optional.

Level 2

Level 2 operation is configured via FDCAN_TTOCF.OM = 10 and FDCAN_TTOCF.GEN. The information related to the reference message is stored in the first four data bytes as shown in Table 508. Cycle_Count and the lower four bits of FDCAN_NTU_Res are optional. The TTCAN does not evaluate NTU_Res[3:0] from received reference messages, it always transmits these bits as 0.
Level 0

Level 0 operation is configured via FDCAN_TTOCF.OM = 11. External event-synchronized time-triggered operation is not available in level 0. The information related to the reference message is stored in the first four data bytes as shown in the table below. In level 0 Next_is_Gap is always 0. Cycle_Count and the lower four bits of NTU_Res are optional. The TTCAN does not evaluate NTU_Res[3:0] from received reference messages, it always transmits these bits as 0.

59.4.8 TTCAN configuration

TTCAN timing

The network time unit (NTU) is the unit in which all times are measured. The NTU is a constant of the whole network and is defined as a priority by the network system designer. In TTCAN level 1 the NTU is the nominal CAN bit time. In TTCAN level 0 and level 2 the NTU is a fraction of the physical second.

The NTU is the time base for the local time. The integer part of the local time (16-bit value) is incremented once each NTU. Cycle time and global time are both derived from local time. The fractional part (3-bit value) of local time, cycle time, and global time is not readable.

In TTCAN level 0 and level 2 the length of the NTU is defined by the time unit Ratio TUR. The TUR is in general a non-integer number, given by TUR = FDCAN_TURN.ANAV / FDCAN_TURCF.DC. The NTU length is given by NTU = CAN clock period x TUR.
The TUR numerator configuration NC is an 18-bit number, FDCAN_TURCF\[NCL\[15:0\]] can be programmed in the range 0x0000 to 0xFFFF. FDCAN_TURCF\[NCH\[17:16\]] is hard wired to 0b01. When 0xnnnn is written to FDCAN_TURCF\[NCL\[15:0\]], FDCAN_TURNA.NAV starts with the value 0x10000 + 0x0nnnn = 0x1nnnn. The TUR denominator configuration FDCAN_TURCF.DC is a 14-bit number. FDCAN_TURCF.DC may be programmed in the range 0x0000 to 0x3FFF (0x0000 is an illegal value).

In level 1, NC must be equal to or higher than 4 x FDCAN_TURCF.DC. In level 0 and level 2 NC must be equal to or higher than 8 x FDCAN_TURCF.DC to get the 3-bit resolution for the internal fractional part of the NTU.

A hardware reset presets FDCAN_TURCF.DC to 0x1000 and FDCAN_TURCF.NCL to 0x10000, resulting in an NTU consisting of sixteen CAN clock periods. Local time and application watchdog are not started before either the FDCAN_CCCR.INIT is reset, or FDCAN_TURCF.ELT is set. FDCAN_TURCF.ECC may not be set before the NTU is configured. Setting FDCAN_TURCF.ELT to 1 also locks the write access to register FDCAN_TURCF.

At startup FDCAN_TURNA.NAV is updated from NC (= FDCAN_TURCF.NCL + 0x10000) when FDCAN_TURCF.ECC is set. In TTCAN level 1 there is no drift compensation. FDCAN_TURNA.NAV does not change during operation, it is always equal to NC.

In TTCAN level 0 and level 2 there are two possibilities for FDCAN_TURNA.NAV to change. When operating as time slave or backup time master, and when FDCAN_TTOCF.ECC is set, FDCAN_TURNA.NAV is updated automatically to the value calculated from the monitored global time speed, as long as the TTCAN is in synchronization state In_Schedule or In_Gap. When it loses synchronization, it returns to NC. When operating as the actual time master, and when FDCAN_TTOCF.EECS is set, the user may update FDCAN_TURCF.NCL. When the user sets FDCAN_TTOCN.ECS, FDCAN_TURNA.NAV is updated from the new value of NC at the next reference message. The status flag FDCAN_TTOST.WECS is set when FDCAN_TTOCN.ECS is set and is cleared when FDCAN_TURNF.NAV is updated. FDCAN_TURCF.NCL is write locked while FDCAN_TTOST.WECS is set.

In TTCAN level 0 and level 2 the clock calibration process adapts FDCAN_TURNA.NAV in the range of the synchronization deviation limit SDL of NC ± 2(FDCAN_TTOCF.LDSDL + 5). FDCAN_TURCF.NCL should be programmed to the largest applicable numerical value in order to achieve the best accuracy in the calculation of FDCAN_TURNA.NAV.

The synchronization deviation SD is the difference between NC and FDCAN_TURNA.NAV (SD = | NC - FDCAN_TURNA.NAV |). It is limited by the synchronization deviation limit SDL, which is configured by its dual logarithm FDCAN_TTOCF.LDSDL (SDL = 2 (FDCAN_TTOCF.LDSDL + 5)) and should not exceed the clock tolerance given by the CAN bit timing configuration. SD is calculated at each new basic cycle. When the calculated TURNANAV deviates by more than SDL from NC, or if the Disc_Bit in the reference message is set, the drift compensation is suspended and FDCAN_TTIR.GTE is set and FDCAN_TTOSC.QCS is reset, or in case of the Disc_Bit = 1, FDCAN_TTIR.GTD is set.

Table 510. TUR configuration example
FDCAN_TTOCN.ECS schedules NC for activation by the next reference message. FDCAN_TTOCN.SGT schedules FDCAN_TTGTP.TP for activation by the next reference message. Setting FDCAN_TTOCN.ECS and FDCAN_TTOCN.SGT requires FDCAN_TTOCF.EECS to be set (external clock synchronization enabled) while the FDCAN is actual time master.

The TTCAN module provides an application watchdog to verify the function of the application program. The user has to serve this watchdog regularly, else all CAN bus activity is stopped. The application watchdog limit FDCAN_TTOCF.AWL specifies the number of NTUs between two times the watchdog must be served. The maximum number of NTUs is 256. The application watchdog is served by reading register FDCAN_TTOST. FDCAN_TTOST.AWE indicates whether the watchdog has been served in time. In case the application failed to serve the application watchdog, interrupt flag FDCAN_TTIR.AW is set. For software development, the application watchdog may be disabled by programming FDCAN_TTOCF.AWL to 0x00, see Section 59.6.3.

Timing of interface signals

The timing events that cause a pulse at output FDCAN trigger time mark interrupt pulse fdcan1_tmp for more than one instance and fdcan_tmp if only one instance; FDCAN register time mark interrupt pulse fdcan1_rtp for more than one instance and fdcan_rtp if only one instance are generated in the CAN clock domain.

There is a clock domain crossing delay to be considered before the same event is visible in the APB clock domain (when FDCAN_TTIR.TTMI is set or FDCAN_TTIR.RTMI is set). As an example, the signals can be connected to the timing input(s) of another FDCAN node (fdcan_swf/fdcan_evt), in order to automatically synchronize two TTCAN networks.

Output FDCAN start of cycle_fdcan1_soc for more than one instance and cycle_fdcan1_soc if only one instance gets active whenever a reference message is completed (either transmitted or received). The output is controlled in the APB clock domain.

59.4.9 Message scheduling

FDCAN_TTOCF.TM controls whether the TTCAN operates as potential time master or as a time slave. If it is a potential time master, the three LSBs of the reference message identifier FDCAN_TTRMC.RID define the master priority, 0 giving the highest and 7 giving the lowest. There cannot be two nodes in the network using the same master priority. FDCAN_TTRMC.RID is used for recognition of reference messages. FDCAN_TTRMC.RMPS is not relevant for time slaves.

The initial reference trigger offset FDCAN_TTOCF.IRTO is a 7-bit-value that defines (in NTUs) how long a backup time master waits before it starts the transmission of a reference message when a reference message is expected but the bus remains idle. The recommended value for FDCAN_TTOCF.IRTO is the master priority multiplied with a factor depending on the expected clock drift between the potential time masters in the network. The sequential order of the backup time masters, when one of them starts the reference message in case the current time master fails, should correspond to their master priority, even with maximum clock drift.

FDCAN_TTOCF.OM decides whether the node operates in TTCAN level 0, level 1, or level 2. In one network, all potential time masters have to operate on the same level. Time slaves may operate on level 1 in a level 2 network, but not vice versa. The configuration of the TTCAN operation mode via FDCAN_TTOCF.OM is the last step in the setup. With FDCAN_TTOCF.OM = 00 (event-driven CAN communication), the FDCAN operates...
according to ISO 11898-1: 2015, without time triggers. With FDCAN_TTOCF.OM = 01 (level 1), the FDCAN operates according to ISO 11898-4, but without the possibility to synchronize the basic cycles to external events, the Next_is_Gap bit in the reference message is ignored. With FDCAN_TTOCF.OM = 10 (level 2), the TTCAN operates according to ISO 11898-4, including the event-synchronized start of a basic cycle. With FDCAN_TTOCF.OM = 11 (level 0), the FDCAN operates as event-driven CAN but maintains a calibrated global time base as in level 2.

FDCAN_TTOCF.EECS enables the external clock synchronization, allowing the application program of the current time master to update the TUR configuration during time-triggered operation, to adapt the clock speed and (in levels 0 and level 2 only) the global clock phase to an external reference.

FDCAN_TTMLM.ENTT in the TT matrix limits register specifies the number of expected Tx_Triggers in the system matrix. This is the sum of Tx_Triggers for exclusive, single arbitrating and merged arbitrating windows, excluding the Tx_Ref_Triggers. Note that this is usually not the number of Tx_Trigger memory elements; the number of basic cycles in the system matrix and the trigger repeat factors have to be taken into account.

An inaccurate configuration of FDCAN_TTMLM.ENTT results either in a TxCount Underflow (FDCAN_TTIR.TXU = 1 and FDCAN_TTOST.EL = 01, severity 1), or in a Tx count Overflow (FDCAN_TTIR.TXO = 1 and FDCAN_TTOST.EL = 10, severity 2).

Note: In case the first reference message seen by a node does not have Cycle_Count 0, this node may finish its first matrix cycle with its Tx count resulting in a Tx count underflow condition. As long as a node is in state Synchronizing, its Tx_Triggers do not lead to transmissions.

FDCAN_TTMLM.CCM specifies the number of the last basic cycle in the system matrix. The counting of basic cycles starts at 0. In a system matrix consisting of eight basic cycles FDCAN_TTMLM.CCM would be 7. FDCAN_TTMLM.CCM is ignored by time slaves, a receiver of a reference message considers the received cycle count as the valid cycle count for the actual basic cycle.

FDCAN_TTMLM.TXEW specifies the length of the Tx enable window in NTUs. The Tx enable window is that period of time at the beginning of a time window where a transmission may be started. If a transmission of a message cannot be started inside the Tx enable window because of for example, a slight overlap from the previous time window message, the transmission cannot be started in that time window at all. FDCAN_TTMLM.TXEW must be chosen with respect to the network synchronization quality and with respect to the relation between the length of the time windows and the length of the messages.

**Trigger memory**

The trigger memory is part of the external message RAM to which the TTCAN is connected to (see Section 59.5.26). It stores up to 64 trigger elements. A trigger memory element consists of time mark TM, cycle code CC, trigger type TYPE, filter type FTYPE, message number MNR, message status count MSC, time mark event internal TMIN, time mark event external TMEX (see Section 59.4.23).

The time mark defines at which cycle time a trigger becomes active. The triggers in the trigger memory have to be sorted by their time marks. The trigger element with the lowest time mark is written to the first trigger memory word. Message number and cycle code are ignored for triggers of type Tx_Ref_Trigger, Tx_Ref_Trigger_Gap, Watch_Trigger, Watch_Trigger_Gap, and End_of_List.

When the cycle time reaches the time mark of the actual trigger, the FSE switches to the next trigger and starts to read the following trigger from the trigger memory. In case of a
transmit trigger, the Tx handler starts to read the message from the message RAM as soon as the FSE switches to its trigger. The RAM access speed defines the minimum time step between a transmit trigger and its preceding trigger, the Tx handler must be able to prepare the transmission before the transmit trigger time mark is reached. The RAM access speed also limits the number of non-matching (with regard to their cycle code) triggers between two matching triggers, the next matching trigger must be read before its time mark is reached. If the reference message is n NTU long, a trigger with a time mark lower than n never becomes active and is treated as a configuration error.

Starting point of the cycle time is the sample point of the reference message start of frame bit. The next reference message is requested when cycle time reaches the Tx_Ref_Trigger time mark. The FDCAN reacts on the transmission request at the next sample point. A new Sync_Mark is captured at the start of frame bit, but the cycle time is incremented until the reference message is successfully transmitted (or received) and the Sync_Mark is taken as the new Ref_Mark. At that point in time, cycle time is restarted. As a consequence, cycle time can never (with the exception of initialization) be seen at a value lower than n, with n being the length of the reference message measured in NTU.

Length of a basic cycle: Tx_Ref_Trigger time mark + 1 NTU + 1 CAN bit time.

The trigger list is different for all nodes in the CAN FD network. Each node knows only the Tx_Triggers for its own transmit messages, the Rx_Triggers for those receive messages that are processed by this node, and the triggers concerning the reference messages.

**Trigger types**

Tx_Ref_Trigger (TYPE = 0000) and Tx_Ref_Trigger_Gap (TYPE = 0001) cause the transmission of a reference message by a time master. A configuration error (FDCAN_TTOST.EL = 11, severity 3) is detected when a time slave encounters a Tx_Ref_Trigger_Gap in its trigger memory. Tx_Ref_Trigger_Gap is only used in external event-synchronized time-triggered operation mode. In that mode, Tx_Ref_Trigger is ignored when the FDCAN synchronization state is In_Gap (FDCAN_TTOST.SYS = 10).

Tx_Trigger_Single (TYPE = 0010), Tx_Trigger_Continuous (TYPE = 0011), Tx_Trigger_Arbitration (TYPE = 0100), and Tx_Trigger_Merged (TYPE = 0101) cause the start of a transmission. They define the start of a time window.

Tx_Trigger_Single starts a single transmission in an exclusive time window when the message buffer transmission request pending bit is set. After successful transmission the transmission request pending bit is reset.

Tx_Trigger_Continuous starts a transmission in an exclusive time window when the message buffer transmission request pending bit is set. After successful transmission the transmission request pending bit remains set, and the message buffer is transmitted again in the next matching time window.

Tx_Trigger_Arbitration starts an arbitrating time window, Tx_Trigger_Merged a merged arbitrating time window. The last Tx_Trigger of a merged arbitrating time window must be of type Tx_Trigger_Arbitration. A configuration error (FDCAN_TTOST.EL = 11, severity 3) is detected when a trigger of type Tx_Trigger_Merged is followed by any other Tx_Trigger than one of type Tx_Trigger_Merged or Tx_Trigger_Arbitration. Several Tx_Triggers may be defined for the same Tx message buffer. Depending on their cycle code, they may be ignored in some basic cycles. The cycle code must be considered when the expected number of Tx_Triggers (FDCAN_TTMLM.ENTT) is calculated.
Watch_Trigger (TYPE = 0110) and Watch_Trigger_Gap (TYPE = 0111) check for missing reference messages. They are used by both time masters and time slaves. Watch_Trigger_Gap is only used in external event-synchronized time-triggered operation mode. In that mode, a Watch_Trigger is ignored when the FDCAN synchronization state is In_Gap (FDCAN_TTOST.SYS = 10).

Rx_Trigger (TYPE = 1000) is used to check for the reception of periodic messages in exclusive time windows. Rx_Triggers are not active until state In_Schedule or In_Gap is reached. The time mark of an Rx_Trigger must be placed after the end of that message transmission, independent of time window boundaries. Depending on their cycle code, Rx_Triggers may be ignored in some basic cycles. At the time mark of the Rx_Trigger, it is checked whether the last received message before this time mark and after start of cycle or previous Rx_Trigger had matched the acceptance filter element referenced by MNR. Accepted messages are stored in one of the two receive FIFOs, according to the acceptance filtering, independent of the Rx_Trigger. Acceptance filter elements referenced by Rx_Triggers should be placed at the beginning of the filter list to ensure that the filtering is finished before the Rx_Trigger time mark is reached.

Time_Base_Trigger (TYPE = 1001) are used to generate internal/external events depending on the configuration of TMIN and TMEX.

End_of_List (TYPE = 1010 … 1111) is an illegal trigger type, a configuration error (FDCAN_TTOST.EL = 11, severity 3) is detected when an End_of_List trigger is encountered in the trigger memory before the Watch_Trigger and Watch_Trigger_Gap.

Restrictions for the node trigger list

There may not be two triggers that are active at the same cycle time and cycle count, but triggers that are active in different basic cycles (different cycle code) may share the same time mark.

Rx_Triggers and Time_Base_Triggers may not be placed inside the Tx enable windows of Tx_Trigger_Single/Continuous/Arbitration, but they may be placed after Tx_Trigger_Merged.

Triggers that are placed after the Watch_Trigger (or the Watch_Trigger_Gap when FDCAN_TTOST.SYS = 10) never become active. The watch triggers themselves do not become active when the reference messages are transmitted on time.

All unused trigger memory words (after the Watch_Trigger or after the Watch_Trigger_Gap when FDCAN_TTOST.SYS = 10) must be set to trigger type End_of_List.

A typical trigger list for a potential time master begins with a number of Tx_Triggers and Rx_Triggers followed by the Tx_Ref_Trigger and the Watch_Trigger. For networks with external event-synchronized time-triggered communication, this is followed by the Tx_Ref_Trigger_Gap and the Watch_Trigger_Gap. The trigger list for a time slave is the same but without the Tx_Ref_Trigger and the Tx_Ref_Trigger_Gap.

At the beginning of each basic cycle, that is at each reception or transmission of a reference message, the trigger list is processed starting with the first trigger memory element. The FSE looks for the first trigger with a cycle code that matches the current cycle count. The FSE waits until cycle time reaches the trigger time mark and activates the trigger. Afterwards the FSE looks for the next trigger in the list with a cycle code that matches the current cycle count.

Special consideration is needed for the time around Tx_Ref_Trigger and Tx_Ref_Trigger_Gap. In a time master competing for master ship, the effective time mark of
a Tx_Ref_Trigger may be decremented in order to be the first node to start a reference message. In backup time masters the effective time mark of a Tx_Ref_Trigger or Tx_Ref_Trigger_Gap is the sum of its configured time mark and the reference trigger offset FDCAN_TTOCF.IRTO. In case error level 2 is reached (FDCAN_TTOST.EL = 10), the effective time mark is the sum of its time mark and 0x127. No other trigger elements should be placed in this range otherwise it may happen that the time marks appear out of order and are flagged as a configuration error. Trigger elements which are coming after Tx_Ref_Trigger may never become active as long as the reference messages come in time.

There are interdependencies between the following parameters:

- APB clock frequency
- Speed and waiting time for trigger RAM accesses
- Length of the acceptance filter list
- Number of trigger elements
- Complexity of cycle code filtering in the trigger elements
- Offset between time marks of the trigger elements

**Example for trigger handling**

The example shows how the trigger list is derived from a node system matrix. Assumption is that node A is first time master and has knowledge of the section of the system matrix shown in Table 511.

<table>
<thead>
<tr>
<th>Cycle count</th>
<th>Time mark</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

The cycle count starts with 0 and runs until 0, 1, 3, 7, 15, 31, 63 (the corresponding number of basic cycles in the system matrix is, respectively, 1, 2, 4, 8, 16, 32, 64). The maximum cycle count is configured by FDCAN_TTMLM.CCM. The cycle code CC is composed of repeat factor (= value of most significant 1) and the number of the first basic cycle in the system matrix (= bit field after most significant 1).

As an example, with a cycle code of 0b0010011 (repeat factor = 16, first basic cycle = 3) and a maximum cycle count of FDCAN_TTMLM.CCM = 0x3F matches occur at cycle counts 3, 19, 35 and 51.

A trigger element consists of time mark TM, cycle code CC, trigger type TYPE, and message number MNR. For transmission MNR references the Tx buffer number (0 ... 31). For reception MNR references the number of the filter element (0 ... 127) that matched during acceptance filtering. Depending on the configuration of the filter type FTYPE, the 11-bit or 29-bit message ID filter list is referenced.
In addition, a trigger element can be configured for generation of time mark event internal TMIN, and time mark event external TMEX. The message status count MSC holds the counter value (0 ... 7) for scheduling errors for periodic messages in exclusive time windows at the point in time when the time mark of the trigger element became active.

In Table 512, the node A trigger list is shown:

</table>

Tx_Trigger_Single, Tx_Trigger_Continuous, Tx_Trigger_Merged, Tx_Trigger_Arbitration, Rx_Trigger, and Time_Base_Trigger are only valid for the specified cycle code. For all other trigger types the cycle code is ignored.

The FSE starts the basic cycle with scanning the trigger list starting from 0 until a trigger with time mark higher than cycle time and with its cycle code CC matching the actual cycle count is reached, or a trigger of type Tx_Ref_Trigger, Tx_Ref_Trigger_Gap, Watch_Trigger, or Watch_Trigger_Gap is encountered.

When the cycle time reached the time mark TM, the action defined by trigger type TYPE and message number MNR is started. There is an error in the configuration when End_of_List is reached.

At mark 6 the reference message (always TxRef) is transmitted. After transmission of the reference message the FSE returns to the beginning of the trigger list. When the watch trigger at mark 7 is reached, the node was not able to transmit the reference message; error treatment is started.

Detection of configuration errors

A configuration error is signaled via FDCAN_TTOST_EL = 11 (severity 3) when:

- The FSE comes to a trigger in the list with a cycle code that matches the current cycle count but with a time mark that is less than the cycle time.
- The previous active trigger was a Tx_Trigger_Merged and the FSE comes to a trigger in the list with a cycle code that matches the current cycle count but that is neither a
Tx_Trigger_Merged nor a Tx_Trigger_Arbitration nor a Time_Base_Trigger nor an Rx_Trigger.

- The FSE of a node with FDCAN_TTOCF.TM=0 (time slave) encounters a Tx_Ref_Trigger or a Tx_Ref_Trigger_Gap.
- Any time mark placed inside the Tx enable window (defined by FDCAN_TTMLM.TXEW) of a Tx_Trigger with a matching cycle code.
- A time mark is placed near the time mark of a Tx_Ref_Trigger and the reference trigger offset FDCAN_TTOST.RTO causes a reversal of their sequential order measured in cycle time.

**TTCAN schedule initialization**

The synchronization to the TTCAN message schedule starts when FDCAN_CCCR.INIT is reset. The TTCAN can operate strictly time-triggered (FDCAN_TTOCF.GEN = 0) or external event-synchronized time-triggered (FDCAN_TTOCF.GEN = 1). All nodes start with cycle time 0 at the beginning of their trigger list with FDCAN_TTOST.SYS = 00 (out of synchronization), no transmission is enabled with the exception of the reference message. Nodes in external event-synchronized time-triggered operation mode ignore Tx_Ref_Trigger and Watch_Trigger and use instead Tx_Ref_Trigger_Gap and Watch_Trigger_Gap until the first reference message decides whether a Gap is active.

**Time slaves**

After configuration, a time slave ignores its Watch_Trigger and Watch_Trigger_Gap if it does not receive any message before reaching the Watch_Triggers. When it reaches Init_Watch_Trigger, interrupt flag FDCAN_TTIR.IWT is set, the FSE is frozen, and the cycle time becomes invalid, but the node is still able to take part in CAN bus communication (to acknowledge or to send error flags). The first received reference message restarts the FSE and the cycle time.

*Note:* Init_Watch_Trigger is not part of the trigger list. It is implemented as an internal counter that counts up to 0xFFFF = maximum cycle time.

When a time slave has received any message but the reference message before reaching the Watch_Triggers, it assumes a fatal error (FDCAN_TTOST.EL = 11, severity 3), set interrupt flag FDCAN_TTIR.WT, switch off its CAN bus output, and enter the bus monitoring mode (FDCAN_CCCR.MON set to 1). In the bus monitoring mode it is still able to receive messages, but cannot send any dominant bits and therefore cannot give acknowledge.

*Note:* To leave the fatal error state, the user has to set FDCAN_CCCR.INIT = 1. After reset of FDCAN_CCCR.INIT, the node restarts TTCAN communication.

When no error is encountered during synchronization, the first reference message sets FDCAN_TTOST.SYS = 01 (Synchronizing), the second sets the TTCAN synchronization state (depending on its Next_is_Gap bit) to FDCAN_TTOST.SYS = 11 (In_Schedule) or FDCAN_TTOST.SYS = 10 (In_Gap), enabling all Tx_Triggers and Rx_Triggers.

**Potential time masters**

After configuration, a potential time master starts the transmission of a reference message when it reaches its Tx_Ref_Trigger (or its Tx_Ref_Trigger_Gap when in external event-synchronized time-triggered operation). It ignores its Watch_Trigger and Watch_Trigger_Gap when it does not receive any message or transmit the reference message successfully before reaching the Watch_Triggers (assumed reason: all other nodes still in reset or configuration, giving no acknowledge). When it reaches
Init_Watch_Trigger, the attempted transmission is aborted, interrupt flag FDCAN_TTIR.IWT is set, the FSE is frozen, and the cycle time becomes invalid, but the node is still able to take part in CAN bus communication (to give acknowledge or to send error flags). Resetting FDCAN_TTIR.IWT re-enables the transmission of reference messages until next time the Init_Watch_Trigger condition is met, or another CAN message is received. The FSE is not be restarted by the reception of a reference message.

When a potential time master reaches the Watch_Triggers after it has received any message but the reference message, it assumes a fatal error (FDCAN_TTOST.EL = 11, severity 3), sets interrupt flag FDCAN_TTIR.WT, switches off its CAN bus output, and enters the bus monitoring mode (FDCAN_CCCR.MON set to 1). In bus monitoring mode, it is still able to receive messages, but cannot send any dominant bits and therefore cannot give acknowledge.

When no error is detected during initialization, the first reference message sets FDCAN_TTOST.SYS = 01 (synchronizing), the second sets the FDCAN synchronization state (depending on its Next_is_Gap bit) to FDCAN_TTOST.SYS = 11 (In_Schedule) or FDCAN_TTOST.SYS = 10 (In_Gap), enabling all Tx_Triggers and Rx_Triggers.

A potential time master is current time master (FDCAN_TTOST.MS = 11) when it was the transmitter of the last reference message, else it is backup time master (FDCAN_TTOST.MS = 10).

When all potential time masters have finished configuration, the node with the highest time master priority in the network becomes the current time master.

59.4.10 TTCAN gap control

All functions related to gap control apply only when the FDCAN is operated in external event synchronized time-triggered mode (FDCAN_TTOCF.GEN = 1). In this operation mode the FDCAN message schedule may be interrupted by inserting gaps between the basic cycles of the system matrix. All nodes connected to the CAN network have to be configured for external event- synchronized time-triggered operation.

During a gap, all transmissions are stopped and the CAN bus remains idle. A gap is finished when the next reference message starts a new basic cycle. A gap starts at the end of a basic cycle that itself was started by a reference message with bit Next_is_Gap = 1 for example gaps are initiated by the current time master.

The current time master has two options to initiate a gap. A gap can be initiated under software control when the application program writes FDCAN_TTOCN.NIG = 1. The Next_is_Gap bit is transmitted as 1 with the next reference message. A gap can also be initiated under hardware control when the application program enables the event trigger input pin fdcan_evt by writing FDCAN_TTOCN.GCS = 1. When a reference message is started and FDCAN_TTOCN.GCS is set, a HIGH level at event trigger pin fdcan_evt sets Next_is_Gap = 1.

As soon as that reference message is completed, the FDCAN_TTOST.WFE bit announces the gap to the time master as well as to the time slaves. The current basic cycle continues until its last time window. The time after the last time window is the gap time.

For the actual time master and the potential time masters, FDCAN_TTOST.GSI is set when the last basic cycle has finished and the gap time starts. In nodes that are time slaves, bit FDCAN_TTOST.GSI remains at 0.

When a potential time master is in synchronization state In_Gap (FDCAN_TTOST.SYS = 10), it has four options to intentionally finish a gap:
1. Under software control by writing FDCAN_TTOCN.FGP = 1.
2. Under hardware control (FDCAN_TTOCN.GCS = 1) an edge from HIGH to LOW at the event-trigger input pin fdcan_evt sets FDCAN_TTOCN.FGP and restarts the schedule.
3. The third option is a time-triggered restart. When FDCAN_TTOCN.TMG = 1, the next register time mark interrupt (FDCAN_TTIR.RTMI = 1) sets FDCAN_TTOCN.FGP and starts the reference message.
4. Finally any potential time master finishes a gap when it reaches its Tx_Ref_Trigger_Gap, assuming that the event to synchronize on did not occur in time.

None of these options can cause a basic cycle to be interrupted with a reference message. Setting of FDCAN_TTOCN.FGP after the gap time begins starts the transmission of a reference message immediately and thereby synchronizes the message schedule. When FDCAN_TTOCN.FGP is set before the gap time has started (while the basic cycle is still in progress), the next reference message is started at the end of the basic cycle, at the Tx_Ref_Trigger - there is no gap time in the message schedule.

Setting of FDCAN_TTOCN.FGP after the gap time begins starts the transmission of a reference message immediately and thereby synchronizes the message schedule. When FDCAN_TTOCN.FGP is set before the gap time has started (while the basic cycle is still in progress), the next reference message is started at the end of the basic cycle, at the Tx_Ref_Trigger - there is no gap time in the message schedule.

In strictly time-triggered operation, bit Next_is_Gap = 1 in the reference message is ignored, as well as the event-trigger input pin fdcan_evt and the bits FDCAN_TTOCN.NIG, FDCAN_TTOCN.FGP, and FDCAN_TTOCN.TMG.

59.4.11 Stop watch

The stop watch function enables capturing of FDCAN internal time values (local time, cycle time, or global time) triggered by an external event.

To enable the stop watch function, the application program first has to define local time, cycle time, or global time as stop watch source via FDCAN_TTOCN.SWS. When FDCAN_TTOCN.SWS is different from 00 and TT interrupt register flag FDCAN_TTIR.SWE is 0, the actual value of the time selected by FDCAN_TTTOCN.SWS is copied into FDCAN_TTCPT.SWV on the next rising / falling edge (as configured via FDCAN_TTOCN.SWP) on stop watch trigger pin fdcan_swt. This sets interrupt flag FDCAN_TTIR.SWE. After the application program has read FDCAN_TTCPT.SWV, it may enable the next stop watch event by resetting FDCAN_TTIR.SWE to 0.

59.4.12 Local time, cycle time, global time, and external clock synchronization

There are two possible levels in time-triggered CAN:
1. Level 1 only provides time-triggered operation using cycle time.
2. Level 2 additionally provides increased synchronization quality, global time and external clock synchronization. In both levels, all timing features are based on a local time base - the local time.

The local time is a 16-bit cyclic counter, it is incremented once each NTU. Internally the NTU is represented by a 3-bit counter which can be regarded as a fractional part (three binary digits) of the local time. Generally, the 3-bit NTU counter is incremented eight times each NTU. If the length of the NTU is shorter than eight CAN clock periods (as may be configured in level 1, or as a result of clock calibration in level 2), the length of the NTU fraction is adapted, and the NTU counter is incremented only four times each NTU.

Figure 788 describes the synchronization of the cycle time and global time, performed in the same manner by all FDCAN nodes, including the time master. Any message received or transmitted invokes a capture of the local time taken at the message is frame
synchronization event. This frame synchronization event occurs at the sample point of each start of frame (SoF) bit and causes the local time to be stored as Sync_Mark. Sync_Marks and Ref_Marks are captured including the 3-bit fractional part.

Whenever a valid reference message is transmitted or received, the internal Ref_Mark is updated from the Sync_Mark. The difference between Ref_Mark and Sync_Mark is the cycle sync mark (cycle sync mark = Sync_Mark - Ref_Mark) stored in register FDCAN_TTCSM. The most significant 16 bits of the difference between Ref_Mark and the actual value of the local time is the cycle time (cycle time = local time - Ref_Mark).

**Figure 788. Cycle time and global time synchronization**

The cycle time that can be read from FDCAN_TTCTC.CT is the difference of the node local time and Ref_Mark, both synchronized into the APB clock domain and truncated to 16 bit.

The global time exists for TTCAN level 0 and level 2 only, in level 1 it is invalid. The node view of the global time is the local image of the global time in (local) NTUs. After configuration, a potential time master uses its own local time as global time. The time master establishes its own local time as global time by transmitting its own Ref_Marks as Master_Ref_Marks in the reference message (bytes 3 and 4). The global time that can be read from FDCAN_TTLGT.GT is the sum of the node local time and its local offset, both synchronized into the APB clock domain and truncated to 16 bit. The fractional part is used for clock synchronization only.

A node that receives a reference message calculates its local offset to the global time by comparing its local Ref_Mark with the received Master_Ref_Mark (see Figure 789). The node view of the global time is local time plus local offset. In a potential time master that has never received another time master reference message, Local_Offset is 0. When a node becomes the current time master after first having received other reference messages,
Local_Offset is frozen at its last value. In the time receiving nodes, Local_Offset may be subject to small adjustments, due to clock drift, when another node becomes time master, or when there is a global time discontinuity, signaled by Disc_Bit in the reference message. With the exception of global time discontinuity, the global time provided to the application program by register FDCAN_TTLGT is smoothed by a low-pass filtering to have a continuous monotonic value.

Figure 789. TTCAN level 0 and level 2 drift compensation

Figure 789 describes how in TTCAN levels 0 and 2 each time receiving node compensates the drift between its own local clock and the time master clock by comparing the length of a basic cycle in local time and in global time. If there is a difference between the two values and the Disc_Bit in the reference message is not set, a new value for FDCAN_TURN.A.Nav is calculated. If the synchronization deviation SD = | NC - FDCAN_TURN.A.Nav | ≤ SDL (synchronization deviation limit), the new value for FDCAN_TURN.A.Nav takes effect. Else the automatic drift compensation is suspended.

In TTCAN level 0 and level 2, FDCAN_TTOST.QCS indicates whether the automatic drift compensation is active or suspended. In TTCAN level 1, FDCAN_TOST.QCS is always 1.

The current time master may synchronize its local clock speed and the global time phase to an external clock source. This is enabled by bit FDCAN_TTOCF.EECS.

The stop watch function (see Section 59.4.11) may be used to measure the difference in clock speed between the local clock and the external clock. The local clock speed is adjusted by first writing the newly calculated numerator configuration low to
FDCAN_TURCF.NCL (FDCAN_TURCF.DC cannot be updated during operation). The new value takes effect by writing FDCAN_TTOCN.ECS to 1.

The global time phase is adjusted by first writing the phase offset into the TT global time Preset register FDCAN_TTGTP. The new value takes effect by writing FDCAN_TTOCN.SGT to 1. The first reference message transmitted after the global time phase adjustment has the Disc_Bit set to 1.

FDCAN_TTOST.QGTP shows whether the node global time is in phase with the time master global time. FDCAN_TTOST.QGTP is permanently 0 in TTCAN level 1 and when the synchronization deviation limit is exceeded in TTCAN level 0, 2 (FDCAN_TTOST.QCS = 0). It is temporarily 0 while the global time is low-pass filtered to supply the application with a continuous monotonic value. There is no low-pass filtering when the last reference message contained a Disc_Bit = 1 or when FDCAN_TTOST.QCS = 0.

59.4.13 TTCAN error level

The ISO 11898-4 specifies four levels of error severity:
1. S0 - No error
2. S1 - Warning - Only notification of application, reaction application-specific.
3. S2 error - Notification of application. All transmissions in exclusive or arbitrating time windows are disabled (i.e. no data or remote frames may be started). Potential time masters still transmit reference messages with the reference trigger offset FDCAN_TTOST.RTO set to the maximum value of 127.
4. S3 - Severe error - Notification of application. All CAN bus operations are stopped, i.e. transmission of dominant bits is not allowed, and FDCAN_CCCR.MON is set. The S3 error condition remains active until the application updates the configuration (set FDCAN_CCCR.CCE).

If several errors are detected at the same time, the highest severity prevails. When an error is detected, the application is notified by FDCAN_TTIR.ELC. The error level is monitored by FDCAN_TTOST.EL.

The TTCAN signals the following error conditions as required by ISO 11898-4:
- **Config_error** (S3)
  - Sets error level FDCAN_TTOST.EL to 11 when a merged arbitrating time window is not properly closed or when there is a Tx_Trigger with a time mark beyond the Tx_Ref_Trigger.
- **Watch_Trigger_Reached** (S3)
  - Sets error level FDCAN_TTOST.EL to 11 when a watch trigger was reached because the reference message is missing.
- **Application_Watchdog** (S3)
  - Sets error level FDCAN_TTOST.EL to 11 when the application failed to serve the application watchdog. The application watchdog is configured via FDCAN_TTOCF.AWL. It is served by reading register FDCAN_TTOST. When the watchdog is not served in time, bit FDCAN_TTOST.AWE and interrupt flag
FDCAN_TTIR.AW are set, all FDCAN communication is stopped, and the FDCAN is set into bus monitoring mode (FDCAN_CCCR.MON set to 1).

- **CAN_Bus_Off (S3)**
  - Entering CAN_Bus_Off state sets error level FDCAN_TTOST.EL to 11.
  - CAN_Bus_Off state is signaled by FDCAN_PSR.BO = 1 and FDCAN_CCCR.INIT = 1.

- **Scheduling_Error_2 (S2)**
  - Sets error level FDCAN_TTOST.EL to 10 if the MSC of one Tx_Trigger has reached 7. In addition, interrupt flag FDCAN_TTIR.SE2 is set. The error level FDCAN_TTOST.EL is reset to 00 at the beginning of a matrix cycle when no Tx_Trigger has an MSC of 7 in the preceding matrix cycle.

- **Tx_Overflow (S2)**
  - Sets error level FDCAN_TTOST.EL to 10 when the Tx count is equal to or higher than the expected number of Tx Triggers FDCAN_TTMLM.ENTT and a Tx_Trigger event occurs. In addition, interrupt flag FDCAN_TTIR.TXO is set. The error level FDCAN_TTOST.EL is reset to 00 when the Tx count is no more than FDCAN_TTMLM.ENTT at the start of a new matrix cycle.

- **Scheduling_Error_1 (S1)**
  - Sets error level FDCAN_TTOST.EL to 01 if within one matrix cycle the difference between the maximum MSC and the minimum MSC for all trigger memory elements (of exclusive time windows) is larger than two, or if one of the MSCs of an exclusive Rx_Trigger has reached seven. In addition, interrupt flag FDCAN_TTIR.SE1 is set. If within one matrix cycle none of these conditions is valid, the error level FDCAN_TTOST.EL is reset to 00.

- **Tx_Underflow (S1)**
  - Sets error level FDCAN_TTOST.EL to 01 when the Tx count is less than the expected number of Tx_Triggers FDCAN_TTMLM.ENTT at the start of a new matrix cycle. In addition, interrupt flag FDCAN_TTIR.TXU is set. The error level FDCAN_TTOST.EL is reset to 00 when the Tx count is at least FDCAN_TTMLM.ENTT at the start of a new matrix cycle.

### 59.14 TTCAN message handling

#### Reference message

For potential time masters the identifier of the reference message is configured via FDCAN_TTRMC.RID. No dedicated Tx buffer is required for transmission of the reference message. When a reference message is transmitted, the first data byte for TTCAN level 1 (that is, the first four data bytes for TTCAN level 0 and the first four data bytes for TTCAN level 2) is provided by the FSE.

In case the reference message Payload select FDCAN_TTRMC.RMPS is set, the rest of the reference message payload (level 1: bytes 2-8, level 0, 2: bytes 5-6) is taken from Tx buffer 0. In this case the data length DLC code from message buffer 0 is used.

<table>
<thead>
<tr>
<th>FDCAN_TTRMC.RMPS</th>
<th>FDCAN_TXBRP.TRPO</th>
<th>Level 0</th>
<th>Level 1</th>
<th>Level 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>4</td>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>4</td>
<td>1</td>
<td>4</td>
</tr>
</tbody>
</table>
To send additional payload with the reference message in level 1 a DLC > 1 must be configured, for level 0 and level 2 a DLC > 4 is required. In addition, the transmission request pending bit FDCAN_TXBRP.TRP0 of message buffer 0 must be set (see Table 513). In case bit FDCAN_TXBRP.TRP0 is not set when a reference message is started, the reference message is transmitted with the data bytes supplied by the FSE only.

For acceptance filtering of reference messages the reference identifier FDCAN_TTRMC.RID is used.

**Message reception**

Message reception is done via the two Rx FIFOs in the same way as for event-driven CAN communication (see *Rx handler*).

The message status count MSC is part of the corresponding trigger memory element and must be initialized to 0 during configuration. It is updated while the TTCAN is in synchronization states In_Gap or In_Schedule. The update happens at the message Rx_Trigger. At this point in time it is checked at which acceptance filter element the latest message received in this basic cycle had matched. The matching filter number is stored as the acceptance filter result. If this is the same the filter number as defined in this trigger memory element, the MSC is decremented by one. If the acceptance filter result is not the same filter number as defined for this filter element, or if the acceptance filter result is cleared, the MSC is incremented by one. At each Rx_Trigger and at each start of cycle, the last acceptance filter result is cleared.

The time mark of an Rx_Trigger should be set to a value where it is ensured that reception and acceptance filtering for the targeted message has completed. This has to take into consideration the RAM access time and the order of the filter list. It is recommended, that filters which are used for Rx_Triggers are placed at the beginning of the filter list. It is not recommended to use an Rx_Trigger for the reference message.

**Message transmission**

For time-triggered message transmission the TTCAN supplies 32 dedicated Tx buffers (see *Transmit pause*). A Tx FIFO or Tx queue is not available when the FDCAN is configured for time-triggered operation (FDCAN_TTOCF.OM = 01 or 10).

Each Tx_Trigger in the trigger memory points to a particular Tx buffer containing a specific message. There may be more than one Tx_Trigger for a given Tx buffer if that Tx buffer contains a message that is to be transmitted more than once in a basic cycle or matrix cycle.

The application program has to update the data regularly and on time, synchronized to the cycle time. The user is responsible that no partially updated messages are transmitted. To assure this the user has to proceed in the following way:

---

### Table 513. Number of data bytes transmitted with a reference message (continued)

</tr>
</tbody>
</table>
Tx_Trigger_Single / Tx_Trigger_Merged / Tx_Trigger_Arbitration

- Check whether the previous transmission has completed by reading FDCAN_TXBTO
- Update the Tx buffer configuration and/or payload
- Issue an add request to set the Tx buffer request pending bit

Tx_Trigger_Continuous

- Issue a cancellation request to reset the Tx buffer request pending bit
- Check whether the cancellation has finished by reading FDCAN_TXBCF
- Update Tx buffer configuration and/or payload
- Issue an add request to set the Tx buffer request pending bit

The message MSC stored with the corresponding Tx_Trigger provides information on the success of the transmission.

The MSC is incremented by one when the transmission cannot be started because the CAN bus was not idle within the corresponding transmit enable window or when the message was started and cannot be completed successfully. The MSC is decremented by one when the message was transmitted successfully or when the message may have been started within its transmit enable window but was not started because transmission was disabled (TTCAN in error level S2 or user has disabled this particular message).

The Tx buffers may be managed dynamically, i.e. several messages with different identifiers may share the same Tx buffer element. In this case the user must ensure that no transmission request is pending for the Tx buffer element to be reconfigured by checking FDCAN_TXBRP.

If a Tx buffer with pending transmission request should be updated, the user must first issue a cancellation request and check whether the cancellation has completed by reading FDCAN_TXBCF before it starts updating.

The Tx handler transfers a message from the message RAM to its intermediate output buffer at the trigger element, which becomes active immediately before the Tx_Trigger element (which defines the beginning of the transmit window). During and after the transfer time the transmit message may not be updated and its FDCAN_TXBRP bit may not be changed. To control this transfer time, an additional trigger element may be placed before the Tx_Trigger. This may be example of a Time_Base_Trigger which need not cause any other action. The difference in time marks between the Tx_Trigger and the preceding trigger must be large enough to guarantee that the Tx handler can read four words from the message RAM even at high RAM access load from other modules.

Transmission in exclusive time windows

A transmission is started time-triggered when the cycle time reaches the time mark of a Tx_Trigger_Single or Tx_Trigger_Continuous. There is no arbitration on the bus with messages from other nodes. The MSC is updated according the result of the transmission attempt. After successful transmission started by a Tx_Trigger_Single the respective Tx buffer request pending bit is reset. After successful transmission started by a Tx_Trigger_Continuous the respective Tx buffer request pending remains set. When the transmission was not successful due to disturbances, it is repeated next time (one of) its Tx_Trigger(s) become(s) active.
Transmission in arbitrating time windows

A transmission is started time-triggered when the cycle time reaches the time mark of a Tx_Trigger_Arbitration. Several nodes may start to transmit at the same time. In this case the message has to arbitrate with the messages from other nodes. The MSC is not updated. When the transmission was not successful (lost arbitration or disturbance), it is repeated next time (one of) its Tx_Trigger(s) become(s) active.

Transmission in merged arbitrating time windows

The purpose of a merged arbitrating time window is, to enable multiple nodes to send a limited number of frames which are transmitted in immediate sequence, the order given by CAN arbitration. It is not intended for burst transmission by a node. Since the node does not have exclusive access within this time window, it may happen that not all requested transmissions are successful.

Messages which have lost arbitration or were disturbed by an error, may be re-transmitted inside the same merged arbitrating time window. The re-transmission is not started if the corresponding transmission request pending flag is reset by a successful Tx cancellation.

In single transmit windows, the Tx handler transmits the message indicated by the message number of the trigger element. In merged arbitrating time windows, it can handle up to three message numbers from the trigger list. Their transmission is attempted in the sequence defined by the trigger list. If the time mark of a fourth message is reached before the first is transmitted (or canceled by the user), the fourth request is ignored.

The transmission inside a merged arbitrating time window is not time-triggered. The transmission of a message may start before its time mark, or after the time mark if the bus was not idle.

The messages transmitted by a specific node inside a merged arbitrating time window are started in the order of their Tx_Triggers, so a message with low CAN priority may prevent the successful transmission of a following message with higher priority, if there is compelling bus traffic. This must be considered for the configuration of the trigger list.

Time_Base_Triggers may be placed between consecutive Tx_Triggers to define the time until the data of the corresponding Tx buffer needs to be updated.

59.4.15 TTCAN interrupt and error handling

The TT interrupt register FDCAN_TTIR consists of four segments. Each interrupt can be enabled separately by the corresponding bit in the TT interrupt enable register FDCAN_TTIE. The flags remain set until the user clears them. A flag is cleared by writing a 1 to the corresponding bit position.

The first segment consists of flags CER, AW, WT, and IWT. Each flag indicates a fatal error condition where the CAN communication is stopped. With the exception of IWT, these error conditions require a re-configuration of the FDCAN module before the communication can be restarted.

The second segment consists of flags ELC, SE1, SE2, TXO, TXU, and GTE. Each flag indicates an error condition where the CAN communication is disturbed. If they are caused by a transient failure, for example by disturbances on the CAN bus, they are handled by the FDCAN protocol failure handling and do not require intervention by the application program.

The third segment consists of flags GTD, GTW, SWE, TTMI, and RTMI. The first two flags are controlled by global time events (level 0, 2 only) that require a reaction by the application program. With a stop watch event triggered by a rising edge on pin fdcan_swt internal time
values are captured. The trigger time mark interrupt notifies the application that a specific Time_Base_Trigger is reached. The register time mark interrupt signals that the time referenced by FDCAN_TTOCN.TMC (cycle, local, or global) is equal to the time mark FDCAN_TTTMK.TM. It can also be used to finish a gap.

The fourth segment consists of flags SOG, CSM, SMC, and SBC. These flags provide a means to synchronize the application program to the communication schedule.

59.4.16 Level 0

TTCAN level 0 is not part of ISO11898-4. This operation mode makes the hardware, that in TTCAN level 2 maintains the calibrated global time base, also available for event-driven CAN according to ISO11898-1.

Level 0 operation is configured via FDCAN_TTOCF.OM = 11. In this mode the FDCAN operates in event driven CAN communication, there is no fixed schedule, the configuration of FDCAN_TTOCF.GEN is ignored. External event-synchronized operation is not available in level 0. A synchronized time base is maintained by transmission of reference messages.

In level 0 the trigger memory is not active and therefore needs not to be configured. The time mark interrupt flag (FDCAN_TTIR.TTMI) is set when the cycle time has reached FDCAN_TTOCF.IRTO ∗ 0x200, it reminds the user to set a transmission request for message buffer 0. The Watch_Trigger interrupt flag (FDCAN_TTIR.WT) is set when the cycle time has reached 0xFF00. These values were chosen to have enough margin for a stable clock calibration. There are no further TT-error-checks.

Register time mark interrupts (FDCAN_TTIR.RTMI) are also possible.

The reference message is configured as for level 2 operation. Received reference messages are recognized by the identifier configured in register FDCAN_TTRMC. For the transmission of reference messages only message buffer 0 may be used. The node transmits reference messages any time the user sets a transmission request for message buffer 0, there is no reference trigger offset.

Level 0 operation is configured via:

- FDCAN_TTRMC
- FDCAN_TTOCF except EVTP, AWL, GEN
- FDCAN_TTMLM except ENTT, TXEW
- FDCAN_TURCF

Level 0 operation is controlled via:

- FDCAN_TTOCN except NIG, TMG, FGP, GCS, TTMIE
- FDCAN_TTGTP
- FDCAN_TTTMK
- FDCAN_TTIR excluding bits CER, AW, IWT SE2, SE1, TXO, TXU, SOG (no function)
- FDCAN_TTIR the following bits have changed function
  - TTMI not defined by trigger memory - activated at cycle time FDCAN_TTOCF.IRTO 0x200
  - WT not defined by trigger memory - activated at cycle time 0xFF00

Level 0 operation is signaled via:

- TTOST excluding bits AWE, WFE, GSI, GFI, RTO (no function)
Synchronizing

*Figure 790* describes the states and the state transitions in TTCAN level 0 operation. Level 0 has no In_Gap state.

*Figure 790. Level 0 schedule synchronization state machine*

- **T0**: Transition condition always taking prevalence
- **T1**: Init state left, cycle time is 0
- **T2**: At least two consecutive reference messages observed (last reference message didn't contain a set Disc_Bit or Next_is_Gap bit)

Handling of error levels

During level 0 operation only the following error conditions may occur:
- Watch_Trigger_Reached (S3), reached cycle time 0xFF00
- CAN_Bus_Off (S3)

Since no S1 and S2 errors are possible, the error level can only switch between S0 (No error) and S3 (Severe error). In TTCAN level 0 an S3 error is handled differently. When error level S3 is reached, both FDCAN_TTOST.SYS and FDCAN_TTOST.MS are reset, and interrupt flags FDCAN_TTIR.GTE and FDCAN_TTIR.GTD are set.

When error level S3 (FDCAN_TTOST.EL = 11) is entered, bus monitoring mode is (contrary to TTCAN level 1 and level 2) not entered. S3 error level is left automatically after transmission (time master) or reception (time slave) of the next reference message.
Master slave relation

*Figure 791* describes the master slave relation in TTCAN level 0. In case of an S3 error the FDCAN returns to state Master_Off.

*Figure 791. Level 0 master to slave relation*

59.4.17 Synchronization to external time schedule

This feature can be used to synchronize the phase of the FDCAN schedule to an external schedule (for example that of a second TTCAN network or FlexRay network). It is applicable only when the FDCAN is current time master (FDCAN_TTOST.MS = 11).

External synchronization is controlled by event trigger input pin fdcan_evt. If bit FDCAN_TTOCN.ESCN is set, a rising edge at event trigger pin fdcan_evt the FDCAN compares its actual cycle time with the target phase value configured by FDCAN_TTGTP.CTP.

Before setting FDCAN_TTOCN.ESCN the user has to adapt the phases of the two time schedules for example by using the FDCAN gap control (see *Section 59.4.10*). When the user sets FDCAN_TTOCN.ESCN, FDCAN_TTOSTSPL is set.

If the difference between the cycle time and the target phase value FDCAN_TTGTP.CTP at the rising edge at event trigger pin fdcan_evt is greater than 9 NTU, the phase lock bit FDCAN_TTOST.SPL is reset, and interrupt flag FDCAN_TTIR.CSM is set.
FDCAN_TTOST.SPL is also reset (and FDCAN_TTIR.CSM is set), when another node becomes time master.

If both FDCAN_TTOST.SPL and FDCAN_TTOCN.ESCN are set, and if the difference between the cycle time and the target phase value FDCAN_TTGTP.CTP at the rising edge at event trigger pin fdcan_evt is lower or equal to nine NTU, the phase lock bit FDCAN_TTOST.SPL remains set, and the measured difference is used as reference trigger offset value to adjust the phase at the next transmitted reference message.

Note: The rising edge detection at event trigger pin fdcan_evt is enabled with the start of each basic cycle. The first rising edge triggers the compare of the actual cycle time with FDCAN_TTGTP.CTP. All further edges until the beginning of the next basic cycle are ignored.

59.4.18 FDCAN Rx buffer and FIFO element

Up to 64 Rx buffers and two Rx FIFOs can be configured in the message RAM. Each Rx FIFO section can be configured to store up to 64 received messages. The structure of a Rx buffer / FIFO element is shown in Table 514, the description is provided in Table 515.

59.4.19 FDCAN Tx buffer element

The Tx buffers section can be configured to hold dedicated Tx buffers as well as a Tx FIFO / Tx queue. In case that the Tx buffers section is shared by dedicated Tx buffers and a Tx FIFO / Tx queue, the dedicated Tx buffers start at the beginning of the Tx buffers section followed by the buffers assigned to the Tx FIFO or Tx queue. The Tx handler distinguishes between dedicated Tx buffers and Tx FIFO / Tx queue by evaluating the Tx buffer configuration FDCAN_TXBC.TFQS and FDCAN_TXBC.NDTB. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via register FDCAN_TXESC.

59.4.20 FDCAN Tx event FIFO element

Each element stores information about transmitted messages. By reading the Tx event FIFO the user gets this information in the order the messages were transmitted. Status information about the Tx event FIFO can be obtained from register FDCAN_TXEFS.

</table>
| E1 bits 23:22 EFC | Event type  
  – 00: Reserved  
  – 01: Tx event  
  – 10: Transmission in spite of cancellation (always set for transmissions in DAR mode)  
  – 11: Reserved |
| E1 bit 21 EDL | Extended data length  
  – 0: Standard frame format  
  – 1: FDCAN frame format (new DLC-coding and CRC) |
| E1 bit 20 BRS | Bitrate switching  
  – 0: Frame transmitted without bitrate switching  
  – 1: Frame transmitted with bitrate switching |
| T1 bits 19:16 DLC[3:0] | Data length code  
  – 0 - 8: Frame with 0-8 data bytes transmitted  
  – 9 - 15: Frame with eight data bytes transmitted |
| E1 bits 15:0 TXTS[15:0] | Tx timestamp  
  Timestamp counter value captured on start of frame transmission. Resolution depending on configuration of the timestamp counter prescaler FDCAN_TSCC.TCP. |
### Table 521. Standard message ID filter element field description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| Bit 31:30 SFT[1:0](1) | Standard filter type  
- 00: Range filter from SFID1 to SFID2  
- 01: Dual ID filter for SFID1 or SFID2  
- 10: Classic filter: SFID1 = filter, SFID2 = mask  
- 11: Filter element disabled |
| Bit 29:27 SFEC[2:0] | Standard filter element configuration  
All enabled filter elements are used for acceptance filtering of standard frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached. If SFEC = “100”, “101”, or “110” a match sets interrupt flag FDCAN_IR.HPM and, if enabled, an interrupt is generated. In this case register FDCAN_HPMS is updated with the status of the priority match.  
- 000: Disable filter element  
- 001: Store in Rx FIFO 0 if filter matches  
- 010: Store in Rx FIFO 1 if filter matches  
- 011: Reject ID if filter matches  
- 100: Set priority if filter matches  
- 101: Set priority and store in FIFO 0 if filter matches  
- 110: Set priority and store in FIFO 1 if filter matches  
- 111: Store into Rx buffer or as debug message, configuration of FDCAN_SFT[1:0] ignored |
| Bits 26:16 SFID1[10:0] | Standard filter ID 1  
First ID of standard ID filter element. When filtering for Rx buffers or for debug messages this field defines the ID of a standard message to be stored. The received identifiers must match exactly, no masking mechanism is used. |
| SFID2[15:10] | Standard filter ID 2  
This bit field has a different meaning depending on the configuration of SFEC:  
- SFEC = 001 ... 110 Second ID of standard ID filter element  
- SFEC = 111 Filter for Rx buffers or for debug messages |
| SFID2[10:9] | Decides whether the received message is stored into an Rx buffer or treated as message A, B, or C of the debug message sequence.  
- 00: Store message into an Rx buffer  
- 01: Debug message A  
- 10: Debug message B  
- 11: Debug message C |
| SFID2[8:6] | Is used to control the filter event pins at the Extension Interface. A 1 at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one fdcan_pclk period in case the filter matches. SFID2[8] is used by the calibration unit. |
| SFID2[5:0] | Defines the offset to the Rx buffer start address FDCAN_RXBC.RBSA for storage of a matching message. |

1. With SFT = “11” the filter element is disabled and the acceptance filtering continues (same behavior as with SFEC = “000”).

**Note:** In case a reserved value is configured, the filter element is considered disabled.
59.4.22 **FDCAN extended message ID filter element**

Up to 64 filter elements can be configured for 29-bit extended IDs. When accessing an Extended message ID filter element, its address is the filter list extended start address FDCAN_XIDFC.FLESA plus two times the index of the filter element (0 … 63).

</tbody>
</table>

1. The trigger memory elements have to be written when the FDCAN is in INIT state. Write access to the trigger memory elements outside INIT state is not allowed. There is an exception for TMIN and TMEX when they are defined as part of a trigger memory element of TYPE Tx_Ref_Trigger. In this case they become active at the time mark modified by the actual reference trigger offset (TTOST|RTO|).
59.5 **FDCAN registers**

59.5.1 **FDCAN core release register (FDCAN_CREL)**

</tbody>
</table>

Bits 31:28 **REL[3:0]**: Core release = 3
Bits 27:24 **STEP[3:0]**: Step of core release = 2
Bits 23:20 **SUBSTEP[3:0]**: Sub-step of core release = 1
Bits 19:16 **YEAR[3:0]**: Timestamp year = 4

59.5.2 **FDCAN Endian register (FDCAN_ENDN)**

Address offset: 0x0004
Reset value: 0x8765 4321

<table>
<thead>
<tr>
<th>ETV[31:16]</th>
</tr>
</thead>
<tbody>
<tr>
<td>15 14 13 12</td>
</tr>
</tbody>
</table>

Bits 31:0 **ETV[31:0]**: Endianness test value

The endianness test value is 0x8765 4321.
59.5.3 FDCAN data bit timing and prescaler register (FDCAN_DBTP)

Address offset: 0x000C

Reset value: 0x0000 0A33

This register is dedicated to data bit timing phase and only writable if bits FDCAN_CCCR.CCE and FDCAN_CCCR.INIT are set. The CAN time quantum may be programmed in the range from 1 to 32 FDCAN clock periods. \( t_q = (DBRP + 1) \) FDCAN clock periods.

DTSEG1 is the sum of Prop_Seg and Phase_Seg1. DTSEG2 is Phase_Seg2. Therefore the length of the bit time is \((DTSEG1 + DTSEG2 + 3) t_q\) for programmed values, or \((Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2) t_q\) for functional values.

The information processing time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.

| Bit 31:24 | Reserved, must be kept at reset value. |
| Bit 23   | **TDC**: Transceiver delay compensation |
| 0:       | Transceiver delay compensation disabled |
| 1:       | Transceiver delay compensation enabled |

| Bit 22:21 | Reserved, must be kept at reset value. |

| Bit 20:16 | **DBRP[4:0]**: Data bitrate prescaler |
|          | The value by which the oscillator frequency is divided to generate the bit time quanta. The bit time is built up from a multiple of these quanta. Valid values for the baudrate prescaler are 0 to 31. The hardware interpreters this value as the programmed value plus 1. |

| Bit 15:13 | Reserved, must be kept at reset value. |

| Bit 12:8 | **DTSEG1[4:0]**: Data time segment before sample point |
|          | Valid values are 0 to 31. The value used by the hardware is the one programmed, incremented by 1, i.e. \( t_{BS1} = (DTSEG1 + 1) x t_q \). |

| Bit 7:4  | **DTSEG2[3:0]**: Data time segment after sample point |
|          | Valid values are 0 to 15. The value used by the hardware is the one programmed, incremented by 1, i.e. \( t_{BS2} = (DTSEG2 + 1) x t_q \). |

| Bit 3:0  | **DSJW[3:0]**: Synchronization jump width |
|          | Valid values are 0 to 15. The value used by the hardware is the one programmed, incremented by 1, i.e. \( t_{SJW} = (DSJW + 1) x t_q \). |

**Note:** With an FDCAN clock of 8 MHz, the reset value 0x00000A33 configures the FDCAN for a fast bitrate of 500 kbit/s.

**Note:** The data phase bit rate must be higher than or equal to the nominal bit rate.
59.5.4 **FDCAN test register (FDCAN_TEST)**

Write access to this register must be enabled by setting bit FDCAN_CCCR.TEST to 1. All register functions are set to their reset values when bit FDCAN_CCCR.TEST is reset.

Loop back mode and software control of Tx pin FDCANx_TX are hardware test modes. Programming TX differently from 00 may disturb the message transfer on the CAN bus.

Address offset: 0x0010
Reset value: 0x0000 0000

Bit 7 **RX**: Receive pin
- Monitors the actual value of transmit pin FDCANx_RX
  - 0: The CAN bus is dominant (FDCANx_RX = 0)
  - 1: The CAN bus is recessive (FDCANx_RX = 1)

Bits 6:5 **TX[1:0]**: Control of transmit pin
- 00: Reset value, FDCANx_TX TX is controlled by the CAN core, updated at the end of the CAN bit time
- 01: Sample point can be monitored at pin FDCANx_TX
- 10: Dominant (0) level at pin FDCANx_TX
- 11: Recessive (1) at pin FDCANx_TX

Bit 4 **LBCK**: Loop back mode
- 0: Reset value, loop back mode is disabled
- 1: Loop back mode is enabled (see Test modes)

Bits 3:0 Reserved, must be kept at reset value.

59.5.5 **FDCAN RAM watchdog register (FDCAN_RWD)**

The RAM watchdog monitors the READY output of the message RAM. A message RAM access starts the message RAM watchdog counter with the value configured by the FDCAN_RWD.WDC bits.

The counter is reloaded with FDCAN_RWD.WDC bits when the message RAM signals successful completion by activating its READY output. In case there is no response from the message RAM until the counter has counted down to 0, the counter stops and interrupt flag FDCAN_IR.WDI bit is set. The RAM watchdog counter is clocked by the fdcan_pclk clock.

Address offset: 0x0014
Reset value: 0x0000 0000
RM0399

Controller area network with flexible data rate (FDCAN)

59.5.6  FDCAN CC control register (FDCAN_CCCR)

Address offset: 0x0018
Reset value: 0x0000 0001

For details about setting and resetting of single bits, see **Software initialization**.

</tbody>
</table>

Bits 31:16  Reserved, must be kept at reset value.

Bits 15:8  **WDV[7:0]**: Watchdog value

- Actual message RAM watchdog counter value.

Bits 7:0  **WDC[7:0]**: Watchdog configuration

- Start value of the message RAM watchdog counter. With the reset value of 00 the counter is disabled.
- These are write-protected bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

## Bits 31:16

### Bit 31  **NISO**: Non ISO operation

- If this bit is set, the FDCAN uses the CAN FD frame format as specified by the Bosch CAN FD Specification V1.0.
  - 0: CAN FD frame format according to ISO11898-1
  - 1: CAN FD frame format according to Bosch CAN FD Specification V1.0

### Bit 15  **TXP**:

- If this bit is set, the FDCAN pauses for two CAN bit times before starting the next transmission after successfully transmitting a frame.
  - 0: Disabled
  - 1: Enabled

### Bit 14  **EFBI**: Edge filtering during bus integration

- 0: Edge filtering disabled
- 1: Two consecutive dominant tq required to detect an edge for hard synchronization
Bit 12 **PXHD**: Protocol exception handling disable
0: Protocol exception handling enabled
1: Protocol exception handling disabled

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **BRSE**: FDCAN bitrate switching
0: Bitrate switching for transmissions disabled
1: Bitrate switching for transmissions enabled

Bit 8 **FDOE**: FD operation enable
0: FD operation disabled
1: FD operation enabled

Bit 7 **TEST**: Test mode enable
0: Normal operation, register TEST holds reset values
1: Test mode, write access to register TEST enabled

Bit 6 **DAR**: Disable automatic retransmission
0: Automatic retransmission of messages not transmitted successfully enabled
1: Automatic retransmission disabled

Bit 5 **MON**: Bus monitoring mode
Bit MON can be set only by software when both CCE and INIT are set to 1. The bit can be reset by the user at any time.
0: Bus monitoring mode is disabled
1: Bus monitoring mode is enabled

Bit 4 **CSR**: Clock stop request
0: No clock stop is requested
1: Clock stop requested. When clock stop is requested, first INIT and then CSA is set after all pending transfer requests have been completed and the CAN bus reached idle.

Bit 3 **CSA**: Clock stop acknowledge
0: No clock stop acknowledged
1: FDCAN may be set in power down by stopping APB clock and kernel clock

Bit 2 **ASM**: ASM restricted operation mode
The restricted operation mode is intended for applications that adapt themselves to different CAN bitrates. The application tests different bitrates and leaves the restricted operation mode after it has received a valid frame. In the optional restricted operation mode the node is able to transmit and receive data and remote frames and it gives acknowledge to valid frames, but it does not send active error frames or overload frames. In case of an error condition or overload condition, it does not send dominant bits, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication. The error counters are not incremented. Bit ASM can be set only by software when both CCE and INIT are set to 1. The bit can be reset by the software at any time. This bit is set automatically set to 1 when the Tx handler was not able to read data from the message RAM in time. If the FDCAN is connected to a clock calibration on CAN unit, ASM bit is set by hardware as long as the calibration is not completed.
0: Normal CAN operation
1: Restricted operation mode active

Bit 1 **CCE**: Configuration change enable
0: The CPU has no write access to the protected configuration registers
1: The CPU has write access to the protected configuration registers (while FDCAN_CCCR.INIT = 1 CCE bit is automatically cleared when INIT bit is cleared)
Note: Due to the synchronization mechanism between the two clock domains, there may be a delay until the value written to INIT can be read back. Therefore the programmer must ensure that the previous value written to INIT has been accepted by reading INIT before setting INIT to a new value.

59.5.7 FDCAN nominal bit timing and prescaler register (FDCAN_NBTP)

Address offset: 0x001C
Reset value: 0x0600 0A03

This register is dedicated to the nominal bit timing used during the arbitration phase, and is only writable if bits FDCAN_CCCR.CCE and FDCAN_CCCR.INIT are set. The CAN bit time may be programed in the range of 4 to 81 tq. The CAN time quantum may be programmed in the range of \([1 \ldots 1024]\) FDCAN kernel clock periods.

tq = (BRP + 1) FDCAN clock period fdcan_tq_ck

NTSEG1 is the sum of Prop_Seg and Phase_Seg1. NTSEG2 is Phase_Seg2. Therefore the length of the bit time is (programmed values) \([NTSEG1 + NTSEG2 + 3]\) tq or (functional values) \([Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2]\) tq.

The information processing time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.

Bits 31:25 **NSJW[6:0]**: Nominal (re)synchronization jump width
Should be smaller than NTSEG2, valid values are 0 to 127. The value used by the hardware is the one programmed, incremented by 1, i.e. \(t_{SJW} = (NSJW + 1) \times tq\).
These are write-protected bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bits 24:16 **NBRP[8:0]**: Bitrate prescaler
Value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta. Valid values are 0 to 511. The value used by the hardware is the one programmed, incremented by 1.
These are write-protected bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.
Note: With a CAN kernel clock of 8 MHz, the reset value of 0x00000A33 configures the FDCAN for a bitrate of 125 kbit/s.

59.5.8 FDCAN timestamp counter configuration register (FDCAN_TSCC)

Bits 15:2 Reserved, must be kept at reset value.

Bits 19:16 TCP[3:0]: Timestamp counter prescaler
Configures the timestamp and timeout counters time unit in multiples of CAN bit times [1 ... 16].
The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.
In CAN FD mode the internal timestamp counter TCP does not provide a constant time base due to the different CAN bit times between arbitration phase and data phase. Thus CAN FD requires an external counter for timestamp generation (TSS = 10).
These are write-protected bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bits 15:2 Reserved, must be kept at reset value.

Bits 1:0 TSS[1:0]: Timestamp select
00: Timestamp counter value always 0x0000
01: Timestamp counter value incremented according to TCP
10: External timestamp counter from TIM3 value used (tim3_cnt[0:15])
11: Same as 00.
These are write-protected bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.
### 59.5.9 FDCAN timestamp counter value register (FDCAN_TSCV)

Address offset: 0x0024  
Reset value: 0x0000 0000

<td></td>
<td></td>
</tr>
</tbody>
</table>

- **TSC[15:0]:** Timestamp counter  
  - The internal/external timestamp counter value is captured on start of frame (both Rx and Tx). When FDCAN_TSCC.TSS = 01, the timestamp counter is incremented in multiples of CAN bit times [1 ... 16] depending on the configuration of FDCAN_TSCC.TCP. A wrap around sets interrupt flag FDCAN_IR.TSW. Write access resets the counter to 0. When FDCAN_TSCC.TSS = 10, TSC reflects the external timestamp counter value. A write access has no impact.

- **Note:** A “wrap around” is a change of the timestamp counter value from non-0 to 0 not caused by write access to FDCAN_TSCV.

**EP**  
- 0: Error passive  
- 1: Error active

**ACT[1:0]**  
- 00: FDCAN_INACTIVE  
- 01: FDCAN_FULL  
- 10: FDCAN_STANDBY  
- 11: FDCAN_RESERVED

**LEC[2:0]**: Link error counter  
- 0: Error passive  
- 1: Error active

**Bits 31:24**  
Reserved, must be kept at reset value.

**Bits 23:16**  
**CEL[7:0]**: CAN error logging  
The counter is incremented each time when a CAN protocol error causes the transmit error counter or the receive error counter to be incremented. It is reset by read access to CEL. The counter stops at 0xFF; the next increment of TEC or REC sets interrupt flag FDCAN_IR.ELO.

**Bit 15**  
**RP**: Receive error passive  
- 0: The receive error counter is below the error passive level of 128  
- 1: The receive error counter has reached the error passive level of 128

**Bits 14:8**  
**REC[6:0]**: Receive error counter  
Actual state of the receive error counter, values between 0 and 127.

**Bits 7:0**  
**TEC[7:0]**: Transmit error counter  
Actual state of the transmit error counter, values between 0 and 255.  
When FDCAN_CCCR.ASM is set, the CAN protocol controller does not increment TEC and REC when a CAN protocol error is detected, but CEL is still incremented.

**Bits 31:23**  
Reserved, must be kept at reset value.

**Bits 22:16**  
**TDCV[6:0]**: Transmitter delay compensation value  
Position of the secondary sample point, defined by the sum of the measured delay from FDCAN_TX to FDCAN_RX and FDCAN_TDCR.TDCO. The SSP position is, in the data phase, the number of minimum time quanta (mtq) between the start of the transmitted bit and the secondary sample point. Valid values are 0 to 127 mtq.
Bit 15  Reserved, must be kept at reset value.

Bit 14  **PXE**: Protocol exception event
- 0: No protocol exception event occurred since last read access
- 1: Protocol exception event occurred

Bit 13  **REDL**: Received FDCAN message
This bit is set independent of acceptance filtering.
- 0: Since this bit was reset by the CPU, no FDCAN message has been received
- 1: Message in FDCAN format with EDL flag set has been received
Access type is RX: reset on read.

Bit 12  **RBRS**: BRS flag of last received FDCAN message
This bit is set together with REDL, independent of acceptance filtering.
- 0: Last received FDCAN message did not have its BRS flag set
- 1: Last received FDCAN message had its BRS flag set
Access type is RX: reset on read.

Bit 11  **RESI**: ESI flag of last received FDCAN message
This bit is set together with REDL, independent of acceptance filtering.
- 0: Last received FDCAN message did not have its ESI flag set
- 1: Last received FDCAN message had its ESI flag set
Access type is RX: reset on read.

Bits 10:8  **DLEC[2:0]**: Data last error code
Type of last error that occurred in the data phase of an FDCAN format frame with its BRS flag set.
Coding is the same as for LEC. This field is cleared to 0 when an FDCAN format frame with its BRS flag set has been transferred (reception or transmission) without error.
Access type is RS: set on read.

Bit 7  **BO**: Bus_Off status
- 0: The FDCAN is not Bus_Off
- 1: The FDCAN is in Bus_Off state

Bit 6  **EW**: Warning status
- 0: Both error counters are below the Error_Warning limit of 96
- 1: At least one of error counter has reached the Error_Warning limit of 96

Bit 5  **EP**: Error passive
- 0: The FDCAN is in the Error_Active state. It normally takes part in bus communication and sends an active error flag when an error has been detected
- 1: The FDCAN is in the Error_Passive state

Bits 4:3  **ACT[1:0]**: Activity
Monitors the module CAN communication state.
- 00: Synchronizing: node is synchronizing on CAN communication
- 01: Idle: node is neither receiver nor transmitter
- 10: Receiver: node is operating as receiver
- 11: Transmitter: node is operating as transmitter
Bits 2:0  **LEC[2:0]: Last error code**

The LEC indicates the type of the last error to occur on the CAN bus. This field is cleared to 0 when a message has been transferred (reception or transmission) without error.

000: No error: No error occurred since LEC has been reset by successful reception or transmission.

001: Stuff error: More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed.

010: Form error: A fixed format part of a received frame has the wrong format.

011: AckError: The message transmitted by the FDCAN was not acknowledged by another node.

100: Bit1Error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value 1), but the monitored bus value was dominant.

101: Bit0Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (data or identifier bit logical value 0), but the monitored bus value was recessive. During Bus_Off recovery this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus_Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed).

110: CRCError: The CRC check sum of a received message was incorrect. The CRC of an incoming message does not match with the CRC calculated from the received data.

111: NoChange: Any read access to the protocol status register re-initializes the LEC to ’7. When the LEC shows the value 7, no CAN bus event was detected since the last CPU read access to the protocol status register.

Access type is RS: set on read.

**Note:** When a frame in FDCAN format has reached the data phase with BRS flag set, the next CAN event (error or valid frame) is shown in FLEC instead of LEC. An error in a fixed stuff bit of an FDCAN CRC sequence is shown as a Form error, not Stuff error.

**Note:** The Bus_Off recovery sequence (see CAN Specification Rev. 2.0 or ISO11898-1) cannot be shortened by setting or resetting FDCAN_CCCR.INIT. If the device goes Bus_Off, it sets FDCAN_CCCR.INIT of its own, stopping all bus activities. Once FDCAN_CCCR.INIT has been cleared by the CPU, the device waits for 129 occurrences of bus Idle (129 × 11 consecutive recessive bits) before resuming normal operation. At the end of the Bus_Off recovery sequence, the error management counters are reset. During the waiting time after the reset of FDCAN_CCCR.INIT, each time a sequence of 11 recessive bits has been monitored, a Bit0 error code is written to FDCAN_PSR.LEC, enabling the CPU to readily check up whether the CAN bus is stuck at dominant or continuously disturbed and to monitor the Bus_Off recovery sequence. FDCAN_ECR.REC is used to count these sequences.

### 59.5.14 FDCAN transmitter delay compensation register (FDCAN_TDCR)

**Address offset:** 0x0048

**Reset value:** 0x0000 0000

**Note:**
59.5.15 **FDCAN interrupt register (FDCAN_IR)**

The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the user clears them. A flag is cleared by writing a 1 to the corresponding bit position.

Writing a 0 has no effect. A hard reset clears the register. The configuration of IE controls whether an interrupt is generated. The configuration of ILS controls on which interrupt line an interrupt is signaled.

Bits 14:8 **TDCO[6:0]**: Transmitter delay compensation offset

Offset value defining the distance between the measured delay from FDCAN_TX to FDCAN_RX and the secondary sample point. Valid values are 0 to 127 msq.

These are write-protected bits, which means that write access by the bits is possible only when the bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bits 6:0 **TDCF[6:0]**: Transmitter delay compensation filter window length

Defines the minimum value for the SSP position, dominant edges on FDCAN_RX that would result in an earlier SSP position are ignored for transmitter delay measurements.

These are write-protected bits, which means that write access by the bits is possible only when the bit CCE and bit INIT of FDCAN_CCCR register are set to 1.
Bit 25 **BO**: Bus_Off status
- 0: Bus_Off status unchanged
- 1: Bus_Off status changed

Bit 24 **EW**: Warning status
- 0: Error_Warning status unchanged
- 1: Error_Warning status changed

Bit 23 **EP**: Error passive
- 0: Error_Passive status unchanged
- 1: Error_Passive status changed

Bit 22 **ELO**: Error logging overflow
- 0: CAN error logging counter did not overflow
- 1: Overflow of CAN error logging counter occurred

Bits 21:20 Reserved, must be kept at reset value.

Bit 19 **DRX**: Message stored to dedicated Rx buffer
The flag is set whenever a received message has been stored into a dedicated Rx buffer.
- 0: No Rx buffer updated
- 1: At least one received message stored into a Rx buffer

Bit 18 **TOO**: Timeout occurred
- 0: No timeout
- 1: Timeout reached

Bit 17 **MRAF**: Message RAM access failure
The flag is set when the Rx handler
- Has not completed acceptance filtering or storage of an accepted message until the arbitration field of the following message has been received. In this case acceptance filtering or message storage is aborted and the Rx handler starts processing of the following message.
- Was unable to write a message to the message RAM. In this case message storage is aborted. In both cases the FIFO put index is not updated or the New data flag for a dedicated Rx buffer is not set. The partly stored message is overwritten when the next message is stored to this location. The flag is also set when the Tx handler was not able to read a message from the message RAM in time. In this case message transmission is aborted. In case of a Tx handler access failure the FDCAN is switched into restricted operation mode (see *Restricted operation mode*). To leave restricted operation mode, the user has to reset FDCAN_CCCR.ASM.
- 0: No message RAM access failure occurred
- 1: Message RAM access failure occurred

Bit 16 **TSW**: Timestamp wraparound
- 0: No timestamp counter wraparound
- 1: Timestamp counter wraparound

Bit 15 **TEFL**: Tx event FIFO element lost
- 0: No Tx event FIFO element lost
- 1: Tx event FIFO element lost, also set after write attempt to Tx event FIFO of size 0

Bit 14 **TEFF**: Tx event FIFO full
- 0: Tx event FIFO not full
- 1: Tx event FIFO full

Bit 13 **TEFW**: Tx event FIFO watermark reached
- 0: Tx event FIFO fill level below watermark
- 1: Tx event FIFO fill level reached watermark
Bit 12 **TEFN**: Tx event FIFO new entry
- 0: Tx event FIFO unchanged
- 1: Tx handler wrote Tx event FIFO element

Bit 11 **TFE**: Tx FIFO empty
- 0: Tx FIFO non-empty
- 1: Tx FIFO empty

Bit 10 **TCF**: Transmission cancellation finished
- 0: No transmission cancellation finished
- 1: Transmission cancellation finished

Bit 9 **TC**: Transmission completed
- 0: No transmission completed
- 1: Transmission completed

Bit 8 **HPM**: High priority message
- 0: No high priority message received
- 1: High priority message received

Bit 7 **RF1L**: Rx FIFO 1 message lost
- 0: No Rx FIFO 1 message lost
- 1: Rx FIFO 1 message lost, also set after write attempt to Rx FIFO 1 of size 0

Bit 6 **RF1F**: Rx FIFO 1 full
- 0: Rx FIFO 1 not full
- 1: Rx FIFO 1 full

Bit 5 **RF1W**: Rx FIFO 1 watermark reached
- 0: Rx FIFO 1 fill level below watermark
- 1: Rx FIFO 1 fill level reached watermark

Bit 4 **RF1N**: Rx FIFO 1 new message
- 0: No new message written to Rx FIFO 1
- 1: New message written to Rx FIFO 1

Bit 3 **RF0L**: Rx FIFO 0 message lost
- 0: No Rx FIFO 0 message lost
- 1: Rx FIFO 0 message lost, also set after write attempt to Rx FIFO 0 of size 0

Bit 2 **RF0F**: Rx FIFO 0 full
- 0: Rx FIFO 0 not full
- 1: Rx FIFO 0 full

Bit 1 **RF0W**: Rx FIFO 0 watermark reached
- 0: Rx FIFO 0 fill level below watermark
- 1: Rx FIFO 0 fill level reached watermark

Bit 0 **RF0N**: Rx FIFO 0 New message
- 0: No new message written to Rx FIFO 0
- 1: New message written to Rx FIFO 0
### FDCAN interrupt enable register (FDCAN_IE)

The settings in the interrupt enable register determine which status changes in the interrupt register is signaled on an interrupt line.

59.5.19 FDCAN global filter configuration register (FDCAN_GFC)

Global settings for message ID filtering. The global filter configuration register controls the
filter path for standard and extended messages as described in Figure 781 and Figure 782.

Address offset: 0x0080
Reset value: 0x0000 0000

| Bit 31:6 | Reserved, must be kept at reset value. |
|-----------------------------|

Bits 5:4 **ANFS[1:0]:** Accept non-matching frames standard
- Defines how received messages with 11-bit ID that do not match any element of the filter list are treated.
  - 00: Accept in Rx FIFO 0
  - 01: Accept in Rx FIFO 1
  - 10: Reject
  - 11: Reject
  - These are write-protected bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bits 3:2 **ANFE[1:0]:** Accept non-matching frames extended
- Defines how received messages with 29-bit ID that do not match any element of the filter list are treated.
  - 00: Accept in Rx FIFO 0
  - 01: Accept in Rx FIFO 1
  - 10: Reject
  - 11: Reject
  - These are write-protected bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bit 1 **RRFS:** Reject remote frames standard
- 0: Filter remote frames with 11-bit standard ID
- 1: Reject all remote frames with 11-bit standard ID
  - These are write-protected bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bit 0 **RRFE:** Reject remote frames extended
- 0: Filter remote frames with 29-bit standard ID
- 1: Reject all remote frames with 29-bit standard ID
  - These are write-protected bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.
59.5.20  FDCAN standard ID filter configuration register (FDCAN_SIDFC)

</thead>
</table>

---
Bits 31:0 **ND[31:0]: New data[31:0]**

The register holds the new data flags of Rx buffers 0 to 31. The flags are set when the respective Rx buffer has been updated from a received frame. The flags remain set until the user clears them. A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect. A hard reset clears the register.

0: Rx buffer not updated
1: Rx buffer updated from new message

Bits 31:0 **ND[63:32]: New data[63:32]**

The register holds the new data flags of Rx buffers 32 to 63. The flags are set when the respective Rx buffer has been updated from a received frame. The flags remain set until the user clears them. A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect. A hard reset clears the register.

0: Rx buffer not updated
1: Rx buffer updated from new message

**59.5.26 FDCAN Rx FIFO 0 configuration register (FDCAN_RXF0C)**

**Bit 31 F0OM: FIFO 0 operation mode**

FIFO 0 can be operated in blocking or in overwrite mode.

0: FIFO 0 blocking mode
1: FIFO 0 overwrite mode
Bits 30:24 **F0WM[6:0]**: FIFO 0 watermark
0: Watermark interrupt disabled
1-64: Level for Rx FIFO 0 watermark interrupt (FDCAN_IR.RF0W)
>64: Watermark interrupt disabled
These are write-protected bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bit 23 Reserved, must be kept at reset value.

Bits 22:16 **F0S[6:0]**: Rx FIFO 0 size
0: No Rx FIFO 0
1-64: Number of Rx FIFO 0 elements
>64: Values greater than 64 are interpreted as 64
The Rx FIFO 0 elements are indexed from 0 to F0S-1.

Bits 15:2 **F0SA[13:0]**: Rx FIFO 0 start address
Start address of Rx FIFO 0 in message RAM (32-bit word address, see Figure 780).

Bits 1:0 Reserved, must be kept at reset value.

### 59.5.27 FDCAN Rx FIFO 0 status register (FDCAN_RXF0S)

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **RF0L**: Rx FIFO 0 message lost
This bit is a copy of interrupt flag FDCAN_IR.RF0L. When FDCAN_IR.RF0L is reset, this bit is also reset.
0: No Rx FIFO 0 message lost
1: Rx FIFO 0 message lost, also set after write attempt to Rx FIFO 0 of size 0

Bit 24 **F0F**: Rx FIFO 0 full
0: Rx FIFO 0 not full
1: Rx FIFO 0 full

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:16 **F0PI[5:0]**: Rx FIFO 0 put index
Rx FIFO 0 write index pointer, range 0 to 63.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **F0GI[5:0]**: Rx FIFO 0 get index
Rx FIFO 0 read index pointer, range 0 to 63.

Bit 7 Reserved, must be kept at reset value.
Bits 6:0  **F0FL[6:0]:** Rx FIFO 0 fill level
Number of elements stored in Rx FIFO 0, range 0 to 64.

### 59.5.28 FDCAN Rx FIFO 0 acknowledge register (FDCAN_RXF0A)

Address offset: 0x00A8
Reset value: 0x0000 0000

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   | F0AI[5:0]|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   | rw | rw | rw | rw | rw | rw |

Bits 31:6  Reserved, must be kept at reset value.

Bits 5:0  **F0AI[5:0]:** Rx FIFO 0 acknowledge index
After the user has read a message or a sequence of messages from Rx FIFO 0 it has to write the buffer index of the last element read from Rx FIFO 0 to F0AI. This sets the Rx FIFO 0 get index FDCAN_RXF0S.F0GI to F0AI + 1 and update the FIFO 0 fill level FDCAN_RXF0S.F0FL.

### 59.5.29 FDCAN Rx buffer configuration register (FDCAN_RXBC)

Address offset: 0x00AC
Reset value: 0x00000000

Bit 31 Reserved, must be kept at reset value.

Bit 30 **TFQM**: Tx FIFO/queue mode

0: Tx FIFO operation
1: Tx queue operation.

These are write-protected bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bits 29:24 **TFQS[5:0]**: Transmit FIFO/queue size

0: No Tx FIFO/queue
1-32: Number of Tx buffers used for Tx FIFO/queue
>32: Values greater than 32 are interpreted as 32.

These are write-protected bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bits 23:22 Reserved, must be kept at reset value.

Bits 6:4 **F1DS[2:0]**: Rx FIFO 0 data field size

000: 8-byte data field
001: 12-byte data field
010: 16-byte data field
011: 20-byte data field
100: 24-byte data field
101: 32-byte data field
110: 48-byte data field
111: 64-byte data field

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **F0DS[2:0]**: Rx FIFO 1 data field size

000: 8-byte data field
001: 12-byte data field
010: 16-byte data field
011: 20-byte data field
100: 24-byte data field
101: 32-byte data field
110: 48-byte data field
111: 64-byte data field
59.5.35 FDCAN Tx FIFO/queue status register (FDCAN_TXFQS)

The Tx FIFO/queue status is related to the pending Tx requests listed in register FDCAN_TXBRP. Therefore the effect of add/cancellation requests may be delayed due to a running Tx scan (FDCAN_TXBRP not yet updated).

Address offset: 0x00C4
Reset value: 0x0000 0000

| Bit 31:22 | Reserved, must be kept at reset value. |
| Bit 21   | **TFQF**: Tx FIFO/queue full |
| 0        | Tx FIFO/queue not full |
| 1        | Tx FIFO/queue full |

| Bits 20:16 | **TFQPI[4:0]**: Tx FIFO/queue put index |
| 0-31      | Tx FIFO/queue write index pointer, range 0 to 31 |

| Bit 15:13 | Reserved, must be kept at reset value. |
| Bits 12:8 | **TFGI[4:0]**: |
| 0-31      | Tx FIFO get index. |
|           | Tx FIFO read index pointer, range 0 to 31. Read as 0 when Tx queue operation is configured (FDCAN_TXBC.TFQM = 1) |

| Bits 7:6  | Reserved, must be kept at reset value. |
59.5.36 FDCAN Tx buffer element size configuration register (FDCAN_TXESC)

Configures the number of data bytes belonging to a Tx buffer element. Data field sizes >8 bytes are intended for CAN FD operation only.

Address offset: 0x00C8
Reset value: 0x0000 0000

 Bits 31:3 Reserved, must be kept at reset value.

 Bits 2:0 **TBDS[2:0]**: Tx buffer data Field size:
- 000: 8-byte data field
- 001: 12-byte data field
- 010: 16-byte data field
- 011: 20-byte data field
- 100: 24-byte data field
- 101: 32-byte data field
- 110: 48-byte data field
- 111: 64-byte data field

59.5.37 FDCAN Tx buffer request pending register (FDCAN_TXBRP)

Address offset: 0x00CC
Reset value: 0x0000 0000
Bits 31:0  **TRP[31:0]: Transmission request pending**

Each Tx buffer has its own transmission request pending bit. The bits are set via register FDCAN_TXBAR. The bits are reset after a requested transmission has completed or has been canceled via register FDCAN_TXBCR.

FDCAN_TXBRP bits are set only for those Tx buffers configured via FDCAN_TXBC. After an FDCAN_TXBRP bit has been set, a Tx scan (see Filtering for Debug messages) is started to check for the pending Tx request with the highest priority (Tx buffer with lowest message ID).

A cancellation request resets the corresponding transmission request pending bit of register FDCAN_TXBRP. In case a transmission has already been started when a cancellation is requested, this is done at the end of the transmission, regardless whether the transmission was successful or not. The cancellation request bits are reset directly after the corresponding FDCAN_TXBRP bit has been reset.

After a cancellation has been requested, a finished cancellation is signaled via FDCAN_TXBCF after successful transmission together with the corresponding FDCAN_TXBTO bit when the transmission has not yet been started at the point of cancellation when the transmission has been aborted due to lost arbitration when an error occurred during frame transmission

In DAR mode all transmissions are automatically canceled if they are not successful. The corresponding FDCAN_TXBCF bit is set for all unsuccessful transmissions.

0: No transmission request pending
1: Transmission request pending

**Note:** FDCAN_TXBRP bits set while a Tx scan is in progress are not considered during this particular Tx scan. In case a cancellation is requested for such a Tx buffer, this add request is canceled immediately, the corresponding FDCAN_TXBRP bit is reset.

**59.5.38  FDCAN Tx buffer add request register (FDCAN_TXBAR)**

Address offset: 0x00D0
Reset value: 0x0000 0000

Bits 31:0  **AR[31:0]: Add request**

Each Tx buffer has its own add request bit. Writing a 1 sets the corresponding add request bit; writing a 0 has no impact. This enables the user to set transmission requests for multiple Tx buffers with one write to FDCAN_TXBAR. FDCAN_TXBAR bits are set only for those Tx buffers configured via FDCAN_TXBC. When no Tx scan is running, the bits are reset immediately, else the bits remain set until the Tx scan process has completed.

0: No transmission request added
1: Transmission requested added.

**Note:** If an add request is applied for a Tx buffer with pending transmission request (corresponding FDCAN_TXBRP bit already set), the request is ignored.
59.5.39  FDCAN Tx buffer cancellation request register (FDCAN_TXBCR)

Address offset: 0x00D4
Reset value: 0x0000 0000

Bits 31:0  CR[31:0]: Cancellation request
Each Tx buffer has its own cancellation request bit. Writing a 1 sets the corresponding cancellation request bit; writing a 0 has no impact.
This enables the user to set cancellation requests for multiple Tx buffers with one write to FDCAN_TXBCR. FDCAN_TXBCR bits are set only for those Tx buffers configured via FDCAN_TXBC. The bits remain set until the corresponding FDCAN_TXBRP bit is reset.
0: No cancellation pending
1: Cancellation pending

59.5.40  FDCAN Tx buffer transmission occurred register (FDCAN_TXBTO)

Address offset: 0x00D8
Reset value: 0x0000 0000

Bits 31:0  TO[31:0]: Transmission occurred
Each Tx buffer has its own transmission occurred bit. The bits are set when the corresponding FDCAN_TXBRP bit is cleared after a successful transmission. The bits are reset when a new transmission is requested by writing a 1 to the corresponding bit of register FDCAN_TXBAR.
0: No transmission occurred
1: Transmission occurred
59.5.41 FDCAN Tx buffer cancellation finished register (FDCAN_TXBCF)

Address offset: 0x00DC
Reset value: 0x0000 0000

</tr>
</thead>
<tbody>
<tr>
<td>r r r r r r r r r r r r r r r</td>
</tr>
</tbody>
</table>

Bits 31:0 **CF[31:0]**: Cancellation finished

Each Tx buffer has its own cancellation finished bit. The bits are set when the corresponding FDCAN_TXBRP bit is cleared after a cancellation was requested via FDCAN_TXBCR. In case the corresponding FDCAN_TXBRP bit was not set at the point of cancellation, CF is set immediately. The bits are reset when a new transmission is requested by writing a 1 to the corresponding bit of register FDCAN_TXBAR.

0: No transmit buffer cancellation
1: Transmit buffer cancellation finished

59.5.42 FDCAN Tx buffer transmission interrupt enable register (FDCAN_TXBTIE)

</tbody>
</table>

Bits 31:30 **Reserved**, must be kept at reset value.

Bits 29:24 **EFWM[5:0]**: Event FIFO watermark
0: Watermark interrupt disabled
1-32: Level for Tx event FIFO watermark interrupt (FDCAN_IR.TEFW)
>32: Watermark interrupt disabled
These are write-protected bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bits 23:22 **Reserved**, must be kept at reset value.

Bits 21:16 **EFS[5:0]**: Event FIFO size.
0: Tx event FIFO disabled
1-32: Number of Tx event FIFO elements
>32: Values greater than 32 are interpreted as 32
The Tx event FIFO elements are indexed from 0 to EFS-1.
These are write-protected bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.
Bits 15:2 **EFSA[13:0]**: Event FIFO start address
Start address of Tx event FIFO in message RAM (32-bit word address, see Figure 780).
These are write-protected bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bits 1:0 Reserved, must be kept at reset value.

### 59.5.45 FDCAN Tx event FIFO status register (FDCAN_TXEFS)

### 59.5.46 FDCAN Tx event FIFO acknowledge register (FDCAN_TXEFA)

Address offset: 0x00F8  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Offset</th>
<th>Register name</th>
<th>Reset value</th>
<th>Description</th>
</tr>
</thead>
</table>
| 0x0000 | FDCAN_CREL REL[3:0] STEP[3:0] SUBSTEP [3:0] YEAR[3:0] MON[7:0] DAY[7:0] | 0 0 1 1 0 0 1 0 0 0 0 1 0 1 0 0 0 0 1 0 0 1 0 0 1 0 0 1 0 0 1 1 0 0 0 | Reserved, must be kept at reset value. **EFAI[4:0]**: Event FIFO acknowledge index  
After the user has read an element or a sequence of elements from the Tx event FIFO, it must write the index of the last element read from Tx event FIFO to EFAI. This sets the Tx event FIFO get index FDCAN_TXEFS.EFGI to EFAI + 1 and update the FIFO 0 fill level FDCAN_TXEFS.EFFL.

  |                              |               |        | These are write-protected bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1. |
| 29  | Reserved, must be kept at reset value. |           | rw     | |
| 28:0| RID[28:0]: Reference identifier. | 0x0001 0000  | rw     | Identifier transmitted with reference message and used for reference message filtering. Standard or extended reference identifier depending on bit XTD. A standard identifier must be written to ID[28:18].  
  |                              |               |        | These are write-protected bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1. |

Bits 31:27 Reserved, must be kept at reset value.

- **Bit 26**: EVTP: Event trigger polarity.  
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Rising edge trigger</td>
</tr>
<tr>
<td>1</td>
<td>Falling edge trigger</td>
</tr>
<tr>
<td></td>
<td>These are write-protected bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.</td>
</tr>
</tbody>
</table>

- **Bit 25**: ECC: Enable clock calibration.  
<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Automatic clock calibration in FDCAN level 0, 2 is disabled</td>
</tr>
<tr>
<td>1</td>
<td>Automatic clock calibration in FDCAN level 0, 2 is enabled</td>
</tr>
<tr>
<td></td>
<td>These are write-protected bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.</td>
</tr>
</tbody>
</table>
Bit 24 **EGTF**: Enable global time filtering.
0: Global time filtering in FDCAN level 0, 2 is disabled
1: Global time filtering in FDCAN level 0, 2 is enabled
These are write-protected bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bits 23:16 **AWL[7:0]**: Application watchdog limit.
The application watchdog can be disabled by programming AWL to 0x00.
0x00 to FF: Maximum time after which the application has to serve the application watchdog. The application watchdog is incremented once each 256 NTUs.
These are write-protected bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bit 15 **EECS**: Enable external clock synchronization
If enabled, TUR configuration (FDCAN_TURCF.NCL only) may be updated during FDCAN operation.
0: External clock synchronization in FDCAN level 0, 2 disabled
1: External clock synchronization in FDCAN level 0, 2 enabled
These are write-protected bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bits 14:8 **IRTO[6:0]**: Initial reference trigger offset.
0x00 to 7F Positive offset, range from 0 to 127
These are write-protected bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bits 7:5 **LDSDL[2:0]**: LD of synchronization deviation limit.
The synchronization deviation limit SDL is configured by its dual logarithm LDSDL with SDL = 2 \(^*(LDSDL + 5)\). SDL is comprised between 32 and 4096. It should not exceed the clock tolerance given by the CAN bit timing configuration.
These are write-protected bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bit 4 **TM**: Time master.
0: Time master function disabled
1: Potential time master
These are write-protected bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bit 3 **GEN**: Gap enable.
0: Strictly time-triggered operation
1: External event-synchronized time-triggered operation
These are write-protected bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

Bit 2 Reserved, must be kept at reset value.

Bits 1:0 **OM[1:0]**: Operation mode.
00: Event-driven CAN communication, default
01: TTCAN level 1
10: TTCAN level 2
11: TTCAN level 0
These are write-protected bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.
59.6.4  FDCAN TT matrix limits register (FDCAN_TTMLM)

Address offset: 0x010C

</tr>
</tbody>
</table>

**Note:** ISO 11898-4, Section 5.2.1 requires that only the listed cycle count values are configured. Other values are possible, but may lead to inconsistent matrix cycles.
59.6.5 **FDCAN TUR configuration register (FDCAN_TURCF)**

The length of the NTU is given by: \( NTU = \text{CAN clock period} \times \text{NC/DC}. \)

NC is an 18-bit value. Its high part, NCH[17:16] is hard wired to 0b01. Therefore the range of NC extends from 0x10000 to 0x1FFFF. The value configured by NCL is the initial value for FDCAN_TURN.A.NAV[15:0]. DC is set to 0x1000 by hardware reset and it may not be written to 0x0000.

- Level 1: NC 4 × DC and NTU = CAN bit time
- Levels 0 and 2: NC 8 × DC

The actual value of FDCAN_TUR may be changed by the clock drift compensation function of TTCAN level 0 and level 2 in order to adjust the node local view of the NTU to the time master view of the NTU. DC is not changed by the automatic drift compensation, FDCAN_TURN.A.NAV may be adjusted around NC in the range of the synchronization deviation limit given by FDCAN_TTOCF.LDSDL. NC and DC should be programmed to the largest suitable values in achieve the best computational accuracy for the drift compensation process.

Address offset: 0x0110

Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bit</th>

<td>DC[13:0]: Denominator configuration.</td>
</tr>
</tbody>
</table>

#### Bit 31: ELT

- 0: Local time is stopped, default
- 1: Local time is enabled

These are write-protected bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

**Note:** The local time is started by setting ELT, it remains active until ELT is reset or until the next hardware reset. FDCAN_TURCF.DC is locked when FDCAN_TURCF.ELT = 1. If ELT is written to 0, the readable value stays at 1 until the new value has been synchronized into the CAN clock domain. During this time write access to the other bits of the register is locked.

### Address offset: 0x0110

</tbody>
</table>

#### Bit 31: ELT

- 0: Local time is stopped, default
- 1: Local time is enabled

These are write-protected bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.

### Bits 29:16: DC[13:0]

- 0x0000: Illegal value
- 0x0001 to 0x3FFF: Denominator configuration

These are write-protected bits, write access is possible only when bit CCE and bit INIT of FDCAN_CCCR register are set to 1.
Note: If NC < 7 × DC in TTCAN level 1, subsequent time marks in the trigger memory must differ by at least two NTUs.

59.6.6 **FDCAN TT operation control register (FDCAN_TTOCN)**

Address offset: 0x0114  
Reset value: 0x0000 0000

<table>
<thead>
<tr>
<th>Bits 31:16</th>
<th>Reserved, must be kept at reset value.</th>
</tr>
</thead>
</table>
| Bit 15    | **LCKC**: TT operation control register locked.  
Set by a write access to register FDCAN_TTOCN. Reset when the updated configuration has been synchronized into the CAN clock domain.  
0: Write access to FDCAN_TTOCN enabled  
1: Write access to FDCAN_TTOCN locked |
| Bit 14    | Reserved, must be kept at reset value. |
| Bit 13    | **ESCN**: External synchronization control  
If enabled the FDCAN synchronizes its cycle time phase to an external event signaled by a rising edge at event trigger pin (see Section 59.4.17: Synchronization to external time schedule).  
0: External synchronization disabled  
1: External synchronization enabled |
| Bit 12    | **NIG**: Next is gap.  
This bit can be set only when the FDCAN is the actual time master and when it is configured for external event-synchronized time-triggered operation (FDCAN_TTOCF.GEN = 1)  
0: No action, reset by reception of any reference message  
1: Transmit next reference message with Next_is_Gap = 1 |
| Bit 11    | **TMG**: Time mark gap.  
0: Reset by each reference message  
1: Next reference message started when register time mark interrupt FDCAN_TTIR.RTMI is activated |
Bit 10 **FGP**: Finish gap.
Set by the CPU, reset by each reference message
0: No reference message requested
1: Application requested start of reference message

Bit 9 **GCS**: Gap control select
0: Gap control independent from event trigger
1: Gap control by input event trigger pin

Bit 8 **TTIE**: Trigger time mark interrupt pulse enable
External time mark events are configured by trigger memory element TMEX. A trigger time mark interrupt pulse is generated when the trigger memory element becomes active, and the FDCAN is in synchronization state In_Schedule or In_Gap.
0: Trigger time mark interrupt output fdcan1_tmp for more than one instance and fdcan_tmp if only one instance disabled
1: Trigger time mark interrupt output fdcan1_tmp for more than one instance and fdcan_tmp if only one instance enabled

Bits 7:6 **TMC[1:0]**: Register time mark compare.
00: No register time mark interrupt generated
01: Register time mark interrupt if time mark = cycle time
10: Register time mark interrupt if time mark = local time
11: Register time mark interrupt if time mark = global time

*Note: When changing the time mark reference (cycle, local, global time), it is recommended to first write TMC = 00, then reconfigure FDCAN_TTTMK, and finally set FDCAN_TMC to the intended time reference.*

Bit 5 **RTIE**: Register time mark interrupt pulse enable.
Register time mark interrupts are configured by register FDCAN_TTTMK. A register time mark interrupt pulse with the length of one fdcan_tq_ck period is generated when time referenced by FDCAN_TTOCN.TMC (cycle, local, or global) is equal to FDCAN_TTTMK.TM, independently from the synchronization state.
0: Register time mark interrupt output disabled
1: Register time mark interrupt output enabled

Bits 4:3 **SWS[1:0]**: Stop watch source.
00: Stop watch disabled
01: Actual value of cycle time is copied to FDCAN_TTCPT.SWV
10: Actual value of local time is copied to FDCAN_TTCPT.SWV
11: Actual value of global time is copied to FDCAN_TTCPT.SWV

Bit 2 **SWP**: Stop watch polarity.
0: Rising edge trigger
1: Falling edge trigger

Bit 1 **ECS**: External clock synchronization.
Writing a 1 to ECS sets FDCAN_TTOST.WECS if the node is the actual time master. ECS is reset after one APB clock period. The external clock synchronization takes effect at the start of the next basic cycle.

Bit 0 **SGT**: Set global time.
Writing a 1 to SGT sets FDCAN_TTOST.WGDT if the node is the actual time master. SGT is reset after one APB clock period. The global time preset takes effect when the node transmits the next reference message with the Master_Ref_Mark modified by the preset value written to FDCAN_TTGTP.
59.6.7  **FDCAN TT global time preset register (FDCAN_TTGTP)**

If TTOST.WGDT is set, the next reference message is transmitted with the Master_Ref_Mark modified by the preset value and with Disc_Bit = 1, presetting the global time in all nodes simultaneously.

TP is reset to 0x0000 each time a reference message with Disc_Bit = 1 becomes valid or if the node is not the current time master. TP is locked while FDCAN_TTOST.WGTD = 1 after setting FDCAN_TTOCN.SGT until the reference message with Disc_Bit = 1 becomes valid or until the node is no longer the current time master.

Bits 31:16  **CTP[15:0]:** Cycle time target phase
CTP is write-protected while FDCAN_TTOCN.ESCN or FDCAN_TTOST.SPL are set (see Section 59.4.17: Synchronization to external time schedule).
0x0000 to FFFF defines the target value of cycle time when a rising edge of event trigger is expected.

Bits 15:0  **TP[15:0]:** Time preset
TP is write-protected while FDCAN_TTOST.WGTD is set.
0x0000 to 7FFF next master reference mark = master reference mark + TP
0x8000 reserved
0x8001–FFFF Next master reference mark = master reference mark - (0x10000 - TP).

59.6.8  **FDCAN TT time mark register (FDCAN_TTTMK)**

A time mark interrupt (FDCAN_TTIR.TMI = 1) is generated when the time base indicated by FDCAN_TTOCN.TMC (cycle time, local time, or global time) has the same value as TM.

Address offset: 0x011C
Reset value: 0x0000 0000

<th>TM[15:0]</th>
<th>rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw</th>
</tr>
</thead>
</table>
Bit 31 **LCKM**: TT time mark register locked
Always set by a write access to registers FDCAN_TTOCN. Set by write access to register FDCAN_TTTMK when FDCAN_TTOCN.TMC 00. Reset when the registers have been synchronized into the CAN clock domain.
0: Write access to FDCAN_TTTMK enabled
1: Write access to FDCAN_TTTMK locked

Bits 30:23 Reserved, must be kept at reset value.

Bits 22:16 **TICC[6:0]**: Time mark cycle code
- Cycle count for which the time mark is valid.
- 0b000000x valid for all cycles
- 0b000001c valid every second cycle at cycle count mod2 = c
- 0b00001cc valid every fourth cycle at cycle count mod4 = cc
- 0b0001ccc valid every eighth cycle at cycle count mod8 = ccc
- 0b001cccc valid every sixteenth cycle at cycle count mod16 = ccccc
- 0b01cccc valid every thirty-second cycle at cycle count mod32 = ccccccc
- 0b1cccccc valid every sixty-fourth cycle at cycle count mod64 = cccccc

Bits 15:0 **TM[15:0]**: Time mark
0x0000 to FFFF time mark

**Note:** When using byte access to register FDCAN_TTTMK it is recommended to first disable the time mark compare function (FDCAN_TTOCN.TMC = 00) to avoid comparisons on inconsistent register values.

### 59.6.9 FDCAN TT interrupt register (FDCAN_TTIR)

The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the user clears them. A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect. A hard reset clears the register.

**Bits 31:19** Reserved, must be kept at reset value.

- **Bit 18 CER**: Configuration error
  - Trigger out of order.
  - 0: No error found in trigger list
  - 1: Error found in trigger list

- **Bit 17 AW**: Application watchdog
  - 0: Application watchdog served in time
  - 1: Application watchdog not served in time
Bit 16 **WT**: Watch trigger  
0: No missing reference message  
1: Missing reference message (level 0: cycle time 0xFF00)  

Bit 15 **IWTG**: Initialization watch trigger  
The initialization is restarted by resetting IWT.  
0: No missing reference message during system startup  
1: No system startup due to missing reference message  

Bit 14 **ELC**: Error level changed  
Not set when error level changed during initialization.  
0: No change in error level  
1: Error level changed  

Bit 13 **SE2**: Scheduling error 2  
0: No scheduling error 2  
1: Scheduling error 2 occurred  

Bit 12 **SE1**: Scheduling error 1  
0: No scheduling error 1  
1: Scheduling error 1 occurred  

Bit 11 **TXO**: Tx count overflow  
0: Number of Tx trigger as expected  
1: More Tx trigger than expected in one cycle  

Bit 10 **TXU**: Tx count underflow  
0: Number of Tx trigger as expected  
1: Less Tx trigger than expected in one cycle  

Bit 9 **GTE**: Global time error  
Synchronization deviation SD exceeds limit specified by FDCAN_TTOCF.LDSDL, TTCAN level 0, 2 only.  
0: Synchronization deviation within limit  
1: Synchronization deviation exceeded limit  

Bit 8 **GTD**: Global time discontinuity  
0: No discontinuity of global time  
1: Discontinuity of global time  

Bit 7 **GTW**: Global time wrap  
0: No global time wrap occurred  
1: Global time wrap from 0xFFFF to 0x0000 occurred  

Bit 6 **SWE**: Stop watch event  
0: No rising/falling edge at stop watch trigger pin detected  
1: Rising/falling edge at stop watch trigger pin detected  

Bit 5 **TTMI**: Trigger time mark event internal  
Internal time mark events are configured by trigger memory element TMIN (see Section 59.4.23).  
Set when the trigger memory element becomes active, and the FDCAN is in synchronization state In_Gap or In_Schedule.  
0: Time mark not reached  
1: Time mark reached (level 0: cycle time FDCAN_TTOCF.RTO x 0x200)
Bit 4  **RTMI**: Register time mark interrupt  
Set when time referenced by TTOCN.TMC (cycle, local, or global) is equal to FDCAN_TTTMK.TM, independently from the synchronization state.  
0: Time mark not reached  
1: Time mark reached

Bit 3  **SOG**: Start of gap  
0: No reference message seen with Next_is_Gap bit set  
1: Reference message with Next_is_Gap bit set becomes valid

Bit 2  **CSM**: Change of synchronization mode  
0: No change in master to slave relation or schedule synchronization  
1: Master to slave relation or schedule synchronization changed, also set when FDCAN_TTOST.SPL is reset

Bit 1  **SMC**: Start of matrix cycle  
0: No matrix cycle started since bit has been reset  
1: Matrix cycle started

Bit 0  **SBC**: Start of basic cycle  
0: No basic cycle started since bit has been reset  
1: Basic cycle started

### 59.6.10 FDCAN TT interrupt enable register (FDCAN_TTIE)

The settings in the TT interrupt enable register determine which status changes in the TT interrupt register result in an interrupt.

### 59.6.11  FDCAN TT interrupt line select register (FDCAN_TTILS)

The TT interrupt line select register assigns an interrupt generated by a specific interrupt flag from the TT interrupt register to one of the two module interrupt lines. For interrupt generation the respective interrupt line must be enabled via FDCAN_ILE.EINT0 and FDCAN_ILE.EINT1.

</tr>
</tbody>
</table>

2730/3556 RM0399 Rev 4
Bit 31 **SPL**: Schedule phase lock
The bit is valid only when external synchronization is enabled
(FDCAN_TTOCN.ESCN = 1). In this case it signals that the difference between cycle time
configured by FDCAN_TTGTP.CTP and the cycle time at the rising edge at event trigger pin is less
than or equal to 9 NTU (see Section 59.4.17: Synchronization to external time schedule).
0: Phase outside range
1: Phase inside range

Bit 30 **WECS**: Wait for external clock synchronization.
0: No external clock synchronization pending
1: Node waits for external clock synchronization to take effect. The bit is reset at the start of the next
basic cycle.

Bit 29 **AWE**: Application watchdog event
The application watchdog is served by reading FDCAN_TTOST. When the watchdog is not served in
time, bit AWE is set, all FDCAN communication is stopped, and the FDCAN is set into bus
monitoring mode.
0: Application watchdog served in time
1: Failed to serve application watchdog in time

Bit 28 **WFE**: Wait for event
0: No gap announced, reset by a reference message with Next_is_Gap = 0
1: Reference message with Next_is_Gap = 1 received

Bit 27 **GSI**: Gap started indicator
0: No gap in schedule, reset by each reference message and for all time slaves
1: Gap time after basic cycle has started

Bits 26:24 **TMP[2:0]**: Time master priority
0x0-7 Priority of actual time master

Bit 23 **GFI**: Gap finished indicator
Set when the CPU writes FDCAN_TTOCN.FGP, or by a time mark interrupt if TMG = 1, or via input
pin (event trigger) if FDCAN_TTOCN.GCS = 1. Not set by Ref_Trigger_Gap or when Gap is finished
by another node sending a reference message.
0: Reset at the end of each reference message
1: Gap finished by FDCAN

Bit 22 **WGTD**: Wait for global time discontinuity
0: No global time preset pending
1: Node waits for the global time preset to take effect. The bit is reset when the node has transmitted
a reference message with Disc_Bit = 1 or after it received a reference message.

Bits 21:16 Reserved, must be kept at reset value.

Bits 15:8 **RTO[7:0]**: Reference trigger offset
The reference trigger offset value is a signed integer with a range from -127 (0x81) to 127 (0x7F).
There is no notification when the lower limit of -127 is reached. In case the FDCAN becomes time
master (MS[1:0] = 11), the reset of RTO is delayed due to synchronization between user and CAN
clock domain. For time slaves the value configured by FDCAN_TTOCF.IRTO is read.
0x00-FF Actual reference trigger offset value

Bit 7 **QCS**: Quality of clock speed
Only relevant in TTCAN level 0 and level 2, otherwise fixed to 1.
0: Local clock speed not synchronized to time master clock speed
1: Synchronization deviation ≤ SDL
There is no drift compensation in TTCAN level 1 (NAV = NC). In TTCAN level 0 and level 2, the drift between the node local clock and the time master local clock is calculated. The drift is compensated when the synchronization deviation (difference between NC and the calculated NAV) is lower than 2 * (FDCAN_TTOCF.LDSDL + 5). With FDCAN_TTOCF.LDSDL < 7, this results in a maximum range for NAV of (NC - 0x1000) ≤ NAV ≤ (NC + 0x1000).

59.6.13  **FDCAN TUR numerator actual register (FDCAN_TURNRA)**

There is no drift compensation in TTCAN level 1 (NAV = NC). In TTCAN level 0 and level 2, the drift between the node local clock and the time master local clock is calculated. The drift is compensated when the synchronization deviation (difference between NC and the calculated NAV) is lower than 2 * (FDCAN_TTOCF.LDSDL + 5). With FDCAN_TTOCF.LDSDL < 7, this results in a maximum range for NAV of (NC - 0x1000) ≤ NAV ≤ (NC + 0x1000).

Bits 31:16 **GT[15:0]**: Global time  
Non-fractional part of the sum of the node local time and its local offset (see Section 59.4.12).  
0x0000 to FFFF Global time value of FDCAN network

Bits 15:0 **LT[15:0]**: Local time  
Non-fractional part of local time, incremented once each local NTU (see Section 59.4.12).  
0x0000 to FFFF Local time value of FDCAN node

### 59.6.15 FDCAN TT cycle time and count register (FDCAN_TTCTC)

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:16 **CC[5:0]**: Cycle count  
0x00 to 3F Number of actual basic cycle in the system matrix

Bits 15:0 **CT[15:0]**: Cycle time  
Non-fractional part of the difference of the node local time and Ref_Mark (see Section 59.4.12).  
0x0000 to FFFF: cycle time value of FDCAN basic cycle
59.6.16 FDCAN TT capture time register (FDCAN_TTCPT)

Address offset: 0x013C
Reset value: 0x0000 0000

</tbody>
</table>

Bits 31:16 **SWV[15:0]**: Stop watch value

On a rising / falling edge (as configured via FDCAN_TTOCN.SWP) at the stop watch trigger pin, when FDCAN_TTOCN.SWS is different from 00 and FDCAN_TTIR.SWE is 0, the actual time value as selected by FDCAN_TTOCN.SWS (cycle, local, global) is copied to SWV and TFDCAN_TIR.SWE is set to 1. Capturing of the next stop watch value is enabled by resetting FDCAN_TTIR.SWE.

0x0000 to FFFF Captured stop watch value

Bits 15:6 Reserved, must be kept at reset value.

Bits 5:0 **CCV[5:0]**: Cycle count value

Cycle count value captured together with SWV.

0x00 to 3F: captured cycle count value

59.6.17 FDCAN TT cycle sync mark register (FDCAN_TTCSM)

Address offset: 0x0140
Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **CSM[15:0]**: Cycle sync mark

The cycle sync mark is measured in cycle time. It is updated when the reference message becomes valid and retains its value until the next reference message becomes valid.

0x0000 to FFFF Captured cycle time
59.6.18  FDCAN TT trigger select register (FDCAN_TTTS)

The settings in the FDCAN_TTTS register select the input to be used as event trigger and stop watch trigger.

Address offset: 0x0300
Reset value: 0x0000 0000

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:4 EVTSEL[1:0]: Event trigger input selection
These bits are used to select the input to be used as event trigger
00: fdcan1_evt0
01: fdcan1_evt1
10: fdcan1_evt2
11: fdcan1_evt3

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 SWTDEL[1:0]: Stop watch trigger input selection
These bits are used to select the input to be used as stop watch trigger
00: fdcan1.swt0
01: fdcan1.swt1
10: fdcan1.swt2
11: fdcan1.swt3

59.6.19  FDCAN TT register map

Refer to Table 527. FDCAN TT register map and reset values (continued) for the register boundary addresses.

59.7.2 Calibration configuration register (FDCAN_CCU_CCFG)

Address offset: 0x0004
Reset value: 0x0000 0004

Refer to Table 527. FDCAN TT register map and reset values (continued) for the register boundary addresses.
Bit 31  **SWR**: Software reset
Writing a 1 to this bit resets the calibration FSM to state Not_Calibrated (FDCAN_CCU_CSTAT.CALS = 00). The calibration watchdog value CWD.WDV is also reset. Registers FDCAN_CCFG, FDCAN_CCU_CSTAT and the calibration watchdog configuration CWD.WDC are unchanged. The bit remains set until reset is completed.
Write access by the user to registers/bits marked with “P = Protected Write” is possible only when FDCAN control bits FDCAN_CCCR.CCE = 1 AND FDCAN_CCCR.INIT = 1.

Bits 30:20  Reserved, must be kept at reset value.

Bits 19:16  **CDIV[3:0]**: Clock divider
The clock divider must be configured when the clock calibration is bypassed (BCC = 1) to ensure that the FDCAN requirement is fulfilled.
0000: Divide by 1
0001: Divide by 2
0010: Divide by 4
0011: Divide by 6
0100: Divide by 8
0101: Divide by 10
0110: Divide by 12
0111: Divide by 14
1000: Divide by 16
1001: Divide by 18
1010: Divide by 20
1011: Divide by 22
1100: Divide by 24
1101: Divide by 26
1110: Divide by 28
1111: Divide by 30
Write access by the user to registers/bits marked with “P = Protected Write” is possible only when FDCAN control bits FDCAN_CCCR.CCE = 1 AND FDCAN_CCCR.INIT = 1.

Bits 15:8  **OCPM[7:0]**: Oscillator clock periods minimum
Configures the minimum number of periods in two CAN bit times. OCPM is used in basic calibration to avoid false measurements in case of glitches on the bus line. The configured number of periods is OCPM × 32. The configuration depends on the frequency and the bitrate configured in FDCAN modules (from 125 kbit/s up to 1 Mbit/s). It is recommended to configure a value slightly below two CAN bit times. The reset value is 1.6 bit times at 80 MHz fdcan_ker_ck and 1 Mbit/s CAN bitrate.
Write access by the user to registers/bits marked with “P = Protected Write” is possible only when FDCAN control bits FDCAN_CCCR.CCE = 1 AND FDCAN_CCCR.INIT = 1.

Bit 7  **CFL**: Calibration field length
0: Calibration field length is 32 bits
1: Calibration field length is 64 bits
Write access by the user to registers/bits marked with “P = Protected Write” is possible only when FDCAN control bits FDCAN_CCCR.CCE = 1 AND FDCAN_CCCR.INIT = 1.

Bit 6  **BCC**: Bypass clock calibration
If this bit is set, the clock input fdcan_ker_ck is routed to the time quanta clock through a clock divider configurable via CDIV. In this case the baudrate prescaler of the connected FDCANs must be configured to generate the FDCAN internal time quanta clock.
0: Clock calibration unit generates time quanta clock
1: Clock calibration unit bypassed (default configuration)

Bit 5  Reserved, must be kept at reset value.

- 10: Precision_Calibrated  
- 11: Reserved  

Note: Bit 29 must be kept at reset value.

**Bits 28:18** **TQC[10:0]:** Time quanta counter  
Captured number of time quanta in calibration field (32 or 64 bits). Only valid when the clock calibration unit is in state Precision_Calibrated.

**Bits 17:0** **OCPC[17:0]:** Oscillator clock period counter  
Captured number of oscillator clock periods in calibration field (32 or 64 bits). Only valid when the clock calibration unit is in state Precision_Calibrated.

### Calibration watchdog register (FDCAN_CCU_CWD)

**Address offset:** 0x0000C  
**Reset value:** 0x0000 0000

The calibration watchdog is started after the first falling edge when the calibration FSM is in state Not_Calibrated (FDCAN_CCU_CSTAT.CALS = 00). In this state the calibration watchdog monitors the message received. In case no message was received until the calibration watchdog has counted down to 0, the calibration FSM stays in state Not_Calibrated (FDCAN_CCU_CSTAT.CALS = 00), the counter is reloaded with FDCAN_RWD.WDC and basic calibration is restarted after the next falling edge.

When in state Basic_Calibrated (FDCAN_CCU_CSTAT.CALS = 01), the calibration watchdog is restarted with each received message. In case no message was received until the calibration watchdog has counted down to 0, the calibration FSM returns to state...
Not_Calibrated (FDCAN_CCU_CSTAT.CALS = 00), the counter is reloaded with FDCAN_RWD.WDC and basic calibration is restarted after the next falling edge.

When a quartz message is received, state Precision_Calibrated (FDCAN_CCU_CSTAT.CALS = 10) is entered and the calibration watchdog is restarted. In this state the calibration watchdog monitors the quartz message received input. In case no message from a quartz controlled node is received by the attached TTCAN until the calibration watchdog has counted down to 0, the calibration FSM transits back to state Basic_Calibrated (FDCAN_CCU_CSTAT.CALS = 01). The signal is active when the CAN protocol engine on the attached TTCAN is started i.e. when the INIT bit is reset.

A calibration watchdog event also sets interrupt flag FDCAN_CCU_IR.CWE. If enabled by FDCAN_CCU_IE.CWEE, interrupt line is activated (set to high). Interrupt line remains active until interrupt flag FDCAN_CCU_IR.CWE is reset.

### 59.7.5 Clock calibration unit interrupt register (FDCAN_CCU_IR)

The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the user clears them. A flag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect. A hard reset clears the register. The configuration of FDCAN_CCU_IE controls whether an interrupt is generated or not.

Address offset: 0x0001

Reset value: 0x0000 0000

USB on-the-go high-speed (OTG_HS)

Introduction

Portions Copyright (c) Synopsys, Inc. All rights reserved. Used with permission.

This section presents the architecture and the programming model of the OTG_HS controller.

The following acronyms are used throughout the section:

- FS  Full-speed
- LS  Low-speed
- HS  High-speed
- MAC  Media access controller
- OTG  On-the-go
- PFC  Packet FIFO controller
- PHY  Physical layer
- USB  Universal serial bus
- UTMI  USB 2.0 Transceiver Macrocell interface (UTMI)
- ULPI  UTMI+ Low Pin Interface
- LPM  Link power management
- BCD  Battery charging detector
- HNP  Host negotiation protocol
- SRP  Session request protocol

References are made to the following documents:

- USB On-The-Go Supplement, Revision 2.0
- Universal Serial Bus Revision 2.0 Specification
- USB 2.0 Link Power Management Addendum Engineering Change Notice to the USB 2.0 specification, July 16, 2007
- Errata for USB 2.0 ECN: Link Power Management (LPM) - 7/2007
- Battery Charging Specification, Revision 1.2

The USB OTG is a dual-role device (DRD) controller that supports both device and host functions and is fully compliant with the On-The-Go Supplement to the USB 2.0 Specification. It can also be configured as a host-only or device-only controller, fully compliant with the USB 2.0 Specification. OTG_HS supports the speeds defined in the Table 529: OTG_HS speeds supported below. The USB OTG supports both HNP and SRP. The only external device required is a charge pump for $V_{BUS}$ in OTG mode.
60.2 OTG_HS main features

The main features can be divided into three categories: general, host-mode and device-mode features.

60.2.1 General features

The OTG_HS interface general features are the following:

- It is USB-IF certified to the Universal Serial Bus Specification Rev 2.0
- OTG_HS supports the following PHY interfaces:
  - An on-chip full-speed PHY
  - A ULPI interface for external high-speed PHY
- It includes full support (PHY) for the optional On-The-Go (OTG) protocol detailed in the On-The-Go Supplement Rev 2.0 specification
  - Integrated support for A-B device identification (ID line)
  - Integrated support for host Negotiation protocol (HNP) and session request protocol (SRP)
  - It allows host to turn V_BUS off to conserve battery power in OTG applications
  - It supports OTG monitoring of V_BUS levels with internal comparators
  - It supports dynamic host-peripheral switch of role
- It is software-configurable to operate as:
  - SRP capable USB HS Peripheral (B-device)
  - SRP capable USB HS/LS host (A-device)
  - USB On-The-Go Full-Speed Dual Role device
- It supports HS SOF and LS Keep-alives with
  - SOF pulse PAD connectivity
  - SOF pulse internal connection to timer (TIMx)
  - Configurable framing period
  - Configurable end of frame interrupt
- OTG_HS embeds an internal DMA with thresholding support and software selectable AHB burst type in DMA mode.
- It supports Descriptor-Based Scatter/Gather DMA controller for device and host mode. (Descriptor-Based Congruent-Sequential DMA is not supported). Scatter/Gather DMA operation is supported in both device and host mode. This feature will improve performance for device mode isochronous endpoints. Note that hubs (split transfers)
are not supported in host scatter/gather DMA mode of operation. Split transfers are supported only in host buffer DMA (internal DMA) mode of operation.

- It includes power saving features such as system stop during USB suspend, switch-off of clock domains internal to the digital core, PHY and DFIFO power management.
- It features a dedicated RAM of 4 Kbytes with advanced FIFO control:
  - Configurable partitioning of RAM space into different FIFOs for flexible and efficient use of RAM
  - Each FIFO can hold multiple packets
  - Dynamic memory allocation
  - Configurable FIFO sizes that are not powers of 2 to allow the use of contiguous memory locations
- It guarantees max USB bandwidth for up to one frame (1 ms) without system intervention.
- It supports charging port detection as described in Battery Charging Specification Revision 1.2 on the FS PHY transceiver only.

60.2.2 Host-mode features

The OTG_HS interface main features and requirements in host-mode are the following:
- External charge pump for $V_{BUS}$ voltage generation.
- Up to 16 host channels (pipes): each channel is dynamically reconfigurable to allocate any type of USB transfer.
- Built-in hardware scheduler holding:
  - Up to 16 interrupt plus isochronous transfer requests in the periodic hardware queue
  - Up to 16 control plus bulk transfer requests in the non-periodic hardware queue
- Management of a shared Rx FIFO, a periodic Tx FIFO and a nonperiodic Tx FIFO for efficient usage of the USB data RAM.

60.2.3 Peripheral-mode features

The OTG_HS interface main features in peripheral-mode are the following:
- 1 bidirectional control endpoint 0
- 8 IN endpoints (EPs) configurable to support bulk, interrupt or isochronous transfers
- 8 OUT endpoints configurable to support bulk, interrupt or isochronous transfers
- Management of a shared Rx FIFO and a Tx-OUT FIFO for efficient usage of the USB data RAM
- Management of up to 9 dedicated Tx-IN FIFOs (one for each active IN EP) to put less load on the application
- Support for the soft disconnect feature.
60.3 **OTG_HS implementation**

60.4 **OTG_HS functional description**

60.4.1 **OTG_HS block diagram**

In STM32H7, two instances of OTG_HS are present (OTG_HS1 and OTG_HS2).

Only OTG_HS1 has an accessible ULPI interface which will allow high speed operation using an external HS transceiver.
Figure 792. USB1 OTG_HS high-speed block diagram (OTG_HS1)

Figure 793. USB2 OTG_HS high-speed block diagram (OTG_HS2)

1. This instance cannot be used in HS mode for pinning reasons
60.4.2 OTG_HS pin and internal signals

The USB OTG_HS receives the 48 MHz clock from the reset and clock controller (RCC). This clock is used for driving the 48 MHz domain at full-speed (12 Mbit/s) and must be enabled prior to configuring the OTG core.

The CPU reads and writes from/to the OTG core registers through the AHB peripheral bus. It is informed of USB events through the single USB OTG interrupt line described in Section 60.12: OTG_HS interrupts.

60.4.3 OTG_HS core

The USB OTG_HS receives the 48 MHz clock from the reset and clock controller (RCC). This clock is used for driving the 48 MHz domain at full-speed (12 Mbit/s) and must be enabled prior to configuring the OTG core.

The CPU reads and writes from/to the OTG core registers through the AHB peripheral bus. It is informed of USB events through the single USB OTG interrupt line described in Section 60.12: OTG_HS interrupts.
The CPU submits data over the USB by writing 32-bit words to dedicated OTG locations (push registers). The data are then automatically stored into Tx-data FIFOs configured within the USB data RAM. There is one Tx FIFO push register for each in-endpoint (peripheral mode) or out-channel (host mode).

The CPU receives the data from the USB by reading 32-bit words from dedicated OTG addresses (pop registers). The data are then automatically retrieved from a shared Rx FIFO configured within the 4-Kbyte USB data RAM. There is one Rx FIFO pop register for each out-endpoint or in-channel.

The USB protocol layer is driven by the serial interface engine (SIE) and serialized over the USB by the transceiver module within the on-chip physical layer (PHY) or external HS PHY.

**Caution:** To guarantee a correct operation for the USB OTG_HS peripheral, the AHB frequency should be higher than 30 MHz.

### 60.4.4 Embedded full-speed OTG PHY connected to OTG_HS

The embedded full-speed OTG PHY is controlled by the OTG_HS core and conveys USB control & data signals through the full-speed subset of the UTMI+ Bus (UTMIFS). It provides the physical support to USB connectivity.

The full-speed OTG PHY includes the following components:

* FS/LS transceiver module used by both host and device. It directly drives transmission and reception on the single-ended USB lines.
* DP/DM integrated pull-up and pull-down resistors controlled by the OTG_HS core depending on the current role of the device. As a peripheral, it enables the DP pull-up resistor to signal full-speed peripheral connections as soon as \( V_{BUS} \) is sensed to be at a valid level (B-session valid). In host mode, pull-down resistors are enabled on both DP/DM. Pull-up and pull-down resistors are dynamically switched when the peripheral role is changed via the host negotiation protocol (HNP).
* Pull-up/pull-down resistor ECN circuit. The DP pull-up consists of 2 resistors controlled separately from the OTG_HS as per the resistor Engineering Change Notice applied to USB Rev2.0. The dynamic trimming of the DP pull-up strength allows to achieve a better noise rejection and Tx/Rx signal quality.

### 60.4.5 OTG detections

Additionally the OTG_HS uses the following functions:

* integrated ID pull-up resistor used to sample the ID line for A/B device identification.
* \( V_{BUS} \) sensing comparators with hysteresis used to detect \( V_{BUS} \) valid, A-B session valid and session-end voltage thresholds. They are used to drive the session request protocol (SRP), detect valid startup and end-of-session conditions, and constantly monitor the \( V_{BUS} \) supply during USB operations.

### 60.4.6 High-speed OTG PHY connected to OTG_HS

**Note:** Refer to implementation table to determine if an HS PHY is embedded.

The USB OTG_HS core includes an ULPI interface to connect an external HS PHY.

**Note:** In case of multiple OTG_HS instances, ULPI may not be available on each one. Refer to implementation table.
60.5 OTG_HS dual role device (DRD)

Figure 794. OTG_HS A-B device connection

1. External voltage regulator only needed when building a VBUS powered device.
2. STMPS2141STR needed only if the application has to support a VBUS powered device. A basic power switch can be used if 5 V are available on the application board.

60.5.1 ID line detection

The host or peripheral (the default) role is assumed depending on the ID input pin. The ID line status is determined on plugging in the USB cable, depending on whether a MicroA or MicroB plug is connected to the micro-AB receptacle.

- If the B-side of the USB cable is connected with a floating ID wire, the integrated pull-up resistor detects a high ID level and the default peripheral role is confirmed. In this configuration the OTG_HS complies with the standard FSM described in section 4.2.4: ID pin of the On-the-Go specification Rev2.0, supplement to the USB2.0.
- If the A-side of the USB cable is connected with a grounded ID, the OTG_HS issues an ID line status change interrupt (CIDSCHG bit in OTG_GINTSTS) for host software initialization, and automatically switches to the host role. In this configuration the OTG_HS complies with the standard FSM described by section 4.2.4: ID pin of the On-the-Go specification Rev2.0, supplement to the USB2.0.

60.5.2 HNP dual role device

The HNP capable bit in the Global USB configuration register (HNPCAP bit in OTG_GUSBCFG) enables the OTG_HS core to dynamically change its role from A-host to A-peripheral and vice-versa, or from B-Peripheral to B-host and vice-versa according to the host negotiation protocol (HNP). The current device status can be read by the combined values of the connector ID status bit in the Global OTG control and status register (CIDSTS bit in OTG_GOTGCTL) and the current mode of operation bit in the global interrupt and status register (CMOD bit in OTG_GINTSTS).

The HNP program model is described in detail in Section 60.15: OTG_HS programming model.
60.5.3 SRP dual role device

The SRP capable bit in the global USB configuration register (SRPCAP bit in OTG_GUSBCFG) enables the OTG_HS core to switch off the generation of VBUS for the A-device to save power. Note that the A-device is always in charge of driving VBUS regardless of the host or peripheral role of the OTG_HS.

The SRP A/B-device program model is described in detail in Section 60.15: OTG_HS programming model.

60.6 OTG_HS as a USB peripheral

This section gives the functional description of the OTG_HS in the USB peripheral mode. The OTG_HS works as an USB peripheral in the following circumstances:

- **OTG B-Peripheral**
  - OTG B-device default state if B-side of USB cable is plugged in

- **OTG A-Peripheral**
  - OTG A-device state after the HNP switches the OTG_HS to its peripheral role

- **B-device**
  - If the ID line is present, functional and connected to the B-side of the USB cable, and the HNP-capable bit in the Global USB Configuration register (HNPCAP bit in OTG_GUSBCFG) is cleared.

- **Peripheral only**
  - The force device mode bit (FDMOD) in the Section 60.14.4: OTG USB configuration register (OTG_GUSBCFG) is set to 1, forcing the OTG_HS core to work as an USB peripheral-only. In this case, the ID line is ignored even if it is present on the USB connector.

*Note:* To build a bus-powered device implementation in case of the B-device or peripheral-only configuration, an external regulator has to be added, that generates the necessary power-supply from VBUS.
60.6.1 SRP-capable peripheral

The SRP capable bit in the Global USB configuration register (SRPCAP bit in OTG_GUSBCFG) enables the OTG_HS to support the session request protocol (SRP). In this way, it allows the remote A-device to save power by switching off \( V_{BUS} \) while the USB session is suspended.

The SRP peripheral mode program model is described in detail in the B-device session request protocol section.

60.6.2 Peripheral states

**Powered state**

The \( V_{BUS} \) input detects the B-session valid voltage by which the USB peripheral is allowed to enter the powered state (see USB2.0 section 9.1). The OTG_HS then automatically connects the DP pull-up resistor to signal full-speed device connection to the host and generates the session request interrupt (SRQINT bit in OTG_GINTSTS) to notify the powered state.

The \( V_{BUS} \) input also ensures that valid \( V_{BUS} \) levels are supplied by the host during USB operations. If a drop in \( V_{BUS} \) below B-session valid happens to be detected (for instance because of a power disturbance or if the host port has been switched off), the OTG_HS automatically disconnects and the session end detected (SEDET bit in OTG_GOTGINT) interrupt is generated to notify that the OTG_HS has exited the powered state.

In the powered state, the OTG_HS expects to receive some reset signaling from the host. No other USB operation is possible. When a reset signaling is received the reset detected interrupt (USBRST in OTG_GINTSTS) is generated. When the reset signaling is complete, the enumeration done interrupt (ENUMDNE bit in OTG_GINTSTS) is generated and the OTG_HS enters the Default state.
Soft disconnect

The powered state can be exited by software with the soft disconnect feature. The DP pull-up resistor is removed by setting the soft disconnect bit in the device control register (SDIS bit in OTG_DCTL), causing a device disconnect detection interrupt on the host side even though the USB cable was not really removed from the host port.

Default state

In the Default state the OTG_HS expects to receive a SET_ADDRESS command from the host. No other USB operation is possible. When a valid SET_ADDRESS command is decoded on the USB, the application writes the corresponding number into the device address field in the device configuration register (DAD bit in OTG_DCFG). The OTG_HS then enters the address state and is ready to answer host transactions at the configured USB address.

Suspended state

The OTG_HS peripheral constantly monitors the USB activity. After counting 3 ms of USB idleness, the early suspend interrupt (ESUSP bit in OTG_GINTSTS) is issued, and confirmed 3 ms later, if appropriate, by the suspend interrupt (USBSUSP bit in OTG_GINTSTS). The device suspend bit is then automatically set in the device status register (SUSPSTS bit in OTG_DSTS) and the OTG_HS enters the suspended state.

The suspended state may optionally be exited by the device itself. In this case the application sets the remote wake-up signaling bit in the device control register (RWUSIG bit in OTG_DCTL) and clears it after 1 to 15 ms.

When a resume signaling is detected from the host, the resume interrupt (WKUPINT bit in OTG_GINTSTS) is generated and the device suspend bit is automatically cleared.

60.6.3 Peripheral endpoints

The OTG_HS core instantiates the following USB endpoints:

- Control endpoint 0:
  - Bidirectional and handles control messages only
  - Separate set of registers to handle in and out transactions
  - Proper control (OTG_DIEPCTL0/OTG_DOEPCTL0), transfer configuration (OTG_DIEPTSIZ0/OTG_DOEPTSIZ0), and status-interrupt (OTG_DIEPINT0/OTG_DOEPINT0) registers. The available set of bits inside the control and transfer size registers slightly differs from that of other endpoints

- 8 IN endpoints
  - Each of them can be configured to support the isochronous, bulk or interrupt transfer type
  - Each of them has proper control (OTG_DIEPCTLx), transfer configuration (OTG_DIEPTSIZx), and status-interrupt (OTG_DIEPINTx) registers
  - The device IN endpoints common interrupt mask register (OTG_DIEPMSK) is available to enable/disable a single kind of endpoint interrupt source on all of the IN endpoints (EP0 included)
  - Support for incomplete isochronous IN transfer interrupt (IISOIXFR bit in OTG_GINTSTS), asserted when there is at least one isochronous IN endpoint on
which the transfer is not completed in the current frame. This interrupt is asserted along with the end of periodic frame interrupt (OTG_GINTSTS/EOPF).

- **8 OUT endpoints**
  - Each of them can be configured to support the isochronous, bulk or interrupt transfer type
  - Each of them has a proper control (OTG_DOEPCTLx), transfer configuration (OTG_DOEPTSIZx) and status-interrupt (OTG_DOEPINTx) register
  - Device OUT endpoints common interrupt mask register (OTG_DOEPMSK) is available to enable/disable a single kind of endpoint interrupt source on all of the OUT endpoints (EP0 included)
  - Support for incomplete isochronous OUT transfer interrupt (INCOMPISOOUT bit in OTG_GINTSTS), asserted when there is at least one isochronous OUT endpoint on which the transfer is not completed in the current frame. This interrupt is asserted along with the end of periodic frame interrupt (OTG_GINTSTS/EOPF).

**Endpoint control**

- The following endpoint controls are available to the application through the device endpoint-x IN/OUT control register (OTG_DIEPCTLx/OTG_DOEPCTLx):
  - Endpoint enable/disable
  - Endpoint activate in current configuration
  - Program USB transfer type (isochronous, bulk, interrupt)
  - Program supported packet size
  - Program Tx FIFO number associated with the IN endpoint
  - Program the expected or transmitted data0/data1 PID (bulk/interrupt only)
  - Program the even/odd frame during which the transaction is received or transmitted (isochronous only)
  - Optionally program the NAK bit to always negative-acknowledge the host regardless of the FIFO status
  - Optionally program the STALL bit to always stall host tokens to that endpoint
  - Optionally program the SNOOP mode for OUT endpoint not to check the CRC field of received data

**Endpoint transfer**

The device endpoint-x transfer size registers (OTG_DIEPTSIZx/OTG_DOEPTSIZx) allow the application to program the transfer size parameters and read the transfer status. Programming must be done before setting the endpoint enable bit in the endpoint control register. Once the endpoint is enabled, these fields are read-only as the OTG_HS core updates them with the current transfer status.

The following transfer parameters can be programmed:

- Transfer size in bytes
- Number of packets that constitute the overall transfer size

**Endpoint status/interrupt**

The device endpoint-x interrupt registers (OTG_DIEPINTx/OTG_DOPEPINTx) indicate the status of an endpoint with respect to USB- and AHB-related events. The application must read these registers when the OUT endpoint interrupt bit or the IN endpoint interrupt bit in
the core interrupt register (OEPINT bit in OTG_GINTSTS or IEPINT bit in OTG_GINTSTS, respectively) is set. Before the application can read these registers, it must first read the device all endpoints interrupt (OTG_DAINt) register to get the exact endpoint number for the device endpoint-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG_DAINt and OTG_GINTSTS registers.

The peripheral core provides the following status checks and interrupt generation:

- Transfer completed interrupt, indicating that data transfer was completed on both the application (AHB) and USB sides
- Setup stage has been done (control-out only)
- Associated transmit FIFO is half or completely empty (in endpoints)
- NAK acknowledge has been transmitted to the host (isochronous-in only)
- IN token received when Tx FIFO was empty (bulk-in/interrupt-in only)
- Out token received when endpoint was not yet enabled
- Babble error condition has been detected
- Endpoint disable by application is effective
- Endpoint NAK by application is effective (isochronous-in only)
- More than 3 back-to-back setup packets were received (control-out only)
- Timeout condition detected (control-in only)
- Isochronous out packet has been dropped, without generating an interrupt

### 60.7 OTG_HS as a USB host

This section gives the functional description of the OTG_HS in the USB host mode. The OTG_HS works as a USB host in the following circumstances:

- OTG A-host
  - OTG A-device default state when the A-side of the USB cable is plugged in
- OTG B-host
  - OTG B-device after HNP switching to the host role
- A-device
  - If the ID line is present, functional and connected to the A-side of the USB cable, and the HNP-capable bit is cleared in the Global USB Configuration register (HNPCAP bit in OTG_GUSBCFG). Integrated pull-down resistors are automatically set on the DP/DM lines.
- Host only
  - The force host mode bit (FHMOD) in the OTG USB configuration register (OTG_GUSBCFG) forces the OTG_HS core to work as a USB host-only. In this case, the ID line is ignored even if present on the USB connector. Integrated pull-down resistors are automatically set on the DP/DM lines.

**Note:** On-chip 5 V V_{BUS} generation is not supported. For this reason, a charge pump or, if 5 V are available on the application board, a basic power switch must be added externally to drive the 5 V V_{BUS} line. The external charge pump can be driven by any GPIO output. This is required for the OTG A-host, A-device and host-only configurations.
60.7.1 SRP-capable host

SRP support is available through the SRP capable bit in the global USB configuration register (SRPCAP bit in OTG_GUSBCFG). With the SRP feature enabled, the host can save power by switching off the VBUS power while the USB session is suspended.

The SRP host mode program model is described in detail in the A-device session request protocol section.

60.7.2 USB host states

Host port power

On-chip 5 V VBUS generation is not supported. For this reason, a charge pump or, if 5 V are available on the application board, a basic power switch, must be added externally to drive the 5 V VBUS line. The external charge pump can be driven by any GPIO output or via an I²C interface connected to an external PMIC (power management IC). When the application decides to power on VBUS, it must also set the port power bit in the host port control and status register (PPWR bit in OTG_HPRT).

VBUS valid

When HNP or SRP is enabled the VBUS sensing pin must be connected to VBUS. The VBUS input ensures that valid VBUS levels are supplied by the charge pump during USB operations. Any unforeseen VBUS voltage drop below the VBUS valid threshold (4.4 V) leads to an OTG interrupt triggered by the session end detected bit (SEDET bit in OTG_GOTGINT). The application is then required to remove the VBUS power and clear the port power bit.

When HNP and SRP are both disabled, the VBUS sensing pin does not need to be connected to VBUS.

The charge pump overcurrent flag can also be used to prevent electrical damage. Connect the overcurrent flag output from the charge pump to any GPIO input and configure it to generate a port interrupt on the active level. The overcurrent ISR must promptly disable the VBUS generation and clear the port power bit.
Host detection of a peripheral connection

If SRP or HNP are enabled, even if USB peripherals or B-devices can be attached at any time, the OTG_HS does not detect any bus connection until VBUS is no longer sensed at a valid level (5 V). When VBUS is at a valid level and a remote B-device is attached, the OTG_HS core issues a host port interrupt triggered by the device connected bit in the host port control and status register (PCDET bit in OTG_HPRT).

When HNP and SRP are both disabled, USB peripherals or B-device are detected as soon as they are connected. The OTG_HS core issues a host port interrupt triggered by the device connected bit in the host port control and status (PCDET bit in OTG_HPRT).

Host detection of peripheral a disconnection

The peripheral disconnection event triggers the disconnect detected interrupt (DISCINT bit in OTG_GINTSTS).

Host enumeration

After detecting a peripheral connection the host must start the enumeration process by sending USB reset and configuration commands to the new peripheral.

Before starting to drive a USB reset, the application waits for the OTG interrupt triggered by the debounce done bit (DBCDNE bit in OTG_GOTGINT), which indicates that the bus is stable again after the electrical debounce caused by the attachment of a pull-up resistor on DP (FS) or DM (LS).

The application drives a USB reset signaling (single-ended zero) over the USB by keeping the port reset bit set in the host port control and status register (PRST bit in OTG_HPRT) for a minimum of 10 ms and a maximum of 20 ms. The application takes care of the timing count and then of clearing the port reset bit.

Once the USB reset sequence has completed, the host port interrupt is triggered by the port enable/disable change bit (PENCHNG bit in OTG_HPRT). This informs the application that the speed of the enumerated peripheral can be read from the port speed field in the host port control and status register (PSPD bit in OTG_HPRT) and that the host is starting to drive SOFs (FS) or Keep alives (LS). The host is now ready to complete the peripheral enumeration by sending peripheral configuration commands.

Host suspend

The application decides to suspend the USB activity by setting the port suspend bit in the host port control and status register (PSUSP bit in OTG_HPRT). The OTG_HS core stops sending SOFs and enters the suspended state.

The suspended state can be optionally exited on the remote device’s initiative (remote wake-up). In this case the remote wake-up interrupt (WKUPINT bit in OTG_GINTSTS) is generated upon detection of a remote wake-up signaling, the port resume bit in the host port control and status register (PRES bit in OTG_HPRT) self-sets, and resume signaling is automatically driven over the USB. The application must time the resume window and then clear the port resume bit to exit the suspended state and restart the SOF.

If the suspended state is exited on the host initiative, the application must set the port resume bit to start resume signaling on the host port, time the resume window and finally clear the port resume bit.
60.7.3 Host channels

The OTG_HS core instantiates 16 host channels. Each host channel supports an USB host transfer (USB pipe). The host is not able to support more than 16 transfer requests at the same time. If more than 16 transfer requests are pending from the application, the host controller driver (HCD) must re-allocate channels when they become available from previous duty, that is, after receiving the transfer completed and channel halted interrupts.

Each host channel can be configured to support in/out and any type of periodic/nonperiodic transaction. Each host channel makes use of proper control (OTG_HCCHAR\(x\)), transfer configuration (OTG_HCTSIZ\(x\)) and status/interrupt (OTG_HCINT\(x\)) registers with associated mask (OTG_HCINTMSK\(x\)) registers.

Host channel control

- The following host channel controls are available to the application through the host channel-\(x\) characteristics register (OTG_HCCHAR\(x\)):
  - Channel enable/disable
  - Program the HS/FS/LS speed of target USB peripheral
  - Program the address of target USB peripheral
  - Program the endpoint number of target USB peripheral
  - Program the transfer IN/OUT direction
  - Program the USB transfer type (control, bulk, interrupt, isochronous)
  - Program the maximum packet size (MPS)
  - Program the periodic transfer to be executed during odd/even frames

Host channel transfer

The host channel transfer size registers (OTG_HCTSIZ\(x\)) allow the application to program the transfer size parameters, and read the transfer status. Programming must be done before setting the channel enable bit in the host channel characteristics register. Once the endpoint is enabled the packet count field is read-only as the OTG_HS core updates it according to the current transfer status.

- The following transfer parameters can be programmed:
  - transfer size in bytes
  - number of packets making up the overall transfer size
  - initial data PID

Host channel status/interrupt

The host channel-\(x\) interrupt register (OTG_HCINT\(x\)) indicates the status of an endpoint with respect to USB- and AHB-related events. The application must read these register when the host channels interrupt bit in the core interrupt register (HCINT bit in OTG_GINTSTS) is set. Before the application can read these registers, it must first read the host all channels interrupt (OTG_HAINT) register to get the exact channel number for the host channel-\(x\) interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG_HAINT and OTG_GINTSTS registers.
The mask bits for each interrupt source of each channel are also available in the OTG_HCINTMSKx register.

- The host core provides the following status checks and interrupt generation:
  - Transfer completed interrupt, indicating that the data transfer is complete on both the application (AHB) and USB sides
  - Channel has stopped due to transfer completed, USB transaction error or disable command from the application
  - Associated transmit FIFO is half or completely empty (IN endpoints)
  - ACK response received
  - NAK response received
  - STALL response received
  - USB transaction error due to CRC failure, timeout, bit stuff error, false EOP
  - Babble error
  - frame overrun
  - data toggle error

60.7.4 Host scheduler

The host core features a built-in hardware scheduler which is able to autonomously re-order and manage the USB transaction requests posted by the application. At the beginning of each frame the host executes the periodic (isochronous and interrupt) transactions first, followed by the nonperiodic (control and bulk) transactions to achieve the higher level of priority granted to the isochronous and interrupt transfer types by the USB specification.

The host processes the USB transactions through request queues (one for periodic and one for nonperiodic). Each request queue can hold up to 8 entries. Each entry represents a pending transaction request from the application, and holds the IN or OUT channel number along with other information to perform a transaction on the USB. The order in which the requests are written to the queue determines the sequence of the transactions on the USB interface.

At the beginning of each frame, the host processes the periodic request queue first, followed by the nonperiodic request queue. The host issues an incomplete periodic transfer interrupt (IPXFR bit in OTG_GINTSTS) if an isochronous or interrupt transaction scheduled for the current frame is still pending at the end of the current frame. The OTG_HS core is fully responsible for the management of the periodic and nonperiodic request queues. The periodic transmit FIFO and queue status register (OTG_HPTXSTS) and nonperiodic transmit FIFO and queue status register (OTG_HNPTXSTS) are read-only registers which can be used by the application to read the status of each request queue. They contain:

- The number of free entries currently available in the periodic (nonperiodic) request queue (8 max)
- Free space currently available in the periodic (nonperiodic) Tx FIFO (out-transactions)
- IN/OUT token, host channel number and other status information.

As request queues can hold a maximum of 8 entries each, the application can push to schedule host transactions in advance with respect to the moment they physically reach the SB for a maximum of 8 pending periodic transactions plus 8 pending non-periodic transactions.

To post a transaction request to the host scheduler (queue) the application must check that there is at least 1 entry available in the periodic (nonperiodic) request queue by reading the
PTXQSAV bits in the OTG_HNPTXSTS register or NPTQXSAV bits in the OTG_HNPTXSTS register.

### 60.8 OTG_HS SOF trigger

**Figure 797. SOF connectivity (SOF trigger output to TIM and ITR1 connection)**

The OTG_HS core provides means to monitor, track and configure SOF framing in the host and peripheral, as well as an SOF pulse output connectivity feature. Such utilities are especially useful for adaptive audio clock generation techniques, where the audio peripheral needs to synchronize to the isochronous stream provided by the PC, or the host needs to trim its framing rate according to the requirements of the audio peripheral.

#### 60.8.1 Host SOFs

In host mode the number of PHY clocks occurring between the generation of two consecutive SOF (HS/FS) or Keep-alive (LS) tokens is programmable in the host frame interval register (HFIR), thus providing application control over the SOF framing period. An interrupt is generated at any start of frame (SOF bit in OTG_GINTSTS). The current frame number and the time remaining until the next SOF are tracked in the host frame number register (HFNUM).

A SOF pulse signal, is generated at any SOF starting token and with a width of 20 HCLK cycles. The SOF pulse is also internally connected to the input trigger of the timer, so that the input capture feature, the output compare feature and the timer can be triggered by the SOF pulse.

#### 60.8.2 Peripheral SOFs

In device mode, the start of frame interrupt is generated each time an SOF token is received on the USB (SOF bit in OTG_GINTSTS). The corresponding frame number can be read from the device status register (FNSOF bit in OTG_DSTS). A SOF pulse signal with a width of 20 HCLK cycles is also generated. The SOF pulse signal is also internally connected to the TIM input trigger, so that the input capture feature, the output compare feature and the timer can be triggered by the SOF pulse.
The end of periodic frame interrupt (OTG_GINTSTS/EOPF) is used to notify the application when 80%, 85%, 90% or 95% of the time frame interval elapsed depending on the periodic frame interval field in the device configuration register (PFIVL bit in OTG_DCFG). This feature can be used to determine if all of the isochronous traffic for that frame is complete.

60.9 **OTG_HS low-power modes**

Table 534 below defines the STM32 low power modes and their compatibility with the OTG.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
<th>USB compatibility</th>
</tr>
</thead>
<tbody>
<tr>
<td>Run</td>
<td>MCU fully active</td>
<td>Required when USB not in suspend state.</td>
</tr>
<tr>
<td>Sleep</td>
<td>USB suspend exit causes the device to exit Sleep mode. Peripheral registers content is kept.</td>
<td>Available while USB is in suspend state.</td>
</tr>
<tr>
<td>Stop</td>
<td>USB suspend exit causes the device to exit Stop mode. Peripheral registers content is kept(1).</td>
<td>Available while USB is in suspend state.</td>
</tr>
<tr>
<td>Standby</td>
<td>Powered-down. The peripheral must be reinitialized after exiting Standby mode.</td>
<td>Not compatible with USB applications.</td>
</tr>
</tbody>
</table>

1. Within Stop mode there are different possible settings. Some restrictions may also exist, refer to Section 7: Power control (PWR) to understand which (if any) restrictions apply when using OTG.

The following bits and procedures reduce power consumption.

The power consumption of the OTG PHY is controlled by two or three bits in the general core configuration register, depending on OTG revision supported.

- **PHY power down (OTG_GCCFG/PWRDWN)**
  It switches on/off the full-speed transceiver module of the PHY. It must be preliminarily set to allow any USB operation

- **VBUS detection enable (OTG_GCCFG/VBDEN)**
  It switches on/off the VBUS sensing comparators associated with OTG operations

Power reduction techniques are available while in the USB suspended state, when the USB session is not yet valid or the device is disconnected.

- **Stop PHY clock (STPPCLK bit in OTG_PCGCCTL)**
  When setting the stop PHY clock bit in the clock gating control register, most of the 48 MHz clock domain internal to the OTG core is switched off by clock gating. The dynamic power consumption due to the USB clock switching activity is cut even if the 48 MHz clock input is kept running by the application
  Most of the transceiver is also disabled, and only the part in charge of detecting the asynchronous resume or remote wake-up event is kept alive.

- **Gate HCLK (GATEHCLK bit in OTG_PCGCCTL)**
  When setting the Gate HCLK bit in the clock gating control register, most of the system clock domain internal to the OTG_HS core is switched off by clock gating. Only the register read and write interface is kept alive. The dynamic power consumption due to
the USB clock switching activity is cut even if the system clock is kept running by the application for other purposes.

- **USB system stop**
  
  When the OTG_HS is in the USB suspended state, the application may decide to drastically reduce the overall power consumption by a complete shut down of all the clock sources in the system. USB System Stop is activated by first setting the Stop PHY clock bit and then configuring the system deep sleep mode in the power control system module (PWR).

  The OTG_HS core automatically reactivates both system and USB clocks by asynchronous detection of remote wake-up (as an host) or resume (as a device) signaling on the USB.

To save dynamic power, the USB data FIFO is clocked only when accessed by the OTG_HS core.

### 60.10 OTG_HS Dynamic update of the OTG_HFIR register

The USB core embeds a dynamic trimming capability of micro-SOF framing period in host mode allowing to synchronize an external device with the micro-SOF frames.

When the OTG_HFIR register is changed within a current micro-SOF frame, the SOF period correction is applied in the next frame as described in [Figure 798](#).

For a dynamic update, it is required to set RLDCTRL=1.

![Figure 798. Updating OTG_HFIR dynamically (RLDCTRL = 1)](ai18440b)

### 60.11 OTG_HS data FIFOs

The USB system features 4 Kbytes of dedicated RAM with a sophisticated FIFO control mechanism. The packet FIFO controller module in the OTG_HS core organizes RAM space into Tx FIFOs into which the application pushes the data to be temporarily stored before the USB transmission, and into a single Rx FIFO where the data received from the USB are temporarily stored before retrieval (popped) by the application. The number of instructed FIFOs and how these are organized inside the RAM depends on the device’s role. In peripheral mode an additional Tx FIFO is instructed for each active IN endpoint. Any FIFO size is software configured to better meet the application requirements.
60.11.1 Peripheral FIFO architecture

Figure 799. Device-mode FIFO address mapping and AHB FIFO access mapping

Peripheral Rx FIFO

The OTG peripheral uses a single receive FIFO that receives the data directed to all OUT endpoints. Received packets are stacked back-to-back until free space is available in the Rx FIFO. The status of the received packet (which contains the OUT endpoint destination number, the byte count, the data PID and the validity of the received data) is also stored by the core on top of the data payload. When no more space is available, host transactions are NACKed and an interrupt is received on the addressed endpoint. The size of the receive FIFO is configured in the receive FIFO size register (OTG_GRXFSIZ).

The single receive FIFO architecture makes it more efficient for the USB peripheral to fill in the receive RAM buffer:

- All OUT endpoints share the same RAM buffer (shared FIFO)
- The OTG_HS core can fill in the receive FIFO up to the limit for any host sequence of OUT tokens

The application keeps receiving the Rx FIFO non-empty interrupt (RXFLVL bit in OTG_GINTSTS) as long as there is at least one packet available for download. It reads the packet information from the receive status read and pop register (OTG_GRXSTSP) and finally pops data off the receive FIFO by reading from the endpoint-related pop address.
Peripheral Tx FIFOs

The core has a dedicated FIFO for each IN endpoint. The application configures FIFO sizes by writing the endpoint 0 transmit FIFO size register (OTG_DIEPTXF0) for IN endpoint0 and the device IN endpoint transmit FIFOx registers (OTG_DIEPTXFx) for IN endpoint-x.

60.11.2 Host FIFO architecture

Figure 800. Host-mode FIFO address mapping and AHB FIFO access mapping

Host Rx FIFO

The host uses one receiver FIFO for all periodic and nonperiodic transactions. The FIFO is used as a receive buffer to hold the received data (payload of the received packet) from the USB until it is transferred to the system memory. Packets received from any remote IN endpoint are stacked back-to-back until free space is available. The status of each received packet with the host channel destination, byte count, data PID and validity of the received data are also stored into the FIFO. The size of the receive FIFO is configured in the receive FIFO size register (OTG_GRXFSIZ).

The single receive FIFO architecture makes it highly efficient for the USB host to fill in the receive data buffer:

- All IN configured host channels share the same RAM buffer (shared FIFO)
- The OTG_HS core can fill in the receive FIFO up to the limit for any sequence of IN tokens driven by the host software

The application receives the Rx FIFO not-empty interrupt as long as there is at least one packet available for download. It reads the packet information from the receive status read and pop register and finally pops the data off the receive FIFO.
Host Tx FIFOs

The host uses one transmit FIFO for all non-periodic (control and bulk) OUT transactions and one transmit FIFO for all periodic (isochronous and interrupt) OUT transactions. FIFOs are used as transmit buffers to hold the data (payload of the transmit packet) to be transmitted over the USB. The size of the periodic (nonperiodic) Tx FIFO is configured in the host periodic (nonperiodic) transmit FIFO size OTG_HPTXFSIZ / OTG_HNPTXFSIZ) register.

The two Tx FIFO implementation derives from the higher priority granted to the periodic type of traffic over the USB frame. At the beginning of each frame, the built-in host scheduler processes the periodic request queue first, followed by the nonperiodic request queue.

The two transmit FIFO architecture provides the USB host with separate optimization for periodic and nonperiodic transmit data buffer management:

- All host channels configured to support periodic (nonperiodic) transactions in the OUT direction share the same RAM buffer (shared FIFOs)
- The OTG_HS core can fill in the periodic (nonperiodic) transmit FIFO up to the limit for any sequence of OUT tokens driven by the host software

The OTG_HS core issues the periodic Tx FIFO empty interrupt (PTXFE bit in OTG_GINTSTS) as long as the periodic Tx FIFO is half or completely empty, depending on the value of the periodic Tx FIFO empty level bit in the AHB configuration register (PTXFELVL bit in OTG_GAHBCFG). The application can push the transmission data in advance as long as free space is available in both the periodic Tx FIFO and the periodic request queue. The host periodic transmit FIFO and queue status register (OTG_HPTXSTS) can be read to know how much space is available in both.

OTG_HS core issues the non periodic Tx FIFO empty interrupt (NPTXFE bit in OTG_GINTSTS) as long as the nonperiodic Tx FIFO is half or completely empty depending on the non periodic Tx FIFO empty level bit in the AHB configuration register (TXFELVL bit in OTG_GAHBCFG). The application can push the transmission data as long as free space is available in both the nonperiodic Tx FIFO and nonperiodic request queue. The host nonperiodic transmit FIFO and queue status register (OTG_HNPTXSTS) can be read to know how much space is available in both.

60.11.3 FIFO RAM allocation

Device mode

Receive FIFO RAM allocation: the application must allocate RAM for SETUP packets:

- 10 locations must be reserved in the receive FIFO to receive SETUP packets on control endpoint. The core does not use these locations, which are reserved for SETUP packets, to write any other data.
- One location is to be allocated for Global OUT NAK.
- Status information is written to the FIFO along with each received packet. Therefore, a minimum space of \((\text{largest packet size} / 4) + 1\) must be allocated to receive packets. If multiple isochronous endpoints are enabled, then at least two \((\text{largest packet size} / 4) + 1\) spaces must be allocated to receive back-to-back packets. Typically, two \((\text{largest packet size} / 4) + 1\) spaces are recommended so that when the previous packet is being transferred to the CPU, the USB can receive the subsequent packet.
- Along with the last packet for each endpoint, transfer complete status information is also pushed to the FIFO. One location for each OUT endpoint is recommended.
Device RxFIFO =

\[(5 \times \text{number of control endpoints} + 8) + \left(\frac{\text{largest USB packet used}}{4}\right) + 1 \text{ for status information} + (2 \times \text{number of OUT endpoints}) + 1 \text{ for Global NAK}\]

Example: The MPS is 1,024 bytes for a periodic USB packet and 512 bytes for a non-periodic USB packet. There are three OUT endpoints, three IN endpoints, one control endpoint, and three host channels.

Device RxFIFO = \((5 \times 1 + 8) + ((1,024 / 4) + 1) + (2 \times 4) + 1 = 279\)

**Transmit FIFO RAM allocation:** the minimum RAM space required for each IN endpoint Transmit FIFO is the maximum packet size for that particular IN endpoint.

Note: More space allocated in the transmit IN endpoint FIFO results in better performance on the USB.

**Host mode**

Receive FIFO RAM allocation:

Status information is written to the FIFO along with each received packet. Therefore, a minimum space of \(\left(\frac{\text{largest packet size}}{4}\right) + 1\) must be allocated to receive packets. If multiple isochronous channels are enabled, then at least two \(\left(\frac{\text{largest packet size}}{4}\right) + 1\) spaces must be allocated to receive back-to-back packets. Typically, two \(\left(\frac{\text{largest packet size}}{4}\right) + 1\) spaces are recommended so that when the previous packet is being transferred to the CPU, the USB can receive the subsequent packet.

Along with the last packet in the host channel, transfer complete status information is also pushed to the FIFO. So one location must be allocated for this.

Host RxFIFO = \(\left(\frac{\text{largest USB packet used}}{4}\right) + 1 \text{ for status information} + 1 \text{ transfer complete}\)

Example: Host RxFIFO = \(((1,024 / 4) + 1) + 1 = 258\)

Transmit FIFO RAM allocation:

The minimum amount of RAM required for the host Non-periodic Transmit FIFO is the largest maximum packet size among all supported non-periodic OUT channels.

Typically, two largest packet sizes worth of space is recommended, so that when the current packet is under transfer to the USB, the CPU can get the next packet.

Non-Periodic TxFIFO = \(\frac{\text{largest non-periodic USB packet used}}{4}\)

Example: Non-Periodic TxFIFO = \((512 / 4) = 128\)

The minimum amount of RAM required for host periodic Transmit FIFO is the largest maximum packet size out of all the supported periodic OUT channels. If there is at least one isochronous OUT endpoint, then the space must be at least two times the maximum packet size of that channel.

Host Periodic TxFIFO = \(\frac{\text{largest periodic USB packet used}}{4}\)

Example: Host Periodic TxFIFO = \((1,024 / 4) = 256\)

Note: More space allocated in the Transmit Non-periodic FIFO results in better performance on the USB.
60.12 OTG_HS interrupts

When the OTG_HS controller is operating in one mode, either device or host, the application must not access registers from the other mode. If an illegal access occurs, a mode mismatch interrupt is generated and reflected in the core interrupt register (MMIS bit in the OTG_GINTSTS register). When the core switches from one mode to the other, the registers in the new mode of operation must be reprogrammed as they would be after a power-on reset.

*Figure 801* shows the interrupt hierarchy.
Figure 801. Interrupt hierarchy

1. OTG_HS_WKUP becomes active (high state) when resume condition occurs during L1 SLEEP or L2 SUSPEND states.
OTG_HS control and status registers

By reading from and writing to the control and status registers (CSRs) through the AHB slave interface, the application controls the OTG_HS controller. These registers are 32 bits wide, and the addresses are 32-bit block aligned. The OTG_HS registers must be accessed by words (32 bits).

CSRs are classified as follows:
- Core global registers
- Host-mode registers
- Host global registers
- Host port CSRs
- Host channel-specific registers
- Device-mode registers
- Device global registers
- Device endpoint-specific registers
- Power and clock-gating registers
- Data FIFO (DFIFO) access registers

Only the core global, power and clock-gating, data FIFO access, and host port control and status registers can be accessed in both host and device modes. When the OTG_HS controller is operating in one mode, either device or host, the application must not access registers from the other mode. If an illegal access occurs, a mode mismatch interrupt is generated and reflected in the core interrupt register (MMIS bit in the OTG_GINTSTS register). When the core switches from one mode to the other, the registers in the new mode of operation must be reprogrammed as they would be after a power-on reset.

60.13.1 CSR memory map

The host and device mode registers occupy different addresses. All registers are implemented in the AHB clock domain.

Global CSR map

These registers are available in both host and device modes.

**Data FIFO (DFIFO) access register map**

These registers, available in both host and device modes, are used to read or write the FIFO space for a specific endpoint or a channel, in a given direction. If a host channel is of type IN, the FIFO can only be read on the channel. Similarly, if a host channel is of type OUT, the FIFO can only be written on the channel.
Power and clock gating CSR map

There is a single register for power and clock gating. It is available in both host and device modes.

### Table 539. Power and clock gating control and status registers

#### 60.14 OTG_HS registers

These registers are available in both host and device modes, and do not need to be reprogrammed when switching between these modes.

Bit values in the register descriptions are expressed in binary unless otherwise specified.

#### 60.14.1 OTG control and status register (OTG_GOTGCTL)

Address offset: 0x000

Reset value: 0x0001 0000

The OTG_GOTGCTL register controls the behavior and reflects the status of the OTG function of the core.
Bits 31:22  Reserved, must be kept at reset value.

Bit 21  CURMOD: Current mode of operation
Indicates the current mode (host or device).
0: Device mode
1: Host mode

Bit 20  OTGVER: OTG version
Selects the OTG revision.
0: OTG Version 1.3. OTG1.3 is obsolete for new product development.
1: OTG Version 2.0. In this version the core supports only data line pulsing for SRP.

Bit 19  BSVLD: B-session valid
Indicates the device mode transceiver status.
0: B-session is not valid.
1: B-session is valid.
In OTG mode, the user can use this bit to determine if the device is connected or disconnected.

Note: Only accessible in device mode.

Bit 18  ASVLD: A-session valid
Indicates the host mode transceiver status.
0: A-session is not valid
1: A-session is valid

Note: Only accessible in host mode.

Bit 17  DBCT: Long/short debounce time
Indicates the debounce time of a detected connection.
0: Long debounce time, used for physical connections (100 ms + 2.5 µs)
1: Short debounce time, used for soft connections (2.5 µs)

Note: Only accessible in host mode.

Bit 16  CIDSTS: Connector ID status
Indicates the connector ID status on a connect event.
0: The OTG_HS controller is in A-device mode
1: The OTG_HS controller is in B-device mode

Note: Accessible in both device and host modes.

Bits 15:13  Reserved, must be kept at reset value.

Bit 12  EHEN: Embedded host enable
It is used to select between OTG A device state machine and embedded host state machine.
0: OTG A device state machine is selected
1: Embedded host state machine is selected

Bit 11  DHNPEN: Device HNP enabled
The application sets this bit when it successfully receives a SetFeature.SetHNPEnable command from the connected USB host.
0: HNP is not enabled in the application
1: HNP is enabled in the application

Note: Only accessible in device mode.
Bit 10 **| HSHNPEN**: host set HNP enable

The application sets this bit when it has successfully enabled HNP (using the SetFeature.SetHNPEnable command) on the connected device.

0: Host Set HNP is not enabled
1: Host Set HNP is enabled

*Note: Only accessible in host mode.*

Bit 9 **| HNPRQ**: HNP request

The application sets this bit to initiate an HNP request to the connected USB host. The application can clear this bit by writing a 0 when the host negotiation success status change bit in the OTG_GOTGINT register (HNSSCHG bit in OTG_GOTGINT) is set. The core clears this bit when the HNSSCHG bit is cleared.

0: No HNP request
1: HNP request

*Note: Only accessible in device mode.*

Bit 8 **| HNGSCS**: Host negotiation success

The core sets this bit when host negotiation is successful. The core clears this bit when the HNP request (HNPRQ) bit in this register is set.

0: Host negotiation failure
1: Host negotiation success

*Note: Only accessible in device mode.*

Bit 7 **| BVALOVAL**: B-peripheral session valid override value.

This bit is used to set override value for Bvalid signal when BVALOEN bit is set.

0: Bvalid value is '0' when BVALOEN = 1
1: Bvalid value is '1' when BVALOEN = 1

*Note: Only accessible in device mode.*

Bit 6 **| BVALOEN**: B-peripheral session valid override enable.

This bit is used to enable/disable the software to override the Bvalid signal using the BVALOVAL bit.

0: Override is disabled and Bvalid signal from the respective PHY selected is used internally by the core
1: Internally Bvalid received from the PHY is overridden with BVALOVAL bit value

*Note: Only accessible in device mode.*

Bit 5 **| AVALOVAL**: A-peripheral session valid override value.

This bit is used to set override value for Avalid signal when AVALOEN bit is set.

0: Avalid value is '0' when AVALOEN = 1
1: Avalid value is '1' when AVALOEN = 1

*Note: Only accessible in device mode.*

Bit 4 **| AVALOEN**: A-peripheral session valid override enable.

This bit is used to enable/disable the software to override the Avalid signal using the AVALOVAL bit.

0: Override is disabled and Avalid signal from the respective PHY selected is used internally by the core
1: Internally Avalid received from the PHY is overridden with AVALOVAL bit value

*Note: Only accessible in host mode.*
Bit 3 **VBVALOVAL**: \( V_{BUS} \) valid override value.
This bit is used to set override value for vbusvalid signal when VBVALOEN bit is set.
0: vbusvalid value is '0' when VBVALOEN = 1
1: vbusvalid value is '1' when VBVALOEN = 1

*Note: Only accessible in host mode.*

Bit 2 **VBVALOEN**: \( V_{BUS} \) valid override enable.
This bit is used to enable/disable the software to override the vbusvalid signal using the VBVALOVAL bit.
0: Override is disabled and vbusvalid signal from the respective PHY selected is used internally by the core
1: Internally vbusvalid received from the PHY is overridden with VBVALOVAL bit value

*Note: Only accessible in host mode.*

Bit 1 **SRQ**: Session request
The application sets this bit to initiate a session request on the USB. The application can clear this bit by writing a 0 when the host negotiation success status change bit in the OTG_GOTGINT register (HNSSCHG bit in OTG_GOTGINT) is set. The core clears this bit when the HNSSCHG bit is cleared.
If the user uses the USB 1.1 full-speed serial transceiver interface to initiate the session request, the application must wait until \( V_{BUS} \) discharges to 0.2 V, after the B-session valid bit in this register (BSVLD bit in OTG_GOTGCTL) is cleared.
0: No session request
1: Session request

*Note: Only accessible in device mode.*

Bit 0 **SRQSCS**: Session request success
The core sets this bit when a session request initiation is successful.
0: Session request failure
1: Session request success

*Note: Only accessible in device mode.*

### 60.14.2 OTG interrupt register (OTG_GOTGINT)

**Address offset:** 0x04

**Reset value:** 0x0000 0000

The application reads this register whenever there is an OTG interrupt and clears the bits in this register to clear the OTG interrupt.
Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **DBCDNE**: Debounce done
The core sets this bit when the debounce is completed after the device connect. The application can start driving USB reset after seeing this interrupt. This bit is only valid when the HNP Capable or SRP Capable bit is set in the OTG_GUSBCFG register (HNPCAP bit or SRPCAP bit in OTG_GUSBCFG, respectively).

*Note:* Only accessible in host mode.

Bit 18 **ADTOCHG**: A-device timeout change
The core sets this bit to indicate that the A-device has timed out while waiting for the B-device to connect.

*Note:* Accessible in both device and host modes.

Bit 17 **HNGDET**: Host negotiation detected
The core sets this bit when it detects a host negotiation request on the USB.

*Note:* Accessible in both device and host modes.

Bits 16:10 Reserved, must be kept at reset value.

Bit 9 **HNSSCHG**: Host negotiation success status change
The core sets this bit on the success or failure of a USB host negotiation request. The application must read the host negotiation success bit of the OTG_GOTGCTL register (HNGSCS bit in OTG_GOTGCTL) to check for success or failure.

*Note:* Accessible in both device and host modes.

Bits 7:3 Reserved, must be kept at reset value.

Bit 8 **SRSSCHG**: Session request success status change
The core sets this bit on the success or failure of a session request. The application must read the session request success bit in the OTG_GOTGCTL register (SRQSCS bit in OTG_GOTGCTL) to check for success or failure.

*Note:* Accessible in both device and host modes.

Bit 2 **SEDET**: Session end detected
The core sets this bit to indicate that the level of the voltage on VBUS is no longer valid for a B-Peripheral session when VBUS < 0.8 V.

*Note:* Accessible in both device and host modes.

Bits 1:0 Reserved, must be kept at reset value.
60.14.3 OTG AHB configuration register (OTG_GAHBCFG)

Address offset: 0x008
Reset value: 0x0000 0000

This register can be used to configure the core after power-on or a change in mode. This register mainly contains AHB system-related configuration parameters. Do not change this register after the initial programming. The application must program this register before starting any transactions on either the AHB or the USB.

</thead>
</table>

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 PTXFELVL: Periodic Tx FIFO empty level
Indicates when the periodic Tx FIFO empty interrupt bit in the OTG_GINTSTS register (PTXFE bit in OTG_GINTSTS) is triggered:
0: PTXFE (in OTG_GINTSTS) interrupt indicates that the Periodic Tx FIFO is half empty
1: PTXFE (in OTG_GINTSTS) interrupt indicates that the Periodic Tx FIFO is completely empty

Note: Only accessible in host mode.

Bit 7 TXFELVL: Tx FIFO empty level
In device mode, this bit indicates when IN endpoint Transmit FIFO empty interrupt (TXFE in OTG_DIEPINTx) is triggered:
0: The TXFE (in OTG_DIEPINTx) interrupt indicates that the IN endpoint Tx FIFO is half empty
1: The TXFE (in OTG_DIEPINTx) interrupt indicates that the IN endpoint Tx FIFO is completely empty
In host mode, this bit indicates when the nonperiodic Tx FIFO empty interrupt (NPTXFE bit in OTG_GINTSTS) is triggered:
0: The NPTXFE (in OTG_GINTSTS) interrupt indicates that the nonperiodic Tx FIFO is half empty
1: The NPTXFE (in OTG_GINTSTS) interrupt indicates that the nonperiodic Tx FIFO is completely empty

Bit 6 Reserved, must be kept at reset value.
Bit 5 **DMAEN**: DMA enabled
- 0: The core operates in slave mode
- 1: The core operates in DMA mode

Bits 4:1 **HBSTLEN[3:0]**: Burst length/type
- 0000 Single: Bus transactions use single 32 bit accesses (not recommended)
- 0001 INCR: Bus transactions use unspecified length accesses (not recommended, uses the INCR AHB bus command)
- 0011 INCR4: Bus transactions target 4x 32 bit accesses
- 0101 INCR8: Bus transactions target 8x 32 bit accesses
- 0111 INCR16: Bus transactions based on 16x 32 bit accesses
- Others: Reserved

Bit 0 **GINTMSK**: Global interrupt mask
The application uses this bit to mask or unmask the interrupt line assertion to itself. Irrespective of this bit’s setting, the interrupt status registers are updated by the core.
- 0: Mask the interrupt assertion to the application.
- 1: Unmask the interrupt assertion to the application.

**Note**: Accessible in both device and host modes.

### 60.14.4 OTG USB configuration register (OTG_GUSBCFG)
Address offset: 0x00C
Reset value: 0x0000 1400
This register can be used to configure the core after power-on or a changing to host mode or device mode. It contains USB and USB-PHY related configuration parameters. The application must program this register before starting any transactions on either the AHB or the USB. Do not make changes to this register after the initial programming.
Bit 31  Reserved, must be kept at reset value.

Bit 30  **FDMOD**: Force device mode
Writing a 1 to this bit, forces the core to device mode irrespective of the OTG_ID input pin.
0: Normal mode
1: Force device mode
After setting the force bit, the application must wait at least 25 ms before the change takes effect.

*Note:* Accessible in both device and host modes.

Bit 29  **FHMOD**: Force host mode
Writing a 1 to this bit, forces the core to host mode irrespective of the OTG_ID input pin.
0: Normal mode
1: Force host mode
After setting the force bit, the application must wait at least 25 ms before the change takes effect.

*Note:* Accessible in both device and host modes.

Bits 28:26  Reserved, must be kept at reset value.

Bit 25  **ULPIIPD**: ULPI interface protect disable
This bit controls the circuitry built in the PHY to protect the ULPI interface when the link tri-states stp and data. Any pull-up or pull-down resistors employed by this feature can be disabled. Refer to the ULPI specification for more details.
0: Enables the interface protection circuit
1: Disables the interface protection circuit

Bit 24  **PTCI**: Indicator pass through
This bit controls whether the complement output is qualified with the internal VBUS valid comparator before being used in the VBUS state in the RX CMD. Refer to the ULPI specification for more details.
0: Complement Output signal is qualified with the Internal VBUS valid comparator
1: Complement Output signal is not qualified with the Internal VBUS valid comparator

Bit 23  **PCCI**: Indicator complement
This bit controls the PHY to invert the ExternalVbusIndicator input signal, and generate the complement output. Refer to the ULPI specification for more details.
0: PHY does not invert the ExternalVbusIndicator signal
1: PHY inverts ExternalVbusIndicator signal

Bit 22  **TSDPS**: TermSel DLine pulsing selection
This bit selects utmi_termselect to drive the data line pulse during SRP (session request protocol).
0: Data line pulsing using utmi_tvalid (default)
1: Data line pulsing using utmi_termselect

Bit 21  **ULPIEVBUSI**: ULPI external VBUS indicator
This bit indicates to the ULPI PHY to use an external VBUS overcurrent indicator.
0: PHY uses an internal VBUS valid comparator
1: PHY uses an external VBUS valid comparator

Bit 20  **ULPIEVBUSD**: ULPI External VBUS Drive
This bit selects between internal or external supply to drive 5 V on VBUS, in the ULPI PHY.
0: PHY drives VBUS using internal charge pump (default)
1: PHY drives VBUS using external supply.
Bit 19 **ULPI: ULPI Auto-resume**
This bit sets the AutoResume bit in the interface control register on the ULPI PHY.
0: PHY does not use AutoResume feature
1: PHY uses AutoResume feature

Bit 18 **ULPIFSLS: ULPI FS/LS select**
The application uses this bit to select the FS/LS serial interface for the ULPI PHY. This bit is valid only when the FS serial transceiver is selected on the ULPI PHY.
0: ULPI interface
1: ULPI FS/LS serial interface

Bit 17 **Reserved, must be kept at reset value.**

Bit 16 **Reserved, must be kept at reset value.**

Bit 15 **TRDT[3:0]: USB turnaround time**
These bits are used to set the turnaround time in PHY clocks. They must be configured according to Table 540: TRDT values, depending on the application AHB frequency. Higher TRDT values allow stretching the USB response time to IN tokens in order to compensate for longer AHB read access latency to the data FIFO.

**Note:** Only accessible in device mode.

Bit 9 **HNPCAP: HNP-capable**
The application uses this bit to control the OTG_HS controller’s HNP capabilities.
0: HNP capability is not enabled.
1: HNP capability is enabled.

**Note:** Accessible in both device and host modes.

Bit 8 **SRPCAP: SRP-capable**
The application uses this bit to control the OTG_HS controller’s SRP capabilities. If the core operates as a non-SRP-capable B-device, it cannot request the connected A-device (host) to activate VBUS and start a session.
0: SRP capability is not enabled.
1: SRP capability is enabled.

**Note:** Accessible in both device and host modes.

Bit 7 **Reserved, must be kept at reset value.**

Bit 6 **PHYSEL: Full speed serial transceiver mode select**
0: USB 2.0 external ULPI high-speed PHY.
1: USB 1.1 full-speed serial mode.
Bit 5 Reserved, must be kept at reset value.
Bit 4 Reserved, must be kept at reset value.
Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **TOCAL[2:0]: FS timeout calibration**

The number of PHY clocks that the application programs in this field is added to the full-speed interpacket timeout duration in the core to account for any additional delays introduced by the PHY. This can be required, because the delay introduced by the PHY in generating the line state condition can vary from one PHY to another.

The USB standard timeout value for full-speed operation is 16 to 18 (inclusive) bit times. The application must program this field based on the speed of enumeration. The number of bit times added per PHY clock is 0.25 bit times.

### 60.14.5 OTG reset register (OTG_GRSTCTL)

Address offset: 0x10

Reset value: 0x8000 0000

The application uses this register to reset various hardware features inside the core.

```

Bit 31 **AHBIDL**: AHB master idle

Indicates that the AHB master state machine is in the Idle condition.

*Note*: Accessible in both device and host modes.

Bit 30 **DMAREQ**: DMA request signal enabled

This bit indicates that the DMA request is in progress. Used for debug.

Bits 29:11 Reserved, must be kept at reset value.
Bits 10:6 **TXFNUM[4:0]**: Tx FIFO number

This is the FIFO number that must be flushed using the Tx FIFO Flush bit. This field must not be changed until the core clears the Tx FIFO Flush bit.

00000:
- Non-periodic Tx FIFO flush in host mode
- Tx FIFO 0 flush in device mode

00001:
- Periodic Tx FIFO flush in host mode
- Tx FIFO 1 flush in device mode

00010: Tx FIFO 2 flush in device mode

... 01111: Tx FIFO 15 flush in device mode
10000: Flush all the transmit FIFOs in device or host mode.

*Note:* Accessible in both device and host modes.

Bit 5 **TXFFLSH**: Tx FIFO flush

This bit selectively flushes a single or all transmit FIFOs, but cannot do so if the core is in the midst of a transaction.

The application must write this bit only after checking that the core is neither writing to the Tx FIFO nor reading from the Tx FIFO. Verify using these registers:

Read—NAK Effective interrupt ensures the core is not reading from the FIFO
Write—AHBIDL bit in OTG_GRSTCTL ensures the core is not writing anything to the FIFO.

Flushing is normally recommended when FIFOs are reconfigured. FIFO flushing is also recommended during device endpoint disable. The application must wait until the core clears this bit before performing any operations. This bit takes eight clocks to clear, using the slower clock of phy_clk or hclk.

*Note:* Accessible in both device and host modes.

Bit 4 **RXFFLSH**: Rx FIFO flush

The application can flush the entire Rx FIFO using this bit, but must first ensure that the core is not in the middle of a transaction.

The application must only write to this bit after checking that the core is neither reading from the Rx FIFO nor writing to the Rx FIFO.

The application must wait until the bit is cleared before performing any other operations. This bit requires 8 clocks (slowest of PHY or AHB clock) to clear.

*Note:* Accessible in both device and host modes.

Bit 3 Reserved, must be kept at reset value.
Bit 2 **FCRST**: Host frame counter reset

The application writes this bit to reset the (micro-)frame number counter inside the core. When the (micro-)frame counter is reset, the subsequent SOF sent out by the core has a frame number of 0.

When application writes "1" to the bit, it might not be able to read back the value as it gets cleared by the core in a few clock cycles.

*Note:* *Only accessible in host mode.*

Bit 1 **PSRST**: Partial soft reset

Resets the internal state machines but keeps the enumeration info. Can be used to recover some specific PHY errors.

*Note:* *Accessible in both device and host modes.*

Bit 0 **CSRST**: Core soft reset

Resets the HCLK and PHY clock domains as follows:

- Clears the interrupts and all the CSR register bits except for the following bits:
  - GATEHCLK bit in OTG_PCGCCTL
  - STPPCLK bit in OTG_PCGCCTL
  - FSLSPCS bits in OTG_HCFG
  - DSPD bit in OTG_DCFG
  - SDIS bit in OTG_DCTL
  - OTG_GCCFG register

All module state machines (except for the AHB slave unit) are reset to the Idle state, and all the transmit FIFOs and the receive FIFO are flushed.

Any transactions on the AHB Master are terminated as soon as possible, after completing the last data phase of an AHB transfer. Any transactions on the USB are terminated immediately. The application can write to this bit any time it wants to reset the core. This is a self-clearing bit and the core clears this bit after all the necessary logic is reset in the core, which can take several clocks, depending on the current state of the core. Once this bit has been cleared, the software must wait at least 3 PHY clocks before accessing the PHY domain (synchronization delay). The software must also check that bit 31 in this register is set to 1 (AHB Master is Idle) before starting any operation.

Typically, the software reset is used during software development and also when the user dynamically changes the PHY selection bits in the above listed USB configuration registers. When the user changes the PHY, the corresponding clock for the PHY is selected and used in the PHY domain. Once a new clock is selected, the PHY domain has to be reset for proper operation.

*Note:* *Accessible in both device and host modes.*
### 60.14.6 OTG core interrupt register (OTG_GINTSTS)

Address offset: 0x014  
Reset value: 0x0400 0020

This register interrupts the application for system-level events in the current mode (device mode or host mode).

Some of the bits in this register are valid only in host mode, while others are valid in device mode only. This register also indicates the current mode. To clear the interrupt status bits of the rc_w1 type, the application must write 1 into the bit.

The FIFO status interrupts are read-only; once software reads from or writes to the FIFO while servicing these interrupts, FIFO interrupt conditions are cleared automatically.

The application must clear the OTG_GINTSTS register at initialization before unmasking the interrupt bit to avoid any interrupts generated prior to initialization.

<tr>
<td></td>
<td>Note: Accessible in both device and host modes.</td>
</tr>
</tbody>
</table>
Bit 27 **LPMINT**: LPM interrupt
In device mode, this interrupt is asserted when the device receives an LPM transaction and responds with a non-ERRORed response.
In host mode, this interrupt is asserted when the device responds to an LPM transaction with a non-ERRORed response or when the host core has completed LPM transactions for the programmed number of times (RETRYCNT bit in OTG_GLPMCFG).
This field is valid only if the LPMEN bit in OTG_GLPMCFG is set to 1.

Bit 26 **PTXFE**: Periodic Tx FIFO empty
Asserted when the periodic transmit FIFO is either half or completely empty and there is space for at least one entry to be written in the periodic request queue. The half or completely empty status is determined by the periodic Tx FIFO empty level bit in the OTG_GAHBCFG register (PTXFELVL bit in OTG_GAHBCFG).

*Note: Only accessible in host mode.*

Bit 25 **HCINT**: Host channels interrupt
The core sets this bit to indicate that an interrupt is pending on one of the channels of the core (in host mode). The application must read the OTG_HAINT register to determine the exact number of the channel on which the interrupt occurred, and then read the corresponding OTG_HCINTx register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the OTG_HCINTx register to clear this bit.

*Note: Only accessible in host mode.*

Bit 24 **HPRTINT**: Host port interrupt
The core sets this bit to indicate a change in port status of one of the OTG_HS controller ports in host mode. The application must read the OTG_HPRT register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the OTG_HPRT register to clear this bit.

*Note: Only accessible in host mode.*

Bit 23 **RSTDET**: Reset detected interrupt
In device mode, this interrupt is asserted when a reset is detected on the USB in partial power-down mode when the device is in suspend.

*Note: Only accessible in device mode.*

Bit 22 **DATAFSUSP**: Data fetch suspended
This interrupt is valid only in DMA mode. This interrupt indicates that the core has stopped fetching data for IN endpoints due to the unavailability of TxFIFO space or request queue space. This interrupt is used by the application for an endpoint mismatch algorithm. For example, after detecting an endpoint mismatch, the application:
- Sets a global nonperiodic IN NAK handshake
- Disables IN endpoints
- Flushes the FIFO
- Determines the token sequence from the IN token sequence learning queue
- Re-enables the endpoints

Clears the global nonperiodic IN NAK handshake if the global nonperiodic IN NAK is cleared, the core has not yet fetched data for the IN endpoint, and the IN token is received: the core generates an "IN token received when FIFO empty" interrupt. The OTG then sends a NAK response to the host. To avoid this scenario, the application can check the FetSusp interrupt in OTG_GINTSTS, which ensures that the FIFO is full before clearing a global NAK handshake. Alternatively, the application can mask the "IN token received when FIFO empty" interrupt when clearing a global IN NAK handshake.
Bit 21 **IPXFR**: Incomplete periodic transfer
In host mode, the core sets this interrupt bit when there are incomplete periodic transactions still pending, which are scheduled for the current frame.

**INCOMPISOOUT**: Incomplete isochronous OUT transfer
In device mode, the core sets this interrupt to indicate that there is at least one isochronous OUT endpoint on which the transfer is not completed in the current frame. This interrupt is asserted along with the End of periodic frame interrupt (EOPF) bit in this register.

Bit 20 **ISOIXFR**: Incomplete isochronous IN transfer
The core sets this interrupt to indicate that there is at least one isochronous IN endpoint on which the transfer is not completed in the current frame. This interrupt is asserted along with the End of periodic frame interrupt (EOPF) bit in this register.

*Note: Only accessible in device mode.*

Bit 19 **OEPINT**: OUT endpoint interrupt
The core sets this bit to indicate that an interrupt is pending on one of the OUT endpoints of the core (in device mode). The application must read the OTG_DAINT register to determine the exact number of the OUT endpoint on which the interrupt occurred, and then read the corresponding OTG_DOEPINTx register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the corresponding OTG_DOEPINTx register to clear this bit.

*Note: Only accessible in device mode.*

Bit 18 **IEPINT**: IN endpoint interrupt
The core sets this bit to indicate that an interrupt is pending on one of the IN endpoints of the core (in device mode). The application must read the OTG_DAINT register to determine the exact number of the IN endpoint on which the interrupt occurred, and then read the corresponding OTG_DIEPINTx register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the corresponding OTG_DIEPINTx register to clear this bit.

*Note: Only accessible in device mode.*

Bits 17:16 Reserved, must be kept at reset value.

Bit 15 **EOPF**: End of periodic frame interrupt
Indicates that the period specified in the periodic frame interval field of the OTG_DCFG register (PFIVL bit in OTG_DCFG) has been reached in the current frame.

*Note: Only accessible in device mode.*

Bit 14 **ISOODRP**: Isochronous OUT packet dropped interrupt
The core sets this bit when it fails to write an isochronous OUT packet into the Rx FIFO because the Rx FIFO does not have enough space to accommodate a maximum size packet for the isochronous OUT endpoint.

*Note: Only accessible in device mode.*

Bit 13 **ENUMDNE**: Enumeration done
The core sets this bit to indicate that speed enumeration is complete. The application must read the OTG_DSTS register to obtain the enumerated speed.

*Note: Only accessible in device mode.*

Bit 12 **USBRST**: USB reset
The core sets this bit to indicate that a reset is detected on the USB.

*Note: Only accessible in device mode.*
Bit 11 **USBSUSP**: USB suspend
The core sets this bit to indicate that a suspend was detected on the USB. The core enters the suspended state when there is no activity on the data lines for an extended period of time.

*Note: Only accessible in device mode.*

Bit 10 **ESUSP**: Early suspend
The core sets this bit to indicate that an Idle state has been detected on the USB for 3 ms.

*Note: Only accessible in device mode.*

Bits 9:8 Reserved, must be kept at reset value.

Bit 7 **GONAKEFF**: Global OUT NAK effective
Indicates that the Set global OUT NAK bit in the OTG_DCTL register (SGONAK bit in OTG_DCTL), set by the application, has taken effect in the core. This bit can be cleared by writing the Clear global OUT NAK bit in the OTG_DCTL register (CGONAK bit in OTG_DCTL).

*Note: Only accessible in device mode.*

Bit 6 **GINAKEFF**: Global IN non-periodic NAK effective
Indicates that the Set global non-periodic IN NAK bit in the OTG_DCTL register (SGINAK bit in OTG_DCTL), set by the application, has taken effect in the core. That is, the core has sampled the Global IN NAK bit set by the application. This bit can be cleared by clearing the Clear global non-periodic IN NAK bit in the OTG_DCTL register (CGINAK bit in OTG_DCTL).

This interrupt does not necessarily mean that a NAK handshake is sent out on the USB. The STALL bit takes precedence over the NAK bit.

*Note: Only accessible in device mode.*

Bit 5 **NPTXFE**: Non-periodic Tx FIFO empty
This interrupt is asserted when the non-periodic Tx FIFO is either half or completely empty, and there is space for at least one entry to be written to the non-periodic transmit request queue. The half or completely empty status is determined by the non-periodic Tx FIFO empty level bit in the OTG_GAHBCFG register (TXFELVL bit in OTG_GAHBCFG).

*Note: Accessible in host mode only.*

Bit 4 **RXFLVL**: Rx FIFO non-empty
Indicates that there is at least one packet pending to be read from the Rx FIFO.

*Note: Accessible in both host and device modes.*

Bit 3 **SOF**: Start of frame
In host mode, the core sets this bit to indicate that an SOF (FS), or Keep-Alive (LS) is transmitted on the USB. The application must write a 1 to this bit to clear the interrupt. In device mode, in the core sets this bit to indicate that an SOF token has been received on the USB. The application can read the OTG_DSTS register to get the current frame number. This interrupt is seen only when the core is operating in FS.

*Note: This register may return ‘1’ if read immediately after power on reset. If the register bit reads ‘1’ immediately after power on reset it does not indicate that an SOF has been sent (in case of host mode) or SOF has been received (in case of device mode). The read value of this interrupt is valid only after a valid connection between host and device is established. If the bit is set after power on reset the application can clear the bit.*

*Note: Accessible in both host and device modes.*
Bit 2  **OTGINT**: OTG interrupt
The core sets this bit to indicate an OTG protocol event. The application must read the OTG interrupt status (OTG_GOTGINT) register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the OTG_GOTGINT register to clear this bit.

*Note*: *Accessible in both host and device modes.*

Bit 1  **MMIS**: Mode mismatch interrupt
The core sets this bit when the application is trying to access:
- A host mode register, when the core is operating in device mode
- A device mode register, when the core is operating in host mode

The register access is completed on the AHB with an OKAY response, but is ignored by the core internally and does not affect the operation of the core.

*Note*: *Accessible in both host and device modes.*

Bit 0  **CMOD**: Current mode of operation
Indicates the current mode.
0: Device mode
1: Host mode

*Note*: *Accessible in both host and device modes.*

### 60.14.7  OTG interrupt mask register (OTG_GINTMSK)

Address offset: 0x018
Reset value: 0x0000 0000

This register works with the core interrupt register to interrupt the application. When an interrupt bit is masked, the interrupt associated with that bit is not generated. However, the core interrupt (OTG_GINTSTS) register bit corresponding to that interrupt is still set.
Bit 31 **WUIM**: Resume/remote wake-up detected interrupt mask
   0: Masked interrupt  
   1: Unmasked interrupt  
   *Note: Accessible in both host and device modes.*

Bit 30 **SRQIM**: Session request/new session detected interrupt mask
   0: Masked interrupt  
   1: Unmasked interrupt  
   *Note: Accessible in both host and device modes.*

Bit 29 **DISCINT**: Disconnect detected interrupt mask
   0: Masked interrupt  
   1: Unmasked interrupt  
   *Note: Only accessible in host mode.*

Bit 28 **CIDSCHGM**: Connector ID status change mask
   0: Masked interrupt  
   1: Unmasked interrupt  
   *Note: Accessible in both host and device modes.*

Bit 27 **LPMINTM**: LPM interrupt mask
   0: Masked interrupt  
   1: Unmasked interrupt  
   *Note: Accessible in both host and device modes.*

Bit 26 **PTXFEM**: Periodic Tx FIFO empty mask
   0: Masked interrupt  
   1: Unmasked interrupt  
   *Note: Only accessible in host mode.*

Bit 25 **HCIM**: Host channels interrupt mask
   0: Masked interrupt  
   1: Unmasked interrupt  
   *Note: Only accessible in host mode.*

Bit 24 **PRTIM**: Host port interrupt mask
   0: Masked interrupt  
   1: Unmasked interrupt  
   *Note: Only accessible in host mode.*

Bit 23 **RSTDETM**: Reset detected interrupt mask
   0: Masked interrupt  
   1: Unmasked interrupt  
   *Note: Only accessible in device mode.*

Bit 22 **FSUSPM**: Data fetch suspended mask
   0: Masked interrupt  
   1: Unmasked interrupt  
   Only accessible in peripheral mode.
Bit 21  **IPXFRM**: Incomplete periodic transfer mask  
0: Masked interrupt  
1: Unmasked interrupt  
*Note:* Only accessible in host mode.

**IISSOIXFRM**: Incomplete isochronous OUT transfer mask  
0: Masked interrupt  
1: Unmasked interrupt  
*Note:* Only accessible in device mode.

Bit 20  **IIISOIXFRM**: Incomplete isochronous IN transfer mask  
0: Masked interrupt  
1: Unmasked interrupt  
*Note:* Only accessible in device mode.

Bit 19  **OEPINT**: OUT endpoints interrupt mask  
0: Masked interrupt  
1: Unmasked interrupt  
*Note:* Only accessible in device mode.

Bit 18  **IEPINT**: IN endpoints interrupt mask  
0: Masked interrupt  
1: Unmasked interrupt  
*Note:* Only accessible in device mode.

Bits 17:16  Reserved, must be kept at reset value.

Bit 15  **EOPFM**: End of periodic frame interrupt mask  
0: Masked interrupt  
1: Unmasked interrupt  
*Note:* Only accessible in device mode.

Bit 14  **ISOODRPM**: Isochronous OUT packet dropped interrupt mask  
0: Masked interrupt  
1: Unmasked interrupt  
*Note:* Only accessible in device mode.

Bit 13  **ENUMDNEM**: Enumeration done mask  
0: Masked interrupt  
1: Unmasked interrupt  
*Note:* Only accessible in device mode.

Bit 12  **USBRST**: USB reset mask  
0: Masked interrupt  
1: Unmasked interrupt  
*Note:* Only accessible in device mode.

Bit 11  **USBSUSPM**: USB suspend mask  
0: Masked interrupt  
1: Unmasked interrupt  
*Note:* Only accessible in device mode.

Bit 10  **ESUSPM**: Early suspend mask  
0: Masked interrupt  
1: Unmasked interrupt  
*Note:* Only accessible in device mode.
Bits 9:8  Reserved, must be kept at reset value.

Bit 7  **GONAKEFFM:** Global OUT NAK effective mask  
0: Masked interrupt  
1: Unmasked interrupt  
*Note:*  Only accessible in device mode.

Bit 6  **GINAKEFFM:** Global non-periodic IN NAK effective mask  
0: Masked interrupt  
1: Unmasked interrupt  
*Note:*  Only accessible in device mode.

Bit 5  **NPTXFEM:** Non-periodic Tx FIFO empty mask  
0: Masked interrupt  
1: Unmasked interrupt  
*Note:*  Only accessible in host mode.

Bit 4  **RXFLVLM:** Receive FIFO non-empty mask  
0: Masked interrupt  
1: Unmasked interrupt  
*Note:*  Accessible in both device and host modes.

Bit 3  **SOFM:** Start of frame mask  
0: Masked interrupt  
1: Unmasked interrupt  
*Note:*  Accessible in both device and host modes.

Bit 2  **OTGINT:** OTG interrupt mask  
0: Masked interrupt  
1: Unmasked interrupt  
*Note:*  Accessible in both device and host modes.

Bit 1  **MMISM:** Mode mismatch interrupt mask  
0: Masked interrupt  
1: Unmasked interrupt  
*Note:*  Accessible in both device and host modes.

Bit 0  Reserved, must be kept at reset value.
60.14.8 OTG receive status debug read register (OTG_GRXSTSR)

Address offset for read: 0x01C
Reset value: 0x0000 0000

This description is for register OTG_GRXSTSR in Device mode.

A read to the receive status debug read register returns the contents of the top of the receive FIFO.

The core ignores the receive status read when the receive FIFO is empty and returns a value of 0x0000 0000.

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 STSPHST: Status phase start
Indicates the start of the status phase for a control write transfer. This bit is set along with the OUT transfer completed PKTSTS pattern.

Bits 26:25 Reserved, must be kept at reset value.

Bits 24:21 FRMNUM[3:0]: Frame number
This is the least significant 4 bits of the frame number in which the packet is received on the USB. This field is supported only when isochronous OUT endpoints are supported.

Bits 20:17 PKTSTS[3:0]: Packet status
Indicates the status of the received packet
0001: Global OUT NAK (triggers an interrupt)
0010: OUT data packet received
0011: OUT transfer completed (triggers an interrupt)
0100: SETUP transaction completed (triggers an interrupt)
0110: SETUP data packet received
Others: Reserved

Bits 16:15 DPID[1:0]: Data PID
Indicates the data PID of the received OUT data packet
00: DATA0
10: DATA1
01: DATA2
11: MDATA

Bits 14:4 BCNT[10:0]: Byte count
Indicates the byte count of the received data packet.

Bits 3:0 EPNUM[3:0]: Endpoint number
Indicates the endpoint number to which the current received packet belongs.
60.14.9  OTG receive status debug read [alternate] (OTG_GRXSTSR)

Address offset for read: 0x01C
Reset value: 0x0000 0000

This description is for register OTG_GRXSTSR in Host mode.

A read to the receive status debug read register returns the contents of the top of the receive FIFO.

The core ignores the receive status read when the receive FIFO is empty and returns a value of 0x0000 0000.

60.14.10 OTG status read and pop registers (OTG_GRXSTSP)

Address offset for pop: 0x020
Reset value: 0x0000 0000

This description is for register OTG_GRXSTSP in Device mode.

Similarly to OTG_GRXSTSR (receive status debug read register) where a read returns the contents of the top of the receive FIFO, a read to OTG_GRXSTSP (receive status read and pop register) additionally pops the top data entry out of the Rx FIFO.

The core ignores the receive status pop/read when the receive FIFO is empty and returns a value of 0x0000 0000. The application must only pop the receive status FIFO when the receive FIFO non-empty bit of the core interrupt register (RXFLVL bit in OTG_GINTSTS) is asserted.

Maximum value is 1024
Programmed values must respect the available FIFO memory allocation and must not exceed the power-on value.
Host mode

Bits 31:16 **NPTXFD[15:0]**: Non-periodic Tx FIFO depth
This value is in terms of 32-bit words.
Minimum value is 16
Programmed values must respect the available FIFO memory allocation and must not exceed the power-on value.

Bits 15:0 **NPTXFSA[15:0]**: Non-periodic transmit RAM start address
This field configures the memory start address for non-periodic transmit FIFO RAM.

Device mode

Bits 31:16 **TX0FD**: Endpoint 0 Tx FIFO depth
This value is in terms of 32-bit words.
Minimum value is 16
Programmed values must respect the available FIFO memory allocation and must not exceed the power-on value.

Bits 15:0 **TX0FSA**: Endpoint 0 transmit RAM start address
This field configures the memory start address for the endpoint 0 transmit FIFO RAM.

60.14.14 **OTG non-periodic transmit FIFO/queue status register (OTG_HNPTXSTS)**

Address offset: 0x02C
Reset value: 0x0008 0400

*Note*: *In device mode, this register is not valid.*

This read-only register contains the free space information for the non-periodic Tx FIFO and the non-periodic transmit request queue.

</table>
Bits 31:22  Reserved, must be kept at reset value.

Bit 21  **VBDEN**: USB VBUS detection enable
    Enables VBUS sensing comparators to detect VBUS valid levels on the VBUS PAD for USB host and device operation. If HNP and/or SRP support is enabled, VBUS comparators are automatically enabled independently of VBDEN value.
    0 = VBUS detection disabled
    1 = VBUS detection enabled

Bit 20  **SDEN**: Secondary detection (SD) mode enable
    This bit is set by the software to put the BCD into SD mode. Only one detection mode (DCD, PD, SD or OFF) must be selected to work correctly.

Bit 19  **PDEN**: Primary detection (PD) mode enable
    This bit is set by the software to put the BCD into PD mode. Only one detection mode (DCD, PD, SD or OFF) must be selected to work correctly.

Bit 18  **DCDEN**: Data contact detection (DCD) mode enable
    This bit is set by the software to put the BCD into DCD mode. Only one detection mode (DCD, PD, SD or OFF) must be selected to work correctly.

Bit 17  **BCDEN**: Battery charging detector (BCD) enable
    This bit is set by the software to enable the BCD support within the USB device. When enabled, the USB PHY is fully controlled by BCD and cannot be used for normal communication. Once the BCD discovery is finished, the BCD must be placed in OFF mode by clearing this bit to '0' in order to allow the normal USB operation.

Bit 16  **PWRDWN**: Power down control of FS PHY
    Used to activate the FS PHY in transmission/reception. When reset, the PHY is kept in power-down. When set, the BCD function must be off (BCDEN=0).
    0 = USB FS PHY disabled
    1 = USB FS PHY enabled

Bits 15:4  Reserved, must be kept at reset value.

Bit 3  **PS2DET**: DM pull-up detection status
    This bit is active only during PD and gives the result of comparison between DM voltage level and VLGC threshold. In normal situation, the DM level must be below this threshold. If it is above, it means that the DM is externally pulled high. This can be caused by connection to a PS2 port (which pulls-up both DP and DM lines) or to some proprietary charger not following the BCD specification.
    0: Normal port detected (connected to SDP, CDP or DCP)
    1: PS2 port or proprietary charger detected

Bit 2  **SDET**: Secondary detection (SD) status
    This bit gives the result of SD.
    0: CDP detected
    1: DCP detected

Bit 1  **PDET**: Primary detection (PD) status
    This bit gives the result of PD.
    0: no BCD support detected (connected to SDP or proprietary device).
    1: BCD support detected (connected to CDP or DCP).

Bit 0  **DCDET**: Data contact detection (DCD) status
    This bit gives the result of DCD.
    0: data lines contact not detected
    1: data lines contact detected
60.14.16 OTG core ID register (OTG_CID)

Address offset: 0x03C

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 ENBESL: Enable best effort service latency
This bit enables the BESL feature as defined in the LPM errata:
0: The core works as described in the following document:
USB 2.0 Link Power Management Addendum Engineering Change Notice to the USB 2.0 specification, July 16, 2007
1: The core works as described in the LPM Errata:
Errata for USB 2.0 ECN: Link Power Management (LPM) - 7/2007
Note: Only the updated behavior (described in LPM Errata) is considered in this document and so the ENBESL bit must be set to ‘1’ by application SW.

Bits 27:25 LPMRCNTSTS[2:0]: LPM retry count status
Number of LPM host retries still remaining to be transmitted for the current LPM sequence.
Note: Accessible only in host mode.
Bit 24 **SNDLPM**: Send LPM transaction
When the application software sets this bit, an LPM transaction containing two tokens, EXT and LPM is sent. The hardware clears this bit once a valid response (STALL, NYET, or ACK) is received from the device or the core has finished transmitting the programmed number of LPM retries.

*Note:* This bit must be set only when the host is connected to a local port.
*Note:* Accessible only in host mode.

Bits 23:21 **LPMRCNT[2:0]**: LPM retry count
When the device gives an ERROR response, this is the number of additional LPM retries that the host performs until a valid device response (STALL, NYET, or ACK) is received.

*Note:* Accessible only in host mode.

Bits 20:17 **LPMCHIDX[3:0]**: LPM Channel Index
The channel number on which the LPM transaction has to be applied while sending an LPM transaction to the local device. Based on the LPM channel index, the core automatically inserts the device address and endpoint number programmed in the corresponding channel into the LPM transaction.

*Note:* Accessible only in host mode.

Bit 16 **L1RSMOK**: Sleep state resume OK
Indicates that the device or host can start resume from Sleep state. This bit is valid in LPM sleep (L1) state. It is set in sleep mode after a delay of 50 μs (T_{L1Residency}).
This bit is reset when SLPSTS is 0.
1: The application or host can start resume from Sleep state
0: The application or host cannot start resume from Sleep state

Bit 15 **SLPSTS**: Port sleep status
**Device mode:**
This bit is set as long as a Sleep condition is present on the USB bus. The core enters the Sleep state when an ACK response is sent to an LPM transaction and the T_{L1TokenRetry} timer has expired. To stop the PHY clock, the application must set the STPPCLK bit in OTG_PGCCTL, which asserts the PHY suspend input signal.
The application must rely on SLPSTS and not ACK in LPMRSP to confirm transition into sleep.
The core comes out of sleep:
– When there is any activity on the USB line state
– When the application writes to the RWUSIG bit in OTG_DCTL or when the application resets or soft-disconnects the device.

**Host mode:**
The host transitions to Sleep (L1) state as a side-effect of a successful LPM transaction by the core to the local port with ACK response from the device. The read value of this bit reflects the current Sleep status of the port.
The core clears this bit after:
– The core detects a remote L1 wake-up signal,
– The application sets the PRST bit or the PRES bit in the OTG_HPRT register, or
– The application sets the L1Resume/ remote wake-up detected interrupt bit or disconnect detected interrupt bit in the core interrupt register (WKUPINT or DISCINT bit in OTG_GINTSTS, respectively).
0: Core not in L1
1: Core in L1
Bits 14:13  **LPMRSP[1:0]:** LPM response

**Device mode:**
The response of the core to LPM transaction received is reflected in these two bits.

**Host mode:**
Handshake response received from local device for LPM transaction
- 11: ACK
- 10: NYET
- 01: STALL
- 00: ERROR (No handshake response)

Bit 12  **L1DSEN:** L1 deep sleep enable

Enables suspending the PHY in L1 Sleep mode. For maximum power saving during L1 Sleep mode, this bit must be set to '1' by application SW in all the cases.

Bits 11:8  **BESLTHRS[3:0]:** BESL threshold

**Device mode:**
The core puts the PHY into deep low power mode in L1 when BESL value is greater than or equal to the value defined in this field BESL_Thres[3:0].

**Host mode:**
The core puts the PHY into deep low power mode in L1. BESLTHRS[3:0] specifies the time for which resume signaling is to be reflected by host ($T_{L1HubDrvResume2}$) on the USB bus when it detects device initiated resume.

BESLTHRS must not be programmed with a value greater than 1100b in host mode, because this exceeds maximum $T_{L1HubDrvResume2}$: Thres[3:0] host mode resume signaling time (μs):
- 0000: 75
- 0001: 100
- 0010: 150
- 0011: 250
- 0100: 350
- 0101: 450
- 0110: 950
- All other values: reserved

Bit 7  **L1SEN:** L1 Shallow Sleep enable

Enables suspending the PHY in L1 Sleep mode. For maximum power saving during L1 Sleep mode, this bit must be set to '1' by application SW in all the cases.

Bit 6  **REMWAKE:** bRemoteWake value

**Host mode:**
The value of remote wake up to be sent in the wIndex field of LPM transaction.

**Device mode (read-only):**
This field is updated with the received LPM token bRemoteWake bmAttribute when an ACK, NYET, or STALL response is sent to an LPM transaction.
Bits 5:2 **BESL[3:0]**: Best effort service latency

**Host mode:**
The value of BESL to be sent in an LPM transaction. This value is also used to initiate resume for a duration $T_{\text{LHubDrvResume}}$ for host initiated resume.

**Device mode (read-only):**
This field is updated with the received LPM token BESL bmAttribute when an ACK, NYET, or STALL response is sent to an LPM transaction.

$\text{BESL[3:0]} \cdot T_{\text{BESL}}$ (μs)
0000: 125
0001: 150
0010: 200
0011: 300
0100: 400
0101: 500
0110: 1000
0111: 2000
1000: 3000
1001: 4000
1010: 5000
1011: 6000
1100: 7000
1101: 8000
1110: 9000
1111: 10000

Bit 1 **LPMACK**: LPM token acknowledge enable
Handshake response to LPM token preprogrammed by device application software.
1: ACK
Even though ACK is preprogrammed, the core device responds with ACK only on successful LPM transaction. The LPM transaction is successful if:
- No PID/CRC5 errors in either EXT token or LPM token (else ERROR)
- Valid bLinkState = 0001B (L1) received in LPM transaction (else STALL)
- No data pending in transmit queue (else NYET).
0: NYET
The preprogrammed software bit is over-ridden for response to LPM token when:
- The received bLinkState is not L1 (STALL response), or
- An error is detected in either of the LPM token packets because of corruption (ERROR response).

**Note**: Accessible only in device mode.

Bit 0 **LPMEN**: LPM support enable
The application uses this bit to control the OTG_HS core LPM capabilities.
If the core operates as a non-LPM-capable host, it cannot request the connected device or hub to activate LPM mode.
If the core operates as a non-LPM-capable device, it cannot respond to any LPM transactions.
0: LPM capability is not enabled
1: LPM capability is enabled

Bits 31:16 INEPTXF[15:0]: Host periodic Tx FIFO start address
This field configures the memory start address for periodic transmit FIFO RAM.
60.14.20 Host-mode registers

Bit values in the register descriptions are expressed in binary unless otherwise specified.

Host-mode registers affect the operation of the core in the host mode. Host mode registers must not be accessed in device mode, as the results are undefined. Host mode registers can be categorized as follows:

60.14.21 OTG host configuration register (OTG_HCFG)

Address offset: 0x400
Reset value: 0x0000 0000

This register configures the core after power-on. Do not make changes to this register after initializing the host.

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 PERSSCHEDENA: Enable periodic scheduling
Applicable in host scatter/gather DMA mode only. Enables periodic scheduling within the core. Initially, the bit is res and the core does not process any periodic channels. As soon as this bit is set, the core gets ready to start scheduling periodic channels and sets OTG_HCFG.PERSCHEDSTAT. The setting of PERSCHEDSTAT indicates the core has enabled periodic scheduling. Once PERSSCHEDENA is set, the application is not supposed to reset the bit unless PERSCHEDSTAT is set. As soon as this bit is reset, the core gets ready to stop scheduling periodic channels and resets HCFG. PerSchedStat. In non-Scatter/Gather DMA mode, this bit is reserved.

Bits 25:24 FRLSTEN[1:0]: Frame list entries
The value in the register specifies the number of entries in the Frame list. This field is valid only in Scatter/Gather DMA mode.
2'b00: Reserved
2'b01: 8 Entries
2'b10: 16 Entries
2'b11: 32 Entries In non-Scatter/Gather

Bits 31:16 INEPTXF[15:0]: IN endpoint Tx FIFO depth
This value is in terms of 32-bit words.
Minimum value is 16

Bits 15:0 INEPTTXSA[15:0]: IN endpoint FIFOx transmit RAM start address
This field contains the memory start address for IN endpoint transmit FIFOx. The address must be aligned with a 32-bit memory location.
Bit 23 **DESCDMA**: Enable scatter/gather DMA in host mode

The application can set this bit during initialization to enable the Scatter/Gather DMA operation. This bit must be modified only once after a reset. The following combinations are available for programming:

- OTG_GAHBCFG.DMAEN=0, OTG_HCFG.DESCDMA=0 => Slave mode
- OTG_GAHBCFG.DMAEN=0, OTG_HCFG.DESCDMA=1 => Invalid
- OTG_GAHBCFG.DMAEN=1, OTG_HCFG.DESCDMA=0 => Buffered DMA mode
- OTG_GAHBCFG.DMAEN=1, OTG_HCFG.DESCDMA=1 => Scatter/Gather DMA mode

Bits 22:3 Reserved, must be kept at reset value.

Bit 2 **FSLSS**: FS- and LS-only support

The application uses this bit to control the core’s enumeration speed. Using this bit, the application can make the core enumerate as an FS host, even if the connected device supports HS traffic. Do not make changes to this field after initial programming.

Bits 1:0 **FSLSPCS[1:0]**: FS/LS PHY clock select

- When the core is in FS host mode
  - 01: PHY clock is running at 48 MHz
  - Others: Reserved
- When the core is in LS host mode
  - 00: Reserved
  - 01: Select 48 MHz PHY clock frequency
  - 10: Select 6 MHz PHY clock frequency
  - 11: Reserved

*Note: The FSLSPCS must be set on a connection event according to the speed of the connected device (after changing this bit, a software reset must be performed).*

### 60.14.22 OTG host frame interval register (OTG_HFIR)

**Address offset**: 0x404

**Reset value**: 0x0000 EA60

This register stores the frame interval information for the current speed to which the OTG_HS controller has enumerated.
Bits 31:17  Reserved, must be kept at reset value.

Bit 16  **RLDCTRL**: Reload control
- This bit allows dynamic reloading of the HFIR register during run time.
- 0: The HFIR cannot be reloaded dynamically
- 1: The HFIR can be dynamically reloaded during run time.

This bit needs to be programmed during initial configuration and its value must not be changed during run time.

**Caution**: RLDCTRL = 0 is not recommended.

Bits 15:0  **FRIVL[15:0]**: Frame interval
- The value that the application programs to this field, specifies the interval between two consecutive micro-SOFs (HS) or Keep-Alive tokens (LS). This field contains the number of PHY clocks that constitute the required frame interval. The application can write a value to this register only after the port enable bit of the host port control and status register (PENA bit in OTG_HPRT) has been set. If no value is programmed, the core calculates the value based on the PHY clock specified in the FS/LS PHY clock select field of the host configuration register (FSLSPCS in OTG_HCFG). Do not change the value of this field after the initial configuration, unless the RLDCTRL bit is set. In such case, the FRIVL is reloaded with each SOF event.
  - Frame interval = 125 μs × (FRIVL - 1) in high speed operation
  - Frame interval = 1 ms × (FRIVL - 1) in low/full speed operation

60.14.23  **OTG host frame number/frame time remaining register**  
(OTG_HNUM)

Address offset: 0x408

Reset value: 0x0000 3FFF

This register indicates the current frame number. It also indicates the time remaining (in terms of the number of PHY clocks) in the current frame.

</table>

Bits 31:16  **FTREM[15:0]**: Frame time remaining
- Indicates the amount of time remaining in the current frame, in terms of PHY clocks. This field decrements on each PHY clock. When it reaches zero, this field is reloaded with the value in the Frame interval register and a new SOF is transmitted on the USB.

Bits 15:0  **FRNUM[15:0]**: Frame number
- This field increments when a new SOF is transmitted on the USB, and is cleared to 0 when it reaches 0x3FFF.
60.14.24 OTG_Host periodic transmit FIFO/queue status register
(OTG_HPTXSTS)

Address offset: 0x410
Reset value: 0x0008 0100

This read-only register contains the free space information for the periodic Tx FIFO and the periodic transmit request queue.

<table>

</table>
60.14.25 OTG host all channels interrupt register (OTG_HAINT)

Address offset: 0x414
Reset value: 0x0000 0000

When a significant event occurs on a channel, the host all channels interrupt register interrupts the application using the host channels interrupt bit of the core interrupt register (HCINT bit in OTG_GINTSTS). This is shown in Figure 801. There is one interrupt bit per channel, up to a maximum of 16 bits. Bits in this register are set and cleared when the application sets and clears bits in the corresponding host channel-x interrupt register.

HAINT[15:0]

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 HAINT[15:0]: Channel interrupts
One bit per channel: Bit 0 for Channel 0, bit 15 for Channel 15

60.14.26 OTG host all channels interrupt mask register (OTG_HAINTMSK)

Address offset: 0x418
Reset value: 0x0000 0000

The host all channel interrupt mask register works with the host all channel interrupt register to interrupt the application when an event occurs on a channel. There is one interrupt mask bit per channel, up to a maximum of 16 bits.

HAINTM[15:0]

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 HAINTM[15:0]: Channel interrupt mask
0: Masked interrupt
1: Unmasked interrupt
One bit per channel: Bit 0 for Channel 0, bit 15 for Channel 15
60.14.27 OTG host frame list base address register (OTG_HFLBADDR)

Address offset: 0x41C
Reset value: 0x0000 0000

This register holds the starting address of the frame list information (scatter/gather mode).

<table>

</tbody>
</table>

60.14.28 OTG host port control and status register (OTG_HPRT)

Address offset: 0x440
Reset value: 0x0000 0000

This register is available only in host mode. Currently, the OTG host supports only one port.

A single register holds USB port-related information such as USB reset, enable, suspend, resume, connect status, and test mode for each port. It is shown in Figure 801. The rc_w1 bits in this register can trigger an interrupt to the application through the host port interrupt bit of the core interrupt register (HPRTINT bit in OTG_GINTSTS). On a port interrupt, the application must read this register and clear the bit that caused the interrupt. For the rc_w1 bits, the application must write a 1 to the bit to clear the interrupt.
Bits 31:19  Reserved, must be kept at reset value.

Bits 18:17  **PSPD[1:0]: Port speed**
Indicates the speed of the device attached to this port.
01: Full speed
10: Low speed
11: Reserved
00: High speed

Bits 16:13  **PTCTL[3:0]: Port test control**
The application writes a nonzero value to this field to put the port into a Test mode, and the corresponding pattern is signaled on the port.
0000: Test mode disabled
0001: Test_J mode
0010: Test_K mode
0011: Test_SE0_NAK mode
0100: Test_Packet mode
0101: Test_Force_Enable
Others: Reserved

Bit 12  **PPWR: Port power**
The application uses this field to control power to this port, and the core clears this bit on an overcurrent condition.
0: Power off
1: Power on

Bits 11:10  **PLSTS[1:0]: Port line status**
Indicates the current logic level USB data lines
Bit 10: Logic level of OTG_DP
Bit 11: Logic level of OTG_DM

Bit 9  Reserved, must be kept at reset value.

Bit 8  **PRST: Port reset**
When the application sets this bit, a reset sequence is started on this port. The application must time the reset period and clear this bit after the reset sequence is complete.
0: Port not in reset
1: Port in reset
The application must leave this bit set for a minimum duration of at least 10 ms to start a reset on the port. The application can leave it set for another 10 ms in addition to the required minimum duration, before clearing the bit, even though there is no maximum limit set by the USB standard.
High speed: 50 ms
Full speed/Low speed: 10 ms

Bit 7  **PSUSP: Port suspend**
The application sets this bit to put this port in suspend mode. The core only stops sending SOFs when this is set. To stop the PHY clock, the application must set the port clock stop bit, which asserts the suspend input pin of the PHY.
The read value of this bit reflects the current suspend status of the port. This bit is cleared by the core after a remote wake-up signal is detected or the application sets the port reset bit or port resume bit in this register or the resume/remote wake-up detected interrupt bit or disconnect detected interrupt bit in the core interrupt register (WKUPINT or DISCINT in OTG_GINTSTS, respectively).
0: Port not in suspend mode
1: Port in suspend mode
Bit 6 **PRES**: Port resume
The application sets this bit to drive resume signaling on the port. The core continues to drive the resume signal until the application clears this bit.
If the core detects a USB remote wake-up sequence, as indicated by the port resume/remote wake-up detected interrupt bit of the core interrupt register (WKUPINT bit in OTG_GINTSTS), the core starts driving resume signaling without application intervention and clears this bit when it detects a disconnect condition. The read value of this bit indicates whether the core is currently driving resume signaling.
0: No resume driven
1: Resume driven
When LPM is enabled and the core is in L1 state, the behavior of this bit is as follows:
1. The application sets this bit to drive resume signaling on the port.
2. The core continues to drive the resume signal until a predetermined time specified in BESLTHRS[3:0] field of OTG_GLPFCFG register.
3. If the core detects a USB remote wake-up sequence, as indicated by the port L1Resume/Remote L1Wakeup detected interrupt bit of the core interrupt register (WKUPINT in OTG_GINTSTS), the core starts driving resume signaling without application intervention and clears this bit at the end of resume. This bit can be set or cleared by both the core and the application. This bit is cleared by the core even if there is no device connected to the host.

Bit 5 **POCCHNG**: Port overcurrent change
The core sets this bit when the status of the port overcurrent active bit (bit 4) in this register changes.

Bit 4 **POCA**: Port overcurrent active
Indicates the overcurrent condition of the port.
0: No overcurrent condition
1: Overcurrent condition

Bit 3 **PENCHNG**: Port enable/disable change
The core sets this bit when the status of the port enable bit 2 in this register changes.

Bit 2 **PENA**: Port enable
A port is enabled only by the core after a reset sequence, and is disabled by an overcurrent condition, a disconnect condition, or by the application clearing this bit. The application cannot set this bit by a register write. It can only clear it to disable the port. This bit does not trigger any interrupt to the application.
0: Port disabled
1: Port enabled

Bit 1 **PCDET**: Port connect detected
The core sets this bit when a device connection is detected to trigger an interrupt to the application using the host port interrupt bit in the core interrupt register (HPRTINT bit in OTG_GINTSTS). The application must write a 1 to this bit to clear the interrupt.

Bit 0 **PCSTS**: Port connect status
0: No device is attached to the port
1: A device is attached to the port
60.14.29 OTG host channel x characteristics register (OTG_HCCHARx)

Bit 31 CHENA: Channel enable
When Scatter/Gather mode is enabled:
1'b0: Indicates that the descriptor structure is not yet ready
1'b1: Indicates that the descriptor structure and data buffer with data is setup and this channel can access the descriptor
When Scatter/Gather mode is disabled: This field is set by the application and cleared by the OTG host.
0: Channel disabled
1: Channel enabled

Bit 30 CHDIS: Channel disable
The application sets this bit to stop transmitting/receiving data on a channel, even before the transfer for that channel is complete. The application must wait for the Channel disabled interrupt before treating the channel as disabled.

Bit 29 ODDFRM: Odd frame
This field is set (reset) by the application to indicate that the OTG host must perform a transfer in an odd frame. This field is applicable for only periodic (isochronous and interrupt) transactions.
0: Even frame
1: Odd frame

Bits 28:22 DAD[6:0]: Device address
This field selects the specific device serving as the data source or sink.

Bits 21:20 MCNT[1:0]: Multicount
This field indicates to the host the number of transactions that must be executed per frame for this periodic endpoint. For non-periodic transfers, this field is not used.
00: Reserved. This field yields undefined results
01: 1 transaction
10: 2 transactions per frame to be issued for this endpoint
11: 3 transactions per frame to be issued for this endpoint

Note: This field must be set to at least 01.

Bits 19:18 EPTYP[1:0]: Endpoint type
Indicates the transfer type selected.
00: Control
01: Isochronous
10: Bulk
11: Interrupt
Bit 17  **LSDEV**: Low-speed device
This field is set by the application to indicate that this channel is communicating to a low-speed device.

Bit 16  Reserved, must be kept at reset value.

Bit 15  **EPDIR**: Endpoint direction
Indicates whether the transaction is IN or OUT.
0: OUT
1: IN

Bits 14:11  **EPNUM[3:0]**: Endpoint number
Indicates the endpoint number on the device serving as the data source or sink.

Bits 10:0  **MPSIZ[10:0]**: Maximum packet size
Indicates the maximum packet size of the associated endpoint.

### 60.14.30  OTG host channel x split control register (OTG_HCSPLTx)

Bit 31  **SPLITEN**: Split enable
The application sets this bit to indicate that this channel is enabled to perform split transactions.

Bits 30:17  Reserved, must be kept at reset value.

Bit 16  **COMPLSPLT**: Do complete split
The application sets this bit to request the OTG host to perform a complete split transaction.

Bits 15:14  **XACTPOS[1:0]**: Transaction position
This field is used to determine whether to send all, first, middle, or last payloads with each OUT transaction.
11: All. This is the entire data payload of this transaction (which is less than or equal to 188 bytes)
10: Begin. This is the first data payload of this transaction (which is larger than 188 bytes)
00: Mid. This is the middle payload of this transaction (which is larger than 188 bytes)
01: End. This is the last payload of this transaction (which is larger than 188 bytes)

Bits 13:7  **HUBADDR[6:0]**: Hub address
This field holds the device address of the transaction translator’s hub.

Bits 6:0  **PRTADDR[6:0]**: Port address
This field is the port number of the recipient transaction translator.
60.14.31 OTG host channel x interrupt register (OTG_HCINTx)

Address offset: 0x508 + 0x20 * x, (x = 0 to 15)

Reset value: 0x0000 0000

This register indicates the status of a channel with respect to USB- and AHB-related events. It is shown in Figure 801. The application must read this register when the host channels interrupt bit in the core interrupt register (HCINT bit in OTG_GINTSTS) is set. Before the application can read this register, it must first read the host all channels interrupt (OTG_HAINT) register to get the exact channel number for the host channel-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG_HAINT and OTG_GINTSTS registers.

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **DESCROLL**: Descriptor rollover interrupt.

This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when the corresponding channel descriptor list rolls over. For non Scatter/Gather DMA mode, this bit is reserved.

Bit 12 **XCSXACTERR**: Excessive transaction error.

This bit is valid only when Scatter/Gather DMA mode is enabled. The core sets this bit when 3 consecutive transaction errors occurred on the USB bus. XCS_XACT_ERR is not generated for isochronous channels. For non Scatter/Gather DMA mode, this bit is reserved.

Bit 11 **BNA**: Buffer not available interrupt.

This bit is valid only when Scatter/Gather DMA mode is enabled. The core generates this interrupt when the descriptor accessed is not ready for the core to process. BNA interrupt is not generated for isochronous channels. For non Scatter/Gather DMA mode, this bit is reserved.

Bit 10 **DTER**: Data toggle error. In Scatter/Gather DMA mode, the interrupt due to this bit is masked.

Bit 9 **FRMOR**: Frame overrun. In Scatter/Gather DMA mode, the interrupt due to this bit is masked.

Bit 8 **BBERR**: Babble error. In Scatter/Gather DMA mode, the interrupt due to this bit is masked.

Bit 7 **TXERR**: Transaction error. In Scatter/Gather DMA mode, the interrupt due to this bit is masked.

Indicates one of the following errors occurred on the USB.

- CRC check failure
- Timeout
- Bit stuff error
- False EOP
Bit 6 **NYET**: Not yet ready response received interrupt. In Scatter/Gather DMA mode, the interrupt due to this bit is masked.

Bit 5 **ACK**: ACK response received/transmitted interrupt. In Scatter/Gather DMA mode, the interrupt due to this bit is masked.

Bit 4 **NAK**: NAK response received interrupt. In Scatter/Gather DMA mode, the interrupt due to this bit is masked.

Bit 3 **STALL**: STALL response received interrupt. In Scatter/Gather DMA mode, the interrupt due to this bit is masked.

Bit 2 **AHBERR**: AHB error
This error is generated only in Internal DMA mode when an AHB error occurs during an AHB read/write operation. The application can read the corresponding DMA channel address register to get the error address.

Bit 1 **CHH**: Channel halted.
In non scatter/gather DMA mode indicates the transfer completed abnormally either because of any USB transaction error or in response to disable request by the application.
In scatter/gather DMA mode, this indicates that transfer completed due to any of the following:
- EOL being set in descriptor
- AHB error
- Excessive transaction errors
- In response to disable request by the application
- Babble
- Stall

Bit 0 **XFRC**: Transfer completed.
Transfer completed normally without any errors.

### 60.14.32 OTG host channel x interrupt mask register (OTG_HCINTMSKx)

Address offset: 0x50C + 0x20 * x, (x = 0 to 15)

Reset value: 0x0000 0000

This register reflects the mask for each channel status described in the previous section.
Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **DESCLSTROLLMSK**: Descriptor rollover interrupt mask register.
   This bit is valid only when Scatter/Gather DMA mode is enabled.
   In non Scatter/Gather DMA mode, this bit is reserved.

Bit 12 Reserved, must be kept at reset value.

Bit 11 **BNAMSK**: Buffer not available interrupt mask register.
   This bit is valid only when Scatter/Gather DMA mode is enabled.
   In non Scatter/Gather DMA mode, this bit is reserved

Bit 10 **DTERMM**: Data toggle error mask. In Scatter/Gather DMA mode, the interrupt due to this bit is masked.
   0: Masked interrupt
   1: Unmasked interrupt

Bit 9 **FRMORM**: Frame overrun mask. In Scatter/Gather DMA mode, the interrupt due to this bit is masked.
   0: Masked interrupt
   1: Unmasked interrupt

Bit 8 **BBERRM**: Babble error mask. In Scatter/Gather DMA mode, the interrupt due to this bit is masked.
   0: Masked interrupt
   1: Unmasked interrupt

Bit 7 **TXERRM**: Transaction error mask. In Scatter/Gather DMA mode, the interrupt due to this bit is masked.
   0: Masked interrupt
   1: Unmasked interrupt

Bit 6 **NYET**: response received interrupt mask. In Scatter/Gather DMA mode, the interrupt due to this bit is masked.
   0: Masked interrupt
   1: Unmasked interrupt

Bit 5 **ACKM**: ACK response received/transmitted interrupt mask. In Scatter/Gather DMA mode, the interrupt due to this bit is masked.
   0: Masked interrupt
   1: Unmasked interrupt

Bit 4 **NAKM**: NAK response received interrupt mask. In Scatter/Gather DMA mode, the interrupt due to this bit is masked.
   0: Masked interrupt
   1: Unmasked interrupt

Bit 3 **STALLM**: STALL response received interrupt mask. In Scatter/Gather DMA mode, the interrupt due to this bit is masked.
   0: Masked interrupt
   1: Unmasked interrupt
60.14.33 OTG host channel x transfer size register (OTG_HCTSIZx)

**NTD[7:0]**

**SCHED_INFO[7:0]**

Bit 31 **DOPNG**: Do Ping

This bit is used only for OUT transfers. Setting this field to 1 directs the host to do PING protocol.

*Note: Do not set this bit for IN transfers. If this bit is set for IN transfers, it disables the channel.*

Bits 30:29 **PID[1:0]**: Pid

The application programs this field with the type of PID to use for the initial transaction. The host maintains this field for the rest of the transfer.

- 00: DATA0
- 01: DATA2
- 10: DATA1
- 11: MDATA (non-control) / SETUP (control)
Bits 28:16  Reserved, must be kept at reset value.

Bits 15:8  **NTD[7:0]**: Number of transfer descriptors

**Non isochronous**: this value is in terms of number of descriptors. The maximum number of descriptor that can be present in the list is 64. The values can be from 0 to 63.

0: 1 descriptor
1: 2 descriptors
...
63: 64 descriptors

Others: Reserved

This field indicates the total number of descriptors present in that list. The core will wrap around after servicing NTD number of descriptors for that list.

**Isochronous**: this field indicates the number of descriptors present in that list.

The possible values for FS are:

1: 2 descriptors
3: 4 descriptors
7: 8 descriptors
15: 16 descriptors
31: 32 descriptors
63: 64 descriptors

Others: Reserved

The possible values for HS are:

7: 8 descriptors
15: 16 descriptors
31: 32 descriptors
63: 64 descriptors
127: 128 descriptors
255: 256 descriptors

Others: Reserved

Bits 7:0  **SCHED INFO[7:0]**: Schedule information

Every bit in this 8 bit register indicates scheduling for that microframe. Bit 0 indicates scheduling for 1st microframe and bit 7 indicates scheduling for 8th microframe in that frame. A value of 0b11111111 indicates that the corresponding interrupt channel is scheduled to issue a token every microframe in that frame. A value of 0b10101010 indicates that the corresponding interrupt channel is scheduled to issue a token every alternate microframe starting with second microframe. Note that this field is applicable only for periodic (isochronous and interrupt) channels.
### 60.14.35 OTG host channel x DMA address register in buffer DMA [alternate] (OTG_HCDMAx)

Address offset: $0x514 + 0x20 \times x$, $(x = 0$ to $15)$

Reset value: $0x0000\ 0000$

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Bits 31:0 **DMAADDR[31:0]**: DMA address
This field holds the start address in the external memory from which the data for the endpoint must be fetched or to which it must be stored. This register is incremented on every AHB transaction.

### 60.14.36 OTG host channel x DMA address register in scatter/gather DMA [alternate] (OTG_HCDMASGx)

Address offset: $0x514 + 0x20 \times x$, $(x = 0$ to $15)$

Reset value: $0x0000\ 0000$

<table>
<thead>
<tr>
<th>Bit 31:0</th>

</thead>
<tbody>
<tr>
<td></td>
<td>rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw rw</td>
</tr>
</tbody>
</table>
Bits 31:3  **DMASG[31:3]:** DMA scatter/gather information

The DMASG information is composed of two parts DMASG_ADDR = DMASG[31:N] and DMASG_CTD = DMASG[N-1:3].

Non-isochronous case (N = 9):
The DMASG_ADDR field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value.
The DMASG_CTD field holds a value in terms of number of descriptors. The values can be from 0 (1 descriptor) to 63 (64 descriptors). This field indicates the current descriptor processed in the list. For example, if the application enables the channel after programming CTD = 5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of 8 * 5 = 40 bytes (decimal) to DMAAddr.

Isochronous case (N=4 to 11):
The DMASG_ADDR field holds the address of the 2*(NTD+1) bytes of locations in which the isochronous descriptors are present where N is based on NTD as per the following table:

- **HS ISOC; NTD = 7:** N = 6
- **HS ISOC; NTD = 15:** N = 7
- **HS ISOC; NTD = 31:** N = 8
- **HS ISOC; NTD = 63:** N = 9
- **HS ISOC; NTD = 127:** N = 10
- **HS ISOC; NTD = 255:** N = 11
- **FS ISOC; NTD = 1:** N = 4
- **FS ISOC; NTD = 3:** N = 5
- **FS ISOC; NTD = 7:** N = 6
- **FS ISOC; NTD = 15:** N = 7
- **FS ISOC; NTD = 31:** N = 8
- **FS ISOC; NTD = 63:** N = 9

The DMASG_CTD field is based on the current frame/(micro)frame value. Need to be set to zero by application.

Bits 2:0  Reserved, must be kept at reset value.

**60.14.37 OTG host channel-n DMA address buffer register (OTG_HCDMABx)**

Address offset: 0x51C + 0x20 * x, (x = 0 to 15)

Reset value: 0x0000 0000 (0x0000 0000)

Bits 31:0  **HCDMAB[31:0]:** DMA address
This register holds the current buffer address (scatter/gather mode).
### 60.14.38 Device-mode registers

These registers must be programmed every time the core changes to device mode.

### 60.14.39 OTG device configuration register (OTG_DCFG)

**Address offset**: 0x800  
**Reset value**: 0x0220 0000

This register configures the core in device mode after power-on or after certain control commands or enumeration. Do not make changes to this register after initial programming.

**Bits 31:26**  
Reserved, must be kept at reset value.

**Bits 25:24** **PERSCHIVL[1:0]**: Periodic schedule interval  
This field specifies the amount of time the Internal DMA engine must allocate for fetching periodic IN endpoint data. Based on the number of periodic endpoints, this value must be specified as 25, 50 or 75% of the (micro) frame.  
– When any periodic endpoints are active, the internal DMA engine allocates the specified amount of time in fetching periodic IN endpoint data  
– When no periodic endpoint is active, then the internal DMA engine services nonperiodic endpoints, ignoring this field  
– After the specified time within a (micro) frame, the DMA switches to fetching nonperiodic endpoints  
00: 25% of (micro)frame  
01: 50% of (micro)frame  
10: 75% of (micro)frame  
11: Reserved

**Note**: Periodic Scheduling Interval (PERSCHIVL) must be programmed for Scatter/Gather DMA mode.

**Bit 23** **DESCDMA**: Enable scatter/gather DMA in device mode  
The application can set this bit during initialization to enable the Scatter/Gather DMA operation. This bit must be modified only once after a reset. The following combinations are available for programming:  
OTG_GAHBCFG.DMAEN=0,OTG_DCFG.DESCDMA=0 => Slave mode  
OTG_GAHBCFG.DMAEN=0,OTG_DCFG.DESCDMA=1 => Invalid  
OTG_GAHBCFG.DMAEN=1,OTG_DCFG.DESCDMA=0 => Buffer DMA mode  
OTG_GAHBCFG.DMAEN=1,OTG_DCFG.DESCDMA=1 => Scatter/Gather DMA mode

**Bits 22:16**  
Reserved, must be kept at reset value.
Bit 15 **ERRATIM**: Erratic error interrupt mask
   1: Mask early suspend interrupt on erratic error
   0: Early suspend interrupt is generated on erratic error

Bit 14 **XCVRDLY**: Transceiver delay
   Enables or disables delay in ULPI timing during device chirp.
   0: Disable delay (use default timing)
   1: Enable delay to default timing, necessary for some ULPI PHYs

Bit 13 Reserved, must be kept at reset value.

Bits 12:11 **PFIVL[1:0]**: Periodic frame interval
   Indicates the time within a frame at which the application must be notified using the end of periodic frame interrupt. This can be used to determine if all the isochronous traffic for that frame is complete.
   00: 80% of the frame interval
   01: 85% of the frame interval
   10: 90% of the frame interval
   11: 95% of the frame interval

Bits 10:4 **DAD[6:0]**: Device address
   The application must program this field after every SetAddress control command.
   Bit 3 Reserved, must be kept at reset value.

Bit 2 **NZLSOHSH**: Non-zero-length status OUT handshake
   The application can use this field to select the handshake the core sends on receiving a nonzero-length data packet during the OUT transaction of a control transfer’s status stage.
   1: Send a STALL handshake on a nonzero-length status OUT transaction and do not send the received OUT packet to the application.
   0: Send the received OUT packet to the application (zero-length or nonzero-length) and send a handshake based on the NAK and STALL bits for the endpoint in the device endpoint control register.

Bits 1:0 **DSPD[1:0]**: Device speed
   Indicates the speed at which the application requires the core to enumerate, or the maximum speed the application can support. However, the actual bus speed is determined only after the chirp sequence is completed, and is based on the speed of the USB host to which the core is connected.
   00: High speed
   01: Full speed using HS
   10: Reserved
   11: Full speed using internal FS PHY
60.14.40  OTG device control register (OTG_DCTL)

Address offset: 0x804
Reset value: 0x0000 0002

| Bit 31:19 Reserved, must be kept at reset value. |
| Bit 18 DSBE SLRJCT: Deep sleep BESL reject |
| Core rejects LPM request with BESL value greater than BESL threshold programmed. NYET response is sent for LPM tokens with BESL value greater than BESL threshold. By default, the deep sleep BESL reject feature is disabled. |
| Bit 17 ENC ONTONBN A: Enable continue on BNA |
| This bit enables the core to continue on BNA for Bulk OUT and INTR OUT endpoints. With this feature enabled, when a Bulk OUT or INTR OUT endpoint receives a BNA interrupt the core starts processing the descriptor that caused the BNA interrupt after the endpoint re-enables the endpoint. |
| 0: After receiving BNA interrupt, the core disables the endpoint. When the endpoint is re-enabled by the application, the core starts processing from the DOEPDMA descriptor. |
| 1: After receiving BNA interrupt, the core disables the endpoint. When the endpoint is re-enabled by the application, the core starts processing from the descriptor that received the BNA interrupt. It is a one-time programmable after reset bit like any other OTG_DCTL register bit. |
| Bits 16:12 Reserved, must be kept at reset value. |
| Bit 11 POPRDN E: Power-on programming done |
| The application uses this bit to indicate that register programming is completed after a wake-up from power down mode. |
| Bit 10 CGONAK: Clear global OUT NAK |
| Writing 1 to this field clears the Global OUT NAK. |
| Bit 9 SGONAK: Set global OUT NAK |
| Writing 1 to this field sets the Global OUT NAK. The application uses this bit to send a NAK handshake on all OUT endpoints. The application must set the this bit only after making sure that the Global OUT NAK effective bit in the core interrupt register (GONAKEFF bit in OTG_GINTSTS) is cleared. |
| Bit 8 CGINAK: Clear global IN NAK |
| Writing 1 to this field clears the Global IN NAK. |
| Bit 7 SIG NAK: Set global IN NAK |
| Writing 1 to this field sets the Global non-periodic IN NAK. The application uses this bit to send a NAK handshake on all non-periodic IN endpoints. The application must set this bit only after making sure that the Global IN NAK effective bit in the core interrupt register (GINAKEFF bit in OTG_GINTSTS) is cleared. |
Bits 6:4 **TCTL[2:0]**: Test control
- 000: Test mode disabled
- 001: Test_J mode
- 010: Test_K mode
- 011: Test_SE0_NAK mode
- 100: Test_Packet mode
- 101: Test_Force_Enable
- Others: Reserved

Bit 3 **GONSTS**: Global OUT NAK status
- 0: A handshake is sent based on the FIFO status and the NAK and STALL bit settings.
- 1: No data is written to the Rx FIFO, irrespective of space availability. Sends a NAK handshake on all packets, except on SETUP transactions. All isochronous OUT packets are dropped.

Bit 2 **GINSTS**: Global IN NAK status
- 0: A handshake is sent out based on the data availability in the transmit FIFO.
- 1: A NAK handshake is sent out on all non-periodic IN endpoints, irrespective of the data availability in the transmit FIFO.

Bit 1 **SDIS**: Soft disconnect
The application uses this bit to signal the USB OTG core to perform a soft disconnect. As long as this bit is set, the host does not see that the device is connected, and the device does not receive signals on the USB. The core stays in the disconnected state until the application clears this bit.
- 0: Normal operation. When this bit is cleared after a soft disconnect, the core generates a device connect event to the USB host. When the device is reconnected, the USB host restarts device enumeration.
- 1: The core generates a device disconnect event to the USB host.

Bit 0 **RWUSIG**: Remote wake-up signaling
When the application sets this bit, the core initiates remote signaling to wake up the USB host. The application must set this bit to instruct the core to exit the suspend state. As specified in the USB 2.0 specification, the application must clear this bit 1 ms to 15 ms after setting it.
- If LPM is enabled and the core is in the L1 (sleep) state, when the application sets this bit, the core initiates L1 remote signaling to wake up the USB host. The application must set this bit to instruct the core to exit the sleep state. As specified in the LPM specification, the hardware automatically clears this bit 50 µs \((t_{\text{L1DevDrvResume}})\) after being set by the application. The application must not set this bit when \(b\text{RemoteWake}\) from the previous LPM transaction is zero (refer to REMWAKE bit in GLPMCFG register).

**Table 541** contains the minimum duration (according to device state) for which the Soft disconnect (SDIS) bit must be set for the USB host to detect a device disconnect. To accommodate clock jitter, it is recommended that the application add some extra delay to the specified minimum duration.

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:22 **DEVLNSTS[1:0]:** Device line status
Indicates the current logic level USB data lines.
- Bit [23]: Logic level of D+
- Bit [22]: Logic level of D-

Bits 21:8 **FNSOF[13:0]:** Frame number of the received SOF

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **ERR:** Erratic error
The core sets this bit to report any erratic errors. Due to erratic errors, the OTG_HS controller goes into suspended state and an interrupt is generated to the application with Early suspend bit of the OTG_GINTSTS register (ESUSP bit in OTG_GINTSTS). If the early suspend is asserted due to an erratic error, the application can only perform a soft disconnect recover.

Bits 2:1 **ENUMSPD[1:0]:** Enumerated speed
Indicates the speed at which the OTG_HS controller has come up after speed detection through a chirp sequence.
- 00: High Speed using HS PHY
- 01: Full Speed using HS PHY
- 11: Full speed using embedded FS PHY
Others: reserved

Bit 0 **SUSPST:** Suspend status
In device mode, this bit is set as long as a suspend condition is detected on the USB. The core enters the suspended state when there is no activity on the USB data lines for a period of 3 ms. The core comes out of the suspend:
- When there is an activity on the USB data lines
- When the application writes to the remote wake-up signaling bit in the OTG_DCTL register (RWUSIG bit in OTG_DCTL).
60.14.42 OTG device IN endpoint common interrupt mask register (OTG_DIEPMSK)

Address offset: 0x810
Reset value: 0x0000 0000

This register works with each of the OTG_DIEPINTx registers for all endpoints to generate an interrupt per IN endpoint. The IN endpoint interrupt for a specific status in the OTG_DIEPINTx register can be masked by writing to the corresponding bit in this register. Status bits are masked by default.

### 60.14.43 OTG device OUT endpoint common interrupt mask register (OTG_DOEPMSK)

Address offset: 0x814

Reset value: 0x0000 0000

This register works with each of the OTG_DOEPINTx registers for all endpoints to generate an interrupt per OUT endpoint. The OUT endpoint interrupt for a specific status in the OTG_DOEPINTx register can be masked by writing into the corresponding bit in this register. Status bits are masked by default.

OTG device all endpoints interrupt register (OTG_DAINT)

Address offset: 0x818
Reset value: 0x0000 0000

When a significant event occurs on an endpoint, a OTG_DAINT register interrupts the application using the device OUT endpoints interrupt bit or device IN endpoints interrupt bit of the OTG_GINTSTS register (OEPINT or IEPINT in OTG_GINTSTS, respectively). There is one interrupt bit per endpoint, up to a maximum of 16 bits for OUT endpoints and 16 bits for IN endpoints. For a bidirectional endpoint, the corresponding IN and OUT interrupt bits are used. Bits in this register are set and cleared when the application sets and clears bits in the corresponding device endpoint-x interrupt register (OTG_DIEPINTx/OTG_DOEPINTx).

| Bit 7 | Reserved, must be kept at reset value. |
| Bit 6 | **B2BSTUPM**: Back-to-back SETUP packets received mask |
|       | Applies to control OUT endpoints only. |
|       | 0: Masked interrupt |

Bits 31:16  **OEPINT[15:0]**: OUT endpoint interrupt bits
   One bit per OUT endpoint:
   Bit 16 for OUT endpoint 0, bit 19 for OUT endpoint 3.

Bits 15:0  **IEPINT[15:0]**: IN endpoint interrupt bits
   One bit per IN endpoint:
   Bit 0 for IN endpoint 0, bit 3 for endpoint 3.

### 60.14.45 OTG all endpoints interrupt mask register (OTG_DAINTMSK)

Address offset: 0x81C

Reset value: 0x0000 0000

The OTG_DAINTMSK register works with the device endpoint interrupt register to interrupt
the application when an event occurs on a device endpoint. However, the OTG_DAINT
register bit corresponding to that interrupt is still set.

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **OEP1INTM**: OUT endpoint 1 interrupt mask bit

Bits 16:2 Reserved, must be kept at reset value.

Bit 1 **IEP1INTM**: IN endpoint 1 interrupt mask bit

Bit 0 Reserved, must be kept at reset value.

### 60.14.52 OTG device each IN endpoint-1 interrupt mask register (OTG_HS_DIEPEACHMSK1)

Address offset: 0x844  
Reset value: 0x0000 0000  
This register works with the OTG_DIEPINT1 register to generate a dedicated interrupt OTG_HS_EP1_IN for endpoint #1. The IN endpoint interrupt for a specific status in the OTG_DOEPINT1 register can be masked by writing into the corresponding bit in this register. Status bits are masked by default.

<table>
<thead>

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **NAKM**: NAK interrupt mask

0: Masked interrupt  
1: Unmasked interrupt

Bits 12:10 Reserved, must be kept at reset value.
Bit 9 **BNAM**: BNA interrupt mask
   0: Masked interrupt
   1: Unmasked interrupt

Bit 8 **TXFURM**: FIFO underrun mask
   0: Masked interrupt
   1: Unmasked interrupt

Bit 7 Reserved, must be kept at reset value.

Bit 6 **INEPNEM**: IN endpoint NAK effective mask
   0: Masked interrupt
   1: Unmasked interrupt

Bit 5 Reserved, must be kept at reset value.

Bit 4 **ITTXFEMSK**: IN token received when Tx FIFO empty mask
   0: Masked interrupt
   1: Unmasked interrupt

Bit 3 **TOM**: Timeout condition mask (Non-isochronous endpoints)
   0: Masked interrupt
   1: Unmasked interrupt

Bit 2 **AHBERRM**: AHB error mask
   0: Masked interrupt
   1: Unmasked interrupt

Bit 1 **EPDM**: Endpoint disabled interrupt mask
   0: Masked interrupt
   1: Unmasked interrupt

Bit 0 **XFRCM**: Transfer completed interrupt mask
   0: Masked interrupt
   1: Unmasked interrupt

### 60.14.53 OTG device each OUT endpoint-1 interrupt mask register (OTG_HS_DOEPEACHMSK1)

Address offset: 0x884

Reset value: 0x0000 0000

This register works with the OTG_DOEPINT1 register to generate a dedicated interrupt OTG_HS_EP1_OUT for endpoint #1. The OUT endpoint interrupt for a specific status in the OTG_DOEPINT1 register can be masked by writing into the corresponding bit in this register. Status bits are masked by default.
Bits 31:15  Reserved, must be kept at reset value.

Bit 14  **NYETMSK**: NYET interrupt mask
- 0: Masked interrupt
- 1: Unmasked interrupt

Bit 13  **NAKMSK**: NAK interrupt mask
- 0: Masked interrupt
- 1: Unmasked interrupt

Bit 12  **BERRM**: Babble error interrupt mask
- 0: Masked interrupt
- 1: Unmasked interrupt

Bits 11:10  Reserved, must be kept at reset value.

Bit 9  **BNAM**: BNA interrupt mask
- 0: Masked interrupt
- 1: Unmasked interrupt

Bit 8  **OUTPKTERRM**: Out packet error mask
- 0: Masked interrupt
- 1: Unmasked interrupt

Bit 7  Reserved, must be kept at reset value.

Bit 6  **B2BSTUPM**: Back-to-back SETUP packets received mask
- Applies to control OUT endpoints only.
- 0: Masked interrupt
- 1: Unmasked interrupt

Bit 5  Reserved, must be kept at reset value.

Bit 4  **OTEPDM**: OUT token received when endpoint disabled mask
- Applies to control OUT endpoints only.
- 0: Masked interrupt
- 1: Unmasked interrupt

Bit 3  **STUPM**: STUPM: SETUP phase done mask
- Applies to control endpoints only.
- 0: Masked interrupt
- 1: Unmasked interrupt

Bit 2  **AHBERRM**: AHB error mask
- 0: Masked interrupt
- 1: Unmasked interrupt

Bit 1  **EPDM**: Endpoint disabled interrupt mask
- 0: Masked interrupt
- 1: Unmasked interrupt

Bit 0  **XFRCM**: Transfer completed interrupt mask
- 0: Masked interrupt
- 1: Unmasked interrupt
60.14.54 OTG device IN endpoint x control register (OTG_DIEPCTLx)

Address offset: 0x900 + 0x20 * x, (x = 0 to 8)
Reset value: 0x0000 0000

The application uses this register to control the behavior of each logical endpoint other than endpoint 0.

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Bit 31 **EPENA**: Endpoint enable
The application sets this bit to start transmitting data on an endpoint. The core clears this bit before setting any of the following interrupts on this endpoint:
– SETUP phase done
– Endpoint disabled
– Transfer completed

Bit 30 **EPDIS**: Endpoint disable
The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the endpoint disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the endpoint disabled interrupt. The application must set this bit only if endpoint enable is already set for this endpoint.

Bit 29 **SODDFRM**: Set odd frame
Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd frame (EONUM) field to odd frame.

Bit 28 **SD0PID**: Set DATA0 PID
Applies to interrupt/bulk IN endpoints only. Writing to this field sets the endpoint data PID (DPID) field in this register to DATA0.

Bit 27 **SNAK**: Set NAK
A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit for OUT endpoints on a transfer completed interrupt, or after a SETUP is received on the endpoint.

Bit 26 **CNAK**: Clear NAK
A write to this bit clears the NAK bit for the endpoint.
Bits 25:22 **TXFNUM[3:0]**: Tx FIFO number

These bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints.

Bit 21 **STALL**: STALL handshake

Applies to non-control, non-isochronous IN endpoints only (access type is rw). The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core.

Bit 20 Reserved, must be kept at reset value.

Bits 19:18 **EPTYP[1:0]**: Endpoint type

This is the transfer type supported by this logical endpoint.

- 00: Control
- 01: Isochronous
- 10: Bulk
- 11: Interrupt

Bit 17 **NAKSTS**: NAK status

It indicates the following:

- 0: The core is transmitting non-NAK handshakes based on the FIFO status.
- 1: The core is transmitting NAK handshakes on this endpoint.

When either the application or the core sets this bit:

For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there are data available in the Tx FIFO.

For isochronous IN endpoints: The core sends out a zero-length data packet, even if there are data available in the Tx FIFO.

Irrespective of this bit’s setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 16 **EONUM**: Even/odd frame

Applies to isochronous IN endpoints only. Indicates the frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd frame number in which it intends to transmit/receive isochronous data for this endpoint using the SEVNFRM and SODDFRM fields in this register.

- 0: Even frame
- 1: Odd frame

**DPID**: Endpoint data PID

Applies to interrupt/bulk IN endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The application uses the SD0PID register field to program either DATA0 or DATA1 PID.

- 0: DATA0
- 1: DATA1
Bit 15 **USBAEP**: USB active endpoint
Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.

Bits 14:11 Reserved, must be kept at reset value.

Bits 10:0 **MPSIZ[10:0]**: Maximum packet size
The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.

**60.14.55 OTG device IN endpoint x interrupt register (OTG_DIEPINTx)**

Address offset: 0x908 + 0x20 * x, (x = 0 to 8)
Reset value: 0x0000 0080

This register indicates the status of an endpoint with respect to USB- and AHB-related events. It is shown in Figure 801. The application must read this register when the IN endpoints interrupt bit of the core interrupt register (IEPINT in OTG_GINTSTS) is set. Before the application can read this register, it must first read the device all endpoints interrupt (OTG_DAINT) register to get the exact endpoint number for the device endpoint-x interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG_DAINT and OTG_GINTSTS registers.

</table>

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **NAK**: NAK input
The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to unavailability of data in the Tx FIFO.

Bit 12 Reserved, must be kept at reset value.

Bit 11 **PKTDRPSTS**: Packet dropped status
This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt.

Bit 10 Reserved, must be kept at reset value.

Bit 9 **BNA**: Buffer not available interrupt
The core generates this interrupt when the descriptor accessed is not ready for the core to process, such as host busy or DMA done.
This bit is only valid when Scatter/Gather DMA mode is enabled.
Bit 8 **TXFIFOUDRN**: Transmit Fifo Underrun (TxfifoUndrn)
   The core generates this interrupt when it detects a transmit FIFO underrun condition for this endpoint. Dependency: This interrupt is valid only when Thresholding is enabled

Bit 7 **TXFE**: Transmit FIFO empty
   This interrupt is asserted when the Tx FIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the Tx FIFO Empty Level bit in the OTG_GAHBCFG register (TXFELVL bit in OTG_GAHBCFG).

Bit 6 **INEPNE**: IN endpoint NAK effective
   This bit can be cleared when the application clears the IN endpoint NAK by writing to the CNAK bit in OTG_DIEPCTLx.
   This interrupt indicates that the core has sampled the NAK bit set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit set by the application has taken effect in the core.
   This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit.

Bit 5 **INEPNM**: IN token received with EP mismatch
   Indicates that the data in the top of the non-periodic TxFIFO belongs to an endpoint other than the one for which the IN token was received. This interrupt is asserted on the endpoint for which the IN token was received.

Bit 4 **ITTXFE**: IN token received when Tx FIFO is empty
   Indicates that an IN token was received when the associated Tx FIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received.

Bit 3 **TOC**: Timeout condition
   Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint.

Bit 2 **AHBERR**: AHB error
   This is generated only in internal DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address.

Bit 1 **EPDISD**: Endpoint disabled interrupt
   This bit indicates that the endpoint is disabled per the application’s request.

Bit 0 **XFRC**: Transfer completed interrupt
   This field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint.
60.14.56 OTG device IN endpoint 0 transfer size register
(OTG_DIEPTSIZ0)

Address offset: 0x910
Reset value: 0x0000 0000

The application must modify this register before enabling endpoint 0. Once endpoint 0 is
enabled using the endpoint enable bit in the device control endpoint 0 control registers
(EPENA in OTG_DIEPCTL0), the core modifies this register. The application can only read
this register once the core has cleared the endpoint enable bit.

Nonzero endpoints use the registers for endpoints 1–3.

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:19 **PKTCNT[1:0]:** Packet count
Indicates the total number of USB packets that constitute the transfer size amount of data for
endpoint 0.
This field is decremented every time a packet (maximum size or short packet) is read from
the Tx FIFO.

Bits 18:7 Reserved, must be kept at reset value.

Bits 6:0 **XFRSIZ[6:0]:** Transfer size
Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only
after it has exhausted the transfer size amount of data. The transfer size can be set to the
maximum packet size of the endpoint, to be interrupted at the end of each packet.
The core decrements this field every time a packet from the external memory is written to
the Tx FIFO.

60.14.57 OTG device IN endpoint x DMA address register
(OTG_DIEPDMAx)

60.14.58 OTG device IN endpoint transmit FIFO status register
(OTG_DTXFSTSx)

Address offset: 0x918 + 0x20 * x, (x = 0 to 8)
Reset value: 0x0000 0200

This read-only register contains the free space information for the device IN endpoint Tx FIFO.

Bits 31:0 DMAADDR[31:0]: DMA Address
This field holds the start address in the external memory from which the data for the endpoint must be fetched. This register is incremented on every AHB transaction.

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 INEPTFSAV[15:0]: IN endpoint Tx FIFO space available
Indicates the amount of free space available in the endpoint Tx FIFO.
Values are in terms of 32-bit words:
0x0: Endpoint Tx FIFO is full
0x1: 1 word available
0x2: 2 words available
0xn: n words available
Others: Reserved

60.14.59 OTG device IN endpoint x transfer size register (OTG_DIEPTSIZx)

Address offset: 0x910 + 0x20 * x, (x = 1 to 8)
Reset value: 0x0000 0000

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using the endpoint enable bit in the OTG_DIEPCTLx registers (EPENA bit in OTG_DIEPCTLx), the core modifies this register. The application can only read this register once the core has cleared the endpoint enable bit.

Error
Bit 31  Reserved, must be kept at reset value.

Bits 30:29  **MCNT[1:0]: Multi count**
For periodic IN endpoints, this field indicates the number of packets that must be transmitted per frame on the USB. The core uses this field to calculate the data PID for isochronous IN endpoints.
- 01: 1 packet
- 10: 2 packets
- 11: 3 packets

Bits 28:19  **PKTCNT[9:0]: Packet count**
Indicates the total number of USB packets that constitute the transfer size amount of data for this endpoint.
This field is decremented every time a packet (maximum size or short packet) is read from the Tx FIFO.

Bits 18:0  **XFRSIZ[18:0]: Transfer size**
This field contains the transfer size in bytes for the current endpoint. The core only interrupts the application after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet.
The core decrements this field every time a packet from the external memory is written to the Tx FIFO.

### 60.14.60 OTG device control OUT endpoint 0 control register (OTG_DOEPCTL0)

Address offset: 0xB00
Reset value: 0x0000 8000

This section describes the OTG_DOEPCTL0 register. Nonzero control endpoints use registers for endpoints 1–3.

**Bit 31  EPENA: Endpoint enable**
The application sets this bit to start transmitting data on endpoint 0.
The core clears this bit before setting any of the following interrupts on this endpoint:
- SETUP phase done
- Endpoint disabled
- Transfer completed

**Bit 30  EPDIS: Endpoint disable**
The application cannot disable control OUT endpoint 0.

Bits 29:28  Reserved, must be kept at reset value.
Bit 27  **SNAK**: Set NAK
A write to this bit sets the NAK bit for the endpoint.
Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit on a transfer completed interrupt, or after a SETUP is received on the endpoint.

Bit 26  **CNAK**: Clear NAK
A write to this bit clears the NAK bit for the endpoint.

Bits 25:22  Reserved, must be kept at reset value.

Bit 21  **STALL**: STALL handshake
The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit’s setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 20  **SNPM**: Snoop mode
This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory.

Bits 19:18  **EPTYP[1:0]**: Endpoint type
Hardcoded to 2'b00 for control.

Bit 17  **NAKSTS**: NAK status
Indicates the following:
0: The core is transmitting non-NAK handshakes based on the FIFO status.
1: The core is transmitting NAK handshakes on this endpoint.
When either the application or the core sets this bit, the core stops receiving data, even if there is space in the Rx FIFO to accommodate the incoming packet. Irrespective of this bit’s setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 16  Reserved, must be kept at reset value.

Bit 15  **USBAEP**: USB active endpoint
This bit is always set to 1, indicating that a control endpoint 0 is always active in all configurations and interfaces.

Bits 14:2  Reserved, must be kept at reset value.

Bits 1:0  **MPSIZ[1:0]**: Maximum packet size
The maximum packet size for control OUT endpoint 0 is the same as what is programmed in control IN endpoint 0.
00: 64 bytes
01: 32 bytes
10: 16 bytes
11: 8 bytes
60.14.61 OTG device OUT endpoint x interrupt register (OTG_DOEPINTx)

Address offset: 0xB08 + 0x20 * x, (x = 0 to 8)

Reset value: 0x0000 0080

This register indicates the status of an endpoint with respect to USB- and AHB-related events. It is shown in Figure 801. The application must read this register when the OUT endpoints interrupt bit of the OTG_GINTSTS register (OEPINT bit in OTG_GINTSTS) is set. Before the application can read this register, it must first read the OTG_DAINT register to get the exact endpoint number for the OTG_DOEPINTx register. The application must clear the appropriate bit in this register to clear the corresponding bits in the OTG_DAINT and OTG_GINTSTS registers.

### Bits 31:16 Reserved, must be kept at reset value.

**Bit 15** **STPKTRX**: Setup packet received

Applicable for control OUT endpoints in only in the Buffer DMA Mode. Set by the OTG_HS, this bit indicates that this buffer holds 8 bytes of setup data. There is only one setup packet per buffer. On receiving a setup packet, the OTG_HS closes the buffer and disables the corresponding endpoint after SETUP_COMPLETE status is seen in the Rx FIFO. OTG_HS puts a SETUP_COMPLETE status into the Rx FIFO when it sees the first IN or OUT token after the SETUP packet for that particular endpoint. The application must then re-enable the endpoint to receive any OUT data for the control transfer and reprogram the buffer start address. Because of the above behavior, OTG_HS can receive any number of back to back setup packets and one buffer for every setup packet is used.

**Bit 14** **NYET**: NYET interrupt

This interrupt is generated when a NYET response is transmitted for a non isochronous OUT endpoint.

**Bit 13** **NAK**: NAK input

The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to unavailability of data in the Tx FIFO.

**Bit 12** **BERR**: Babble error interrupt

The core generates this interrupt when babble is received for the endpoint.

**Bits 11:10** Reserved, must be kept at reset value.

**Bit 9** **BNA**: Buffer not available interrupt

The core generates this interrupt when the descriptor accessed is not ready for the core to process, such as host busy or DMA done. This bit is only valid when Scatter/Gather DMA mode is enabled.
Bit 8 **OUTPKTERR**: OUT packet error
   This interrupt is asserted when the core detects an overflow or a CRC error for an OUT
   packet. This interrupt is valid only when thresholding is enabled.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **B2BSTUP**: Back-to-back SETUP packets received
   Applies to control OUT endpoint only.
   This bit indicates that the core has received more than three back-to-back SETUP packets
   for this particular endpoint.

Bit 5 **STSPHSRX**: Status phase received for control write
   This interrupt is valid only for control OUT endpoints. This interrupt is generated only after
   OTG_HS has transferred all the data that the host has sent during the data phase of a
   control write transfer, to the system memory buffer. The interrupt indicates to the application
   that the host has switched from data phase to the status phase of a control write transfer.
   The application can use this interrupt to ACK or STALL the status phase, after it has
   decoded the data phase.

Bit 4 **OTEPDIS**: OUT token received when endpoint disabled
   Applies only to control OUT endpoints.
   Indicates that an OUT token was received when the endpoint was not yet enabled. This
   interrupt is asserted on the endpoint for which the OUT token was received.

Bit 3 **STUP**: SETUP phase done
   Applies to control OUT endpoint only. Indicates that the SETUP phase for the control
   endpoint is complete and no more back-to-back SETUP packets were received for the
   current control transfer. On this interrupt, the application can decode the received SETUP
   data packet.

Bit 2 **AHBERR**: AHB error
   This is generated only in internal DMA mode when there is an AHB error during an AHB
   read/write. The application can read the corresponding endpoint DMA address register to
   get the error address.

Bit 1 **EPDISD**: Endpoint disabled interrupt
   This bit indicates that the endpoint is disabled per the application’s request.

Bit 0 **XFRC**: Transfer completed interrupt
   This field indicates that the programmed transfer is complete on the AHB as well as on the
   USB, for this endpoint.
60.14.62 OTG device OUT endpoint 0 transfer size register (OTG_DOEPTSIZ0)

Address offset: 0xB10
Reset value: 0x0000 0000

The application must modify this register before enabling endpoint 0. Once endpoint 0 is enabled using the endpoint enable bit in the OTG_DOEPCTL0 registers (EPENA bit in OTG_DOEPCTL0), the core modifies this register. The application can only read this register once the core has cleared the endpoint enable bit.

Nonzero endpoints use the registers for endpoints 1–8.

Bit 31  Reserved, must be kept at reset value.

Bits 30:29 **STUPCNT[1:0]:** SETUP packet count

This field specifies the number of back-to-back SETUP data packets the endpoint can receive.

01: 1 packet
10: 2 packets
11: 3 packets

Bits 28:20 Reserved, must be kept at reset value.

Bit 19 **PKTCNT:** Packet count

This field is decremented to zero after a packet is written into the Rx FIFO.

Bits 18:7 Reserved, must be kept at reset value.

Bits 6:0 **XFRSIZ[6:0]:** Transfer size

Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet.

The core decrements this field every time a packet is read from the Rx FIFO and written to the external memory.
60.14.63 OTG device OUT endpoint x DMA address register

USBA

This register is used to control the behavior of each logical endpoint other than endpoint 0.
Bit 31 **EPENA**: Endpoint enable
Applies to IN and OUT endpoints.
The application sets this bit to start transmitting data on an endpoint. 
The core clears this bit before setting any of the following interrupts on this endpoint:
– SETUP phase done
– Endpoint disabled
– Transfer completed

Bit 30 **EPDIS**: Endpoint disable
The application sets this bit to stop transmitting/receiving data on an endpoint, even before
the transfer for that endpoint is complete. The application must wait for the endpoint
disabled interrupt before treating the endpoint as disabled. The core clears this bit before
setting the endpoint disabled interrupt. The application must set this bit only if endpoint
enable is already set for this endpoint.

Bit 29 **SD1PID**: Set DATA1 PID
Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the endpoint
data PID (DPID) field in this register to DATA1.

**SODDFRM**: Set odd frame
Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd
frame (EONUM) field to odd frame.

Bit 28 **SD0PID**: Set DATA0 PID
Applies to interrupt/bulk OUT endpoints only.
Writing to this field sets the endpoint data PID (DPID) field in this register to DATA0.

**SEVNFRM**: Set even frame
Applies to isochronous OUT endpoints only.
Writing to this field sets the Even/Odd frame (EONUM) field to even frame.

Bit 27 **SNAK**: Set NAK
A write to this bit sets the NAK bit for the endpoint.
Using this bit, the application can control the transmission of NAK handshakes on an
endpoint. The core can also set this bit for OUT endpoints on a transfer completed interrupt,
or after a SETUP is received on the endpoint.

Bit 26 **CNAK**: Clear NAK
A write to this bit clears the NAK bit for the endpoint.

Bits 25:22 Reserved, must be kept at reset value.

Bit 21 **STALL**: STALL handshake
Applies to non-control, non-isochronous OUT endpoints only (access type is rw).
The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK
bit, Global IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes
priority. Only the application can clear this bit, never the core.
Applies to control endpoints only (access type is rs).
The application can only set this bit, and the core clears it, when a SETUP token is received
for this endpoint. If a NAK bit, Global IN NAK, or Global OUT NAK is set along with this bit,
the STALL bit takes priority. Irrespective of this bit’s setting, the core always responds to
SETUP data packets with an ACK handshake.

Bit 20 **SNPM**: Snoop mode
This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check
the correctness of OUT packets before transferring them to application memory.
Bits 19:18 **EPTYP[1:0]**: Endpoint type
This is the transfer type supported by this logical endpoint.
00: Control
01: Isochronous
10: Bulk
11: Interrupt

Bit 17 **NAKSTS**: NAK status
Indicates the following:
0: The core is transmitting non-NAK handshakes based on the FIFO status.
1: The core is transmitting NAK handshakes on this endpoint.
When either the application or the core sets this bit:
The core stops receiving any data on an OUT endpoint, even if there is space in the Rx FIFO to accommodate the incoming packet.
Irrespective of this bit’s setting, the core always responds to SETUP data packets with an ACK handshake.

Bit 16 **EONUM**: Even/odd frame
Applies to isochronous IN and OUT endpoints only.
Indicates the frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd frame number in which it intends to transmit/receive isochronous data for this endpoint using the SEVNFRM and SODDFRM fields in this register.
0: Even frame
1: Odd frame

**DPID**: Endpoint data PID
Applies to interrupt/bulk OUT endpoints only.
Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The application uses the SD0PID register field to program either DATA0 or DATA1 PID.
0: DATA0
1: DATA1

Bit 15 **USBAEP**: USB active endpoint
Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit.

Bits 14:11 Reserved, must be kept at reset value.

Bits 10:0 **MPSIZ[10:0]**: Maximum packet size
The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes.
60.14.65 OTG device OUT endpoint x transfer size register (OTG_DOEPTSIZx)

Address offset: 0xB10 + 0x20 * x, (x = 1 to 8)
Reset value: 0x0000 0000

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using endpoint enable bit of the OTG_DOEPCTLx registers (EPENA bit in OTG_DOEPCTLx), the core modifies this register. The application can only read this register once the core has cleared the endpoint enable bit.

XFRSIZ[15:0]

| rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

Bit 31 Reserved, must be kept at reset value.

Bits 30:29 RXDPID[1:0]: Received data PID
Applies to isochronous OUT endpoints only.
This is the data PID received in the last packet for this endpoint.
00: DATA0
01: DATA2
10: DATA1
11: MDATA

STUPCNT[1:0]: SETUP packet count
Applies to control OUT endpoints only.
This field specifies the number of back-to-back SETUP data packets the endpoint can receive.
01: 1 packet
10: 2 packets
11: 3 packets

Bits 28:19 PKTCNT[9:0]: Packet count
Indicates the total number of USB packets that constitute the transfer size amount of data for this endpoint.
This field is decremented every time a packet (maximum size or short packet) is written to the Rx FIFO.

Bits 18:0 XFRSIZ[18:0]: Transfer size
This field contains the transfer size in bytes for the current endpoint. The core only interrupts the application after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet.
The core decrements this field every time a packet is read from the Rx FIFO and written to the external memory.
60.14.66 OTG power and clock gating control register (OTG_PCGCCTL)

Address offset: 0xE00
Reset value: 0x200B 8000

This register is available in host and device modes.

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **SUSP**: Deep Sleep
This bit indicates that the PHY is in Deep Sleep when in L1 state.

Bit 6 **PHYSLEEP**: PHY in Sleep
This bit indicates that the PHY is in the Sleep state.

Bit 5 **ENL1GTG**: Enable sleep clock gating
When this bit is set, core internal clock gating is enabled in Sleep state if the core cannot assert utmi_l1_suspend_n. When this bit is not set, the PHY clock is not gated in Sleep state.

Bit 4 **PHYSUSP**: PHY suspended
Indicates that the PHY has been suspended. This bit is updated once the PHY is suspended after the application has set the STPPCLK bit.

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **GATEHCLK**: Gate HCLK
The application sets this bit to gate HCLK to modules other than the AHB Slave and Master and wake-up logic when the USB is suspended or the session is not valid. The application clears this bit when the USB is resumed or a new session starts.

Bit 0 **STPPCLK**: Stop PHY clock
The application sets this bit to stop the PHY clock when the USB is suspended, the session is not valid, or the device is disconnected. The application clears this bit when the USB is resumed or a new session starts.
## 60.14.67 OTG_HS register map

The table below gives the USB OTG register map and reset values.

| Offset | Register name | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

Refer to Section 2.3 on page 134 for the register boundary addresses.
60.15 OTG_HS programming model

60.15.1 Core initialization

The application must perform the core initialization sequence. If the cable is connected during power-up, the current mode of operation bit in the OTG_GINTSTS (CMOD bit in OTG_GINTSTS) reflects the mode. The OTG_HS controller enters host mode when an “A” plug is connected or device mode when a “B” plug is connected.

This section explains the initialization of the OTG_HS controller after power-on. The application must follow the initialization sequence irrespective of host or device mode operation. All core global registers are initialized according to the core’s configuration:

1. Program the following fields in the OTG_GAHBCFG register:
   - Global interrupt mask bit GINTMSK = 1
   - Rx FIFO non-empty (RXFLVL bit in OTG_GINTSTS)
   - Periodic Tx FIFO empty level

2. Program the following fields in the OTG_GUSBCFG register:
   - HNP capable bit
   - SRP capable bit
   - OTG_HS timeout calibration field
   - USB turnaround time field

3. The software must unmask the following bits in the OTG_GINTMSK register:
   - OTG interrupt mask
   - Mode mismatch interrupt mask

4. The software can read the CMOD bit in OTG_GINTSTS to determine whether the OTG_HS controller is operating in host or device mode.
60.15.2 Host initialization

To initialize the core as host, the application must perform the following steps:

1. Program the HPRTINT in the OTG_GINTMSK register to unmask
2. Program the OTG_HCFG register to select full-speed host
3. Program the PPWR bit in OTG_HPRT to 1. This drives \( V_{BUS} \) on the USB.
4. Wait for the PCDET interrupt in OTG_HPRT0. This indicates that a device is connecting to the port.
5. Program the PRST bit in OTG_HPRT to 1. This starts the reset process.
6. Wait at least 10 ms for the reset process to complete.
7. Program the PRST bit in OTG_HPRT to 0.
8. Wait for the PENCHNG interrupt in OTG_HPRT.
9. Read the PSPD bit in OTG_HPRT to get the enumerated speed.
10. Program the HFIR register with a value corresponding to the selected PHY clock 1
11. Program the FSLSPCS field in the OTG_HCFG register following the speed of the device detected in step 9. If FSLSPCS has been changed a port reset must be performed.
12. Program the OTG_GRXFSIZ register to select the size of the receive FIFO.
13. Program the OTG_HNPTXFSIZ register to select the size and the start address of the Non-periodic transmit FIFO for non-periodic transactions.
14. Program the OTG_HPTXFSIZ register to select the size and start address of the periodic transmit FIFO for periodic transactions.

To communicate with devices, the system software must initialize and enable at least one channel.
60.15.3 Device initialization

The application must perform the following steps to initialize the core as a device on power-up or after a mode change from host to device.

1. Program the following fields in the OTG_DCFG register:
   - DESCDMA
   - Device speed
   - Non-zero-length status OUT handshake
   - Periodic Frame Interval

2. Program the Device threshold control register. This is required only if you are using DMA mode and you are planning to enable thresholding.

3. Clear the DCTL.SDIS bit. The core issues a connect after this bit is cleared.

4. Program the OTG_GINTMSK register to unmask the following interrupts:
   - USB reset
   - Enumeration done
   - Early suspend
   - USB suspend
   - SOF

5. Wait for the USBRST interrupt in OTG_GINTSTS. It indicates that a reset has been detected on the USB that lasts for about 10 ms on receiving this interrupt.

6. Wait for the ENUMDN E interrupt in OTG_GINTSTS. This interrupt indicates the end of reset on the USB. On receiving this interrupt, the application must read the OTG_DSTS register to determine the enumeration speed and perform the steps listed in Endpoint initialization on enumeration completion on page 2903.

At this point, the device is ready to accept SOF packets and perform control transfers on control endpoint 0.

60.15.4 DMA mode

The OTG host uses the AHB master interface to fetch the transmit packet data (AHB to USB) and receive the data update (USB to AHB). The AHB master uses the programmed DMA address (OTG_HCDMAx register in host mode and OTG_DIEPDMAx/OTG_DOEPDMAx register in peripheral mode) to access the data buffers.

Scatter/Gather DMA mode

In Scatter/Gather DMA mode, the core implements a true scatter/gather memory distribution in which data buffers are scattered over the system memory. However, the descriptors themselves are continuous. Each channel memory structure is implemented as a contiguous list of descriptors; each descriptor points to a data buffer of predefined size. In addition to the buffer pointer (a 32-bit word), the descriptor also has a status quadlet (32-bit word). When the list is implemented as a ring buffer, the list processor switches to the first element of the list when it encounters last bit. All channels (control, bulk, interrupt, and isochronous) implement these structures in memory. When Scatter/Gather DMA is enabled in device mode, OTG_DIEPDMAx and OTG_DOEPDMAx registers are used to access the base descriptor.
60.15.5 Host programming model

Channel initialization

The application must initialize one or more channels before it can communicate with connected devices. To initialize and enable a channel, the application must perform the following steps:

1. Program the OTG_GINTMSK register to unmask the following:
2. Channel interrupt
   - Non-periodic transmit FIFO empty for OUT transactions (applicable when operating in pipelined transaction-level with the packet count field programmed with more than one).
   - Non-periodic transmit FIFO half-empty for OUT transactions (applicable when operating in pipelined transaction-level with the packet count field programmed with more than one).
3. Program the OTG_HAINTMSK register to unmask the selected channels' interrupts.
4. Program the OTG_HCINTMSK register to unmask the transaction-related interrupts of interest given in the host channel interrupt register.
5. Program the selected channel's OTG_HCTSIZx register with the total transfer size, in bytes, and the expected number of packets, including short packets. The application must program the PID field with the initial data PID (to be used on the first OUT transaction or to be expected from the first IN transaction).
6. Program the OTG_HCCHARx register of the selected channel with the device's endpoint characteristics, such as type, speed, direction, and so forth. (The channel can be enabled by setting the channel enable bit to 1 only when the application is ready to transmit or receive any packet).
7. Program the selected channels in the OTG_HCSPLTx register(s) with the hub and port addresses (split transactions only).
8. Program the selected channels in the OTG_HCDMAx register(s) with the buffer start address (DMA transactions only).

Halting a channel

The application can disable any channel by programming the OTG_HCCHARx register with the CHDIS and CHENA bits set to 1. This enables the OTG_HS host to flush the posted requests (if any) and generates a channel halted interrupt. The application must wait for the CHH interrupt in OTG_HCINTx before reallocating the channel for other transactions. The OTG_HS host does not interrupt the transaction that has already been started on the USB.

To disable a channel in DMA mode operation, the application does not need to check for space in the request queue. The OTG_HS host checks for space to write the disable request on the disabled channel’s turn during arbitration. Meanwhile, all posted requests are dropped from the request queue when the CHDIS bit in OTG_HCCHARx is set to 1.

Before disabling a channel, the application must ensure that there is at least one free space available in the non-periodic request queue (when disabling a non-periodic channel) or the periodic request queue (when disabling a periodic channel). The application can simply flush the posted requests when the request queue is full (before disabling the channel), by programming the OTG_HCCHARx register with the CHDIS bit set to 1 which automatically clears the CHENA bit to 0.

The application is expected to disable a channel on any of the following conditions:
1. When an STALL, TXERR, BBERR or DTERR interrupt in OTG_HCINTx is received for an IN or OUT channel. The application must be able to receive other interrupts (DTERR, Nak, data, TXERR) for the same channel before receiving the halt.

2. When an XFRC interrupt in OTG_HCINTx is received during a non periodic IN transfer or high-bandwidth interrupt IN transfer

3. When a DISCINT (disconnect device) interrupt in OTG_GINTSTS is received. (The application is expected to disable all enabled channels).

4. When the application aborts a transfer before normal completion.

Ping protocol

When the OTG_HS host operates in high speed, the application must initiate the ping protocol when communicating with high-speed bulk or control (data and status stage) OUT endpoints. The application must initiate the ping protocol when it receives a NAK/NYET/TXERR interrupt. When the OTG_HS host receives one of the above responses, it does not continue any transaction for a specific endpoint, drops all posted or fetched OUT requests (from the request queue), and flushes the corresponding data (from the transmit FIFO). This is valid in slave mode only. In Slave mode, the application can send a ping token either by setting the DOPING bit in OTG_HCTSIZx before enabling the channel or by just writing the OTG_HCTSIZx register with the DOPING bit set when the channel is already enabled. This enables the OTG_HS host to write a ping request entry to the request queue. The application must wait for the response to the ping token (a NAK, ACK, or TXERR interrupt) before continuing the transaction or sending another ping token. The application can continue the data transaction only after receiving an ACK from the OUT endpoint for the requested ping. In DMA mode operation, the application does not need to set the DOPING bit in OTG_HCTSIZx for a NAK/NYET response in case of bulk/control OUT. The OTG_HS host automatically sets the DOPING bit in OTG_HCTSIZx, and issues the ping tokens for bulk/control OUT. The OTG_HS host continues sending ping tokens until it receives an ACK, and then switches automatically to the data transaction.

Operational model

The application must initialize a channel before communicating to the connected device. This section explains the sequence of operation to be performed for different types of USB transactions.

- **Writing the transmit FIFO**
  The OTG_HS host automatically writes an entry (OUT request) to the periodic/non-periodic request queue, along with the last 32-bit word write of a packet. The application must ensure that at least one free space is available in the periodic/non-periodic request queue before starting to write to the transmit FIFO. The application must always write to the transmit FIFO in 32-bit words. If the packet size is non-32-bit word aligned, the application must use padding. The OTG_HS host determines the actual packet size based on the programmed maximum packet size and transfer size.
- **Reading the receive FIFO**
  The application must ignore all packet statuses other than IN data packet (bx0010).
• **Bulk and control OUT/SETUP transactions**

A typical bulk or control OUT/SETUP pipelined transaction-level operation is shown in *Figure 804*. See channel 1 (ch_1). Two bulk OUT packets are transmitted. A control SETUP transaction operates in the same way but has only one packet. The assumptions are:

− The application is attempting to send two maximum-packet-size packets (transfer size = 1,024 bytes).
− The non-periodic transmit FIFO can hold two packets (1 Kbyte for HS).
− The non-periodic request queue depth = 4.

• **Normal bulk and control OUT/SETUP operations**

The sequence of operations in (channel 1) is as follows:

1. Initialize channel 1
2. Write the first packet for channel 1
3. Along with the last word write, the core writes an entry to the non-periodic request queue
4. As soon as the non-periodic queue becomes non-empty, the core attempts to send an OUT token in the current frame
5. Write the second (last) packet for channel 1
6. The core generates the XFRC interrupt as soon as the last transaction is completed successfully
7. In response to the XFRC interrupt, de-allocate the channel for other transfers
8. Handling non-ACK responses
Figure 804. Normal bulk/control OUT/SETUP

1. The grayed elements are not relevant in the context of this figure.
The channel-specific interrupt service routine for bulk and control OUT/SETUP transactions is shown in the following code samples.

- **Interrupt service routine for bulk/control OUT/SETUP and bulk/control IN transactions**
  a) Bulk/control OUT/SETUP

Unmask (NAK/TXERR/STALL/XFRC)

```c
if (XFRC)
{
    Reset Error Count
    Mask ACK
    De-allocate Channel
}
else if (STALL)
{
    Transfer Done = 1
    Unmask CHH
    Disable Channel
}
else if (NAK or TXERR )
{
    Rewind Buffer Pointers
    Unmask CHH
    Disable Channel
    if (TXERR)
    {
        Increment Error Count
        Unmask ACK
    }
    else
    {
        Reset Error Count
    }
}
else if (CHH)
{
    Mask CHH
    if (Transfer Done or (Error_count == 3))
    {
        De-allocate Channel
    }
    else
    {
        Re-initialize Channel
    }
}
```
else if (ACK)
{
    Reset Error Count
    Mask ACK
}

The application is expected to write the data packets into the transmit FIFO when the space is available in the transmit FIFO and the request queue. The application can make use of the NPTXFE interrupt in OTG_GINTSTS to find the transmit FIFO space.

b) Bulk/control IN

Unmask (TXERR/XFRC/BBERR/STALL/DTERR)
if (XFRC)
{
    Reset Error Count
    Unmask CHH
    Disable Channel
    Reset Error Count
    Mask ACK
}
else if (TXERR or BBERR or STALL)
{
    Unmask CHH
    Disable Channel
    if (TXERR)
    {
        Increment Error Count
        Unmask ACK
    }
}
else if (CHH)
{
    Mask CHH
    if (Transfer Done or (Error_count == 3))
    {
        De-allocate Channel
    }
else
{
    Re-initialize Channel
}
}
else if (ACK)
{
    Reset Error Count
    Mask ACK
}
else if (DTERR)
{
    Reset Error Count
}

The application is expected to write the requests as and when the request queue space is available and until the XFRC interrupt is received.

- **Bulk and control IN transactions**
  A typical bulk or control IN pipelined transaction-level operation is shown in Figure 805. See channel 2 (ch_2). The assumptions are:
  - The application is attempting to receive two maximum-packet-size packets (transfer size = 1024 bytes).
  - The receive FIFO can contain at least one maximum-packet-size packet and two status words per packet (520 bytes for HS).
  - The non-periodic request queue depth = 4.
Figure 805. Bulk/control IN transactions

1. The grayed elements are not relevant in the context of this figure.
The sequence of operations is as follows:

1. Initialize channel 2.
2. Set the CHENA bit in OTG_HCCHAR2 to write an IN request to the non-periodic request queue.
3. The core attempts to send an IN token after completing the current OUT transaction.
4. The core generates an RXFLVL interrupt as soon as the received packet is written to the receive FIFO.
5. In response to the RXFLVL interrupt, mask the RXFLVL interrupt and read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. Following this, unmask the RXFLVL interrupt.
6. The core generates the RXFLVL interrupt for the transfer completion status entry in the receive FIFO.
7. The application must read and ignore the receive packet status when the receive packet status is not an IN data packet (PKTSTS in OTG_GRXSTSR ≠ 0b0010).
8. The core generates the XFRC interrupt as soon as the receive packet status is read.
9. In response to the XFRC interrupt, disable the channel and stop writing the OTG_HCCHAR2 register for further requests. The core writes a channel disable request to the non-periodic request queue as soon as the OTG_HCCHAR2 register is written.
10. The core generates the RXFLVL interrupt as soon as the halt status is written to the receive FIFO.
11. Read and ignore the receive packet status.
12. The core generates a CHH interrupt as soon as the halt status is popped from the receive FIFO.
13. In response to the CHH interrupt, de-allocate the channel for other transfers.
14. Handling non-ACK responses

- **Control transactions**
  Setup, data, and status stages of a control transfer must be performed as three separate transfers. Setup-, data- or status-stage OUT transactions are performed similarly to the bulk OUT transactions explained previously. Data- or status-stage IN transactions are performed similarly to the bulk IN transactions explained previously. For all three stages, the application is expected to set the EPTYP field in
OTG_HCCHAR1 to control. During the setup stage, the application is expected to set the PID field in OTG_HCTSIZ1 to SETUP.

- **Interrupt OUT transactions**
  A typical interrupt OUT operation is shown in *Figure 806*. The assumptions are:
  - The application is attempting to send one packet in every frame (up to 1 maximum packet size), starting with the odd frame (transfer size = 1 024 bytes)
  - The periodic transmit FIFO can hold one packet (1 Kbyte)
  - Periodic request queue depth = 4
  The sequence of operations is as follows:
  1. Initialize and enable channel 1. The application must set the ODDFRM bit in OTG_HCCHAR1.
  2. Write the first packet for channel 1.
  3. Along with the last word write of each packet, the OTG_HS host writes an entry to the periodic request queue.
  4. The OTG_HS host attempts to send an OUT token in the next (odd) frame.
  5. The OTG_HS host generates an XFRC interrupt as soon as the last packet is transmitted successfully.
  6. In response to the XFRC interrupt, reinitialize the channel for the next transfer.
Figure 806. Normal interrupt OUT

1. The grayed elements are not relevant in the context of this figure.

    Unmask CHH
    Disable Channel
}
else
if (CHH)
{
  Mask CHH
  if (Transfer Done or (Error_count == 3))
  {
    De-allocate Channel
  }
  else
  {
    Re-initialize Channel (in next b_interval - 1 /Frame)
  }
}
else
if (ACK)
{
  Reset Error Count
  Mask ACK
}

- **Interrupt IN transactions**
  The assumptions are:
  - The application is attempting to receive one packet (up to 1 maximum packet size) in every frame, starting with odd (transfer size = 1024 bytes).
  - The receive FIFO can hold at least one maximum-packet-size packet and two status words per packet (1031 bytes).
  - Periodic request queue depth = 4.

- **Normal interrupt IN operation**
  The sequence of operations is as follows:
  1. Initialize channel 2. The application must set the ODDFRM bit in OTG_HCCHAR2.
  2. Set the CHENA bit in OTG_HCCHAR2 to write an IN request to the periodic request queue.
  3. The OTG_HS host writes an IN request to the periodic request queue for each OTG_HCCHAR2 register write with the CHENA bit set.
  4. The OTG_HS host attempts to send an IN token in the next (odd) frame.
  5. As soon as the IN packet is received and written to the receive FIFO, the OTG_HS host generates an RXFLVL interrupt.
  6. In response to the RXFLVL interrupt, read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. The application must mask the RXFLVL interrupt before reading the receive FIFO, and unmask after reading the entire packet.
  7. The core generates the RXFLVL interrupt for the transfer completion status entry in the receive FIFO. The application must read and ignore the receive packet status when the receive packet status is not an IN data packet (PKTSTS in GRXSTSR ≠ 0b0010).
  8. The core generates an XFRC interrupt as soon as the receive packet status is read.
  9. In response to the XFRC interrupt, read the PKTCNT field in OTG_HCTSIZ2. If the PKTCNT bit in OTG_HCTSIZ2 is not equal to 0, disable the channel before re-
initializing the channel for the next transfer, if any). If PKTCNT bit in OTG_HCTSZ2 = 0, reinitialize the channel for the next transfer. This time, the application must reset the ODDFRM bit in OTG_HCCHAR2.
1. The grayed elements are not relevant in the context of this figure.

- **Isochronous OUT transactions**

  A typical isochronous OUT operation is shown in Figure 808. The assumptions are:
  - The application is attempting to send one packet every frame (up to 1 maximum...
packet size), starting with an odd frame. (transfer size = 1 024 bytes).

– The periodic transmit FIFO can hold one packet (1 Kbyte).
– Periodic request queue depth = 4.

The sequence of operations is as follows:

1. Initialize and enable channel 1. The application must set the ODDFRM bit in OTG_HCCHAR1.
2. Write the first packet for channel 1.
3. Along with the last word write of each packet, the OTG_HS host writes an entry to the periodic request queue.
4. The OTG_HS host attempts to send the OUT token in the next frame (odd).
5. The OTG_HS host generates the XFRC interrupt as soon as the last packet is transmitted successfully.
6. In response to the XFRC interrupt, reinitialize the channel for the next transfer.
7. Handling non-ACK responses

- Isochronous IN transactions
  The assumptions are:
  - The application is attempting to receive one packet (up to 1 maximum packet size) in every frame starting with the next odd frame (transfer size = 1024 bytes).
  - The receive FIFO can hold at least one maximum-packet-size packet and two status word per packet (1031 bytes).
  - Periodic request queue depth = 4.
  The sequence of operations is as follows:
1. Initialize channel 2. The application must set the ODDFRM bit in OTG_HCCHAR2.
2. Set the CHENA bit in OTG_HCCHAR2 to write an IN request to the periodic request queue.
3. The OTG_HS host writes an IN request to the periodic request queue for each OTG_HCCHAR2 register write with the CHENA bit set.
4. The OTG_HS host attempts to send an IN token in the next odd frame.
5. As soon as the IN packet is received and written to the receive FIFO, the OTG_HS host generates an RXFLVL interrupt.
6. In response to the RXFLVL interrupt, read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. The application must mask the RXFLVL interrupt before reading the receive FIFO, and unmask it after reading the entire packet.
7. The core generates an RXFLVL interrupt for the transfer completion status entry in the receive FIFO. This time, the application must read and ignore the receive packet status when the receive packet status is not an IN data packet (PKTSTS bit in OTG_GRXSTSR ≠ 0b0010).
8. The core generates an XFRC interrupt as soon as the receive packet status is read.
9. In response to the XFRC interrupt, read the PKTCNT field in OTG_HCTSIZ2. If PKTCNT ≠ 0 in OTG_HCTSIZ2, disable the channel before re-initializing the channel for the next transfer, if any. If PKTCNT = 0 in OTG_HCTSIZ2, reinitialize the channel for the next transfer. This time, the application must reset the ODDFRM bit in OTG_HCCHAR2.
Figure 809. Isochronous IN transactions

1. The grayed elements are not relevant in the context of this figure.

- **Selecting the queue depth**

  Choose the periodic and non-periodic request queue depths carefully to match the
  number of periodic/non-periodic endpoints accessed.

  The non-periodic request queue depth affects the performance of non-periodic
transfers. The deeper the queue (along with sufficient FIFO size), the more often the core is able to pipeline non-periodic transfers. If the queue size is small, the core is able to put in new requests only when the queue space is freed up.

The core’s periodic request queue depth is critical to perform periodic transfers as scheduled. Select the periodic queue depth, based on the number of periodic transfers scheduled in a microframe. If the periodic request queue depth is smaller than the periodic transfers scheduled in a microframe, a frame overrun condition occurs.

- **Handling babble conditions**
  OTG_HS controller handles two cases of babble: packet babble and port babble. Packet babble occurs if the device sends more data than the maximum packet size for the channel. Port babble occurs if the core continues to receive data from the device at EOF2 (the end of frame 2, which is very close to SOF).
  When OTG_HS controller detects a packet babble, it stops writing data into the Rx buffer and waits for the end of packet (EOP). When it detects an EOP, it flushes already written data in the Rx buffer and generates a Babble interrupt to the application.
  When OTG_HS controller detects a port babble, it flushes the Rx FIFO and disables the port. The core then generates a port disabled interrupt (HPRTINT in OTG_GINTSTS, PENCHNG in OTG_HPRT). On receiving this interrupt, the application must determine that this is not due to an overcurrent condition (another cause of the port disabled interrupt) by checking POCA in OTG_HPRT, then perform a soft reset. The core does not send any more tokens after it has detected a port babble condition.

- **Bulk and control OUT/SETUP transactions in DMA mode**
  The sequence of operations is as follows:
  1. Initialize and enable channel 1 as explained in Section : Channel initialization.
  2. The OTG_HS host starts fetching the first packet as soon as the channel is enabled. For internal DMA mode, the OTG_HS host uses the programmed DMA address to fetch the packet.
  3. After fetching the last 32-bit word of the second (last) packet, the OTG_HS host masks channel 1 internally for further arbitration.
  4. The OTG_HS host generates a CHH interrupt as soon as the last packet is sent.
  5. In response to the CHH interrupt, de-allocate the channel for other transfers.
**NAK and NYET handling with internal DMA:**

1. The OTG_HS host sends a bulk OUT transaction.
2. The device responds with NAK or NYET.
3. If the application has unmasked NAK or NYET, the core generates the corresponding interrupt(s) to the application. The application is not required to service these interrupts, since the core takes care of rewinding the buffer pointers and re-initializing the Channel without application intervention.
4. The core automatically issues a ping token.
5. When the device returns an ACK, the core continues with the transfer. Optionally, the application can utilize these interrupts, in which case the NAK or NYET interrupt is masked by the application.
The core does not generate a separate interrupt when NAK or NYET is received by the host functionality.

- **Bulk and control IN transactions in DMA mode**
  
The sequence of operations is as follows:
  
  1. Initialize and enable the used channel (channel x) as explained in Section : Channel initialization.
  2. The OTG_HS host writes an IN request to the request queue as soon as the channel receives the grant from the arbiter (arbitration is performed in a round-robin fashion).
  3. The OTG_HS host starts writing the received data to the system memory as soon as the last byte is received with no errors.
  4. When the last packet is received, the OTG_HS host sets an internal flag to remove any extra IN requests from the request queue.
  5. The OTG_HS host flushes the extra requests.
  6. The final request to disable channel x is written to the request queue. At this point, channel 2 is internally masked for further arbitration.
  7. The OTG_HS host generates the CHH interrupt as soon as the disable request comes to the top of the queue.
  8. In response to the CHH interrupt, de-allocate the channel for other transfers.
Interrupt OUT transactions in DMA mode

1. Initialize and enable channel x as explained in Section : Channel initialization.
2. The OTG_HS host starts fetching the first packet as soon the channel is enabled and writes the OUT request along with the last 32-bit word fetch. In high-bandwidth transfers, the OTG_HS host continues fetching the next packet (up to the value specified in the MC field) before switching to the next channel.
3. The OTG_HS host attempts to send the OUT token at the beginning of the next odd frame/micro-frame.
4. After successfully transmitting the packet, the OTG_HS host generates a CHH interrupt.
5. In response to the CHH interrupt, reinitialize the channel for the next transfer.

**Figure 812. Normal interrupt OUT transactions - DMA mode**

- **Interrupt IN transactions in DMA mode**
  The sequence of operations (channelx) is as follows:
  1. Initialize and enable channel x as explained in Section: Channel initialization.
  2. The OTG_HS host writes an IN request to the request queue as soon as the channel x gets the grant from the arbiter (round-robin with fairness). In high-bandwidth transfers, the OTG_HS host writes consecutive writes up to MC times.
3. The OTG_HS host attempts to send an IN token at the beginning of the next (odd) frame/micro-frame.
4. As soon the packet is received and written to the receive FIFO, the OTG_HS host generates a CHH interrupt.
5. In response to the CHH interrupt, reinitialize the channel for the next transfer.

Figure 813. Normal interrupt IN transactions - DMA mode

- Isochronous OUT transactions in DMA mode
  1. Initialize and enable channel x as explained in Section : Channel initialization.
  2. The OTG_HS host starts fetching the first packet as soon as the channel is enabled, and writes the OUT request along with the last 32-bit word fetch. In high-bandwidth
transfers, the OTG_HS host continues fetching the next packet (up to the value specified in the MC field) before switching to the next channel.

3. The OTG_HS host attempts to send an OUT token at the beginning of the next (odd) frame/micro-frame.

4. After successfully transmitting the packet, the OTG_HS host generates a CHH interrupt.

5. In response to the CHH interrupt, reinitialize the channel for the next transfer.

*Figure 814. Normal isochronous OUT transaction - DMA mode*

- **Isochronous IN transactions in DMA mode**

  The sequence of operations ((channel x)) is as follows:

  1. Initialize and enable channel x as explained in *Section : Channel initialization*.

  2. The OTG_HS host writes an IN request to the request queue as soon as the channel x gets the grant from the arbiter (round-robin with fairness). In high-bandwidth transfers, the OTG_HS host performs consecutive write operations up to MC times.
3. The OTG_HS host attempts to send an IN token at the beginning of the next (odd) frame/micro-frame.
4. As soon the packet is received and written to the receive FIFO, the OTG_HS host generates a CHH interrupt.
5. In response to the CHH interrupt, reinitialize the channel for the next transfer.

Figure 8. Normal isochronous IN transactions - DMA mode

- **Bulk and control OUT/SETUP split transactions in DMA mode**
  
  The sequence of operations in (channel x) is as follows:
  
  1. Initialize and enable channel x for start split as explained in Section : Channel initialization.
  
  2. The OTG_HS host starts fetching the first packet as soon the channel is enabled and writes the OUT request along with the last 32-bit word fetch.
  
  3. After successfully transmitting start split, the OTG_HS host generates the CHH interrupt.
  
  4. In response to the CHH interrupt, set the COMPLSPLT bit in OTG_HCSPLT1 to send the complete split.
5. After successfully transmitting complete split, the OTG_HS host generates the CHH interrupt.
6. In response to the CHH interrupt, de-allocate the channel.

- **Bulk/control IN split transactions in DMA mode**
  
The sequence of operations (channel x) is as follows:
  1. Initialize and enable channel x as explained in *Section : Channel initialization*.
  2. The OTG_HS host writes the start split request to the nonperiodic request after getting the grant from the arbiter. The OTG_HS host masks the channel x internally for the arbitration after writing the request.
  3. As soon as the IN token is transmitted, the OTG_HS host generates the CHH interrupt.
  4. In response to the CHH interrupt, set the COMPLSPLT bit in OTG_HCSPLT2 and re-enable the channel to send the complete split token. This unmasks channel x for arbitration.
  5. The OTG_HS host writes the complete split request to the nonperiodic request after receiving the grant from the arbiter.
  6. The OTG_HS host starts writing the packet to the system memory after receiving the packet successfully.
  7. As soon as the received packet is written to the system memory, the OTG_HS host generates a CHH interrupt.
  8. In response to the CHH interrupt, de-allocate the channel.

- **Interrupt OUT split transactions in DMA mode**
  
The sequence of operations in (channel x) is as follows:
  1. Initialize and enable channel 1 for start split as explained in *Section : Channel initialization*. The application must set the ODDFRM bit in OTG_HCCHAR1.
  2. The OTG_HS host starts reading the packet.
  3. The OTG_HS host attempts to send the start split transaction.
  4. After successfully transmitting the start split, the OTG_HS host generates the CHH interrupt.
  5. In response to the CHH interrupt, set the COMPLSPLT bit in OTG_HCSPLT1 to send the complete split.
  6. After successfully completing the complete split transaction, the OTG_HS host generates the CHH interrupt.
  7. In response to CHH interrupt, de-allocate the channel.

- **Interrupt IN split transactions in DMA mode**
  
The sequence of operations in (channel x) is as follows:
  1. Initialize and enable channel x for start split as explained in *Section : Channel initialization*.
  2. The OTG_HS host writes an IN request to the request queue as soon as channel x receives the grant from the arbiter.
  3. The OTG_HS host attempts to send the start split IN token at the beginning of the next odd micro-frame.
  4. The OTG_HS host generates the CHH interrupt after successfully transmitting the start split IN token.
  5. In response to the CHH interrupt, set the COMPLSPLT bit in OTG_HCSPLT2 to send the complete split.
6. As soon as the packet is received successfully, the OTG_HS host starts writing the data to the system memory.
7. The OTG_HS host generates the CHH interrupt after transferring the received data to the system memory.
8. In response to the CHH interrupt, de-allocate or reinitialize the channel for the next start split.

- **Isochronous OUT split transactions in DMA mode**
  The sequence of operations (channel x) is as follows:
  1. Initialize and enable channel x for start split (begin) as explained in Section : Channel initialization. The application must set the ODDFRM bit in OTG_HCCHAR1. Program the MPS field.
  2. The OTG_HS host starts reading the packet.
  3. After successfully transmitting the start split (begin), the OTG_HS host generates the CHH interrupt.
  4. In response to the CHH interrupt, reinitialize the registers to send the start split (end).
  5. After successfully transmitting the start split (end), the OTG_HS host generates a CHH interrupt.
  6. In response to the CHH interrupt, de-allocate the channel.

- **Isochronous IN split transactions in DMA mode**
  The sequence of operations (channel x) is as follows:
  1. Initialize and enable channel x for start split as explained in Section : Channel initialization.
  2. The OTG_HS host writes an IN request to the request queue as soon as channel x receives the grant from the arbiter.
  3. The OTG_HS host attempts to send the start split IN token at the beginning of the next odd micro-frame.
  4. The OTG_HS host generates the CHH interrupt after successfully transmitting the start split IN token.
  5. In response to the CHH interrupt, set the COMPLSPLT bit in OTG_HCSPLT2 to send the complete split.
  6. As soon as the packet is received successfully, the OTG_HS host starts writing the data to the system memory. The OTG_HS host generates the CHH interrupt after transferring the received data to the system memory. In response to the CHH interrupt, de-allocate the channel or reinitialize the channel for the next start split.
60.15.6 Device programming model

Endpoint initialization on USB reset

1. Set the NAK bit for all OUT endpoints
   - SNAK = 1 in OTG_DOEPCTLx (for all OUT endpoints)
2. Unmask the following interrupt bits
   - INEP0 = 1 in OTG_DAINTMSK (control 0 IN endpoint)
   - OUTEP0 = 1 in OTG_DAINTMSK (control 0 OUT endpoint)
   - STUPM = 1 in OTG_DOEPMSK
   - XFRCM = 1 in OTG_DOEPMSK
   - XFRCM = 1 in OTG_DIEPMSK
   - TOM = 1 in OTG_DIEPMSK
3. Set up the data FIFO RAM for each of the FIFOs
   - Program the OTG_GRXFSIZ register, to be able to receive control OUT data and setup data. If thresholding is not enabled, at a minimum, this must be equal to 1 max packet size of control endpoint 0 + 2 words (for the status of the control OUT data packet) + 10 words (for setup packets).
   - Program the OTG_DIEPTXF0 register (depending on the FIFO number chosen) to be able to transmit control IN data. At a minimum, this must be equal to 1 max packet size of control endpoint 0.
4. Program the following fields in the endpoint-specific registers for control OUT endpoint 0 to receive a SETUP packet
   - STUPCNT = 3 in OTG_DOEPTSIZ0 (to receive up to 3 back-to-back SETUP packets)
5. For USB OTG_HS in DMA mode, the OTG_DOEPDMA0 register should have a valid memory address to store any SETUP packets received.

At this point, all initialization required to receive SETUP packets is done.

Endpoint initialization on enumeration completion

1. On the Enumeration Done interrupt (ENUMDNE in OTG_GINTSTS), read the OTG_DSTS register to determine the enumeration speed.
2. Program the MPSIZ field in OTG_DIEPCTL0 to set the maximum packet size. This step configures control endpoint 0. The maximum packet size for a control endpoint depends on the enumeration speed.
3. For USB OTG_HS in DMA mode, program the OTG_DOEPCTL0 register to enable control OUT endpoint 0, to receive a SETUP packet.

At this point, the device is ready to receive SOF packets and is configured to perform control transfers on control endpoint 0.

Endpoint initialization on SetAddress command

This section describes what the application must do when it receives a SetAddress command in a SETUP packet.

1. Program the OTG_DCFG register with the device address received in the SetAddress command
2. Program the core to send out a status IN packet
Endpoint initialization on SetConfiguration/SetInterface command

This section describes what the application must do when it receives a SetConfiguration or SetInterface command in a SETUP packet.

1. When a SetConfiguration command is received, the application must program the endpoint registers to configure them with the characteristics of the valid endpoints in the new configuration.

2. When a SetInterface command is received, the application must program the endpoint registers of the endpoints affected by this command.

3. Some endpoints that were active in the prior configuration or alternate setting are not valid in the new configuration or alternate setting. These invalid endpoints must be deactivated.

4. Unmask the interrupt for each active endpoint and mask the interrupts for all inactive endpoints in the OTG_DAINTMSK register.

5. Set up the data FIFO RAM for each FIFO.

6. After all required endpoints are configured; the application must program the core to send a status IN packet.

At this point, the device core is configured to receive and transmit any type of data packet.

Endpoint activation

This section describes the steps required to activate a device endpoint or to configure an existing device endpoint to a new type.

1. Program the characteristics of the required endpoint into the following fields of the OTG_DIEPCTLx register (for IN or bidirectional endpoints) or the OTG_DOEPCTLx register (for OUT or bidirectional endpoints).
   - Maximum packet size
   - USB active endpoint = 1
   - Endpoint start data toggle (for interrupt and bulk endpoints)
   - Endpoint type
   - Tx FIFO number

2. Once the endpoint is activated, the core starts decoding the tokens addressed to that endpoint and sends out a valid handshake for each valid token received for the endpoint.

Endpoint deactivation

This section describes the steps required to deactivate an existing endpoint.

1. In the endpoint to be deactivated, clear the USB active endpoint bit in the OTG_DIEPCTLx register (for IN or bidirectional endpoints) or the OTG_DOEPCTLx register (for OUT or bidirectional endpoints).

2. Once the endpoint is deactivated, the core ignores tokens addressed to that endpoint, which results in a timeout on the USB.

Note: The application must meet the following conditions to set up the device core to handle traffic:
NPTXFEM and RXFLVLM in the OTG_GINTMSK register must be cleared.
Operational model

SETUP and OUT data transfers:

This section describes the internal data flow and application-level operations during data OUT transfers and SETUP transactions.

- Packet read

This section describes how to read packets (OUT data and SETUP packets) from the receive FIFO.

1. On catching an RXFLVL interrupt (OTG_GINTSTS register), the application must read the receive status pop register (OTG_GRXSTSP).
2. The application can mask the RXFLVL interrupt (in OTG_GINTSTS) by writing to RXFLVLM = 0 (in OTG_GINTMSK), until it has read the packet from the receive FIFO.
3. If the received packet’s byte count is not 0, the byte count amount of data is popped from the receive data FIFO and stored in memory. If the received packet byte count is 0, no data is popped from the receive data FIFO.
4. The receive status readout of the packet of FIFO indicates one of the following:
   a) Global OUT NAK pattern:
      PKTSTS = Global OUT NAK, BCNT = 0x000, EPNUM = (0x0), DPID = (0b00).
      These data indicate that the global OUT NAK bit has taken effect.
   b) SETUP packet pattern:
      PKTSTS = SETUP, BCNT = 0x008, EPNUM = Control EP Num, DPID = DATA0. These data indicate that a SETUP packet for the specified endpoint is now available for reading from the receive FIFO.
   c) Setup stage done pattern:
      PKTSTS = Setup Stage Done, BCNT = 0x0, EPNUM = Control EP Num, DPID = (0b00).
      These data indicate that the setup stage for the specified endpoint has completed and the data stage has started. After this entry is popped from the receive FIFO, the core asserts a setup interrupt on the specified control OUT endpoint.
   d) Data OUT packet pattern:
      PKTSTS = Data OUT packet, BCNT = size of the received data OUT packet (0 ≤ BCNT ≤ 1 024), EPNUM = EPNUM on which the packet was received, DPID = Actual Data PID.
   e) Data transfer completed pattern:
      PKTSTS = Data OUT transfer done, BCNT = 0x0, EPNUM = OUT EP Num on which the data transfer is complete, DPID = (0b00).
      These data indicate that an OUT data transfer for the specified OUT endpoint has completed. After this entry is popped from the receive FIFO, the core asserts a transfer completed interrupt on the specified OUT endpoint.
5. After the data payload is popped from the receive FIFO, the RXFLVL interrupt (OTG_GINTSTS) must be unmasked.
6. Steps 1–5 are repeated every time the application detects assertion of the interrupt line due to RXFLVL in OTG_GINTSTS. Reading an empty receive FIFO can result in undefined core behavior.

*Figure 816* provides a flowchart of the above procedure.
SETUP transactions

This section describes how the core handles SETUP packets and the application's sequence for handling SETUP transactions.

- **Application requirements**
